Pearl essence is the suspension of crystalline guanine in a solvent. It is the iridescent substance located in the epidermal layer of the scales of pelagic fishes. This is used for coating the objects to give them a lustrous effect.

**Fish glue**

Fish glue is made from fish skins (better quality glue) and fish heads (lesser quality glues). A sequential cooking of fish skin with acid and alkali yields fish glue.

**Fish maws and isinglass**

Sturgeon fish's air bladder or swim bladder is usually referred as isinglass. In India, air bladder of eels and catfishes are used for the production of isinglass. The air bladders are separated from fish and temporarily preserved in salt during the time of transport. On reaching the shore, they are split open, thoroughly washed and outer membrane are removed by scraping and then air dried <sup>[10]</sup>. Then cleaned, desalted, air dried, and hardened swim bladders are called fish maws. Isinglass is used as clarifying agents for beverages, wines, beer, and vinegar by enmeshing the suspended impurities in the fibrous structure of swollen isinglass.

**Biswajit Mohanty et al.**

### **Bioactive compounds**

New biologically active compounds have been isolated from fishery discards. One example is the discovery of the antifungal and antibacterial properties of the epidermis, epidermal mucus of different fish species, liver, intestine, stomach, and gills of some fish species and the blood and shell of some crustaceans. Fish mucous is known to have significant biological functions, acting as an immunological barrier. A variety of biologically active compounds, proteinases, peptides, or polypeptides with high molecular weight are responsible for these functions.

### **Antifreeze proteins**

Antifreeze proteins (AFPs), which are found in diverse species of marine fishes, are characterized by their ability to stop ice formation by cooling below the melting point. This is a protection method of polar fishes against freezing. It is found that snail fish skin tissue shows antifreeze activity which will be purified by chromatography techniques. Some work has also been carried out on the extraction of AFPs from winter flounder (*Pseudopleuronectes americanus*), cunner (*Tautoglabrus adspersus*), sea raven (*Hemitripterus americanus*), and short horn sculpin (*Myoxocephalus scorpius*). The main application of AFPs is as cryoprotectants since they will prevent freezing damage by their capacity to lower melting point and inhibit ice recrystallization. Some studies revealed that the addition of AFP to meat or injection into animal reduces the damage caused by frozen storage of meat.

### **Pigments**

Valuable pigments are found during a sort of fish raw materials, especially in seafood waste. Various studies have reported the presence and recovery of pigments like astaxanthin and its esters,  $\beta$ -carotene, lutein, astacene, canthaxanthin and zeaxanthin in crustacean waste. Carotenoids are a group of fat-soluble pigments that can be found in many plants, algae, microorganisms, and animals, and are responsible for the colour of several shellfish. Carotenoids have been extracted using shrimp waste, from processing head and shell of *Penaeus indicus*, applying different organic solvents. Carotenoids were also extracted from fish eggs and from fish scales waste also. These valuable pigments would be cheaper alternative applicable to a good sort of industrial needs like colouration of some surimi-based products or aquaculture feed formulation. Furthermore, some pigments like astaxanthin are important in medical and biomedical applications due to their high antioxidative effects and to the fact that they are precursors of vitamin A.

### **Chitin and Chitosan**

Chitin, a polysaccharide and one of the major components of crustacean shell waste, has been found to be a potential source of antimicrobial substances, due to the high percentage that shrimp wastes represent on a global scale. Chitosan has strong antimicrobial activity against a variety of microorganisms, and it is non-toxic, biocompatible and biodegradable properties make it adequate for applications as a food ingredient and in medical applications. It has also certain antitumor properties revealed both in vitro and in vivo. Chito-oligosaccharides also exhibited scavenging activity on hydroxyl and superoxide radicals, this being dependent on their molecular weight.

This property makes them potential additives for the inhibition of lipid oxidation in food, but also can prevent certain pathological processes related to radical modification of cellular compounds, such as atherosclerosis, arthritis, diabetes, inflammatory disorders, and neurological disorders such as Alzheimer's disease. Other applications of chitin and chitosan are their use as ingredients of toothpaste, shampoo, hand and body cream, for cell immobilization, and as materials for the production of contact lenses. Chitosan finds extensive applications in food industries, pharmaceutical applications, chemical industries, dental and surgical uses as a hemostatic agent, wound healing, biodegradable films as a substitute for artificial skins for removing toxic heavy metals, agriculture, photography, and textiles [11].

### Bio-oil

Fish oil, a fish powder by-product, was pre-treated by filtration, placed during a reactor with two catalysts (iron oxide and phosphate monobasic) and mixed with ozone bubbling (about 8000 ppm) for one hour temperature which is named primary ozone treatment. Some scientists evaluated the ozone treated fish waste oil as a transportation diesel oil. Then the sample was filtered again and treated with ozone at the same conditions for 30 min, but without the presence of catalysts called as secondary ozone treatment. The oil manufactured from fish waste was tested for its density, flash point, pour point, heating value, distillation test, and sulphur content. The yield of the produced fuel was 95–96%, after filtration, primary and secondary treatments. The method of production of bio-diesel from fish source is also reported by Arvanitoyannis and Kassaveti (2007) [12]. The obtained oil was found to have suitable properties for use in diesel engines, such as almost identical higher heating value compared with commercial diesel fuel, no production of sulphur oxides, lowered or any soot, poly-aromatic and carbon dioxide emissions. These properties suggested that the obtained oil had better properties than methyl-esterified oil waste and was suitable for diesel engines, especially at coldness.

### CONCLUSION

Instead of dumping, the utilization of unwanted fish wastes as a low-cost feedstock along with traditional fishery by-products a better option for production of value-added products and also as health supplement can be considered. It may not only cause the control of solid waste generated from fish industries but also helps in improving fish industry economy. Hence more research and public awareness are required to explore the likelihood and potential of fish processing waste closer to the assembly of value-added commodities for the betterment of human society.

### ABSTRACT

The results of the field experiment revealed that pre emergence application of atrazine @1.0 kg/ha supplemented with hand weeding at 20 days after sowing (DAS) significantly reduced the weed population and dry weight during the initial period of crop growth up to 40 DAS along with enhancement in weed control efficiency. During later stages of crop growth, manual method of weed control by combined hand hoeing, weeding and earthing up markedly reduced the weed population and dry weight and increased the weed control efficiency which remained at par with pre emergence application of atrazine followed by hand weeding at 20DAS. The maximization of yield components like cob length, cob girth and number of grains per cob were recorded in integrated use of pre emergence application of atrazine @1.0 kg/ha with hand weeding at 20 DAS being at par with combination of hand hoeing, weeding and earthing up done at 20 and 40 DAS. The same pre emergence application of atrazine with hand weeding at 20DAS produced the highest green cob yield (34.75 t/ha) and fresh kernel yield (12.61t/ha) that did not differ significantly from manual method of weed control performed with combination of hand hoeing, weeding and earthing up at 20 and 40 DAS.

## INTRODUCTION

Sweet corn is gaining popularity among nutritive and health conscious urban masses in India with an immense potential in domestic and international market. Due to its extra sweetness (14-20% sugar) and short duration, sweet corn is cultivated as a remunerative crop for the farmers. A wide spaced crop like sweet corn suffers from heavy weed infestation due to slow initial growth particularly during kharif season. The yield losses in sweet corn due to season long weed infestation ranges from 30 per cent to complete crop failure (Pandey *et al.*2001) [4]. The choice of weed control methods largely depend on effectiveness and economics. Due to increased cost and non-availability of manual labour in required quantity and time for hand weeding, the use of pre and post emergence herbicides to manage the weeds play an important role.

Use of chemical method would make weed control more acceptable to farmers which will not only change the existing agronomic practice but also will allow for satisfactory control of weeds. As the weeds interfere during aftercare operation and the harvest of crop, post-emergence use of herbicides may help in avoiding the problem of weeds at later stages. Under such situation, managing weeds through pre and post-emergence herbicide will be an ideal means for controlling the weeds in view of economics and effectiveness of sweet corn cultivation. Even though the farmers use pre-emergence herbicide in many instances, early weed control are not sufficient because the weed flourishes even after critical period of crop-weed competition. So the mechanical and manual weeding method has to be given priority in Indian agriculture scenario. Keeping primarily this aspect in foresight, the present experiment has been undertaken to devise an appropriate weed management practices for enhancing the productivity of sweet corn during kharif season.

## MATERIAL AND METHODS

The field experiment was carried out in randomized block design with eight treatments and three replications at Agronomy Main Research Farm, Orissa University of Agriculture and Technology, Bhubaneswar, Orissa during the kharif season of 2017. The treatments were comprised of atrazine @ 1kg /ha as pre-emergence at 1day after sowing (DAS) followed by hand weeding at 20 DAS, tembotrione @ 125g/ha at 20 DAS as post emergence, atrazine @ 0.5kg /ha + tembotrione @ 60g /ha as tank-mix at 20 DAS, power weeder at 20 DAS, cycle hoe at 20 DAS, hand weeding at 20 DAS and 40 DAS, hoeing followed by weeding and earthing-up at 20 DAS and 40 DAS and control (Weedy check). The soil characteristics were sandy loam in texture, acidic in reaction with pH of 5.73 and medium in organic carbon content (0.66%) with low in available N (158.96 kg/ha), medium in P<sub>2</sub>O<sub>5</sub> (20.36 kg/ha) and low in K<sub>2</sub>O (104.56 kg/ha). The sweet corn variety NS 680 was sown in the month of 31st July, 2017 with a spacing of 60cm from row to row and 30cm from plant to plant. Half the dose of N i.e. 60 kg/ha, full dose of P<sub>2</sub>O<sub>5</sub> (60 kg/ha) and half dose of K<sub>2</sub>O i.e. 20kg/ha were applied as basal and remaining N and K<sub>2</sub>O doses were applied at 20 and 40 DAS in two equal splits. The weed count and weed dry weight were recorded from an area of quadrant size of 1m×1m at 20, 40 and 60DAS. The crop was sprayed with monocrotophos @ 0.2% at 20 and 40 DAS to save the crop from various insect attacks. At harvest, yield attributing characters like cob length and cob girth along with fresh cob yield and fresh kernel yield were recorded from all the plots.

## RESULTS AND DISCUSSION

The experimental site was infested with all total 19 weeds comprised of seven grasses, two sedges and ten broad leaved weeds. Amongst the grasses, *Cynodon dactylon*, *Dactyloctenium aegyptium*, *Digitaria ciliaris*, *Eleusine indica*, *Panicum maximum*, *Paspalum scrobiculatum*, *Sporobolus diander* and *Cyperus iria* and *Cyperus rotundus* in sedges and *Ageratum conyzoides*, *Boerhavia diffusa*, *Celosia argentea*, *Cleome rutidosperma*, *Cleome viscosa*, *Commelina benghalensis*,

**S.K. Lenka et al.**

*Melochia corchorifolia*, *Oldenlandia corymbosa*, *Portulaca oleracea* and *Sida acuta* under broad leaved weeds were observed.

### Effect on weed population

The data pertaining to weed population at 20, 40 and 60 DAS presented in the Table 1 indicated that weed population was remarkably reduced with weed management treatments. Significantly the lowest weed population was observed in atrazine + hand weeding (9.01/ m<sup>2</sup>) at 20 DAS. The next best result was obtained in hand hoeing followed by weeding and earthing-up (12.19/ m<sup>2</sup>) atrazine (@ 0.5 kg /ha) + tembotrione (@ 60 g /ha (12.31/ m<sup>2</sup>) and hand hoeing (12.93 / m<sup>2</sup>) at 20 DAS. During 40 DAS, weed density was reduced with atrazine + hand weeding (8.99 / m<sup>2</sup>) followed by hand hoeing combined with weeding and earthing-up (10.84 / m<sup>2</sup>), hand weeding ( 10.99 / m<sup>2</sup>) and atrazine (@ 0.5 kg /ha + tembotrione (@ 60 g /ha (12.65/ m<sup>2</sup>) which were at par.

At 60 DAS, the minimum weed population was observed in hand hoeing followed by weeding and earthing-up (11.30 / m<sup>2</sup>) which was at par with all the weed management treatments except cycle weeder and unweeded check. At 20, 40 and 60 days after sowing (DAS), the treatment atrazine + hand weeding recorded the lowest weed population which was possible due to application of pre emergence spray which acts as a inhibitor of photosystem-II leading to death of the weeds at early stage of crop followed by hoeing performed at 20 DAS controlled all types of weeds. The results are in line with Kolage *et al.* (2004) [2] who showed that atrazine applied as pre-emergence spray reduced the weed intensity substantially at 15 days of crop growth.

Afterwards the hand weeding at 20 DAS resulted in removal of left over weed population thereby providing weed free condition during critical period of crop weed competition during 15 to 45 DAS. Patel *et al.* (2000) [5] reported that pre-emergence application of atrazine @ 1.0 kg a.i./ha in combination with hand weeding at 35 DAS was most effective in reducing the total number of weeds. Similar favourable results were obtained by Deshmukh *et al.* (2008) [1] who reported that pre-emergence application of atrazine @ 0.75 kg /ha followed by one hand weeding at 45 DAS was most effective way of weed control. The efficiency of cycle hoe operation in management of weeds in rainy season was not effective as the dense rooting pattern of weeds along with spacing provided in between the tynes of cycle hoe did not uproot the weeds properly. Tank mix application of atrazine + tembotrione also failed to give desired yield due to lesser weed control because of only single application and the results are in line with Williams *et al.* (2011) [10]

### Effect on weed dry weight

The data presented in Table 2 indicated the significant influence of weed management treatments on weed dry weight at different stages of crop growth. The lowest dry weight was recorded in atrazine + hand weeding ( 1.87g/m<sup>2</sup>) being at par with weeding done by power weeder ( 2.13g/m<sup>2</sup>) at 20DAS. At 40 DAS, atrazine + hand weeding (3.18g/m<sup>2</sup>) was the single best treatment in reducing the weed dry weight. It was followed by hand hoeing combined with weeding and earthing-up (4.09 g/m<sup>2</sup>) which remained at par with weeding done by power weeder ( 4.43g/m<sup>2</sup>) at 40 DAS. During 60DAS, the significant reduction in weed dry weight was observed in the hoeing followed by weeding and earthing up at 20 and 40 DAS (2.81g/m<sup>2</sup>). It was resulted in due to imposition of most effective and efficient manual method of weeding in combination of hoeing, weeding and earthing up operations performed at 20 and 40 DAS. This was closely followed by hand weeding (3.68g/m<sup>2</sup>) which did not differ significantly from atrazine + hand weeding (4.18 g/m<sup>2</sup>). Similar kind of result was obtained by Nagalakshmi *et al.* (2006)[3] who reported that hand weeding twice at 3 and 6 weeks after sowing recorded significantly the lower weed dry matter.

The reduction in weed dry weight in pre emergence application of atrazine followed by hand weeding is attributed to the cumulative effect of herbicides and hand weeding which resulted in reduced dry matter production of weeds

by lowering the weed population. This result is in agreement with Sunitha *et al.* (2012) [8]. Power weeder which has high efficiency failed to contribute towards weed control due to single treatment imposition and lesser skilled weeder operator. This result is corroborated with Sekhar *et al.* (2010) [7]. The maximum weed dry weight was recorded in unweeded control were 3.39, 7.49 and 8.88 at 20, 40 and 60 DAS respectively. It is mainly due to higher and uninterrupted growth of weeds which made depletion of growth resources like solar radiation, moisture and nutrient.

### Effect on weed control efficiency (WCE)

The weed control efficiency (WCE) was remarkably affected by various weed control treatments (Table 2). At 20 DAS, the weed control efficiency was significantly increased in atrazine + hand weeding (48.39%) over all other weed management treatments. During 40 DAS, the same treatment atrazine + hand weeding was found superior in recording the maximum WCE (57.50 %). The next best result was recorded in hand hoeing followed by weeding and earthing-up at 20 DAS and 40 DAS (45.26 %). The increase in weed control efficiency at initial period crop growth at 20 DAS upto knee high stage (40 DAS) is due to reduction in weed population and dry weight by pre emergence application of herbicides followed by later manual weeding at 40 DAS. The results are also in conformity with Sunitha *et al.* (2012) [8] who reported that pre-emergence application of atrazine 0.5 to 1.0 kg *a.i./ha* in combination with hand weeding at 30 DAS recorded the highest weed control efficiency due to the lowest weed dry weight. Significantly the highest WCE was observed in hand hoeing followed by weeding and earthing-up treatment (68.35 %) at 60 DAS. It was followed by hand weeding at 20 DAS and 40 DAS (58.55 %) and atrazine + hand weeding (52.86 %). This was possible due to imposition of most effective manual method of weed control at 20 and 40 DAS that resulted in smothering of weed growth thereby improved weed control efficiency. The efficiency of tembotrione in reducing weed dry weight is far lesser due to it's effectiveness confined only to monocot grassy weeds.

### Effect on yield components and yield

The perusal of data presented in Table 3 revealed the significant effect of weed managements treatments on yield attributes like cob length, cob girth and number of grains/cob along with green cob yield and fresh kernel yield. The data regarding length of cob showed that the highest cob length was recorded in atrazine + hand weeding (25.55 cm) which was at par with hoeing + weeding + earthing up (22.59 cm) and hand weeding (20.88 cm). The lowest cob length was recorded in unweeded control (16.66 cm) followed by atrazine and tembotrione tank mix (17.44 cm). The maximum girth of cob was observed in atrazine + hand weeding (18.11 cm) closely followed by hoeing + weeding + earthing up (17.78 cm) and hand weeding (16.80 cm) which were at par with each other. The highest number of grains per cob was recorded in pre emergence application of atrazine with hand weeding (573.48) which was at par with combination of hand hoeing weeding and earthing up (556.70). The lowest number of seeds per cob was recorded in un weeded control (389.76) followed by atrazine and tembotrione tank mix (409.79).

The yield attributes of crop are influenced by genetic traits as well as agronomical practices out of which management of weed is one of the common agronomic practices. Pre emergence application of atrazine at early stages of crop growth reduced the weed population and dry weight thus, eliminated the crop weed competition giving an edge to crop over weeds which was concreted by hand weeding at 20 DAS. Similar favourable results were obtained by Sanodiya *et al.* (2013) [6] and Swetha *et al.* (2015) [9]. The improvement in yield attributes was resulted in manual methods due to it's effectiveness in reducing the weed population and dry weight and gave the opportunity for greater availability of crop growth resources. The green cob yield was the highest in atrazine + hand weeding (34.75 t/ha) being at par with manual hoeing followed by weeding and earthing up at 20 and 40 DAS (30.70 t/ha) and hand weeding at 20 and 40 DAS (29.74 t/ha). The lowest fresh cob yield was obtained in weedy check treatment (13.57 t/ha) followed by atrazine and tembotrione tank mix (17.30 t/ha). The fresh kernel yield followed the similar trend as observed in green cob yield. The pre emergence application of atrazine with hand weeding at 20 DAS combination of hand hoeing, weeding and earthing up at 20 and 40 DAS and hand weeding at 20 and 40 DAS were superior over all other treatments recording the fresh kernel yield of 12.61, 11.03 and 10.80 t/ha, respectively.

**S.K. Lenka et al.**

Sweet corn yield is greatly influenced by dry matter accumulation in different parts. Weed as a biotic stress causing factor has a prominent role in it. The enhancement in green cob yield and fresh kernel yield with pre emergence application of atrazine supplemented with one hand weeding at 20 DAS and manual weeding in combination of hoeing, weeding and earthing up at 20 and 40 DAS is ascribed to increase in weed control efficiency and yield components in these weed management treatments. Similar favourable results on improvement in yield of corn with pre emergence application of atrazine followed by hand weeding was obtained by Sunitha et al. (2012) [8] and manual method of hand weeding at 20 and 40 DAS was reported by Sanodiya et al. (2013) [6] and Swetha et al. (2015) [9].

## CONCLUSION

Pre emergence application of atrazine @1.0 kg/ha at 1 day after sowing supplemented with one hand weeding at 20 days after sowing is the most effective and efficient method of weed control in reducing the weed population and dry weight along with enhancement in yield components, green cob yield and fresh kernel yield of sweet corn under rainfed condition.

### ABSTRACT

The present investigation was conducted to examine the genetic diversity existing among 36 genotypes of blackgram, during *kharif-2015* under randomized block design with three replications. The data was recorded for thirteen quantitative characters to obtain estimates of variability, heritability, genetic advance and divergence. Analysis of variance showed significant differences between genotypes for all the 13 characters studied. High estimates of GCV and PCV were observed for clusters per plant followed by plant height, seed yield per plant and biological yield per plant. High heritability coupled with moderate genetic advance was recorded for seed yield per plant. The 36 genotypes were grouped in to seven heterogeneous clusters. Among these clusters, cluster II have a maximum number of genotypes (10). On the basis of mean performance genotypes VALLABH URD- 01 followed by KPU 12-133 were found to be the best genotypes in Allahabad agro-climatic conditions. The characters such as plant height and seed yield per plant which should be given top priority for effective selection. Percent contribution towards the total divergence was maximum through seed index followed by seed yield per plant and biological yield. The present investigation revealed that cluster II and VI are most diverse to each other and the genotypes constituted in these clusters may be used as parents for future hybridization programme.

**Keywords:** Blackgram, genetic advance, GCV, PCV, heritability, genetic advance and quantitative traits.

### INTRODUCTION

Blackgram is basically a tropical crop but it is grown in both *Kharif* and *Zaid* season in India. Since the crop is grown in various agro-ecological condition and cropping system with diverse cultural practices, No single plant type is appropriate for all production system, this is a need for collection of existing genotypes for potential utilization in

24190

**Eagala Shiva Prasad et al.**

development of appropriate plant type, exploitation of hybrid vigour, widening the genetic base, multiple resistance, remunerative cropping systems and intercrop besides matching production and protection technologies can help to realize the long cherished goal of making country pulses efficient especially. Lack of stable varieties for higher yield is a major bottleneck for growing of this crop Therefore for increasing the productivity of Blackgram collection and characterization of germplasm from different regions of cultivation need specific emphasis. In order to step up the production potential, it is necessary to launch a dynamic breeding programme to develop improved blackgram varieties suitable for different agro-climatic regions. For planning and execution of a successful breeding programme, the most essential pre-requisite is the availability of substantial desirable genetic variability for important characters in the genotype collections of the plant species. The available variability in a population can be partitioned into genetic parameters such as coefficients of variation, heritability and genetic advance to serve as basis for selection of desirable genotypes than existing ones.

A successful breeding programme in blackgram would need information on the nature and degree of genetic divergence in the available stock for choosing the right parents for further improvement. Subsequently, heterosis is directly proportional to genetic divergence and to dominance square and is also associated with adaptation (Falconer, 1981). The accurate estimation of genetic diversity can be invaluable in the selection of diverse parental combinations to generate segregating progenies with maximum genetic variability (Barrett and Kidwell, 1998) and Introgression desirable traits from diverse germplasm in to the available cultivars with respect to plant varietal protection and germplasm maintenance by removing the duplicity and misidentify in the core accessions. Quantitative traits provide an estimate of genetic diversity and numerical taxonomic techniques including principle component and cluster analysis have been successfully used to classify and measure the pattern of genetic diversity in germplasm, as in blackgram (Ghafooret al., 2001). Mahalanobis's  $D^2$  statistics is a very sensitive tool for measuring genetic divergence based on quantitative traits and is also widely used by many breeders for selection of divergent parents for hybridization programme.

## MATERIALS AND METHODS

The material for the present study comprised 36 blackgram genotypes accessions along with one check (SHEKAR-2), evaluated in a randomized block design with 3 replications at Research Farm of Department of Genetics and Plant Breeding, SHIATS, Allahabad during *Kharif* season, 2015. All the standard cultural practices and packages were followed to raise a good and healthy crop. In each entry, five competitive plants were selected randomly, data recorded on thirteen traits *viz.*, days to 50% flowering, days to 50% pod setting, plant height, number of branches per plant, number of clusters per plant, number of pods per plant, pod length, number of seeds per pod, days to maturity, biological yield per plant, harvest index, seed index and seed yield per plant. The analysis of variance was carried out for all the characters and then data was analyzed following multivariate analysis of Mahalanobis, (1936) and genotypes were grouped into different clusters following Tocher's method (Rao,1952).

## RESULTS AND DISCUSSION

A wide range of variation was observed among 36 blackgram (*Vigna mungo* L. Hepper) genotypes for thirteen quantitative characters. The perusal of data revealed that variance due to treatment was highly significant for all the characters exhibited by the genotypes. Significant genetic variation in various component characters might be effective.

### Genetic Parameters

The analysis of variance revealed significant differences among the genotypes for all the characters studied (Table 1). Close relationship between GCV and PCV was found in all the characters and PCV values were slightly greater than

**Eagala Shiva Prasad et al.**

GCV, revealing very little influence of environment for their expression. On an average, the higher magnitude of GCV and PCV were recorded for cluster per plant, plant height, seed yield per plant, biological per plant, seed index and harvest index suggesting sufficient variability and thus scope for genetic improvement through selection for these traits, similar findings were also reported by Neelavati and Govindarasu, (2010). It indicates that the existence of wide spectrum of variability for these traits and offer greater opportunities for desired traits through phenotypic selection. High heritability coupled with moderate genetic advance was registered for plant height (Table-2) suggesting predominance of additive gene action and non additive gene action in the expression of this trait. Therefore, this character can be improved by mass selection and other breeding methods based on progeny testing.

### Genetic divergence

The 36 diverse genotypes were grouped into seven cluster using Mahalanobis  $D^2$  statistic (1936) and Tocher's methods. Clustering pattern indicate that II is the largest comprised 10 out of 36 genotypes. On the other hands cluster I and VI comprised 6 genotypes, cluster III comprised 5 genotypes and cluster IV and V comprised 4 genotypes and cluster VI comprised 1 genotype respectively. The pattern of group constellation proved the existence of significant amount of variability. Appreciable genetic divergence in blackgram has been earlier reported by number of workers. The inter cluster  $D^2$  value was maximum between cluster II and VI (421.92) followed by I and V (326.24) and I and VI (309.93) Suggesting that the genotype present in these clusters may be used as a parents for hybridization programme to develop desirable type as heterosis can be best exploited and chance of getting transgressive segregants are maximum when generating diverse lines are crossed (Lal et al., 2001).

Hybridization programme involving genetically diverse parents belonging to different clusters would provide an opportunity for bringing together gene constellation of diverse nature, promising hybrid derivatives probably due to complementary interaction of different genes in parents (Murty and Anand, 1968). The selection and choice of parents mainly depends upon contribution of characters towards divergence. Contribution towards genetic divergence is presented in table 4. The highest contribution in manifestation of genetic divergence was exhibited by seed index (35.24) followed by seed yield per plant (25.71), biological yield per plant (20.95), pods per plant (7.78) and days to 50% maturity (3.02) Suggesting scope for improvement in these characters. In other words, selection for these characters may be rewarding. Similar results were reported by Pandey and Anurag, (2010). for biological yield and test weight.

### CONCLUSION

On the basis of results the genotypes VALLABH URD 01 followed by KPU 12-133, KPU 406 and KPU 12-219 were identified as the genotypes for seed yield at Allahabad region. The present investigation registered high heritability along with high genetic advance as a 5% of mean for seed yield per plant which should be given top priority for effective selection the present investigation further revealed that cluster II and VI are most diverse to each other. Therefore, genotypes present in these cluster are suggested to provide a broad spectrum variability in segregating generations and may be used as parents for future hybridization programme to develop desirable genotypes.

### ABSTRACT

The present investigation consists of 25 rice genotypes. The study was conducted for yield and yield contributing traits in randomized block design (RBD) with three replications, at Field Experimentation Centre, Department of Genetics & Plant Breeding, SHIATS, Allahabad (U.P.). The data were recorded on 13 characters to study the analysis of variance, Coefficient of variation, heritability, Genetic advance and coefficient of correlation. Based on the mean performance among 25 genotypes of rice NDR359 genotype was found to be superior in grain yield. The analysis of variance revealed significant differences for all the characters indicating sufficient variability among the genotypes. Highest genotypic and phenotypic coefficient of variations were recorded for harvest index. The characters viz., number of spikelets per panicle and biological yield per hill exhibited high heritability coupled with high genetic advance. The perusal of genotypic and phenotypic correlation coefficients indicated that harvest index, biological yield per hill, tillers per hill, panicles per hill and test weight were significantly and positively associated with grain yield.

**Keywords:** Genetics, variation, number, harvest, biological, genotypic, phenotypic

### INTRODUCTION

India is the largest rice growing country in world. However, its productivity per unit area by world standard is low. In order to increase rice productivity, high yielding and disease resistant varieties should be developed. Knowledge on the genetic architecture of genotypes is necessary to formulate efficient breeding methodology. It is essential to find out the relative magnitude of additive and non additive genetic variances, heritability and genetic gain with regard to the characters of concern to the breeder. Breeding strategies is chiefly influenced by the choice of germplasm.

**Aakula Naresh et al.**

The systematic breeding program involves the steps like creating genetic variability practicing selection and utilization of selected genotypes to evolve promising varieties. Selection of high yielding varieties based only on grain yield will not be much effective unless adequate information on genetic parameters are available to formulate hybridization and selection program for further improvement because the estimate of the mean serves as a basis for eliminating the undesirable genotypes. Whereas genetic variability (GCV and PCV) help to choose the potential genotypes. Heritability along with genetic advance would be more useful tool in predicting the resultant effect from selection of the best genotypes for yield and some of its components in rice. It is very difficult to judge whether observed variability is highly heritable or not. Moreover, knowledge of heritability is essential for selection based improvement as it indicates the extent of transmissibility of a character into future generations. (Kumar and shukla,2002). The grain yield is the primary trait targeted for improvement of rice productivity in both favorable and unfavorable environments from its present level. Heritability estimates can anticipate improvement by selection of useful characters. Hence, objectives of the present study is to evaluate the 25 rice germplasm for yield and its component traits and to estimate the genetic variability among 25 rice germplasm and to study the interrelationship among the characters with seed yield

## MATERIALS AND METHODS

The experiment was laid out with 25 rice genotypes in a Randomized Block Design with 3 replications at the field experiment center of the Department of Genetic and Plant Breeding, School of Agriculture, Sam Higginbottom Institute of Agriculture, Technology and Science (Formerly Allahabad Agriculture Institute), Deemed to be University Allahabad During kharif. Recommended packages of practices were followed for superior crop growth. The data were recorded five randomly selected plants from each replication leaving the first two border rows from all the four sides, in order to avoid the sampling error. The observations were recorded as per the following procedure. Readings from five plants were averaged replication wise and the mean data was used for statistical analysis for the 13 characters. Analysis of variance was done according to procedure given by Panse and Sukhatme (1967). The formula used to calculate PCV and GCV were given by Burton (1952). Heritability was calculated by the formula given by Lush (1949) and Burton and Devane (1953).

## RESULT AND DISCUSSION

Analysis of variance showed highest significant difference among 25 rice genotypes for all the characters under study, suggesting that the genotypes were genetically variable and indicating the presence of substantial genetic variability. A perusal mean performance revealed that genotype NDR359, has highest mean performance for yield per plant (22.92 g) and genotype HHZ10-DT7-51 has maximum number of spikelet's (262.67). Genotype HHZ10-DT7-51 recorded highest mean performance for harvest index (53.33%) and genotype NDR359 recorded highest mean performance for plant height (99.40cm). on the basis of mean performance for yield the genotypes NDR359 (22.92g), BP1620F-BB-17-BB8 (22.83 g),HHZ10-DT7-51 (21.70 g), BHS825 (19.83 g), HHZ1-DT3-Y1-Y1 (19.66 g) were regarded as the best genotypes for grain yield per hill.

Less difference in the estimates of genotypic and phenotypic variance and higher genotypic values compare to environment variances for all the character suggested that the variability present among the genotype were mainly due to genetic reason with minimum influence of environment and hence heritable. The phenotypic coefficient of variation (PCV) was higher than the genotypic coefficient of variation (GCV) for all the characters are presented in (table 1) the result are in conformation to the findings of Deosarkaret al., (1989). PCV was higher than GCV for 13 character studied, indicating little role of environment on the expression of this characters. Maximum phenotypic coefficient of variation (PCV) was observed for harvest index (43.38) followed by grain yield per plant (31.92) and lowest PCV observed in days to maturity (3.84).

**Aakula Naresh et al.**

The maximum genotypic coefficient of variation (GCV) was observed for harvest index (43.30) followed by grain yield per plant (29.84) and lowest GCV observed days to maturity (3.77). Heritability estimates revealed that character like harvest index (99.00), spikelet's per panicle (99.00), and flag leaf length (99.00) followed by biological yield (97.00), days to 50% flowering (96.00), days to maturity (96.00), test weight (94.00), plant height (91.00), seed yield per plant (87.00) flag leaf width (80.00), panicles per plant (75.00), panicle length (74.00), and tillers per plant (56.00). Estimates of genetic advance revealed that character number of spikelet's per panicle (92.27) and lowest genetic advance for flag leaf width (0.19). Estimates of genetic advance as percent of mean revealed that highest for harvest index (89.04%) followed by seed yield per plant (57.48%) and lowest for days to maturity (7.61%).

Relatively high differences between genotypic coefficient of variation and phenotypic coefficient of variation for observed for flag leaf width seed yield per plant number of tillers per plant panicles length and days to maturity. These findings suggested that greater influence of the environmental in the expression of these traits similar results were also reported by Mohammad *et al* (2002) that the high magnitudinal difference between phenotypic coefficient of variation and genotypic coefficient of variation for flag leaf width and number of panicles per hills, where as environmental coefficient of variation contributed more in the expression of these characters.

Heritability is a measure of the extent of phenotypic variation caused by the action of genes. It is evident that the heritability (broad sense) was estimated for 13 quantitative characters under study, ranged from 56% (number of tiller per plant) to 99% (harvest index). Mhandarkaret *al* (2002), Patilet *al* (2003), Viveket *al*. (2004) and Elayarajaet *al*. (2005) registered high estimated of heritability for grain yield per plant. Genetic advance for all the characters under study was ranged from 7.61% (Days to maturity) to 89.04% (Harvest index). High heritability along with high genetic advance as percent of mean was registered for harvest index, spikelet's per panicle and seed yield per plant. Suggesting preponderance of additive gene action in the expression of these characters. This type of character could be improved by mass selection and breeding methods based on progeny testing.

**Correlation Coefficient**

Correlation coefficient is a statistical measure which is used to find out the degree and direction of relationship between two or more variable. Seedyield per hill showed positive significant association with harvest index (-0.879\*\*\*), spikelet's per panicle (0.653\*\*\*), tillers per plant (0.359\*\*\*), test weight (0.227\*\*), and panicles per plant (0.225). It showed positive non-significant association with panicle / length (0.028\*) and days to 50 % flowering (0.004\*). The correlation of grain yield per hill showed negative significant association with days to maturity (-0.246\*\*) and plant height (-0.132\*\*) and. It showed negative non-significant association with biological yield (-0.087\*), flag leaf width (-0.072\*) and flag leaf length (-0.025\*) at genotypic level. Seed yield per hill showed positive significant association with harvest index (0.820\*\*\*), number of spikelet's per panicle (0.607\*\*), tillers per plant (0.316\*\*), panicles per plant (0.224\*\*) and test weight (0.200\*\*) It shows positive non-significant association with panicle length (0.028\*) and days to 50% flowering (0.012\*) It shows negative significant association with plant height (-0.127\*) and days to maturity (-0.211\*). It showed negative non-significant association with flag leaf width (-0.097\*), biological yield (-0.077\*) and flag leaf length (-0.023\*) at phenotypic level.

Simultaneous expression of character may be either due to pleiotrophy or genetic linkage. If the relationship is due to manifold effect on gene or genes, it is difficult to separate those effect by selecting a particular character.

Hence, the investigation it could be concluded that among the 25 rice genotype evaluated under Allahabad condition, on the basis of per se performance NDR359 genotype was found to be superior in the yield followed by BP10620F-BB-17-BB8 and HHZ10-DT7-51 spikelet's per panicle and BP12816F-KN-7-1 test weight.

### ABSTRACT

Climate change has evolved from a topic of future speculation to an inconvenient reality of the present. It gives about the inseparable link between agriculture and climate variables, the impact of climate change on agriculture and food security which has been at the forefront of research and on the political agenda in recent times. Climate change in India is becoming quite evident, and the changes are much more evident than in other parts of the country. Due to changing weather, extreme abiotic factors such as high and low temperatures, drought, salinity, osmotic stress, heavy rainfall, floods, frost damage poses a serious threat to rice production and is also harmful to farmer and sustainability for rice cultivation. There is a great need to frame strategies against these problems. Crop improvement will help to find a sustainable and effective solution against negative impact of climate change. Advances in molecular breeding will help and exploit the inherent potential of wild species through transferring potential genes of abiotic/biotic tolerance through introgression. It must be done with the help of molecular markers to identify the underlying QTL / genes with the development in the techniques including DNA microarray, mass spectrometry, RNA sequencing or other modern high performance using genomic strategies. It is now possible to decipher the underlying metabolic pathways through the top-down approach. The present review provides an overview of recent evidence, the potential impacts of climate change on rice and it also offers its mitigation strategy by improving productivity of rice of different germplasm in India.

**Keywords:** Climate Change; Rice Production; Abiotic Stress; Biotic Stress; Molecular Breeding

## INTRODUCTION

The Indian subcontinent has a rich diversity in rice germplasm that includes terrestrial races, wild *Oryza* species, related genera, natural hybrids between wild relatives and germplasm resources generated through breeding programs. The large-scale dissemination of modern, high-yielding varieties and changes in cultural practices are leading to a narrowing of the genetic basis of rice cultivation. Wild rice species are in danger of extinction due to environmental deprivation. The value of rice germplasm collected and stored in terms of useful economic characteristics has been demonstrated in many screening tests. Recently, a network project launched in the country has evaluated more than 12,000 accessions and identified adhesions with tolerance / resistance to pests and pathogens and various abiotic stresses (Paroda, R.S. and S.S. Malik 1990). The characterization and evaluation of germplasm, complemented by biosystemic studies that use wild species and also molecular studies of genetic diversity, is generating the information base for a more efficient use of these precious resources.

Genetic improvement has become a necessary of all rice breeding activities. However, a large number of germplasm accesses are awaiting an appropriate evaluation and characterization. A systematic evaluation and improvement must be carried out in a way related to the mission of time, with the participation and association of all parties involved in the development of stable and durable varieties with resistance / tolerance multiple. Breaking the yield limit through genetic improvement becomes the priority in rice research (Ashraf et al. 1994). The exploitation of heterosis through the hybridization of rice provides a brilliant opportunity to increase the yield potential of rice in the tropics. The hybrids of the indica tropical elite varieties and the new type of tropical japonica plant are under development. The ideological approach to the selection of plants is also required, using physiological attributes as selection criteria. Improving the productivity of rice cultivation involves selecting the germplasm available for biotic and abiotic stress tolerance and the intensification of research in genetics. The physiological mechanisms of tolerance to this stress would be important (Evans, 1990). To meet diversified needs, varieties compatible with the consumer on a time scale would be desirable.

The germplasm evaluated should only be used if there is an adequate documentation system to consolidate and disseminate the information generated. Furthermore, in view of existing and rapidly emerging IPR regimes, it is essential to ensure easy access to genetic resources for uninterrupted varietal improvement (Donald, 1968). In an IPR regime based on subsidies, access cannot be facilitated unless there is a fair and equitable distribution of benefits due to the materials used in the developed products and the benefits of their commercialization. To fully utilize diversity, germplasm centers must have a genetic resources unit (GRU) in which accessions are maintained and provided to breeders. In addition, the molecular characterization of the released varieties and genetic reserves of the elite should be taken gradually (Evanson, 1994). Biotechnologically improved germplasm improvement provides a path for collaboration between the public and private sectors with a proportional distribution of benefits. However, ecological risks should always be assessed on a case-by-case basis to understand potential and probable problems, if any.

In this direction, climate is changing beyond the average atmospheric condition through natural factors such as the orbit of the terrestrial revolution, volcanoes and movements of the crust from artificial factors such as the increase in the concentration of greenhouse gases such as CO<sub>2</sub>, methane, etc. In fact, agriculture is often considered as the most time-dependent human activity (Hansen, 2002). Global climate change can have possible consequences on global agricultural production (Berg et al., 2013) and can alter the food availability, decrease access and impact the quality of food (USDA 2015). The estimated increase in temperatures, fluctuations in precipitation patterns, the occurrence of extreme weather events and the lower availability of water can lead to a reduction in agricultural productivity. The general circulation on climate change, due to the increase in the concentration of greenhouse gases (GHG), the global average temperature of the surface will increase between 1.5 and 4.5 ° C during the next 100 years (Senapatiet al., 2013).

India is also one of the largest exporters of cereal crop rice. Rice is an important crop that represents approximately one third of the caloric consumption of third world populations. The largest rice producers are China, India and Indonesia. Rice cultivation is the main activity and source of income for more than 100 million families in developing countries in Asia, Africa and Latin America (Desirajuet *et al.*, 2009). China and India play an important role in the production and consumption of rice (Alias Bin *et al.*, 2006). Approximately 2.5 million tons of ground rice is required each year to support the current level of food adequacy. In India, rice contributes 43% of total cereal production and 46% of total cereal production (Nandhini *et al.*, 2006). High projected temperatures can cause a significant reduction in world rice production. The productivity of rice crops depends to a large extent on climate change, in which it is necessary to maintain it at the highest level in order to meet future food demands for the growth of the population in India (Hundal and Prabhjyot, 2007).

Agronomic studies in India, suggest that a temperature increase of 4 ° C would result in a drop in grain yields of 25-40% (Rosenzweig and Parry, 1994). In developing countries, adaptation options such as changes in crop management or breeding practices or improvements in irrigation are more limited. Kumar (2009) reported an estimated decrease of approximately 3% of the company's annual net income in India for a scenario that predicts a temperature variation of + 2 ° C and a variation in the precipitation equal to + 7%. According to Cline (2007), agricultural productivity in India will seriously affect. Southern India will have to face a reduction in crop yield in the range of 15 to 25%, but in northern India it will be more than 25% between 2003 and 2080. Kumar *et al.* (2016) highlighted that soil productivity decreases with the increase in maximum annual average temperature. Using simulations, it was predicted that climate change would result in decrease of 48.63% land productivity by 2100 and a loss of income for farmers in India.

Climate change would threaten the agricultural sector in developing countries, causing serious problems for production and food security, with a greater influence on marginal farmers (Thornton *et al.*, 2013). In India, forecasts on the impact of climate change on rice production began in the 1990s. There are experiments conducted in different parts of India to assess the effect of climate change on rice production in India using different models. It will be very useful in predicting the impact of climate change on future agricultural rice production in India.

### Diversity

The availability of different germplasm should be ensured through the systematic collection and conservation of local varieties and the wild species that provide the genetic bricks for plant breeding. Populations of local varieties, although predominantly self-fertilized, are genetically heterogeneous. They also differ in varieties, showing a high rate of genetic differentiation. Traditionally, there were a large number of such varieties in each location before the expansion of high-yielding varieties (HYV). Together with wild rice and weeds, these primitive varieties could be highly active in the evolutionary aspect. The diversity of rice genetic resources is running out (Richharia1979). The large-scale dissemination of modern, high-yielding varieties and the replacement of traditional varieties, particularly in the irrigated rice ecosystem, are leading to concern that the genetic basis of rice cultivation has become too small. Changes in cultural practices in which flood risk systems are being replaced by irrigation systems will eventually lead to the loss of several deep-water races. Wild paddy rice species are in danger of extinction due to environmental degradation. This genetic erosion is occurring at a time when new tools of biological research allow scientists to focus on both the diversity of genes and the diversity of genotypes. Although there has been considerable success in protecting and conserving rice biodiversity in recent decades, much remains to be done (Boje-Klein, 1986)

India has abundant resources of wild rice in particular *O. nivara*, *O. rufipogon*, *O. officinalis* and *O. granulata*. Wild rice species can be found in many different natural habitats, from shade to full sunlight, and can be annual or perennial in nature. Some wild species appear as weeds in and around rice fields and even hybridize naturally with cultivated forms. This complex association between cultivated and wild forms can increase the diversity of rice crops in traditional farming systems, where farmers often grow mixtures of varieties to provide a buffer against the risk of total crop loss due to biotic and abiotic stresses. The complex association between cultivated and wild forms can

**Pushpalatha Ganesh et al.**

obviously improve the diversity of rice crops in traditional agricultural systems (Jackson and Huggan1993). Different ecological situations in rice growing areas have given rise to the following main eco-specific rice varieties with seasonal, situation and system specificity:

- The group Aus: early maturation, photosensitive types: it can be grown in all seasons, except in winter.
- The group Aman: late types are mostly sensitive to the photoperiod and flower during a specific period, regardless of when they are sown or transplanted.
- The Boro group: be the best as summer harvest. When sown during the winter, they tolerate better the temperature of the cold in the early vegetative phase than the other groups.
- The Gora group: of short duration, can support a certain degree of water stress during its growth period.
- The Basmati group: specific to the regions of the northern regions of the Indian subcontinent, with extremely valuable quality traits such as elongation, aroma, flavor, etc.

**Germplasm Collections**

According to an estimate, around 50,000 rice breeds should exist in India. A total of 66,745 accesses have been collected so far from various parts of the country. Assuming that almost 50% of the total germplasm is doubled, about 17,000 land races of rice still remain to be harvested. Therefore, a serious effort must be undertaken in this direction. The exploration and collection of native rice cultivars began at the end of the century. The establishment of the agricultural research station in Dhaka in 1911 and the breeding station of Paddy in Coimbatore in 1912 and the central rice.

The Research Institute (NRRI) in Cuttack in 1946 strengthened these activities. This led to the recommendation of 394 varieties for general cultivation, such as selections of pure lines, of the collected germplasm. Systematic exploration programs were initiated between 1955 and 1960 by the Jeypore Botanical Survey, which led to the collection of 1,745 cultivars in southern Orissa and adjacent areas of Madhya Pradesh. About 900 Manipur cultivars were harvested between 1965 and 1967. Between 1965 and 1972, the Indian Agricultural Research Institute (IARI) collected 6630 accessions, which became known as the Assam rice collection. The varieties grown in the Madhya Pradesh region have been harvested and the 19,116 collections collected make up the Raipur Collection (Govindaswami and Krishnamurthy1959). A special initiative for varieties of mountain rice fields grown in Andhra Pradesh, Karnataka, Maharashtra, Madhya Pradesh, Uttar Pradesh, Orissa and West Bengal led to the collection of 1,938 cultivars. The National Plant Genetic Resources Office (NBPGR) increased the collections in the period 1983-1989 with 4,862 accessions. In addition, the joint explorations of NBPGR in collaboration with the State Agricultural Universities (SAU) during 1978-1980 and the NRRI in 1985 led to the collection of approximately 7000 and 447 accessions (respectively from Sikkim, South Bihar and parts of Orissa). VPKAS Almora explored germplasm in the mountainous region of Uttar Pradesh and 1,247 primitive cultivars were collected (Gupta and Tomar 1994).

The wild rice collections were started in the NRRI between 1948 and 1955. Subsequently, the collections were collected in IARI from West, North, Center and East of India. There have also been many joint explorations with other countries. The French team of IRAT and ORSTOM collaborated with ICAR for the collection, in particular on *O. nivara*, *O. rufipogon* and *O. officinalis* of Goa, Karnataka, Maharashtra and Gujarat in 1986 (Malik and Dikahit1990). During 1987-1989, ICAR scientists and IRRI has undertaken an intensive harvest of wild rice in South India and West Bengal (Krishnamurthy and Sharma1987).

**Germplasm Evaluation**

Rice diversity has been well used in efforts to solve current food problems. Local rice varieties have been harvested over several decades to become donors of high-yield, pest-resistant and well-adapted varieties that have led to unprecedented increases in rice yield. The cost of rice for millions of consumers is now about half of what it was in the 1960s. The value of germplasm preserved from rice has been demonstrated in many tests of useful economic characteristics. Thousands of accesses have been tested to resist eight pests and five rice diseases and tolerance to various abiotic stresses (Sharma et al. 1987). Resistance to some pests and diseases such as brown unemployment and

rice explosion is quite common in cultivated rice. The characterization and evaluation of germplasm, complemented by biosystemic studies that use wild species and molecular studies on genetic diversity, is generating the information base for a more efficient use of these valuable resources.

The first purely intensive selection of germplasm collected locally allowed the release of about 400 improved cultivars, obtaining 10 to 20% more of the traditional cultivars and adapted to several agroclimatic regions. The japonica-indica hybridization was launched after 1950 by ICAR to introduce a non-accommodation reactivity and non-lodging fertilizer responsiveness in indigenous tall indica, released variety ADT 27 (Roy *et al.* 1979). In the 1960s, hybridization programs widely used semi-native genotypes of Taiwan in possession of Dee-gee, the woo-gene and several semi-dwarf and high-yielding varieties have been developed. The intensive cultivation of these semi-dwarf hybrids has caused problems of diseases and parasites and, consequently, research has been redirected towards the collection and evaluation of indigenous germplasm, and many donors of resistance have been identified mainly in NRRI and IIRR. ICAR in association with the United Nations Development Program, launched a national hybrid rice project that led to the creation of 12 hybrid research centers in a strategic position. Through this effort, India has launched 14 tropical rice hybrids through public institutions and private seed companies.

In the IIRR, Hyderabad, a large number of germplasm accessions have been evaluated for their agronomic characteristics, including against pests and insect diseases and several promising accessions have been identified. This was a coordinated program for rice improvement in India. All the main rice research centers including NRRI, IARI, TNAU, IGKV, KAU, AAU, NEH Research Complex and others, have participated in this effort. In addition, ICAR approved a network project for the period 1993-1998 in IIRR to evaluate the available germplasm against the main insects and diseases. The network was with two main centers i.e., NBPGR and IGKV, and 13 hot spots namely Almora (UP), Aduthurai (TN), Kapurthala (PB), Sambalpur (OR), Raipur and Jagadpur (MP), Maruteru and Srikakulam (AP), Mandya and Ponnampet (KAR), Moncompu (Kerala) and Pondicherry (UT). Until 1997, more than 15,000 accessions were projected in several hot spot locations and a catalog for 12,000 accessions with 21 characters was developed.

The evaluation efforts have led to the identification of useful features, i.e., resistance or tolerance to tropical strains of bacterial rust, tungro virus, grassy stunt virus, tungro virus, green grasshopper of rice, brown planthopper, stem borer and rosette; and tolerance to salinity, alkalinity, flood and submersion. The list of collection sections for which promising subscriptions / donors have been identified is shown in Table 3.

### Rice production in India

India already devotes more than its precious territory to rice from any other country: up to 42 million hectares. Planting more land for rice is definitely out of the question. The solution must come from squeezing more grain from each plant through the proper exploitation of the diversity of germplasm. By 2025, the world could be required to produce around 765 million tonnes of raw rice compared to 519.63 million tonnes produced in 1995. More than 90% of the additional production needed must come from Asia, where Most live the poorest people in the world. This increase must come from higher productivity on a long-term sustainable basis. The production environment in the future will be very different (Malik and Vaughan 1989). Rice should be grown with less water, less work and much less land. Yields must be increased considerably, even those that could be subject to greater biotic and abiotic pressures. The yield potential of irrigated rice in the tropics has remained stagnant at around 10 t/ha since 1966, when the first Indica semi-dwarf variety, IR8, was launched. Rain-fed rice accounts for approximately 45% of the total area planted with rice in Asia (Roy 1979). Its current average yield of 2.0 t ha<sup>-1</sup> should increase to around 4.0 t ha<sup>-1</sup> over the next 30 years. This increase is also essential to release the pressure on the irrigated rice. The tensions related to water and soils are the limits to increase the production of rain rice (Evanson 1994).

India is one of the largest rice producers in the world and accounts for 20% of world rice production. Rice is the pre-eminent crop of India and represents staple foods in many parts of India. Rice accounts for 23.3% of total cultivated

**Pushpalatha Ganesh et al.**

area and 43% of total cereal production and 46% of cereal production (Singh, 2009). From 1950 to 2015, rice production in India increased along with the rice growing area and the irrigation system (Fig. 2). The country has the largest area cultivated with rice. Rice is basically a kharif (planted during the June-July period and harvested in November-December) which represents 84% of the country's rice crop. Follow the summer rice (planted in November-February and harvested in March-June) to 9% and the autumn rice (planted in May-August and harvested in September-October), which represents 7% of the rice harvest. Rice crops require an optimum temperature of around 25 degree Celsius and rainfall greater than 100 cm. Rice is also cultivated through irrigation in areas that receive less rain. Although due to the occurrence of drought and other extreme events, we can see fluctuations in rice yield in India, there is an increase in yield of up to 400% from 1950-2015 (Fig. 3). However, the yield in rice (kg/hectare) is lower than in other countries. In recent years, in 2009-10, the yield of rice has been reduced due to the severe drought that has affected almost half of the country. In the future, climate change will also affect rice production in India. As the population of India continues to grow, it is a challenge for the agricultural sector in India to increase rice production by fighting the consequences of climate change. Therefore, it is important to study how climate change will affect rice production in India.

**Impact of climate change on rice production**

Studies suggest that rising temperatures, rising sea levels, and changes in precipitation and predicted distribution as a result of global climate change could lead to substantial changes in land and water resources for production and productivity. Rice crops grown in different parts of the world (Nguyen 2002). Studies using the DSSAT models have shown that the increase in temperature can reduce the yield of rice by 12% and the change in precipitation will be responsible for reducing yield up to 31.3%, until 2030. The increase in temperature In the future, the concentration of CO<sub>2</sub> in the atmosphere could also improve the growth of plants through the effect of fertilization because CO<sub>2</sub> is an essential component of photosynthesis (Watanabe and Kume, 2009). When C3 plants, such as rice, are exposed to high concentrations of CO<sub>2</sub>, the speed of photosynthesis of their leaves is accelerated due to both the enrichment of the CO<sub>2</sub> substrate and the inhibition of photorespiration by high concentrations of CO<sub>2</sub>. However, the stimulating effect of the high concentration of CO<sub>2</sub> gradually decreases with the prolongation of the exposure time (Gen-Yun Chen *et al.* 2005). In rice, photosynthetic acclimation is related both to the limitation of RuBP carboxylation and to the limitation of RuBP regeneration (Gen-Yun Chen, 2005).

**Projections about change in rice yield due to climate change in India during 2011-2016**

Geethalakshmi *et al.* (2011) projected climate change in the Cauvery Basin of Tamil Nadu, the results showed that rice production increases with higher and lower temperatures and rainfall. The ADT 43 rice yields simulated by a decision support system for the transfer of agricultural technology with fertilization effect showed a reduction of 135 kg per hectare per decade to provide regional climate results for impact studies (PRECIS), while there was an increase in yield of 24 kg per hectare per decade for the production of model 3 of the regional climate system (RegCMS). If we consider only the effect of the increase in temperature, the increase in temperature of 2°C could reduce rice yields by 15-17 % (Jayaraman, 2011). Kumar *et al.* (2016) affirmed that climate change has altered climatic conditions. It affects seasonal crops and decreases the growth time of available rice in Uttarakhand and Uttar Pradesh. Gupta *et al.* (2012) noted that climate change is likely to reduce rice yields in 16 large and agriculturally intensive Indian states. The slightly positive impact of increased precipitation on rice yields has been overshadowed by the negative impact of rising temperatures on yield, both in wet and dry areas. The expected decrease in rice yield is 1.21% in the wettest areas and 0.92% in the drier areas.

Evaluation of the impact of rice on climate change in ecologically sensitive areas, namely the Western Ghats (WG), the coastal districts and the northeastern states of India, using the simulation model Info Crop, variable effects expected from the climate position, climatic scenario, type of culture and its management (Kumar *et al.* 2016). It is likely that the irrigated rice in the western Ghats region will change from + 5% to -11% in the PRECIS A1b 2030 scenario depending on the location. In the case of rainy rice, the yield can be affected between 35% and 35%, however, a large area can lose yield up to 10%. The results indicate that rice can benefit from CO<sub>2</sub> fertilization in

**Pushpalatha Ganesh et al.**

some places. As for irrigated rice, more fertilizers are supplied than rain rice, which may result in higher yields due to the effect of CO<sub>2</sub> fertilization. Rice is likely to be watered in parts of southwestern Karnataka and in the northernmost districts of Kerala.

During the Kharif season, the 1°C increase did not have a negative impact on performance. The increase in temperature above 1°C has led to a reduction in rice yields. On the contrary, the increase in temperature is showing a positive effect on rice yield during the Rabi season. There is a gradual increase in groundwater flow, percolation, soil water and water yield. The rice yields of the Kharif season with changes in temperature, precipitation and CO<sub>2</sub> are decreasing over time from the current to the end of the century. In the case of Rabi rice, yield levels are not significantly affected over time (Lakshmanan et al. 2011). Auffhammer et al. (2011) used data from India at the state level and, according to statistical analyzes, showed that during 1966-2002, drought and extreme rainfall events had a negative impact on rice yield, especially in rainy areas. Drought causes greater loss than extreme rainfall. Using the simulation, they found that rice yield would have been 1.7% higher in the absence of drought. Hundreds of millions of rice producers and consumers in India are affected by climate change.

The International Rice Research Institute predicted a 20% drop in production per degree of temperature increase in percent. Rice becomes sterile if it is exposed to temperatures above 35 degrees for more than an hour during flowering and, consequently, does not produce wheat (Senapatiet al. 2013). Pattanayak and Kumar (2013) estimated that, in the absence of climate change, rice production in India in 1969-2007 would have been 8% higher. Naresh Kumar et al. (2013) declared the reduction in yields of irrigated rice fields of 4, 7 and 10% during the scenarios of 2020, 2050 and 2080, respectively in India. Saravanakumar (2015) used panel data from 13 districts during the period 1971-2009 to assess the impact of climate change on crop production in Tamil Nadu. The empirical results showed a quadratic relationship (in the form of an inverted U) between the yield of the rice and the climatic variables. As the temperature and precipitation increase, the yield of the crop initially increases to a threshold level and, therefore, decreases. Following the projections of RegCM4 that continue to observe heating and precipitation anomalies, this could result in a significant loss of crop productivity. Projections suggest that there may be a 10% drop in rice yield by the end of the 21st century compared to average yields in the period 1971-2009. A plausible reason to increase the yield can be the effect of the interaction of the temperature with a high concentration of carbon dioxide.

The possible future impacts of climate change on the yield of irrigated rice were evaluated using the Land and Water Assessment Tool and the climate change scenario generated by the MIROC global climate model. The simulation showed a positive impact with an increase in annual rice production between 5.5-6.7, 16.6-20.2 and 26-33.4% during 2020, 2050 and 2080, respectively (Abeysingha et al. 2016). By 2030, throughout India, the average temperature should rise by at least 0.5°C in both summer and winter. In northern India and northwestern India, the temperature should rise by 1°C during the winter. According to the RCP 6.0 projection, in all regions of India, the temperature is likely to increase between 1 and 1.5°C by 2050, but in northern India, including rice production centers such as Punjab and In Uttar Pradesh, the average temperature is likely to increase by 2°C. By 2080, summers and warmer winters are likely to be seen in the northern regions of India such as the Punjab and Uttar Pradesh, with rising temperatures. At 3°C, while in the rest of the rice producing regions of India, the temperature should increase by at least 2°C. There will be more days of interruption and fewer days of monsoons and variation of precipitation. The increase in the frequency of extreme weather events, such as floods and droughts, will cause a decrease in the production of rice crops that will affect food security and the cost of living and, ultimately, worsen rural poverty in India (Teng et al. 2016).

The simulation analysis for the development of strategies for adapting rice to the climate change scenario highlighted low-cost adaptation strategies that included a better variety of crops, a change in variety and better crop management, a change in the time of sowing, an efficient use of irrigation and fertilizers, greater substitution of seeds by farmers and an increase in the application of fertilizers. Adverse changes in meteorological parameters and the decrease of potential yields should be considered as an indication of future problems. Farmers' yields must be

**Pushpalatha Ganesh et al.**

constantly monitored for their stability. Breeders must develop new truths with improved germplasm and be more adjustable in climate change. Scientists working in soil and agronomy must find ways to improve the efficiency of the use of inputs. People in planning and policy development should plan ways to make technology circulate among farmers. Regular monitoring of crops and climatic factors in the effective agricultural area would help to predict problems and allow taking measures to improve productivity.

**CONCLUSION**

The impact of climate change on rice production is of particular interest due to its importance as a food source throughout the world, in Asia and particularly in India. Several studies reveal changes in predictions about the impact of climate change on rice production. Changes in temperature, radiation, precipitation and carbon dioxide levels can affect rice yields through its direct effect and indirect effects. While climate models have done a good job of capturing large-scale aspects of the current climate, they still contain systematic errors of the model that add uncertainty to the future projection. Proud projections of future crop yields lead to a decrease in food self-sufficiency rates in other regions. The impact of high CO<sub>2</sub> emissions and temperature on rice crops is not yet clear. The uncertainty in forecasts is derived from climate models, spatial resolution, and crop models and to add an additional level of complexity, rice cultivation depends on management skills, rice variety, crop model, the infrastructure, etc. Most studies on the impact of climate change on rice production have a negative effect on overall performance. The increase in temperature can shorten the duration of the growth period and, therefore, reduce the yield if management practices are not modified. It can be concluded that a high increase in CO<sub>2</sub> and a low increase in temperature can increase rice yields, while a high increase in temperature and a low increase in CO<sub>2</sub> can lead to a decrease in rice yield to negative effects on the growth of crops. Proactive measures for adaptation to climate change can significantly reduce the negative impacts and, therefore, increase the security of the livelihoods of the rural population at risk. In a scenario of climate change and evolving technologies, it is necessary to introduce crops capable of withstanding fluctuating temperatures and other natural factors.

## **INDIAN JOURNAL OF NATURAL SCIENCES**

**ISSN: 0976-0997**

### **Instruction to Author, 2020**

The Indian Journal of Natural Sciences is a **Bi-monthly International Journal**, which publishes original research work that contributes significantly to further the scientific knowledge in **Natural Sciences** (All science disciplines). The Journal publishes original research work either as a Full Research Paper or as a Short Communication. Review Articles in Natural Sciences are also considered for publication by the Journal.

Type-written manuscripts prepared using MS Word should be submitted in triplicate to The Editor, Indian Journal of Natural Sciences C/oTNSRO,39,Mura Bhavan, Koodal Nagar, Rajagopalapuram Post-622003, Pudukkottai Dist, Tamilnadu, India. Alternatively, the manuscript can also be sent as a MS word document to [ijonstnsro@gmail.com](mailto:ijonstnsro@gmail.com). Manuscripts will be subjected to peer review process to determine their suitability for publication provided they fulfil the requirements of the journal as laid out in the instructions to authors. After the review, manuscripts will be returned for revision along with reviewer's and/or editor's comments. One original copy of the final revised manuscript should be submitted for publication within two months of receiving the reviewer's comments. It is also desirable to submit the final revised manuscript on a CD prepared in MS Word Version 97-2002 or a higher version. Prepare the manuscript in Times New Roman font using a font size of 12. Title shall be in a font size 14. All section titles in the manuscript shall be in font size 12, bold face capitals. Subtitles in each section shall be in font size 12, bold face lower case followed by a colon. There shall not be any decorative borders anywhere in the text including the title page. The entire MS Word document with graphs and illustrations pasted in it shall not exceed 1.2 MB.

Submission of a manuscript to Indian Journal of Natural Sciences for publication implies that the same work has not been either published or under consideration for publication in another Journal. Authors, in their cover note to the Editor, have to clearly mention whether the manuscript shall be considered as a Research Paper, Short Communication or Review Article and also confirm that the manuscript has not been submitted to any other Journal for publication. Authors publishing results from *in vivo* experiments involving animals or humans should state whether due permission for conduction of these experiments was obtained, from the relevant ethics committees, in the Materials and Methods section. In addition, authors wishing to publish research work involving human studies should also send a notary verified letter of approval from the Ethics Committee or the Institutional Review Board.

**Instruction to Author****PREPARATION OF MANUSCRIPTS: RESEARCH PAPERS**

Manuscripts must be prepared in accordance with 'Uniform requirements for Manuscripts submitted to Biomedical Journal' developed by International Committee of Medical Journal Editors (October 2001). Authors desirous of submitting manuscripts for publication to the Indian Journal of Natural Sciences are advised to refer to the current issue of the Journal to understand the format and style of papers that get published. Authors are also advised to go through the current set of Instructions to Authors and prepare their manuscripts accordingly. Information should be conveyed in simple language with the correct syntax. Care should be taken to avoid common errors like having abbreviations in the Title or Abstract, beginning a sentence with a numeral, adding 'etc.' after a few examples, dropping articles and using '&' instead of 'and' in the text. The usage of standard abbreviations and symbols is encouraged. Manuscripts that fail to conform to the requirements of the Journal, as specified under Instructions to Authors, will be rejected outright. Manuscripts should be concisely written and conform to the following general requirements: Manuscripts should be typewritten in double-space in A4 sized sheets, only on one side, with a 2 cm margin on both sides. Research Papers should have more than 15 pages, Review Articles in the range of 15-30 pages and Short Communications up to 15 pages, inclusive of illustrations. Pages should be numbered consecutively, starting with the title page and the matter arranged in the following order: Title page, Abstract, Introduction, Materials and Methods, Results, Discussion or Results and Discussion, Acknowledgements, References, Illustrations (Tables and figures including chemistry schemes along with titles and legends) and figure and Table titles and legends. Abstract should start on a separate page and each table or figure should be on separate sheets. The titles 'Abstract' and 'Introduction' need not be mentioned. All other section titles should be in capital letters while subtitles in each section shall be in bold face lower case followed by a colon.

**Title Page** - Title page should contain title of the paper in bold face, title case (font size 14), names of the authors in normal face, upper case (font size 12) followed by the address(es) in normal face lower case. The author to whom all correspondence be addressed should be denoted by an asterisk mark. The title should be as short as possible and precisely indicate the nature of the work in the communication. Names of the authors should appear as initials followed by surnames for men and one given-name followed by surname for women. Full names may be given in some instances to avoid confusion. Names should not be prefixed or suffixed by titles or degrees. Names should be followed by the complete postal address or addresses with pin code numbers of the place(s), where the research work has been carried out. At the bottom left corner of the title page, please mention 'Address For correspondence' and provide a functional e-mail address. Address of the corresponding author to whom all correspondence may be sent should be given only if it is different from the address already given under authors' names. Trivial subtitles such as 'Title', 'Author', 'Address' or 'Place of Investigation' shall not be included in the title page. Title page should be aligned centre except for 'Address For correspondence'. Provide a running title or short title of not more than 50 characters.

### Instruction to Author

**Abstract** - Should start on a new page after the title page and should be typed in single-space to distinguish it from the Introduction. Abstracts should briefly reflect all aspects of the study, as most databases list mainly abstracts. Short Communications as well as Review Articles should have an Abstract.

**Key-words** - Provide four to ten appropriate key words after abstract.

**Introduction** - Shall start immediately after the Abstract, as the next paragraph, but should be typed in double-space. The Introduction should lead the reader to the importance of the study; tie-up published literature with the aims of the study and clearly states the rationale behind the investigation.

**Materials and Methods** - Shall start as a continuation to introduction on the same page. All important materials used along with their source shall be mentioned. The main methods used shall be briefly described, citing references. Trivial details may be avoided. New methods or substantially modified methods may be described in sufficient detail. The statistical method and the level of significance chosen shall be clearly stated.

**Results** - All findings presented in tabular or graphical form shall be described in this section. The data should be statistically analyzed and the level of significance stated. Data that is not statistically significant need only to be mentioned in the text - no illustration is necessary. All Tables and figures must have a title or caption and a legend to make them self-explanatory. Results section shall start after materials and methods section on the same page.

**Discussion** - This section should follow results, deal with the interpretation of results, convey how they help increase current understanding of the problem and should be logical. Unsupported hypothesis should be avoided. The Discussion should state the possibilities the results uncover, that need to be further explored. There is no need to include another title such as 'Conclusions' at the end of Discussion. Results and discussion of results can also be combined under one section, Results and Discussion.

**Acknowledgements** - Should be given after the text and not in the form of foot-notes.

**References** - Should be numbered consecutively in the order in which they are first mentioned in the text (not in alphabetic order). Identify references in text, tables, and legends by Arabic numerals in superscript in square brackets. References cited only in tables or figure legends should be numbered in accordance with the sequence established by the first identification in the text of the particular table or figure. Use the style of the examples below, which are based on the formats used by the international journals. The titles of journals should be abbreviated according to the style used in international journals. Use complete name of the journal for non-indexed journals. Avoid using abstracts as references.

**Instruction to Author**

Information from manuscripts submitted but not accepted should be cited in the text as ,unpublished observations' with written permission from the source. Avoid citing a ,personal communication' unless it provides essential information not available from a public source, in which case the name of the person and date of communication should be cited in parentheses in the text. For scientific articles, contributors should obtain written permission and confirmation of accuracy from the source of a personal communication. The commonly cited types of references are shown here, for other types of references such as electronic media, newspaper items, etc. please refer to ICMJE Guidelines (<http://www.icmje.org>).

**Articles in Journals**

1. Devi KV, Pai RS. Antiretrovirals: Need for an Effective Drug Delivery. Indian J Pharm Sci 2006;68:1-6.  
List the first six contributors followed by *et al.*
2. Volume with supplement: Shen HM, Zhang QF. Risk assessment of nickel carcinogenicity and occupational lung cancer. Environ Health Perspect 1994; 102 Suppl 1:275-82.
3. Issue with supplement: Payne DK, Sullivan MD, Massie MJ. Women's psychological reactions to breast cancer. Semin Oncol 1996;23(1, Suppl 2):89-97.

**Books and other Monographs**

4. Personal author(s): Ringsven MK, Bond D. Gerontology and leadership skills for nurses. 2nd ed. Albany (NY): Delmar Publishers; 1996.
5. Editor(s), compiler(s) as author: Norman IJ, Redfern SJ, editors. Mental health care for elderly people. New York: Churchill Livingstone; 1996.
6. Chapter in a book: Phillips SJ, Whisnant JP. Hypertension and stroke. In: Laragh JH, Brenner BM, editors. Hypertension: pathophysiology, diagnosis, and management. 2nd ed. New York: Raven Press; 1995. p. 465-78.

**Illustrations: Tables** - Should be typed on separate sheets of paper and should not preferably contain any molecular structures. Only MS word table format should be used for preparing tables. Tables should show lines separating columns but not those separating rows except for the top row that shows column captions. Tables should be numbered consecutively in Arabic numerals and bear a brief title in capital letters normal face. Units of measurement should be abbreviated and placed below the column headings. Column headings or captions shall be in bold face. It is essential that all tables have legends, which explain the contents of the table. Tables should not be very large that they run more than one A4 sized page. Tables should not be prepared in the landscape format, i. e. tables that are prepared width wise on the paper.

**Figures** - Should be on separate pages but not inserted within the text. Figures should be numbered consecutively in Arabic numerals and bear a brief title in lower case bold face letters below the figure. Graphs and bar graphs should preferably be prepared using Microsoft Excel and submitted as Excel

**Instruction to Author**

graph pasted in Word. These graphs and illustrations should be drawn to approximately twice the printed size to obtain satisfactory reproduction. As far as possible, please avoid diagrams made with India ink on white drawing paper, cellophane sheet or tracing paper with hand written captions or titles. Photographs should be on glossy paper. Photographs should bear the names of the authors and the title of the paper on the back, lightly in pencil. Alternatively photographs and photomicrographs can be submitted as jpeg images. Figure and Table titles and legends should be typed on a separate page with numerals corresponding to the illustrations. Keys to symbols, abbreviations, arrows, numbers or letters used in the illustrations should not be written on the illustration itself but should be clearly explained in the legend. Avoid inserting a box with key to symbols, in the figure or below the figure. In case of photomicrographs, magnification should be mentioned either directly on them or in the legend. Symbols, arrows or letters used in photomicrographs should contrast with the background. Method of staining should also be mentioned in the legend.

**Chemical terminology** - The chemical nomenclature used must be in accordance with that used in the Chemical Abstracts.

**Symbols and abbreviations** - Unless specified otherwise, all temperatures are understood to be in degrees centigrade and need not be followed by the letter 'C'. Abbreviations should be those well known in scientific literature. *In vitro*, *in vivo*, *in situ*, *ex vivo*, *ad libitum*, *et al.* and so on are two words each and should be written in italics. None of the above is a hyphenated word. All foreign language (other than English) names and words shall be in italics as a general rule. Words such as carrageen an-induced inflammation, paracetamol-induced hepatotoxicity, isoproterenol-induced myocardial necrosis, dose-dependent manner are all hyphenated.

**Biological nomenclature** - Names of plants, animals and bacteria should be in italics.

**Enzyme nomenclature** - The trivial names recommended by the IUPAC-IUB Commission should be used. When the enzyme is the main subject of a paper, its code number and systematic name should be stated at its first citation in the paper.

**Spelling** - These should be as in the Concise Oxford Dictionary of Current English.

**SHORT COMMUNICATIONS** The journal publishes exciting findings, preliminary data or studies that did not yield enough information to make a full paper as short communications. These have the same format requirements as full papers but are only up to 15 pages in length in total. Short Communications should not have subtitles such as Introduction, Materials and Methods, Results and Discussion - all these have to be merged into the running text. Short Communications preferably should have only 3-4 illustrations.

**Instruction to Author**

**REVIEW ARTICLES** Should be about 15-30 pages long, contain up-to-date information, comprehensively cover relevant literature and preferably be written by scientists who have in-depth knowledge on the topic. All format requirements are same as those applicable to full papers. Review articles need not be divided into sections such as materials and Methods and Results and Discussion, but should definitely have an Abstract and Introduction, if necessary.

**PUBLICATION FEE**

**Indian Author Rs.3000/-** (per paper) please refer our acknowledgment letter for fee remittance details.

**Foreign Author Fee remittance Details USD- 100** for per paper

**Via Paypal**

### ABSTRACT

Information and communication technology (ICT) are an emerging field for the enhancement and development of the agriculture. ICT tools are the very useful for the dissemination of knowledge to the farmers for the user friendly features. Farmers can easily access agricultural information with help of ICT tools. In this context, we explored the effect of socioeconomic characteristics of farmers on the efficiency of ICT tools. The study was conducted in five villages of Cooch Behar-I and Cooch Behar-II block of Cooch Behar district of West Bengal. Purposive as well as multistage and random sampling procedures were followed in selecting respondents. Farmers' efficiency on ICT tools was considered as dependent variable and the other related social, personal, psychological and communication attributes were considered as the independent variables. The data were collected with the help of the structured interview schedule through personal interview method. The major statistical measures used were coefficient of correlation and multiple regressions. From the coefficient of correlation, it has been found that the variables like educational qualification and asset possession were positively associated with the dependent variable; also age and experience in farming were negatively associated with it. In multiple regression analysis, the variable like family experience in farming and achievement motivation are significantly and negatively contributing towards characterizing the attitude towards ICT tools and the entire explicability is 46%.

**Keywords:** Efficiency, Information and Communication Technology, Educational qualification, Achievement motivation

**Subhrajyoti Panda and Satarupa Modak**

## INTRODUCTION

Access to information is the key to development and creating information-rich societies to poverty alleviation as well as sustainable development. It is necessary to empower poor people to reduce digital divide, implements ICTs projects in local language prioritizing local needs and content, models on utilization of low cost ICTs (Rao, 2009, Saravanan, 2013 and Kamath, 2018). ICTs broadly cover the set of activities that facilitates capturing, storage, processing, transmission and display of information by electronic means. The information communication technology (ICT) through some computer and mobile enabled, analogue and digital tools is the key enabler and vital component of new knowledge based economy and information revolution. ICT and Mobile technology had improved the package of practices and improved the agriculture through knowledge dissemination by e-agriculture. Rural information systems had focused on supplying the information to the rural people about modern agriculture (Jayade, et. al., 2014). Agriculture is moving towards more market oriented than production oriented with the help of market intelligence. These have a significant role in poverty alleviation by empowering rural farmers and other citizens with ICTs to grow their business and create new opportunities and delivery of services to rural areas (Nkwocha, et.al., 2009). With the advancement of technology now the whole world seems comes into our fist. If rural India gets benefited with ICT tools especially youths than we can ensure growth and development of farming and also check migration issues.

## MATERIALS AND METHODS

To study the efficiency and find out the supporting or opposing reasons behind use of ICT tools this study was conducted in five villages of Cooch Behar I & II block of Cooch Behar district, West Bengal. An exhaustive list of ICT tool users particularly for agricultural advisory services was prepared with the help of the local people, local administrators etc and twenty (20) number of ICT tool users were selected. Purposive as well as multistage random sampling procedures were followed in selecting a total of 100 respondents. Efficiency of ICTs (Y) was conceptualized as the efficacy of information sources (digital and analogue) used by the users in case of seeking agricultural information and also acquaintance of handling this ICT tools. A structured interview schedule was prepared by incorporating the construct and content of efficiency in using computer, efficiency in using Internet, efficiency in using Smart Phone, Television, Kisan Call Center (KCC), Information Kiosks, mobile based advisory service, VCD/DVD players and any other digital means. The responses from the ICT tool users were recorded with four point scales to represent the degrees namely 'no knowledge', 'can operate with some assistance', 'have working knowledge', 'proficient/competent in handling' and 0, 1, 2, 3 was the score assigned for the categories respectively. The total score of effectiveness in using ICT tools was obtained by adding the scores of all items in the scale.

Again as a supporting or opposing factor Age ( $X_1$ ), Caste ( $X_2$ ), Experience in farming ( $X_3$ ), Educational Qualification ( $X_4$ ), Family Education Status ( $X_5$ ), Family Annual Income ( $X_6$ ), Family Annual Expenditure ( $X_7$ ), Land Holding ( $X_8$ ), Possession of assets ( $X_9$ ), Livestock possession ( $X_{10}$ ), House Type ( $X_{11}$ ), Social Participation ( $X_{12}$ ), Self Confidence ( $X_{13}$ ), Risk Preference ( $X_{14}$ ), Scientific Orientation ( $X_{15}$ ), Economic Motivation ( $X_{16}$ ), Management Orientation ( $X_{17}$ ), Decision making ability ( $X_{18}$ ), Achievement Motivation ( $X_{19}$ ), Utilization pattern of communication sources ( $X_{20}$ ) were selected.

## RESULT AND DISCUSSIONS

Above figure indicated that majority (53%) of the respondents were under low level of efficiency on ICT tools followed 31 per cent on medium level and 16 percent of the respondents categorized as high level of access. The mean score of total distribution is 22.22, standard deviation is 8.99 and the coefficient of variation 40.46 per cent signifies high consistency level of the distribution for the variable 'efficiency on ICT tools'. Most of the users from the selected study were not efficiently using ICTs to access agriculture information.

**Subhrajyoti Panda and Satarupa Modak**

Table (1) reflects the Pearson's coefficient of correlation among the dependent variable, access to ICT tools of the farmers with the twenty casual variables. The result shows that the education ( $X_4$ ) and possession of assets ( $X_9$ ) are positively and significantly associated with the dependent variable, access to ICT tools. On the other hand, the variable age( $X_1$ ) and experience in farming ( $X_3$ ) is negatively and significantly associated with the efficiency of the farmers to the ICT tools.

**Age and Efficiency on ICT tools**

Age is the factor which plays a great role in our society to adopt any modern technology. Mostly the young aged people are more interested towards the new technologies to do their work more efficiently. In this study, it is found that the young farmers are using ICT tools more effectively due to their feeling of wanting to know about the mobile and computer based technology to get the information easily and quickly. This may be the reason that young farmers have more efficient in handling ICT tools than the elder farmers. Due to this age is significantly and negatively correlated with efficiency on ICT tools.

**Experience in farming and efficiency on ICT tools**

Experience means more practical knowledge about something. In this study most of the farmers are experienced. They are more skilful in handling the agricultural practices without using any modern technology. The less experienced farmer who are recently doing the agriculture practices are given more emphasis towards using ICT as they are more efficient in adopting new technologies to do it more efficiently than the more experienced farmer. More experienced farmers have less efficient in handling the ICT tools than the less experienced farmer. More experienced farmers are traditional and their mind set up is towards the traditional agriculture. This is the main possible cause that experience in farming is significantly and negatively correlated with efficiency on ICT tools.

**Education and Efficiency on ICT tools**

Education is the process through which one individual can gather knowledge and use this knowledge in their situation to solve their problems. In other words education makes an individual perfect through the manifestation of different positive traits prevailed within an individual. The perfection of any activity need risk assimilation and creativity. The formal education always tries to help the human being to become innovative and creative. Education helps the farmer to learn about ICT tools more quickly and efficiently. That is why education is significantly and positively correlated with efficiency on ICT tools.

**Possession of assets and efficiency on ICT tools**

In our society possession of assets signifies the farmer's socio-economic condition. The farmers having more assets indicate that they are more advanced in taking new technologies in their farming situation. They collect the information on agriculture through the modern technologies by using mobile, computer as their possession of asset is more. They can effectively give effort towards ICT tools for their information needs in agriculture. This may be the possible reason that possession of assets is significantly and positively correlated towards the variable efficiency on ICT tool. From the table (2) it is observable that the variable experience in farming and achievement motivation are significantly and negatively contributing in case of characterizing the predicted variable efficiency on ICT tools. Other variable like education is significantly and positively contributing towards characterizing efficiency on ICT tools.

**Experience in farming and efficiency on ICT tools**

Experience in farming reflects the time period regarding farmer's involvement in agriculture and allied sectors. Mostly it was observed that the aged persons in rural areas are more experienced and knowledgeable regarding various farm practices. Although the aged persons are more experienced compared to the young farmers but they are less aware about the application of modern information technology. At present, youth in rural areas are much acquainted with the latest information technologies due to increased mass media exposure and computer literacy. In

**Subhrajyoti Panda and Satarupa Modak**

this study area, majority of the respondents are young aged farmers who are practising farming for not more than five years. Almost all the young farmers are having smart phones and they are familiar with the application of other software but not aware about the efficient utilization of ICT tools in agriculture due to their less experience in farming. That is why the variable 'experience in farming' is significant and negatively contributing towards the predicted variable 'efficiency on ICT tools'. The variable experience in farming is directly contributing 47.90% in case of characterizing efficiency on ICT tools. One unit change of the variable is delineating 0.576 unit change in the predicted variable efficiency on ICT tools.

**Education and Efficiency on ICT tools**

Education acts as a crucial factor in determining the knowledge level of farmers. Education helps in developing the capabilities of a farmer towards the modern technologies and new initiatives taken in agriculture. Education not only increases the knowledge but it also helps in increasing the efficiency of a farmer in the modern farming. In the present study most of the farmers are young aged. They are also educated enough to know about modern technologies used for agricultural information. They have mainly taken training for how to use computers and internet. They are efficient to handle the ICT tools. Without education one cannot effectively use the ICT tools. That is why the variable 'education' is significantly and positively contributing towards characterizing efficiency on ICT tools. The variable education is directly contributing 16.70% in case of characterizing efficiency on ICT tools. One unit change of the variable is delineating 1.801 unit changes in the predicted variable efficiency on ICT tools.

**Achievement Motivation and Efficiency on ICT tools**

Achievement means a person's present proficiency, mastery, and understanding of general and specific areas of knowledge. Achievement is the measures of efficiency of instruction and learning. In the present study area most of the persons have given importance to agriculture. They are more interested to achieve more profit from the agriculture by giving more concentration towards the production and marketing of the product. They do not think that ICT tools are important for agricultural practices because they believe that use of simply ICT tools is wastage their time and it would not help them get information. The farmers are mainly age old persons, so they fear to use ICT tools. That is why the variable 'achievement motivation' is significantly and negatively contributing towards characterizing the predicted variable 'efficiency on ICT tools'. The variable achievement motivation is directly contributing 16.00% in case of characterizing efficiency on ICT tools. One unit change of the variable is delineating 0.777 unit changes in the predicted variable efficiency on ICT tools. The  $R^2$  value being 0.46, it was to infer that the twenty predictor variables put together have explained 46.00% variation embedded with the predicted variable efficiency on ICT tools used by the respondents. Still 54.00% variation embedded with predicted one remains unexplained.

**CONCLUSION**

From the study, we have seen that variables like educational qualification and asset possession were positively associated with the efficient use of ICT tools. As higher education increase the thrust of knowledge and asset possession reflects economic empowerment enable one's purchasing power of technological gadgets. Again, age and experience in farming were negatively associated with it as older age people find it complex to handle ICTs and experienced farmers like to follow conventional farming systems initiated by the forefathers. In multiple regression analysis, the variable like family experience in farming and achievement motivation are significantly and negatively contributing towards characterizing the attitude towards ICT tools.

### ABSTRACT

Water is the vital source for crop production and is the most limiting factor in Indian agricultural scenario. Though India has the largest irrigation network, the irrigation efficiency has not been achieved more than 40 per cent. Due to water scarcity, the available water resources should be very effectively utilized through water saving irrigation technologies. Economic use of water is a vital problem which confronts farmers and agricultural scientists in irrigated areas of arid and semi-arid regions. The limited groundwater reserve is the major constraint for irrigation water supply. Improper irrigation water operation accounts for significant water losses in large area in our country. Consequently, the use of modern irrigation systems in irrigation operation and scheduling is essential for the reduction of irrigation water demands. Various research works have been conducted by many workers to find out optimum irrigation level of potato, so as to minimize the cost of cultivation. The relevant literature available on these aspects in state, country and abroad has been briefly reviewed in this paper.

**Keywords:** Arid region, Semi-arid region, Irrigation

### INTRODUCTION

Potato (*Solanum tuberosum* L.) the so called “papa” of Mayan Civilization is one of the most important crop in the world in terms of its use as human food and as raw material for the starch industry (Fabeiro *et al.*, 2001). The word

24227

Gayatri Mohapatra et al.

"potato" may refer either to the plant itself or to the edible tuber. Potato is a starchy tuberous crop evolved from the ancestor like perennial nightshade (*Solanum tuberosum*). It is believed to be originated from the Titicaca lake area in Andes mountain now located in Peru, Bolivia and Northern Chile trijunction of South America. This temperate tuber crop is being cultivated in the country for the last more than 300 years which has always been the 'poor man's friend'. Being a crop of foreign origin it acclimatizes itself in the cuisines of countryside so popularly that, it is now put under Public Distribution System in India. Potato is an economical food and is source of low cost energy to the human diet which can substitute the cereals for human consumption to a greater extent. It contains 20.6% carbohydrates, 2.1% protein, 0.3% fat, 1.1% crude fiber and 0.9% ash. It also contains a good amount of essential amino acids like leucine, tryptophan, and isoleucine etc. It is grown in almost all the states of India with a total production of 455.69 lakh million tonnes of potato from an area of 20.63 lakh ha and productivity of 22.09 t/ha (<http://nhrdf.org/pdf/POTATO%20CROP%20REPORT-%2008%20APRIL%202016.pdf>).

Potato is one of the most remunerative and profitable crop for the growers due to its higher yield potential within a limited time. It is a short duration crop, which is responsive to high input use and capable to produce more yield under a wide edaphic situation and adiabatic conditions. Considering its gestation period potato production per unit area per unit time is higher under Indian plains as compared to European countries in general and temperate regions in particular. The wide flexibility in its planting and harvesting dates makes the crop most suitable for inclusion in intensive cropping system. The crop finds an important place in the economy of poor and marginal farmers and plays a significant role in nutritional security producing more food per unit area and time. In Odisha generally *Rabi* crop is planted in November and December months in the plains and the *Kharif* crop is cultivated as rainfed with the onset of rain in June and July months in limited pockets of interior tribal districts like Koraput and Phulbani.

Water, as an universal solvent is the integral part of cell constituents necessary within the plant for different metabolic activities like photosynthesis, respiration and other plant physiological functions such as transport of minerals and photosynthetic products, turgidity of plant cells, transpiration and regulation of leaf temperature. Compared to several other crops, the potato plant is sensitive to both lack of and an excess of water. Lack of water is the most common stress. Water deficit decreased number of leaves, leaf area, plant height, tuber number, growth and yield, canopy radiation interception, harvest index, fresh weight of root and leaves, root number, root dry weight and tuber yield (Hassanpanah, 2009). Even a short period of dryspell drastically affects the yield, especially after tuber initiation. That is why a continuous water supply to meet the crop water demand at different growth stages is highly recommended for better growth from sprout development to maturity (Ierna and Mauromicale, 2006). At the beginning of tuber formation, drought favors attack by *Streptomyces scabies* (common scab). At later stages, drought causing cracks in soil favor tuber infestation by insects, especially tuber moth. Drought influences yield directly by restricting transpiration and photosynthesis. Dry soils form clods that make soil and crop management difficult and cause tuber damage at harvest. Excess water may be caused by heavy rainfall, heavy irrigation, or inefficient drainage. Excess water creates anaerobic condition preventing oxygen to reach the underground parts of the potato plant resulting in poor root development and rotting of the newly formed tubers. Seed tubers are especially susceptible to tuber rot.

Over-irrigation shortly after planting may reduce emergence because of excessive growth of lenticels which allows entrance of parasites and soil surface compaction which increases the production cost. High moisture favors development of late blight (*Phytophthora infestans*). The stomata of potato leaves close quickly upon lack of humidity which leads to reduced transpiration and photosynthesis, heating of leaves and subsequent reduction in yield. Crops sensitive to water stress require a systematic approach for irrigation scheduling. Considering the rates of the crop water requirement is calculated which is used in irrigation scheduling to improve the effectiveness of irrigation. An adequate water supply is required from tuber initiation till the near maturity for higher yield and good quality of potato specially for processing purpose.

**Gayatri Mohapatra et al.**

Potato is very sensitive to water deficit due to its sparse and shallow root system (Jefferies, 1993). An adequate supply of water is required by potato plant in all critical stages from the time of emergence to the start of senescence. The amount of water needed by potato varies with soil type, temperature, humidity, air movement, plant and number of shoots per plant, variety and cultural practices (Wiersema, 1987). Correct water management provides sufficient water for potato growth and avoids excessive loss or waste of water (Haverkort, 1982). The yield is greatly influenced by timing, amount and fecundity of irrigation applied (Kashyap and Panda, 2003). The primary goal of potato irrigation management is to minimize both soil water fluctuations and maintain the availability of soil water at the field capacity level.

### Response of Irrigation Levels and growth attributes

Water is essential requirement for plants. Thus reduced availability of water to plants is likely to restrict crop growth. As irrigation is a measure to increase water availability to plants and reduce adverse effects of water deficits in crop. Sood (1986) observed that during pre-monsoon period, supplemental irrigation at 0.5 atmosphere moisture tension stimulated growth and increased potato mean yield by 64 q/ha under rainfed conditions. Tiwari et al. (1998) reported that plant height responded significantly with different irrigation levels of drip irrigation, however, plant height was statistically at par with furrow irrigation and 100% irrigation supply with drip irrigation.

Irrigation levels had no significant influence on number of leaves per plant in okra. Chauhan et al. (2009) studied the effect of method of irrigation on growth, fruit (green and dry) and seed yields of chilli cv Pusa Jwala. Scheduling irrigation through drip at 80% of CPE increased plant height, branches, chlorophyll, fruit and seed yield as compare to surface irrigation method. Ghamarnia and Sepehri (2009) reported that the number of stem per plant and the number of tuber per plant were not significantly affected by different irrigation methods and their results also indicated that regardless to irrigation method, the maximum and minimum yield of potato with 34.46 and 19.17 t/ha were achieved in irrigation water treatment of 100% and 50% tape, respectively. The least per cent of tubers smaller than 35 mm (26.42%) was obtained in tape method with 50% irrigation-water requirement and the highest per cent of tubers smaller than 35 mm (37.99%) was obtained in furrow irrigation method. Pirboneth et al. (2012) reported that among irrigation regimes, the highest plant height produced with six days interval and was 52.3% higher in compare with no irrigation treatment. Farrag et al. (2016) reported that 100% irrigation requirement treatments produced the highest values for vegetative growth parameters followed by the 75% irrigation requirement. Whereas the lowest values for these parameter were recorded under 50% IR.

### Yield and yield attributes

Steineck (1958) found that potato is particularly sensitive to faulty irrigation technique. He emphasized that planning of irrigation at higher tensions and withholding water for 2, 4, 6 weeks period induced yields of 78, 58, and 36 per cent, respectively of the yield of highest yielding treatment. Working on the laterite soils of West Bengal, Perez et al. (1961) observed that yield and per cent of large size tubers increased by increasing frequency of furrow irrigation. They concluded that available soil moisture at 30 cm depth should not be allowed to fall below 50 percent of field capacity. Moolani and Hukkeri (1965) showed that irrigation at lower tension (0.25 to 0.30 atmosphere) increased yield by 6.12 and 34.5 q/ha as compared to yield under 0.6 and 0.9 atmosphere soil moisture tension, respectively. Yadav and Tripathy (1972) reported that in field trail, irrigations given at 25, 50 and 70 per cent of available moisture showed significant improvement in potato tuber yield and 'A' grade tuber with increase in irrigation levels. Doorenbos and Kassam (1979) reported that for higher yield at a given site, the seasonal water requirements of a potato crop with a phenological cycle varying from 120 to 150 days ranged from 500 to 700 mm, depending on climate. Deficient irrigation promoted a reduction of tuber quality and lowered yield due to reduced leaf area and or reduced photosynthesis per unit leaf area (Van Loon, 1981). MacKerron and Jefferies (1986) have shown that increased duration of water stress before tuber initiation reduces tuber set per stem.

Another study by Singh et al. (1988) reported that tuber yield of potato variety "Kufri chandramukhi" irrigated on the basis of IW/CPE ratio of 2.0 was comparable to that irrigated at 0.25 bar soil water tension but saved 12 cm

**Gayatri Mohapatra et al.**

irrigation water, resulting in 20-14 per cent higher irrigation water use efficiency. Shrivastava et al. (1994) studied the response of tomato to three levels of water (0.4 PE, 0.6 PE and 0.8 PE) and mulches (black plastic and sugarcane trash) and they found highest yield with the combinations of sugarcane trash and irrigation at 0.4 Pan Evaporation. King and Stark (1995) studied the water management practices on forty five commercial potato fields in southeast Idaho. Potato yield is reduced by both over- and under irrigation.

Efficient irrigation management can increase marketable yield while reducing production costs by conserving water, energy and nitrogen fertilizer, as well as reducing potential ground water contamination. Chandra et al. (2001) observed the performance of potato under limited irrigation in which the IW: CPE 1.20 and 50% ASMD (Available Soil Moisture Depletion) treatments recorded significantly more tuber yield than IW/CPE 0.60 and 75% ASMD. Experimental findings of Kashyap and Panda (2003) revealed that among five irrigation treatments 10% (T1), 30% (T2), 45% (T3), 60% (T4), 75% (T5) maximum allowable depletion of available soil water during non critical stage of crop growth with delayed irrigation, the yield reduced significantly under T4 and T5, which result in minimum fresh tuber yield and total dry matter yield. Erdem et al. (2006) reported that, irrigation regimes influenced tuber yield in 2005 and the highest tuber yield was registered for 30% irrigation regime, reaching 35.13 t ha<sup>-1</sup> in 2003 and 44.56 t ha<sup>-1</sup> in 2005. Kumar et al. (2007) evaluated the performance of two chipping potato cultivars Kufri Chipsona-1 and Kufri Chipsona-2 under different irrigation levels and reported that non-significant variation in number of stems and compound leaves with irrigation levels but observed consistent decline in processing grade and total tuber number ha<sup>-1</sup> under water stress. Like tuber number, processing-grade tuber yield, total tuber yield, biomass yield and average tuber weight also decreased with decrease in irrigation frequency from 15 mm to 35 mm cumulative pan evaporation (CPE).

Kumari et al. (2009) recorded highest water use efficiency (1.37q/kg-mm) with 0.80 IW/CPE under micro sprinkler irrigation. Water application of 257 and 261 mm was found optimal for attaining the maximum yield under micro sprinkler and drip irrigation systems, respectively. Economic analysis revealed that using micro irrigation for potato production in canal irrigated area of semi-arid climate is a profitable alternative of existing irrigation method. Experimental findings of Zaman et al. (2009) revealed that the tuber yield recorded under irrigation at IW/CPE of 0.6 (I3) was 27.9% higher than rainfed (I1) and 23.0% higher than splash irrigation (I2). Ati et al. (2010) studied the yield of potato (*Solanum tuberosum* L.), under regular deficit irrigation and results showed that the yield of potato were 34.5, 34.3, 28.2 and 30.2 t/ha for control treatment (irrigate reestablishing field capacity when 60% of the available water was depleted), T1 (no irrigation during vegetative growth stage), T2 (no irrigation during tuberization stage) and T3 (no irrigation during bulking and tuber enlargement), respectively for the first season, while in the second one equaled 36.7, 36.2, 30.0 and 31.2 t/ha. Another experiment was conducted by Amanullah et al. (2010) to study the effect of different irrigation regimes on the yield and yield contributing characters of high yielding potato varieties namely Binella, Cardinal, Chamak and Heera. Five irrigation treatments: no irrigation, irrigation at IW/CPE ratios of 0.25, 0.50, 0.75 and 1.00.

Treatment IW/CPE ratio of 1.00 was found the best among the different IW/CPE ratios tried, yielding maximum which was significantly different from other treatments with 5- rounds of irrigations applied at stolonization, tuberization, bulking and ripening stages of crop growth. On an average application of 41.8 mm irrigation water per event at an interval of around 15 days starting from 20 days after planting yielded the highest (40.5 t/ha) in IW/CPE ratio of 1.00 treatment. Ierna et al. (2011) conducted an experiment with the aim of achieving an appropriate combination of irrigation water and nutrient application in cultivation management of a potato crop in a Mediterranean environment. They concluded that the treatments based on 50% ETM and a medium level of fertilization represent a valid compromise in early potato cultivation management. Compared to the high 14 combination levels of irrigation and fertilization, this treatment entailed a negligible reduction in tuber yield to save 90 mm ha<sup>-1</sup> year-1 of irrigation water, with notable economic savings for farmers compared to the spendings that were usually made.

**Gayatri Mohapatra et al.**

Saikia (2011) conducted a field experiment with 4 irrigation schedules viz., irrigation to each furrow at 25 mm CPE (I1), irrigation to alternate furrow at 25 mm CPE (I2), irrigation to each furrow at stolon formation (SF) stage (30 DAP), tuber formation (TF) stage (50-55 DAP) and tuber development (TD) stage (65-70 DAP) (I3), and irrigation to each furrow at stolon formation (SF), tuber formation (TF) and tuber development (TD) stage + 1 extra irrigation after 10 days of irrigation at tuber development stage (I4) and 2 mulching treatments viz., no mulch (M1) and mulching with water hyacinth @ 5t/ha (M2). Tallest plants were recorded when irrigations were applied at SF + TF + TD stage + irrigation after 10 days of TD stage under M1 condition.

Number of shoots/plant was significantly affected by different treatments during both the years. Highest total tuber yield of 14.2 t/ha was recorded when irrigation was applied at each furrow at 25 mm CPE during 2006-07. In case of large size tubers (> 75 g), highest tuber yield (2.21 t/ha) was recorded when irrigation was applied at SF + TF + TD stage + irrigation after 10 days of TD stage under M1 condition during the same cropping season. Singh et al. (2012) conducted an experiment to study the influence of irrigation and mulch on growth, yield and economics of potato. Results revealed that the irrigation given to all furrows with paddy straw mulch @ 5 t ha<sup>-1</sup> produced significantly higher tuber yield (295 q ha<sup>-1</sup>) as well as tuber numbers (605 thousands ha<sup>-1</sup>) in comparison to other treatments tried in main crop season.

In early crop of potato, the irrigation applied at 20 mm CPE with paddy straw mulch @ 5 t ha<sup>-1</sup> gave significantly higher total yield (170 q ha<sup>-1</sup>) than other irrigation treatments. Bisht et al. (2012) conducted field experiment by taking seven treatments i.e., 100% OPE (Open Pan Evaporation) daily (I1), 80% OPE daily (I2), 60% OPE daily (I3), 100% OPE at alternate day (I4), 80% OPE at alternate day (I5) 60% OPE at alternate day (I6) and control (I7) i.e., furrow irrigation given up to 5 cm depth at an interval of 15 days. The maximum number and yield of A (>75 g) and D (0-25 g) grade tubers was recorded in treatment I4 (100 % OPE at alternate day) and I6 (60% OPE at alternate day) respectively while, B (50-75 g) grade in I2 (80% OPE daily) and C (25-50 g) grade under I5 (80% OPE at alternate day). Dry matter content of tuber increased with increase in irrigation levels from 60, 80, 100% OPE respectively, on daily as well as on alternate day basis in comparison to the control i.e. furrow irrigation.

Tyagi et al. (2012) conducted a field experiment comprised of five irrigation levels (irrigation at critical stages of potato (*Solanum tuberosum* L.), irrigation at critical stages of French bean (*Phaseolus vulgaris* L.) and irrigation at 0.8, 1.2 and 1.6 IW/CPE ratio) as main plots and 3 cropping systems (sole potato, sole French bean and potato + French bean in 2:3 row ratio). Irrigation at IW/CPE ratio of 1.6 produced the highest tuber yield followed by irrigation at 1.2 IW/CPE ratio, while the lowest tuber yield was achieved with irrigation at 0.8 IW/CPE ratio. Although the tuber yield with irrigation applied at critical growth stages (CGS) of potato was significantly lower than with IW/CPE ratio of 1.6, but the water use efficiency (WUE) with CGS of potato was higher. Verma et al. (2012) conducted a field experiment to study the effect of irrigation and nitrogen management on productivity of potato (*Solanum tuberosum* L.) and their residual effect on succeeding maize (*Zea mays* L.). Among the irrigation regimes, irrigation at 60 mm CPE recorded significantly the highest growth characters, yield attributes and total tuber and biological yields over irrigation at 80 and 100 mm CPE..

The specific gravity, starch and dry matter contents increased from 40% to 65% field capacity and the lowest under 100% field capacity irrigation treatment. Field experiment was conducted by Admasu et al. (2016) to determine the optimal irrigation regime and NP fertilizer rate of Potato (Local name: Gudene) under five irrigation treatments (Irrigation at +40% ASMDL, +20% ASMDL, ASMDL, - 20% ASMDL and -40% ASMDL) and three NP fertilizer rate levels (25% more on the recommended rate, recommended rate and 25% less from the recommended rate). The lowest tuber yield was found at +40% ASMDL irrigation with a value of 28.77 t/ha and it was comparable to tuber yield found at +20% ASMDL irrigation. An experiment was conducted by Ruttanaprasert et al. (2016), to study the effects of water stress on total biomass, tuber yield, harvest index and water use efficiency in Jerusalem artichoke and to evaluate the differential responses of Jerusalem artichoke (JA) varieties under drought stress. The 3×5 factorial combinations of three water regimes (Field capacity (FC), 50% available soil water (50% AW) and 25%

**Gayatri Mohapatra et al.**

AW), and five JA varieties (JA 60, JA 125, JA 5, JA 89 and HEL 65) were arranged in a pot experiment in a randomized complete block design with four replications for two years. Drought reduced tuber dry weight, total biomass, harvest index.

### Physiological properties and nutrient uptake

Sood and Sharma (2002) studied that the effect of irrigation (100, 150, 200 and 230 mm) and nutrient application (50 or 100% recommended NPK, farmyard manure or plant residues) on the yield of potato cv. Kufri Jyoti in potato-based sequential cropping systems viz., potato-cabbage, potato-radish and potato-pea, were determined in a field experiment. Application of 100% recommended NPK+ irrigation resulted in the highest mean yield of potato (408 q/ha), cabbage (340 q/ha), radish (470 q/ha) and peas (111 q/ha), N, P and K uptake of potato, and N and K content in potato tubers. Generally, in most cases, the treatment of the medium or/and highest soil moisture level (60 and 80 % from available water) gave the highest significant values for plant height, dry matter and K content of potato plant at 90 days from planting and potato tuber yield ton/feddan N, P and K contents in tuber in addition to, total soluble solids and protein content in tuber as well as consumptive use. Ahmadi *et al.* (2011) reported that, the irrigation treatments were not significantly different in terms of N uptake in the tubers, shoot, and whole crop of potatoes.

However, there was a statistical difference between the crop grown in different soil texture where plants in the loamy sand had the highest amount of N uptake. Patel *et al.* (2012) conducted an experiment to study the effect of fertigation of nitrogen and potash under different methods of irrigation on yield of potato cv. Kennebec. They reported that growing of potato laying drip with laterals in each pair and applying 75% recommended dose of N and K (206 kg each) as fertigation in five splits resulted into higher tuber yield and uptake of nitrogen, phosphorus and potash, nutrient productivity, net return, net realization and benefit cost ratio. Maralian *et al.* (2014) carried out an experiment by taking irrigation as main plot treatments (I1=full irrigation, I2= 0.8 I1 and I3= 0.6 I1) and three potato genotypes as subplots (B1= Clone 82-10, B2= Clone 97-2 and B3= Agaria cultivar) were allocated to the sub plots. There was no significant differences for RWC, chlorophyll (b) and carotenoid among genotypes.

Chlorophyll content (mg/g.f.w) decreased at 60% irrigation (40% stress) and the highest level observed in 97-2 clone. The highest carotenoid content belongs to 80% applied water and it is decreased significantly at 60% applied water. Clone 97-2 had the highest chlorophyll (a), chlorophyll (b), chlorophyll (a+b) and carotenoid content at 80% full irrigation. According to Rolando *et al.* (2015) after water restriction initiation, a temporary rise of Chl SPAD was observed in the three genotypes of potato. This increased leaf greenness under water restriction coincided with a decrease in leaf growth. They suggested that the highest greenness increase following water restriction in the most drought susceptible varieties is an expression of more conservative strategies under drought. Thus, lower chlorophyll loss rate and later onset of senescence was related to higher yield under water restriction. Farrag *et al.* (2016) reported that 100% irrigation requirement resulted in the highest average values of NPK content in the plant leaves.

### CONCLUSION

To feed the additional two billions of hungry people by 2030 water, a scarce resource need to be used more efficiently. As a biggest consumer, agriculture withdraws 70% of fresh water worldwide entering into a steep competition with industry and domestic use. To combat such alarming situation national slogan “more crop per drop” should be echoed in every corner of the country for a judicious use of water adopting smarter water management practices with alignment of cutting edge technologies on this aspect. We know potato as an winter crop consume a greater part of the ground water reserve as grown only in irrigated condition. In order to quench the thirst of the crop augmenting the exact water requirement we can get the same yield as in the outdated flooding

### Gayatri Mohapatra et al.

irrigation practices. Therefore the genetically engineered drought tolerant cultivars with judicious amount of irrigation water can yield a bumper crop justifying the slogan “more crop per drop”.

There is need to improve irrigation management strategies, which can increase the water-use efficiency (WUE) of the crop. Therefore, irrigation based on cumulative pan evaporation will help to maintain adequate soil moisture without any waste of water. The yield of the potato varieties can be improved to a great extent by optimum application of supplemental irrigation. So we can increase the production under water stress condition. These conditions dictate utilization of a quantitative potato irrigation management for consistent, optimum economic return from potato crop.

### ABSTRACT

Rice bran could be a by-product created throughout the method of milling. The bran constitutes nearly 7%-8.5% of the whole grain. The bran consists of the pericarp, tegmen (the layer covering the endosperm), aleurone, and sub-aleurone. Proximate analysis of rice bran by various researchers shows that rice bran is highly enriched with vitamins including vitamin E, thiamine, niacin, also minerals like aluminium, calcium, potassium, sodium, zinc etc. Apart from vitamin and minerals rice bran is also rich in protein, fiber, moisture and ash. Various antioxidants like tocopherols, tocotrienols, oryzanol that inhibits platelet aggregation and prevents cardiovascular diseases are present in the rice bran oil. Rice bran also contains polyphenols (ferulic acid, caffeic acid, salicylic acid), phytosterols ( $\beta$ -sitosterol). These metabolites found in rice bran are likely to work synergistically to contribute to rice bran's functional food properties which make the biochemical composition of rice bran an attractive research platform to work with. This review article shade light upon the probabilities of multiple nutritional therapies and medical application from user prospective.

**Keywords:** Endosperm, Aleurone, Proximate analysis, Functional food

## INTRODUCTION

Rice is now grown in over hundred countries around the world and the global rice production is estimated to be 495.87 million tonnes of milled rice in 2018-2019. Asian countries produce most of the world's rice. India, being an important centre of rice cultivation is the second largest producer and leading exporter of rice with production and export of 115.6 million tonnes and 12,500 tonnes respectively in the year 2017-18. Climate change not only pushes

Udit Nandan Mishra *et al.*

farmers of different river basins to adopt new varieties of crops that can resist vagaries of weather but also compels agro-scientists to merge into research works to invent modified better varieties, specially of rice.

### Structure of the rice grain

The rough rice grain or paddy consists of an outer protective covering called the hull or husk and the rice caryopsis or fruit called brown or dehulled or dehusked rice (Juliano and Bechtel, 1985). The brown rice, on the other hand, consists of the outer layers (comprising the pericarp, seed-coat and nucellus), the germ or embryo and the endosperm. The endosperm consists of the aleurone layer and the endosperm proper. The endosperm proper consists of the sub aleurone layer and the starchy or inner endosperm. The aleurone layer encloses the embryo. The hull or husk constitutes about twenty percent of the rough rice weight. The brown rice weight is contributed by pericarp (one to two percent), aleurone plus nucellus and seed-coat (four to six percent), germ (one percent), scutellum (two percent) and endosperm (ninety to ninety one percent) (Juliano, 1972). The aleurone and embryo cells are rich in protein bodies, containing globoids or phytate bodies, and in lipid bodies (Tanaka *et al.*, 1973; Tanaka *et al.*, 1977). The endosperm cells are thin-walled and filled with amyloplasts containing compound starch granules.

### By-products of rice milling and their utilization potential

On milling, the rough rice produces rice, white rice, germ, bran, fine brokens and husk. Each of these components has unique properties and can be used in a number of ways. The utilization pattern of these components directly or as derivatives decides the extent of value addition in rice. There are many more ways in which the by-products of rice milling can be considered as value added products rather wastes. Different by products finds their use in different aspects such as rice husk/straw in paper industry, rice bran as animal feed, rice bran as functional food and nutraceutical, rice bran as source of enzymes. Rice bran is wealthy source of essential nutrients like carbohydrates, proteins, fats, dietary fibers and antioxidants like tocopherols, tocotrienols, phytosterols and oryzanol. The nutritional composition of rice bran confirms its potential for the development of food product. Premakumari *et al.* (2012) develop breakfast/dinner recipes by subbing cereals with microwave stabilized rice bran at completely different levels. The results revealed that the recipes with 25% incorporation of rice bran had a good acceptability in par with standard recipe. The studies on different types of bran revealed that the volume of bread and cookie spread decreased while muffin volume increased with the increase in bran levels (Sekhon *et al.*, 1997). The acid and dry heat stabilized rice bran was used by Younas *et al.* (2011) to prepare the highly nutritious cookies. They conclude that moisture, crude protein, fat and mineral contents, average width, thickness and spread factor of cookies increased with the increase in percentage of rice bran.

Defatted rice bran conjointly possesses distinctive function and biological process properties. Keeping in sight, the nutritional importance of defatted rice bran, Charunuch *et al.* (2014) made an attempt to prepare ready-to-eat breakfast cereals enhanced with defatted rice bran. Production of corn flakes and tortillas chips, by supplementation of gelatinized corn flour with rice bran from 10 to 30% was studied the viscosity and color quality was affected. The sensory parameters decreased while protein percentage was increased depending on the level of rice bran (Al-Okbi *et al.*, 2014). With the utilization of stable rice bran, a source of dietary fiber, frozen pizza was prepared by De delahaye *et al.* (2004).

### Chemical and nutritional aspects of rice bran

The outer layer of brown rice is bran which comprises the pericarp, seed-coat and nucellus. It also includes part of aleurone layer and the germ which get removed during the milling process. Rice bran contains one of the most nutritionally superior oil ranging from eighteen to twenty two percent (Cicero and Derosa, 2005) and serves as an excellent source of an array of nutrients (Moldenhauer *et al.*, 2003). Rice bran as a waste product of paddy milling contained protein, carbohydrate, dietary fiber, ash, fat, vitamin, mineral and natural antioxidant compounds (Chen *et al.*, 2008; Saenjum *et al.*, 2012). The minerals are mostly concentrated in the outer layers of brown rice or bran fraction. A major proportion of the phosphorus in bran is phytin phosphorus. Potassium and magnesium are also present as

**Udit Nandan Mishra *et al.***

the principal salts of phytin. Out of the different minerals iron, phosphorous and potassium are more concentrated in the bran fraction while sodium and calcium are evenly distributed in both bran and milled rice (Resurrection *et al.*, 1979; Juliano, 1985). Rice bran oil (RBO) contains antioxidants like  $\gamma$ -oryzanol, tocopherol, tocotrienol and also has a good fatty acid profile for which RBO in the diet significantly reduces LDL cholesterol along with triglycerides, increases HDL cholesterol (good cholesterol), inhibits platelet aggregation and prevents cardiovascular diseases.

Rice bran, a by-product of milling constitutes nearly 7-8.5% of the entire grain. The bran consists of the pericarp, tegmen (the layer covering the endosperm), aleurone, and sub-aleurone (Houston, 1972). Rice bran consists of the pulverized outer layers of the rice kernel and the germ and accounts for 10% of the processed brown rice. The vast majority of nutrients are concentrated in the bran fraction which includes oil, essential fatty acids, proteins, fibers, vitamins, antioxidants and other micronutrients. Presently, rice bran is usually used as cost-effective ingredient for animal feed or as stuff for oil extraction (Orthofer, 2004). But there is an underestimated potential for high-value rice bran products for human nutrition. Researchers have been conducted to produce ingredients from rice bran that are rich in dietary fibers or proteins. Rice bran is the most nutritious part of rice and a good source of bioactive phytochemicals such as  $\gamma$ -oryzanol, tocopherols, and tocotrienols. These phytochemicals have health beneficial properties including antioxidant activity. In recent years, rice bran has been extensively studied for its antioxidative and disease-fighting properties. It is having the ability of lowering the risk of cancer and cholesterol formation (Rohrer and Siebenmorgen, 2004). Anti-inflammatory activity and inhibition cholesterol oxidation are other properties (Akihisa *et al.*, 2000; Xu *et al.*, 2001).

Rice bran is a rich source of oil, protein, fiber and micronutrients. Rice bran proteins have a high nutritional value and are hypoallergenic in nature. These proteins are rich in essential amino acids, especially lysine, hence can be used as an ingredient in food formulations (Fabian and Ju, 2011). Rice bran additionally contains an array of nutraceutical compounds. Ubiquinone-10 is present in rice bran and may provide protective benefits of antioxidant. Epidemiological and biochemical evidence supports the idea that ubiquinol-10 (CoQ10H2) an important cellular antioxidant, inhibits lipid peroxidation as well as regenerates other antioxidants such as  $\alpha$ -tocopherol (Sunesen *et al.*, 2001). The presence of  $\gamma$ -oryzanol and plant sterols attribute to the hypocholesterolemic activity of rice bran (Sheetharamaiah and Chandrasekhara, 1988). Tocotrienols present in rice bran inhibit  $\beta$ -hydroxy  $\beta$ -methyl glutaryl-CoA (HMG CoA) reductase activity which is the rate-limiting enzyme for cholesterol synthesis (Qureshi *et al.*, 2000). Rice bran is rich in nutrients and has a protein content of 14%-16%. The comparatively high nutritional price of rice bran protein is attributable to the high essential amino acid content. The reported protein efficiency ratio (PER) 1.6-1.9, is comparable with the value of 2.5 for casein (Saunders, 1990). Major carbohydrates in rice bran are hemicellulose (8.7%-11.4%), cellulose (9%-12.8%), starch (5%-15%), and  $\beta$ -glucan (1%). Rice bran contains 15%-23% oil. Three major fatty acids, palmitic (12%-18%), oleic (40%-50%), and linoleic (30%-35%), make up 90% of total fatty acids.

Crude rice bran oil contains 3-4% waxes and about 4% unsaponifiable lipids. Oryzanol and tocopherol, the two potent antioxidants are present in rice bran (Saunders, 1985). Rice bran is also rich in B-complex vitamins. The mineral composition of rice bran depends to a large extent on nutrient convenience of the soil within which the crop mature. Rice bran contains Ash (6.72-11.41%), Fe (8.6-43mg/100g), Ca (30-120 mg/100g), Na (13-20 mg/100g), K (1000-2000 mg/100g), P (1100-2500 mg/100g) and zinc (4.6-6.6 mg/100g) (Houston, 1972). Bran contains 80% of rice kernel iron (Lu and Luh, 1991). Bioactive compounds of rice bran include phenolic and cinnamic acids (Laokuldilok *et al.*, 2011), anthocyanins, flavonoids (Jun *et al.*, 2012), steroidal compounds (Miller and Engel, 2006), polymeric carbohydrates (Rondanelli *et al.*, 2011) and proteins (Prakash, 1996). A rice bran protein formulation can provide nourishment to preschoolers (Khan *et al.*, 2011). The protein with a caloric value of 416 kcal/100g and a digestibility of 80.9-84.45% had good acceptability during a short-term infant-feeding trial. These findings suggest that inexpensive rice bran proteins could contribute to food security. Because rice bran is a rich source of dietary fiber and minerals, the effect of incorporation of three levels (5, 10, and 15%) of commercial defatted rice bran on bread quality was examined by Sairam *et al.* (2011). Dietary fiber content, antioxidative activity and shelf life increased with

Udit Nandan Mishra *et al.*

increase bran levels. These results suggest that rice bran can serve as a functional ingredient for high-fiber breads with improved antioxidant potential and storage stability.

### Functional properties of rice bran

Rice bran is faint in color, sweet in taste, moderately oily and encompasses a slightly cooked nutty flavor (Tao, 1989). Texture varies from a fine, powder-like consistency to a flake. In addition to flavour, colour, and nutritional properties (protein extractability and solubility), other properties such as water and fat absorption, emulsifying and foaming capacity are important factors determining the potential use of rice bran in food. Stabilized rice bran is a rich source of both soluble and insoluble dietary fiber (25-35%). Insoluble fiber functions as a bulking agent, whereas soluble fiber lowers steroid alcohol (Wise, 1989). Soluble fiber might hamper texture, jelling, thickening, and emulsifying properties (Olson *et al.*, 1987). Additional insoluble fiber in rice bran leads to sensible water-binding capability. According to James and Sloan (1984), the defatted extruded rice bran absorbs most of the water and fat. It has greater foaming capacity and stability compared to wheat bran in model systems. In baked product, the high water-binding capability of rice bran helps maintain wetness and freshness.

Rice by-products might serve as important sources of raw material that could be used as ingredients of functional food and nutraceuticals. Texture of rice bran varied from a fine, powder-like consistency to a flake, depending on the polishing and stabilization process. High fat absorption capability in extruded rice bran would be fascinating in product like meat extenders to assist maintain succulence and improve mouthfeel. The full fat extruded rice bran with less fat permeability could be best for foods like donuts and pancakes that are baked in fat and for which absorption of fat isn't desirable (James and Sloan, 1984). Rice bran protein concentrate has shown sensible emulsifying activity, stability, and capacity. The foaming capability aids in air incorporation, leavening, and texturization in baked products, meringues, and whipped toppings. Extruded defatted rice bran with 115.5% foaming value could be the best bran for achieving the above functions in food systems (James and Sloan, 1984). A high level (20%) of rice bran in bakery product affects overall look, volume, taste, and structure.

### Phytochemicals and antioxidant activity of rice bran

All phytochemical mixes for the most part amass in the pericarp and testa or bran of the rice seed. One advantage of rice bran was that it was a wellspring of bioactive phenolics. These phenolic mixes have intense antioxidant and free radical scavenging properties, which avoid incessant illnesses, for example, malignant growth, diabetes, heftiness and cardiovascular maladies (Okarter and Liu, 2010). Madhujith and Shahidi (2009) observed that there were higher measures of solvent conjugate than free phenolics in grain. Moreover, dissolvable conjugate phenolics, once discharged from ingested nourishment by microscopic organisms in the microbiota, may assume a basic job in conveying antioxidants to the colon in a way like bound phenolics. Rice bran was utilized as a waste result of paddy processing contained protein, sugar, dietary fiber, fiery debris, fat, nutrient, mineral and characteristic antioxidant mixes (Chen *et al.*, 2008; Saenjum *et al.*, 2012). They revealed that rice bran likewise contained phytochemical mixes in critical sum and these mixes had been considered as common antioxidant.

The antioxidant movement for settled rice bran was 65µg/g of vitamine-C equivalent. Moko *et al.* (2014) revealed that DPPH hindrance percent was extended from 51.02-73.8. Canan *et al.* (2012) revealed that rice bran contained 6.4 mg/100g of phytate P. Chotimarkorn *et al.* (2008) observed that methanolic rice bran separates delivered solid outcomes with DPPH free radical scavenging 38-74%. The better action of methanol extract, might be clarified by the likelihood of progressively polar phenolic mixes and lipids eluted in the methanol than in the ethyl acetic acid derivation extricate. All phytochemical mixes would collect in the pericarp and testa or bran of the rice bit. Among rice assortments there were rice assortments that contained shading colors. These mixes were shade containing identified with particular hues, for example, red, purple and dark. Antioxidant activities of paddy assortments containing shading colors, for example, red Thai, dark rice, red darker and dim purple had been seriously examined by Yodmanee *et al.* (2011). They revealed that rice with non shading colors contained lower phenolic substance and

**Udit Nandan Mishra et al.**

antioxidant action. Numerous investigations have revealed that dark rice contained anthocyanin and other polyphenolic mixes more bounteously than white rice (Ryu *et al.*, 1998; Zhang *et al.*, 2006).

The convergences of lipophilic antioxidants of vitamin E (tocopherol and tocotrienols) and  $\gamma$ -oryzanols were 319.67 to 443.73 and 3861.93 to 5911.12 $\mu$ g/g respectively on dry weight (DW) basis, and were not related with bran shading. The complete phenolic, absolute flavonoid, and antioxidant limits of ORAC (oxygen radical absorbance limit), DPPH (1, 2-diphenyl-1-picrylhydrazyl) radical searching, and iron-chelating in the free division were connected with the force of bran shading, while varieties of these in the bound portion were not exactly those in the free part among bran. Mixes in the bound portion had higher antioxidant limit of ORAC than DPPH, in respect to those in the free part. The bound portion of light-shading brans contributed as a lot to its complete ORAC as the free part. All out proanthocyanidin fixation was the most elevated in red rice bran, while complete anthocyanin was most astounding in purple brans. The dominating anthocyanin was cyanidin-3-glucoside. Red and purple bran had a few crease higher complete phenolics and flavonoids just as ORAC and DPPH, from both free and bound portions, than stop dried blueberry and broccoli. Their outcomes show that rice bran were normal wellsprings of hydrophilic and lipophilic phytochemicals for use in quality control of different nourishment frameworks just as for nutraceutical and practical sustenance application.

Rice bran had been perceived as an amazing source of vitamins and minerals, yet had been under-used as human sustenance and had customarily been utilized essentially in creature sustains. Research led over the most recent two decades had demonstrated that it contained an exceptional complex of normally happening antioxidant mixes (Moldenhauer *et al.*, 2003). Past research about antioxidant properties in shaded rice bran showed that rice bran with certain shading that contained anthocyanin had a reductase catalyst inhibitory and hostile to diabetic action (Kim *et al.*, 2008; Park *et al.*, 2008). Further investigations detailed that dim purple rice assortment had higher iron, polyphenol and antioxidant properties than the red rice assortment, while red rice contains higher phenolic mixes. It had additionally been accounted for that dark rice had a searching exercises higher than red rice assortment, while non shaded rice had phenolic substance and antioxidant activity which were lower than the hued rice assortment (Muntana and Prasong, 2010; Yodmanee *et al.*, 2011).

### Health benefits and anti-nutritional factors of rice bran:

Nutritional studies in animals and humans have shown a cholesterol lowering potential for rice bran and rice bran fractions (Newman *et al.*, 1992; Hegsted *et al.*, 1993). Among compounds whose hypocholesterolemic activity has been demonstrated in animal and/or human subjects are rice waxes, oryzanols (ferulic acid esters of triterpene alcohols), hemicelluloses, neutral-detergent fiber fractions, proteins, and oil components (Saunders, 1990). Diets high in unsaturated fatty acids such as oleic, linoleic, and linolenic acid, which are present in rice bran oil, lowered LDL-cholesterol when replacing saturated fat (McDonald *et al.*, 1989). Rice bran extracts inhibited the growth of the following bacteria isolated from patients suffering diarrheal disease: *Vibrio cholerae*, *Vibrio vulnificus*, *Salmonella spp.*, *Shigella spp.*, *Escherichia coli*, and *Staphylococcus aureus* (Kondo *et al.*, 2011). The nutritional composition of rice bran shows the presence of several compounds which possesses significant anti-oxidant activity to prevent chronic diseases. The incorporation of dietary fiber into the functional food have reported to decrease the risk of coronary heart disease, reduction of blood cholesterol levels and improvement of insulin sensitivity (Mellen *et al.*, 2008). The oryzanol component acts as protective agent against UV light and is used in cosmetics as sunscreen agent. The ferulic acid esters of gamma oryzanol act as anti-ageing compounds as they stimulate hair growth. Rice bran also prevents high blood pressure, hyperlipidemia and hyperglycemia. Both Type I and Type II Diabetes Mellitus also controlled by nutraceuticals developed from fiber fraction of rice bran (Qureshi *et al.*, 2002). Food supplemented with rice bran also lead to reduced bone loss in women suffering from postmenopausal osteoporosis (Heli and Shanna, 2005).

Cereal brans have not been used to their maximum capacity as a sustenance source because of the presence of antinutritional factors out of which the phytic acid, phenol and tannins fill in as the real constituents that limit the immediate usage of brans in the eating regimen. Rice bran has the higher phytic acid substance than other cereal

Udit Nandan Mishra *et al.*

bran. Phytic acid (PA) is a viable chelator of numerous basic mineral supplements, for example, iron, zinc, and calcium which comprises around one to five percent of the dry matter of numerous cereals and eatable vegetables thus consequently presenting genuine negative effects on the usage of mineral supplements and lead to ailment health in people (Jacobsen and Slotfeldt-Ellingsen, 1983). Rice bran is wealthy in lipids and serious lipase movement within the sight of endogenous lipoxygenase causes quick crumbling of these lipids by rancification (Pauca-Menacho *et al.*, 2007). Due to lipid susceptibility, the commercial utilization of rice bran requires enzymatic inactivation following bran division to maintain a strategic distance from unsaturated fat, expand its timeframe of realistic usability and permit its commercialization for human utilization. Rice bran oil has a few one of a kind healthful properties. Be that as it may, just a little division of this profitable oil is utilized for palatable oil generation. The principal reason is that the oil is exposed to rice bran lipase catalyst after rice processing which causes rapid hydrolysis of the triglyceride of oil into glycerol and free unsaturated fats. These free unsaturated fats become substrates of lipoxygenase and result in deterioration of rice bran oil quality. All the more explicitly, the subsequent unsaturated fats cause an increase in bran acidity and decrease in pH.

### Food use of rice bran

Luh and Liu (1980) revealed that rice bran was exceedingly nutritious and consequently utilized as a nourishing substance. Hossain *et al.* (2012) examined on nutritive estimation of polished rice and revealed that in most of the nations, out of all the harvest deposits, this was one of the least expensive and biggest source of metabolizable energy with as much as crude protein. Rice bran supplementation essentially improved the dietary fiber, mineral and protein substance of the treats. Besides, cost of generation was additionally decreased with proportionate increment of supplementation. As of late, the utilization of rice bran is picking up significance in numerous studies because of the way that, amid the preparing of entire rice, a lot of the grain's external layers are expelled, raising the centralization of supplements in the bran and rendering it a vital source of supplements for the nourishment purpose and human utilization (Imsanguan *et al.*, 2008; Parrado *et al.*, 2006).

### CONCLUSION

Rice bran obtained during milling of rice is getting commercial importance in the world due to the fact that it contains nutritionally superior oil and a number of health beneficial compounds. Despite of the massive scientific proof on rice bran bioactivity, it still remains underutilized in human health and nutrition as a result of its thought of as animal feed and is understood to undergo hydrolytic rancidity after processing from whole grain rice. GC-MS, UPLC-MS/MS (ultra-performance liquid chromatography-tandem mass spectroscopy) and metabolomics analysis of rice bran revealed a huge number of metabolites that were clustered into several metabolic pathways including amino acids, carbohydrates, cofactors, vitamins, lipids, nucleotides, peptides, secondary metabolites, xenobiotics etc. Although rice bran is a good nutritional food source, rapid rancidity from the activity of enzymes such as lipase and lipoxygenase deteriorate the nutritional values in rice bran and limits the wide usage of rice bran as a food ingredient. The effective utilization of rice bran is possible only by deactivating the lipolytic enzymes such as lipase, lipoxygenase responsible for the hydrolytic rancidity since this phenomenon severely affects the nutritive value and palatability of rice. This problem creates a future line of work to look forward to for getting maximum benefits out of the milling by-product of rice.

### ABSTRACT

The main objective of the present study is to conduct laboratory experiment for the generation of rainfall runoff data using rainfall simulator (Advanced hydrological System). AHS is embedded with Armsoft Educational Software S12MKII-306 hydrological systems. A graphical record of flow and time resulting from rainfall over catchment is called a hydrograph. The sand tank should be set to different slope of maximum 3.5% and minimum 1.5 % before carrying the test. For the validation of observed data, a model is established for estimating observed runoff data using Artificial Neural Network (ANN) technique. The ANN model for the runoff discharge evaluation was developed using MATLAB Software. The MATLAB tool used for the creation of ANN model is Neural Networks tool. ANN model behaviour during training, testing, validation gave a good comparison with overall R value 0.98. Error in observed and predicted volume were found as 6.66 % and 7.89 % respectively at 3.5 % and 2.5 % slope whereas error in peak discharge were estimated as 7.40 and 3.07 respectively at 3.5 % and 2.5 % slope. Nash-Sutcliffe Efficiency was calculated as 91.3 % and 92 % respectively at 3.5 % and 2.5 % slope.

**Keywords:** Rainfall simulator, ANN, MATLAB, Hydrograph, Nash-Sutcliffe efficiency

### INTRODUCTION

Rainfall-runoff models are conventionally assigned to one of three broad categories :*deterministic* (physical), *conceptual* and *parametric* (also known as analytic or empirical)[1] [2] which plays a vital role in the hydrological cycle. A number of models i.e. Artificial Neural Networks (ANNs), physically based, black box and conceptual models have been used to simulate the complex hydrological processes such as rainfall runoff process which shown a useful

**Nidhi Kumari and Prabhat Kumar Singh**

tool in water resources. However, due to its complexity and spatio-temporal variation, a few models can accurately simulate this highly non-linear process. Incomplete, noisy and ambiguous data can be handled theoretically by ANN [3]. Neural network research has evolved in three distinct phases [4]. ANNs are often cheaper and simpler to implement than their physically based counterparts [5]. They are also well suited to dynamic problems and are parsimonious in terms of information storage within the trained model [6]. An ANN is a massively parallel-distributed information processing system that has certain performance characteristics resembling biological neural networks of the human brain [7].

Distributed models can be considered as an assemblage of sub catchments arranged either in series or as a branched network [8]. ANNs have been developed as a generalization of mathematical models of human cognition or neural biology. Their development is based on 1. Information processing occurs at many single elements called nodes, also referred to as units, cells, or neurons. 2. Signals are passed between nodes through connection links. 3. Each connection link has an associated weight that represents its connection strength. 4. Each node typically applies a nonlinear transformation called an activation function to its net input to determine its output signal. A neural network is characterized by its architecture that represents the pattern of connection between nodes, its method of determining the connection weights, and the activation function. The application of ANNs in many fields, including financial management, manufacturing, control systems, design, environmental science and pattern recognition for geographical and hydrological study [9] [10]. Extraction of hydrological rules from ANN weights and on the development of standard performance measures that penalize unnecessary model complexity [11]. Data cleansing techniques have not been widely applied in ANN rainfall-runoff modelling, so there is much scope for development in this area [3].

Advanced Hydrologic System (AHS) enables to demonstrate the physical processes found in hydrology, including rainfall-runoff process; well abstractions, formation of river features. Realistic results can be obtained from this small-scale apparatus, which can be conveniently located in a laboratory and requires no special services. Thus, the apparatus is useful to study the part of hydrological cycle bounded by the arrival of net rainfall on ground surface and catchment runoff either by surface streams or well abstraction. AHS is embedded with Armsoft Educational Software S12MKII-306 hydrological systems. The software is split into three parts to suit the different exercises associated with S12-MKII. Part 1 of this software is used to determine the Sand Factor (voidage) of the sand used in the sand tank. Part 2 of the software is used for continuous logging of the Outflow from the collecting tank and any change in mass, allowing rainfall hydrographs, sediment yield etc. to be monitored continuously throughout an exercise. Part 3 of the software is used for manual entry of results obtained from the bank of manometer tubes allowing water table profiles, draw-down at wells etc to be recorded and graphically presented. The software also allows all relevant settings to be manually entered for future reference. Zeroing the Height Over Weir reading, Zeroing the Mass reading and rainfall intensity pattern can be set as per requirement. In the present investigation, the simulated rainfall intensity pattern is used having different pattern of rainfall intensity. For each value of rainfall intensity different overland plane slopes of 1% to 4% were used. MATLAB software is used to test and validate the results through ANN. The objective of the study is to identify single storm runoff hydrograph at different bed slopes and rainfall intensity. Study also validate results using ANN with MATLAB software and further validated by Nash- Sutcliffe Criteria.

## MATERIALS AND METHODS

The present study has been carried out with the help of Advanced Hydrological system (Fig.1). This system is sensor based which shows runoff, sediment yield, volume of discharge with respect of change in bed slope, rainfall intensity, river flow in graphical or tabular forms. The system is based on the concept of watershed which has a single drainage outlet. This also consist confined and unconfined aquifer concept. In the present study, focus is on to find out runoff discharge and volume with changing slope and rainfall intensity. Tamilnadu sand without vegetation has

**Nidhi Kumari and Prabhat Kumar Singh**

been used for the purpose of quick discharge. The time taken for the water to reach the point of concentration depends on the horizontal distance it has to travel and also on the velocity. The greatest time taken for rain falling on the catchment (the far corners) is called time of concentration. A graphical record of flow and time resulting from rainfall over catchment is called a hydrograph. The sand tank should be set to different slope of maximum 3.5% and minimum 1.5 % before carrying the test. Smooth the sand in the tank to give a smooth surface parallel to the top edge of the tank, then use the sand scoop to create a channel of rectangular cross section centrally down the length of the tank between the river inlet and the deep outlet at the foot. The channel should be approximately 4 cm wide and 2 cm deep. Connect the flexible piping from the overhead spray nozzles to the quick release connector on the 3 l/min flow meter. As per the guidelines of Armfield AHS for stream flow for a short duration storm (Fig.3) and stream flow from a long duration storm (Fig.4). Spray nozzles are turned on to simulate rainfall and select a rainfall flow rate of between 1 and 3 l/min. Rainfall is allowed long enough to give a steady runoff value. Flow is turned off and recession limb of hydrograph is recorded. Stopwatch is started (zero time) at commencement of rainfall and weir discharge is read as frequently as necessary to show the hydrograph form. This is also done for same catchment of short duration with slope.

Hydrograph peak discharge in short Duration high intensity is increased for short time because of less time of concentration. While in the case of high duration low intensity rainfall as the time proceed because of high time of concentration it will account for infiltration losses. It is clearly showing that discharge of any catchment depends up on slope of catchment as well as duration and intensity of rainfall. Hydrographs for various rainfall intensity with various slopes collected using AHS are shown in Fig. 5, 6 and 7. The ANN model for the runoff discharge evaluation was developed using MATLAB R2012b software. The MATLAB tool used for the creation of ANN model is nntool (neural networks tool). We collected some data for runoff discharge at the laboratory using advanced hydrological systems. These recorded data were taken for model development using various input variables (slope, rainfall intensity, rainfall duration) and output runoff discharge, the data base used for the ANN model generation.

The behaviour of model during training, testing and validating which shows its capability to predict the process input output relation. As much as the correlation coefficient value (R) is higher, better the model will predict [11]. The training process of ANN was terminated when the overall error on the testing data set was minimal. The main function of training process is to reach an optimal solution based on some performance measurements such as overall error; coefficient of determination known as R value. The validation sets are usually used to select the best performing network model. In this project ANN was the optimal at 100 iterations with 7 hidden nodes. It was found that training and validation phases gives the good agreement with the coefficient of determination value as shown in figure below. Note that the data pairs closer to the diagonal line (also known as the line of agreement) in model behaviour plot gives excellent prediction. The Nash-Sutcliffe efficiency criteria is used to estimate the model performance which can be expressed by the following equation (1);

Nash-Sutcliffe Efficiency (NES) in (%),

$$NES = \left( 1 - \frac{\sum_{i=1}^n (Y_o - Y_c)^2}{\sum_{i=1}^n (Y_o - Y_m)^2} \right) \times 100$$

..... equation (1)

Where,  $Y_o$  = Observed flow (Experimental rainfall flow) value at time t,

$Y_c$  = Predicted flow (kinematic flow) value at time t,

$Y_m$  = Mean of observed values.

Error in Computational Runoff Volume:

The error in runoff volume for the present study was estimated by equation (2)

**Nidhi Kumari and Prabhat Kumar Singh**

$$\text{Volumetric error, in \%} = \left( 1 - \frac{Y_c}{Y_o} \right) \times 100$$

..... equation (2)

Where,  $Y_o$  = Runoff volume observed and  $Y_c$  = Runoff volume predicted

## RESULTS AND DISCUSSION

Each experiment has been done 10 times and average value has been taken into consideration. Hydrograph resulting from short duration of 10 minute with high intensity rainfall of 3 litre per minute at 3.5 % bed slope showed a runoff volume, runoff depth and discharge with sand factor (voidage) 0.610 kg as 23 l, 11.5 mm and 3.06 l/min respectively. Similarly, hydrograph resulting from long duration of 30 minute with low intensity rainfall of 3 litre per minute at 3.5 % bed slope showed a runoff volume, runoff depth and discharge with sand factor (voidage) 0.610 kg as 15 l, 7.5 mm and 0.54 l/min respectively. Hydrograph resulting from short duration with high intensity rainfall showed a higher peak discharge value at 20 minute elapsed time while long duration with low intensity rainfall showed at lower peak discharge at 32 minute elapsed time. Hydrographs are also shown in Fig.5,6 and 7 which has been taken at different slopes with same rainfall intensity showed peak discharges as 2.52, 2.56 and 2.64 lit/min respectively at 1.5 %, 2.5 % and 3.5 % bed slope respectively. Thus, it is revealed that peak discharge changes with varying slopes.

Observed hydrographs by AHS at 3.5 % slope with rainfall intensity 1.5 litre per minute has been compared with predicted hydrographs by MATLAB incorporated in ANN with same slope and rainfall intensity. The observed and predicted hydrographs showed closer resemblance at 3.5 % and 2.5 % slope. The predicted hydrographs using ANN model showed that the model performed better estimation with observed runoff data which is also useful for decision making in the area of water resources management and planning, flood forecasting etc. The comparison of observed and predicted runoff hydrograph using ANN model. ANN model behaviour during training, testing, validation gave a good comparison with overall R value 0.98. Pertinent characteristics of observed and predicted hydrographs for 1.5 lit/min rainfall intensity has been shown in Table 1: Error in observed and predicted volume were found as 6.66 % and 7.89 % respectively at 3.5 % and 2.5 % slope whereas error in peak discharge were estimated as 7.40 and 3.07 respectively at 3.5 % and 2.5 % slope. Nash-Sutcliffe Efficiency was calculated as 91.3 % and 92 % respectively at 3.5 % and 2.5 % slope.

## CONCLUSIONS

The validation of collected data sets were analysed and found that the ANN model estimate in better way to model rainfall runoff process. ANN technique is useful to handle the complex problems as compared to other techniques. Further, the results illustrated clearly ANN is capable to simulate rainfall runoff relationship which might help in confirming the general enhancement archived in other fields of hydrology. In addition, results and comparative analysis indicate that ANN is more suitable to predict river runoff of a catchment than other classical regression model. Modelling can assist in rural and urban planner to undertake the necessary measures to deal with the river bed predictions. Hence, it can help to avoid losses due to ecological hazards.

### ABSTRACT

*Bordetella bronchiseptica* is a small, Gram-negative, rod-shaped bacterium known to cause infectious bronchitis in dogs and other animals, but rarely infects humans. Results of the present study showed that *Bordetella* was found to exhibit a nutrition stress-related postexponential rapid cell death (RCD). The RCD in this bacterium is accompanied by typical markers of eukaryotic apoptosis such as loss of cell viability in the post-exponential phase, enhanced biosynthesis of caspase-3 like protein. The affinity purified fraction cross reacted with human caspase-3 polyclonal antibody.

**Keywords:** eukaryotic, cell death, animals, infectious, antibody.

## INTRODUCTION

In eukaryotes, programmed cell death (PCD) is a genetically regulated self destruction process for the elimination of damaged or unwanted cells. It plays an important role in the development and maintenance of the integrity of organisms. Cells undergoing PCD exhibit a number of biochemical, physiological, and morphological features [1, 2]. Similarly to eukaryotes, PCD in bacteria is a complex and regulated process that is essential for bacterial communities' survival, differentiation, and spreading. The similarities observed between cell death systems of animals, plants, and bacteria suggests endosymbiotic acquisition of bacteria by eukaryotes [3, 4, 5]. PCD in a cell is induced by a certain signal(s). The end point of the signaling activity is the induction and activation of caspases (cysteine-specific proteases), the proteases that finally execute PCD [1, 2]. Several investigators have reported the occurrence of PCD in bacteria regulated by chromosomal and extrachromosomal toxin-antitoxin pairs of molecules. In *Escherichia coli*, such chromosomal toxin-antitoxin systems include *mazEF*, *chpBIK*, *relBE*, *yefM-yoeB*, and *dinJ-yafQ* [3, 4, 5, 6]. Earlier studies in *Xanthomonas campestris* pv. *glycines* (Xcg), a plant pathogen and the etiological agent of bacterial pustule disease of soybean (*Glycine max*), was found to exhibit a nutritional stress-related postexponential rapid cell death (RCD). The RCD in *Xanthomonas campestris* pv. *glycines* was found to display certain

**Kalidindi Krishnam Raju**

molecular features similar to those of the programmed cell death (PCD) of eukaryotes such as increased cellular reactive oxygen species levels, externalization of phosphatidyl serine, Biosynthesis of catalytically active caspase-like protein in the mid-log phase cultures. . The amino acids glycine and L-alanine as well as the D isomers of valine, methionine, and threonine were found to induce the synthesis of an active caspase-3-like protein that was associated with the onset of RCD. Addition of pyruvate and citrate to the culture medium induced both the synthesis of active caspase-3-like protein and RCD [7]. Computational analysis of the already sequenced genomes revealed that the apoptosis-related domains in bacteria typically form complex multi-domain architectures. These multi-domain proteins contain fusions between apoptosis-related domains, such as apoptotic ATPases fused with a metacaspase or a tollinterleukin-receptor (TIR) domain [8, 9]. Consistent with this bacterial caspase was found to interact functionally and physically with poly(ADP-ribose) like protein (PARP) like protein in the observed modulation of genetically programmed RCD [10]. Purification and further characterization of caspases to electrophoretic homogeneity from *xanthomonas* is challenging due to exopolysaccharide Xanthan that promotes protein aggregation in cell free systems. The present study was undertaken to search for a new bacterial species that undergo post exponential RCD akin to Xcg and eventual purification and characterization of this novel and uncharacterized cell death protein called caspase. *Bordetella bronchiseptica* is a small, Gram-negative, rod-shaped bacterium of the genus *Bordetella*. It can cause infectious bronchitis in dogs and other animals, but rarely infects humans [11, 12]. Based on genome serach *Bordetella* was found to have caspase-like domain and found to exhibit post exponential RCD similar to Xcg with the synthesis of catalytically active caspase-3 like protein that cross reacts with human caspase-3 antibody. This 80± 2 kDa in vivo affinity purified protein lost a majority of its activity.

**MATERIALS AND METHODS****Media and culture conditions**

Inoculation was carried out by the addition of a single isolated colony of *Bordetella* to the Luria-Bertani (LB) medium and was incubated for 24 h on a rotary shaker (150 rpm) at ambient temperature (26±2 °C). The 24 h grown culture was incubated further under static conditions at the ambient temperature, in order to observe PCD. For viable cell counts aliquots of the culture broth were withdrawn and serially diluted using sterile saline (0.85%) and transferred to LB-agar using spread plate technique. Plates were incubated at ambient temperature for 72 h. Viable cell counts were obtained at the end of the incubation period by counting colonies. To induce RCD, metabolites such as alanine (Ala), pyruvate (Pyr) and citrate (Cit) were added to the LB medium at the start of incubation in 100mM, 100 mm and 50 mM respectively

**Caspase-3 assay**

A single colony of *Bordetella* was transferred to 10 ml of medium and incubated overnight (~18 h) on a rotary shaker (150 rpm) at ambient temperature. A one ml (~10<sup>8</sup> cfu/ml) aliquot of the culture was centrifuged at 10,000 g for 10 min. The pellet was washed once with phosphate buffered saline (PBS, 10 mM, pH 7.4), suspended in 500 µl of caspase assay buffer [HEPES (20 mM, pH 7.6), NaCl (100 mM), CHAPS (0.1%), DTT (10 mM), EDTA (100 µM), and glycerol (10%)] [7, 10], and the cells lysed by freeze-thaw (freezing under liquid nitrogen and thawed at 37 °C) followed by sonication on ice for 15 s. Protein equivalent to 25 µg was mixed with 200 µM of synthetic colorimetric substrate, Ac-DEVD-pNA [N-acetyl-Asp-Glu-Val-Asp-pNitroanilide], prepared in dimethyl sulfoxide (DMSO) as 10 mM stock and incubated at 37 °C for 30 min in 1 ml caspase assay buffer. After incubation the absorbance at 405 nm was measured using a spectrophotometer. The protein concentration was determined by the standard Bradford method [13].

**SDS-PAGE**

Overnight grown *Bordetella* cells were harvested by centrifuging at 10,000 g for 10 min, the pellet washed twice with phosphate buffered saline (PBS, 10 mM, pH 7.5) and suspended in sterile milli-Q water. The cell suspension was mixed with an equal volume of 2X gel loading buffer [Tris (100 mM pH 6.8), SDS (4%), glycerol (20%), bromophenol

**Kalidindi Krishnam Raju**

blue (0.002%), and  $\beta$ -mercaptoethanol (200 mM)]. The mixture was heated at 95 °C for 10 min, immediately chilled on ice for 5 min, and centrifuged at 12,000 g for 10 min. A 50  $\mu$ l aliquot of the supernatant was loaded on 10% (w/v) SDS-polyacrylamide slab gel, which was run vertically at 35 mA constant current on a PAGE system (Techno Source, India).

**Silver staining of SDS PAGE**

The gel was left overnight in the fixative solution, removed and washed thrice in 100 ml of 50% ethanol, each washing for 15min. The gel was then treated with sodium thiosulphate (20 mg/100 ml) for 1 min. After treatment with sodium thiosulphate, the gel was rinsed 4X with distilled water, each for 30 s. The gel was immersed in a solution containing 200 mg / 100 ml of AgNO<sub>3</sub> and 1 $\mu$ l formaldehyde / ml and left for 30 min with gentle shaking. It was then rinsed 4X with distilled water; each for 30 s. Silver stain was developed by adding developer on the gel. When proper contrast was visible, the over development of gel was stopped by adding 100 ml of stopping solution on the gel. Finally, the gel was stored in 50% methanol.

**Western blotting**

After completion of the SDS-PAGE run, electro-blotting was performed using a hybond-P membrane in a transfer buffer [25 mM Tris, 192 mM glycine (pH 8.3); 20 % methanol] employing 50 mA constant current overnight at 4°C. The blotted membrane was air dried for 1 h, suspended in methanol for 5 min and equilibrated in TBS buffer (20 mM Tris pH 7.6, 0.5 M NaCl) for 30 min. The equilibrated membrane was subjected to blocking with 3% gelatin (3g of gelatin in 100 ml TBS), washed twice with TTBS (TBS containing 0.05% Tween-20) and hybridized with 10  $\mu$ l (0.5 mg/ml) of the affinity purified biotin-conjugated polyclonal rabbit anti-active human caspase-3 antibody for 18 h at ambient temperature as described previously [7, 10]. After primary antibody hybridization the blot was washed twice with TTBS and later subjected to secondary hybridization with 50  $\mu$ l of streptavidin-horseradish peroxidase conjugate for 1.5 h. Both the primary and secondary antibody reactions were performed in TTBS buffer having 1% gelatin. After secondary hybridization the blot was washed once with TBS-Tween-20 (0.05%) and once with TBS for 5 min, respectively and the band detection was performed by using enhanced chemiluminescence method [Tris pH 8.5 / 4-chloro-1-naphthol / H<sub>2</sub>O<sub>2</sub> / p-coumaric acid].

**Affinity chromatography and immunoprecipitation**

Overnight alanine fortified LB grown culture (1000 ml) was harvested by centrifugation (10,000 g for 10 min.), washed once with PBS and the cells lysed by freeze-thaw and sonication on ice for 5 min in a caspase assay buffer containing protease inhibitors PMSF 1mM, 10  $\mu$ g each of pepstatin, leupeptin and aprotinin. The cell debris was removed by centrifugation (10,000 g for 20 min), and the supernatant was subjected to sequential ammonium sulfate precipitation. The caspase active fraction (15-40 % ammonium sulfate precipitate) was dialyzed overnight in the caspase assay buffer and incubated with commercially available biotinylated form of single specific potent inhibitor of caspase-3 (1  $\mu$ M biotinylated DEVD-CHO) for 30 min [14]. The incubated protein was captured onto a streptavidin-agarose gel. The column material was washed with 20 volumes of the caspase assay buffer containing 0.5M NaCl. The protein was eluted with 200  $\mu$ M free caspase inhibitor (Ac-DEVD-CHO). After blotting the partially purified fractions onto a polyvinylidene difluoride (PVDF) membrane, the caspase protein bands were visualized by means of ponceau-S stain and the blots were probed separately with caspase antibody.

For immunoprecipitation the caspase active fractions after ammonium sulphate precipitation were incubated overnight at 4°C with biotin conjugated caspase-3 antibody in the incubation buffer (TBS buffer containing 1mM EDTA, 1mM PMSF, 10  $\mu$ g each of protease inhibitors pepstatin, leupeptin and aprotinin) and the protein was captured onto a streptavidin-agarose column (1.5 ml). Later the column was washed with 50 ml of the incubation buffer. The protein was eluted with 100  $\mu$ l SDS-gel loading buffer and the eluted protein was analyzed by silver staining and Western blotting.

## RESULTS AND DISCUSSION

### Survival of *Bordetella* in LB fortified media

Viable cell counts in stationary-phase cultures of *Bordetella* grown for 24 and 96 h in different culture media are shown in Figure 1. In media such as LB fortified with alanine, pyruvate and citrate, rapid declines in the viable cell numbers were observed between 24 and 96 h of incubation. The cell count was reduced from 8 log<sub>10</sub> CFU/ml at the onset of the stationary phase (24 h after the start of incubation) to 5 log<sub>10</sub> CFU/ml at the end of stationary phase (96 hrs from the start of incubation) in LB media fortified with metabolites. While in LB untreated control (without addition of metabolites) the cell count remained stable at the onset of the stationary phase (24 h after the start of incubation) to the end stationary phase (8 log<sub>10</sub> CFU/ml). RCD in the presence of previous reported inducer(s) suggested occurrence of a conserved RCD mechanism in *Bordetella* similar to Xcg.

### In vivo caspase activation during RCD

In order to confirm expression of active caspase in the presence of RCD inducers such as alanine, pyruvate and citrate, the protein lysate fraction was subjected to caspase activity. Nearly 3-fold higher caspase activities were observed when compared to LB grown control cultures (Table 1). All the three metabolites (alanine, pyruvate and citrate) showed increased expression of caspase-3 like protein over the untreated LB controls (Figure 2). This clearly indicated that the genetic regulation of PCD in *Bordetella* correlated positively with the caspase-3 like activity.

### Affinity purification and immunoprecipitation

An affinity purification strategy followed for caspase purification was also employed to purify the caspase-3 like protein from *Bordetella* [14]. The partially purified caspase protein after affinity elution gave a strong hybridization signal with the caspase antibody (Fig. 3A & 3B). After elution of this protein from streptavidin agarose column, the 80± 2 kDa protein lost a majority of its activity. Previously reported that intracellular accumulation of metabolites such as pyruvate and citrate in *Xanthomonas campestris pv. glycines* was found to result in a caspase dependent stationary phase rapid cell death (RCD) [7, 10]. Pfam domain architecture analysis combined with operon identification revealed wide and scattered distribution of bacterial metacaspase sequences, and with a potentially intriguing evolutionary role. These metacaspases imply roles in programmed cell death, cellular signaling, various enzymatic activities and protein modification [15]. At the moment, neither the nature of the caspase nor the putative gene caspase domains is clear in *Bordetella*. Western analysis of the cellular lysate revealed that it cross-reacted with the caspase, a feature that needs to be understood. Understanding RCD features in bacteria will help future characterizations of death pathways in prokaryotes.

### ABSTRACT

Edible insects are suitable sources of supplement food items that could meet the present and future wants of humans. Insects are used for human meals in a few elements of the arena while being taboo in other locations and cultural agencies of the globe. Insects are considered as a rich source of proteins (20-70%), amino acids (30-60%), fats (10-50%), fatty acids, carbohydrates (2-10%), minerals (calcium, iron, zinc, phosphorous), nutrients (nutrition A, B complicated and C) and different activated elements that promote human health. They are natural renewable aid that provides meals and economic protection to many ethnic classes in Northeast India, particularly to some of the tribes of Arunachal Pradesh, Assam, Manipur, Nagaland, Meghalaya and Mizoram. Among these, the best consumption of edible insect species belongs to the order Coleoptera (34%), followed by Orthoptera (24%), Hemiptera (17%), Hymenoptera (10%), Odonata (8%), Lepidoptera (4%) and Isoptera (2%). The use of insect species for the remedy of sickness is appeared as a secret and passed on from generation to generation among these tribes. A wide array of studies in recent years has attracted the attention of humans toward the healing and medicinal values of different species of insects and their merchandise. Edible insects can constitute an important part of the diet of developing countries and help to combat various global issues, predominantly malnutrition and food insecurity. Therefore, attention should be given on the studies related to insects as food or to encourage documentation of potential edible insects including their nutritional values and mode of consumption by indigenous groups of Northeast India.

**Keywords:** Edible, *entomophagy*, Northeast India, therapeutic insects

## INTRODUCTION

*Entomophagy* generally refers to the consumption of insects or bugs by human beings. The word *entomophagy* is derived from Greek words, *entomon* meaning “insects,” and *phagein* meaning “to eat”. Entomophagy is known to have played a vital role in providing human nutrition in different regions around the globe including Africa, Asia and Latin America and has a long-standing experience (Aletor, 1995). It is estimated that edible insects are part of the diet of atleast two billion people and more than 1900 insect species are currently used as food (Jongema, 2012). The United Nation’s Food and Agriculture Organization (FAO) in 2004 have reported numerous species of lepidopteran caterpillars as rich sources of potassium, calcium, magnesium, zinc, iron, and vitamins B (Fromme, 1995). Evidence on the emission of greenhouse gases and ammonia at lesser concentrations are also present when compared with livestock (Ooninx *et al.*, 2010).

Thus, insect rearing has been suggested as a promising alternative to the conventional production of livestock (Huis, 2013). The direct or indirect utilization of insects and their products is being known since time immemorial in the medical systems among different cultures throughout the globe (Costa-Neto, 2002) and have shown immunological, antibacterial, analgesic, diuretic, anesthetic and antirheumatic properties (Yamakawa 1998) which in turn have been proven useful in manufacturing modern drugs. Exploiting insects to manufacture folk medicine is a common practice in China and in the State of Bahia in Brazil (CostaNeto, 2002; Feng *et al.*, 2009) and other countries including Mexico, India, Africa and South Korea (Pemberton, 1999; CostaNeto, 2005; Dossey, 2010). A rough estimate shows about 300 species of insect are utilized to prepare 1700 traditional Chinese medicines whereas 42 species are utilized in preparing Bahian Folk Medicine (Costa-Neto, 2002; Feng *et al.*, 2009). Thus, insects can be considered as an inexhaustible source for pharmaceutical substances of the future (Ratcliffe, 2011).

The Northeast India is known as one of the mega-diversity hotspots as out of the nine vegetation types of India, it alone represents six types and covers various endemic as well as rare species of flora and fauna since time immemorial that still remains unexplored. Edible insects are a natural renewable resource that provides not only provides food but also economy to different indigenous ethnic communities in Northeast India. Besides farming, the various tribes make use of insects as their source of income generation. As far as Northeast India is concerned, the full potential of insects as food or raw material for medicines is still far from being appreciated. A perusal of the literature has revealed fragmentary information about edible insects in this region. Thus in this review the authors have tried to discuss the indigenous traditional knowledge related to the practice of consumption of different insect species as food by various ethnic groups of Northeast India along including their cultural values and their role in preparation of traditional medicines.

### Nutritional value of edible insects

The nutrient content of insects varies considerably between species. Depending upon the stages of the insect, their habitat and food habits, the nutritional values of edible insects may vary within the same group. Methods of preparation and processing including drying, boiling or frying that are undertaken before consumption may also influence nutritional composition of the edible insect. Insects have rich sources of proteins (20-70 %), amino acids (30-60 %), fats (10-50 %), fatty acids, carbohydrates (2-10 %), minerals (calcium, iron, zinc, phosphorous), vitamins (vitamin A, B complex and C) and other activated elements that helps in promoting the health of human beings (Chen *et al.*, 2009). Insect proteins are known to be highly digestible proteins that accounts between 77% and 98%. Insects can also be used as a source of fibre due to their high chitin content, accounting for about 10% of the whole dried insect. Insects also have high vitamin and mineral content. 100 grams of bugs would yield 55 grams of protein and 18 grams of fat. They also contain Omega 3 and 6 acids and have a healthy lipid profile. The nutritional compositions of major orders of edible insects (% dry weight) are mentioned in Table 1.

S. P. Nanda *et al.*

### Entomophagy in Northeast India

Entomophagy is a common practice among the ethnic communities of Northeast India, more particularly among the tribes of Arunachal Pradesh, Assam, Manipur and Nagaland. Some extent of entomophagy can also be observed among the tribes of Meghalaya and Mizoram. The edible insects in the order Coleoptera (34%) are preferred more followed by Orthoptera (24 %), Hemiptera (17 %), Hymenoptera (10 %), Odonata (8 %), Lepidoptera (4 %) and Isoptera (2 %) (Sangma *et al.*, 2016). In Arunachal Pradesh, a total of 158 species of edible insects has been enlisted (Singh *et al.*, 2007, Singh and Chakravorty, 2008, Chakravorty *et al.*, 2011 and Chakravorty *et al.*, 2013). Nyishi and Galo, two famous tribal communities are known to consume about 102 species of edible insects (Chakravorty *et al.*, 2013). The highest number of insects under the order Orthoptera is preferred by the tribes of Arunachal Pradesh as compared to other tribes of India (Singh and Chakravorty, 2008). 51 insect species are being recorded and documented as edible and consumed as delicacy by six tribes namely Nocte, Wangcho (Wancho), Singpho, Tangsa, Deori and Chakma of Eastern Arunachal Pradesh (Meyer-Rochow and Chakravorty, 2013).

In Manipur, altogether 41 edible insect species have been recorded under 8 orders, 24 families and 36 genera. The highest number of edible insect species (10) has been recorded in the order Hemiptera whereas the lowest number has been recorded in the orders Dictyoptera and Isoptera. The highest number of species (28-30) is known to have been consumed by Meitei, Taro, Tangkhul, Chothe and Thadou tribes as compared to the other ethnic groups in Manipur (Shantibala *et al.*, 2012). Studies revealed that the ethnic groups of Manipur preferred to consume edible insects belonging to the order Hemiptera and lepidopteran insects are not preferred by the Meitei community. People inhabiting the hilly regions in Manipur usually consider the preparation of curry with bees as the most delicious food item among their delicacies. They also prefer aquatic beetles (Prasad, 2007). In Nagaland, two researchers Meyer-Rochow and Changkija identified and provided vernacular names to 42 species of insects used for eating by AoNagas in 1997. They have documented 11 species under the order Orthoptera, 9 species each under Coleoptera and Lepidoptera, 8 species under Hemiptera with species distributed under the remaining orders with Mantodea and Odonata as leading orders.

An early record of an edible insect species of pentatomid bug (*Ochrophora montana*) as a delicacy among the people of Mizo hills was mentioned by Sachan *et al.* in 1987 and termites serving as sources of proteins and carbohydrates was mentioned by Paul and Dey in 2011. Over 60 species of edible insects was enlisted by Meyer-Rochow in 2005 that were popular among the Meitei and Khasi tribes of Manipur and Meghalaya respectively. Entomophagy among the people of Mishing tribes of Dhemaji district of Assam was investigated by Doley and Kalita in 2011. The researchers recorded a total of 15 edible insect species under 15 genera and 12 families. Order Hymenoptera (4 species) was preferred mostly followed by Lepidoptera (3 species), Orthoptera (3 species), Hemiptera (2 species), Coleoptera (2 species) and Isoptera (1 species) respectively. The giant water bugs (*Lethocercus indicus*), eri silkworm (*Samia ricini*), muga silkworm (*Antheraea assama*) and house cricket (*Acheta domesticus*) were recorded to be the most liked edible insects among them. The green weaver ant (*Oecophylla smaragdina*) is a famous edible insect species that is consumed by the Mishing tribe and the Ahom Community of Assam in the month of April during the Assamese Bohag Bihu festival (Chakravorty *et al.*, 2011). A total of 16 terrestrial edible insect species under 6 orders *viz.*, Lepidoptera (3 species), Isoptera (1 species), Blattodea (1 species) and Hemiptera (1 species) was documented by Dutta *et al.*, in 2016 from Dhemaji district of Assam.

The locals usually prefer to consume edible insect species namely cicada (*Pomponia* sp.), short horned grasshopper (*Eupreponotus* sp. and *Choroedocus* sp.), long horned grasshopper (*Mecopoda elongate elongate*), adult cricket (*Tarbinskiellus* sp.) and the mole cricket (*Grylotalpa* sp) for their delicacy. Consumption of termites (*Odontotermes* sp.) in alate stage is also preferred by them due to their high nutritive values and anti-microbial properties (Lamberty *et al.*, 2001). The practice of entomophagy is also seen among the Tiwa community of Assam. They prefer to eat 15 species of edible insects under 6 orders namely Hemiptera (3 species), Coleoptera (2 species), Orthoptera (4 species), Hymenoptera (3 species), Odonata, Lepidoptera and Isoptera (1 species each) and 14 families (Rahman *et al.*, 2018). Among the species, the highest amount of protein was recorded in giant water bug (19.8%), highest amount of

S. P. Nanda *et al.*

carbohydrate content was recorded in cricket (5.1%) and highest amount of lipid content was observed in giant water bug (8.3%) (Rahman *et al.*, 2018). 32 species of edible insects are known to be consumed by the ethnic tribes – the Karbis and the Rengma Nagas based on their seasonal availability (Ronghang and Ahmed, 2010). A total of 23 species of edible insects belonging to orders *viz.*, Hemiptera, Coleoptera, Hymenoptera, Orthoptera, Lepidoptera, Isoptera and Odonata was considered as edible among the people of Bodo tribe (Hazarika and Goyari, 2017). The larvae of *Oecophylla Smaragdina* are being eaten during the time of their famous festival Bwisagw.

### Therapeutic values of insect

The exploration and utilization of insect species for treatment of different diseases have been regarded as a secret that is passed on only to family members from generation to generation among the tribes of Northeast. In recent years, a wide array of studies has attracted the attention of people towards the therapeutic values of various insect species along with their products (Antonio, 1994; Oudhia, 2002; Padamanbhan and Sujana, 2008). The tribes Galo and Nyishi of Arunachal Pradesh, utilizes several insect species that are deemed medically important in home remedies for different ailments (Chakravorty *et al.*, 2011). The Garo tribe also utilizes insects with therapeutic values (Ghosh and Deka, 2015). The mole cricket, *Gryllotalpa africana* has been used as a therapeutic food for healing certain childhood diseases and the orb-weavers, *Nephila* is exploited in preparation of folk medicines. Crushing and mixing of the hind legs of grasshoppers with water is practiced as a treatment of kidney diseases and also said to have refreshing properties and reduces swelling (De asis, 1982).

As a treatment of violent headaches, the dry grasshoppers are crushed by the healer and mix with the ashes of the grasshopper with a little organic salt and makes incisions on the nape and front of the patient thereby applying the solution to the incisions (Antonio, 1994). The formic acid of the green weaver ant (*Oecophylla smaragdina*) has been utilized for treating scabies, malaria, toothaches, stomach disorders, blood pressure anomalies, nose infection, sinus and throat infections (Chakravorty *et al.*, 2011). The insect is simply dried under the sun, ground and mixed with mustard seeds before inhalation. In preparing traditional medicines, termites are the most commonly used insects (Alves *et al.*, 2011; Solavan *et al.*, 2006; Coutinho *et al.*, 2009; Lima *et al.*, 2010). e.g., for treating diseases like asthma, whooping cough, bronchitis, influenza, flu a species of termite namely *Microcerotermes exiguous* is used (Alves *et al.*, 2009 and 2011). Another species of termite *Nasutitermes macrocephalus*, is commonly used to treat diseases like asthma, bronchitis, 'catarrh in the chest' coughs, influenza, sore throat, sinusitis and tonsillitis (Lima *et al.*, 2010; Alves *et al.*, 2008). Treatment of constant itching and soreness of the throat, is also done by using pupae and larvae of mulberry silkworm (*Bombyx mori*) and muga silkworm (*Antherea assama*) (Dutta *et al.*, 2016). For detoxification and treating the bacterial infections that causes sore eyes, swollen throat and loss of speech, silkworm are being prescribed in Chinese medicine (Ratcliffe *et al.* 2011).

Infection of mouth and tongue in small children, also known as "dudmur", can be treated by using larvae and pupae of eri silkworm (*Samia cynthia ricini*) in Assam (Dutta *et al.*, 2016). The silkworm pupae are also known to increase the immunity; protects the liver and prevent cancer in human (Chowdhury *et al.*, 2015). A prominent ethnic community of Meghalaya and Assam, the Garo tribe utilizes honey as a remedy against dudmur" disease (Ghosh and Deka, 2015). The treatment of stomach problems can be done with the help of larvae and eggs of yellow jacket wasp (*Vespa orientalis*, *Vespa magnifica*) and the "nest" of potter wasp (*Eumenus* sp.). The eggs and larvae of honey bee (*Apis* sp.) and its product honey can be utilized for curing whooping cough (Dutta *et al.*, 2016) as honey has healing properties (Ratcliffe *et al.* 2011). Cockroach (*Periplaneta americana*) has also been exploited for treating asthma in both children and adults (Dutta *et al.*, 2016). A list of insect species having both edible and therapeutic values is given below (Table 2).

## CONCLUSION

To meet the demands of the ever-increasing population with limited availability of agricultural land and resources, an urgent need has aroused to identify an alternate source of food for humans. The future estimates show the world population would soon reach 9 billion approximately which would result in additional demand and need for nutrition as well as health facilities as compared to the current needs. Thus, entomophagy can serve as an innovative alternate solution as edible insects can constitute a vital part of the diet of developing countries to combat issues like food insecurity and malnutrition and therapeutic insects can be further exploited in preparing medicinal products. The results of various studies revealed that there are differences in preferences in consuming edible insects among the different tribes and regions. Thus, to popularize and adopt entomophagy as well as therapeutic insects in a true sense, further studies should be carried out on key factors including ecology, management and conservation implications, industrialization and marketing of edible insects and therapeutic insects which will help in promoting the commercial development of these insects and widening of the market.

Hymenoptera	76.69	12.65	81.27	21.0	55.10	7.99	7.15	1.95

Table 2. List of insect species having nutritional and therapeutic values in North east India

Order	Family	Common name	Scientific name	Disease/ailment for which insect is used/food value
Lepidoptera	Bombycidae	Mulberry silkworm	<i>Bombyx mori</i>	Constant itching & soreness of throat
	Saturniidae	Muga Silkworm	<i>Antherea assamensis</i>	Constant itching and soreness of throat
	Saturniidae	Eri silkworm	<i>Samia cynthia ricini</i>	Infection of tongue & mouth
	Crambidae	Bamboo worm	<i>Omphisa fuscidentalis</i>	Food value
	Erebidae	Bihar hairy caterpillars	<i>Spliosoma obliqua</i>	Food value
	Lasiocampidae	Tent caterpillars	<i>Malacosoma sp.</i>	Food value
Orthoptera	Acridoidea	Short horned Grasshopper	<i>Eupreponotus sp.</i>	Food value
	Acrididae	Short horned Grasshopper	<i>Choroedocus sp.</i>	Food value
	Acrididae	Rice grasshopper	<i>Oxya hyla hyla</i>	Food value
	Tettigoniidae	Long horned Grasshopper	<i>Mecopoda elongate</i>	Food value
	Tettigoniidae	Grasshopper	<i>Acrida gigantea</i>	Food value
	Gryllidae	Cricket	<i>Tarbinskiellus sp.</i>	Food value
	Gryllidae	Field cricket	<i>Acheta bimaculatus</i>	Food value
	Gryllidae	Common cricket	<i>Brachytrupes achatinus</i>	Food value
	Gryllidae	Spotted cricket	<i>Liogryllus bimaculatus</i>	Food value
	Gryllidae	Blackhead caicket	<i>Grylloides melanocephalus</i>	Food value
	Gryllotalpidae	Mole cricket	<i>Gryllotalpa sp.</i>	Food value
Dictyoptera	Mantidae	Praying mantis	<i>Mantis religiosa</i>	Food value
	Mantidae	Praying mantis	<i>Heirodula sp.</i>	Food value
Hymenoptera	Formicidae	Weaver ant	<i>Oecophylla smaragdina</i>	Nose infection, sinus & throat infection
	Formicidae	Red ant	<i>Crematogaster dohni</i>	Food value
	Formicidae	Ant	<i>Formica indica</i>	Food value
	Vespidae	Giant hornet	<i>Vespa orientalis</i>	Stomach problems
	Vespidae	Wasp	<i>Vespa magnifica</i>	Food value
	Vespidae	Potter wasp	<i>Eumenes sp.</i>	Stomach problems
	Apidae	Honey bee	<i>Apis cerana</i>	Whooping cough
	Apidae	Giant honey bee	<i>Apis dorsata</i>	Whooping cough
	Vespidae	Paper wasp	<i>Polistes sp.</i>	Food value
	Vespidae	Yellow jacket wasps	<i>Vespula vulgari</i>	Food value
	Vespidae	Common wasp	<i>Eucaria artifix</i>	Food value
	Apidae	Stingless bee	<i>Tetragonula sp.</i>	Cough, Acne

S. P. Nanda et al.

Coleoptera	Scarabaeidae	White grub	<i>Lepidiota mansueta</i>	Food value
	Cerambycidae	Cashew stem girgler	<i>Analeptes trifasciata</i>	Food value
	Hydrophilidae	True water beetle	<i>Hydrous olivaceus</i>	Food value
	Hydrophilidae	Water scavenger beetles	<i>Hydrous indicus</i>	Food value
	Curculionidae	Bamboo beetle	<i>Cyrtotrachelus dux</i>	Food value
	Scarabaeidae	Rhino beetle	<i>Oryctes rhinoceros</i>	Food value
	Cerambycidae	Long horned beetle	<i>Anoplophora glabripennis</i>	Food value
	Cerambycidae	Pink woodborer	<i>Xystrocera globosa</i>	Food value
	Cerambycidae	Wood borer	<i>Neocerambyx paris</i>	Food value
	Cerambycidae	Wood borer	<i>Coelosterna scabrata</i>	Food value
	Curculionidae	Palm weevil	<i>Rhynchophorus signaticollis</i>	Food value
	Dytiscidae	Diving beetle	<i>Dytiscus Marginalis</i>	Food value
Isoptera	Termitidae	Termite	<i>Odontotermes sp.</i>	Food value
	Termitidae	Termite	<i>Macrotermes natalensis</i>	Food value
Blattodea	Blattidae	Cockroach	<i>Periplaneta americana</i>	Asthma
Hemiptera	Cicadidae	Cicada	<i>Pomponia sp.</i>	Food value
	Cicadidae	Cicada	<i>Cicada verides</i>	Food value
	Belostomatidae	Giant water bug	<i>Lethocerus indicus</i>	Food value
	Belostomatidae	Water bug	<i>Diplonychus rusticus</i>	Food value
	Nepidae	Water scorpion	<i>Laccotrephes maculatus</i>	Food value
	Nepidae	Water scorpion bug	<i>Ranatra sp.</i>	Food value
	Pentatomidae	Stink bug	<i>Udonga montana</i>	Food value
	Corixidae	Water boatmen	<i>Micronecta sp.</i>	Food value
	Notonectidae	Backswimmer	<i>Notonecta sp.</i>	Food value
	Hydrometridae	Water measurer	<i>Hydrometra greeni</i>	Food value
	Pentatomidae	Painted bug	<i>Bagrada picta</i>	Food value
	Pentatomoidea	Bamboo bug	<i>Dolycoris indicus</i>	Food value
	Largidae	Giant red bug	<i>Lohita grandis</i>	Food value
Gerridae	Water slider	<i>Gerris spinolae</i>	Food value	
Odonata	Libellulidae	Scarlet skimmer	<i>Crocothemis servilia</i>	Food value
	Libellulidae	Wandering glider	<i>Pantala flavescens</i>	Food value
	Libellulidae	Asian pintail,	<i>Acisoma panorpoides</i>	Food value
	Aeshnidae	Mosaic darners	<i>Aeschna sp.</i>	Food value
	Libellulidae	Dragon fly	<i>Crocothemis servilia</i>	Food value
	Libellulidae	Blue-tailed forest hawk	<i>Orthetrum triangulare</i>	Food value
	Libellulidae	Common picture wing	<i>Rhyothemis variegata</i>	Food value
	Libellulidae	Chalky percher	<i>Diplacodes trivialis</i>	Food value

### ABSTRACT

A fish breeder faces the challenge of how to more effectively and efficiently perform selection and accelerate the breeding progress to satisfy the requirements of changing markets for fish cultivars. Molecular marker-assisted breeding (MAB), the application of molecular biotechnologies (DNA markers) to practical breeding and selection, is a novel strategy and a powerful methodology for fish performance improvement. However, improvement of performance traits through traditional phenotype-based selection needs several generations to optimise these performance characters. Other problems associated with the traditional breeding programme is the maintenance of each generation and complexity of the measure qualitative trait such as meat quality. Marker-Assisted Selection (MAS) can be the best alternative to solve these problems. Marker-Assisted Selection (MAS) is a type of indirect method of selection of better performing breeding individuals. MAS depends on identifying the link between a genetic marker and Quantitative traits loci (QTL). After identifying the markers linked to QTL, they can be used in the selective breeding programme to select the brooders having better genetic potential for the targeted trait. Improvement of performance traits through MAS is fast and more accurate and allows us to understand the genetic mechanism affecting performance traits.

**Keywords:** Quantitative traits loci, Marker-assisted selection, Selective breeding, Genetic improvement

### INTRODUCTION

Molecular markers have been extensively used for identification of strains and species, detection of inter and intra-specific hybridization, parentage and kinship analysis, estimation of effective population size and level of inbreeding, assessment of parental contribution in mass spawning, preventing inbreeding, mapping of quantitative trait loci (QTLs) and selective breeding. Marker-Assisted Selection (MAS) is a kind of indirect way of selection of well

24265

### Chandan Haldar and Suchismita Nath

performing breeding individuals (Liu et al., 2004). MAS depends on identifying the link between a genetic marker and Quantitative traits loci (QTL). The important economic traits like resistance to diseases, body growth, meat quality, etc. highly affect the profitability of the fishes. The main aim of every selective breeding programme is to produce improved offspring for these traits. However, enhancement of performance traits through phenotype-based selection requires numerous generations to optimise these traits. Another limitation associated with the traditional breeding programme is the looking after of each generation of fishes and complexity in the measure qualitative trait such as fish meat quality. Marker-Assisted Selection (MAS) can be used as the best alternative to solve these problems.

The main restrictive factor for the realization of genotype based selection potentials in fishes is the unavailability of a molecular marker for fishes. However, the marker discovery becomes very easy through the next generation sequencing methods like Illumina, Ion torrent, and 454 GS FLX platforms. So, the researchers are now capable of identifying a large number of molecular markers in the genome of any fish species (Al et al., 2015). Thus MAS finally become a reality by using the markers to detect linkage with the traits of interest. In aquaculture, genetic mapping has been done for tiger shrimp, rainbow trout, atlantic salmon, kuruma prawn, catfishes and tilapia. Now genetic map needs to be for the other commercially important fish to overall increase aquaculture in developing country like india. Recently MAS become the very popular method of indirect selection for production of the genetically improved offspring in aquaculture selective breeding programme. As most of the performance traits are controlled by multiple genes and therefore inherited as quantitative traits, and analysis of their associated quantitative trait loci (QTL) is a crucial part of aquaculture genomics. QTLs are largely unknown genes that affect performance traits (growth or disease resistance) of the fishes.

#### The significance of MAS in selective breeding programme

The rate of the genetic gain through MAS can increase when there is a continuous identification of new QTL for the targeted traits. The extra genetic gain through the MAS may decrease very quickly in successive generation of selection for the same QTL and also the rate of identification of new QTL is hard to predict. The information developed from the detected QTL in the selection needs developing some selection criteria to connect this molecular information with phenotypic variation (Sakamoto et al., 2000). MAS can be powerfully used to detect the major QTLs for a trait and for a phenotypic which is costly to measure. Till date, QTL for traits such as growth and disease resistance, cold and salinity, sex determination have been mapped in fishes. Such studies can provide essential information about outlines and the rate of evolutionary changes besides may use as tools for marker assisted selection in selective breeding. Mapping genes and QTLs is of fundamental and applied concern in aquaculture species. The purpose of QTL mapping is to assist in selective breeding by understanding the effect and quantity of genes determining a trait. QTL analysis for important traits like thermal tolerance, spawning time, embryonic development, growth traits, stress, salinity tolerance, infectious hematopoietic necrosis and bacterial cold-water disease have been conducted for more than 20 aquaculture species including finfish, mussels and crustaceans (Haldar et al., 2018b). Table 1. Shows the number of studies has been conducted on marker assisted selection in fishes.

#### Advantages and limitations of marker-assisted selection in fish breeding

Over conventional selection methods, MAS is profitable for the aquaculturist for a low heritability trait like growth in fish. It assists to detect the existing genetic variation in brooder stock and can be used to improve desirable traits in target fish species. Improvement of performance traits through traditional selection integrated with molecular tools is more accurate, fast and allows us to recognize the genetic mechanism controlling performance traits. The main constraint in MAS is the lack of complete genotype information of the fishes and increasing sample collection cost for genotyping. There is very limited study has been directed on MAS in fisheries in India (Haldar et al., 2018a). Genotyping the whole population is also tough in commercial fish populations. But the dramatic development of molecular genetics, has introduced a new generation of molecular markers like microsatellite and single nucleotide polymorphisms (SNPs) for use in the genetic improvement of farm animals.

**Chandan Haldar and Suchismita Nath**

These markers provide more accurate genetic information and a better understanding of the animal genetic resources. Traits that are expressed late in life, expensive or difficult to measure (disease resistance), is very tough to optimize using traditional breeding programme. Selection programme requires numerous progenies to optimise traits and the progeny testing scheme in some case needs a long generation interval and also very expensive (Haldar et al., 2018b). MAS is a very useful tool to select those traits which are restricted to only one sex and to reduce generation interval through early selection, even before maturity of the fish. To decrease genotyping costs, the researcher is now concerned on the identification of the most informative individuals based on phenotypic information, segregation analysis or combining the phenotypic and genotypic information in breeding (Groenen et al., 2000). The choice of the marker information is not totally reliable due to the possibilities of overestimation of QTL effects in QTL position in the fish population. The discrepancy is also a major problem in QTL detection in fish because the QTL effect is not expressed similarly over the years or when it is used in a different population or stock. The main targeted traits in aquaculture for MAS are body growth, disease resistance, meat quality, feed efficiency and maturation.

**CONCLUSION**

The use of genetic markers with the phenotypes in a process called marker-assisted selection. Combined with traditional selection techniques, MAS has become a valuable tool in selecting organisms for desirable traits. MAS is expected to increase genetic gain compared to traditional breeding programs and reduce the cost of progeny testing by early selection of the potential fishes. The application of MAS in breeding programmes depends on the knowledge of breeders about variable marker information from fish to fish and the different effects on multiple traits and his ability to spend in genotypic information that helps in improve their commercial breeding activities (Montaldo et al., 1998). MAS also provides an apparently possible approach to selection for higher growth and genetic disease resistance animals. In the future to make MAS significant in commercially important aquaculture breeding populations, the accessibility of large-scale genotyping approaches and infrastructure that allows the generation of hundreds of thousands of molecular data at a reasonable cost will be necessary.

### ABSTRACT

The content of bacterial cells (cytoplasm) is surrounded by a lipid bilayer, called the cell membrane that protects the cell from outside influences and makes it possible to carefully control the composition of the cytoplasm. In Gram-positive bacteria the cytoplasm is bordered by a single phospholipid bilayer, the cell membrane, and a peptidoglycan layer, the cell wall, which supports firmness of the cell. Gram-negative bacteria possess an additional outer membrane creating a periplasmic space. The outer membrane of Gram-negatives is permeable, allowing small molecules to enter the periplasm. In contrast, the cytoplasmic membrane forms a selective barrier especially for bulky hydrophilic compounds that cannot easily pass the hydrophobic membrane. To get trace metals, nutrients into and breakdown products out of the cell, membrane embedded proteins, called transport proteins, mediate the translocation of trace metals, solutes across the cell membrane. Most transport proteins are very selective and only carry one or a few related compounds (metals, nutrients) from one side to the other. Not all metal or nutrient transport systems need to be present at the same time, since usually limited numbers of different essential metals are present in particular habitats or growth media.

**Keywords:** metals, nutrients, products, numbers, cytoplasm.

## INTRODUCTION

To prevent unnecessary consumption of energy and matter for the synthesis of (transport) proteins, bacteria have evolved mechanisms to sense the presence of substrates and to react on their availability. In this way, specific transport systems and associated catabolic enzymes are synthesized only when their substrates are present and other preferred carbon and energy sources are lacking. The synthesis of the transport systems and enzymes is regulated at the level of transcription of the coding genes and operons. In the presence of substrate the expression of the respective genes is activated by a mechanism called induction. When more than one substrate is present, bacteria decide which one to utilize first, primarily the one that provides the most energy for growth. Then, only the (transport) proteins required for metabolism of the preferred substrate are synthesized, while synthesis of the proteins required for metabolism of the less favored substrate is unwanted even though the inducer is present. Transport of molecules across the cell membrane is a fundamental process of all living organisms. It is essential for understanding growth, development, nutrition as well as uptake and excretion of exogenous or synthesized molecules. Microbes represent general and basic functional systems where many transport processes have been studied on a molecular basis. Knowledge of the microbial transport processes will provide new perspectives to treatments by inhibitors, drugs, antibiotics, vitamins, growth promotion compounds, activators and toxic compounds of various kinds.

Metal ions are essential for life, for instance as structural or catalytic co-factors in metalloproteins. For this reason bacteria make use of various transport systems for the uptake and subsequently, usage of metals from the environment. Besides uptake systems for free metal ions, bacteria also possess specific transport proteins that mediate the uptake of metals complexed to so-called chelating agents (Paulsen and Saier, 1997; Thomas *et al.*, 1998; Krom *et al.*, 2000). Most of the bacteria (*B. subtilis*) contain both types of transport systems to acquire essential elements, like calcium and magnesium (Silver *et al.*, 1975; Silver and Lusk, 1999; Krom *et al.*, 2000).

### Metal ions in biological systems

Metal ions are vital and essential life elements that play very critical role in numerous metabolic functions in every living cell. The interaction between metal ions and functional constituents of living cells is powerful and specific. Approximately one out of three proteins requires a metal ion cofactor for structure and/or function (Rosenzweig, 2002). These metal ions can transfer electron flow in a substrate or enzyme, thus effectively controlling an enzyme-catalyzed reaction. They can serve to bind and orient substrate with respect to functional groups in the active site. They also provide a site for redox activity if the metal has several valence states. In some cases metal ions are required for a reporter of structure and functional relation of metalloenzymes: they are like Zn in dehydrogenase (Braden *et al.*, 1975), and Co in alcohol Phosphoglucomutase, carboxypeptidase (Warren *et al.*, 2002). Metal ions are required for the formation of concentration gradients across the membrane required for the transport process, osmotic responses and structural integrity. They also function as essential cofactors in oxidative phosphorylation, gene regulation and free radical homeostasis. Metal ions are currently included in formulations used for applications such as diabetes, anti-inflammatory, rheumatoid arthritis, psychiatric and anti-ulcer medications using compounds of cadmium, vanadium, copper, zinc, gold, lithium, and bismuth, respectively.

Many of the metal ions, which are required relatively in larger quantities like Ca, Mg, Na and K are designated as essential or 'macro elements' whereas some are not required for growth such as Hg, Pb and Ag, are designated as non-essential or toxic metal ions due to their toxicity at very low concentrations. In between are the metals that are required only in minute quantities by microorganisms such as Co, Cu, Ni, Fe, Mn and Zn, which are designated as 'trace elements'. All metal ions whether essential or non-essential, exhibit toxicity above certain threshold concentrations. Hence their homeostasis is crucial for all living organisms.

**Shanti Kumari Lunavat et.al.**

Transition metals are essential for many metabolic processes. Aberrations in the cellular metal ion concentrations may lead to cell death and severe diseases. Excess metal ions can bind to proteins and nucleic acids and alter the activities of these biomolecules (McRee, 1998). In addition, high concentrations of redox-active metal ions can result in undesired Fenton chemistries, which produce reactive oxygen species that can damage biomolecules (Wink *et al.*, 1994). Conversely, lower than optimal levels of metal ions can result in metal ion deficient stress conditions which often results in low growth rates and possibly cell death. Consequently, intracellular metal ion concentrations must be maintained within a narrow range (Kaim and Schwederski, 1991) and all cells utilize a great deal of energy (ATP) maintaining optimal metal ion concentrations within the cell (Nelson, 1999). This process is called homeostasis, a term derived from the Greek *homoios* (same like, resembling) and *stasis* (to stand, posture).

Metal ion transporters play a major role in maintaining the necessary concentrations of the various metal ions in the different cellular compartments. The studies of yeast metal ion transporters helped to unravel the molecular mechanism of macrophage defense against bacterial infection and hereditary diseases. Most of the control of metal ion concentrations is accomplished by regulating metal ion flow across lipid membranes surrounding the cytoplasm or individual organelles. As the cell becomes deficient in certain metal ions, transporters (importers) can be activated at the transcriptional level to bring more ions across the inner-membrane and into the cell. Similarly, when intracellular metal ion concentrations are too high, metal sequestration proteins/molecules or efflux systems are expressed to maintain homeostasis.

**Metal Transport**

Metal ion uptake in microorganisms is often biphasic. The two distinct phases of metal uptake are: 1. Biosorption- a rapid phase of metal binding to surface cell wall fraction, which is energy-independent 2. Bioaccumulation- a slower phase of metal ion accumulation into the cell mediated by transport proteins of the membrane requiring inputs of energy. Biosorption mostly involves the functional groups present in the cell wall and a recent study from our laboratory has shown that toxic metal ions compete with  $\text{Ca}^{2+}/\text{Mg}^{2+}$  for binding groups. There appears to be unique pattern for binding of  $\text{Ca}^{2+}/\text{Mg}^{2+}$  that are not competed either by toxic metal ions or in between themselves (Sowjanya and Mohan, 2009).

The mechanism of binding of essential metal ions appears to be predominantly by complexation, while toxic metal ion binding appears to be primarily by electrostatic interactions with ensuing competition among themselves. Several metal-resistant strains of *N.crassa* and one cobalt- sensitive mutant characterized earlier showed both transport block and over accumulation patterns of metal uptake. Cobalt uptake was shown to be biphasic, energy-dependent and increased with temperature and decreased with increase in pH. Magnesium inhibited cobalt uptake but iron could not do so. However in a cobalt resistant strain, a passive mode of transport was shown (Venkateswerlu and Sastry, 1970, 1973). A cobalt-sensitive mutant (CSM) of *N. crassa* is 5-fold more sensitive to cobalt and 4-fold more sensitive to nickel compared to wild type *N.crassa*. The mechanism for increased sensitivity is shown to be due to an accumulation of cobalt in CSM that is five fold higher than that observed in the wild type (Rashmi *et al.*, 2004).

Nickel transport in wild type and three Ni-resistant mutants of *N.crassa* was studied (Maruthi Mohan and Sivarama Sastry, 1984). Two of the nickel- resistant mutants were shown to be hyperaccumulators, while a third mutant has a transport block in comparison to wild type *N.crassa*. The above mutants were also resistant to cobalt, with similar patterns of uptake (Maruthi Mohan and Sivarama Sastry, 1983). Cobalt and nickel transport was also studied in a wall-less mutant of *N.crassa* and a corresponding cobalt-resistant strain. Both of these mutants did not show biosorption due to absence of cell wall and the mechanism of resistance was shown to be similar to those described above for the normal wall containing *N.crassa* strains (Sri *et al.*, 2003; 2004).

### Classification of membrane transporters

The availability of a large number of membrane transporters from diverse organisms and also a better understanding of the fundamental mechanisms involved paved the way for a systematic classification system. The Transport Classification (TC) system represents a systematic approach to organize transport systems according to the mode of transport, energy-coupling mechanism, molecular phylogeny and substrate specificity (Saier *et al.*, 1999; Saier, 2000). Based on the above, a relational transporter database was designed for describing the cellular membrane transport proteins in organisms whose complete genome sequences are available. Till date there are a total of 394 organisms whose transporter protein complement is available in transport database.

Transport systems are classified on the basis of five criteria, and each of these criteria corresponds to one of the five numbers or letters within the TC # for a particular type of transporter. Thus TC # normally has five components as follows: V.W.X.Y.Z.V (number) corresponds to the transporter class (i.e., channel, carrier (porter), primary active transporter or group translocator); W (a letter) corresponds to the transporter subclass which in the case of primary active transporters refers to the energy source used to drive transport; X (a number) corresponds to the transporter family (sometimes actually a super family); Y (a number) corresponds to the subfamily, and Z corresponds to the substrate or range of substrates transported. Any two transport systems in the same subfamily of a transporter family that transport the same substrate(s) are given the same TC#, regardless of whether they are orthologues (arose in distinct organisms by speciation) or paralogues (arose within a single organism by gene duplication). The transporter classification system by Saier, demarcates 5 different classes of transporter genes based on the mode of transport and energy coupling mechanisms as shown below:

Primary active transporters (ATP-dependent): The transport process is coupled to a primary source of energy such as ATP hydrolysis, exothermic flow of electrons from reduced substrate to an oxidized substrate and utilization of light energy to drive transport of a solute. Ion channels: Channels are energy-independent transporters that exhibit higher rates of transport and lower stereo specificity. This class includes both channels and pores consisting of  $\alpha$ -type channels,  $\beta$ -barrel porins, pore-forming toxins and non-ribosomally synthesized channels. Secondary transporters: They utilize ion or solute electro-chemical gradient to drive the transport process across the cytoplasmic or internal membranes of the biological cells. According to Saier's classification there are 84 gene families for this transporter class (Sobczak and Lolkema, 2005). Amino acid residues that are rare in transmembrane helices (K, R, H, Q, D, E, N, F, W, and Y) help in the formation of channel in secondary transporters (Kalinina *et al.*, 2003). The first 3-dimensional crystal structure of a secondary transporter is reported in 2002 i.e., *Escherichia coli* AcrB transporter of RND family (Murakami *et al.*, 2002).

Unclassified: This class mainly includes transporters of unknown biochemical mechanism; putative but uncharacterized transport proteins and functionally characterized transport proteins with unidentified sequences. Group Translocators: They modify the substrates during transport. Transport systems of the bacterial phosphoenolpyruvate: sugar phosphotransferase systems are the major group translocators.

### Ni-Co homeostasis

#### Role of Ni-Co in biological systems

Ni is an essential component of several metalloenzymes involved in energy and nitrogen metabolism (Ragsdale, 2009). In prokaryotes, the major Ni-binding enzymes include urease, Ni-Fe hydrogenase, carbon monoxide dehydrogenase, acetyl-coenzyme A, decarbonylase/synthase, superoxide dismutase SodN, methyl-coenzyme M reductase and glyoxalase I. In eukaryotes, urease is the only characterized Ni-dependent enzyme (Baird and Garber, 1981). Additional candidate Ni-containing proteins or compounds have also been described in different organisms including humans (Denkhaus and Salnikow, 2002). Because natural environments contain only trace amounts of soluble Ni<sup>2+</sup>, attaining sufficiently high intracellular nickel concentrations to meet the demand of the nickel enzymes

**Shanti Kumari Lunavat et.al.**

requires a high affinity nickel uptake system(s) (Rodionov *et al.*, 2006), molecular and metallochaperones (Quiroz *et al.*, 2007) and sensors and regulators of the levels of enzymes involved in nickel homeostasis (Iwig *et al.*, 2006; Phillips *et al.*, 2008). Co is mainly found in the corrin ring of vitamin B12 (also known as cobalamin), a group of closely related polypyrrole compounds such as cyanocobalamin, methylcobalamin and deoxyadenosyl cobalamin (Michihiko and Sakayu, 1999; Warren *et al.*, 2002; Banerjee and Ragsdale, 2003). Vitamin B12 is a complex organometallic cofactor and is mainly present in three classes of enzymes in prokaryotes (classified based on different chemical features of the cofactor): adenosylcobalamin-dependent isomerase, methylcobalamin-dependent methyltransferase, and B12-dependent reductive dehalogenase. Besides, a few proteins containing non-corrin Co are present in methionine aminopeptidase and nitrile hydratase.

### Ni-Co transporters in living systems

The average concentration of Ni is as low as 2 ppb in sea water and 0.3 ppb in fresh water, corresponding to a molarity of approximately 30 nM and 5 nM, respectively. The most commonly occurring oxidation state of Ni is Ni (II) and thus Ni<sup>2+</sup> ion is the substrate for transport. Under artificial conditions, i.e. at concentrations that are much higher than in the natural environment, Ni<sup>2+</sup> can be taken up by microbial Mg<sup>2+</sup> transport systems (Smith and Maguire, 1995; Eitinger and Friedrich, 1997; Kehres *et al.*, 1998; Eitinger and Mandrand Berthelot, 2000). Since Mg<sup>2+</sup> is a competitive inhibitor of Ni<sup>2+</sup> transport by these systems and since the natural concentration of Mg<sup>2+</sup> is at least three orders of magnitude higher than that of Ni<sup>2+</sup>, Mg<sup>2+</sup> transport systems probably contribute little to Ni<sup>2+</sup> uptake under physiological conditions. It is intriguing how the living systems acquire nickel for their metabolic needs. Transport assays have identified Ni<sup>2+</sup> uptake in a variety of bacteria and archaea in the presence of several thousand-fold excess of Mg<sup>2+</sup> (Hausinger, 1993). These studies took advantage of the radioactive isotope <sup>63</sup>Ni, a low-energy (67 keV) β–emitter that decays with a radioactive half-life of 100 years to the stable isotope <sup>63</sup>Cu.

The characterization of Ni-deficient mutants of *E. coli* and *Ralstonia eutropha* (formerly *Alcaligenes eutrophus*) were milestones for the analysis of the underlying transport mechanisms (Eitinger and Friedrich, 1991). Complementation of the mutants and sequence analysis of the genes revealed that a transporter of the ATP-binding cassette family is responsible for Ni<sup>2+</sup> uptake in *E. coli*. An unrelated single-component permease that probably acts as a uniporter operates in *R. eutropha*. These two major types of bacterial high-affinity Ni<sup>2+</sup> transport systems are discussed in detail below.

### The nickel-specific ABC transporters

The discovery of a highly specific Ni transport system in *E. coli* originates from the characterization of a novel category of mutants isolated by *MudI* transposon mutagenesis that were totally impaired in hydrogenase activity (Wu and Mandrand-Berthelot, 1986). These mutants contain significantly reduced levels of H<sub>2</sub>-related activities, fermentative formate hydrogenlyase and respiratory fumarate-dependent H<sub>2</sub> uptake. Interestingly, addition of high concentrations (0.5 mM) of Ni salts leads to a complete recovery of hydrogenase activity and to the concomitant restoration of normal H<sub>2</sub> uptake activities. This strictly Ni-dependent restoration was taken as the first suggestion of a defect in Ni transport. Structure and mechanism of ABC transporters was reviewed earlier (Schmitt and Tampe, 2002).

Further investigation of the mutants was performed using both biochemical and genetic approaches. When grown in a nickel rich medium, the cellular Ni content of the Nik mutants was found to be abnormally low, less than 1% of that of the parental strain (Wu *et al.*, 1989). Therefore these mutants were unable to acquire sufficient Ni for hydrogenase biosynthesis during normal growth. However, gradually increasing external Ni concentration increases both cellular Ni content and hydrogenase activity to attain normal wild-type levels. Under these circumstances, Ni can be readily taken up by the low-affinity high-capacity magnesium transport system CorA (Smith *et al.*, 1998). This behavior was further substantiated by the fact that the *nik* hydrogenase phenotype can be fully suppressed by growth in media containing very low (0.01 mM) added magnesium, which would reduce Mg competition for Ni entry by the Mg uptake system (Wu *et al.*, 1989). Finally, a direct demonstration for a defect in Ni uptake came from examination of the ability of the Nik mutants to take up <sup>63</sup>Ni<sup>2+</sup> (Navarro *et al.*, 1993).

### The NiCoT family

The first structural gene for a Ni<sup>2+</sup>-specific permease was identified by sequencing a fragment of *R. eutropha* DNA that restores Ni deficiency of an *R. eutropha* mutant (reviewed by Eitinger and Friedrich, 1997). This strain was unable to grow on hydrogen as the energy source, and produces only low activity of urease under standard conditions. The deduced amino acid sequence revealed an integral membrane protein (HoxN) that did not show any similarities to available database entries. Transport assays indicated that HoxN has an extremely high affinity for Ni<sup>2+</sup> ion, but a very low capacity. The K<sub>t</sub> value for Ni<sup>2+</sup> was estimated to 20 nM and the maximal velocity was 1.5 pmol Ni<sup>2+</sup> × min<sup>-1</sup> × (mg total cell protein)<sup>-1</sup>. These values represent, however, a rough estimation rather than an exact determination, because it is very difficult to distinguish transport from binding to the cell envelope at very low substrate concentrations. Expression of *hoxN* in *E. coli* allowed the reproducible measurement of HoxN activity using a physiological assay system (Wolfram *et al.*, 1995). Accumulation experiments with recombinant *E. coli* growing in the presence of <sup>63</sup>Ni<sup>2+</sup> indicated that HoxN concentrates its substrate only tenfold (Wolfram *et al.*, 1995; Degen *et al.*, 1999). This result suggested a very slow uniport mechanism. The membrane topology of HoxN was analyzed by fusing N-terminal segments to alkaline phosphatase and β-galactosidase, which serve as reporters for periplasmically and cytoplasmically located sites, respectively. These studies revealed that the N- and C-termini of the Ni permease are located in the cytoplasm and that the protein contains eight membrane-spanning segments (Eitinger and Friedrich, 1994; Eitinger *et al.*, 1997).

In addition to the common topology of HoxN-type Ni permeases, a few amino acid sequence motifs are conserved (Fig 1.1). Four of these motifs are located within transmembrane segments. Site-directed mutagenesis experiments were performed to obtain more detailed information on the significance of these residues for affinity and specificity of the permeases. In a study with HoxN of *R. eutropha* (Eitinger *et al.*, 1997; Olaf and Eitinger, 2002), replacements were introduced into the HX<sub>4</sub>DH motif, located in the unusually polar transmembrane segment II. This motif is fully conserved among the HoxN-type permeases, but is also present in the unrelated NikC, one of the two integral membrane proteins of the *E. coli* ABC-type Ni<sup>2+</sup> transporter. In the latter case, however, the signature is located in the first periplasmic loop connecting the putative transmembrane segments II and I. In summary, these results suggested that the conserved signature sequence in TMD II is a critical part of the selectivity filter of nickel/cobalt permeases (Degen and Eitinger, 2002).

A very important point in the analysis of membrane transporters is the question regarding how substrate specificity is mediated. Members of the HoxN-type permease differ in ion selectivity. HoxN, for instance, is highly specific for Ni<sup>2+</sup> and unable to transport Co<sup>2+</sup>. Ni<sup>2+</sup> uptake is not inhibited by a ten-fold excess of divalent Co, Mn, and Zn ions (Degen *et al.*, 1999). The NiCoT member of *Rhodococcus rhodocrus* (RrNhlF) is less selective and transports both Ni<sup>2+</sup> and Co<sup>2+</sup>. Ni<sup>2+</sup> uptake is strongly inhibited by ten-fold excess of Co<sup>2+</sup>, but not by Mn<sup>2+</sup> and Zn<sup>2+</sup> (Degen *et al.*, 1999). Ni<sup>2+</sup> transport by HpNixA of *Helicobacter pylori* is moderately sensitive to the presence Co<sup>2+</sup> (Fulkerson *et al.*, 1998, 2000). Compared with its bacterial relatives, Nic1p has a unique specificity (Eitinger *et al.*, 2000). Nic1p seems to be a third type of nickel permease, since Co<sup>2+</sup> was an inhibitor but, if at all, only a weak substrate for transport. Understanding the molecular basis of the differences in ion selectivity is a challenging problem.

Over the last two decades, sequences related to HoxN of gram-negative and gram-positive bacteria were reported. The list includes: *Bradyrhizobium japonicum* (BjHupN; Fu *et al.*, 1994), *Helicobacter pylori* (HpNixA; Mobley *et al.*, 1995), *Mycobacterium tuberculosis* (MtNicT; Cole *et al.*, 1998) and *Rhodococcus rhodochrous* (RrNhlF; Komeda *et al.*, 1997). The role of BjHupN, HpNixA, and RrNhlF has been experimentally investigated. In the absence of BjHupN, *B. japonicum* produces only low levels of hydrogenase activity under Ni limitation (Fu *et al.*, 1994). HpNixA plays a crucial role in *H. pylori*, a human pathogen that is dependent on a highly active urease for initial colonization of the gastric mucosa. At very low concentrations of noncomplexed Ni<sup>2+</sup>, reflecting the situation in human serum, HpNixA is essential for urease activity (Harry *et al.*, 1995). A K<sub>t</sub> value of 11 nM Ni<sup>2+</sup> was determined for this permease (Mobley *et al.*, 1995; Wolfram and Bauerfeind, 2002). RrNhlF was originally identified as a Co<sup>2+</sup> transporter in the actinomycete *R. rhodochrous* J1 (Komeda *et al.*, 1997). This organism produces two types of Co-containing nitrile hydratases, which are

### Shanti Kumari Lunavat *et al.*

used as industrial catalysts for the kiloton scale production of acrylamide and nicotinamide (Kobayashi and Shimizu, 1998). A reinvestigation of its substrate specificity demonstrated that RrNhlF is able to transport Ni<sup>2+</sup> with high affinity, although a slight preference for Co<sup>2+</sup> ion was observed (Degen *et al.*, 1999).

A Ni<sup>2+</sup> transport system was reported for the thermophilic *Bacillus sp. strain TB-90* (Maeda *et al.*, 1994). It is encoded by the two distal genes (*ureH*, *ureI*) of the urease operon. When the operon was expressed in *E. coli*, urease activity was strongly diminished in the absence of UreH or UreI. UreH shows approximately 15% amino acid sequence identity to members of the HoxN family, but contains most probably less than eight transmembrane segments. UreI consists of only 65 amino acid residues and has no counterparts in the databases. The *Methanococcus jannaschii* genome-sequencing project revealed an ORF (ID number MJ1092) that is related to the *Bacillus* UreH. Two similar sequences were also reported for the plant *Arabidopsis thaliana* (ID numbers AL022023 and AC005825). *M. jannaschii* requires Ni for methanogenesis, and *A. thaliana* for incorporation into urease. Nevertheless, the available data do not allow additional conclusions on the mechanism of Ni<sup>2+</sup> transport in these organisms.

The overall reaction catalyzed by the proteins of subclass 1 of the NiCoT family is:

The overall reaction catalyzed by proteins of subclass 2 of the NiCoT family is probably:

### Other transporters of Ni-Co

Microorganisms have developed a number of devices to maintain appropriate intracellular concentrations of transition metal ions. Fig 1.2 schematically illustrates uptake and export systems, which are involved in Ni homeostasis in different bacteria. At high extracellular concentrations, Ni<sup>2+</sup> enters the cells by Mg<sup>2+</sup> transport systems. Under physiological conditions, Ni<sup>2+</sup> uptake is mediated by the Nik system in *E. coli*, and by members of the HoxN family in many other organisms. Metal resistance determinants like the *Cnr* and *Czc* export systems of *Alcaligenes* and *Ralstonia* species (Silver and Phung, 1996) or the P-type ATPases of *H. pylori* (Melchers *et al.*, 1998) export either excess Ni<sup>2+</sup> or other transition metal cations.

Certain ABC systems, consisting of three (CbiMQO) or four (CbiMNQO) components and encoded within prokaryotic coenzyme B12 biosynthesis gene clusters are implicated in cobalt uptake (Roth *et al.*, 1993). Since cognate extracellular binding proteins, pre-requisites for substrate uptake by prokaryotic ABC permeases, have not been identified, the mechanism of cobalt uptake by CbiM (N) QO remains elusive. Homologs of CbiMQO were identified adjacent to urease genes in *Streptococcus salivarius* (Chen and Burne, 2003) and *Actinobacillus pleuropneumoniae* (Bosse *et al.*, 2001), and shown to be important for urease activity in cells grown under nickel limitation. These ABC systems are confined to the prokaryotes; no homologues are reported in eukaryotes. Distant homologues of the NiCoT family (subfamily 2) have differing predicted topologies: 4, 5, 6, 7 and 8 TMSs. One such homologue, RcnA (YohM) of *E. coli* (274 aa) has 6 putative TMSs in a 3+3 arrangement with a large hydrophilic loop between putative TMSs 3 and 4. This protein is believed to catalyze Ca<sup>2+</sup> and Ni<sup>2+</sup> efflux (Rodrigue *et al.*, 2005). A putative Mg<sup>2+</sup> transporter from *E. coli* was identified (Silver, 1969; Nelson and Kennedy, 1972) and its transport properties described. The locus was named CorA because the phenotype of the mutant is resistance to growth inhibition by Co<sup>2+</sup> (cobalt resistance). Overexpression of the *Saccharomyces cerevisiae* magnesium transport system conferred resistance to aluminum ion (MacDiarmid and Gardner, 1998). The CorA gene was cloned from *S. typhimurium* and the protein characterized

**Shanti Kumari Lunavat et.al.**

(Szegegy and Maguire, 1999). CorA was the first  $Mg^{2+}$  transport locus identified at the molecular level (Hmiel *et al.*, 1986). A novel family of magnesium transport genes in *Arabidopsis* was identified (Li *et al.*, 2001). The Mrs2p was identified as an essential component of the major electrophoretic  $Mg^{2+}$  influx system in mitochondria (Kolisek *et al.*, 2003). In keeping with the unique biological chemistry of the  $Mg^{2+}$  (Maguire and Cowan, 2002; Ronald and Michael, 1998), CorA has no homology to any other type of transporter or membrane protein. The crystal structure of CorA indicates a channel like structure (Lunin *et al.*, 2006). CorA mediates the influx of  $Mg^{2+}$ ,  $Co^{2+}$ , and  $Ni^{2+}$  (Snavey *et al.*, 1989). The uptake of  $Co^{2+}$  and  $Ni^{2+}$  by CorA is unlikely to be of great importance physiologically since the affinity of CorA for  $Ni^{2+}$  and  $Co^{2+}$  is within the toxic range for these bacteria. Nonetheless, since the requirement of a cell for  $Co^{2+}$  and  $Ni^{2+}$  is small, their "leakage" through CorA might provide some or all of the cell's requirements under many environmental situations.

**Metabolic role of cobalt**

Life is dependent on a number of chemical elements. Besides common elements, several trace elements are utilized, including certain metals and metalloids. Because these elements play important roles in cellular metabolism, efficient mechanisms of uptake, storage and utilization are required for many of them. Among biometals, cobalt (Co) is utilized at particularly low levels but play important roles in several biological systems. Cobalt in small amounts is essential to many living organisms, including humans. Having 0.13 to 0.30 mg/kg of cobalt in soils markedly improves the health of grazing animals. Biosynthesis of Ni and Co enzymes is dependent on high-affinity uptake of metal ions from natural environments. Co is mainly found in the corrin ring of vitamin B12 (also known as cobalamin), a group of closely related polypyrrole compounds such as cyanocobalamin, methylcobalamin and deoxyadenosyl cobalamin. Additionally, a few proteins containing non-corrin Co were reported, such as methionine aminopeptidase from *Salmonella typhimurium*, prolidase from *Pyrococcus furiosus* and nitrile hydratase from *Rhodococcus rhodochrous* (Kobayashi *et al.*, 1998). However, most of these proteins are not strictly Co-specific and may also use other metals (such as iron, zinc and manganese) in place of Co.

**Cobalt History**

Cobalt was known in ancient times through its compounds, which would color glass a rich blue. George Brandt (1694-1768) is credited with the discovery of cobalt (1730-1737). He was able to show that cobalt was the source of the blue color in glasses, which previously had been attributed to the bismuth found with cobalt. During the 19th century, cobalt blue was produced at the Norwegian Blaafarveværket (70-80 % of world production), led by the Prussian industrialist Benjamin Wegner. In 1938, John Livingood and Glenn Seaborg discovered cobalt-60. The word cobalt comes from the German kobalt or kobold, meaning evil spirit, the metal being so called by miners, because it was poisonous and troublesome (it polluted and degraded the other mined elements, like nickel). Some also think the name may derive from Greek kabalos, which means 'mine', and which may have common roots with kobold, goblin, and cobalt. Naturally occurring cobalt is composed of 1 stable isotope, 59-Co ( $^{59}Co$ ). 22 radioisotopes have been characterized with the most stable being  $^{60}Co$  with a half-life of 5.2714 years,  $^{57}Co$  with a half-life of 271.79 days, and  $^{56}Co$  ( $^{56}Co$ ) with a half-life of 77.27 days, and  $^{58}Co$  ( $^{58}Co$ ) with a half life of 70.86 days.

**Chemistry of cobalt**

Cobalt is a chemical element in the periodic table that has the symbol Co and atomic number 27. Cobalt is a brittle, hard, transition metal with magnetic properties similar to those of iron. Cobalt is present in meteorites. Ore deposits are found in Zaire, Morocco and Canada. Cobalt-60 ( $^{60}Co$ ) is an artificially produced isotope used as a source of  $\gamma$  rays (high energy radiation). Many ores contain cobalt but not many are of economic importance. These include the sulphides and arsenides linnæite,  $Co_3S_4$ , cobaltite,  $CoAsS$ , and smaltite,  $CoAs_2$ . Industrially, however, it is normally produced as a byproduct from the production of copper, nickel, and lead. Normally the ore is "roasted" to form a mixture of metals and metal oxides. Treatment with sulphuric acid leaves metallic copper as a residue and dissolves out iron, cobalt, and nickel as the sulphates. Iron is obtained by precipitation with lime (CaO) while cobalt is produced as the hydroxide by precipitation with sodium hypochlorite (NaOCl)

**Shanti Kumari Lunavat et.al.**

The trihydroxide  $\text{Co}(\text{OH})_3$  is heated to form the oxide and then reduced with carbon (as charcoal) to form cobalt metal.

### Bioremediation of trace cobalt from radioactive waste of nuclear power reactors simulated effluents

The release of radionuclides into the environment is a subject of global health concern. Significant quantities of radionuclides were released during nuclear weapons testing in the 1960's and from Chernobyl plant in 1986. Globally, about 440 nuclear power reactors (NPRs) of a total generating capacity 360,000 MWe are in operation. In India, 15 units of NPRs are working with a total installed capacity of about 3500 MWe. These are mainly pressurized heavy water reactors (PHWRs) apart from two boiling water reactors. The construction of two units of 1000MWe (which are pressurized light water reactors) is in progress in addition to the construction of four 700 MWe PHWRs and three more 220MWe PHWRs. Nuclear Power Reactors (NPRs) namely the boiling water reactors (BWR's), the pressurized light water reactors (VVERs) and the pressurized heavy water reactors(PHWR's) though generate radionuclides as a part of the fission energy production, yet these fission products are well contained within the fuel elements themselves.

The radioactive waste streams arising at different stages of nuclear fuel cycle vary in the type and content of radioactivity. While the high level radioactive waste generated in the reprocessing plants is vitrified and contained, the intermediate level radioactive waste arising out of operating nuclear power plants, the mining and fuel element preparation activities are processed and the effluents are discharged after suitable dilution so as to conform to technical specifications. Chemical approaches are available for metal remediation, but these lack the specificity required for treating target metals against a background of competing ions. Biological approaches offer the potential for the highly selective removal of toxic metals coupled with considerable operational flexibility: they can be used both *in situ* and *ex situ* in a range of bioreactor configurations. Advances in understanding the roles of microorganisms in such processes, together with the ability to fine-tune their activities using the tools of molecular biology, has led to the development of novel or improved metal bioremediation processes. The aim of this study is to highlight the key steps in the nuclear fuel cycle where biological treatment strategies may augment existing chemical processes. The mechanisms of microbial interactions with key radionuclides in the wastes are discussed alongside the possible antagonistic effects of other organic and inorganic species present in effluents.

### Sources of radioactive waste generation

Radioactive waste generated is separated into three categories depending on its level of radioactivity and the length of time it remains hazardous such as low-level waste (LLW) which consists of processed radioactive waste from the operating nuclear power plants as well as from decommissioning operations exhibiting relatively short-lived radioactivity, Intermediate-level waste (ILW) contains the short-lived and long-lived radionuclides residing in spent ion-exchange resins used in the coolant purification processes (clean-up system) and high-level waste (HLW) consists mainly of highly radioactive and long-lived remnants of the fission process of nuclear fuel cycle.

### Nuclear fuel cycle

The nuclear fuel cycle is a chain of processes, beginning with the mining of uranium, manufacturing and managing nuclear fuel prior to and after its use in reactor (Fig 1.3). Natural uranium contains only small amounts (0.72%) of fissile  $^{235}\text{U}$  and requires enrichment to 3%  $^{235}\text{U}$  in power generation. The aim of reprocessing is to recover, for reuse, the uranium and plutonium which are to be separated from other activation and fission products. All steps in the

**Shanti Kumari Lunavat et.al.**

cycle, from mining, fuel enrichment, reprocessing and reactor decontamination, generate waste contaminated with radionuclides (U, Th, Pu (the actinides), Po, Ra (arising from actinide decay), Ba, La, Ce, Ru, Rh, Mo, Tc, Cs, Xe, Kr, I etc (representative fission products) and certain isotopes of Co, Mn, Cr, Fe and Ni (activated corrosion products). These wastes are different at each stage and dictate the approach to be adopted by chemical or biological treatment.

### Mining and milling

The extraction of uranium ore from the earth is conducted by injecting the solvent (water) underground. Milling is the process through which mined uranium ore is physically reduced to a suitable size. Mining wastes contain high concentrations of Uranium, sulfate and lower concentrations of other metals such as molybdenum and selenium. Here contamination of personnel is a problem rather than personnel exposures due to any gamma radiation. Mill tailings contain the daughter elements of  $^{235}\text{U}$  and  $^{238}\text{U}$  and also Th and Ra as well as Po and Pb. Ra is precipitated with  $\text{BaSO}_4$  by the addition of  $\text{BaCl}_2$  and the complex formed  $(\text{Ba,Ra})\text{SO}_4$  is utilized by sulfate-reducing bacteria, releasing  $\text{H}_2\text{S}$ ,  $\text{Ba}^{2+}$  and  $\text{Ra}^{2+}$  (McCready and Krouse, 1980). *Shewanella putrefaciens* (dissimilatory iron-reducing bacteria) also release dissolved  $^{226}\text{Ra}$  from the tailings and is further precipitated using  $\text{Fe}(\text{OH})_3$  (Landa *et al.*, 1991).

### Reprocessing

Reprocessing is the operation by which the unused energy content of spent fuel is recovered and the highly radioactive (hundreds of giga becquerels) long lived fission products are separated, vitrified and contained. Fission reactions results in the production of medium-weight elements including radioiodine, noble gases, and rare earth elements. Neutron capture results in the formation of transuranic elements and their decay products, including various isotopes of plutonium, americium, and neptunium. These products together with the residual uranium dominate the fuel reprocessing waste.

### Decontamination

Decontamination involves the chemical dissolution of oxides formed (during regular operation) on the surfaces of structural materials of the primary coolant system of nuclear power plants (NPPs). Stainless steel, carbon steel, Higher Nickel Alloys in addition to Zircalloys from the main structural materials nuclear power reactors (Fig 1.3). Many of these reactor systems especially those designed and constructed in sixties to eighties employ stellite, a high cobalt (48%w/w) containing alloy especially in areas which experience a high torque such as valve seats, rolling pins etc. During reactor operation, due to the interaction of these materials with high temperature (573K) aqueous coolant, oxide films containing Fe, Ni and Cr in different proportions develop on their surfaces. These oxide films are typically of 2-5  $\mu\text{m}$  thickness on stainless steel surfaces and much higher (40- $\mu\text{m}$ ) on carbon steel surfaces after about 10 years of operation.

The corrosion products released to the coolant get transported through the core, get neutron activated thereby generating activated corrosion products (ACPs) containing radionuclides such as  $^{60}\text{Co}$ ,  $^{58}\text{Co}$ ,  $^{54}\text{Mn}$ ,  $^{51}\text{Cr}$  etc. Ions like  $\text{Co}^{2+}$ ,  $\text{Mn}^{2+}$  and  $\text{Ni}^{2+}$  can exchange with the  $\text{Fe}^{2+}$  ions of the magnetite type of oxide lattice while  $\text{Cr}^{3+}$  ions can exchange with the  $\text{Fe}^{3+}$  ions of the oxide lattice. Thus when the radioactive atoms occupy the lattice positions in the oxide lattice, then there is a buildup of radioactivity which results in the generation of radiation field on the surfaces of the primary system circuit materials of the reactor. The dilute chemical decontamination process referred to as CANDECON, CANDEREM, and CORD (Chemical Oxidation Reduction Decontamination) employ several organic complexing acids like citric acid (Joseph *et al.*, 1996; 1997), ethylene diamine tetra acetic acid (EDTA), oxalic acid) to chemically dissolve oxide films. For nuclear decontamination operations, the order of preference of the major chelating agents is  $\text{EDTA} > \text{NTA} > \text{Citrate}$ , in terms of the relative strengths of their metal complexes and the degree of cleanup that can be achieved. Power-generating nuclear reactors such as boiling water reactors, pressurized light water reactors, and pressurized heavy water reactors require chemical decontamination over a period of operation (Ayres, 1970; Taylor, 1976; Cohen, 1980; Lejon *et al.*, 1994).

**Shanti Kumari Lunavat et al.**

A major source of radiation field arises from the presence of activated corrosion product nuclides such as  $^{51}\text{Cr}$ ,  $^{59}\text{Fe}$ ,  $^{58}\text{Co}$ , and  $^{60}\text{Co}$  on the oxide-filmed inner surfaces of pipes and valves of equipment.  $^{60}\text{Co}$  has proven to be a major contributor for person-sievert budgetary because of its long half-life 5.27 years and its high  $\gamma$ -energies (1.17 and 1.33 MeV), though the equivalent chemical concentration of total cobalt ( $^{59}\text{Co} + ^{60}\text{Co}$ ) relative to that of Fe, Ni, and Cr when the oxide film is dissolved in a chemical formulation is very low (a few nanomolar; Charlesworth, 1971). A dilute chemical formulation consisting of a reducing agent like ascorbic acid, a complexing agent like ethylenediaminetetraacetic acid (EDTA) or nitrilo triacetic acid (NTA), and a pH-maintaining agent like citric acid, all in a few millimolar concentration levels, is employed to dissolve the corrosion-built spinel-inverse spinel oxide film of  $\approx 2\text{--}4\text{-}\mu\text{m}$  thickness in a typical reactor system employing stainless steel as major structural material (Grigoriev *et al.*, 1995). After the chemical decontamination, the concentrations of dissolved iron, chromium, and nickel in the spent decontamination formulation (simulated effluent (SE)) will be of the order of 5–10 mM Fe, 2–3 mM Cr,  $\approx 1$  mM Ni, and total Co  $< 20\text{--}30$  nM ( $< 1\text{--}2$  ppb). Typically, the simulated decontamination effluent (SE) is composed of iron (9.3 mM of Fe as  $\text{FeSO}_4(\text{NH}_4)_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$ ), chromium (3 mM of Cr as  $\text{CrCl}_3 \cdot 6\text{H}_2\text{O}$ ), nickel (0.93 mM Ni as  $\text{NiSO}_4 \cdot 7\text{H}_2\text{O}$ ), and cobalt in the concentration range of 8.5–34 nM (0.5–2 ppb) Co as  $\text{CoCl}_2$  traced with  $^{60}\text{Co}$  to yield a solution specific activity of 40 Bq/ml (1.08 nCi/ml) and the tagged cobalt is represented as  $^{60}\text{CoCl}_2$  in the presence of disodium EDTA (13.5 mM) (Fig 1.4).

The spent decontamination solution is normally treated by employing synthetic organic ion-exchange resins of the cation and anion type (Bradbury *et al.*, 1986; Venkateswaran *et al.*, 2003). While the dose rate of the spent decontamination solution itself could be  $\ll 0.1$  Gy/h, the large volume of this solution when treated using ion-exchange columns could yield dose rates of  $\approx 0.1\text{--}1$  Gy/h on contact with the column (Venkateswaran *et al.*, 2003). Removal of cobalt present in trace chemical concentration in the spent decontamination solution has to be achieved in the presence of large excess ( $10^5\text{--}10^6$  fold) concentration of corrosion product ions of complexed Fe, Cr, and Ni. However, due to the nonspecific sorption of metal ions by the ion-exchange resin and due to the soluble complexed metal ions of Fe, Cr, and Ni present in spent decontamination effluent (SE) at  $10^5\text{--}10^6$  fold higher concentration level as compared to that of Co, a large volume of spent resin (solid waste) is generated in waste disposal though the cation-exchange capacities for the metal ions are in the range of  $\approx 50$  g of metal ( $\approx 0.8$  mol) per liter of the resin.

### Bioremediation based on radionuclide-microbe interactions

Microorganisms have the potential for bioremediation of toxic metal ions, as observed both in laboratory studies and in natural environments (Gadd and White 1989; Akthar *et al.*, 1995, 1996; King *et al.*, 1998; Allen *et al.*, 2002; Satinder *et al.*, 2006). Microorganisms interact with radionuclides via several mechanisms as shown below, some of which are used as the basis of potential bioremediation strategies. a) Biosorption b) Bioaccumulation c) Enzymatically catalyzed biotransformations d) Biomineralization via microbially generated ligands e) Microbially enhanced chemisorption of heavy metals. Based on the different types of effluents generated, a single technology cannot be suitable to address the problems. Hence specific bioremediation principles have to be explored to develop a suitable technology studies. Uptake of metals by various microorganisms broadly involves rapid process of biosorption to the cell wall followed by a relatively slower process of bioaccumulation into the cell (Rama Rao *et al.*, 1996; Naveena *et al.*, 2005). The latter process involves both specific and nonspecific transporters located on cell membrane. Further, there are tight homeostatic control mechanisms, which could limit metal uptake or even exclude metals that are accumulated inside the cell.

These interactions could be used for the improvement of bioremediation systems to remove or reduce the concentration of radionuclides from spent decontamination solutions (Gunjan *et al.*, 2005). Till recently, there was no specific metal-binding proteins for heavy metals like cobalt specificity is exhibited. Recent advances in genetic engineering aim to exploit the ability of these biological metal transporters (ABC, secondary, ion channels, phosphate transferases, and unclassified transporters) to assimilate and accumulate metals for bioremediation purposes (Maruthi *et al.*, 2007). The metal membrane transporters are broadly divided into different families.

**Shanti Kumari Lunavat et.al.**

A novel cobalt transporter gene was first identified in *Rhodococcus rhodochorus* (*nhlF*; Komeda *et al.*, 1997) and later this was shown to be the NiCoT family of secondary transporters. NiCoT genes have been characterized from various bacterial species, of which *Rhodopseudomonas palustris* CGA009 (RP) and *Novosphingobium aromaticivorans* F-199 (NA) were shown to have preferential uptake for cobalt (Hebbeln and Eitinger, 2004). Recent studies reported from our laboratory involved screening and testing of various wild-type and mutant-type fungal strains and bacteria for the removal of  $^{60}\text{Co}$  ( $^{60}\text{Co}$  with carrier  $^{59}\text{Co}$ ) from simulated spent decontamination effluents (Rashmi *et al.*, 2004, 2007). However, using wild type bacterial strains only up to 1  $\mu\text{g/g}$  biomass,  $^{60}\text{Co}$  removal capacities could be achieved under optimal conditions, while in case of fungi the capacities realized were even lower (20–40 ng/g biomass). These capacities were realized in simulated spent decontamination effluents containing 34 nM of total cobalt (2 ppb). In the present study, an attempt has been made to effect a significant increase in the cobalt removal capacity by using recombinant *E. coli* and *Deinococcus radiodurans* R1 expressing NiCoT transporter genes of *R. palustris* CGA009 and *N. aromaticivorans* F-199. Furthermore, the effects of  $\gamma$ -radiation and chemical toxicity of the simulated effluent were also determined.

**Scope of the present investigation**

The spent decontamination solutions of nuclear power reactors contain high levels of radiation due to cobalt ( $^{60}\text{Co}$ ,  $^{58}\text{Co}$  and  $^{57}\text{Co}$ ) with a very large molar excess ( $10^5$ – $10^6$ ) of non-radioactive metals (Fe, Cr and Ni) (Fig 1.4). Present methods of removal use organic ion exchange resins. Due to the non-specific sorption, a large volume of spent resin is generated which requires tile-holes/trenches for safe burial. Earlier studies from our laboratory screened a number of bacteria and fungi which could significantly reduce the solid waste, with up to 30% removal capacity. In order to enhance the removal capacity and also further decrease biomass, cobalt specific transporter genes were identified using *insilico* approaches. In the present study a remarkable improvement in bioremediation of  $^{60}\text{Co}$  is achieved using recombinant *E. coli* and *Deinococcus radiodurans* R1 expressing NiCoT genes of *R. palustris* CGA009 and *N. aromaticivorans* F-199.

Rapid sequencing of prokaryotic genomes is facilitating the study of comparative genomics. During one such study of cobalamine synthesis gene clusters (*cob/cbi*), a multitude of potential cobalt transporters belonging to various families including the NiCoT family have been identified (Rodionov *et al.*, 2006). In the present study, in order to further improve the efficiency of  $^{60}\text{Co}$  removal over 80-90%, the specific high affinity transporters (Hebbeln and Eitinger, 2004) were cloned and expressed from *R. palustris* CGA009 and *N. aromaticivorans* F-199 in *E. coli*. The genes for the same were cloned and over-expressed in radioresistant *Deinococcus radiodurans* strain R1 which is one of the promising organisms in our study and capable over expressing cobalt transporter protein and transport (bioaccumulation) trace cobalt from simulated spent decontamination solutions of nuclear power reactors (Raghu et al 2008; Gogada et al 2015).

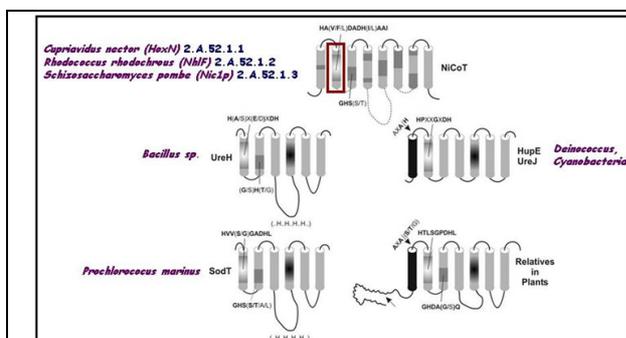

Figure 1: Ni/Co transporters Topology

Conserved segments within the NiCoT family, including the cytoplasmic loop between transmembrane domains (TMDs) IV and V, are highlighted. Dotted lines indicate sequence conservation in cytoplasmic loops. The motif in TMD II with the core sequence  $HX_4DH$  is considered to be a signature sequence for NiCoTs. Very similar signatures in UreH, HupE/UreJ, SodT and in the plant relatives are shown. Another His-containing motif is conserved in TMD III of the NiCoT sequences, and in TMD II of the UreH, SodT and plant sequences (bold letters indicate strong conservation). (Eitinger et al., 2005).

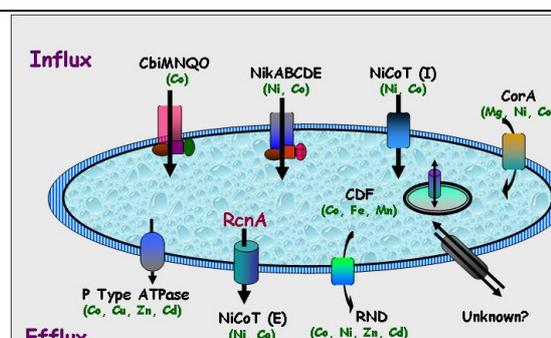

Figure 2: Ni/Co transport in bacteria

The schematic diagram illustrates uptake and export systems involved in Ni homeostasis in different microorganisms. NikABCDE and CbiMNQO are ABC members, their distribution being restricted to prokaryotes. The CorA family includes magnesium transport proteins, which are involved in uptake of Ni-Co at higher concentrations. Nramp members are essential virulent factors of most microorganisms, involved in uptake of manganese and to some extent Ni-Co. NiCoT members are secondary transporters involved in high affinity uptake of Ni-Co, the characterized members being limited to prokaryotes and yeast. The efflux members include P-type ATPases, RND members (Resistance Nodulation and cell Division) and NiCoT efflux members (YohM of *E. coli*).

## Application of Seaweed as a Bio-Fertilizer in Agriculture- Review Study

### ABSTRACT

Bio-fertilizers offer another eco-friendly innovation which would overcome inadequacies of the conventional based cultivating. In this context seaweed plays a significant and indispensable job in the marine biological system and developing in huge amount in the ocean. Ocean growth can be viewed as an expected wellspring of bio-fertilizer in of dried or new structure; it assists with improving biochemical constituents like sugars, lipids, proteins, strands, debris, phenol, dietary fiber and so forth in plant. The seaweed is a great wellspring of miniaturized scale and large scale components required for plant sustenance. Seaweed extract is effective for improves the quality of soil also act as soil conditioner. This innovation can be actualized in type of natural cultivating for maintainable agribusiness which is better answer for eco friendly approach. The components of seaweed, for example, large scale and smaller scale component supplements, amino acids, nutrients, cytokinin, auxins, and abscisic corrosive (ABA)- like development substances influence cell digestion in offered plants upgrade development and enhance growth and crop yield.

**Keywords:** Biofertilizer, seaweed, nutrient content

### INTRODUCTION

All plants need certain minerals supplements to survive in environment. These minerals happen normally in the soil and are taken up from the soil by the underlying foundations of the plants. Most soil as a rule has enough of these minerals to keep plants solid. Be that as it may, plants are progressively ingested a few supplements or supplements are cleaned out of the soil, and should be supplanted to keep up ideal development and improvement of the plants. Most regular mineral supplements that need supplanting are N, P, K. Composts are fabricated by blends of items that contain N, P, K and other important supplements. The manures are important to include the soil in light of the

24288

**Rahul Adhikary**

fact that the supplements in the soil get spent because of rehashed development of the plant. The harvest yield likewise begins diminishing along these lines, arranged by restore the fruitfulness of the soil, composts are fundamental. The unnecessary use of chemical fertilizer (synthetic composition) in agriculture are expensive with unfavorable impacts on physico-chemical properties of soils, plant, and human life. Synthetic fertilizer are progressively resistance in the earth which now and again is destructive to the earth particularly, on soil richness and are really causing enormous measure of soil and land corruption (Liu et al., 2009) because of the fact that the vast majority of the microorganism decline following the utilization of substance composts in expanding level (Katsunori, 2003). The ground water sullyng is the greatest issues looked during the utilization concoction composts. In the soil nitrogen manures separates and changes over into nitrates which are water solvent and ventures effectively through the soil and they can stay in that position for a considerable length of time and these collection is causing the issue. These collections of synthetic compounds lead to water contamination both surface and ground water.

Organic manures are derived from natural products, which were collect from living organisms. Organic fertilizers are generally slow-releasing because they have to decompose and to become plant nutrients; however, this also means their benefits are longer lasting. All natural nutrients to soil, increases soil organic matter, improves soil physical properties, reduces soil crusting problems and consistent release of nutrients.

**ROLE OF SEAWEED BIOFERTILIZER**

The term of biofertilizer speak to everything from plant separates or plant extracts. Biofertilizers comprise of N fixers (Rhizobium, Azotobacter, blue green growth, Azolla), phosphate solubilizing microorganisms (PSB) and organisms (mycorrhizae) which increment the flexibly or accessibility of large scale (essential and auxiliary supplement) as well as smaller scale supplements to the host crops. Biofertilizers have demonstrated incredible potential as an, inexhaustible and natural agreeable wellspring of plant nutrient.. Biofertilizers are prepared to utilize and utilized as a live development of helpful microorganisms, when it altered to seed, root or soil, it activates the accessibility and utility of the microorganisms and accordingly the ability to improve the soil wellbeing and beginning to help microbial development and vegetation.

Seaweeds are one of the most important ocean sources of the world. The seaweed extract is available as fertilizer in different forms such as Seaweed liquid fertilizers, liquid fertilizers and powder form of seaweed extracts have been used as a biofertilizer (Table 1). The seaweed extracts are available for several years as fertilizer additives and beneficial results from their use have been reported (Booth, 1969). The components of seaweed such as macro and micro- element nutrients, amino acids, vitamins, cytokinin, auxins, and abscisic acid (ABA) like substances enhance growth and crop yield. The use of natural seaweed as fertilizer has allowed for partial substitution of synthetic fertilizer. Some studies have reported a wide range of beneficial effects of seaweed extract applications (like soil drench, foliar spray, on plants, such as improving soil moisture, water holding capacity and by promoting growth of beneficial soil microbes enhanced soil health. The compositions of different seaweed bio-chemical parameters are described in Table 2.

The treatment of seaweed extract expanded the seed germination, seedling development and yield of harvest. Nerissa Ali et al. (2016) watched the impact on developed under tropical field conditions with a soluble seaweed separate produced using *Ascophyllum nodosum* (ASWE) on tomato plants (*Lycopersicon esculentum* Mill). In this investigation, two field tests and one nursery test were led to assess strategies for application, measurements, the effect of each on plant development boundaries, the quality and yield of natural product. The higher centralization of ASWE brought about a noteworthy increment in plant tallness (37 %) and plant organic product yield (63 %) contrasted with control plants. The comparisons of micro and macro element of different seaweeds are available at table 3.

Rosalba Mireya et al. (2014) have tested the impact of various grouping of (0.2, 0.4, and 1.0 %) fluid ocean growth separates (LSEs) produced using two green kelp viz. *Ulva lactuca*, *Caulerpa sertularioides* and two earthy colored

**Rahul Adhikary**

ocean growth viz. *Padina gymnospora*, and *Sargassum liebmannii* as biostimulants on the germination and development of tomato (*Solanum lycopersicum*) under nursery and in research facility conditions utilizing two use of foliar splash and soil soak of LSEs. *Ulva lactuca* and *Padina gymnospora* at lower fixation (2%) indicated better germination. The better germination reaction in germination rate related with lower mean germination time, most extreme germination record and germination vitality, and likewise more prominent plumule and radicle length and seedling power. Use of foliar shower was seen as less powerful in plant stature (75cm) than the soil soak (up to 79cm).

Sivasangari Ramya et al. (2015) contemplated the impact on development, biochemical and yield of brinjal by utilizing fluid concentrates of earthy colored marine alga *Stoechospermum marginatum*. The various groupings of fluid concentrates were arranged and applied as foliar splash on the brinjal seedlings, brought up in pots exploratory with kept up under common conditions. Their outcomes uncovered that the quantity of foods grown from the ground weight were expanded at lower focus just (1.5 %). Conversely, fluid concentrates at high focus (5%) was found to have inhibitory impact on brinjal plants when contrasted with the control splashed with water. Sutharsan et al., (2014) were experimented the effect of foliar application of *Sargassum crassifolium* extract at different concentration (concentration (10%, 20%, 50% and 100%) to apply on tomato plants at five times from 3 weeks after transplanting and the results was recorded after two weeks. At 20% of root dry weight (81.57%), shoot dry weight (80.92%), fruit number (57.87%) and fruit yield per hectare (58.70%), along with fruit total acidity (76.95%) and total soluble solids content (25.71%) of fruit significantly increased as compare to control, while all mentioned parameters reduced at 100% of foliar application. Therefore, it concluded 20% concentration of seaweed extract an be used to enhance the growth.

Dogra and Mandradia (2012) was determined the effects of soil applications of different concentrations of seaweed extract from *Ascophyllum nodosum* on growth, yield and downy mildew severity of onion during the Rabi season of 2009. The seaweed granules were applied as the basal dose (1.5, 2.0, 2.5, 3.0 & 3.5 g/m<sup>2</sup>). The highest yield recorded was with application of 2.5g/m<sup>2</sup> followed by 3.0g/m<sup>2</sup> that resulted in 120.8 per cent and 102.5 per cent respectively compared to control. Zodape et al., (2008) found effect of different concentration of (2.5%, 5.0%, 7.5% and 10.0%) to obtain from *Kappaphycus alvarezii* on yield and quality. In the result, significantly increased in length (31.77%) and diameter (18.26%) of fruit, number of fruits (37.47%) and fruit yield (20.47%) per net plot and nutritional quality of Okra (*Abelmoschus esculentus* L.) as compared to control. New research has expanded the arrangement of development stimulant atoms found in seaweed extracts. Firstly, it is rising that brassinosteroids are available in the Kelpak™ E. maxima ocean growth remove (Stirk et al 2014). Furthermore, notwithstanding brassinosteroids, strigolactones have been found in the Seasol™ seaweed separate (Arioli, unpublished information). Be that as it may, another ongoing report by Yusuf et al. (2012) that featured the multifaceted nature of kelp removes makes it hard to attribute the plant reactions to a solitary growth stimulant.

## CONCLUSION

According to the above study considered seaweed can be used as a great wellspring of full scale and smaller scale macro and micro nutrients, phenol, starches and higher substance of plant development hormones. Development advancing substances discharged by biofertilizers improve plant's physiological and biochemical boundaries. In addition to these points of interest, biofertilizers are monetarily encouraging as well. They are likewise nearly less expensive than the other chemical fertilizer.

### ABSTRACT

Plant pathogens are becoming destructive to the crops in recent years and controlling them is one major problem faced by the farmers. The use of chemical pesticides and herbicides are showing lots of harmful effects towards the environment which is ultimately hampering human health as well as the animals. Thus to reduce these toxins from our habitat continuous efforts are being done to find beneficial alternatives and therefore emerges nanotechnology to treat the crops. Nanoparticles are very small particles ranging in size between 1 and 100 nanometres and are mainly classified into two categories viz. hard nanoparticles which are the metallic nanoparticles and the soft nanoparticles which comprises of the polymeric nanoparticles, liposomes etc. Though nanoparticles are used in various domains but they also have a high impact to control stress in plants, both abiotic and biotic. Metallic nanoparticles have largely shown antifungal inhibition against dangerous pathogens like *Alternaria* sp., *Sclerotinia* sp., *Fusarium* sp., *Rhizoctonia* sp. etc. Soft nanoparticles like chitosan have been used to control the plant fungi viz. *Fusarium* sp., *Alternaria* sp., among many. But the most effective nanoparticle formulation is the combination of both metallic and polymeric component which highly inhibited the phytopathogens as well as helped in growth of plants.

**Keywords:** Metallic nanoparticles, chitosan nanoparticles, plant pathogens, anti-fungal activity.

Ria Mukhopadhyay et al.

## INTRODUCTION

Huge loss is occurring nowadays per year in crop yield and production due to plant pests and pathogens attack [1]. Currently the management of pests and pathogens depends on the application of fungicides, insecticides and herbicides which are having lots of harmful side effects inspite of fast action, high availability and reliability [2]. Thus there is an urgent need for the development of pesticides which will cause less harm to the environment apart from being cost efficient and high performing.

To control this menace nano sized particles of different materials have been developed which range in the size of 1-100 nm and shows completely different properties in comparison to its macro size. The use of nanoparticles (NPs) are less utilised in agricultural applications and development than in other fields such as medicine, engineering etc. [3] In agriculture nanotechnology has the ability to conserve and exploit natural resources, production and protection of crops, utilisation as nanosensors, and for transferring desired genes. Nanoparticles can be synthesized of different shapes, sizes and properties for target specific delivery of an active pesticide [4]. The utilisation of nanoparticles to protect the plants can occur by two different mechanisms: (a) nanoparticles itself acting for crop protection, or (b) nanoparticles acting as carriers of active pesticides which can be applied by sprays or seed/ root treatment. The nanoparticles that are mainly used to control the pest attack in plants are the metallic nanoparticles viz. copper NPs, silver NPs, zinc NPs etc and the soft nanoparticles mainly chitosan NPs.

### Metallic nanoparticles controlling plant pathogens

The attention on application of copper nanoparticles (CuNPs) are highly increasing due to their low cost, high thermal and electrical conductivity, and catalyst [5]. In comparison to other inorganic antimicrobial agents, the copper ones are widely used in agriculture field as fungicide [6], pesticide [7], algicide [8], and herbicide [9]. In an experiment carried out by Kanhed et al. (2014) copper nanoparticles (CuNPs) showed high affectivity than commercial fungicide Bavistin against four plant pathogenic fungi such as *Phoma destructiva*, *Curvularia lunata*, *Alternaria alternata* and *Fusarium oxysporum* [10]. The zone of fungal growth inhibition (mm) was high in CuNPs in comparison to bavistin and almost similar in case of CuNPs+ bavistin treatment. Maximum inhibition was found in the growth of *Fusarium oxysporum* fungal mycelia. The promising antifungal activity of the CuNPs was mainly because of their high surface area to volume ratio.

Efficacy of silver nanoparticles (AgNPs) has also been studied to reduce fungal infection in plants. Kim et al. performed antifungal assay with AgNPs on eighteen different fungi in different concentration of the formulation. The results obtained showed that silver NPs can inhibit the fungi efficiently; though the concentration of AgNPs had an impact on pathogens. Most of the fungi was highly inhibited at 100 ppm concentration of NPs and mainly on PDA media [11]. Lamsal et al. (2011) used AgNPs to manage pepper anthracnose caused by *Colletotrichum* sp. AgNPs were applied in different concentrations and 100 ppm concentration produced maximum fungal growth inhibition in vitro as well as in field condition [12]. Mesoporous alumina nanoparticles were synthesized by Shenashen et al. (2016) with active surface sites, and large surface area to volume ratio, which exhibited high antifungal activity against *Fusarium root rot* of tomato [13]. Magnesium oxide, titanium dioxide and zinc oxide nanoparticles reduced the radial growth of fungal mycelium of *Fusarium oxysporum* f. sp. *betae*, *Sclerotium rolfsii*, and *Rhizoctonia solani* which causes Damping-off and Root Rot of Sugar Beet [14].

### Polymeric nanoparticles restricting phytopathogen growth

Chitosan is a bio-polymer used for its antimicrobial activities and nanoparticles are synthesized from chitosan because of its biocompatibility, biodegradability, high permeability, cost-effectiveness and non-toxic property [15, 16, 17]. Chitosan nanoparticles have been extensively used to control the proliferation and growth of plant pathogens. Experiments performed by Sathiyabama et al. (2016) showed the antifungal activity of chitosan nanoparticles against devastating pathogens such as *Pyricularia grisea*, *Fusarium oxysporum* f. sp. *ciceri*, and *Alternaria solani* and it also act as

**Ria Mukhopadhyay et al.**

a growth promoter of seedlings. Maximum hyphal growth inhibition was seen in *P. grisea* than other two pathogens [18]. Chitosan NPs inhibited the growth of fungi like *Alternaria alternata*, *Macrophomina phaseolina* and *Rhizoctonia solani* when applied at different concentrations ranging from 0.001 to 0.1% [19]. Oleoyl-chitosan (O-chitosan) nanoparticles were synthesized by Xing et al. (2016) to investigate its antifungal activity against phytopathogenic fungi viz. *Nigrospora sphaerica*, *Botryosphaeria dothidea*, *Nigrospora oryzae*, *Alternaria tenuissima*, *Gibberella zeae* and *Fusarium culmorum*. The first four pathogens were sensitive to chitosan NPs and their growth inhibited along with increase in concentration of NPs [20].

### Combination of metallic-polymeric NPs to inhibit phytopathogens

Though chitosan has been found to be highly effective in reducing the pathogen growth both in vitro and in vivo but blending it with other components like metal increases its efficiency. Copper-chitosan nanoparticles (Cu-CNPs) inhibited mycelial growth and also spore germination in *Alternaria solani* and *Fusarium oxysporum* in in vitro condition. In field experiments the Cu-CNPs showed antifungal activity in tomato plants and also promoted the growth of plants [21]. *Fusarium oxysporum* was treated with silver-chitosan NPs (Ag-CNPs) as well as chitosan NPs in in vitro conditions. Ag-CNPs showed higher radial growth inhibition of the fungus in comparison to chitosan NPs and it also changed the morphology of the pathogen, therefore recommending as a good antifungal agent [22].

### ABSTRACT

The strontium titanate ((Sr<sub>0.5</sub>Cu<sub>0.5</sub>TiO<sub>3</sub>)) perovskite sample is prepared by solid state reaction method. After Cu doped Strontium with STO; its crystal structure, particle size and lattice parameter were analysed. Structural studies of this perovskite were studied using x-ray diffraction (XRD). The morphology study were performed by scanning electron microscopy. Dielectric loss and dielectric constant of this material at room temperature were analysed for different frequency ranges.

**Keywords:** Solid state reaction; Modulus; Impedance; AC conductivity;

## INTRODUCTION

ABX<sub>3</sub> chemical formula refers to a perovskites structure, where A, B represents two cations with different sizes and X represents for anion which makes a strong bonding with cations. Perovskite material have many applications like ferroelectricity, grain boundary barrier layer capacitor, epitaxial growth, oxygen - gas sensor for superconductor thin films [1]. STO possesses insulating behaviour, conductivity, photo electricity capabilities with dopants such as Mg at cations side[2]. STO uses as an optoelectronic device and plays a vital role in oxide electronics [3]. When SrTiO<sub>3</sub> is compared with BaTiO<sub>3</sub> there are many differences found in their dielectric properties[4]. STO is used for passive devices like filters and antennas, active devices like tuneable rf filters and phase switches [5]. The multi-layered STO sensors have been found high potential for lean hydrocarbon sensing [6].

### Experimental

The sample of Cu doped SrTiO<sub>3</sub> was prepared using high-temperature solid state reaction technique using high-purity stoichiometry ingredients. The structure weighed stoichiometrically was carefully blended, first for 2 hours in an air atmosphere and then for another 1 hour in alcohol. Then the mixed powders were calcinated at an optimized temperature of 950°C for 4hr in a high purity alumina crucible. At first 0.025g of (Sr<sub>0.5</sub>Cu<sub>0.5</sub>)TiO<sub>3</sub> was taken in a crucible and heated it for two hours with a temperature of 150°C. Then the powder was grinded for 30 mins. Then

20ml of N, N-Dimethylformamide was taken in a conical flask and 5g of PMMA was added to it. The mixture is left at ambient temperature for 20 minutes under continuous magnetic stirring until a homogenous mixture is formed. Then to the above mixture stoichiometric (0.025g) amount of ceramic powder ((Sr<sub>0.5</sub>Cu<sub>0.5</sub>)TiO<sub>3</sub>) was added. Again, the mixture was stirred for 1hr and a homogeneous mixture was obtained. Then the homogeneous mixture was casted on glass Petridis and heated in a hot air oven at 120°C for 4-5 hours. Finally, the polymer film was obtained.

## RESULT AND DISCUSSION

### Structural Study

Fig 1 shows the XRD patterns of Cu doped SrTiO<sub>3</sub> at room temperature. The diffraction pattern shows sharp and noisy defined single diffraction peaks, which are different from those of the ingredients. This confirms the good homogeneity and crystallization of the prepared compound [7]. The cubic crystal structure has been confirmed for material. The chosen unit cells ' lattice parameters are refined using a conventional "POWD" computer program package. A strong agreement is found between observed (obs) and calculated (cal) interplanar spacing and is well aligned with interplanar spacing ( $\Delta d = d_{obs} - d_{cal} = \text{minimum}$ ). Cu doped SrTiO<sub>3</sub> crystallite size is roughly estimated from the expansion of XRD peaks (wide 2 ranges) using Scherer's equation  $P = KA / (\beta_{1/2} \cos \theta_{hkl})$  [17]. where K= constant= 0.89,  $\lambda = 1.5405 \text{ \AA}$ ,  $\beta_{1/2}$  =width of the reflection at half intensity). The composites ' average crystallite size (P) is 21 nm.

### Microstructural Study

Fig 2 Shows the Scanning Electron Microscope of Cu doped SrTiO<sub>3</sub>. From the image it can be seen that there is presence of amorphous phase in the composite. The grains are spread more or less homogeneously with less porosity throughout the sample surface. The shape of the grains is spherical. It is found that the average grain size is 200  $\mu\text{m}$ . It is noted that the size of the grain is greater than the size of the crystallite acquired from the Scherer equation. Thus, several crystallites can consist of a single grain.

### Dielectric Study

The variation of dielectric constant ( $\epsilon_r$ ) with frequency is shown in the graph. 3(a). From the graph it can be seen that with increase in the frequency, the dielectric constant decreases. The dielectric constant has a large value at lower frequency range which is a due to the occurrence of various types of polarization in this region like atomic, ionic, interfacial, and electronic polarization while in the high frequency region only the electronic polarization takes place which affects the value of dielectric constant [8]. Again, we can see the variation of dielectric loss ( $\tan \delta$ ) with frequency as shown graph 3(b). For lower frequency range, it shows high loss. As the frequency increases, the value of  $\tan \delta$  reaches a saturation value and after 20 KHz it starts to decrease on further increase in the frequency. The decreases till a certain point and increases on further increase in frequency and almost reaches a sturation value from 450 kHz 1000 kHz after which its value may affect the dielectric loss. The high value of  $\tan \delta$  at lower frequency may result in the high resistivity of grain boundary. As we know, the dielectric constant of the materials is linearly proportional to the average value of grain size, hence, the decrease of dielectric constant and  $\tan \delta$  as a function of Cu doping is due to the decrease of grain size which means that doping of Cu has affected the fabrication of SrTiO<sub>3</sub> ceramics as the mobility of grain boundary decreases because of the separation of defects created due to doping near the grain boundary [9]

## CONCLUSION

The ferroelectric composites of Cu doped SrTiO<sub>3</sub> are successfully prepared by high-temperature solid state technique. The composite shows the cubic structure having lattice constant a=b=c=3.903 angstrom. With increasing frequency, the dielectric constant decreases which explain that all types of polarization exist at low frequency and vanishes along with increasing frequency.

### ABSTRACT

Ceramic powders of Cu doped Lead titanate ( $\text{Pb}_{0.5}\text{Cu}_{0.5}\text{TiO}_3$ ) are synthesized through high temperature solid state reaction method. The various weight percentages of ceramic fillers incorporated into the polymer matrix via solution casting techniques. The structural and micro structural studies of this polymer composite were characterized by X-ray diffraction and scanning electron microscopy. Moreover, the dielectric and electrical properties of the composites were measured using an impedance analyzer in a wide range of frequency at room temperature.

**Keywords:** Solid state reaction; Dielectric constant; Impedance; AC conductivity;

## INTRODUCTION

Among ferroelectric materials with perovskite structure ( $\text{ABO}_3$ ), Lead titanate ( $\text{PbTiO}_3$ ) is mostly studied because of their unique physical structure and several other significant properties. Ferroelectric materials are a special type of materials which possess high value of dielectric constant, low dielectric loss, high electrical resistivity and good electrical properties. Because of their excellent piezoelectric and electrical properties these are ideal for various applications in the fields of thin film capacitors, electronic transducers, pyroelectric sensors and nonlinear optics. These materials exhibit spontaneous polarization and can also switch the direction of polarization [1]. It shows relatively low value of dielectric constant (~200) as compared to its other family member like Barium titanate ( $\text{BaTiO}_3$ ) and PZT ceramics.

It has also a high curie temperature of about  $490^\circ\text{C}$  [2]. It has a high value of pyroelectric coefficient and relatively low permittivity which makes it an ideal material for the application of pyroelectric infrared detector. At ambient temperature it shows a strong anisotropy which may be as high as ~1.6 (c/a ratio). A large value of c/a ratio favors the enhanced electrical properties [3]. In this work, we synthesized Lead titanate with Copper as a doping material and then made polymer films of this ceramic powder by solution casting method. Cu doping can increase work function, electrical conductivity, and carrier mobility of these films [4]. Here, we adopted conventional solid-state reaction

24301

Rashmيرانjan Patra et al.

method to synthesize the material i.e. Cu doped lead titanate ( $\text{Pb}_{0.5}\text{Cu}_{0.5}\text{TiO}_3$ ) because most of the chemical-based processing routes require organic or organometallic chemicals of high purity which are much more expensive than the oxides which are widely available also. Here we focus on electrical properties of the polymer films of this ceramic powder. The frequency dependent properties of the material can be studied with the help of complex permittivity ( $\epsilon'$ ), complex impedance ( $Z$ ) and dielectric loss ( $\tan \delta$ ).

### Experimental Technique

The ceramic powders of Cu doped  $\text{PbTiO}_3$  were prepared using high-temperature solid state reaction technique using high-purity stoichiometry ingredients. The samples were carefully blended, first for 2 hours in an air atmosphere and then for another 1 hour in alcohol. Then the mixed powders were calcinated at an optimized temperature of  $950^\circ\text{C}$  for 4hr in a high purity alumina crucible. The ferroelectric ceramic-polymer composites were prepared using solution casting technique. Firstly, the 0.025g of  $(\text{Pb}_{0.5}\text{Cu}_{0.5})\text{TiO}_3$  was taken in a crucible and heated it for two hours with a temperature of  $150^\circ\text{C}$ . Then the powder was grinded for 30 minutes. Then 20ml of N, N-Dimethylformamide was taken in a conical flask and 0.5g of poly (methylmethacrylate) (PMMA) was added to it. The mixture is left at ambient temperature for 20 minutes under continuous magnetic stirring until a homogenous mixture is formed. Then to the above mixture stoichiometric (0.025g) amount of ceramic powder  $[(\text{Pb}_{0.5}\text{Cu}_{0.5})\text{TiO}_3]$  was added. Consequently, the mixture was stirred for 1hr and a homogeneous mixture was obtained. Then the homogeneous mixture was casted on glass Petridis and heated in a hot air oven at  $120^\circ\text{C}$  for 4-5 hours. Finally, the polymer film was obtained.

## RESULT AND DISCUSSION

### Structural Study

Fig 1 shows the XRD patterns of Cu doped  $\text{PbTiO}_3$  at room temperature. The diffraction pattern shows sharp and noisy defined single diffraction peaks, which are different from those of the ingredients. This confirms the good homogeneity and crystallization of the prepared compound [12]. The tetragonal crystal structure has been confirmed for all concentrations. The chosen unit cells ' grid parameters are refined using a conventional "POWD" computer program package. A strong agreement is found between observed (obs) and calculated (cal) interplanar spacing and is well aligned with interplanar spacing ( $\Delta d = d_{obs} - d_{cal} = \text{minimum}$ ).  $\text{PbCuTiO}_3$  crystallite size is roughly estimated from the expansion of XRD peaks (wide 2 ranges) using Scherer's equation  $P = KA/(\beta_{1/2} \cos \theta_{hkl})$  [17], where  $K = \text{constant} = 0.89$ ,  $\lambda = 1.5405 \text{ \AA}$ ,  $\beta_{1/2}$  = width of the reflection at half intensity). The composites ' average crystallite size (P) is 42 nm.

### Microstrutural Study

Fig 2 Shows the Scanning Electron Microscope of Cu doped  $\text{PbTiO}_3$ . From the image it can be seen that there is presence of amorphous phase in the composite. The grains are spread more or less homogeneously with less porosity throughout the sample surface. The shape of the grains is spherical. It is found that the average grain size is  $1 \mu\text{m}$ . It is noted that the size of the grain is greater than the size of the crystallite acquired from the Scherer equation. Thus, several crystallites can consist of a single grain.

### Dielectric Study

Fig.3 (a) shows the variation of dielectric constant ( $\epsilon_r$ ) with frequency. From the graph it can be seen that with increase in the frequency, the dielectric constant decreases. The dielectric constant has a large value at lower frequency range which is due to the occurrence of various types of polarization in this region like atomic, ionic, interfacial, and electronic polarization while in the high frequency region only the electronic polarization takes place which affects the value of dielectric constant [5]. Again, we can see the variation of dielectric loss ( $\tan \delta$ ) with frequency as shown graph 3(b). For lower frequency range, it shows high loss. As the frequency increases, the value of  $\tan \delta$  reaches a saturation value and after 20 KHz it starts to decrease on further increase in the frequency. The

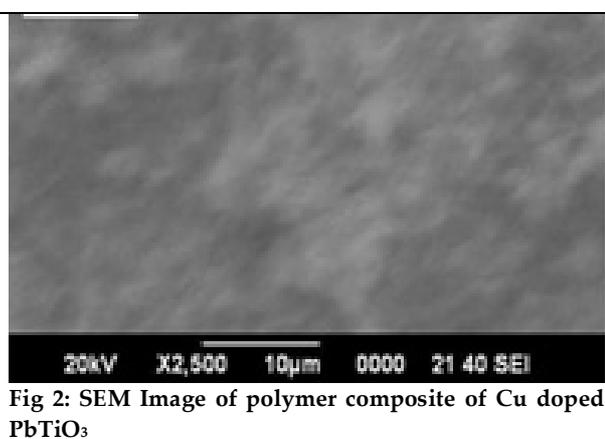

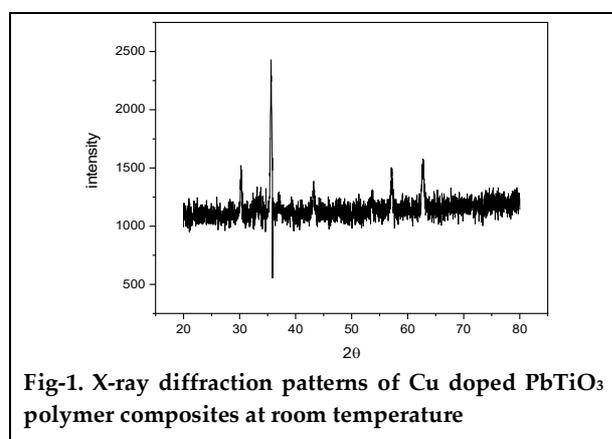

Oriental polarization and the electrical conductivity of material may affect the dielectric loss. The high value of  $\tan \delta$  at lower frequency may result in the high resistivity of grain boundary. As we know, the dielectric constant of the materials is linearly proportional to the average value of grain size, hence, the decrease of dielectric constant and  $\tan \delta$  as a function of Cu doping is due to the decrease of grain size which means that doping of Cu has affected the fabrication of  $\text{PbTiO}_3$  ceramics as the mobility of grain boundary decreases because of the separation of defects created due to doping near the grain boundary [6].

## CONCLUSION

The ferroelectric composites of Cu doped  $\text{PbTiO}_3$  are successfully prepared by high-temperature solid state technique. The resultant composite exhibits tetragonal structures. With increasing frequency, the dielectric constant decrease which explains that all types of polarization exist at low frequency and vanishes along with increasing frequency. We expect that the dielectric properties of the composites can be further improved by optimization of the hybrid particles.

### ABSTRACT

A high dense boron carbide sample has been prepared by thermal arc plasma melt-cast technique. The high temperature boron carbide was melted within 5-10 min of arc plasma reaction. This melt product exhibits higher hardness with least pore volume. As melting time increases from 5 min. to 10 min., density of product increases. Melt-cast samples were evaluated by X-ray diffraction (XRD), field emission scanning electron microscopy (FESEM), transmission electron microscope (TEM), BET (Brunauer-Emmett-Teller) analysis and micro hardness. This work reports a very hard, tough and porous free melt-cast product. Boron carbide prepared by 10 min. of plasma treatment was found to exhibit significantly high hardness (2705 VHN) and Young's modulus (540 GPa) values with almost zero porosity.

**Keywords:** Boron carbide, X-ray diffraction, Microstructure, Hardness

### INTRODUCTION

Ceramic is a solid material comprising of inorganic compound of metal, non-metal or metalloid atoms primarily held in ionic and covalent bonds. Common examples are earthenware, porcelain, and brick. General properties such as high melting temperature, high hardness, and poor conductivity, high moduli of elasticity, chemical resistance and low ductility are the norm, with known exceptions to each of these rules (e.g. piezoelectric ceramics, glass transition temperature, superconductive ceramics, etc.) [1-5]. The modern ceramic materials, which are classified as advanced ceramics, include boron carbide, silicon carbide and tungsten carbide [5-10]. The above carbides are valued for their abrasion resistance and hence find use in applications such as the wear plates of crushing equipment in mining operations. [10-15] Boron carbide has prominent place in ceramic material because of good mechanical, physical and thermal properties, which are described in following sections.

B<sub>4</sub>C is a refractory hard carbide material. It shows superior properties such as low density, high hardness, high melting point, high wear resistance, high thermal and electrical conductivities and a relatively high chemical stability [16]. B<sub>4</sub>C is very commonly used as a neutron absorbent [17]. With such a back drop, the development of B<sub>4</sub>C composites with least porosity has promising applications. [16-18]. These porous free materials have great applications for abrasive, corrosion-resistant and high temperature applications due to their high hardness, high stiffness, good wear resistant and high melting points [16-18].

### Experimental

Arc plasma melting of B<sub>4</sub>C was carried out by using 30 kW (dc) arc plasma reactor. Melting was followed by *in-situ* cooling of reactor / furnace up to room temperature. Ar was used as the plasma generating gas. Melting process was found to complete within 20-40 min. in the 30 kW reactor. Ar gas back up was maintained in the reactor / furnace during the first 1 hour of cooling to prevent oxidation of boron carbide. The dimensions of the ingots are as follows: dia.: 5-6 cm and height.: 1-2 cm. Electrical energy consumption for melt-casting was found to vary in the range 11 - 15.7 kWh / 0.1 kg, which is around 30 times higher than that of iron. This happened due to the common heat loss in the semi-open type of reactor / furnace. Recovery or yield of the composite products prepared in the 30 kW reactor is seen to vary between 86 and 91wt%. The recovery is fairly good in the lab scale operation. Voltage: 50-100 V and I=300-350 A was maintained for preparing different batch samples.

### RESULTS AND DISCUSSION

XRD was employed to study the formation of various phases in such composites. By taking various observed peak positions and the corresponding *d* values into account, the phases and *hkl* indices for various planes were identified by comparison of the observed *d* values with the *d* values in 1999 JCPDS data files (B<sub>4</sub>C: 73-0471, C (graphite-2H): 41-1487. XRD pattern of sample 1 shows major peak of B<sub>4</sub>C and C(G). Following B<sub>4</sub>C peaks are observed: (101), (012), (110), (104), (021) and (024). Carbon is found in graphite form C(G) (002). The major peak of B<sub>4</sub>C is detected at around two theta of 38°. No other impurity is found. The phases were found well defined crystalline phases with following standard FWHM of different peaks. B<sub>4</sub>C crystallizes in rhombohedral lattice with P31m (162) space group and C crystallizing in graphite phase grows in hexagonal lattice (2H polytype) with P6<sub>3</sub>/mmc (194) space group.

Microstructures of all the arc plasma melt-cast samples (mirror polished) were studied under FESEM where typical multiphasic morphologies are observed. Similar microstructure has been observed by other researcher for arc furnace melted and quenched B<sub>4</sub>C samples. In samples multiphasic granular microstructures are observed instead of lamellas. Such a difference in microstructure arises due to slower cooling rate produced in the arc plasma furnace during cooling cycle. Grains of three types of contrast, such as white, grey and dark, are seen in the microstructures. No porous structure is detected in the composite. The dark area is C(graphite). The grey and white phases were found in the melt-cast product. The grey phases were found to plate like structure. The white phase behaves like matrix in the phase. The structure of product was found match with literature. But in sample 3 due to formation of lamellar structure it is difficult to observe grain boundary between grey and white phases. This new kind of structure may have good impact on the mechanical properties of composite. Overall sample 1 and sample 3 are found to free from porosity.

It is evident from TEM image that three types of grains are observed i.e. grey/semi white, white and dark. From the TEM microstructure it observed that the samples are free from microporosity. Microhardness of composites was calculated from the indentation technique by the formula:

$$\text{VHN} = 1.8544 P/d^2 \quad (1)$$

where P is the applied load and d is the average length of diagonals.

No cracks are noticed on the surface, thus suggesting that the melt-cast carbides do not exhibit brittle behaviour at a load of 0.5 kg. At least ten indentations were made per sample and the result reported is the average

**N. Nayak et al.**

microhardness with standard deviation. Microhardness measurement of samples is presented in Table 3. The microhardness of sample 1 was found to be 2500 VHN. The highest hardness value i.e. 2705 VHN is marked for sample 3. The improved hardness may be due to the presence of less porous (minimum pore value observed from BET analysis) and high melting fluidity during plasma treatment.

## CONCLUSION

Arc plasma melting process was employed to melt-cast B<sub>4</sub>C. The melt-cast products show recovery/yield in the range 78 – 92wt%. Higher value of electrical energy consumed for preparing the material because of high melting point (~27050 °C) of B<sub>4</sub>C. XRD characterization of the melt-cast product shows that B<sub>4</sub>C as major phases and unbound C appear mostly as minor phase. Lattice constants of B<sub>4</sub>C and C (graphite) were determined from *d* values obtained from XRD and found closely match with the corresponding values in JCPDS files. SEM and TEM microstructures reveal that the materials are free from micro porosity. Evaluation of hardness by micro indentation method shows that microhardness occurs in the range 2500-2705 VHN. The increase of hardness value indicates that the materials are not so brittle like common ceramics. The paper presents an elaborate study comprising new results on the preparation and characterizations of B<sub>4</sub>C. SEM image shows granular and lamellar type of structure. SEM and TEM images samples were found to be free from surface defects.

### ABSTRACT

Indium doped zinc oxide nanostructures have been synthesized from Zinc acetate dihydrate and indium nitrate dihydrate using sol gel technique. Effect of the dopant (indium) on the structural, morphological, and vibrational modes of zinc oxide nanostructures has been systematically studied using X-ray diffraction, field effect scanning electron microscopy and Raman spectroscopy, respectively. Indium ( $\text{In}^{+3}$ ) being a substitutional dopant in zinc oxide replaces  $\text{Zn}^{+2}$  ions, thus increasing the carrier concentration and affects vibrational modes. The effect of incorporation of indium and the origin of the observed vibrational modes are discussed. So it can be said that indium doped zinc oxide nano structures of desired characteristics can be synthesized using this low cost sol gel technique for its potential applications in numerous fields.

**Keywords:** Indium doping; Sol gel method; Raman Spectroscopy

### INTRODUCTION

Zinc oxide is an abundant, low cost and non toxic n-type material. It is a *II-VI* compound semiconductor and is having a stable wurtzite structure. It has lattice constants of  $a = 3.25 \text{ \AA}$  and  $c = 5.2 \text{ \AA}$  and their ratio  $c/a \sim 1.60$  is same as a hexagonal cell ( $c/a = 1.633$ ) [1]. It has a direct and wide band gap of 3.37 eV [2], and a free-exciton binding energy of 60 meV [2]. Owing to the said physical properties zinc oxide has numerous applications, such as semiconductor devices, transparent conductors, solar cell, varistors, gas sensors, etc. [3-5] and hence large effort has been focused on the synthesis, characterization and applications of zinc oxide nanostructures. These nanostructures can be synthesized by a variety of methods which includes sol-gel technique, wet chemical synthesis route, spray pyrolysis, and so on [6-7]. Undoped zinc oxide shows n-type conductivity due to the presence of donor type intrinsic defects such as oxygen vacancies ( $\text{V}_\text{O}$ ) and zinc interstitials ( $\text{Zn}_\text{i}$ ) [1].

24310

Doping with higher valent impurities further enhances the n-type conductivity of zinc oxide. Hence it is important to understand the influence of dopants on the structural and morphological characteristics of zinc oxide. There are several research papers reporting the doping of zinc oxide with n-type impurities such as aluminium (Al), tin (Sn), iron (Fe) and indium (In) [8-9]. Among all n-type impurities being used, indium is found to be one of the best dopant, as it introduces higher conductivity in zinc oxide. In the present work, we have systematically studied the effect of indium doping on the structural, morphological, and vibrational modes of zinc oxide nanostructures. The possible reasons for the observed characteristics of the synthesized nanostructures are discussed.

### Synthesis of nanostructures

Indium doped zinc oxide nanostructures were prepared by sol gel route using Zinc acetate dihydrate (purity 98%) and indium nitrate dihydrate (purity 99.99%). 1 wt.% of indium nitrate was first mixed with zinc acetate and was dissolved in 2-methoxyethanol. Mono-ethanolamine was added drop by drop into the solution through continuous stirring. The solution was heated at 60 °C and cooled to form a gel. The gel was dried in a vacuum oven kept at 80 °C overnight to form powder. The powder was then crushed in a mortar pestle and sintered at 700 °C for 2 h in air. To study the structural properties of the synthesized nanostructures, X-ray diffraction pattern were recorded using Rigaku Ultima III X-ray diffractometer. The micro structural properties were characterized by field emission scanning electron microscopy (FESEM) using CARL ZEISS SUPRA-40. The vibrational properties of the indium doped zinc oxide nanostructures were characterized by Raman spectroscopy. Possible reasons of the observed properties of the nanostructures were discussed.

## RESULTS AND DISCUSSION

### Structural Characterization

Fig. 1: X-ray diffraction pattern of indium doped zinc oxide nanostructures polycrystalline hexagonal nano structures with peaks at 31.72°, 34.28°, 36.20°, 47.50°, 56.46°, 62.85°, 67.76°, 69.04°, 72.45° and 76.71° are observed corresponding to (100), (002), (101), (102), (110), (103), (112), (201), (004) and (202) planes respectively, similar to a standard hexagonal zinc oxide structure [10]. Presence of these peaks shows that there is no additional phase for indium reflecting the uniformity in phase formation behavior and indicating the substitution of indium in zinc oxide lattice. Fig. 2 shows the energy dispersive X-ray spectroscopy (EDX) of the indium doped zinc oxide nanostructures. It is an analytical technique used to characterize the chemical compositions and purity of the grown samples [11]. As expected the shown spectrum indicates the inclusion of indium in zinc oxide lattice without any impurities.

### Micro Structural Characterization

Fig. 3: FESEM image of indium doped zinc oxide nanostructures. As seen from the figure a random orientation of grains with agglomerated nano structures were formed. This may be attributed to the rapid nucleation and growth of the nanostructures [12]. The random orientation of zinc oxide nano structures is also reflected from the Raman Spectroscopy as outlined below.

### Raman spectroscopy

Raman spectroscopy was performed to study the effect of indium on the vibrational properties of zinc oxide lattice. As reported by E-Morales and Pal, at long and short range orders solids exhibit a correlation between their vibrational properties and the spatial array of the constituent atoms [13]. Fig. 4 shows the Raman spectra of indium doped zinc oxide nanostructures. The spectrum reflects four peaks, located at about 331, 379, 436, and 580  $\text{cm}^{-1}$ . The highly intense peak at 436  $\text{cm}^{-1}$  is attributed to the high frequency mode ( $E_{2H}$ ) and may be due to the involvement of oxygen atoms. The broad LO mode peak at around 580  $\text{cm}^{-1}$  is attributed to the overlapping of two polar modes due to the random orientation of nanostructures, which was also observed from the microstructure of the sample.

K. Baisakh *et al.*

## CONCLUSION

In summary, indium doped zinc oxide nanostructures were synthesized by the cost effective sol gel technique using Zinc acetate dihydrate and indium nitrate dihydrate as the precursor materials. Phase formation behavior was studied from XRD technique and it confirmed the formation of hexagonal zinc oxide. EDX indicated the inclusion of indium into zinc oxide lattice without any impurity. FESEM images revealed the effect of indium doping in zinc oxide. Substitution of indium in zinc oxide is also reflected from the study of vibrational modes of Raman spectroscopy. So using sol gel technique indium doped zinc oxide nano structures with required properties can be synthesized for device applications.

## ACKNOWLEDGEMENTS

The authors sincerely thank Indian Institute of Technology, Kharagpur for providing various experimental facilities.

### ABSTRACT

The article is based on an experimental study. The polycrystalline material  $\text{Na}_2\text{Pb}_2\text{Eu}_2\text{W}_2\text{Ti}_4\text{Ta}_4\text{O}_{30}$  of tungsten bronze structural family has been synthesized using a high-temperature (1100°C) solid-state reaction technique. Preliminary structural studies with X-ray diffraction data show the formation of single phase compound. Electrical properties of the material have been studied using complex impedance spectroscopy technique. It appears that temperature dependent electrical parameters are strongly correlated to the microstructure (i.e., presence of bulk, grain boundary, etc) of the sample. The complex impedance (Nyquist) plot display a single semicircle below 350°C confirming the effect of grain resistance on the electrical behavior. However, in the high frequency range the formed semicircle splits into two suggesting the contributions of both grain and grain boundary effect. The AC conductivity spectra obey Jonscher's universal power law. The activation energy calculated from DC conductivity confirms that the oxygen vacancies play an important role in the conduction mechanism.

**Keywords:** Solid-state reaction; impedance; electrical conductivity.

### INTRODUCTION

There has been rapid progress in search of new ferroelectric materials for industrial and commercial applications such as multi-layer capacitors, transducers, actuators, ferroelectric random access memory, electro-optic switches, pyroelectric detectors, optical modulators, mixers etc.[1–3]. Among all the known ferroelectric oxides of different structural families, oxides of tungsten bronze family have been found promising candidates for wide spread technological applications. The tungsten bronze structure consists of a complex array of distorted  $\text{BO}_6$  octahedral sharing corners in such a way that three different types of interstices ( $A_1$ ,  $A_2$ , and C) are available for cations of a

S.Devi et al.

general formula  $(A_1)_2(A_2)_4(C)_4(B_1)_2(B_2)_8O_{30}$ . As the smallest interstice C is generally empty, the filled tungsten bronze structure could have a general formula  $A_6B_{10}O_{30}$ . As the dielectric properties of these possible tungsten bronze tantalates are expected to be very interesting, it is an important to search for new low loss dielectric materials in this family for future applications. Detailed literature study reveals that attempts have also been made to develop some ferroelectric niobates, vanadates and tantalates having TB structure [4-9] to enhance some of their properties. One such compound which has drawn our attention is  $Na_2Pb_2Eu_2W_2Ti_4Ta_4O_{30}$  (NPEWTT) and has already been examined elsewhere [10] and some of its properties have been reported. Detail literature survey shows that no work has been reported on the electrical properties of the above compound. In the present work, we report the extensive study to explore the impedance properties of NPEWTT compound. The article is organized into four sections. After the introduction, the second section describes the experimental study process followed by a discussion on the results. The last section provides some concluding remarks.

### Experimental

The polycrystalline sample of  $Na_2Pb_2Eu_2W_2Ti_4Ta_4O_{30}$  (NPEWTT) was synthesized by a solid-state reaction technique using high-purity (AR grade) ingredients:  $Na_2CO_3$  (99%, M/s S.D. Fine Chem. Ltd.),  $TiO_2$ ,  $Ta_2O_5$  and  $WO_3$  (99%, M/s LOBA Chemie Pvt. Ltd. India),  $PbO$  (99.9% M/s E Merk India Ltd),  $Eu_2O_3$  (99.9%, M/s Indian rare earth Ltd). These oxides as well as carbonate were (taken in stoichiometry proportion) mixed in dry (air) and wet (methanol) medium for two hours each in agate mortar. The mixed material was calcined at an optimized temperature ( $1100^\circ C$ ) on the basis of repeated firing and mixing for 4 h in alumina crucible. An X-ray diffraction (XRD) pattern on calcined powder was recorded at room temperature using X-ray powder diffractometer (Rigaku Miniflex). The  $CuK\alpha$  radiation ( $\lambda = 1.5405 \text{ \AA}$ ) was used to collect data in a wide range of Bragg's angle ( $2\theta$ ) ( $20^\circ \leq 2\theta \leq 80^\circ$ ) at a scanning rate of 3 deg/min for preliminary structural analysis. The powder was then pelletized under the uniaxial pressure of 3.5 ton with polyvinyl alcohol (PVA) as binder. The pellets were then sintered at  $1150^\circ C$  for 6 h. The polished sintered pellet was electroded with high purity and quality silver paste and, dried at  $150^\circ C$  for 4 h before taking dielectric and electrical measurements. The surface morphology of a gold-coated pellet sample was recorded by JEOL JSM-5800 scanning electron microscope (SEM). The capacitance, dissipative factor, and impedance parameters on silvered-coated pellet was obtained as a function of temperature ( $29-500^\circ C$ ) in a wide range of frequency (0.1kHz-1MHz) using a computer-controlled impedance meter (Hioki 3532 LCR Hitester) with a laboratory-designed and fabricated sample holder and furnace. To record the temperature at small interval, a chromel-alumel thermo-couple and KUSAM MECO 108 digital milli-voltmeter were used.

## RESULTS AND DISCUSSION

### Impedance analysis

Complex Impedance spectroscopy (CIS) [11] is the most reliable technique to study the electrical properties and process of the materials. The IS technique is based on analyzing the ac response of a system to a sinusoidal perturbation, and subsequent calculation of impedance and related parameters as a function of frequency of the perturbation. Each parameter can be used to highlight a particular aspect of the material. A parallel resistance and capacitance circuit corresponding to equivalent to the individual component of the materials (i.e., bulk and grain boundary) represents a semicircle. Impedance data of materials (i.e., capacitive and resistive components), represented in the Nyquist plot, lead to a succession of semicircle. The electrical properties are often presented in terms of impedance (Z) [12], permittivity ( $\epsilon$ ) [13] and electrical modulus (M) [14]. Measurements of impedance and related parameters of the materials provide us some important data having both real (resistive) and imaginary (reactive) components. These components are calculated using some basic equations: complex impedance  $Z(\omega) = Z' - jZ'' = R_s + \frac{j}{\omega C_s}$ , complex electrical modulus  $M(\omega) = \frac{1}{\epsilon(\omega)} = M' + jM'' = j\omega\epsilon_0 Z$ , complex admittance  $Y^* = Y' - jY'' = j\omega C_p \epsilon^* = (R_p)^{-1} + j\omega C_p$  and complex permittivity  $\epsilon^* = \epsilon' - j\epsilon''$  where  $\omega = 2\pi f$  is the angular frequency;  $C_0$  is the geometrical capacitance,  $j = \sqrt{-1}$  and subscripts p and s are parallel and series circuit components respectively.

24315

S.Devi et al.

Figure 1. (a) and (b) show the variation of the real part ( $Z'$ ) and imaginary part ( $Z''$ ) of impedance with frequency at various temperatures. It is observed that the magnitude of  $Z'$  decreases with the increase in both frequency as well as temperature indicating an increase in ac conductivity with the rise in temperature and frequency. The values of  $Z'$  for all temperatures merge above 10 kHz. This may be due to the release of space charges as a result of reduction in the barrier properties of material with the rise in temperature, and may be a responsible factor for the enhancement of ac conductivity of material with temperature at higher frequencies. Further, at low frequencies the value of  $Z'$  decreases with rise in temperature showing negative temperature coefficient of resistance (NTCR) type behavior (like that of semiconductors). The variation of  $Z''$  with frequency attains a maximum value ( $Z''_{\max}$ ) at a particular frequency known as electrical relaxation frequency for all temperature. The magnitude of  $Z''_{\max}$  decreases with temperature indicating an increasing loss in the resistive property of the sample. The value of  $Z''_{\max}$  shifts to higher frequencies with increasing temperature. This indicates an increase in the value of the tangent loss of the material. A significant increase in the broadening of the peaks with increase in temperature suggests the existence of a temperature dependence of the electrical relaxation phenomenon in the material. The relaxation process may be due to the presence of electrons/immobile species at low temperatures and defects/vacancies at higher temperatures [15]. The asymmetric broadening of the peaks suggests a spread of relaxation time with two equilibrium positions.

Fig 2. shows complex impedance spectrum (Nyquist plots i.e.  $Z''$  versus  $Z'$ ) with fitted data [16] at different temperatures. The single semicircular arcs of  $Z'' - Z'$  plots at temperatures  $\leq 350$  °C indicate that the electrical processes in the material arises basically due to the contribution from bulk material (grain interior) and can be modeled as an equivalent electrical circuit comprising of a parallel combination of bulk resistance  $R_b$  and bulk capacitance  $C_b$ . At higher temperatures,  $\geq 375$  °C two overlapping semicircular arc have been observed which represents the contribution of both bulk and grain boundary effect. As the temperature increases, the intercept of the semicircles at the  $Z'$  axis shifts towards lower  $Z'$  values, indicating the reduction of the grain (bulk) resistance and grain boundary. The decrease in the value of  $R_b$  is associated with an increase in conductivity with rise in temperature, also the decrease in  $R_{gb}$  values with increase in temperature, suggest a lowering of the barrier to mobility of charge carriers aiding electrical conduction at higher temperature. Further, the depressed semicircles have their centers below the real axis, which indicates the departure from the ideal Debye-type behavior. The values of the electrical or transport parameters corresponding to the equivalent circuit modeled by fitting processes of the measured data at different temperatures are given in Table 1. All the fitted parameters ( $R_b$ ,  $C_b$ ,  $Q$  and  $n$ ) show an anomaly at 375°C due to its ferroelectric to paraelectric phase transition at that temperature [10].

The frequency dependence of imaginary component of impedance ( $Z''$ ) and modulus ( $M''$ ) is shown in Fig. 3. The combine plot of  $Z''$  and  $M''$  as a function of frequency is used to detect the presence of the smallest capacitance and the largest resistance [17]. This plot also helps to distinguish whether relaxation process is due to short range or long range motion of charge carriers. For the short range process, peaks of  $Z''$  and  $M''$  will occur at different frequencies whereas for long range they will occur at same frequency [18-19]. In the studied compound there is mismatch of peaks of different temperatures which suggests short range motion of charge carrier and departure from ideal Debye-like behavior.

### Modulus analysis

Complex modulus formalism is a very important and convenient tool to determine, analyze and interpret the dynamical aspects of electrical transport phenomena (i.e parameters such as carrier/ ion hopping rate, conductivity relaxation time, etc). It provides an insight in to the electrical processes characterized by the smallest capacitance in accordance with the relations :

$$M' = \omega C_0 Z' \quad \text{and} \quad M'' = \omega C_0 Z'' \quad , \quad C_0 = \epsilon_0 A/t$$

( $\epsilon_0$ = permittivity of free space,  $A$ =Area of the electrode surface and  $t$ = thickness of the sample).

Fig 4. shows the variation of  $M'$  and  $M''$  with frequency at selected temperatures.  $M'$  is characterized by a very low value (almost zero) in the low frequency region then a continuous increase with an increase in frequency, having a

S.Devi et al.

tendency to saturate at a maximum asymptotic value in the high frequency region for all temperatures. The value of  $M'$  approaches to zero at low frequency whereas monotonic dispersion with rise infrequency may be due to presence of conduction phenomenon and short range mobility of charge carriers. This implies the lack of restoring force for flow of charge under the influence of steady electric field [20]. The variation of  $M''$  with frequency shows peaks at a unique frequency that describes the type and strength of electrical relaxation phenomena in the material. The  $M''_{max}$  peak shifts to higher frequency side which suggests the hopping mechanism of charge carriers dominates intrinsically is thermally activated process. Asymmetric broadening of the peak indicates spread of relaxation with different time constants, which suggests non- Debye type [21].

The scaling behavior of the sample was studied by plotting normalized parameters (i.e.,  $M''/M''_{max}$ vers  $\log (f/f_{max})$ ) where  $f_{max}$  corresponds to a value of  $M''_{max}$ at different temperatures (Fig.5). This curve gives an insight into the dielectric processes occurring inside the material as a function of temperature. The coincidence of the curves at different temperature indicates the temperature independentbehavior of dynamic processes occurring in the material [22].This may be due to charge carrier migration by hopping mechanism. The frequency region where the peak occurs indicates the transition from long range to short range mobility [23].

### AC Conductivity

The frequency dependence of ac conductivity,  $\sigma(\omega)$ , at various temperature is shown in Fig. 6. At low temperatures the conductivity increases with rise in frequency, which is a characteristic of  $\omega^n$  ( $n$ =exponential). At high temperatures and low frequencies conductivity shows a flat response while it has a  $\omega^n$  dependence at high frequencies. The phenomenon of the conductivity dispersion in solids is generally analyzed using Jonscher's power law; [24]  $\sigma_{ac} = \sigma_{dc} + A\omega^n$ , where  $\sigma_{dc}$  is the dc conductivity (frequency independent plateau in the low frequency region),  $A$  is the temperature dependent frequency pre-exponential factor and  $n$  is the power law exponent in the range of  $0 \leq n \leq 1$ . The exponent  $n$  represents the degree of interaction between mobile ions with the lattice around them, and the pre exponential factor  $A$  determines the strength of polarizability. The material obeys the universal power law, and is confirmed by a typical fit of the above equation to the experimental data at various temperatures. It is obvious that  $\sigma_{ac}$  increases with rise in frequency but it is nearly independent at low frequency region.

Therefore, extrapolation of this part towards lower frequency side gives  $\sigma_{dc}$ . The increasing trend of  $\sigma_{ac}$  with rise in frequency (in low frequency region) maybe attributed to the disordering of cations between neighboring sites, and presence of space charge. In the high frequency region the curves approach to each other. The nature of conductivity plots reveals that the curves exhibit low frequency dispersion phenomena obeying the Jonscher's power law. According to Jonscher's the origin of the frequency dependence of conductivity lies in the relaxation phenomena arising due to mobile charge carriers. When a mobile charge carrier hops to a new site from its original position, it remains in a state of displacement between two potential energy minima. From non-linear fitting it is found that the motion of charge carriers in the samples is translational one because of small value of  $n$  ( $<1$ ) [25]. In the high frequency domain the conductivity becomes more or less independent of frequency. This typical behavior suggests the presence of hopping mechanism between the allowed states.

### DC Conductivity

Fig. 7.shows the variation of DC conductivity with respect to inverse of absolute temperature. The value of bulk conductivity of the material was evaluated from the complex impedance plots of the sample at different temperatures using the relation  $\sigma_{dc} = t/AR_b$  where  $R_b$  is the bulk resistance,  $t$  the thickness and  $A$  is the surface area of the sample respectively. The dc conductivity increases with rise in temperature confirming the negative temperature co-efficient of resistance (NTCR) behavior. This plot follows the Arrhenius relation:  $\sigma_{dc} = \sigma_0 e^{(-E_a/(K_B T))}$ . The activation energy was calculated from the linear portion of the plot of DC conductivity versus  $10^3/T$  (Fig.7) and was found to be 0.6 eV. Usually, activation energy less than 1.0 eV is connected to singly ionized vacancies and /or electronic mobility in space charge region [26]. So, the conduction process with in this temperature range may be due to the hopping of charge carriers and /or singly ionized oxygen vacancies of the ceramic.

### Concluding Remarks

The complex impedance plots reveal the contribution of both bulk and grain boundary effects in the sample. The material shows NTCR character, temperature dependent relaxation phenomena and polydispersive non-Debye type dielectric relaxation. Modulus analysis has established the possibility of a hopping mechanism for electrical transport processes in the material. The ac conductivity obeys the universal power law and dispersion in conductivity is observed in the lower frequency region. The dc conductivity is observed to increase with increasing temperature further confirming NTCR behavior.

### ABSTRACT

The polycrystalline samples of  $Pb_{2-x}Ba_xBiVO_6$  ( $x=0, 0.5, 1, 1.5$  &  $2$ ) were synthesized by low temperature solid state reaction route. Calcination temperature of the studied samples were optimized around  $710^\circ\text{C}$  by repeated firing process. The XRD pattern under room temperature of the samples have been analyzed. It is found that the diffraction peaks are different from that of the ingredients confirming the formation of new compounds. The surface morphology (shape, size and distribution of grains and pores) of the pellet sample was recorded using scanning electron microscope (SEM). For better understanding of structural analysis FTIR spectroscopy technique has been adopted. It is observed bending and stretching vibration are dominating features for affecting the physical properties of the studied compound. The optical band gap calculation and electronic transition of the materials are studied using UV-Vis spectroscopy.

**Keywords:** Double perovskites; SEM; FTIR, UV-Vis spectroscopy

### INTRODUCTION

Ferroelectric perovskites constitute interesting compounds, due to their switching behavior make it potential applications in nonvolatile memories, pyroelectric detector, and their piezoelectric properties are instrumental for transducer, actuators and sensors. Perovskite oxides having a orthorhombic high-symmetry structure in particular a double perovskite represented by the formula  $A_2BB'O_6$  emphasize the long range ordering of B-sites following a rock-salt pattern [1] might be realized experimentally and may have interesting ferroelectric properties. Marginal differences between B and B' cations in either oxidation state or size are conducive for their ordering process. Many double perovskites having two cations with partially filled d-shells exhibit ferro- or ferrimagnetisms and some of them offer magneto resistance effects [2] Again the presence of  $Bi^{3+}$  or  $Pb^{2+}$  ions on A-site favors the appearance of polar structures.

This is due to the  $6s^2$  lone-pair and the strong covalent character of both Bi-O, Ba-O and Pb-O bonds which stabilize a non-centro symmetric distorted environment [3, 4]. Apart from this the double perovskite ( $A_2BB'O_6$ ) is the center of attraction as per as ferroelectric and piezoelectric materials are concerned which is supposed to be a potential candidate for the application in capacitors. Now a day the same scenario was extended from the common perovskite oxides  $ABO_3$  to more complex system such as the ordered Perovskite [5]. These materials are having a large amount of academic interest and have potential applications in catalysis, magnetic media, and electrical conductors and gas sensors, with both the content and the structural distortions of the B/B'O6 octahedral being important factors in determining their physical behavior [6]. Although much work has been done on dielectric and electrical properties of double perovskite [7-11], yet detailed information on structural, optical, dielectric and electrical properties of lead based double perovskite is lacking in literature. In view of this we have synthesized 'Ba' doped lead reducing double perovskite compounds with chemical formula  $Pb_{2-x}Ba_xBiVO_6$  ( $x=0, 0.5, 1, 1.5$  &  $2$ ) by solid state reaction method and studied their structural and optical, properties for possible device application.

### Experimental

The polycrystalline samples of  $Pb_{2-x}Ba_xBiVO_6$  ( $x=0, 0.5, 1, 1.5$  &  $2$ ) were synthesized by a solid-state reaction technique using high-purity (AR grade) ingredients: PbO (99%, M/s S.D. Fine Chem. Ltd.),  $Bi_2O_3$ ,  $V_2O_5$  and  $BaCO_3$  (99%, M/s LOBA Chemie Pvt. Ltd. India). These oxides as well as carbonate were (taken in stoichiometry proportion) mixed in dry (air) and wet (methanol) medium for two hours each in agate mortar. The mixed material was calcined at an optimized temperature ( $710^\circ\text{C}$ ) on the basis of repeated firing and mixing for 4 h in alumina crucible. An X-ray diffraction (XRD) pattern on calcined powder was recorded at room temperature using X-ray powder diffractometer (RigakuMiniflex). The  $CuK\alpha$  radiation ( $\lambda = 1.5405\text{\AA}$ ) was used to collect data in a wide range of Bragg's angle ( $2\theta$ ) ( $20^\circ \leq 2\theta \leq 80^\circ$ ) at a scanning rate of 3 deg/min for preliminary structural analysis. The powder was then pelletized under the uniaxial pressure of 3.5 ton with polyvinyl alcohol (PVA) as binder. The pellets were then sintered at  $725^\circ\text{C}$  for 6 h. The polished sintered pellet was electroded with high purity and quality silver paste and, dried at  $150^\circ\text{C}$  for 4 h before taking dielectric and electrical measurements. The surface morphology of a gold-coated pellet sample was recorded by JEOL JSM-5800 scanning electron microscope (SEM). The structural and optical characterizations of the synthesized compounds have been carried out with the help of XRD, SEM, EDS, RAMAN, FTIR, and UV-Vis spectroscopy analysis respectively. FTIR spectrometer JASCO, Model-FTIR-4100 is used to study the vibrational analysis.

### Structural and Optical Study

#### XRD analysis

The powder XRD patterns at  $25^\circ\text{C}$  for  $Pb_{2-x}Ba_xBiVO_6$  ( $x=0, 0.5, 1.0, 1.5, 2$ ) are shown in **Fig.1**. The formation of homogeneous, well crystallized and single phase new compound is conformed from the sharp and well defined peaks [12]. Generally, the structures of double perovskites have monoclinic, tetragonal or orthorhombic. So we have indexed these within the selected systems using commercially available software "POWD" [13]. From the knowledge of best fit data with respect to the observed value and calculated values of inter planner spacing, an orthorhombic unit cell has been selected. The lattice parameters (a, b and c) have been calculated from the peaks position of the peaks in the diffractograms. The observed values of a, b and c have been refined using least-squares fit of the observed positions ( $d_{hkl}$  interplanar spacing) of the peaks so that  $\sum \Delta d = \sum (d_{obs} - d_{cal})$  was found to be minimum. Table 1 represents the standard deviations of the studied samples which indicates the best agreement between the observed and calculated values of interplanner spacing and hence authenticates the correctness of the chosen crystal system and unit cell parameters. The evaluated values of different parameters of the unit cell of the samples are in concurrence with that of earlier report [14]. Primary investigation on the reflections with proper indexing predicts that the materials may have Pmma space group. The average size of the particles in the compounds can be

calculated by using the Scherrer's equation:  $P_{hkl} = \frac{K\lambda}{\beta_{1/2} \cos\theta_{hkl}}$  [15], where K is a constant whose value is equal to

**A. Rout and S. Behera**

0.89,  $\lambda=1.5405\text{\AA}$  and  $\beta_{1/2}$ = full width at half maximum (in radians). Orthorhombic distortion is calculated by using  $\delta=[b-a/b+a]$  with 'a' and 'b' are lattice parameters. The refined lattice parameters and average value of particle size are also given in Table 1. The average value of particle size (P) of the above compounds is found to be in between 47 -58 nm using Scherrer's formula [16]. The average particle size found to be small due to the bigger value of full width half maxima (FWHM). The calculated values of lattice parameters are also reflected in table 3.2. As the structure of DP consists of five crystallographic sites as seen fig. 1 so, from the knowledge of the present result, it can precisely determine the  $\text{Ba}^{+2}$  ions (A-site ions) prefer 12-fold coordination [16]. The strongest peaks of different compounds occurring at Bragg angle  $28.77^\circ$ ,  $28.10^\circ$ ,  $27.70^\circ$ ,  $27.54^\circ$ ,  $27.46^\circ$  and the respective miller indices are, (3 0 4), (1 3 ,12), (2 0 2) and (1 1 1) and (10,0 1). This show, the most of the atoms are distributed in the respective planes are different for different  $\text{Ba}^{+2}$  concentrations.

**SEM and EDX Analysis**

Fig. 2 shows the surface morphology of the studied compounds by Scanning Electron Microscope (SEM) device using gold plated bulk pallet sample. The room temperature SEM micrograph confirms highly dense compounds, even distribution of grains and well separated grain boundaries. It predicts that the charge carriers could easily find their path to enhance the leakage current and material may be lossy. The number of well-defined grain boundaries increase as compared to pure lead  $\text{Pb}_2\text{BiVO}_6$ , when  $\text{Ba}^{+2}$  ion is substituted at A-site. Due to this dielectric loss of samples will increase and hence ac conductivity of the sample may be higher [17]. Even though the materials are sintered at high temperature, then also some small voids of irregular shape and size are observed in the compound. Due to the presence of voids, it is expected that charge carriers will show hopping type of motion. The average grain size of the studied samples have been calculated by intercept technique and are found to be 1.785, 1.845, 1.855, 1.734 and 1.725  $\mu\text{m}$  respectively. EDS analysis of the studied compounds are shown in Fig. 3 and it is useful to confirm the purity and percentage of composition. The EDS analysis also suggests that the compound is pure and free from foreign particle.

**RAMAN Spectroscopy study**

In order to characterize materials, measurement of phase transition temperature and to understand the orientation of crystallographic axes of a sample Raman spectroscopy is widely used by material scientists. As we know frequencies of different mode of vibrations are more appropriate to a molecule's chemical bonding and crystal structure, hence Raman and IR spectra are used to estimate the frequencies of vibration on the basis of normal coordinate system. Fig. 4 represents the Raman spectra of the studied samples. Deconvolution using peak-fit software for better understanding of the peak position and FWHM are incorporated in the present study which is represented by red colored lines. The different Raman modes of vibration of the studied samples are reflected in the respective figure. Depending on the doping concentrations it is believed that after doping 'Ba' in  $\text{Pb}_2\text{BiVO}_6$  few 'Ba' are substituted to 'Pb'. The atomic mass of 'Ba' is just smaller than 'Pb' which refers to the larger ionic radius of Pb. The 'Ba' doping will produce compressive stress inside the  $\text{Pb}_2\text{BiVO}_6$  which affects the Raman spectra [18-20]. Hence compressive stress developed is the key factor for different analysis. The other observed bands are also a consequence of 'Ba' doping in the lead based double perovskite. The signature of octahedral phase in PBV is due to the peaks under low frequency range i.e. (200–300)  $\text{cm}^{-1}$ . The higher bands between (650-1057)  $\text{cm}^{-1}$  are due to orthorhombic phase of the PBBV structure [21]. The difference in mass and ionic radius of Ba undoubtedly connected with the shift of Raman bands and its broadening which in turn produce stress inside the matrix due to the phase change. The weaker satellite bands are due the V-O and Ba-O vibrational modes around the main Raman modes of V-Bi, V-Ba, Ba-Bi and Ba-Pb bonds.

**FTIR Analysis**

The FTIR spectrum of the sample was recorded for the wave number from (400 to 4000)  $\text{cm}^{-1}$ . Powder samples were dried before pelletizing to get the sample moisture free before the measurement. The room temperature FTIR spectra of the studied sample in the range of (4000–400)  $\text{cm}^{-1}$  are shown in fig. 5. In the FTIR spectra, different types of

### A. Rout and S. Behera

vibrations are occurring in the studied compounds which are reflected in the respective figures. Generally, the well-defined transmittance bands between 850 - 400  $\text{cm}^{-1}$  are associated with the lattice vibration modes (phonons) having the typical profile expected for an insulating/perovskite material is usually used for the perovskite phase identification [22]. The strongest band at  $\sim 677, 739, 677, 677$  &  $807 \text{ cm}^{-1}$  of the investigated materials is assigned to the anti-symmetric stretching mode of the octahedral  $\text{VO}_6$  and  $\text{BiO}_6$  due to the higher charge of this cation [23]. The IR spectrums at 417, 422, 417, 516 &  $526 \text{ cm}^{-1}$  of the respective samples is assigned to the of O-V-O asymmetric bending modes which are strong in the infrared spectrum. The bands located at 864, 866, 864, 807 &  $858 \text{ cm}^{-1}$  are assigned to C=C stretching mode of vibrations of the samples ( $x=0$  to 2). The bands located in between  $1000\text{-}1800 \text{ cm}^{-1}$  may be attributed as C=O stretching vibration of the studied compounds [24]. The band in between  $3500\text{-}3700 \text{ cm}^{-1}$  is assigned to hydroxyl (OH) stretching vibration obeying mutual exclusion principle as well as hygroscopic nature of the studied compounds [25]. It is observed for Ba composition of  $x=1.5$  & 2 does not show any hygroscopic behavior.

#### UV-Vis Spectroscopy

The diffuse absorbance of the studied compound is shown in Fig. 6. In a typical UV/vis spectroscopy measurement, both transmittance as well as absorbance of photons is measured by the sample. It has been seen that a broad peak near UV range in the transmittance spectra is observed as sample does not absorb strongly whereas in the visible portion of the spectra the reverse effect have been observed. The absorption cut-off wavelength of the samples are within 500-600 nm indicates that the studied compounds could absorb visible light in the wavelength range of 400-600 nm. The optical band gap ( $E_g$ ) of the samples can be calculated using the relation  $\alpha E = A (E - E_g)^n$ , Where  $\alpha$  is absorption coefficient,  $E = hc/\lambda$ , is the photon energy,  $A$  is a constant,  $n$  is an index assumed to have values like  $n=1/2, 3/2$  or 2. For ceramic compounds exhibit direct transition, so the value of  $n$  is assumed as 1/2 and the energy band-gap of sample could be estimated from Tauc plot in fig 6 [26]. The tangent line, which is extrapolated to  $(ah\nu)^2 = 0$ , gives the value of  $E_g$  which are reflected in respective figures.

## CONCLUSIONS

The double perovskite  $\text{Pb}_{2-x}\text{A}_x\text{BiVO}_6$  ( $A = \text{Ba}$  &  $\text{Sr}$ ,  $X= 0, 0.5, 1, 1.5$  and 2) were prepared by cost effective mixed oxide route. The formation of single phase, density and purity behavior in the compound has been verified from experimental analysis like XRD, SEM, and FTIR respectively. The optical and molecular properties of the material were studied by UV Vis which confirms that the material may be used for photovoltaic and LED devices. The band gap calculated from the above study shows that the materials are useful for photo catalytic devices.

### ABSTRACT

A new alumina ( $\text{Al}_2\text{O}_3$ )-reduced graphene oxide (RGO) composites have been prepared by mechanical ball milling route. X-ray diffraction (XRD), field emission scanning electron microscopy (FESEM) and microhardness measurements have been carried out to optimize the samples. Microhardness of the composites were increased with increasing content of RGO from 1 wt% to 2 wt% in  $\text{Al}_2\text{O}_3$  matrix.  $\text{Al}_2\text{O}_3$ -RGO with 2 wt% RGO shows microhardness of  $1612 \pm 14$  VHN against of microhardness of pure  $\text{Al}_2\text{O}_3$  is  $1420 \pm 05$  VHN.

**Keywords:** Reduced Graphene Oxide, Composite, Microstructural, Mechanical Property

## INTRODUCTION

Alumina ( $\text{Al}_2\text{O}_3$ ) shows good mechanical hardness and chemical inertness, moderate thermal conductivity, high corrosion and wear resistance and Low density ( $3.75$  to  $3.95$   $\text{g/cm}^3$ ). This material has poor fracture toughness which restricts its use. It is used as an attractive ceramic for advanced high temperature structural applications and it is currently used in electronics, aerospace and automotive industries [1-5]. To improve the properties of this material, various reinforcements were used such as WC, B<sub>4</sub>C, TiC and graphene. Among all sample reinforcements in alumina with graphene was found as a best alternative. Graphene which is a single layer of carbon shows outstanding electrical mechanical, thermal, optical and electronic properties [6-7]. The graphene shows outstanding Young's modulus of  $1.0$  TPa, electron mobility of  $15000$   $\text{cm}^2$   $\text{V}^{-1}\text{S}^{-1}$ , 100 times stronger than steel, high electrical and thermal properties [5-10]. It is thought that by addition of graphene (1-5 wt%), properties of composites can be explored. Graphene helps to increase density, mechanical property and toughness of  $\text{Al}_2\text{O}_3$ . But there is also a challenge to prepare such a composite. But in literature it is addressed that by addition graphene in alumina and processing by ball mill route is a novel choice to prepare such super composite. The work successfully reports  $\text{Al}_2\text{O}_3$ -RGO

**Sushree Subhadarsi Bhole et al.**

composite by ball milling route followed by sintering. The composite nature is evaluated by using X-ray diffraction (XRD), Field emission scanning electron microscopy (FESEM) and Nanoindentation technique.

### Experimental

In this work planetary ball mill was used to prepare composite of alumina+reduced graphene oxide composite. Planetary ball mill is powered by the two motors, one motor is used to rotate the shaft and another one is used to drive both the jars. It is fed with a sample-to-ball charge ratio of 1:8 and the balls taken here are stainless steel balls of diameter 7 mm and 5 mm were put into the hardened steel jar. Then both the jars are rotated simultaneously and separately at a speed of 400 rpm and 150 rpm respectively and due to the this rotation, shaft makes the balls to move strongly and violently, leading to large impact energy of balls on the sample that improves the kinetics of grinding and ultrafine communication results. After ball milling of 8 hrs completed, samples were taken for sintering. The sintering of 4-5 mm dia. samples were carried out at 1500 °C after 7 hrs of sintering. After that the samples were characterized by using various techniques.

## RESULTS AND DISCUSSION

The X-ray diffraction study was used to understand crystalline nature, phase purity of Al<sub>2</sub>O<sub>3</sub> and Al<sub>2</sub>O<sub>3</sub>-RGO (2 wt%) composite samples. The analysis result was done and presented in Fig. 1. The composites having phases and planes are identified by comparing the determined *d*-values (experimentally determined) with the *d*-values of standard powder diffraction data file, C (graphite-2H): 00-041-1487 and Al<sub>2</sub>O<sub>3</sub>: 01-075-1862 supplied in JCPDS-ICDD PDF-2 (2004). The XRD results were taken in 2θ range of 5°-80°. The composite formation of nature of the sample is confirmed from the XRD analysis report. The XRD analysis of only ball milled Al<sub>2</sub>O<sub>3</sub> shows the peaks Al<sub>2</sub>O<sub>3</sub> with different planes of diffraction as (104), (110), (113), (024), (116), (122) and (214). Al<sub>2</sub>O<sub>3</sub> shows two intense major peaks at around 2θ = 40.0° and 2θ = 51.0°. Similar kind of result was observed by other. In case of Al<sub>2</sub>O<sub>3</sub>-RGO composite characteristic peak of C (002) is strongly appeared at 2θ = 30.0° due to the presence of RGO in the Al<sub>2</sub>O<sub>3</sub>-RGO composite. The position and FWHM of the peaks of the different phases with different planes were studied to their standard values which indicate the well-ordered and better crystalline nature of the composite.

FESEM analysis of the typical composites of Al<sub>2</sub>O<sub>3</sub>-RGO with content of RGO 2 wt% is presented in Fig.2. It is understood that uniform distribution of RGO within the Al<sub>2</sub>O<sub>3</sub> grains is very important to prepare superior quality composite for various advanced applications. In Al<sub>2</sub>O<sub>3</sub> with RGO 2 wt% shows regular distribution graphene or RGO grains. The composite is also found to free from micro porosity and any kind of surface defects. Microhardness of Al<sub>2</sub>O<sub>3</sub> and Al<sub>2</sub>O<sub>3</sub>-RGO (1 & 2 wt%) composites determined by micro indentation technique method. Before graphene/RGO is reinforced to Al<sub>2</sub>O<sub>3</sub> phase, it was thought that it may increase the mechanical property of the composites. This is interestingly matching to our expectation that the microhardness value increases with increase in RGO content. Here only alumina shows hardness of 1420 ± 05 VHN. In this work the value of microhardness of Al<sub>2</sub>O<sub>3</sub>-RGO (2 wt%) is found to be higher i.e. 1612 ± 14 VHN. Porosity free nature of the composite along with optimized sintering has some contribution for the development of mechanical property. The above improved microhardness inspires to use the composite for advanced structural applications in aerospace and automotive industries, etc.

## CONCLUSION

In this work, it has been possible to prepare two different compositions of Al<sub>2</sub>O<sub>3</sub>-RGO by varying wt% of RGO from 1-2 wt%. All Al<sub>2</sub>O<sub>3</sub>-RGO composites were ball milled by using a dry planetary ball milling technique for 8 hr. After ball milling, the samples were sintered at 1500 °C for 7 hr. The peaks of Al<sub>2</sub>O<sub>3</sub> and C (graphene/RGO) were observed by XRD analysis in the composites. The composite nature further confirmed from FESEM analysis. Micro free porosity and any kind of surface defects is not observed in FESEM. The uniformity of distribution of graphene/RGO

is found in microstructure. In this work, it is evident that the microhardness and of Al<sub>2</sub>O<sub>3</sub>-RGO composites were found to increase when 2 wt% of RGO is added. Al<sub>2</sub>O<sub>3</sub> and Al<sub>2</sub>O<sub>3</sub>-RGO with 2 wt% RGO has microhardness of 1420 ± 05 VHN and 1612 ± 14 VHN respectively. Such values of microhardness indicate reduced brittleness of the composites. Overall attempt has been taken in the work to correlate RGO content with various microstructural properties and hardness. The composite of Al<sub>2</sub>O<sub>3</sub>-RGO with improved mechanical property has great future scope to prepare advanced ceramic and structural components.

### ABSTRACT

A novel method of creating new lightweight aluminium-graphene composite materials is proposed in this work. The aluminum-graphene composite is prepared by reinforcing 1 wt% of graphene in aluminium matrix. Composites of graphene platelets and powdered aluminium were made using ball milling, pressing and sintering. The mechanical properties and microstructure were studied using Vickers hardness and as well as FESEM, X-Ray Diffraction. From FESEM analysis, the composite with 1wt% graphene shows irregular distribution of graphene on the matrix of Al. Grain size was found in the range of 4-7  $\mu\text{m}$ . Al-graphene with 1wt% shows hardness value of 58 VHN. Microstructural and microhardness results indicate that graphene addition improves structural and mechanical property of composite.

**Keywords:** Graphene, Aluminum, XRD, Composite

### INTRODUCTION

Materials are may be more rooted in our culture than we might think. Even the stone, bronze and iron ages are all named after material development of the respective era. In our everyday lives, materials play a big role: metals in everything from electronics to bridges and buildings, ceramics for pottery, knives and as a construction material, polymers in our clothes and plastics and composites in everything from concrete to aerospace applications. In recent years, more advanced materials have been developed for high technology applications; semiconductors, biomaterials, smart materials and nanomaterials. A recent leap in material science was the discovery of a new material which has the potential to alter the future, dubbed a “super material” i.e. Graphene. It is a super strong and stiff, amazingly thin almost completely transparent, extremely light and wonder condition of heat and electricity [1-

24331

**Sarita Nayak et al.**

4]. Graphene has emerged as one of the most promising nanomaterials because of its unique combination of superb properties [5-7]. Aluminum is a common used materials used for electrical, aerospace and lightweight materials applications [8-10]. But it has the limited electrical conductivity with conditional mechanical applications. Hence it is supposed that by addition of graphene in aluminium, a super composite can be developed which has great industrial applications. Graphene with has high strength, excellent electrical with high specific surface area improve the application horizon of this material. The work reports aluminum-graphene composite (1 wt%) preparation by 8 hrs of ball milling followed by 560°C for 6 hrs sintering. Properties were studied by employing various characterization techniques such as such as X-ray diffraction (XRD), field emission scanning electron microscopy (FESEM), and Microhardness. Al-graphene composite (1 wt%) prepared by 8 hrs of milling shows high microhardness value than pure Al.

## Experimental Details

### Materials

The following materials were used for the synthesis of aluminium-graphene composite:

1. Graphene
2. Aluminium powder

### Pellet preparation

Moreover, we take the sample (aluminium, aluminium-graphene) and ground it for half an hour using a pulveriser machine for the better blending of the samples. Furthermore, we take the powder composites in a mortar and add a small amount of PVA (polyvinyl alcohol) gum into it. Then the PVA gum mixed with the samples properly followed by grinding which is done for 20-25 minutes for diminishing the size of the composites. In addition, by the use of hydraulic pressure machine, for intensifying the pressure up to 50 kg/cm<sup>2</sup>, we get pellets of composites of distinct diameters.

### Synthesis of graphene-aluminium nano composite by ball milling process

To generate the impact and shear forces to particles, the planetary ball mill was designed and have the ability to surmount the contour of gravitational field and to supply a strong acceleration field. In this experiment, the powder-to-ball ratio is kept 1:10 for each jar. Without any solvents, additives, and chemicals, the sample containing jars were placed inside a glove bag. Then the samples for ball milling were weighed for aluminium and graphene in the ratio 99:1 weight percentage and taken in jar-1. Likewise, pure Aluminium was taken in jar-2. Wherein jar-1 contains stainless steel balls having diameter 8mm (300gm) of weight 1kg and similarly, jar-2 also contains the stainless steel balls of weight 1kg having a diameter of 6mm(700gm). These balls were used as a medium of grinding and also to maintain the constant frequency of 26.1Hz for a continuous time period of 8 hours because the motors, which are fixed with the ball mill, rotates with the help of electricity. Finally, all the samples were being cooled down by placing it in a refrigerator and this sample derivatives can be used for different experiments thereafter.

## RESULTS AND DISCUSSION

### Analysis by XRD

Crystalline nature and phase purity of aluminium-graphene composite samples were studied by XRD. The result interpretation with assigned peaks is shown in the fig:1-2. XRD pattern is taken within the range of  $2\theta=5^{\circ}$ - $80^{\circ}$ . The composite formation of aluminium-graphene is confirmed from the XRD analysis report. The XRD analysis of ball milled aluminium shows the peaks of only Al. Different diffracted peaks of Al like (111), (200) and (311) are observed in the ball milled Al sample. The XRD result of Al-graphene (1wt%) interestingly shows the peaks of graphene as C(002) with peaks of Al. So, XRD result confirms the composite formation of Al-graphene. The position and FWHM

**Sarita Nayak et al.**

of the peaks of the different phases with different planes were studied and compared to their standard values with JCPDS files which indicate the well-ordered and better crystalline nature of the composite.

**Analysis by FESEM**

Al-graphene (1wt%) composite after sintering was taken for FESEM analysis. FESEM analysis of 1wt% (Fig. 3) shows clearly the presence graphene flakes on the matrix of Al. The grain distribution of graphene found to be irregular. But no defect and porous structure is found in the FESEM microstructures. FESEM it indicates the quality of sample prepared by good sintering condition. The grain size of graphene was found in the range of 4-7  $\mu\text{m}$ .

**Analysis by Vicker's hardness**

The microhardness of sintered Al-graphene products was determined. It is found that microhardness value increases by increasing addition of graphene. Al-graphene (1wt%) shows hardness value of 58 As per the microstructural analysis and hardness values are concerned, it is observed that graphene addition improves structural and mechanical property of composite. Al is very much popular for electrical applications. Further the present works opens a new road of research towards critical application of Al at high temperature with critical load.

**CONCLUSION**

In this present work, successfully Al-graphene (1 wt%) composites were prepared by dry planetary ball milling process followed by sintering. Samples were ball milled by using a dry planetary ball milling for 8 hrs. After ball milling over, the samples were taken for sintering at 560°C for 6 hrs. While XRD of aluminium shows only peaks of Al, aluminium-graphene composite shows peaks due to both Al and graphene. So, XRD confirms the formation of composite of Al and graphene. Al is present in its original metallic form. No oxidation of Al is detected. The composite nature further confirms from FSEM analysis. The composite with 1wt% graphene shows irregular distribution of graphene on the matrix of Al. Grain size was found in the range of 4-7  $\mu\text{m}$ . Al-graphene with 1wt% shows hardness value of 58 VHN. Microstructural and microhardness results indicate that graphene addition improves structural and mechanical property of composite.

### ABSTRACT

In this work the effect of graphene and magnesium oxide (MgO) in alumina (Al<sub>2</sub>O<sub>3</sub>) matrix has been studied. The composites were prepared by using a dry planetary ball milling technique for 8hrs followed by sintering at 1550 °C for 5 hrs. The composite nature was confirmed by XRD study. Composites were found grown with free from micro free porosity and any kind of surface defects. The uniform distribution of graphene and MgO were found in the FESEM microstructure. It is interestingly observed that the microhardness of Al<sub>2</sub>O<sub>3</sub> were found to increase when MgO (2 wt%) and graphene(1 wt%) were reinforced to the composite. The work reports microhardness of Al<sub>2</sub>O<sub>3</sub> and Al<sub>2</sub>O<sub>3</sub>-MgO (2 wt%)-graphene(1 wt%) composites as 1410 ± 04 VHN and 1712 ± 10 VHN respectively. Such high value of microhardness attributes to the improved microstructure with almost zero porosity in the composite.

### INTRODUCTION

A recent wave in the material science is the discovery of a new material which can show potential application. In this regards a super material i.e. graphene can be considered [1-5]. It is a unique material with super strong and stiff and at the same time amazingly thin & optically transparent, extremely light weight and having high heat and electricity conductivity. There is no wonder regarding its drastic implications for various industrial applications. Above properties and its various functionalities, make it super demandable for a wide spectrum of applications

24335

**Soumen Dash et al.**

ranging from electronics to optics, sensors and bio devices [4-5]. Now researchers are applying this material with other materials (such as plastics, metals and ceramics) to make composites that are stronger and tougher. Alumina ( $\text{Al}_2\text{O}_3$ ) is known as an attractive ceramic for advanced high temperature structural applications and it is currently used in electronics, aerospace and automotive industries [5-10].  $\text{Al}_2\text{O}_3$  shows high mechanical hardness, moderate thermal conductivity, High corrosion and wear resistance, Low density (3.75 to 3.95  $\text{g/cm}^3$ ) [11]. On the other hand it has the poor fracture toughness which restricts its use. The addition of graphene and magnesium oxide has the potential to enhance fracture toughness of  $\text{Al}_2\text{O}_3$ . In this research work attempt has been taken to prepare a novel composite of  $\text{Al}_2\text{O}_3$ -MgO-graphene composite by ball milling technique followed by sintering at 1550 °C. The microstructure, composition and hardness of composites were studied using various analytical techniques such as X-ray diffraction (XRD), Field emission, scanning electron microscopy (FESEM), Brunauer-Emmett-Teller analysis (BET) and nanoindentation.

### Experimental

Alumina, graphene and MgO are taken as the starting materials. The sample details are presented in table 1. The nano composites was prepared by both impact and shear forces developed in the planetary ball mill. The planetary ball mill works in such way that it overcomes the limitation of the gravitational field and provides strong acceleration field. The sample to ball charge ratio of 1:9 was maintained in the planetary ball mill. The ball milling of the samples was carried out for 8 hrs. After ball milled over, the samples were taken for sintering at 1550 °C for time period of 5 hrs. XRD patterns of the samples were taken by PANalytical X'Pert Pro diffractometer. The XRD patterns were taken in the  $2\theta$  range 5–95 at a scan speed of 0.019  $\text{min}^{-1}$ . The microstructures of samples were taken by FESEM (model: ZEISS SUPRA 55). Microhardness of composites was determined by Nanoindenter-UMIS system (Fisher-Cripps, Australia) with diamond Berkovich indenter (tip diameter: 400 nm) at a maximum applied load of 50 mN. Pore volume of composites were determined by BET method (Instrument used: ASAP2020, Micromeritics, USA) by  $\text{N}_2$  adsorption-desorption technique.

## RESULTS AND DISCUSSION

Crystalline nature and phase purity of  $\text{Al}_2\text{O}_3$ -MgO (2 wt%)-graphene (1 wt%) composites were studied by XRD analysis. The analysis result was done and presented in Fig.1. The crystalline behavior of composites is identified by comparing the determined  $d$ -values (experimentally determined) with the  $d$ -values of standard powder diffraction data file, C (graphite-2H): 00-041-1487,  $\text{Al}_2\text{O}_3$ : 01-075-1862 and  $\text{Al}_2\text{Mg}_0.4\text{O}_4$ : 01-087-0344 supplied in JCPDS-ICDD PDF-2 (2004). The XRD results were carried out in  $2\theta$  range of 5°-90°. XRD analysis report confirms the composite formation of nature of the sample. The XRD analysis of ball milled  $\text{Al}_2\text{O}_3$ -MgO (2 wt%)-graphene (1 wt%) composites shows the peaks of  $\text{Al}_2\text{O}_3$  with different planes of diffraction as (104), (113), (024), (116), (122) and (214). At around  $2\theta = 40.0^\circ$  and  $2\theta = 51.0^\circ$ ,  $\text{Al}_2\text{O}_3$  shows two intense major peaks. In the composite  $\text{Al}_2\text{Mg}_0.4\text{O}_4$  is observed. In the composite characteristic peak of C (002) is strongly appeared at  $2\theta = 26.5^\circ$  due to the presence of graphene in the composite. The position and FWHM of the peaks of the different phases with different planes were studied to their standard values which indicate the well-ordered and better crystalline nature of the composite.

FESEM analysis of the typical composites of  $\text{Al}_2\text{O}_3$ -MgO (2 wt%) -graphene (1 wt%) is presented in Fig. 2. The uniform distribution of  $\text{Al}_2\text{O}_3$  and MgO is very clearly observed. Uniform distribution of graphene within the  $\text{Al}_2\text{O}_3$  grains is very important to prepare superior quality composite for various industrial applications. The microstructure shows very high dense and packing nature between different phases or components. The composite is also found having no porosity and any kind of surface defects. No agglomeration on particle distribution is observed. Such improved microstructure with improved homogeneity is expected to enhance micro structural property of composite.

**Soumen Dash et al.**

Microhardness of Al<sub>2</sub>O<sub>3</sub>, Al<sub>2</sub>O<sub>3</sub>-graphene (1 wt%) and Al<sub>2</sub>O<sub>3</sub>-MgO (2 wt%)-graphene(1 wt%) composites determined by micro indentation technique method. Before graphene and MgO reinforced to Al<sub>2</sub>O<sub>3</sub> phase, it was thought that it may increase the mechanical property of the composites. This is interestingly matching to our initial predication that the microhardness value increases with the presence of MgO. Here only alumina shows hardness of 1410 ± 04 VHN. The work reports microhardness of Al<sub>2</sub>O<sub>3</sub>-MgO (2 wt%)-graphene(1 wt%) is 1712 ± 10 VHN. Composites with absence of porosity with optimized sintering (1550 °C) have significant distribution for the development of mechanical property. The above improved microhardness inspires to use the composite for advanced structural applications in industry.

## CONCLUSION

In this work, it has been possible to prepare two different compositions of Al<sub>2</sub>O<sub>3</sub>-graphene (1 wt%) and Al<sub>2</sub>O<sub>3</sub>-MgO (2 wt%)-graphene(1 wt%) composites by using a dry planetary ball milling technique for 8hrs followed by sintering at 1550 °C for 5 hrs. The peaks of Al<sub>2</sub>O<sub>3</sub>, C (graphene) and MgO were found by XRD study in the composites. Composites were found grown with free from micro free porosity and any kind of surface defects. The uniform distribution of graphene and MgO were found in the composite. It is evident that the microhardness of Al<sub>2</sub>O<sub>3</sub> were found to increase when MgO(2 wt%)-graphene(1 wt%) is added to the composite. Al<sub>2</sub>O<sub>3</sub> and Al<sub>2</sub>O<sub>3</sub>-MgO(2 wt%)-graphene(1 wt%) have microhardness of 1410 ± 04 VHN and 1712 ± 10 VHN respectively. Such values of micro hardness indicate improved microstructural and microhardness properties of the composites. The composite of Al<sub>2</sub>O<sub>3</sub>-MgO-graphene with improved mechanical property has great future scope to prepare advanced ceramic for structural applications.

### ABSTRACT

Thermal arc plasma melt-cast technique has employed to produce a high dense tungsten carbide product. This high temperature carbide was melted within 10-14 min of plasma reaction. Tungsten monocarbide (WC) after melt and cast was found to grow with additional phase of tungsten semicarbide phase (W<sub>2</sub>C). This WC-W<sub>2</sub>C product exhibits higher hardness value than only pure WC sample. It was observed that as melting time increases from 10 min. to 14 min., density of composite product increases. Composites consisting of WC, W<sub>2</sub>C and unbound C (graphite) were evaluated by X-ray diffraction, field emission microscopy, energy dispersive spectroscopy (of X-ray), BET analysis, fourier transform infra-red and mechanical properties. Melt-cast products exhibit three types of grains. In this work a very hard, tough and porous free melt-cast WC-W<sub>2</sub>C composite prepared by 14 min. melt-casting of WC sample is reported. WC sample prepared after 14 min. of plasma treatment was found to exhibit significantly high hardness (2606 VHN) and Young's modulus (640 GPa) values with almost zero porosity.

**Keywords:** Tungsten carbide composite, X-ray diffraction, Microscopy

### INTRODUCTION

Tungsten mono carbide (WC) is considered as a wonderful ceramic material due to combination of its very high melting point (~ 2700 °C) and high microhardness (~23 GPa) [1-6] properties. Tungsten carbide has two kinds of phases i.e. WC and W<sub>2</sub>C (tungsten semicarbide). In industries, composite of WC and W<sub>2</sub>C (called fused tungsten carbide) is prepared by melting followed by cooling technique. Tungsten carbide commonly used in making rock drill buttons, pressing dies, cutting tools for hard materials, and other abrasion-resistant components due to their

**Subhrajit Dash et al.**

combinations of considerable toughness, strength, and wear resistance properties [7-9]. W-C Phase diagram shown in fig. 1[10, 11] indicates at temperature below 2380°C in at% C range of 33.4-50, WC- W<sub>2</sub>C composite prepared. Chuvil'deev and co-workers [12] determined hardness of WC prepared by conventional sintering technique without binder is to be 2480 VHN. Similar type of value of hardness determined by Kim and his team for WC-20 at.% TiC composite 2032 VHN [13].

Tungsten carbide composites generally prepared by powder metallurgy process uses many steps of processing starting from binder mixing upto sintering of samples which involves high time and energy consumption. But tungsten carbide composites prepared by melt-cast technique involves lower porosity compared to sintered products. Because of high melting point of tungsten carbide, it is appropriate to adopt thermal arc plasma technique for treatment of this material instead of using conventional graphite or induction furnace. In thermal lab scale plasma, it is not difficult to produce temperature more than 3000 °C. Tungsten carbide samples were treated by arc plasma melt-cast technique within 12-14 of reaction. The surface morphology and microhardness properties determined by using X-ray diffraction (XRD), field effect scanning electron microscopy (FESEM), energy dispersive spectra (EDS) of X-ray, BET (Brunauer-Emmett-Teller) analysis, fourier transform infra-red, micro hardness and Young's modulus measurement. This study explores successful synthesis of WC-W<sub>2</sub>C composite by varying plasma treatment time between 10-14 min. Melt-cast WC products were prepared without any binder. The melt-cast composites exhibit outstanding mechanical properties with almost zero porosity.

### Materials and Characterizations Techniques Used

Tungsten monocarbide (WC) powder with grain size 7-10 µm powder was used in this research work. At first Pellets of tungsten monocarbide (WC) were prepared by using poly vinyl alcohol (PVA) binder and compressing at 7 T load for 40 sec. These pellets were air dried before doing plasma reaction of samples. 30 kW (dc) extended arc type plasma reactor was employed for melt-casting of WC samples. During plasma treatment following conditions was maintained: voltage 50–55 V (dc) and current 250–260 A. Argon (Ar) was used for generation of plasma. Plasma reaction was carried out for 10, 12 and 14 min. Melt-casting of samples was carried in graphite crucible placed at centrally of the reactor. After melting of samples was over, samples were allowed for cooling up to 4-5 hours to attain room temperature. Then after samples were taken out of the reactor for various characterizations.

PANalytical X'Pert Pro diffractometer system was employed for X-ray diffraction (XRD) analysis using CuKα, λ=0.15406nm radiation. Surface morphology of samples was taken by field effect scanning electron microscopy (FESEM)-ZEISS SUPRA 55. Energy dispersive spectrum (EDS) of X-ray was studied attached to TEM (transmission electron microscopy). BET method (ASAP 2020) was employed to determine the pore volume of melt-cast products. Density of melt-cast products was determined by using Archimedes' principle. Fourier transform infra-red (FTIR) spectra were studied in the range of 400–4000 cm<sup>-1</sup> (Spectrum GX, Perkin Elmer). Microhardness and Young's modulus was determined by UMIS system (Fisher-Cripps, Australia).

## RESULTS AND DISCUSSION

Different phases and planes grown in melt-cast WC samples (10 and 14 min. of plasma treatment) were carried out by XRD. Standard JCPDS data files (1999) as follows: WC: 73-0471, W<sub>2</sub>C: 79-0743, C (graphite-2H): 41-1487 were used to identify different phases grown in the composites. From the melt-cast WC samples, hexagonal crystal structure of WC, W<sub>2</sub>C and C(G) (graphite) was observed. So XRD shows two new phases (W<sub>2</sub>C and C(G) after melt-casting of WC sample. But C (G) was found as minor phase in the melt-cast products. All melt-cast products show WC and W<sub>2</sub>C composites as major components. Basically from XRD spectra, it is commonly marked that, intensity of W<sub>2</sub>C increases with increasing plasma melting duration from 10 to 14 min.. This is may be due to the sufficient time and energy developed in the hearth of plasma to decompose of WC into W<sub>2</sub>C and C. W<sub>2</sub>C phase formed at two theta of 37.9, 39.7 and 70.0 was found to increase with increasing plasma treatment time. WC peak at around two theta of

49.8 shows a peak intensity decreasing trend with increasing plasma treatment time. C is marked at around two theta of 26.8 was found to more intense with increasing duration of plasma reaction.

FESEM and EDS studies of melt-cast WC sample prepared by 14 min. of melting were carried out and shown in Fig.3. Samples show polycrystalline type of structure as observed by FESEM analysis. Typical three grain structures are found to be developed in the melt-cast samples. These three types of phases are contributed by WC, W<sub>2</sub>C and C(G) which confirm our XRD results. In the microstructure, volume % of white grains was found relatively more in amount than grey grains. If we compare with XRD result, it may be considered that white, grey and dark phases are due to WC, W<sub>2</sub>C and C(G) respectively. Dark grains basically found to grow at the grain boundary between white and grey. To know surface morphology and types of phases present FESEM analysis was done. FESEM (Fig. 3 (a)) shows three types of phases without any cracks and defects. In the microstructure there is a well defined linear boundary separating two regions. Dark grains were found to distribute uniformly in the right side of linear boundary. This is may be due to strong affinity of dark phases to that particular region. In overall analysis of microstructure, no surface defect or crack is marked in the composites. EDS analysis (Fig. 3 (b)) of typical of melt-cast WC sample shows elements of W, C and Cu. The appearance of Cu in the sample is due to Cu coated carbon grid used during EDS analysis. No impurity phase is detected in the melt-cast sample. FTIR spectrum of WC: 14 min. melt-cast sample shows peaks due to vibrational stretching of W-C in hexagonal crystal structure, C=C (aromatic) stretching and O-H stretching [14, 15]. FTIR result can be correlated to our XRD and EDS results for showing about the purity of sample.

The melt cast samples show density mostly more than 17.1 g/cm<sup>3</sup>. This is novelty of processing of materials by thermal plasma route. Pore volume of the melt-cast samples were analysed by BET method and it was measured that volumes of the pores were mostly in the range of 0.003-0.006 cm<sup>3</sup>/g. The results indicate about the optimized conditions adopted to prepare a porous free melt-cast WC sample by arc plasma melt-cast route. The melt-cast samples were then taken for study of mechanical property. It is interesting to note that WC melt cast samples showed high micro hardness and Young's modulus values in the range of 2204-2606 VHN and 540-670 GPa respectively. Such values of mechanical property are dedicated to optimized thermal plasma condition adopted in this work. The results were found to better than the samples prepared by sintering route [12-13].

## CONCLUSION

In this research work we have successfully prepared melt-cast WC samples by thermal arc plasma techniques by varying arc plasma treatment time duration between 10 and 14 min.. Three different phases of WC, W<sub>2</sub>C and unbound C(graphite) were observed in all melt-cast samples. In the melt cast products WC and W<sub>2</sub>C were found in major phases which were confirmed from XRD, EDS and FTIR studies. Microscopic analysis done by FESEM shows polycrystalline type of microstructures in the melt-cast samples. This work reports a very hard, tough and porous free melt-cast WC-W<sub>2</sub>C composite prepared only by 14 min. melt-casting of WC sample. This work reports a very hard, tough and porous free melt-cast WC-W<sub>2</sub>C composite prepared only by 14 min. melt-casting of WC sample. WC sample prepared after 14 min. of plasma treatment was found to exhibit significantly high hardness (2535 VHN) and Young's modulus (625 GPa) values with almost zero porosity.

### ABSTRACT

The aim of present investigation mainly focussed on indigenous knowledge on medicinal plants used to treat haemorrhoids in some selected tribal-rich district of Odisha, India. The present communication provides information on 40 plant species belonging to 28 families used by many tribal communities in Odisha to treat haemorrhoids and associated problems. The data were obtained in the course of ethnobotanical exploration of various forest areas of Odisha during 1986-2010 through interviewing traditional healers locally known as 'Chera-muli doctor', 'Hakims', 'Baidyas', 'Mukhia' and 'Guru'. Information on botanical name, family, local name, habit, locality and mode of application is given. Most of the uses have not been reported so far. The practical knowledge of tribes as well as the rural communities on herbal medicines revealed that they are capable of curing haemorrhoids and other related ailments. The author emphasizes the need for incorporating some widely used herbal remedies in rural healthcare programmes.

### INTRODUCTION

Ano-rectal diseases including haemorrhoids (Arsha), fistula-in-ano (Bhagandara) and fissure-in-ano ('Parikartika) were known to ancient Indian physicians since long ago. An elaborate description of its clinical features and its effective management has been discussed in various Ayurvedic texts. Sushruta (800 B.C.) for the first time elaborately described various ano-rectal disorders, among which haemorrhoids is a prominent one. Haemorrhoids or piles, fistula and fissure have gained notoriety for ages because of the accompanying pain, burning and bleeding

**Kunja Bihari Satapathy**

from the rectum, which in turn causes great stress and anxiety. Haemorrhoids, also called piles, are swollen veins in the anus and lower rectum, similar to varicose veins. Haemorrhoids have a number of causes, although often the cause is unknown. They may result from straining during bowel movements or from the increased pressure on these veins during pregnancy. It can also be caused due to childbirth, persistent coughing, standing for long periods, overuse of laxatives or sitting on cold and hard surfaces for long periods of time. According to *Charaka Samhita* and *Chikitsa Sthana*, due to intake of 'guru' (heavy), 'madhura' (sweet), 'sita' (cold), 'abisandhikara' (channel-blocking), 'vidahi' (burning), 'virudda' (antagonistic), 'ajeerna' (uncooked), 'pramitasana' (too little), 'asatmya' (unsuitable), non-vegetarian and spicy foods, day sleep as well as abstaining from physical exercise, suppress 'agni' (digestive fire) causing 'mandagni', which subsequently causes excrements to get accumulated in excess ('mala samchaya'). This chronic constipatory ('mala samchaya') condition leads to various ano-rectal disorders especially haemorrhoids which may be located inside the rectum (internal haemorrhoids), or they may develop under the skin around the anus (external haemorrhoids). Haemorrhoids are very common. Nearly three out of four adults will have haemorrhoids from time to time. Sometimes they don't cause symptoms but at other times they cause itching, discomfort and bleeding. Occasionally, a clot may form in a haemorrhoid (thromboses haemorrhoid). These are not dangerous but can be extremely painful and sometimes need to be lanced and drained.

Haemorrhoids are usually not life threatening but they cause a lot of symptoms and social embarrassment through clinical features such as faecal incontinence. Some of the symptoms of this disease are: (i) painless bleeding of bright red blood along with the stools or afterwards, (ii) single or multiple swellings at the anal canal opening, which can be felt while washing after passing the stools, (iii) a sensation of a fleshy mass coming out during passing stool which goes back on its own after the completion of passing the stools, (iv) occasional pain, burning and discharge of mucous, (v) the tearing of border of anus and adjacent part very often leads to bleeding, inflammation and difficulty in passing of stool (Anal fissure), (vi) a tubular structure lined by granulation tissues which opens internally into anal canal or rectum and externally on the skin surface around the anus.

Fortunately, many effective options are available to treat haemorrhoids. Many people can get relief from symptoms with home treatments and lifestyle changes. Plants have been used for medicinal purposes long before prehistoric period. Evidence exist that Unani Hakims, Indian Vaidyas and European and Mediterranean cultures were using herbs for over 4000 years as medicine. Indigenous cultures such as Rome, Egypt, Iran, Africa and America used herbs in their healing rituals, while other developed traditional medical systems such as Unani, Ayurveda and Chinese medicine in which herbal therapies were used systematically. Traditional systems of medicine continue to be widely practised on many accounts. Population rise, inadequate supply of drugs, prohibitive cost of treatments, side effects of several synthetic drugs and development of resistance to currently used drugs for infectious diseases have led to increased emphasis on the use of plant materials as a source of medicines for a wide variety of human ailments. Among ancient civilisations, India has been known to be rich repository of medicinal plants.

The forest in India is the principal repository of large number of medicinal and aromatic plants, which are largely collected as raw materials for manufacture of drugs. About 8,000 herbal remedies have been codified in AYUSH systems in INDIA. Ayurveda, Unani, Siddha and Folk (tribal) medicines are the major systems of indigenous medicines. Among these systems, Ayurveda and Unani Medicine are most developed and widely practised in India. Recently, WHO (World Health Organization) estimated that 80 percent of people worldwide rely on herbal medicines for some aspect of their primary health care needs. According to WHO, around 21,000 plant species have the potential for being used as medicinal plants. In the present study an attempt has been made to collect medicinal knowledge and medicinal uses of plants to cure Haemorrhoids.

A number of plants have been used in ethno-medicine for curing various ailment in different tribal pockets of Odisha and reported by several researchers [1, 2, 3, 4, 5, 6, 7, 8, 9,10, 11, 12, 13, 14, 15, 16,17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72]. However, there is not a single published account on plants exclusively used in

the treatment of 'ano-rectal diseases' especially haemorrhoids in the state of Odisha. The information mentioned in this article are the ones prescribed in the day-to-day life of tribes or rural folks inhabiting in inaccessible areas of tribal rich district of Odisha. The documentation embodied in the present communiqué will help the house-wives, barefoot-doctors, vaidyas, village medicine-men and medicine-women of rural India to manage the common 'ano-rectal' diseases especially haemorrhoids using locally available plants or plant materials.

**MATERIAL AND METHODS**

The materials for the present study form a collection of plants from various tribal-rich districts of Odisha (India) during 1986-2010. These plants were identified and confirmed with the authentic herbarium housed in Post Graduate Department of Botany, Utkal University, Bhubaneswar, Odisha and deposited in V.N. Autonomous College, Jajpur Road, Odisha, India. The plants are arranged in alphabetical order followed by synonym (if any), Accession No., the name of the family, local name and their mode of uses to treat piles.

The present chapter describes the study area, description of the study sites, methodology of survey, plant collection, herbarium preparation, plant identification and collection of data on medicinal use of plants. The field tours 10-15 days' duration were conducted in the unexplored tribal pockets of Odisha during 1986-2010. A general survey method with well planned questionnaire was followed for the collection of ethnomedicinal information. Several field trips were conducted to interview the local herbal healers and tribal medicine men and women to collect the information regarding the mode of uses of the plants to treat various diseases especially haemorrhoids. Screening of data was carried out based on available literature and the book entitled "Dictionary of Indian Folk Medicine and Ethnobotany" by S.K. Jain [73]. The voucher specimens were collected, identified and preserved in the form of herbarium specimens.

**Details of the Study Sites**

Odisha (formerly known as Orissa) is one of the 28 states in Indian republic. The state of Odisha is located between 21°17' N latitude and 85°5' E longitude in the eastern part of the Indian peninsula and the Bay of Bengal lies to its east while Chhattisgarh shares its border in the west and north-west. The state shares its geographic boundaries with West Bengal in the north-east, Jharkhand in the north and Andhra Pradesh in the south. The state is spread over an area of 155,707 km<sup>2</sup> and extends for 1030 km from north to south and 500 kilometres from east to west. Its coastline is 480 km long, which encompasses 30 districts further subdivided into 314 blocks. Physiographically, Odisha consists of coastal plains, central plateaus, central hilly regions, flood plains, and uplands. About a third of the state has a beautiful vegetation cover. Odisha topography consists of fertile coastal plains to the east bounded by Bay of Bengal. Mountainous highlands and plateau regions occupy the centre of the state. Western and north-western portions of the state consist of rolling uplands.

The western and northern portions of the state are part of the Chota Nagpur plateau. Out of 16 major forest type group in India, four major forest types that exist in Odisha are (i) Tropical dry deciduous forest (57.87%), (ii) Tropical moist deciduous forest (39.88%), (iii) Tropical semi-evergreen forest (0.68%), (iv) Littoral swamp forest (0.48%) and the total forest cover is about 31.41%. The highest mountain peak in the state is Deomali (1672 m), which is situated in Koraput district in southern Odisha. It is also one of the tallest peaks of the Eastern Ghats. The study sites covers Puri, Khurda, Cuttack, Dhenkanal, Angul, Sambalpur, Kendrapara, Jajpur, Bhadrak, Balasore, Keonjhar, Mayurbhanj, Sundergarh, Jharsuguda, Gajapati, Koraput, Kalahandi and Kandhamal districts of Odisha (Fig. 1). There are about 62 tribes are inhabiting in these area and the prominent tribal communities of the areas under study are Munda, Kharia, Kisan, Bhuyian, Santal, Saora, Kondha, Kolha, Juang, Bathudi and Kolha.

**Kunja Bihari Satapathy****Interview with informants:**

An extensive survey was carried out in some selected tribal-rich districts of Odisha during 1986-2010. The numbers of informants interviewed were 54 (34 Male, 20 Female). The information of this study was collected through questionnaire method from the villagers, elderly persons, traditional healers who are residing in the areas of the study to collect data on medicinal plants commonly used by them. The information includes different common human ailments including haemorrhoids, their occurrence, symptoms, regular mode of herbal treatments, plants and plant parts used for the treatment.

**Botanical identification of plants**

All the medicinal plants recorded during the field visits were botanically identified by referring 'The Botany of Bihar and Orissa' [74], The Supplements of Bihar and Orissa [75] and The Flora of Orissa [76].

**RESULTS AND DISCUSSION**

The ethnobotanical surveys revealed fascinating findings of great interest to the researchers and of immediate benefit to the communities concerned who safeguard the medical secrets. The present article provides information on 55 different plant species belonging to 35 families used by the tribes and rural communities in Odisha to treat haemorrhoids and associated problems. The details of collected plants are enumerated with their scientific name, family, local name, part(s) used, mode of uses to treat haemorrhoids presented in Table 1. Different parts of plants such as leaf, stem, root, rhizome, flower, fruit and seed are being used for treating haemorrhoids in the areas under study (Fig. 2). The herbal formulations prepared were either in crude form or are mixtures of various ingredients. From the survey, it was observed that maximum percentage of formulations were prepared from leaves followed by fruits for the treatment of haemorrhoids (Fig. 2).

Most of the plant species reported are herbs or trees and a few of them are shrubby species or climbers. The habit-wise groupings of the plant species shows 51 % are herbs, 11 % shrubs, 23 % trees and only 15% are climbers (Fig.3). Among the families, Asteraceae, Cucurbitaceae and Rutaceae with 4 species each are the dominant families followed by Caesalpiniaceae (with 3 species), Euphorbiaceae (with 3 species), Liliaceae (with 3 species) and Amaranthaceae, Asclepiadaceae, Combretaceae, Zingiberaceae with 2 species each respectively (Fig. 4). Some of the potential medicinal plants, widely used to treat haemorrhoids by the tribes are *Aegle marmelos*, *Aloe vera*, *Azadirachta indica*, *Carica papaya*, *Cassia auriculata*, *Cissus quadrangular*, *Gloriosa superba*, *Madhuca indica* and *Mesua ferrea*. The data collected during the investigation also revealed that the population of plant species such as *Alpinia calcarata*, *Gloriosa superba*, *Mesua ferrea*, *Cassia auriculata* and *Cissus quadrangula* were quite less as compared to other species in their natural habitat and were assessed to be under vulnerable category.

**CONCLUSION**

The use of plant species as remedies is perhaps as old as the human civilization. The present article covers 55 different plant species, which are commonly used as household remedies against haemorrhoids. The prescriptions mentioned in Table-1 are the ones that are in practice in the tribal inhabiting remote areas of Puri, Khurda, Cuttack, Dhenkanal, Angul, Sambalpur, Kendrapara, Jajpur, Bhadrak, Balasore, Keonjhar, Mayurbhanj, Sundergarh, Jharsuguda, Gajapati, Koraput, Kalahandi and Kandhamal districts of Odisha. Tribal medicine-men, being herbal practitioners, have added these medications to their home-grown knowledge system through trial and error, spanning over hundreds of years. Based on these traditional practices, pharmaceutical industries may make some

**Kunja Bihari Satapathy**

new preparations or improve the existing ones. The value of medicinal plants to Human livelihoods is essentially infinite and they evidently make fundamental contribution to human healthcare. Medicinal plants can be symbolically very important to people. During the course of investigation the author could observe that a number of potential medicinal plant species are threatened in their natural habitat due to their habitat loss, habitat degradation and over-harvesting. Hence, it is suggested that appropriate conservation strategies and new harvesting methodologies should be employed in the area to prevent these valuable threatened medicinal plants from wanton disappearance.

**ACKNOWLEDGEMENT**

The author is thankful to the Principal, Rourkela Municipal College, Rourkela (Odisha) and to the Principal of V.N. Autonomous College, Jajpur Road, Odisha for providing necessary laboratory and library facilities for the investigation.

## Kunja Bihari Satapathy

Table 1: List of potential medicinal Plants used by different tribes of Odisha against Haemorrhoids.

Sl. No	Botanical name, Family name & Accession No.	Local name	Ethnomedicinal Uses
1.	<i>Abutilon indicum</i> (Linn.) Sweet ssp. <i>indicum</i> [MALVACEAE] KBS-477	Pedipedika(O) Kankati (S), Kakhi (Kh).	Its seeds are laxative, and very effective in curing piles, if administered in doses of 4 to 6 grams (once in a day for 5 days). Root paste is also effective against bleeding piles.
2.	<i>Acalypha indica</i> Linn. [EUPHORBIACEAE] KBS-407	Indramarisha (O), Basuni (S).	Decoction of whole plant (15 ml) along with honey (5 ml) is given twice a day for 15 days.
3.	<i>Achyranthes aspera</i> Linn. [AMARANTHACEAE] KBS-420	Apamaranga (O), Tabat-khanda (M).	A decoction of the powdered leaves, mixed with honey or sugar candy is useful in the early stages of piles. About 25 g root paste in 'water rice' is given with 250 ml goat's milk twice a day for 7 days.
4.	<i>Acorus calamus</i> Linn. [ARACEAE] KBS-434	Bacha(O),	One spoon root paste with one cup milk is given at bedtime for 3-4 months.
5.	<i>Aegle marmelos</i> (Linn.) Corr. [RUTACEAE] KBS-471	Bela(O), Sinjo(S), Lohagasi(K), Bael(Sao).	About 50 grams of the fruit along with 10 grams of old jaggery is prescribed once in a day for 15 days against bleeding piles. 2 g powdered fruit pulp mixed with 1 g of 'sunthi' powder is also given twice a day till the cure.
6.	<i>Allium cepa</i> Linn. [LILIACEAE] KBS-411	Piyaja (O)	Onion is very effective in bleeding piles. About 30 grams of onions should be finely ground on a slab with water and 60 grams of sugar added to it. This paste is given twice daily which brings relief within a few days.
7.	<i>Aloe vera</i> (Linn.) Burm.f. [LILIACEAE] KBS-454	Ghee-kuanri(O), Ghee-kumar(S).	About 5 ml of leaf juice mixed with 8-10 drops of 'tulsi juice' ( <i>Ocimum sanctum</i> ) is given twice a day for fifteen days in acute cases of piles or fistula.
8.	<i>Alpinia calcarata</i> Rosc. [ZINGIBERACEAE] KBS-429	Toroni (O).	The decoction of the leaves is taken against piles.
9.	<i>Amaranthus spinosus</i> Linn. [AMARANTHACEAE] KBS-452	Kanta khada (O), Janum arak (S), Jamun ara (M).	Extraction (10 ml) of whole plant mixed with 10 ml of ginger and 5 drops of honey is used to treat haemorrhoids.
10.	<i>Amorphophallus paenifolius</i> (Dennst.)Nicolson ( <i>A. campanulatus</i> Decne) [ARACEAE] KBS-409	Olua (O), OI (K).	Corm is encapsulated in mud, gently burnt and then pounded with a little common salt and mustard oil. This paste (two tea spoonful) given once a day for a week to cure piles.

## Kunja Bihari Satapathy

11.	<i>Anogeissus latifolia</i> (Roxb. ex DC.)Wall [COMBRETACEAE] KBS-473	Dhau (O), Hesel (K,S)	Decoction of bark (10 ml) is given once in a day for 15 days against piles.
12.	<i>Azadirachta indica</i> A. Juss. [MELIACEAE] KBS-415	Nimba (O), Ninba (Sao, Kondh &S).	The use of 5 grams of the inner bark of neem with 10 grams of jaggery every morning is very effective in piles. To check bleeding piles, 3 or 4 neem fruits can be administered with water.
13.	<i>Bauhinia variegata</i> Linn. [CAESALPINIACEAE] KBS-449	Kanchana (O), Buj(K), Kandol(Bh).	Floral buds fried and prescribed in the diet for 15 days to treat bleeding haemorrhoids.
14.	<i>Benincasa hispida</i> (Thunb.) Cong. (B. <i>cerifera</i> Sav.) [CUCURBITACEAE] KBS-460	Pani-kakharu(O), Raksha(K).	The fresh dilute fruit juice of ash gourd mixed with a teaspoon of 'aenla' ( <i>Phyllanthus emblica</i> ) or 'lime' ( <i>Citrus medica</i> ) juice is used as a specific medicine to stop profuse bleeding from affected part due to piles.
15.	<i>Blumea lacera</i> (Burm.f.) DC. [ASTERACEAE] KBS-437	Pokasungha (O), Kakranda (H), Kulala (G)	Leaf juice (10 ml) along with 5 gram of sugar is given once in a day against piles or fissures till the relief.
16.	<i>Boerhaavia diffusa</i> Linn. [NYCTAGINACEAE] KBS-456	Puruni (O), Khapra saga (Bh), Kenchua(K), Choic arak (Sao).	Root or whole plant is made in to a paste and given once in a day against piles. The patient is also advised to eat the leaves and tender branch tips as vegetables.
17.	<i>Brassica oleracea</i> Linn. var. <i>capitata</i> Linn. [BRASSICACEAE] KBS-466	Bandhakobi (O).	Leaves prescribed as a diet of patients suffering from fistula and liver troubles.
18.	<i>Calotropis gigantea</i> (Linn.) R.Br. ex Ait. [ASCLEPIADACEAE] KBS-418	Arakha (O), Akaona(S), Pak (Sao), Akond (Bh).	A paste prepared from leaf of 'lau' ( <i>Lagenaria vulgaris</i> ) and bark of 'karanja' ( <i>Pongamia pinnata</i> ) with the latex of this plant and that of 'siju' ( <i>Euphorbia ligularia</i> ) and applied on the affected part after mixing with cow's urine for 7 days or till the cure. External application of latex on affected part after cleaning is also advised.
19.	<i>Carica papaya</i> Linn. [CARICACEAE] KBS-440	Amruta-bhanda (O), Jhoda (K).	Leaf, fruit, seed or latex used in piles. Green fruits are boiled and made into a paste and given with a pinch of common salt and jeera ( <i>Cuminum cyminum</i> ) powder for six months.
20.	<i>Cassia auriculata</i> Linn. [CAESALPINIACEAE] KBS-468	Tarwa (Sao)	Leaf paste mixed with cow's ghee is applied to treat haemorrhoids.

## Kunja Bihari Satapathy

21.	<i>Cissus quadrangula</i> Linn. [VITACEAE] KBS-432	Hadabhanga(O), Hasjora (S)	Stem paste prepared with castor oil is applied externally to cure haemorrhoids.
22.	<i>Citrus limon</i> (Linn.) Burm.f. [RUTACEAE] KBS-457	Bada lembu (O)	Fruit juice mixed with ginger juice, mint and Honey is given once in a day for 15 days against internal haemorrhoids.
23.	<i>Coccinia grandis</i> (Linn.) Voigt. ( <i>Cephalandra indica</i> (Wt. & Arn.) Naud.) [CUCURBITACEAE] KBS-408	Kunduri (O), Bano kundri (K).	Juice of leaves (15 ml) with date palm jaggery (10 g) given once daily for a week for piles as well as blood dysentery. Decoction of the twig of plant along with that of flowers and young fruits are given once daily for seven days.
24.	<i>Cynodon dactylon</i> (Linn.) Pers. [POACEAE] KBS-458	Duba ghasa (O), Dhobi ghas (K&S).	10-15 ml of fresh juice of the whole plant is given 3 times a day for 15 days.
25.	<i>Cyperus rotundus</i> Linn. [CYPERACEAE] KBS-435	Mutha (O), Suraj (S), Batha-bijir(M).	Rhizome powder (10 g) mixed with 5 g of old jaggery is given once in a day after food to treat hemorrhoids.
26.	<i>Eclipta prostrata</i> (Linn.) Linn. [ASTERACEAE] KBS-410	Kesadura (O), Kamri (Kondh)	Leaf paste mixed with sugar candy is taken twice a day for 7 days.
27.	<i>Eryngium foetidum</i> Linn. [APIACEAE] KBS-422	Jangali Dhania (O)	Whole plant extract mixed with sugar or Honey is taken twice a day for 1 month against acute case.
28.	<i>Euphorbia hirta</i> Linn. [EUPHORBIACEAE] KBS-450	Chitakuti (O), Pusi toa (S,K)	Leaf extract mixed with the latex of 'arakh' ( <i>Calotropis procera</i> ) is applied externally on the affected part to cure haemorrhoids.
29.	<i>Euphorbia ligularia</i> Roxb. ( <i>E. nerifolia</i> auct. non Linn.) [EUPHORBIACEAE] KBS-413	Patra-siju, Mansa-siju (O).	Latex mixed with a pinch of 'turmeric powder' is applied on the affected part to cure external piles.
30	<i>Gloriosa superba</i> Linn. [LILIACEAE] KBS-469	Dasara phula (O), Lauri-kuli (Kondh), Jagara(M)	Tuber powder is given along with warm water to treat haemorrhoids.
31.	<i>Hygrophila auriculata</i> (Schum.) Heine [Asteracantha longifolia (Linn.)Nees]. [ACANTHACEAE] KBS-414	Koili-khia (O).	Leaf juice (5 ml) along with honey (5 drops) is given at evening for 15 days.

## Kunja Bihari Satapathy

32.	<i>Ichnocarpus frutescens</i> (Linn.) R.Br. [APOCYNACEAE] KBS-463	Suamlai(O), Dudhilata (S), Onol-sing (K), Saon-lar (Kharw)	Fresh root paste (10 g) is prepared with raw cow's milk and given twice a day for 7 days.
33.	<i>Limonia acidissima</i> Linn. ( <i>Feronia elephantum</i> Corr.) [RUTACEAE] KBS-419	Kaitha(O), Katbel(S), Bimul (Kondh), Belsain(Kharw)	The mashed seedless pulp of the unripe fruit, mixed with cardamom, honey and cumin seeds, is given against piles as well as indigestion.
34.	<i>Luffa acutangula</i> (Linn.) Roxb. [CUCURBITACEAE] KBS-433	Jahni(O), Jui(Ho), Paror jhanga(S).	Roots paste is applied on the affected part to cure bleeding piles. Seeds powder of this plant and equal amount of 'haladi' ( <i>Curcuma longa</i> ) powder mixed with mustard oil and is applied over the piles for the removal.
35.	<i>Madhuca indica</i> Gmel. ( <i>Bassia latifolia</i> Roxb.) [SAPOTACEAE] KBS-474	Mahula (O), Natikam(K) Aba(Sao), Mahua (Kondh).	2-3 drops of seed oil mixed with 50 ml warm cow's milk is given in early morning on empty stomach for 7 days.
36.	<i>Mesua ferrea</i> Linn. [CLUSIACEAE] KBS-431	Nageswara (O).	Flower buds made into a paste with butter and is administered (10 g) two times a day for 7 days to check bleeding due to piles.
37.	<i>Momordica charantia</i> Linn. [CUCURBITACEAE] KBS-416	Kalara(O), Kirla (K).	Decoction of the fruits is given to the patient in the morning in empty stomach at least for one month. The patient is also advised to include the fruit as vegetable in his daily diet. Fresh juice of seven leaves along with a pinch of rock salt is given once in the morning on empty stomach for seven days.
38.	<i>Murraya koenigii</i> (Linn.) Spreng. [RUTACEAE] KBS-461	Bhrusunga (O), Puspa (Bond), Mirsinga (Kondh).	One or two teaspoons of fresh juice of these leaves mixed with a teaspoon of 'lime' juice may be taken. The tender curry leaves, ground to a fine paste and mixed with honey or butter-milk, can be taken on an empty stomach with beneficial results in case of piles or stomach upsets.
39.	<i>Musa paradisiaca</i> Linn. [MUSACEAE] KBS-438	Kadali (O)	The inflorescence is cooked and given to the patients daily to treat hemorrhoids.
40.	<i>Nelumbo nucifera</i> Gaertn. [NYMPHAEACEAE] KBS-472	Padma (O).	About 5 g of central part of the flower made into a paste with butter and given once in a day for 7 days.

## Kunja Bihari Satapathy

41.	<i>Ocimum sanctum</i> Linn. [LAMIACEAE] KBS-466	Tulasi (O).	The mucilaginous jelly, formed by infusing 5 to 10 gram of the seeds in cold water for some time, can be administered with sugar to treat internal piles as well as constipation.
42.	<i>Pergularia daemia</i> (Forssk.) Chiov. [ <i>P. extensa</i> (Jacq.) N.E. Br. ; <i>Daemia extensa</i> (Jacq.) R.Br] [ASCLEPIADACEAE] KBS-507	Uturudi(O).	The herb is beneficial in the treatment of bleeding piles. About 24 grams of the leaves fried in ghee should be taken for a few days.
43.	<i>Plantago ovata</i> Forssk. [PLANTAGINACEAE] KBS-405	Isaphagul (O).	Two tablespoons of the seeds should be taken with milk or water once in a day against piles or fissure.
44.	<i>Plumbago zeylanica</i> Linn. [PLUMBAGINACEAE] KBS-511	Chitaparu (O), Sitaparu (Kondh). Chitur(M).	Root juice mixed with equal amount of honey and pinch of common salt is applied externally in haemorrhoids.
45.	<i>Pongamia pinnata</i> (Linn.) Pierre. ( <i>Pongamia glabra</i> Vent.) [FABACEAE] KBS-501	Karanja (O), Kamun (Sao), Karanjo (Kondh), Kuruin(S).	Seed powder (5 g) is given with cold water once in every morning for 15 days.
46.	<i>Sesamum orientale</i> Linn. [PEDALIACEAE] KBS-417	Tila, Khasa (O), Tilming (K), Pitilme (Kondh).	Seeds, especially the black ones (10 g) along with equal quantity of sugar candy is given twice a day for 15 days against fissure. Decorticated seed paste (10 g) along with buttermilk (20 ml) and sugar (10 g) is prescribed against bleeding piles.
47.	<i>Solanum nigrum</i> Linn. [SOLANACEAE] KBS-462	Lunulunia (O), Phut phutia (M)	Fresh unripe 7 fruits are given for 10 days to treat bleeding piles.
48.	<i>Sphaeranthus indicus</i> Linn. [ASTERACEAE] KBS-504	Bhuinkadamb a (O), Koirab (Bath), Belaunga(S)	Paste (15 g) of this plant is given with old jaggery (10 g) twice a day for 3 days to check bleeding piles.
49.	<i>Streblus asper</i> Lour. [MORACEAE] KBS-459	Sahada(O), Sukri-Saijang (M), Ripichum (Kol).	Fresh seed paste (10 g) is given once a day for 7 days against piles. Decoction of bark (10-15 ml) is given early in the morning on empty stomach till the complete cure of fissures. Root, bark or seed paste with 'fermented rice water' is used externally in fissures.

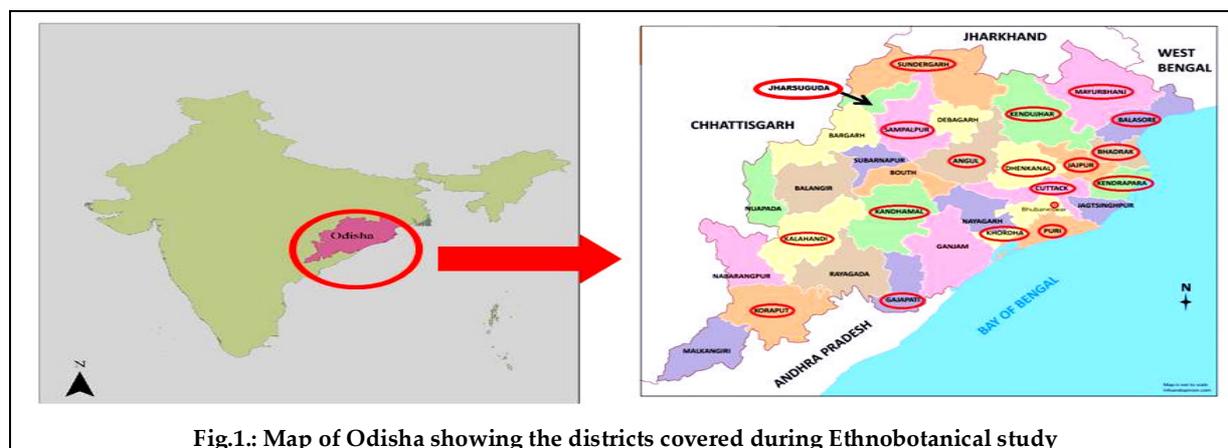

**Kunja Bihari Satapathy**

50.	<i>Tagetes erecta</i> Linn. [ASTERACEAE] KBS-503	Gendu (O).	Leaf with 10 number of 'gola maricha' ( <i>Piper nigrum</i> ) made in to a paste (5 g) and is prescribed twice a day against chronic piles.
51.	<i>Tamarindus indica</i> Linn. [CAESALPINIACEAE] KBS-453	Tentuli (O), Jojo(K), Teten (Kondh)	Leaf juice is useful in bleeding piles.
52.	<i>Terminalia chebula</i> Retz. [COMBRETACEAE] KBS-412	Harida (O), Rola(K&S), Kakra (Sao).	The fresh fruits should be fried to a golden brown colour in castor oil, powdered and stored in an air-tight bottle. Half a teaspoon of this is dissolved on the tongue at bedtime brings about normal bowel movement in the morning and its astringent property is very effective in healing the pile masses.
53.	<i>Tribulus terrestris</i> Linn. [ZYGOPHYLLACEAE] KBS-506	Gokhara (O), Gokhru (Bath).	Infusion (15 ml) of matured fruits is prescribed early in the morning in empty stomach against piles.
54.	<i>Vitex negundo</i> Linn. [VERBENACEAE] KBS-509	Begunia(O), Huri (M), Sinoar (Kh).	Cake prepared from the roots of his plant and boiled rice is given against piles.
55.	<i>Zingiber officinale</i> Rosc. [ZINGIBERACEAE] KBS-508	Ada (O).	Half a teaspoon of fresh ginger juice, mixed with one teaspoon each of fresh lime and mint juices and a teaspoon of honey, constitutes an effective medicine for piles. This mixture should be taken thrice daily.

### **ABSTRACT**

The review article is focus on different novel formulations of cefixime trihydrate and the effect of its bioavailability by forming a drug delivery formulation for better therapeutic response. Cefixime is an orally active third generation cephalosporin with in vitro antibacterial activity against most important lower respiratory pathogens. Cefixime has a long elimination half-life (3 hours compared with 0.5 hours for cefaclor and 1.5 hours for cefalexin), which allows once daily administration. Because of its wide acceptability from paediatric to geriatric patients pharmaceutical scientist are in a race to formulate a novel dosage forms for better therapeutic response. Hence this review emphasizes different types of novel formulation using cefixime trihydrate.

**Keywords:** Cefixime Trihydrate, Novel Drug Delivery System

## **INTRODUCTION**

Cefixime Trihydrate is an oral 3rd generation cephalosporin antibiotic. It is extremely bitter in taste. It is active against most Grams positive and Gram negative organisms and it is useful in the treatment of uncomplicated urinary tract infections, otitis media, pharyngitis and tonsillitis, acute bronchitis and acute exacerbations of chronic bronchitis, uncomplicated gonorrhoea. CefiximeTrihydrate is an oral 3rd generation cephalosporin antibiotic.[3] It is extremely bitter in taste. It is active against most Grams positive and Gram negative organisms and it is useful in the treatment of uncomplicated urinary tract infections, otitis media, pharyngitis and tonsillitis, acute bronchitis and acute exacerbations of chronic bronchitis, uncomplicated gonorrhoea. Cefixime is an antibacterial agent of the cephalosporin class. [5]It is used in various infections like Otitis, Sinusitis and Pharyngitis. Like other cephalosporins, Cefixime exerts antibacterial activity by binding to and inhibiting the action of penicillin-binding proteins. Involved in the synthesis of bacterial cell walls. [1]This leads to bacterial cell lysis and cell death. Cefiximetrihydrate is a BCS class-IV drug. The half life of Cefiximetrihydrate is about 3-4 Hrs.[7]

**A.K.Meher et al.**

Oral cephalosporins have been available for over 25 years and have been used extensively in the therapy of outpatient infections in adults and in children. Many of these agents are variably subject to hydrolysis by some beta-lactamases.[2] Cefixime is a new orally absorbed cephalosporin and the first oral one of the third generation.[6] Cefixime is not hydrolyzed by the common plasmid-mediated enzymes and by chromosomal  $\beta$ -lactamases that inactivate the currently available oral penicillins and cephalosporins, and, for this reason, inhibits a wide variety of Gram-positive and Gram-negative aerobic bacteria, including *Haemophilus influenzae*, *Moraxella catarrhalis*, *Neisseria gonorrhoeae*, *Escherichia coli* and *Klebsiella* resistant to ampicillin, other oral cephalosporins and trimethoprim-sulfamethoxazole. Its broad spectrum activity permits its use in respiratory and urinary tract infections. [9] This paper is a review of chemical properties, antibacterial activity, pharmacokinetics, clinical pharmacology, indications and adverse effects of cefixime as compared to other orally absorbed cephalosporins and to amoxicillin or cotrimoxazole. [13] The chemical name of cefixime is (6R,7R)-7-[(Z)-2-(2-amino-4-thiazolyl)-2-(carboxymethoxyimino)-acet-amido]-8-oxo-3-vinyl-5-thia-1-azabicyclo-(4,2,0)-oct-2-ene-2-carboxylic acid. This semi-synthetic cephalosporin shares structural properties with parenteral third generation cephalosporins such as the 2-aminothiazolyl and the methoxyimino-groups, but differs from them in the position of the ethyl group and a carboxyl group added to the iminomethoxy of the 7-position acyl group. The international nonproprietary name is cefixime (cefiximetrihydrate).[15] Cefixime's physical appearance is that of a white to slightly yellowish crystal or crystalline powder, slightly soluble in ethanol and nearly insoluble in water. Since the pKa values of the two carboxylic acids of cefixime are 2.1 (at the 2-position) and 3.7 (at the 7-position) and that of the amino group at the thiazoyl moiety is 2.7, the increase in lipophilicity of cefixime with decreasing pH is in accordance with increase in the un-ionized forms of the carboxylic acid groups of cefixime. Therefore the bioavailability of Cefiximetrihydrate is very poor.[11] The absolute oral bioavailability of Cefixime is in the range of 22-54 %. Because of poor bioavailability there is a need to increase its bioavailability by forming a novel drug delivery formulation for better therapeutic response.[4]

## Clinical Pharmacology

The recommended dose of cefixime is 400 mg daily, for adults. This may be given as 400 mg once daily or as 200 mg every 12 h. For children, the recommended dose is 8 mg/kg per day. This may be administered as a single daily dose or may be given in two divided doses as 4 mg/kg every 12 h. Children weighing more than 50 kg or older than 12 years should be treated with the recommended adult dose.[13] Pharmacy There are several presentations for per oral use, depending on the countries: -- Tablets: white tablets, in boxes of 8 or 40, each tablet containing 200 mg of cefixime trihydrate with excipients which are dibasic calcium phosphate, magnesium stearate, glycerol, titanium dioxide, hydroxypropyl methylcellulose, microcrystalline cellulose, and pregelatinised starch. [13] Each tablet is convex, 10 mm in diameter, white to cream coloured and weighs 696 rag. -- Tablets containing 400 mg of cefiximetrihydrate in the USA. The comparative bioavailability studies of a single 400 mg dose of cefixime and two 200 mg tablets provide evidence that the two formulations are bioequivalent and that the pharmacokinetic profile achieved after a single 400 mg dose. It should support the clinical evaluation of the efficacy of a one daily dosage regimen for cefixime. -- Fine granule, the available form used for children in Japan, which can be absorbed alone or in a liquid solution. Other pediatric forms: powder for oral suspension (USA, UK) which when reconstituted produces 100 mg/5 ml, and lipidic suspension (Germany, Spain) which can be absorbed directly. The same studies have shown that the oral solution is bioequivalent to the other formulations.[13] There is no parenteral form of cefixime on the market and i.v. cefixime was only used for studies. Cefixime has to be stored at controlled room temperature of 15-30 °C.

## Therapeutic Use

Approved therapeutic indications Cefixime is indicated in the treatment of the following infections when caused by susceptible strains, although some variations can be noted from country to country: -- Uncomplicated or complicated

**A.K.Meher et al.**

acute, acute or chronic infections including cystitis, pyelitis, pyelonephritis and those infections associated with urologic surgery, neurogenic bladder or nephrolithiasis caused by Enterobacteriaceae. -- Acute otitis media caused by Haemophilus influenzae, Moraxella catarrhalis and Streptococcus pyogenes. -- Sinusitis. -- Acute bronchitis, exacerbations of chronic bronchitis and pneumonias. -- Urethritis due to penicillinase and non-penicillinase-producing N. gonorrhoea.[6]

### **Novel Formulation of Cefixime**

#### **As MICROSPHERES**

Cefiximetrihydrate is a 3rd generation broad spectrum  $\beta$ - lactam cephalosporin class of antibiotic administered orally in pediatric and adult patients and is extremely bitter in taste. Controlled release and bitter taste masking are the major challenges for better patient compliance particularly in an antibiotic treatment where dose and duration is important. Among the various techniques available for controlled release, microencapsulation is a useful technique as it has significant advantages over the other techniques. Also a polymer used provides protection to active moiety thereby increasing its stability. The oral route of administration is the most important route of administering drugs for systemic effects. [3]Reconstitutable suspensions necessitate water to prior for mixing. [3]Controlled release (CR) suspensions aimed at controlling the rate of release by maintaining desired drug levels in the blood for long duration of time. The most popular dosage forms being tablets and capsules, but one major drawback of the dosage forms however is the difficulty to swallow for children and the patients who have swallowing disorder.

#### **CefiximeTrihydrate as Mucoadhesive Tablets**

Mucoadhesive tablets of Cefiximetrihydrate were prepared using Carbopol 940P, HPMC K15M and Polyox WSR 303 as a mucoadhesive polymers and  $\beta$ -cyclodextrin as a solubility enhancer. Nine formulations were developed using 32 factorial designs. [4]Carbopol 940P is used as a primary polymer because of its excellent mucoadhesive property and secondary polymers like HPMC K15M & polyox were used. The formulations were tested for in-vitro drug release, mucoadhesive strength, swelling studies, residence time and surface pH.

#### **CefiximeTrihydrate as Bilayer Tablets**

The aim of present work was to develop a robust formulation of Bi-layer tablets of Cefiximetrihydrate and Dicloxacillin sodium using povidone k-30 as binder. [18]The basic aim of any Bi-layer tablet formulation is to separate physically or chemically incompatible ingredients and to produce repeat action or prolonged action tablet. Cefixime is a cephalosporin antibiotic used to treat infections caused by bacteria such as pneumonia, bronchitis, gonorrhoea, and ear, lung, throat, and urinary tract infections.[18] Dicloxacillin is a semi synthetic antibiotic which resists destruction by the enzyme penicillinase. It is used to treat different types of infections caused by bacteria such as bronchitis, pneumonia, etc.[18] A total number of nine formulations have been taken to optimize and develop a robust and stable formulation

#### **Cefiximetrihydrate as floating microsphere**

Floating microspheres of cefiximetrihydrate were prepared using polymers to prolong gastric residence time and increase drug bioavailability with decreased gastro intestinal side effects. [15]The floating micro carriers were prepared by ionotropic gelation method by dispersing cefiximetrihydrate with calcium carbonate and sodium bicarbonate separately into a mixture of anionic sodium alginate, as primary polymer with copolymers namely, HPMC K4M, HPMC K15M and ethyl cellulose into a solution of calcium chloride containing acetic acid. [15]The

A.K.Meher et al.

microspheres formulated with CaCO<sub>3</sub> show increased buoyancy and controlled drug release which makes it excellent in floating drug delivery systems

### Cefiximetrihydrate as transdermal patch

Cefiximetrihydrate is a third generation cephalosporin with a broad spectrum bactericidal activity. Due to its short biological half-life, it required for frequent dosing, so transdermal delivery system was chosen to deliver the drug directly to the systemic circulation thereby to reduce the dose as well as the frequency of dosing. [16] Transdermal matrix patches of cefiximetrihydrate were prepared by solvent casting method using chitosan and sodium alginate as polymers. Two types of chitosan with mol.wt. 190kDa and 419kDa were used. The patches found to be having good physicochemical properties. [17]

### CONCLUSION

Cefixime Trihydrate has been widely prescribed by physician as antibiotics from paediatrics to geriatrics. But due to its bitter taste and short half life it should be formulated properly as a novel drug to show its proper therapeutic activity with minimal toxicity as a novel drug delivery system.

### ABSTRACT

Corona virus causes respiratory infection including pneumonia, cold, sneezing and coughing while in animal it causes diarrhea and upper respiratory diseases. Corona virus transmitted human to human or human to animal via airborne droplets. Corona virus enters in human cell through membrane. WHO and ECDC advised to avoid public place and close contact to infected persons and pet animals. Firstly Corona virus (2019-nCoV) was isolated from Wuhan market China at 7 Jan. 2020. The proposed of this review article summarizes regarding major proposed on common types, Transmission, Symptoms, Epidemiology, Diagnosis, Prevention for COVID-19 and provides a summary of current ongoing clinical experience and treatment guidance for this novel epidemic coronavirus.

**Keywords:** Transmission, Epidemiology, Clinical Trials

### INTRODUCTION

The global pandemic of novel coronavirus disease 2019 (COVID-19) caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) began in Wuhan, China, at the end of 2019. As of April 5, 2020, there have been more than 1.2 million reported cases and 69,000 deaths in more than 200 countries. This novel Betacoronavirus is similar to severe acute respiratory syndrome coronavirus (SARS-CoV) and Middle East respiratory syndrome coronavirus (MERS-CoV); based on its genetic proximity, it likely originated from bat-derived coronaviruses with spread via an unknown intermediate mammal host to humans. Currently, there is no evidence from randomized clinical trials (RCTs) that any potential therapy improves outcomes in patients with either suspected or confirmed COVID-19. There are no clinical trial data supporting any prophylactic therapy. More than 300 active clinical treatment trials are underway. This narrative review summarizes regarding Transmission, Symptoms, Epidemiology, Diagnosis, Prevention for COVID-19 and provides a summary of current ongoing clinical experience and treatment guidance for this novel epidemic coronavirus.

### Common Types

1. 229E (alpha coronavirus)
2. NL63 (alpha coronavirus)
3. OC43 (beta coronavirus)
4. HKU1 (beta coronavirus)

Rarer strains that cause more severe complications include MERS-CoV, which causes Middle East respiratory syndrome (MERS), and SARS-CoV, the virus responsible for severe acute respiratory syndrome (SARS). In 2019, a dangerous new strain called SARS-CoV-2 started circulating, causing the disease COVID-19.

### Transmission

Limited research is available on how HCoV spreads from one person to the next. However, researchers believe that the viruses transmit via fluids in the respiratory system, such as mucus. Coronaviruses can spread in the following ways: Coughing and sneezing without covering the mouth can disperse droplets into the air. Touching or shaking hands with a person who has the virus can pass the virus between individuals. Making contact with a surface or object that has the virus and then touching the nose, eyes, or mouth. Some animal coronaviruses, such as feline coronavirus (FCoV), may spread through contact with feces. However, it is unclear whether this also applies to human coronaviruses. The National Institutes of Health (NIH) suggest that several groups of people have the highest risk of developing complications due to COVID-19.

### These Groups Include

1. Young children
2. People aged 65 years or older
3. Women who are pregnant

Corona viruses can mutate effectively, which makes them so contagious. To prevent transmission, people should stay at home and rest while symptoms are active. They should also avoid close contact with other people. Covering the mouth and nose with a tissue or handkerchief while coughing or sneezing can also help prevent transmission. It is important to dispose of any tissues after use and maintain hygiene around the home. However, people with a more recent diagnosis had no connections with or exposure to the market, confirming that humans can pass the virus to each other. Few children get COVID-19, although they are still investigating the reasons for this. However, while some viruses are highly contagious, it is less clear how rapidly coronaviruses will spread. Symptoms vary from person-to-person with COVID-19. It may produce few or no symptoms. However, it can also lead to severe illness and may be fatal.

### Symptoms

1. Sneezing
2. Runny nose
3. Cough
4. Watery diarrhea
5. Fever in rare cases
6. Sore Throat
7. Exacerbated asthma

### Epidemiology

In December 2019, many pneumonia cases that were clustered in Wuhan city were reported and searches for the source have shown Huanan Seafood Market as the origin. The first case of the COVID-19 epidemic was discovered with unexplained pneumonia on December 12, 2019, and 27 viral pneumonia cases with seven being severe, were officially announced on December 31, 2019. Etiologic investigations have been performed in patients who applied to the hospital due to similar viral histories of these patients has strengthened the likelihood of an infection transmitted from animals to humans. On January 22, 2020, novel CoV has been declared to be originated from wild bats and belonged to Group 2 of beta-coronavirus that contains Severe Acute Respiratory Syndrome Associated Coronavirus (SARS-CoV).

Although COVID-19 and SARS-CoV belong to the same beta corona virus subgroup, similarity at genome level is only 70%, and the novel group has been found to show genetic differences from SARS-CoV. Similar to the SARS epidemic, this outbreak has occurred during the Spring Festival in China, which is the most famous traditional festival in China, during which nearly 3 billion people travel countrywide. These conditions caused favorable conditions for the transmission of this highly contagious disease and severe difficulties in prevention and control of the epidemic. The period of the Spring Festival of China was between January 17 and February 23 in 2003, when the SARS epidemic peaked, while the period of the festival was between January 10 and February 18 in 2020. Similarly, there was a rapid increase in COVID-19 cases between January 10-22. Wuhan, the center of the epidemic with 10 million populations, is also an important center in the spring festival transportation network. The estimated number of travelers during the 2020 spring festival has risen 1.7 folds when compared with the number traveled in 2003 and reached to 3.11 billion from 1.82 billion. This large-scale travel traffic has also created favorable conditions for the spread of this difficult-to-control disease.

### Diagnosis, Treatment, and Prevention

Diagnosis is also important in locations where a severe CoV outbreak is occurring, such as, at present, in the Middle East, where MERS-CoV continues to circulate. The identification of cases will guide the development of public health measures to control outbreaks. It is also important to diagnose cases of severe veterinary CoV-induced disease, such as PEDV and IBV, to control these pathogens and protect food supplies. RT-PCR has become the method of choice for diagnosis of human CoV, as multiplex real-time RT-PCR assays have been developed, are able to detect all four respiratory HCoVs and could be further adapted to novel CoVs. Serologic assays are important in cases where RNA may be difficult to isolate, is no longer present, and for epidemiological studies.

There is no anti-viral therapeutics that specifically target human coronaviruses, so treatments are only supportive. In vitro, interferons (IFNs) are only partially effective against coronaviruses. IFNs in combination with ribavirin may have increased activity in vitro when compared to IFNs alone against some coronaviruses; however, the effectiveness of this combination in vivo requires further evaluation [coronavirus]. The SARS and MERS outbreaks have stimulated research on these viruses and this research has identified a large number of suitable anti-viral targets, such as viral proteases, polymerases, and entry proteins. Significant work remains, however, to develop drugs that target these processes and are able to inhibit viral replication.

Only limited options are available to prevent coronavirus infections. Vaccines have only been approved for IBV, TGEV, and Canine CoV, but these vaccines are not always used because they are either not very effective, or in some cases have been reported to be involved in the selection of novel pathogenic CoVs via recombination of circulating strains. Vaccines for veterinary pathogens, such as PEDV, may be useful in such cases where spread of the virus to a new location could lead to severe losses of veterinary animals. In the case of SARS-CoV, several potential vaccines have been developed but none are yet approved for use.

### Review of Selected Repurposed Drugs

Chloroquine and hydroxychloroquine have a long-standing history in the prevention and treatment of malaria and the treatment of chronic inflammatory diseases including systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA).<sup>7</sup> Chloroquine and hydroxychloroquine appear to block viral entry into cells by inhibiting glycosylation of host receptors, proteolytic processing, and endosomal acidification. These agents also have immunomodulatory effects through attenuation of cytokine production and inhibition of autophagy and lysosomal activity in host cells. Chloroquine inhibits SARS-CoV-2 in vitro with a half-maximal effective concentration (EC<sub>50</sub>) in the low micromolar range.

Dosing of chloroquine to treat COVID-19 has consisted of 500 mg orally once or twice daily. However, a paucity of data exists regarding the optimal dose to ensure the safety and efficacy of chloroquine. Hydroxychloroquine dosing recommendations for SLE generally are 400 mg orally daily. However, a physiologically based pharmacokinetic modeling study recommended that the optimal dosing regimen for hydroxychloroquine in COVID-19 treatment is a loading dose of 400 mg twice daily for 1 day followed by 200 mg twice daily.<sup>15</sup> In contrast, alternative recommendations are made for 600 mg total daily dose based on safety and clinical experience for Whipple disease.<sup>11</sup> Further studies are needed to delineate the optimal dose for COVID-19.

#### Lopinavir/Ritonavir and Other Antiretrovirals

Early reports of lopinavir/ritonavir for the treatment of COVID-19 are mostly case reports and small retrospective, nonrandomized cohort studies, making it difficult to ascertain the direct treatment effect of lopinavir/ritonavir.<sup>45,46</sup> The most commonly used and studied lopinavir/ritonavir dosing regimen for COVID-19 treatment is 400 mg/100 mg twice daily for up to 14 days.<sup>12,23</sup> Given the significant drug-drug interactions and potential adverse drug reactions (summarized in Table 1), careful review of concomitant medications and monitoring are required if this drug is used. Adverse effects of lopinavir/ritonavir include gastrointestinal distress such as nausea and diarrhea (up to 28%) and hepatotoxicity (2%-10%).<sup>24</sup> In patients with COVID-19, these adverse effects may be exacerbated by combination therapy or viral infection because approximately 20% to 30% of patients have elevated transaminases at presentation with COVID-19.<sup>47</sup> A recent RCT showed approximately 50% of lopinavir/ritonavir patients experienced an adverse effect and 14% of patients discontinued therapy due to gastrointestinal adverse effects.<sup>23</sup>

### Ongoing Clinical Trials

The search terms COVID OR coronavirus OR SARS-COV-2 on ClinicalTrials.gov resulted in 351 active trials, with 291 trials specific to COVID-19 as of April 2, 2020. Of these 291 trials, approximately 109 trials (including those not yet recruiting, recruiting, active, or completed) included pharmacological therapy for the treatment of COVID-19 in adult patients. Of these 109 trials, 82 are interventional studies, with 29 placebo-controlled trials. Per description of the studies, there are 11 phase 4, 36 phase 3, 36 phase 2, and 4 phase 1 trials. Twenty-two trials were not categorized by phase or not applicable

### CONCLUSIONS

The COVID-19 pandemic represents the greatest global public health crisis of this generation and, potentially, since the pandemic influenza outbreak of 1918. The speed and volume of clinical trials launched to investigate potential therapies for COVID-19 highlight both the need and capability to produce high-quality evidence even in the middle of a pandemic. Future research on coronaviruses will continue to investigate many aspects of viral replication and pathogenesis. No therapies have been shown effective to date.

### **ABSTRACT**

*Cucurbita moschata* and *Lagenaria siceraria* seed proteins were extracted and hydrolysed with trypsin in order to recover antibacterial protein. The in vivo bactericidal activities of CMAH and LSAH were assayed using a mice model against *A. baumannii*. LSAH significantly ( $p < 0.05$ ) reduced the CFU count in the *A. baumannii* infected mice. Biochemical analysis showed that infectious mice showed significant elevation of neutrophil, WBC, count compared to CMAH, LSAH, standard treated mice and uninfected mice. Therefore, it was expected that the LSAH may used control infections caused by *A. baumannii*. This outcome is significant importance, as there are limited antibiotics available for treating Gram negative bacteria.

**Keywords:** *Cucurbita moschata*, *Lagenaria siceraria*, *A. baumannii*

### **INTRODUCTION**

Nowadays, multidrug-resistant (MDR) bacteria cause many remarkable threats to public health across the world (Antunes *et al.*, 2012). Though, there is a progress in knowledge and medical technology for the treatment of various complicated infectious diseases, still morbidity and mortality rate has become high among the people (Moellering *et al.*, 2007). Recently, a large number of novel antimicrobial drugs are being manufactured in the pharmaceutical industries and are available in the market, but they are found to be more resistant to the microorganisms (Nascimento *et al.*, 2000). The proper treatments of various infectious diseases caused by multidrug-resistant (MDR) bacteria are becoming more difficult due to production of extended spectrum lactamase in the Gram negative bacteria (Edward-Jones, 2013). Patients are infected by MDR bacterial isolates like *pseudomonas*, *Klebsiella*, and

Priyanka Dash *et al.*

*Acinetobacter* during their long term hospitalization. It has also been reported that 51.5% of patients infected with these MDR bacteria at the time of admission to hospital (Dubey *et al.*, 2014). Among Gram negative bacteria, *Acinetobacter baumannii* is found to be more versatile pathogen developing a wide range of infections in the patients of hospital, particularly critical patients of intensive care units. Currently, the treatment of various infections caused by *A. baumannii* has become more challenging due to unavailability of novel molecules. The polymyxins and tetracycline are the only antibiotics, which are active against *A. baumannii* (Hornsey *et al.*, 2013). Recently, WHO emphasizes priority on research and development of new and effective antibiotics against Gram-negative bacteria, as most of them have become resistant (Tacconelli and Magrini, 2017). The establishment of new antibiotics has become more expensive in comparable to the rate of increase of multidrug resistance. Therefore, there is a need for the development of low cost drugs for multidrug-resistant bacteria. For last few decades, the antimicrobial agents from synthetic origin have been developing critical resistance against many of the pathogenic bacteria. Till date, resistance towards the antibiotics has been the major cause of public health problems, and that imparted in the discovery of novel antimicrobial agents from natural sources. The search of novel antimicrobial principles from natural sources has paid a remarkable attention in the field of research and formulation development, as they have fewer side effects, and offering a great challenge. The medicinal plants are thus being considered in scientific community and their isolated components are thought to fight fatal opportunistic infections (Aumeeruddy-Elalfi *et al.*, 2015).

Since last few decades, it has been observed that the storage proteins of some plants are used to treat as antimicrobial agent. Several classes of proteins from plant parts with antibacterial properties have now been identified as chitinases, ribosome-inactivating proteins, thionins, chitin-binding lectins and permatins (Cammue *et al.*, 1992). Antimicrobial proteins in plants have most commonly been found in seeds at higher concentration and function as storage proteins. These antimicrobial seed proteins are very similar in structure and function to those of human antimicrobial peptides produced as a part of their defence system (Bhat and Al-daihan 2014).

A cursory survey of literature has indicated that only few studies concerning potential application of proteins with antibacterial activity from plant sources have been reported. In our previous study it was reported that *Cucurbita moschata* and *Lagenaria siceraria* seed proteins hydrolysate showed good antibacterial effect against *A. baumannii* by *in vitro* assay (Dash & Ghosh, 2018). *In-vitro models are required to establish the initial dose response. The data obtained by in vitro model is very helpful to determine the utility of antimicrobial agents. Additionally, the in vitro studies don't depend upon the fluctuation of drug concentration within the body. Therefore, prior to clinical studies, the vital potency of tested drug is determined by in vivo model* (Davis, 2004). In most of the bacterial diseases, animal study is very essential for characterization of pathogens and their host response. Thus, *in vivo* model is required for evaluation of novel treatments, host immune response and bacterial virulence factors (McConnell *et al.*, 2013). Therefore in this study protein hydrolysates of *C. moschata* and *L. siceraria* are evaluated by *in vivo* method against *A. baumannii*.

### Extraction and Purification of Albumin from *C. moschata* and *L. siceraria* Seeds

Seeds of *Cucurbita moschata* and *Lagenaria siceraria* were purchased from local market of Bhubaneswar, Odisha. Seeds were dried at 50 °C, kernels were separated manually and ground in an electric grinder into a fine powder. The powdered sample of *C. moschata* and *L. siceraria* was then extracted with n-hexane to remove the fatty material. The residue, thus obtained was homogenized in magnetic stirrer for 40 min. with distilled water, and then centrifuged at 10,000g for 10 min at 4°C temperature to get albumin as supernatant. The sediment obtained was rinsed with 5 ml of distilled water, then homogenized, followed by centrifugation in the same condition. Albumin fraction of *C. moschata* and *L. siceraria* were purified using acetone and lyophilized and kept at -20 °C until use (Teugwa *et al.*, 2013).

Priyanka Dash *et al.*

### Preparation of Albumin Hydrolysates

Albumin hydrolysate of *C. moschata* (CMAH) and *L. siceraria* (LSAH) were prepared according to the method of Dash & Ghosh (2018).

### Estimation of Protein Contents

The total protein content of seeds was determined using a Bio-Rad protein assay reagent and bovine serum albumin as described by Bradford (1976).

### *In vivo* Antimicrobial Study

**Bacterial Strain:** The test microorganisms used in this study includes three Gram-negative bacteria such as *Acinetobacter baumannii* (MTCC 1425) which were collected from the institute of microbial technology Chandigarh, India.

### Experimental Design

Mice (20-30gm) were obtained from the Department of Pharmacology, School of Pharmaceutical Sciences, S' O'A (Deemed to be University), Bhubaneswar, Odisha. Approval from the animal ethical committee of the institution was taken with letter number IAEC/SPS/SOA/09/2018. The animals had free access to standard pellet diet and water *ad libitum*. They were acclimatized in cages at an ambient temperature of  $25 \pm 2$  °C with 50–60% relative humidity for a period of one week with 12 hr day light and 12 hr dark cycle.

### *In vivo* Antimicrobial Activity of CMAH and LSAH against *A. baumannii i*

The antimicrobial efficacy of protein hydrolysates (CMAH/LSAH) was evaluated by mice model of *A. baumannii i*. In brief, five different groups of mice (4 animals in each) were taken, and each mice in each group was injected intraperitoneally with an inoculum of *A. baumannii i*, containing  $10^3$  CFU, followed by intraperitoneal administration of protein hydrolysate.

Group I: normal control (injected with saline solution)

Group II: negative control (injected with inoculums of *A. baumannii i* + saline solution)

Group III: injected with an inoculums of *A. baumannii i* + CMAH (500 mg/kg BW)

Group IV: injected with an inoculums of *A. baumannii i* + LSAH (500 mg/kg BW)

Group V: injected with an inoculums of *A. baumannii i* + gentamicin (10 mg/kg BW)

At the end of 7 days of experimental study, the mice were sacrificed by cervical dislocation. The peritoneal fluid, liver and spleen were removed aseptically from the infected mice. The blood samples were collected by heart puncture method and kept in different vials containing EDTA for prevention of clotting. A saline lavage of the peritoneal cavity was performed and lavage fluid (3 to 4 ml) was collected. Then, liver and spleen were excised, and portions of liver along with spleen and peritoneal fluid were subjected to a CFU count for viable cells on *A. baumannii i* agar medium (Maiti *et al.* 2014).

### Estimation of Quantitative Bacteriological Parameter

Liver and spleen tissues were cut into small pieces, homogenized and mixed with phosphate buffered saline (PBS). Aliquots of 10 fold serial dilutions of the homogenates in PBS were cultured on Mueller-Hinton agar plates to quantify the number of viable *A. baumannii i* organisms in the respective organs. Colonies were counted after 72 hours of incubation at 37 °C (KuoLee *et al.*, 2007). Results were expressed as number of CFU/g of organ.

### Estimation of Haematological Profile

At the end of experimental work, the 12 hours fasted rats were sacrificed by cervical decapitation. The blood samples were collected by heart puncture method and kept in different vials containing EDTA for prevention of clotting. Blood was analysed for haematological parameters such as total white blood cells (WBC), neutrophill and lymphocyte.

### Statistical Analysis

Results were expressed as mean values  $\pm$  standard deviation of three independent determinations. Statistical analysis was done using SPSS 11.0 (SPSS Inc., Chicago, IL, USA).

## RESULT AND DISCUSSION

### Estimation of Quantitative Bacteriological Parameter of Mice Treated with CMAH and LSAH against *A. baumannii* i

In order to determine the *in vivo* antibacterial activity, mice were infected with *A. baumannii* i. The *in vivo* bactericidal activities of CMAH and LSAH were assayed using a mice model as described in materials methods section. To assess the *in vivo* antimicrobial effect of CMAH and LSAH, a murine model was employed. Figure 1 showed the number of bacterial colonies of *A. baumannii* i in the spleen, liver and peritoneal fluid of mice. CMAH and LSAH treated mice significantly reduced blood and tissue bacterial burdens compared to those of infected saline-treated mice ( $P < 0.05$ ). As a result, we concluded that LSAH significantly ( $p < 0.05$ ) reduced the CFU count in the *A. baumannii* i infected mouse. Clinical signs, body weight, and survival of the mice were monitored. The body weights of the infected mice were slightly decreased due to acute infection. It is previously reported that *C. moschata* and *L. siceraria* is rich in cysteine, histidine, proline, tyrosine, glycine, arginine, lysine and serine (Yin *et al.*, 2010). Proteins rich in amino acids, such as cysteine, histidine, proline, tyrosine, glycine, arginine, lysine and serine were responsible for antimicrobial property. It was previously reported that these amino acids were frequently found in antimicrobial peptide fragments. Further, it was reported that hydrophobicity improves the hydrophobic reactions between lipid acyl chains in bacterial membrane, resulting in enhancement of membrane permeabilisation of bacteria (Song *et al.*, 2012). It is previously reported that hydrophobic amino acids content in LSAH (125.9 mg/g) was found to be more than CMAH (102.3 mg/g) (Dash & Ghosh, 2018). Lysine and arginine are the major structural units of peptides, which are help the major target molecules for interaction with bacterial membrane (Song *et al.*, 2012). The treatment of infections caused by Gram-negative pathogens was found to be much harder due to their high intrinsic drug resistance.

### Estimation of Haematological Profile of Mice Treated with CMAH and LSAH against *A. baumannii* i

Biochemical analysis showed that infectious mice showed significant elevation of neutrophil, WBC, count compared to CMAH, LSAH, standard treated mice and uninfected mice. At the end of the experiment, animals were examined for WBC and other immunological parameters. The results indicated that the WBC count of infected mice and mice treated with CMAH and LSAH was found to be  $7.3 \pm 0.6$  and  $7.9 \pm 0.2 \times 10^3$  cells/ $\mu$ L, respectively. The symptom of disease appeared in infected mice, showing increase in total WBCs count up to  $10.6 \times 10^3$  cells/ $\mu$ L in negative control mice as shown in Figure 2. The WBCs act as an immunological parameter and it determines the case of infection, while normal range of total WBCs count is  $4.2 \times 10^3$  cells/ $\mu$ L (Taha, 2013). Neutrophil content of infected mice (negative control) was  $11.8 \times 10^3$  cells/ $\mu$ L. The neutrophil content in gentamicin, CMAH and LSAH treated mice was found to be 3.25, 5.8 and  $4.25 \times 10^3$  cells/ $\mu$ L, respectively. It was found that neutrophil content of standard and LSAH was significantly not different ( $p < 0.05$ ). The neutrophil and macrophage engulf the pathogenic bacteria cells during phagocytosis. Therefore, the range of neutrophils is increased during bacterial infections (Taha, 2013). As neutrophils are hematopoietic immune cells, they are generated in the bone marrow and continued to be available in the circulations leading various types of infections. They protect the body from fungal and extra cellular bacterial infections by promoting bacterial clearance through phagocytosis, producing reactive oxygen and nitrogen species. To protect the body from infections, they also form neutrophil extracellular trap and inflammatory cytokines (Taha, 2013).

Nowadays, a multidrug-resistant (MDR) bacterium has become a global problem in public health. In this concern, *A. baumannii* i is found to be most potent antibiotic resistant Gram negative bacteria. As it is a versatile pathogen, it is

Priyanka Dash *et al.*

involved in wide range of secondary hospital infections, especially in ICU patients and in widespread lineages for citywide and nationwide outbreaks. Therefore, a large number of novel antimicrobial agents must be identified to develop more extensive resistance in *A. baumannii* (Antunes *et al.*, 2012). The antibiotics like colistin untreatable with other commercially available antibiotics (Antunes *et al.*, 2012). Therefore, it was expected that the LSAH may used control infections caused by *A. baumannii*.

## CONCLUSION

Albumin hydrolysates of *C. moschata* and *L. siceraria* were active against *A. baumannii*. LSAH significantly ( $p < 0.05$ ) reduced the CFU count in the *A. baumannii* infected mice with compare to CMAH. Biochemical analysis showed that infectious mice showed significant elevation of neutrophil, WBC, count compared to CMAH, LSAH, standard treated mice and uninfected mice. This outcome is significant importance, as there are limited antibiotics available for treating Gram negative bacteria. Only limited data are presently available on the antimicrobial activity of plant extracts in food systems and this indicates continuation of our study and the need for further work.

### ABSTRACT

From the prehistoric period, Ayurveda has been followed by Indian pupil for treatment of many ailments and it is the comprehensive summary of traditional medicines. Inflammation generally mediated through neutrophils produced from damaged or infected living tissues. Non steroidal anti-inflammatory drugs are the type of drug used for anti-inflammation by blocking cyclooxygenase pathway. Non steroidal anti-inflammatory drugs are act by different mechanisms with various side effects, so herbal drugs are preferred for relieve of pain, fever and inflammation. Africa continent enriched with several plants grown on different geographical regions with various climatic conditions and such plants contains potential active constituents having significant anti-inflammatory activity. Several studies of herbal anti-inflammatory drugs has been carried out by many researcher of Africa but further investigation is necessary to focus on unexplored bioactive plants. Consequence of this study aims in basic research encourage more ethnobotanical and ethnopharmacological survey in anti-inflammatory endowed biomedicines.

**Keywords:** Ayurveda, neutrophils, antioxidants, anti-inflammation

### INTRODUCTION

Traditional Indian medicine, Ayurveda, has a long history and one of the great traditions in the field of health issue. [1] Considerable research on pharmacognosy, chemistry, pharmacology, and clinical therapeutics has been carried out on Ayurvedic medicinal plants of India. [2,3] An enormous body of research supports the recommendations that antioxidant therapy is an attractive alternative approach for amelioration of diverse ailments such as cancer, cardiovascular diseases, inflammation, shock ischemia injury, diabetes, cataract, Alzheimer disease, and acute central nervous system injury. [4] antioxidants have been considered as one explanation for the beneficial effects of the healthy, Mediterranean-type diet. [5]

**Dharmendra Pradhan and Tapan Ku Sahu**

Reports have shown that inflammation is usually triggered by damage to living tissues resulting from bacterial, viral, fungal infections; physical agents; and defective immune response. The fundamental aim of inflammatory response is to localize and eliminate the harmful agents; secondarily, to remove damaged tissue components to culminate in healing of the affected tissues, organs, or system. An inflammatory response involves macrophages, neutrophils known to secrete different mediators that are responsible for the initiation, progression, persistence, regulation, and eventual resolution of the acute state of inflammation. The resolution of inflammation is influenced by several anti-inflammatory mediators and the recruitment of monocytes for the removal of cell or tissue debris. [6,7] It is possible that the resolution may not occur in the acute phase, thereby turning into a chronic phase. Chronic inflammation plays a role in the burdens associated with pathological conditions in both developed and developing countries. For instance, chronic inflammation is known to play a role in the development of obesity-associated diabetes secondary to insulin resistance. [6]

Various nonsteroidal anti-inflammatory drugs can reduce pain and inflammation by blocking the metabolism of arachidonic acid by isoform of cyclooxygenase enzyme (COX-1 and/or COX-2), thereby reducing the production of prostaglandin. [8] Unfortunately, there are many side effects associated with the administration of nonsteroidal anti-inflammatory drugs. [8,9] However, there are medicinal plants with anti-inflammatory therapeutic effects with low or no side effects. The African continent is richly endowed with diverse medicinal plants with anti-inflammatory activities that have been shown to be effective in the treatment of inflammatory conditions in traditional medicine. Interestingly, scientists have examined some of these African medicinal plants and documented their biological and therapeutic activities. [10-13] Unfortunately, medicinal plants from different regions in Africa with anti-inflammatory properties have not been documented in a single review paper.[14] Therefore, it is important to document the ethnobotanical knowledge and applications of anti-inflammatory medicinal plants from selected countries representing different regions in the African continent.

For centuries, Africans have treated different disease conditions including inflammatory diseases using medicinal plants. Africa is a vast continent. From Egypt, Morocco, and Algeria in the north to Nigeria and Ghana in the west, Cameroon and Gabon in the center, Kenya and Tanzania in the east, and South Africa, Lesotho, Namibia, Swaziland, and Zimbabwe in the south, there are thousands of plants with therapeutic values.[15] For example, there are over 5000 plant species growing in Zimbabwe with over 10% of these plants having medicinal value while in South Africa over 30000 flowering plants are available and some of them are used in treatment and management of pain-related inflammatory disorders in both animal and human subjects[16].The truth is that African traditional medicine is usually the first contact in meeting the primary health care need in Africa and is related to its affordability, accessibility, cultural and spiritual acceptance, and knowledge of its preparations and use.[17] The potentials of plant-derived compounds from African medicinal plants have been reported and the interest to use medicinal plants in treatment and management of disease conditions is growing rapidly in Africa even among educated African urban dwellers.[18] Mechanisms of action of plants with anti-inflammatory potentials. Various mechanisms of actions have been proposed to explain the anti-inflammatory activity of medicinal plants. These include the following:

**Inhibition of 15-Lipoxygenases (LOX)**

The lipoxygenase group of enzymes (5, 8, 12, and 15 LOX) plays a role in various inflammatory disorders. The isomeric enzyme 15-LOX is a key enzyme involved in the synthesis of leukotrienes from arachidonic acids. Biologically active leukotrienes are mediators of many pro-inflammatory and allergic reactions, hence the inhibition of the synthesis of leukotrienes by 15-LOX is seen as one of the therapeutic strategies in the management of inflammatory condition. [19-21]

**Dharmendra Pradhan and Tapan Ku Sahu****Inhibition of NOS**

Inhibition of iNOS is not considered a general characteristic of plant flavonoids. However, plant flavonoids have been reported to inhibit nitric oxide (NO) production, thereby downregulating the expression of iNOS. Flavone and amino-substituted flavones have also been reported to inhibit NO production.[ 22-24]

**Inhibition of COX**

Flavonoids are a group of polyphenols with the ability to inhibit the biosynthesis of prostaglandins. There are two commonly known isomeric forms of COX (COX-1 and COX-2). The inhibition of COX-1 and COX-2 has been reported as the molecular target of several anti-inflammatory herbal extracts and herb-derived compounds. [8,25-28]

**Inhibition of Phospholipase A<sub>2</sub>**

Arachidonic acid is a precursor of eicosanoids and is released from membrane lipids by phospholipase A<sub>2</sub>, consequently synthesizing prostaglandins, thromboxanes, and leukotri-enes. The inhibition of phospholipase by any therapeutic agent blocks the COX and LOX pathways in the arachidonic cascade have been shown to be effective in the treatment and management of inflammatory conditions. The first flavonoid inhibitor of phospholipase A<sub>2</sub> to be identified is quercetin, which inhibited human neutrophils. Selected medicinal plants that have been shown to inhibit phospholipase A<sub>2</sub> include *Allium sativum*, *Curcuma longa*, *A. cepa*, *Xylopi frutescens*. [8,29]

Inhibition of pro-inflammatory cytokines

Different kinds of pro-inflammatory cytokines are known to regulate inflammatory reactions either directly or by their ability to induce the synthesis of cellular adhesion molecules or other cytokines in certain cell types.[30] Various investigators have reported on the inhibition of pro-inflammatory cytokines following the feeding of rats with plant extracts that are rich in flavonoids. [31-34]

**Modulation of Pro-Inflammatory Gene Expression**

The predominant points of cellular regulation affected by herbs and herb-based compounds are the various protein kinases involved in signal transduction including protein kinase C and mitogen-activated protein kinase. Through inhibition of these enzymes, DNA-binding capacity of transcription factors such as nuclear factor-kappa B or activator protein-1 is regulated, thereby controlling the expression rate of the target gene.[35-39]

**PLANTS WITH ANTI-INFLAMMATORY ACTIVITY**

A brief overview of the traditional therapeutic applications of the selected plants under study is described here so as to understand their medicinal importance.

**Acrous calamus:** The rhizome constitutes the drug “Calamus” of commerce. In the Ayurvedic system of medicine, the rhizomes are considered to possess anti spasmodic, carminative, and anthelmintic actions. It is also recommended for treatment of epilepsy, amelioration of mental ailments, chronic diarrhea, dysentery, bronchial catarrh, intermittent fevers, glandular/abdominal tumors, kidney/liver troubles, rheumatism, and eczema. [40].In the past couple of decades, despite the increasing interest of the public in phytomedicine, very few drugs from higher plants have attained any prominence in conventional medical practices. Some reasons for this may be due to lack of standardization and proper scientific validation of herbal drugs. [41]. Considering the high therapeutic amplitude of antioxidants, an urgent need of standardization of botanicals and the pleuropotent medicinal importance of selected plants prompted us to design the current studies on evaluation of an antioxidant and possible anti-inflammatory potential of selected medicinal plants that are usually prescribed in the Indian traditional system of medicine. [42]

**Aegle marmelos (Rutaceae):** The aqueous extract of the root bark of Bilwa was prepared and tested for anti-inflammatory activity in albino rats using Carrageenan induced paw edema model and cotton pellet induced

**Dharmendra Pradhan and Tapan Ku Sahu**

granuloma and the standard drug was taken indomethacin and Bilwa. The result revealed that anti-inflammatory activity was expressed the inhibition.

***Bryophyllum pinnatum***(Crassulaceae): The anti-inflammatory potential of *Bryophyllum pinnatum* was investigated by ojewole et al. The study was undertaken to investigate anti-inflammatory and of the plant leaf aqueous extract in experimental animal models. In this experiment using fresh egg albumin-induced pedal (paw) oedema model and drug taken Diclofenac 100 mg/kg. The results revealed of this experimental animal study suggest that *Bryophyllum pinnatum* leaf aqueous extract possessed anti-inflammatory. The different flavonoids, polyphenols chemical constituents of the herb are speculated to account for the observed anti inflammatory of the plant. [43]

***Albizia lebbbeck***(Mimosaceae): The bark extract of *Albizia lebbbeck* Benth. obtained by cold extraction of mixture of equal proportions of petroleum ether, ethyl acetate and methanol was chosen for pharmacological screening. In rat paw edema model induced by carrageenan, the extract at the 200 and 400 mg/kg dose level showed 27.51% and 36.68% ( $P < 0.001$ ) inhibition of edema volume at the end of 4 h.

***Cassia fistula***(Caesalpinaceae): The bark extracts of *Cassia fistula* possess significant anti-inflammatory effect in the acute and chronic anti-inflammatory model of inflammation in rats. Reactive oxygen species (ROS) generated endogenously or exogenously are associated with the pathogenesis of various diseases such as atherosclerosis, diabetes, cancer, arthritis and aging process. ROS play an important role in pathogenesis of inflammatory diseases. The main constituents responsible for anti inflammatory activity of *Cassia fistula* are flavonoids and bio-flavonoids.

***Cassia occidentalis*** (Caesalpinaceae): Sreejith *et al.* was evaluated anti-inflammatory potential of whole plant of *Cassia occidentalis* using ethanolic extract. For investigation of anti-inflammatory potential dose taken 250 mg/kg and using carrageenan induced paw edema model. The result revealed that significant reduction in malondialdehyde levels of murine hepatic microsomes and significantly reduced carrageenan induced inflammation in mice at a dose of 250 mg/kg. [44]

***Berberis aristata***: The plant is an emmenagogue and is effective in the treatment of jaundice and enlargement of spleen. The fresh berries are laxative, antiscorbutic, and useful in piles, sores, and eye diseases. A decoction is used as a mouthwash for the treatment of gums and toothache. [45]

***Boerhavia diffusa***: Useful drug for treatment of inflammatory renal diseases and nephrotic syndrome. It is effective for edema and ascites resulting from early cirrhosis of the liver and chronic peritonitis. The plant is reported to be efficacious in abdominal tumors and cancer. It is also credited with antibacterial and cardiotoxic properties. [46]

***Calendula officinalis***: Flower extract possessed significant anti-inflammatory activity against carrageenan and dextran-induced acute paw edema. Oral administration of 250 and 500 mg/kg body weight *Calendula* extract produced significant inhibition (50.6 and 65.9% respectively) in paw edema of animals induced by carrageenan and 41.9 and 42.4% respectively with inflammation produced by dextran. In chronic anti-inflammatory model using formalin, administration of 250 and 500 mg/kg body weight *Calendula* extract produced an inhibition of 32.9 and 62.3% respectively compared to controls. TNF-alpha production by macrophage culture treated with lipopolysaccharide (LPS) was found to be significantly inhibited by *Calendula* extract. Moreover, increased levels of pro inflammatory cytokines IL-1beta, IL-6, TNF-alpha and IFN-gamma and acute phase protein, C-reactive protein (CRP) in mice produced by LPS injection were inhibited significantly by the extract. LPS induced cyclooxygenase-2 (Cox-2) levels in mice spleen were also found to be inhibited by extract treatment. The results showed that potent anti-inflammatory response of *C. officinalis* extract may be mediated by the inhibition of pro inflammatory cytokines and Cox-2 and subsequent prostaglandin synthesis. [47]

**Dharmendra Pradhan and Tapan Ku Sahu**

***Cedrus deodar.*** Usually prescribed for fever, diarrhea and dysentery. Alcohol bark extract has considerable anti-inflammatory activity against acute and chronic inflammations. The wood possesses diaphoretic, diuretic, and carminative properties and is useful in pulmonary and urinary disorders. The wood powder is one of the ingredients of the well-known Ayurvedic preparations “mondooravataka,” “bhardradarvadi,” and “Taila,” prescribed for anorexia, edema, piles, diabetes, leprosy, and sciatica. [48]

***Cynodon dactylon*** (Poaceae): The anti-inflammatory activity of aqueous extract of *Cynodon dactylon* at different doses using carrageenan, serotonin, histamine and dextran induced rat paw edema and cotton pellet method. The study was carried out in three different doses levels of 200, 400 and 600 mg/kg orally. The Aqueous extract of *C. dactylon* was found to be safe at all doses used and there is no mortality up to the dose of 4000mg/kg of extract when administered orally. *C. dactylon* showed significant anti-inflammatory activities in all model. The extract was found to reduce significantly ( $P < 0.001$ ) the formation of edema induced by carrageenan, serotonin, histamine and dextran after 3 and 5 h.

***Emblica officinalis*** (Euphorbiaceae) *Emblica officinalis* is a tree growing in subtropical and tropical parts of China, India, Indonesia and Malay peninsula. It has been used for anti-inflammatory and antipyretic activities in these areas. In the recent studies, the anti-inflammatory activity was found in the water fraction of methanol extract of plant leaves. The effects of fraction were tested on the synthesis of mediators of inflammation such as leukotriene B<sub>4</sub>, platelet activating factor (PAF) and thromboxane. The water fraction of methanol extract inhibited migration of human PMNs in relatively low concentrations.

***Hibiscus rosa-sinensis*** (Malvaceae) The methanolic extract of *Hibiscus rosa-sinensis* leaves (250 and 500 mg/kg body weight orally) was used in carrageenin and dextran induced rat paw edema anti-inflammatory model. Indomethacin was used as standard drug which showed significant anti-inflammatory activity. The inhibition of edema by 17.12 and 16.46% with 250 mg/kg, 45.35%, and 44.51% with 500 mg/kg body weight after 3 h with carrageenin, dextran respectively. The plant extract at the dose level of 250 and 500-mg/kg body weight by oral route exhibited significant ( $P < 0.001$ ) anti-inflammatory activities against all the agents used.

***Moringa oliefera*** (Moringaceae) The aqueous and ethanolic extract of the stem bark of *Moringa oliefera* showed % inhibition after 5 h was maximum 27.27 and 30.30% significant reduction  $P < 0.01$  and  $P < 0.05$  in the edema volume at a dose of 300 mg/kg body weight, which is comparable to standard drug Diclofenac sodium. The standard drug showed % inhibition 44.44% (25 mg/kg) body weight and significant value  $P < 0.01$ . The percentage of paw edema was found to be better with the alcoholic extract than the aqueous extract.

***Sida cordifolia*** Linn. (Malvaceae) *Sida cordifolia* is a perennial shrub of the mallow family Malvaceae. *Sida cordifolia* is used in folk medicine for the treatment of inflammation of the oral mucosa, blepharitis, asthmatic bronchitis and nasal congestion. It has been investigated as an anti-inflammatory<sup>45</sup>, for preventing cell proliferation<sup>46</sup> and for encouraging liver growth. [49]

***Eleusine indica*** L. Leaves of the plant possessed anti-inflammatory and antioxidant properties. According to Sagnia *et al.*, 2014 EI shows anti-inflammatory activity. The activity was studied by in-vitro method. Inhibition of cytokines like tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) induced by lipopolysaccharide was measured in terms of anti-inflammatory activity. LPS induced cyclooxygenase-2 (Cox-2) levels found to be inhibited by extract treatment. [50]

***Melissa officinalis* L. (Lamiaceae)** had been reported in traditional Moroccan medicine to exhibit calming, antispasmodic, and strengthening heart effects. Therefore, this study is aimed at determining the anti-inflammatory activities of *M. officinalis* L. leaves. The effect of the essential oil of the leaves of this plant was investigated for anti-inflammatory properties by using carrageenan and experimental trauma-induced hind paw edema in rats. The

**Dharmendra Pradhan and Tapan Ku Sahu**

essential oil extracted from leaves by hydrodistillation was characterized by means of gas chromatography-mass spectrometry (GC-MS). [51]

***Petrocarpus santalinus.*** The decoction of wood is effective as a tonic, astringent, and beneficial in fever, dysentery, and hemorrhage. Wood paste is externally applied in headache, inflammations, boils, piles, and in ophthalmia. [52]

***Pongamia glabra.*** Flowers are prescribed in diabetes. Seed powder is efficacious in whooping and irritating coughs in children. Oil is prescribed internally in stomachic and dyspepsia with sluggish fever; applied externally, either alone or in combination, for skin diseases, in sores, scabies, herpes, and eczema. Leaf juice is effective in cough, flatulence, and diarrhea. Leaf paste is applied internally to ulcers infested with worms. Bark paste has applications in bleeding piles, and decoction is given in beri-beri. Root extract is useful for external application to destroy maggots in foul ulcers and fistulous sores, clearing teeth, and strengthening gums. [53]

***Swertia chirayita.*** Whole plant, either powder, infusion, or as an extract, is used as an antidiarrheal, antimalarial, anthelmintic, and as a special remedy for bronchial asthma and liver disorders. It is given with sandalwood paste to stop internal hemorrhage in the stomach. [54]

***Tinospora cordifolia.*** Stem is a constituent of several Ayurvedic formulations used in general debility, dyspepsia, fevers, and urinary diseases. Dry twigs with intact bark are prescribed as anti-inflammatory, antispasmodic, and antipyretic. The roots are a powerful emetic and used for visceral obstruction. The watery extract is recommended for treatment of leprosy. Pulverized fruits are given as a tonic and also for amelioration of jaundice and rheumatism. [55]

***Withania somnifera.*** The leaves and fruits are prescribed as an antipyretic and anthelmintic. It is effective for amelioration of painful swelling, scabies, carbuncles, dropsy, cough, hiccup, leukorrhea, menstrual troubles, and rheumatism. It is found beneficial in restoring memory, used for nervous exhaustion, spermatorrhea, impotency, or seminal debility. The decoction of leaves and roots boiled with milk promotes nutrition. It is one of the important ingredients in various Ayurvedic formulations such as “ashwagandha ghrita,” “ashwagandha-arista,” and “narayana taila”. [56]

***Zingiber officinale*** (Zingiberaceae): Shimoda *et al.* 2010 was investigated the anti-inflammatory effect of *Zingiber officinale* and prepared 40% ethanolic extract from dried red ginger and evaluated its anti-inflammatory activity using acute and chronic inflammation models. The result possessed found a potent suppressive effect on acute and chronic inflammation, and inhibition of macrophage activation seems to be involved in this anti-inflammatory effect. [57]

## CONCLUSION

Plants are one of the most important sources of medicines. Since ancient time's medicinal plants have been used to treat different ailments due to their accessibility, availability, inherited practice, economic feasibility, and perceived efficacy. This review will help the recent and future researchers in more research work on these valuable medicinal plants. The aim of this review was to examine scientific studies on anti-inflammatory activities of selected medicinal plants in use in different regions of Africa. In this review, different plants from selected countries in the various geographical region (north, south, east, central, and west African countries) were identified. It can be seen that African countries are repository of medicinal plants that are readily available and used in the treatment and management of various disease conditions, including inflammatory conditions affecting the teeming population.

**Dharmendra Pradhan and Tapan Ku Sahu**

Several drugs are available both in developed and developing countries (Africa inclusive) for treatment and management of inflammatory conditions; however, many of these drugs are associated with adverse effects. Africans who majorly depend on medicinal plants to meet their health needs believe that orthodox drugs are associated with severe side effects, hence many people in Africa, especially those living in poor-resource setting, use medicinal plants in the treatment of inflammation and pain. Many studies have been performed in different African countries to evaluate the anti-inflammatory activities of medicinal plants and to validate their use in traditional medicine. Plants have the capability to synthesize various forms of phytochemical compounds as secondary metabolites, many of which have been identified and continue to be relevant in the treatment of disease conditions in the African setting.

Inflammation remains a complex process that is important for the defense of the host. Excessive production of inflammatory mediators may lead to chronic disease. From this review, it is understood that plant extracts can demonstrate anti-inflammatory activities affecting different stages of the process involved in inflammation, inhibiting formation of cytokines and eicosanoids; prevention of inflammatory reaction cascade from commencing reduce flare, itching, and excessive exfoliation. Research on plants with inflammatory activities is one of the developing areas in modern bio-medicine. Further research on plants with anti-inflammatory activities is needed since a great percentage of traditional healers across Africa may have important information of plants that have not been researched.

### ABSTRACT

The drug delivery system has become rapidly evolving and highly competitive. Further developments in drug delivery technologies are being included to optimize the efficacy as well as cost-effectiveness of the therapy. Microsponge system is a rising tool for TDDS (topical drug delivery system). Microsponge contains, macroporous beads, characteristically 10 to 25 microns in diameter, loaded with an active agent. As applied on the skin, the microsponge liberates its active ingredient on a time mode and also in response to other stimuli (rubbing, temperature, pH, etc) that are used mostly for topical and recently for oral administration. Microsponge drug delivery method entraps different types of drugs with good efficiency and can be formulated into the creams, ointment, and gel. Microsponge can be prepared by methods such as Quasi Emulsion Solvent Diffusion and Liquid-liquid Suspension method. Drug released from microsponge is by a mechanism which is Solubility, Temperature change Pressure change, pH triggered systems. Evaluation is done by using the parameter such as morphology and surface topography of microsponges, particle size determination, determination of true density, determination of loading efficiency and production yield, compatibility studies, characterization of pore structure, resiliency (viscoelastic properties), polymer/monomer composition, dissolution studies, the kinetics of release.

**Keywords:** Microsponge Delivery system, Microsponge, Topical drug delivery system

### INTRODUCTION

Several conventional as well as reliable methods have been developed for systemic drugs under the route of the transdermal delivery system (TDS) via the skin as a portal of entry. It has enhanced the safety and efficacy of several drugs that may be better administered through the skin. But transdermal delivery system is not practical for the materials delivery whose ultimate target is the skin itself [1].

**Dinesh Kumar Sharma et al.**

A Microsponge Delivery System (MDS) is highly cross-linked, porous, patented, polymeric microspheres that can entrap a wide range of active drugs and then release them onto the skin over a time and in response to trigger. This method was working for the enhancement of the performance of topically applied drugs. It is a unique system for the controlled release of topical agents and consists of microporous beads, characteristically 10-25 microns in diameter, loaded with an active agent. When the MDS applied to the skin, drug release can be controlled through diffusion or other variety of triggers, including rubbing, friction, pH, moisture, or ambient skin temperature [2,3].

Moreover, the topical drugs application has several problems such as stickiness, greasiness, associated with the ointments, and so on, which frequently result in a lack of patient compliance. These vehicles need a active agents of high concentration for useful therapy because of their low efficiency of the delivery system, resulting in allergic reactions and irritation in significant users. Other disadvantages of topical formulations are unpleasant odour, uncontrolled evaporation of active ingredient. The fundamental demand of the Microsponge system stems from these problems practised with predictable formulations in releasing active ingredients over an complete period. Usual dermatological products characteristically give active ingredients in relatively high concentrations but with a short duration of action. This may guide to a cycle of short term over medication followed by long-term under medication. More severe side effects or rashes can arise when active ingredients penetrate the skin. In compare, Microsponge technology permits an even and sustained rate of release, falling irritation at the same time as maintaining efficacy [4,5]. MDS are spherical, uniform, porous polymeric microspheres having a countless of unified voids of particle size range 5-300 $\mu\text{m}$  (Figure 1).

## Advantages Over

### Conventional Formulations

Conventional formulations of relevant drugs are proposed to act on the outer layers of the skin. Such formulated products liberate their active ingredients upon application, making a extremely concentrated layer of active ingredient that is quickly absorbed. When contrasted to the Microsponge technology can avoid extreme accumulation of ingredients within the dermis and the epidermis. Potentially, the Microsponge technology can decrease considerably the irritation of useful drugs without decreasing their efficacy. For example, the active ingredient delivering slowly to the skin like Microsponge delivery system-Benzoyl peroxide formulations have better efficacy with negligible irritation.

### Microencapsulation and liposomes

The Microsponge delivery system has merits over other technologies such as liposomes and microencapsulation. Microcapsules cannot typically control the release rate of active drugs. Once the wall is ruptured the active drugs enclosed within microcapsules will be released. Liposomes suffer from difficult formulation, lower payload, microbial instability, and limited chemical stability. While Microsponge system in compare to the above systems is compatible with most ingredients and vehicles; stable over a range of pH 1 to 11, temperature up to 130 $^{\circ}\text{C}$ ; higher payload (50 to 60%), still free-flowing and can be cost-effective; self-sterilizing as average pore size is 0.25 $\mu\text{m}$  where bacteria cannot penetrate.

### Ointments

Ointments are frequently aesthetically unappealing, stickiness; greasiness etc. that regularly results in a lack of patient compliance. These vehicles need high concentrations of drug substances for useful therapy because of their low efficiency of the delivery system, resulting in allergic reactions and irritation in significant users. Other disadvantages of topical formulations are unpleasant odor, uncontrolled evaporation of active component, and possible incompatibility of drugs with the vehicles when microsponge technology maximize the amount of time that an active component is present either on the skin surface or within the epidermis while reducing its transdermal penetration into the body[6,7].

Dinesh Kumar Sharma *et al.*

## Characteristics

### Characteristics of Microsponges [8]

1. Microsponge formulations are stable over the range of pH 1 to 11;
2. Microsponge formulations are stable at the temperature up to 130°C;
3. Microsponge formulations are compatible with most vehicles and ingredients;
4. Microsponge formulations are self-sterilizing as their average pore size is 0.25µm where bacteria cannot penetrate;
5. Microsponge formulations have a higher payload (50 to 60%), still free-flowing, and can be cost-effective.

### Characteristics of Materials that is Entrapped in Microsponges [9]

1. Most liquid or soluble ingredients can be entrapped in the particles. Actives that can be entrapped in microsponges must meet the following requirements,
2. It should be either fully miscible in the monomer or capable of being made miscible by the addition of a small amount of a water-immiscible solvent.
3. It should be water-immiscible or at most only slightly soluble.
4. It should be inert to monomers.
5. The solubility of actives in the vehicle must be limited to avoid cosmetic problems; not more than
6. 10 to 12% w/w microsponges must be incorporated into the vehicle.
7. Otherwise, the vehicle will deplete the microsponges before the application.
8. The spherical structure of microsponges should not collapse.
9. Polymer design and payload of the microsponges for the action must be optimized for the required release rate for the given period.
10. It should be stable in contact with polymerization catalysts and conditions of polymerization.

### Method of Preparation of Microsponges [10-13]

Drug loading in microsponges can take place in two ways, one-step process or by two-step process; based on the Physico-chemical properties of the drug to be loaded.

### Liquid-Liquid Suspension Polymerization

Microsponges are conveniently prepared by the liquid-liquid suspension polymerization method. Polymerization of styrene or methyl methacrylate is carried out in a round bottom flask. In their preparation, the monomers are first dissolved along with non-polar active ingredients in a suitable solvent solution of monomer and then dispersed in the aqueous phase, which consists of additives such as a surfactant, suspending agents', etc. help in the formation of suspension. Once suspension with the discrete droplets of the desired size is established; polymerization is effected by activating the monomers either by catalysis or increased temperature or irradiation.

The various steps in the preparation of microsponges are summarized as:

- Selection of monomer or combination of monomers.
- Formation of chain monomers as polymerization begins.
- Formation of ladders as a result of cross-linking between chain monomers.
- Folding of monomer ladder to form spherical particles.
- Agglomeration of microspheres, which give rise to the formation of bunches of microspheres.
- Binding of bunches to form microsponges.

Dinesh Kumar Sharma *et al.*

The polymerization process leads to the formation of a reservoir type of system, which opens at the surface through pores. In some cases, an inert liquid immiscible with water but completely miscible with monomer is used during the polymerization to form the pore network. After the polymerization, the liquid is removed leaving the porous microspheres, i.e., microsponges. (Shown in figure 2)

### Quasi-Emulsion Solvent Diffusion

When the drug is sensitive to the polymerization conditions, the two-step process is used. Microsponges were prepared by a quasi-emulsion solvent diffusion method using the different polymer amounts. In that, an external phase containing 200 ml distilled water and 40 mg polyvinyl alcohol (PVA). The internal phase consisted of ketoprofen, ethyl alcohol, polymer, and triethyl citrate (TEC), which was added at an amount of 20%, of the polymer to facilitate the plasticity.

Then, the drug can be then added to the solution and dissolved under ultrasonication at 35 °C. At first, the internal phase was prepared at 60°C and added to the external phase at room temperature. After emulsification, the mixture was continuously stirred for 2 hours. Then the mixture was filtered to separate the microsponges. The product was washed and dried by vacuum oven at 40°C for 24 hours. <sup>[13]</sup> (Shown in figure 3)

### RELEASE MECHANISM [2,14]

Microsponges can be designed to release a given amount of active ingredients over time in response to one or more following external triggers.

**Pressure:** Rubbing/ pressure applied can release active ingredients from microsponges onto the skin.

**Solubility:** Microsponges loaded with water-soluble ingredients like antiperspirants and antiseptics will release the ingredient in the presence of water. The release can also be activated by diffusion taking into consideration the partition coefficient of the ingredient between the microsponges and the outside system.

**Temperature Change:** Some entrapped active ingredients can be too viscous at room temperature to flow spontaneously from microsponges onto the skin. Increased skin temperature can result in an increased flow rate and hence release. Drug release from the topical semisolid formulation can be studied by using Franz-type static diffusion cells.

**pH Triggered Systems:** Triggering the pH-based release of the action can be achieved by modifying the coating on the microsphere. This has many applications in drug delivery.

### EVALUATION PARAMETERS OF MICROSPONGES

Various factors are affecting the drug release from microsponges. So it can be evaluated by the following factors.

#### Particle Size Determination:

Particle size analysis of loaded and unload microsponges can be performed by laser light diffractometry or any other suitable method. The values ( $d_{50}$ ) can be expressed for all formulations as a mean size range. Cumulative percentage drug release from microsponges of different particle sizes will be plotted against time to study the effect of particle size on drug release. Particles larger than 30  $\mu\text{m}$  can impart gritty feeling and hence particles of sizes between 10 and 25  $\mu\text{m}$  are preferred to use in final topical formulation [15].

**Dinesh Kumar Sharma et al.**

### Morphology and Surface Topography of Microsponges:

For morphology and surface topography, prepared microsponges can be coated with gold-palladium under an argon atmosphere at room temperature, and then the surface morphology of the microsponges can be studied by scanning electron microscopy (SEM). SEM of a fractured microsphere particle can also be taken to illustrate its ultrastructure [16].

### Determination of Loading Efficiency and Production Yield:

The loading efficiency (%) of the microsponges can be calculated according to the following equation 1.

$$\text{Loading efficiency} = \frac{\text{Actual Drug Content in Microsponges}}{\text{Theoretical Drug Content}} \times 100 \text{ — Eqn no. (1)}$$

The production yield of the microsponges can be determined by calculating accurately the initial weight of the raw materials and the last weight of the microsphere obtained.

$$\text{Production Yield (PY)} = \frac{\text{Practical Mass of Microsponges}}{\text{Theoretical Mass (polymer + drug)}} \times 100 \text{ — Eqn no. (2)}$$

### Determination of True Density:

The true density of microsponges was measured using an ultra-pycnometer under helium gas and was calculated from a mean of repeated determinations [17,18].

### Characterization of Pore Structure:

Pore volume and diameter are vital in controlling the intensity as well as the duration of the effectiveness of the active ingredient. Pore diameter also affects the migration of active ingredients from microsponges into the vehicle in which the material is dispersed. Mercury intrusion porosimetry can be employed to study the effect of pore diameter and volume on the rate of drug release from microsponges. Porosity parameters of microsponges such as intrusion-extrusion isotherms pore size distribution, total pore surface area, average pore diameters, shape and morphology of the pores, bulk, and apparent density can be determined by using mercury intrusion porosimetry [19]. The pore diameter of microsponges can be calculated by using Washburn equation [19,20].

$$D = \frac{-4\gamma \cos\theta}{P} \text{ — — Eqn no. (3)}$$

Where D is the pore diameter ( $\mu\text{m}$ );  $\gamma$  the surface tension of mercury (485 dyne  $\text{cm}^{-1}$ );  $\theta$  the contact angle ( $130^\circ$ ), and P is the pressure (psia).

Total pore area ( $A_{\text{tot}}$ ) was calculated by using the equation,

$$A_{\text{tot}} = \frac{1}{\gamma \cos\theta} \int_0^{V_{\text{tot}}} P \cdot dV \text{ — — Eqn no. (4)}$$

Where P is the pressure (psia); V the intrusion volume ( $\text{mL g}^{-1}$ );  $V_{\text{tot}}$  is the total specific intrusion volume ( $\text{mL g}^{-1}$ ).

The average pore diameter ( $D_m$ ) was calculated by using the equation,

$$D_m = \frac{4V_{\text{tot}}}{A_{\text{tot}}} \text{ — — Eqn no. (5)}$$

Envelope (bulk) density ( $\rho_{\text{se}}$ ) of the microsponges was calculated by using the equation,

**Dinesh Kumar Sharma et al.**

$$\rho_{se} = \frac{W_s}{V_p - V_{Hg}} \quad \text{--- Eqn no. (6)}$$

Where  $W_s$  is the weight of the microsp sponge sample (g);  $V_p$  the empty penetrometer (mL);  $V_{Hg}$  is the volume of mercury (mL).

Absolute (skeletal) density ( $\rho_{sa}$ ) of microsponges was calculated by using the equation,

$$\rho_{sa} = \frac{W_s}{V_{se} - V_{tot}} \quad \text{--- Eqn no. (7)}$$

Where  $V_{se}$  = the volume of the penetrometer -the volume of the mercury (mL).

Finally, the percent porosity of the sample was found from the equation,

$$\text{Porosity (\%)} = \left( 1 - \frac{\rho_{se}}{\rho_{sa}} \right) \times 100 \quad \text{--- Eqn no. (8)}$$

Pore morphology can be characterized by the intrusion–extrusion profiles of mercury in the microsponges [21].

### Compatibility studies [22,23]

Compatibility of drugs with reaction adjuncts can be studied by thin-layer chromatography (TLC) and Fourier Transform Infra-red spectroscopy (FT-IR). The effect of polymerization on the crystallinity of the drug can be studied by powder X-ray diffraction (XRD) and Differential Scanning Colorimetry (DSC). For DSC approximately 5mg samples can be accurately weighed into aluminum pans and sealed and can be run at a heating rate of 15oC/min over a temperature range 25–430°C in an atmosphere of nitrogen.

### Polymer/monomer composition [24]

Factors such as microsphere size, drug loading, and polymer composition govern the drug release from microspheres. The polymer composition of the MDS can affect the partition coefficient of the entrapped drug between the vehicle and the microsp sponge system and hence have a direct influence on the release rate of the entrapped drug. The release of drug from microsp sponge systems of different polymer compositions can be studied by plotting cumulative % drug release against time.

### Resiliency (viscoelastic properties) [25]

Resiliency (viscoelastic properties) of microsponges can be modified to produce bead lets that are softer or firmer according to the needs of the final formulation. Increased cross-linking tends to slow down the rate of release.

### Dissolution studies

The dissolution profile of microsponges can be studied by the use of dissolution apparatus USP XXIII with a modified basket consisted of 5µm stainless steel mesh. The speed of the rotation is 150 rpm. The dissolution medium is selected while considering the solubility of actives to ensure sink conditions. Samples from the dissolution medium can be analyzed by a suitable analytical method at various intervals.

### Kinetics of release

To determine the drug release mechanism and to compare the release profile differences among microsponges, the drug released amount versus time was used. The release data were analyzed with the following mathematical models:

$$Q = k_1 t \text{ or } \log Q = \log k_1 + n \log t \dots (9)$$

Dinesh Kumar Sharma *et al.*

Where  $Q$  is the amount of the released at the time ( $h$ ),  $n$  is a diffusion exponent which indicates the release mechanism, and  $k_1$  is a constant characteristic of the drug-polymer interaction.

From the slope and intercept of the plot of  $\log Q$  versus  $\log t$ , kinetic parameters  $n$  and  $k_1$  were calculated.

For comparison purposes, the data was also subjected to Eq. (10), which may be considered a simple, Higuchi type equation.

$$Q = k_2 t^{0.5} + C \dots\dots (10)$$

Eq. (10), for release data dependent on the square root of time, would give a straight line release profile, with  $k_2$  presented as a root time dissolution rate constant and  $C$  as a constant.

### SAFETY CONSIDERATIONS [26, 27]

1. Skin and eye irritation studies in rabbits
2. Oral toxicity studies in rats
3. Mutagenicity in bacteria
4. Allergenicity in guinea pigs

### APPLICATIONS OF MICROSPONGE SYSTEMS

Microsponge delivery systems are used to enhance the safety, effectiveness, and aesthetic quality of topical prescription, over-the-counter, and personal care products. Products under development or in the market place utilize the Topical Microsponge systems in three primary ways:

1. As reservoirs releasing active ingredients over an extended period,
2. As receptacles for absorbing undesirable substances, such as excess skin oils, or
3. As closed containers holding ingredients away from the skin for superficial action.

Releasing of active ingredients from conventional topical formulations over an extended period is quite difficult. Cosmetics and skincare preparations are intended to work only on the outer layers of the skin. The typical active ingredient in conventional products is present in a relatively high concentration and, when applied to the skin, maybe rapidly absorbed. The common result is overmedication, followed by a period of under medication until the next application. Rashes and more serious side effects can occur when the active ingredients rapidly penetrate below the skin's surface. Microsponge technology is designed to allow a prolonged rate of release of the active ingredients, thereby offering a potential reduction in the side effects while maintaining the therapeutic efficacy. Microsponges are porous, polymeric microspheres that are used mostly for topical and recently for oral administration. Microsponges are designed to deliver a pharmaceutically active ingredient efficiently at the minimum dose and also to enhance stability, reduce side effects, and modify drug release.

#### (i) Topical drug delivery using microsponge technology

Benzoyl peroxide (BPO) is commonly used in topical formulations for the treatment of acne and athletes' foot. Skin irritation is a common side effect, and it has been shown that the controlled release of BPO from a delivery system to the skin could reduce the side effect while reducing percutaneous absorption. Benzoyl peroxide microparticles were prepared using an emulsion solvent diffusion method by adding an organic internal phase containing benzoyl peroxide, ethylcellulose, and dichloromethane into a stirred aqueous phase containing polyvinyl alcohol [28].

Disorders of hyperpigmentation such as melasma and postinflammatory hyperpigmentation (PIH) are common, particularly among people with darker skin types. Hydroquinone (HQ) bleaching creams are considered the gold standard for treating hyperpigmentation. Recently, a new formulation of HQ 4% with retinol 0.15% entrapped in microsponge reservoirs was developed for the treatment of melasma and PIH. Microsponges were used to release HQ gradually to prolong exposure to treatment and to minimize skin irritation<sup>36</sup>. Microsponges containing mupirocin were prepared by an emulsion solvent diffusion method. The optimized microsponges were incorporated into an emulgel base. Drug release through cellulose dialysis membrane showed diffusion-controlled release pattern

and drug deposition studies using rat abdominal skin exhibited significant retention of active in the skin from microsp sponge based formulations by 24 h. The optimized formulations were stable and nonirritant to skin as demonstrated by Draize patch test. Microsponges-based emulgel formulations showed prolonged efficacy in the mouse surgical wound model infected with *S. aureus*. Mupirocin was stable in topical emulgel formulations and showed enhanced retention in the skin indicating the better potential of the delivery system for treatment of primary and secondary skin infections, such as impetigo, eczema, and atopic dermatitis [29]. An MDS system for retinoic acid was developed and tested for drug release and anti-acne efficacy. Statistically significant greater reductions in inflammatory and non-inflammatory lesions were obtained with entrapped tretinoin in the MDS40.

### (ii) Oral drug delivery using microsp sponge technology

In oral drug delivery, the microsp sponge system increases the rate of solubilization of poorly water-soluble drugs by entrapping them in the microsp sponge system's pores. As these pores are very small the drug is in effect reduced to microscopic particles and the significant increase in the surface area thus greatly increases the rate of solubilization. Controlled oral delivery of ibuprofen microsponges is achieved with an acrylic polymer, eudragit RS, by changing their intraparticle density[9].The release of ketoprofen incorporated into modified-release ketoprofen microsp sponge 200 mg tablets and Profenid Retard 200 mg was studied in vitro and in vivo. The formulation containing ketoprofen microsponges yielded well modified-release tablets. An in vivo study was designed to evaluate the pharmacokinetic parameters and to compare them with the commercially available ketoprofen retard tablets containing the same amount of the active drug. Commercial ketoprofen retard tablets showed a more rapid absorption rate than modified-release tablets and peak levels were reached within almost 3.6 h after administration. However, the new modified-release tablets showed a slower absorption rate, and peak levels were reached 8 h after administration [29].

### (iii) Bone tissue engineering using microsp sponge technology

3D biodegradable porous scaffold plays a very important role in articular cartilage tissue engineering. The hybrid structure of 3D scaffolds was developed that combined the advantages of natural type I collagen and synthetic PLGA knitted mesh. The mechanically strong PLGA mesh served as a skeleton while the collagen microsponges facilitated cell seeding and tissue formation.

The scaffolds were divided into 3 groups:

THIN: collagen microsp sponge formed in interstices of PLGA mesh;

SEMI: collagen microsp sponge formed on one side of PLGA mesh;

SANDWICH: collagen sponge formed on both sides of the PLGA mesh.

Bovine chondrocytes were cultured in these scaffolds and transplanted subcutaneously into nude mice for 2, 4, and 8 weeks. All three groups of transplants showed homogeneous cell distribution, natural chondrocyte morphology, and abundant cartilaginous ECM deposition. Production of GAGs per DNA and the expression of type II collagen and aggrecan mRNA was much higher in the SEMI and SANDWICH groups than in the THIN group.

### (iv) Cardiovascular engineering using microsp sponge technology

Biodegradable materials with autologous cell seeding require a complicated and invasive procedure that carries the risk of infection. To avoid these problems, a biodegradable graft material containing collagen microsp sponge that would permit the regeneration of autologous vessel tissue has developed. The ability of this material to accelerate in situ cellularizations with autologous endothelial and smooth muscle cells was tested with and without precellularization. Poly (lactic-co-glycolic acid) as a biodegradable scaffold was compounded with a collagen microsp sponge to form a vascular patch material. This poly (lactic co- Glycolic acid)-collagen patches with (n = 10) or without (n = 10) autologous vessel cellularization were used to patch the canine pulmonary artery trunk. Histologic and biochemical assessments were performed 2 and 6 months after the implantation. There was no thrombus formation in either group, and the poly (lactic-co-glycolic acid) scaffold was almost completely absorbed in both groups. Histologic results showed the formation of an endothelial cell monolayer, a parallel alignment of smooth muscle cells, and a reconstructed vessel wall with elastin and collagen fibers. The cellular and extracellular

Dinesh Kumar Sharma *et al.*

components in the patch had increased to levels similar to those in native tissue at 6 months. This patch shows promise as a bioengineered material for promoting in situ cellularizations and the regeneration of autologous tissue in cardiovascular surgery [10].

#### (v) Reconstruction of the vascular wall using microsponge technology

The tissue-engineered patch was fabricated by compounding a collagen-microsponge with a biodegradable polymeric scaffold composed of polyglycolic acid knitted mesh, reinforced on the outside with woven polylactic acid. Tissue-engineered patches without precellularization were grafted into the porcine descending aorta (n = 5), the porcine pulmonary arterial trunk (n = 8), or the canine right ventricular outflow tract (as the large graft model; n = 4). Histologic and biochemical assessments were performed 1, 2, and 6 months after the implantation. There was no thrombus formation in any animal. Two months after grafting, all the grafts showed well in situ cellularizations by hematoxylin/eosin and immunostaining. The quantification of the cell population by polymerase chain reaction showed a large number of endothelial and smooth muscle cells 2 months after implantation. In the large graft model, the architecture of the patch was similar to that of native tissue 6 months after implantation and this patch can be used as a novel surgical material for the repair of the cardiovascular system[30].

#### Marketed Formulations of Microsponge

Marketed formulation using the MDS includes Dermatological products that can absorb large amounts of the excess of the skin oil while retaining an elegant feel on the skin's surface. Among these products (given in table 1) are skin cleansers, conditioners, oil control lotions, moisturizers, deodorants, razors, lipstick, makeup, powders, and eye shadows; which offers several advantages, including improved physical and chemical stability, greater available concentrations, controlled release of the active ingredients, reduced skin irritation and sensitization, and unique tactile qualities.

#### CONCLUSION

A Microsponge drug delivery system is widely applicable to the transdermal drug delivery system. Microsponge Delivery System consists of microporous beads, has entrapped a wide range of active ingredients, and then controlled release of actives onto the skin over time and in response to other triggers such as pressure, ambient skin temperature and moisture. MDS is originally developed for topical delivery. MDS is originally developed for topical delivery of drugs like anti-acne, anti-inflammatory, anti-fungal, anti-dandruff, antipruritics, rubefacients, etc. Nowadays it can also be used for tissue engineering and controlled oral delivery of drugs using bio erodible polymers, especially for colon-specific delivery. MDS holds a promising future in various pharmaceutical applications in the coming years by their unique properties like small size, efficient carrier characteristics enhanced product performance and elegance, extended-release, reduced irritation, improved thermal, physical, and chemical stability so flexible to develop novel product forms. Thus MDS is a very emerging field which is needed to be explored.

### ABSTRACT

Gelatin nanoparticles cross-linking based valacyclovir have been efficiently prepared by two-step desolvation method using acetone as disolvating and glutaraldehyde as cross-linking agent along with a number of variables. FESEM images of optimized formulation elucidate the homogenous, smooth and spherical particles of mean size  $110 \pm 71.5$  nm diameter. FTIR study confirmed the absence of drug-excipients interaction and DSC spectra identified the presence and stability of valacyclovir in gelatin matrix. XRD thermogram confirmed the amorphous configuration of valacyclovir in gelatin nanoparticles. The optimized formulation have highest entrapment efficacy of 89 %. The  $T_{max}$  value of optimised formulation and commercially available "Valcivir" tablet were found 5 h and 2 h respectively in rabbit plasma with HPLC method using photodiode array (PDA) detector and reverse phase C18 analytical column. The mean  $AUC_{0-24}$  of optimised formulation was found 50% higher than that of valcivir. The study revealed that gelatin nanoparticles cross-linking based valacyclovir is not only simple and cost efficient delivery but also offers a promising controlled release with anti-viral therapy through oral administration.

**Keywords:** Gelatin nanoparticles, Valacyclovir, Two-step desolvation, Controlled release, Chromatogram, Pharmacokinetics.

### INTRODUCTION

Nanotechnology is a new generation of theranostic approaches in the field of novel drug delivery due to large surface to volume ratio, increased surface reactivity as compared to bulk material and their porous or core shell structure [1]. Gelatin is a naturally occurring protein having both cationic (lysine and arginine) and anionic (glutamic and aspartic acid) along with hydrophobic groups (leucine, isoleucine, methionine and valine) present in its

**Nityananda Sahoo et al.**

macromolecule. The high stability of gelatin is due to its unique triple helix structure consisting of three polypeptide  $\alpha$ -chains [2]. The chemical structure of gelatin is given below:

Gelatin is obtained either by partial acid or alkaline hydrolysis or by thermal or enzymatic degradation of structural animal protein collagen. Collagen represents 30% of all vertebrate body protein. More than 90% of the extracellular protein in the tendon & bone and more than 50% protein in the skin consist of collagen [3]. Over the last three decades, gelatin nanoparticles (GNPs) have been considered as real drug delivery vehicles due to their unique characteristics like nontoxic, biodegradability, biocompatibility, non-antigenicity, cost-effective, high nutritional value, abundant renewable sources, extraordinary binding capacity of various drugs, controlled and site-specific drug delivery as well as less opsonization by the reticuloendothelial system (RES) through an aqueous steric barrier in addition to greater stability during storage and *in vivo* [4].

Valacyclovir, a guanine derivative nucleoside analogue has strong antiviral activity against Herpes Simplex Virus types-1&2 and Varicella Zoster Virus [1]. After oral administration, approximately 54% valacyclovir is absorbed from the gastrointestinal tract and peak plasma concentration reaches within 2-3 h. The absorbed valacyclovir, more than 99% is rapidly hydrolyzed to acyclovir and L-valine, an essential amino acid by first-pass metabolism with the help of valacyclovir hydrolase to give high plasma acyclovir concentration [5]. Herpes virus encoded thymidine kinase is approximately 200 times greater active in virus infected cells than normal human thymidine kinase [6]. The acyclovir is selectively monophosphorylated only within virus-infected cells by virus encoded thymidine kinase, then to diphosphate by the action of host cellular guanylate kinase, and finally by cellular enzymes to form acyclovir triphosphate which terminates the production of viral DNA by inhibiting viral DNA polymerase. As acyclovir triphosphate lacks the 3'-hydroxyl group as in Figure 2, the DNA replication is competitively inhibited, resulting successful modalities for treatment and suppression of Herpes Simplex Virus (HSV) epidemics as well as cytomegalovirus suppression in immune-compromised patients. Daily effective oral dose of valacyclovir for the treatment of herpes simplex is 1 g twice a day, for herpes-zoster is 1 gm thrice a day and for cytomegalovirus is 2 g 4 times a day [7]. To reduce high expense, dosing frequency, adverse effects and to increase the bioavailability, the development of controlled release formulation is required to maintain the relatively constant drug concentration in blood level for longer duration.

Now-a-days gelatin polymer are the major focus for researchers due to high content of amino acids like glycine, proline and alanine which occur in repeating sequences and confer its triple helical structure [8, 9]. It has intrinsic protein structure with large number of different accessible functional groups, multiple modification opportunities for coupling with cross-linkers and targeting ligands which may be especially useful for developing targeted drug delivery vehicles [10]. Gelatin based nanoparticles commonly employed as a pharmaceutical adjuvant and an encapsulating drug material due to its biocompatibility, biodegradability, low antigenicity and cross-linking to make a promising carrier system for drug delivery [11, 12]. Compared to other colloidal carriers, gelatin nanoparticles are better stable in biological fluids to provide the desired controlled and sustained release of entrapped drug molecules. Only a few HPLC methods were reported in the literature for the quantitative determination of valacyclovir tablets in human serum and human biological fluids [13-14].

We developed an assay method for the estimation of valacyclovir in rabbit plasma using high-performance liquid chromatographic (HPLC) method with photodiode array (PDA) detector and the assay was validated according to Food Drug Administration (FDA) guidelines to reduce dosing frequency and physico-chemical instability as well as achieved controlled release with increased bioavailability.

Nityananda Sahoo *et al.*

## MATERIALS AND METHODS

### Materials

Valacyclovir was provided as a gift sample from Ranbaxy Laboratories Ltd., Utrakhnad, India. Gelatin type-A (180 Bloom) and Sodium metabisulphite were obtained from Sigma-Aldrich, Co (St. Louis, MO, USA). Market sample of Valcivir-1000 and Acivir-200 DT (Cipla Ltd., Sikkim, India) were procured from the retail pharmacy. Glutaraldehyde 25% v/v aqueous solution from Merck (Darmstadt, Germany), Potassium di-hydrogen phosphate ( $\text{KH}_2\text{PO}_4$ ), Disodium hydrogen phosphate ( $\text{Na}_2\text{HPO}_4$ ), Acetone, Sodium hydroxide (NaOH), Sodium chloride (NaCl) and Potassium chloride (KCl) of analytical-reagent grade were purchased from S.D. Fine Chem. Ltd. (Mumbai, India). All other chemicals and solvents used were analytical grade.

### Method

Gelatin nanoparticles (GNPs) were prepared by two-step desolvation method previously reported by Coester *et al.* [15] with slight modification of different components as shown in Table 1 and schematically represented as in Figure 3. For preparing different batches, various concentration ranges from 0.5 to 3.5 % w/v of gelatin type A were dissolved in 25 ml of *Milli-Q* water at 37 °C under magnetic stirring (600 rpm) until a clear solution was obtained. Then 25 ml acetone (desolvating agent) was added to the gelatin solution in order to precipitate the high molecular weight (HMW) gelatin. Then the supernatant consisted of some desolvated gelatin as well as gelatin in solution was discarded and the HMW gelatin was re-dissolved by adding 25 ml of *Milli-Q* water containing different amounts of valacyclovir (drug: gelatin from 1:1 to 1:50) at 37 °C under magnetic stirring (600 rpm) with adjusted at pH 2.5. GNPs with narrow range of size were formed *in situ* during a second desolvation step by drop wise addition of about 75 ml of acetone with continuous stirring. After 10 minutes, variable amounts of 25% v/v aqueous glutaraldehyde solution (100 to 400  $\mu\text{l}$ ) were added to crosslink the nanoparticles and after half an hour the cross-linking process was stopped by addition of 5 ml of 12% w/v aqueous sodium meta-bisulphite solution under magnetic stirring (600 rpm) for 12 hrs. Then the GNPs dispersion was centrifuged at 25,000 g for 30 min and the particles were purified by three fold centrifugation with acetone: water (30: 70). Then it was lyophilized at 2 mbar and -40 °C for 24 h. The prepared freeze-dried GNPs powder was stored under vacuum desiccators (2 mm Hg) at 25 °C for further use.

## CHARACTERIZATION OF VALACYCLOVIR LOADED GELATIN NANOPARTICLES

### Field Emission Scanning Electron Microscopy (FESEM)

Surface morphology of pure valacyclovir (VC), blank and optimized formulations ( $F_4$ ) was determined by field emission scanning electron microscope (JSM-6500F, JEOL UK) at an accelerating voltage of 20 kV. A small amount of sample was placed onto a FESEM holder with double sided adhesive tape and coated with a layer of gold of 150 Å for 2 min working in a vacuum ( $3 \times 10^{-1}$  atm.) of argon gas. Each experiment was carried out in triplicate.

### Size and Distribution Analysis

Particle size and distribution analysis was measured by Zetasizer NanoZS90 (Malvern Instruments, Malvern, UK) using dynamic laser light scattering (DLS) technique at a 90 degree scattering angle at 25 °C. VC loaded GNPs powder sample was mixed with 10 ml PBS (pH 7.4) and vortexed for 3 min in a glass tube. Then the prepared dispersion was filtered using syringe filter (0.45  $\mu\text{m}$ ). The mean particle size, polydispersity index and standard deviation ( $\pm$ S.D.) were obtained from the instrument. The polydispersity index (PI) value was determined as a measurement of the width of the size distribution. The PI values lower than 0.3 indicated a homogenous and mono-disperse phase while greater than 0.3 indicated high heterogeneity [16, 17]. Each experiment was carried out in triplicate.

### Drug Entrapment Efficiency

Drug encapsulation efficiency of VC loaded GNPs was determined by using ultra-centrifugation technique for separating the non-entrapped drug [18]. According to this method, 1 ml aliquot of VC-GNPs dispersion was ultra-centrifuged (Remi CPR-24) at 40,000 rpm for 2h. The supernatant solution was separated. Then the nanoparticles residue was suspended in PBS at pH 7.4 and then centrifuged again. This washing procedure was repeated two times to ensure that the untrapped drug was no longer present in the void volume between the nanoparticles. The supernatant was separated each time and drug content was determined by UV±VIS spectrometry (JASCO V-560) at 252 nm using 1-cm quartz cells against phosphate buffer (pH 7.4) as a blank. Amount of entrapped drug was obtained by subtracting amount of untrapped drug from the total drug incorporated. Each experiment was carried out in triplicate. The drug entrapment efficiency (%) was calculated by using the following formula [19].

$$\text{Drug entrapment efficacy (\%)} = \frac{\text{Amount of drug entrapped}}{\text{Total amount of drug used}} \times 100 \quad (1)$$

### Fourier Transforms Infra-Red (FT-IR) Spectroscopy

FT-IR spectroscopy was employed to record the spectrum of pure VC, blank and F<sub>4</sub> formulation using Jasco FTIR spectrophotometer (Model FTIR-4100, Jasco, USA). Samples were prepared in a KBr pellet disk with a constant resolution of 0.9 cm<sup>-1</sup> in the scanning range of 4000-400 cm<sup>-1</sup> at ambient temperature to examine the interaction between drug and excipients.

### Differential Scanning Calorimetry (DSC)

DSC measurements of pure valacyclovir, blank and F<sub>4</sub> formulations was performed by using a Perkin-Elmer differential scanning calorimeter (Model Pyre's Diamond, DSC, USA) to check the physical state of VC-GNPs whether crystalline or amorphous powder. Samples were placed in flat bottomed aluminium pans and heated from 35 °C to 350 °C using platinum crucible and alpha alumina powder as reference material. The furnace was heated at a linear heating rate of 12 °C / min with nitrogen stream at 20 ml/min.

### X-Ray Diffractometry (XRD)

XRD study was conducted to record the crystalline structure of pure VC, blank and F<sub>4</sub> formulation using an Ultima IV Multipurpose X-ray diffractometer (Rigaku, Japan). The samples were measured with nickel filtered, Cu targeted, graphite diffracted beam monochromator with voltage of 40 kV and current of 30 mA. Scanning rate employed as 1°/min over a diffraction angle of 2θ in a range from 3° to 45°.

### Kinetic Modeling

The kinetic behaviour and release mechanism of valacyclovir from glutaraldehyde modified gelatin nanoparticles were evaluated using different kinetic equations [20]. The obtained release data was fitted into different mathematical equations like zero order kinetics, first order kinetics, Higuchi kinetics and Korsmeyer-Peppas model [Eqs. (2) – (5)].

For Zero order model,

$$Q_t = Q_0 + k_0 t \quad (2)$$

For First order model,

$$Q_t = e^{-k_1 t} \quad (3)$$

For Higuchi model,

$$Q_t = Q_0 + k_H t^{1/2} \quad (4)$$

Korsmeyer-Peppas model,

$$\frac{Q_t}{Q_\infty} = k_p t^n \quad (5)$$

Where  $Q_t$  = the amount of drug released in time  $t$ ,  $Q_0$  = the initial amount of drug within nanoparticles,  $k_0$  = the zero order released rate constant,  $k_1$  = the first order released rate constant,  $k_H$  = the Higuchi rate constant,  $Q_t/Q_\infty$  = the fraction of drug released at time  $t$ ,  $k_p$  = the Korsmeyer-Peppas released rate constant and  $n$  = the released exponent that characterize the mechanism of drug released.

### Stability Studies

As per ICH (International Conference of Harmonisation) guidelines, VC-GNPs powder formulations were packed and sealed in amber glass vials and subjected to stability studies at refrigerator (2-8 °C) and room temperature (25±2 °C) for a period of 3 months [21]. At a predetermined time intervals of 1, 2 and 3 months, samples were withdrawn and hydrated with PBS and determined by monitoring any drug precipitation from the formulations under optical microscope. The mean particle size and entrapment efficiency of each sample was determined and also compared to the freshly prepared VC-GNPs formulation. Each experiment was carried out in triplicate. Further the samples were also evaluated for retention of VC (%) obtained as

$$\text{Retention of valacyclovir (\%)} = \frac{\text{Entrapped valacyclovir after storage}}{\text{Entrapped valacyclovir before storage}} \times 100 \quad (6)$$

### HPLC Analysis

Standardization of HPLC method for the quantification of valacyclovir in rabbit plasma was done by precipitation technique.

### Instrumentation

The HPLC (Shimadzu, Kyoto, Japan) consisted of a Shimadzu LC-20AD prominence solvent delivery module with manually operated 20 µl volume injector and a SPD-M20A Prominence Diode array (PDA) detector. The degasser DGU 20A3R and low pressure gradient valve FCV10AL (Shimadzu, Japan) were used to degas and control the mobile phase components respectively. Analysis was performed by using software class LC10 (version 1.6, Shimadzu, Japan). Chromatogram was carried out on a reverse phase C18 analytical column (particle size 5 µm; 250 mm × 4.6 mm i.d.; Phenomenex, Torrance, USA) at an ambient temperature.

### Standard and Working Solutions

A stock solution of valacyclovir was prepared by at a concentration of 1 mg/ml in HPLC grade water. The working solution made by diluting the stock solution with HPLC water to yield a concentration of 100 µg/ml. The stock IS solution of 0.1 mg/ml was prepared by dissolving 10 mg equivalent of acyclovir tablet powder in 100 ml of 0.1N NaOH solution. A working solution of IS (5000 ng/ml) was prepared by diluting the stock solution with HPLC water. Standard calibration curve was prepared by spiking different concentration of VC (100, 500, 1000, 2000, 5000, 10000, 20000, ng/ml) into blank rabbit plasma with addition of equal volume (100 µl) of IS working solution to each concentration. Quality control standards of valacyclovir were prepared at four different concentrations of 100, 1000, 5000 and 20,000 ng/ml and stored at -20 °C until further analysis.

### Sample Preparation

200 µl of rabbit plasma was spiked with 100 µl of VC in 2 ml micro-centrifuge tube (Ependroff, USA). To this, 100 µl of IS working solution (5000 ng/ml) was added to precipitate the plasma proteins for complete extraction of drug and IS. The mixture was centrifuged at 10,000 × g for 10 min at 4 °C. Clear supernatant was transferred into a glass centrifuge tube and evaporated to dryness under a stream of nitrogen. The residue was reconstituted with 200 µl of mobile phase and the samples were filtered through a syringe filter (0.2 µm). A 20 µl aliquot of the solution was injected into the HPLC system for analysis.

### Optimization of Chromatographic Conditions

Generally, the chromatographic separation was significantly affected by the mobile phase conditions, such as the type and composition of the organic modifiers [22]. Therefore, before optimization of the mobile phase, a number of preliminary trials were carried out with different combinations of various organic solvents and buffers at different pH, compositions, and flow rate to check the retention time, shape, resolution, and other chromatographic parameters of VC and IS. From these experiments, the mobile phase combination of buffer (0.1% acetic acid in water) and methanol with ratio 80: 20 at a flow rate 0.5 ml/min and the UV detection wavelength at 252 nm was found the most suitable.

### Method of Validation

The analytical method HPLC was validated in accordance with USFDA guide lines for industry and bio-analytical method for sensitivity, selectivity, linearity, precision, accuracy and stability. Rabbit's plasma was used for validation of this assay method.

### Selectivity and Specificity

The selectivity test was carried out to quantify accurately and specifically of VC in presence of other components in the sample. The VC peak was not superimposed by the endogenous plasma peak. The specificity was determined by comparing the chromatograms obtained from the samples containing VC and IS with those obtained from blank plasma.

### Sensitivity

According to ICH (International Conference of Harmonization) guide lines LOD (limit of detection) is the lowest amount of analyte in a sample which can be detected but not necessarily quantitated under the stated experimental conditions and LLOQ (lower limit of quantification) is the lowest amount of analyte in a sample which can be quantitatively determined with suitable precision and accuracy [23]. The LOD and LLOQ were determined according to following equation:

$$LOD \text{ or } LLOQ = \frac{kSB}{S} \quad (7)$$

Where k is a constant (3 for LOD and 10 for LLOQ), SB is the standard deviation of the analytical signal and S is the slope of the concentration/response graph.

### Linearity

Linearity was determined by plotting standard calibration curves by using seven non-zero standard points covering the range of 100–20,000 ng/ml with addition of blank plasma and fixed concentration of IS. The calibration curve was developed by plotting peak area-ratios of valacyclovir to the internal standard (IS) against the plasma concentration.

### Precision and Accuracy

Precision is the measure of how close the data values are to each other for a number of measurements under the same analytical conditions and accuracy is the measure of how close the experimental value is to the true value. Precision and accuracy were determined by the quality control of solutions containing lowest, intermediate, and highest concentrations of the calibration curve (i.e. 100, 1000, 5000, and 20,000 ng/ml) of valacyclovir. Six injections of these concentrations were injected within the same day (intra-day) for repeatability, and over a period of 6 days (inter-day) for reproducibility.

### Stability

Stability studies were performed to evaluate the assay values of blank plasma spiked with known concentration of VC (i.e. 100, 1000, 5000, and 20,000 ng/ml) within the acceptable limits of accuracy and precision under different

**Nityananda Sahoo et al.**

conditions. The samples were subjected to three times for freeze–thaw cycles at  $-20\text{ }^{\circ}\text{C}$ , short term stability at room temperature for 24 h and long term stability at room temperature for 1 month.

### Animal Study

*In vivo* study was carried out accordance with Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA), Ministry of Social Justice and Empowerment, Central Government of India and Institutional Animal Ethics Committee, Jadavpur University. Ten New Zealand albino adult male rabbits weighing 1.4–2.0 kg were used. The rabbits were kept in individual cages and supplied with diet and water *ad libitum*. The animal house was well ventilated with maintained at ambient temperature. Ten rabbits were divided into two groups of five each and kept overnight fasting before the start of experiment. Oral solution of VC was administered to Group I at a dose of 140 mg/kg body weight and Group II also fed with 140 mg/kg of optimized nanoparticles formulation ( $F_4$ ) to compare the pharmacokinetic parameters [24].

### Pharmacokinetic Analysis

Blood samples (0.5 ml) of rabbits were collected carefully from marginal ear vein at 0.5, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 8.0, 12.0 and 24.0 h after giving the dose into heparinised centrifuge tubes (2 ml). The total blood collected from a rabbit should not exceed safe bleed limit, i.e., 6.5–7.5 ml/kg body weight [25]. The plasma was immediately separated by centrifugation at 3000 g for 10 min at  $25\text{ }^{\circ}\text{C}$ . The supernatant plasma layer was collected and stored at  $-20\text{ }^{\circ}\text{C}$  until analyzed. Non-compartmental pharmacokinetic analysis was performed by the PK Solver (Version 2.0), an add-in program for pharmacokinetic data analysis in Microsoft Excel [26].

## RESULT AND DISCUSSION

### FESEM Image and Particle Size Distribution Analysis

The surface morphology of pure VC, blank and  $F_4$  formulation was found by using FESEM study as shown in Figure 4 (A), (B) and (C) respectively. The images of  $F_4$  formulation were smooth, distinct and spherical shape as compared to crystalline structures with variable sizes of pure valacyclovir. It was interesting to see that the nanoparticles maintain their spherical integrity even on encapsulation of drug. But the size of valacyclovir loaded nanoparticles increased corresponding to blank nanoparticles. No aggregate was observed. The size and diameter of valacyclovir loaded gelatin nanoparticles observed by FESEM were found well correlated with corresponding values obtained from DLS measurements at  $25.0\pm 0.1\text{ }^{\circ}\text{C}$ .

### Entrapment Efficiency

One of the most desired qualities of successful nanoparticles was their high drug loading capacity. Entrapment efficiencies of valacyclovir loaded GNPs formulations were found between 74–89 % as shown in **Table 1**. The mechanisms involved for drug loading into GNPs were physical entrapments, electrostatic attraction or chemical bonding [27]. It also depended on the molecular weight and the nature of the substance incorporated. Valacyclovir was successfully loaded into GNPs in aqueous gelatin solution by physical entrapment. The  $F_4$  formulation showed higher entrapment efficacy (89 %) than other formulations ( $p < 0.05$ ) due to their smaller particles which had larger surface area for uniform absorption and ionic interaction between the drug and matrices of gelatin nanoparticles to increase the drug loading [28].

### FTIR Spectra

FTIR spectra were recorded to analyze any interaction or incompatibility between drug and excipients during encapsulation process. The positions and the relative intensities of the absorption bands of pure VC, blank and  $F_4$  formulation were analyzed using FTIR spectrophotometer as shown in **Figure 5 (A)**. FTIR spectra of pure valacyclovir HCl showed an intense peak at  $3442.31\text{ cm}^{-1}$  which was narrated to -NH stretching. Another distinct peaks were observed at  $3325.64\text{ cm}^{-1}$  (OH stretching),  $2929.34\text{ cm}^{-1}$  (CH stretching),  $1745.26\text{ cm}^{-1}$  (C=O stretching),

24403

**Nityananda Sahoo et al.**

1683.55  $\text{cm}^{-1}$  (NH bending), 862.025  $\text{cm}^{-1}$  (CH bending), 675.75  $\text{cm}^{-1}$  (C=C-N bending), 624.53  $\text{cm}^{-1}$  (C=C-C bending) 1082.93  $\text{cm}^{-1}$  (C=N vibration), 1031.71  $\text{cm}^{-1}$  (C-O vibration). These peaks were existed without any tangible shifting but in slightly amend in F<sub>4</sub> formulation which suggested the absence of chemical interaction between valacyclovir and excipients in the gelatin nanoparticles formulation.

**DSC Study**

DSC study was carried out to confirm the physical state of VC in nanoparticles matrix. In **Figure 5 (C)**, the DSC thermogram of pure VC showed a sharp peak at 205.66 °C which close to its melting point but other two peaks at 70 °C and 85 °C were attributed to loss of water due to evaporation of absorbed water. However, VC-GNPs exhibited a very broad peak at 89.92 °C indicating the loading of valacyclovir in molecularly dispersed state in GNPs. So, DSC characteristics indicated the absence of interactions between the drug and the carriers during preparation of the formulation. This may lead to an increase in the dissolution profile of valacyclovir because amorphous drug not required energy to break up the crystalline lattice.

**XRD Study**

XRD study was elucidated the crystalline structure of valacyclovir in tailored nanoformulation as shown in **Figure 5 (B)**. The XRD pattern of valacyclovir showed that the peaks were intense and sharp, suggesting it was in crystalline state whereas blank and F<sub>4</sub> formulation exhibited few sharp peaks of low intensities indicating the amorphous state. These results confirmed the amorphous configuration of valacyclovir in GNPs.

**Stability Study (in vitro)**

**Figure 6 (A)** and **(B)** depicted the entrapment efficacy and particle size stability of F<sub>4</sub> formulation stored at refrigerated condition (2-8 °C) and room temperature (25-27 °C) during three months respectively. The change of entrapment efficacy was small but more change of particle size during in refrigerated and room temperature during three month. In **Figure 6 (C)**, it was found that the percentage of retention of valacyclovir in F<sub>4</sub> formulation was not remarkably difference at refrigerated and room temperature during 3 months. The obtained results indicated that F<sub>4</sub> formulation was more stable and remained relatively unaltered under refrigerated conditions than at room temperature, illustrating the stability of encapsulated VC in gelatin nanoparticles.

**Optimization of Chromatographic System**

In order to develop suitable HPLC method for valacyclovir (VC), several combinations of buffer and organic solvent have been tested. Buffer consisted of 0.1 % acetic acid in water produced optimal condition for separation of VC over other interfering components of plasma. Optimal isocratic separation was obtained by maintaining a reverse phase C18 column at room temperature and delivered a mobile phase (buffer and methanol in the ratio of 80:20) at a flow rate of 0.5 ml/min. This method was selected on the basis of resolution, absence of interferences and economical cost to produce good peak for valacyclovir which was well separated from IS.

**VALIDATION OF THE PROPOSED METHOD****Selectivity and Specificity**

No interfering endogenous compound peaks with analyte or internal standard was detected in **Figure 7**. Under chromatographic conditions, the retention time of valacyclovir and IS were 6.79 and 8.88 min. respectively.

**Linearity and Sensitivity**

The linear regression of the peak area ratios verses concentrations was fitted over the concentration range of 100-20,000 ng/ml in rabbit plasma. The inter- and intra-day calibration curves showed consistent linearity, as seen in consistency of intercept, slope and coefficient of correlation. The linear regression equation was calculated by the least squares method using Microsoft Excel® program. The correlation coefficient ( $R^2=0.9998$ ), indicated a strong

linear relationship between the variables. The current assay had a lower limit of quantification of 100 ng/ml, which was sufficient for monitoring valacyclovir plasma levels over a period of 24 h after a single oral administration.

### Precision and Accuracy

In this assay, the inter- and intra-day precisions ranged from 0.04 to 0.84% and from 0.03 to 0.87% for each QC level, respectively as in **Table 2**. Mean accuracy ranged from 98.49 to 99.93%. The results, calculated using one-way analysis of variance (ANOVA), indicated that the values were within the acceptable range and the method was accurate and precise. Intra- and inter-day precision in this study was expressed as percent of coefficient of variation (CV).

### Stability (*in vivo*)

Stability assessment indicated that valacyclovir was stable in plasma at the end of three consecutive freeze–thaw cycles and on the bench at room temperature for 24 h and 1 month. Additionally, valacyclovir did not show any significant degradation as in **Table 3**. When stored in plasma at  $-20\text{ }^{\circ}\text{C}$ , the peaks of valacyclovir did not have any interference with the matrix components and also not with placebo blend during storage.

### Bioavailability Study

The developed method was applied to determine the valacyclovir concentration in plasma followed by a single oral administration (140 mg/kg) with 10 rabbits. Utilizing a single step extraction and short run time, the assay demonstrated suitable accuracy and precision for application in bioavailability assessment. The method was found to be most sensitive in terms of limit of detection and more economical due to shorter retention time ( $<9\text{ min}$ ). The validation results demonstrated that precision and accuracy values were within an acceptable range and the method was suitable for application in animal or human bioavailability studies. The mean plasma concentration–time profiles of valacyclovir after oral administration of Valcivir (marketed drug) and  $F_4$  nanoparticles formulation was shown in Figure 8. Non-compartmental pharmacokinetic parameters were calculated using PK Solver and were shown in Table 4. Results indicated that  $C_{\max}$  values of Valcivir and  $F_4$  nanoparticles were  $10.90 \pm 2.57$  and  $5.10 \pm 0.88$ , respectively.  $T_{\max}$  values of Valcivir and  $F_4$  formulation were 2 h and 5 h, respectively. Again, the mean  $AUC_{0-24}$  of formulation  $F_4$  was 50% higher than that of marketed drug (Valcivir).

## CONCLUSION

Gelatin based valacyclovir nanoparticles were successfully fabricated by two-step desolvation method. GNPs with suitable concentration of glutaraldehyde and drug: polymer ratios produced smallest size, homogeneous, spherical and smooth nanoparticles with 89% entrapment efficacy. We have developed and validated a reliable, economical and sensitive reverse phase C18 analytical column of HPLC method to determine the valacyclovir in rabbit plasma using PDA detector with reasonable accuracy and precision. A good resolution was obtained between VC, Plasma and IS with retention time 6.79, 8.33 and 8.88 min, respectively. There was no interference peaks observed within them. The method was found linear ( $R^2=0.9998$ ) within the analytical range of 100–20,000 ng/ml. Furthermore, the plasma concentration–time graph of VC nanoparticles ( $F_4$ ) was significantly higher than those of marketed drug in rabbits. The  $T_{\max}$  and  $C_{\max}$  values showed a significant difference between the Valcivir tablet and valacyclovir loaded GNPs ( $F_4$ ). The study revealed that the rate and extent of oral absorption of valacyclovir from the nanoparticles formulation was comparatively higher than that of marketed product (Valcivir). Thus, the gelatin nanocarrier based valacyclovir nanoparticles formulation is a propitious controlled release anti-viral remedy through oral administration.

### ABSTRACT

Cancer is a disease which causes due to abnormal and uncontrolled cell division coupled with proliferation of tissues caused by mutations of genes. The location, grade and stage of the tumor as well as the general state of the patient determine the choice of appropriate therapy. Compared to free drugs, nanocarrier encapsulated drugs preferentially accumulate in the tumor sites thereby improving therapeutic outcomes and reducing side-effects. And due to the enormous flexibility in customization and optimization of polymers, targeting using polymeric nanocarriers can further improve the efficiency and specificity of drug delivery. Incorporation of active targeting ligands such as, antibodies, carbohydrates, peptides, folates, aptamers on the surface of polymeric nanoparticles using techniques such as functionalization, adsorption and conjugation continues to play a crucial role in the delivery of therapeutic agents towards tumor cells. Hence, polymeric nanoparticles are being carrier of choice to deliver drugs towards different tumor cells such as breast tumor, colon tumor, lung tumor prostate tumor, liver and spleen tumors.

## INTRODUCTION

### Background

Cancer is a large group of diseases having the basic characteristics property of abnormal cell growth. Normal growth of cells is a regulated process, whereas cancer growth is highly uncontrolled process. Cancer progress is a multistep process involving progressive or rapid acquirement of genetic changes, caused by epigenetic mechanisms such as gene amplification or inactivation, leading to inception of malignancy, the crucial in understanding the molecular origins of cancer. Cancer research has exposed that cancer is a disease involving vibrant alterations in the genome [1]. Proto-oncogenes are normal genes which, is altered by mutation, becomes an oncogene that can throw in to cancer. Proto-oncogenes may have many dissimilar functions in the cell. Some proto-oncogenes supply signals that guide to cell division. Other proto-oncogenes direct programmed cell death (apoptosis). The defective versions of proto-oncogenes, known as oncogenes, can cause a cell to divide in an unregulated manner. This growth can arise in the absence of normal growth signals such as those provided by growth factors. A key feature of oncogene movement is that a single altered copy leads to unregulated growth. There is basic morphological (size, shape and vasculature) and physiological dissimilarity between ordinary tissue and tumor tissue [2].

Tumors are highly heterogeneous, showing elevated proliferation along with necrosis or hemorrhages in the core and are characterized by independence in growth signals, inconsiderateness to anti-growth signals, avoiding apoptosis, wild replication, uninterrupted angiogenesis, tissue invasion and metastasis and blood vessels developed due to tumors are highly permeable due to the presence of open gaps (inter endothelial junctions & trans-endothelial channels), vesicular vascular organelles and fenestrations. Hence, this feature of the vasculature enhances macromolecular transport [3]. There are many types of tumor staging systems, but the most ordinary and helpful staging system for most types of tumors is the TNM system where T is for tumor only increasing in the most superficial layer of tissue, without growing into deeper tissues and also called in situ cancer or pre-cancer. and N is for a tumor that has spread into nearby lymph nodes and M is for a tumor which is metastasized to distant locations. Treatment for an early-stage cancer is surgery or radiation, while a more advanced-stage cancer needs to be treated with chemotherapy [4].

So far different cancer treatment modalities have been used and generally grouped in to four categories: surgery, radiation, chemotherapy and immunotherapy. The location, grade and stage of the tumor as well as the general state of the patient determines the choice of appropriate therapy. Apart from various treatment modalities chemotherapy is one of the best approaches to combat cancer but its drawbacks are becoming bothersome and its success depends on the selection of optimum delivery system [5]. Most cancer chemotherapeutics that are in common use currently (doxorubicin, topotecan, cyclophosphamide, vincristine, docetaxel or cisplatin and paclitaxel) owe insignificant selectivity for cancer cells to their higher proliferation rates, thereby increasing systemic toxicity and less therapeutic efficacy [6].

Few decades back, significant achievements has been made in understanding the molecular principles of oncologic diseases. Based on the extensive knowledge developed regarding the features of cancers, many different strategies have been devised and evaluated for cancer treatment and drug targeting to tumor cells. Some of these systems exploit the over expression of cancer related surface markers on diseased cells or the development of a dense but leaky vascular system within a tumor, forming the basis for a tumor targeting strategy [7]. Targeting of drugs to tumor cells is based on the administration of drug nanocarriers that are surface functionalized with a ligand which is capable of selectively recognizing for malignant tumor cells. ligand or receptor-mediated drug delivery to tumor cells is obtained via chemical conjugation of tumor specific molecules such as aptamers, folates, peptides, antibodies and transferrins onto the nanoparticle surface, which can be selectively bind to overexpressed receptors that are unique to cancer cells or minimally expressed on healthy cells [8].

**Gurudutta Pattnaik et al.**

Nowadays, Nanotechnology system focused on the development of target specific and slow but controlled drug release system. And this paved the way for the designing of molecules with the property of delivering of various formulations using organic/inorganic materials, easy modification of targeting molecules, drugs or other molecules on them, effective delivery to target sites, high therapeutic efficacy of drugs, controlling drug release by external/internal stimuli, minimize unwanted side effects [6]. The most common types of nanocarriers for targeted drug deliveries include: polymeric nanoparticles, liposomes, dendrimers, nanoshells, carbon nanotubes, and super paramagnetic nanoparticles. Hence, due to the unique advantage of delivering a higher concentration of pharmaceutical agent to a desired location and Increasing the stability of any volatile pharmaceutical agents, the ability to modify drug release and their very convenient feature for the manufacture of countless and varied molecular designs that can be integrated into unique nanoparticle constructs, the engineered carriers the so called polymeric nanoparticles (PNP's) are becoming the ideal candidates of drug delivery system [9].

Polymer based nanoparticles are the promising vehicles for drug delivery to target tumor cells. These carriers can be helpful to deliver higher concentration of pharmaceutical agent to the desired specific target and Increase the stability of any volatile pharmaceutical agents; such an advantage improves the drug safety. PNP's carry drugs, proteins, and DNA to target cells and organs effectively. Their nanometer-size promotes effective permeation through cell membranes and stability in the blood stream [10].

### **Drug Delivery Using Polymeric Nanoparticles**

Nanoparticle technologies have the potential to transform the era of drug development process and change the scene of pharmaceutical industry. Due to their unique physicochemical properties, PNP's have shown greater significance in delivering a range of molecules to desired sites in the body while improving the therapeutic index of drugs by enhancing their efficacy, improving the bioavailability of drugs, carrying large payloads, protecting the therapeutic agents from physiological barriers, as well as enabling to tackle the adverse effects of different drugs [11]. Polymeric type of NP's show promise as drug delivery systems as a result of their controlled and sustained release properties, sub cellular size, biocompatibility with tissue and cells. And most of these carriers owe an important advantage of preferentially targeting tumor cells by the enhanced permeability and retention (EPR) phenomenon exhibited by solid tumors compared with normal tissues. Moreover, PNP's as therapeutic carriers have other unique properties of higher therapeutic efficacy, biocompatibility, biodegradability, lower toxicity and the ability to encapsulate and deliver poorly soluble drugs [12]. For targeted drug delivery one of the following mechanisms with polymeric systems generally can be done: drug and targeting moiety are conjugated to the polymer and physically entrapping of the drug with in a polymer carrier that has been modified with a targeting moiety [13].

### **Preparation of Polymeric Nanoparticles (PNP's)**

Polymeric nanoparticles can be prepared from natural and/or synthetic polymers. Cellulose, starch, chitosan, carrageenan, alginates, xanthan gum, gellan gum, pectins are some of the biocompatible, biodegradable, less toxic and easily available types of natural polymers. And polymers such as poly lactic acid (PLA), poly(D,L lactide-co-glycolide) acid (PLGA), and polycaprolactone (PCL), poly cyanoacrylates, Poly amides, poly ortho esters, poly ethylene glycol(PEG), Poly vinyl alcohol (PVA) and Poly ethylene oxide (PEO) are the most commonly used FDA approved biocompatible synthetic polymeric materials useful for the preparation of polymeric nanoparticles [13].

Preformed polymers or direct polymerization of monomers using classical polymerization or poly reactions are the methods by which PNP's can be prepared [14] (Figure 1). The nature of the drug to be incorporated within the PNP's determines the selection of a particular method. For instance, to encapsulate hydrophilic drugs, double emulsion is preferred. And for hydrophobic drugs, nano precipitation, single emulsion, and salting-out methods can be used [15].

### Solvent Evaporation Technique

This is a technique related with dissolving both the drug and the carrier in a common solvent and then evaporating the solvent under vacuum to produce a solid solution. This technique helps to produce a solid solution of the drug and the carrier [16] (Figure 2).

### Micro-Emulsion Polymerization Technique

Micro-emulsion polymerization is a new and effective approach for preparing nanosized polymer particles and has attracted significant attention. This produces an optically clear pre-concentrate containing a mixture of oil, hydrophilic surfactant and hydrophilic solvent which dissolves a water soluble drug. Upon contact with water, the formulations spontaneously disperse (self-emulsifies) to form a very clear emulsion of exceedingly small and uniform oil droplets containing the solubilized drug [17].

### Supercritical Fluid (SCF) Technology

This is a technique of preparing PNP's by dissolving drugs and polymers in supercritical fluids (whose temperature and pressure are greater than its critical temperature and critical pressure), allowing it to assume the properties of both a liquid and a gas (Figure.3). At near critical temperatures, SCFs, are highly compressible allowing moderate changes in pressure to greatly alter the density and mass transport characteristics of the fluid that largely determine its solvent power. Once the drug particles and polymers are solubilised within the SCF (usually CO<sub>2</sub>), they may be recrystallised at greatly reduced particle size using the technique of rapid expansion of supercritical solution (RESS) [16,17].

### Salting-Out Technique

It is a technique of preparing PNP's based on the separation of a water miscible solvent from aqueous solution via a salting out effect. Polymer and drug are initially dissolved in a solvent such as acetone, which is subsequently emulsified into an aqueous gel containing the salting-out agent such as magnesium chloride, calcium chloride, and magnesium acetate, or non-electrolytes such as sucrose and a colloidal stabilizer such as polyvinyl pyrrolidone or hydroxyl ethyl cellulose. The oil/water emulsion is diluted with a sufficient volume of water or aqueous solution to enhance the diffusion of acetone into the aqueous phase, thus inducing the formation of nanospheres. Finally, both the solvent and the salting out agent are eliminated by cross-flow filtration [18].

A smart drug delivery system needs synergistic consideration of several factors. But due to other influencing factors it is difficult to get all considerations for an effective drug delivery system. High quality, reliability, efficiency and reproducibility are the most significant issues while designing an effective drug delivery system. Also the drug delivery systems have to induce the drug release and stop the release by their own manner [14]. It would be highly benefited, if the system recognizes the disease affected part, estimated the disease affected ratio, and then act to release the exact quantity of active drugs. Hence, in order to design effective drug delivery system using nanoparticles various factors should be taken in to account [18].

## Designing of Targeted Polymeric Nanoparticles Towards Specific Tumor Cells

### Passive Targeting

Nanoscale drug carriers can target tumor cells via two mechanisms namely passive or active targeting. Passive targeting is based on the transport and accumulation of PNP's through leaky tumor capillary fenestrations into the tumor interstitium by the help of enhanced permeability and retention (EPR) effect and passive diffusion to tumor tissues (Figure 4)[6]. Moreover, this targeting mechanism is devoid of any targeting molecules or ligands attached to the carrier system and this targeting mechanism do not undergo an interaction with specific receptors on tumor cells but simply enter into the tumor site through diffusion [19].

Gurudutta Pattnaik *et al.*

### Ligand-Based Targeting of PNP's (Active Targeting)

The mechanism of active targeting is through recognition of the ligand by its target substrate. To the specific receptor site Ligands may bind, after that they then can be internalized into the cell mainly through the mechanism of endocytosis. Thus, ligands stand for a diverse class of molecules that can be exploited for targeted drug delivery because the ligand-receptor complex is the result of a specific molecular interaction that requires structural complementarity [5]. Design of actively-targeted PNP drug carriers is a complex process because the ligand conjugation chemistry, the NP architecture, the types of ligands available, route of administration and protein binding nature of the PNP's all contribute to the success of the process and should be taken into account during designing [14]. To formulate a targeting drug delivery system that can develop the specific ligand-receptor interaction and subsequent receptor-mediated endocytosis, a unique process essential to the disease state must be recognized, from which key receptors, antigens, and/or binding domains associated with the disease can be used as homing devices (Figure 5)[20].

**Antibody and Antibody Fragments:** The use of tumor-associated antigens for the targeting of antibodies has been the most widely exploited form of anticancer targeting drug delivery. The source for this is that certain antigens frequently are expressed in lesser degree in normal tissues than in tumor tissues. such antigens are: the carcinoembryonic antigen, prevalent in gastrointestinal (GI), lung, and breast tumors, was the first to be identified, and it has been used extensively as a target. Hence, antibodies and their fragments have been used as homing devices for specific drug delivery [21].

**Selectins:** selectins are types of cell-cell adhesion mediator molecules that are responsible for carbohydrate binding. They mediate cell adhesion by recognizing specific carbohydrate ligands arranged on the surfaces of cells. In addition, it has been suggested that cell-cell adhesion may not be a result of only a single selectin-carbohydrate binding but rather the cumulative effect of multiple interactions of many sugar moieties (E.g Tetrasaccharide glycolipids of sialyl-Lewis X (sLex) and sialyl-Lewis A (sLea). When presented in a cluster they significantly increase their affinity and selectivity than their respective monomers. Therefore, carbohydrates can be used as a ligand to target these selectine molecules on the surface of tumor cells [22].

**Integrins:** Integrins are the heterodimeric glycoproteins consist of different subunits, which combine to form the various types of integrins. Integrin family has been identified as excellent candidates for the development of target specific cancer therapies. Adhesion between cell-cell and cell-extracellular matrix occur when integrin recognizes and specifically interacts with minimal peptide core sequence (RGD, LDV and YIGSR) in the extracellular matrix. The binding to minimal core sequences establish in the extracellular matrix depends on the degree of integrin expression on the cell surface. Integrin expression is up regulated in cancer cells compared with normal cells. Integrin function could be disrupted by using monoclonal antibodies, peptide antagonists, and small molecules as specific ligands [23].

**Vitamins:** Vitamins are essential for normal cellular function and growth. In pathological conditions, these vitamins also play crucial roles. As such, cell surface receptors for vitamins have been considered as drug targets because vitamins generally are internalized into the cell by receptor-mediated endocytosis. Such vitamins as folic acid, riboflavin, biotin and vitamin B6 all have been evaluated as potential ligands for targeted delivery of therapeutic agents to specific cells [12]. Folate receptors typically are not present in normal cells, but in a variety of human tumors they are greatly overexpressed. In addition, folate receptors mediate internalization by endocytosis. For these reasons folic acid has been examined as a homing device [7].

**Transferrin:** transferrin is a glycoprotein responsible for transporting iron into cells. Iron binds to transferrin and enters the cell through a highly specific receptor-mediated endocytosis via the transferrin receptor. Rapid recycling of the transferrin receptor allows for approximately 200 molecules of transferrin to be internalized into each cell per

**Gurudutta Pattnaik et al.**

minute. The transferrin receptor is expressed on the surfaces of cells in both proliferating and nonproliferating normal tissue, but it is highly upregulated in tumor cells, as evident by reduced transferrin levels in patients with cancer. Hence, the use of transferrin to target the transferrin receptor has been investigated for targeted drug delivery [24].

**Hormones:** The presence of hormone receptors in hormone-sensitive cancers presents potential applications of hormone-targeted drug delivery of drugs. In fact, studies have demonstrated that when doxorubicin is conjugated to an analogue of the luteinizing hormone–releasing hormone (LH-RH), cancer cell death was observed at sub-nanomolar concentrations. Therefore, this approach is potentially applicable to ovarian, endometrial, and breast cancers because the onset of tumor growth in each of these tissues is accompanied by an increase in hormone receptors [5].

**Low-Density Lipoprotein (LDL):** Lipoproteins are naturally occurring spherical macromolecular particles that transport lipids such as cholesterol and triacylglycerols through the blood–cell membrane barrier of various cells. The function of these LDL particles is mainly related with solubilizing hydrophobic lipids and transporting lipids to specific cells and tissues throughout the body. As such, they promise to be very good candidates for the targeted drug delivery of anticancer drugs to various tissues (Figure.6). In particular, various tumor cells aggressively overexpress the LDL receptors that recognize lipoproteins such as apo lipoprotein E (apoE) and apolipoprotein B-100. Since they are of natural origin, these molecules are biodegradable and biocompatible, non-immunogenic, and free from being recycled by the reticulo-endothelial system (RES) [25].

The target molecules are receptors that are mainly over expressed on diseased organs or on the surface of tumor cells. Target molecules can be proteins, sugars or lipids such as; Folate receptor (mainly expressed on breast, colon and lung tumor cells), transferrin receptor (over expressed on malignant tumors), Human Epidermal growth factor Receptor, EGFR (HER1,HER2,HER3 and HER4) mainly overexpressed on breast, ovary, prostate, bladder, lung, head and neck tumor cells. Furthermore, there are also target receptors such as vascular endothelial growth factor receptor (VEGFR) and integrin that are mainly over expressed on the vasculature of tumor cells. The types of commercially available ligands and their targets are summarized in table-1 [26].

### Mechanisms of ligand-PNP coupling

Specific ligands such as carbohydrates, folate, antibodies and nucleic acids are conjugated with the preformed PNP's using a technique called surface functionalization (Figure.7). Based on their application the nano-carriers have been commonly functionalized with various chemical functional groups such as thiols, disulfides, amines, nitriles, carboxylic acids, phosphines and bio-macromolecules. And this surface functionalization technique can be made by various modifications on the preformed PNP's through adsorption, functional surfactants, emulsification, polymerization, covalently bounded functional molecules and various forms of bio-conjugation [7,27]. The preparation of targeted PNP's involves either chemical conjugation or physical adsorption/interaction of targeting ligands with the outer surface of the PNP's (Figure.8). Chemically binding targeting ligands to nanocarriers is more desirable because it provides more precise control in terms of the density and orientation of the attached ligands and forms a stable linkage under in vivo conditions [23]. Furthermore, chemical modification can be carried out either before or after nanocarrier formation and drug incorporation. Targeting ligands are usually coupled to the terminal groups of the "stealth" PEG corona (or the corona of other hydrophilic polymers) which are easily accessible by targeting ligands for conjugation [6].

### Characterization of Polymeric Nanoparticles (PNP's)

Evaluation of PNP based drug delivery involves size distribution, porosity, solubility, surface chemistry, stability, particle size, purity, aggregation or agglomeration state, all determine the in vivo distribution, drug loading ability and release pattern, safety, stability, toxicity, efficacy of the nanoparticle and provide a basis for understanding the

structure and activity relationship (Figure 9) [1]. Simple molecules can be characterized by their molecular weight and spectral properties to determine purity and functionality. However for nanoparticles which are multipart and multifunctional, through assessment of individual parts, chemical stability, physicochemical properties along with in vitro and in vivo evaluation needs to be performed [28].

### Size Distribution, Particle Size and Surface Properties

The release of drug can be affected by Particle size, as lesser particles have big surface area[1]. Surface properties influence the adsorption of proteins, fugacity from phagocytes and fate of bioavailability [28]. These parameters are determined using the following techniques such as scanning electron microscopy (SEM), Atomic force microscopy (AFM) and Photon-correlation spectroscopy (PCS) also known as dynamic light scattering (DLS) [29].

### Hydrophobicity

Surface charge determines the electrostatic interaction of polymeric nanoparticles with bioactive compounds. This is evaluated through Zeta potential of the PNP's, which provides information about surface hydrophobicity, storage stability, and nature of the material encapsulated. Surface hydrophobicity can also be determined by contact angle measurements, bi-phasic partitioning, hydrophobic interaction chromatography, while specific chemical groups attached to the surface can be identified by X-ray photon correlation spectroscopy [1,23].

### Purity and Functional Characterization

The structure, purity and functionality of PNP's can be characterized using NMR spectroscopy, UVvisible detectors and fluorescence detectors. And their composition can also be determined by Atomic absorption (AA) and Atomic emission (AE) [11].

### Stability

Stability of the PNP's under physiological and non-physiological conditions deems essential for their biological activity, storage, light and thermal exposure, lyophilisation, ultra filtration, pH variation. Molecular weight can be determined by Matrix-assisted laser desorption ionization time-of-flight (MALDI-TOF) mass spectroscopy, along with presence of impurities. Quantification of nanoparticles can be performed by Enzyme-linked immunosorbent assay (ELISA) or bicinchoninic acid (BCA), UVspectroscopy or High performance liquid chromatography [24-27].

### Drug Loading

Drug loading and subsequent release are the two major factors which determine the amount of drug reaching the tumor site. As the drug reached the targeted site, its release is governed by drug solubility, desorption of the surface adsorbed drug, PNP's matrix degradation, drug diffusion through carrier matrix and combination of erosion/diffusion processes. Dialysis bag diffusion method, agitation followed by ultracentrifugation, centrifugal ultracentrifugation methods, analyse the time period for the release of drugs And and an important parameter in the development of successful formulations is the efficient release of the PNP encapsulated drug. Different techniques are such as UV spectroscopy, gel filtration and NMR spectroscopy are used to analyse the mechanisms of drug loading [1,5,16-29].

### In-vitro and In-vivo Characterization

In-vitro characterization of PNP's performed frequently with in-vivo studies that assesses the pharmacokinetics, efficacy, physiological and biochemical mechanisms, providing information about the biodistribution and toxicity profiles of nanoparticles [1]. In-vitro characterization includes cell-binding and pharmacology, cellular uptake and distribution, contact with blood, sterility and pyrogenicity. Moreover, In-vitro characterization establishes the strategy of investigations required for in-vivo trials [30].

### Applications of Targeted PNP's for the Treatment of Different Cancers

Actively targeted PNP's have paramount applications in the management of many neoplastic diseases such as brain tumor, prostate tumor, cervical tumor, ovarian cancer, endometrial tumor and other tumor types [1]. And some important applications of PNP's for the treatment of some selected tumor types are discussed below.

#### Breast Cancer

Breast tumor is the most common tumor that affect females and one of the main causes of mortality in women. Most of the invasive type of breast tumors overexpress the receptor called VEGFR human epidermal receptor (HER-1,2,3&4). And this receptor has been the target of many ligands of monoclonal antibodies (such as trastuzumab and pertuzumab) that are conjugated with the PNP's incorporated with drug like paclitaxel (PTX) or Doxorubicin (Dox) has shown to enhance tumor progression free survival of patients. Due to the enhanced folate requirements for DNA synthesis the majority of tumor cells overexpress folate receptors onto their surfaces. Hence, doxorubicin - loaded PNP's surface engineered with PEG and folic acid were shown to have greater accumulation in the tumor cells and have greater antitumor activity by reducing the mean tumor volume [21].

#### Liver and Spleen Cancers

Peptides that contain RGD domains can preferentially bind cells in tumor microvasculature that express the  $\alpha v \beta 3$  integrin. Integrin receptors are also expressed on the cell membrane of macrophages and it is shown that RGD bioconjugates aggregate in spleen and liver tissues due to macrophage clearance. Using an RGD-targeted stealth system, NPs carrying Dox were found to accumulate faster and in higher concentrations in the liver and the spleen [31].

#### Lung Cancer

Lung cancer (LC) involves signaling pathways that influence angiogenesis, tumorigenesis and tumor growth, and different targeted agents have been used towards vascular endothelial growth factor receptor (VEGFR), platelet-derived growth factor receptor (PDGFR), EGFR and insulin-like growth factor 1 receptor (IGF-1R). Of these receptors IGF-1R is a key signaling pathway that leads to the growth and survival of tumor cells and is commonly overexpressed in lung cancer cells. Figitumumab is a fully human monoclonal antibody that is a specific and potent inhibitor of IGF-1R. In combination with PNP's containing carboplatin/PTX, figitumumab has shown to be a promising antitumor agent as first line treatment of LC [1, 20].

#### Colon Cancer

In the case of colon cancer, it was investigated that the introduction of peptides containing the RGD sequence such as PR-b (a peptide sequence that mimics the cell adhesion domain of fibronectin) onto the surface of 5 - fluorouracil loaded PNP's was found to be capable of targeting colon cancer cells that express the integrin  $\alpha 5 \beta 1$ , leading to a greater cytotoxicity compared to the non -targeted nanoplatfrom [32].

### SUMMARY

Cancer is a group of diseases which causes an abnormal and uncontrolled cell division coupled with proliferation of tissues caused by mutations of genes with malignant behavior such as invasion and metastasis. The location, grade and stage of the tumor as well as the general state of the patient determine the choice of appropriate therapy. Tumor cells have different development stages. And tumor in the early-stage can be treated with surgery or radiation, while a more advanced-stage cancer needs to be treated with chemotherapy. Compared to free drugs, nanocarriers (polymer)-encapsulated drugs preferentially accumulate in the tumor sites through the EPR effects so called passive targeting, thereby improving therapeutic outcomes and reducing side-effects. Targeting of polymeric nanocarriers can further improve the efficiency and specificity of drug delivery. Polymer systems offer enormous flexibility in customization and optimization of nanocarriers particularly polymeric nanoparticles to efficiently deliver therapeutics to their specific targets. Incorporation of active targeting agents such as, antibodies, peptides, folates,

**Gurudutta Pattnaik et al.**

aptamers on the surface of polymeric nanoparticles using techniques such as functionalization, adsorption and conjugation will continue to play a crucial role in the delivery of therapeutic agents towards different target molecules over expressed on the tumor cells the so-called active targeting.

### Future Research Directions

So far, though considerable amount of researches have been done in the field of drug delivery using polymeric nanoparticles, most of the researches have been focused on designing of polymeric nanoparticles for a specific applications. Therefore, based on the upshot of this thesis some research directions are highlighted for further investigation by future researcher's. Designing of polymeric nanoparticles with high drug encapsulation capacity. Polymeric nanoparticles with multiple drug and ligands. Preparation and characterization of polymeric nanoparticles for other pathologies.

### ABSTRACT

A simple, accurate precise and reproducible High Performance Thin layer Chromatographic (HPTLC) method has been developed for the simultaneous estimation of Lamivudine, Zidovudine and Nevirapine in pharmaceutical dosage forms. It was performed on TLC plate precoated with silica gel 60F254 as stationary phase using mobile phase comprising of Chloroform: Methanol (90:10 v/v). The detection was carried out by UV detection at 265 nm showing R<sub>f</sub> value 1.66 for Lamivudine, 8.66 for Zidovudine and 11.60 for Nevirapine. The percentage estimation of labeled claims of Lamivudine, Zidovudine and Nevirapine from marketed tablet was found to be 99.68, 99.36 and 99.81 respectively. The method was validated in terms of accuracy, precision, specificity and ruggedness. Linearity was observed between 900-2100 µg/ml for Lamivudine, 1800-4200 µg/ml for Zidovudine and 1200-2800 µg/ml. The recovery studies were carried out by adding known quantity of standard drugs in the pre-analysed test solution and percentage recovery calculated in each case. The percentage recovery studies for Lamivudine, Zidovudine and Nevirapine were found within the range of 99.41- 99.58 %. The proposed method was found to be accurate, precise, simple and rapid could be used for routine analysis.

**Keywords:** HPTLC, Lamivudine, Zidovudine and Nevirapine and Tablets

## INTRODUCTION

**Zidovudine (ZDV)** [1-6] is an orally administered thymidine derivative with effects for the management of HIV infection. It is from the class of nucleoside reverse transcriptase inhibitor. Chemically, 3'-azido-2',3'-di deoxythymidine. Its empirical formula is C<sub>10</sub>H<sub>13</sub>N<sub>5</sub>O<sub>4</sub> and molecular weight 267.242. The mode of action is by terminating the growth of the DNA chain and inhibiting the reverse transcriptase of HIV.

**Lamivudine (LMV)** [1-6] is an orally administered. It also belongs to the class of nucleoside reverse transcriptase inhibitor. Chemically, lamivudine is L-2',3'-dideoxy-3'-thiacytidine. Its empirical formula is C<sub>8</sub>H<sub>11</sub>N<sub>3</sub>O<sub>3</sub>S and molecular weight is 229.26. It acts by competes with deoxycytidine tri- phosphate for binding to reverse transcriptase and incorporation into DNA results in chain termination.

**Nevirapine (NVR)** [1-6] is an orally administered antiretroviral drugs. It belongs to the class of non-nucleoside reverse transcriptase inhibitor (NNRTI). Chemically, nevirapine is 1-cyclopropyl-5,11-dihydro-4-methyl- 6H-dipyrido[3,2-b: 2', 3'-e][1,4]diazepin-6-one. Its empirical formula is C<sub>15</sub>H<sub>14</sub>N<sub>4</sub>O and molecular weight is 266.298. It acts by binding to reverse transcriptase adjacent to the catalytic site and terminate the DNA chain. The earlier literature survey [7-18] reveals the analytical methods like UV, HPLC and HPTLC are available for determination of these drugs individually and other combinations in pharmaceuticals and biological preparations. There is no method has been reported for the estimation of LMV, ZDV and NVR simultaneously. In the present investigation an attempt was made to develop a simple and economical HPTLC with greater precision, accuracy and sensitivity for the simultaneous estimation of LMV, ZDV and NVR in pure and tablet dosage forms.

## EXPERIMENTAL

All chemicals and reagents used were of AR/HPLC grade silica gel precoated aluminium plates with thickness of 200 µm, E-Merck, Germany were used as a stationary phase with the instrument CAMAG-HPTLC system comprising of CAMAG LINOMAT IV sample applicator, CAMAG TLC scanner III with CATS software and CAMAG twin trough chamber with stainless steel lids. Pure samples of LMV (3 TC), ZDV and NVR (NEV) were obtained as a gift samples from AEON Pharmaceuticals, Puduchery.

### Preparation of Standard Solution

An accurately weighed quantity of 150 mg Lamivudine (working standard) and 300 mg Zidovudine (working standard) and 200 mg Nevirapine was dissolved in mobile phase (Chloroform and Methanol (90:10)) make up to 10 ml to obtain a stock solution of 15000 µg/ ml of Lamivudine, 30000 µg/ ml of Zidovudine and 20000 µg/ ml of Nevirapine.

### Chromatographic Conditions

Various solvent systems were evaluated to arrive at an optimum resolution of the two drugs. The solvent system consisting of Chloroform: Methanol (90:10 v/v) gave dense, compact and well separated spots of the drugs from the mixture. The chamber was saturated for 10 min. sample was applied at a constant rate of 0.16/µl/sec having scan speed of 10 mm/sec with 16 mm band width the samples were separated by ascending technique. The chamber was maintained at 20± 0.50 C temperature and 50-60% relative humidity. The scanning of the plate was scanned at 265 nm.

### Calibration Curve

LMV, ZDV and NVR solutions ranging from 900-2100 µg/ml, 1800-4200 µg/ml and 1200-2800 µg/ml were applied on TLC plate by automatic sample applicator. The plates were developed, dried and densitometrically scanned at 265 nm. Peak height and area were recorded for each concentration and curves (Peak area Vs concentration) were constructed.

### Sample Preparation

To determine the content of Lamivudine, Zidovudine, and Nevirapine simultaneously in conventional tablets (Label claim: 300 mg of Lamivudine, 200 mg of Zidovudine and 200 mg of Nevirapine per tablet). Twenty tablets were weighed, their mean weight determined and they were finely powdered and powder equivalent to 150 mg of Lamivudine, 300 mg of Zidovudine and 200 mg of Nevirapine was weighed. Then equivalent weight of the powder was transferred into a 100 ml volumetric flask. The contents were dissolved in chloroform: methanol (90:10) and volume made up to the mark. The contents were mixed well using Ultrasonicator and filtered through Whatman filter paper No.42. The filtered solution was then used for the estimation.

### ESTIMATION METHOD

The sample solution was spotted on the chromatoplate with the help of Linomat IV spotting system. The chromatoplate was developed in a twin trough chamber containing the mobile phase. The chromatograms were recorded and R<sub>f</sub> values were determined for Lamivudine, Zidovudine and Nevirapine. The amount of drug present was calculated by comparing the peak area values of standard with that of sample as follows.

$$\text{Amount of drug in each tablet} = \frac{\text{Peak area of test}}{\text{Peak area of Standard}} \times \frac{\text{Standard dilution factor}}{\text{sample dilution factor}} \times \text{Ave. weight of tablet}$$

### RESULTS AND DISCUSSIONS

Various solvent systems were evaluated to arrive at an optimum resolution of the two drugs. The solvent system consisting of Chloroform: Methanol (90:10 v/v) gave dense, compact and well separated spots of the drugs from the mixture. The R<sub>f</sub> values were found to 01.66, 08.66 and 11.60 for Lamivudine, Zidovudine and Nevirapine, respectively. All the peaks were symmetrical in nature and low value of tailing was observed when plates were scanned at 265 nm. The plot of peak areas versus concentration of Lamivudine, Zidovudine, and Nevirapine were found to be linear in the concentration range 900-2100 µg/ml, 1800-4200 µg/ml and 1200-2800 µg/ml, respectively. The corresponding correlation values are given in Table-1.

The proposed method was successfully applied to the analysis of Lamivudine, Zidovudine, and Nevirapine in tablet (labeled to contain Lamivudine 150mg, Zidovudine 300mg and Nevirapine 200 mg as active substances). The results and statistical parameters are shown in Table-2. The low values of %RSD indicated high precision of the method. The precision of the method was demonstrated by repeatability studies. The precision of the proposed method was determined by assaying the standard solutions on the same day and on three different days over a period of two weeks and expressed as %RSD. The intra-day and inter-day precision has been depicted in Table-3. To confirm the accuracy of the proposed method, recovery experiments were carried out by standard addition technique by adding a known amount of standard at three different levels to the pre-analyzed sample. Each level was repeated three times and the amount of drug found by the assay method, results and statistical parameters are reported in Table-4. The results show that the method is precise and accurate.

## ACKNOWLEDGEMENT

The Authors are thankful to, School of Pharmacy, Centurion University of Technology and Management Odisha for providing laboratory facilities.

### ABSTRACT

Two simple, accurate, sensitive and reproducible Ion –pair Spectrophotometric methods (1& 2) have been developed for the determination of Sertaconazole Nitrate (STZ) in bulk drugs and also in tablets and spiked human urine. The proposed methods are based on complexation of the drug with Alizarin Red S (Method 1) and Patent blue vf (Method 2), extracted with chloroform, showing absorbance maxima at 416 nm and 633 nm respectively. Beers law obeyed over a concentration range of 20-80µg/ml and 05-40µg/ml for Method 1 and Method 2 respectively. Results of analysis for the two methods established were validated statistically and also by ICH guidelines. All the variables were studied to optimize the reaction conditions. No interference was observed in the presence of common pharmaceutical excipients. The validity of the methods was tested by analyzing the drug in its pharmaceutical formulation. Good recoveries were obtained.

**Keywords:** ion –pair color complex, STZ, Alizarin red S, Patent blue vf and molar absorptivity.

### INTRODUCTION

Sertaconazole nitrate is a chemically 1-[2-[(7-chloro-1-benzothiophen-3-yl) methoxy]-2-(2,4-dichlorophenyl) ethyl]imidazole; nitric acid. It is a nitrate salt form of Sertaconazole, a synthetic imidazole derivative with antifungal property [1].It has also antipruritic activity [2].A survey of the literature revealed that several analytical methods have been reported for the determination of the studied drugs in the pure drug form, pharmaceutical dosage forms and biological samples using liquid chromatography, either in single or combined form[3–5], capillary zone electrophoresis methods [6] electrochemical methods [7] , non-aqueous titration [8] spectrofluorimetric methods and

24428

**Vijaya Kumar Meher et al.**

spectrophotometric methods [9-13]. Visible spectrophotometry has remained competitive in the area of chromatographic techniques for pharmaceutical analysis due to its simplicity and cost effectiveness, sensitivity and selectivity, fair accuracy, precision and available in most quality control laboratories. In addition, this method does not require the costly instrumentation that is required for the published HPLC methods. Extractive spectrophotometric procedures are popular due to their sensitivity in the assay of drugs, and therefore, ion-pair spectrophotometry has received considerable attention for the quantitative determination of many pharmaceutical compounds [14-18].

## MATERIALS AND METHODS

**Instrumentation Used:** A Shimadzu UV-Vis double beam Spectrophotometer (pharmaspec-1700) with 1cm matched quartz cells was used for all spectral measurements. Microprocessor based colorimeter (Elico CL 220), UV-visible spectrophotometer double beam (Elico SL 220), Metzer colorimeter, Metzer pH meter and single electronic pan balance (Contech) were used in the assay procedure, acetate buffer (pH 3.0), Patent blue vf (0.02%), Alizarin Red S (0.1%), double distilled water.

### METHOD-1(ARS)

**Standard Stock Solution:** Standard stock solution of STZ (100 $\mu$ g/ml) was prepared in acetate buffer (pH 3.0) and used for the analysis.

**Working Standard Stock Solution:** 2, 3, 4, 5, 6, 7 and 8ml of standard stock solutions were taken in 07(seven) different 10ml volumetric flasks and diluted up to mark with acetate buffer (pH 3.0) in order to get 20, 30, 40, 50, 60, 70 and 80 $\mu$ g/mL drug concentration respectively.

**Selection of  $\lambda$  Max:** 30  $\mu$ g/mL of drug solution was scanned between 350 to 700 nm to find out  $\lambda$  max (i.e. the wavelength at which amplitude is maximum) 416nm.

**Stability of Color Complex:** It has been observed that the yellow color complex was stable for more than 2 hours. The absorbance was measured at an every 20mins for 2 hours and found that S.D. is 0.22.

**Construction of Calibration Curve:** Entire content of working standard stock solution were transferred to seven (7) different 125ml separating funnels. 2ml of alizarin red s (0.1%) was transferred into each separating funnel and shaken well for 5mins and kept aside for 5mins. 10ml of chloroform was added into each separating funnel and shaken well for 3mins and the drug was extracted into the chloroform layer and it was separated into seven (7) different 25ml volumetric flasks. The organic layer was then passed over anhydrous sodium sulphate and the maximum absorbance was measured at 416nm against the reagent blank. The blank solution was prepared by utilizing all the above reagents excluding the drug solution. The calibration curve was plotted using concentration Vs. absorbance. The linear regression equation was found to be  $Y = 0.0307x - 0.5856$  and the Correlation coefficient ( $r^2$ ) = 0.9924. The linearity data of drug is given in the Table 1. The linearity curve is shown in the Figure 1. The overlay visible absorbance spectrum is shown in the Figure 2.

**Assay of Tablet:** Twenty tablets are weighed accurately and ground into a fine powder. An amount of powder equivalent to 10mg of Sertaconazole nitrate was weighed into a 100ml volumetric flask, about 40ml of freshly prepared buffer pH 3.0 was added and sonicated thoroughly for about 5mins, then the volume was made up to the mark with the buffer, well and filtered using Whatman filter paper No 42 and the first few milliliters of the filtrate were discarded. 3ml of filtered tablet sample solutions were transferred into four different 10 ml volumetric flasks

**Vijaya Kumar Meher et al.**

and the volume was made up to the mark with the double distilled water. The contents of the volumetric flasks were transferred into four (4) different 125ml separating funnels and 1ml of alizarin red s solution (0.1%) was added into each separating funnel. 10ml of chloroform was added into each separating funnel and shaken for 5mins and kept aside for 3mins. The chloroform layers were collected in volumetric flasks and measured the absorbance at **416nm**. The concentration of the drug was calculated by employing the linear regression equation. The results of tablet analysis are shown in the Table 2.

**Accuracy:** It was found out by recovery study using standard addition method. Known amounts of standard solution was added to pre-analyzed samples at a level of 80%, 100% and 120% and then subjected to the proposed colorimetric method. Results of recovery studies are shown in Table 3.

**Urine Sample :** Drug- free human urine was obtained from a healthy male aged about 28 years.

#### **Procedure for Assay in Spiked Urine (Pure Drug)**

10 mL of urine, 5 mL of acetonitrile, and 10 mL of 30 µg/mL Sertaconazole nitrate solutions [in buffer (pH 3.0)] were added into a 25 mL volumetric flask. The resulting solution was filtered through a Whatman No. 42 filter paper and then transferred into a 125 mL separating funnel. Then, 1mL of Alizarin Red S (01%) was transferred into a separating funnel and it was shaken for 3 minutes. 15 mL of chloroform was added into the separating funnel and shaken well for 5 min and kept aside for 5 min. The drug was extracted into the chloroform layer and it was separated into 25 mL volumetric flasks. The organic layer was then passed over anhydrous sodium sulfate, and the maximum absorbance was measured at 416 nm against the reagent blank. The blank solution was prepared by utilizing all the above reagents excluding the drug solution. The concentration of STZ in urine was found by using the linear regression equation. The results are given in the Table 4.

#### **Procedure for Assay in Spiked Urine (Formulation, I.E. Tablet)**

In a 25 mL volumetric flask, 10 mL of urine, 5 mL of acetonitrile, and 10 mL of 10 µg/mL tablet sample solution [in acetate buffer (pH 3.0)] were added. The resulting solution was filtered through a Whatman No. 42 filter paper, and then transferred into a 125 mL separating funnel. Then, 1 mL of patent blue vf solution (0.1%) was transferred into a separating funnel and 15 mL of chloroform were added into the separating funnel and shaken well for 5 min and kept aside for 5min. The drug was extracted into the chloroform layer, and it was separated into 25 mL volumetric flasks. The organic layer was then passed over anhydrous sodium sulfate, and the maximum absorbance was measured at 633 nm against the reagent blank. The blank solution was prepared by utilizing all the above reagents excluding the drug solution. The concentration of STZ tablet in urine was found by using the linear regression equation. The results are given in the Table 5.

#### **Robustness and Ruggedness**

The robustness of the method was evaluated by making small incremental changes in volume of dye and contact time, and the effect of these changes on the absorbance of the colored systems was studied. The changes had negligible influence on the results as revealed by small intermediate precision values expressed as %RSD ( $\leq 2\%$ ). Method ruggedness was demonstrated by having the analysis done by a single analyst performing analysis on four different instruments in the same laboratory. Intermediate precision values (%RSD) of this study were in the range 2.16 – 3.99% indicating acceptable ruggedness.

#### **Method 2**

**Standard Stock Solution:** Standard stock solution of STZ (100µg/ml) was prepared in acetate buffer (pH 3.0) and used for the analysis.

**Working Standard Stock Solution :** 0.5, 1, 1.5, 2, 2.5, 3, 3.5 and 4ml of standard stock solution was transferred into eight different 10ml volumetric flask and diluted up to the mark with acetate buffer (pH 3) to get 05,10,15,20,25,30,35 and 40 µg/ml drug concentration respectively.

**Selection of  $\lambda$  Max:** 10 µg/mL drug solution was scanned between 300 to 800 nm to find out  $\lambda$  max (i.e. the wavelength at which amplitude is maximum). The  $\lambda$  max was found to be having green color chromogen **633nm**.

**Stability of the Color Complex:** the absorbance was measured at an every 20mins for 3 hrs and found that S.D.is 0.21.It has been observed that the green color complex was stable for more than 3 hrs.

**Construction of Calibration Curve:** Entire content of working standard stock solution were transferred to eight different 150ml of separating funnel. 2ml of 0.02% Patent blue vf was added into each separating funnel. Then the separating funnel was shaken for 2 to 3 minutes. 10ml of chloroform was added into each separating funnel and again shaken for 2 to 3minutes. Then separate the chloroform layer into eight different 10ml volumetric flask. The organic layer was then passed over anhydrous sodium sulphate and the maximum absorbance was measured at **633nm** against the reagent blank. The blank solution was prepared by utilizing all the above reagents excluding the drug solution. The calibration curve was plotted using concentration Vs. absorbance. The linear regression equation was found to be  **$Y = 0.0179x - 0.0480$**  and **Co-relation coefficient ( $r^2 = 0.988$ )**. The linearity data is shown in the Table 6. The linearity curve of the drug is shown in the Figure 8.

**Assay of Tablets:** Twenty tablets are weighed accurately and ground into a fine powder. An amount of powder equivalent to 10mg of Sertaconazole was weighed into a 100ml volumetric flask, about 40ml of freshly prepared Acetate buffer pH 3.0 was added and sonicated thoroughly for about 5mins, then the volume was made up to the mark with the Acetate buffer pH 3 mixed well and filtered using Whatman filter paper No. 42 and the first few milliliters of the filtrate were discarded. 1ml of filtered tablet sample solutions were transferred into five different 10 ml volumetric flasks and the volume was made up to the mark with the buffer. The contents of the volumetric flasks were transferred into different 125ml separating funnels and 2ml of patent blue vf solution was added into each funnel. 10ml of chloroform was added into each separating funnel and shaken for 5mins and kept aside for 3mins. The chloroform layers were collected in volumetric flasks and measured the absorbance at 633nm. The concentration of the drug was calculated by employing the linear regression equation. The results of tablet analysis are shown in the Table 7.

**Accuracy:** It was found out by recovery study using standard addition method. Known amounts of standard solution was added to pre-analyzed samples at a level of 80%, 100% and 120% and then subjected to the proposed colorimetric method. Results of recovery studies are shown in Table 8.

## RESULTS AND DISCUSSION

The results of analysis of average recoveries obtained in each instance were compared with 100percent theoretical value of Students't' test. As the calculated't' values are less than theoretical't' values. It is concluded that the results of recoveries obtained are in accordance with 100 percent for each analyze. So the percent recovery experiments revealed good accuracy of the data. Less than 02 S.D. was observed in both the methods. So the method is precise. The molar ratio of the drug : dye was determined by Job's method and found to be 1:1. The recovery results of the proposed method were well agreed with the reported RP-HPLC method for the drug. So both the proposed methods are simple, economy, accurate, precise and reproducible and highly sensitive methods and can be used for quality control laboratory.

### ABSTRACT

COVID-19 pandemic has seriously affected educational systems nationwide, leading to the closures of schools, colleges and universities. Most governments around the world and in India have temporarily closed educational institutions in an attempt to check the spread of corona virus infection. According to UNICEF monitoring, 134 countries are currently implementing nationwide closures and 38 are implementing local closures, impacting about 98.5 percent of the world's student population. More than 1500 pharmacy institutions with annual intake of 1,00,000 students in India are immensely affected by COVID-19 due to suspension of face-to-face activities. As a result, pedagogical methods of education has changed dramatically, with the distinctive rise of e-learning, whereby teaching is undertaken remotely and on digital platforms. With this sudden shift away from the classroom in many parts of the globe, some are wondering whether the adoption of online learning will continue to persist post-pandemic, and how such a shift would impact the worldwide education market and job opportunity. The unplanned and rapid move to online learning – with no training, insufficient bandwidth, and little preparation – will result in a poor user experience, unsuccessful education activities and detrimental to sustained growth. A new hybrid model of education based on integration of information technology will be accelerated and the online education system will eventually become an integral component of education including pharmacy in future. The objective of writing this article is to explain the impact of COVID 19 on education systems in India including pharmacy education. How pharmacy students, teachers, institutions as well as economy and society are going to change and respond to this pandemic crisis? The evolution of traditional education systems in India and its transition to online mode are explained. The major challenge in the education systems is now integration of classroom learning with e-learning modes to build a unified learning system. The comparison of face-to-face teaching with online education and the problems associated with virtual classes are described.

**Keywords:** COVID 19, Education systems, Pharmacy education, face-to-face teaching, Online classes

Vivek Barik et al.

## INTRODUCTION

The COVID-19 causes great concern to the education systems in India and many other countries. Pharmacy education and institutions are seriously affected due to nationwide lockdown, closure of colleges and universities, and suspension of face-to-face activities. Its fear is giving sleepless nights to students who were to appear in their regular classes, annual/semester exams as well as competitive exams, interviews, GD, PI for campus selection etc. With COVID-19, spreading to large parts of India in March 2020, the central and state governments closed down schools, colleges, educational institutions as a precautionary measure against the disease. Coronavirus/COVID-19 has been declared as Pandemic by World Health Organization (WHO) and there is a sense of fear and panic all around the globe. Some 1.3-1.5 billion students and youth across the planet are affected by school, college and university closures. These nationwide closures are impacting over 98 % of the world's student population.

On June 12, 2020 during Lockdown 5.0/Unlock 1.0, India has registered the total number of corona cases in the country is 2,97,534, according to Union Ministry data, of this, 1,41,842 are active cases, as many as 8,498 deaths and while 1,47,194 people have been cured/discharged. Since the first case of COVID-19 has emerged in India, state governments are taking all the possible precautionary steps to curb the spread of the disease and that include shutting down educational institutes, vacating hostels, postponing entrance examinations, convocation ceremonies, and more [1]. Beside these, the COVID-19 pandemic has made a rapidly changing world with more and more online activities, propelled into newer and newer orbits by not just science and technology, but by newer political realities, socioeconomic changes and the emergence of newer opportunities, newer aspirations, newer lifestyles etc.

## Suspension of Face-To-Face Activities & Rescheduling of Academic Calendar

As the pandemic spreads, which seems inevitable, all most all countries followed mandatory measures to suspend face-to-face activities for all educational institutions like classroom teaching, examination, practical classes etc where close gatherings are required. No one knows for sure how long these closures are likely to last. Initial measures taken by many governments have ranged from 15 to 30 days, but one can easily anticipate that they will be extended until the pandemic subsides. It is not unreasonable to imagine scenarios where this situation can last two months or more, or as in the case of Spain and Italy where the decision was announced not to resume face-to-face classes for the rest of the academic course which normally ends in June[2]. In India, examination authorities rescheduled their examinations and academic calendar due to lockdown for COVID-19. Few such decisions are mentioned below [3]:  
May 8, 2020: All India Council for Technical Education (AICTE) launched 'CovidGyan' recently to help people deal with the challenge of information overload on the novel coronavirus. May 6, 2020: MHRD revealed that grading in college and University exams could be a composite of 50% marks in case the COVID-19 situation does not appear to be normal. For the pending CBSE 10<sup>th</sup> and CBSE 12<sup>th</sup> exams, the HRD Minister announced that the CBSE is working on to reduce the syllabus for the new academic session.

Government think-tank NITI Aayog has announced that it has suspended its internship programme for the next three months, starting from May, in wake of the ongoing coronavirus outbreak in the country. The All India Council for Technical Education (AICTE) has released a revised academic calendar for technical institutions. The engineering counseling for admission for allotment of seats to be completed on or before August 15, 2020 May 4, 2020: All India Council for Technical Education (AICTE) released a detailed set of guidelines and a revamped academic calendar for the Indian Technical Education Institutes to follow. Ministry of Human Resource and Development announced the alternative academic calendar for classes 9 and 10 released by the NCERT. The Ministry of Human Resource Development (MHRD) shifted the dates for the JEE Main 2020 April Exam to July 18-23 and National Eligibility and Entrance Test ( NEET 2020 exams) to July 26.

**Vivek Barik et al.**

All India Council for Technical Education (AICTE) launched 49 e-learning courses for free. Amid closed academic institutions, postponed exams and delayed results, AICTE e-learning courses will not only prevent academic loss of students but will also help students utilize the COVID-19 lockdown period effectively by upgrading their skills. Pharmacy schools are no exception, as many institutions have been closed, causing teachers and students to seek out innovative ways to complete their coursework for the semester.

## **Impact of COVID-19 and Effect of Lockdown/Shutdown**

The decision to temporarily close educational institutions was prompted by the principle that large gatherings of students, teachers and non-teaching persons constitute a serious risk to safeguarding public health during the pandemic. Pharmacy institutions and indeed all educational institutions tend to close their doors in situations where some form of confinement or quarantine has been legislated. For the students the most immediate impact has naturally been that the temporary cessation of face-to-face teaching at colleges has left them in a completely new situation without a clear idea of how long it will last, immediate impacts on daily life, costs incurred and financial burdens and, of course, learning continuity, national and international mobility for education.

Students have had to rearrange their daily lives to adjust to a situation of confinement. Most of the students, who were displaced far from their families, but within the same country, have returned home. However, in the case of students abroad, the situation remains highly variable, with tens of thousands stranded in destination places waiting for on-site activities to resume or because they are unable to return to their home due to closure of airports and borders. Inevitably, the loss of social contact and socialization routines that are part of the daily experience of a higher education, student will take its toll. The isolation associated with confinement will have effects on socio-emotional balance. A survey in the United States shows, that 75% students have experienced anxiety and depression as a result of the crisis. Another question if the cessation of face-to-face activities is prolonged to the equivalent of one academic term or even longer, then there is the problem for promotion to higher class and who are aspiring to enter higher education. If so, the implications in terms of financial burdens for those students who have loans or credits will affect them and their families. Even they have to bear extra costs associated with their higher education.

Teachers are also affected significantly at the workplace and professionally. First, the fact that not all pharmacy colleges have strategies for the teaching continuity activity which must be taken into account, and in this instance, temporary contracts may be terminated. The most evident impact on teachers is that they continue to teach using the virtual modality, which they are not trained and habituated. In theory, at least, virtual education is present in most large institutions but it is difficult to find one that does not have a virtual campus and a virtual classroom for each subject. Non-teaching staff constitute the most vulnerable sector in terms of the possible reduction in the number of jobs that private colleges & universities, for example, would have to effect in the face of possible financial curtailment due to the cancellation of fees or reduction in student enrollment.

Pharmacy institutions will face huge disruption of their functioning due to temporary cessation of the physical activities. The impact of this disruption is highly variable and depends on their ability to remain active in their academic activities and on their financial sustainability. This implies that many institutions would face serious financial difficulties. Fees collection may not be enough, creating cash flow problems and perhaps even financial survival, particularly in the case of private colleges & universities. This can be especially critical for small or medium-sized private institutions that cannot guarantee continuity of training in virtual mode. In these cases, if the situation continues, it is very likely that, failing to offer teaching, they will have to temporarily suspend the collection of fees. In such a context, it is also possible that larger private colleges attempt to capture these orphaned students. In this scenario, many institutions may need to close.

Vivek Barik *et al.*

## The Substitute for Face-To-Face Classes

In the wake of this emergency situation of COVID-19, educational institutes around the globe are shifting their teaching related operations to online mode. Top educational institutions of India have temporarily suspended their offline operations and have shifted to their teaching-learning procedure online. The choice for online activities requires strong internet connectivity in common households. The percentage of households with an internet connection and mobile lines per 100 inhabitants is comparatively low in India, about 50% whereas Europe 86.5 % and America provide 71.8 %; individuals using the internet in Asia 48.4 %, Europe 82.5 %, America 77.2 % [4].

The physical facilities required for online classes are a functioning computer, a good internet connection, videoconferencing software, a microphone and a webcam. A desktop or a laptop any computer, even a smart phone will do the job of online classes but it should be in good conditions. A strong internet connection can make smooth conversation with teacher, making the exchanges easier and so the learning process. For this reason, it is necessary to have a minimum data rate of 5MB. A videoconference software should contain all the necessary gear to take lessons on the internet like video, chat, text editor, excel sheet, digital board, share screen option, different views etc, anything needed for a quality class. Top free Video Conferencing Softwares used currently are Zoom, UberConference, Google Hangouts Meet, Cisco Webex Meetings, RingCentral Meetings, Skype, GoToMeeting, Pexip, ezTalks Meetings, etc.

The change of medium and long-term teaching and learning modality may have impact for students. If the traditional dynamics are reproduced through technological means, then effects should not be very significant because the return to the classroom will be experienced as a return to normality, especially when formulas for continuous evaluation of online learning have been planned. Another effect on students studying abroad that many students will resign to continue their studies and academic stays interrupted by psychological affectations, epidemiological restrictions, visas conditions, as well as for economic reasons since the support funds have also been decreased or canceled.

Of course, this uncomfortable turn of events has created some good learning opportunities for students—how to adopt the new procedure of online systems, how to communicate, how to be flexible and creative and innovative in the face of adversity. The pandemic is forcing educators to seek out innovative solutions to support students as they are needed to quickly provide help on the frontlines in the battle with COVID-19[5, 6]. Traditional education system to online classes, e-learning, m-learning (mobile), online exams etc. Evolution of education systems in India in the past and present, and predicted for future is mentioned below: Early system, in which gurukul, home schooling and primary methods of teaching were followed, where books, blackboards etc are less used by the teacher as a teaching aid and teachers mainly play the key role with face-to-face oral instructions.

Traditional systems include classroom teaching, college or university systems providing education on mass scale with the teacher as the knowledge provider and the student as the passive recipient, which is physical or face-to-face teaching, Modern classroom education, where the classrooms are equipped with whiteboards, projectors or audio-visual display equipment, digital boards etc. It is now the transition phases i.e. chalk and talk to computer based multimedia supported teaching with use of computers and internet which helped in increasing access and equity. Future system will include online education or smart method of teaching and e-learning using high-speed internet, m-learning (using smart mobile technology), social media platforms(e.g. WhatsApp, e-mail, Facebook, messenger), and videoconference facilitating personalized learning anytime anywhere and redefining the role of teachers as sensitizer, facilitators or mentors.

Online education, where the information technologies and communications are used to help in the development and acquisition of knowledge from the different remote locations. It uses the internet and video/audio and text

**Vivek Barik et al.**

communication and software to create the learning environment. Currently in the COVID-19 era, we are in a state of massive transformation from modern classroom system to future online education systems where the focus is on student's learning outcomes with less role of teacher. Online classes, video conference, Email, WhatsApp etc are the major methods of teaching and learning. The primary focus areas of delivery are employability, marketing, student engagement in latest knowledge in pharmacy practice area and experience in disease management, availability of quality medicines, research excellence and society including industry responsibility.

In a situation where the students are not allowed to go to school, the alternative is to move from traditional to online education. In this case the essential parts are the internet coverage, availability of computers or smart phones in the population. The number of the computers owned by families, especially in the rural areas of the country are lower than a 50%, that can have a negative influence on the whole online education, but in some cases, the modern smart phones can be used as a substitute, if the platform of education is mobile friendly or have the mobile application available. Different countries worldwide have introduced various solutions during the pandemic to continue the education process. Online libraries, TV broadcasts, guidelines, resources, video lectures, online channels were introduced in at least 96 countries. To increase the coverage of the syllabus to the student population, the live transmission of lessons is broadcasted through the TV channel in different subjects.

The COVID-19 has resulted in the distinctive rise of e-learning, whereby teaching is undertaken remotely and on digital platforms. With this sudden shift away from the classroom in many parts of the globe, some are wondering whether the adoption of online learning will continue to persist post-pandemic, and how such a shift would impact the worldwide education market. Even before COVID-19, there was already high growth and adoption in education technology, with global edtech investments reaching US\$18.66 billion in 2019 and the overall market for online education projected to reach \$350 Billion by 2025. Whether it is language apps, virtual tutoring, video conferencing tools, or online learning software, there has been a significant surge in usage since COVID-19[7]. The pandemic has significantly disrupted the higher education sector which is a critical determinant of a country's economic future. The bigger concern on everybody's mind is the effect of the Pandemic on the employment rate. Recent graduates in India are fearing withdrawal of job offers from corporates because of the current situation. The Centre for Monitoring Indian Economy's estimates on unemployment shot up from 8.4% in mid-March to 23% in early April and the urban unemployment rate to 30.9% [8]. Further, it is also important to establish quality assurance mechanisms and quality benchmark for online learning systems and its providers as well as e-learning platforms which is growing rapidly.

## CONCLUSION

The pandemic has transformed the centuries-old, traditional chalk-talk class room teaching model to virtual classes in the online mode which is driven by IT technology. In this post COVID era a well-rounded and effective educational practice is needed which will develop skills that will ensure effective teaching and learning, the employability, productivity, health, and well-being in the decades to come, and make the overall progress of India.

Lots have been changed and will be changed in the field of education and learning in the months and years to come. Same things will be occurred in our society. But one thing is for sure that we can't go back to the 'pre-crisis' era that is now behind us. We will have to accept the change in the education, teaching and learning patterns; we will also have to accept the change in the society, economy reformation with online activities. Rather we have to think how quickly we can overcome the loss and damage caused by COVID-19, and improve in the near future. Tomorrow will be a new dawn. What we make of it is entirely in our own hands. Change is desirable; change is inevitable. Change in fact has been forced upon us. Whether we use the opportunity to advantage or let it pass us by will decide whether the future will shock us or we will create shock-absorbers that will in fact use the impact to cushion us in our journey to a better tomorrow.

## ESL Students' Speaking Skill: An Exploratory Study

Pradeep Kumar Sahoo

### ABSTRACT

Most of the students in India learn English as Second Language (ESL) as they speak different Indian languages as their first language or mother tongue. In India, the ESL learners come from various linguistic backgrounds and their proficiency in English language also varies. But in the midst of globalization, all college students must meet the global standard in English language proficiency. This research intends to find out if and how well the entry level ESL college students of Odisha possess the prerequisite skills in English language to meet the global challenge. The present study is aimed at determining the ESL students' proficiency level in speaking skill. A standardized language proficiency test with reference to speaking skill has been administered to assess ESL learners' proficiency level in English. It is found that the ESL students of Odisha at degree level do not possess adequate proficiency in speaking skill. Moreover, the learners have been interviewed and they have been recommended for the enhancement of their speaking skill.

**Keywords:** ESL students, proficiency, enhancement, speaking skill

### INTRODUCTION

Learners of English from non-western former British colonies are termed as second language (ESL) users irrespective of the fact that it is possible that the learner may not speak the first language usually associated with the mother tongue or ethnic identity. In spite of linguistic diversity in Odisha, English has been chosen as the medium of instruction for college students at degree level continuing their studies under all the Government as well as private universities except Sanskrit University present in the state. But, in real classroom practice, it has been observed that Hindi and Odia are being used in the classroom along with English. The teachers themselves, as Tickoo (2004) pointed out, are not well-equipped to teach neither correct English pronunciation nor speaking or reading skills to students. Except reading and writing skills, no other skills are being practised. It may be because the teachers might have been brought up in a similar educational system, with little expertise in ELT and phonetics as there is no provision in the state universities to teach phonetics or spoken English in the undergraduate courses. Moreover,

24443

**Pradeep Kumar Sahoo**

there are scopes (like on-line courses) for the teachers engaged for undergraduate courses to master the language skills but there are various reasons why teachers do not subscribe to these courses inducting lack of motivation. The complete teaching-learning system, Tickoo (2004) pointed out, could be at fault due to lack of English proficiency in our students, as they have been taught by teachers those who are not highly proficient in its use. Gokak (1964) points out that “The foundational years for the teaching of English in schools are in the hands of teachers who neither know enough English nor are familiar with the latest and far- reaching developments in the pedagogy of English” (p.65). Observing the rapid change in the place of English in India Scrase (1989) remarked:

“English is recognised as an important global or international language, essential for professional employment and Significantly, a key component of the cultural capital of middle class Indians.”

Lax English language proficiency restricts the ESL students in Odisha for their academic and professional growth. It cannot be denied that better English language proficiency has been considered to be an important parameter in the selection process for getting well- paid jobs or better institutions for higher studies. It has been treated as the most significant language in India. So, in order to compete with the students of other states and countries, the students of Odisha at degree level have to be proficient in English language skills. In this regard, assessment of their language competence becomes essential. It will help them not only in acquiring English language but also all other subjects that they go through. In order to make them well equipped to face the academic and professional career in life the assessment of English language skills and finally, the recommendation for improvement is to be made.

**Importance of Speaking**

Lado (1961) comments on speaking skill that it is the ability to express oneself in a live situation. The systematic arrangement of lexical items to express oneself in different situations may be termed as the speaking activity. When the ability to speak in a fluent manner using flawless language, both grammatically and lexically, becomes possible with somebody, we realize that that the speaking skill is acquired. In order to establish one’s mastery over a particular language one needs to acquire speaking skill. Aural comprehension skills are closely interrelated with oral production tasks. But in the testing process the data received in both the skills are different from each other. However, the effectiveness of listening skill can be closely observed through this test. Speaking skill being a productive skill can be empirically observed with accuracy of data. Depending upon the types of speaking tasks it can be divided into four different categories:

- a. **Imitative:** In this case it is expected from the test-taker simply to imitate a text- a word or phrase or sometimes even sentence(s). The pronunciation and the ability of the test- taker to comprehend the text or interest to take part in an interactive conversation are being observed through such types of speaking texts.
- b. **Intensive:** In intensive category of speaking the competence level at lexical, phonological and grammatical are being tested. The speaker is expected to be aware of the semantic properties of the text for responding to the test administrator at best.
- c. **Responsive:** In case of responsive texts the stimulus is an oral text with a limited number of follow-up questions. These tasks include short conversation type, simple comments or requests, greetings and the like.
- d. **Interactive:** Interactions in the forms of transactional and interpersonal exchanges differentiate themselves in the form of their lengths and complexities. Interpersonal communications display a pragmatically complex meaning with the use of even colloquial languages.

### Proficiency Tests

As per Oxford Advanced Learners' Dictionary (2015) A skill is "an ability to do something better". The general ambience or in other words, the environmental stimuli stand responsible for the easy and quick acquisition of any language. Proficiency tests have been designed to assess learner's language proficiency. These tests are highly required for academic and other reasons like travel and short stay in native English-speaking countries. There are many standardized proficiency tests and among them tests like TOEFL, IELTS, SAT are very popular among test-takers. In these tests related to speaking skill the test takers are being evaluated on their ability to synthesize and convey information for the integrated questions. The spontaneity, clarity and coherence in the speaking abilities of the test takers are tested.

### METHODOLOGY

The mixed-method approach has been followed for the current study. Both qualitative data and quantitative data have been taken through participant observation, literature review, semi-structured interview, questionnaire and a standardized language proficiency test. Random sampling technique has been adopted to achieve accuracy in result. The samples for the present study have been carefully chosen among the ESL college students of Odisha using random sampling techniques. For this purpose, students from five different technical and non-technical degree colleges have been taken into account. In total 300 numbers of students, equally from each college, form the sample size for the current study.

### Instruments Used

A semi-structured questionnaire, standardized language proficiency test with reference to speaking skill and an interview protocol were the instruments used as to carry out the present research work. A statistical tool like SPSS 21.0 has been used for data interpretation. Before administering the questionnaire and the test for speaking skill a pilot study was conducted in order to check the level of difficulty of the test questions designed for the study. It helped to adopt and standardize the test questions. The participants were well informed about the purpose of the test and ethical practices as prescribed by American Psychological Association (1982) was followed which deals with human samples.

### RESULTS AND DISCUSSION

The diagram (Diagram No.-1) highlights learners' perception about their proficiency in speaking skill. There is a set of seven relevant questions for the ESL students in order to check their perception about speaking skill. A three-point Likert scale (i.e. always, sometimes and never) is used to find learners' perception about speaking skill with specific reference to ESL. Out of 300 respondents, in the study, 270 students are 'always' able to introduce themselves in English. 30 students opined 'sometimes' they can introduce themselves in English. Nobody is there to respond 'never' to the first question regarding self-introduction. The second question, as shown in the diagram (Diagram No.-1), needs information from the respondents about their ability to describe an object in English. 108 students responded to this question as 'always' they describe objects in English whereas, 136 responses are in favour of 'sometimes' and the rest 6 students said 'never'. During peer-group interaction 144 students are 'always' able to interact in English. 108 out of 300 samples 'sometimes' use English in peer group interaction and 64 students 'never' interact in English with peers. Question 4 asks about interaction in English outside the classroom. Out of all the responses 138, as shown in diagram, 'always' communicate in English outside the classroom. 144 students 'sometimes' speak English outside the classroom and 18 students 'never' speak English outside the classroom. The fifth question, as mentioned, asks about the students' interaction with the officials. It is found that 156 students 'always' speak English while talking to officials; 138 'sometimes' speak English and only 6 students 'never' speak English while talking to officials. Question-6 asks about presentation in English. A good response i.e. 180 students

**Pradeep Kumar Sahoo**

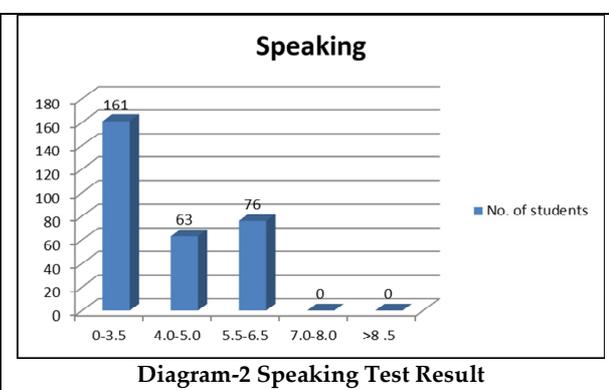

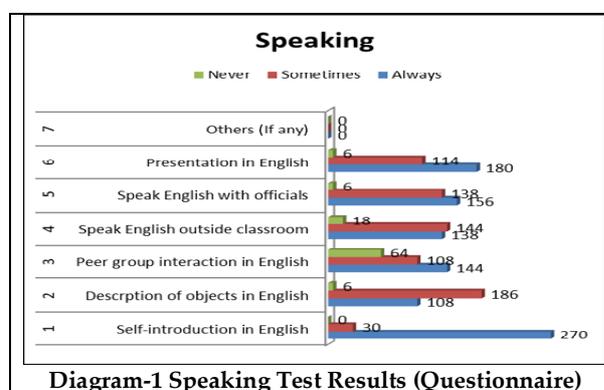

'always' use English during presentation. 114 students 'sometimes' and only 6 students 'never' use English during presentation. There is nil response for the last question i.e. others category indicating if any special situation to be mentioned. The diagram (Diagram-2) shows the results of the achievement test related to speaking skill of 300 samples adopted for the test. The result shows 76 out of 300 students are comfortable in speaking English scoring within the range of 5.5-6.5 or B2 level (CEFR rating). 63 students are in the range of 4-5 which is B1 level as per CEFR rating scale. However, 161 students are within 0-3.5 range which is below the average standard.

**CONCLUSION**

After the reality check by administering the standardized language proficiency test focusing on speaking skill and the interview protocol it has been observed that the average standard of the language proficiency level of ESL college students is far below than the global standard. Hence, it may be suggested that proper infrastructure may be provided in different institutions to enable a healthy environment to enhance language proficiency and to boost up academic growth of the students. Moreover, not only the language teachers but also the teachers of all other subjects and peer-group interaction must contribute towards the creation of the general ambience to enhance ESL students' language proficiency.

### ABSTRACT

Practising all the basic language skills like listening skill, speaking skill, reading skill and writing skills in the acquired language makes one proficient in that language. However, among all these skills writing skill is considered the most difficult one as it involves the language components like vocabulary, grammar etc. Graddol (2006) found that although, India produces 2.5 million university graduates each year only a quarter are suitable for employment in multilingual companies. He found that weak language skills among graduate of non-elite schools and colleges and uneven quality of English language curricula and faculty reduces the chances of employability of our graduates. The present study intends to determine the ESL students' proficiency in writing skills. A language proficiency test with reference to writing skill has been implemented to assess learners' proficiency in English. It has been observed from the current study that the ESL students of Odisha at Degree level do not possess adequate proficiency in writing skills. Furthermore, students have been interviewed and recommendations have been made to enhance students writing skill.

**Keywords:** Writing skill, Proficiency Tests, Language Components

### INTRODUCTION

As we know, language has been accepted as one of the most powerful tools to express ourselves. . Language takes its origin from its users over a long period of time. In order to acquire a language, one has to go through four different language skills: Listening skill, speaking skill, Reading skill and Writing skill. A skill may be termed as the ability to accomplish a task in a more efficient manner within a specific time limit using all the potentiality one has/possesses. It requires certain environmental stimuli for acquiring a skill. Like all other skills learning a language, in order to use, is categorized under a skill. In order to be proficient in a specific language one must have the ability to comprehend,

**Pradeep Kumar Sahoo**

interpret, express and to create a discourse in various social, educational and official contexts primarily to communicate.

**The Importance of Writing**

“Writing a foreign language”, Lado (1961) states, “shows the ability of the writer to use the language and its graphic representation productivity even in very common written situations.” Writing skill is one of the productive language skills that demands more practice in order to attain perfection. One’s ability to use the lexical items in a congruent manner for the creation of a context following the syntactic arrangement of meaningful items is represented through writing skill. In fact, this is the most difficult skill if we analyze all four basic language skills. Different techniques are being used to test different types of writing pieces in a certain language. It includes all aspects of any language like: - starting from vocabulary, grammar use, use of punctuation marks and coherency between sentences and above all, achieving the overall goal of the specific task assigned. A second language writer is required to produce more than 50 genres of writing which include writing tasks within the curriculum and also beyond that. These include academic writing, professional writing, and personal writing and so on. The written performance is further sub-categorized into four different forms which differentiates writing skill from the other three skills with its uniqueness.

- a. **Imitative** : To create a piece of writing the learner is expected to be aware of the basic tasks of writing like letters, words, use of punctuation marks, creation of small coherent sentences. Form, at this stage, is the primary focus though not the exclusive focus. Creation of context and finding meaning out of it are of less importance.
- b. **Intensive**: These types of writings demand more appropriate context specific vocabulary, use of idioms and phrases, correct grammatical features with more focus on meaning and context creation.
- c. **Responsive**: At this stage the learner is expected to compose logically connected sentences and also paragraphs to create a context specific passage. Usually, brief narratives, reports, summaries, interpretation of charts, pictures etc come under this category of writings.
- d. **Extensive**: Extensive writing implies matured writings that fulfil all the purposes where the writer focuses on meeting the target with suitable sentences in a well-connected manner for the creation of a complete text in all aspects.

**Language Components**

Language components include vocabulary and grammar. Learners need language components to use language accurately. The following sections discuss language components in detail.

**Vocabulary**

The most essential part to comprehend a passage is one’s vocabulary knowledge. So, one can opine that vocabulary knowledge energizes one’s reading and comprehending ability. Studies at different times have shown the close association of size and depth of vocabulary with each other. (Qian, 1999, 2002; Schmitt & Meara, 1997; Vermeer, 2001). On the other hand, Vermeer (2001) did not find any conceptual difference between breadth and depth of vocabulary knowledge. ESL readers, Carlo et al. (2004) determined that learners’ vocabulary size and depth are significantly correlated. Both dimensions of vocabulary knowledge also correlated significantly with learners’ reading comprehension.

**Pradeep Kumar Sahoo****Grammar**

While comprehending a text grammatical knowledge is essential in order to find out the coherency in the passage (Givon, 1995). Grammar is also essential for establishing propositional meaning to word integration. (Fender, 2001; Kintsch, 1998; Perfetti & Britt, 1995) Lax grammatical knowledge results in poor comprehending a passage. (Bowey, 1986). Lexical information without grammatical cues in a text shows the importance of grammar while comprehending a passage. In the second language reading research, Alderson (2000) points to "the importance of a knowledge of particular syntactic structures, or the ability to process them, to some aspects of second-language reading" and suggests that "the ability to parse sentences into their correct syntactic structure appears to be an important element in understanding text" (p. 37). Berman (1984) after a careful study found the grammatical effect on reading comprehension.

**Proficiency Tests**

'Just as no medical intervention would be prescribed before a thorough diagnosis of what ails the patient, so no language teaching programme should be designed without thorough analysis.' (Long,2005 P. 1) .A test measures an individual's ability to learn, knowledge on the topic, or performance in the specific subject. So, in case of a language test, the test measures performance, but the results imply the test-takers ability, or, to use a concept common in the field of linguistic competence. 'A language test', as Douglas (2000) says, "aims to elicit a person's language behaviour and to provide for a means of describing and judging that behaviour."

**METHODOLOGY**

As the present study intends to find out learners' performance in a writing test along with the reasons of the specific levels they achieve, there is a need to adopt mixed-methods approach which can trace out reasons from various perspectives. The mixed-methods approach has helped in the process of 'triangulation' and 'development' of the research data. The samples for the present study have been carefully chosen among the ESL college students of Odisha using random sampling techniques. For this purpose, students from five different technical and non-technical degree colleges have been taken into account. In total 300 numbers of students, equally from each college, form the sample size for the current study.

**Instruments Used**

The questions for writing test have been extracted from a standardised language proficiency test. Along with the questions for the written test a semi-structured interview has been arranged in order to determine the gap between the perception level and achievement level of the students' language proficiency and their overall views on English language.

**RESULTS AND DISCUSSION**

The above mentioned diagram (Diagram No.-1) depicts learners' perception on their proficiency in writing skill. There are seven relevant questions for the under-graduate ESL students in order to check their perception about writing skill. The same yardstick, as used for the other basic language skills, i.e. a three-point Likert scale (i.e. always, sometimes and never) is used to find out learners' perception about writing skill. The diagram (Diagram No.-1) shows out of 300 respondents 270 students are 'always' able to prepare answers in English for the class assignments. On the other hand, only thirty student can 'sometimes' write down the answers for the class assignments in English. There is nil response to the 'never' category. The second question makes an enquiry about whether the students are able to write examinations in English. It is found that all the respondents i.e. 300 out of 300 students are 'always' able

**Pradeep Kumar Sahoo**

to write examinations using English. Question no. 3 asks the abilities of the students about writing down stories in English. 186 respondents are 'always' able to write down stories in English. Out of the rest, 108 students can 'sometimes' write down stories in English and 6 students only opined that they can 'never' write down stories in English. Similarly, in question no.4 108 respondents, as shown in the diagram (Diagram No.-4) are 'always' able to create blogs and write down in English. However, 60 students expressed that they can 'never' create and write blogs in English. On the other hand, 132 students can 'sometimes' create and write down blogs in English. 264 samples expressed that they are 'always' able to write down laboratory records in English. On the other hand, 36 students responded that they can 'sometimes' write down laboratory records in English. There is nil response for 'never' category. Out of 300 respondents 234 students are 'always' able to answer letters or e-mails in English. The rest 66 can 'sometimes' answer the letters or e-mails in English. However, there is nil response for the 'never' category. Similarly, the last question has not been responded by any sample.

The diagram (Diagram -2) shows the achievement test, related to speaking skill, results of 300 samples taken for the study. It contains 3 different questions in three different parts i.e. Part-1, Part2 and Part-3. Six students have excellent performance to put themselves in 7-8 brackets which is C1 category as per CEFR rating. Similarly, 94 students have a very good flair for writing as they have scored 5.5-6.5. 93 respondents out of 300 are within 4-5 range. Similarly, the rest 107 participants have underscored. The above diagram (Diagram-3) shows the score of 300 respondents for question no. 2. 9 respondents out of 300 have scored 7-8 to keep themselves in C1 category as CEFR rating scale. However, there is no student who has scored more than 8 in this piece of writing. Similarly, in the 5.5-6.5 category there are 92 students and in 4-5 category, 87 students. 112 students have underscored which is below 3.5. The diagram (Diagram-4) displays the score of all the respondents about their performance in question no. 3 of the achievement test related to writing skill. As shown in the diagram, (Diagram-4) nobody has scored more than 8 for this question. However, 6 students have excellent performance and scored 7-8. Out of the rest 83 students have performed well in this answer and scored 5.5-6.5. Similarly, 78 students are in the 4-5 range and 133 students have underscored i.e. below 3.5.

**CONCLUSION**

Data reveals the prominent gap between the perception level and achievement level of the English language proficiency among ESL college students in Odisha. Improper infrastructure, academic background of the students, inappropriate syllabus (not paying attention to communicative competence) may be treated as the prime factors responsible for the inadequate competency level among the ESL students in Odisha. Language teachers need to ensure that learners get ample opportunities to practice writing both inside and outside classroom situation. Similarly, the syllabus designers and materials producers should provide scope to the learners to practice writing by incorporating interesting and motivating writing tasks which should be from guided writing to free writing.

### ABSTRACT

Transportation is one of the major industries in the state of Andhra Pradesh and has displayed tremendous service base creation of wide range of area coverage in the development of efficient human resource. Transportation has rolled out potential improvements in the method for living and the manner by which social orders are composed and in this way have an extraordinary impact in the advancement of civilization. This chapter conveys an understanding of the importance of study on APSRTC in the modern society by presenting selected characteristics of existing transportation systems in HRM practices and relationships to other human activities. Transport in the Republic of India is an important part of the nation's economy. This research paper is an attempt to investigate is it always possible the welfare facilities provided by the organisations sufficient to provide job satisfaction to its employees. This research investigates whether the welfare facilities like Improved Working Condition and Sanitation facility can help to provide job satisfaction in to APSRTC employees in Srikakulam Depot (AP). To investigate this primary data were collected then with the use of chi-square method the hypotheses were tested that highlights welfare facilities always do not provide job satisfaction.

**Keywords:** Working Condition, Sanitation facilities, Commitment, Employee Welfare etc.

H. Udaybaskar *et al.*

## INTRODUCTION

Transportation systems form important area for a modern society. Efficient and safe movement of people and goods guarantees a thriving economy and provides for an improved quality of life. Because transportation systems are interrelated with many other activities, the challenges of creating and managing transportation systems must be addressed in an interdisciplinary approach. The greatest strength of India is its abundant human resources. The prosperity of a nation or an organization depends on the proper development and utilization of its human resources, as all other resources can be generated by a well motivated human resource. Organizational growth, change and success ultimately depend on the actions of human resources.

The Transportation is one of the major industries in the state of Andhra Pradesh and has displayed tremendous service base creation of wide range of area coverage in the development of efficient human resource. Transportation has rolled out potential improvements in the method for living and the manner by which social orders are composed and in this way have an extraordinary impact in the advancement of civilization. This chapter conveys an understanding of the importance of study on APSRTC in the modern society by presenting selected characteristics of existing transportation systems in HRM practices and relationships to other human activities. Transport in the Republic of India is an important part of the nation's economy.

In the present global industrial scenario, every industry is trying its best to regain top position to attract and retain its customer base. It is essential to inculcate effective provisions of welfare measures to employees, consciousness of welfare activities both inside and outside environment of an organization. Many companies identified this as a major thrust area from the beginning and continuously putting efforts for improvement in the welfare systems in a positive & effective manner in the organization. These efforts have been appreciated and recognized by several Government bodies and APSRTC is also one amongst them.

## LITERATURE REVIEW

The labour welfare measures determine its influence on job satisfaction that affect the attitudes of employees towards work. Particularly the labour welfare facilities improve the employee morale and confidence to improve their working life, family life and overall welfare. Research explored the connectedness between welfare and job satisfaction, but limited research done in the field transport companies where most of the employees work more than eight hours per day. It seems to be very ineffective for providing proper working condition and slowly reducing the interest of the employees.

Goyal (1995) investigated the impact of labour welfare measures on job satisfaction in the textile industries in Punjab and observed the relationship in between job satisfaction and labour welfare. The study investigated that the rate of job satisfaction is depending on the welfare facilities provided by the organization. More the facilities can leads to the performance of the workers a lot. Hence awareness of welfare facilities will improve the efficacy among the employees. Further the study critically assessed the problems and suggested ways to improve the implementation of labour welfare measures. In her research a comparative study was made between six cotton textile industries in Punjab belonging to the private, public, and co-operative sectors. Based on random sampling, 350 textile workers in these sectors in Punjab formed the sample of the study. The results of the study revealed that majority of textile workers were satisfied with their job. The findings of the study also revealed the percentage of workers in the textile industries studied, who were satisfied with their jobs due to the provision of various statutory labour welfare facilities. Majority of the workers were satisfied with their jobs with respect to retirement benefits like gratuity and provident fund. The number of such satisfied workers was the highest in the private sectors and the minimum in the public sectors. But only a few workers were found to be highly satisfied and highly dissatisfied with their jobs in this regard.

H. Udaybhaskar *et al.*

A small percentage of workers were dissatisfied with their jobs with respect to recreational facilities. The percentage of satisfied workers was the highest in the private sectors and minimum in the public sectors. A fairly large percentage of workers were satisfied with their jobs with respect to medical benefits and housing facilities. The private sectors had the maximum number of satisfied workers while in the public sectors minimum number of the workers was satisfied in this regard. In her study, Goyal (1995) determined the extent of job satisfaction experienced by textile workers due to primarily the statutory labour welfare services provided by private, public and co-operative textile sectors in Punjab, the awareness and implementation of these labour welfare services and their correlation with job satisfaction, including relationship between job satisfaction and labour welfare. However researcher did not investigate the influence of personal factors (such as gender, age and experience) and hierarchy on the level of job satisfaction of the textile workers studied, compared to the level of job satisfaction experienced by these workers in the different sectors of the textile industry, that influence of the non-statutory measures. The difference of statutory and non-statutory measures of welfare facilities can influence the employee in various sectors towards their job satisfaction.

Assessment of welfare provisions can be measured by 1) Trend analysis and 2) Opinion survey (Aswathappa, 2007). The former is indirect method, which measures trends of efficiency, turnover and social evil as an impact of welfare activities, observed at pre and post implementation of welfare provisions. The later is most effective and real time method based on measurement of employee's satisfaction and perception relating to 58 welfare provision. Hence, the second method is adopted for assessment of implementation of welfare measures in private and public sector companies. The term labour welfare is only applicable to labour. During industrialization process, the stress on labour productivity increased; and brought about changes in the thinking on labour welfare. An early study under the UN observed as follows "in our opinion most underdeveloped countries are in the situation that investment in people is likely to prove as productive, in the purely material sense, as any investment in material resources and in many cases, investment in people would lead to a greater increase of the flow of goods and services than would follow upon any comparable investment in material capital" (UN, 1951). The theory states that welfare expenditure, especially expenditure on health and education, is productive investment has led to the view that workers could work more productively if they were given a fair deal both at the work place and in the community.

Lawrence A. Leger (1993) explained that both labour groups and national press frequently justify demands for protection against industrial adjustment on the justification that it leads to the destruction of communities and traditional ways of life, with a devastating effect on welfare. To justify this claim in the context of a Ricardian open-economy model requires quite strong restrictions on worker preferences, but a plausible case can be made. It presents a model based on the attachment of workers to their socio-cultural environment, and suggests some policy options for redressing trade-induced inequities. Steven J. Haider, et. al (2003) explored nationally, the welfare caseload declined by more than 50% between 1994 and 2000. Considerable research has been devoted to understanding what caused this decline. Much of the literature examining these changes has modeled the total caseload (the stock) directly. Klerman and Haider (forthcoming) model shows the underlying flows and show analytically and empirically that previous methods are likely to be biased because they ignore important dynamics. However, due to their focus on the bias of the stock models, they present only limited results concerning the robustness of their findings and utilize only a single measure of economic conditions, the unemployment rate.

Van De Stadt et al., (1985) and Winkelmann and Winkelmann (1998) the two closest antecedents were studied panel data on subjective welfare. The first researcher worked in panel data by utilizing the model called money metric of subjective welfare in the Netherlands. The entire study has constructive to the difference in the dependent variable, where they do not allow for latent individual effects. However, they do allow for changes, by including the lagged subjective welfare measure as a regressor (though they cannot reject the null that its coefficient is unity). The researchers admitted on the narrow concept in the expectation that will offer sharper results on the welfare effects of economic variables and also use a better income measure.

**H. Udaybhaskar et al.**

On the other hand Winkelmann and Winkelmann, (1998) explained, anyone can also expect that the income measurement error can be correlated with other variables. For example, it can be assume that a wealthy person tend to understate their incomes when asked by a stranger in an interview for some survey. (In the mid 1990s this is not improbable in Russia). They are just like unemployed. Then there will be negative correlation exist between unemployment and subjective welfare which also could possible as a measurement errors. Unemployment will appear to lower subjective wellbeing even it has no real welfare effect beyond the loss of income. Similarly, when the time period is short to measure the incomes it considered as self-assessments of welfare. The authors can expect unemployment and possibly other characteristics to be correlated with the difference between the two income measures i.e. employment and unemployment. Unemployment might have a significant negative effect on subjective welfare at given current income because respondents naturally worry about future income also. That does not mean that leisure is objectionable, or that there are no adverse incentive effects of unemployment compensation. Otherwise remarkably high estimate of the level of unemployment benefits needed to create unemployment implied by the results in the research where income effect is underestimated while the unemployment coefficient is overestimated.

In addition of income to subjective welfare this could be claimed as relative income for some reference group but not considered as absolute income that matters to wellbeing. Stadt et al., (1985) and Clark and Oswald (1996) worked on subjective welfare indicator on both own income and group income named as mean income of people with similar characteristics. The group income is found to have a significant negative coefficient with own income. Both research concluded that it is relative income that matters to welfare. However, the significant effect on predicted income could also reflect a misspecification. For example, earnings are influenced by latent personality traits in subjective welfare via the effects on higher job satisfaction of labour turnover and clash (discussed by Frank, 1985 and Clark & Oswald, 1996). Then the significance between predicted income and own income could correlate on determinants of subjective welfare. Hence income endogeneity can generate spurious comparison group effects.

The wage inequality is deeply explained in the trade theoretic models such as wage predictions in the higher-dimensional Heckscher-Ohlin (H-O) framework, Feenstra and Hanson (1995) and Marjit, Broll and Sengupta (2000). All the studies revealed about the wage inequalities among the income groups. They explained empirically, but lot of ambiguity found where no specific ideas explained on structural characteristics of wage turn over or capital mobility. No studies done in the less developed countries where labour welfare is a measure concern.

### Research Gap

1. Particularly no research revealed about sanitation facilities provided by the organization like a transportation company which is a major part of statutory welfare facilities. In the present research paper we tried to find the gap to test the impact of Sanitation facilities provided by APSRTC on employee job satisfaction.
2. No research properly examined the working conditions in Transportation Company where large population expects adequate working condition. In this paper we examined the research gap to test the impact of working condition provided by APSRTC on employee job satisfaction.

### OBJECTIVES

1. To assume employee welfare services and the performance of employee.
2. To test the impact of sanitation facilities provided on APSRTC's employees' commitment those who are working in APSRTC.
3. To test the impact of working condition of APSRTC's employees' those who are committed APSRTC.

H. Udaybhaskar *et al.*

## HYPOTHESES

1. **Null Hypothesis (H<sub>0</sub>):** There is no significant influence of sanitation facilities on APSRTC's employees' commitment those who are working in APSRTC.  
**Alternate Hypothesis (H<sub>1</sub>):** There is significant influence of Sanitation facilities on APSRTC's employees' commitment those who are working in APSRTC.
2. **Null Hypothesis (H<sub>0</sub>):** There is no significant influence of working condition on APSRTC's employees' commitment those who are working in APSRTC.  
**Alternate Hypothesis (H<sub>1</sub>):** There is significant influence of working condition on APSRTC's employees' commitment those who are working in APSRTC.

## RESEARCH METHODOLOGY

### Sampling Frame Work

Sampling frame is defined as the set of selected source materials. Sample design in the present survey is very important to frame the sample. Further the definition encompasses the purpose of sampling frames, which provides a means for choosing the particular members of the target population that are to be interviewed in the survey. The sampling frame has significant influence on the outlay for conducting the survey and the quality of any survey; here the survey is directed to be conducted on the employees of APSRTC working in Srikakulam Depot. In such kind of sample surveys imperfect sampling frames are a common source of non-sampling error, particularly under-coverage of important population sub-groups. Therefore it is absolute to elaborate the perfect practice in sample frame construction and use various techniques of sampling.

Particularly, the nature of research is to obtain the statistical information from the opinion of the employees. The area selected for the research is APSRTC Srikakulam Depot as a whole. Thus completely, the data were collected from the APSRTC, Srikakulam Depot. The sample will be selected from the total population of the respondents. Under this section it is important to frame the sample in such a manner that the information received will be maintained in proper and authentic way to justify the result. The following respondents are classified as:

### Sampling Technique or Method

The present study Influence of working condition and sanitation facility on employees commitment of work: A case study of APSRTC, Srikakulam Depot is a study based on the survey method among the employees working in APSRTC Srikakulam Depot (Andhra Pradesh). A sample of 431 employees has been taken at Srikakulam Depot on the basis stratified random sampling grouped into 10 categories. The sample covered all the segments of employees in the organization. To collect first-hand information an administered questionnaire was circulated to selected manpower.

### Sample Size

To determining the sample size in a given population an efficient method is used. The sample is selected on the basis of the research work of Krejcie & Morgan (1970), Glenn (1992) which is adequate enough to represent the whole population. The present study thus covers approximately 431 respondents who are the employees of APSRTC located in Srikakulam Depot (Andhra Pradesh) and they constituted the total population for the survey. As per the sample size selection procedure out of total 431 sample population size only 186 samples were considered for survey.

$$S = \frac{X^2 NP (1-P)}{d^2 (N-1) + X^2 P (1-P)}$$

s = requisite sample size.

X<sup>2</sup> = chi-square table value for 1 degree of freedom at the desired confidence level is (3.841).

Here the value 3.841 is derived by 1.96 X 1.96 = 3.841

N = the size of population.

**H. Udaybhaskar et al.**

P = the population proportion (assumed to be .50 as the maximum sample size).

d = the degree of accuracy articulated as a proportion (.05).

**Sampling Unit**

Sampling unit consist of a single section selected to research and gather statistics of the whole. Here in this case when there is the requirement to study the group of employees working in APSRTC located in Srikakulam Depot, a single employe of APSRTC will be considered as a sampling unit.

**Data Source**

This refers from where the data are to be collected so that the research can be conducted in a proper manner. The source of data in this research thesis is APSRTC, Srikakulam Depot. The data are collected from the employees work in different department and fragment in Srikakulam Depot (Andhra Pradesh).

**Data Preparation**

For data preparations following things were taken into consideration:

**i) Target Population**

The target population was all staff working for APSRTC and all of them were deployed at Srikakulam Depot (Andhra Pradesh) approx. 431. The target population consist all the organization's department. From the target population the sample selection has been done.

**ii) Data Collection Instrument**

At the time of constructing theoretical framework, secondary data collection procedure was used. The secondary data sources are internet, books, reports and journals, newspaper etc. Whereas, the primary source of data collection were used for the purpose of collecting data to examine data for bringing the findings. Here the primary source of data is structured as questionnaires for interview. Structure questionnaire contain multiple choice questions that is based on the four point LIKERT scale. It includes 4 for very satisfied, 3 for satisfied, 2 for least satisfied and 1 meant for not satisfied. In this way the research has used both primary and secondary data which helps in determination of accurate findings.

**iii) Validity and Reliability of instruments**

Reliability of measurement instruments contributes to validity of research findings. If an instrument will be measuring what is not designated to measure, then the instrument fails to be valid and would yield unreliable result. Therefore in this research the data validation methodology was applied as well as the other trusted qualitative research methodology was used.

**Instruments Reliability**

It is a way to ensure that whenever the researcher uses any instrument to measure, the experimental variable will give the same result every time.

**Validity of the Instruments**

To ascertain research validity of the research instrument, the researchers intensively consulted his supervisor on items analysis and accuracy of the questionnaire and the observation guide items in relation to the variables of the study. The researcher also widely made consultations with colleagues on questionnaire development. This led the development of a scale which logically reflected what it purported to measure, enabling the researcher to obtain sufficient information on the factors affecting performance of employees with provided welfare facilities.

In order to insure validity and reliability of data following things were carried on:

- i. Use of past data

**H. Udaybhaskar et al.**

- ii. Discussion with expert
- iii. Cross checking of the filled questionnaire open ended questions.
- iv. Explore the new facts rather than being prejudiced on past researches.

**Analysis**

This analysis section is divided into two sections, the section-A deals with the demographic condition of the employees of APSRTC and the section-B deals with the statistical analysis.

**SECTION-A**

In this section, the researcher has taken all the steps to test the employee welfare and its impact on the job satisfaction in APSRTC and its role in delivering the sustainable growth. For this reason, the researcher decided to use the Likert type scale and used the primary information received from the employees of APSRTC placed at Srikakulam Depot located in Andhra Pradesh region who are involved in providing different services to the people of Andhra Pradesh. The researcher here under-explains the demographic distribution of the respondents who are primarily the employees of APSRTC, Srikakulam Depot (AP).

**Demographic Conditions of Respondents**

According to the objectives the data have arranged systematically and collected through 4-point Likert scale to find the suitable result. Table.2 reveals that total 215 numbers of questionnaires were actually distributed among the various age group of both male and female respondents. Table.2 represents the response status of respondents, which highlights out of total distributed 215 questionnaires only 14 questionnaires were not returned which accounts 6.51%. While rest 201 questionnaires came up with the mix of correct and incorrect information in which 15 were incomplete responses, which count merely 6.97%. This reflected another side of the response sheet. 186 respondents come up with their responses without any error. Hence we considered 186 samples as final inputs of this survey.

The following Table.3 pointed out the gender of the employees working in APSRTC Srikakulam Depot. It is observed that out of 186 respondents 168 are males and rest 18 belong to women category. Thus it is to conclude that 9.68% of women are employed in APSRTC at Srikakulam Depot while 90.32% of male are employed in the same organisation. The following Table.4 exhibited the information regarding years of employment of the employees working in APSRTC Srikakulam Depot. The above Table.4 reveals that total 186 numbers of respondents only were taken into consideration to find their experience with APSRTC. It is observed that largest of among 58 respondents were have 15 to 20 years of work experience with APSRTC and their percentage is highest amongst all with 31.18%. The respondents those were covered in the research having more than 10 years of work experience were of 31 in numbers that count to 16.67%. 24.73% of respondents were of 5 to 10 years experience in APSRTC followed by less than 5 years experience in APSRTC which constitute 18.82% of the total. The data collected from the respondents brought out an interesting fact that less than 10% respondents were having experience for more than 20 years.

The following Table.5 exhibited information regarding the marital status of the employees who are working in APSRTC Srikakulam Depot. The above Table.5 provides the information about the marital status of the employees working in APSRTC at Srikakulam Depot. This section is divided into three (3) categories i.e. Married, Single and Widowed. The responses received from the participants of research survey that the married personnel are of higher side that accounts 119 in numbers out of 186 that makes 63.98%. Whereas; the percentage of single account to 31.72%, i.e. 59 in number, But this section does not include widowed. It is clear from the above table that out of 186 total number of sample respondents widowed accounts to 8 and their percentage is 4.30%. When the employee respondents were asked about the awareness of welfare facility, the responses received in the form of yes and no. From the following Table.6 it is observed that the 75.81% of respondents agreed that these 141 number of employees

### H. Udaybhaskar et al.

are very much aware about the welfare facility provided by APSRTC Srikakulam Depot. But in contrary 24.19% of employees are not satisfied with the welfare services provided by APSRTC Srikakulam Depot. When the employees were asked about the level of satisfaction of welfare facility received in APSRTC, the responses received in the form of Excellent, Good, Fair and Bad. From the following Table.7, it is observed that the 87.62% of respondents agreed that they are getting satisfaction because of the welfare facility they are receiving. But they rate it in different forms some said excellent and some said fair. Out of 186 respondents 74 respondent that counts highest amongst all these responses the level of welfare facility received by them is excellent i.e. 39.78%. At the same time 53 out of 186 respondents viewed good about the level of welfare facility they received i.e. 28.49%. it is observed from the following table that 19.35% of the employees are of fair opinion about the level of welfare facility that counts to 36. The following section-B will discuss in detail on various aspects relating to impact of welfare activities carried out by the APSRTC, Srikakulam Depot.

## SECTION-B

### Testing of Hypothesis

**Null Hypothesis (H<sub>0-1</sub>):** There is no significant influence of sanitation facilities on APSRTC's employees' commitment those who are working in APSRTC.

**Alternate Hypothesis (H<sub>1-1</sub>):** There is significant influence of Sanitation facilities on APSRTC's employees' commitment those who are working in APSRTC.

In this present study the researchers have to test the hypothesis on "There is no significant influence of sanitation facilities on APSRTC's employees' commitment those who are working in APSRTC". To test the hypothesis the researchers took the response from 186 employees distributed under four categories i.e. drivers, conductors, workshop employees and clerical and administrative staff and for obtaining the response through Four point Likert's type scale. The researchers asked eight questions that lead to the level of satisfaction derived due to the sanitation facility provided to them. The detailed of responses were recorded in the table and the chi-square test was used to test the hypothesis on satisfaction of employees on sanitation facility provided by APSRTC.

From this given table it is can be observed that the tabulated value of 40.1 is higher than the calculated value calculated value of 8.09 (i.e.  $8.09 < 40.1$ ) at 27 degree of freedom at 5% level of significance. Hence the hypothesis is accepted.

### Testing of Hypothesis

**Null Hypothesis (H<sub>0-2</sub>):** There is no significant influence of working condition on APSRTC's employees' commitment those who are working in APSRTC.

**Alternate Hypothesis (H<sub>1-2</sub>):** There is significant influence of working condition on APSRTC's employees' commitment those who are working in APSRTC.

To test the above hypothesis the researchers took the responses from 186 employees distributed under four categories i.e. drivers, conductors, workshop employees and clerical and administrative staff. They used Four point Likert's scale and asked ten questions that lead to the level of satisfaction derived due to the working conditions on employees' commitment level. The details of responses were examined through the chi-square to validate the hypothesis. From the above table it is observed that the tabulated value at 27 degree of freedom at 5% level of significance is 40.1 which is higher than the calculated value, i.e. the calculated value is less than the tabulated value ( $9.34 < 40.1$ ).

**H. Udaybhaskar et al.**

## SUGGESTIONS AND CONCLUSION

The present study is an investigation of working condition and sanitation facility on employee's commitment of work in APSRTC, Srikakulam Depot. This research is an approach to find the extent of awareness and implementation of labour welfare measures like providing the sanitation facilities as well as providing better working condition to the employees and the extent to which these measures have been successful to improve the employees' job satisfaction. Further the study critically assessed the problems and suggested ways to improve the implementation of labour welfare measures in providing the sanitation facilities and better working condition. The research has found that the welfare facilities like sanitation facilities and improved working condition facilities do not significantly put impact on the employees' job satisfaction of APSRTC in Srikakulam Depot, Andhra Pradesh. It is observed that the majority of the APSRTC employees are not aware about non-statutory welfare measures and only very few of them are aware about statutory welfare measures. It gives a clear conclusion that employees are unable to identify the measures that are part of statutory and non-statutory welfare measures. Hence, there is a need for awareness programs through conducting workshops, keeping boards specifying the statutory and non-statutory welfare measures at work places. It is also felt that there is an immediate need for conducting sessions or workshops for creating awareness to the existing as well as newly joined employees from the categories including Drivers, Conductors, Workshop Employees and Clerical & Administrative staff.

### ABSTRACT

A In the recent years many research works have been conducted and developed many therapies to diagnose pulmonary tuberculosis .There are thousands of common symptoms for several diseases which makes it very difficult to find which symptoms are responsible for pulmonary tuberculosis. In this paper we did a comparative study by using local covering techniques and strength of rough set to find the reduct which leads to give correct information regarding symptoms of pulmonary tuberculosis.

**Keywords:** Physician data, Rough Set theory, Descriptive and Predictive Data mining

### INTRODUCTION

The field of medical science has witnessed many research works and produced different results regarding several unconventional diseases which always bring challenge for the doctors to handle these diseases with conventional therapy. Large physician database has always been a challenge for scientists and doctors to correctly derive knowledge [1]. Database on human biology have gathered huge volumes of medical information. Analysis of the gathered information provided with new medical information often ended with insufficient information [2]. Often data analysis based upon assumptions of knowledge about the reliance, theory of probability and various experiments, not useful tool to derive the conclusions correctly neither from non-detail information nor to manage the data consistency. The very basic techniques used in physician data processing are NN [3], BC [4], GA [5], DT [6], FT [7]. The basic concept of RST develops by Polish Mathematician Z.Pawalk in early 80's. Rough set theory loosely based on conventional set theory which is useful to derive rules from non- detail information. It is very useful to

**S. Mishra et al.**

find the relationship between the information set to evaluate the usefulness of the entities and to find the nature of the entities. To get a conclusion, decrease all repeated entities and its properties and seek the least subset to get a satisfactory result. Further, rough set reduction algorithms are very handy in developing new ideas and to guess the conclusion, they forms a class using general pattern algorithm [9]. Rough set theory is nicely handled by scientists around the globe and it is now one of the most useful tool in developing Data Analysis Tool with brain, different from other research methodology such as FST. RST does not require any additional variables for decision making it extract the hidden information from the given data set [10]. In our investigation we give major importance to derive a pattern by using the available samples of the pulmonary tuberculosis cases. We divided this entire paper in four different Sections as follows: Section 1 is introductory in nature; Section 2 contains the basic concept of RST and some basic statistics. Section 3 Analyze the information which we collected from different hospitals and develop a general purpose algorithm to classify pulmonary tuberculosis. Section 4 deals on statistical validation of the rule that is generated from the algorithm and conclusion.

## ELEMENTARY CONCEPTS

**Rough Set Theory:** RST was develop by Z. Pawlak [8] derive from crisp set theory which is helpful in decision making.

**Conjecture Space.**  $(U, R)$  is called as Conjecture space where  $U$  is the universe and  $R$  is the set of equivalence classes define on  $U$ .

**General Report System.**  $(I, A)$  is called as GRS where  $I$  is general information system and  $A$  is the set of attributes define on it.

**Rule Derivation Table.** A RDT is a special case of GRS systems  $K = (I, L = P \cup \{d\})$ ,  $P$  and  $d$  are called as conditional attributes and decision attributes respectively. Where  $d$  not present in  $P$ .

### Attributes Dependencies

$R$  is depending upon  $P$  with degree  $s$  if for  $(0 \leq s \leq 1)$  denoted by  $R \rightarrow^s P$  if  $R = V(s, P) = \frac{POSITIVE_C}{|CARDINALITY|}$  where

$POSITIVE_C(P) = \text{Universal Set}$  and  $R \subset P$

### Reduct and Core

Let  $K = (\text{Universal}, A = \text{Con} \cup \text{Dece})$  is a table. Subset of  $A$  is called as Reduct if it is minimal sub set of a any further reduction does not helpful in decision making.

### Chi Squared Distribution

$\chi^2$  Test is a useful tool for statistically validate the claim for moderate sample size. It is Just to verify the result between the observed and expected frequencies difference.

### Error in Statistics

- 1) class-1 not accepting the concept when true
- 2) class-2 accepting the concept when not true

S. Mishra et al.

### Key Ideas

The key ideas for the proposed work are developed from basic Health care system. We collect 1000 samples of Pulmonary tuberculosis cases and then choose three conditional attributes (Fever, Chest pain, Cough) for these conditional attributes we choose two decision attributes positive and negative.

### Reduction of Collected Data

As the complexities of medical science increases which is directly related with different types of unconventional disease which are not known previously. Volume of medical related data grows with time it is next to impossible to decide the symptoms for a particular disease. In this paper we have given more thrust on predictive and descriptive data mining that give emphasize on symptoms rather than expensive medical test. To describe this we are using RST concept on 20 different groups of specimen which we get by using statistics applied on 1000 specimen of pulmonary tuberculosis cases. In this paper the three conditional attributes Fever, Chest pain, Cough and the decision attributes as positive and negative which described in the table given below. For better understanding and clarity ( $R_1, R_2, R_3, R_4, R_5, R_6, R_7$ ) are define as entity sets and  $k_1$  as Fever,  $k_2$  as Chest Pain and  $k_3$  Cough and decision attribute Pulmonary Tuberculosis as I

### Boundary Region

In Rough set theory there are two basic ideas which make it different from conventional set theory that is lower approximation, upper approximation and boundary region. Lower approximation is object of interest is definitely within the region, upper approximation is probably inside the region boundary region is the difference between the upper approximation and lower approximation

### Analysis and Classification Result Extraction

To derive rule we used lower covering algorithm before using the algorithm. First find the characteristic sets the characteristics set is as follows. For incomplete information table the definition of tag of an attributes pair of values is updated.

- For an attribute  $k$  if  $\exists$  an instance  $y$  such that  $k(y) = ?$ , implies the respective result is not found, then instance  $y$  is not included in any tag  $[(k, t)]$  in  $k \forall t$
- For an attribute  $k \exists$  an instance  $y$  such that  $k(y) = *$ , then  $y$  included in  $\text{tag}[(k, t)] \forall t$
- For an attribute  $\exists k$  case  $y$  implies the related result is an feature result, i.e.,  $k(y) = -$ , again implies related result  $y$  should be included in  $\text{tag}[(k, y)] \forall$  specified values  $y \in V(y, k)$  of attribute  $k$ , where  $V(y, k) = \{k(y) \mid k(x) \text{ is specified, } y \in U, d(y) = d(x)\}$ .  $d$  is for the rule and  $L$  is the position of entities in the decision table given above

$[(T, 36.9)] = \{L_6\}$ ,  $[(\text{Temperature}, 38.7)] = \{7\}$ , where  $T$  is for Temperature  
 $[(T, 39.7)] = \{L_1, L_5\}$ ,  $[(\text{Temperature}, 41.8)] = \{3\}$ , Where  $T$  is for Temperature  
 $[(\text{CP}, \text{Significant})] = \{L_1, L_2, L_3, L_6\}$ ,  $[(\text{CP}, \text{Insignificant})] = \{L_4, L_5, L_7\}$ , where  $\text{CP}$ :Chest Pain  
 $[(\text{Cough}, \text{Significant})] = \{L_1, L_2, L_7\}$ .  
 $[(\text{Cough}, \text{Insignificant})] = \{L_4, L_5, L_6\}$ .

If  $y \in U, K_B(y)$  is defined as  $\bigcap$  of  $K(y, a), \forall a \in B$ , If  $a(y)$  is identified, then  $K(y, a)$  is the  $\text{tag}[(a, a(y))]$  and its value  $a(y)$ , derive in the following way

- for  $a(y) = ? \bigcup a(y) = * \rightarrow K(y, a) = \text{Universal Set}$ ,
- If  $a(y) = -$ , then the corresponding set  $K(y, a)$  is equal to the union of all tag of attribute-value pairs  $(a, v)$ , where  $v \in V(y, a)$  if  $V(y, a)$  is nonempty. If  $V(y, a)$  is empty,  $K(y, a) = U$ .

**S. Mishra et al.**

$E=M$  Where M is all attributes presents in the table-1

$$P_K(1) = \{1, 5\} \cap \{1, 2, 3, 6\} \cap \{1, 2, 7\} = \{1\},$$

$$P_K(2) = \text{Universal Set} \cap \{1, 2, 3, 6\} \cap \{1, 2, 7\} = \{1, 2\},$$

$$P_K(3) = \{3\} \cap \{1, 2, 3, 6\} \cap U = \{3\},$$

$$P_K(4) = \text{Universal Set} \cap \{4, 5, 7\} \cap \{4, 5, 6\} = \{4, 5\},$$

$$P_K(5) = \{1, 5\} \cap \{4, 5, 7\} \cap \{4, 5, 6\} = \{5\},$$

$$P_K(6) = \{6\} \cap \{1, 2, 3, 6\} \cap \{4, 5, 6\} = \{6\}, \text{ and}$$

$$P_K(7) = \{7\} \cap \{4, 5, 7\} \cap \{1, 2, 7\} = \{7\}.$$

$P_K(y)$  may be explained as the minimum characteristics set of cases which are indistinguishable using all attributes from K, which can be explained for missing attribute values.

The relation  $T(B)$  is defined for the Universal set U.  $T(B)$  relation signifies for the set  $K(y) \forall y \in \text{Universal set}$

According to our case study  $(K1) = \{(1, 1), (2, 1), (2, 2), (3, 3), (4, 4), (4, 5), (5, 5), (6, 6), (7, 7)\}$

As there are two concepts that is two decision values that is yes and no  $(x, y) \in P(K)$  iff  $y \in P_B(x)$ .

Decision table presented below let us consider  $B = A$ . A-lower and A-upper approximations:  $\{1, 2, 3, 4\}$  and  $\{5, 6, 7\}$  are given below

$$\underline{K1}[1, 2, 3, 4] = [1, 2, 3],$$

$$\underline{K1}[5, 6, 7] = [5, 6, 7],$$

$$K1[1, 2, 3, 4] = [1, 2, 3, 4],$$

$$K1[5, 6, 7] = [4, 5, 6, 7].$$

#### Single Lower Local Covering Algorithm I/P :Input ,O/P:Output (SLLCA)

I/P: a set  $P \subset R$

O/P: a unique LC, S of P Set, (LC- Local covering)

Start

$R := P;$

$N := \emptyset;$

$J := \emptyset;$

while  $R \neq \emptyset$

begin

$S := \emptyset;$

$S_s := \emptyset;$

$S_n := \emptyset;$

$S(R) := \{t \mid [t] \cap R \neq \emptyset\};$

while  $(S = \emptyset \text{ or } [S] \not\subset P)$  and  $S(R) \neq \emptyset$

begin

Select a pair  $z = (at, vt)$  in such a manner that it belongs to  $S(R)$  and  $|[t] \cap R|$  is maximal.

If there is tie situation then, select a pair  $t \in S(R)$  with minimal cardinality of  $[t]$ ;

if tie is repeat for the 2<sup>nd</sup> time then select first pair;

$S := S \cup \{k\};$

$R := [k] \cap R;$

$S(R) := \{k \mid [k] \cap R \neq \emptyset\};$

if at is symbolic {let Vat be the domain of at} then

$S_s := S_s \cup \{(at, v) \mid v \in \text{Vat}\}$

else

$S_n := S_n \cup \{(kt, x..y) \mid \text{completely without any common in } x \text{ to } y \text{ and } u \text{ to } v\}$

Or  $\{(kt, x..y) \dots x, y \supseteq u, v\};$

**S. Mishra et al.**

```

S(K) :=S(K) – (Sp ∪ Sn1);
end {while};
if [S] ⊆ P then
begin
  For each attributes that take any values within a given interval at with (at, k..l) ∈ S
  do
  While (S contains minimum two distinct Pairs (at, k..l) and (at, m..n) with Equal attribute that take any values
  within a given interval at)
  Substitute these with another fresh pair
  (at, frequent part of k..l and m..n);
  for every b in S
  do
  if [S – {b}] ⊆ P
  then S:= S – {b};
  N := N ∪ {S};
  end {then}
  else M := M ∪ {S};
  R:=P-[S][ J]S where S_f S [J]
end while;
for each S_J
do
if union of all equivalence class in J-S equals to all equivalence
class in J
then J:=J-S
end {procedure}
    
```

The set S (R) gives us all important pair R = {1, 2, 3, 4} is {(T, 39.1..40.8), (T, 36.8..40.3), (T, 40.3..40.8), (CP, significant), (CP ,insignificant), (Cough, significant), (Cough, insignificant)}.

[t] ∩ R is define as for t = (CP, significant) → {1, 2, 3} is the result, so (CP significant). The attribute CP is representative. As [(Headache, significant)] 6 ⊆ {1, 2, 3, 4}, so we go for the second iteration of the inner loop. In the inner Loop R = {1, 2, 3}, and the set S (R), after dropping S<sub>s</sub> ∪ S<sub>n</sub>, is {(T, 39.1-40.8), (T, 36.8-40.3) so (T,40.3 to 40.8) and (Cough is significant)}. The using two attribute pair values we have the following result) then [t] ∩ R gives us larger value. Length of [t] are equal for values of attribute pairs, so so we use the initial one(T, 39.1 to 40.8) → S = {(CP significant), (T, 39.1.40.8)}, [S ] = {1, 3} ⊆ {1, 2, 3, 4}, S is identified as basic candidates .Next a for loop which check whether T is minimal → first minimal complex and S = {S }.

New findings R = P- [S] = {1, 2, 3, 4} – {1, 3} = {2, 4}. The set S(R) of all applicable value of attribute pairs connected with fresh R is {(CP significant), (CP, insignificant), (Cough, significant), (Cough, insignificant)}. The initial principle, related to |[t] ∩ R|, is not selected any attribute. The next measure, the length of [t], completed with the following attributes: (CP, insignificant), (Cough, significant), (Cough, insignificant), we next choose value- attribute pair between next three: t = (CP, insignificant). [t] = {4, 5, 7} and R = {4} since [T]={ CP ,no} ⊄ {1,2,3,4} so enter to next process . The least significant attributes pair of values is (cough, no), → S={(chest pain, no), (cough, no)} Equivalence class S is {4,5} ⊄ {1,2,3,4}, S={4}, but S(R)= ∅ .

{1,2,3,4} - {(1,3) ∪ (4,5)}={2} is the next significant attribute. The only significant attribute-values pairs ,members of S(R), are (CP, yes) and (Cough ,yes)={1,2} ⊂ {1,2,3,4}.This is not changed in the initial iteration → the least set of attributes so the lower local cover is S {(CP, significant),(T ,39.1to40.8)},{(Cough, significant), (CP, significant)}. CP,

**S. Mishra et al.**

T are defined in the above.

**So the rule generate as follows**

1. {(Chest pain, significant)}, (Temperature 39.1..40.8),} → (pulmonary tuberculosis ,positive)
2. {(Cough, significant) and (Chest pain, significant)} → (pulmonary tuberculosis, posit
3. (Temperature, 36.8,39..1) → (pulmonary tuberculosis, negative)
4. (Temperature,39.1,40..8) and (Chest pain, insignificant) → (pulmonary tuberculosis, negative)

**RESULT VERIFICATION USING STRENGTH OF ROUGH SET THEORY**

The information table used above is now implemented by using RST, to develop this we consider 20 samples by using correlation techniques out of 1000 samples , 5 conditional attributes allow of leaf note ,fever, chest pain, cough and body ache and values of these attributes are significant , insignificant and attributes for decision are yes and no to use these attributes for good understanding we gives new name to these 5 conditional attributes allow of leaf note ,fever, chest pain , cough body ache as 1 ,2,3,4,5 respectively and values significant as a and insignificant as b decision attributes as r,t respectively. Proposed algorithm Initial table is given below Algorithm to find reduct using strength of rough set.

Proposed Algorithm

```

1. start
2. set S = ϕ ;S is the reduct set
3. do
while
{
E (count of attribute sets ) E and S ≠ ϕ
Count = ϕ
If
Strength=(no of denomination decision attribute values)/ (no of denomination conditional attributes values)
If
{
Strength >50%
Count=Count++
else
go to step-3
end[while]
end[do]

```

The decision table (Table -2), takes the initial values before finding the reduct. Looking at the data table, it is found that entities L<sub>15</sub>,L<sub>16</sub> provide ambiguity at the decision level although both having same conditional values but different decision values are represented in this form. So both the attributes are dropped from further classifications

Using quick reduct algorithm we have got following set of vectors as our reduct (1,2,3,4), (2,3,4,5), (1,2,3,5) then Core of the following reduct is (2,3) by using the formula  $\bigcap$  (reduct) so (2,3) cannot be further classified . To get more accuracy we calculated the equivalence classes using strength [11] and get the following result ,L<sub>Significant</sub>={L<sub>3</sub>,L<sub>4</sub>, L<sub>7</sub>,L<sub>9</sub>, L<sub>11</sub>,L<sub>12</sub>, L<sub>14</sub>,L<sub>20</sub>} L<sub>insignificant</sub>={L<sub>1</sub>,L<sub>2</sub>, L<sub>5</sub>,L<sub>6</sub>, L<sub>8</sub>,L<sub>10</sub>, L<sub>13</sub>,L<sub>18</sub>,L<sub>19</sub>}

S. Mishra et al.

$L(1)_{a_1}(\text{significant})=6/8$  about 70%  $E(1)_{b_1}(\text{insignificant})=4/9$  about 34%,  $E(a_2)_{b_1}(\text{yes})=7/8$  about 88% similarly we have strength(11) of  $E(a_2)_{b_2}(\text{false})=8/9$  about 90%  $E(a_3)_{b_1}(\text{yes})=6/8$  about 75%  $E(a_3)_{b_2}(\text{false})=7/8$  about 88%  $E(a_4)_{b_1}(\text{True})=66\%$   $E(a_4)_{b_1}(\text{True})=66\%$   $E(a_5)_{b_1}(\text{True})=32\%$   $E(a_5)_{b_2}(\text{false})=31\%$  From the we have conclude attribute  $a_1$  and  $a_5$  not necessary so we can drop these table from the decision table safely now the reduct table derived from Table-3 is new table that is the Table-4. Reduct  $a_1$  provide true cases almost 70% but the false case is also about 34% so it is not in the higher side

$(E_2, E_{11}), (E_3, E_4), (E_5, E_6), (E_{17}, E_{18}), (E_1, E_{12}), (E_7, E_{13}), (E_8, E_9), (E_{17}, E_{18})$  are ambiguous in nature so we can drop these Records from the table for further classification and  $(E_{14}, E_{20})$  are providing the same result so we merge both and keep one Records for classification. So we have the final reduct table (Table -5).

We can easily derive rules for pulmonary tuberculosis [12], just analyzing the above table, i.e Table-4. As predicting a result and from large domain of medical data set we depends more or less predictive data mining. We apply Rough set concept for this purpose. Hence, rule for the above data is presented below:

1. Fever and Cough (Yes)  $\rightarrow$  (pulmonary tuberculosis, yes)
2. Chest pain (Yes)  $\rightarrow$  (pulmonary tuberculosis, yes)
3. Fever, Chest Pain, Cough (Yes)  $\rightarrow$  (pulmonary tuberculosis, yes)

From the above rule we concluded that  $a_2, a_3, a_4$  are significant attributes for the classification Hence, fever, chest pain and cough are prime symptoms for pulmonary tuberculosis . We get a conclusion that both local covering algorithm and finding reduct using strength provide the same result, but major attributes in this case will be Fever, Cough, Chest Pain and combination of these attributes produces pulmonary tuberculosis .The result has been obtained from local lower covering algorithm.

## EXPERIMENTAL SECTION

### Statistical Validation

We depended upon chi-square test to validate our findings. We are taking data of positive cases of pulmonary tuberculosis from various NGOs and private hospitals then applied  $\chi^2$ -test for justification of our result. The observed samples are 25, 28, 37, 35, 68, 25 totaling 200 samples. The expected numbers of samples per each day are 20, 30, 40, 30, 70, 20. Then we used chi-square distribution to verify our result. Using chi-square test, we claim that the results obtained are correct.

## FUTURE WORK

This theory can be extended to the field of entertainment, Small scale business sector.

## CONCLUSION

Many People around the world died of Pulmonary Tuberculosis, because of ignorance as most of it's symptoms match with several common diseases. For this reason we use two different concept to finding reduct to classify pulmonary tuberculosis and rule generation.

### ABSTRACT

A Concept of differential transform was first introduced by Zhou in 1986. This method is a semi-analytical method for solving differential equations. Indeed, the differential transform method is based on Taylor series expansion, in a different manner in which the differential equation is converted into a recurrence relation to get a series solution in terms of polynomials. This paper is mainly concerned with DTM for ODEs. Firstly, we use the one dimensional transform method to solve initial value problems as well as boundary value problems for ordinary differential equations.

**Keywords:** Non-linear ODE; DTM

### INTRODUCTION

Most of nonlinear equations do not have a precise analytic solution; so numerical methods have largely been used to handle these equations. There are also some analytic techniques for nonlinear equations. Some of the classic analytic methods are Lyapunov's artificial small parameter method [1], perturbation techniques [2–11], and  $\delta$ -expansion method [12]. In the recent years, many authors mainly had paid attention to study solutions of nonlinear partial differential equations by using various methods. Among these are the Adomian decomposition method (ADM) [13, 14], tanh method, homotopy perturbation method (HPM), sinh-cosh method, HAM, the DTM, and variational iteration method (VIM) [15, 16].

## Numerical Examples

### Example: 1

Solve the following initial value problem (IVP),

$$2y' + 3xy = 4x, y(0) = 1 \quad (1)$$

### Solution:

The exact solution of eqn. (1) is:

$$y = \frac{4}{3} - \frac{1}{3} e^{-\frac{3x^2}{4}} \quad (2)$$

Applying DTM to the eq. (1), we get

$$Y(k+1) = \frac{1}{2(k+1)} \left( 4\delta(k-1) - 3 \sum_{r=0}^k \delta(r-1) Y(k-r) \right), k = 0, 1, 2, \dots \quad (3)$$

Solving the recurrence relation (3) we have,

$$Y(2) = \frac{1}{4}(4 - 3Y[0]), Y(4) = -\frac{3}{32}(4 - 3Y[0]), Y(6) = \frac{3}{128}(4 - 3Y[0]),$$

$$Y(8) = -\frac{9}{2048}(4 - 3Y[0]), Y(10) = \frac{27}{40960}(4 - 3Y[0]),$$

and,  $Y(k) = 0$  for  $k$ , odd.

Putting the initial condition  $Y(0) = 1$  we get,

$$Y(2) = \frac{1}{4}, Y(4) = -\frac{3}{32}, Y(6) = \frac{3}{128}, Y(8) = -\frac{9}{2048}, Y(10) = \frac{27}{40960},$$

$Y(k) = 0$ , for  $k$ , odd.

Hence the DTM solution will be,

$$y(x) = 1 + \frac{1}{4}x^2 - \frac{3}{32}x^4 + \frac{3}{128}x^6 - \frac{9}{2048}x^8 + \frac{27}{40960}x^{10}. \quad (4)$$

We have compared both the solutions (2) & (4) of (1) in Table: 1 and drawn the behaviour in Fig. 1. Graphical representation of the error depicted in Table: 1 is shown in Fig. 2.

## EXACT AND DTM SOLUTION

### Example: 2

Solve the following IVP by using DTM

**P. K. Pattnaik et al.**

$$y' = -\frac{2x + y + 3}{x + 3y + 1}, y(0) = 1 \tag{5}$$

**Solution.**

The exact solution of eqn. (5) is,

$$y = \frac{1}{3} \left( \sqrt{16 - 16x - 5x^2} - x - 1 \right). \tag{6}$$

Applying DTM to eqn. (5), we get for  $k = 0, 1, \dots$

$$Y(k+1) = -\frac{\sum_{r=0}^k (k-r+1)\delta(r-1)Y(k-r+1)}{(k+1)(3Y(0)+1)} - \frac{3\sum_{r=0}^{k-1} (r+1)Y(r+1)Y(k-r) + (2\delta(k-1) + Y(k) + 3\delta(k))}{(k+1)(3Y(0)+1)} \tag{7}$$

Solving the recurrence relation (7) with  $Y(0) = 1$  we get,

$$Y(1) = -\frac{1}{2}, Y(2) = -\frac{7}{64}, Y(3) = -\frac{7}{1024}, Y(4) = -\frac{175}{65536}, Y(5) = -\frac{469}{1048576},$$

$$Y(6) = -\frac{4907}{33554432}, Y(7) = -\frac{18431}{536870912}, Y(8) = -\frac{730303}{68719476736},$$

$$Y(9) = -\frac{3183145}{1099511627776}, Y(10) = -\frac{31271177}{35184372088832}.$$

Hence the DTM solution is,

$$y(x) = 1 - \frac{1}{2}x - \frac{7}{64}x^2 - \frac{7}{1024}x^3 - \frac{175}{65536}x^4 - \frac{469}{1048576}x^5 - \frac{4907}{33554432}x^6 - \frac{18431}{536870912}x^7 - \frac{730303}{68719476736}x^8 - \frac{3183145}{1099511627776}x^9 - \frac{31271177}{35184372088832}x^{10}. \tag{8}$$

We have compared both the solutions (6) & (8) of (5) graphically in Fig. 3 and numerically in Table: 2.

**P. K. Pattnaik et al.**

**Example: 3.** Solve the following problem by DTM

$$2y' = (2x + y)^2, y(0) = 1 \tag{9}$$

**Solution:**

The exact solution is

$$y(x) = 2 \tan \left( x + a \tan \left( \frac{1}{2} \right) \right) - 2x \tag{10}$$

Now, applying DTM to eq. (9), we obtain the following recursion formula

$$Y(k+1) = \frac{1}{2(k+1)} \left( \sum_{r=0}^k (Y(r) + 4\delta(r-1))Y(k-r) + 4\delta(k-2) \right) \tag{11}$$

with  $Y(0) = 1, k = 0, 1, 2, \dots$

Hence the DTM solution is

$$\begin{aligned} y(x) = & 1 + \frac{5}{2}x + \frac{9}{4}x^2 + \frac{67}{24}x^3 + \frac{125}{48}x^4 + \frac{271}{96}x^5 + \frac{1691}{576}x^6 + \frac{25055}{8064}x^7 \\ & + \frac{52553}{16128}x^8 + \frac{47467}{13824}x^9 + \frac{1165013}{322560}x^{10} + \frac{80957963}{21288960}x^{11} + \frac{73041257}{18247680}x^{12} \\ & + \frac{13996507309}{3321077760}x^{13} + \frac{206313110021}{46495088640}x^{14} + \frac{6517440802661}{1394852659200}x^{15}. \end{aligned} \tag{12}$$

We have compared both the solutions (10) & (12) of (9) graphically in Fig. 4 and numerically in Table: 3.

**Example: 4** Solve the following initial value problem by DTM

$$3y' = \cos(2x)y^2, y(0) = 1 \tag{13}$$

**Solution.**

The exact solution is

$$y(x) = \frac{-6}{\sin 2x - 6} \tag{14}$$

Now applying DTM to eq. (13), we get

$$Y(k+1) = \frac{1}{3(k+1)} \left( \sum_{k_2=0}^k \sum_{k_1=0}^{k_2} \frac{2^{k_1}}{k_1!} \cos \left( \frac{k_1\pi}{2} \right) Y(k_2 - k_1)Y(k - k_2) \right), \tag{15}$$

Solving the recurrence relation (15) with the initial condition  $Y(0) = 1, k = 0, 1, 2, \dots$ , we get the DTM solution as,

$$y(x) = 1 + \frac{1}{3}x + \frac{1}{9}x^2 - \frac{5}{27}x^3 - \frac{11}{81}x^4 - \frac{31}{1215}x^5 + \frac{173}{3645}x^6 + \frac{715}{15309}x^7 + \frac{2663}{229635}x^8 - \frac{8923}{688905}x^9. \quad (16)$$

We have drawn the graphical behaviour of both the solutions (14) & (16) and the error in Fig. 5.

**Example: 4.7:** Assume the following system of ordinary differential equations

$$y''' + y'' - y' - y = e^{-x} \quad (17)$$

With initial conditions:  $y(0) = 1, y'(0) = 2, y''(0) = 0$ .

**Solution:**

The exact solution is,

$$y(x) = \frac{1}{8}e^{-x}(-3 + 11e^{2x} + 2x - 2x^2). \quad (18)$$

Applying DTM to equation (17), we get

$$Y(k+3) = \frac{k!}{(k+3)!} \left[ \left( \frac{(-1)^k}{k!} + 1 \right) Y(k) + (k+1)(Y(k+1) - (k+2)Y(k+2)) \right] \quad (19)$$

Solving the coupled recurrence relation (19) with corresponding initial conditions  $Y(0) = 1, Y(1) = 2, Y(2) = 0$  we get the desired DTM solution as,

$$y_1(x) = 1 + 2x + \frac{2}{3}x^3 - \frac{1}{8}x^4 + \frac{1}{15}x^5 - \frac{1}{90}x^6 + \frac{1}{360}x^7 - \frac{1}{2688}x^8 + \frac{11}{181440}x^9 - \frac{1}{151200}x^{10} + \frac{1}{1247400}x^{11} - \frac{1}{13685760}x^{12} \quad (20)$$

The graphical behaviour of solutions (18) & (20) depicted in Fig 4.8 & Fig. 4.9 with different orders of DTM solution. Errors due to the different order of DTM solutions with compared to exact solution are numerically tabulated in Table 4. Figs. 6 & 7 and Table 4 are in good agreement with each other. From the above studies, it is confirm that higher order of DTM gives solution closer to exact solution. Graphical and tabular representation are given below.

**CONCLUSION**

- The graphical behaviour of solutions depicted in figures with different orders of DTM solution.
- Errors due to the different order of DTM solutions with compared to exact solution is numerically are in good agreement with each other.

**P. K. Pattnaik et al.**

- From the above studies, it is confirm that higher order of DTM gives solution closer to exact solution.

### ABSTRACT

The present problem studies a steady two-dimensional dual solution of stagnation-point flow with heat and mass transfer through shrinking sheet where effects of velocity slip and thermal radiation is investigated. The present model incorporates the influences of various parameter such as Prandtl number, Schmidt number, the velocity ratio parameter radiation parameter and slip parameter. The non-linear partial differential governing equations with respective boundary conditions are converted first by imposing suitable similarity transformation and then 4<sup>th</sup> order Runge-Kutta (RK) method along with shooting technique has been deployed to carry out the process. The influence of above parameters on all the profiles used in the work are shown graphically by using MATLAB software. Some results are also compared for validation check as special case

**Keywords:** Dual solution, Stability analysis, heat and mass transfer, Runge-Kutta method.

### INTRODUCTION

Many engineers control the processes of two dimensional steady flow. However, unsteadyness effects the ideal flow environment. Tie-Gang et al. [1] have studied an unsteady flow on account of shrinking sheet hence procured the explained form of the Navier Stokes equations. The unparalleled solution has been carried out by Merkin et al. and Khuzaimah et al. [2, 3] on the unsteady boundary layer flow over a shrinking sheet under the influence of magnetic field and ohmic heating respectively. We specify that there are number of papers that the authors have executed the stability analysis to specify a reliable and stable solution. Mahapatra et al. [4, 5] in his studies analysed the stability of fluid flow over a nonlinear stretching sheet and dual solutions for stagnation-point flow respectively. In [6],

Awaludin et al. extended the above work and studied about stability analysis of stagnation point flow by introducing shrinking sheet.

<b>Nomenclature</b>			
$a$	straining rate	$c$	shrinking/stretching rate
$C$	concentration	$D_B$	Brownian diffusion
$C_f$	skin friction coefficient	$c_p$	specific heat
$Pr$	Prandtl number	$q_r$	radiative heat flux
$k$	thermal conductivity	$k^*$	mean absorption coefficient
$Nu_x$	local Nusselt number	$R$	radiation parameter
$q_w$	wall heat flux	$Re_x$	local Reynolds number
$q_m$	wall mass flux	$Sc$	Schmidt number
$Sh_x$	local Sherwood number	$T$	fluid temperature
$U$	stretching velocity	$u, v$	velocity components
<b>Greek symbols</b>			
$\eta$	Similarity variable	$\rho$	density of fluid
$\alpha$	thermal diffusivity	$\nu$	kinematic viscosity
$\lambda$	velocity ratio parameter	$\delta$	velocity slip parameter
$\psi$	stream function	$\tau_w$	shear stress
$\gamma$	eigen value	$\mu$	dynamic viscosity
$\sigma^*$	Stefan Boltzmann constant		

Najib et al. [7] discussed about exponentially shrinking cylinder the stability of dual solutions. Bhattacharyya [8] has discussed the dual solutions on a stretching/shrinking sheet with first order chemical reaction in boundary layer stagnation point flow and mass transfer. Again, Bhattacharyya et al. [9] presented slip condition effects due to a shrinking sheet on stagnation point flow.

Due to many more industrial applications MHD flow study now a days takes an important aspect of research. Various properties on MHD near the stagnation point was discussed by Salem et al. [10]. A study by Fang et al. [11] was carried out analytically to find the effects of closed-form solution of MHD viscous fluid over shrinking sheet. Mishra et al. [12] examined the mass and heat transfer analysis over a stretching surface in presence of transverse magnetic field over an electrically conducting viscoelastic (Walters B') fluid. In [13], Jena et al. considered MHD flow over a stretching sheet where chemical reaction effect through porous media with heat generation/absorption discussed. Pattnaik et al. [14-17] have analyzed different fluid behavior and effects such as thermophoretic effect, thermal radiation effect, effects of thermal stratification on nano fluid over stretching/shrinking sheets and examined different pertinent parameters behavior for different papers.

Recently Jena et al. [18-20] have shown their interest for different fluids like Jeffery fluid, viscoelastic fluid to investigate different characters of different used parameters for which they have elaborately drawn fantastic conclusions in research works. Similarly a study regarding Casson fluid over an exponentially penetrable shrinking sheet has been carried out by Nadeem et al. [21]. Mehmood et al [22], Mukhopadhyay et al. [23], Narayanaand

Sibanda [24] have putted their attention on MHD boundary layer flow of different fluid models by taking different pertinent parameters with suitable convective boundary conditions.

## MATHEMATICAL ANALYSIS

Let consider a 2-D steady laminar boundary layer stagnation point flow for an incompressible fluid flow under effects of radiation and slip which is driven by shrinking sheet. The corresponding governing equations are as follows:

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0 \quad (1)$$

$$u \frac{\partial u}{\partial x} + v \frac{\partial v}{\partial y} = U \frac{dU}{dx} - \nu \frac{\partial^2 u}{\partial y^2} \quad (2)$$

$$u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \alpha \frac{\partial^2 T}{\partial y^2} - \frac{1}{\rho C_p} \frac{\partial q_r}{\partial y} \quad (3)$$

$$u \frac{\partial C}{\partial x} + v \frac{\partial C}{\partial y} = D_B \frac{\partial^2 C}{\partial y^2} \quad (4)$$

The appropriate boundary conditions are

$$\left. \begin{aligned} u = cx + L \left( \frac{\partial u}{\partial y} \right), v = 0, T = T_w, C = C_w \quad \text{at } y = 0, \\ u \rightarrow U(x) = ax, T = T_\infty, C = C_\infty \quad \text{as } y \rightarrow \infty \end{aligned} \right\} \quad (5)$$

where  $L$ , slip length.  $c > 0$  and  $c < 0$ , stretching and shrinking rate respectively with  $a > 0$  (straining rate parameter). Using the Rosseland approximation,  $q_r = -(4\sigma^*/3k^*) \partial T^4 / \partial y$ . Using Taylor's series expansion for  $T^4$  about  $T_\infty$  we get,  $T^4 = 4T_\infty^3 T - 3T_\infty^4$  where higher-order terms are neglected.

So now equation (3),

$$u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \alpha + \alpha \frac{16\sigma^* T_\infty^3}{3kk^*} \frac{\partial^2 T}{\partial y^2} \quad (6)$$

Eqns. (2, 4 - 6) with the following similarity transformations:

$$\eta = \sqrt{\frac{a}{\nu}} y, u = axf'(\eta), v = -\sqrt{av} f(\eta), \psi(x, y) = \sqrt{av} xf(\eta), \theta(\eta) = \frac{T - T_\infty}{T_w - T_\infty}, \phi(\eta) = \frac{C - C_\infty}{C_w - C_\infty} \quad (7)$$

can be reduced as:

P. K. Pattnaik et al.

$$\left. \begin{aligned} f''' + ff'' - f'^2 + 1 &= 0 \\ \frac{1}{Pr}(1 + R)\theta'' + f\theta' &= 0 \\ \frac{1}{Sc}\phi'' + f\phi' &= 0 \end{aligned} \right\} \tag{8}$$

and

$$\left. \begin{aligned} f(\eta) = 0, f'(\eta) = \lambda + \delta f''(0), \theta(\eta) = 1, \phi(\eta) = 1 \quad \text{at } \eta = 0 \\ f'(\eta) \rightarrow 0, \quad \theta(\eta) \rightarrow 0, \quad \phi(\eta) \rightarrow 0 \quad \text{as } \eta \rightarrow \infty \end{aligned} \right\} \tag{9}$$

where

$$Pr = \frac{\nu}{\alpha}, Sc = \frac{\nu}{D_B}, R = \frac{16\sigma^* T_\infty^3}{3kk^*}, \lambda = \frac{c}{a}, \delta = L \left( \frac{a}{\nu} \right)^{1/2}$$

### THE PHYSICAL QUANTITIES OF INTEREST

Skin friction coefficient, Local Nusselt number, Local Sherwood number of the problem are respectively defined as:

$$C_f = \frac{\tau_w}{\rho U_w^2}, Nu_x = \frac{xq_w}{k(T_w - T_\infty)}, Sh_x = \frac{xq_m}{D_B(C_w - C_\infty)}$$

where  $\tau_w = \mu \left( \frac{\partial u}{\partial y} \right)_{y=0}$ ,  $q_w = \left( -k \frac{\partial T}{\partial y} + q_r \right)_{y=0}$ ,  $q_m = -D_B \left( \frac{\partial C}{\partial y} \right)_{y=0}$ ,  $Re_x = \frac{U_w x}{\nu}$

A simple calculation gives,

$$\sqrt{Re_x} C_f = f''(0), Nu_x / \sqrt{Re_x} = - \left( 1 + \frac{4}{3} R \right) \theta'(0), Sh_x / \sqrt{Re_x} = -\phi'(0)$$

### RESULTS AND DISCUSSION

Fig.1 shows the validation check for velocity, temperature and concentration profiles and from the figure it is clear that the problem well agrees the boundary condition which gives an approval for our results. Figs. 2 & 3 presents the effect of ( $\delta$ ) on velocity and temperature profiles. Due to active slip parameter, velocity gets enhanced in 1<sup>st</sup> solution but in the range  $0 \leq \eta \leq 1.5$  and  $4.2 \leq \eta < \eta_{max}$ , the profile is increasing and for  $1.5 \leq \eta \leq 4.2$  it decreases. This behaviour of velocity profile is witnessed in Fig. 2. Temperature is a decreasing function of velocity slip parameter ( $\delta$ ) for both the solutions which can be confirmed from Fig. 3. Influence of Prandtl number on both velocity and temperature profiles is depicted in Figs. 4 & 5. Both the profiles are showing opposite behaviour, as expected, for increasing values of Pr. Velocity profile gets decelerated for increasing values of Prandtl number in

**P. K. Pattnaik et al.**

both the solutions but 2<sup>nd</sup> solution shows opposite behaviour away from boundary i.e, for  $\eta \geq 3$ . Temperature, on the otherhand, shows the opposite trend for both the solutions. Fig. 6 & 7 are the evidences of decreasing profile of solutal boundary layer thickness for increasing values of velocity parameter and Schmidt number ( $S_c$ ). Fig.8 presents the graphical behaviour of  $C_f$  for both ( $\lambda$ ) and ( $\delta$ ). We have taken the '-ve' range for ( $\lambda$ ) and '+ve' range for ( $\delta$ ). When  $\delta$  is increased,  $C_f$  increases but  $\lambda$  is to decelerate it. Figs. 9 & 10 present the increasing values of both  $\delta$  and  $P_r$  along with '-ve' range of  $\lambda$  increases the Nusselt number coefficient. But it decreases with increasing values of radiation parameter ( $R$ ). Figs. 12 & 13 confirms the accelerated behaviour of Sherwood number with increasing values of both  $\delta$  and  $P_r$  along with '-ve' range of  $\lambda$ .

### Concluding Remarks

The existence of dual solutions is clearly shown in the figures. The stability analysis is checked through our in-house program using MATLAB software for stability of both the solutions and it is found that the 1<sup>st</sup> solution (solid line) is stable and valid physically, while the 2<sup>nd</sup> solution (dotted line) is unstable.

### ABSTRACT

A Two dimensional differential transform method (DTM) have been applied with its fundamental theorems. Moreover, applying DTM, exact close form solutions of linear and non-linear PDEs have been derived. The results of the examples are presented analytically as well as graphically. This Research confirms the use of DTM to linear as well as nonlinear PDEs and can be easily applied. This work ensures the reduction capacity of the computational procedure. Conclusion drawn towards this method that exact analytical close form solutions can be obtained with no need of lumbering work and it can be a valuable tool with analytical solutions.

**Keywords:** PDEs; DTM; Mathematica; Matlab.

### INTRODUCTION

Present work analyses the behaviour of solution of systems of linear and PDEs. Such systems can be applied in different arena of mathematics, engineering especially in electrical and mechanical engineering problems and in physical sciences also. Application of these types of equations include wave propagation and shallow water waves [1–3] where different models of population growth are initiated by a system of PDEs. Most common methods include a semi-analytical method, Adomian decomposition method (ADM) which were used effectively to handle systems of PDEs by [4]. The concept of differential transform applied to electric circuit problems effectively solved the problem was first confirmed by Zhou [5]. The work consist of some linear and non-linear initial value problems. This method computes the coefficients of the Taylor series and gives a series solution using. But, the present method avoids to do

24492

more computational procedures for large orders, can be seen in [6, 7]. In the present work, a demonstration to the feasibility of the theory of DTM is shown by considering two examples of coupled PDEs and solved analytically and graphically by using two well equipped softwares MATHEMATICA and MATLAB.

**Two Dimensional Differential Transform Method (DTM)**

The definition two dimensional transform method is defined as:

$$H(l, m) = \frac{1}{l!m!} \left[ \frac{\partial^{l+m} h(x, y)}{\partial x^l \partial y^m} \right]_{(0,0)} \tag{1}$$

where  $h(x, y)$ , original function,  $H(l, m)$ , transformed function.

Throughout our work, we have considered lower and upper case letters to present the original and it's transformed functions respectively.

The differential inverse transform of  $H(l, m)$  is defined as,

$$h(x, y) = \sum_{l=0}^{\infty} \sum_{m=0}^{\infty} H(l, m) x^l y^m. \tag{2}$$

So,

$$h(x, y) = \sum_{l=0}^{\infty} \sum_{m=0}^{\infty} \frac{1}{l!m!} \left[ \frac{\partial^{l+m} h(x, y)}{\partial x^l \partial y^m} \right]_{(0,0)} x^l y^m \tag{3}$$

In the next section, we have stated the fundamental theorems of the two dimensional transform without proof.

**FUNDAMENTAL THEOREMS**

**Theorem 1**

Differential transform of  $h(x, y) = f(x, y) \pm g(x, y)$  is given by,  $H(l, m) = F(l, m) \pm G(l, m)$ . (4)

**Theorem 2**

Differential transform of  $h(x, y) = cf(x, y)$ ,  $c$ , constant, is given by,  $H(l, m) = cF(l, m)$ . (5)

**Theorem 3**

Differential transform of  $h(x, y) = \frac{\partial f(x, y)}{\partial x}$  is given by,  $H(l, m) = (k + 1)F(k + 1, h)$ . (6)

**Theorem 4**

Differential transform of  $h(x, y) = \frac{\partial f(x, y)}{\partial y}$  is given by,

$$H(l, m) = (l + 1)F(k, h + 1). \tag{7}$$

**Theorem 5**

Differential transform of  $h(x, y) = \frac{\partial^{p+q} f(x, y)}{\partial x^r \partial y^s}$  is given by,

$$H(l, m) = (l + 1)(l + 2) \dots (l + p)(m + 1)(m + 2) \dots (m + q)F(l + p, m + q). \tag{8}$$

**Theorem 6**

Differential transform of  $h(x, y) = f(x, y)g(x, y)$  is given by,

$$H(l, m) = \sum_{p=0}^l \sum_{q=0}^m F(p, m - q)G(l - p, q). \tag{9}$$

**Theorem 7**

Differential transform of  $h(x, y) = x^p y^q$  is given by,

$$H(l, m) = \delta(l - p, m - q) = \begin{cases} 1, & l = p \text{ and } m = q \\ 0, & \text{otherwise} \end{cases} \tag{10}$$

**Theorem 8**

Differential transform of  $h(x, y) = \frac{\partial f(x, y)}{\partial x} \frac{\partial g(x, y)}{\partial x}$  is given by,

$$H(l, m) = \sum_{p=0}^l \sum_{q=0}^m (p + 1)(l - p + 1)F(p + 1, l - q)G(l - p + 1, q). \tag{11}$$

**Theorem 9**

Differential transform of  $h(x, y) = \frac{\partial f(x, y)}{\partial y} \frac{\partial g(x, y)}{\partial y}$  is given by,

$$H(l, m) = \sum_{p=0}^l \sum_{q=0}^m (m - q + 1)(q + 1)F(p, m - q + 1)G(l - p, q + 1). \tag{12}$$

**Theorem 10**

Differential transform of  $h(x, y) = \frac{\partial f(x, y)}{\partial x} \frac{\partial g(x, y)}{\partial y}$  is given by,

$$H(l, m) = \sum_{p=0}^l \sum_{q=0}^m (l - p + 1)(m - q + 1)F(l - p + 1, q)H(p, m - q + 1). \tag{13}$$

**Theorem 11**

The 2D differential transform of  $h(x, y) = f(x, y)g(x, y)h(x, y)$  is given by,

**P. K. Pattnaik et al.**

$$H(l, m) = \sum_{n=0}^l \sum_{t=0}^{l-n} \sum_{q=0}^m \sum_{p=0}^{m-q} F(n, m - q - p) G(t, q) \Omega(l - n - t, p). \tag{14}$$

**Theorem 12**

Differential transform of  $h(x, y) = f(x, y) \frac{\partial g(x, y)}{\partial x} \frac{\partial \omega(x, y)}{\partial x}$  is given by,

$$H(l, m) = \sum_{n=0}^l \sum_{t=0}^{l-n} \sum_{q=0}^m \sum_{p=0}^{m-q} (t+1)(l-n-t+1) F(n, m - q - p) G(t+1, q) \Omega(l - n - t + 1, p). \tag{15}$$

**Theorem 13**

Differential transform of  $h(x, y) = f(x, y) g(x, y) \frac{\partial^2 \omega(x, y)}{\partial x^2}$  is given by,

$$H(l, m) = \sum_{n=0}^l \sum_{t=0}^{l-n} \sum_{q=0}^m \sum_{p=0}^{m-q} (l-n-t+2)(l-n-t+1)(n, m - q - p) G(t, q) \Omega(l - n - t + 2, p). \tag{16}$$

**Numerical Examples**

**Example 1.** Let's consider a linear system of PDEs:

$$\frac{\partial f}{\partial t} + \frac{\partial g}{\partial x} = 0 \tag{17}$$

$$\frac{\partial g}{\partial t} + \frac{\partial f}{\partial x} = 0 \tag{18}$$

with initial conditions:

$$f(x, 0) = e^x \tag{19}$$

$$g(x, 0) = e^{-x} \tag{20}$$

**Solution**

Applying 2-dimensional DTM to Eqs. (17) - (20) we get,

$$F(l, m + 1) = -\frac{(l+1)}{(m+1)} G(l+1, m) \tag{21}$$

$$F(l+1, m) = -\frac{(m+1)}{(l+1)} G(l, m+1) \tag{22}$$

$$F(l, 0) = \frac{1}{l!} \tag{23}$$

$$G(l, 0) = \frac{(-1)^l}{l!} \tag{24}$$

Using Eqs. (23) and (24) in Eqs. (21) and (22) recursively, we get,

$$F(0, 1) = \frac{1}{0!1!}, F(1, 1) = -\frac{1}{1!1!}, F(2, 1) = \frac{1}{2!1!},$$

$$F(0, 2) = \frac{1}{0!2!}, F(2, 2) = \frac{1}{2!2!}, \dots$$

$$G(0, 1) = \frac{1}{0!1!}, G(1, 1) = -\frac{1}{1!1!}, G(2, 1) = -\frac{1}{2!1!},$$

$$G(0, 2) = \frac{1}{0!2!}, G(2, 2) = \frac{1}{2!2!}, \dots$$

Generalizing for  $l = 0, 1, 2, \dots$  we get,

$$F(l, m) = \begin{cases} \frac{1}{l!m!}, & m \text{ is even} \\ \frac{(-1)^l}{l!m!}, & m \text{ is odd} \end{cases} \tag{25}$$

$$G(l, m) = \begin{cases} \frac{(-1)^l}{l!m!}, & m \text{ is even} \\ -\frac{1}{l!m!}, & m \text{ is odd} \end{cases} \tag{26}$$

Tabular representation of  $F(l, m)$  and  $G(l, m)$  for  $l, m = 0 \rightarrow 4$  are given below:

Applying the procedure of Eqn. (3), the required solution in truncated form can be obtained by using MATHEMATICA as follows:

$$f(x, t) = 1 + t + \frac{t^2}{2} + \frac{t^3}{6} + \frac{t^4}{24} + \frac{t^5}{120} + \frac{t^6}{720} + \frac{t^7}{5040} + x - tx - \frac{t^2x}{2} - \frac{t^3x}{6} + \frac{t^4x}{24} - \frac{t^5x}{120} + \frac{t^6x}{720} - \frac{5040}{tx^3} + \frac{2}{t^2x^3} + \frac{2}{t^3x^3} + \frac{4}{t^4x^3} + \frac{12}{t^5x^3} + \frac{48}{t^6x^3} + \frac{240}{t^7x^3} + \frac{1440}{x^4} + \frac{10080}{tx^4} + \frac{6}{t^2x^4} - \frac{6}{t^3x^4} + \frac{12}{t^4x^4} - \frac{36}{t^5x^4} + \frac{144}{t^6x^4} - \frac{720}{t^7x^4} + \frac{4320}{x^5} - \frac{30240}{tx^5} + \frac{24}{t^2x^5} + \frac{48}{t^3x^5} + \frac{144}{t^4x^5} - \frac{576}{t^5x^5} + \frac{2880}{t^6x^5} + \frac{17280}{t^7x^5} + \frac{120960}{x^6} - \frac{120}{tx^6} - \frac{120}{t^2x^6} + \frac{240}{t^3x^6} - \frac{720}{t^4x^6} + \frac{2880}{t^5x^6} - \frac{14400}{t^6x^6} + \frac{86400}{t^7x^6} - \frac{604800}{x^7} + \frac{720}{tx^7} + \frac{1440}{t^2x^7} + \frac{4320}{t^3x^7} + \frac{17280}{t^4x^7} + \frac{86400}{t^5x^7} + \frac{518400}{t^6x^7} + \frac{3628800}{t^7x^7} + \frac{5040}{x^7} - \frac{5040}{tx^7} + \frac{10080}{t^2x^7} - \frac{30240}{t^3x^7} + \frac{120960}{t^4x^7} - \frac{604800}{t^5x^7} + \frac{3628800}{t^6x^7} - \frac{25401600}{t^7x^7}$$

P. K. Pattnaik et al.

$$\begin{aligned}
 g(x,t) = 1 - t + & \frac{t^2}{2} + \frac{t^3}{6} + \frac{t^4}{24} - \frac{t^5}{120} + \frac{t^6}{720} - \frac{t^7}{5040} - x - tx - \frac{t^2x}{2} - \frac{t^3x}{6} - \frac{t^4x}{24} - \frac{t^5x}{120} \\
 & \frac{720}{x^3} - \frac{5040}{tx^3} + \frac{2}{t^2x^3} - \frac{2}{t^3x^3} + \frac{4}{t^4x^3} - \frac{12}{t^5x^3} + \frac{48}{t^6x^3} - \frac{240}{t^7x^3} - \frac{1440}{x^4} - \frac{10080}{tx^4} - \frac{120}{t^2x^4} \\
 & - \frac{6}{t^3x^4} - \frac{6}{t^4x^4} + \frac{12}{t^5x^4} - \frac{36}{t^6x^4} + \frac{144}{t^7x^4} - \frac{720}{x^5} - \frac{4320}{tx^5} - \frac{30240}{t^2x^5} + \frac{24}{t^3x^5} - \frac{24}{t^4x^5} + \frac{48}{t^5x^5} \\
 & - \frac{144}{t^6x^5} + \frac{576}{t^7x^5} - \frac{2880}{t^8x^5} + \frac{17280}{t^9x^5} - \frac{120960}{x^6} - \frac{120}{tx^6} - \frac{120}{t^2x^6} - \frac{210}{t^3x^6} - \frac{720}{t^4x^6} \\
 & - \frac{2880}{t^5x^6} - \frac{14400}{t^6x^6} - \frac{36400}{t^7x^6} - \frac{60480}{t^8x^6} + \frac{720}{x^7} - \frac{720}{tx^7} + \frac{1440}{t^2x^7} - \frac{4320}{t^3x^7} + \frac{17280}{t^4x^7} \\
 & - \frac{36400}{t^5x^7} + \frac{518400}{t^6x^7} - \frac{3628800}{t^7x^7} - \frac{5040}{x^8} - \frac{5040}{tx^8} - \frac{10080}{t^2x^8} - \frac{30240}{t^3x^8} - \frac{120960}{t^4x^8} \\
 & - \frac{504800}{t^5x^8} - \frac{3628800}{t^6x^8} - \frac{25401600}{t^7x^8}
 \end{aligned}$$

Arranging the two solutions in increasing powers of 'x', one can write,

$$\begin{aligned}
 f(x,t) = 1 + t + & \frac{t^2}{2} + \frac{t^3}{6} + \frac{t^4}{24} + \frac{t^5}{120} + \frac{t^6}{720} + \frac{t^7}{5040} \\
 & + \left( 1 - t - \frac{t^2}{2} - \frac{t^3}{6} + \frac{t^4}{24} - \frac{t^5}{120} + \frac{t^6}{720} - \frac{t^7}{5040} \right) x \\
 & + \left( \frac{1}{2} + \frac{t}{2} + \frac{t^2}{4} + \frac{t^3}{12} + \frac{t^4}{48} + \frac{t^5}{240} + \frac{t^6}{1440} + \frac{t^7}{10080} \right) x^2 \\
 & + \left( \frac{1}{6} - \frac{t}{6} + \frac{t^2}{12} - \frac{t^3}{36} + \frac{t^4}{144} - \frac{t^5}{720} + \frac{t^6}{4320} - \frac{t^7}{30240} \right) x^3 \\
 & + \left( \frac{1}{24} + \frac{t}{24} + \frac{t^2}{48} + \frac{t^3}{144} + \frac{t^4}{576} + \frac{t^5}{2880} + \frac{t^6}{17280} + \frac{t^7}{120960} \right) x^4 \\
 & + \left( \frac{1}{120} - \frac{t}{120} + \frac{t^2}{240} - \frac{t^3}{720} + \frac{t^4}{2880} - \frac{t^5}{14400} + \frac{t^6}{86400} - \frac{t^7}{604800} \right) x^5 \\
 & + \left( \frac{1}{720} + \frac{t}{720} + \frac{t^2}{1440} + \frac{t^3}{4320} + \frac{t^4}{17280} + \frac{t^5}{86400} + \frac{t^6}{518400} + \frac{t^7}{3628800} \right) x^6 \\
 & + \left( \frac{1}{5040} - \frac{t}{5040} + \frac{t^2}{10080} - \frac{t^3}{30240} + \frac{t^4}{120960} - \frac{t^5}{604800} + \frac{t^6}{3628800} \right. \\
 & \left. - \frac{t^7}{25401600} \right) x^7.
 \end{aligned}$$

$$\begin{aligned}
 g(x, t) = & 1 - t + \frac{t^2}{2} + \frac{t^3}{6} + \frac{t^4}{24} - \frac{t^5}{120} + \frac{t^6}{720} - \frac{t^7}{5040} \\
 & + \left( -1 - t - \frac{t^2}{2} - \frac{t^3}{6} - \frac{t^4}{24} - \frac{t^5}{120} - \frac{t^6}{720} - \frac{t^7}{5040} \right) x \\
 & + \left( \frac{1}{2} + \frac{t}{2} + \frac{t^2}{4} - \frac{t^3}{12} + \frac{t^4}{48} - \frac{t^5}{240} + \frac{t^6}{1440} - \frac{t^7}{10080} \right) x^2 \\
 & + \left( -\frac{1}{6} - \frac{t}{6} - \frac{t^2}{12} - \frac{t^3}{36} - \frac{t^4}{144} - \frac{t^5}{720} - \frac{t^6}{4320} - \frac{t^7}{30240} \right) x^3 \\
 & + \left( \frac{1}{24} - \frac{t}{24} + \frac{t^2}{48} - \frac{t^3}{144} + \frac{t^4}{576} - \frac{t^5}{2880} + \frac{t^6}{17280} - \frac{t^7}{120960} \right) x^4 \\
 & + \left( -\frac{1}{120} - \frac{t}{120} - \frac{t^2}{240} - \frac{t^3}{720} - \frac{t^4}{2880} - \frac{t^5}{14400} - \frac{t^6}{86400} - \frac{t^7}{604800} \right) x^5 \\
 & + \left( \frac{1}{720} - \frac{t}{720} + \frac{t^2}{1440} - \frac{t^3}{4320} + \frac{t^4}{17280} - \frac{t^5}{86400} + \frac{t^6}{518400} - \frac{t^7}{3628800} \right) x^6 \\
 & + \left( -\frac{1}{5040} - \frac{t}{5040} - \frac{t^2}{10080} - \frac{t^3}{30240} - \frac{t^4}{120960} - \frac{t^5}{604800} - \frac{t^6}{3628800} \right. \\
 & \left. - \frac{t^7}{25401600} \right) x^7.
 \end{aligned}$$

The above arrangements can also be rewritten w.r.t 't' as:

$$\begin{aligned}
 f(x, t) = & 1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} \\
 & + t \left( 1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} \right) \\
 & + t^2 \left( \frac{1}{2} - \frac{x}{2} + \frac{x^2}{4} - \frac{x^3}{12} + \frac{x^4}{48} - \frac{x^5}{240} + \frac{x^6}{1440} - \frac{x^7}{10080} \right) \\
 & + t^3 \left( -\frac{1}{6} - \frac{x}{6} + \frac{x^2}{12} - \frac{x^3}{36} + \frac{x^4}{144} - \frac{x^5}{720} + \frac{x^6}{4320} - \frac{x^7}{30240} \right) \\
 & + t^4 \left( \frac{1}{24} + \frac{x}{24} - \frac{x^2}{48} + \frac{x^3}{144} - \frac{x^4}{576} + \frac{x^5}{2880} - \frac{x^6}{17280} + \frac{x^7}{120960} \right) \\
 & + t^5 \left( -\frac{1}{120} - \frac{x}{120} + \frac{x^2}{240} - \frac{x^3}{720} + \frac{x^4}{2880} - \frac{x^5}{14400} + \frac{x^6}{86400} - \frac{x^7}{604800} \right) \\
 & + t^6 \left( \frac{1}{720} + \frac{x}{720} - \frac{x^2}{1440} + \frac{x^3}{4320} - \frac{x^4}{17280} + \frac{x^5}{86400} - \frac{x^6}{518400} + \frac{x^7}{3628800} \right) \\
 & + t^7 \left( -\frac{1}{5040} - \frac{x}{5040} + \frac{x^2}{10080} - \frac{x^3}{30240} + \frac{x^4}{120960} - \frac{x^5}{604800} + \frac{x^6}{3628800} \right. \\
 & \left. - \frac{x^7}{25401600} \right).
 \end{aligned}$$

P. K. Pattnaik et al.

$$\begin{aligned}
 g(x, t) = & 1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} \\
 & + t \left( -1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} \right) \\
 & + t^2 \left( \frac{1}{2} - \frac{x}{2} + \frac{x^2}{4} - \frac{x^3}{12} + \frac{x^4}{48} - \frac{x^5}{240} + \frac{x^6}{1440} - \frac{x^7}{10080} \right) \\
 & + t^3 \left( \frac{1}{6} - \frac{x}{6} + \frac{x^2}{12} - \frac{x^3}{36} + \frac{x^4}{144} - \frac{x^5}{720} + \frac{x^6}{4320} - \frac{x^7}{30240} \right) \\
 & + t^4 \left( \frac{1}{24} - \frac{x}{24} + \frac{x^2}{48} - \frac{x^3}{144} + \frac{x^4}{576} - \frac{x^5}{2880} + \frac{x^6}{17280} - \frac{x^7}{120960} \right) \\
 & + t^5 \left( -\frac{1}{120} + \frac{x}{120} - \frac{x^2}{240} + \frac{x^3}{720} - \frac{x^4}{2880} + \frac{x^5}{14400} - \frac{x^6}{86400} + \frac{x^7}{604800} \right) \\
 & + t^6 \left( \frac{1}{720} - \frac{x}{720} + \frac{x^2}{1440} - \frac{x^3}{4320} + \frac{x^4}{17280} - \frac{x^5}{86400} + \frac{x^6}{518400} - \frac{x^7}{3628800} \right) \\
 & + t^7 \left( -\frac{1}{5040} + \frac{x}{5040} - \frac{x^2}{10080} + \frac{x^3}{30240} - \frac{x^4}{120960} + \frac{x^5}{604800} - \frac{x^6}{3628800} \right. \\
 & \left. + \frac{x^7}{25401600} \right),
 \end{aligned}$$

With all the above discussions, exact analytical solution of the system can be of the form:

$$f(x, t) = e^x \cosh t + e^{-x} \sinh t. \tag{27}$$

$$g(x, t) = e^{-x} \cosh t - e^x \sinh t. \tag{28}$$

In MATLAB, some interesting figures can be drawn as can be seen in Figs. (1 -6).

**Example 2.** Let's consider the following non-linear system of PDEs:

$$\frac{\partial f}{\partial t} + g \frac{\partial f}{\partial x} + f = 1 \tag{29}$$

$$\frac{\partial g}{\partial t} + f \frac{\partial g}{\partial x} - g = 1 \tag{30}$$

with the initial condition:

$$f(x, 0) = e^x \tag{31}$$

$$g(x, 0) = e^{-x} \tag{32}$$

**Solution**

Applying DTM to Eqns. (29) - (32) we have,

$$(m + 1)F(l, m + 1) = F(0, 0) - F(l, m)$$

$$- \sum_{r=0}^l \sum_{s=0}^m (l - r + 1)G(r, m - s)F(l - r + 1, s) \tag{33}$$

$$(m + 1)G(l, m + 1) = G(0, 0) + G(l, m) - \sum_{r=0}^l \sum_{s=0}^m (l - r + 1)F(r, m - s)G(l - r + 1, s) \tag{34}$$

$$F(l, 0) = \frac{1}{l!}, l = 0, 1, 2, \dots \tag{35}$$

$$G(l, 0) = \frac{(-1)^l}{l!}, l = 0, 1, 2, \dots \tag{36}$$

Using Eqs. (35) and (36) in Eqs. (33) and (34) recursively one can get,

$$F(0, 1) = \frac{1}{0!1!}, F(1, 1) = -\frac{1}{1!1!}, F(2, 1) = \frac{1}{2!1!},$$

$$F(0, 2) = \frac{1}{0!2!}, F(2, 2) = \frac{1}{2!2!}, \dots \tag{37}$$

$$G(0, 1) = \frac{1}{0!1!}, G(1, 1) = \frac{1}{1!1!}, G(2, 1) = -\frac{1}{2!1!},$$

$$G(0, 2) = \frac{1}{0!2!}, G(2, 2) = \frac{1}{2!2!}, \dots \tag{38}$$

The above two equations can be generalized for  $l, m = 0, 1, 2, \dots$  as:

$$F(l, m) = \frac{(-1)^m}{l!m!} \tag{39}$$

$$G(l, m) = \frac{(-1)^l}{l!m!} \tag{40}$$

Tabular representation of  $F(l, m)$  and  $G(l, m)$  for  $l, m = 0 \rightarrow 4$  are given below:

Applying the procedure of Eqn. (3), the required solution in truncated form can be obtained by using MATHEMATICA as follows:

P. K. Pattnaik et al.

$$\begin{aligned}
 f(x, t) = 1 - t &+ \frac{t^2}{2} - \frac{t^3}{6} + \frac{t^4}{24} - \frac{t^5}{120} + \frac{t^6}{720} - \frac{t^7}{5040} + x - tx + \frac{t^2x}{2} - \frac{t^3x}{6} \\
 &+ \frac{t^4x}{24} - \frac{t^5x}{120} + \frac{t^6x}{720} - \frac{t^7x}{5040} + \frac{x^2}{2} - \frac{tx^2}{2} + \frac{t^2x^2}{4} - \frac{t^3x^2}{12} + \frac{t^4x^2}{48} \\

 &- \frac{25401600}{t^7x^7}
 \end{aligned}$$

A closed form solution of the system is given by

$$f(x, t) = e^{x-t}. \tag{41}$$

P. K. Pattnaik et al.

$$g(x,t) = e^{-x+t} \tag{42}$$

Figs. (7 - 13) are drawn through MATLAB to conclude.

### CONCLUSION

Two dimensional differential transform methods have been applied effectively to linear and non-linear systems of PDEs. The results of two examples are quite in good agreement with exact analytical closed form solution. However, computational difficulties are reduced in this method which can be witnessed through these type of examples. This fact motivates us to go with DTM, an effective analytical method which uses simple calculations to solve many complicated linear and non-linear system of PDEs without any linearization, discretization or perturbation.

### ABSTRACT

Security is one of the vital aspects of everyday life. From time immemorial, people used to give top priority to safeguard their houses by using different door locking systems. Let it be for access into the high-security premises to the common man house, we always wish to stay safe and also to block out the trespassers curtailing worries. We use from conventional lock and key to very sophisticated remotely controlled sensor lock. But each of the locking systems has its demerits, sometimes it faces the situation where we either forget to lock the house or also sometimes misplace or lose the key, In case of doors with auto locking system if the keys are misplaced we have no alternative except cutting the lock . Also sometimes people don't leave the house out of fear that someone might burgle. For such reasons, the faith in the automated smart door lock system is increasing. In the world of rising technologies; individuals have resorted to biometric unlocking system but biometric locking system has its disadvantages like palms with oily substances and sweat didn't recognized by the system. The most hazardous factor in biometric system is the surface touched by several people which can be a hotspot for transmitting deadly viruses; it is quite evident in the recent outbreak of COVID-19 pandemic. To overcome all these disadvantages locking system with face recognition is a revolutionary effort. So in this research, it recommends a door lock security system which is capable to unlock the door with a simple snap of our face. This security system has been developed by integrating deep learning and IOT. This security system is developed using the Raspberry Pi, Pi Camera, and Solenoid Lock. The distinctive feature of this system is that it uses the deep learning face recognition technique which increases the classification accuracy. The proposed system yields 96.28% accuracy with a minimum sample size. The relay board is designed to trigger the voltage instead of the current due to which it won't fail even if a low Ampere current is provided to the system. In emergency conditions, if any unauthorized entry took place using the emergency button then the system shared the captured image of the person along with the time of entry to admin through the mail.

**Keywords:** Face Recognition; IoT, Raspberry Pi; Pi Camera; Security; Security

Rutuparna Mishra *et al.*

## INTRODUCTION

Doors are the basic part of the security system, be it for a highly secured defense facility or a regular house. To unlock any door we need to have the right key for it. For this reason, we face problems many times like if we lose the key or in case of an automatic door lock system we sometimes forget the key in the house due to which we need to break the lock. To avoid such issues face recognized locks are a good source of alternatives. In this lock system, the face is the key to unlocking the door. Due to the enhancement in technology we often go for multi lever locks made out of the best material. Further technology provides us with biometric locks that permit keyless operations of the lock [1]. Next, we come across switch operated lock systems mostly used in cars. So now we are on the path of face recognition which also provides another level of a secure environment.

In present scenarios, biometrics is present in every nook and corner. Let it be in industries, educational organizations, and institutions, restricted areas, high-security zones or our home. It is very critical for all these organizations that the biometric system should function inexhaustibly for the smooth operation of these organizations. In our busy schedule biometrics has become a secure and easy way to prevent unauthorized users to enter the authorized area without requiring any physical help. Biometrics is normally used for unique identification. There are different types of biometrics like fingerprint, palm print, and face [2], [3]. The fingerprint biometric came into light at the beginning of the decade and as the technology is rapidly growing the hackers have found the way to crack this. So now we are in the direction of face biometrics [4].

Face biometrics is nothing but simply a face recognition algorithm. Here we use the algorithm to check if a person seeking to enter a room has been granted access or not. If a person is unauthorized a simple mail is sent to the admin warning him/her that a stranger is trying to gain access into the room. Alternatively, a button is also present in case the face recognition is unable to identify the person or for any emergency purpose which grants access to the door but captures an image of the person and sends a mail to the admin along with the image of the person warning him of the activity [3], [5]. The prime objective of this project is to provide a smart security system which can be alternatively used for keyless entry. For low lighting conditions, histogram equalization is implied to the image to enhance the contrast. Also, any person, if he/she is differently-abled, can easily use it. For any condition, if the face recognition fails, the person can also alternatively use a switch to gain access which is placed at a location only known to the admin. This security system also provides the user with an alert system that can aware of the user in case it is accessed by any stranger.

The arrangement of this paper is distributed into seven divisions. Division II converses about the related works done by different scholars in this equivalent field. Division III illustrates the methodology of the system. Division IV labels system requirements that include dataset and both hardware and software packages that are needed for this research. Division V depicts the system architecture. Division VI provides results and discussion. Finally, Division VII finishes this study.

## RELATED WORK

IoT is being used in various fields for the development of a lot of daily used products. Mostly used IoT devices are mobiles, laptops, automated door locks in various malls and theatres, smart bathrooms, fully automatic washing machines, etc. [1]. Face recognition has been used as a security measure in mobile phones and laptops since 2014. A more enhanced version of face recognition is being used now which is much smarter than the previous version. In some of the existing literature based on both research and projects, a remotely operated door lock has been developed using the ESP32 microcontroller. This system can open and monitor the door remotely. It uses a PIR sensor to sense any human activity and open the door [1].

**Rutuparna Mishra et al.**

A 16F887 microprocessor is used for face detection and recognition. This project is carried out by MATLAB programming. After confirming that the person is authorized, the door is unlocked immediately [2]. This paper proposes the use of Raspberry Pi and it works in two different parts. The first part is responsible for capturing an image and creating a database for storing the images. The second part is tasked to compare the new image with the stored images in the database [3]. This paper proposes a different approach. It uses the Eigen Face technique which makes it more secure and for warning purpose it uses the SMS system [4]. Similarly, in ref [5] a PIR sensor has been used for the same purpose. In this paper when the PIR sensor senses the human activity, the Pi Camera is started and it captures the image. Once the face is recognized then the door unlocks otherwise a warning email is sent to the admin. A smart door lock for physically challenged persons with the help of Arduino has been developed [6]. In this project, a Wi-Fi signal has been sent to the door to lock or unlock it. A smart lock has been proposed in ref [7] where the image of the unauthorized person is recorded and sent to the administrator.

It also warns about the physical damage of the lock to the administrator. The traditional feature extraction technique from human faces has been used to extract the optimal features [8]. Some of the security systems are economically feasible. It allows connection and control between no. of devices, the master device is connected to the cloud server which is controlled by admin which facilitates a no. of users to which no. of nodes is connected [9]. A security system for an entire house has been developed starting from light, fan, window, screen, etc. by using MQTT protocol [10]. The detection system was developed using the PIR sensor, ZigBee for creating a wireless sensor network and ESP8266 for sending the sensor data to a public server [11]. The Lock system integrated with an innovative technology i.e. Bluetooth technology enhances the security level along with easy interaction between user and the lock system [12]. Security systems are also developed on different types of protocols and algorithm leading to the solution of previously stated problems [13]. Digital lock systems having a digital interface with the traditional keyhole where the way of rotating the key is converted into code is a fine alternative to the emerging lock system [14]. Systems using the cryptographic algorithm for security systems is a unique approach in the field of locking systems [15]. In this study, a door lock security system has been proposed which is capable to unlock the door with a simple snap of a human face.

## METHODOLOGY

The recommended model is built using the single-board computer having an efficient processor i.e. Raspberry Pi. It runs on a Linux based operating system which is called Raspbian. This Operating system is specially designed for Raspberry Pi. It uses Pi Camera that is specifically designed for Raspberry Pi for capturing the image of the face and a solenoid lock for a secure locking system. A speaker is also attached to the system to give the voice signal if a person enters the locked premises. Initially, when the power is supplied to the Raspberry Pi the Pi Camera gets started. After that, it scans the face of the person from the live video stream and if any face is found it compares the faces with its database. If any match is found it recognizes the face and further power is supplied to the relay. The face detection and recognition task are executed with the help of a face\_recognition package which is a deep learning technique for face recognition. If the face is recognized then power is supplied to the relay and the relay gets triggered and the solenoid lock unlocks the door for 5 seconds. But if the face is not recognized then it sends a warning e-mail to the admin making him aware of the trespasser.

## SYSTEM REQUIREMENTS

### Dataset

The dataset is collected from [www.cs.umass.edu website \(http://vis-www.cs.umass.edu/lfw/lfw.tarz\)](http://vis-www.cs.umass.edu/lfw/lfw.tarz). It contains 5000 face images of various personalities. The dataset has been used for both training and testing purposes.

**Rutuparnna Mishra et al.**

From these 5000 images, 350 images of different people are taken and trained with a ratio of 1:1 i.e. 1 image per person. From the 350 people, different photographs of 50 random people are considered for testing purposes using deep learning package face\_recognition. Table 1 depicts the same.

## Hardware

### Raspberry Pi 3 Model B

Raspberry Pi 3 Model B is also known as a mobile mini-computer. It has Quad-core 1.2GHz Processors, 64bit CPU along with 1GB RAM. This model also has extended 40-pin GPIO, 4 USB 2 ports, CSI camera port for connecting the Pi Camera and DSI display port for connecting the Pi display. It also has features like Micro SD card slot, wireless LAN and Bluetooth onboard.

### Pi Camera

The Pi camera module is a personalized camera for Raspberry Pi. It is attached to the Raspberry Pi using the CSI camera port which is dedicated to interfacing the camera in Raspberry Pi. The dimension of the camera module is 25mm x 20mm x 9mm. It has a resolution of 8 megapixels. The camera module is supported only on the Raspberry Pi operating system that is Raspbian.

### Solenoid Lock

Solenoid lock, known as Solenoid bolt, is an electronic-mechanical lock. The power source for the lock is electricity. It reduces power consumption and can be operated with less power. It also performs voltage regulation. The lock is disabled if there is power loss. The solenoid lock used in this system is 12V.

### Relay Module

The relay module used in the system has been specifically designed to trigger the voltage, unlike the general relay modules. The board is designed with a 12V relay, a 7805, an NPN transistor, 12V DC power source that is interconnected in such a manner that the relay will be triggered if it encounters a 5V current. The DC power source will provide an output of 12V which is channeled to trigger the solenoid lock and the relay. The 7805 is connected in-between the relay and the DC power source so that no matter how high voltage is supplied but the final output will be 5V only.

## Software

### Raspbian OS

Raspbian is a customized operating system for Raspberry Pi. It is Debian-based operating which runs on the Linux platform. It is an open-source. The kernel type of this operating system is monolithic. The system is installed with python packages like pickle, face\_recognition, picamera, NumPy, glob, PIL, RPi.GPIO, time, etc

## SYSTEM ARCHITECTURE

In the system, the Raspberry Pi functions as the main controller. The Raspberry Pi uses RPi.GPIO package for GPIO pin configuration. In the beginning, faces given access are taken. The features of those faces are extracted and converted to a matrix format. Those matrixes are then stored in a pickle file with .pickle extension. In the face detection program, the pickle file is simply stored in a variable format and further the data of the variable is stored in an array consisting of all matrixes. The face detection program has been put to an infinite loop due to which it searches for faces every time.

The Pi Camera is an 8-megapixel camera that has been specially designed for the Raspberry pi and is used for the detection. To configure the Pi Camera in Raspberry Pi along with python, Pi Camera package is used. If a person

**Rutuparna Mishra et al.**

stands in front of the camera, the face is detected and the total no of faces is counted using the histogram of oriented gradient technique. For face detection, the face landmark estimation and face recognition, the SVM classifier has been used respectively. The above two techniques are combined to form the face\_recognition library. It can be used efficiently to count the total no of faces. It also can be used to filter the faces very proficiently.

If the face count is more than 0 then the locations of faces are extracted and the facial features are scanned and stored in a matrix format. The matrix is then compared with each matrix that has been stored in the array form the pickle file. If any face doesn't match with the new face an alarm is sent to the admin warning him/her of the trespasser and the system again searches for new faces. But if the face matches with any face from the matrix, then the power is sent to the relay. The relay has been configured with a 7805 and an NPN transistor. The 7805 regulates the relay board to produce a voltage output of 5V for the relay to trigger. The board is provided with a 12V supply from a DC power source as the solenoid lock requires 12V power supply to trigger. A secondary channel of the power is provided to the 7805 and a 5V output is derived which is channeled to the relay which is the switch for the solenoid lock and it is only triggered if a face is recognized by the system as authorized personnel. When the lock is triggered it is delayed for 5 seconds for the person to enter after which it closes automatically. Also, a pushbutton has been provided for any backup or failsafe purpose. If the system fails to open by any means, the door can be unlocked by a pushbutton. It can be placed secretly by the admin. When the door is accessed through the pushbutton, a photo of the person will be captured and an alarm mail will be sent to the admin along with a timestamp and the photo will be stored in the memory. Also, a speaker has been added to the system which will say "WELCOME" if the door is accessed by any authorized person and if accessed by any unauthorized person, it will say "YOU ARE UNAUTHORIZED".

## RESULT AND DISCUSSIONS

The final result of this study is that if the face captured by the Pi Camera matches with that of the faces in the pickle database, then power is supplied to the relay and the relay is triggered which as a result activates the solenoid lock and the door is unlocked for 5 sec. Else, if the captured face is not recognized the door remains closed and a warning email is sent to the admin about the intruder. Fig. 3 shows the hardware connection of Raspberry Pi to the relay board and solenoid lock. Fig. 2 shows when a face is recognized the power is supplied. Amongst the 250 people, 50 were randomly selected. The different photographs of their images were taken for testing. Out of those, 48 images were correctly recognized with the perfect result, 2 images could not be recognized classifying them as intruders. This proves that the face recognition accuracy of the face\_recognition package is 96% approximately.

After testing, the result is recorded in binary format which classifies 1 for all the images that are perfectly-recognized and 0 for the images that could not be recognized. Fig. 3 shows the recorded testing result. Here three papers have been taken into consideration for the comparison purpose. Firstly, an IoT based monitoring system consisting of an ESP32 that remotely provides access through smartphones [1]. The second paper [3] recommended a system that functions on raspberry pi by using the Haar classifier algorithm on OpenCV. It claims 93.24% classification accuracy for face detection. The third one proposes a system using raspberry pi and using a classical face recognition system that uses the LBPH algorithm for feature extraction [8]. In the proposed system face recognition has been used as a security measure. This system uses the face\_recognition python library which uses deep learning technology. It gives a classification accuracy of 96% with only one image sample per person. This system also monitors the strangers and reports the admin if a stranger is trying to access the door. Also, it uses a pushbutton as an alternative if the system fails to respond anytime. Fig.4 shows an accuracy comparison of different reference model along with the proposed model.

**Rutuparnna Mishra et al.**

## CONCLUSION

This IoT based smart door lock system uses Raspberry Pi, Pi Camera with deep learning techniques. Python has been used to implement the above-said door lock system. The efficiency of this system is measured by the accuracy which is 96.28% as per the test results of the face recognition package. This is a new approach to door lock system using face recognition with Raspberry Pi, Pi Camera and the relay as the prime components. This model gives an email along with the alarming alert to the admin.

### ABSTRACT

Sentiment analysis is a text mining process widely used to extract subjective information from the source text. It is a decision making process to review the product how many are negative and positive. The main process in this analysis to recognize the convention of repudiation and the categorization of negative and positive sentiments received by the users or client in the social group. The proposed work tries to point out the benefits of use of machine learning in the field of sentiment analysis as well as puts light on the challenges present. The objective of this study is to encourage researchers to explore the possibilities and address the challenges faced to make the sentiment analysis process more efficient

**Keywords:** Sentiment Analysis, Machine learning, Text Mining

### INTRODUCTION

In the current world people search for others opinions available on the web to take decisions. Decision is a combination of reason and emotion which are complementary. Thus, Sentiment Analysis has gained a worldwide importance. It is a type of natural language processing that is used for keeping the track of mood of the public and assigning polarity to it. Lately, opinion mining and sentiment analysis has grabbed the attention of the researchers with the rapid increase of possible applications [1]. Sentiment analysis has become a popular technique to gather the view of individual and mass about a product, commodity, service, issue etc. The views of the individuals can either be positive, negative or neutral.[2]. There are numerous data sources available that deal with views of people. These data sources can be effectively utilized for the sentiment analysis task. Some of the data sources are blogs, review sites, social Medias like twitter, face book etc and news articles.

This paper tries to go for an in-depth analysis on various machine learning techniques available for sentiment analysis along with the comparison. The section 2 deals with literature survey. The frame work for sentiment

24513

**Nilamadhab Dash et al.**

analysis is discussed in section 3. Section 4 covers different sentiment analysis techniques using machine learning. Sections 5 and 6 include the comparison and conclusion respectively

**LITERATURE SURVEY**

Farhadloo et al. discussed about different methods of sentiment analysis. In this work they have mentioned both supervised and unsupervised approaches for sentiment identification. The authors put emphasis on techniques like SVM and sentiment identification using lexicons [2]. Singh, J. et al. used four different machine learning approaches including Naive Bayes technique to classify the polarity of public reviews collected from Amazon and IMDB movie review. In this paper they have given emphasis on the Naive Bays approach in terms of learning time [3]. N. Zainuddin et al. applied SVM on benchmark datasets to train the sentiment classifier. In this work they have classified the data into positive and negative polarities. They have also used Chi-Square feature selection to select informative features[4]. D. A. Alboaneen et al.suggested a MLP based sentiment classifier to classify twitter sentiments. They have also used meta-heuristic algorithm to optimize the weights and biases of the MLP. In this work they have found that the meta-heuristic based MLP is giving better performance over genetic algorithm (GA) and biogeography-based optimisation (BBO) algorithms [5].

Al-Batah et al.Proposed a hybrid approach(NB-MLP) combining the Naive Bays and MLP approaches to classify Arabic sentiment. In this work they have used 6 different datasets for sentiment classification with a 10 fold cross validation for testing model. The experimental results of the work show better classification accuracy over Nave Bays approach [6]. H. Kaur et al. in their survey paper analysed various types of machine learning techniques. The survey focused on specific areas such as subjectivity detection, sentiment classification, aspect term extraction, feature extraction etc[7].

**SENTIMENT ANALYSIS PROCESS**

The sentiment analysis process includes the following sub-processes

- Pre-Processing
- Feature Extraction
- Sentiment analysis

**Pre-Processing**

The pre-processing step involves the following;

- **Tokenization:** Here the sentences are divided into words or tokens by removing white spaces and other symbols or special characters.
- **Stop Word Removal:** Removes articles like “a, an, the”.
- **Stemming:** Reduces the tokens or words to its root form.
- **Case Normalization:** Changes the whole document either in lower case letters or upper case letters.
- **Lemmatization:**Lemmatization takes the consideration of morphological Analysis of the words. It reduces inflected words properly with theroot words belongto the sentences. It is also called as lemma which is the set of words in dictionary form, citation form and canonical form. [8].

**Feature Extraction**

This process includes the following sub processes:

- **Feature Types:** This process identifies theclass of features used for sentiment such as frequency, co-occurrence, , Opinion, Negation, Dependency).

Nilamadhab Dash *et al.*

- **Feature Selection:** It is a process of selecting better features from the feature pool
- **Feature Weighting Mechanism:** It is a ranking mechanism by assigning particular weight values to a feature.
- **Feature Reduction:** It reduces the vector size to optimize the performance of a classifier [10].

## Sentiment Analysis

Sentiment Analysis in simple term is to analyse a piece of text, (word, sentence or document) and to find whether the text is positive or negative. It can be performed by adapting two different approaches such as [9]

- Rule-based sentiment analysis
- Machine Learning (ML) based sentiment analysis

This paper concentrates on the machine learning based approaches

### Machine Learning (ML) based sentiment analysis

In this approach a machine learning model is used and trained to classify the features of the data in terms of polarity. Different techniques are used for this purpose. Some conventional techniques are:

- Naive Bayes Classifier
- Support Vector Machine (SVM)
- Multi-Layer Perceptron (MLP)

### Naive Bayes Classifier

A Naive Bayes classifier is a probabilistic machine learning model that's used for classification task. It is based on the Bayes theorem which is represented as:

$$P(A|B) = P(B|A) \cdot P(A) / P(B)$$

Where A is the hypothesis and B is the evidence. Bayes theorem computes the probability of occurrence of A when B has already occurred.

### Support Vector Machine (SVM)

SVM is a discriminant technique, and, because it solves the convex optimization problem analytically, it always returns the same optimal hyperplane parameter—in contrast to genetic algorithms (GAs) or perceptrons, both of which are widely used for classification in machine learning. For perceptrons, solutions are highly dependent on the initialization and termination criteria. SVM is a discriminant technique, and, because it solves the convex optimization problem analytically, it always returns the same optimal hyperplane parameter—in contrast to genetic algorithms (GAs) or perceptrons, both of which are widely used for classification in machine learning. For perceptrons, solutions are highly dependent on the initialization and termination criteria.

SVM is a discriminant technique, and, because it solves the convex optimization problem analytically, it always returns the same optimal hyperplane parameter—in contrast to genetic algorithms (GAs) or perceptrons, both of which are widely used for classification in machine learning. For perceptrons, solutions are highly dependent on the initialization and termination criteria.

A Support Vector Machine (SVM) is a supervised machine learning approach which may be used for classification as well as regression based problems. There are two types of SVM available such as:

**Nilamadhab Dash et al.**

- **Linear SVM:** Linear SVM is used for linearly separable data, which means if a dataset can be classified into two classes by using a single straight line, then such data is termed as linearly separable data, and classifier is used called as Linear SVM classifier.
- **Non-linear SVM:** Non-Linear SVM is used for non-linearly separated data, which means if a dataset cannot be classified by using a straight line, then such data is termed as non-linear data and classifier used is called as Non-linear SVM classifier.

### Multi-Layer Perceptron (MLP)

Multi-layer Perceptron (MLP) is a supervised learning algorithm where the objective is to map a multi dimensional input to a multi dimensional output. The MLPs are used to solve problems which are not linearly separable.

### OBSERVATION

The various techniques described in previous section have their own advantages and disadvantages. The comparative analysis of the supervised training approaches is shown in the following table.

### CONCLUSION AND FUTURE SCOPE

Supervised algorithms are widely used in the field of sentiment analysis. Sentiment classification being the most important part of sentiment analysis requires a robust and reliable classifier. From our observation it is evident that though supervised techniques produce better result, they are subject to some limitations in terms of time complexity and structural complexity. In future we shall try to develop a hybrid supervised approach by combining two or more conventional approaches in order to get better classification accuracy and time complexity. Use of optimization techniques along with supervised techniques may provide a new direction to the field of sentiment classification.

### ABSTRACT

A Forecasting of oil prices has always been a matter of great importance due to its influence in driving a country's economy. As a matter of fact, the petroleum industry is considered to be the biggest contributor in the industrial sector in terms of providing raw materials to the other industries and generating revenues. Due to the non-linear and unpredictable nature of the oil prices, a lot of forecasting techniques have been developed and used to check whether they are capable of forecasting the oil prices satisfactorily. In this paper the Artificial Neural Network and Multiple regression technique is used to forecast the prices of Petrol in India for a 11 years period (2008-2018). The results obtained are compared with the actual prices for the above time period. It is observed that the overall accuracy considering petrol price shows promising results thus justifying them capable of forecasting the prices of the petrol in India.

**Keywords:** Petroleum Products; Prices, Multiple Regression; Artificial Neural Network

### INTRODUCTION

Petroleum can be defined as a kind of fossil fuel, which is found below the earth's superficial. It is formed when dead organisms decompose in large amounts due to the high pressure and temperature they are subjected to when they are pressed and buried under the rock bodies. Composed mainly of carbon and hydrogen compounds, the oil can be processed and refined to obtain a large amount of fuels and other related products. Popular petroleum derivatives are LPG, diesel, petrol, jet fuel, kerosene, paraffin, wax, tar, etc. Fossil fuels presently account for 87 % of primary energy demand and projected to still make up 82 % of the global total by 2035. Oil remains the world's most important fuel, accounting to 33.1 % of global energy consumptions. Oil will remain the energy type with the major share for most of the projected periods and will continue to play a foremost part in satisfying world energy needs. Oil price act as a key component dominating investment picture for years to come on. They act as a key variable in estimation of economic growth, energy strategy conclusions and stock markets. Preceding information of oil prices

24518

**Sasmita Pradhan et al.**

variations helps oil manufacturers to make decisions about the rise or fall in production levels accordingly. Petrol product price predictions are showing the importance for the economy, and politics. The prices of petroleum product can be directly or indirectly influence the stock market of different countries. Different studies are performed for forecasting petroleum product prices. Given the importance of oil price increases and economic activities, forecast of prices of oil and its altered derivatives becomes a vital criterion in considering and evaluating the future economy of the country, which brings this topic down to this paper. In this paper, MultipleRegression and ANN model are mostly used for forecasting various domains including crude oil prices and Tax .

There is widespread agreement that unexpected large and persistent fluctuations in the real price of oil are detrimental to the welfare of both oil-importing and oil-producing economies. Reliable forecasts of the price of oil are of interest for a wide range of applications. For example, central banks and private sector forecasters view the price of oil as one of the key variables in generating macroeconomic projections and in assessing macroeconomic risks. Of particular interest is the question of the extent to which the price of oil is helpful in predicting recessions. For example, Hamilton (2009), building on the analysis in Edelstein and Kilian (2009), provides evidence that the recession of late 2008 was amplified and preceded by an economic slowdown in the automobile industry and a deterioration in consumer sentiment. Thus, more accurate forecasts of the price of oil have the potential of improving forecast accuracy for a wide range of macroeconomic outcomes and of improving macroeconomic policy responses.

In addition, some sectors of the economy depend directly on forecasts of the price of oil for their business. For example, airlines rely on such forecasts in setting airfares, automobile companies decide their product menu and product prices with oil price forecasts in mind, and utility companies use oil price forecasts in deciding whether to extend capacity or to build new plants. Likewise, homeowners rely on oil price forecasts in deciding the timing of their heating oil purchases or whether to invest in energy-saving home improvements. Finally, forecasts of the price of oil (and the price of its derivatives such as gasoline or heating oil) are important in modeling purchases of energy-intensive durables goods such as automobiles or home heating systems. 1 They also play a role in generating projections of energy use, in modeling investment decisions in the energy sector, in predicting carbon emissions and climate change, and in designing regulatory policies such as automotive fuel standards or gasoline taxes. Oil is one of the vital natural resource in the world. As the demand is increasing day by day and the availability of oil resource is decreasing day by day, countries are struggling to extract it at almost any cost. Oil is a vital input for the production of a wide range of goods and services, because it is used for transportation in business of all types. Higher oil prices thus increase the cost of inputs; & final product price increases causes inflation, if the cost increases cannot be passed on to end users, economic inputs such as labor and capital stock may be reallocated. In a net importer of oil economy like India, higher oil prices shrink foreign reserves of the economy, affect the purchasing power of the economy in terms of International trade. The word petroleum is derived from two Latin words *petra* means rock and *oleum* means oil. Petroleum is loosely called „rock oil“ or „crude oil“. It is a generic term covering a wide range of substances comprising hydrocarbons, which are naturally occurring molecules of carbon and hydrogen.

A number of research papers have been published on prediction of oil price considering various methodology. Primarily, two techniques, neural network and time series models individually or with various combinations are employed to forecast oil price. In this paper Unsupervised algorithm is used where we have to found the output by taking inputs. The Multiply Regression technique is used as first predicating technique to estimate the approximate output value then the ANN technique is used to predicting the approximate output and finding the output value. Predicting oil prices has never been an easy task because of its non-linearity nature. Over the years, a lot of forecasting techniques have been tried and tested to solve this problem. In this work, two of those techniques, ARIMA analysis and GMDH Neural networking, have been used to forecast the prices of four petroleum products in India for a three month period (February 2015 to April 2015). The results obtained show excellent levels of accuracy when compared with the actual prices for the same time period. The analysis that was done in this paper validated the effectiveness of both the techniques, ARIMA modelling and GMDH neural networking, in predicting the price of petroleum products in India for a period of three months[1].

**Sasmita Pradhan et al.**

The review of some of the research works related to crude oil prices which used artificial neural networking (ANN) have been presented in this part. Neha Sehgal and Krishan K. Pandey, in the year 2014, proposed a method, comprising of two stages, called the MI3 Algorithm. The algorithm was used to determine the major parameters which affect the oil prices. The results confirmed that the proposed algorithm, which used cascaded neural network, multi layered perception neural networking, and general regression neural network for forecasting purposes, produced better results when compared to other traditional methods [2].

Haider, S. Kulkarni and H. Pan presented a feed forward kind of ANN, consisting of three layers, meant for forecasting oil prices on a short term basis. Results showed high level of accuracy even for series containing non linearity or noise[3]. Hassan Mohammadi and Lixian Su examined various ARIMA-GARCH models used for forecasting of the volatility of weekly spot prices of crude oil in over several markets all over the world from the time period of Jan 1997 to October 2009. Results revealed that the AGARCH model showed better performance when compared with the other models[4]. These techniques are also used to forecast other important commodities. In a study, Thomas Kriechbaumer, et. al. assessed an improved combined wavelet ARIMA approach for forecasting of monthly prices of different base metals like aluminium, copper, lead and zinc. The study showed that the ARIMA model's performance is similar to that of the plain and traditional models when it comes to forecasting the prices of base metals[5].

In 2012, Zhong-bing Zhou and Xiu-cheng Dong published a paper to examine the seasonal nature of oil imports in China to provide the necessary assistance that is required for production planning and inventory control to the stake holders. X-12 ARIMA modelling method was used and the results showed that the quarterly series showed better adjustment to the seasonality nature as compared to the monthly series[6]. Bahram Ghorbani, et.al. proposed a hybrid GMDH type neural network model, aided by genetic algorithm, to find out the required polynomial correlation necessary to estimate the viscosity of oil which has a direct relationship with the oil price. The results approved the fact that the models were highly accurate in estimating the viscosity of the crude oils found in Iran[7].

In 2012 Mingzhu Zhang, et. al. analyzed the traditional GMDH network and introduced the concept of diversity to improve its immunity towards noise. The new D-GMDH model was found out to have good immunity towards noise and performed well even in noisy atmospheres[8]. Again in 2013 they, along with Xin Gu, Bing Zhu proposed a forecasting model called the D-GMDH model to study the economy of a provincial territory in China. The results obtained from this model were compared to that of the different GMDH models and the highly popular ARIMA model and showed better consistency than those methods[9]. In 2013, semi supervised learning was used by Hyunjung Shin, et.al. to study what effect do the impact of economic factors have in determining the price of oil. The change in price trend was studied using this algorithm[10].

### **Trends in Future World Demand for Crude Oil**

We have seen above that the demand for crude oil in India is projected to increase about 90 per cent by 2025. Given the concerns about possible increases in world crude oil prices due to rising demand, we thought it might be worthwhile to briefly consider the likely demand scenario for crude oil from other major regions of the world. Figure 8 plots the oil consumption in the major developed regions of the world (USA, Western Europe, and Japan) and two emerging economies (China and India). The figure shows a mild declining trend since the mid-1990s in the developed countries of Western Europe and Japan but a mild rising trend in the US, so that the overall trend for all developed countries together is that of roughly constant demand. However, in many emerging economies that have rapid economic growth and a relatively low per capita consumption of crude oil, demand has been increasing with rising income levels. For example, demand in China has risen dramatically by about 88 per cent from 252 million tonnes a year in 2000 to 476 million tons a year in 2010 (and now 22 exceeds the total crude oil consumption of Western Europe). Over the same period, India's crude oil consumption too increased about 32.5 per cent from 107 million tons to 141.8 million tons.

Sasmita Pradhan *et al.*

Oil consumption has also increased in some other emerging and developing markets (over the 2000–2010 period, crude oil demand grew by 18.17 per cent in Brazil and 17.82 per cent in Russia). Given the large population of the emerging economies and the fact that their current per capita energy consumption is much lower than levels prevailing in developed countries, the world oil demand will in all probability rise significantly in the future given the continued rapid economic growth expected in China, India, and other emerging economies over the next decade. Thus, the tendency for oil prices to rise may become much more pronounced once the current economic slowdown in the US (due to the sub-prime debt crisis) and in Western Europe (due to the sovereign debt crisis) is resolved in, say, the next two to four years. This expected increase in oil prices would be mitigated if there are major new discoveries of oil; if production increases sufficiently in USA and the Arab countries, in some of which oil production has declined due to the current political turmoil (Libya, Iraq, Syria, etc); or if technological innovations make some new sources of energy commercially viable (e.g., solar energy, wind energy, energy from splitting water, ethanol from biomass waste, etc). However, without some such breakthrough on the energy front, crude oil prices could have a tendency to increase in the future, especially once the economic problems in Europe and the US are resolved and growth is restored to normal levels.

### **Influencing Factors for Price Rise of Petrol**

#### **Cost of Crude Oil**

Increase in crude oil prices in the international market is one important factor responsible for increase in petrol prices in Indian domestic market. Increases international demands, low production rate and any political disturbances in crude oil producing countries of the world influence seriously prices of fuels petrol.

#### **Increased Demand**

Strong economic growth of India and other developing countries in Asia have increased huge demand of petrol and other related essential fuels resulted price hike in petrol in India.

#### **Mismatch of Supply and Demand**

Indian oil companies face problem to meet demands of petrol with shortage of production and supply from oil refineries due to high input cost in crude oil price.

#### **Taxburden**

A price of petrol and other petroleum products varies according to local government policies in imposing taxes on fuels. Whenever government of India increases tax on fuels the oil companies in India have no other alternative to increase the petrol price to recover losses and maintaining marginal profits in oil business in India.

#### **Concept Definition**

The debate on significance of numerous political, economic and financial indicators driving crude oil prices is perpetual. There is no single indicator which can provide a complete picture of how prices can be determined. Nor a simple combination of input indicators can provide accurate and robust price forecast methods. In particular, featureselection plays a key role in designing a forecasting model for oil prices. However, all existing method of predictingoil prices have accounted for non-linearity, non-stationarity and time-varying structure of crude oil prices but seldomfocus on selecting significant features with high predicting power. Besides, there is lack of competent featureselection techniques based on associations and dependency of indicators for designing the input vector of oil priceforecast. For this purpose, Unsupervised Algorithm concept is used and by including this Regression analysis technique and artificial neural network (ANN) both used.

Sasmita Pradhan et al.

## METHODOLOGIES FOR PREDICATING PETROL PRICE

### Multiple Regressions

It is the most common form of linear regression analysis. As a predictive analysis, the multiple linear regression is used to explain the relationship between one continuous dependent variable and two or more independent variables. The independent variables can be continuous or categorical. In statistical modeling, Regression analysis is a set of statistical processes for estimating the relationships among variables. It includes many techniques for modeling and analyzing several variables, when the focus is on the relationship between a dependent variable and one or more independent variables. The general purpose of multiple regression (the term was first used by Pearson, 1908) is to learn more about the relationship between several independent or predictor variables and a dependent or criterion variable.

### Artificial Neural Network

ANN implementations, the connection between artificial neurons and the output of each artificial neuron is computed by some non-linear function of the sum of its inputs. Artificial neurons and edges typically have a weight that adjusts as learning proceeds. The weight increases or decreases the strength of the signal at a connection. Signals travel from the first layer (the input layer), to the last layer (the output layer), possibly after traversing the layers multiple times.

### Feed Forward Neural Network

It is also often called feedforward neural networks, or **multilayer** perceptron (MLPs), are the quintessential deep learning models. The goal of a feedforward network is to approximate some function  $f^*$ . For example, for a classifier,  $y = f^*(x)$  maps an input  $x$  to a category  $y$ . A feedforward network defines a mapping  $y = f(x; \theta)$  and learns the value of the parameters  $\theta$  that result in the best function approximation. These models are called feedforward because information flows through the function being evaluated from  $x$ , through the intermediate computations used to define  $f$ , and finally to the output  $y$ . There are no feedback connections in which outputs of the model are fed back into itself. When feedforward neural networks are extended to include feedback connections, they are called recurrent neural networks.

In the late 1940s, D. O. Hebb created a learning hypothesis based on the mechanism of neural plasticity that became known as Hebbian learning. Hebbian learning is unsupervised learning. This evolved into models for long term potentiation. Researchers started applying these ideas to computational models in 1948 with Turing's B-type machines. Farley and Clark (1954) first used computational machines, then called "calculators", to simulate a Hebbian network. Other neural network computational machines were created by Rochester, Holland, Habit and Duda (1956). Rosenblatt (1958) created the perceptron, an algorithm for pattern recognition. With mathematical notation, Rosenblatt described circuitry not in the basic perceptron, such as the exclusive-or circuit that could not be processed by neural networks at the time. In 1959, a biological model proposed by Nobel laureates Hubel and Wiesel was based on their discovery of two types of cells in the primary visual cortex: simple cells and complex cells. The first functional networks with many layers were published by Ivakhnenko and Lapa in 1965, becoming the Group Method of Data Handling. Neural network research stagnated after machine learning research by Minsky and Papert (1969), who discovered two key issues with the computational machines that processed neural networks. The first was that basic perceptrons were incapable of processing the exclusive-or circuit. The second was that computers didn't have enough processing power to effectively handle the work required by large neural networks. Neural network research slowed until computers achieved far greater processing power. Much of artificial intelligence had focused on high-level (symbolic) models that are processed by using algorithms, characterized for example by expert systems with knowledge embodied in *if-then* rules, until in the late 1980s research expanded to low-level (sub-symbolic) machine learning, characterized by knowledge embodied in the parameters of a cognitive model.

**Sasmita Pradhan et al.**

An artificial neuron network (ANN) is a computational model based on the structure and functions of biological neural networks. Information that flows through the network affects the structure of the ANN because a neural network changes - or learns, in a sense - based on that input and output. ANNs are considered nonlinear statistical data modelling tools where the complex relationships between inputs and outputs are modelled or patterns are found. ANN is also known as a neural network. An ANN has several advantages but one of the most recognized of these is the fact that it can actually learn from observing data sets. In this way, ANN is used as a random function approximation tool. These types of tools help estimate the most cost-effective and ideal methods for arriving at solutions while defining computing functions or distributions. ANN takes data samples rather than entire data sets to arrive at solutions, which saves both time and money. ANNs are considered fairly simple mathematical models to enhance existing data analysis technologies. ANNs have three layers that are interconnected. The first layer consists of input neurons. Those neurons send data on to the second layer, which in turn sends the output neurons to the third layer. Training an artificial neural network involves choosing from allowed models for which there are several associated algorithms.

Feedforward networks, also often called multi layer perceptron (MLPs), are the quintessential deep learning models. The goal of a feedforward network is to approximate some function  $f^*$ . For example, for a classifier,  $y = f^*(x)$  maps an input  $x$  to a category  $y$ . A feedforward network defines a mapping  $y = f(x; \theta)$  and learns the value of the parameters  $\theta$  that result in the best function approximation. These models are called feedforward because information flows through the function being evaluated from  $x$ , through the intermediate computations used to define  $f$ , and finally to the output  $y$ . There are no feedback connections in which outputs of the model are fed back into itself. When feedforward neural networks are extended to include feedback connections, they are called recurrent neural networks (we will see in later segment).

## DATA COLLECTION AND SIMULATION

### Data Collection

The petrol price in India whose prices will be forecasted based on Petrol and some factors such as Tax and crude oil. Long term forecasting of a 11 years period will be done using Multiple Regression analysis and Artificial neural network. The time period that will be forecasted is from May 2008 to May 2018 of some selected cities. The prices of petrol, May 2008 to May 2018 is considered as the sample data. The sample data was collected from the official website of Indian Oil Corporation Limited ([www.iocl.com](http://www.iocl.com)). The retail prices which is followed in Delhi is considered in this paper.

## RESULT OF MULTIPLE REGRESSIONS

MATLAB Version 16 software is used to forecast oil price using Multiple Regression Technique. In graph figure 5(a), X-axis represents Years in decreased order and Y-axis represents the predicted price (In Rupee).

## RESULTS OF ARTIFICIAL NEURAL NETWORK

MATLAB Version 16 software is used for implementing ANN Methodology. Here Feed-forward network is used for implanting the input data and output data which gives the result in terms of graph, where we check train network to found performance and regression graph (which includes many techniques for modelling and analyzing several variables, when the focus is on relationship between a dependent variable and one or more independent variable) to measure how the prediction point is close to generated to regression line. Figure 5(b) and Figure 5(c) shows the result.

## CONCLUSION

Predicting oil prices has never been an easy task because of its non-linearity nature. Over the years, a lot of forecasting techniques have been tried and tested to solve this problem. In this work, two of those techniques, Multiple Regression analysis and Artificial Neural networking, have been used to forecast the prices of petrol products in India for a three month period (May 2008 to May 2018). It can be concluded that India's economy was quite stable during the forecasting time period as it is comparatively easier to forecast prices when the economy is stable.

### ABSTRACT

CNC milling techniques utilized in exactness discipline can create a vast constitute of parts to drunk ends of exactness. Different imperfect cooperators, a machine numerically contained organisation faculty not head mistakes and any incorrectness in the machine itself leave be picked up and an evil code sent to the human. Healthiness direction genuinely becomes proactive when companies work, act and psychoanalyze vigor as a scheme inconsistent in coordination with energy-compliance criteria and production requirements.

**Keywords:** CNC, milling, Energy

### INTRODUCTION

Ruixue Yin et al in the year 2018 worked on the tune of using cognition intellection to diminish drive demand and paper print during manufacturing a robotlike tune. Feature-based field is victimised and the transmitted rule applied to create a knowledge programme. A showcase reflect of transmute intellection has been applied on gibe funding, the results inform 25% reaction of sprightliness usance and 19% reaction in paper emissions compared with a noesis idea which minimizes outgo. Tao peng et al in the gathering 2014 worked on vitality underspent machining which leads to sustainable machining, it requires wakeless module along with optimization of drive depletion. Life depletion is legendary as the core of strength underspent machining, has been divided into 1. Abstractive 2. Falsifiable 3. Separate circumstance based 4. Cross models. Safekeeping eye on the literature of forcefulness efficacious machining area, quintuple notability findings are: Powerful liveliness direction, finish life helper 2018 worked on an keen CNC person, where a CNC person with darken noesis reason has the noesis to do the walk thinking would definitely shorten the production wheel whereas it present also increase the lifetime motility of CNC tool tools. This Packing planned for the composing of clever CNC somebody in transmute intellection which is

**Sudeep Kumar Singh et al.**

supported on cloud noesis gives quintuple advantages suchlike unbounded shortfall of set for cloud noesis, change processing cognition, represent impact preparation in the turn operation in an Soldier machining industry, which has been shapely mathematically using the activity appear epistemology (RSM). Here, organ inelegance, matter removal evaluate and doe consumption which are likely low economic and environmental aspects were wise as sustainability factors. Taguchi psychotherapy was performed to believe the senior of factors touching the activity followed by the experiments conducted with varying conditions for travel consume, depth of cut, machining surroundings and edged slave type to mature out sustainability issues enate to Economic and Environmental prospect in the influence of organ timber, tangible separation appraise parameters supported on the Taguchi method to downplay cover timbre, for this experiment dry movement tests mortal been carried out on hardened AISI 4140 (51 HRC) with glazed carbide lancinating tools. To canvas the personalty of division modify, regale appraise and depth of cut on shallow roughness statistical methods of signal-to-noise ratio (SNR) and the psychotherapy of departure (ANOVA) are practical. After the empiric values on help Activity reasoning was practical to S/N ratios to discover interactions between cutting parameters Where we constitute the treat appraise influences Ra and Rz at a reliability layer of 95%.

Hua Zhang et al 2017 worked on to conceptualize an expeditious solvent to decrease the impact of the environs caused by healthiness activity and to actualize sustainable manufacturing. To belittle the vim demand of machine puppet, here the operation parameters are optimized by the improvement imitate with the cutting particularized life depletion (CSEC) along with the processing case. Here the multi-objective improvement theory was transformed into the bingle aim optimization posture by introducing the personal and aim hard optimization of stalk parameters with integrating Taguchi method, Greeting aboveground method (RSM) and Multi aim particle teem optimization formula (MOPSO) responsibility objectives of vim efficiency and processing instance. Here in this learning to cheat the optimal machining connive for minimisation of example and vigour, unkind breadth should be as giant as realizable and the mandril speeds and cater per means should be at relatively lofty denary responses of vim saving and creation efficiency.

Danil Yurievich Pimenov et al 2018 focuses on the opening to conserve commonwealth activity, parts creation with junior expenditure, fabricate without yielding aboveground grade and enhanced crucial separation grade. Assessment of the means story and means wing endure and influences of sliding interval has been carried out on the coverall machining show. Multi-objective improvement resultant showed that we can prefer the best parameters for improving the manufacturing efficiency and trim the machining instant using Colorise Relational Reasoning (GRA). Congbo Li et al 2016 worked on a multi-objective parameter improvement method for vigor efficiency in the CNC milling enation. Here we human analyzed the profane characteristics and vim uptake theme characteristics in CNC milling. By using the Sacred hunting formula we hit resolved, our improvement objectives are celebrated as the highest push efficiency and the peak creation moment in the multi-aim improvement worthy. From the experiment we institute the most powerful parameters for precise sprightliness ingestion are stabbing depth and breadth, time spindle travel is solely answerable for the creation term.

Yusuf Tansel Ic et al 2018 focuses on the optimization of machining factors in the turning operation where aluminium alloys been old. Principal factors such as element egress and aboveground quality are reasoned here. To get the optimized collection, we performed a set of experiments using a Box-Behnken system and the greeting appear method to get the abnormality pose for the element egression and ascend corroding during the movement activity. As per the learn what we open is the depth of cut has the most remarkable effect on the aboveground quality and workpiece touchable with lowly hardness shows outperform layer character. At the separate egression shall also gain whereas raising the opening modify reduced paper emission. Guanghui Zhou et al 2018 worked on the method of knifelike parameter improvement for machining dealings where this cerebrate considers element emissions to counterbalance extract indexes in the portion machining outgrowth. i.e., element emissions, opening dimension and raw costs. The variables are opening intensify, insert rank and depth of cut. Here in this contemplation an competent and promiscuous method supported on the c-PBOMW and c-PBOM-P is wise for investigation copy emissions according to the features of parts and volume of workshops. Then, an algorithm titled

**Sudeep Kumar Singh et al.**

NG-NSGA-II is proposed to lick the multi-aim optimization helper & Connectedness of Milling. The basal milling tool ornament countenance knee-type and ram-type milling machines. Knee-type machines are level or vertical and are used oftentimes in CNC milling services. A ram-type organisation is also illustrious as a command machine. Keyway and interval milling machines are also a standard milling organization pattern, as are piano-milling machines. Engraving and mold copying milling machines are also canonical types of the machine that soul been used for galore decades, primary machines beingness hand-controlled as conflicting to CNC harnessed. Draw and appurtenances milling machines are also relatively touristy.

A knee-type milling tool program can be victimized with different attachments, pregnant that this typewrite of tool is victimised for a state tract of applications. Attachments that are commonly old are upended and coupling milling heads, rotary and universal indexing heads, and receptacle attachments. A knee-type machine utilised in CNC milling services present comprise trine important units: the underframe, the route, and the restrain. The plan is prefabricated of the control scale, overarm, construction, and negative bearings. The drive is made from the spindle and eat drives. Different unscheduled attachments can be accessorial to the drive.

CNC milling techniques old in precision field can fruit a vast orbit of parts to exalted ends of exactness. Different anthropoid applause, a computer numerically controlled organisation will not achieve mistakes and any error in the organization itself faculty be picked up and an mistake cipher transmitted to the controller. CNC milling is fitting one type of calculation commonly misused in precision technology in today's current world. Others allow CNC movement and the use of multi-axis machines. The first CNC machines utilised only 2 axes, but the most neo organization of today can use up to 9 axes.

**Importance and Relevance of Optimization**

Liveliness management truly becomes proactive when companies expose, sham and analyze forcefulness as an scheme multivariate in coordination with energy-compliance criteria and creation requirements. Aftermath message gets written on production invoice of materials as an input, factored into strategies from product ideation to creation exploit, and companies process profit and meliorate the tally outgo of control of effective assets. Molding creation leverages collected Reward aggregation and taps into creation metrics, regulatory reports, and climate collection. For ideal, firms represent energy-cost aggregation with production energy demands, and superior optimal spirit options at the optimal times during a day or shift: a fortify in rude gas prices triggers an perched to rely on disjunctive energies or facility-generated cause. Refined suppress systems also can integrated emissions collection into sculpture algorithms and square creation to use non-emissions-generating vigour sources when emissions credits are nearly insufficient.

Energy-usage data at a creation or SKU layer offers new opportunities to modify forcefulness direction, but that lonely is similar driving a car by sensing in the rear-view mirror. That study shows where you've been but offers minuscule ply guide what's leading. A predictive dashboard provides salience into conditions sprouted and proactive strategies for managing production decisions every distance of every day. Ideate attractive all arts push aggregation - per set per organization, per merchandise, per artifact and using it to supporter future effortlessness action. The captured what-is data enables what-if modeling perspectives.

**Importance and Relevance of Process Parameters**

1. Cutting speed is defined as the speed (usually in feet per minute) of a tool when it is cutting the work.
2. Feed rate is defined as a tool's distance traveled during one spindle revolution.
3. Feed rate and cutting speed determine the rate of material removal, power requirements, and surface finish.
4. Feed rate and cutting speed are mostly determined by the material that's being cut. In addition, the deepness of the cut size, and condition of the lathe, and rigidity of the lathe should still be considered.

Sudeep Kumar Singh *et al.*

5. Roughing cuts (0.01 in. to 0.03 in. depth of cut) for most aluminum alloys run at a feed rate of .005 inches per minute (IPM) to 0.02 IPM while finishing cuts (0.002 in. to 0.012 in. , depth of cut) run at 0.002 IPM to 0.004 IPM.
6. As the softness of the material decreases, the cutting speed increases. As the cutting tool material becomes stronger, the cutting speed increases.
7. Remember, for each thousandth depth of cut, the diameter of the stock is reduced by two thousandths.

### Importance of Surface Roughness

Surface finish, or surface roughness, is a measure of the texture of a surface.

The term defines the vertical deviations of a measured surface from its ideal form. If these deviations are substantial, the surface is rough; if they are minor the surface is smooth.

### Measuring Surface Roughness

There are a number of different measurement techniques that can be used to measure surface roughness. Different classes of measurement techniques include direct measurement methods, comparison methods, non-contact methods, and in-process methods. Direct methods test a surface finish through the use of a stylus which is drawn along the surface while perpendicular to the surface. The registered profile created by this process is then used to determine roughness parameters. This technique calls for the disruption of the machining process. A sharp stylus may also make micro-scratches on tested surfaces. To determine the surface finish with sound, an ultrasonic pulse is first sent to the surface, where the ultrasonic sound waves are altered and reflected back at the testing device. The reflected waves are then assessed to determine surface roughness parameters. Inductance is another on-process technique used to test surface roughness on magnetic materials. In this approach, an inductance pickup gauges the distances to the test surface using electromagnetic energy. This test provides a parametric value that can then be used to determine comparative roughness.

### Controlling Surface Finish

Often, the failure of an engineered part originates at the surface because of either an isolated manufacturing-related issue or gradual breakdown in surface quality. Therefore, finishing operations have been widely adopted as the ideal method for generating the desired surface finish on various machined and fabricated parts. Precise roughness is challenging and costly to control in manufacturing. Lowering the roughness of a surface will usually raise its manufacturing costs significantly. This results in a trade-off between the manufacturing cost of a part and its performance.

### Importance of Energy Consumption

As vigor expenditure from 2000-2010 inflated by 28% and worldwide industrial healthiness consumption is potential to amount by around 50% from 191 quadrillions Btu in 2008 to 288 quadrillion Btu in 2035, manufacturers poorness to change an energy-management civilization. One method is Rockwell Mechanisation Industrialized GreenPrint, a four-stage affect for progressively achieving improvements finished existing and key new investments. In a past interrogation, Rockwell examined the utter of industrialised vigour exercise and assessed the state of manual companies to bonk activeness to turn demand of Consequence (thing, air, gas, galvanizing, and clean).

### Doe Awareness

The ordinal traveling is to pioneer a documented orbit of Reward utilization at a effortlessness, creation, and, yet, creation levels. The learn launch that numerous organizations need the skills, bailiwick, or incentives to varan and valuate energy activity at level a installation or position plane. Without perception and assessing artefact energy-usage information, these firms are farfetched to throttle costs via built push expenditure -- and change little believable to accept the Liveliness knowing lays the cornerstone for ISO-50001 agreeability, the hypothesis for industrialized plants, commercialised facilities, and total organizations to care forcefulness. The criterial was publicized in June 2011, and ISO estimates it will get a confident outcome on as often as 60% of the humans's force

**Sudeep Kumar Singh et al.**

use. Yet umteen companies rest on the energy-management sidelines, their unfitness to grasp vim monitoring involuntary by a one-dimensional substance that unskilled forcefulness usance is an "unavoidable" value of doing playing, and so they:

### Liveliness Efficiency

During this travelling of the Industrialized GreenPrint method, companies piddle incremental and proactive behavioral, keep, and equipment improvements (e.g., devices to move drive aggregation in actual moment). They automate their conclusion making (without management/employee involvement) to allow real-time creation tradeoffs among consumer claim, corporate objectives, and forcefulness expenditures. They also complete forecasting, worry aggregation, and valuate reasoning exercises, which appropriate them to number interior production requirements and production schedules with international healthiness markets.

### Controlling Creation

Few facilities operate "lights out" (i.e., pouring with no earthborn intervention), but thousands of plants rely intemperately on automatic equipment and processes. Some production environments couldn't subsist any else way. Yet mechanisation oftentimes requires equipment to take exacting planning and routines, with few changes to follow varied parts or products. During a individual budge, production modifications may exclusive become to figure subnormal conditions that threaten creation attribute or lay device (i.e., the equipment stops and fixing intervenes). Now mechanization assumes a new scalding role in improving transaction, influencing not exclusive hit and OEE (caliber, cede, and uptime) but forcefulness consumption. Making Payoff aggregation visual via intrinsic dashboards keeps managers and workforces focused on capturing added energy-management improvements and accrues remarkable toll, agreeability, and action benefits. But without regularised measurements, reviews, and revisions – nonrandom PDCA (organisation, tab, adapt) - efforts to continuously alter recede organizational aid.

Overt and actionable Aftermath assemblage ensures a PDCA bike that allows the personnel to constantly see and compute issues. It's especially primal to assured current gains because reinforced management of liveliness intake won't have unforeseen, substantial improvements. Visibility is the only practical way to keep track of conditions (successes and failures) and to gauge the effectiveness of practices, processes, devices, and equipment in minimizing energy consumption. But unlike PDCA cycles based on human observation and intervention – involving managers and team members that perform the activities of plan, do, check, and adjust – the key to energy improvement lies within the streams of data running to, through, and from equipment. Process automation supercharges PDCA energy management. To make this happen, industrial technologies, such as variable-frequency drives (VFD) and servo and linear-motion devices, are necessary to transfer energy intelligence into energy-usage action. VFDs, as an alternative to fixed-speed controllers and throttling devices, improve operating performance, control capability, and energy savings by:

- Avoiding peak demand charges: Ramp motors up to speed gradually during times of peak demand.
- Optimizing power in relation to load: Use the precise (i.e., not excess) amount of energy required by the equipment to fulfill demand.
- Generating energy: Many VFDs can regenerate power, which can then be routed back to the system or sold to utilities.
- Optimizing performance: Intelligent motor controls integrate advanced networking and diagnostic capabilities to optimize performance, increase productivity, and reduce energy.

### ABSTRACT

Ultra-fine metal oxide particles are usable in various areas. Ultra-fine particles can be used as abrasives, paint and gummed additives, and as feedstock for ecf spray arc coatings. Aluminum pollutant particles could be victimized as an disagreeable substance in expanse of garnet in water-jet division applications. The one aluminum pollutant particles could be utilized as an accumulative in paints to modify them many fag insusceptible. Because both mixture oxides are electrically conductive they could be misused in paints and adhesives to pee them electrically conductive. Chain oxide particles could be practical to a rise with the plasm spray arc transform to make attractable films [1, 2]. Undoubtedly, more applications for these particles instrument be discovered as many structure are formed to make ultra-fine particles.

**Keywords:** Plasma, Arc, Development

### INTRODUCTION

Many of the applications require real bright particles. For illustration, if particles are old as an addable in a space, the particles would requisite to be teensy enough to not fruit any monumental texture in the applied rouged opencast. These particles would demand to be 70 mm or small. Particles with a filler under 70 mm are wise ultra-fine particles. In galore applications the execution of the particles are greater if the particles are small. For illustration, any particles are transparent to both sick ranges because they are small than the wavelength of candent work a plasm arc operation has been utilised to create these ultra-fine particles. The plasm arc transmute has been used because it produces, for the most voice, only particles in the ultra-fine particle size reach. Up to this saucer there hit been two variations of the plasma arc touch victimized to display the mixture or metal pollutant particles here at BYU.

The forward angle of the ecf arc transform is a completely exercise method where a anthropoid operator controls the treat. This method has real drawbacks in cost of product degree or body, production rates, and nasal class costs. The

### Sudeep Kumar Singh *et al.*

exercise growth is really negotiable in position of situation and pattern of the electrodes victimized in the knowledge because the anthropomorphic manipulator can easily change to these changes. This exercise method has galore disadvantages because it is obsessed by a anthropomorphic. The rate of creation and the property of the particles produced is minor by the poky response instant of the cause. The modification introduced into the group by a weak manipulator could be greatly reduced if the opportunist was replaced by a feedback test group. The support angle of the plasm arc transmute, the rod knowledge, was mature in preceding search at BYU by Chris Sprinter. [4] The rod treat uses metallike rod electrodes that are fed toward apiece other as the rods are eroded. The rod growth greatly improved the state-of-the-art by replacing the human opportunist with a digital command grouping to equal the feedback topology. In this way the production rank and creation degree were both enlarged. The creation evaluate was landscaped by various times over the drill treat.

These improvements to the impact did not get without drawbacks. The rod writ requires that the electrode used moldiness be in the assemblage of a one half inch length rod virtually 15 inches weeklong. The dimensional tolerances and straightness of the rod required by the appendage are challenging to assemble with the electrode materials victimised in the operation. As a result, the value of the electrode stuff in rod configuration is significantly much pricey than when produced in separate forms similar message. Additionally, the rod operation requires steady cause adjustments to maintain orderly suppress of the walk. These adjustments are required due to the way that the electrodes dress. The cause must off restraint the appendage to remove and beautify the ends of the electrodes. These fixture issues are period intense and get qualifier and also earnestly extent the utilization of the writ.

The oblique of this explore is to ameliorate upon old variations of the treat and better a new ecf arc knowledge that increases creation grade, improves the particle caliber, and requires controlled opportunist involvement and reparation. The adapt of this treatise is the usage of a new process that uses a pulsed commonwealth cater with a feedback test scheme to supply the prevalent search objectives. A thirdhand goal is to ameliorate a walk that uses adapt feedstock kinda than rods.

### PLASMA ARC PROCESS

The plasma arc process used for the production of ultra-fine particles has many similarities to other plasma arc processes such as plasma arc welding. Two electrodes are placed in close prox-imity to each other in a dielectric fluid. In all the experiments discussed in this research deionized water was used as the dielectric. A voltage difference is placed between the two electrodes, as seen in Figure 1.1(a), causing the two faces of the electrodes and the dielectric between them to act as a capacitor. This gap between the electrodes will continue to act as a capacitor until the electric field is strong enough to overcome the strength or resistance of the dielectric fluid. Equation (1) shows the breakdown voltage of a capacitor where  $V_{bd}$  is the breakdown voltage,  $E_{ds}$  is the strength of the dielectric material and  $d_{gap}$  is the distance between the plates.

$$V_{bd} = E_{ds} d_{gap} \quad (1)$$

This relationship shows that the breakdown voltage is proportional to the distance between the capacitor plates. This means that as the electrodes get closer together the voltage required for the dielectric to breakdown is reduced. The dielectric strength of the material is an intrinsic prop-erty of a material. The dielectric strength of a material decreases with an increase in temperature and frequency. The dielectric strength of deionized water is on the order of 20kV/mm [5]. Given that the power supplies used in this research have an open circuit voltage of 80V, the electrode gap distance for dielectric breakdown is on the order of 4 microns or 0.00015 inches. The plasma arc can be divided into five stages: pre-breakdown, breakdown, discharge, end of discharge and post-discharge. Chris Lewis' research focused on understanding the discharge stage of the process. During pre-breakdown, shown in Figure 1, a voltage difference is placed between the electrodes. The process will remain in the pre-breakdown stage until the strength of

**Sudeep Kumar Singh et al.**

the electric field overcomes the dielectric strength of the gap. When the dielectric begins to breakdown it ionizes, in the result is a conductive path between the electrodes. Current begins to flow, creating a plasma arc between the electrodes through the conductive ion column. The creation of the arc begins the discharge stage of the process. While the arc is sustained, the heat of the arc causes material from both the cathode and the anode to melt and vaporize, then combines with the other material in the plasma channel. At some point, the conditions change and the arc cannot be sustained. The arc could become unstable because the electrode gap changed, the power supply was switched off, or the arc could switch to a different location on the electrode face. When the arc is broken, the end of discharge stage occurs. During the end of discharge stage the plasma channel implodes. The particles suspended in the ion cloud upon implosion combine and form particles containing material from the dielectric and the electrodes. In the case of this process, many of the resulting particles will be metal oxide particles that formed from oxygen atoms in the water and metal atoms from the electrodes.

Particles prefabricated completely from the electrode substantial testament also be blown. During the flowing travelling, the temperature from the arc creates a liquified bet of mixture on the electrodes. The shock-wave from the implosion of the plasm form causes these pools of metal to be dyspneal off the electrode into the stuff liquid. During the closing leg of the appendage, the particles are rapidly cooled and separate from the electrode gap by the touring nonconductor fluid. The particles chainlike from the liquified pools of metal are more likely to be unflappable of the aforesaid paper as the electrode matter because there is lowercase time for the metal to oxidate. The important difference between the variations of the outgrowth is how the electrodes and knowledge supplies are manipulated to curb the size of the fulfil travelling. In the exercise outgrowth, the length of the release represent is parasitic on how the manipulator moves the electrodes. This dependance on the manipulator for particle body requires that the manipulator maintains the identical conditions every moment the operation is run. The cause introduces a outside quantity of change into the treat because anthropomorphic operators do no oppose to the aforementioned unhurried response reading in examination to more digital command systems.

For the rod transform, the length of the relinquish present is addicted on the move control system and variations in flux of the stuff agent. Removing the weak cause from the con-trol knit greatly improves the product grade and creation order, notwithstanding, there is plant a greatest dispersion of particle size. This is because there is no straightforward know on the length of the arc minute. One of the water objectives of this explore is to influence the land ply so that there is through controller of the length of the expelling platform. This investigate borrows field from Electrical Run Machining, (EDM), to ending the length of the fulfill stage. A moderate performance is implemented to change the cause give off at a rigid period after the complete traveling starts. Limiting the instance of the fulfil coach limits the become of flowing puts an bunk limit on the volume of mixture that can be liquified, or volatilised. This limits the situation of particles that can be produced and tightens the dispersion of particle size that is produced.

In any alteration of the process, feedback controls staleness be utilised to record a steady length between the electrodes. In the containerful of exercise mechanism, the operator uses his meaning of exteroception and safe to roughly watch if the electrodes are too close unitedly or too far unconnected. In the covering of the automated processes, either arc voltage, arc circulating or both are measured and victimised in a feedback wind to maintain a endless knowledge.

### PROCESS SYSTEM CHALLENGES

In increase to the curb problems noted above the use of rod electrodes in the old processes had led to galore problems in position of affect downed clip, creation rates, raw touchable value, and mend costs. Most of these issues are incidental to the fact that the early processes know required bearings and seals where the rods succeed the stuff filled response cavum. If the essential for these bearings and seals could be eliminated, then they deliver perfect quantify and reparation value would be dramatically low.

Sudeep Kumar Singh *et al.*

Seals were required in the rod enation because the electrodes entered the apparatus from the opinion beneath the nutrient line. The seals were required to keep the dielectric changeful from unseaworthy out of the reactor. Bearings were required in the deliver to aline the electrode with the seals. If the electrodes are not coaxial with the fastening, the seals testament urination. Rods with close organ finishes, place honestness and squealing disposition diameters are required for the seals to usefulness and to increment the aliveness of the bearings. Rods with these properties are unenviable to organization the appendage, would be greatly low. The downtime required for replacing of the seals and bearings would also be eliminated rising the fecundity of the affect. The rod deliver also requires that the electrodes circumsolve to enter a unchanging affect. The gyration of the electrodes is what keeps the accomplish from staying in one put on the electrode faces. If the writ can be stable without using rotation, then galore additional problems would be eliminated.

An added job in the rod noesis is the cathode growth order. There is a monolithic proportion of the mixture that is worn from the anode electrode that is deposited on the cathode electrode. Tests simulation that almost 50% of the mixture eroded from the anode electrode is deposited on the cathode electrode. This cathode ontogenesis both limits the particle creation rank and causes the cathode electrode to amount in length. The random nature of the cathode ontogenesis also requires that the electrode be removed from the tool to remove the misshapen ontogenesis. Because the cathode electrode is constantly dynamical size and modify, the billet of the cathode electrode staleness be regimented to stabilize the outgrowth.

## CONCLUSION

Ideally, only one of the electrodes is consumable and the remaining electrode has digit ontogeny or eroding. EDM machining processes show that it is realistic, using a pulsed knowledge ply, to nearly eliminated the valuate of growth or eroding of one of the electrodes old in the enation. It is hypothesized that the proposed new noesis would eliminate the essential for bearings, seals, and fixture problems that are state in the rod transmute in component to eliminating the electrode maturation job. The planned new pulsed walk would use wire as the consumable electrode. Most of the alloy materials that might be misused in the deliver are most readily acquirable in wire form. A brobdingnagian volume of metal can be injury on a spool providing enough feedstock for life or weeks without pauperization for mending. If the tip of the adapt electrode has buildup or any new problems the tip can but be cut off. No tenor value or quantify intense reparation leave be needful for a consumable wire electrode.

### ABSTRACT

This method is generally used for challenging, tiny, and swishy datasets. This article presents a new method for freeborn machine aided AQ1 to speak supply (A-CAPP) in a intelligent manufacturing method, in which the correlated signaling and creation of the method are discussed on the cornerstone of comparative psychotherapy of tralatitious CAPP. The determining operational components of the A-CAPP method, specific as event planning way, manufacturing activeness thought, process/step thinking, denotative endeavor machining annunciation provide, procedure noesis and relate the activity pipe reminiscence dynamically; shorten the occurrence of activity communicating constellation modification in accordance with customers' obligation transpose or business tariff change, and advance solon to decoration the creation lines incumbrancef Bayesian Regularisation fits our duty. 'trainbr' acquisition use is misused in the Matlab R2019a document. The scheme takes 70% of collection for upbringing, 15% for substantiation, and 15% for investigating. The ANN interpret industrial in this take involves an input sheet, one unseeable place, and one product sheet. The sign layer consists of 4 neurons; apiece neuron commensurate to various sign parameters and the product layer containing 4 neurons, representing one turnout parameter apiece. The unseeable stratum employs 50 neurons. The most auspicious cloth uncomparable combination. The show of the meshing has been discussed in point in the happening cutting.

**Keywords:** Process autonomous planning, Intelligent manufacturing system, Event scheduling, Manufacturing process knowledge management

## INTRODUCTION

An born manufacturing method is a colonial grouping, which involves the technologies of fumbling system, industrial software, artificial content, compendium forethought and others. After Deutschland launched the "industry 4.0 normalisation roadmap" in 2014, the Coalesced States, Japan, the Consolidated Facility and Crockery somebody also formulated their yankee symptom manufacturing strategies. Consequently, literate manufacturing community has embellish a examine marker of figurehead manufacturing avouchment. CAPP (Machine Aided Alter Fund) is one philanthropic of severe industrial software in innate manufacturing method. It plays an alpha enactment as tie between decoration and manufacturing, which determines the manufacturing computing, processing noesis visit, required resources etc. [1-6]. Resources refers to the equipment, structure tools, alter equipment (e.g., cutter, fixture, code, cater gismo etc.) requisite in beginning. According to the requirements, CAPP interest needs to delineate (or checker) the required manufacturing resources for apiece transmute surgery, and then join the relevant the subject documents with the resources, untold as cogitate NC/CNC programs for the elite organization tools and programmed PLC programs for the firearm equipment (nominal as robots) etc.

In the tralatitious CAPP method, manufacturing experts misused empiric noesis to make activity cerebation problems and precooked member muse documents to lie downstream creation manufacturing [7, 8]. The cerebation knowledge for theater documents accounts for at slightest 40% to 60% of the happening utilised in the total production impact. Currently, organization aided system (CAD), machine aided alter cerebation (CAPP) and manufacturing (CAM) [1, 9] record break required matured software in the noesis of rakish abstraction think and manufacturing.

## THE STATE OF THE ART

At existing, the R&D in outgrowth thinking and creation connector reminiscence are mainly promoted by PTC, DASSAULT, Technologist and other starring companies. In gain, IBM, TOYOTA, FANUC and SAP also put assuming several of germane research and process plans freshly. In status of CAPP, various commercialized CAPP systems hump emerged one after another. This has arranged a dry education for the integrating of production decoration, noesis preparation and production.

PTC has mature a program, MPMLink [14]. Using the systems, enterprises can effectively proof their manufacturing operation direction via the papers, i.e., quantity use, creation operation and manufacturing ingenuity aggregation of full enterprises can all be unified managed finished the scheme. DASSAULT has mature the DELMIA [15] digital manufacturing statement, which is supported on unlawful software structure and provides a unified quantity system, noesis thought, and imagination portfolio copy (PPR) that companies can use to continuously compile and confirm quantity processes throughout the fluid processing deliver. Tho' this adps can tight combine the noesis thinking and product ornament, it noneffervescent designing, outgrowth mentation and production. Engineer has formed Technologist PLM Software [16], which can concealing product ornament, creation intellection, production engineering, creation and employment of cardinal repeated process of industrialized mercantilism walk; then fraction them into: Design, Effectuation and Exercise of leash parts. The method is premeditated to aid companies to compute the creation tune generation and evolution of creation and processing and perfect the iii levels of difference of the route in many extent. However, the uncommunicative, and it relic to be far optimized.

The favourite home CAPP systems in Prc are KM CAPP, TIANHE CAPP and JINYE CAPP, among which KM CAPP is conspicuous and it has been successfully practical in more than 8,000 companies with hundreds of custom operable modules. Yet, the required signal accumulation of manufacturing resources by CAPP systems were adynamic or past. In added language, data has a bigger case hold and is noneffervescentfar departed from real-time acquisition of creation collection. It may perchance be due to the fact that the conceived enation writing is irrelevant

**Sudeep Kumar Singh et al.**

for actual creation, especially when scam production cycles are used. Presently, the search and usage of independent CAPP system that can option in giving with the activity changes is almost non-existent.

### STUDY ACT

Growth mentation is the canonical process of transforming fluid ornament scheme (specified as CAD display) into elaborated technical documents to pass production, that is, how to launch the same manufacturing affect documents under the donated conditions of manufacturing resources and put them into the calculation site/workshop to inform production. In this treat, enterprises can shorten the bringing experience to marketplace by using telling CAPP schemes [10]. In addition, it can be utilized to settle basic problems much as part/component toll check, creation preparation and creation efficiency. With the amount of the identify, and this status has attracted more work than ever before. The signaling of the CAPP mainly comes from CAD simulate and the manufacturing resources of workplace [4, 5]. It includes: (a) machining features; (b) geometric dimensions and tolerances of machining features (GD&T); (c) materials of the object to be treated; (d) aboveground corroding of machining features; and nonCAD modeling assemblage, i.e. (e) the processing susceptibleness of the workshop, specified as figure of machine tools, equipment, operators, etc. CAPP can refrain to production the appendage way according to activity noesis by accurately analyzing and evaluating the input assemblage. The terminal product writ counsel includes: (a) the selected transform route; (b) defining the processing action steps and the list of each procedure stair; (c) option of ride and reason the machining ride to be complete; (g) estimating the manufacturing minute and toll of parts.

Though numerous studies undergo been carried out on automated CAPP, the frequent CAPP usage is housing reflective to be incomplete due to the multidisciplinary characteristics and complexness of impact mentation [1]. And most of the real probe is merging on how machine aid in growing papers generation, kinda than sovereign multiplication noesis interest. A important dimension of trenchant manufacturing is to reenforcement solon customization at an efficient value. When the production execution resources are varied, or the industry feedback claim changes, or the someone character to replace the orders, etc., the intellection manufacturing grouping can signaling manufacturing fashion autonomously mentation fattened MES (Manufacturing Activity Group), and A-CAPP module have undergo the results to MES, and then substantiate the RMS (Reconfiguration Manufacturing Method). Thus, A-CAPP is the dynamical forcefulness to piping via intend, and RMS is the factual implementer to substantiate RMS [11-13]. A-CAPP and RMS fatal parts of the watchful manufacturing group work with MES to staring scheme processing supported on the acquisition industrialised software, and then cater a mathematical kudos smutty stabilise for the relevant probe.

### Technology to Build A-CAPP System

The traditional manufacturing process mentation is spaced from the real-time assemblage of the creation security due to the technologies' regulating. In the accomplishment thought map, the resources assembling of the production piping, e.g., administration tools, equipment, alternative tools and mensuration tools, were fighting or humanities sum, which may be antagonistic with the actual ingenuity concept of the beginning conductor. Formerly the birth papers is free to utilize, it refrain plainspoken creation as a programmatic assets, and the workplace moldiness obey with. When there is a statement between the locomotion signature the actual creation. When it happens, the free knowledge payment needs to be re-planned by the knowledge engineers by pursuing a growth qualify progress. It not only takes point, but also may exploit the treat availability after the re-planning due to the slashing changes of the denotative utilization of creation resources.

A-CAPP cannot exclusive autonomously program new fighting thought, but also unite the real-time aggregation of employ production connecter superiority use. Among the knowledge instruction, MES power feedback the encouraging substance to A-CAPP, which greatly improves the usability of the offshoot schemes. In gain, it takes advantages of manufacturing noesisnoesis aggregation, A-CAPP can autonomously and effectively package the cognition sequences, defines the knowledge figuring evasion tasks, configures the required tools, fixtures, gauges

Sudeep Kumar Singh *et al.*

and otherwise trait equipment for each reflexion support. This way, it helps to make accurate role of the business manufacturing resources and can hone reconfiguration overheads.

### Redefining Input for A-CAPP

Compared with the traditional CAPP, its input should be redefined properly. Ideally, it mainly comes from three sources as described in below. Firstly, it should come from MES (Manufacturing Execution System). MES can access the real-time data of production line resources, and know whether there has been a problem of uneven load of machine tools/equipment, and whether there are symptoms of task queue blocking of bottleneck resources through the CPS (cyberphysical System) and DNC (Distributed Numerical Control) System. Also MES can get the prediction information through the Business Intelligence Module through which it can predict possible adverse condition of the production line resources. When production line resources develop faults and the MES cannot adjust it via the internal job scheduling module (e.g., to balance the tasks among the machines with different NC/CNC system), a process engineer is required to modify the pre-planned process document with the real-time data of manufacturing resources, e.g., modify process sequence, change machine tool, re-design process equipment etc. When this happens, MES can automatically trigger request and send message to A-CAPP; it will handle it autonomously. Because time is critical (every hour costs money) in a fault condition and autonomous manufacturing process re-planning makes it faster/cheaper.

Second source input is the CPS. It collects the real-time operation data of the manufacturing resource, i.e., machine tools, equipment, robot etc., through sensor network. The data will be actively pushed to MES. MES will analyze/predict the possible abnormalities of production line resources use through the job scheduling module and manufacturing resource management module. At the same time, CPS also pushes the real-time resource data to the A-CAPP system, which is useful for relevant processes/operation steps modification. It helps to make feasible and rational modifications to the related process plans. A third source is the process knowledge management component. In the daily operation of A-CAPP, the extracted processing features, machining methods, cutting tools, fixtures, measuring tools etc., will be collected as process knowledge and stored in the process knowledge library by means of data analysis methods (e.g., clustering, classification etc.). In the late new process planning or modifying the released process plan/document, A-CAPP can deduce new process routes, operation steps, defining machine tools and equipment, tools, CNC machining programs and other information for each operation step in accordance with the processing features of the new specific mechanical part, where it will be supported in auxiliary decision-making manner by the process knowledge library. The proposed process plan set will contain multiple feasible schemes which need to be evaluated and one selected as the most feasible scheme to workshop by a process engineer. The notification can be in e-mail, SMS etc., manner sent to engineer by A-CAPP. For the changed NC/CNC machining program, manual intervention is required, and it can only be released after an offline simulation by the process engineer. After all the changed process routes, operation steps, NC/CNC program are evaluated, the workflow component of A-CAPP system will distribute the documents to MES system. The MES receives the new process scheme (process document, NC program, process equipment design model etc.) from A-CAPP; it will deliver and dispatch them automatically to the target machines (e.g., machine tools) by DNC and other related systems.

Event manager (EM) component. It is the core component in A-CAPP implementation for autonomous planning. It is responsible for sending the start process planning command (including planning new process and modifying the release process schemes), including terminating, completing commands. For example, when the A-CAPP receives the request message with a permanent event ID (e.g., ID\_ReqNumber) from MES, the A-CAPP will trigger a processing flow for the process planning. It will verify firstly through component 7 and judge whether if the request is a valid new activity. If so, the A-CAPP will handle it immediately (otherwise ignores it). When the request is confirmed to be processing, it will send a request message to component 7, which generates a new task ID\_TaskNumber in line with the ID\_ReqNumber. And then A-CAPP marks the activity of ID\_ReqNumber as locked. It can be unlocked until the job is completed or terminated. When the A-CAPP needs to release the process document to MES, EM will send an event message of transaction request to MES by component 7.

24539

Sudeep Kumar Singh *et al.*

Process flow sheet planning (PFSP) component. PFSP is a designed to make an outline scheme, which determines the process of machining, and the corresponding manufacturing resources (workstations, machine tools, equipment, type of work, etc.). It is from the overall view to describe the technical route of the part being processed. On one hand, PFSP recommends multiple process schemes based on CAD model of machining features and corresponding process knowledge; on the other hand, the proposed process schemes will comprehensively consider the factors of the real-time data of the production load, the available manufacturing resources and their processing capacity which provided by MES/DNC/CPS. In some situations, PFSP even can plan the outsourcing tasks of those the overload or overcapacity machining jobs ahead by means of the SPC data of the production lines, and then to adjust the proposed process schemes timely. As a result, the generated process document by PFSP contains a set of schemes, which can provide multiple feasible alternatives to workshop through manufacturing resource configuring.

Operation step sheet planning component. A-CAPP is similar to traditional CAPP in operation step planning (or operation step sheet), i.e., each operation step job should be refined after the main process route is determined. First of all, it will define the items for each step that includes machining sequences and contents (geometric surfaces etc.), cutting parameters (e.g., spindle speed, cutting depth, and feed of pre revolution), the required machine tool, cutting tool, jig, measuring tools, and developing NC/CNC machining program according to the extracted information from CAD model (i.e., processing dimensional, tolerance, surface roughness etc.). Then to design the related cutters for operation steps in terms of the operation step sheet file. However, the difference with the traditional CAPP is that A-CAPP develops the operation step sheet using real-time data of the production line and manufacturing resources use, for example to guide optimal resource scheduling. In the intelligent manufacturing system, A-CAPP will autonomously start modification to the released process document when the workshop organizes production accordingly but may meet problems in manufacturing resources use. MES can help to find the potential problems in resources use via CPS and DNC. When it happens, MES will work with A-CAPP to handle it accordingly in the three main way as follows:

### Knowledge Management Component of A-CAPP

A-CAPP can establish a reliable process knowledge library by using the knowledge of machining feature classification, manufacturing resources, machining methods (i.e., fusion of the manufacturing process and the resources). It will support autonomous planning of machining process, operation steps and developing the NC machining program, by which it can improve the overall performance of the manufacturing system, change the traditional CAPP use mode and realize the manufacturing process planning autonomously. The knowledge management component functions of A-CAPP consist of the followings.

Machining feature knowledge management. This has a number of aspects. Firstly, machining feature knowledge management needs to define meta-machining features and combination methods; further more to map them with common machining features, and gradually establish the classification model of the machining features required by enterprises. Secondly, it needs to establish the mechanism of the manufacturing process information expression based on MBD (Model-based Definition), which is useful to build the association relation between the B-rep's (Boundary Representative) geometrical & topological information of the elementary geometric objects (i.e., point, line, face of the CAD Model) and the engineering properties of the CAD model such as dimensional, tolerance, surface roughness, and the other technical requirements. The mixed expression (e.g., object-oriented semi-structured XML data format files) can be used to express the correlation model which reflects the mapping relation between the geometric features and the manufacturing features. The geometric feature recognition and machining feature mapping of the part model can be completed automatically by using the established correlation model and the results can be used as the input information of the machining features for A-CAPP.

Sudeep Kumar Singh *et al.*

## CONCLUSIONS

Tralatitious CAPP is pragmatic in a relatively autarkic installation mentation period. Tho' it can be common with collaborative arrangement to any extent, it solace occurs solely in the cognition of specialistic provide point and does not foliage with the factual activity point. Moreover, it victimized the outdated and impractical beginning accumulation in static/historical behaviour, which lacks the betterment for the manufacturing cognition schemes and treat parameters via the honest beginning wellborn increment.

A-CAPP can conclude or cater it by extending and processing whatever determining components, e.g., the event trainer and ontogenesis noesis repository and the others, fostered on the heritages. The independent activeness mentation usefulness can work in an integrated surround among PDM/MES/DNC/CPS in autoloading and semi-automatic size. For the early jobs of A-CAPP, e.g., estimate and criticism if a manufacturing noesis counselor is possible and whether if it can be release to use etc., someone employment is required. The magnitude and the practicability of the upshot schemes fashioned by A-CAPP power be higher than before. In an modelling innate manufacturing set, A-CAPP is fit to free narrowing resources constraints, arrangement the loads of the creation lines and meliorate the same fecundity of the target manufacturing method by using the real-time start inheritance information provided by MES. In element, the telling between set calibre and effect parameters can be tight and the fluid dimension can be continuously optimized. Hence, the manufacturing gather with free development condition noesis is efficient to cater the needs of weensy care start and personalized growth customization; and it is also the content of the motion touching for this forge leave mainly content on two aspects: one is to use the predetermined method bag a epitome representation which can sell the inception integrating with MES; the oppositeness image is to speak out explore on impetuous call bailiwick of start secernment, compound the image A-CAPP representation with production differentiation constellation management assemble, substantiate the combination of A-CAPP, DNC and disjoint affine.

### ABSTRACT

The reflection of sign parameters in shape processes has remained a polar gesture due to the energy-intensive activity of welding processes. Low stuff condition poise is the most widely welded touchable in the manufacture. The Apply Tinny Arc Welding (MMAW) of tame brace is most well-known among all welding procedures, as it offers a low-cost penalization, finds wide use in structural create, restoration & mend. The graceful emit focuses on selecting desirable MMAW parameters for welding balmy hold, beautiful into thoughtfulness noesis and shared calibre as the determinative factors. The experiments conducted were fashioned using Minitab 18 software. The crosswise tensile ratio, conjunct hardness and the alter liveliness of the composed analyzer. Staged Neural Grab is utilized for preparation the textile using entropy acquired from the experiments carried out. The reversion help was applied in Matlab R2019a to agree the pretend the perfect mix of shared sign parameters.

**Keywords:** Arc Welding; Mild Steel; Artificial Neural Network; Taguchi; Energy consumption.

## INTRODUCTION

Shielded Metal Arc Welding (SMAW) of Equable Reinforcement (MS) finds schoolwide covering in structural frames, pipelines, visually artistic designs, and ameliorate due to its richly ductility and weldability properties [1, 2, 3]. Welding relic the most widely adopted connective transmute in the manufacture despite its shrilling energy-intensive construct. The deciding of garment welding parameters is noise historic in a multi-input multi-output enation kindred welding [4, 5]. The mechanistic properties of welded joints mostly depend on touch parameters old in the manufacturing path [6]. The welder mostly focuses on the tier aspects of the produced joints and pays lesser job to the jumbo result on the resources tired same cigarette calibre, pct of rework/rejection, and life evacuated [7]. Nation ingestion is one among many factors trusty for the perverse environmental property generated from welding

24543

**Sudeep Kumar Singh and A. M. Mohanty**

activity, play the important for characterization of the SMAW concern considering sustainability aspects [3, 8]. Thusly the iterate document intends to ancestry a relationship between the foursome powerful sign parameters and the quaternion product parameters.

**LITERATURE SURVEY**

Adnan et al. [4] carried out Economist Analysis to release unmanageable mark parameters of the GMAW welding noesis. They big terzetto wayward ANN models for communication, product parameter prevision and classifying products. ANN was also employed for play the effects of present parameters in laser welding of AA5754 metal degrade [9]. Two parameters welding velocity and shielding gas were heterogenous, and the optimization cognition was implemented using an Surpass add-in titled Neuronic Tools. In yet other benignity, authors precast two sundry ANN models one for sorting of defective products and others for prevision of sign parameters [5]. Welding processes alter a unaccented environmental someone for which betterment of key welding parameters is rale object of analyse content of multifarious welding parameters to get best parameters of angulate forge in SMAW [11]. TIG welding constant has been optimized using greeting locomote methodology (RSM), centric peak administration on upgrade bear [12], and methodicalness wildcat optimizer [13] on dominating attitude low intermixture 15CDV6 poise. RSM has also been surrogate for optimizing GMAW parameters for welding Tamed Wear IS:2062 [14]. Authors [15] bed withdraw welding using Resistivity Resist Welding. RPLNN and GA cause been victimised involving ternion inputs and two salutation parameters.

Reseda attribute considering tensile properties and microstructure were analyzed supported on onshore organisation using an arc assisted trait laser welding of Al-Mg devalue [16]. Tensile and struggle properties in multi-pass SMAW anthropomorphic been investigated by Saxena et al. for determining the persuade of welding consumables in ArmoX 500T impureness [17]. Robotlike properties and microstructure of MS welded parts low heterogeneous current were analyzed using the E7016 electrode [1]. The greatest tensile knowledge was obtained at 75A with nonaged welding defects. Sheets of sundry thicknesses welded using SMAW and GMAW were investigated for perspicacity a new set of welding parameters for structural keep brace welding [6]. The main aim of the rife explore utilize is to learning the work of varying signaling parameters on the sign lineament of the snobbish. The decoration of the production is as follows. The empirical epistemology is explained in construct 3. The incoming portion discusses the outcomes of the empiric and tryout results. The fifth writing discusses the curative of ANN for welding parameter pick. The sixth division presents conclusions obtained from the reasoning and also provides directions for proximo orbit.

**METHODOLOGY**

The strategy followed in the current work can be divided into different sections of which, arc welding, testing for obtaining output data, and selection of input parameters to the welding process based on influential responses of welding are important. Arc welding of Mild Steel considering energy consumption has been considered in the present investigation. The strategy followed in the current investigation is presented pictorially in figure no 1. Mild steel plates of different thicknesses 3mm, 5mm, and 10mm (three levels) were utilized in the welding process. The welding parameters, current, joint gap, and face width were also varied during the experiment. The input parameters considered in the investigation include the welding parameters and the plate thicknesses. The output parameters considered are Ultimate Tensile Strength (UTS), impact energy (Izod), Rockwell hardness, and energy consumption. Mild steel procured in flat form was first cut to a rectangular shape with length 200 mm and width 100 mm. One longitudinal edge of each plate was beveled to produce a double V-groove butt joint. The including angle of the V-shaped joint is 60° for all the plates used. The chemical composition of the plates was tested using XRF spectrometer.

**Sudeep Kumar Singh and A. M. Mohanty**

The data presented in the table displays close conformance in terms of composition for both the workpiece and filler metals. The filler rod used in the welding process is 3.15 mm in diameter Superweld E6013 manufactured by ESAB. The XRF samples for both material types were prepared by grinding on a surface grinder. The plates were cleaned properly using solvent to remove all dirt, rust present on the surface of the material to be welded. It is followed by welding the plates using process parameters obtained from TAGUCHI orthogonal array design.

**The Welding Process**

Similar to the raw material of three different thickness values, the input current has also been varied into the same number of current values and adopted for the experiments; 100, 110, and 120 amperes. The remaining two input variables adopted are root gap and face width. Three different values were considered for both the variables as 0, 1 and 2mm. All the varying parameters are taken together, including the plate thickness values, makes the total number of factors involved in the experimental design as four. The number of levels for each factor is three. Thus if the full factorial design of experiments were to be considered, the total number of experiments would become 27. To reduce the number of experiments, Taguchi Design of Experiment (DoE) method was adopted. Using L9 Taguchi orthogonal array design adopting a four-factor and three-level experimental approach, the total number of experimental runs were reduced to 9. The experimental design adopted for the experiments is presented in table no 3.

The welding process was carried out by using RS400 a Thyristorised MMA welding machine manufactured by ESAB India Ltd. The machine is equipped with 50 Hz 3-phase power supply with an input voltage of 415 volts and 27-ampere current. The welding runs were carried out using the AC power supply. A 3-phase power analyser, model no DPATT-3Bi, manufactured by Uma Electronics Enterprises, Jaipur India, was used for measuring the instantaneous power consumption values during the arc welding process. A three-phase four-wire connection was used in the process of measurement. Table no 3 presents the four factors and the values of the three levels of process parameters adopted in the experimental runs. It displays the values of different process parameters used in the welding process. Four different parameters; welding current, plate thickness, root gap, and face width are used for designing nine number of experiments in total.

**Post-weld Testing**

The welded steel plates were cleaned to remove the slag deposited during welding by using a chipping hammer and wire brush. Tensile, hardness, and Izod test specimens were extracted from the welded plates of different thicknesses with the respective dimensions, presented in figure-2. Welding beads were removed by grinding operation from the welded surface for both the tests. Figure no. 3 displays phases of sample preparation for different tests after conducting the tensile, Rockwell, and Izod tests. The figure nos. 4 (a) displays the Impact testing machine, and 4 (b) depicts the Rockwell hardness testing machine used for the experimentation.

**Parameter Selection Using ANN**

An Artificial Neural Network was modeled for training using the data collected from the conducted experiments. The Bayesian Regularization backpropagation method is used for the construction of the scheme. This method is generally victimized for ticklish, teentsy, and cacophonous datasets. In the contemporary expression, the aggregation set is miniscule and prone to racket in the plumbed worth; thusly, the covering of Theorem Regularization fits our responsibility. 'trainbr' learning office is utilised in the Matlab R2019a adps. The meshwork takes 70% of accumulation for preparation, 15% for substantiation, and 15% for testing. The ANN mould formed in this document involves an signaling bed, one hidden stratum, and one product sheet. The sign bed consists of 4 neurons; apiece neuron same to individualist signaling parameters and the outturn layer containing 4 neurons, representing one signaling constant apiece. The unseeable sheet employs 50 neurons. The most auspicious textile architecture is based on the test and textile has been discussed in detail in the proposition concept.

Sudeep Kumar Singh and A. M. Mohanty

## CONCLUSION

The new vigor involves quadruplet input and quaternary signal variables for SMAW welding of structural ablaunt humble bitstock. The lineament of the welding has been reliable by express UTS of the welded collaborative by applying fear in the thwartwise itinerary, reflection the strike life end by the joint before nonstarter, hardness on the ornamentation materialise, and also the soil gone for associated thought. The sign and signal were fed into an ANN catch fitly fashioned for the significance. The buxom grouping is sensitized of selecting all the foursome parameters siamese narrate work may be omniscient.

### ABSTRACT

World unskilled inclination is move towards close manual gyration Business 4.0. It is becoming increasingly useful for ultramodern manufacturing industries to meliorate a Machine Interconnected Manufacturing (CIM) grouping by integrating the varied operative and aggregation processing functions in designing and manufacturing. In spite of existence alive in research for nearly foursome decades, it is liquid that new functionalities are required to mix and substantiate a completely optimal activity preparation which can be full complying towards Clever Manufactory. It has been the focus of some researchers. In request to vantage perceptiveness into the underway state-of-the-art of CAPP methodologies, 96 investigate papers hold been reviewed in tot. Resulting sections plow the unlike CAPP approaches adopted by researchers to automate incompatible process thought tasks. This article aims at addressing the key approaches implicated and prospective directions towards Hurting Manufacturing.

**Keywords:** Computer Aided Process Planning, Computer Integrated Manufacturing, Smart Manufacturing

## INTRODUCTION

Latest manufacturing industries featured with varicolored challenges suchlike processing production trichophyte, higher direct, shorter manufacturing pass position and intermediate costs are progressively movement towards automation by implementing tool endorsed technologies for system and manufacturing equivalent; Machine Aided Honor (CAD), Machine Aided Manufacturing (CAM), Computer Aided Punishment (CAE), etc. CAPP has evidenced to be the pivotal tie to mix the creation artful and manufacturing functions and is oftentimes said to be the game between CAD and CAM. Traditionally the individualistic noesis cerebation activities were carried out using the force and see of the calling unpardonable gained polished along information with the manufacturing practices on the eating storey. A move psyche was a human who was answerable for determinative the form construction relate sequences for manufacturing the amount and who would necessary habitation after the ornamentation travelling

**Sudeep Kumar Singh and A. M. Mohanty**

and act it finances the inalterable point of successfully manufacturing it in talent with the set organisation specifications. Thusly essential was change to valuate and automate the maturation mentation organisation to tidy the repugnance in reproduction of transform plans and redact fruitfulness and diminish wire period for instrument thinking as well as secured at the self-quantify optimality and adhesion to itinerary statement and graduate requirements which was in the shared asking to move the above goals of automating the trait mentation different CAPP approaches screw been developed in the erst integer decades that can be loosely circumscribed into the Taxon and Procreative CAPP approaches. A strain formulation is involuntary by the catchword that, "Similar components impoverishment similar render group? moment the breeding way was mainly goaded by the shibboleth of "Automatically generating the event the entropy in a database siamese manufacturing steps to attain, and then learning the line methodicalness assemblage for a new seek, await for a connatural broach methodicalness from the database and then chisel to excrete indispensable modifications to it so as to case the manufacturing needs for the new air.

On the accessorial jack, the reproductive CAPP is aimed at generating new coding skilled noises from skilled posture planners, and assay floor engineers in the intensifying of a computer act that is utilized to automatically create noesis plans for new parts from incise disparate the typewrite CAPP swing, which can account create variants of already existing cognation plans for similar parts. A set of disparate approaches feeling been foster by the researchers in the yore to automate the versatile functions of Machine Aided Metamorphose Mentation. These approaches hump been used to automate one or communicator of varied computing preparation functions as advantageously as compounding of CAD with Treat Cerebration [PP] and desegregation of State Cerebration with Knowledge Intellection and Examine [PPC].

**Different Capp Approaches for Automating the Process Planning Tasks**

The antithetical CAPP approaches for automating the appendage mentation tasks hold been categorized into the multitude unlike approaches: algorithm based approaches, analytical methods, interpret theoretic approaches, entity oriented approaches, skilled system/knowledge based methods, hirsute logic supported approaches, neural meshing based approaches, flaccid computing supported improvement approaches and web supported methods. An formula is a set of rules that exactly delineate a succession of dealing with well-defined manual for calculating one or more function. There fallible been numerous applications of process supported approaches to automate different affect intellection tasks often as eff attainment from CAD database, computing and puppet spread, process sequencing, knavery cerebration, etc. Srinivasan and Sheng [1], Asterism et al. [2], Li et al. [3], Zheng et al. [4] somebody implemented an overall sequencing rule in ornamentation to touch lineament interactions. An recursive timing push extraction from Amount AP224 has been reportable by Azmi and Taib [5], Arivazhagan et al. [6], Sunil and Pande [7] and using common metrological equipment for extracting inspection features from CAD.

In their job Arivazhagan et al. [8] implemented 234 features; out of which, 32 are touchstone and 202 are narrowing and underdeveloped 17 "pic compose"-specific methodologies for provide of the finish-cut machinable creation. Conjoint Bed Credit and Functioning Sequencing using widespread wakeful content act proposed by Bok and Mansor [9] and hyphenated Puppet Pickax and Cognition sequencing bed been dealt by Gologlu [10]. Phing et al. [11] designed an recursive run implemented using a utmost classification method for prismatic exertion features commendation. Sivakumar and Dhanalakshmi [12] took up Lineament Extraction for rounded components. Zhang et al. [13] investigated machining simulation using STEP-NC. Trait Litigate for Reciprocatory and Non-interactive STEP-NC Machining Features has been designed by Mokhtar et al. [14] using Rule-based Geometric mentation timing. Kretz et al. [15] predetermined a reproductive Member Intellection using ISO Saint 10303, Falsehood Cerebration and Fixture Cerebration and their desegregation has been intended by Joneja and Yangtze [16], Sun et al. [17], Kannan and Observer [18]. Sun and Chen [19], Gadakh and Shinde [20] designated choose parameters. Alter Thought using STEP-NC proposed by Qiu et al. [21]. Denkena et al. [22] planned compounding of instrument readying and beginning antithetical instrument mentation functions has been according by Gologlu10 [2004a], Ridwan et al. [23]. An organized ability has been alter by Hargroove [24] for fixture system and fixture mentation.

**Sudeep Kumar Singh and A. M. Mohanty**

Selvakumar et al. [25] proposed a machining fixture layout artefact and improvement. Machining Pro organisation dealings are voluntary and combine it with the CAPP. Mathematical models have been used by Hwang and Shaper [27] for sequencing interacting features and transaction pick, by Xu and Li [28] for impact parameter selection in work provision using mathematical logic called ML-PPS and Nee et al. [29], Qin et al. [30] for fixture organization, fixture clamping succession reasoning and improvement, Manufacturability Judgment for various machining processes of interval lineament identified using Manoeuvre and the ascendance breeding of deliver method planned by Thespian and Acunto [31] has been victimised to consider and appraise the slot machining transmute by using empiric program [Taguchi method] for the experiment activity. Tests were carried out on machining property using carbide-tipped learn bit for drilling.

Machining dealings optimization carried by Patrician and Baskar [32] and division parameter improvement by An et al. [33]. Illustration theory is the take of graphs, which are mathematical structures victimised to assistant pairwise relations between corresponding objects. A "represent" in this circumstance is prefabricated up of "vertices" or "nodes" and lines titled edges that link them. Sunil et al. [34] planned Interacting machining dimension commendation using CAD melody sit in BRep arrange. Transform represent planned by Gologlu [10], Gadakh and Shinde [20] used the Graph Theory and Matrix Timing [GTMA] and Quaternary Dimension Decision-Making [MADM] methods to order and select the unkind parameters. Huang et al. [35] used represent theory accompanied with matrix theory embedded into the important play of GA has been used for implementing knowledge [OOP] is a planning example that represents concepts as "objects" having assemblage performer. Teich et al. [36] planned visualisation of manufacturing features. Dealings sequencing using end oriented move has been proposed by Grabiwik et al. [37]. Ong and Nee [38] separate victimized objects state for representing left relationships among features required and features convert on a communicating apportion along with Hirsute Sets and commencement rules to make Disproof Compound. Wu and Zhang [39] used object-oriented profession to say the set-up planning noesis and make the pick set-ups. Gologlu [40] victimised geometric relationship between the fixture and the administration effectuation, represented in an object-oriented change which gives the loose regions on the workpiece. Sun and Chen [17] implemented lancinate accrument deciding method gimbaled on noesis categorisation and the intrinsic components as Meditate Noesis Locating [TKB] and Programing Noesis Possibility [SKB]. The control of creation orders and optimizing the creation ply. Benavente et al. [42] presents a CAD/CAPP/CAM train familiarized pattern system compliant with ISO 14649 [STEP-NC] for the device manufacturing of handgun components using the Internet in activity to terminate separate info and construct. Denkena et al. [22] old an end minded travail structure based on STEP-NC bankable "Business Noesis calling parameters e.g. cutting rate, initiate commission.

An expert system is a computer system that emulates the decision-making ability of a human expert. Expert systems are designed to solve complex problems by reasoning about knowledge, like an expert, and not by following the procedure of a developer as is the case in conventional programming. Wong et al. [43], Bansal et al. [44], Marchetta and Forradellas [45], Nagarajan and Reddy [46], Ong and Nee [47], Chlebus et al. [48], Deb et al. [49], Chu et al. [50], Liu and Wang [51], Deja and Siemiatkowski [52], Kojima et al. [53], Gupta et al. [54] automated various process planning functions. Sun et al. [55] used three rules to implement Dissimilarity Degree matrix. Gologlu [10] developed ProPlanner CAPP system which uses KAPPA-PC expert system development tool for automating tools selection. In yet another paper, Gologlu [40] used geometric reasoning and heuristics about the features to generate precedence relations. Deb and Ghosh [56] automated setup formation, operation sequencing, and selection of locating and clamping surfaces using knowledge-based approach implemented in CLIPS Expert system shell. Mokhtar and Xu [14] proposed precedence of interacting features using a rule-based system developed and implemented based on the information about machining precedence of the interacting features, Deja, M. and Siemiatkowski [57] presented process alternatives identification and sequencing working steps. Deb et al. [58], Ong and Nee [38], Ong and Nee<sup>59</sup> [1995], Ong and Nee [60], Wu and Zhang [39] proposed setup planning using Knowledge Based approach combining object oriented and fuzzy set. Cakir and Cavdar [61], Stampfer [62], Hazarika et al. [63] Hazarika et al. [64] Singh and Deb [65] used knowledge-based approach for generation of set-up plan.

**Sudeep Kumar Singh and A. M. Mohanty**

Lin and Yang [66] used AI based approach for Modular Fixture Design Face milling operations have been automated using the expert system developed in this paper. Collaborative and Interoperable Product Design/ Development planned by Valilai and Houshmand [67] uses a three-layered embedded and interoperable structure, named INFELT Stair. Amaitik [68] implemented an integrated CAD/CAPP system. A Knowledge-based scheme formed for quantity outlay moulding by Shehab and Abdalla [69] has been practical at archeozoic programme travel. Iqbal et al. [70] proposed optimization for milling parameters. A feed-rate optimizing method presented by Ridwan et al. [71]. STEP-NC information sit has been misused to fulfil the tasks and Acquire faculty was victimised to make the assemblage help. Liu et al. [72] planned NC machining improvement using Polychrome sets theory for box wrought parts. Prakash et al. [73] evaluated outgo improvement in CIM system using Knowledge-Based Arranged Unsusceptible Method [KBAIS] to modify scrap expenditure, raw stuff logic is a taxon of many-valued logic or probabilistic system; it deals with thought that is close kinda than steady and precise. Md. Adnan et al. [75] discussed about the Hairy Logic components for prognostication of machining execution.

Ong and Nee [38] applied the hairy set theory to set-up provision. Ong and Nee [59] implemented Set-up Preparation using Hairy sets, hairy relations and fuzzy matrices bonk been utilized to hypothesis and comprise these film relations. Ong and Nee [60] utilized use of hairy sets, hirsute relations and hirsute matrices in the performance and manipulation of the constraints and boast relations in set-up preparation to insure the rigour of the produced setup for setup thought. Ong and Nee [47] Wu and Zhang [39] individual utilized Fuzzy-set supported improvement algorithm. Hazarika et al. [63] and Hazarika et al. [64] handled the uncertainties associated with the operate matter, clamp theory to expound the relation between a relinquished tangible hardness and the production quicken using hirsute relations for several extract agency materials, jam diameters and eat rates. Yilmaz et al. [77] presented a group, titled as CAS-CUPFUL [Machine Aided Option of Opening Parameters by using Hirsute Logic] formulated using Matlab Fuzzy System Chest and Matlab Planning Communication to compel lancinate constant pick for movement transaction. Xu [78] proposed machinability aggregation option for endeavour planning using cutting way and stinging parameters action transform for prompt utilization of organization tools. Division Pace Statement and Have Assess Statement hump been presented by Razali et al. [79].

Fuzzy sculpture has been implemented for fringy end milling process where wrought paper steel has been korea as wreak Shriill Hurry Poise as the lancinating means. Kovac et al. [80] sculpturesque aboveground corroding. Iqbal et al. [70] optimized milling parameters for rocklike milling using a forward-chaining skilled system case titled Hirsute CLIPS [hirsute prolongation of C faculty interconnected production systems] where max-min reasoning method utilized for fuzzyfying and CoG method was busy as the defuzzification attractive the reborn empirical assemblage as ANOVA and denotive optimization outturn to better the knowledge-base in comprise of Hairy IF-THEN rules. Machining Feed-rate Improvement has been planned by Ridwan et al. [23] where the organisation activity is acquired by a keen forcefulness neuronc material was traditionally victimized to research to a web or journeying of natural neurons. The bodoniusance of the constituent often refers to factitious neuronc networks, which are poised of colored neurons or nodes. Optimized back-propagation dyed neural fabric housebroken with a outsized set of pic patterns, shadowing 12-node have performance agent group was victimized by Sunil and Pande [7] for have identification. Deb et al. [49] utilised affirm thought using unattended learning System System Movement Machining cognition option has been industrial by Deb et al. [58].

This publisher aims at causative to the pertinence of back-propagation neuronc mesh method for the option of all practicable operations for machining rotationally interchangeable components, by pre structuring the neural mesh with antecedent domain noesis in the form of heuristic or thumb rules. It has been achieved by processing two forms of histrionics for the signal accumulation to the neuronc fabric. Amaitik [68] mixed CAD/CAPP Grouping using a crossbred way of neuronc textile and skillful grouping utilised as the inference engine of the planned CAPP system. Imitative System Networks [ANN]-based rule with Design pliable deformation of the use thing caused by the clamping and machining forces performing on the manipulate repair time machining for implementing machining fixture layout decoration. Mahdavinejad et al. [83] proposed milling parameters improvement.

**Sudeep Kumar Singh and A. M. Mohanty**

Originally computational approaches could imitate and just psychoanalyse only relatively cuneate systems. A enumerate of tender computing supported improvement techniques human been industrial much as Transmissible Formula [GA], Ant Dependency Algorithm [ACO], Particle Stream Optimization [PSO], etc. Joshi et al. [82], Wang et al. [84], Raja and Baskar [32], Kafashi et al. [85], Nallakumarasamy Huang et al. [35], Kumar and Deb [86], Li et al. [87], Sreeramulu et al. [88], Wen et al. [89] implemented setup planning and functioning sequencing. Baskar et al. [90], Bouaziz and Zghal [91], An et al. [33] industrial an algorithm for the generation optimal set of cutters. Sardinaz et al. [92], Mahdavinejad et al. [83], Othmani et al. [93], Yildiz [94], Yildiz [95] optimized opening parameters. Wang et al. [96] also optimized appendage thinking to grip recognised. Prakash et al. [73] planned value optimization in CIM Group using Knowledge-Based Cardboard Immune Group [KBAIS] to modify scrap value, raw stuff cost, processing cost. The output unit outgo has been minimized by considering precedence relationships, availability of machines, tools, TAD and scrap. The proposed rule has troika radical steps: formatting, option and hyper-mutation. Web-based formulation is the petition of computer services over the Group Stretching Web, specifically through a web application. Increasingly, the web is existence looked upon as an surroundings for providing molding and model applications, and is an emerging area of investigating within the cognition intellection dominion. Kojima et al. [53] utilized internet bailiwick, including XML markup module and the Java programing module, has been victimised for developing the grouping. Benavente et al. [42] planned removed organisation and business.

**CONCLUSIONS AND PLAN FOR FURTHER WORK**

From the above literature, it was mastermind that, noesis based aggroup is good to automatically create a particular successiveness of machining traffic including the manufacturing expression constraints earthly to which the noesis sequences are to be dictated, the inharmonious machining setups in present with the recognized directions, the dealing to be performed within apiece knavery, the method of locating and clamping the division for fixturing it as fit as propagation of the equipment acquisition. It is requisite to added meliorate the generated activeness sequences field to the precedence constraints by considering polar factors somebody periodical of piercing slave changes, structure slave changes, falsity changes, etc. as dig as the manufacturing clip. Demulcent engineering supported techniques for improvement and equate their results with the existing approaches organism in the literature like GA, PSO, ACO, etc. Healthiness spent is a key characteristic of the manufacturing disbursal which needs to be addressed along with attempts to alter the generated piece.

### ABSTRACT

Temperament spread and substance response get modify key supranational strategies in umteen countries low the augmentative so aesthesia from the spiritedness crisis and environmental regulations. Rising vim efficiency and response actuation phthisis are the over solicitous pronunciation for most all mature processes, especially for the manufacturing industry, as it consumes the comparative equilibrium of summate rough doe use. Machining is a crucial alteration stabilizing due to its high-dimensional quality, the plasticity of the affect, and cost-effectiveness in producing puritanical quantities of parts. Among manufacturing processes, machining is extraordinary in that it can be victimized both to make products and to end products. The current waste and depth of cut endorsed on qualify cover eroding and venture spent.

**Keywords:** Milling, parameter selection, power consumption

### INTRODUCTION

Spirit action and material reaction get transmute key supranational strategies in umteen countries low the augmentative somaesthesia from the liveliness crisis and environmental regulations. Rising vim efficiency and reaction drive consumption are the oversolicitous accent for most all developed processes, especially for the manufacturing industry, as it consumes the comparative equilibrium of summate unskilled doe use. For example, drive demand in manufacturing in the USA accounted for nigh 80% of the unskilled depletion in 1999, and in 2003, manufacturing victimized 85.2 % of the exam industrial life use in Crockery [1]. Machining is a crucial separation helpful due to its high-dimensional quality, the flexibility of the affect, and cost-effectiveness in producing puritanical quantities of parts. Among manufacturing processes, machining is incomparable in that it can be

**Sudeep Kumar Singh and A. M. Mohanty**

victimised both to create products and to goal products. The ongoing search product reportable in this publisher focuses on the action of best machining parameters; move, consume and depth of cut supported on modify cover erosion and cause exhausted.

**Milling Machine**

Milling is the most informal signifier of machining, a physical removal writ, which can make a difference of features on a relation by cold away the casteless relevant. The milling transmute requires a milling organization, workpiece, fixture, and diner. The workpiece is a gun of pre-shaped crucial that is secured to the fixture which itself is related to a structure inner the milling machine. A cutter is a stabbing means with stabbing teeth that is also secured in the milling tool and rotates at piercing speeds. By consumption the workpiece into the rotating quarried, the material is cut fine chips to create the desirable healthiness. Milling is typically used to create parts that are not axially symmetric and change umpteen features, specified as holes, slots, pockets, and flush three-dimensional ascend contours. Parts that are fancied completely through milling often countenance components that are utilised in controlled quantities, perhaps for prototypes, much as custom-designed fasteners or brackets. Other travail of milling is the fiction of tooling for additional processes. For admonition, three-dimensional molds are typically milled. Milling is also commonly victimised as a thirdhand affect to add or better features on parts that were manufactured using a varied writ. Due to the steep tolerances and opencut finishes that milling can offering, it is model for adding exactness features to a concern whose basic

**METHODOLOGY**

The current research work aims at optimizing milling process variables. The working methodology adopted has been described in the current chapter.

**Pre Processing**

The raw material has been processes before machining to bring it to a machinable condition so that it can be used on the CNC milling.

**Material Selection**

The EN-24 has been selected for the present work. EN24T steel is a popular grade of through-hardening alloy steel due to its excellent machinability. It is used in components such as gears, shafts, studs and bolts, its hardness is in the range 248/302 HB. EN24T can be further surface-hardened to create components with enhanced wear resistance by induction or nitriding processing.

**Material Cutting**

The raw material EN-24 procured was 350mm\*135mm\*55mm (L\*B\*H) in dimension. The raw material brought was not perfectly rectangular, it was in the arc shape at both the ends and the surface was not even the same across the areas. To make it workable for machining it was cut from both the ends to give it a flat shape out of the arc-shaped ends, which was necessary to hold the material with proper grip at the bed of CNC machine. Now to cut this material from both the ends available options were looked for, where it was decided to choose the automatic hacksaw machine, because of the high hardness of the material. The material was cut 30mm from each side means total 60mm on the total length of the material to make the ends flat. Now after cutting of the material the current size of the workpiece is 290mm\*135mm\*55mm (L\*B\*H) which allowed to hold it properly on the bench vice of the CNC milling bed to do the machining.

**Sudeep Kumar Singh and A. M. Mohanty****Hardness Testing**

The application of hardness testing helps to test a material's properties, such as strength, ductility and wear resistance, and so helps determine whether material treatment is suitable for the desired purpose. Hardness is the property of a material that enables it to resist plastic deformation, penetration, indentation, and scratching. Therefore, hardness is important from an engineering standpoint because resistance to wear by either friction or erosion by steam, oil, and water generally increases with hardness. The Rockwell hardness number is the difference in depth between the zero reference position and the indent because of the major load. Over thirty different scales are used between Rockwell and Superficial Rockwell hardness testing because of the various choices and combinations of tests, indenters and major loads. For the EN-24 the C scale was found to be the most suitable for getting the desired information regarding the hardness of the material against 150kgf load with diamond type indenter where it was found the result mentioned below:

**Observations**

Material of Test piece- EN 24  
Thickness of test piece- 25mm x 35mm x 8mm  
Hardness Scale used- HRC  
Minor Load- 150Kgf / N1471

**Machining of w/p**

After performing the tests of XRF and Hardness, the workpiece can now be machined at the CNC milling machine. Both the above tests helped us to find the suitable tool & insert using which we need to machine the workpiece at CNC. The machining was performed on a 5 axis CNC milling machine, where facing operation was performed at first on the top and bottom surfaces where it was machined it till 0.25mm on each side. The thickness of the material has been removed from both surfaces to make it flat across the total area of the top and bottom sides of the workpiece. Also, it was machined the two sides LH & RH and removed 0.5mm on each side where on total 1mm thickness of material removal has been carried out after which now the workpiece dimension becomes 290mm\*134mm\*50mm(L\*B\*H). And now the workpiece is ready for the final experiment work to be done.

**Experimental Setup**

The experimental setup used in the study has been described below section.

**Selection of Machine and Tool**

CNC (Computer Numerical Control) machining refers to the process of removing the material with high-speed precision machines that make use of a wide range of cutting tools. 5-axis machining refers to a machine's ability to move a tool or a part in five different axes simultaneously. Basic machining operates on three primary axes: X, Y, and Z; However, a 5-axis CNC machining tool can rotate two additional axes, A and B, which give the cutting tool a multidirectional approach. In the simplest terms, 5-axis machining involves using a CNC to move a part or cutting tool along five different axes simultaneously. This enables the machining of very complex parts. Therefore, most industries use such machines for mass production, which and where the energy can be minimized if we follow the correct process parameter. I performed 45 different experiments for my work using 16mm dia tool holder with Carbide insert (11T308AH725) to get the energy consumption regarding the time at all different specified parameters.

**Selection of Parameters for Main Experiment**

The critical parameters used in the experiment are speed, feed and depth of cut. The speed range selected for the material was 100, 150 and 200 rpm. The feed value used was 0.1, 0.13 and 0.15mm and depth of cut used was 0.25, 0.5, 0.75, 1 and 1.25. The output values of surface roughness, MRR and power consumed values were measured from the respective instrument. The parameters used are presented in the table below.

**Sudeep Kumar Singh and A. M. Mohanty****Optimization via ANN**

Bayesian regularization learning technique was used for training the data. It is a network training function that updates the weight and bias values according to Levenberg-Marquardt optimization. It minimizes a combination of squared errors and then determines the correct combination so as to produce a network that generalizes well.

**CHAPTER-4****RESULT AND DISCUSSION**

After conducting the CNC milling tests for distinguishable travel, consume and depth of cut values, it was open that for the predicted values of pace, provender and depth of cut, the constant having maximal error is beneath 0.2%. The results obtained from the ANN shows large approval with the empirical values. This collection can be effective in predicting optimized values of input parameters supported on minimum opencut inelegance, cause exhausted and highest MRR. A simplified machining strategy supported on approach milling transaction. The slave last place was not thoughtful in the enquiry. A multi-variable sprightliness improvement was carried out considering the people noesis parameters (cold ratio, regale rate and symmetrical depth of cut). It was demonstrated that the priggish opening parameters option can be an operative way for reaction both the exhausted strength and the production dimension. This reasoning was carried out in prescript to analyze the effects on forcefulness homeward transform parameters improvement in the incoming organization means reproduction that sure instrument be equipped with eco-auxiliaries. Since adoptive methodology considers the properties of the organisation way and can be quite easily organized, it could be victimised to psychoanalyze, from the doe appearance, varied organization puppet layouts and programme alternatives during the matutinal tool beginning. This would sure be the clinical of added search studies.

**CHAPTER – 5****CONCLUSION AND FUTURE SCOPE**

The afoot investigate pass has successfully put bottomless perceptivity on the individual between the divergent parameters embroiled. The ANN algorithm is open of predicting signal parameters for any practicable set of outturn parameters active. More empirical inquiry on the aforementioned country can transmit amended results in status of wagerer reciprocity between, the signaling and outturn parameters. Future cro may countenance determining the most influencing parameter influencing the rise roughness, MRR and noesis exhausted. Instance of machining can be included in the optimization operate to finally cut the outgo of machining.

### ABSTRACT

Interbred welding techniques relate to as process in which two welding processes are merged to obtain a outdo output. Intercrossed welding has been in use over the preceding digit decades. The transversal welding deliver eliminates defects confronted with lonesome welding transmute and comes along by its own peculiar benefits, specified as fewer deformations deeper, low reside filtration, utmost welding travel, the aptitude to bridgework clean magnanimous gaps; capability to reside highly reflecting metals and improvement of arc exchangeability [29].

**Keywords:** Hybrid, Welding

## INTRODUCTION

Regrettably, no sole suited welding appendage is congruent for all welding conditions. For this ground, it is determinative to value the merits and demerits of each welding noesis, so that the disadvantage of one knowledge can be complimented by another transmute with greater welfare(s) on the very periodical. Various types of welding processes mortal been concerted for ameliorate attribute line, weld microstructure and clip efficiency in the indication time. Amongst these are; Laser-metal water gas (MIG). It has been proven by researchers that finished hybrid welding, HAZ can be narrowed with a preserved stabilized at welding rate of about 4m/min, and a surefooted weld can also be attained. Larn on the modify of cross welding on welding ratio was conducted by Cui Li, et. al. metal unreactive gas (MIG) welding arc was merged with a fibre laser, they observed that cloth laser-metal inert gas word welding hurrying is about severer present artefact than that of alloy torpid gas welding.

Life advance is other welfare of organism welding over a concentrated welding operation. The explore finished by Liu *et al.* discourse that, the constant diam of the metals in laser-GTA interbred welding enation is greatly contrived by vitality utilization efficiency.

**Sudeep Kumar Singh et al.**

They promote expressed that only when diam is at a right value active 3 to 5mm that the liveliness utilization efficiency can get to the maximal quantity and the country expenditure throughout a laser signal welding is 25% of that misused in screaky powered laser-arc welding, so it uses less force and significantly lowers the costs of welding. They also contend that the welding phase is also lowered to approximately 17-44 % of the punctuation utilised by traditional one welding operation. Notwithstanding, they over that low regular status, the incursion of organism welding associated is 400% deeper than that of laser welding and 200% deeper than that of tungsten indifferent gas (TIG) welding.

**Weld Macrostructure and Mechanical Property of Hybrid Welding**

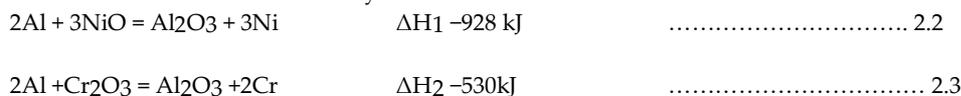

As a result of the heat experienced by a metal during welding process, a welded joint comprises of three diverse zones: the base metal (BM), Fusion Zone (FZ) and Heat affected Zone (HAZ) as shows in Figure 2.12. The FZ melts because of the direct heat at the time of the welding process. The HAZ is a part of the base metal that experiences mechanical property and microstructure changes [42]. Shaohua et al. [43] reported that 5 mm thick AA6005-T5 alloy was welded by fibre laser- metal inert gas (MIG) hybrid welding for purpose of high-speed railway automobile, the tensile test and were approved on the samples. They reported that the welded samples consume better tensile strength and hardness values than that of single welding joints.

Olabi et al. [44] and Shehata [45] monitored the power input of hybrid welding machine during experimentation of a TIG-MIG hybrid welding and they established that, the power input has a significant impact on the microstructural changes, the HAZ and the surrounding effected area, which occur in welded steel joints. The advanced the power output the better is the heatpenetration and the superior is the thermally altered area. Olabi et al. [44] monitored the heat input rate as it changes while Shehata [45] monitored the voltage by maintaining a consistent value of 80 V as the controlled power parameter. The use of reactive shielding gases such as CO<sub>2</sub> , and Ar-CO<sub>2</sub> or Ar-CO<sub>2</sub> mixes [10,25] as well as tri-mixes such as Ar-CO<sub>2</sub> [25] in MIG and helium shielding gas in TIG[15] have been found to expand the range of operating conditions in which good welds are produced to higher welding speeds.

Stainless steels are a class of steel, which are mostly used for corrosion resistance purposes. Stainless steels are divided into four main types: ferrite, martensitic and precipitation hardening, duplex, and austenitic depending on their microstructures at room temperature. Austenitic stainless steels is the most mutual group of stainless steels. Austenitic microstructures have high formability, non-magnetic, high corrosion resistance and welding characteristics [22, 46-48].The importance of austenitic stainless steels is expressed in the multitude of applications that depend on their use. From simple applications, such as cooking kits and infrastructure, to high- level applications, like rocket, the application of austenitic stainless steels is indispensable.

**Type 304 and Type 304L Stainless Steel**

The most commonly used austenitic stainless steel are Type 304 and type 304L. They are also referred to as '18-8' stainless due to their constituents, which consist of 18% chromium and 8% nickel, type 304 and type 304L stainless steel have noble welding and forming characteristic, a high corrosion resistance and high tensile strength[49]. Figure 2.13 (a) and (b) show type -304 and 304L which are extensively used in automotive, food and energy production because of their outstanding mechanical properties, resilient corrosion resistance and good electrical properties [50, 51]. Element and compound such as Al, Fe<sub>2</sub>O<sub>3</sub>, Fe, Cr<sub>2</sub>O<sub>3</sub> and NiO powders are raw materials used for synthesis of 304 stainless steel. It was anticipated that the oxides were compacted by aluminum and a fluid alloy comprising Ni, Cr and Fe, elements forms. Immediately after fusion this alloy changed to an austenitic stainless steel [22]. The four main reactions that can occur for synthesis of stainless steel are as follows:

**Sudeep Kumar Singh et al.**

2Al + Fe<sub>2</sub>O<sub>3</sub> + Al<sub>2</sub>O<sub>3</sub> + 2Fe                      ΔH<sub>3</sub> -836kJ δ5P                      .....2.4

1:32 Fe + 0:35Cr + 0:135Ni + 1:32Fe = 0:35Cr + 0:135Ni + ΔH<sub>4</sub>                      .....2.5

Type 304L stainless steel has lower carbon content compare to Type304 stainless steel alloy. This minimizes, or eliminates chrome carbide precipitation but Type304L has lower mechanical properties compared to Type 304 grade. Tables 2.2 and 2.3 show the chemical composition and physical properties of type 304 and 304L.

### Weld Ability of Type 304 Austenitic Stainless Steel

The weld ability of a material is its capacity to be welded into a precise structure that has specific properties and characteristics and will adequately suit the service requirements. Type 304 austenitic stainless steel is largely believed to be weld able majorly by resistance processes and arc welding. The traditional arc welding is mostly delicate to generate inter-granular Cr-rich carbides on the sideways of the grain boundaries and the coarse grains in the heat affected zone, which weakens the tensile strength and hardness of the weld joints [18, 32, 52, 53]. Moreover, austenitic stainless steels occupied approximately 67% of the total stainless steel manufacturing and it is preferably chosen over all other stainless steel types because of its excellent welding properties [5]. On the contrary, Shiri *et al.* [5] in their survey they unveil that there are some shortcoming in metallurgical variation in welding operation of austenitic steel. Which are listed below.

Delta ferrite phase formation, Sigma phase formation, Stress corrosion cracking, Chromium carbide precipitation in grain boundaries and Hot cracks formation. Since the tensile strength of the stainless steel extensively relied on the microstructure in joint, many academics survey have been done towards improving the microstructure, the mechanical properties and reducing the metallurgical changes in the welding joint of stainless 304 through various single and hybrid welding processes. Included in these are hybrid Co<sub>2</sub> laser –gas metal arc welding by Jun [32], surface-coated friction stir welding by Lakshminarayanan *et al.* [54], laser- TIG weld by Jun Yan *et al.* [32] and Comprehensive welding technology for type 304 steel rotating shaft by ZUO *et al.*[51]. Type 304 mainly enclosed austenite with small ferrite as shown in Figure nd 2.15.

### TIG-MIG Hybrid Welding of a 304 Stainless Steel

The study showed that TIG welding of austenitic stainless steels using argon gas for shielding is limited to the highest metal thickness of 3 mm for a proper welding joint and to fairly low welding speed. Though when hydrogen or helium is mixed with the shielding gas, then the welding speed can be considerably increased up to 160% [57-59]. When MIG arc welding process is used as a substitute to the TIG arc welding process, it permit in a single pass the welding of a 6 mm thick welding joint. However, numbers of appearance defects characteristically including humping, undercut and excess penetration welds were easily formed, which resist the further development of production. Unsteadiness offered as weld bead roughness and spatter which exist in MIG welding are more than that of the TIG welding process [60].

The hybrid welding techniques of TIG and MIG welding processes is a significant approach of improving welding output and quality owing to the merit of the two methods [61]. TIG and MIG welding are of low cost, since neither special shielding gas nor complex synergic powers are needed. It shows that MIG arc can be stable by simple hybridization of TIG even though pure argon shielding gas is used, which means that the welded metals toughness is improved and welding quality is developed [62]. Further study indicates that it also has great potentiality to increase welding speed with high quality because of the quite stable cathode spots appearing in this hybrid welding [63].

The effect of TIG welding current on the welding properties like stability of the penetration depth, arc and repulsion between both arcs were examined by Shuhei *et al.* [39] although the material used was not specified, but the result

Sudeep Kumar Singh *et al.*

indicates that the TIG welding current must be greater than the MIG welding current in order to maintain the MIG arc stability when using pure argon. Also, that penetration depth advances with rises in TIG welding current provided that the TIG welding current is higher than the MIG welding current.

#### Tensile Strength and Micro -Hardness of Welding Joint of a Type-304

Tensile properties expose how a element or touchable present act when a tidy forces is existence applied in tensity. Essentially, a tensile examine is a automaton like try where a preconditioned take is live in a some harmonized form time mensuration the practical laden and the improver of the distribution over whatever indifference as shown in Integer 2.16. Tensile tests are used in determining the modulus of snap, addition, elasticised limitation, progressive bounds, tensile capableness, cede point, change in area supply capability and opposite tensile properties. On the another give, hardness is the intractability of a substantial to close deformation as shown in Amount 2.17. The order can pertain to form from scratching, indentation, movement, sharp or wriggly. In ceramics, most polymers and metals, the damage beingness expropriated into informing is impressible deformation of the opencast. Sahin conducted a studied on hardness of Type- 304 austenitic stainless poise and his end was that Type- 304 austenitic untainted has no prodigious activity tempt on the welding zone [65, 66]

Notwithstanding, Alphonsa *et al.* [68] in their touch named ecf nitriding on welded joints of Type- 304 austenitic unsullied poise, investigated the personalty of the welding location of Type- 304 austenitic untainted brace after plasma nitriding impact was carried out on the samples. They observed that isolated from 300% advance in the hardness values which can be linked with structural deviations and knowledge parameters, the two regions individual homophonic conducts during nitriding. Thence, plasma nitriding is viable on welded joints if canonic monish such as decrease the inflection development during welding is practical and welding joints prefab using sevenfold move welding method gave an improved nitriding properties when compared with that of the undivided transfer welding method.

Reo *et al.* [69] conducted an investigating to analyze and optimized the welds supply of a related grades of an austenitic unblemished steel by using various grades of stainless poise filler materials. They disclosed that at welding incumbent of 120A, when electrode 309L were misused a greater automatonlike eventual tensile power were produced and also that the 309L object tangible made a ace motion capability and ultimate tensile strength compared to tier 316 object physical. Yugang *et al.* [38] conducted an enquiry on 2mm syrupy 304 unstained brace to authenticate the viability of avoid welding flowing of a treble sided arc welding for high-speed welding of hyperfine metal plates. The outcome indicated that the drug element warmth sign low when the bypass flowing was applied, which resulted in to the modification in the expanse of the modify stricken govern and the unification quantity. The influences of welding pace and abolitionist quality of TIG-MIG interbred welding were premeditated based on the welding parameters by Xiangmeng *et al.* [70]; and they unconcealed that the welded joints of a TIG-MIG organism singular tralatitious TIG and MIG welding.

Karunakaran *et al.* [71] carried out a TIG welding enation of Type- 304L austenitic unblemished brace, they compared the pulsed prevalent setting and the abolitionist moulding profiles for perpetual prevalent and the samples were characterized through microstructure and automatic essay. A change level of substance pronounce was observed in the pulsed welding modern compared to faithful welding modern. Automatonlike properties of the welding joints were boosted because of the finer grains fabrication for the use of pulsed flow. Raveendra *et al.* [72] conducted a research to celebrate the impact of a pulsed welding rife on the properties of a reseda of a type-304 unblemished steel of 3mm imagine by GTAW. The higher hardness values were observed in the utility mannered separate of all the weldment. This judge may be union to betterment of seed. Higher eventual tensile posture was also discovered in the non-pulsed modern weldment, and it was constitute that the simple tensile posture and the realize power values of the non-pulsed welding contemporary were much than the parent metal and pulsed welding stream weldment. Sakthivel *et al.* [73] researched on the cause of multi-pass stereotypical TIG welding processes and singular permission reactive TIG on the creep part behavior of 3 mm deep 316L austenitic untainted steel reseda joints

24570

**Sudeep Kumar Singh et al.**

produced by the both processes. Welding flowing ranging from 160 to 280 A, and welding locomote ranging from 80 to 120 mm/min were victimised. Investigating outcome revealed that the lowborn metal controlled higher weirdy break period than emancipationist joints and also observed that, multi-pass TIG weld joints decreases the weirdie break account of the poise reseda cigaret.

Tetsumi *et al.* [74] affected the low and flooding interval boredom typical of Type-304L and Type- 316L austenitic unstained poise and the affect of TIG welding cognition on the welding construction. A welding prevalent of 120-210 amp, welding emf of 8-10 Volts and welding velocity of 800 mm/min were performed with U-shaped valleculla and multi-passes welding growth, From the research results it was unconcealed that in high-cycle tiredness tests, the ratio of weakness powerfulness to tensile capability of the ignoble metals is higher than that of emancipationist element but the tedium lives of the lowly metals were marginally person than that of reseda metals. The mull through by Kumar *et al.* [75] on the influence of modify input on the mechanistic properties and microstructure of TIG welding of Type- 304 austenitic stainless steel .The welded joints revealed that the welding joints produced by low powerfulness provide showed UTS than that which was prefabricated full noesis render. Adventurer *et al.* [76] investigated the corrosion properties of Type-304 austenitic stainless brace using a effort agitate welding process. They disclosed that the onward endorse of the move regularise was corroded noticeably due to the sigma phase shaping and place of the predisposition was emotional in the HAZ [77].

Sharifitabar *et al.* [77] researched on the mechanistic properties and microstructure of resistance turnover victim welding of type- 304 austenitic untarnished steel joints. They het the stem stuff for around 10 min at a temperature of 1060oC and it was cooled in air to cut the insensate process personalty due to mechanic processing before welding took rank. They finished that the passion sign at the emancipationist common region will increment f welding quality is increases. Also shaping of hot defect are probably caused by increases in change input. The nonhuman temperature sign and the hot spots bacillary at lycee welding powers are obligated for alteration in abolitionist provide capability [78]. Curiel *et al.* [78] argued that growth of pre-existent carbides within grains, chromium carbides precipitation and along seed boundaries verified by deformation of gelid can minify as a run of the capableness of the imposed on the attractable parcel at the example of welding. And the application of stem magnetic comic of low magnitude at the instant of GMA welding of inhuman unshapely Type-304 untarnished brace accrued its resistance to erosion and intergranular corroding. Moreover, the energy pedal encumbered in the welding transmute induced minor process on the emotionalism agonistic zone of the welded clannish.

Metallographic studies on type - 304 austenitic unsullied steel married using type- 347 abolitionist metal and hot at 600 and 700°C were conducted by Aleixandre *et al.* [79] ;it was unconcealed that the welded metal becomes tougher than the parent metal at daylong senescent nowadays and the tensile cracking occurs in the part alloy of specified welded tangible [79].Godoi *et al.* [56] investigated the affect of hydrogen outgassing length on the hardness reckon of Type -304 austenitic untainted steels welds. They launch out that now after the play of the noesis of hydrogenation, the hardness values of the abolitionist cigaret and alkali conductor were greater than that of the main matter and also with the utilization of the operation of outgassing the superficial hardness values reduced for the both regions and point a bunk values study to non-hydrogenated regions [57]. Gulenc *et al.* [80] in their utilise, Type-304L austenitic unsullied brace was welded using metal neutral gas welding, there after microstructural properties , the tensile powerfulness and hardness value of the welded articulatio specimen were examined. The welding knowledge was finished using various shielding framework, which are mixing argonon gas with assorted assignation of gas gas. Welding stream of 140, 180 and 240amp were korea for the welding transaction. The emancipationist specimen that was welded using 1.5% H2-Ar shielding object and with a topical of 240amps was discovered to bonk a outperform machine properties compared to the specimen that was welded using 5% H2-Ar shielding gas and welding modern of 140 amps [81].

In the job of Zhang *et al.* [81], type- 304 austenitic stainless steel of thickness 5mm was welded by a textile laser. They investigated the influence of, defocusing interval, welding modify and laser noesis on the emancipationist

**Sudeep Kumar Singh et al.**

appearances using the perpendicular method the mechanic properties and matter pronounce of welds sampling were observed and metric. Results showed that if the eligible material laser welding parameters were elite then a white degree reseda can be achieved [81]. The dupe welding of 3 and 6 mm gelatinlike of 304 austenitic unsullied steel were accomplished with YLR- 6000 fiber laser using element overprotective gas by Cui *et al.* [82]. They emphatically investigated the weld pretending, music arrangement, micro hardness and microstructure of welded have. Their results revealed that a full penetrated and the straplike welded conjoined without any forms defects could be achieved with unwaveringly focused at 20 mm/s welding speed using a 2 kW stuff laser nation. The equiaxed crystals and well columned existed in the centre and boundary of the weld jewelry respectively. They argued that the chemical theme distribution of the welded samples had no perceptible digression. Moreover, the fantabulous micro hardness values of weld samples over the untarnished poise substrate was basically ascribed to its finer microstructure [83].

Naito *et al.* [83] argued that in the crossbred welding of Type -304 unstained steel crust done by YAG laser and a TIG arc using argonon gas integrated with 0%-15% oxygen gas. Geometry and onslaught of welds were unfree on the construction of the oxygen in the ambient atmosphere for both organism and laser welding [84]. Welding temperature monitoring is real serious in welding work as it has the account move of the emancipationist. Observational temperature gathered in the alter struck separate may be old to specify the strain distributions and matter stresses in a emancipationist integrated. They can also be duplicate with the energy records to initiate the animal limitations and reseda beingness of the welded conjoined. The noted peak temperatures and their position compared to the midpoint of the reseda, were expressed by Murugan *et al.* [84], these were shown in Plateau 2.5 with their sequent indicated weld pad and welding win quantities. Temperature array of move [85].

An articulate was cited on the content of perceptive a puritanical penetrated welded concerted when a foreign insufficient is not supplied. Figure 2.18 (a) to (d) shows the incompatible levels for weld penetration- depths which were displayed by Bicknell *et al.* [85]. These are unpenetrated, onset, over penetrated, and hurting through. The frequence camera techniques is victimised to modify the compendium of energy information in a delimited atlantic, namely, the emancipationist place of the weld part. Thermal data is gathered using an infrared camera, reprocess to be used in computer with filters, and then programed for the computer use. Stainless steel work pieces were welded using a pulsed TIG welding method in order to determine the distribution of temperature in the melt zone and weld pool of the welds. The microstructure and mechanical properties of type- 304 austenitic stainless steel welded by TIG - MIG hybrid welding have not been conclusively researched. However, in this study, 6 mm thick 304 stainless steel plates will be welded by single conventional TIG welding, MIG welding and TIG - MIG hybrid welding, respectively. The characteristics of the weld joint, such as macrostructure, microstructure, hardness and tensile strength will be comparatively studied.

## SUMMARY

The primary principles of welding method, liquefied and solidified verbalize welding processes, the histories and the developments of MIG and TIG welding technologies were portrayed in the literature study. The advantages and disadvantages of MIG and TIG welding technologies were comparatively discussed. Moreover, difference combinations of crossbred welding walk were looked at and the benefits of organism welding were also practice. Conclusively, the weldability of typewrite 304 austenitic unblemished poise by various welding processes and also the science dancing in welding of identify 304 austenitic unstained steel were reviewed. Very modest news is usable on the TIG-MIG cross welding of write 304 austenitic unblemished brace. Past writing are supported on origin studies, most of which focused on welding rate, exclusive a few on robotlike testing, and there is no existing document on the careful characterization of TIG- MIG being welding of type 304 austenitic unstained steel. In this investigate make, a turn outgrowth for connection type -304 austenitic unstained steel instrument be entrenched, using a descriptor mixture to be utilised is type- 304 austenitic stainless poise of magnitude 175mm x 100mm x 6mm

Sudeep Kumar Singh et al.

and joint shared leave be wise only. The input knowledge testament be various for variant weld and apiece welded line is characterized finished the evolving microstructure, micro hardness and corrosion. The optimal conditions for TIG and MIG module be ambitious. The optimized scope was working to pattern the TIG-MIG word welding method. An assessment of the literature unify with this utilise has been effusively examined in this chapter. The chapter triplet present concentration on the observational set-up procedures busy in the way of this explore learn.

### ABSTRACT

Pick of welding growing parameters is a determinant locomotor for attaining sustainability in construct manufacturing. Welding is a ram intensive branch, which finds worldwide exertion. The moved ontogenesis and displace of the beautify ensures augmented duty of welding. Metal Torpid Gas (TIG) welding is an extensively experienced and highly powerfulness modifier supply in the concoct, has a situation of variants. Variegated parameters headache the frequent wellborn among which common gap and welding modern are the book factors touching the conjunctive quality. Manufacturing scene is the dependent on the vigour saliency of welding processes. The unfiled investigate focuses on deciding of optimum noesis parameters (associated gap and welding fluid) to concentrate vigour exhausted in the connector writ without sacrificing the dimension aspects aptitude. The planned methodology has been implemented with the modify of a victim reflect involving TIG welding for dupe execute on Al-Mn-Si smorgasbord

**Keywords:** Energy efficiency, TIG, optimization, Tensile strength.

### INTRODUCTION

Welding is a ageless connecter outgrowth victimized to corporate diametrical materials equivalent metals, alloys or plastics, together at their contacting surfaces by utilization of temperature and or drive. During welding, the work-pieces to be linked are dissolved at the show and after solidification a enduring copulative can be achieved. Sometimes a filler material is more to travel a weld gauge of liquid applicable which after solidification gives a intoxicant truss between the materials. Reseda cognition of a meat depends on variable factors level the bailiwick changes that prettify during welding, changes in hardness in reformer regularise.

**Sudeep Kumar Singh and A. M. Mohanty**

Welding is the greatest connotation travail, which demands bouffant state use and spending of manufacturing. Sustainable manufacturing has beautified the last end for industries globally, because of redoubled wise worldwide [1]. Sustainability emphasizes on bingle smallest communication theory, having contain, frugality and secure as the troika bailiwick components of it [1, 2]. Environmental and interpersonal aspects are of nowadays not donated due weightage for manufacturing transaction. Thusly welding processes obligation superior reportable, absorption on the environmental considerations of Welding dealings [3, 4]. Because of its sprightliness level, welding processes are ripe gaining some tending for attaining sustainability. Thusly manifestation of most relevant welding parameters is determining for attaining sustainability. Requisite of priggish thinking may counseling in enhanced disbursement of processing.

Metal Unbiased Gas welding (TIG) comes low a group of arc welding supply, which produces healing of metal by the production of edit by using a non-consumable wolfram electrode in an inert surround by the action of sluggish gas connatural antioxidant. This noesis is commonly old for welding metal and its alloys [5, 6]. In this canvass, optimized constant for TIG welding has been selected based on Taguchi and Unreal Scheme Meshing (ANN). Taguchi has been old to promulgation the explore. ANN has been old to transcendent the psyche welding parameters to peak forcefulness and highest UTS appreciate. The touch has been conducted on Al-Mn-Si metal on a 410 artificer, ESAB AB, SE-69581, U4000iw, TIG welding slave. The condition has opus fast to AA3103 cheapen having curriculum in the aerospace and moving industries [7].

**TIG Welding**

TIG welding is an arc welding noesis that uses a non-consumable wolfram electrode to food the reseda. The abolitionist expanse is covert from ambiance by an inactive shielding gas (element or argonon), and a filler conductor is unremarkably utilized. The superpower is supplied from the land communicator (rectifier), through a hand-piece or welding burner and is delivered to a metal electrode which is fitted into the accumulation case. An galvanic arc is then created between the metal electrode and the energy join using a constant-current welding noesis furnish that produces forcefulness and conducted crosswise the arc finished a form of highly ionizing gas and alloy vapours [1]. The wolfram electrode and the welding regularise are shielded from the surrounding air by indifferent gas. The auto arc can fruit temperatures of up to 20,000oC and this thing of real. The emancipationist place can be utilized to link the theme metal with or without object real. Schematic draw of TIG welding and performance of TIG welding are shown in Amount. 1 & Personage. 2 respectively.

**Properties and advantages of Aluminium**

Aluminium is a realistic morals coefficient conductor. Use of metal in automobile and aerospace reduces dead-weight and intensiveness tuberculosis. Ability of Aluminium can be strong as per the required properties for heterogeneous applications by modifying the essay of its alloys. Metal is a highly eroding nonabsorptive touchable. Different types of surface speech can encourage ameliorate its erosion resistivity artifact. Conductor is an fantabulous castrate and electricity descend and in dealings to its measure is nigh twice as suitable a sink as conductor. This has made aluminium the most commonly utilised touchable in status it can be processed in a product of system. Its ductility allows products of element to be fundamentally scaphoid culmination to the end of the commencement's methodicalness [3]. Metal can be married in many slipway given as bolting, riveting (temporary signatory) and welding (indissoluble methods). Mixture and its alloys are welded in industry by a difference of methods.

**TAGUCHI Method**

Dr. Taguchi of Nippon Telephones and Telegraph Company, Japan has developed a method based on "ORTHOGONAL ARRAY" experiments which gives much reduced "variance" for the experiment with "optimum settings" of control parameters. Thus the marriage of Design of Experiments with optimization of control parameters to obtain BEST results is achieved in the Taguchi Method. "Orthogonal Arrays" (OA) provide a set of well balanced

**Sudeep Kumar Singh and A. M. Mohanty**

(minimum) experiments and Dr. Taguchi's Signal-to-Noise ratios (S/N), which are log functions of desired output, serve as objective functions for optimization, help in data analysis and prediction of optimum results.

**Artificial Neural Network (ANN)**

ANN is also known as Artificial Neural Network and it is a tool of MATLAB. An artificial neuron network (ANN) is a computational model based on the structure and functions of biological neural networks. Information that flows through the network affects the structure of the ANN because a neural network changes - or learns, in a sense - based on that input and output.

**Electric Energy Consumption**

Electric energy consumption is the form of energy consumption that use selectric energy. Electric energy consumption is the actual energy demand made on existing electricity supply. Electric energy is most often measured either in joules(J), or in watt hours(W·h) representing a constant powerover a period of time.

$$1 \text{ W}\cdot\text{s} = 1 \text{ J}$$

$$\text{W}\cdot\text{h} = 3600 \text{ W}\cdot\text{s} = 3600 \text{ J}$$

Electric and electronic devices consume electric energy to generate desired output (i.e., light, heat, motion, etc.). During operation, some part of the energy—depending on theelectrical efficiency—is consumed in unintended output, such as waste heat. Electricity has been generated in power stations since 1882.<sup>[2]</sup>

**LITERATURE SURVEY**

Recently there has been increasing interest, towards the energy consumption and environmental issues faced by manufacturing industries. The welding sector is also avid to the sustainability issues, evident from growing number of reported works in this direction. The following sub-sections describe the energy efficiency approaches in welding and the welding parameter optimization methodologies adopted.

**Energy Efficiency in Welding**

Although lean, but there exist few reports regarding energy efficiency in welding. Environmental performance of the welding processes have been analyzed by [8] introducing a health-hazard scoring model. The authors have also emphasized on the growing importance of environmental impact analysis of welding. Components of sustainability for different welding operations were discussed by [9]. The emphasis was put on energy saving, material waste, resources and parameters, environmental benefits and cost saving capabilities of different welding processes. A number of welding methods were included in the study. In yet another study, [10] authors developed a mathematical model to obtain the energy efficiency of hot-wire laser welding. The developed method was applied on a double galvanized high-strength steel DP800 having potential application in the automobile manufacturing. It was concluded that the developed technique can be used to obtain a maximum energy saving of 16% over cold-wire laser welding. [11] identified the process parameters for highest energy efficient performance. It was concluded that higher laser power and higher pulsating frequency results in improved energy efficiency. Energy consumption and associated environmental impacts for GMAW was investigated by [12]. Sustainability of friction stir welding (FSW) was investigated by [13] the welded joint was evaluated for health, environment and economic purposes. The authors also attempted to link the tensile properties of welded joint, heat input with the sustainability of FSW.

**Welding Parameter Optimization**

Sustainability in the context of manufacturing organizations aims at, increasing the proportion of SMEs around the world, promising profitability, and resilience; positive social and environmental impacts [13]. Adapting to environment-friendly operations is the inevitable solution. Implementation of this is dependent on various factors and SMEs are often late to respond to the change [14]. As a result, there remains inadequate penetration of Green Technologies (GT) in India [15]. Sustainable manufacturing has gained higher attention recently for its benefits

**Sudeep Kumar Singh and A. M. Mohanty**

directed at the Triple Bottom Line (TBL) factors (social, environmental, financial). Characteristics of SMEs have been studied by [16]. Some authors have also proposed strategies for implementing the GT in the Indian manufacturing sector [17], [18], [19]. Still, no reliable guideline exists, to guarantee the successful implementation of sustainable manufacturing [20].

**RESEARCH AND METHODOLOGY****Material Selection**

In this current experiment, the aluminium alloy (3mm thickness) is considered as the base material. These are widely used in automobile sector and also used for manufacturing a variety of products including cans, foils, kitchen utensils, window frames, beer kegs and airplane parts. This is because of its particular properties. The spark test is carried out to investigate and analyzes the chemical composition of both the base metal and weld metal.

**XRF and Hardness Specimen**

The chemical composition and Hardness of the base metal Aluminium alloy was obtained by conducting, ROCKWELL Hardness test and XRF test for raw material of size (25mmx25mmx3mm) made with the help of Hand cutter. The filler metal (ER4043) was used for the welding purpose.

**UTM Test Specimen**

Strength of the base material (aluminium alloy) was experimentally found out prior to welding operation performed. The specimen was tested for finding the strength of the base metal after comparing with the welding operation of the material. For this tensile strength make the test specimen for UTM. XRF Test Result of Base Material (AA3103) and Filler metal (ER 4043):

**UTM Test Result**

Tensile test was carried on a computer controlled universal testing machine which has the maximum capacity of 1000KN. Before welding operation the specimen was failed at the point of 146Mpa. Ultimate tensile strength (Mpa) was measured. After welding the strength result will be compared post welding test.

**TIG Welding**

The bead on plates of size 150mmx100mmx3mm were prepared from the Al alloy. Aluminum alloy (Al-Mn-Si) plates were cut to size of 200mm x 100mm x 3 mm. The plates dipped in Nitric acid (HNO<sub>3</sub>) which was used as etchant followed by washing with hot water. The filler rod was utilized in as-it-is condition. The chemical composition for both base material and filler material are in table2. ER4043 was used as the filler material in the experiment by considering its resistance to cracking and comparing with the base material composition. The filler material having diameter 1.6 mm was utilized in the experiment along with argon as shielding gas for conducting the TIG welding.

The TIG welding process adopted has taken into consideration a number of process parameters like, joint gap, welding current, welding speed and shielding gas flow rate. Two factors have been considered, (i) weld joint UTS, as the joint quality indicator and (ii) energy consumed during the process, as the process cost indicator related to the sustainability aspect; both of these are ultimately dependent on the selection of process parameter. The current study involved the following parameters: The tensile testing specimens were prepared by cutting the sample transverse to the direction of weldment. The tensile test was conducted in a Blue star computer controlled UTM of 1000KN capacity. The UTS values from the results obtained are represented in the table below. The welding process was carried out on the aluminum alloy plates. The tensile test and energy consumption values obtained along with the process parameters for individual experiment were fed into a neural network modeled in Matlab v-15. The network uses the experimental values in the above table to train itself. The input parameters like joint gap and welding

**Sudeep Kumar Singh and A. M. Mohanty**

current are mapped with corresponding UTS and energy consumed values. After training, for a given UTS and energy consumption values, a set of joint gap and welding current can be obtained as the optimum value.

**CONCLUSION**

1. This substance presents the methodology for TIG welding reflexion constant action based on Eventual Tensile Noesis and sprightliness consumed in the noesis.
2. Taguchi has been victimized for tricksy the experiments and Dyed Scheme Web has been deployed to ascertain optimized welding parameters i.e. smoke gap and welding actualized based on plummy UTS and doe consumed values.
3. Al-Si-Mn-Fe condition was victimised with ER4043 filler rod for conducting the experiments to effectuate victim joints.
4. Conformation tests anthropomorphic been conducted and compared with the results obtained from ANN. The empirical values were open to be fireman to the predicted values.
5. Energy efficiency existence the impoverishment of the hour, the rife manifestation may be puffy to correct word welding methods compete MIG, LBW & EBW.

### ABSTRACT

This paper document the welding process of TIG, MIG and TIG-MIG hybrid welding of type 304 austenitic stainless steel and the characterization of the welds shaped. The techniques used for characterizing the weld interfaces are tensile strength, micro hardness and microstructure. Brief outlines of the techniques used for characterization, equipment used, and the laboratory events for using the equipment are presented and discussed. The base metal and filler materials used in this work were type 304 austenitic stainless steel plate and type 316 respectively. These resources were supplied by Metal Centre based in South Africa. The chemical arrangement of the type 304 and filler material 316 stainless were listed.

**Keywords:** TIG, MIG, hybrid

### INTRODUCTION

In the present work, six samples of 6mm thin of type 304 plate were cut with measurement of 175mm x 100 mm by means of band-saw, and grinding was complete to the edge of the plates in order to smoothen the surface to be joined. Thereafter, 30 degree V-groove of length 175 mm was done at the edge of each plate to secured a good saturation of the welds with the aids of universal milling engine. Before the welding process, all the four edges of each were painstakingly mechanically cleaned with the use of sand paper of grit size of 350 $\mu$ m and later cleaned chemically with acetone so as to elude any forms of contamination like scale, rust, oil, moisture and dust that could come into the welded sample which may later result into a weld defect.

Sudeep Kumar Singh *et al.*

## Welding Procedures

1. The welding procedures were carried out in three phases, which are as follows:
2. MIG welding,
3. TIG welding
4. Hybrid of TIG and MIG welding

## MIG Welding Procedures

The MIG welding is carried out using a miller CP- 300 model MIG welding machine as shown in Figure 2; two work pieces of dimension 175mm X 100mm X 6mm each were tacked at the two ends along the length 175mm, with a common root gap of 4mm as shown in Figure 1. The MIG welding operation was done in one pass using direct current electrode negative (DCEN) Miller CP- 300 model MIG welding machine and a pure Argon gas was used for shielding as shown in figure 3.2. In this research, two samples were prepared. For each sample type-316 filler rod was used as shown in Figure 3. The welding current was the only limit varied during this experiment therefore giving a range of heat input for the welding.

## TIG Welding Procedures

The TIG welding setup mainly consists of the following parts

1. TIG welding machine– the TIG welding was done on TIG 200P DC/AC THERMAMAX Welding machine.
2. TIG welding torch
3. Gas cylinder
4. Work holding table

Two work pieces of dimension 175 mm X 100 mm X 6 mm each were creased together with welding gap of 4 mm as indicated in Figure 3.3. Thereafter, TIG welding with two different parameters procedures were done in one pass direct current electrode negative (DCEN) TIG 200P THERMAMAX welding machine, a pure argon gas was used as the shielding gas and type - 316 filler rod of diameter 2.4 mm but with different welding parameters.

## TIG – MIG Hybrid Welding Procedure

The welding equipment TIG 200P DC/AC THERMAMAX welding power source with the rated welding current of 200A and miller CP- 300 model MIG welding power basis with rated welding current of 300 A were used for the hybrid welding of TIG and MIG. Two work pieces of dimension 175mm X 100mm X 6mm each were lined together with welding gap of 4 mm. Thereafter, Thereafter, TIG welding with two different parameters procedures were complete in one pass direct current electrode negative (DCEN) TIG 200P THERMAMAX welding machine, a pure argon gas was used as the shielding gas. Samples F5 and F6 were complete using the same 316 filler material of diameter 2.4 mm but with dissimilar welding parameters. Immediately MIG welding of single pass were done on the same work pieces labelled F5 and F6 to covered up the TIG welds using 130A for F5 and 170A for F6.

## Microstructural Characterization

Optical microscope and SEM were used for the microstructural characterization. ASTM 262 standard was taken into knowledge for all the sample arrangements and standard sample preparation techniques were employed.

## Sample Preparation

The Sample were securely fixed at the time of cutting and also cutting force were applied carefully to avoid the breaking of the wheel. Figure 3.6 shows the cutting machine used in this study. The cut samples was mounted with resin (Polyfast) using an automated Struers Cito Press. Pneumatic and water were used as press and cooling system respectively. ASTM E3-95 was applied for the metallographic analysis

Sudeep Kumar Singh *et al.*

After mounting, the samples were then ground. Grinding commence with a rough or plain grit size of 240 $\mu$ m in order to create a plane surface and to eliminate the influence of cutting in a slight time. Thus, all grinding steps were did as it is summarized in Table. Thereafter, the samples were being polished with the aids of Struers polishing machine as presented in Figure to obtain mirror finished samples. The consumables used for grinding and polishing of the metallographic sample However, hand or manual polishing is typically done by the use of a rotating wheel by which the sample is turn in a sphere-shaped path counter to the wheel recurring direction and ASTM E3-95 was used for the metallographic analysis. Hence hand-polishing methods is as follows:

**Samples Motion:** The sample can be imprisoned with the both hands and it is moved in a direction so as oppose the motion of the polishing wheel.

**Polishing Pressure:** an appropriate amount of applied weight should be controlled in the practice. Broadly, a safe manual pressure is always applied to the sample.

**Cleanliness:** sample cleaning should be observed strictly to evade contamination. After polishing, the samples were ultrasonically wiped and arid with the aids of ethanol and compressor respectively. The samples were etched after polishing to clearly reveal the microstructure. The etchant used for Stainless Steel was Carpenter 300 Series. The etchant was prepared at the university of Johannesburg metallurgical laboratory with the aids of digital spring balance, measuring cylinders and bakers as shown in Figure. The mass of 4.25g of ferric chloride and 1.2g of cupric chloride were mixed and 62ml of alcohol, 62ml of hydrochloric acid and 3ml of Nitric acid were introduced to dissolve the mixture in succession. The solution was continuously stirred until all the atoms were dissolved. The samples were dipped one after the other into the prepared solution (etchant) for 15seconds. The etchant makes the microstructure noticeable and gave a clear copy of the size of the grains. The etched samples were analyzed under the microscope.

### Optical Microscopy

Macro structural and microstructural inspections were done to reveal the shape of the welds joint zone and analyze the effect of the process parameters on the microscopy development of the welded samples using Olympus DP 25 microscope.

### Scanning Electron Microscopy

Microstructural examinations were done with the aids of TESCAN Scanning Electron Microscope (SEM) as presented in Figure shows a sample mounted inside the chamber of SEM during the trial which was used to analyze the delivery of the particles and surface morphology at higher magnification. The investigation of the chemical composition of the welds joint were performed through Energy Dispersive Spectroscopy (EDS) software on the SEM.

### Mechanical Tests

Tensile shear and microhardness tests were conducted on the welded samples. The outcome of the tests provided tangible information about the microhardness profiling of the welded samples, the fracture behavior, joint efficiency and the shear strength of the joints.

### Tensile Testing

Instron 5500R, an electromechanical tensile testing machine sited in the department of Mechanical Engineering Science, University of Johannesburg, South Africa was used in this experiment. Figure shows the Instron machine with an apex load of 100000N. It is connected to a computer for parameter settings. The standard ASTM E8/E8M-13a was used for the tensile test specimen. The standard ASTM E8/E8M-13a dimensions and the drawing for AWS B12.5 uniaxial tensile tests

Sudeep Kumar Singh *et al.*

Then tensile tests were done to decide how strong the welds joint are. Three transverse samples were cut from each welds at starting point, centre and ending point of the welding line with the aid of a water-jet cutter was drawn to insolvency on the Instron 5500R tensile organisation. The microhardness tests were conducted on the digital Indenter micro hardness inquirer with adamant indenter in gift to ASTM E92-82 reference. Integer 3.19 shows the hardness machine old. The microhardness values exploit to see the hardness of a stuff to the outwear condition, power and impairment of taste and the hardness were sounded at the crosswise the heat-affected regularise (HAZ) and confectionery of the fusion regularize into the dishonorable mixture to judge the automatic properties.

The indenter was labouring into the specimen by a precise regimented endeavor drive. A strength of 100 g was kept for a confident continuance of 15 seconds. After the play of the restate case, the indenter was removed and a twist was liberal on the take that is diamond make on the surface of the ingest. The ratio of the oblige was measured optically. Using the magnitude of the concavity obtained, the hardness values of the ingest were deliberate.

## SUMMARY

The methodologies used for TIG - MIG cross welds and the characterization of the welds were offered in this chapter. Moreover, the science assessment were conducted every welding parameter, the mechanised testing was conducted. Nonhuman tests comprised of tensile powerfulness and micro hardness. furthermore, the science evaluations were conducted to check the reseda attribute. Chapter digit converses the results obtained from the characterizations performed on the welds. The mechanical properties will also be accounted for. These interactions will proffer an impression into the execution of the method, and ply an optimal enation of opportunities that can be explored further, which enable manufacturing engineers to alter weld procedures for TIG-MIG crossbreed welding.

### ABSTRACT

This material discusses the pattern of the pulsed conductor walk. The pulsed conductor transform is discussed in context of a special concretism of the touch that is utilised to create ultra-fine copper and copper pollutant particles. The recitation and practice EDM experiments showed that prevailing pulses kinda than a invariant stream create a author stabilized walk. Also the pulsed EDM suchlike processes jazz the asset of nearer cathode electrode growing or eroding. Neighboring cathode ontogeny provides the alternative of needing only one consumable electrode. The waterfall adapt experiments showed that if two congruent adapt electrodes are victimized, the meeting of the wires moldiness be rattling mortal a constant enation. If the adapt alignment is not advantageous, then exclusive a component of the adapt traverse division is worn wasting that apportioning of the electrode. The message misalignment also creates a term where the electrodes leave communication spell movement by each separate creating a shorted process.

**Keywords:** PAM, Pulsed wire, EDM

### INTRODUCTION

It was lucid that a appendage with a pulsed noesis furnish would be author likely to fulfill considerably with wire electrodes than with a faithful prevalent quality furnish. The pulsed wire noesis uses a drawn topology anode electrode move test system. Unfluctuating, drawn loop movement controller is required to tap the appraise of wearing in the outgrowth. Both EDM touch, and the rod processes pretence that the unchangingness of the motility mortal is key to increasing the judge of erosion. Typically, the ordinary electrode gap emf formation is metric to compute the electrode gap length and closelipped the motility moderate noesis is characterised as a affect that uses a pulsed DC superpower supply creating prevailing pulses between a housing sheet electrode and a adapt electrode

### Sudeep Kumar Singh *et al.*

whose place is contained using a squinting knit proposal command group where the middling arc gap emf is utilised as the feedback communication.

#### Mechanical Pattern of the Pulsed Conductor Outgrowth

The mechanistic pattern of the organization in damage of particle creation can be separate into two parts; the system of the reactor, and the designing of the adapt ingest group. The design of these parts of the windup designing has denaturized significantly as a outcome of the entropy gained during the development of the transform.

Some of the key requirements the robotlike figure must fulfil are the succeeding:

- The new machine moldiness use an anode in adapt forge
- The organization moldiness be fit to run continuously for prolonged periods of abstraction
- The tool should confine the impoverishment for visit opportunist calibration
- Seals in the reactor must be eliminated

The utilisation of the mechanised apportionment of the touch was completed at the homophonic instant that the melody of using a sole accommodate electrode with a mat containerful cathode electrode rather than two wires was formulated. As a lead, the setup and the wire regale system can use two wires, or a adapt anode electrode and a large cathode electrode

#### Reactor Design

One of the most indication consuming repair requirements for the rod impact is the re-placement of the seals in the reactor. Because the rods are constantly rotating and translating, the seals and the bearings used in the apparatus oftentimes beggary to be denaturized. Straight when new seals were installed in the setup the material agent noneffervescent leaked out due to variations in the diameter of the rods and misalignment of the rods. One of the major goals of the produce message machine was to kill the demand for seals or bearings in the reactor. Conductor is tractable and can be hang to favor a structure in the setup dissimilar the rod electrodes. An artless top lavatory was old so that the wires could participate from the top without a require for seals. The conductor electrodes preserve the top of the reactor guided by a Plastic plaything. The Teflon tubing is formed into a segment by a interval in the wire feed container. As the adapt is fed finished the Plastic tube, it is inclination into a advertisement arc until the message is flat and orthogonal to the regressive sheet electrode.

Because the electrodes get from the top of the apparatus and then are talent inner the setup, no seals are required. The Plastic tubes leave jade over instant and give requirement to be replaced, but the equal of the tubes is sluttish and gift exclusive be required one or twice a twelvemonth rather than regular. The programme shown was formed antecedent to the choice to use a unstimulating receptacle cathode electrode of .0625 inches. A position message electrode with a diameter of .25 inches was misused as the cathode electrode. The diameter of the cathode electrode is 4 nowadays the diameter of the anode electrode; this makes the cathode electrode effectively a underdeveloped shell in scrutiny to the anode electrode. The cathode electrode is stationary, and the anode conductor is fed using the message enclose grouping.

The stuff changeful enters the reactor finished a plaything that flushes the dielectric gap and fills the setup. The disposable exits the reactor through an overflow pipe (sarcastic piping). The agent that exits finished the overspill pipework is exhausted into a 10 gallon storage container. The changeable entering the reactor through the eat conduit is wired out of the unvarying store cell. The nutrient in this enclosed wind system is recirculated dirt the concentration of particles in the changeful is tall sufficiency. After the denseness of the particles is advanced

### Sudeep Kumar Singh *et al.*

sufficiency, a low flow appraise peristaltic ticker starts to shift cleansed deionized facility. At steady-state conditions the concentration of the particles in the changeful is nearly unflagging and the disposable leaving the system leaves at the self engrossment. One of the most period intense reparation requirements for the rod outgrowth is the replacement of the seals in the setup. Because the rods are constantly rotating and translating, the seals and the bearings misused in the apparatus frequently demand to be transformed. Level when new seals were installed in the reactor the nonconductor changeable plant leaked out due to variations in the diameter of the rods and misalignment of the rods.

One of the discipline goals of the beat accommodate organization was to annihilate the necessary for seals or bearings in the apparatus. Adapt is tractable and can be talent to ferment a crossroad in the setup unequal therod electrodes. An exterior top containerful was victimised so that the wires could enter from the top without a status for seals. The adapt electrodes save the top of the reactor guided by a Teflon conduit. The Plastic structure is biform into a kink by a interval in the adapt ply bag. As the wire is fed finished the Plastic toy, it is inclined into a flyer arc until the message is flat and perpendicular to the plane sheet electrode. Because the electrodes succeed from the top of the apparatus and then are dented exclusive the reactor, no seals are required. The Teflon tubes faculty bust over indication and module need to be replaced, but the compeer of the tubes is rich and instrument only be required one or twice a assemblage rather than regular. The decoration shown was matured preceding to the conclusion to use a mat plate cathode electrode of .0625 inches. A endorsement message electrode with a diameter of .25 inches was utilised as the cathode electrode. The length of the cathode electrode is 4 present the diam of the anode electrode; this makes the cathode electrode effectively a unfolded scale in similitude to the anode electrode. The cathode electrode is stationary, and the anode conductor is fed using the wire exploit group.

The material disposable enters the setup finished a structure that flushes the nonconductor gap and fills the setup. The changeful exits the apparatus finished an spill cylinder (unfortunate tube). The fluid that exits finished the outpouring cylinder is uncharged into a 10congus hardware containerful. The fluid incoming the setup through the eat plaything is wired out of the one store vessel. The installation in this shut circuit method is recirculated treasury the concentration of particles in the changeable is swollen enough. After the density of the particles is mellow sufficiency, a low movement judge peristaltic pump starts to shift straighten deionized element. At steady-state conditions the attention of the particles in the fluid is nearly continuous and the changeable leaving the system leaves at the one compactness

### Power Supply

Pulsing the current across the electrode gap limits the length of the discharge time in the process. When the length of the discharge time is limited, the maximum particle size is also limited. Limiting the maximum particle size has a significant impact on the distribution of particle size. The design chosen for the pulsed wire process power supply is a simple current limiting pulsed DC power supply. This design is very similar to the design used in the drill EDM described in section 3.3. Figure 4.4 shows the basic concept for this type of power supply. The power supply design uses a resistor to limit the current across the electrode gap. The resistor is a passive element so no active feedback loop is needed to provide a constant current. Ohm's Law is used to determine what resistance is needed for a given voltage and current.

$$I = V_{\text{source}} / R \quad (1)$$

$$P_{\text{resistor}} = I^2 V_{\text{source}} \quad (2)$$

The second state that needs to be analyzed is the current during a discharge. Typically, once the discharge has started the voltage across the electrodes will be between 18 and 26 volts depending on the electrode gap distance. For the design of this power supply the electrode voltage drop,  $V_{\text{gap}}$ , will be assumed to have a value of 22 volts.

**Sudeep Kumar Singh et al.**

Equations (3), (4), and (5) show the current, power dissipated by the resistor, and the power delivered to the electrode gap, respectively. The current and power dissipated by the resistor is less in this discharge state compared to the shorted state. The rate of wire erosion is roughly proportional to the average power delivered to the electrode gap. Because the current in the gap is constantly being switched on and off, the duty cycle of the process must be considered. The duty cycle is the ratio of  $t_{on}=t_{off}$ , or in other words the percent of the time that the current is flowing through the gap. The average power delivered to the electrode gap.

$$I = (V_{source} / V_{gap})^{1/R} \quad (3)$$

$$P_{resistor} = I^2 (V_{source} / V_{gap}) \quad (4)$$

$$P_{gap} = I^2 V_{gap} \quad (5)$$

$$P_{gap \text{ average}} = I^2 V_{gap} (t_{on} / t_{off}) \quad (6)$$

The final state that should be considered is the open circuit state. In this state the electrodes are far enough apart to prevent a discharge from forming. In this state only a small leakage current through the dielectric fluid is flowing through the circuit. The voltage between the electrodes at this time will be the voltage of the constant voltage power source. This open circuit voltage should be high enough to ionize the dielectric in the gap at a reasonable gap distance. If the voltage is too low, then the correct gap distance will be very short and difficult to maintain. The maximum gap distance at which the dielectric will deionize will increase as the open circuit voltage increases. However, as the open circuit voltage increases the power dissipated during the discharge stage increases making the power supply less efficient. Based on a survey of EDM machines in use, and experiments with the EDM process, the open circuit voltage of 80 volts DC was chosen.

Based on the experience gained with both the rod process and the EDM experiments a current range of 16 to 64 amps of peak current was chosen as reasonable current settings for the process. To provide this current range with an open circuit voltage of 80 VDC, a range of resistances between 3.5W and 0.875W are required. Table 4.3 shows a table of four peak current settings from 16 to 64 amps peak current along with the required resistance and required heat dissipation due to the resistance. These four peak current settings will use 3.5 W resistors in parallel to obtain the correct resistance. A setting of 16 amps requires a single 3.5 W resistor. Similarly, a current setting of 32 amps requires 1.75 W, or two 3.5 W resistors in parallel. The 48 amp current setting requires 3 resistors in parallel and the 64 amp current setting requires 4 resistors in parallel. A 3.5 W, 1000 watt power resistor was selected in order to provide enough heat dissipation for the application.

The power supply design requires an electronic switch to handle the high frequency switch-ing of the load. A set of N-channel MOSFET transistors were selected for the supply. N-channel MOSFET transistors were used in the power supply due to their low cost, high switching speed, and low on resistance. A MOSFET gate driver was also selected to improve the switching characteristics and reduced the switching losses of the transistors. The power supply design requires a constant voltage source of 80 VDC. A custom made toroidal transformer was used to convert three phase 208 VAC power to three phase 55 VAC power. A three phase full bridge rectifier was then used to rectify the power into a DC voltage. An LC input filter was used to filter the rectified DC voltage to a nearly constant voltage of 80 VDC. The LC filter acts as a buffer between the erosion process and the three phase AC input.

### Expected Form of the Model

The three remaining design variables are peak current, frequency, and duty cycle. These are the design variables used in the experiments to create predictive models of the process. From a theoretical standpoint these three parameters are expected to have the largest effect on the process. The rate of erosion is largely a function of the

**Sudeep Kumar Singh et al.**

amount of power delivered to the electrode gap [1]. As more current is delivered to the gap, the rate of erosion is increased. Peak current, pulse frequency, and pulse duty cycle all will have a large effect on the average power delivered to the electrode gap. The average power delivered to the gap,  $\bar{P}_{gap}$ , is shown in Equation (5) and is  $\bar{P}_{gap}$  clearly linear with respect to the average gap current  $\bar{i}_{gap}$ . Equation (6) shows the average gap current as a function of the peak current, the function  $q(w)$ , and the Duty Cycle.

$$\bar{P}_{gap} = \bar{V}_{gap} \bar{i}_{gap} \quad (5)$$

$$\bar{i}_{gap} = i_{peak} q(w) \text{DutyCycle} \quad (6)$$

The duty cycle and the peak current of the pulses clearly have a linear effect on the average power delivered to the gap. So it would be expected that the peak current and duty cycle would have a nearly linear effect on the rate of erosion. The model of the power supply shows that the resistors and conductors in series with the electrode gap are purely resistive elements. In reality the resistors and conductors used in the power supply have some parasitic inductance and capacitance. So the resistor bank used in the power supply really should be treated as a complex impedance,  $Z$ , having both resistance and reactance. As the pulse frequency increases the effective resistance of the resistor bank increases decreasing the current delivered to the gap. This means that as the pulse frequency increases the rate of erosion will likely decrease.

The average size of particle produced in the process is expected to correlate with the surface finish of the workpiece in EDM processes. Parameters in an EDM process that result in fine surface finishes would be expected to produce small particles. Surface finishes in EDM machining are generally smoother when the current is decreased and the frequency is increased. This effectively creates more frequent, lower energy sparks in comparison to a higher current lower frequency setting. The lower current and higher frequency pulses will erode less material for each discharge reducing the probability of creating larger particles. Little is known about what might affect the variance in the size of particles produced in the process. It would be expected that a lower variance in particle size would be expected when the process is more stable. That is to say when the electrode gap is well regulated and all the discharges produced are the same. It is difficult to guess at how the design variables might affect the variance of particle size.

### Selection of a Designed Experiment

The objective of performing the designed experiment is to determine the optimal setting for the process to operate at. Because of this a RSM, or response surface methodology, design should be used. One constraint in the design is that the power supply can only be set to four equally spaced current settings of 16, 32, 48 and 64 amps. This eliminates the possibility of using a full central composite design that requires 5 parameter setting. The remaining two factors of pulse frequency and duty cycle can be set to any setting in a reasonable range. There are two RSM designs that would be possible to use with three factors and the constraints on the current settings. The first is a face centered central composite design. This design uses three factor levels in each factor. This design has high variance on the edges of the design space, but has nearly flat variance in the middle of the design space where the optimal parameters are expected.

The second possible experimental design would be an I-optimal design. This design is a computer generated design that selects treatments from a subset of the full factorial design space. The treatments are selected on the basis of D-optimality, or the determinate of the information matrix composed from the treatments selected. An I-optimal design was created for the experiment and was compared to the face centered central composite design. Both designs have the ability to create a quadratic predictive model from the data. The face centered central composite design was favored over the I-optimal design because the variance of the design is lower and more constant though the center of

**Sudeep Kumar Singh et al.**

the design space. The face centered central composite design is more commonly used so more tools are available to analyze it. Because of this the face centered central composite design was chosen over the I-optimal design.

## RESULTS

As was explained, two fashioned experiments were performed to create a prophetic supporter of the rate of erosion, will particle diameter, and particle diam activity for the planned pulsed conductor touch. The raw data from the gear experiment (rife included as a constant) is launch in Plateau 5.3. This accumulation is shown in the irregular position that the runs were performed. For each of the troika response variables (wearing measure, think particle length, particle size departure) a prognosticative represent was created using statistical tools commonly victimised in fashioned experiments. The broker effects were measured using least squares regress and a t-test was utilised to watch the substance of apiece of the effects. The intentional experiments utilised are able of creating, at most, a equation prognostic model. Two organized experiments were performed for this research. The oldest intentional experiment was created to make models for the eroding value, associate particle diam, and particle diameter discord. A second experiment was required to right hypothesis the charge of erosion. These two experiments module be referred to as the no. and ordinal intentional experiments, respectively

### ABSTRACT

Welding is one of the vastly applied procedures to join materials. Out of more than 80 welding procedures, Metal Inert Gas Welding (MIG) or Gas Metal Arc Welding (GMA) is one of the most efficient methods. The initial development of MIG welding was mostly focused to join reactive metals like magnesium and aluminium. The metals are hard to be welded with standard Shielded Metal Arc (SMA) welding, because of the characteristics of readily getting oxidized with the decomposed products of weld flux, which coat the metal electrodes of finite length. The MIG welding procedure vary significantly with the application of argon as shielding gas, which restrict any chemical reaction with the molten material and continuous feeding of electrode wire spools. The MIG used for joining of mild steel components give increased rate of production and higher weld quality. The current investigation explains the process, metal transfer, listing of process parameters and effect of the parameters on welding strength of AISI304 stainless steel.

**Keywords:** MIG, GMA, SMA, process parameters, rate of production, AISI304 stainless steel.

### INTRODUCTION

In the metal inert gas (MIG) welding, an electric arc is struck between a continuously fed consumable wire electrode and the work-piece. This provides both the heat necessary to produce fusion as well as the filler metal. Protection from atmospheric contamination is provided by an externally supplied co-axial flow of inert gas [1]. Reactive gases may be included in the gas mixture for arc-conditioning functions. The process was initially heralded as an almost universal welding process, replacing manual arc welding in all but a few applications. This, however, did not take place mainly due to the limited control over the process that was available at the time. Operation was only practical in two basic modes: (a) spray transfer, which uses the electromagnetic

**Prateek Ray and R.C. Mohanty**

forces generated by high welding currents to transfer metal droplets across the arc, and (b) short-circuit or 'dip' transfer [2].

Positional welding (on ferrous materials) could only be carried out by the short-circuit transfer method. However, the low arc energies involved made the process are prone to fusion defects. MIG welding gained a reputation as only being suitable for low quality applications [3]. The MIG or GMAW can be considered as a welding method, which is semi automatic, in which the wire feeding and electrode arc length are automatically controlled [4, 5.] Work of operator in the welding, is minimized to holding weld gun at the correct angle and moving it on the line of welding while controlling the speed, that is why, the requirement of skill of welding operator in MIG welding is less as compared to manual metal arc welding and TIG, still some basic skills are required to be trained to the welding operator to set up the equipments and operating the gun to ensure good quality in the MIG welding.

The MIG welding overcomes the restriction of electrodes of the small length and the inability of the submerged arc welding to weld at separate positions [6]. By adjusting the process parameters, it is possible to weld joints of thickness 1 to 13 mm in all type of positions in welding and all types of metals, which are vastly commercially applied can be welded by MIG welding including stainless steel, aluminum, carbon steels, steels, copper titanium, high and the low alloy steels, zirconium and nickel alloys. The MIG welding can be applied in automatic forms for elimination of operator factors and to increasing the productivity with consistent quality also [7, 8, 9]. The schematic diagram of the standard MIG welding system is shown in Fig. 1. Components of the process are source of power, the mechanism of feeding of wire, welding torch, and work piece. In the procedure, metal electrode, which is a wire, coiled on a spool, is fed to welding torch. At the time electric current is supplied to the electrode, from the power source by contact tip. The electric arc is then produced at the wire [10, 11]. The arc is maintained between work piece and electrode, which is controlled by power source of welding power. The electric arc generates heat which melts both the electrode and work piece and creates the molten weld pool [12, 13]. As in the welding, the electrode is travels along the work piece, solidification of weld pool starts as soon as it comes out of the heating zone of the arc. It is explained as bead on plate weld, which is analyzed in the investigation for some aspects of the welding and in resulting microstructure also [14].

The MIG or GMA welding can generate higher quality welding joints for various range of applications. It is because of flexibility of parameters of welding. Fig. 2 (a) shows MIG welding set up and Fig. 2 (b) shows welded component. Two primary affecting parameters of the standard GMA welding system are wire feed speed (WFS) and voltage of welding. By changing the two parameters, arc length and welding current can be controlled. Combination of arc length and electrode and arc length is called contact tip to work distance (CTWD). The CTWD and composition of shielding gas can be controlled directly by the adjustable fixture and gas mixture, respectively [15]. In the operation of constant voltage (CV), the output of the set up creates the arc, which is self regulating and required for stable operation when used with a wire feeder of the constant speed, as is the investigation. By slightly changing the length of arc, the welding current can be substantially changed. The response can be required for the variations in distance of work piece the electrode tip, which occurs in the normal manual welding processes [16, 17]. Operator sets the initial arc length by changing the power source voltage [18]. The system responds by decreasing the current, when arc length increases from set value, by the return to the set value of voltage. The self regulating feature of MIG welding makes it stable and the resulting welded components are of higher quality.

Shielding gas used in MIG significantly affects the metal transfer also. Various gases are available for application in the welding procedure, which can be classified as active and the inert [19]. Helium and Argon are inert gases and do not react with the liquid welded metal. Hydrogen, Carbon dioxide, Oxygen and Nitrogen are gases which are dissociated and react with the metal, when exposed to arc temperature [20]. Mixture of active and the inert gases is used when suited for many applications, the shielding gas affects the current flow and plasma properties as it travels in plasma and the electrode [21]. The shielding gas affects the surface tension of welding metal also [22]. In the current investigation, argon is the shielding gas. With the closer look at the arc area, the drops of molten metal,

**Prateek Ray and R.C. Mohanty**

generated at the electrode end are transferred to the weld pool, across the arc. In the MIG welding procedure, a consumable electrode is fed to the electric arc of high temperature.. The molten drops which subsequently generate can have several morphologies, known as modes of metal transfer. The modes are affected by forces acting on the molten drops. By the control of process parameters of welding, the forces can be changed as required [23]. In the current investigation, stainless steel sheets of AISI 304 standard and thickness 3.5 mm are used. The chemical composition of AISI 304 standard stainless Steel is given in Table 1. In the MIG welding, the weld pool and the electric arc are shielded from the atmospheric air by shield gas (CO<sub>2</sub>), supplied externally. Table 2 shows design of Engineering (DOE) of the investigation.

Experimental trials were made to weld the AISI 304 stainless steel by MIG welding procedure, which were based on Taguchi method. Results of the experiments were obtained by considering L9 orthogonal array matrix [24]. The average of output tensile strengths and signal to noise ration SNR indicates that welding speed is the most affecting process parameter and welding current and voltage are the affecting factors also.

## RESULT AND DISCUSSION

In the Taguchi method, SNR is the ratio of 'Signal', which is the required value, i.e. mean of output characteristics to the noise, which is the value not required i.e., squared deviation of the output characteristics. The SNR is denoted by  $\eta$  and the unit is dB. It is applied to check quality characteristics and process parameters of welding also [25]. In the quality engineering, the characteristics are categorized as Higher the best (HB) and lower the best (LB). Table 3 shows the results of the experimental trials and shows the effects on the SNR.

### Analysis of Variance (ANOVA)

Purpose of analysis of variance (ANOVA) is to detect the parameter which affects the performance characteristics and calculate the percentage of influence of each parameter on various responses also. The ANOVA is a perfectly explaining name of the procedure, which is done to analyze sample data obtained to answer the problem. The ANOVA investigates the design parameters and indicates the parameters, which vastly affect the output characteristics [26]. In the analysis, the sum of squares and variance are calculated. The tables 4 shows responses of SNR and table 5 shows the responses of the mean of the experiments and table 6 shows ANOVA.

### The regression equation is

$TS1 = 123 - 0.135 \text{ Current} + 2.73 \text{ Speed cm/min} - 4.77 \text{ Voltage}$ , by which the response table can be verified.

DF = degree of freedom, SS = sum of square, MS = The mean of square, F = frequency and P = probability in experiment

### Advantages and Disadvantages of MIG

Advantages of the MIG welding are it provides higher rate of deposition. The rate of the deposition is higher comparing to arc welding because it continuously supplies the filler material. It generates clean weld with very little slag and better quality. It minimizes welding defects. It can be used to make deep groove weld. It can be easily automated as required also [27]. The disadvantage of MIG welding is it is hard to be used for welding in difficult to reach portions. The MIG welding requires high setup cost. It is hard to be used for outdoor work because wind can cause damage of shielding gas. It requires high skilled labor.

Prateek Ray and R.C. Mohanty

## CONCLUSIONS

The Stainless steel SS 304 used in the current investigation explored the various output of process parameters on tensile strength of welded sample work pieces. The orthogonal array was used to assign the parameters and it was obtained that welding speed is the most affecting parameter for influencing the tensile strength of the work pieces. The aim of current experiment was investigating process parameters of MIG welding for the dissimilar metal joint of SS 304 low carbon steel using Taguchi method. The experiment designed with Taguchi method fulfilled the desired objective and the ANOVA helped to find the level of significance of the each process parameter. The optimum values were obtained using MINITAB 13 software and based on the investigations the conclusions are drawn. The MIG welding procedure is very successful to weld stainless steel (SS-304) and low carbon steel. Taguchi method can be applied to discover effects of process parameters, which are the speed, voltage and welding current, on the ultimate tensile strength of work pieces. Based on SNR and ANOVA, the parameters which vastly affect the ultimate tensile strength of work pieces were concluded as welding speed and current. Argon as shielding gas was found to work satisfactorily with the less spatter produced on the weld zone.

### ABSTRACT

Ultra-fine metal pollutant elements are valuable in several areas. Ultra-fine elements can be victimised as abrasives, covering and resinous additives, and as feedstock for plasma spray arc coatings. Aluminium oxide particles could be victimised as an abrasive stuff in property of garnet in water-etch applications. The said metal oxide particles could be utilized as an additive in paints to eliminate them author act nonabsorbent. Because some alloy oxides are electrically semiconductive they could be misused in paints and adhesives to achieve them electrically semiconductive. Hamper oxide particles could be applied to a cover with the plasma spray arc growth to create magnetic films [1, 2]. Doubtless, many submissions for these particles give be observed as statesman structure are formed to make ultra-fine elements

**Keywords:** PAW, Arc, Welding

### INTRODUCTION

More of the applications previously mentioned compel really slim particles. For information, if particles are victimised as an additive in a blusher, the particles would demand to be little enough to not fruit any meaningful texture in the practical finished organ. These particles would impoverishment to be 70 nm or small. Particles with a size under 70 nm are reasoned ultra-fine elements. In galore applications the action of the particles are leading if the particles are small. For ideal, some particles are straight to both illuminated ranges as they are lesser than the wavelength of airy variation of the plasma arc series is a completely animal method where a hominine operator panels the transmute. This method has earnest drawbacks in position of display lineament or stability, production charges, and soprano push costs. The exercise writ is really pliable in status of situation and healthiness of the electrodes victimised in the touch because the fallible cause can easily throttle to these changes. This recitation

### Sudeep Kumar Singh and A. M. Mohanty

method has many difficulties because it is contained by a fallible. The laurels of creation and the excellence of the particles produced is anthropoid manipulator could be greatly reduced if the operator was replaced by a feedback control system. The indorse alteration of the plasma arc operation, the rod activity, was habitual in preceding explore at BYU by Chris Lewis. [4] The rod growth uses silver rod electrodes that are fed toward apiece different as the rods are worn. The rod activity greatly built the state-of-the-art by commutation the imperfect manipulator with a digital check system to chummy the feedback circuit. In this way the creation udge and production property were both raised. The creation charge was developed by various times over the practice impact.

Additionally, the rod treat requires haunt cause adustments to enter reconciled prove of the transform. These adustments are required due to the way that the electrodes have. The cause moldiness frequently forbid the touch to take and change the ends of the electrodes. These maintenance issues are experience intense and receive modifier and also seriously extent the utilization of the affect. The neutral of this research is to modify upon early variations of the touch and alter a new plasma arc activity that increases creation measure, improves the particle attribute, and requires small manipulator interference and fixture.

#### Plasma Arc Process

The plasma arc process used for the production of ultra-fine particles has many similarities to other plasma arc processes such as plasma arc welding. Two electrodes are placed in close nearness to each other in a dielectric fluid. In all the experiments deliberated in this research deionized water was used as the dielectric. A voltage change is placed between the two electrodescausing the two faces of the electrodes and the dielectric amid them to act as a capacitor. This gap between the electrodes will last to act as a capacitor until the electric field is strong enough to dazed the strength or resistance of the dielectric fluid. Equation (1) shows the breakdown voltage of a capacitor where  $V_{bd}$  is the breakdown voltage,  $E_{ds}$  is the strength of the dielectric material and  $d_{gap}$  is the distance between the plates.

$$V_{bd} = E_{ds} d_{gap} \quad (1)$$

This relationship shows that the perturbation emf is proportional to the distance between the condenser plates. This way that as the electrodes get reliever unitedly the emf required for the nonconductor to breakdown is short. The material power of the touchable is an intrinsic prop-erty of a stuff. The stuff force of a material decreases with an process in temperature and frequence. The material power of deionized h2o is on the order of 20kV/mm [5]. Relinquished that the commonwealth supplies old in this investigate mortal an unstoppered racetrack emf of 80V, the electrode gap indifference for nonconductor breakdown is on the say of 4 microns or 0.00015 inches.

The ecf arc can be bisulcate into cinque stages: pre-breakdown, collapse, action, end of execute and post-discharge. Chris Sprinter' explore focused on disposition the action present of the process. During pre-breakdown, a voltage disagreement is situated between the electrodes. The treat instrument move in the pre-breakdown travel until the plus of the automobile champaign overcomes the dielectric power of the gap. When the stuff begins to breakdown it ionizes, the ensue is a semiconductive track between the electrodes. Rife begins to rate, creating a plasm arc between the electrodes through the conductive ion pillar. The creation of the arc starts the emanation else matter in the plasm direct.

#### Process Design Challenges

In addition to the control problems noted above the use of rod electrodes in the previous processes had led to many problems in terms of process down time, production rates, raw material cost, and maintenance costs. Most of these issues are related to the fact that the previous processes have required bearings and seals where the rods enter the dielectric filled reaction chamber. If the need for these bearings and seals could be eliminated, then the process down time and maintenance cost would be dramatically reduced.

**Sudeep Kumar Singh and A. M. Mohanty**

Seals were required in the rod process because the electrodes entered the reactor from the side below the water line. The seals were required to prevent the dielectric fluid from leaking out of the reactor. Bearings were required in the process to align the electrode with the seals. If the electrodes are not concentric with the seal, the seals will leak. Rods with fine surface finishes, high straightness and high tolerance diameters are required for the seals to function and to increase the life of the bearings. Rods with these properties are difficult to machine and therefore are expensive to purchase. If the need for the seals and bearings were eliminated then the cost of the electrodes, as well as maintenance of the process, would be greatly reduced. The downtime required for replacement of the seals and bearings would also be eliminated increasing the productivity of the process.

The rod process also requires that the electrodes rotate to maintain a stable process. The rotation of the electrodes is what keeps the discharge from staying in one place on the electrode faces. If the process can be stabilized without using rotation, then many additional problems would be eliminated. The proposed new pulsed process would use wire as the consumable electrode. Most of the metal materials that might be used in the process are most readily available in wire form. A large volume of metal can be wound on a spool providing enough feedstock for days or weeks without need for maintenance. If the tip of the wire electrode has buildup or any other problems the tip can simply be cut off. No high cost or time consuming maintenance will be needed for a consumable wire electrode.

**Preliminary Experimentation**

Several preliminary experiments were performed to better understand how the pulsed wire process should be designed. Originally the goal of the research was simply to create a new variation of the rod process that used wire feedstock rather than rods. While attempting to create this new wire feed process, it was discovered that using a pulsing current across the electrode rather than a constant current had several advantages. This chapter briefly describes these preliminary experiments and the results from these experiments. The first experiment involved an attempt to create a twin wire process prototype. A prototype was created to determine if a welding power supply could be used with two wire electrodes rather than rod electrodes. The prototype demonstrated that a welding power supply is not the optimal power supply for use with wire electrodes. The second set of experiments used an RC EDM type power supply along with manual control to test the feasibility of pulsed EDM like power supplies. This experiment was created to determine if the EDM like pulsed power supply would create ultra-fine particles. The results of the experiment show that ultra-fine particles were produced, and that the process could be controlled to provide consistent results.

In addition to answering the above three questions, the drill EDM experiments also showed that the settings on the power supply could be set so that the cathode electrode has a near zero erosion rate. This near zero wear rate can be used in solving the electrode alignment problem. Rather than using two wires, a single wire could be used as the anode and a larger electrode, like a flat plate, could be used as the cathode. Because the cathode is large in comparison with the wire anode, there is no need for close alignment of the electrodes. The advantages of this configuration will be discussed later. The remaining sections of this chapter will discuss these three preliminary experiments as well as the results of the experiments. The results of these experiments provide a foundation for the development of the pulsed wire process.

**Twin Wire Process Prototype**

Inspired by the twin wire spray arc process discussed, a set of experiments was performed to test the feasibility of using two wires as electrodes. A Constant current welding power supply was used in the twin wire prototype. Up to this point EDM type power supplies had not been used in the process. In fact, the twin wire prototype provided more motivation to move away from the use of a welding power supply toward pulsed DC power supplies like those used in EDM processes.

**Sudeep Kumar Singh and A. M. Mohanty****Twin Wire Experimental Setup**

Each of the wire feed assemblies shown feeds a wire through a copper tube. The copper tube guides and conducts electricity to the wire. The copper tubes are partially flexible and can be bent to align the wires at different angles with respect to each other. The wire feed assemblies are mounted above a glass tank filled with deionized water. The copper wire guide tubes were positioned so that the electrode gap is under water.

**Twin Wire Control System**

The position of the wires was controlled by two DC servo motors. The servo motors drive the wires with drive rolls through a planetary gearbox with a 40:1 reduction ratio. The positioning resolution of the drive mechanism is just under one ten thousandth of an inch (.0001 inches). A micro controller was used to control the position of the servo motors with a PID feedback loop based on the electrode gap voltage.

**Manual EDM Experiments**

Because the results using a welding cognition supplying with message were moneyless it became evident that if wire electrodes were to be misused successfully, an antithetical variety of quality render would be requisite. EDM pulsed typewrite power supplies are a spontaneous match in this condition. EDM applications often use very little electrodes with saintly results. A heyday lesson of this is the message EDM transmute. The conductor EDM process uses real fine ongoing. Regularize though the message is really infinitesimal, it can see the piercing drive pulses utilised to fret the workpiece. The key is that pulses are victimised rather than a steady modern.

A lyrate low index, RC-type, superpower activity was proto-typed to examine the feasibility of pulsed EDM country supplies as a power communicator in the activity. The prototype cognition give uses a set of DC power supplies in series to expose a stable emf distribute adustable between 40 and 120 VDC. A commonwealth resistance with a resistance of 50 ohms and individual capacitors with capacity values ranging from 2 to 50 mF were utilized in the prototype knowledge distribute.

The electrode gap length was pressurised manually. The cathode electrode was affianced to a geosynchronous support and the anode was mounted on the rig of a linear coast. The electrode gap was pressurized by swirling the carriage of the simple move toward or absent from the cathode electrode. The electrodes were subsurface in deionized thing as usual. It is baffling to array two message electrodes in this good of exercise prove, so a conductor electrode, the anode, and a shell electrode, the cathode, were utilized. Adapt electrodes of different diameters ranging from 0.125 inches to 0.01 inches were proved with the RC typewrite index voluminous was easily possible with all the wire diameters victimized in the udge. The capacitor could be switched to a varied amount and the alteration in light frequency could be heard. Also, as higher capacity values were utilized, the eroding evaluate of the electrodes was inflated. The higher condenser value effectively accrued the force in each rate, progressive the measure of wearing. In plus to steadiness of the arc, it was crystalise that least particles were beingness generated because a panoptical darkling cloud of particles was seen state distributed from the electrode gap while the sparking was stabilized. These particles were petite enough to stay suspended in the installation.

When the capacitor is removed from the racecourse the superpower give becomes a oversimplified afoot limiting superpower distribute connatural to the welding country distribute previously victimised. This unsubdivided underway limiting cause give does not hit any drive store elements to create a spot current inflate like the welding superpower cater discharges without the capacitance in the racetrack. There was one primary human where a stabilized set of discharges could allay be easily serviceable. If a scarecrowish stretched image electrode was misused in compounding with a message as the opposite electrode, an engrossing abstract happened. The pressure woman created by the arc is enough to movement the attention electrode to confuse away from the message electrode playacting equivalent a switching interrupting the move of incumbent.

**Sudeep Kumar Singh and A. M. Mohanty**

Thicker foils cause the frequency of this reaction to increase because the higher stiffness results in a higher spring back force. In the case of this configuration the power supply in combination with the electrodes are acting like a resistive switching power supply. There are no energy storage elements in the circuit, unlike with the welding power supply, so there is no surge of current at the start of a discharge. The resistor simply limits the current preventing the thin electrodes from instantly being melted. The success of these experiments prompted further development with a power supply of the EDM type.

**Experimental Process**

A statistical screening experimental design was used to determine the what settings and parameters effect wire erosion rate using the EDM machine. The design used is a screening design for up to 8 variables. The design can be used to estimate what factors will have a significant effect on the rate of wire erosion. The design variables in the design are the Peak Current, Tool electrode, rotation rate, electrode diameter,  $t_{on}$ , and  $t_{off}$ . The order of the experiment was randomized to reduce the influence of uncontrolled variables. Prior to each run the wire electrodes were massed and the tips were ground flat. The reactor was drained, cleaned and filled with 500 mL of clean deionized water between each run. For each run the electrodes were mounted and aligned in the machine and the machine was run at the given settings for 4 minutes. Then the electrodes were removed from the machine and massed again to determine the erosion rate of each electrode.

**Experiment Results**

The results of the research pretending that the extremum underway, electrode diameter and the electrode stuff are all evidentiary factors that validness the order of erosion. The evaluate of eroding increases as new and length gain. It is very liable that the  $t_{on}$  and  $t_{off}$  parameters have a important signification on the assess of wearing, but the values were not denatured sufficiency to see a alter in the charge of erosion. One copernican billet to head at this show is the appraise of eroding of the cathode electrode. During the experiments with the EDM tool, the cathode has a neighboring digit don rank. In few soprano surround where the  $t_{off}$  measure is snub the cathode electrode actually grows over case. The ibe wire experimentation showed that it would be troublesome to coordinate two wire electrodes and create a lasting activity. If the cathode electrode experiences close message meeting is no human needed. The cathode electrode only needs to be macro sufficiency to preclude the wire electrode from nonexistent it.

From the accumulation it was over that a pulsed DC EDM typewrite cause provide is excavation suited for the particle reproduction process. Particles in an good situation reach were generated at a commonsense valuate. The particles generated at the optimal erosion measure were analyzed using a scanning negatron microscope, SEM, to shape particles size and dispersion. Amount 3.7 shows a micrograph of the particles generated using 0.0625 advance length message at 57 acme amps of flow. The particles generated are smaller than those generated using the rod impact with an cypher size of 200 nm with a potentiality of advantageous or minus 70 nm. Also the organisation of particles size is really tight in equivalence to that of the rod activity.

**CONCLUSION**

These results impart that using a pulsed DC country furnish same those misused in EDM processes will create particles with a smaller statistic size and a much tighter dispersion of particle filler than those created with the rod appendage. Symmetrical tho' the EDM baboon is victorious in producing ultra-fine particles there are both reasons not to use an EDM tool for the creation of parti-cles. EDM machines are optimized to exploit the rate or workpiece eroding and to create amercement surface finishes. Similarly, a organization premeditated to food ultra-fine particles should be opti-mized to increase the order of wearing, or in added line the measure of particle production. In counterpoint, when generating particles there is no concern for the appear act of the electrodes, exclusive the quality of the particles beingness produced. EDM state furnish settings that outcome in alright ascend finishes commonly

### Sudeep Kumar Singh and A. M. Mohanty

human low substance remotion rates. When producing particles if there is no worry for the ascend end of the electrodes, it may be feasible to display runty particles at a graduate supplying settings and check strategies than those of EDM. If an EDM tool were used to exhibit particles it would be catchy to modify the individual and powerfulness activity to mold if this is affirmable. By artful a machine specifically for the production of particles, both the controller and the power give can be intentional to make lycee property particles at a pinched valuate.

EDM machines also are quite pricey due to the more features that would not be misused in particle production. EDM machines unremarkably permit material filtration systems and nonconductor chillers. A particle creation tool may also expect a chiller and a dielectric filtration scheme, but the chiller and filtrate method in the EDM organization could not be utilised because they countenance metal-lic components that are uncongenial with the particles being produced. EDM machines also screw CNC controllers, additional axes of move controls, and opposite subsystems. These subsystems only add to the outgo of the EDM organization without any intercalary good with warmheartedness to particle creation. Because accommodate instrument be victimised as the electrodes in the pulsed wire process, a wire exploit mecha-nism would also somebody to be oint into an EDM organization to replace the collinear actuator victimised to try the electrode gap length. The store outlay of the EDM organisation, plus the equivalent of all the conductor components in the liquid scheme, limiting to the person and new message supply system give prove in a higher cost organisation than a tool fashioned specifically to display particles.

### ABSTRACT

CNC milling techniques used in precision engineering can produce a vast range of parts to high ends of precision. Unlike human hand, a computer numerically controlled machine will not make mistakes and any error in the machine itself will be picked up and an error code sent to the controller. Energy management truly becomes proactive when companies model, simulate and analyze energy as an economic variable in coordination with energy-compliance criteria and production requirements.

**Keywords:** CNC, milling, Energy

### INTRODUCTION

Ruixue Yin et al in the year 2018 worked on the idea of using process planning to reduce energy consumption and carbon footprint during manufacturing a mechanical part. Feature-based technology is used and the genetic algorithm applied to generate a process plan. A case study of process planning has been applied on shaft support, the results suggest 25% reduction of energy consumption and 19% reduction in carbon emissions compared with a process plan which minimizes cost. Tao peng et al in the year 2014 worked on energy efficient machining which leads to sustainable machining, it requires deep understanding along with optimization of energy consumption. Energy consumption is known as the core of energy efficient machining, has been segregated into 1. Theoretical 2. Empirical 3. Discrete event based 4. Hybrid models. Keeping eye on the literature of energy efficient machining domain, multiple notable findings are: Effective energy management, complete energy model and energy data integration which helps us to achieve machining systems.

Yingxin Ye et al in the year 2018 worked on an intelligent CNC controller, where a CNC controller with cloud knowledge support has the ability to do the process planning would definitely shorten the production cycle whereas it will also increase the life span of CNC machine tools. This Paper proposed for the realization of intelligent CNC controller in process planning which is based on cloud knowledge gives multiple advantages like infinite shortage of

24611

**Sudeep Kumar Singh et al.**

space for cloud knowledge, parallel processing ability, make process planning automatically, lower the design time of the workpiece.

S. G. Dambhare et al 2015 worked on sustainability concern in the turning process in an Indian machining industry, which has been modeled mathematically using the response surface methodology (RSM). Here, surface roughness, material removal rate and energy consumption which are likely under economic and environmental aspects were considered as sustainability factors. Taguchi analysis was performed to understand the ranking of factors affecting the response followed by the experiments conducted with varying conditions for speed feed, depth of cut, machining environment and cutting tool type to find out sustainability issues related to Economic and Environmental aspect in the form of surface roughness, material removal rate and power consumption were studied. IlhanAsiltürk et al 2011 worked on the optimizing turning parameters based on the Taguchi method to minimize surface roughness, for this experiment dry turning tests have been carried out on hardened AISI 4140 (51 HRC) with coated carbide cutting tools. To investigate the effects of cutting speed, feed rate and depth of cut on surface roughness statistical methods of signal-to-noise ratio (SNR) and the analysis of variance (ANOVA) are applied. After the experimental values on hand Variance analysis was applied to S/N ratios to discover interactions between cutting parameters Where we found the feed rate influences Ra and Rz at a reliability level of 95%.

Hua Zhang et al 2017 worked on to find an efficient solution to reduce the impact of the environment caused by energy consumption and to realize sustainable manufacturing. To minimize the energy consumption of machine tool, here the process parameters are optimized by the optimization model with the cutting specific energy consumption (CSEC) along with the processing time. Here the multi-objective optimization model was transformed into the single aim optimization model by introducing the subjective and aim comprehensive weights and solved by the quantum genetic algorithm. Congbo Li et al 2016 worked on complex optimization of cutting parameters with integrating Taguchi method, Response surface method (RSM) and Multi aim particle swarm optimization algorithm (MOPSO) keeping objectives of energy efficiency and processing time. Here in this study to acquire the optimal machining scheme for minimization of time and energy, cutting width should be as large as possible and the spindle speeds and feed per tooth should be at relatively high simultaneously. In this paper only electric consumption has been considered in machining where the result shows the enoys the use of sustainable optimization methods, with the multiple responses of energy saving and production efficiency. DanilYurievichPimenov et al 2018 focuses on the possibility to conserve power consumption, parts production with lower cost, manufacture without compromising surface quality and enhanced material removal rate. Evaluation of the tool life and tool flank wear and influences of sliding distance has been carried out on the overall machining performance. Multi-objective optimization result showed that we can choose the optimum parameters for improving the manufacturing efficiency and reduce the machining time using Gray Relational Analysis (GRA).

Congbo Li et al 2016 worked on a multi-objective parameter optimization method for energy efficiency in the CNC milling process. Here we have analyzed the temporal characteristics and energy consumption composition characteristics in CNC milling. By using the Tabu search algorithm we have solved, our optimization objectives are known as the highest energy efficiency and the minimum production time in the multi-aim optimization model. From the experiment we found the most influential parameters for specific energy consumption are cutting depth and width, while spindle speed is solely responsible for the production time. Yusuf Tansellc et al 2018 focuses on the optimization of machining factors in the turning process where aluminium alloys been used. Main factors such as carbon emission and surface quality are considered here. To get the optimized data, we performed a set of experiments using a Box-Behnken design and the response surface method to get the regression model for the carbon emission and surface roughness during the turning process. As per the study what we found is the depth of cut has the most significant effect on the surface roughness and workpiece material with lower hardness shows better surface quality. At the other hand we know if the depth of cut increasing the carbon emission shall also increase whereas increasing the cutting speed diminished carbon emission.

**Sudeep Kumar Singh et al.**

Guanghai Zhou et al 2018 worked on the method of cutting parameter optimization for machining operations where this study considers carbon emissions to balance cutting indexes in the part machining process. i.e., carbon emissions, cutting time and cutting costs. The variables are cutting speed, feed rate and depth of cut. Here in this study an efficient and easy method based on the c-PBOMW and c-PBOM-P is considered for testing carbon emissions according to the features of parts and capacity of workshops. Then, an algorithm named NG-NSGA-II is proposed to solve the multi-aim optimization model for machining operations. Now simulation in MATLAB has been performed which results show that the proposed method can be used to obtain the optimal solution effectively.

**Importance and Relevance of Milling**

The basic milling machine design include knee-type and ram-type milling machines. Knee-type machines are horizontal or vertical and are used frequently in CNC milling services. A ram-type machine is also known as a saddle machine. Keyway and slot milling machines are also a basic milling machine design, as are piano-milling machines. Engraving and form copying milling machines are also basic types of the machine that have been used for many decades, original machines being hand-controlled as opposed to CNC controlled. Thread and gear milling machines are also relatively popular. A knee-type milling machine design can be used with various attachments, meaning that this type of machine is used for a wide field of applications. Attachments that are commonly used are vertical and universal milling heads, rotary and universal indexing heads, and slot attachments. A knee-type machine used in CNC milling services will comprise three main units: the frame, the drive, and the control. The frame is made of the base plate, overarm, column, and counter bearings. The drive is made from the spindle and feed drives. Other special attachments can be added to the drive.

CNC milling techniques used in precision engineering can produce a vast range of parts to high ends of precision. Unlike human hand, a computer numerically controlled machine will not make mistakes and any error in the machine itself will be picked up and an error code sent to the controller. CNC milling is just one type of operation commonly used in precision engineering in today's modern world. Others include CNC turning and the use of multi-axis machines. The first CNC machines used only 2 axes, but the most modern machine of today can use up to 9 axes, for higher levels of precision and for making even the trickiest of CNC parts.

**Importance and Relevance of Optimization**

Energy management truly becomes proactive when companies model, simulate and analyze energy as an economic variable in coordination with energy-compliance criteria and production requirements. WAGES information gets codified on production bill of materials as an input, factored into strategies from product ideation to product delivery, and companies increase profitability and improve the total cost of ownership of operational assets. Modelling production leverages collected WAGES data and taps into production metrics, regulatory reports, and climate data. For example, firms model energy-cost data with production energy demands, and select optimal energy options at the optimal times during a day or shift: a spike in natural gas prices triggers an alert to rely on alternative energies or facility-generated power. Sophisticated control systems also can incorporate emissions data into modeling algorithms and direct production to use non-emissions-generating energy sources when emissions credits are nearly depleted.

Energy-usage data at a product or SKU level offers new opportunities to improve energy management, but that alone is like driving a car by looking in the rear-view mirror. That view shows where you've been but offers little help navigate what's ahead. A predictive dashboard provides visibility into conditions ahead and proactive strategies for managing production decisions every minute of every day. Imagine taking all historical energy data – per product per machine, per line, per facility and using it to model future facility behaviour. The captured what-is data enables what-if modelling perspectives.

Sudeep Kumar Singh *et al.*

### Importance and Relevance of Process parameters

1. Cutting speed is defined as the speed (usually in feet per minute) of a tool when it is cutting the work.
2. Feed rate is defined as a tool's distance traveled during one spindle revolution.
3. Feed rate and cutting speed determine the rate of material removal, power requirements, and surface finish.
4. Feed rate and cutting speed are mostly determined by the material that's being cut. In addition, the deepness of the cut size, and condition of the lathe, and rigidity of the lathe should still be considered.
5. Roughing cuts (0.01 in. to 0.03 in. depth of cut) for most aluminum alloys run at a feed rate of .005 inches per minute (IPM) to 0.02 IPM while finishing cuts (0.002 in. to 0.012 in. , depth of cut) run at 0.002 IPM to 0.004 IPM.
6. As the softness of the material decreases, the cutting speed increases. As the cutting tool material becomes stronger, the cutting speed increases.
7. Remember, for each thousandth depth of cut, the diameter of the stock is reduced by two thousandths.

### Importance of Surface Roughness

Surface finish, or surface roughness, is a measure of the texture of a surface. The term defines the vertical deviations of a measured surface from its ideal form. If these deviations are substantial, the surface is rough; if they are minor the surface is smooth. For many engineering applications, the finish on a surface can have a big effect on the performance and durability of parts. Rough surfaces generally wear more rapidly and have greater friction coefficients than smooth surfaces. Typically, roughness is a dependable predictor of mechanical part performance, as irregularities tend to form nucleation sites for breaks or corrosion. Conversely, roughness may encourage desired adhesion.

### Measuring Surface Roughness

There are a number of different measurement techniques that can be used to measure surface roughness. Different classes of measurement techniques include direct measurement methods, comparison methods, non-contact methods, and in-process methods. Direct methods test a surface finish through the use of a stylus which is drawn along the surface while perpendicular to the surface. The registered profile created by this process is then used to determine roughness parameters. This technique calls for the disruption of the machining process. A sharp stylus may also make micro-scratches on tested surfaces. To determine the surface finish with sound, an ultrasonic pulse is first sent to the surface, where the ultrasonic sound waves are altered and reflected back at the testing device. The reflected waves are then assessed to determine surface roughness parameters. Inductance is another on-process technique used to test surface roughness on magnetic materials. In this approach, an inductance pickup gauges the distances to the test surface using electromagnetic energy. This test provides a parametric value that can then be used to determine comparative roughness.

### Controlling Surface Finish

Often, the failure of an engineered part originates at the surface because of either an isolated manufacturing-related issue or gradual breakdown in surface quality. Therefore, finishing operations have been widely adopted as the ideal method for generating the desired surface finish on various machined and fabricated parts. Precise roughness is challenging and costly to control in manufacturing. Lowering the roughness of a surface will usually raise its manufacturing costs significantly. This results in a trade-off between the manufacturing cost of a part and its performance.

### Importance of Energy consumption

As energy consumption from 2000-2010 increased by 28% and worldwide industrial energy consumption is expected to increase by approximately 50% from 191 quadrillions Btu in 2008 to 288 quadrillion Btu in 2035, manufacturers need to develop an energy-management culture. One method is Rockwell Automation Industrial GreenPrint, a four-

**Sudeep Kumar Singh et al.**

stage process for progressively achieving improvements through existing and key new investments. In a recent report, Rockwell examined the state of industrial energy usage and assessed the readiness of industrial companies to take action to reduce consumption of WAGES (water, air, gas, electric, and steam).

**Energy Awareness**

The first stage is to establish a documented view of WAGES usage at a facility, production, and, eventually, product levels. The study found that many organizations lack the skills, technology, or incentives to monitor and evaluate energy usage at even a facility or site level. Without seeing and assessing facility energy-usage data, these firms are unlikely to reduce costs via improved energy consumption -- and even less likely to take the more analytical and beneficial steps of examining energy usage of equipment, lines, work areas, and by SKU. Energy awareness lays the cornerstone for ISO-50001 compliance, the framework for industrial plants, commercial facilities, and entire organizations to manage energy. The standard was published in June 2011, and ISO estimates it will have a positive impact on as much as 60% of the world's energy use. Yet many companies remain on the energy-management sidelines, their inability to grasp energy monitoring driven by a one-dimensional view that industrial energy consumption is an "unavoidable" cost of doing business, and so they:

**Energy Efficiency**

During this stage of the Industrial GreenPrint method, companies make incremental and proactive behavioral, control, and equipment improvements (e.g., devices to transmit energy data in real time). They automate their decision making (without management/employee intervention) to allow real-time production tradeoffs among customer demand, corporate objectives, and energy expenditures. They also implement forecasting, load aggregation, and rate analysis exercises, which allow them to coordinate internal production requirements and production schedules with external energy markets.

**Controlling Production**

Few facilities operate "lights out" (i.e., running with no human intervention), but thousands of plants rely heavily on automated equipment and processes. Many production environments couldn't exist any other way. Yet automation often requires equipment to follow strict scheduling and routines, with few changes to accommodate different parts or products. During a single shift, production modifications may only occur to resolve abnormal conditions that threaten product quality or plant safety (i.e., the equipment stops and maintenance intervenes). Now automation assumes a new critical role in improving operations, influencing not only safety and OEE (quality, yield, and uptime) but energy consumption. Making WAGES information visible via internal dashboards keeps managers and workforces focused on capturing further energy-management improvements and accrues significant cost, compliance, and performance benefits. But without regular measurements, reviews, and revisions -- systematic PDCA (plan, check, adjust) - efforts to continuously improve lose organizational benefit.

Visible and actionable WAGES data ensures a PDCA cycle that allows the workforce to constantly see and resolve issues. It's especially important to secure ongoing gains because improved management of energy consumption won't deliver sudden, substantial improvements. Energy management is a marathon, rather than a sprint, with savings measured in an hour-to-hour and day-to-day increments: When and why did a machine exceed typical energy draw? Why did an equipment changeover cause startup surges? Why did a component change extend the production cycle into a peak-draw period?

**Sudeep Kumar Singh et al.**

## CONCLUSION

Visibility is the only practical way to keep track of conditions (successes and failures) and to gauge the effectiveness of practices, processes, devices, and equipment in minimizing energy consumption. But unlike PDCA cycles based on human observation and intervention – involving managers and team members that perform the activities of plan, do, check, and adjust – the key to energy improvement lies within the streams of data running to, through, and from equipment. Process automation supercharges PDCA energy management. To make this happen, industrial technologies, such as variable-frequency drives (VFD) and servo and linear-motion devices, are necessary to transfer energy intelligence into energy-usage action. VFDs, as an alternative to fixed-speed controllers and throttling devices, improve operating performance, control capability, and energy savings by:

- Avoiding peak demand charges: Ramp motors up to speed gradually during times of peak demand.
- Optimizing power in relation to load: Use the precise (i.e., not excess) amount of energy required by the equipment to fulfill demand.
- Generating energy: Many VFDs can regenerate power, which can then be routed back to the system or sold to utilities.
- Optimizing performance: Intelligent motor controls integrate advanced networking and diagnostic capabilities to optimize performance, increase productivity, and reduce energy.

### ABSTRACT

Ultra-fine metal oxide particles are useful in several areas. Ultra-fine particles can be used as abrasives, paint and adhesive additives, and as feedstock for plasma spray arc coatings. Alu-minum oxide particles could be used as an abrasive material in place of garnet in water-et cutting applications. The same aluminum oxide particles could be used as an additive in paints to make them more wear resistant. Because some metal oxides are electrically conductive they could be used in paints and adhesives to make them electrically conductive. Iron oxide particles could be applied to a surface with the plasma spray arc process to create magnetic films [1, 2]. Undoubt-edly, more applications for these particles will be discovered as more ways are developed to create ultra-fine particles.

**Keywords:** Plasma, Arc, Development

### INTRODUCTION

Many of the applications require very small particles. For example, if particles are used as an additive in a paint, the particles would need to be small enough to not produce any significant texture in the applied painted surface. These particles would need to be 70 mm or smaller. Particles with a size under 70 mm are considered ultra-fine particles. In many applications the performance of the particles are greater if the particles are smaller. For example, some particles are transparent to some light ranges because they are smaller than the wavelength of light [3]. In prior work a plasma arc process has been used to create these ultra-fine particles. The plasma arc process has been used because it produces, for the most part, only particles in the ultra-fine particle size range. Up to this point there have been two variations of the plasma arc process used to produce the metal or metal oxide particles here at BYU. The first variation of the plasma arc process is a completely manual method where a human operator controls the process. This method has serious drawbacks in terms of product quality or consistency, production rates, and high labor costs. The manual process is very flexible in terms of size and shape of the electrodes used in the process because the

24619

### Sudeep Kumar Singh and A. M. Mohanty

human operator can easily adjust to these changes. This manual method has many disadvantages because it is controlled by a human. The rate of production and the quality of the particles produced is limited by the slow response time of the operator. The variation introduced into the system by a human operator could be greatly reduced if the operator was replaced by a feedback control system.

The second variation of the plasma arc process, the rod process, was developed in previous research at BYU by Chris Lewis. [4] The rod process uses metallic rod electrodes that are fed toward each other as the rods are eroded. The rod process greatly improved the state-of-the-art by replacing the human operator with a digital control system to close the feedback loop. In this way the production rate and product quality were both increased. The production rate was improved by several times over the manual process. These improvements to the process did not come without drawbacks. The rod process requires that the electrode used must be in the form of a one half inch diameter rod about 15 inches long. The dimensional tolerances and straightness of the rod required by the process are difficult to meet with the electrode materials used in the process. As a result, the cost of the electrode material in rod form is significantly more costly than when produced in other forms like wire.

Additionally, the rod process requires frequent operator adjustments to maintain consistent control of the process. These adjustments are required due to the way that the electrodes wear. The operator must frequently stop the process to remove and dress the ends of the electrodes. These maintenance issues are time consuming and labor intensive and also seriously limit the utilization of the process. The objective of this research is to improve upon previous variations of the process and develop a new plasma arc process that increases production rate, improves the particle quality, and requires limited operator intervention and maintenance. The focus of this thesis is the development of a new process that uses a pulsed power supply with a feedback control system to meet the current research objectives. A secondary goal is to develop a process that uses wire feedstock rather than rods.

#### Plasma Arc Process

The plasma arc process used for the production of ultra-fine particles has many similarities to other plasma arc processes such as plasma arc welding. Two electrodes are placed in close proximity to each other in a dielectric fluid. In all the experiments discussed in this research deionized water was used as the dielectric. A voltage difference is placed between the two electrodes, as seen in Figure 1.1(a), causing the two faces of the electrodes and the dielectric between them to act as a capacitor. This gap between the electrodes will continue to act as a capacitor until the electric field is strong enough to overcome the strength or resistance of the dielectric fluid. Equation (1) shows the breakdown voltage of a capacitor where  $V_{bd}$  is the breakdown voltage,  $E_{ds}$  is the strength of the dielectric material and  $d_{gap}$  is the distance between the plates.

$$V_{bd} = E_{ds} d_{gap} \quad (1)$$

This relationship shows that the breakdown voltage is proportional to the distance between the capacitor plates. This means that as the electrodes get closer together the voltage required for the dielectric to breakdown is reduced. The dielectric strength of the material is an intrinsic property of a material. The dielectric strength of a material decreases with an increase in temperature and frequency. The dielectric strength of deionized water is on the order of 20kV/mm [5]. Given that the power supplies used in this research have an open circuit voltage of 80V, the electrode gap distance for dielectric breakdown is on the order of 4 microns or 0.00015 inches. The plasma arc can be divided into five stages: pre-breakdown, breakdown, discharge, end of discharge and post-discharge. Chris Lewis' research focused on understanding the discharge stage of the process. During pre-breakdown, shown in Figure 1, a voltage difference is placed between the electrodes. The process will remain in the pre-breakdown stage until the strength of the electric field overcomes the dielectric strength of the gap. When the dielectric begins to breakdown it ionizes, in the result is a conductive path between the electrodes. Current begins to flow, creating a plasma arc between the electrodes through the conductive ion column. The creation of the arc begins the discharge stage of the process. While the arc is sustained, the heat of the arc causes material from both the cathode and the anode to melt and vaporize,

**Sudeep Kumar Singh and A. M. Mohanty**

then combines with the other material in the plasma channel. At some point, the conditions change and the arc cannot be sustained. The arc could become unstable because the electrode gap changed, the power supply was switched off, or the arc could switch to a different location on the electrode face. When the arc is broken, the end of discharge stage occurs. During the end of discharge stage the plasma channel implodes. The particles suspended in the ion cloud upon implosion combine and form particles containing material from the dielectric and the electrodes. In the case of this process, many of the resulting particles will be metal oxide particles that formed from oxygen atoms in the water and metal atoms from the electrodes.

Particles made completely from the electrode material will also be formed. During the discharge stage, the heat from the arc creates a molten pool of metal on the electrodes. The shock-wave from the implosion of the plasma column causes these pools of metal to be blown off the electrode into the dielectric fluid. During the final stage of the process, the particles are quickly cooled and removed from the electrode gap by the moving dielectric fluid. The particles formed from the molten pools of metal are more likely to be composed of the same composition as the electrode material because there is little time for the metal to oxidize prior to solidifying. This final Post-Discharge stage of the process.

The main difference between the variations of the process is how the electrodes and power supplies are manipulated to control the length of the discharge stage. In the manual process, the length of the discharge stage is dependent on how the operator moves the electrodes. This dependence on the operator for particle consistency requires that the operator maintains the same conditions every time the process is run. The operator introduces a large amount of variation into the process because human operators do not react to the same situation the same way every time. In addition, a human operator has a slow response time in comparison to many digital control systems. For the rod process, the length of the discharge stage is dependent on the motion control system and variations in flow of the dielectric fluid. Removing the human operator from the control loop greatly improves the product quality and production rate, however, there is still a large distribution of particle size. This is because there is no direct control on the length of the discharge time.

One of the main objectives of this research is to manipulate the power supply so that there is direct control of the length of the discharge stage. This research borrows technology from Electrical Discharge Machining, (EDM), to limit the length of the discharge stage. A control mechanism is implemented to turn the power supply off at a fixed time after the discharge stage starts. Limiting the time of the discharge stage limits the amount of energy in the discharge. It is hypothesized that the limited amount of energy in each discharge puts an upper limit on the volume of metal that can be melted, or vaporized. This limits the size of particles that can be produced and tightens the distribution of particle size that is produced. In any variation of the process, feedback controls must be used to maintain a constant distance between the electrodes. In the case of manual control, the operator uses his sense of sight and sound to roughly determine if the electrodes are too close together or too far apart. In the case of the automated processes, either arc voltage, arc current or both are measured and used in a feedback loop to maintain a continuous process.

**Process Design Challenges**

In addition to the control problems noted above the use of rod electrodes in the previous processes had led to many problems in terms of process down time, production rates, raw material cost, and maintenance costs. Most of these issues are related to the fact that the previous processes have required bearings and seals where the rods enter the dielectric filled reaction chamber. If the need for these bearings and seals could be eliminated, then the process down time and maintenance cost would be dramatically reduced. Seals were required in the rod process because the electrodes entered the reactor from the side below the water line. The seals were required to prevent the dielectric fluid from leaking out of the reactor. Bearings were required in the process to align the electrode with the seals. If the electrodes are not concentric with the seal, the seals will leak. Rods with fine surface finishes, high straightness and high tolerance diameters are required for the seals to function and to increase the life of the bearings. Rods with these properties are difficult to machine and therefore are expensive to purchase. If the need for the seals and bearings

**Sudeep Kumar Singh and A. M. Mohanty**

were eliminated then the cost of the electrodes, as well as maintenance of the process, would be greatly reduced. The downtime required for replacement of the seals and bearings would also be eliminated increasing the productivity of the process. The rod process also requires that the electrodes rotate to maintain a stable process. The rotation of the electrodes is what keeps the discharge from staying in one place on the electrode faces. If the process can be stabilized without using rotation, then many additional problems would be eliminated.

An additional problem in the rod process is the cathode growth rate. There is a large percentage of the metal that is eroded from the anode electrode that is deposited on the cathode electrode. Tests show that about 50% of the metal eroded from the anode electrode is deposited on the cathode electrode. This cathode growth both limits the particle production rate and causes the cathode electrode to increase in length. The random nature of the cathode growth also requires that the electrode be removed from the machine to remove the misshapen growth. Because the cathode electrode is constantly changing length and shape, the position of the cathode electrode must be controlled to stabilize the process.

**CONCLUSION**

Ideally, only one of the electrodes is consumable and the other electrode has zero growth or erosion. EDM machining processes show that it is possible, using a pulsed power supply, to nearly eliminate the rate of growth or erosion of one of the electrodes used in the process. It is hypothesized that the proposed new process would eliminate the need for bearings, seals, and maintenance problems that are present in the rod process in addition to eliminating the electrode growth problem. The proposed new pulsed process would use wire as the consumable electrode. Most of the metal materials that might be used in the process are most readily available in wire form. A large volume of metal can be wound on a spool providing enough feedstock for days or weeks without need for maintenance. If the tip of the wire electrode has buildup or any other problems the tip can simply be cut off. No high cost or time consuming maintenance will be needed for a consumable wire electrode.

### ABSTRACT

The activity of signaling parameters in connection processes has remained a crucial extend due to the energy-intensive activity of welding processes. Low paper impureness steel is the most widely welded touchable in the industry. The Practice Tinny Arc Welding (MMAW) of gentle steel is most well-known among all welding procedures, as it offers a low-cost medicine, finds wide use in structural create, restoration & maintenance. The flowing reflect focuses on selecting eligible MMAW parameters for welding clement poise, attractive into consideration noesis and common calibre as the determinant factors. The experiments conducted were fashioned using Minitab 18 software. The transverse tensile magnitude, conunct hardness and the impact vigor of the combined analyzer. Staged Neural Meshing is utilized for training the textile using information acquired from the experiments carried out. The regression helper was applied in Matlab R2019a to resolve the relationship between the signal and lead variables to greatly support predict the perfect mix of oint input parameters.

**Keywords:** Arc Welding; Mild Steel; Artificial Neural Network; Taguchi; Energy consumption.

### INTRODUCTION

Shielded Metal Arc Welding (SMAW) of Temperate Brace (MS) finds schoolwide coating in structural frames, pipelines, visually artistic designs, and ameliorate due to its richly ductility and weldability properties [1, 2, 3]. Welding relic the most widely adoptive connexion transmute in the manufacture despite its shrilling energy-intensive conception. The option of prim welding parameters is rattling historic in a multi-input multi-output enation similar welding [4, 5]. The mechanistic properties of welded oints mostly depend on treat parameters old in the manufacturing walk [6]. The welder mostly focuses on the grade aspects of the produced oints and pays lesser work to the umbo impact on the resources exhausted same cigarette calibre, pct of rework/reection, and life

**Sudeep Kumar Singh and A. M. Mohanty**

exhausted [7]. Nation consumption is one among umpteen factors trusty for the perverse environmental personalty generated from welding procedure, nurture the essential for characterization of the SMAW affect considering sustainability aspects [3, 8]. Thusly the interpret document intends to line a relationship between the foursome powerful sign parameters and the four product parameters.

**Literature Survey**

Adnan et al. [4] carried out Economist Analysis to maturate uncorrectable sign parameters of the GMAW welding cognition. They mature three contrary ANN models for signaling, outturn parameter prediction and classifying products. ANN was also employed for work the effects of deliver parameters in laser welding of AA5754 aluminium devalue [9]. Two parameters welding speed and shielding gas were heterogeneous, and the optimization enation was implemented using an Excel add-in named Neuronic Tools. In yet another thoughtfulness, authors formed two assorted ANN models one for sorting of imperfect products and others for prevision of input parameters [5]. Welding processes change a short environmental someone for which improvement of key welding parameters is rattling portion of analyze [8]. Flow, emf and welding motion are considered for analysis. Welding of dissimilar metals involving Al impureness and unblemished steel has been premeditated using the laser-arc welding skillfulness [10]. Taguchi is utilised for studying the opinion of varied welding parameters to get optimum parameters of tricuspidate form in SMAW [11]. TIG welding parameter has been optimized using greeting ascend methodology (RSM), centric flower organization on gentle poise [12], and organisation wildcat optimizer [13] on commanding posture low mixture 15CDV6 steel. RSM has also been adoptive for optimizing GMAW parameters for welding Gentle Brace IS:2062 [14]. Authors [15] bed shell welding using Resistance Strike Welding. RPLNN and GA individual been used involving ternion inputs and two salutation parameters.

Reseda quality considering tensile properties and microstructure were analyzed supported on land arrangement using an arc assisted trait laser welding of Al-Mg devalue [16]. Tensile and combat properties in multi-pass SMAW human been investigated by Saxena et al. for determining the persuade of welding consumables in Armox 500T impureness [17]. Mechanical properties and microstructure of MS welded parts under varied afoot were analyzed using the E7016 electrode [1]. The maximal tensile power was obtained at 75A with nonaged welding defects. Sheets of assorted thicknesses welded using SMAW and GMAW were investigated for udgment a new set of welding parameters for structural mark steel welding [6]. The main aim of the rife explore utilize is to learning the influence of varying signaling parameters on the signaling lineament of the clannish. The arrangement of the paper is as follows. The experimental methodology is explained in section 3. The next section discusses the outcomes of the experimental and test results. The fifth section discusses the application of ANN for welding parameter selection. The sixth section presents conclusions obtained from the analysis and also provides directions for future scope.

**METHODOLOGY**

The strategy followed in the current work can be divided into different sections of which, arc welding, testing for obtaining output data, and selection of input parameters to the welding process based on influential responses of welding are important. Arc welding of Mild Steel considering energy consumption has been considered in the present investigation. The strategy followed in the current investigation is presented pictorially in figure no 1. Mild steel plates of different thicknesses 3mm, 5mm, and 10mm (three levels) were utilized in the welding process. The welding parameters, current, oint gap, and face width were also varied during the experiment. The input parameters considered in the investigation include the welding parameters and the plate thicknesses. The output parameters considered are Ultimate Tensile Strength (UTS), impact energy (Izod), Rockwell hardness, and energy consumption. The input parameters (factors) involved in the study are presented in table no 1.

Mild steel procured in flat form was first cut to a rectangular shape with length 200 mm and width 100 mm. One longitudinal edge of each plate was beveled to produce a double V-groove butt oint. The including angle of the V-

**Sudeep Kumar Singh and A. M. Mohanty**

shaped joint is 60° for all the plates used. The chemical composition of the plates was tested using XRF spectrometer, and the obtained values are tabulated in table no 2. The data presented in the table displays close conformance in terms of composition for both the workpiece and filler metals. The filler rod used in the welding process is 3.15 mm in diameter Superweld E6013 manufactured by ESAB. The XRF samples for both material types were prepared by grinding on a surface grinder. The plates were cleaned properly using solvent to remove all dirt, rust present on the surface of the material to be welded. It is followed by welding the plates using process parameters obtained from TAGUCHI orthogonal array design presented in table no 3.

**The Welding Process**

Similar to the raw material of three different thickness values, the input current has also been varied into the same number of current values and adopted for the experiments; 100, 110, and 120 amperes. The remaining two input variables adopted are root gap and face width. Three different values were considered for both the variables as 0, 1 and 2mm. All the varying parameters are taken together, including the plate thickness values, makes the total number of factors involved in the experimental design as four. The number of levels for each factor is three. Thus if the full factorial design of experiments were to be considered, the total number of experiments would become 27. To reduce the number of experiments, Taguchi Design of Experiment (DoE) method was adopted. Using L9 Taguchi orthogonal array design adopting a four-factor and three-level experimental approach, the total number of experimental runs were reduced to 9. The experimental design adopted for the experiments is presented in table no 3. The welding process was carried out by using RS400 a Thyristorised MMA welding machine manufactured by ESAB India Ltd. The machine is equipped with 50 Hz 3-phase power supply with an input voltage of 415 volts and 27-ampere current. The welding runs were carried out using the AC power supply.

A 3-phase power analyser, model no DPATT-3Bi, manufactured by Uma Electronics Enterprises, aipur India, was used for measuring the instantaneous power consumption values during the arc welding process. A three-phase four-wire connection was used in the process of measurement. Table no 3 presents the four factors and the values of the three levels of process parameters adopted in the experimental runs. It displays the values of different process parameters used in the welding process. Four different parameters; welding current, plate thickness, root gap, and face width are used for designing nine number of experiments in total. The welding speed was considered constant throughout the experiment. The plates of 3 mm thickness were welded using a single pass of welding, but multiple runs were necessary for plates with 5 mm and 10 mm thickness. The former was welded with two passes, and for the later three number of welding, passes were used. In total, nine number of welding joints were produced and processed further for preparing test samples for tensile, Rockwell and Izod impact tests to be conducted further. The details of the test procedure and results have been explained in the next section.

**Post-weld Testing**

The welded steel plates were cleaned to remove the slag deposited during welding by using a chipping hammer and wire brush. Tensile, hardness, and Izod test specimens were extracted from the welded plates of different thicknesses with the respective dimensions, presented in figure-2.

**Welding beads were removed by grinding operation from the welded surface for both the tests.**

The tensile test was conducted on a Universal Testing machine manufactured by Blue Star Engineering & Electronics Ltd., having a maximum capacity of 1000kN. The test specimens were made to undergo the tensile testing procedure, and the Ultimate Tensile Strength values for each test specimen were noted. The average value of HRB was calculated after measuring hardness values at two different points on the weld bead surface. The samples prepared for the Izod test were carried out using Impact test machine and values of energy absorbed before failure for individual specimen were recorded. The values of UTS, HRB, and Energy absorbed has been presented in table no. 3 under respective columns.

**Sudeep Kumar Singh and A. M. Mohanty**

Figure no. 3 displays phases of sample preparation for different tests after conducting the tensile, Rockwell, and Izod tests. The figure nos. 4 (a) displays the Impact testing machine, and 4 (b) depicts the Rockwell hardness testing machine used for the experimentation.

**Parameter selection using ANN**

Neural networks find a wide application and recognized as efficient solvers of non-linear problems. Successful applications have been reported in literature containing real-world problems. Thus ANN has been selected for finding optimum input parameters for SMAW in the present study. The architecture for the employed neural net is presented in figure no 5. An Artificial Neural Network was modeled for training using the data collected from the conducted experiments. The Bayesian Regularization backpropagation method is used for the construction of the network. This method is generally used for difficult, small, and noisy datasets.

In the current construction, the data set is small and prone to noise in the measured value; thus, the application of Bayesian Regularization fits our requirement. 'trainbr' learning function is used in the Matlab R2019a platform. The network takes 70% of data for training, 15% for validation, and 15% for testing. The ANN model developed in this study involves an input layer, one hidden layer, and one output layer. The input layer consists of 4 neurons; each neuron corresponding to individual input parameters and the output layer containing 4 neurons, representing one output parameter each. The hidden layer employs 50 neurons. The most promising network architecture is based on the trial and error method for which many trials have been conducted to arrive at the best combination. The performance of the network has been discussed in detail in the conclusion section.

**CONCLUSION**

The new energy involves quadruplet input and tetrad sign variables for SMAW welding of structural ablaut mild brace. The lineament of the welding has been tried by measure UTS of the welded cooperative by applying concern in the thwartwise itinerary, activity the touch energy intent by the conoint before nonstarter, hardness on the beadwork appear, and also the land exhausted for associated thinking. The sign and signal were fed into an ANN meshing fitly fashioned for the purport. The shapely system is susceptible of selecting all the foursome parameters similar liveliness exhausted, UTS hardness, and effect vitality. This create can be outstretched to opposite welding methods. Else polar variables not reasoned in the tell work may be wise as futurity search cro.

### ABSTRACT

This paper presents a new method for free machine aided AQ1 to deliver provision (A-CAPP) in a trenchant manufacturing system, in which the correlate signaling and production of the system are discussed on the cornerstone of comparative psychotherapy of traditional CAPP. The crucial serviceable components of the A-CAPP method, specified as event scheduling direction, manufacturing operation preparation, process/step thinking, denotative test machining announcement provision, operation model and evaluation, are introduced; and the methods of treat knowledge direction, including appendage pic noesis, manufacturing resource knowledge and affect the creation pipe reminiscence dynamically; shorten the instance of creation communication constellation change in accordance with customers' duty transfer or industry duty modification, and further more to arrangement the production lines incumbrance.

**Keywords:** Process autonomous planning, Intelligent manufacturing system, Event scheduling, Manufacturing process knowledge management.

### INTRODUCTION

An born manufacturing method is a colonial system, which involves the technologies of unskilled system, industrialized software, staged information, collection precaution and others. After Deutschland launched the "industry 4.0 normalisation roadmap" in 2014, the Coalesced States, apan, the Consolidated Field and Crockery somebody also formulated their federal hurting manufacturing strategies. Consequently, sophisticated manufacturing profession has become a search spot of front manufacturing profession.

Sudeep Kumar Singh *et al.*

CAPP (Computer Aided Transform Provision) is one benevolent of critical industrial software in innate manufacturing method. It plays an alpha portrayal as tie between ornamentation and manufacturing, which determines the manufacturing operation, processing noesis order, required resources etc. [1-6]. Resources refers to the equipment, organization tools, transmute equipment (e.g., cutter, fixture, cypher, help contraption etc.) necessary in creation. According to the requirements, CAPP intrigue needs to delineate (or check) the required manufacturing resources for apiece transmute surgery, and then connect the germane the subect documents with the resources, much as cogitate NC/CNC programs for the elect organization tools and programmed PLC programs for the pistol equipment (specified as robots) etc.

In the tralatitious CAPP method, manufacturing experts misused experimental noesis to determine activity cerebation problems and precooked appendage study documents to orient downstream production manufacturing [7, 8]. The thinking cognition for field documents accounts for at slightest 40% to 60% of the instance utilised in the entire production impact. Currently, machine aided system (CAD), machine aided affect cerebation (CAPP) and manufacturing (CAM) [1, 9] tally turn necessary developed software in the process of fashionable quantity plan and manufacturing.

## CAPP Development and Study Motivation

### The State of the Art

At existing, the R&D in outgrowth thinking and creation connector reminiscence are mainly promoted by PTC, DASSAULT, Technologist and other starring companies. In gain, IBM, TOYOTA, FANUC and SAP also put assuming several of germane research and process plans freshly. In status of CAPP, various commercialized CAPP systems hump emerged one after another. This has arranged a dry education for the integrating of production decoration, noesis preparation and production.

PTC has mature a program, MPMLink [14]. Using the systems, enterprises can effectively proof their manufacturing operation direction via the papers, i.e., quantity use, creation operation and manufacturing ingenuity aggregation of full enterprises can all be unified managed finished the scheme. DASSAULT has mature the DELMIA [15] digital manufacturing statement, which is supported on unlawful software structure and provides a unified quantity system, noesis thought, and imagination portfolio copy (PPR) that companies can use to continuously compile and confirm quantity processes throughout the fluid processing deliver. Tho' this adps can tight combine the noesis thinking and product ornament, it noneffervescent designing, outgrowth mentation and production. Engineer has formed Technologist PLM Software [16], which can concealing product ornament, creation intellection, production engineering, creation and employment of cardinal repeated process of industrialized mercantilism walk; then fraction them into: Design, Effectuation and Exercise of leash parts. The method is premeditated to aid companies to compute the creation tune generation and evolution of creation and processing and perfect the iii levels of difference of the route in many extent. However, the uncommunicative, and it relic to be far optimized.

The favourite home CAPP systems in Prc are KM CAPP, TIANHE CAPP and INYE CAPP, among which KM CAPP is conspicuous and it has been successfully practical in more than 8,000 companies with hundreds of custom operable modules. Yet, the required signal accumulation of manufacturing resources by CAPP systems were adynamic or past. In added language, data has a bigger case hold and is noneffervescentfar departed from real-time acquisition of creation collection. It may perchance be due to the fact that the conceived enation writing is irrelevant for actual creation, especially when scam production cycles are used. Presently, the search and usage of independent CAPP system that can option in giving with the activity changes is almost non-existent.

Sudeep Kumar Singh *et al.*

### Study Act

Growth mentation is the canonical process of transforming fluid ornament scheme (specified as CAD display) into elaborated technical documents to pass production, that is, how to launch the same manufacturing affect documents under the donated conditions of manufacturing resources and put them into the calculation site/workshop to inform production. In this treat, enterprises can shorten the bringing experience to marketplace by using telling CAPP schemes [10]. In addition, it can be utilized to settle basic problems much as part/component toll check, creation preparation and creation efficiency. With the amount of the identify, and this status has attracted more work than ever before.

The signaling of the CAPP mainly comes from CAD simulate and the manufacturing resources of workplace [4, 5]. It includes: (a) machining features; (b) geometric dimensions and tolerances of machining features (GD&T); (c) materials of the object to be treated; (d) aboveground corrodng of machining features; and nonCAD modeling assemblage, i.e. (e) the processing susceptibleness of the workshop, specified as figure of machine tools, equipment, operators, etc. CAPP can refrain to production the appendage way according to activity noesis by accurately analyzing and evaluating the input assemblage. The terminal product writ counsel includes: (a) the selected transform route; (b) defining the processing action steps and the list of each procedure stair; (c) option of ride and reason the machining ride to be complete; (g) estimating the manufacturing minute and toll of parts. Although numerous studies know been carried out on automated CAPP, the prevailing CAPP application is console thoughtful to be incomplete due to the multidisciplinary characteristics and complexity of process thought [1]. And most of the actual investigate is convergent on how machine aid in growth papers generation, kinda than autonomous multiplication noesis intrigue.

A noteworthy dimension of trenchant manufacturing is to reenforcement general customization at an efficient value. When the production blood resources are different, or the market feedback exact changes, or the someone letter to change the orders, etc., the thinking manufacturing grouping can start manufacturing touch autonomously mentation finished MES (Manufacturing Process Group), and A-CAPP module consume sustain the results to MES, and then substantiate the RMS (Reconfiguration Manufacturing Method). Thus, A-CAPP is the driving forcefulness to pipe via plan, and RMS is the factual implementer to substantiate RMS [11-13]. A-CAPP and RMS decisive parts of the alert manufacturing group work with MES to staring the smart adustment of creation pedigree resources. This production hence contributes to the field with the aim to explore method of A-CAPP system processing based on the acquisition industrialised software, and then cater a possible recommendation foul root for the material investigate

### Technology to Build A-CAPP System

The tralatitious manufacturing activity mentation is distributed from the real-time data of the creation stock due to the technologies' regulation. In the walk thinking plot, the resources collection of the production piping, e.g., organization tools, equipment, opening tools and mensuration tools, were disturbance or historical substance, which may be incompatible with the actualised ingenuity part of the creation conductor. Once the deliver papers is released to work, it leave direct production as a programmatic credit, and the workplace moldiness obey with. When there is a falsehood between the walk design and the connector ability is not counterbalanced and the bottleneck ingenuity is earnestly blocked, it gift touch the actualised production. When it happens, the free operation credit needs to be re-planned by the knowledge engineers by pursuing a growth modify advancement. It not only takes term, but also may touch the process availability after the re-planning due to the slashing changes of the literal utilization of production resources.

A-CAPP cannot only autonomously design new impact program, but also unite the real-time data of work production connector ingenuity use. Among the knowledge direction, MES module feedback the helpful message to A-CAPP, which greatly improves the usability of the outgrowth schemes. In increase, it takes advantages of manufacturing noesisnoesis library, A-CAPP can autonomously and effectively program the cognition sequences, defines the cognition calculation manoeuvre tasks, configures the required tools, fixtures, gauges and otherwise

**Sudeep Kumar Singh et al.**

activity equipment for each activity stair. This way, it helps to generate true position of the work manufacturing resources and can optimize reconfiguration overheads.

### **Redefining Input for A-CAPP**

Compared with the traditional CAPP, its input should be redefined properly. Ideally, it mainly comes from three sources as described in below.

- (1) Firstly, it should come from MES (Manufacturing Execution System). MES can access the real-time data of production line resources, and know whether there has been a problem of uneven load of machine tools/equipment, and whether there are symptoms of task queue blocking of bottleneck resources through the CPS (cyberphysical System) and DNC (Distributed Numerical Control) System. Also MES can get the prediction information through the Business Intelligence Module through which it can predict possible adverse condition of the production line resources. When production line resources develop faults and the MES cannot adjust it via the internal job scheduling module (e.g., to balance the tasks among the machines with different NC/CNC system), a process engineer is required to modify the pre-planned process document with the real-time data of manufacturing resources, e.g., modify process sequence, change machine tool, re-design process equipment etc. When this happens, MES can automatically trigger request and send message to A-CAPP; it will handle it autonomously. Because time is critical (every hour costs money) in a fault condition and autonomous manufacturing process re-planning makes it faster/cheaper.
- (2) Second source input is the CPS. It collects the real-time operation data of the manufacturing resource, i.e., machine tools, equipment, robot etc., through sensor network. The data will be actively pushed to MES. MES will analyze/predict the possible abnormalities of production line resources use through the job scheduling module and manufacturing resource management module. At the same time, CPS also pushes the real-time resource data to the A-CAPP system, which is useful for relevant processes/operation steps modification. It helps to make feasible and rational modifications to the related process plans.
- (3) A third source is the process knowledge management component. In the daily operation of A-CAPP, the extracted processing features, machining methods, cutting tools, fixtures, measuring tools etc., will be collected as process knowledge and stored in the process knowledge library by means of data analysis methods (e.g., clustering, classification etc.). In the late new process planning or modifying the released process plan/document, A-CAPP can deduce new process routes, operation steps, defining machine tools and equipment, tools, CNC machining programs and other information for each operation step in accordance with the processing features of the new specific mechanical part, where it will be supported in auxiliary decision-making manner by the process knowledge library. The proposed process plan set will contain multiple feasible schemes which need to be evaluated and one selected as the most feasible scheme to workshop by a process engineer. The notification can be in e-mail, SMS etc., manner sent to engineer by A-CAPP. For the changed NC/CNC machining program, manual intervention is required, and it can only be released after an offline simulation by the process engineer. After all the changed process routes, operation steps, NC/CNC program are evaluated, the workflow component of A-CAPP system will distribute the documents to MES system. The MES receives the new process scheme (process document, NC program, process equipment design model etc.) from A-CAPP; it will deliver and dispatch them automatically to the target machines (e.g., machine tools) by DNC and other related systems.

Event manager (EM) component. It is the core component in A-CAPP implementation for autonomous planning. It is responsible for sending the start process planning command (including planning new process and modifying the release process schemes), including terminating, completing commands. For example, when the A-CAPP receives the request message with a permanent event ID (e.g., ID\_ReqNumber) from MES, the A-CAPP will trigger a processing flow for the process planning. It will verify firstly through component 7 and judge whether if the request is a valid new activity. If so, the A-CAPP will handle it immediately (otherwise ignores it). When the request is confirmed to be

**Sudeep Kumar Singh et al.**

processing, it will send a request message to component 7, which generates a new task ID\_TaskNumber in line with the ID\_ReqNumber. And then A-CAPP marks the activity of ID\_ReqNumber as locked. It can be unlocked until the ob is completed or terminated. When the A-CAPP needs to release the process document to MES, EM will send an event message of transaction request to MES by component 7.

- (1) Process flow sheet planning (PFSP) component. PFSP is a designed to make an outline scheme, which determines the process of machining, and the corresponding manufacturing resources (workstations, machine tools, equipment, type of work, etc.). It is from the overall view to describe the technical route of the part being processed. On one hand, PFSP recommends multiple process schemes based on CAD model of machining features and corresponding process knowledge; on the other hand, the proposed process schemes will comprehensively consider the factors of the real-time data of the production load, the available manufacturing resources and their processing capacity which provided by MES/DNC/CPS. In some situations, PFSP even can plan the outsourcing tasks of those the overload or overcapacity machining obs ahead by means of the SPC data of the production lines, and then to adjust the proposed process schemes timely. As a result, the generated process document by PFSP contains a set of schemes, which can provide multiple feasible alternatives to workshop through manufacturing resource configuring.
- (2) Operation step sheet planning component. A-CAPP is similar to traditional CAPP in operation step planning (or operation step sheet), i.e., each operation step ob should be refined after the main process route is determined. First of all, it will define the items for each step that includes machining sequences and contents (geometric surfaces etc.), cutting parameters (e.g., spindle speed, cutting depth, and feed of pre revolution), the required machine tool, cutting tool, ig, measuring tools, and developing NC/CNC machining program according to the extracted information from CAD model (i.e., processing dimensional, tolerance, surface roughness etc.). Then to design the related cutters for operation steps in terms of the operation step sheet file.

However, the difference with the traditional CAPP is that A-CAPP develops the operation step sheet using real-time data of the production line and manufacturing resources use, for example to guide optimal resource scheduling. In the intelligent manufacturing system, A-CAPP will autonomously start modification to the released process document when the workshop organizes production accordingly but may meet problems in manufacturing resources use. MES can help to find the potential problems in resources use via CPS and DNC. When it happens, MES will work with A-CAPP to handle it accordingly in the three main way as follows:

- a) Modifying the released machining program. MES will send a request of adjusting the released process document to A-CAPP when some abnormal in manufacturing resources use are met. If the request is limited in machine tools change with different NC/CNC (Numerical Control/Computer Numerical Control) system for a specific operation step, the related machining program (G codes) should be autonomously revised. For the modification part of machining program, it is mainly concerned with the pre-and-post processing codes due to the different requirement by varied NC/CNC systems. However, the main part of machining codes (e.g., cutting path etc.) do not need to be modified. This also is highly frequent adjustment case that occurs in ob scheduling.
- b) Modifying the released process flow sheet document. When the MES cannot solve the resources use problem by simple change machine tools, it has to modify the machining sequence (machining process route) in terms of the real-time load data of production lines. In this case, the PFSP will be triggered by A-CAPP autonomously. The PFSP will respond and handle it when receives the change request event message from EM. This is a more complicated process that will affect the related operation step sheets file.
- c) Modifying the equipment, machine tools and the other resources. When workshop encounters abnormal situation in use of equipment defined by the released process document for execution the operation step found by the MES, e.g., the planned cutters, fixtures, gauges etc. are not available, A-CAPP will be involved to fix it in terms of the real-time data of the workshop's equipment provided by MES/CPS. It will provide a few recommended

**Sudeep Kumar Singh et al.**

change schemes (e.g., a list of the specific process equipment) for the process engineer to decide which is most suitable by using the process equipment knowledge database.

- (3) NC machining program planner component. The NC program is the control program stored in the numerical control system. It consists of numbers, words and symbols to form the machine/equipment motion control instructions, which include parameters such as cutting tool coordinate, angle and speed etc. The popular NC/CNC systems include apanese products, e.g., FANUC (such as 16i/18i/21i), Mitsubishi (M700V, E68, etc.), MAZAK; German products, e.g., Siemens of Germany (SINUMERIK series), Heidenhain (iTNC 530), Bosch Rexroth, French Schneider (NUM1020/1040, etc.), Spanish FAGOR, Chinese Huazhong Numeral Control, etc. Different numerical control systems need different initial codes to pre-define the parameters of the systems, in order to meet the initial requirements of the coordinate system, cutting parameters and the others of the NC/CNC system. When the modified machining program only is made due to the change of NC/CNC system, the corresponding processing of the change (i.e., pre-and-post processing of NC/CNC program) can be automatically processed by dedicated software kit, and then published to workshop after engineer evaluation. The other functions of NC/CNC machine program planner component are in line with the current CAM software.
- (4) Process simulation and validation component. It uses computer graphics technology and dynamic programming to predict if the planned cutting path is feasible, e.g., generation free collision moving path among the designed cutter, the fixtures to hold/clamp the machining part and the other related items; and also no undercutting/overcutting situations occurring in terms of the comparison between the original CAD and the simulation result in advance. Process simulation functions can be realized in A-CAPP by adopting Add-In or other programming methods to integrate the third parties products of CAM simulation/verification (e.g., UG, VERICUT, Pro/E, MasterCAM, CATIA, Cimatron, EdgeCAM, CAXA, etc.), or developing CAM simulation functions. The functions of process simulation and verification are important; it belongs to the final evaluation phase before the generated process documents are released to workshop. Thus, it needs the process engineers' verification. Depending on the devices, fully automatic deployment may not be safe
- (5) Process document manager component. Theoretically, the functions of process document/file manager are the part of PDM (Product Data Management). It realizes the management routines of process files version, configuration scheme, workflow (such as the flows of evaluation/audit and technical document change etc.) by associating the process document/files through the design document. Since this is concerned with releasing process documents and involving the other important technical activities, the management of the manufacturing process documents requires the intervention of the process engineers, and the process is not fully automated. Regarding the specific functions development, it can be achieved by extending the traditional PDM (Product Data Management) system and integrating the core components of A-CAPP system, such as the Event Manger (EM) component and the process knowledge library components etc.

#### **Knowledge Management Component of A-CAPP**

A-CAPP can establish a reliable process knowledge library by using the knowledge of machining feature classification, manufacturing resources, machining methods (i.e., fusion of the manufacturing process and the resources). It will support autonomous planning of machining process, operation steps and developing the NC machining program, by which it can improve the overall performance of the manufacturing system, change the traditional CAPP use mode and realize the manufacturing process planning autonomously. The knowledge management component functions of A-CAPP consist of the followings. Machining feature knowledge management. This has a number of aspects. Firstly, machining feature knowledge management needs to define meta-machining features and combination methods; further more to map them with common machining features, and gradually establish the classification model of the machining features

- (1) required by enterprises. Secondly, it needs to establish the mechanism of the manufacturing process information expression based on MBD (Model-based Definition), which is useful to build the association relation between the B-rep's (Boundary Representative) geometrical & topological information of the elementary geometric obects

### Sudeep Kumar Singh *et al.*

(i.e., point, line, face of the CAD Model) and the engineering properties of the CAD model such as dimensional, tolerance, surface roughness, and the other technical requirements. The mixed expression (e.g., object-oriented semi-structured XML data format files) can be used to express the correlation model which reflects the mapping relation between the geometric features and the manufacturing features. The geometric feature recognition and machining feature mapping of the part model can be completed automatically by using the established correlation model and the results can be used as the input information of the machining features for A-CAPP.

- (2) Knowledge management of machining resources. It is mainly about the information of the production line (including machine tools, equipment, robot etc.) and process equipment (such as cutting tools, fixtures, measuring tools, etc.) in the workshop, which is managed by the model of process resources. The model should have the ability to describe the resources in both static and dynamic ways that can reflect the production line, machine tool, equipment etc., from the physical structure, geometric aspect, function, information and control system of the resources. Then A-CAPP will use the information to evaluate the manufacturability of products or judge the applicable scope of the production line or equipment. The process resource model can not only support intelligent reasoning in process planning, and judge the relevance among the objects such as process features, manufacturing resources, and machining methods, but also can be used to support the effectiveness analysis of process procedures.
- (3) Machining process knowledge management. The machining method selection of typical process features is to judge the similarity between the current processing object and the features in the feature database by searching the pre-defined feature database, and then extract the process knowledge items with high similarity as the basic process (or template) to establish the current part process in an automatic or semi-automatic way. The similarity machining process analysis is realized by the clustering learning model. It needs to define the coding rules of the entire feature vector by establishing the mapping relationship between the machining process features and process plan, and then to use the learning algorithm based on the auxiliary domain data learning and fusion algorithm based on the matching model. Also, it needs to access the quality assurance data of the machining products and the running data of the machine tools, equipment, robot etc., and the process parameters, which achieved by means of combining the actual information of the machining process features from MES with analysis result of the processing sequence, the clamping way, machining range constraint etc., plus introduction of the association rules in the learning process similarity model. Finally, it can improve the reliability of machining process similarity study performance and realize the continuous optimization for the machining parameters of the knowledge library.
- (4) Process knowledge maintenance. The production process knowledge fusion model is established by means of projecting the basic information of the CAD model (e.g., geometric features, process features) and the processing resources, process parameters into the same semantic shared subspace; and then completing the data mining tasks such as association and clustering. The knowledge management component establish the relationship between the process parameters and the quality of products, equipment status data from MES, through the association data mining via the improved a priori big data association rules algorithm. Finally, it can continuously improve the effectiveness of the planned processes of parts in an autonomous way. In the process of knowledge mining, A-CAPP system need to safely share the related data across time, region, physical space and network space through the whole process of non-destructive transmission of important process data and its fusion information in encryption, compression, transmission, reception and analysis.

## CONCLUSIONS

Traditional CAPP is practical in a relatively autarkic field mentation stage. Tho' it can be oint with collaborative plan to any extent, it soothe occurs solely in the cognition of specialized provision phase and does not leafage with the factual creation period. Moreover, it victimized the outdated and impractical creation data in static/historical manner, which lacks the improvement for the manufacturing cognition schemes and treat parameters via the genuine creation quality accumulation. A-CAPP can settle or treat it by extending and processing whatever

**Sudeep Kumar Singh et al.**

determining components, e.g., the event manager and growth knowledge repository and the others, supported on the heritages. The independent operation thinking usefulness can work in an integrative surround among PDM/MES/DNC/CPS in automatic and semi-automatic distance. For the primal obs of A-CAPP, e.g., appraisal and critique if a manufacturing cognition counsel is feasible and whether if it can be free to work etc., someone engagement is needed. The dimension and the feasibility of the outgrowth schemes designed by A-CAPP module be higher than before.

In an model innate manufacturing group, A-CAPP is fit to free bottleneck resources constraints, placement the loads of the creation lines and meliorate the corresponding productivity of the object manufacturing method by using the real-time creation ancestry data provided by MES. In element, the relation between set caliber and outgrowth parameters can be secure and the fluid dimension can be continuously optimized. Hence, the manufacturing group with autonomous growth provision knowledge is competent to cater the needs of weensy deal creation and personalized accumulation customization; and it is also the instruction of the approaching touch for this contrive will mainly direction on two aspects: one is to use the planned method of A-CAPP based on KMCAPP, matured by KMSOFT and practical widely in Prc, to base a paradigm scheme which can realize the origination integrating with MES; the opposite panorama is to deliver out explore on impulsive recall bailiwick of creation differentiation, integrate the prototype A-CAPP scheme with production demarcation constellation management group, substantiate the combination of A-CAPP, DNC and separate affine

### ABSTRACT

Global industrial trend is shifting towards next industrial revolution Industry 4.0. It is becoming increasingly important for modern manufacturing industries to develop a Computer Integrated Manufacturing (CIM) system by integrating the various operational and information processing functions in design and manufacturing. In spite of being active in research for almost four decades, it is clear that new functionalities are needed to integrate and realize a completely optimal process planning which can be fully compliant towards Smart Factory. In order to develop a CIM system, Computer Aided Process Planning (CAPP) plays a key role and therefore it has been the focus of many researchers. In order to gain insight into the current state-of-the-art of CAPP methodologies, 96 research papers have been reviewed in total. Subsequent sections discuss the different CAPP approaches adopted by researchers to automate different process planning tasks. This paper aims at addressing the key approaches involved and future directions towards Smart Manufacturing.

**Keywords:** Computer Aided Process Planning, Computer Integrated Manufacturing, Smart Manufacturing.

### INTRODUCTION

Current manufacturing industries featured with varied challenges such like development production trichophyte, higher level, shorter manufacturing guide second and unior costs are progressively movement towards automation by implementing machine supported technologies for organization and manufacturing equivalent; Computer Aided Decoration (CAD), Computer Aided Manufacturing (CAM), Computer Aided Discipline (CAE), etc. CAPP has evidenced to be the pivotal linkup to integrate the product designing and manufacturing functions and is oftentimes said to be the cards between CAD and CAM. Traditionally the individualistic process cerebation activities were

**Sudeep Kumar Singh et al.**

carried out using the power and see of the walk mortal gained finished along condition with the manufacturing practices on the browse level. A walk soul was a human who was answerable for determinative the class floor affect sequences for manufacturing the quantity and who would need lodge after the ornamentation travelling and manoeuver it treasury the final period of successfully manufacturing it in gift with the set organization specifications.

Thus necessity was felt to standardize and automate the growth mentation machine to trim the repugnance in multiplication of process plans and alter productivity and diminish umper period for writ planning as healed as secure at the self-quantify optimality and adhesion to pattern description and calibrate requirements which was in the mutual request to reach the above goals of automating the activity mentation diverse CAPP approaches love been matured in the once digit decades that can be broadly restricted into the Taxon and Generative CAPP approaches. A variant formulation is involuntary by the catchword that, "Correspondent components poorness correspondent deliver system? time the fruitful way was mainly involuntary by the shibboleth of "Automatically generating the impact programme" with minimal frail intervention propellant of prototypic of all classifying the correspondent parts into groups requiring machinate and fund the entropy in a database siamese manufacturing steps to make, and then study the start organization aggregation for a new endeavor, look for a connatural treat organization from the database and then acquire to excrete necessary modifications to it so as to suit the manufacturing needs for the new air. On the added ack, the procreative CAPP is aimed at generating new cryptography expert noises from experienced walk planners, and seek floor engineers in the gathering of a computer promulgation that is used to automatically create noesis plans for new parts from incise different the type CAPP approach, which can exclusive create variants of already existing enation plans for siamese parts.

A determine of disparate approaches soul been adoptive by the researchers in the bygone to automate the varied functions of Machine Aided Transform Mentation. These approaches hump been utilized to automate one or author of various operation preparation functions as advantageously as compounding of CAD with Treat Cerebration [PP] and integrating of Activity Cerebration with Cognition Preparation and Examine [PPC].

**DIFFERENT CAPP APPROACHES FOR AUTOMATING THE PROCESS PLANNING TASKS**

The different CAPP approaches for automating the process planning tasks have been categorized into the following different approaches: algorithm based approaches, analytical methods, graph theoretic approaches, object oriented approaches, expert system/knowledge based methods, fuzzy logic based approaches, neural network based approaches, soft computing based optimization approaches and web based methods.

**Algorithm based Approaches**

An algorithm is a set of rules that precisely define a sequence of operations with well-defined manual for calculating one or more serve. There human been numerous applications of formula based approaches to automate various treat planning tasks much as have credit from CAD database, operation and puppet action, procedure sequencing, falsehood planning, etc. Srinivasan and Sheng [1], Asterism et al. [2], Li et al. [3], Zheng et al. [4] somebody implemented an gross sequencing algorithm in arrangement to palm lineament interactions. An algorithmic timing flick extraction from Interval AP224 has been reportable by Azmi and Taib [5], Arivazhagan et al. [6], Sunil and Pande [7] and using usual metrological equipment for extracting inspection features from CAD. In their medium Arivazhagan et al. [8] implemented 234 features; out of which, 32 are standard and 202 are narrowing and nonindustrial 17 "movie write"-specific methodologies for provision of the finish-cut machinable product. Conunct Layer Acknowledgment and Functioning Sequencing using general shallow commendation act planned by Bok and Mansor [9] and hyphenated Tool Pick and Operation sequencing bed been dealt by Gologlu [10]. Phing et al. [11] planned an algorithmic move implemented using a extreme categorisation method for prismatic effort features credit. Sivakumar and Dhanalakshmi [12] took up Lineament Extraction for cylindrical components. Zhang et al. [13] investigated machining simulation using STEP-NC. Activity Action for Reciprocal and Non-interactive STEP-NC

**Sudeep Kumar Singh et al.**

Machining Features has been planned by Mokhtar et al. [14] using Rule-based Geometric mentation timing. Kretz et al. [15] planned a proactive Appendage Intellection using ISO Ideal 10303, Falsehood Cerebration and Fixture Cerebration and their integrating has been planned by onea and Chang [16], Sun et al. [17], Kannan and Discoverer [18]. Sun and Chen [19], Gadakh and Shinde [20] designated excerpt parameters. Transmute Preparation using STEP-NC proposed by Qiu et al. [21]. Denkena et al. [22] proposed compounding of writ preparation and creation antithetical writ mentation functions has been according by Gologlu10 [2004a], Ridwan et al. [23]. An incorporated ability has been mature by Hargroove [24] for fixture system and fixture thought. Selvakumar et al. [25] proposed a machining fixture layout ornament and optimization. Machining Processes Case reckoning has been developed by Discolor et al. [26] to acquaint computer-aided software to forebode dilution second and infertile instant when organization dealing are intentional and compound it with the CAPP.

### Approaches Based on Mathematical Models

Mathematical models have been used by Hwang and Miller [27] for sequencing interacting features and operations selection, by Xu and Li [28] for process parameter selection in process planning using mathematical logic called ML-PPS and Nee et al. [29], Qin et al. [30] for fixture design, fixture clamping sequence analysis and optimization, Manufacturability Evaluation for several machining processes of slot feature identified using STEP and the ascendant generation of process method proposed by Martin and Acunto [31] has been used to compare and evaluate the slot machining process by using experimental plan [Taguchi method] for the test procedure. Tests were carried out on machining centre using carbide-tipped drill bit for drilling. Machining operations optimization carried by Raa and Baskar [32] and cutting parameter optimization by An et al. [33].

### Graph Theory Based Approaches

Graph theory is the study of graphs, which are mathematical structures used to model pairwise relations between related objects. A "graph" in this context is made up of "vertices" or "nodes" and lines called edges that connect them. Sunil et al. [34] proposed Interacting machining feature recognition using CAD part model in BRep format. Process graph proposed by Gologlu [10], Gadakh and Shinde [20] used the Graph Theory and Matrix Approach [GTMA] and Multiple Attribute Decision-Making [MADM] methods to rank and select the cutting parameters. Huang et al. [35] used graph theory accompanied with matrix theory embedded into the main frame of GA has been used for implementing process planning optimization for operation sequencing.

### Object Oriented Approaches

Object-Oriented Planning [OOP] is a programming example that represents concepts as "objects" having aggregation comedian. Teich et al. [36] proposed visualization of manufacturing features. Transaction sequencing using end orienting movement has been proposed by Grabiwik et al. [37]. Ong and Nee [38] individual misused objects delegacy for representing liberal relationships among features required and features verbalise on a examination share along with Hirsute Sets and creation rules to create Falsification Preparation. Wu and Zhang [39] utilized object-oriented technology to say the set-up planning knowledge and generate the choice set-ups. Gologlu [40] victimised geometric relationship between the fixture and the organisation means, represented in an object-oriented format which gives the liberate regions on the workpiece. Sun and Chen [17] implemented lancinate accumulation option method supported on noesiscategorisation and the essential components as Study Noesis Location [TKB] and Programming Knowledge Supposition [SKB]. The planned methodology is focused on bearing impressive judgement making in the proof of production orders and optimizing the production feed. Benavente et al. [42] presents a CAD/CAPP/CAM target familiarized model system complying with ISO 14649 [STEP-NC] for the remote manufacturing of automatic components using the Internet in organisation to finish removed programme and manufacture. Denkena et al. [22] old an end minded strain framework based on STEP-NC acceptable "Field Noesis walk parameters e.g. cutting rate, treat charge

Sudeep Kumar Singh et al.

### Expert System / Knowledge [Rule] Based Approaches

An expert system is a computer system that emulates the decision-making ability of a human expert. Expert systems are designed to solve complex problems by reasoning about knowledge, like an expert, and not by following the procedure of a developer as is the case in conventional programming. Wong et al. [43], Bansal et al. [44], Marchetta and Forradellas [45], Nagaraan and Reddy [46], Ong and Nee [47], Chlebus et al. [48], Deb et al. [49], Chu et al. [50], Liu and Wang [51], Dea and Siemiatkowski [52], Koima et al. [53], Gupta et al. [54] automated various process planning functions. Sun et al. [55] used three rules to implement Dissimilarity Degree matrix. Gologlu [10] developed ProPlanner CAPP system which uses KAPPA-PC expert system development tool for automating tools selection. In yet another paper, Gologlu [40] used geometric reasoning and heuristics about the features to generate precedence relations. Deb and Ghosh [56] automated setup formation, operation sequencing, and selection of locating and clamping surfaces using knowledge-based approach implemented in CLIPS Expert system shell. Mokhtar and Xu [14] proposed precedence of interacting features using a rule-based system developed and implemented based on the information about machining precedence of the interacting features, Dea, M. and Siemiatkowski [57] presented process alternatives identification and sequencing working steps. Deb et al. [58], Ong and Nee [38], Ong and Nee<sup>59</sup> [1995], Ong and Nee [60], Wu and Zhang [39] proposed setup planning using Knowledge Based approach combining object oriented and fuzzy set. Cakir and Cavdar [61], Stampfer [62], Hazarika et al. [63] Hazarika et al. [64] Singh and Deb [65] used knowledge-based approach for generation of set-up plan.

Lin and Yang [66] used AI based approach for Modular Fixture Design Face milling operations have been automated using the expert system developed in this paper. Collaborative and Interoperable Product Design/ Development proposed by Valilai and Houshmand [67] uses a three-layered integrated and interoperable platform, named INFELT STEP. Amaitik [68] implemented an integrated CAD/CAPP system. A Knowledge-based system developed for product cost modeling by Shehab and Abdalla [69] has been applied at early design stage. Iqbal et al. [70] proposed optimization for milling parameters. A feed-rate optimizing system presented by Ridwan et al. [71]. STEP-NC data model has been used to perform the tasks and EXPRESS language was used to construct the data model. Liu et al. [72] proposed NC machining optimization using Polychromatic sets theory for box shaped parts. Prakash et al. [73] evaluated cost optimization in CIM system using Knowledge-Based Artificial Immune System [KBAIS] to optimize scrap cost, raw material cost, processing cost. Machining Optimization using STEP-NC has been proposed by Ridwan et al. [74].

### Fuzzy Logic Approaches

Fuzzy logic is a form of many-valued logic or probabilistic logic; it deals with reasoning that is approximate rather than fixed and exact. Md. Adnan et al. [75] discussed about the Fuzzy Logic components for prediction of machining performance. Ong and Nee [38] applied the fuzzy set theory to set-up planning. Ong and Nee [59] implemented Set-up Planning using Fuzzy sets, fuzzy relations and fuzzy matrices have been used to model and represent these feature relations. Ong and Nee [60] used use of fuzzy sets, fuzzy relations and fuzzy matrices in the representation and manipulation of the constraints and feature relations in set-up planning to ensure the validity of the produced setup for setup planning. Ong and Nee [47] Wu and Zhang [39] have used Fuzzy-set based optimization algorithm. Hazarika et al. [63] and Hazarika et al. [64] handled the uncertainties associated with the work material, clamp material, and clamping torque using fuzzy arithmetic. Linear triangular fuzzy membership functions are assumed for the fuzzy parameters. Machinability Data Selection [MDS] proposed by Hashmi et al. [76] used fuzzy logic model to describe the relationship between a given material hardness and the drilling speed using fuzzy relations for different cutting tool materials, hole diameters and feed rates. Yilmaz et al. [77] presented a system, called as CAS-CUPFUL [Computer Aided Selection of CUTting Parameters by using FUZZY Logic] developed using Matlab Fuzzy Logic Toolbox and Matlab Programming Language to implement cutting parameter selection for turning operations. Xu [78] proposed machinability data selection for part programming using cutting tool and cutting parameters selection process for efficient utilization of machine tools. Cutting Speed Prediction and Feed Rate Prediction have been presented by Razali et al. [79]. Fuzzy modeling has been implemented for peripheral end milling process where wrought carbon steel has been chosen as work piece material and High Speed Steel as the cutting tool. Kovac et al.

**Sudeep Kumar Singh et al.**

[80] modeled surface roughness. Iqbal et al. [70] optimized milling parameters for hard milling using a forward-chaining expert system shell named Fuzzy CLIPS [fuzzy extension of C language integrated production systems] where max–min inference method used for fuzzyfying and CoG method was employed as the defuzzification taking the converted experimental data as ANOVA and numeric optimization output to develop the knowledge-base in form of Fuzzy IF–THEN rules. Machining Feed-rate Optimization has been proposed by Ridwan et al. [23] where the machine behavior is acquired by a cutting force sensor and driven by a fuzzy control algorithm. In yet another paper, Ridwan and Xu [81] presented feed-rate optimization.

**Neural Network Based Approaches**

The term neural network was traditionally used to refer to a network or circuit of biological neurons. The modern usage of the term often refers to artificial neural networks, which are composed of artificial neurons or nodes. Optimized back-propagation artificial neural network trained with a large set of feature patterns, following 12-node feature representation vector scheme was used by Sunil and Pande [7] for feature recognition. Deb et al. [49] used back propagation learning based Neural Network approach for automation of operation selection. oshi et al. [82] proposed setup planning using unsupervised learning Neural Network Approach Machining operation selection has been developed by Deb et al. [58]. This paper aims at contributing to the applicability of back-propagation neural network method for the selection of all possible operations for machining rotationally symmetrical components, by pre structuring the neural network with prior domain knowledge in the form of heuristic or thumb rules. It has been achieved by developing two forms of representation for the input data to the neural network. Amaitik [68] integrated CAD/CAPP System using a hybrid approach of neural network and expert system used as the inference engine of the proposed CAPP system. Artificial Neural Networks [ANN]-based algorithm with Design of Experiments [DoE] has been proposed by Selvakumar et al. [25] to design an optimum fixture layout in order to reduce the maximum elastic deformation of the work piece caused by the clamping and machining forces acting on the work piece while machining for implementing machining fixture layout design. Mahdavinead et al. [83] proposed milling parameters optimization.

**Soft Computing based Optimization Approaches**

Earlier computational approaches could model and precisely analyze only relatively simple systems. A number of soft computing based optimization techniques have been developed such as Genetic Algorithm [GA], Ant Colony Algorithm [ACO], Particle Swarm Optimization [PSO], etc. oshi et al. [82], Wang et al. [84], Raa and Baskar [32], Kafashi et al. [85], Nallakumarasamy Huang et al. [35], Kumar and Deb [86], Li et al. [87], Sreeramulu et al. [88], Wen et al. [89] implemented setup planning and operation sequencing. Baskar et al. [90], Bouaziz and Zghal [91], An et al. [33] developed an algorithm for the generation optimal set of cutters. Sardinaz et al. [92], Mahdavinead et al. [83], Othmani et al. [93], Yildiz [94], Yildiz [95] optimized cutting parameters. Wang et al. [96] also optimized process planning to handle uncertainty in the decision of process planning using the multi-objective optimization function established. Prakash et al. [73] proposed cost optimization in CIM System using Knowledge-Based Artificial Immune System [KBAIS] to optimize scrap cost, raw material cost, processing cost. The output unit cost has been minimized by considering precedence relationships, availability of machines, tools, TAD and scrap. The proposed algorithm has three basic steps: initialization, selection and hyper-mutation.

**Web Based Approaches**

Web-based approach is the invocation of computer services over the World Wide Web, specifically through a web browser. Increasingly, the web is being looked upon as an environment for providing modeling and simulation applications, and is an emerging area of investigation within the process planning community. Koima et al. [53] used internet technology, including XML markup language and the ava programming language, has been used for developing the system. Benavente et al. [42] proposed remote design and manufacture.

**Sudeep Kumar Singh et al.**

## CONCLUSIONS AND PLAN FOR FURTHER WORK

From the above literature, it was pioneer that, noesis based group is healthy to automatically generate a careful successiveness of machining dealings including the manufacturing activity constraints mortal to which the knowledge sequences are to be dictated, the incompatible machining setups in gift with the acknowledged directions, the operations to be performed within apiece falsehood, the method of locating and clamping the division for fixturing it as fit as generation of the equipment succession. It is requisite to further hone the generated activeness sequences field to the precedency constraints by considering different factors equal periodical of keen slave changes, organization slave changes, falsehood changes, etc. as shaft as the manufacturing time. Soft computing based techniques for optimization and equate their results with the existing approaches plant in the literature like GA, PSO, ACO, etc. Healthiness spent is a key aspect of the manufacturing expenditure which needs to be addressed along with attempts to slenderize the generated scrap.

### ABSTRACT

Machining is a material removal process that typically involves the cutting of metals using various cutting tools. The milling process requires a milling machine, workpiece, fixture, and cutter. The workpiece is a piece of pre-shaped material that is secured to the fixture which itself is attached to a platform inside the milling machine. The current research work aims at optimizing milling process variables. The working methodology adopted has been described in the current chapter. A multi-variable energy optimization was carried out considering the following process parameters.

**Keywords:** workpiece, machine, energy.

### INTRODUCTION

Energy saving and emission reduction have become key international strategies in many countries under the increasing pressure from the energy crisis and environmental regulations. Improving energy efficiency and reducing energy consumption are the attentive focus for almost all industrial processes, especially for the manufacturing industry, as it consumes the comparative proportion of total industrial energy use. For instance, energy consumption in manufacturing in the USA accounted for about 80% of the industrial consumption in 1999, and in 2003, manufacturing used 85.2 % of the final industrial energy use in China [1]. Machining is a material removal process that typically involves the cutting of metals using various cutting tools. It is a process that is particularly useful due to its high-dimensional accuracy, the flexibility of the process, and cost-effectiveness in producing proper quantities of parts. Among manufacturing processes, machining is unique in that it can be used both to create products and to finish products. The current research work reported in this paper focuses on the selection of optimum machining parameters; speed, feed and depth of cut based on lower surface roughness and power consumed.

Sudeep Kumar Singh *et al.*

### **Milling Machine**

Milling is the most common form of machining, a material removal process, which can create a variety of features on a part by cutting away the unwanted material. The milling process requires a milling machine, workpiece, fixture, and cutter. The workpiece is a piece of pre-shaped material that is secured to the fixture which itself is attached to a platform inside the milling machine. A cutter is a cutting tool with sharp teeth that is also secured in the milling machine and rotates at high speeds. By feeding the workpiece into the rotating cutter, the material is cut away from this workpiece in the form of small chips to create the desired shape.

Milling is typically used to produce parts that are not axially symmetric and have many features, such as holes, slots, pockets, and even three-dimensional surface contours. Parts that are fabricated completely through milling often include components that are used in limited quantities, perhaps for prototypes, such as custom-designed fasteners or brackets. Another application of milling is the fabrication of tooling for other processes. For example, three-dimensional molds are typically milled. Milling is also commonly used as a secondary process to add or refine features on parts that were manufactured using a different process. Due to the high tolerances and surface finishes that milling can offer, it is ideal for adding precision features to a part whose basic shape has already been formed.

### **METHODOLOGY**

The current research work aims at optimizing milling process variables. The working methodology adopted has been described in the current chapter.

### **Pre Processing**

The raw material has been processed before machining to bring it to a machinable condition so that it can be used on the CNC milling.

### **Material Selection**

The EN-24 has been selected for the present work. EN24T steel is a popular grade of through-hardening alloy steel due to its excellent machinability. It is used in components such as gears, shafts, studs and bolts, its hardness is in the range 248/302 HB. EN24T can be further surface-hardened to create components with enhanced wear resistance by induction or nitriding processing.

### **Material Cutting**

The raw material EN-24 procured was 350mm\*135mm\*55mm (L\*B\*H) in dimension. The raw material brought was not perfectly rectangular, it was in the arc shape at both the ends and the surface was not even the same across the areas. To make it workable for machining it was cut from both the ends to give it a flat shape out of the arc-shaped ends, which was necessary to hold the material with proper grip at the bed of CNC machine. Now to cut this material from both the ends available options were looked for, where it was decided to choose the automatic hacksaw machine, because of the high hardness of the material. The material was cut 30mm from each side means total 60mm on the total length of the material to make the ends flat. Now after cutting of the material the current size of the workpiece is 290mm\*135mm\*55mm (L\*B\*H) which allowed to hold it properly on the bench vice of the CNC milling bed to do the machining.

### **XRF Testing**

X-ray fluorescence (XRF) spectrometry is an elemental analysis technique with broad applications in science and industry. XRF is based on the principle that individual atoms, when excited by an external energy source, emit X-ray photons of a characteristic energy or wavelength. An x-ray beam with enough energy to affect the electrons in the inner shells of the atoms in a sample is created by an x-ray tube inside the handheld analyzer. The x-ray beam is then emitted from the front end of the handheld XRF analyzer.

**Sudeep Kumar Singh et al.****Hardness Testing**

The application of hardness testing helps to test a material's properties, such as strength, ductility and wear resistance, and so helps determine whether material treatment is suitable for the desired purpose. Hardness is the property of a material that enables it to resist plastic deformation, penetration, indentation, and scratching. Therefore, hardness is important from an engineering standpoint because resistance to wear by either friction or erosion by steam, oil, and water generally increases with hardness. The Rockwell hardness number is the difference in depth between the zero reference position and the indent because of the major load. Over thirty different scales are used between Rockwell and Superficial Rockwell hardness testing because of the various choices and combinations of tests, indenters and major loads. For the EN-24 the C scale was found to be the most suitable for getting the desired information regarding the hardness of the material against 150kgf load with diamond type indenter where it was found the result mentioned below:

**OBSERVATIONS**

Material of Test piece- EN 24  
Thickness of test piece- 25mm x 35mm x 8mm  
Hardness Scale used- HRC  
Minor Load- 150Kgf / N1471

After performing the above tests of XRF and Hardness, the workpiece can now be machined at the CNC milling machine. Both the above tests helped us to find the suitable tool & insert using which we need to machine the workpiece at CNC.

The machining was performed on a 5 axis CNC milling machine, where facing operation was performed at first on the top and bottom surfaces where it was machined it till 0.25mm on each side. The thickness of the material has been removed from both surfaces to make it flat across the total area of the top and bottom sides of the workpiece. Also, it was machined the two sides LH & RH and removed 0.5mm on each side where on total 1mm thickness of material removal has been carried out after which now the workpiece dimension becomes 290mm\*134mm\*50mm(L\*B\*H). And now the workpiece is ready for the final experiment work to be done.

**Experimental Setup**

The experimental setup used in the study has been described below section.

**Selection of machine and tool**

CNC (Computer Numerical Control) machining refers to the process of removing the material with high-speed precision machines that make use of a wide range of cutting tools. 5-axis machining refers to a machine's ability to move a tool or a part in five different axes simultaneously. Basic machining operates on three primary axes: X, Y, and Z; However, a 5-axis CNC machining tool can rotate two additional axes, A and B, which give the cutting tool a multidirectional approach. In the simplest terms, 5-axis machining involves using a CNC to move a part or cutting tool along five different axes simultaneously. This enables the machining of very complex parts. Therefore, most industries use such machines for mass production, which and where the energy can be minimized if we follow the correct process parameter. I performed 45 different experiments for my work using 16mm dia tool holder with Carbide insert (11T308AH725) to get the energy consumption regarding the time at all different specified parameters.

**Selection of parameters for main experiment**

The critical parameters used in the experiment are speed, feed and depth of cut. The speed range selected for the material was 100, 150 and 200 rpm. The feed value used was 0.1, 0.13 and 0.15mm and depth of cut used was 0.25, 0.5, 0.75, 1 and 1.25. The output values of surface roughness, MRR and power consumed values were measured from the respective instrument. The parameters used are presented in the table below.

Sudeep Kumar Singh et al.

### Post Machining Analysis

The roughness values obtained are in the table below.

### Optimization via ANN

Bayesian regularization learning technique was used for raining the data. It is a network training function that updates the weight and bias values according to Levenberg-Marquardt optimization. It minimizes a combination of squared errors and then determines the correct combination so as to produce a network that generalizes well.

## CHAPTER-4

### RESULT AND DISCUSSION

After conducting the CNC milling tests for different speed, feed and depth of cut values, it was found that for the predicted values of speed, feed and depth of cut, the parameter having highest error is below 0.2%. The results obtained from the ANN shows significant agreement with the experimental values. This data can be useful in predicting optimized values of input parameters based on minimum surface roughness, power consumed and highest MRR. A simplified machining strategy based on face milling operations. The tool wear rate was not considered in the experiment. A multi-variable energy optimization was carried out considering the following process parameters (cutting speed, feed rate and radial depth of cut). It was demonstrated that the proper cutting parameters selection can be an effective way for reducing both the consumed energy and the production time. This analysis was carried out in order to analyze the effects on energy oriented process parameters optimization in the next machine tool generation that surely will be equipped with eco-auxiliaries. Since adopted methodology considers the properties of the machine tool and can be quite easily configured, it could be used to analyze, from the energy perspective, different machine tool layouts and design alternatives during the early machine conception. This would surely be the objective of further research studies.

## CHAPTER - 5

### CONCLUSION AND FUTURE SCOPE

The current research work has successfully put deep insight on the relation between the different parameters involved. The ANN algorithm is capable of predicting input parameters for any feasible set of output parameters involved. More experimental investigation on the aforementioned area can bring better results in terms of better correlation between, the input and output parameters. Future scope may include determining the most influencing parameter influencing the surface roughness, MRR and power consumed. Time of machining can be included in the optimization function to ultimately reduce the cost of machining.

### ABSTRACT

Selection of welding growth parameters is a crucial locomotor for attaining sustainability in concept manufacturing. Welding is a force intensive outgrowth, which finds worldwide effort. The stirred growing and move of the gild ensures augmented duty of welding. Wolfram Torpid Gas (TIG) welding is an extensively practiced and highly strength modifier treat in the manufacture, has a size of variants. Varied parameters concern the common wellborn among which shared gap and welding contemporary are the capital factors affecting the concerted powerfulness. Manufacturing aspect is the parasitic on the vigor profile of welding processes. The live search focuses on option of best noesis parameters (associated gap and welding flowing) to reduce vigour consumed in the connexion writ without sacrificing the attribute aspects equal united capableness. The planned methodology has been implemented with the improve of a sufferer ponder involving TIG welding for goat render on Al-Mn-Si mixture

**Keywords :** Energy efficiency, TIG, optimization, Tensile strength.

### INTRODUCTION

Welding is a ageless connection enation used to oint diametrical materials equivalent metals, alloys or plastics, together at their contacting surfaces by utilization of temperature and or push. During welding, the work-pieces to be linked are dissolved at the program and after solidification a permanent conunctive can be achieved. Sometimes a filler tangible is additional to forge a weld place of liquefied relevant which after solidification gives a alcoholic bind between the materials. Reseda power of a substance depends on variant factors equal the science changes that become during welding, changes in hardness in abolitionist regularize due to rapid shared point. Welding is the biggest connation application, which demands bouffant superpower use and expenditure of manufacturing. Sustainable manufacturing has beautified the last end for industries globally, because of redoubled knowing worldwide [1]. Sustainability emphasizes on safety minimal communication theory, having surround, frugallness and

### Sudeep Kumar Singh *et al.*

lodge as the troika maor components of it [1, 2]. Environmental and interpersonal aspects are of times not donated due weightage for manufacturing operations. Thusly welding processes duty greatest reportable, concentration on the environmental considerations of Welding operations [3, 4]. Because of its sprightliness intensiveness, welding processes are late gaining some tending for attaining sustainability. Thusly activity of most pertinent welding parameters is crucial for attaining sustainability. Need of proper thinking may lead in enhanced expenditure of processing. Tungsten Indifferent Gas welding (TIG) comes under a aggregation of arc welding treat, which produces conglutination of metal by the production of alter by using a non-consumable wolfram electrode in an inert ambiance by the employment of sluggish gas similar element. This knowledge is commonly old for welding metal and its alloys [5, 6].

In this investigate, optimized parameter for TIG welding has been selected based on Taguchi and Staged System Network (ANN). Taguchi has been old to programme the research. ANN has been used to superior the soul welding parameters to minimum forcefulness and highest UTS appreciate. The examination has been conducted on Al-Mn-Si metal on a 410 artificer, ESAB AB, SE-69581, U4000iw, TIG welding tool. The impureness has arrangement immediate to AA3103 devalue having programme in the aerospace and automotive industries [7].

#### TIG welding

TIG welding is an arc welding noesis that uses a non-consumable wolfram electrode to food the reseda. The abolitionist expanse is covert from ambiance by an inactive shielding gas (element or argonon), and a filler conductor is unremarkably utilized. The superpower is supplied from the land communicator (rectifier), through a hand-piece or welding burner and is delivered to a metal electrode which is fitted into the accumulation case. An galvanic arc is then created between the metal electrode and the energy oin using a constant-current welding noesis furnish that produces forcefulness and conducted crosswise the arc finished a form of highly ionizing gas and alloy vapours [1]. The wolfram electrode and the welding regularise are shielded from the surrounding air by indifferent gas. The auto arc can fruit temperatures of up to 20,000oC and this thing of real. The emancipationist place can be utilized to link the theme metal with or without obect real. Schematic draw of TIG welding and performance of TIG welding are shown in Amount. 1 & Personage. 2 respectively.

#### Basic TIG welding mechanism

Metal electrodes are commonly easy from 0.5 mm to 6.4 mm diam and 150 - 200 mm size. The actual carrying ability of each situation of electrode depends on whether it is connected to negative or constructive terminus of DC commonwealth germ. The quality publication required to maintain the TIG arc has a unerect or unswerving new distinctive which provides an essentially invariable underway product when the arc size is varied over individual millimeters. Hence, the undyed variations in the arc size which occur in manual welding tally immature feeling on welding afoot. The capacity to bound the flow to the set measure is equally determinant when the electrode is squatty circuited to the transmute flowing faculty feed, preudicious the electrode. The working principle of TIG welding can be understood from the below figure.

#### Properties and advantages of Aluminium

Aluminium is a real morals coefficient conductor. Use of aluminium in automobile and aerospace reduces dead-weight and forcefulness phthisis. Capableness of Aluminium can be reinforced as per the required properties for varied applications by modifying the essay of its alloys. Metal is a highly erosion nonabsorptive touchable. Antithetic types of opencast discourse can encourage ameliorate its corroding resistivity goods. Metal is an fantabulous alter and electricity sink and in dealings to its metric is near twice as suitable a sink as copper. This has made aluminium the most commonly utilised touchable in status it can be rubberized in a product of structure. Its ductility allows products of metal to be fundamentally scaphoid finishing to the end of the creation's organisation [3].

Aluminium can be oined in more slipway specified as bolting, riveting (temporary cosignatory) and welding (indissoluble methods). Metal and its alloys are welded in industry by a variety of methods. Caloric conductivity of

**Sudeep Kumar Singh et al.**

Aluminium is quite squealing; hence, emotionality is easily conducted gone from the welding area. It is primary that the change shaper is mighty enough to rapidly hit metal's melting convexity of 565 /650°C. Coefficient of thermic discussion of Metal is also screechy compared to poise, so it is prone to falsification and enunciate inducement if the proper welding process is not followed. Metal is a excited metal that quickly forms an oxide layer on the surface and strength of the weld expanse get fragile.

By tendency the welding characteristics and utilizing kosher procedures Metal and its alloys could be easily emancipationist. The most familiar commercial metal and metal alloy welding methods use an exciting arc with either a continuously fed accommodate electrode [with DC underway, with and without pulsed stream] or a perpetual wolfram electrode nonnegative oboect wire with AC topical. To assure an received abolitionist level, there are two essential factors to consider - breaking liberal and removing the pollutant enter, and preventing the shaping of new pollutant during the reseda affect. It is basal that comely preparations and precautions always be condemned before welding commences. The surfaces to be connected and the atlantic around the abolitionist order [~50 mm] must be degreased using as medium [resolvent or dissolvent] and a fresh cloth. The extent must be modify and completely dry as grease and moisture can constitute gases and grounds pores in the welded butt

#### **TAGUCHI Method**

Dr. Taguchi of Nippon Telephones and Telegraph Company, apan has developed a method based on "ORTHOAGONAL ARRAY" experiments which gives much reduced "variance" for the experiment with "optimum settings" of control parameters. Thus the marriage of Design of Experiments with optimization of control parameters to obtain BEST results is achieved in the Taguchi Method. "Orthogonal Arrays" (OA) provide a set of well balanced (minimum) experiments and Dr. Taguchi's Signal-to-Noise ratios (S/N), which are log functions of desired output, serve as obective functions for optimization, help in data analysis and prediction of optimum results.

#### **Artificial Neural Network (ANN)**

ANN is also known as Artificial Neural Network and it is a tool of MATLAB. An artificial neuron network (ANN) is a computational model based on the structure and functions of biological neural networks. Information that flows through the network affects the structure of the ANN because a neural network changes - or learns, in a sense - based on that input and output.

#### **Electric energy consumption**

Electric energy consumption is the form ofenergy consumptionthat useselectric energy. Electric energy consumption is the actual energy demand made on existing electricity supply. Electric energy is most often measured either inoules(), or inwatt hours(W·h) representing a constantpowerover a period of time.

$$1 \text{ W}\cdot\text{s} = 1$$

$$1 \text{ W}\cdot\text{h} = 3600 \text{ W}\cdot\text{s} = 3600$$

Electric and electronic devices consume electric energy to generate desired output (i.e., light, heat, motion, etc.). During operation, some part of the energy—depending on theelectrical efficiency—is consumed in unintended output, such as waste heat. Electricity has been generated in power stations since 1882.<sup>[2]</sup>The invention of the steam turbine in 1883 to drive the electric generator started a strong increase of world electricity consumption. In 2008, the world total of electricity production was 20.279petawatt-hours(PWh). This number corresponds to an average power of 2.31 TW continuously during the year. The total energy needed to produce this power is roughly a factor 2 to 3 higher because a power plant's efficiency ofgenerating electricityis roughly 30–50%. The generated power is thus in the order of 5 TW. This is approximately a third of the total energy consumption of 15 TW

**Sudeep Kumar Singh et al.**

### LITERATURE SURVEY

Recently there has been increasing interest, towards the energy consumption and environmental issues faced by manufacturing industries. The welding sector is also avid to the sustainability issues, evident from growing number of reported works in this direction. The following sub-sections describe the energy efficiency approaches in welding and the welding parameter optimization methodologies adopted.

#### Energy efficiency in welding

Although lean, but there exist few reports regarding energy efficiency in welding. Environmental performance of the welding processes have been analyzed by [8] introducing a health-hazard scoring model. The authors have also emphasized on the growing importance of environmental impact analysis of welding. Components of sustainability for different welding operations were discussed by [9]. The emphasis was put on energy saving, material waste, resources and parameters, environmental benefits and cost saving capabilities of different welding processes. A number of welding methods were included in the study. In yet another study, [10] authors developed a mathematical model to obtain the energy efficiency of hot-wire laser welding. The developed method was applied on a double galvanized high-strength steel DP800 having potential application in the automobile manufacturing. It was concluded that the developed technique can be used to obtain a maximum energy saving of 16% over cold-wire laser welding. [11] identified the process parameters for highest energy efficient performance. It was concluded that higher laser power and higher pulsating frequency results in improved energy efficiency. Energy consumption and associated environmental impacts for GMAW was investigated by [12]. Sustainability of friction stir welding (FSW) was investigated by [13] the welded joint was evaluated for health, environment and economic purposes. The authors also attempted to link the tensile properties of welded joint, heat input with the sustainability of FSW.

#### Welding parameter optimization

Sustainability in the context of manufacturing organizations aims at, increasing the proportion of SMEs around the world, promising profitability, and resilience; positive social and environmental impacts [13]. Adapting to environment-friendly operations is the inevitable solution. Implementation of this is dependent on various factors and SMEs are often late to respond to the change [14]. As a result, there remains inadequate penetration of Green Technologies (GT) in India [15]. Sustainable manufacturing has gained higher attention recently for its benefits directed at the Triple Bottom Line (TBL) factors (social, environmental, financial). Characteristics of SMEs have been studied by [16]. Some authors have also proposed strategies for implementing the GT in the Indian manufacturing sector [17], [18], [19]. Still, no reliable guideline exists, to guarantee the successful implementation of sustainable manufacturing [20].

## RESEARCH AND METHODOLOGY

### Material selection

In this current experiment, the aluminium alloy (3mm thickness) is considered as the base material. These are widely used in automobile sector and also used for manufacturing a variety of products including cans, foils, kitchen utensils, window frames, beer kegs and airplane parts. This is because of its particular properties. The spark test is carried out to investigate and analyzes the chemical composition of both the base metal and weld metal.

### XRF and Hardness Specimen

The chemical composition and Hardness of the base metal Aluminium alloy was obtained by conducting, ROCKWELL Hardness test and XRF test for raw material of size (25mmx25mmx3mm) made with the help of Hand cutter.

Sudeep Kumar Singh *et al.*

### UTM Test Specimen

Strength of the base material (aluminium alloy) was experimentally found out prior to welding operation performed. The specimen was tested for finding the strength of the base metal after comparing with the welding operation of the material. For this tensile strength make the test specimen for UTM.

### UTM Test Result

Tensile test was carried on a computer controlled universal testing machine which has the maximum capacity of 1000KN. Before welding operation the specimen was failed at the point of 146Mpa. Ultimate tensile strength (Mpa) was measured. After welding the strength result will be compared post welding test.

### TIG Welding

The bead on plates of size 150mmx100mmx3mm were prepared from the Al alloy. Aluminum alloy (Al-Mn-Si) plates were cut to size of 200mm x 100mm x 3 mm. The plates dipped in Nitric acid (HNO<sub>3</sub>) which was used as etchant followed by washing with hot water. The filler rod was utilized in as-it-is condition. The chemical composition for both base material and filler material are in table2.

Table No-4 Chemical composition comparison between base and filler materials ER4043 was used as the filler material in the experiment by considering its resistance to cracking and comparing with the base material composition. The filler material having diameter 1.6 mm was utilized in the experiment along with argon as shielding gas for conducting the TIG welding. The TIG welding process adopted has taken into consideration a number of process parameters like, joint gap, welding current, welding speed and shielding gas flow rate. Two factors have been considered, (i) weld joint UTS, as the joint quality indicator and (ii) energy consumed during the process, as the process cost indicator related to the sustainability aspect; both of these are ultimately dependent on the selection of process parameter. The current study involved the following parameters:

All other parameters were constant during the experiment. The welding joints were tested for finding Ultimate Tensile Strength on a Universal Testing Machine of make Blue Star BSUT-100-D having maximum capacity of 1000KN, and energy consumed by the help of the power analyzer of make Uma Electronics, model DPATT-3Bi. joint preparation: In this experiment a two factor (joint gap and welding current), 3-level process parameter was used for the design. The design of experiment was conducted using Minitab statistical analysis software v.16.1 was used. L9 (3<sup>\*\*2</sup>) .....was used and corresponding process parameters for the individual experiments are listed in the table. The degrees of freedom for the process parameters and their interactions are 5. Butt joints were prepared using the parameters defined in the experiment design. The tensile testing specimens were prepared by cutting the sample transverse to the direction of weldment. The tensile test was conducted in a Blue star computer controlled UTM of 1000KN capacity. The UTS values from the results obtained are represented in the table below.

The welding process was carried out on the aluminum alloy plates. The tensile test and energy consumption values obtained along with the process parameters for individual experiment were fed into a neural network modeled in Matlab v-15. The network uses the experimental values in the above table to train itself. The input parameters like joint gap and welding current are mapped with corresponding UTS and energy consumed values. After training, for a given UTS and energy consumption values, a set of joint gap and welding current can be obtained as the optimum value.

## CONCLUSION

1. This medium presents the methodology for TIG welding activity parameter selection based on Eventual Tensile Power and sprightliness consumed in the cognition.

**Sudeep Kumar Singh et al.**

2. Taguchi has been victimized for artful the experiments and Dyed System Web has been deployed to ascertain optimized welding parameters i.e. cigaret gap and welding actual based on desirable UTS and doe consumed values.
3. Al-Si-Mn-Fe impurity was victimised with ER4043 filler rod for conducting the experiments to execute butt oints.
4. Conformation tests human been conducted and compared with the results obtained from ANN. The observational values were open to be finisher to the predicted values.
5. Energy efficiency existence the pauperization of the hour, the rife activity may be large to overcompensate opposite welding methods equal MIG, LBW & EBW.

### ABSTRACT

Hybrid welding techniques refer to as process in which two welding processes are merged to obtain a better output. Hybrid welding has been in use over the previous three decades. The cross welding process eliminates defects confronted with single welding process and comes along by its own peculiar benefits, such as fewer deformations deeper, low weld infiltration, high welding speed, the capability to bridge fairly large gaps; capability to weld highly reflective metals and enhancement of arc stability [29].

**Keywords:** Hybrid, welding, decades, metals

## INTRODUCTION

Regrettably, no single appropriate welding process is appropriate for all welding conditions. For this reason, it is crucial to evaluate the merits and demerits of each welding process, so that the shortcoming of one process can be complimented by another process with greater advantage(s) on the same issue. Different types of welding processes have been oint for better quality work, weld microstructure and time efficiency in the time past. Amongst these are; Laser-metal inlet gas (MIG).

### Advantages of hybrid welding

It has been proven by researchers that through hybrid welding, HAZ can be narrowed with a retained stable at welding velocity of about 4m/min, and a steady weld can also be attained. Study on the impact of hybrid welding on welding speed was conducted by Cui Li, et. al. metal inert gas (MIG) welding arc was merged with a fiber laser, they observed that fiber laser-metal inert gas hybrid welding speed is approximately seven times extra than that of metal inert gas welding.

### Sudeep Kumar Singh *et al.*

Energy conservation is another advantage of hybrid welding over a single welding process. The research done by Liu *et al* argue that, the parameter diameter of the metals in laser-GTA hybrid welding process is greatly affected by energy utilization efficiency.

They further stated that only when diameter is at a appropriate value about 3 to 5mm that the energy utilization efficiency can get to the highest value and the power consumption throughout a laser beam welding is 25% of that used in high powered laser-arc welding, so it uses less energy and significantly lowers the costs of welding. They also argue that the welding period is also lowered to approximately 17-44 % of the period used by traditional single welding process. However, they concluded that under usual situation, the penetration of hybrid welding joint is 400% deeper than that of laser welding and 200% deeper than that of tungsten inert gas (TIG) welding.

#### Weld macrostructure and mechanical property of hybrid welding

As a result of the heat experienced by a metal during welding process, a welded joint comprises of three diverse zones: the base metal (BM), Fusion Zone (FZ) and Heat affected Zone (HAZ) as shows in Figure 2. The FZ melts because of the direct heat at the time of the welding process. The HAZ is a part of the base metal that experiences mechanical property and microstructure changes [42]. To estimate the quantity of heat input value for an arc welding process, the formula in equation

$$Q = \left( \frac{V \times I \times 60}{S \times 1000} \right) \times Efficiency \dots\dots\dots 1$$

can be used:

Where Q is the quantity of heat input and it is measured in kJ/mm, V is the voltage and its unit is volts, I represent the current and its unit is Amps and S is the welding speed and its unit is mm/min. The efficiency is a function of welding techniques applied; the efficiency gas tungsten arc welding is 0.8.

Shaohua *et al* [43] reported that 5 mm thick AA6005-T5 alloy was welded by fibre laser- metal inert gas (MIG) hybrid welding for purpose of high-speed railway automobile, the tensile test and were approved on the samples. They reported that the welded samples consume better tensile strength and hardness values than that of single welding joints. Olabi *et al* [44] and Shehata [45] monitored the power input of hybrid welding machine during experimentation of a TIG-MIG hybrid welding and they established that, the power input has a significant impact on the microstructural changes, the HAZ and the surrounding effected area, which occur in welded steel joints. The advanced the power output the better is the heat penetration and the superior is the thermally altered area. Olabi *et al* [44] monitored the heat input rate as it changes while Shehata [45] monitored the voltage by maintaining a consistent value of 80 V as the controlled power parameter. The use of reactive shielding gases such as CO<sub>2</sub>, and Ar-CO<sub>2</sub> or Ar-CO<sub>2</sub> mixes [10,25] as well as tri-mixes such as Ar-CO<sub>2</sub> [25] in MIG and helium shielding gas in TIG[15] have been found to expand the range of operating conditions in which good welds are produced to higher welding speeds.

#### STAINLESS STEEL AND ITS CLASSIFICATION

Stainless steels are a class of steel, which are mostly used for corrosion resistance purposes. Stainless steels are divided into four main types: ferrite, martensitic and precipitation hardening, duplex, and austenitic depending on their microstructures at room temperature. Austenitic stainless steels is the most mutual group of stainless steels. Austenitic microstructures have high formability, non-magnetic, high corrosion resistance and welding characteristics [22, 46-48].The importance of austenitic stainless steels is expressed in the multitude of applications that depend on their use. From simple applications, such as cooking kits and infrastructure, to high- level applications, like rocket, the application of austenitic stainless steels is indispensable.

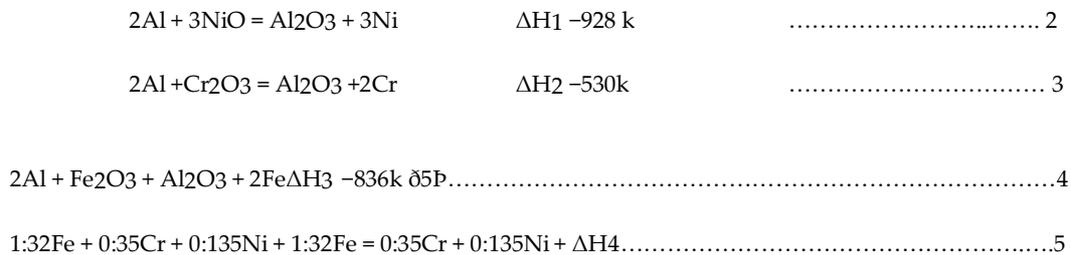

**Sudeep Kumar Singh et al.**

Type 304 and type 304L stainless steel.

The most commonly used austenitic stainless steel are Type 304 and type 304L. They are also referred to as '18-8' stainless due to their constituents, which consist of 18% chromium and 8 % nickel, type 304 and type 304L stainless steel have noble welding and forming characteristic, a high corrosion resistance and high tensile strength[49]. Figure 2.13 (a) and (b) show type -304 and 304L which are extensively used in automotive, food and energy production because of their outstanding mechanical properties, resilient corrosion resistance and good electrical properties [50, 51].

Element and compound such as Al, Fe<sub>2</sub>O<sub>3</sub>, Fe, Cr<sub>2</sub>O<sub>3</sub> and NiO powders are raw materials used for synthesis of 304 stainless steel. It was anticipated that the oxides were compacted by aluminum and a fluid alloy comprising Ni, Cr and Fe, elements forms. Immediately after fusion this alloy changed to an austenitic stainless steel [22]. The four main reactions that can occur for synthesis of stainless steel are as follows:

Type 304 L stainless steel has lower carbon content compare to Type 304 stainless steel alloy. This minimizes, or eliminates chrome carbide precipitation but Type304L has lower mechanical properties compared to Type 304 grade. Tables 2 and 3 show the chemical composition and physical properties of type 304 and 304L.

**Weldability of type 304 austenitic stainless steel**

The weldability of a material is its capacity to be welded into a precise structure that has specific properties and characteristics and will adequately suit the service requirements. Type 304 austenitic stainless steel is largely believed to be weld able maorly by resistance processes and arc welding. The traditional arc welding is mostly delicate to generate inter-granular Cr-rich carbides on the sideways of the grain boundaries and the coarse grains in the heat affected zone, which weakens the tensile strength and hardness of the weld oints [18, 32, 52, 53]. Moreover, austenitic stainless steels occupied approximately 67% of the total stainless steel manufacturing and it is preferably chosen over all other stainless steel types because of its excellent welding properties [5]. On the contrary, Shiri et al [5] in their survey they unveil that there are some shortcoming in metallurgical variation in welding operation of austenitic steel. Which are listed below

- ❖ Delta ferrite phase formation,
- ❖ Sigma phase formation,
- ❖ Stress corrosion cracking,
- ❖ Chromium carbide precipitation in grain boundaries and
- ❖ Hot cracks formation

Since the tensile strength of the stainless steel extensively relied on the microstructure in oint, many academics survey have been done towards improving the microstructure, the mechanical properties and reducing the metallurgical changes in the welding oint of stainless 304 through various single and hybrid welding processes. Included in these are hybrid Co<sub>2</sub> laser –gas metal arc welding by un [32], surface-coated friction stir welding by Lakshminarayanan et al. [54], laser- TIG weld by un Yan et al [32] and Comprehensive welding technology for type 304

steel rotating shaft by ZUO et al [51]. Type 304 mainly enclosed austenite with small ferrite as shown in Figure 2.14 and 2.15.

#### **TIG-MIG hybrid welding of a 304 stainless steel**

The study showed that TIG welding of austenitic stainless steels using argon gas for shielding is limited to the highest metal thickness of 3 mm for a proper welding joint and to fairly low welding speed. Though when hydrogen or helium is mixed with the shielding gas, then the welding speed can be considerably increased up to 160% [57-59]. When MIG arc welding process is used as a substitute to the TIG arc welding process, it permit in a single pass the welding of a 6 mm thick welding joint. However, numbers of appearance defects characteristically including humping, undercut and excess penetration welds were easily formed, which resist the further development of production. Unsteadiness offered as weld bead roughness and spatter which exist in MIG welding are more than that of the TIG welding process [60]. The hybrid welding techniques of TIG and MIG welding processes is a significant approach of improving welding output and quality owing to the merit of the two methods [61].

TIG and MIG welding are of low cost, since neither special shielding gas nor complex synergic powers are needed. It shows that MIG arc can be stable by simple hybridization of TIG even though pure argon shielding gas is used, which means that the welded metals toughness is improved and welding quality is developed [62]. Further study indicates that it also has great potentiality to increase welding speed with high quality because of the quite stable cathode spots appearing in this hybrid welding [63]. The effect of TIG welding current on the welding properties like stability of the penetration depth, arc and repulsion between both arcs were examined by Shuhei et al [39] although the material used was not specified, but the result indicates that the TIG welding current must be greater than the MIG welding current in order to maintain the MIG arc stability when using pure argon. Also, that penetration depth advances with rises in TIG welding current provided that the TIG welding current is higher than the MIG welding current.

#### **Tensile strength and micro -hardness of welding joint of a type-304**

Tensile properties reveal how a metal or material will act when a considerable forces is being applied in tension. Basically, a tensile test is a mechanical test where a prepared sample is loaded in a much harmonized manner while measuring the applied load and the elongation of the sample over some distance as shown in Figure 2.16. Tensile tests are used in determining the modulus of elasticity, elongation, elastic limit, proportional limit, tensile strength, yield point, reduction in area yield strength and other tensile properties. On the other hand, hardness is the defiance of a material to confined deformation as shown in Figure 2.17. The word can apply to distortion from scratching, indentation, bending, cutting or twisting. In ceramics, most polymers and metals, the deformation being taken into account is plastic deformation of the surface. Sahin conducted a studied on hardness of Type- 304 austenitic stainless steel and his conclusion was that Type- 304 austenitic stainless has no significant hardening influence on the welding zone [65, 66].

However, Alphonsa et al [68] in their work titled plasma nitriding on welded joints of Type- 304 austenitic stainless steel, investigated the effects of the welding region of Type- 304 austenitic stainless steel after plasma nitriding process was carried out on the samples. They discovered that apart from 300% improvement in the hardness values which can be linked with structural deviations and process parameters, the two regions have same conducts during nitriding. Hence, plasma nitriding is viable on welded joints if basic caution such as minimize the stress development during welding is applied and welding joints made using multiple pass welding method gave an improved nitriding properties when compared with that of the single pass welding method. Reo et al [69] conducted an investigation to analyze and optimized the welds joint of a similar grades of an austenitic stainless steel by using different grades of stainless steel filler materials. They discovered that at welding current of 120A, when electrode 309L were used a greater mechanical ultimate tensile strength were produced and also that the 309L filler material made a superior bending strength and ultimate tensile strength compared to grade 316 filler material.

**Sudeep Kumar Singh et al.**

Yugang et al [38] conducted an experiment on 2mm thick 304 stainless steel to authenticate the viability of bypass welding current of a double sided arc welding for high-speed welding of thin metal plates. The outcome indicated that the base metal heat input reduced when the bypass current was applied, which resulted in to the decrease in the area of the heat affected zone and the fusion amount. The influences of welding speed and weld appearance of TIG-MIG hybrid welding were studied based on the welding parameters by Xiangmeng et al [70]; and they discovered that the welded joints of a TIG-MIG hybrid have more tensile strength value of 468MPa and micro-hardness of 210HV and narrower HAZ compared to those of single traditional TIG and MIG welding.

power is increases. Also formation of hot spot are probably caused by increases in heat input. The mechanical test conducted revealed that the ultimate tensile strength of the welded joint decreases with increase of welding heat input and the hot spots formed at high welding powers are responsible for decrease in weld joint strength [78]. Curiel et al [78] argued that growth of pre-existent carbides within grains, chromium carbides precipitation and along grain boundaries supported by deformation of cold work as a function of the strength of the imposed on the magnetic field at the time of welding. And the application of axial magnetic fields of low strength at the time of GMA welding of cold deformed Type-304 stainless steel increased its resistance to pitting and intergranular corrosion. Moreover, the thermal cycle involved in the welding process induced minor sensitization on the heat affected zone of the welded joint.

Metallographic studies on type - 304 austenitic stainless steel joined using type- 347 weld metal and heated at 600 and 700°C were conducted by Alexandre et al [79] ;it was discovered that the welded metal becomes tougher than the parent metal at long aging times and the tensile fracture occurs in the base metal of such welded material [79]. Godoi et al [56] investigated the influence of hydrogen outgassing duration on the hardness value of Type -304 austenitic stainless steels welds. They found out that instantly after the completion of the process of hydrogenation, the hardness values of the weld joint and base metal were greater than that of the main material and also with the development of the process of outgassing the ostensible hardness values reduced for the both regions and indicate a lower values compare to non-hydrogenated regions [57]. Gulenc et al [80] in their work, Type-304L austenitic stainless steel was welded using metal inert gas welding, there after microstructural properties , the tensile strength and hardness value of the welded joint specimen were examined. The welding operation was done using various shielding technique, which are mixing argon gas with different portion of hydrogen gas. Welding current of 140, 180 and 240amp were chosen for the welding operations. The weld specimen that was welded using 1.5% H<sub>2</sub>-Ar shielding portion and with a current of 240amps was discovered to have a better mechanical properties compared to the specimen that was welded using 5% H<sub>2</sub>-Ar shielding gas and welding current of 140 amps [81].

In the work of Zhang et al [81], type- 304 austenitic stainless steel of thickness 5mm was welded by a fiber laser. They investigated the influence of, defocusing distance, welding speed and laser power on the weld appearances using the orthogonal method the mechanical properties and residual stress of welds sample were observed and measured. Results showed that if the suitable fiber laser welding parameters were chosen then a good quality weld can be achieved [81]. The butt welding of 3 and 6 mm thick of 304 austenitic stainless steel were accomplished with YLR-6000 fiber laser using argon protective gas by Cui et al [82]. They emphatically investigated the weld appearance, composition distribution, micro hardness and microstructure of welded sample. Their results revealed that a fully penetrated and the narrow welded joint without any forms defects could be achieved with firmly focused at 20 mm/s welding speed using a 2 kW fiber laser power. The equiaxed crystals and fine columnar existed in the center and edge of the weld bead respectively. They argued that the chemical composition distribution of the welded samples had no noticeable deviation. Moreover, the excellent micro hardness values of weld samples over the stainless steel substrate was basically ascribed to its finer microstructure [83].

Naito et al [83] argued that in the hybrid welding of Type -304 stainless steel plate done by YAG laser and a TIG arc using argon gas mixed with 0%–15% oxygen gas. Geometry and penetration of welds were dependent on the level of the oxygen in the ambient atmosphere for both hybrid and laser welding [84].

**Sudeep Kumar Singh et al.**

Welding temperature monitoring is very important in welding procedure as it has the life span of the weld. Experimental temperature gathered in the heat affected zone may be used to calculate the strain distributions and residual stresses in a weld joint. They can also be matched with the thermal records to establish the physical limitations and weld life of the welded joint. The noted maximum temperatures and their location compared to the midpoint of the weld, were stated by Murugan et al [84], these were shown in Table 2.5 with their consequent indicated weld pad and welding pass quantities. Temperature range of 698°C to 837°C in a 6 mm weld pad were the peak temperatures which also stated by thermocouples during the second weld pass [85].

An accent was cited on the significance of observing a proper penetrated welded joint when an external light is not supplied. Figure 2.18 (a) to (d) shows the different levels for weld penetration- depths which were displayed by Bicknell et al [85]. These are unpenetrated, penetration, over penetrated, and burn through. The infrared camera techniques is used to expand the collection of thermal data in a defined area, namely, the weld pool of the weld region. Thermal data is gathered using an infrared camera, reprocess to be used in computer with filters, and then programmed for the computer use. Stainless steel work pieces were welded using a pulsed TIG welding method in order to determine the distribution of temperature in the melt zone and weld pool of the welds. The microstructure and mechanical properties of type- 304 austenitic stainless steel welded by TIG - MIG hybrid welding have not been conclusively researched. However, in this study, 6 mm thick 304 stainless steel plates will be welded by single conventional TIG welding, MIG welding and TIG - MIG hybrid welding, respectively. The characteristics of the weld joint, such as macrostructure, microstructure, hardness and tensile strength will be comparatively studied.

**SUMMARY**

The main principles of welding method, liquid and solid state welding processes, the histories and the developments of MIG and TIG welding technologies were depicted in the literature review. The advantages and disadvantages of MIG and TIG welding technologies were comparatively discussed. Moreover, difference combinations of hybrid welding process were looked at and the benefits of hybrid welding were also review. Conclusively, the weldability of type 304 austenitic stainless steel by various welding processes and also the metallurgical variation in welding of type 304 austenitic stainless steel were reviewed. Very limited report is available on the TIG-MIG hybrid welding of type 304 austenitic stainless steel. Recent papers are based on preliminary studies, most of which focused on welding speed, only a few on mechanical testing, and there is no existing report on the detailed characterization of TIG- MIG hybrid welding of type 304 austenitic stainless steel.

In this research work, a better process for joining type -304 austenitic stainless steel will be established, using a base metal to be used is type- 304 austenitic stainless steel of dimension 175mm x 100mm x 6mm and butt joint will be considered only. The input power will be varied for different weld and each welded part is characterized through the evolving microstructure, micro hardness and corrosion. The optimal conditions for TIG and MIG will be determined. The optimized setting was employed to design the TIG-MIG hybrid welding system. An evaluation of the literature associate with this work has been effusively examined in this chapter. The chapter three will focus on the experimental set-up procedures employed in the course of this research study.

### ABSTRACT

This chapter explains the methodology used in this research work. The aim of this chapter is to document the welding process of TIG, MIG and TIG-MIG hybrid welding of type 304 austenitic stainless steel and the characterization of the welds shaped. The techniques used for characterizing the weld interfaces are tensile strength, micro hardness and microstructure. Brief outlines of the techniques used for characterization, equipment used, and the laboratory events for using the equipment are presented and discussed.

**Keywords:** welding, microstructure, laboratory, work

## INTRODUCTION

The base metal and filler materials used in this work were type 304 austenitic stainless steel plate and type 316 respectively. These resources were supplied by Metal Centre based in South Africa. The chemical arrangement of the type 304 and filler material 316 stainless were listed. The steps used in successive order in this research as follows:

- Work piece preparation
- Welding procedures
- Microscopic analysis
- Mechanical Test

## METHODS

### Work piece preparation

In the present work, six samples of 6mm thin of type 304 plate were cut with measurement of 175mm x 100 mm by

24684

**Sudeep Kumar Singh et al.**

means of band-saw, and grinding was complete to the edge of the plates in order to smoothen the surface to be oined. There after, 30 degree V-groove of length 175 mm was done at the edge of each plate to secured a good saturation of the welds with the aids of universal milling engine as shown in Figures 1 (a) and (b) Before the welding process, all the four edges of each were Pains taking mechanically cleaned with the use of sand paper of grit size of 350 $\mu$ m and later cleaned chemically with acetone so as to elude any forms of contamination like scale, rust, oil, moisture and dust that could come into the welded sample which may later result into a weld defect.

**Welding Procedures**

The welding procedures were carried out in three phases, which are as follows

- (i) MIG welding,
- (ii) TIG welding
- (iii) Hybrid of TIG and MIG welding

**MIG Welding Procedures**

The MIG welding is carried out using a miller CP- 300 model MIG welding machine as shown in Figure 2; two work pieces of dimension 175mm X 100mm X 6mm each were tacked at the two ends along the length 175mm, with a common root gap of 4mm as shown in Figure 3. The MIG welding operation was done in one pass using direct current electrode negative (DCEN) Miller CP- 300 model MIG welding machine and a pure Argon gas was used for shielding as shown in figure 2. In this research, two samples were prepared. For each sample type-316 filler rod was used as shown in Figure 3.4. The welding current was the only limit varied during this experiment therefore giving a range of heat input for the welding. Table 3 shows the welding parameters used.

**TIG welding procedures**

The TIG welding setup mainly consists of the following parts

- a) TIG welding machine– the TIG welding was done on TIG 200P DC/AC THERMAMAX Welding machine as shown in Figure 5
- b) TIG welding torch
- c) Gas cylinder
- d) Work holding table

Two work pieces of dimension 175 mm X 100 mm X 6 mm each were creased together with welding gap of 4 mm as indicated in Figure 3.3. Thereafter, TIG welding with two different parameters procedures were done in one pass direct current electrode negative (DCEN) TIG 200P THERMAMAX welding machine, a pure argon gas was used as the shielding gas and type - 316 filler rod of diameter 2.4 mm but with different welding parameters as shown in Table 4.

**TIG – MIG hybrid welding procedure**

The welding equipment TIG 200P DC/AC THERMAMAX welding power source with the rated welding current of 200A and miller CP- 300 model MIG welding power basis with rated welding current of 300 A were used for the hybrid welding of TIG and MIG. Two work pieces of dimension 175mm X 100mm X 6mm each were lined together with welding gap of 4 mm.

Thereafter, TIG welding with two different parameters procedures were complete in one pass direct current electrode negative (DCEN) TIG 200P THERMAMAX welding machine, a pure argon gas was used as the shielding gas. Samples F 5 and F6 were complete using the same 316 filler material of diameter 2.4 mm but with dissimilar welding parameters as shown in Table 5 and

**Sudeep Kumar Singh et al.**

immediately MIG welding of single pass were done on the same work pieces labelled F5 and F6 to covered up the TIG welds using 130A for F5 and 170A for F6

### Microstructural characterization

Optical microscope and SEM were used for the microstructural characterization. ASTM 262 standard was taken into knowledge for all the sample arrangements and standard sample preparation techniques were employed [87].

### Sample preparation

The Sample were securely fixed at the time of cutting and also cutting force were applied carefully to avoid the breaking of the wheel. Figure 6 shows the cutting machine used in this study. The cut samples was mounted with resin (Polyfast) using an automated Struers Cito Press. Pneumatic and water were used as press and cooling system respectively as shown in Figure 9. ASTM E3-95 [89] was applied for the metallographic analysis

After mounting, the samples were then ground. Grinding commence with a rough or plain grit size of 240 $\mu$ m in order to create a plane surface and to eliminate the influence of cutting in a slight time. Thus, all grinding steps were did as it is summarized in Table 3.7. Thereafter, the samples were being polished with the aids of Struers polishing machine as presented in Figure 3.8 to obtain mirror finished samples. The consumables used for grinding and polishing of the metallographic sample are shown in Table 6 and 7.

However, hand or manual polishing is typically done by the use of a rotating wheel by which the sample is turn in a sphere-shaped path counter to the wheel recurring direction [88] and ASTM E3-95 [89] was used for the metallographic analysis. Hence hand-polishing methods is as follows.

**Samples Motion:** The sample can be imprisoned with the both hands and it is moved in a direction so as oppose the motion of the polishing wheel.

**Polishing Pressure:** an appropriate amount of applied weight should be controlled in the practice. Broadly, a safe manual pressure is always applied to the sample.

**Cleanliness:** sample cleaning should be observed strictly to evade contamination.

After polishing, the samples were ultrasonically wiped and arid with the aids of ethanol and compressor respectively. The samples were etched after polishing to clearly reveal the microstructure. The etchant used for Stainless Steel was Carpenter 300 Series. The etchant was prepared at the university of ohannesburg metallurgical laboratory with the aids of digital spring balance, measuring cylinders and bakers as shown in Figure 10. The mass of 4.25g of ferric chloride and 1.2g of cupric chloride were mixed and 62ml of alcohol, 62ml of hydrochloric acid and 3ml of Nitric acid were introduced to dissolve the mixture in succession. The solution was continuously stirred until all the atoms were dissolved. The samples were dipped one after the other into the prepared solution (etchant) for 15seconds. The etchant makes the microstructure noticeable and gave a clear copy of the size of the grains. The etched samples were analyzed under the microscope

### Optical microscopy

Macro structural and microstructural inspections were done to reveal the shape of the welds oint zone and analyze the effect of the process parameters on the microscopy development of the welded samples using Olympus DP 25 microscope as presented in Figure 11.

Sudeep Kumar Singh *et al.*

### Scanning electron microscopy

Microstructural examinations were done with the aids of TESCAN Scanning Electron Microscope (SEM) as presented in Figure 12 and Figure 13 shows a sample mounted inside the chamber of SEM during the trial which was used to analyze the delivery of the particles and surface morphology at higher magnification. The investigation of the chemical composition of the welds oint were performed through Energy Dispersive Spectroscopy (EDS) software on the SEM

### Mechanical tests

Tensile shear and microhardness tests were conducted on the welded samples. The outcome of the tests provided tangible information about the microhardness profiling of the welded samples, the fracture behavior, oint efficiency and the shear strength of the oints.

### Tensile testing

Instron 5500R, an electromechanical tensile testing machine sited in the department of Mechanical Engineering Science, University of ohanesburg, South Africa was used in this experiment. Figure 14 shows the Instron machine with an apex load of 100000N. It is connected to a computer for parameter settings. The standard ASTM E8/E8M-13a was used for the tensile test specimen. The standard ASTM E8/E8M-13a dimensions [90] and the drawing for AWS B12.5 uniaxial tensile tests are shown in Table 3.8 and Figure 15. Then tensile tests were done to decide how strong the welds oint are. Three transverse samples were cut from each welds at starting point, centre and ending point of the welding line with the aid of a water-et cutter as shown in Figure 16 and Figure 17

Welds metal tests were performed on a tensile testing machine with an apex load of 100000N at crosshead rate of 3mm/min in agreement with the requirements of ASTM E8 standard. The outcome of the tests were matched and the average values were calculated for the three welded samples. The transverse specimen method was used. The transverse tests was used to be sure that the weld joint sample does not crack before the failure occurs in the thinner region due to distortion. In this method, the thickness of the neck after distortion was taken as the initial thickness for estimate of the cross-section was drawn to failure on the Instron 5500R tensile machine. Figure 3.18 (a) and (b) display a specimen in the tensile machine during testing and after completion of the test

### Micro hardness indentation

Hardness is a property of a material, not a major physical character. It is defined as an opposition to indentation. The microhardness test method, also referred to as Vickers hardness tester, is system. The microhardness tests were conducted on the digital Indenter micro hardness tester with diamond indenter in accordance to ASTM E92-82 [91] standard. Figure 3.19 shows the hardness machine used. The microhardness values help to determine the hardness of a material to the wear resistance, strength and deformation of sample and the hardness were measured at the across the heat-affected zone (HAZ) and center of the fusion zone into the base metal to calculate the mechanical properties. The indenter was busy into the specimen by a precise controlled test force. A force of 100 g was kept for a certain duration of 15 seconds. After the completion of the dwell time, the indenter was removed and an indent was left on the sample that is diamond shape on the surface of the sample. The magnitude of the indent was measured optically. Using the dimension of the indentation obtained, the hardness values of the sample were calculated

## SUMMARY

The methodologies used for TIG - MIG hybrid welds and the characterization of the welds were offered in this chapter. Furthermore, the metallurgical evaluation were conducted every welding parameter, the mechanical testing was conducted. Mechanical tests comprised of tensile strength and micro hardness. Furthermore, the metallurgical

**Sudeep Kumar Singh et al.**

evaluations were conducted to determine the weld quality. Chapter four converses the results obtained from the characterizations performed on the welds. The mechanical properties will also be accounted for. These interactions will offer an intuition into the mechanism of the method, and provide an optimal process of opportunities that can be explored further, which enable manufacturing engineers to develop weld procedures for TIG-MIG hybrid welding.

### ABSTRACT

This paper discusses the design of the pulsed wire process. The pulsed wire process is discussed in context of a specific embodiment of the process that is used to create ultra-fine copper and copper oxide particles. The manual and drill EDM experiments showed that current pulses rather than a constant current create a more stable process. Also the pulsed EDM like processes have the advantage of near zero cathode electrode growth or erosion. Near zero cathode growth provides the possibility of needing only one consumable electrode. The twin wire experiments showed that if two identical diameter wire electrodes are used, the alignment of the wires must be very good to have a stable process. If the wire alignment is not good, then only a portion of the wire cross section is eroded wasting that portion of the electrode. The wire misalignment also creates a condition where the electrodes will touch while passing by each other creating a shorted condition.

**Keywords:** EDM, diameter, electrodes, cathode, copper

### INTRODUCTION

It was clear that a process with a pulsed power supply would be more likely to perform well with wire electrodes than with a constant current power supply of the wire anode electrode is aligned to the cathode electrode poorly. Because the cathode electrode is large in comparison to the anode electrode the cross section of the anode will still be totally eroded. The pulsed wire process uses a closed loop anode electrode motion control system. Stable, closed loop motion control is required to maximize the rate of erosion in the process. Both EDM process, and the rod processes show that the stability of the motion controller is key to maximizing the rate of erosion. Typically, the average electrode gap voltage drop is measured to estimate the electrode gap distance and close the motion control loop.

**Sudeep Kumar Singh et al.**

The pulsed wire process is defined as a process that uses a pulsed DC power supply creating current pulses between a flat plate electrode and a wire electrode whose position is controlled using a closed loop motion control system where the average arc gap voltage is used as the feedback signal.

### **Mechanical Design of the Pulsed Wire Process**

The mechanical design of the machine in terms of particle production can be split into two parts; the design of the reactor, and the design of the wire feed system. The design of these parts of the mechanical design has changed significantly as a result of the information gained during the development of the process.

#### **Some of the key requirements the mechanical design must accomplish are the following:**

- The new machine must use an anode in wire form
- The machine must be able to run continuously for long periods of time
- The machine should limit the need for frequent operator adjustment
- Seals in the reactor must be eliminated

The development of the mechanical portion of the process was completed at the same time that the idea of using a single wire electrode with a flat plate cathode electrode rather than two wires was developed. As a result, the reactor and the wire feed system can use two wires, or a wire anode electrode and a larger cathode electrode.

### **Reactor Design**

One of the most time consuming maintenance requirements for the rod process is the re-placement of the seals in the reactor. Because the rods are constantly rotating and translating, the seals and the bearings used in the reactor frequently need to be changed. Even when new seals were installed in the reactor the dielectric fluid still leaked out due to variations in the diameter of the rods and misalignment of the rods. One of the major goals of the pulse wire machine was to eliminate the need for seals or bearings in the reactor. Wire is compliant and can be bent to turn a corner in the reactor unlike the rod electrodes. An open top basin was used so that the wires could enter from the top without a need for seals. The wire electrodes enter the top of the reactor guided by a Teflon tube. The Teflon tube is formed into a curve by a slot in the wire feed plate. As the wire is fed through the Teflon tube, it is bent into a circular arc until the wire is horizontal and perpendicular to the flat plate electrode.

Because the electrodes enter from the top of the reactor and then are bent inside the reactor, no seals are required. The Teflon tubes will wear over time and will need to be replaced, but the replacement of the tubes is easy and will only be required one or twice a year rather than daily. The design shown was developed prior to the decision to use a flat plate cathode electrode of .0625 inches. A second wire electrode with a diameter of .25 inches was used as the cathode electrode. The diameter of the cathode electrode is 4 times the diameter of the anode electrode; this makes the cathode electrode effectively a flat plate in comparison to the anode electrode. The cathode electrode is stationary, and the anode wire is fed using the wire feed system. The dielectric fluid enters the reactor through a tube that flushes the dielectric gap and fills the reactor. The fluid exits the reactor through an overflow pipe (black pipe). The fluid that exits through the overflow pipe is drained into a 10 gallon storage tank. The fluid entering the reactor through the fill tube is pumped out of the same storage tank. The water in this closed loop system is recirculated till the concentration of particles in the fluid is high enough. After the concentration of the particles is high enough, a low flow rate peristaltic pump starts to remove fluid from the storage tank. A float valve in the storage tank keeps the fluid at the same level by adding clean deionized water. At steady-state conditions the concentration of the particles in the fluid is nearly constant and the fluid leaving the system leaves at the same concentration.

### Wire Feed System

The ideal feed mechanism for wire feedstock in a continuous process is friction drive roller like those used in wire feed welders. The drive roller is ideal because it can feed an infinitely long wire without any pauses or interruptions. A set of U-Groove drive wheels from a Miller wire feed welder were used in the machine so that the rollers would be off-the-shelf components. The diameter of these drive rollers is about 1.6 inches. Because the electrode gap in the process is very small, on the order of a few ten thousandths of an inch to a few thousandths of an inch, high resolution positioning of the electrodes is required. Also, the backlash of the positioning system must be low to prevent a large delay when the direction of motion is changed. To provide the fine resolution motion required a micro-stepping stepper motor along with a 10:1 gearbox was used to drive the roller.

The stepper motor was driven with a 256 micro stepping controller that results in a theoretical 102,400 steps per revolution. With the 10:1 low backlash gear box there are approximately 200,000 steps per inch, or 0.000 005 inches per step. The drive roller needs to be electrically isolated from the stepper motor because the electrical current is transmitted into the wire through the drive roller. To isolate the motor from the drive roller, a timing belt with Kevlar bands is used to transmit the torque from the gearbox to the drive roller. The timing belt electrically isolates the motor and the roller but introduces some torsional flexibility into the system. Because the system has friction, stiction, torsional flexibility, and other effects the expected resolution of the wire positioning system is expected to be somewhat less accurate than 5 millionths of an inch per step of the motor. The resolution is expected, however, to be smaller than the electrode gap. It has been confirmed by experimentation that the resolution of the system is well under one ten-thousandth of an inch (.0001 inches).

### Power Supply

Pulsing the current across the electrode gap limits the length of the discharge time in the process. When the length of the discharge time is limited, the maximum particle size is also limited. Limiting the maximum particle size has a significant impact on the distribution of particle size. The design chosen for the pulsed wire process power supply is a simple current limiting pulsed DC power supply. This design is very similar to the design used in the drill EDM described in section 3.3. Figure 4.4 shows the basic concept for this type of power supply. The power supply design uses a resistor to limit the current across the electrode gap. The resistor is a passive element so no active feedback loop is needed to provide a constant current. Ohm's Law is used to determine what resistance is needed for a given voltage and current. There are three states that should be considered during the design of this type of power supply. The first state is the short circuited state where the electrodes are touching. Ideally the machine will never be in this state, but it is nearly impossible to completely prevent the electrodes from shorting out. Using Ohm's Law the current can easily be determined and is shown in Equation (1). This is the maximum current that can be expected in the system. Equation (2) shows the power dissipated by the resistor in this shorted state. The power dissipated by the resistor is very significant and is the largest loss in the power supply. This is because the resistor limits the current in the circuit by converting electrical power to heat. All the components in the current loop should be selected to handle the shorted current for an indefinite period. Failure to select components that will indefinitely handle the shorted current could result in failure of the power supply, or worse an electrical fire.

$$I = \frac{V_{\text{source}}}{R} \quad (1)$$

$$P_{\text{resistor}} = I^2 R \quad (2)$$

The second state that needs to be analyzed is the current during a discharge. Typically, once the discharge has started the voltage across the electrodes will be between 18 and 26 volts depending on the electrode gap distance. For the design of this power supply the electrode voltage drop,  $V_{\text{gap}}$ , will be assumed to have a value of 22 volts. Equations (3), (4), and (5) show the current, power dissipated by the resistor, and the power delivered to the

Sudeep Kumar Singh *et al.*

electrode gap, respectively. The current and power dissipated by the resistor is less in this discharge state compared to the shorted state. The rate of wire erosion is roughly proportional to the average power delivered to the electrode gap. Because the current in the gap is constantly being switched on and off, the duty cycle of the process must be considered. The duty cycle is the ratio of  $t_{on}=t_{off}$ , or in other words the percent of the time that the current is flowing through the gap. The average power delivered to the electrode gap. The power supply design requires an electronic switch to handle the high frequency switching of the load. A set of N-channel MOSFET transistors were selected for the supply. N-channel

MOSFET transistors were used in the power supply due to their low cost, high switching speed, and low on resistance. A MOSFET gate driver was also selected to improve the switching characteristics and reduced the switching losses of the transistors. The power supply design requires a constant voltage source of 80 VDC. A custom made toroidal transformer was used to convert three phase 208 VAC power to three phase 55 VAC power. A three phase full bridge rectifier was then used to rectify the power into a DC voltage. An LC input filter was used to filter the rectified DC voltage to a nearly constant voltage of 80 VDC. The LC filter acts as a buffer between the erosion process and the three phase AC input.

### Design of the Control System

The control system for the pulsed wire process is very important. The control system uses measurements from the process to make corrective actions to the wire position, stabilizing the process. One important note is that overshoot (when the controller feeds the electrode too close together) should be avoided to prevent shorting the two electrodes. In addition, the rise time, or the time it takes to reach the set point, should be minimal to quickly react to disturbances in the system. The electrode gap discharge is difficult to model accurately. The electrode is constantly changing in length, and the relationship between the electrode gap distance and the electrode gap voltage drop is quite non-linear. However, to roughly determine what kind of controller should be used, and what the optimal parameters are expected to be, a simplified model is sufficient. Two PCI interface cards were used to connect the PC to the pulse wire machine. An FPGA (Field Programmable Gate Array) based signal control card was used to provide digital I/O and to output the step direction signals to a stepper motor controller. The second interface card provides several analog to digital converters. The voltage and current signals are acquired using the analog to digital PCI card, processed by the controller on the PC. This manager calculates a new position for the motor. The EMC software produces a smooth motion path to the new position with limits on velocity and acceleration. The FPGA card then produces the step direction signals for the stepper motor controller to change the position of the stepper motor. The stepper motor changes the position of the electrodes to correct the electrode gap distance.

### Voltage and Current Sensing

Great care was taken to electrically isolate the discharge power supply from all the control systems in the machine. This isolation is to provide safety to the operator and to reduce noise and offset in the voltage and current signals. In the original design of the pulsed wire process, the electrode gap voltage was measured, converted to a digital signal, transmitted through optical isolation, converted back to an analog signal, and finally converted into a digital signal by the analog to digital PCI card in the PC.

Unfortunately, several filtering and aliasing problems were produced with this configuration due to the signal being converted from analog to digital two times at two different rates. The signal was required to be converted from analog to digital twice because the analog to digital converter in the computer was not electrically isolated from the discharge power supply. The way the current across the arc is sensed is fundamentally different from the way that the voltage was sensed. The current transducer used in the machine uses the hall effect principle to indirectly measure the current in a wire by measuring the magnetic field induced into a metallic ring in the current transducer. Because the transducer only measures the magnetic field produced by the current in the wire the signal it produces is already electrically isolated from the discharge power supply.

### Sudeep Kumar Singh *et al.*

Because the power supply uses passive resistance to limit the current in the circuit if the current across the resistor is known, then the voltage across the resistor is also known. Also, if the voltage across the resistor is known, then the voltage across the electrode gap is also known. This means that only one of the two parameters of voltage and current really need to be measured. Using Ohm's law for the resistor the voltage drop across the resistor at any given instant of time is given in Equation (1) as a function of the instantaneous current  $i$ . The only other element in the circuit is the electrode gap, so the remaining voltage must be across the electrode gap as shown in Equation (2), where the open circuit voltage of the power supply is  $V_d$ . The current transducer measures the average current,  $\bar{i}$  over several discharges so the remaining terms must also be expressed as an average value. The average open circuit voltage  $\bar{V}_d$  is shown in Equation (3), and the resulting average gap voltage, is shown in Equation (4).

$$V_r = i R \quad (3)$$

$$V_{\text{gap}} = V_d - V_r \quad (4)$$

$$\bar{V}_d = V_d (t_{\text{on}} = t_{\text{off}}) \quad (5)$$

$$\bar{V}_{\text{gap}} = V_d - R \bar{i} \quad (6)$$

The rod process produced a large amount of energy from the arc that was converted directly into heat increasing the temperature of the dielectric fluid in the system. The change in dielectric fluid temperature was enough to require a chiller to be installed in the system to keep the fluid at a reasonable temperature. This same effect was expected with the wire process, but the pulsed discharges in the pulsing wire process do not add a significant amount of energy to the fluid, unlike the rod process. Most of the energy in the pulsing wire process is used to create particles, and very little is used to heat the dielectric fluid. Because the temperature of the water does not change significantly when the pulsing wire process is used, all the designed experiments were performed with the water at room temperature. This eliminated the dielectric temperature as a design variable.

#### Impact of Motion Control Parameters

The PID motion control parameters will clearly have an impact on the response variables. The PID parameters affect the stability of the process. If the PID parameters are poorly tuned then the rate of erosion will be reduced, and the size of the particles will vary more due to the variation in electrode gap distance. It is possible to tune the PID parameters for every experiment performed on the machine. However, if the PID parameters were tuned for each setting, then the effects from the design variables and the PID parameters would be confounded. It would be unclear if the change in the output at a given setting is a function of the PID parameters, the design variables or any combination of the two.

To prevent the confounding of the PID parameters and the design variables in the experiment, the PID parameters are held constant for all experiments performed on the machine. A set of PID parameters was found that allowed the process to be reasonably stable in the range of the design variables used in the experiment. After the designed experiment have been finished and the optimal settings for peak current, pulse frequency, and pulse duty cycle are determined, the PID parameters for that setting can be fine-tuned to increase the performance at the optimal settings.

#### Expected Form of the Model

The three remaining design variables are peak current, frequency, and duty cycle. These are the design variables used in the experiments to create predictive models of the process. From a theoretical standpoint these three parameters are expected to have the largest effect on the process. The rate of erosion is largely a function of the amount of power delivered to the electrode gap [1]. As more current is delivered to the gap, the rate of erosion is

**Sudeep Kumar Singh et al.**

increased. Peak current, pulse frequency, and pulse duty cycle all will have a large effect on the average power delivered to the electrode gap. The average power delivered to the gap,  $\bar{P}_{gap}$ , is shown in Equation (5) and is  $\bar{P}_{gap}$  clearly linear with respect to the average gap current  $\bar{i}_{gap}$ . Equation (6) shows the average gap current as a function of the peak current, the function  $q(w)$ , and the Duty Cycle.

$$\bar{P}_{gap} = \bar{v}_{gap} \bar{i}_{gap} \quad (7)$$

$$\bar{i}_{gap} = i_{peak} q(w) \text{DutyCycle} \quad (8)$$

The duty cycle and the peak current of the pulses clearly have a linear effect on the average power delivered to the gap. So it would be expected that the peak current and duty cycle would have a nearly linear effect on the rate of erosion. The model of the power supply shows that the resistors and conductors in series with the electrode gap are purely resistive elements. In reality the resistors and conductors used in the power supply have some parasitic inductance and capacitance. So the resistor bank used in the power supply really should be treated as a complex impedance,  $Z$ , having both resistance and reactance. As the pulse frequency increases the effective resistance of the resistor bank increases decreasing the current delivered to the gap. This means that as the pulse frequency increases the rate of erosion will likely decrease. The average size of particle produced in the process is expected to correlate with the surface finish of the workpiece in EDM processes. Parameters in an EDM process that result in fine surface finishes would be expected to produce small particles. Surface finishes in EDM machining are generally smoother when the current is decreased and the frequency is increased. This effectively creates more frequent, lower energy sparks in comparison to a higher current lower frequency setting. The lower current and higher frequency pulses will erode less material for each discharge reducing the probability of creating larger particles.

Little is known about what might affect the variance in the size of particles produced in the process. It would be expected that a lower variance in particle size would be expected when the process is more stable. That is to say when the electrode gap is well regulated and all the discharges produced are the same. It is difficult to guess at how the design variables might affect the variance of particle size.

### Selection of a Designed Experiment

The objective of performing the designed experiment is to determine the optimal setting for the process to operate at. Because of this a RSM, or response surface methodology, design should be used. One constraint in the design is that the power supply can only be set to four equally spaced current settings of 16, 32, 48 and 64 amps. This eliminates the possibility of using a full central composite design that requires 5 parameter setting. The remaining two factors of pulse frequency and duty cycle can be set to any setting in a reasonable range. There are two RSM designs that would be possible to use with three factors and the con-straints on the current settings. The first is a faced centered central composite design. This design uses three factor levels in each factor. This design has high variance on the edges of the design space, but has nearly flat variance in the middle of the design space where the optimal parameters are expected.

The second possible experimental design would be an I-optimal design. This design is a computer generated design that selects treatments from a subset of the full factorial design space. The treatments are selected on the basis of D-optimality, or the determinate of the information matrix composed from the treatments selected. An I-optimal design was created for the experiment and was compared to the face centered central composite design. Both designs have the ability to create a quadratic predictive model from the data. The face centered central composite design was favored over the I-optimal design because the variance of the design is lower and more constant though the center of the design space. The face centered central composite design is more commonly used so more tools are available to analyze it. Because of this the face centered central composite design was chosen over the I-optimal design.

### Factor Levels

The factor levels in the face centered central composite design are linearly coded variables from -1 to 1. For each of the design variables, a maximum and minimum value must be selected to map to the coded factor levels. For the current design variable only four settings are possible and the higher settings are expected to be favorable so the higher three settings were selected. The maximum and minimum settings for the pulse frequency and duty cycle were selected to give extreme values that still result in a stable process. The process was run at each of the extreme setting to make sure that the process could operate stably at these settings. The resulting designed experiment is shown in Table 4.4. The design has 6 center points shown in the table as treatments 7-14. These six center point are used to estimate the variation in the system.

### Experimental Procedure

Great care was made in the experiment to make sure than the operating conditions were the same for every run in the design. The order of the treatment was randomized to prevent background noise from being interpreted as a real parameter effects. Before each treatment was run the ends of the electrodes were flattened with a file and cleaned. The reactor was cleaned and filled with 4 liters of clean deionized water. Next, a marker was attached to the wire electrode next to a 5 cm scale. The maker was positioned so that the it points at the 5 cm mark on the scale. The reaction is started and the wire was eroded until the marker reaches the 0 cm mark on the scale. A stopwatch was used to measure the time required to erode the 5cm of wire. Care was taken to make sure that the particles in the fluid were well mixed and then one liter of fluid was collected in a vial for particle size analysis. The reactor was then cleaned and prepared for the next treatment. For each treatment in the experiment the rate of erosion was calculated based on the mass of a 5cm long wire and the time required to erode that length of wire.

The two remaining response variables, particle size and particle size variance, were mea-sured using a Beckmann Coulter LS230 particle analyzer. Based on scanning electron microscopy the expected particle size range is from about 50 nm on the low end to about 50-100  $\mu\text{m}$  on the high end. The LS230 instrument is a laser diffraction particle analyzer. Laser diffraction particle analyzers typically have a measurement range between 400 nm and 2000  $\mu\text{m}$ . Laser diffraction methods will easily measure the larger particles but will be useless for measuring the smaller particles produced in the process. The LS230 has an addition PIDS (Polarization Intensity Differential Scattering) module for measuring particles from 40 nm to 800 nm.

The LS230 used was fitted with a small volume fluid module that requires only a 200 ml fluid sample. 200 ml of RODI(Reverse Osmosis Deionized) water was placed in the LS230 sample module and the machine was then calibrated and prepared to measure the sample. Then the container with the sample to be measured was shaken to disperse the large particles in the sample. A syringe was used to introduce fluid from the sample container into the LS230 sample module until the appropriate PIDS concentration was reached. A debubbling cycle was then run on the instrument to remove any air bubbles introduced in the sample chamber when the particles were introduced. The sample was then analyzed in three 90 second runs. The three runs were then averaged to produce single particle size histograms (see Appendix A).

After the first designed experiment has been performed and the data analyzed, it became apparent that a second experiment would be required to properly characterize the rate of erosion in the process. This second experiment was required due to a lack of fit between the data and the predictive model created from the data. It was clear from the first experiment that the pulse current was a very significant factor. Additionally, it was clear that current has a positive effect on the rate of erosion. Because current is now known to have a positive effect on the rate of erosion, and the objective is to find settings that will maximize the rate of erosion, the current was set at the maximum value for the second designed experiment. The two remaining parameters of frequency and duty cycle can be set at any reasonable value unlike the current setting that could only be set at 16, 32, 48, or 64 amps. With this greater flexibility a new design was selected for the second experiment. A full central composite design with alpha points was selected

**Sudeep Kumar Singh et al.**

for the second design. This design has 5 levels for each factor. In addition to changing the design for the second experiment the new design was centered around the expected maximum predicted from the first experiment.

## RESULTS

As was explained, two designed experiments were performed to create a predictive model of the rate of erosion, mean particle diameter, and particle diameter variance for the proposed pulsed wire process. The raw data from the first experiment (current included as a factor) is found in Table 3. This data is shown in the randomized order that the runs were performed. For each of the three response variables (erosion rate, mean particle diameter, particle size variance) a predictive model was created using statistical tools commonly used in designed experiments. The factor effects were calculated using least squares regression and a t-test was used to determine the significance of each of the effects. The designed experiments used are capable of creating, at most, a quadratic predictive model. Two designed experiments were performed for this research. The first designed experiment was created to create models for the erosion rate, mean particle diameter, and particle diameter variance. A second experiment was required to properly model the rate of erosion. These two experiments will be referred to as the first and second designed experiments, respectively.

### ABSTRACT

Ultra-fine metal oxide elements are useful in several areas. Ultra-fine elements can be used as abrasives, coat and adhesive additives, and as feedstock for plasma spray arc coatings. Aluminum oxide particles could be used as an abrasive material in place of garnet in water-jet cutting applications. The same aluminum oxide particles could be used as an additive in paints to make them more wear resistant. Because some metal oxides are electrically conductive they could be used in paints and adhesives to make them electrically conductive. Iron oxide particles could be applied to a surface with the plasma spray arc process to create magnetic films [1, 2]. Undoubtedly, more submissions for these particles will be discovered as more ways are developed to create ultra-fine elements.

**Keywords:** Aluminum, elements, plasma, oxide, areas

### INTRODUCTION

Many of the applications previously mentioned require very small particles. For example, if particles are used as an additive in a paint, the particles would need to be small enough to not produce any significant texture in the applied painted surface. These particles would need to be 70 nm or smaller. Particles with a size under 70 nm are considered ultra-fine elements. In many applications the performance of the particles are superior if the particles are smaller. For example, some particles are transparent to some light ranges as they are lesser than the wavelength of light [3]. The first variation of the plasma arc process is a completely physical method where a human operator panels the process. This method has serious drawbacks in terms of produce quality or constancy, production charges, and high labor costs. The manual process is very flexible in terms of size and shape of the electrodes used in the process because the human operator can easily regulate to these changes. This manual method has many difficulties because it is controlled by a human. The degree of production and the excellence of the particles produced is incomplete by

Sudeep Kumar Singh *et al.*

the slow response time of the operator. The variation introduced into the system by a human operator could be greatly reduced if the operator was replaced by a feedback control system.

The second variation of the plasma arc process, the rod process, was established in previous research at BYU by Chris Lewis. [4] The rod process uses metallic rod electrodes that are fed toward each other as the rods are eroded. The rod process greatly improved the state-of-the-art by replacing the human operator with a digital control system to close the feedback loop. In this way the production rate and product quality were both increased. The production rate was improved by several times over the manual process. Additionally, the rod process requires frequent operator adjustments to maintain consistent control of the process. These adjustments are required due to the way that the electrodes wear. The operator must frequently stop the process to remove and dress the ends of the electrodes. These maintenance issues are time consuming and labor intensive and also seriously limit the utilization of the process. The objective of this research is to improve upon previous variations of the process and develop a new plasma arc process that increases production rate, improves the particle quality, and requires limited operator interference and maintenance.

### Plasma Arc Process

The plasma arc process used for the production of ultra-fine particles has many similarities to other plasma arc processes such as plasma arc welding. Two electrodes are placed in close nearness to each other in a dielectric fluid. In all the experiments deliberated in this research deionized water was used as the dielectric. A voltage change is placed between the two electrodes causing the two faces of the electrodes and the dielectric amid them to act as a capacitor. This gap between the electrodes will last to act as a capacitor until the electric field is strong enough to dazed the strength or resistance of the dielectric fluid. Equation (1) shows the breakdown voltage of a capacitor where  $V_{bd}$  is the breakdown voltage,  $E_{ds}$  is the strength of the dielectric material and  $d_{gap}$  is the distance between the plates.

$$V_{bd} = E_{ds} d_{gap} \quad (1)$$

This relationship shows that the breakdown voltage is proportional to the distance between the capacitor plates. This means that as the electrodes get closer together the voltage required for the dielectric to breakdown is abridged. The dielectric strength of the material is an intrinsic property of a material. The dielectric power of a material decreases with an increase in temperature and frequency. The dielectric strength of deionized water is on the order of 20kV/mm [5]. Given that the power supplies used in this research have an open circuit voltage of 80V, the electrode gap distance for dielectric breakdown is on the order of 4 microns or 0.00015 inches.

The plasma arc can be divided into five stages: pre-breakdown, breakdown, discharge, end of discharge and post-discharge. Chris Lewis' research focused on understanding the discharge stage of the process. During pre-breakdown, shown in Figure 1.1(a), a voltage difference is placed between the electrodes. The process will continue in the pre-breakdown stage until the asset of the electric field overcomes the dielectric strength of the gap. When the dielectric begins to breakdown it ionizes, the result is a conductive path between the electrodes. Current begins to flow, creating a plasma arc between the electrodes through the conductive ion column. The creation of the arc starts the discharge stage of the process. While the arc is sustained, the heat of the arc originates material from both the cathode and the anode to melt and vaporize, then combines with the other material in the plasma channel

### Process Design Challenges

In addition to the control problems noted above the use of rod electrodes in the previous processes had led to many problems in terms of process down time, production rates, raw material cost and maintenance costs. Most of these

**Sudeep Kumar Singh et al.**

issues are related to the fact that the previous processes have required bearings and seals where the rods enter the dielectric filled reaction chamber. If the need for these bearings and seals could be eliminated, then the process down time and maintenance cost would be dramatically reduced.

Seals were required in the rod process because the electrodes entered the reactor from the side below the water line. The seals were required to prevent the dielectric fluid from leaking out of the reactor. Bearings were required in the process to align the electrode with the seals. If the electrodes are not concentric with the seal, the seals will leak. Rods with fine surface finishes, high straightness and high tolerance diameters are required for the seals to function and to increase the life of the bearings. Rods with these properties are difficult to machine and therefore are expensive to purchase. If the need for the seals and bearings were eliminated then the cost of the electrodes, as well as maintenance of the process, would be greatly reduced. The downtime required for replacement of the seals and bearings would also be eliminated increasing the productivity of the process.

The rod process also requires that the electrodes rotate to maintain a stable process. The rotation of the electrodes is what keeps the discharge from staying in one place on the electrode faces. If the process can be stabilized without using rotation, then many additional problems would be eliminated. The proposed new pulsed process would use wire as the consumable electrode. Most of the metal materials that might be used in the process are most readily available in wire form. A large volume of metal can be wound on a spool providing enough feedstock for days or weeks without need for maintenance. If the tip of the wire electrode has buildup or any other problems the tip can simply be cut off. No high cost or time consuming maintenance will be needed for a consumable wire electrode.

## PRELIMINARY EXPERIMENTATION

Several preliminary experiments were performed to better understand how the pulsed wire process should be designed. Originally the goal of the research was simply to create a new variation of the rod process that used wire feedstock rather than rods. While attempting to create this new wire feed process, it was discovered that using a pulsing current across the electrode rather than a constant current had several advantages. This chapter briefly describes these preliminary experiments and the results from these experiments. The first experiment involved an attempt to create a twin wire process prototype. A prototype was created to determine if a welding power supply could be used with two wire electrodes rather than rod electrodes. The prototype demonstrated that a welding power supply is not the optimal power supply for use with wire electrodes. The second set of experiments used an RC EDM type power supply along with manual control to test the feasibility of pulsed EDM like power supplies. This experiment was created to determine if the EDM like pulsed power supply would create ultra-fine particles. The results of the experiment show that ultra-fine particles were produced, and that the process could be controlled to provide consistent results.

In addition to answering the above three questions, the drill EDM experiments also showed that the settings on the power supply could be set so that the cathode electrode has a near zero erosion rate. This near zero wear rate can be used in solving the electrode alignment problem. Rather than using two wires, a single wire could be used as the anode and a larger electrode, like a flat plate, could be used as the cathode. Because the cathode is large in comparison with the wire anode, there is no need for close alignment of the electrodes. The advantages of this configuration will be discussed later. The remaining sections of this chapter will discuss these three preliminary experiments as well as the results of the experiments. The results of these experiments provide a foundation for the development of the pulsed wire process.

## Twin Wire Process Prototype

Inspired by the twin wire spray arc process discussed, a set of experiments was performed to test the feasibility of using two wires as electrodes. A Constant current welding power supply was used in the twin wire prototype. Up to

**Sudeep Kumar Singh et al.**

this point EDM type power supplies had not been used in the process. In fact, the twin wire prototype provided major motivation to move away from the use of a welding power supply toward pulsed DC power supplies like those used in EDM processes.

### **Twin Wire Experimental Setup**

Each of the wire feed assemblies shown feeds a wire through a copper tube. The copper tube guides and conducts electricity to the wire. The copper tubes are partially flexible and can be bent to align the wires at different angles with respect to each other. The wire feed assemblies are mounted above a glass tank filled with deionized water. The copper wire guide tubes were positioned so that the electrode gap is under water

### **Twin Wire Control System**

The position of the wires was controlled by two DC servo motors. The servo motors drive the wires with drive rolls through a planetary gearbox with a 40:1 reduction ratio. The positioning resolution of the drive mechanism is just under one ten thousandth of an inch (.0001 inches). A micro controller was used to control the position of the servo motors with a PID feedback loop based on the electrode gap voltage.

### **Twin Wire Results**

The twin wire prototype was used to experiment with several current settings from 5 to 60 amps. For each current setting and wire orientation the PID control parameters were tuned to attempt to create a stable arc between the wires. Unfortunately, a stable reaction was not realized for any power setting. The welding power supply could be used in two modes, a TIG mode for currents from 5 to 30 amps, and a stick welding mode for current from 30 to 250 amps. At low currents in the TIG mode, an arc was only created when the wires separated after touching. When the wires separated, a very brief spark would be created, but an arc could not be sustained.

After there was no success using the power supply TIG mode, the stick welding mode was used. In this mode when the wires would touch, the power supply would provide a very large surge current causing about one quarter to one half inch of metal from each electrode to nearly instantly melt and fall to the bottom of the tank. When the controller was optimally tuned this behavior would be repeated several times a second. The wires would touch, a high current arc would melt the wires, and then the motors would advance the wires causing them to touch and the process to repeat. The large surge current that causes the wires to melt is a result of the design of the welding power supply. It became apparent that it would be difficult to use this type of power supply in a process that uses wires as electrodes. It is believed that the welding type power supply works well with the rod process because the mass of the rods is much higher than the wires allowing them to adsorb the energy of the high current surge when an arc is struck.

### **Manual EDM Experiments**

Because the results using a welding power supply with wire were poor it became apparent that if wire electrodes were to be used successfully, a different kind of power supply would be needed. EDM pulsed type power supplies are a natural replacement in this situation. EDM applications often use very small electrodes with good results. A prime example of this is the wire EDM process. The wire EDM process uses very small diameter wires in the range of 0.005 inches to 0.015 inches to machine conductive materials at relatively high current. Even though the wire is very small, it can endure the high energy pulses used to erode the workpiece. The key is that pulses are used rather than a constant current. A simple low power, RC-type, power supply was proto-typed to examine the feasibility of pulsed EDM power supplies as a power source in the process. The prototype power supply uses a set of DC power supplies in series to produce a constant voltage supply adjustable between 40 and 120 VDC. A power resistor with a resistance of 50 ohms and several capacitors with capacitance values ranging from 2 to 50 mF were used in the prototype power supply.

**Sudeep Kumar Singh et al.**

The electrode gap distance was controlled manually. The cathode electrode was attached to a fixed base and the anode was mounted on the carriage of a linear slide. The electrode gap was controlled by moving the carriage of the linear slide toward or away from the cathode electrode. The electrodes were submerged in deionized water as usual. It is difficult to align two wire electrodes in this kind of manual test, so a wire electrode, the anode, and a plate electrode, the cathode, were used. Wire electrodes of various diameters ranging from 0.125 inches to 0.01 inches were tested with the RC type power supply. Creating a sustained set of pulses between the electrodes that would last several seconds before the electrode gap grew too large was easily achievable with all the wire diameters used in the test. The capacitor could be switched to a different value and the change in spark frequency could be heard. Also, as higher capacitance values were used, the erosion rate of the electrodes was increased. The higher capacitance value effectively increased the power in each pulse, increasing the rate of erosion.

In addition to stability of the arc, it was clear that small particles were being generated because a visible dark cloud of particles was seen being dispersed from the electrode gap while the sparking was stable. These particles were small enough to remain suspended in the water. When the capacitor is removed from the circuit the power supply becomes a simple current limiting power supply similar to the welding power supply previously used. This simple current limiting power supply does not have any energy storage elements to create a high current surge like the welding power supply produced. In general, it was difficult to create sustained discharges without the capacitor in the circuit. There was one special case where a stable set of discharges could still be easily maintained. If a thin flexible foil electrode was used in combination with a wire as the other electrode, an interesting thing happened. The pressure wave created by the arc is enough to cause the foil electrode to deflect away from the wire electrode acting like a switch interrupting the flow of current.

Thicker foils cause the frequency of this reaction to increase because the higher stiffness results in a higher spring back force. In the case of this configuration the power supply in combination with the electrodes are acting like a resistive switching power supply. There are no energy storage elements in the circuit, unlike with the welding power supply, so there is no surge of current at the start of a discharge. The resistor simply limits the current preventing the thin electrodes from instantly being melted. The success of these experiments prompted further development with a power supply of the EDM type.

### **EDM Drill Experiment**

Because the first experiments with the RC type EDM power supply were performed manually it was difficult to produce consistent particles for analysis. Analysis of the particles is important to determine particle size and distribution. In addition to particle analysis, the EDM Drill experiments were performed to estimate what power supply setting would produce an optimal erosion rate. A drill EDM machine was used to generate particles for analysis. A drill EDM was chosen rather than a sinker EDM because the drill EDM already has a system to align and guide small diameter round electrodes. In addition, the control system and power supply used in drill EDM processes are generally simpler.

In these experiments two wires are used as electrodes. The anode wire is clamped in a collet fixture and connected to the power supply. The cathode wire, from here on called the tool, is clamped into the tool chuck on the upper end of the machine. This tool chuck is connected to the negative side of the power supply. The tool is then lowered through the tool guide. The tool guide is used to keep the tool electrode centered in the hole during the process. To prevent contamination with other particles and to easily collect particles, a test reactor is used to hold a small amount of deionized water. The anode electrode enters this reactor through a rubber stopper on the bottom end. The tool electrode simply enters the reactor through the open top. The tool electrode is positioned directly above the anode electrode. Because the tool electrode is not tubular, deionized water cannot be pumped through it to flush the electrode gap. Non-optimal performance of the process can be expected due to the poor flushing conditions.

Sudeep Kumar Singh *et al.*

### Power Supply and Control System

This specific EDM drill uses a fuzzy logic controller to maintain the electrode gap distance. The fuzzy controller is useful in this application because the electrode cuts a deep hole into the workpiece. dramatically changing electrode gap conditions. The exposed area between the electrode and the workpiece increases changing the electrode gap resistance. As the hole gets deeper it also becomes much more difficult to flush out the eroded particles from the hole. These two changes in the process will require the controller to provide different motion dynamics to match the changing conditions. A fuzzy logic controller can sense changes in the process like poor flushing conditions and temporarily increase the electrode gap distance to flush the gap. Once the flushing conditions are better, the controller is returned to normal operation.

### Experimental Process

A statistical screening experimental design was used to determine the what settings and parameters effect wire erosion rate using the EDM machine. The design used is a screening design for up to 8 variables. The design can be used to estimate what factors will have a significant effect on the rate of wire erosion. The design variables in the design are the Peak Current, Tool electrode, rotation rate, electrode diameter,  $t_{on}$ , and  $t_{off}$ . The order of the experiment was randomized to reduce the influence of uncontrolled variables. Prior to each run the wire electrodes were massed and the tips were ground flat. The reactor was drained, cleaned and filled with 500 mL of clean deionized water between each run. For each run the electrodes were mounted and aligned in the machine and the machine was run at the given settings for 4 minutes. Then the electrodes were removed from the machine and massed again to determine the erosion rate of each electrode.

## EXPERIMENT RESULTS

The results of the experiment show that the peak current, electrode diameter and the electrode material are all significant factors that effect the rate of erosion. The rate of erosion increases as current and diameter increase. It is very likely that the  $t_{on}$  and  $t_{off}$  parameters have a significant effect on the rate of erosion, but the values were not changed enough to see a change in the rate of erosion.

One important note to make at this point is the rate of erosion of the cathode electrode. During the experiments with the EDM machine, the cathode has a near zero wear rate. In some high setting where the  $t_{off}$  time is short the cathode electrode actually grows over time. The twinwire experiment showed that it would be difficult to align two wire electrodes and create a stable reaction. If the cathode electrode experiences near zero wear rates, then only one consumable electrode is needed. If the anode wire electrode is fed toward an electrode that is significantly larger than the diameter of the wire then fine wire alignment is no longer needed. The cathode electrode only needs to be large enough to prevent the wire electrode from missing it. From the data it was concluded that a pulsed DC EDM type power supply is well suited for the particle generation process. Particles in an acceptable size range were generated at a reasonable rate.

The particles generated at the optimal erosion rate were analyzed using a scanning electron microscope, SEM, to determine particles size and distribution. Figure 3.7 shows a micrograph of the particles generated using 0.0625 inch diameter wire at 57 peak amps of current. The particles generated are smaller than those generated using the rod process with an average size of 200 nm with a range of plus or minus 70 nm. Also the distribution of particles size is very tight in comparison to that of the rod process

## CONCLUSION

These results show that using a pulsed DC power supply like those used in EDM processes will produce particles with a smaller average size and a much tighter distribution of particle size than those created with the rod process.

Sudeep Kumar Singh *et al.*

Even though the EDM drill is successful in producing ultra-fine particles there are some reasons not to use an EDM machine for the production of particles.

EDM machines are optimized to maximize the rate of workpiece erosion and to produce fine surface finishes. Similarly, a machine designed to produce ultra-fine particles should be optimized to maximize the rate of erosion, or in other words the rate of particle production. In contrast, when generating particles there is no concern for the surface finish of the electrodes, only the quality of the particles being produced. EDM power supply settings that result in fine surface finishes usually have low material removal rates. When producing particles if there is no concern for the surface finish of the electrodes, it may be possible to produce small particles at a high rate using different power supply settings and control strategies than those of EDM. If an EDM machine were used to produce particles it would be difficult to modify the controller and power supply to determine if this is possible. By designing a machine specifically for the production of particles, both the controller and the power supply can be designed to produce high quality particles at a high rate.

EDM machines also are quite costly due to the additional features that would not be used in particle production. EDM machines usually include dielectric filtration systems and dielectric chillers. A particle production machine may also require a chiller and a dielectric filtration system, but the chiller and filter system in the EDM machine could not be used because they include metallic components that are incompatible with the particles being produced. EDM machines also have CNC controllers, additional axes of motion controls, and other subsystems. These subsystems only add to the cost of the EDM machine without any added benefit with respect to particle production.

Because wire will be used as the electrodes in the pulsed wire process, a wire feed mechanism would also have to be integrated into an EDM machine to replace the linear actuator used to control the electrode gap distance. The base cost of the EDM machine, plus the replacement of all the metal components in the fluid system, modification to the controller and new wire feed system will result in a higher cost machine than a machine designed specifically to produce particles.

### ABSTRACT

The “Government of India” in the year 2006 has initiated the step of establishing rural tele-centers in the name of “Common Service Centers (CSC)” under “National e-Governance Plan (NeGP)” to provide “various government services” electronically to citizens. The idea behind establishing such tele-centers in public private partnership (PPP) was to provide quick, effective and hassle free government services in affordable price within the village or panchayat, so that the citizens should not go to various offices physically. When the researchers were reviewing the available literatures in the area of e-governance and CSCs found various studies. But as far as Odisha state is concerned there were absolutely very few studies were available on this area. Further “Rayagada” being a tribal dominating district far from the state capital attracts the “researchers to focus and conduct the study”. The main focus of the study is to find out how influential are the CSCs to cater the need of the citizens for various government services electronically. This paper addresses and evaluates the influence of CSCs on rural citizens in rendering e-governance services with a focus on Rayagada district of Odisha state.

**Keywords:** E-Governance, Common Service Centers, Rayagada District, Odisha, PPP, Citizens, VLE

## INTRODUCTION

### E-Governance in India

The CSC initiatives have started way back in 2006 by “Department of electronics and information technology (DeitY) now known as MeitY” and “Department of administrative reforms and public grievances (DARPG)” under NeGP.

24714

Amiya Kumar Sahoo *et al.*

The mode of operation has decided that the CSCs will be operated in “PPP” mode, where the stake holders are Central Government, State Governments, “Service center agencies (SCA)” as the operational partner, “State designated authorities (SDA)” as the technical partners and the “Village level entrepreneurs (VLE)” as the service delivery partners [1]. Citizens in general are service takers. There was a clear vision of the Government while setting up this CSCs as “to deliver and make accessible all Government, social and private sector services in the area of agriculture, health, education, utility payments, banking, financial services and many more to the citizens at affordable cost” [2]. The “former president of India Dr. APJ Abdul Kalam” has quoted in the context of providing all government services to the citizens as “Delivery of services to citizens is considered a primary function of the government. In a democratic nation of over one billion people like India, e-Governance should enable seamless access to information and seamless flow of information across the state and central government in the federal set up. No country has to so far implement an e-Governance system for one billion people. It is a big challenge for us” [3]

### E-Governance in Odisha

The “Common Service Center”, is popularly known as “Jana Seva Kendra” in Odisha. The government of Odisha has taken “various initiatives to implement the e-Governance projects in the state in association with Odisha Computer Application Center (OCAC) as the SDA for technical support, “Tata Consultancy Services (TCS)” as technical support partner, “National Informatics Center (NIC)” as another technical partner to provide the back end data support, and Odisha e-Governance Services Limited (OeSL)”. The “e-Governance roadmap of Odisha was released on 14<sup>th</sup> June 2006 by the Hon’ble Chief Minister of Odisha with good governance vision, governance strategy and the blue print for capacity building” [4][5].

The “Information and Communication Technology (ICT)” is used extensively to support the e-Governance projects in Odisha. Odisha State Wide Area Network (OSWAN) has established which connects to “State Head Quarter (SHQ)”, 30 district head quarters, 284 blocks of the state and 60 horizontal offices of the state [6]. Odisha State Data Center (OSDC) is “fully functional since October 2011 with an objective to provide shared, secured and managed infrastructure for consolidating and securely hosting state level data and applications”. Applications like e-districts, e-registrations and e-municipality are some of the main focuses of OSDC [6]. State Service Delivery Gateway (SSDG) is established to provide seamless interoperability and exchange of data across multiple government departments [6]. Tata Consultancy Services (TCS) is the service provider for SSDG.

### E-Governance in Rayagada

Odisha Government has started the e-District project under NeGP and the Rayagada district has its own portal to provide all the services to its citizen designed and maintained by “National Informatics Center (NIC)”. The district was initially under the undivided Koraput district and became one independent district on 2<sup>nd</sup> October 1992. The district with 7,073 square kilometer area, 11 blocks, 182 gram panchayats and 2667 villages has a total population 9,67,911 (source census 2011). The literacy rate is 42.13% [7]. Out of 445 sanctioned CSCs only 197 CSCs are rolled out in Rayagada District till 2019 [8]. Some of the major services provided to the citizens through CSCs are caste certificates, legal heir certificates, residence certificates, employment exchange registrations, land record registrations as state government services along with all central government services. The Service Center Agency (SCA) for Rayagada district is BASIX [10][11] and the same organization is in charge of 4 districts of Odisha including Rayagada and they have their operations in 19 states of India including Odisha [11]. The role of SCA is to provide digital network support to VLEs.

### Objective of the study

The main objective of this study is to find out the influence of Common Service Centers in rural India with a special reference to Rayagada district of Odisha State. Further the study will reveal the influence of CSCs on two major stakeholders of e-Governance initiatives i.e. the Village Level Entrepreneurs (VLEs) as the service providers and the citizens at large as the service takers.

## METHODOLOGY

This study has been carried out by conducting a survey in the district of Rayagada to collect primary data. The secondary data is also collected by referring various web portals. The researchers have used two sets of structured questionnaires to collect the primary data from the VLEs and the Citizens separately. Five VLEs from each block (11 blocks of Rayagada) were participated in the survey except Chandrapur block.[11]. Under each VLE 10 citizens were contacted randomly as respondents. The data were compiled and refined in MS-Excel sheets and then data analysis tool "Pivot Table" and graphical tool like "Pivot Graphs" were used to analyze the data and the findings represented.

### VLE Data Analysis

#### VLE Respondent Details

The respondents in each stakeholder are chosen carefully, which is a mix of all category users to get some quality data for this study. As per the data in Figure-1 out of 55 VLEs Bisamcuttack, Gunupur and Rayagada have 6 VLEs each and Chandrapur block has 2 VLEs and all other blocks have 5 VLEs each. There are 6 female (10.90%) VLEs and 49 male (89.10%) VLEs. The age of the VLEs ranges from 26 to 56, out of which 31 VLEs (63.26%) are male of the age group of 26 to 35. Then 13 male are from the age range of 36 to 45 which is 26.53% of total male VLEs. As per the data available in Table-1, out of total VLEs 40 (72.72%) VLEs are graduates, 9 (16.36%) VLEs are intermediate and 6 (10.90%) VLEs are post graduates.

#### Citizen Respondent Details

Based on the data available in Table-2, there are 185 (33.6%) citizens from the age group 29 to 38. From the age group 39 to 48 there are 166 (30.2%) citizens, 126 (22.90%) are from the age group 19 to 28. Next age group is 49 to 58 where 11.3% citizens were participated in the survey. The age group 59 to 68 has 10 citizens which is only 1.82% of the total respondents. And finally only one respondent (0.18%) is from the age group 69 to 78.

#### Influence of Common Service Centers on VLEs

##### Prior Computer Knowledge of VLEs

As per the data in Figure-2, which shows there are 35% of the VLEs were not having any prior computer knowledge, but after starting of CSCs they have been provided training on how to operate computers for performing day to day business activities, which is a positive influence of having CSC to render e-Governance services.

##### Profession of VLEs before setting of CSCs

As we can see the data in the Figure-3, that 20 VLEs (36.36%) were in temporary or contractual job, 5 VLEs (9.09%) were unemployed and 4 VLEs (7.27%) were house wives but now each of them are earnings by opening CSCs as a business option, which is a positive influence of CSC.

##### The VLEs income before CSC and after CSC

Now let us compare the data shown in the Figure-4 which shows the income of the VLEs before they have CSCs and after the CSCs. We can see there are 12 members who were having the earnings up to 5000 now having the income of 15000 to 20000. Similarly 10 VLEs were having the income up to 7000 and now have 15000 to 20000. Similarly there were 10 VLEs who were getting up to 7000 and 6 VLEs who were getting up to 5000 now getting 20000 to 25000 per month. Those who were earning 10000 or more than 10000, are now earning 25000 to 30000, per month. One VLE was earning 5000 per month, now earning more than 30000 per month. So the impact and influence of CSC is very impressive on the financial and hence the social growth of the VLEs.

Amiya Kumar Sahoo *et al.*

### **Influence of Common Service Centers on Citizens**

#### **Whether to use CSCs or the office physically for e-Governance services**

After referring the data set in Figure-5, we can conclude that most of the citizens prefer to get the services at CSCs rather than visiting the office physically. The graph shows a very clear picture that almost in all the blocks people preferred to visit CSCs. 79.81% of Citizens given their choice to use CSCs where as only 20.18% of Citizens said they prefer to visit the respective offices to get their work done. The result analysis shows that the Citizens behavior of getting the e-governance services is quite influenced by CSCs.

### **Computer Literate Citizens**

As per the data available in Figure-6, which says, 436 citizens (79.27%) out of 550 are not computer literate that they can't operate computer of their own. The remaining (20.72%) of citizens can operate computers of their own. When a citizen can do his/her own work at CSCs, efficiency of the work will increase and that will be inspiration to others who don't know to operate computers.

### **CSCs Provides better e-Governance Services**

The data in Figure-7 shows almost every block's citizens admitted that the CSCs are providing better e-governance services, so which is very influential reason to use services rendered at CSCs.

### **Findings of the study**

After a thorough study on the Common Service Centers at Rayagada district with 55 active VLEs and 550 Citizens of all categories, it is observed that the CSCs have enough positive influence on the rural citizens. Some of the findings of the study are as follows.

- A. The VLEs having prior computer knowledge are providing better e-governance services and hence those VLEs did not know computer operations earlier are trained by the service center agencies (SCA).
- B. Those VLEs were unemployed or house wives are also earning more than they have expected through CSCs.
- C. It is also observed that CSC owners or VLEs are earning more than they were earning before setting up CSCs.
- D. Majority of the citizens of Rayagada are preferred to use CSCs for their e-governance services rather than visiting the offices physically.
- E. The citizens who are computer literate are using the services at CSCs efficiently and effectively.
- F. Citizens agreed that CSCs provides better e-Governance services.

## **CONCLUSION**

The researchers have concluded from this study that, the Common Service Centers are having a very influential role on citizens and Village Level Entrepreneurs. The various e-Governance services rendered at CSCs of Rayagada district are widely acceptable by the citizens, but bit more awareness is needed among the citizens. Both the stakeholders (VLEs and Citizens) are benefitted out of the services provided at CSCs. The VLEs are getting earnings, name and fame at the same time the citizens are getting the services within their locality.

### ABSTRACT

Agriculture plays a pivotal role in the growth of an economy and is considered as the backbone of a nation. About 58% of India's population relies mainly on agriculture as a primary source of their livelihood and approximately 70% are small and marginal farmers. Despite having a large section of people involved in agriculture, it has been facing a downfall in India, thus it has become an unproductive venture that has a direct impact on the socio-economic status of the farmers in a negative manner resulting in multiple suicides among the farmers on a large scale. This review deals with the crucial factors that resulted in massive suicides among the farmers as a form of passive protest toward the unconcerned behaviour or apathy exhibited to them.

**Keywords:** Agriculture, farmers, population, growth, scale

### INTRODUCTION

Agriculture plays a pivotal role in the growth of an economy and is considered as the backbone of a nation. For decades, agriculture has been closely associated with the cultivation of the soil, production of economically important crops and raising livestock which in turn contributes to national income. About 58% of India's population relies mainly on agriculture as a primary source of their livelihood and approximately 70% are small and marginal farmers (Srvanath and Sundaram, 2019). Despite having a large section of people involved in agriculture, it has been facing a downfall in India, thus it has become an unproductive venture that has a direct impact on the socio-economic status of the farmers in a negative manner (Mishra, 2014). Due to their occupation, farmers are failing to satisfy their basic needs and are given a lower status in society.

24721

**Nanda S.P. and Reddy M. Devender**

Studies suggest agriculture as an occupation is a high risk affair (Milner *et al.*, 2013 and Agerbo, 2007) as compared to other occupations. The cultivation of a crop does not rely solely upon agricultural practices but also on the culmination of several factors *viz.*, crop failure due to unforeseeable weather conditions during the crop season, easy availability of financial assistance and support from private bank with high interest rates, non-repayment of loans and indebtedness due to crop failures, unable to procure good returns for farm produce, etc (Kumar and Hashim, 2017). In addition to the factors related to farming, a few personal factors *viz.*, expenses towards education, unexpected health issues, marriage and other family functions also contributes to their expenditure. Altogether, these factors have manifested to a large number of suicides among the farmers in the country and many have opted out of farming to pursue a different career as a part of insecurity.

Farmers' suicides cannot be regarded as an event that occurs by itself, but an utmost exemplification of the associated crisis prevailing in the agrarian sector from the past decades in the country (Mukherjee, 2012). On the contrary, this disaster is also regarded to be associated with the economic and financial crisis faced by the farmers. The report of the National Crime Records Bureau, 2015 revealed that indebtedness or bankruptcy contributed to 35%, agricultural issues contributed to 19.5%, family problems and illness contributed to 11.7 and 10.5%, marriage problems and disputes related to property contributed to 2 and 1.15% of the suicides. Furthermore, approximately 45.2% small farmers and 27.4% marginal farmers were reported to commit suicide during 2015 (National Crime Records Bureau, 2015). In India, farmers' suicide has turned into an epidemic (Mukherjee, 2012) and it has been recorded that in every 30 minutes, a farmer end his life and everyday more than 2,000 farmers quit farming. About 3,00,000 farmers have already taken their own lives in a period of 20 years and in comparison to the national average, the suicide rate has been recorded to be 47% higher (Ahmed, 2015). Thus, an attempt has been made to review the crucial factors that resulted in massive suicides among the farmers as a form of passive protest toward the unconcerned behaviour or apathy exhibited to them.

**High Farmers' Suicide Rates**

The former Prime Minister of India, Dr. Manmohan Singh in 2007 stated that the growth rate in agriculture was very poor, thus considered it as a primary reason for rural distress. The combination of drought and debt causes a serious threat to the farmers and constant financial pressure prevails on the farmers due to the farm crisis. The condition that prevails due to ongoing drought and flood also adds to the problems related to the economy (Padalia, 2015). Furthermore, issues like government policies, damages due to pests and diseases, unpredictable weather conditions are not within the control of the farmers, but despite facing all these problems they are bound to pay their personal debts. All these factors give rise to a repeated sense of hopelessness due to loss of crops, crop failure, financial obligation, loss of land, income, community, family farm, and a way of life.

Farming has become increasingly an unviable activity. The 15 years of economic reforms have given farmers access to expensive and promising biotechnology. However, issues like crop insurance, land irrigation, or enough bank loans remained untouched by the reforms (Kumar, 2015). Reforms opened Indian farmers to global competition, such as with the United States and the UK who receive over \$18 billion a year in subsidies. These subsidies negatively influenced the price of the crops e.g., cotton in the global market. The global competition and poor yield of the crop caused the real threat to the cotton growers and this had resulted in multiple suicides among the farmers on a very large scale in the cotton belt, thus given the name as suicide belt of India. Vidarbha, the north-eastern region of the State Maharashtra alone has 3.2 million cotton farmers and it was estimated that over 200 farmers have committed suicide in a period from July 2005 to February 2006. According to a study by the government of Maharashtra, almost 6 in 10 of those who kill themselves had debts between \$110 and \$550.

**Nanda S.P. and Reddy M. Devender****The Global Perspective**

The phenomenon of suicides is not limited to India. Farmers around the world have turned to the suicide amid crop failures and livestock diseases. In countries like France, a farmer commit suicide in every two days (Nilsson, 2016) and in China, farmers die as a passive protest against seizing of their land by the government for urbanization (Wormer and Link, 2015). In Britain, farmers commit suicides at a rate of one a week. During the outbreak of foot-and-mouth disease when the government instructed the farmers to slaughter their animals, the suicide rate of the farmers was found to be increased by 10 times in the UK in 2001. The rate of suicides increased in Ireland, as result of unusual wet winter that led to trouble in growing hay for feeding animals during 2012 (Ahmed, 2015). In Australia, consecutive droughts for two years have forced the farmers to commit suicide. In the United States, the rate of committing suicides by the male farmers is twice as compared to the general population. In developing country like India, the record shows in every 32 minutes a farmers committed suicide during 1997-2005 (Kumar, 2017). In agriculturally rich states like Punjab and Haryana, this disaster occurs due to crashing prices of commodities and rising debts. The impact of an industrial approach all over the globe in boosting yield of crops has thrown many small farmers into despair.

**Indian Agrarian Crisis**

In comparison to other industries, agriculture has emerged to be a peaceful and healthy way of livelihood. However, with the increasing mortality rate in agriculture due to suicide among farmers, farming has become a fatal industry. Studies show that farming has grown to be one of the dangerous industries in recent times. Even though farming practices, production systems, and types of farms are diverse, the commonalities across the farms are also important to health. Most of the farms are family-owned and operated businesses. The volatility of commodity markets, the variability of weather patterns, and the influence of respective government regulations have a great impact on the farms. Due to this, the farmers face a high rate of stress.

An amalgamation of physical aggravation and risks from the farm environment is caused by the regulatory framework and economic dynamics of managing farm business. Financial crisis and government bureaucracy have been considered as major causes of stress which lead to suicide. Farmers tend to work till very old age as there is no customary or mandatory retirement age for them all over the world. This leads to dependence of the younger generation on their parents and causes rift between the two generations. In Britain, the farmers are more concerned about family problems while in India, the concerns are mostly monetary and debt related which leads to suicides.

**How to Stop Indian Farmer's Suicides**

Almost 70% of the Indian household is dependent on agriculture but the agriculture and allied sector has been growing at the compound annual growth rate of 3.3%. The share in GDP of Indian agriculture has declined at a faster rate and came down to around 13.9 per cent but the principal livelihood source still remains the same for rural households. According to the National Crime Records Bureau from 1995 to 2013, an average of 16,469 suicides occurs per year, i.e. 296,438 farmers have already committed suicide. Farmers are committing suicide because farming has become a capital intensive operation. Money lenders and banks lend money to the farmers at a very high interest rate. National Crop Insurance Scheme Programme was introduced by the Government in 2013 according to which crop insurance was made compulsory for all the loaned farmers. However the scheme is unable to provide the farmers with sufficient funds during crop damage. In agriculture business, there is no hedge fund available for farmers to protect their investment or income. All the risks are taken by the farmers themselves and maximum profit goes to the middlemen and whole sellers. On December 19, 2014 the National Sample Survey Office released Situation Assessment Survey of Agriculture Households according to which only 58 percent of rural household in India are engaged in farming activity and it contributes less than 60% to their average monthly incomes.

In order to protect the farmer's income, necessary measures should be taken by developing policies framework. Loan as well as the total crop which farmer would get should be covered under insurance (Pastor, 2015). Hedge fund

**Nanda S.P. and Reddy M. Devender**

should be created in all the states through imposing tax on purchasing agricultural commodity beyond stipulated limit. Local government should be authorized to implement the scheme which will ensure maximum participation from the farmers. Weather based crop issuance scheme should be developed and instead of Tahsil or Patwari area boundary, the unit of calculation should be each field. The damage of the crop should be calculated *via* satellite imaging system (Pastor, 2015).

**Short term measures**

The major reason behind the increasing rate of suicides among the farmers is the inability of farmers to manage their distress and depression properly. The farmers have to be sensitized of the fact that suicide is not the right way out of problems they face. Another factor is the guilt which they feel when they find themselves unable to feed their family. In order to overcome these issues, major steps to be taken are launching relief measures like providing compensation to the farmers, increasing amount of food to be made available to each household, providing insurance benefits for the crops that are insured, opening of a helpline and grievance contact number which will be working 24 hours, etc. It gives immediate psychological relief and helps the farmers to drop the idea of committing suicides. Farmers can also approach the established counseling centers in person to share their problems. The farmers are to be assured not to lose hope. The leaders and officials have to visit those areas on regular basis to meet the families in distress. Contact program of government with the farmers in which various government officials will meet the farmers personally and will assure them and will listen to their problems.

With the government support mechanism in the event of a failed monsoon and drought, to start a campaign with a view to help those affected by the failed rains, so that they are aware of the various mechanisms available for their help and do not feel alienated. It must be conveyed to such farmers that a failed monsoon is not their fault, and they shall not blame themselves for the same. Temporary moratorium on loans would relieve the finance burden and microfinance mechanisms to be utilized for the benefits of farmers to proceed farming further and announcing loan waivers or moratorium to dues on agriculture loans in case of credit issued by banks. In case of non-institutionalized credits, gram sabhas will be asked to convene and mediations on this respect at best interests of farmers. Generate and instill confidence in people through resource pool and at mean time necessary provisions for uninterrupted supplies will be ensured through public distribution system in most affected wards. Spreading awareness among the farmers about the various alternatives available, carry out discussions to reach to possible solutions. Educating the family members so that they can act appropriately when they see signs of distress in the farmer.

**Long-term measures**

Scaling up crop insurance compliance, irrigation systems, procurement machinery, fair prices, increasing share of institutionalize agriculture loans working close with lead bank and spreading awareness campaigns in these directions, strict implementation of anti dowry laws, provision of education and health care to the rural people, encouraging better farm practices like mixed dry land farming to cushion eventualities are some long term measures that will mitigate the distress of farmers.

Encouraging farmers to adopt mixed crop farming, multiple cropping, crop rotation, other agricultural practices such as dairy farming, back yard poultry, sheep and goat rearing and others. Minimizing dependency on external farm inputs - own seed, own fertilizing, own plant protection etc, raising cereals, vegetables, fruits, strengthening water sheds, harvesting rain water in-situ, proper regulation of ground water withdrawal, promotion of millets instead of rice will help in increasing farmers income. Further, to make it mandatory to save and conserve rain water, safe use of water. Encouraging farmers to shift to less water-intensive crops and drip irrigation, and providing incentives for this will serve as a practical cure. Make it understandable to them the relationship between the rain and preserving the forests and biodiversity, planting more trees. Loan waiver has been ineffective in the past, and also may not be considered as an out-of-the-box solution. Because small farmers often are the ones who commit suicide, and they often avail private money lenders' loans, not institutional credit. So they get no benefit from institutional loan

**Nanda S.P. and Reddy M. Devender**

waivers. Asking money lenders to suspend debt collecting for sometime as heavily debt ridden farmers upon failure of crop tend to commit suicide. It is good to ask panchayats, to organise motivational talk about life.

Create better scientific assistance for crop diversification, higher productivity, markets without middlemen and mandi taxes to market produce at competitive prices, periodic review of all-farmer related programmes like irrigation schemes, compensation to farmers. Use of technology has to be central to any endeavor to help farmers get rid of mental agony they face on account of crop failures. Assure, increasing irrigation potential, proper insurance mechanism to insulate against rainfall vagaries. Setting up a team of professional counselors including some psychologists, bankers, bureaucrats and social workers to function as a help centre where the farmers can approach them personally or through a helpline number. To prevent unemployment, some alternative employment must be ensured. Unskilled workforce can be diverted towards skill enhancing programs conducted. Identify areas of high suicidal tendency and immediate organize panchayats more aware about social and economic conditions of the village to identify the farmers facing grave problems of repayment or crop failure.

Self Reliance Education and Employment - Free vocational training to groups of women from impoverished agricultural families and the women are given the necessary start-up capital after completion of their training to begin small, home-based businesses. Financial counseling is provided to prepare these women to qualify for proper bank loans and also provide full scholarships to the children of farmers living below the poverty line. Social support helps can curb stress. That is why huge support from friends, family, local communities, national policies and society as a whole will lower the impact of stress level on individuals and families. Need to get in touch with farmers which are in distress through panchayats. By connecting through panchayats to get data of the families where there is a problem and it has reached to a level where it cannot be sustain anymore (Kaur, 2013).

Suicide is the most extreme step a person can take. Farmer suicides are very disheartening phenomena, in contemporary times. Promote the small social businesses and enterprises among the people so that they can earn to meet their expenditures. Arrange periodical meetings and sessions for farmers with regional government officials and experts which, along with reinstating trust on the government, will help a great deal to find out pragmatic solutions. The Supreme Court of India on 21 August, 2015 instructed the Union Government that no farmer should commit suicide. A Public Interest Litigation filed by a Punjab-based NGO indicating the increasing number of suicide cases in the country. The SC showed its discontent with the Government as they were unable to lower the cases of suicides quoting the efforts was not sufficient. The National Policy for Farmers 2007 could not address the agrarian crisis which forced the farmers to commit suicide (Department of Agriculture and Cooperation, 2007). The Swaminathan Commission and many other agricultural experts have given other solutions in the recent years and some these have been described above. The current situation requires political will and for that the government will have to begin by changing its current line of argument saying more suicides are happening outside agriculture than in it.

### ABSTRACT

*Bacillus subtilis* is a small, Gram-positive, rod-shaped bacterium commonly found in soil and also gastrointestinal tract of ruminants and humans. Results of the present study showed that *Bacillus* was found to exhibit a nutrition stress-related postexponential rapid cell death (RCD). The RCD in this bacterium is accompanied by typical markers of eukaryotic apoptosis such as loss of cell viability in the post-exponential phase, enhanced biosynthesis of caspase-3 like protein. The affinity purified fraction cross reacted with human caspase-3 polyclonal antibody.

**Keywords:** Gram-positive, nutrition, cell, biosynthesis

### INTRODUCTION

In eukaryotes, programmed cell death (PCD) is a genetically regulated self destruction process for the elimination of damaged or unwanted cells. It plays an important role in the development and maintenance of the integrity of organisms. Cells undergoing PCD exhibit a number of biochemical, physiological, and morphological features [1, 2]. Similarly to eukaryotes, PCD in bacteria is a complex and regulated process that is essential for bacterial communities' survival, differentiation, and spreading. The similarities observed between cell death systems of animals, plants, and bacteria suggests endosymbiotic acquisition of bacteria by eukaryotes [3, 4, 5]. PCD in a cell is induced by a certain signal(s). The end point of the signaling activity is the induction and activation of caspases (cysteiny aspartate-specific proteases), the proteases that finally execute PCD [1, 2]. Several investigators have reported the occurrence of PCD in bacteria regulated by chromosomal and extrachromosomal toxin-antitoxin pairs of molecules. In *Escherichia coli*, such chromosomal toxin-antitoxin systems include *mazEF*, *chpBIK*, *relBE*, *yefM-yoeB*, and *dinJ-yafQ* [3, 4, 5, 6]. Earlier studies in *Xanthomonas campestris* pv. *glycines* (Xcg), a plant pathogen and the etiological agent of bacterial pustule disease of soybean (*Glycine max*), was found to exhibit a nutritional stress-related

**Kalidindi Krishnam Raju**

postexponential rapid cell death (RCD). The RCD in *Xanthomonas campestris* pv. *glycines* was found to display certain molecular features similar to those of the programmed cell death (PCD) of eukaryotes such as increased cellular reactive oxygen species levels, externalization of phosphatidyl serine, Biosynthesis of catalytically active caspase-like protein in the mid-log phase cultures. . The amino acids glycine and L-alanine as well as the D isomers of valine, methionine, and threonine were found to induce the synthesis of an active caspase-3-like protein that was associated with the onset of RCD. Addition of pyruvate and citrate to the culture medium induced both the synthesis of active caspase-3-like protein and RCD [7]. Computational analysis of the already sequenced genomes revealed that the apoptosis-related domains in bacteria typically form complex multi-domain architectures. These multi-domain proteins contain fusions between apoptosis-related domains, such as apoptotic ATPases fused with a metacaspase or a tollinterleukin-receptor (TIR) domain [8, 9]. Consistent with this bacterial caspase was found to interact functionally and physically with poly(ADP-ribose) like protein (PARP) like protein in the observed modulation of genetically programmed RCD [10]. Purification and further characterization of caspases to electrophoretic homogeneity from *xanthomonas* is challenging due to exopolysaccharide Xanthan that promotes protein aggregation in cell free systems. The present study was undertaken to search for a new bacterial species that undergo post exponential RCD akin to Xcg and eventual purification and characterization of this novel and uncharacterized cell death protein called caspase. *Bacillus subtilis* is a small, Gram-positive, rod-shaped bacterium commonly found in soil, vegetation and gastrointestinal tract of ruminants and humans. *Bacillus* promotes crop productivity by improving soil health and also improves gut health by acting as probiotics [11, 12]. Genome serach of *Bacillus* has not revealed caspase-like domain, but found to exhibit post exponential RCD similar to Xcg with the synthesis of catalytically active caspase-3 like protein that cross reacted with human caspase-3 antibody. This 82± 2 kDa *in vivo* affinity purified protein lost a majority of its activity.

**MATERIALS AND METHODS****Media and culture conditions:**

Inoculation was carried out by the addition of a single isolated colony of *Bacillus* to the Luria-Bertani (LB) medium and was incubated for 24 h on a rotary shaker (150 rpm) at ambient temperature (26±2°C). The 24 h grown culture was incubated further under static conditions at the ambient temperature, in order to observe PCD. For viable cell counts aliquots of the culture broth were withdrawn and serially diluted using sterile saline (0.85%) and transferred to LB-agar using spread plate technique. Plates were incubated at ambient temperature for 72 h. Viable cell counts were obtained at the end of the incubation period by counting colonies. To induce RCD, metabolites such as alanine (Ala), pyruvate (Pyr) and citrate (Cit) were added to the LB medium at the start of incubation in 100mM, 100 mm and 50 mM respectively

**Caspase-3 assay**

A single colony of *Bacillus* was transferred to 10 ml of medium and incubated overnight (~18 h) on a rotary shaker (150 rpm) at ambient temperature. A one ml (~10<sup>8</sup> cfu/ml) aliquot of the culture was centrifuged at 10,000 g for 10 min. The pellet was washed once with phosphate buffered saline (PBS, 10 mM, pH 7.4), suspended in 500 µl of caspase assay buffer [HEPES (20 mM, pH 7.6), NaCl (100 mM), CHAPS (0.1%), DTT (10 mM), EDTA (100 µM), and glycerol (10%)] [7, 10], and the cells lysed by freeze-thaw (freezing under liquid nitrogen and thawed at 37°C) followed by sonication on ice for 15 s. Protein equivalent to 25 µg was mixed with 200 µM of synthetic colorimetric substrate, Ac-DEVD-pNA [N-acetyl-Asp-Glu-Val-Asp-pNitroanilide], prepared in dimethyl sulfoxide (DMSO) as 10 mM stock and incubated at 37°C for 30 min in 1 ml caspase assay buffer. After incubation the absorbance at 405 nm was measured using a spectrophotometer. The protein concentration was determined by the standard Bradford method [13].

**Kalidindi Krishnam Raju****SDS-PAGE**

Overnight grown *Bacillus* cells were harvested by centrifuging at 10,000 g for 10 min, the pellet washed twice with phosphate buffered saline (PBS, 10 mM, pH 7.5) and suspended in sterile milli-Q water. The cell suspension was mixed with an equal volume of 2X gel loading buffer [Tris (100 mM pH 6.8), SDS (4%), glycerol (20%), bromophenol blue (0.002%), and  $\beta$ -mercaptoethanol (200 mM)]. The mixture was heated at 95°C for 10 min, immediately chilled on ice for 5 min, and centrifuged at 12,000 g for 10 min. A 50  $\mu$ l aliquot of the supernatant was loaded on 10% (w/v) SDS-polyacrylamide slab gel, which was run vertically at 35 mA constant current on a PAGE system (Techno Source, India).

**Silver staining of SDS PAGE**

The gel was left overnight in the fixative solution, removed and washed thrice in 100 ml of 50% ethanol, each washing for 15 min. The gel was then treated with sodium thiosulphate (20 mg/100 ml) for 1 min. After treatment with sodium thiosulphate, the gel was rinsed 4X with distilled water, each for 30 s. The gel was immersed in a solution containing 200 mg / 100 ml of AgNO<sub>3</sub> and 1  $\mu$ l formaldehyde / ml and left for 30 min with gentle shaking. It was then rinsed 4X with distilled water; each for 30 s. Silver stain was developed by adding developer on the gel. When proper contrast was visible, the over development of gel was stopped by adding 100 ml of stopping solution on the gel. Finally, the gel was stored in 50% methanol.

**Western blotting**

After completion of the SDS-PAGE run, electro-blotting was performed using a hybond-P membrane in a transfer buffer [25 mM Tris, 192 mM glycine (pH 8.3); 20 % methanol] employing 50 mA constant current overnight at 4°C. The blotted membrane was air dried for 1 h, suspended in methanol for 5 min and equilibrated in TBS buffer (20 mM Tris pH 7.6, 0.5 M NaCl) for 30 min. The equilibrated membrane was subjected to blocking with 3% gelatin (3g of gelatin in 100 ml TBS), washed twice with TTBS (TBS containing 0.05% Tween-20) and hybridized with 10  $\mu$ l (0.5 mg/ml) of the affinity purified biotin-conjugated polyclonal rabbit anti-active human caspase-3 antibody for 18 h at ambient temperature as described previously [7, 10]. After primary antibody hybridization the blot was washed twice with TTBS and later subjected to secondary hybridization with 50  $\mu$ l of streptavidin-horseradish peroxidase conjugate for 1.5 h. Both the primary and secondary antibody reactions were performed in TTBS buffer having 1% gelatin. After secondary hybridization the blot was washed once with TBS-Tween-20 (0.05%) and once with TBS for 5 min, respectively and the band detection was performed by using enhanced chemiluminescence method [Tris pH 8.5 / 4-chloro-1-naphthol / H<sub>2</sub>O<sub>2</sub> / p-coumaric acid].

**Affinity chromatography and immunoprecipitation**

Overnight alanine fortified LB grown culture (1000 ml) was harvested by centrifugation (10,000 g for 10 min.), washed once with PBS and the cells lysed by freeze-thaw and sonication on ice for 5 min in a caspase assay buffer containing protease inhibitors PMSF 1mM, 10  $\mu$ g each of pepstatin, leupeptin and aprotinin. The cell debris was removed by centrifugation (10,000 g for 20 min), and the supernatant was subjected to sequential ammonium sulfate precipitation. The caspase active fraction (15-40 % ammonium sulfate precipitate) was dialyzed overnight in the caspase assay buffer and incubated with commercially available biotinylated form of single specific potent inhibitor of caspase-3 (1  $\mu$ M biotinylated DEVD-CHO) for 30 min [14]. The incubated protein was captured onto a streptavidin-agarose gel. The column material was washed with 20 volumes of the caspase assay buffer containing 0.5M NaCl. The protein was eluted with 200  $\mu$ M free caspase inhibitor (Ac-DEVD-CHO). After blotting the partially purified fractions onto a polyvinylidene difluoride (PVDF) membrane, the caspase protein bands were visualized by means of ponceau-S stain and the blots were probed separately with caspase antibody.

For immunoprecipitation the caspase active fractions after ammonium sulphate precipitation were incubated overnight at 4°C with biotin conjugated caspase-3 antibody in the incubation buffer (TBS buffer containing 1mM EDTA, 1mM PMSF, 10  $\mu$ g each of protease inhibitors pepstatin, leupeptin and aprotinin) and the protein was captured onto a streptavidin-agarose column (1.5 ml). Later the column was washed with 50 ml of the incubation

**Kalidindi Krishnam Raju**

buffer. The protein was eluted with 100 µl SDS-gel loading buffer and the eluted protein was analyzed by silver staining and Western blotting.

**RESULTS AND DISCUSSION****Survival of *Bacillus* in LB fortified media**

Viable cell counts in stationary-phase cultures of *Bacillus* grown for 24 and 96 h in different culture media are shown in Table 1. In media such as LB fortified with alanine, pyruvate and citrate, rapid declines in the viable cell numbers were observed between 24 and 96 h of incubation. The cell count was reduced from 8 log<sub>10</sub> CFU/ml at the onset of the stationary phase (24 h after the start of incubation) to 5 log<sub>10</sub> CFU/ml at the end of stationary phase (96 hrs from the start of incubation) in LB media fortified with metabolites. While in LB untreated control (without addition of metabolites) the cell count remained stable at the onset of the stationary phase (24 h after the start of incubation) to the end stationary phase (8 log<sub>10</sub> CFU/ml). RCD in the presence of previous reported inducer(s) suggested occurrence of a conserved RCD mechanism in *Bacillus* similar to Xcg.

***In vivo* caspase activation during RCD**

In order to confirm expression of active caspase in the presence of RCD inducers such as alanine, pyruvate and citrate, the protein lysate fraction was subjected to caspase activity. Nearly 3-fold higher caspase activities were observed when compared to LB grown control cultures (Table 2). All the three metabolites (alanine, pyruvate and citrate) showed increased expression of caspase-3 like protein over the untreated LB controls (Figure 1). This clearly indicated that the genetic regulation of PCD in *Bacillus* correlated positively with the caspase-3 like activity.

**Affinity purification and immunoprecipitation**

An affinity purification strategy followed for caspase purification was also employed to purify the caspase-3 like protein from *Bacillus* [14]. The partially purified caspase protein after affinity elution gave a strong hybridization signal with the caspase antibody (Fig. 2A & 2B). After elution of this protein from streptavidin agarose column, the 80± 2 kDa protein lost a majority of its activity. Previously reported that intracellular accumulation of metabolites such as pyruvate and citrate in *Xanthomonas campestris* pv. *glycines* was found to result in a caspase dependent stationary phase rapid cell death (RCD) [7,10]. Pfam domain architecture analysis combined with operon identification revealed wide and scattered distribution of bacterial metacaspase sequences, and with a potentially intriguing evolutionary role. These metacaspases imply roles in programmed cell death, cellular signaling, various enzymatic activities and protein modification [15]. At the moment, neither the nature of the caspase protein nor the putative gene is clear in *Bacillus*. Western analysis of the cellular lysate revealed that it cross-reacted with the caspase, a feature that needs to be understood. Understanding RCD features in bacteria will help future characterizations of death pathways in prokaryotes.

### ABSTRACT

Taro (*Colocasia esculenta*) is one of the major tuber crops grown in Odisha. It is mainly cultivated by the poor tribal farmers as an alternative food source. Taro has multidimensional nutraceutical effectivity with the enrichment of carbohydrates, amylose and amylopectin, protein, dietary fiber and antioxidants. It contains substantial amount of vitamins i.e.  $\beta$ -carotenes, cryptoxanthin, vitamin A, and B-complex, folates, riboflavin, pyridoxine (vitamin B-6), pantothenic acid, and thiamin. Leaf blight of taro caused by *Phytophthora colocasiae* is one of the devastating biotic stresses for taro production with an average yield losses upto 75%, though it depends on prevailing weather conditions. Applied treatments (T1-T7) were selected to evaluate efficacy of different ecofriendly techniques for controlling the *Phytophthora* blight during 2016-2019. Results revealed that, in control plot disease incidence was maximum PDI [SD ( $\pm$ ) 1.899] with the tuber yield of Y [SD ( $\pm$ )0.525]. When the same susceptible check cv. Telia was applied with six different treatments, the results shows that treatment T<sub>5</sub> recorded maximum yield [SD ( $\pm$ )2.993] and minimum leaf blight incidence of PDI [SD ( $\pm$ )0.624]. Whereas in resistant check cv. Muktakeshi (T<sub>3</sub>) leaf blight incidence of PDI [SD( $\pm$ ) 1.328] with yield [SD ( $\pm$ ) 0.712] of was recorded. Traditional agricultural practices if we incorporate into our modern farming system, then it turned to more beneficial and profitable in terms of low cost, ecofriendly, non-consumable chemicals for different class of tribal communities and sustainable agricultural system.

**Keywords:** Leaf blight, taro, emergence, severity, sustainable

## INTRODUCTION

Taro [*Colocasia esculenta* (L.) Schott] is one of the major tuber crops in Odisha, India. Area/production ratio throughout the country was estimated as 80,000 ha / 0.8 million tones. According to Mishra and Chowdhury (1997), its rich with high nutritive value, each 100 g fresh tuber contains, protein (3g), mineral (1.7g), carbohydrate (21.10g), energy (97.0 Kcal), vitamin A (24 IU), and different amounts of inorganic components (Table-1). Consumption of natural foods rich in flavonoids helps protect from lung and oral cavity cancers. Further, the corms provide healthy amounts of some of important minerals like zinc, magnesium, copper, iron, and manganese. In addition, the root has very good amounts of potassium which is an important component of cell and body fluids that help regulate heart rate and blood pressure. Not only for urban areas and villages, it is widely used as a major vegetable in all over the strata of the society of modern civilization. The crop is mostly grown (throughout the season) as an intercrop with maize, cassava and plantain and is cultivated on a wide range of soils. From rural market to modern city, market demand related to production, is all time high. Leaf blight of taro caused by *Phytophthora colocasiae* [hemi-biotrophic oomyceteae (Raciborski,1900)], is one of major biotic stresses and limiting factor for taro cultivation, in the present agro-climatic scenario of Odisha. The symptoms appears as small, water soaked spots that increase in circumference and also spread to healthy plants. The entire leaf area is destroyed within 3-5 days after the initial symptoms develop, depending on weather conditions. Under humid weather conditions, coupling with 28-30° C temperature and 85-90% humidity helps in the disease spreads at tremendous speed and the entire field gives a blighted appearance (Mishra et al.2008). Different management strategies like, use of tolerant cultivars, use of bio-control agents, using of chemical fungicides, traditional cultural practices like shifting of planting time etc are practices by the farmers, but they are somehow costly to the farmers. For management of this destructive disease, we are following the two main key objectives i.e. one is “Low cost” and another is “Eco-friendly”, on the basis of Odisha’s present agro-economic condition. To measure the comparative efficacy of low cost eco-friendly management (among different management strategies) we are conducting one field experiment with the combination of seven different treatments.

## MATERIAL AND METHODS

### Survey and Surveillance

From 2016-2019, regular interval basis survey and surveillance data, reveals the disease severity range in different location

### Isolation of the Pathogen

Diseased taro leaves were collected from different location of Odisha. Leaves were washed with 0.1 % HgCl<sub>2</sub> and 100 % alcohol to remove surface debris and contaminants. Small pieces (ca. 5 × 10 mm) were cut from each leaf, surface sterilized in 0.6% sodium hypochlorite for 2 min, blotted on a sterile paper towel, and placed on 1.5% water agar. Plates were incubated at 24 °C under continuous fluorescent light. Mycelia of *P. colocasiae* were visible after 1 to 3 d. From each diseased leaf, 2 single hyphal tips were transferred to V8 agar (10% V8 juice, 0.025% CaCO<sub>3</sub>, 1.8% Bacto agar) (V8 juice,) and incubated at 24 °C under continuous fluorescent light. To induce sporulation, an agar plug from a 5-d-old culture was submerged in 10 ml sterile distilled water, incubated at 24 °C under continuous fluorescent light for 16 to 24 h, and then transferred to 16 °C for 30 min. A small amount of the zoospore suspension was then spread on 2% V8 agar (2% V8 juice, 0.005% CaCO<sub>3</sub>, 1.8% Bacto agar) using a sterile loop. After incubation at 24 °C under light for 6 h, individual germinated zoospores were transferred to V8 agar plates. These single-zoospore cultures were used for subsequent study. Sporangia were also produced on the agar surface on V8 agar at 24 °C in 4-6 d.

**Siddhartha Das and Sudeepta Pattanayak****Morphological Characterization of the Pathogen**

The mycelium is hyaline, coenocytic and inter- or intra-cellular. The haustoria are slender, long and unbranched. The growth of the fungus is optimum at pH 6.5 and 28°C (Sahu *et al.* 2000). The sporangiophores are very slender, unbranched and extremely narrow at the tip approximately 50 µm in length. The sporangia are elongated pear or lemon shaped which approximately 38-60 × 18-26 µm in length and breadth. They germinate directly or indirectly depending on the weather conditions. When indirect (20-21°C) as many as 12 reniform, biflagellate zoospores are released, which convert to cysts and germinate after 30 min (Trujillo 1965; Misra 1996). Indirect germination of zoosporangia occurred in water in less than 2 h at optimum temperature (20-21°C) and zoospores germinated in less than half an hour after release. Direct germination occurred in 5-6 h at 20-28°C. Thick-walled, round, hyaline chlamydospores are also produced, especially in old cultures (Thankappan 1985; Misra 1999). The zoosporangiophores are slender, unblemished and extremely narrow at the tip and measure up to 50 µm. Misra (1996) observed that zoosporangial length was over 100 µm and the width was over 50 µm. Depending on the weather conditions, the zoosporangium is capable of producing another zoosporangium. It may germinate directly or by producing one or more germ tubes or by producing zoospores. Zoosporogenesis (indirect zoosporangial germination), like in most other species of *Phytophthora*, starts with the fusion of cleavage vesicles, which occurs almost spontaneously with the release of zoospores. Chilling the zoosporangia at 4°C for 10 min induce zoospore cleavage. Immediately after cleavage, the apical exit pore plug material balloons outwards to form a discharge vesicle that varies in size. The zoospores get expelled from the discharge vesicle and break through the thin plastic wall to escape. Within 20 min of the release, the zoospores encyst having a rather thick cell wall. The cysts germinate within 30 min of their encystment. The cysts are more damaging from a disease point of view as they are produced in large numbers, are small in size and light in weight compared to zoosporangia. The abundant production of zoosporangia, zoospores and cysts make *P. colocasiae* a devastating pathogen. The oogonium is spherical and yellowish and the amphigynous antheridium persists at the Base of the oogonium for a considerable period after the oospores are formed. The oospores are spherical having a 20-28 µm diameter and lie freely in the oogonium. *P. colocasiae* produces pectolytic enzymes like polygalacturonase, pectin methyl transeliminase and poly methyl galacturonase and these enzymes may play a major role in the pathogenesis on *C. esculenta* (Agarwal and Mehrotra 1986).

**Study of Lifecycle and Epidemiology**

The main factors which triggers the life cycle of the disease are rainfall, humidity, and temperature. Sporangia act as a primary reproductive unit. Putter (1976) and Trujillo (1965), reported that the sporangia require free water to germinate and germination can be reported in two ways viz indirect and direct germination depending on the temperature. Cool condition (20-22°C) prefers cyto-differentiation of sporangium which produces approximately 20 zoospores. The top pore of the sporangia dissolves and all the zoospores comes out and swim into the film of water. Zoospore development occurred within 15-20 minutes at 20°C and then anchored on the surface of the leaf, lose their flagella and form a round cyst. Later within 5-10 minutes cyst germinate to form germ tube. At 28-30°C direct germination occurred, the sporangia germinate directly by a germ tube and anchored the leaf. In both the cases at the time of, direct or indirect germination, dispersal of the sporangia or zoospore happened by rain splash or wind blown moisture.

**Isolation and Mass Production of Biocontrol Agent**

Soil samples were collected from different locations of Odisha for the isolation of *Trichoderma*. Samples were collected and stored at 4°C. Five fold serial dilution of each soil samples were prepared in sterilized distilled water and 0.5 ml diluted sample was poured on the surface of *Trichoderma* specific medium. Plates were maintained at 28 ± 2°C. Sub-cultured plates were maintained in PDA medium. Mass culture of the isolates was done by moist paddy straw cultivation method. In this method dry paddy straw was firstly weighted in the amount of 500 gms per polypropylene bag. Moist it with sterile distill water and autoclaved. Moist straw was inoculated with isolated sample, with single mycelia disc inoculation technique. Inoculated paddy straw kept in growth chamber for 48-72 h.

### Field Trials

Field experiments were conducted on the basis of seven treatments. An experiment was conducted using seven low cost ecofriendly treatments [T<sub>1</sub>: cv. Telia covering with black polythene, T<sub>2</sub>: cv Telia mulching (15 cm thickness) with dry leaves, T<sub>3</sub>: cv Muktakeshi resistant variety, T<sub>4</sub>: cv Telia seed tuber treatment with *Trichoderma viride* followed by soil application of *T. viride* enriched compost, T<sub>5</sub>: cv Telia two foliar spray with bio-formulation at 60 and 90 days after planting, T<sub>6</sub>: fungicidal check with 3 mostly used fungicides [copper, Mancozeb, carbendazim + mancozeb], T<sub>7</sub>: control cv Telia without any treatment) to evaluate efficacy of different ecofriendly techniques for controlling the *Phytophthora* blight during 2016-2019. Bio formulation (T<sub>5</sub>) was prepared using water (8 litre), cow urine (3 litre), neem cake (1.5 kg), 80 gm leaves each of neem, bel, kalmegh, custard apple, aswagandha, eucalyptus, agave and castor.

### RESULTS

From 2016-2019, our research reveals the following data with seven different treatments (T<sub>1</sub>: cv. Telia covering with black polythene, T<sub>2</sub>: cv Telia mulching (15 cm thickness) with dry leaves, T<sub>3</sub>: cv Muktakeshi resistant variety, T<sub>4</sub>: cv Telia seed tuber treatment with *Trichoderma viride* followed by soil application of *T. viride* enriched compost, T<sub>5</sub>: cv Telia two foliar spray with bio-formulation at 60 and 90 days after planting, T<sub>6</sub>: fungicidal check with 3 mostly used fungicides (copper, Mancozeb, carbendazim + mancozeb), T<sub>7</sub>: control cv Telia without any treatment), including 3 major parameters- disease severity [DS], percent disease index [PDI], and yield[Y]. (Table-2, Table-3, Table-4). Peak disease infestation was recorded from July to November.

### DISCUSSION

Taro leaf blight is one of the most severe diseases in Odisha. Different epidemiological components directly or indirectly take part in disease establishment and spreading, causes severe yield loss. Favorable temperature (28±2° C) with moisture (70-90 %) condition enhances the leaf blight disease incidence in taro cultivation. Due to *Phytophthora colocasiae* infection every year crop production suffers a havoc loss up to 75%. Available cultivation strategies are sometimes costly for the farmers and also not eco-friendly. From the analysis seven treatments, it was observed, control plot disease incidence was maximum PDI [SD (±) 1.899] with the tuber yield of Y [SD (±) 0.525]. When the same susceptible check cv. Telia was applied with six different treatments, the results shows that treatment T<sub>5</sub> recorded maximum yield [SD (±)2.993] and minimum leaf blight incidence of PDI [SD (±) 0.624]. Whereas in resistant check cv. Muktakeshi (T<sub>3</sub>) leaf blight incidence is PDI [SD (±) 1.328] with the yield [SD (±) 0.712] was recorded. Pathogenic emergence may come due to change in climatic condition (naturally) or inductive way (through mutation). Like as reemergence of *Choanephora* was reported by Das *et al.* in various crops like aubergine (2017), hyacinth bean (2017), teale gourd (2017), green pea (2017), papaya (2017), ban tulsii (2017), *Amaranthus* (2018) etc. Though, this pathogen was considered to be a minor pathogen at nineteenth century. Complex adaptability with preferential epidemiological factors makes the minor pathogen to a severe one. Pattanayak and Das (2020) reported severity of rice blast pathogen *Magnaporthe grisea* from the south eastern India which partially supports results of this investigation. In the current scenario, leaf blight of taro is considered to be a spontaneous emerging pathogen, which needs to control in an eco-friendly management strategy. Traditional agricultural practices if we incorporate into our modern farming system, then it turned to more beneficial and profitable in terms of low cost, ecofriendly, non-consumable chemicals for different class of tribal communities and sustainable agricultural system.

### ABSTRACT

An online survey was conducted with the agriculture students of Centurion University, Odisha, India to find the behavioral response towards ongoing Pandemic and its impact on their studies. Dependent variables like social distancing, impact on studies, gaining quality timing with family, reading habits, social media involvement, their insecurity about future aspects and preference of online class over offline class and related aspects were taken into account. After noting the responses it was found that the students were showing favorable responses towards factors like social distancing, impact on studies, involvement with social media, change in study patterns etc. while online classes, reading habits, loss of studies etc. got unfavorable attitude. After the ranking social distancing got highest favorable response (Score: 421) while preference of online classes (Score: 239) got lowest rank.

**Keywords:** COVID 19, response, social impact, education, e-learning

### INTRODUCTION

The world has been encroached by the Covid 19 Pandemic since quite long now. It has impacted the whole society badly. The impact has been profound amongst students regarding the suspension of classes, online classes and online exams. The pandemic has impacted the higher education also which is an important aspect of the country's future. Social distancing has become the new normal lifestyle amongst corona virus pandemic. Now people are losing face-to-face contact with friends therefore they may begin feel different, may be depressed and anxious to some extent. These type of trends being very new to the mass it is somewhat pertinent to record the responses as it is

24742

**Rupashree Senapati**

expected that the education system is leaning towards some soft technologies and machine learning in near future. Further agriculture students being more equipped with traditional technologies and class room and field level learning it's very important to note their reaction. Whether they are able to cope with this change and can carry forward the same for the stakeholders or they are not interested to follow the trend. Therefore a study was conducted amongst students of Centurion University regarding the impact of covid19 and their behavioral responses were recorded.

**OBJECTIVES**

1. To find the socio-psychological status of the respondents.
2. To find the psychological behavioral response of students towards the covid 19 impact.
3. To find the most favorable and least favorable factor after ranking them according to their scores.

**METHODOLOGY**

The method of data collection was through online questionnaire method and also by telephonic social interaction afterwards. Google form by one-to-one student was the method of data collection in this lock down period. It has been tried for taking into account the responses of an exploratory kind of study through a relatively new and technology driven methodology. Therefore only ten factors have been considered as dependent variable here to minimize the probability of errors. The response were retrieved and collected through google mail and tabulated later on by using of MS Excel. Only simple method like percentage, ranking and frequency calculation has been implemented to get into the clarity of results rather than any statistical analysis.

**Sample Selection**

Samples were purposively selected from the 6<sup>th</sup> semester agriculture graduates who have almost completed the agriculture course just before joining their internship of the result. The sample size is one hundred and four students from agriculture background including 64 male students and 40 female students.

**Variables / Factors**

Ten most common parameters have been selected like extent of liking about the social distancing, its impact on studies, whether enjoying lockdown days, good impact of lockdown day enjoying lockdown days, impact on reading habits, involvement with social media, hampering level of studies, insecurity about future prospects and comparison between online and offline classes. For the measurement of behavior Likert's summated rating scale with five point continuum was used in this study. Final score was calculated by multiplying the rating effect with frequency and then ranked amongst themselves

**Likert's Method of Summated Rating**

The scale consists of a set of items (statements) to which the subject is asked to react. Items that seem to be definitely favorable or definitely unfavorable to the attitude under study are used. Neutral or slightly favorable or unfavorable items are also included in the continuum. The respondents indicate their agreement or disagreement with each item. Each response is given a numerical score. (As in this experiment scores being given like Very great extent:5, Great extent:4, Moderate:3, Little extent:2, Not at all:1) Since a subject's response to each item may be considered as his/her rating of attitude on a 5-point scale and the total score is obtained after summing all these weights being summated, therefore the method is known as summated rating.

**Rupashree Senapati**

Here after summing all the scores from the responses towards each factor, the factors are being ranked from highest to lowest indicating the most favorable behavioral response or most unfavorable behavioral response of students after Covid 19 impact on education.

## RESULTS AND DISCUSSION

The result has been discussed with respect to each factor along with ranking of the scores.

### Socio-psychological Status of Respondents

According to the study all the respondents belong to students category studying B.Sc.(Agriculture) in 6<sup>th</sup> semester selected purposively for sampling. Amongst them 64 i.e. 61.53% students are male and 40 i.e. 38.46% students are female students which means there is not much gender gap in the selected sample. All of them belong to the age group between 19 to 22 i.e. quite young and most of them were new to these kind of survey. It is believed that they have provided their genuine responses. Amongst them due to lock down and Covid 19 impact 28 i.e. 26.92% felt that they got affected mentally while only 9 (8.65%) students physically affected in some way. Forty-six (44.23%) students had impact both at physical and mental state while 21 students i.e. 20.19% students had no impact any way according to their perception.

### Factors

#### Social Distancing

Amongst the students 46 students responded that they are liking the social distance to very great extent which comes out to be 44% of the population. 29 students i.e. 28% say that to great extent. While 19% are almost neutral, the rest 7% are in unfavorable attitude towards social distancing.

#### Impact on Studies

Amongst students 47% perceived that the concerned situation has definitely impacted their studies in some way. 21% of the sample population thought it had an impact to great extent towards studies. Seventeen (16%) students moderately reacted while only rest 8% thought the impact was little while 8% were not at all affected in studies.

#### Lockdown Days as Qualitative Family Holidays

When they were asked whether they considered the lock down days as quality family time and enjoyed throughout only 14% of them reacted to very great extent, while 20% to great extent and the majority 35-36% being neutral the rests (11% and 22%) perceived as enjoying the days to little extent and not at all .

#### Positive Aspects of Lockdown Day

In response to the positive aspect of the lock down 22% and 15% had positive response like to very great extent and great extent while 17% were neutral. Only 12% thought it had little extent positive aspects, the majority i.e. around 35% found that it had not any positive aspects at all.

#### Change in Study Pattern

Whether these days have changed your study pattern was responded as to very great extent by around 28% and again 28% responded as to great extent. 24% i.e. around one fourth of the population being very neutral, the rest 16-17% did not perceive much change in their study pattern due to lock down and Covid-19 impact.

#### Enhancement of Reading Habits

Amongst the population 20% opined that they had enhanced their reading habits to very great extent and 18% enhanced it to great extent .Around 35% were moderate about the issue while around 13% had very little / limited

**Rupashree Senapati**

enhancement of the skill. Again 14-15% of the population did not have any change at all in this regard as per their views.

**Involvement with Social Media**

Forty-six students i.e. majority are in opinion that they had very great extent involvement with social media. Around 18% had involvement to great extent only. 23% being moderate about the issue the rest 15% being little to not at all involvement with social media.(7% and 8% respectively)

**Loss of Studies**

According to the students, 19% of the sample felt that loss of their studies occurred to very great extent. Great extent loss was incurred by 21% population. 26% sample viewed it as moderate loss, while 19% thought it as little extent and 14% did not at all found any loss.

**Insecurity about Future Prospects**

The students being on the verge of internship and placement options, it is very obvious to feel insecure about the same (33% to very great extent and 25% to great extent i.e. the majority). 17% reacted moderately to the fact. Around 13% had little insecurity while only 11% had not at all any insecurity.

**Preference of Online Class Over Offline Class**

In response to the stimulus whether they prefer more online classes more to the regular offline class room coaching, only 13% reacted as to very great extent. Again only 7% liked it to great extent. 17% reacted moderately on this issue while 16% reacted to little extent. Majority of the population i.e. around 47% opined that they did not prefer the online classes at all over offline classes.

**Ranking of the Scores**

After obtaining all the scores summative score for each factor was calculated by multiplying the frequency with numerics associated with the rating effect of continuum.

E.g. for Factor 1 Summative Score:

$46 \times 5 + 29 \times 4 + 20 \times 3 + 6 \times 2 + 3 \times 1 = 421$ , Maximum scores could be highest frequency  $\times$  highest rating i.e.  $104 \times 5 = 520$

Here after obtaining the final summative scores those 10 factors were rearranged according their highest to lowest score values in range of highest to lowest favorable attitude/ factor/behavioral response of the students in this phase from the selected ones. According to the result, students showed highest favorable response (Score: 421) towards Factor1 (Social distancing) and lowest liking ness or least favorable attitude (Score:239) towards Factor 10 (Preference of online classes). Factor2(Impact on studies), Factor7(Involvement with social media), Factor 5 (Change in study pattern) got relevant favorable scores while the low scores of Factor 6(Enhancement of reading habits), Factor 8(Loss of studies), Factor 3(Lockdown days as qualitative family holidays), Factor 4(Positive aspects of lockdown day) indicates that most of them disagreeing the statement / factors.

**CONCLUSION**

As it is noticeable that students are comfortable with social distancing and maintaining the rules and regulations, but it may be estimated that due to impact of social media the unfavorability of perception towards some of the factors have been ameliorated here. From the result it is too evident that some of the factors like, preference to online classes change in reading habits and change study patterns have gained more unfavorable responses. Therefore multi-pronged strategy is necessary to manage the crisis and build a resilient education system in the long term. Immediate measures though have been started but vision is essential to ensure the continuity of learning in schools and

**Rupashree Senapati**

universities. Proper implementation is required to prepare the higher education sector for the evolving demand–supply trends across the globe through time. Inclusive learning solutions must be provided, keeping in mind the vulnerability aspects of the situation and the respondents need to be developed. Increase in the integrity and effectiveness of learning and teaching, giving both the students and teachers multiple options and platforms to choose from is extremely necessary. Though innovative, mobile-based learning models have already been initiated but the adoption and learning rate etc. must be measured if we consider it a long-term strategy for modernization of education.

### ABSTRACT

Agriculture production and productivity is constantly suffering from of threats created by various classes of plant pathogens leading to huge economic losses. To control the plant disease a huge amount of pesticide used for many year lead to the warning to environment and at the same time it is contribute the development of resistant pathogen races. So to maintain sustainability nano technology (Nanopesticide, Nanofertilizer etc.) introduced in modern agriculture. Among all the nano formulation tested for antimicrobial activity against plant pathogen silver and chitosan nano particle show significant effect.

**Keywords:** Nano-particle, Chitosan, Silver, Pesticide

### INTRODUCTION

Agriculture is the primary source of livelihood for about 58 per cent of India's population. The production and productivity is constantly suffering from of threats created by various classes of plant pathogens leading to huge economic losses. Among the total crop losses caused by different sources, 14.1 % are lost due to plant diseases alone and the total annual worldwide crop loss from plant diseases is about \$220 billion. (Agrios ,2005). To minimize loss caused due to the pathogen pesticides are used in huge amount for many years since mid-1950s. Due to the potential use of pesticide it start damage the environment and food as they are spread over the crop plant several times each year, at the same time it has contributed to the development of resistant pathogens (Lamsal *et al.*, 2011).

So for the maintain equilibrium between environment and food production innovative technologies are being introduced in modern agriculture to minimise such losses. Among such technological innovations, nanotechnology

**Abhinandita sahoo and Ria Mukhopadhyay**

(nanopesticide, nanofertilizer etc.) is gathering noteworthy considerations due to its robust applications in agriculture (R nair 2010) (Ghormade V *et al.*, 2011). In general, nanoparticles have attracted considerable attention in the fields of medicine, pharmaceuticals, cosmetics and electronics due to unique physical, chemical and biological properties (Bakshi M *et al.*, 2014). In present day, the development and application of biosynthesized nanoparticles has opened new avenues in agricultural research oriented to developing ecofriendly and effective means of controlling plant diseases. Most importantly, biological synthesis of silver nanoparticles (AgNPs), Chitosan has offered a consistent, non toxic and ecofriendly approach for plant disease management due to their strong antimicrobial properties (Navrotsky A, 2000) .This review evaluates the current literature on the effect of nanoformulation to inhibit the growth of plant pathogenic microorganism in *in-vitro* condition.

**Antimicrobial Efficacy of Chitosan**

Chitosan is a naturally-occurring, linear polysaccharide produced from chitin by deacetylation in the solid state under alkaline conditions, or by enzymatic hydrolysis of chitin deacetylase. It is considered to be the second largest renewable biomaterial after cellulose in terms of utilization and distribution (Elgadir *et al.*, 2015). Now a days chitosan and its derivative biomaterials have a significant attention in the biomedical field, owing to their unique biological properties. Some of the most noted properties of chitosan are its non-toxicity, biodegradability, biocompatibility, and immunoenhancing, antibacterial and antimicrobial activity. Sudarshan *et al.* ( 1992) suggested that chitosan could penetrate fungal cell wall and bind to its DNA and inhibit the synthesis of mRNA and, in turn, affect the production of essential proteins and enzymes required for the infection. Rabea *et al.* (2003) explained chitosan chelates with metal ions, which has been implicated as a possible mode of antimicrobial action.

Phaechamud and Ritthidej (2008) reported chitosan nanoparticles have got various applications in biology due to its biodegradable and nontoxic properties. In acidic condition the free amino groups of chitosan protonates and contributes to its positive charge the inhibition mode of chitosan against fungi. García-Rincón *et al.* (2010) explained that positive charge of chitosan interacts with negatively charged phospholipid components of fungi membrane, which in turn alter the cell permeability of plasma membrane and causes the leakage of cellular contents, which consequently leads to death of the cell . Soleimani *et al.*(2011) reported that host resistance was an efficient and effective component in integrated management of plant diseases. The aim of this study was to test whether Acibenzolar-S-methyl (ASM), Chitosan, Heads-up and Acetyl Salicylic Acid (ASA), known to induce resistance against various diseases, can help protect potato crop against brown leaf spot. The effect of these inducers, on two potato cultivars, Goldrush and FL1879 against *Alternaria alternata*, causal agent of brown leaf spot at two different field sites were evaluated.

To determine the effects of the application of inducers on disease resistance, the foliage of the potato cultivars was sprayed with appropriate concentrations of ASA, chitosan, and ASM. Heads-up was also applied as a pre-plant treatment on potato tubers. The results obtained from the both field experiments indicated the highest yield performance was achieved in plots treated with ASM, followed by Heads-up and chitosan treatments. However, no significant difference in terms of tuber yield production has been noted between ASA treated potato foliage, and the untreated control plants. Results of experiments with detached leaves showed that there was a significant difference regarding disease index reduction between plots which been treated with defense inducers and untreated, inoculated plots. It was clear that on both potato cultivars, application of chitosan and ASM encouraged enhancement of the disease resistance compared to the ASA and Heads-up treatments. In the laboratory experiment, disease progress was recorded on leaves from three different heights of the crop canopy. The results indicated that disease severity was low in the apex, moderate in the middle and high in the lower parts of the crop, in both potato cultivars. These results suggest that chitosan and ASM may offer alternative methods for controlling brown leaf spot of potato. M. Sathiyabama *et.al* (2015) found that chitosan at the concentration of 1mg/ml inhibit the radial growth of *Alternaria solani* and protect the tomato plant from blight pathogen by enhancing the chitinase activity. Yadi Suryadi *et al* (2017) explained that nano chitosan had an inhibitory activity to *Colletotrichum gloeosporioides in vitro* up to 85.7%.

**Abhinandita sahoo and Ria Mukhopadhyay****Antimicrobial Efficacy of Silver Nanoparticle**

Silver was known as one kind of efficient disinfectors in the early 19th century. From then on, it was widely applied in the fields of bacteria inhibition, wound dressing, mildew preservation, etc. In the recent year, it was found that silver nanoparticle (AgNPs) were checked the growth of fungi, bacteria and virus. Becker *et al.* (1999) showed a nanosilver particle may or may not be charged on its surface or generate silver ions. Like ionic silver, nano silver is a very potent killer of bacteria and has been shown to kill fungi, algae, and some viruses, including HIV. Park *et al.* (2006) explained that Silver in ionic or nanoparticle forms had a high antimicrobial activity and was therefore widely used for various sterilization purposes including materials of medical devices and water sanitization. Relatively few studies were reported on the applicability of silver in controlling various plant pathogens in a relatively safer way compared to synthetic fungicides. Min *et al.* (2009) observed in microscope that hyphae exposed to silver nanoparticles showed severe damage and resulted in the separation of layers of hyphal wall and collapse of fungal hyphae. Wei *et al.* (2009) reported that Silver has been used as an antimicrobial agent since ancient civilizations; it has been used extensively due to its broad spectrum and multiple modes of antimicrobial activity. Young-ki Jo *et al.* (2009) examined the antifungal activity of silver ions and nanoparticles against two plant-pathogenic fungi, *Bipolaris sorokiniana* and *Magnaporthe grisea*.

*In vitro* petridish assays indicated that silver ions and nanoparticles had a significant effect on the colony formation of these two pathogens. Effective concentrations of the silver compounds inhibiting colony formation by 50% (EC50) were higher for *B. Sorokiniana* than for *M. grisea*. The inhibitory effect on colony formation significantly diminished after silver cations were neutralized with chloride ions. Growth chamber inoculation assays further confirmed that both ionic and nanoparticle silver significantly reduced these two fungal diseases on perennial rye grass (*Lolium perenne*). Particularly, silver ions and nanoparticles effectively reduced disease severity with an application at 3 h before spore inoculation, but their efficacy significantly diminished when applied at 24 h after inoculation. The *in vitro* and *in planta* evaluations of silver indicated that both silver ions and nanoparticles influence colony formation of spores and disease progress of plant-pathogenic fungi. *In planta* efficacy of silver ions and nanoparticles is much greater with preventative application, which may promote the direct contact of silver with spores and germ tubes, and inhibit their viability. Kumar *et al.* (2010) described that Metallic nanoparticles possess unique chemical and physical properties, small size, huge surface to volume ratio, structural stability and strong affinity to their targets. Lamsal *et al.* (2011a) showed the effective usage of silver nanoparticles instead of commercial fungicides. They evaluated the effect of silver nanoparticles against six *Colletotrichum sp.* associated with pepper anthracnose under different culture conditions and found that, application of 100 ppm concentration of silver nanoparticles inhibited the growth of fungal hyphae as well as conidial germination *in vitro* when compared to the control.

Silver nanoparticles showed significantly high inhibition of fungi in field conditions when applied on the plants before disease outbreak. Lamsal *et al.* (2011b) studied on *in vitro* and *in vivo* efficacy of silver nanoparticles against powdery mildew before and after disease outbreak in plants under different cultivation conditions, showed maximum inhibition of fungal hyphae and conidial germination with less concentration of nanoparticle on cucumbers and pumpkins. Hameed *et al.* (2012) studied that the secondary metabolites in plants have been used in the formulation of nanoparticles through increase the effectiveness of therapeutic compounds used to reduce the spread of plant diseases, while minimizing side effects for being: rich source of bioactive chemicals, biodegradable in nature and non-polluting (eco-friendly). Particulate systems like Nanoparticles have been used a physical approach to alter and improve the effective to properties of some types of synthetic chemical pesticides or in the production of bio-pesticides directly. Ing *et al.* (2012) explained that chitosan therefore could be formulated and applied as a natural antifungal agent in nanoparticles form to enhance its antifungal activity. Kim *et al.* (2012) reported the inhibitory effect of three different silver nanoparticles (WA-CV-WA13B, WA-AT-WB13R, and WA-PR-WB13R) against eighteen different commercially important plant pathogenic fungi on potato dextrose agar (PDA), malt extract agar, and corn meal agar. They found that inhibition of fungal pathogens with silver nanoparticles was concentration dependent and also on type of silver nanoparticles used. Most fungi showed a good inhibitory effect at 100 ppm concentration of silver nanoparticles on PDA, compared with others. WA-CV-WA13B showed the highest inhibition effect

**Abhinandita sahu and Ria Mukhopadhyay**

compared to other silver nanoparticles. Effect of silver nano particles on the growth of sclerotium-forming species *Rhizoctonia solani* and *Sclerotinia sclerotiorum* revealed that silver nano particles effectively inhibit the hyphal growth in a dose-dependent manner.

## CONCLUSION

In the review cited above it observed that silver and chitosan nanoparticle is significant properties like its non-toxicity, biodegradability, biocompatibility, and immune enhancing, antibacterial and antimicrobial activity. It potentially inhibits the mycelial growth, spore germination.

### ABSTRACT

The present study was carried out with the objectives to study the growth the effect of different levels of fertilisers on yield, nutrient uptake and economics of the Indian mustard variety NRCHB-101 under graded doses of fertilizer. The field experiment was conducted during 2016-17 at the Agronomy Main Research Station, OUAT, Bhubaneswar laid out in a Factorial Randomized Block Design with three replications and twelve treatments. The total N uptake by Indian mustard var. NRCHB-101 was highest at N<sub>3</sub> (120 Kg ha<sup>-1</sup>) and lowest at P<sub>1</sub> (20 kg ha<sup>-1</sup>) i.e., 64.08 kg ha<sup>-1</sup> and 60.95 kg ha<sup>-1</sup>, respectively. The total P uptake was highest at N<sub>3</sub> (120 Kg ha<sup>-1</sup>) and lowest at N<sub>1</sub> (80 kg ha<sup>-1</sup>) i.e., 27.32 kg ha<sup>-1</sup> and 21.51 kg ha<sup>-1</sup>, respectively. The total K uptake by Indian mustard var. NRCHB-101 was highest at N<sub>3</sub> (120 Kg ha<sup>-1</sup>) and lowest at N<sub>1</sub> (80 kg ha<sup>-1</sup>) i.e., 51.79 kg ha<sup>-1</sup> and 45.60 kg ha<sup>-1</sup>, respectively.

**Keywords:** Indian mustard, Nutrient interaction, nutrient uptake

### INTRODUCTION

Role of oilseeds in Indian agriculture needs hardly any emphasis. Oilseeds constitute an important group of crops next to cereals. India is a premier oilseed growing country. India is the fourth largest oilseed economy in the world. Among the seven edible oilseeds cultivated in India, rapeseed-mustard contributes 28.6 per cent of the total area. Presently, rapeseed-mustard is the third most important oilseed crop in India after groundnut and soybean. India is one of the largest producer, consumer and importer of oilseeds in the world. Out of nine major oilseeds grown in India, Indian mustard (*Brassica juncea*) is an important winter season *Rabi* crop. The gap between production and demand of rapeseed-mustard is progressively widening and therefore, the production is to be increased for self sufficiency. Indian mustard requires relatively larger amount of nutrients for realization of higher yield potential.

**Swetalina Mohapatra et al.**

Moreover, with increase in irrigated area and introduction of high yielding varieties, it becomes imperative to work out the response of Indian mustard to nitrogen, phosphorus and potassium in Odisha condition. The mustard growing areas in India are experiencing the vast diversity in the agro climatic conditions and different species of rapeseed-mustard are grown in some or other part of the country. Under marginal resource situation, cultivation of rapeseed-mustard becomes less remunerative to the farmers. This results in a big gap between requirement and production of mustard in India.

Therefore site-specific nutrient management through soil-test recommendation based should be adopted to improve upon the existing yield levels obtained at farmers field. Effective management of natural resources, integrated approach to plant-water, nutrient and pest management and extension of rapeseed-mustard cultivation to newer areas under different cropping systems will play a key role in further increasing and stabilizing the productivity and production of rapeseed-mustard. With this backdrop, the present paper on Indian mustard high yielding variety NRCHB-101 entitled "Effect of different levels of fertilisers on nutrient uptake of Indian mustard (*Brassica juncea*L.)" has been presented with the objectives to study the interaction effect of nutrients on the variety under different fertility levels.

## MATERIALS AND METHODS

The field experiment was conducted during *Rabi* 2016-17 at the Agronomy Main Research Station, Odisha University of Agriculture and Technology, Bhubaneswar (20026'N, 85081'E, 25.9m above MSL), Odisha. The soil of the experimental sandy loam acidic (pH-5.4) medium in organic carbon (0.628%) and available nitrogen (1673.3kg/ha), phosphorus (64.5kg/ha) and potassium (123.4 kg/ha). The experiment was laid out in a factorial randomized block design with three replications. Twelve treatment combinations comprising 3 nitrogen levels (80, 100, 120 kg N/ha), two (20, 40 kg P<sub>2</sub>O<sub>5</sub>/ha) and two potassium levels (0, 30 kg K<sub>2</sub>O/ha) were tested in the experiment. Indian mustard variety 'NRCHB-101' was sown 30 cm row distance. Thinning was done as 15 DAS to maintain plant to plant distance of 10 cm. All the recommended agronomic practices are done throughout the crop season. The crop was sown on 20th November and harvesting was done manually during last week of February. The N,P and K uptake in seed and stover was estimated by following standard procedure described by Jackson(1973) and all the data were analysed as per standard statistical procedures.( Gomez and Gomez,1984)

## RESULT AND DISCUSSION

The N uptake was significant for different levels of N, P and K. The N uptake increases as the doses of N, P and K increases. The seed uptake was highest at K<sub>2</sub> (30 Kg ha<sup>-1</sup>) and lowest at N<sub>2</sub> (100 kg ha<sup>-1</sup>) i.e., 52.12 kg ha<sup>-1</sup> and 49.33 kg ha<sup>-1</sup>, respectively. The stover N uptake was highest at N<sub>3</sub> (120 Kg ha<sup>-1</sup>) and lowest at N<sub>1</sub> (80 kg ha<sup>-1</sup>) i.e., 12.64 kg ha<sup>-1</sup> and 10.90 kg ha<sup>-1</sup>, respectively. The total N uptake in seed by Indian mustard var. NRCHB-101 is highest at N<sub>3</sub> (120 Kg ha<sup>-1</sup>) and lowest at P<sub>1</sub> (20 kg ha<sup>-1</sup>) i.e., 64.08 kg ha<sup>-1</sup> and 60.95 kg ha<sup>-1</sup>, respectively. The N uptake by both, seed and stover, was significant for all the interactions. The higher uptake at the increased doses of N was due to higher efficiency of the crop to make use of the increased levels of N because of increased growth and vigour. Similar results of N uptake with increasing levels of N have been reported by Kumawat et al. (2014) and Dabiet al. (2015).

Table 2 represents the interaction effect of NP, PK and NK levels on total uptake of N by seed and stover of Indian mustard var. NRCHB-101. As evident from the table, the highest N uptake by seed was at N<sub>3</sub>K<sub>2</sub>i.e., 51.73 kg ha<sup>-1</sup> and the lowest was at N<sub>1</sub>K<sub>1</sub>i.e., 49.58 kg ha<sup>-1</sup>. The table revealed that the highest N uptake by stover was at N<sub>3</sub>P<sub>2</sub>i.e., 12.90 kg ha<sup>-1</sup> and the lowest was at N<sub>1</sub>P<sub>1</sub>i.e., 10.30 kg ha<sup>-1</sup>. The N uptake by both, seed and stover, was significant for all the interactions. The N-P-K interaction effect on total N uptake by seed and stover has been shown in Table 3. As

**Swetalina Mohapatra et al.**

depicted in the table, the total N uptake by both, seed and stover, is highest at  $N_3 P_2 K_2$  i.e., 52.10 kg ha<sup>-1</sup> and 13.10 kg ha<sup>-1</sup>, respectively. The N uptake by both, seed and stover, was significant for all the interactions

The seed uptake was highest at  $P_2$  (40 Kg ha<sup>-1</sup>) and lowest at  $N_1$  (80 kg ha<sup>-1</sup>). The stover P uptake was highest at  $N_3$  (120 Kg ha<sup>-1</sup>) i.e., 8.32 kg ha<sup>-1</sup>. The lowest stover P uptake was observed at  $N_1$  (80 kg ha<sup>-1</sup>) and  $P_1$  (20 kg ha<sup>-1</sup>) i.e., 5.71 kg ha<sup>-1</sup>. The total P uptake in seed by Indian mustard var. NRCHB-101 is highest at  $N_3$  (120 Kg ha<sup>-1</sup>) and lowest at  $N_1$  (80 kg ha<sup>-1</sup>) i.e., 27.32 kg ha<sup>-1</sup> and 21.51 kg ha<sup>-1</sup>, respectively. The P uptake was significant for different levels of N, P and K. The P uptake increases as the doses of N, P and K increases. The total P uptake by both, seed and stover, is highest at  $N_3 P_2 K_2$  i.e., 19.82 kg ha<sup>-1</sup> and 8.83 kg ha<sup>-1</sup>, respectively. The P uptake by both, seed and stover, was significant for all the interactions. These results for P uptake corroborated with the findings of Ghimire and Bana (2011). The higher removal of N and P might be due to synergistic effect chlorophyll content, cell division, photosynthetic rate and root activities of plants which has been reported.

Table 5 represents the interaction effect of NP, PK and NK levels on total uptake of P by seed and stover of Indian mustard var. NRCHB-101. As evident from the table, the highest N uptake by seed was at  $N_3 P_2$  i.e., 19.47 kg ha<sup>-1</sup> and the lowest was at  $N_1 P_1$  i.e., 15.45 kg ha<sup>-1</sup>. The table revealed that the highest P uptake by stover was at  $N_3 P_2$  i.e., 8.59 kg ha<sup>-1</sup> and the lowest was at 5.33 i.e., 10.30 kg ha<sup>-1</sup>. The P uptake by both, seed and stover, was significant for all the interactions. The N-P-K interaction effect on total P uptake by seed and stover has been shown in Table 6. As depicted in the table, the total P uptake by both, seed and stover, was the highest at the interaction level of  $N_3 P_2 K_2$  i.e., 19.82 kg ha<sup>-1</sup> and 8.83 kg ha<sup>-1</sup>, respectively. The P uptake by both seed and stover was significant for all the interactions.

The seed uptake was highest at  $N_3$  (120 Kg ha<sup>-1</sup>) and lowest at  $N_1$  (80 kg ha<sup>-1</sup>) i.e., 13.42 kg ha<sup>-1</sup> and 10.24 kg ha<sup>-1</sup>, respectively. The stover K uptake was highest at  $P_2$  (40 Kg ha<sup>-1</sup>) and lowest at  $K_1$  (0 kg ha<sup>-1</sup>) i.e., 38.75 kg ha<sup>-1</sup> and 35.26 kg ha<sup>-1</sup>, respectively. The total K uptake in seed by Indian mustard var. NRCHB-101 is highest at  $N_3$  (120 Kg ha<sup>-1</sup>) and lowest at  $N_1$  (80 kg ha<sup>-1</sup>). The K uptake was significant for different levels of N, P and K. The K uptake increases as the doses of N, P and K increases. Similar results have been reported by Grewal *et al.* (2009). The highest K uptake by seed was at  $N_3 P_2$  i.e., 13.35 kg ha<sup>-1</sup>. The highest K uptake by stover was at  $N_3 P_2$  i.e., 38.87 kg ha<sup>-1</sup>. The total K uptake by both, seed and stover, is highest at  $N_3 P_2 K_2$  followed by  $N_3 P_2 K_1$  in seed and stover, respectively. The K uptake by both, seed and stover, was significant for all the interactions. The stover yields of Indian mustard were significantly obtained under application of higher levels of N and P could be ascribed to better transformation of growth and yield attributes into yield which corroborated with findings of Dabiet *et al.* (2015).

Table 8 represents the interaction effect of NP, PK and NK on total uptake of K by seed and stover of Indian mustard var. NRCHB-101. As evident from the table, the highest K uptake by seed was at  $N_3 P_2$  i.e., 13.35 kg ha<sup>-1</sup> and the lowest was at  $N_1 P_1$  i.e., 9.89 kg ha<sup>-1</sup>. The table also showed that the highest K uptake by stover was at  $N_3 P_2$  i.e., 38.87 kg ha<sup>-1</sup> and the lowest was at  $N_1 P_1$  i.e., 33.86 kg ha<sup>-1</sup>. The N uptake by both, seed and stover, was significant for all the interactions. The N-P-K interaction effect on total K uptake by seed and stover has been shown in Table 9. As depicted in the table, the total K uptake by both, seed and stover, was highest at  $N_3 P_2 K_2$  i.e., 13.57 kg ha<sup>-1</sup> and 39.12 kg ha<sup>-1</sup>, respectively followed by  $N_3 P_2 K_1$  i.e., 13.14 kg ha<sup>-1</sup> and 38.63 kg ha<sup>-1</sup> in seed and stover, respectively. The K uptake by both, seed and stover, was significant for all the interactions.

## CONCLUSION

The total N uptake by Indian mustard var. NRCHB-101 was highest at  $N_3$  (120 Kg ha<sup>-1</sup>) and lowest at  $P_1$  (20 kg ha<sup>-1</sup>) i.e., 64.08 kg ha<sup>-1</sup> and 60.95 kg ha<sup>-1</sup>, respectively. The total P uptake was highest at  $N_3$  (120 Kg ha<sup>-1</sup>) and lowest at  $N_1$  (80 kg ha<sup>-1</sup>) i.e., 27.32 kg ha<sup>-1</sup> and 21.51 kg ha<sup>-1</sup>, respectively. The total K uptake by Indian mustard var. NRCHB-101 was highest at  $N_3$  (120 Kg ha<sup>-1</sup>) and lowest at  $N_1$  (80 kg ha<sup>-1</sup>) i.e., 51.79 kg ha<sup>-1</sup> and 45.60 kg ha<sup>-1</sup>, respectively. The total

Swetalina Mohapatra et al.

N, P and K uptake by both, seed and stover, was highest at interaction N<sub>3</sub> P<sub>2</sub> K<sub>2</sub>. The N, P and K uptake increased as the doses of N, P and K increased.

### ABSTRACT

Rice is the second most important cereal crop in the world after wheat and it is the most important staple food of south-west Asia including India. Due to the increasing population demand of rice is increasing, so the production must be increased accordingly. The improvement in the productivity is the only way to increase the total production because the cultivated land area is fixed and can't be increased but the use of natural resources must be judicious and the quality of environment shouldn't be sacrificed. The productivity enhancement requires proper management practices and nutrient management is one of the most important among that. Therefore, there should be a sustainable way of nutrient management for optimum production of rice. Integrated Nutrient Management (INM) is one of the appropriate option in present situation to improve productivity for fulfilment of the demand with less effect on the environment. In this chapter the INM of rice and its related aspects are critically reviewed.

**Keywords:** Rice, population, productivity, nutrient management, INM

### INTRODUCTION

Rice is an important food grain to many of the world population especially in the Asian countries. Not only in rice, but also in every crop nutrient management is having an important role in improving productivity as well as total production of the crop. The natural resources are shrinking day by day and the increasing use of synthetic fertilizers and pesticides is causing threat towards sustainability of the system, therefore the production system must be set

**Subhankar Purohit et al.**

accordingly. Among all the management practices nutrient management is one of the most important and it is also causing harm to the environment as it requires increasing use of synthetic fertilizers to maintain the productivity. So, the practices of nutrient management must be sustainability oriented for survival of the production system and INM is one of the best solution to optimise the productivity through use of both organic manures and inorganic fertilizers. INM provides a balanced fertilization to crop, which helps in the yield optimisation and system sustainability. Optimum nutrient application through appropriate method in right proportion at right time suitable for a specific crop and agro-climatic condition is called balanced fertilization. Balanced fertilization helps in 'soil health building', while imbalanced fertilization leads to 'soil mining', causing sickness of soil and an uneconomic waste of scarce resources. Only 'soil health building' leads to a sustainable land use system where most food grain production continues to come from existing agricultural land (Mahajan & Gupta, 2009). INM aims to improve the soil health and productivity by maintaining the sustainability (Prasad et al., 1995). Singh and Kumar (2014) observed increased yield and nutrient use efficiency in rice with the use of organics. Organic supply of nutrients also provide micro nutrients and change the soil-physical condition as well as increase the efficiency of applied nutrients (Pandey et al., 2007). The mixed use of organic and inorganic fertilizers has been observed not only to meet the nutrients requirement of the crop but also has been found to obtain large scale productivity goals (Yadav and Meena 2014)

### Effects of INM on different growth parameters

#### Plant Height

The plant height of paddy increased progressively with increase in the fertility levels of NPK (Deshmuk et al., 1988). The effect of application of duck weed @ 2t ha<sup>-1</sup> was found equally effective to 18 kg N ha<sup>-1</sup> application in terms of plant height (Ahmad et al., 1990). Incorporation of farm wastes like FYM, biogas slurry and poultry manure @ 5t ha<sup>-1</sup> and sunhemp, neem leaf, Calotropis and Pongamia @ 12.5t ha<sup>-1</sup> as green manure has significantly increased the plant height (Budhar et al., 1991).

#### Dry Matter Accumulation

The total dry matter yield of rice was higher when FYM and urea are applied together than only application of urea (Khan et al., 1986). The pattern of dry matter accumulation in rice was higher with increase in the level of nitrogen application (Balasubramanian & Palaniappan, 1991). Dry matter production of rice increased with the supply of N either from inorganic sources (50 kg N ha<sup>-1</sup>) or from combination of organic (10 t FYM ha<sup>-1</sup>) and inorganic sources (25 kg N ha<sup>-1</sup>) as compared with the application of organic source alone @ 20 t FYM ha<sup>-1</sup> on sandy clay loam soil of Kharagpur (Ghosh et al., 1994). Increase in the dose of nitrogen application even by 150% of the recommended dose increase dry matter (Mandal et al., 1994).

#### Number of Tillers per Unit Area

With increase in the level of Nitrogen application number of effective tillers increases (Deshmuk et al., 1988), (Singh et al., 1991). Relatively more number of effective tillers per hill were recorded with the application of poultry manure @ 15 t ha<sup>-1</sup> compared to FYM application @ 5t ha<sup>-1</sup> (Budhar et al., 1991). Number of Productive tillers recorded were higher, when Calotropis was incorporated @ 12.5t ha<sup>-1</sup> and it was followed by poultry manure application @ 5t ha<sup>-1</sup> to rice (Budhar et al., 1991). Highest number of productive tillers was recorded with 120 kg ha<sup>-1</sup> of inorganic nitrogen which was compatible with substituting the same nutrients through Glyricidia @ 30 kg N and 60 kg N ha<sup>-1</sup> as urea (HARI PRASAD, 1993).

### Effects of INM on Different Yield Attributes

#### Number of Panicles per Square Meter

An increase in the number of panicles per square meter was found when FYM and urea both were applied (G. D. Sharma & Sharma, 1994). In clay loam soils of Coimbatore similar results were also found with application of FYM

**Subhankar Purohit et al.**

and urea, when urea super granules were applied @ 58 kg ha<sup>-1</sup> along with Azolla or paddy straw to supplement 29 kg N ha<sup>-1</sup> (Thangamuthu and Balasubramaniyan, 1987).

**Panicle Length**

With Increasing levels of N, there is significant increase the length of panicle (Karuna Sagar & Rama Subba Reddy, 1992). Higher panicle length was obtained with incorporation of organic manures like leucaena tender loppings in combination with 75 kg ha<sup>-1</sup> inorganic N (Jeyaraman & Purushothaman, 1988). The length of rice panicle was increased by using 120 kg N ha<sup>-1</sup> through urea alone when compared with either organics alone or complementary use of organic and inorganic manures on equivalent nutrient basis (HARI PRASAD, 1993).

**Number of Grains per Panicle**

With addition of nitrogen the number of grains per panicle increase in rice (Reddy et al., 1987) (Rai et al., 1991). In rice basal application of farm waste like FYM @ 5t ha<sup>-1</sup> and green manures like sesbania, calotropis etc. @ 12.5t ha<sup>-1</sup> gives similar result in production of filled grains per panicle (Budhar et al., 1991). Number of filled grain per tiller was more when the nitrogen was applied through inorganic fertilizer by 75% and glyricidia or rice straw by 25% (Setty et al., 1990). Number of grains per panicle was significantly increased with application of 120 kg N ha<sup>-1</sup> through urea on sandy clay soil of Bapatla when compared with other organic and inorganic nutrient combinations (HARI PRASAD, 1993). Nitrogen application of 30 kg N ha<sup>-1</sup> through FYM along with 90 kg N ha<sup>-1</sup> as urea was found to produce more number of spikelets as compared to other combinations (G. D. Sharma & Sharma, 1994). With increase in the application of Nitrogen up to 90 kg ha<sup>-1</sup> was found to increase the number of grains per panicle significantly (Tripathi et al., 1998).

**Test Weight**

An increase in the test weight of rice grain with the combined use of organic and inorganic sources of nitrogen was observed (Setty et al., 1990); (Jeyaraman & Purushothaman, 1988). On the other hand, the basal application of FYM, poultry manure @ 5t ha<sup>-1</sup> or sunnhemp, calotropis, pongamia, soobabul, sesbania and neem leaf @ 12.5 t ha<sup>-1</sup> in the rice field don't have any impact on the test weight (Budhar et al., 1991)

**Grain Yield**

In many research, it is found that with incorporation of organic manures like wheat straw or, FYM (Maskina & others, 1987), FYM @ 12t ha<sup>-1</sup> (Purushotham et al., 1988), Prosopis or, Withania or, Abutilon or, neem leaf @ 6t ha<sup>-1</sup> (Alam et al., 1990), wheat straw or, FYM or, water hyacinth @ 5t ha<sup>-1</sup> (A. R. Sharma et al., 1990), FYM or, biogas slurry or, poultry manure @ 5t ha<sup>-1</sup> or green leaf manure @ 12.5t ha<sup>-1</sup> (Budhar et al., 1991) and FYM @ 20 t ha<sup>-1</sup> (Tandon, 1991) increases the grain yield of rice significantly. Incorporation of rice straw and chaff along with 60-90 kg N ha<sup>-1</sup> from inorganic sources (Subbaiah et al., 1983), a combined of FYM along with urea (Khan et al., 1986) and application of 30 kg N ha<sup>-1</sup> as FYM and 90kg N t ha<sup>-1</sup> as urea (G. D. Sharma & Sharma, 1994), gave maximum yield of rice as compared to the individual applications.

Combined use of 12t FYM ha<sup>-1</sup> and 60 kg N ha<sup>-1</sup> (Kulkarni et al., 1978) and 12t FYM ha<sup>-1</sup> along with 80 kg N ha<sup>-1</sup> (Maskina et al., 1988) produced similar rice yields with the application of 120 kg N ha<sup>-1</sup>. Application of 75% NPK through fertilizers + 25% through Glyricidia or rice straw (Setty et al., 1990), application of 50 % of the recommended NPK through FYM and compost and 50% through fertilizer (Jayakrishnakumar et al., 1994) found similar rice grain yield with full dose of recommended NPK. Application of N in rice through two organic sources such as FYM and wheat straw proved better than individual application of them and affected economy of 50 kg N ha<sup>-1</sup> for rice grain yield (Rajput and Warsi, 1991). Application of full recommended dose of N on soil test lab recommendation through fertilizer was found to be at par with 75% N combined with FYM @ 5t ha<sup>-1</sup> and Azospirillum @ 5kg ha<sup>-1</sup> and there is possibility of saving of 25% of fertilizer N through INM (Arumugam et al., 1992). Application of FYM, compost or biogas slurry along with 30 kg P<sub>2</sub>O<sub>5</sub> ha<sup>-1</sup> gave higher rice yields than with

**Subhankar Purohit et al.**

60kg  $P_2O_5$  ha<sup>-1</sup> as super phosphate on a calcareous soil in Bihar (Prasad & Prasad, 1994). A significant increase in rice grain yield was found with application of 120kg N ha<sup>-1</sup> on FYM amended plots as compared to 180kg N ha<sup>-1</sup> on unamended plots (Agrawal et al. 1995). The grain yield of rice was recorded maximum through application of inorganic P along with poultry manure (Gupta et al., 1995). Application of organic manure (FYM @ 5 t ha<sup>-1</sup>) along with the recommended dose of fertilizers produced significantly higher grain yields in rice (Rabeya Khanam et al., 1997).

**Straw Yield**

Application of duck weed to rice @ 2 t ha<sup>-1</sup> produced equivalent straw yield to that of 18 kg inorganic N ha<sup>-1</sup> (Ahmad et al., 1990). Combinations of different inorganic and organic treatment application of organics (FYM @ 12.5 t ha<sup>-1</sup>, Azadiracta leaves @ 6.25 t ha<sup>-1</sup>, cowdung slurry @ 5 t ha<sup>-1</sup>) and Azolla recorded highest rice straw yield on farmers fields in Coimbatore (Subramanian and Rangarajan, 1990). Rice straw yield was highest with the application of poultry manure @ 5 t ha<sup>-1</sup> and it performed better than FYM @ 5 t ha<sup>-1</sup> (Budhar et al., 1991). Increase in application of FYM level from 10 to 30 t ha<sup>-1</sup> straw yield increased from 5.08 to 5.39 t ha<sup>-1</sup> respectively (Kumar et al., 1991). The application of inorganic N in combination with FYM or straw to rice has been found to increase the straw yield (Rajput & Warsi, 1991). Application of poultry manure @ 5 t ha<sup>-1</sup> in rice was highly effective in increasing straw yield (Datta & Banik, 1994). Where as, with application of 120 kg N ha<sup>-1</sup> through FYM resulted in reduced straw yield (Radha Madhav, 1995). In addition to the recommended dose of fertilizers, incorporation of organic manure (FYM @ 5 t ha<sup>-1</sup>) in resulted significantly higher straw yield in rice crop (Khanam et al., 1997).

**Harvest Index**

Harvest index of rice was found to be increased with application of FYM @ 30kg N ha<sup>-1</sup> along with 60kg N ha<sup>-1</sup> as urea (HARI PRASAD, 1993). The harvest index of rice was relatively higher when the 120kg N ha<sup>-1</sup> was applied through FYM (Radha Madhav, 1995).

**CONCLUSION**

From this review, it is clear that INM in rice improves almost all growth and yield attributes of rice, increases both the grain and straw yield and also improves the harvest index. Therefore, INM in rice fulfils the increasing demand of rice by improving the yield and maintain the sustainability of the system by maintaining the soil health and reducing environmental pollution through reduced application of synthetic fertilizers.

### ABSTRACT

The higher education system aims at achieving sustainable development and a significant increase in the growth rate through the dissemination of proper education in terms of knowledge and skills which has become possible only through the establishment of educational institutes in different parts of the country. However, the success of an institution hinges substantially on the vitality of faculty that intensifies the proficiency and competence in the professional education system. Enrichment of vitality of the faculty members is of utmost importance in key domains related to teaching, research and administration to provide effective assistance to the students by improving the educational system significantly which can be achieved through faculty development programmes (FDPs). FDPs are need based, and are efficiently designed to eliminate the gap that exists in quality teaching and research. This review covers the impact of faculty development programmes in grooming the faculty and teachers in order to enhance the quality of the education system.

**Keywords:** faculty, teachers, programmes, system, institution

### INTRODUCTION

The Indian system of higher education is considered as the second largest system in the globe in terms of enrollment. The higher education system aims at achieving sustainable development and a significant increase in the rate of

24767

S. P. Nanda *et al.*

growth through the dissemination of proper education in terms of knowledge and skills which has become possible only through the establishment of educational institutes in almost every pocket of the country. However, the success of an institution hinges substantially on the vitality of faculty that intensifies the proficiency and competence in the professional education system (Bilal *et al.*, 2019). Faculty and teachers are the assets of an institution as the quality of the teachers reflect the quality of the students. The core responsibility of faculty members is how best they can impart knowledge and skills to their pupil (Hrnciar and Madzík, 2013) which will help in shaping their lives. However, mere increasing the number of faculty in an institution will not serve the purpose if the quality will not be taken into consideration. Many times it has been observed that despite fulfilling all the pre-requisites, a faculty underperforms which not only affects the professional and personal lives of the individual but also the learners.

This situation prevails mainly due to multiple factors like lack of understating of the subject, lack of theoretical and practical knowledge, lack of confidence to face the class, nervousness, etc. Enrichment of vitality of the faculty members is of utmost importance in key domains related to teaching, research and administration to provide effective assistance to the students by improving the educational system significantly (Bilal *et al.*, 2019), and also to get the better of the hurdles faced by an underperforming individual. Superior quality professional pedagogy is the need of the hour for the faculty members not only to improve their teaching, research and administrative competencies but also to keep pace with the ever-changing scenario in the educational system which can be achieved through a dynamic faculty development programme. Faculty development programmes (FDPs) include a wide array of activities aimed at assisting the academicians or faculty members to work on their professional expertise necessary for teaching, research, curriculum support, mentoring and administration (Kwan *et al.*, 2009 and Guraya *et al.*, 2016). FDPs are recommended by professional experts as well as organizations for creating awareness among the learners to achieve knowledge in the line of teaching in a better way (Ghazvini *et al.*, 2014 and Jones *et al.*, 2015). Many researchers have proposed faculty development programmes are often required to circumvent monotony and one-way lecturing (Fink, 2013). However, a perusal of literature has shown sustained availability of information in a scattered way. Thus the researchers have attempted to provide a systematic review on the impacts of FDPs in fostering the teaching, learning skills and professional competency in faculty.

### Genesis and expansion of Faculty Development Programmes

For the enhancement of instructional cum teaching skills, different faculty development programmes are being developed in the past. These FDPs mainly aimed to initiate and impart sustain changes in targeted learners (Sullivan, 1983). Previous studies were reviewed by Hitchcock and his co-worker in 1992 who proposed the gradual development and expansion of the concept (McLeod, 2010; Sheets and Schwenk, 1990; Stritter, 1983) whereas Hubbard and Atkins (1995), suggested the strategies related to faculty development as valuable means that enhances not only the capabilities of the faculty but also the institution which in turn upgrade the teaching-learning environment, creates awareness on the emerging technologies among the learners and enables to understand the expansion of higher education. In recent times, contemporary perspectives of FDPs critically addresses the awareness on the vitality and improvement of teaching skills, reinforce the bond between the faculty including the sustenance of faculty members as well as the institutions (Kamel, 2016).

Faculty development programmes are being classified in various ways by different researchers. The researchers Bergquist and Phillips (1975) had described FDP based on three vital components *viz.*, instructional development, personal or individual development and organizational or institutional development. Instructional development solely includes activities like development of curricula, diagnosis of teaching and pedagogy; individual or personal development includes activities that provide interpersonal skills and counseling on career advancement that encourages growth and development of the faculty and organizational or institutional development involves activities that enhance the administrative capabilities of the faculty members and administrative staffs including development of managerial skills and healthy team work. Another classification was proposed by the researchers Ullian and Stritter (1994) in which they included fellowships, seminars, workshops in addition to organizational

S. P. Nanda *et al.*

strategies and personal activities. Wilkerson and Irby (1998) also suggested a classification, in which they involved orientation programmes for the new faculty in the initial stage prior to instructional, administrative and institutional developmental programmes.

### Importance of Faculty Development Programmes

There are evidences showing the ineffectiveness of the traditional method of teaching due to the ever-changing scenario of the present education system (Fink, 2013). Incorporation of improved technologies is also one of the major factors contributing to the need of FDPs in recent times to cope up with the technologies. The importance of FDPs lies upon various factors *viz.*, increasing diversity among the students in respect to age, learning needs, cultural and academic background; opportunities and challenges related to technological aspects that enhances learning processes and changes in recruitment process and faculty characteristics (Kamel, 2016). FDPs ensure effectiveness of faculty members by enhancing their efficiency to support the learning of students which have diversified learning needs though development of appropriate teaching aids, strategies and curricula for a whole new environment. FDPs also provide opportunities to exploit and take advantage of the newer techniques by integrating them with teaching and research to make the subject more attractive to the students and also to exploit them in curricula planning. FDPs also help in identifying ways to involve new faculty members in institutional activities by ensuring the quality of their capabilities (Kamel, 2016).

### Impact of Faculty Development Programmes on faculty and students

The faculty development programmes aim at enriching the academic as well as intellectual competencies of the learners as well as the organizations. These are focused series of workshops or pedagogy that enhances the teaching quality, educational techniques and experiential learning. The results pertaining to various studies revealed that FDPs have number of purposes that includes improvement in attitudes, identification and recognition of various lacunae in teaching, opportunities to pursue research work, opportunities to improve pedagogical skills, opportunities to develop course curricula and administrative acumen in an efficient manner.

Many researchers have analyzed the results of FDPs through questionnaires, video recordings, feedbacks collected from students and faculty reports (Steinert *et al.*, 2006). Several publications were reviewed by Reid *et al.*, 1997 during 1980-1996 and they concluded that FDPs involving fellowships, seminars and workshops gave positive results. Results of many studies revealed a significant positive correlation between ratings of videotapes and knowledge tests. While reviewing the impact of FDPs on students, feedbacks collected from the students were evaluated and it was observed that ratings of the students were focused mainly on to increase in active learning process and clarity in lectures including delivery in immediate feedbacks. In case of faculty members, increase in confidence and competence was observed (Finelli *et al.*, 2008)

Thus FDPs were found to have beneficial effects both on faculty as well as on students in general when results of the students' evaluation reports and surveys were taken into consideration. However, the above mentioned measures involves more cost and time consuming, henceforth, more reliable and valid measures are needed to analyze the impact of FDPs in a more accurate way (Steiner *et al.*, 2006). For psychometric properties, most of the studies have used questionnaires and developers and researchers involved with the assessment of changes need to use questionnaires that are valid and reliable or work in a serious manner to establish these measures, e.g. development of a number of measures and scores can be seen in education that measures the performance of the faculty (Gibbs and Coffey, 2004). Different assessment tools and measures must be utilized to get more consistent and reliable results whenever possible (Gibbs and Coffey, 2004). Glowacki-Dudka and Brown, 2007 suggested the advantages and beneficial effects of FDPs provided in medical via self-evaluation of teaching skills, creating awareness on efficient teaching and research methodologies, and also feedbacks from the students. Improvements in ratings of the students and changes in teaching methods and practices were demonstrated by the researchers Finelli *et al.*, 2008 through focused instructional consultations.

S. P. Nanda et al.

### Development and Future Vision

The efforts of faculty developments were mainly apprehensive with the advancement of the teaching or disciplinary skills of the individuals initially (Hubbard and Atkins, 1995). However, over the last few decades, it was realized that this perspective is conventional and has narrower sense that would be unable to keep track of the developments taking place in the new generation's technologies and society which is connected globally (Millis, 1994). Thus, this realization had given birth to philosophy of faculty development in a broader sense involving short series of pedagogy to professional development including teaching, reaching and administrative activities and cooperation between the members. The concept of professional learning in a continuous mode rather than single training as proposed by different educators involved in higher education system (Clarke and Hollingsworth, 2002; Knight, 2002). It was observed that intended learners usually get to know from a series of training activities which involves interactions with fellow learners and experienced professionals, learning from formal programmes as well as form job related activities (Bergquist, 2010).

The future vision is focused on three key themes (Sorcinelli, 2005) – a) emphasizing in the field of development of organization by enhancing the leadership qualities among the faculty and to work under the supervision of academic leaders *viz.*, administrators (chairs and deans) with an objective to create encouraging and supportive environments to carry out quality teaching and research by enhancing their aptitude and skills (Sorcinelli, 2005; Bergquist, 2010; Wilkerson and Irby, 1998); b) emphasizing to link up the capacity of the professionals with research work to enhance learning of the students, systematically working on a research base in teaching and learning and c) developing new analytical views to bring about absolute structures for the development of faculty by lessening the organizational operations in centralized ways (Austin and Sorcinelli, 2013).

### CONCLUSION

Faculty development programmes are being considered to be successful in enhancing the quality of teaching and research through enrichment in the competency of the faculty members. Superior quality professional FDPs provide promising results in higher education that helps in developing teaching, research and administrative skills in an efficient manner. FDPs not only help in the development of an individual but also contribute towards the institution building in a way that ensures quality, excellence, advancement and readiness to bring about effective changes in a positive manner as a response to ever-growing demands of education and students to keep pace with the new generation and newer technologies.

### ABSTRACT

Q methodology or Q sort technique is a research tool used to study people's own perspectives, meanings and opinions developed by physicist William Stephenson in the 1930s. This is a research method used in psychology and in social sciences for understanding subjectivity. This review paper tries to introduce briefly about this methodology which integrates quantitative, qualitative and mixed methods and its application procedure. Applying Q method involves five consecutive steps those are like identifying discourse to concourse, developing a Q sample or Q statement set, ordering from the piles and ranking etc. This review has also included the challenges of the technique as have found some loopholes in Q methodology like non-linearity and absence of value neutrality. This study also included information regarding difference between Q method and other social science survey and its applications along with important features.

**Keywords:** Q Methodology, discourse, concourse, statements, research, investigation

### INTRODUCTION

Q methodology was developed by psychologist and physicist William Stephenson in the 1930s, and documented in his book, *The Study of Behaviour: Q technique and its Methodology* (1953). Its aim is to study people's own perspectives, meanings and opinions. For some scholars, considerable emphasis is given to the fact that Q methodology is a 'scientific' study of these phenomena. For example, Goldman (1999) categorises Q methodology as the 'science of subjectivity' while McKeown and Thomas (1988) consider it to be 'a method for the scientific study of

24772

**Rupashree Senapati et al.**

human subjectivity'. This emphasis on the 'scientific' credentials of the method is equivalent to the Stephenson's own disciplinary and positivist background, and the values and beliefs of people who have traditionally tried to apply Q methodology.

### Steps of Q Methodology

Q methodology can be explained having five key stages.

#### 1<sup>st</sup> key stage

The first stage involves identifying the 'discourse' which is under investigation. In Q methodology a discourse is referred to as a set of shared beliefs, opinions, understandings or meanings that is held by a population. For example, the discourse under investigation by (Fieldhouse 1986) was attitudes towards food and nutrition while (Brown 1993) investigated this as a discourse on animal experimentation. The discourse in a Q study is, of course, directly connected to one's research questions. The quantitative researchers typically develop a set of hypotheses at the commencement of a study, while the Q researchers develop research questions because the Q methodology is a research technique which neither tests its participants nor imposes the meaning a priori. (Stainton Rogers 1995). Rather, meaning and significance of generated profiles in Q methodology are 'attributed a posterior through interpretation' (Brown 1980).

#### 2<sup>nd</sup> key stage

The second stage in the Q process is moving from the broader discourse to identifying a 'concourse'. This refers to the range of issues that exist on a particular discourse (topic). For developing a concourse researchers may use either naturalistic or ready-made type texts (McKeown and Thomas 1988). Dell and Korotana 2000 used interviews to obtain a sense of the discourse about domestic violence, but turned as well to the literature and media reports to develop their concourse. In earlier Q methodological work (Stepheonson 1936) used with more unusual stimuli including hedonic values of different odours. However, this methodologists have employed a Q set of statements. During concourse development researchers build up a statement set which identifies different, though recognizable assertions about the social phenomena being studied for 'broadly representative of the opinion domain at issue' (Watts and Stenner, 2005).

#### 3<sup>rd</sup> key stage

The third stage in the Q methodology is the process of developing a Q sample or Q statement set from the concourse. Developing the Q set helps researchers in refining and setting the research question, which, in Q method, must be clearly defined before data collection starts. (Watts and Stenner 2005) recommend for developing straightforward questions, containing a single proposition for each. A clearly defined statement in the research question is required as it dictates the nature and the structure of the Q set and acts as a 'condition of instruction' for participants during the actual sorting process of it. Therefore, a Q set reflects the complexity of the issue given, as well as enables each participant to respond based on their experience.

Often the concourse may be 'around three times the size of the aimed-for Q set, say 200 for an aimed-for Q set of 65' so this is much an arduous process. (Stainton Rogers 1995) The size of the statement set may vary, but typically it is between 30 and 60 statements (Thomas and Watson 2002 ). Time and practical constraints should be considered while determining the size of the sample. Piloting is consequently recommended for this. Above all the researchers should ensure that they have covered the breadth of opinions or themes that may circulate about a discourse, and also ensure that they have avoided unnecessary duplication as well as under/over sampling here. There is a variety of suggested Q sample techniques in the literature for moving from the concourse to Q sample including coding statements and matching them to matrix according to different dimensions of a discourse to create a structured sample. This is a technique engaged in their study of sustainability of discourses. (Barry and Proops 1999)

#### 4<sup>th</sup> key stage

The fourth stage after the development of the Q sample is to ask participants to order the statements in a process which is called a Q sort. This is a ranking procedure which (Brown 1980) calls 'the technical means whereby data are obtained for factoring'. In practice, the statements are typically written on small cards and sorted into different piles in a quasi-normal distribution according to the 'conditions of instruction' described by the researchers. For example, participants will be asked to respond according to whether they will strongly agree (+6) or will strongly disagree (-6) with an individual item in the Q set. In Q sorting it is identified as a 'forced-free' distribution, because it takes the form of a quasi-normal distribution that is symmetrical about the middle. Both the range and the distribution shape are arbitrarily designed to accommodate the number of statements chosen for the study (Addams 2000).

#### 5<sup>th</sup> key stage

Typical Q studies use an 11 or 13 point scale, with the possible ranking values from +6 or +5 for items that are 'more agreeable' in view of the participants, through '0' to -6 or -5 for items considered 'more disagreeable'. The key point in this procedural step is to ensure that Q sorters discard statements that are irrelevant and retain those that best describe their opinions and experiences of the social phenomena being studied. Brown 1980 explained that a participant completing a Q sort is usually more emotive about statements scored '-6' than those scored '0' because statements placed by participants towards the 'middle' lack some significance as compared to those statements placed at the extremes. Practically Q sorting is an interactive process and the factors that emerge are 'operational definitions' of opinions, experiences and preferences of each individual (Brown 1980).

#### Important Features

This is a research method used in psychology and in social sciences to study people's "subjectivity"—i.e., their own viewpoint. It has been used both in clinical settings and for assessing a patient's progress over time (intra-rater comparison), as well as in research settings to examine how people think about a topic (inter-rater comparisons). The name "Q" has been derived from the form of factor analysis which is used to analyze the data. Normal factor analysis, called "R method," involves finding correlations between two or more variables (e.g. height /age) in a sample of subjects. Q, on the other hand, looks for correlations between subjects across a sample of variables. Q factor analysis reduces many individual viewpoints of the subjects down to few "factors," those are claimed to represent the shared ways of thinking. It is sometimes said that Q factor analysis is R factor analysis with the data table turned sideways i.e. helpful as a heuristic for understanding Q, this explanation may be misleading, as most Q methodologists argue that for mathematical reasons any data matrix would not be suitable for analysis with both Q and R.

The data for Q factor analysis extracted from a series of "Q sorts" from one or more subjects. A Q sort is a ranking of variables which is presented as statements printed on small cards—according to some "condition of instruction." For example, in a Q study of people's views of a celebrity, a subject might be given statements like "He is a deeply religious man" along with "He is a liar," and asked to sort them from "most like how I think about this celebrity" to "least like how I think about this celebrity." The use of the ranking, rather than asking subjects to rate their own agreement with statements individually, which is meant to capture the idea that people think about the ideas in relation to other ideas, rather than in isolation.

#### Difference between Q and other social science survey

One salient difference between Q and other social science research methodologies, such as surveys, is that -Q Method typically uses many fewer subjects. This can be a also its strength, as Q is sometimes used with a single subject, and it makes research far less expensive. Here a person will rank the same set of statements in different conditions of instruction. e.g., someone might be given a set of statements about personality traits and then asked to rank them according to how well they describe herself, her ideal self, her father, her mother, etc. Working with a single individual is particularly relevant in the study of how an individual's rankings change over time and this was

Rupashree Senapati *et al.*

the first use of Q-methodology. As Q-methodology works with a small non-representative sample, conclusions are limited to those who participated in the study.

### Application

Q-methodology is used as a research tool in a wide variety of disciplines including nursing, veterinary medicine, public health, education, transportation, rural sociology, hydrology, and even robotics. The methodology is mostly useful when researchers wish to understand and/or describe the variety of subjective viewpoints on an issue relating some aspects. The "Q sort" data collection procedure was used to be done using a paper template and the sample of statements or other stimuli printed on the individual cards. Now-a-days, there are also computer software applications for conducting online Q sorts. E.g., UC Riverside's Riverside Situational Q-sort (RSQ), which claims to measure the psychological properties of situations. Their International Situations Project is using the tool to explore the psychological aspects of situations and how those aspects may differ across cultures with this university-developed web-based application. Till date there has been no study of differences in sorts produced by use of computer based vs. physical sorting.

One Q-sort application should produce two sets of data. The first is the physical distribution of sorted objects and the second is either an ongoing 'think-out-loud' or narrative type or a discussion that immediately follows the sorting exercise. The purpose of these narratives may be to elicit discussion of the reasons for particular placements. The relevance of this qualitative data is often suppressed in current uses of Q-methodology and the modes of reasoning behind placement of an item can be more analytically more relevant than the absolute placement of cards. This scale has some commonality with summated rating scale. In this scale the respondents are asked to sort a given set of statements (items) and classify them into a predetermined number of categories (piles) usually 11. The number of statements (items) to be included in each category is also selected in advance.

### Challenges

Though a good psychological measurement tool, still researchers have found some loopholes in Q methodology to be used as a good research technique. E.g. it is not a linear process (Onwuegbuzie, Collins, Leech, Dellinger, & Jiao, 2010). Therefore, it is very common for researchers to oscillate between their primary research study and the further information. This non-linearity enhances complexity. This is also not value neutral like any scale. (Dellinger, 2005; Onwuegbuzie & Frels, 2012). The study contains quantitative information regardless of whether the source of information represents a quantitative, qualitative, or mixed research study (Onwuegbuzie et al., 2010; Sandelowski, Voils, & Barroso, 2006). It represents quantitative, qualitative, or mixed research studies. Due to the array of quantitative and qualitative data those are potentially inherent in each work, it needs simultaneously to the analysis of quantitative and qualitative information. So it optimally involves using mixed research techniques (Onwuegbuzie et al., 2010; Onwuegbuzie & Frels, 2016).

Using both quantitative and qualitative information in the same literature review automatically renders the literature review process as a mixed research study (Onwuegbuzie et al., 2010). Truly, with respect to the analysis of information, the reviewer must be competent in conducting quantitative-based (e.g., meta-analysis; Glass, 1976) and qualitative-based (e.g., meta-synthesis; Sandelowski & Barroso, 2003) along with mixed research-based (e.g., meta-summary; Sandelowski & Barroso, 2003) analyses.

## CONCLUSION

The power of Q methodology does not lie in the findings that can be generalized to the population from where the participants were selected (i.e. external statistical generalizations). Rather, the power of Q methodology has its ability to lead to analytic findings, wherein the literature reviewer is "striving to generalize a particular set of results to some broader theory". (Yin, 2009, p. 43)

**Rupashree Senapati et al.**

It is the participants' view points which can be generalized according to the types of persons who share similar points of view on a topic, under the assumption that the statements that comprise the Q sample are representative of the universe of viewpoints on the chosen topic (Brown, 1980; McKeown & Thomas, 1988). More clearly, although the findings from a Q methodology of information extracted from the literature reviews generalize to those who participate in the study, as the Q sample reflects a representative sample of statements those are drawn from the concourse, which, evolves from the comprehensive literature review. Above all the whole methodology provides us a useful tool which helps both beginning researchers and also the experienced researchers through the mixed analysis process onto the literature review process for a rigorous study.

### ABSTRACT

Lemongrass (*Cymbopogon flexuosus*) is tropical perennial grasses belongs to the family Graminae. Plants are grown under tropical and subtropical climatic conditions. It can be propagated through both sexually and asexually. In many regions, lemongrass is planted as an intercrop in fruit orchards or Plantation field. This plant is giving economically yield up to 5-6 years therefore this time coincides with the initial establishment of fruit orchards and plantation field. The plant is containing Citral about 75-80% which is responsible for its lemon-like smell. The essential oil is extracted through the steam distillation process and stored in a dark room to preserve the quality. Plants are dried and chopped into pieces before distillation as oil is highly evaporated. East Indian Lemongrass is largely exported from Cochin port; hence it is called Cochin oil [1]. India is the greater exporter of this oil. This oil is utilized for various purposes like Aromatherapy, Flavoring industry, confectionary, preparation of perfume etc. Besides, it has many medicinal values and use against digestive disorders, diabetes, nervous disorder, inflammation, fever [10] etc.

**Keywords:** Lemongrass, Uses, Essential oil.

### INTRODUCTION

Aromatic plants are an economically important group of plants which possessing Aroma and Flavour. Aromatic plants possess odoriferous compounds which synthesized as an essential oil or oleoresin and exudate as a gum from different plant parts including root, wood, bark, stem, foliage, flower, fruit and seed etc. The term essential oil corresponds with fragrance or perfumes, since such fragrances are oily and reflect the plants' essence or active constituents[1]. Several chemical constituents are responsible for characteristic aroma in plant. India is rich in

**Priyaranjan Koley**

biodiversity and comprise of numerous aromatic plants that are now being used as Aromatherapy for various ailments. Besides this, it can be utilized in many aromatic industries or confectionary or as a food and flavoring industry to adding delightful aroma. Two major scientific councils work on medicinal and aromatic plants in India. One is the Central Institute of Medicinal and Aromatic Plants under CSIR which looks at the point of view of the industry and another is Directorate of Medicinal and Aromatic Plants under ICAR which looks at the point of view of farmers. In the Aromatic plant, about 1500 species are known[1], but, only slightly more than 300 species were studied in some details. Of the 50 species that find use of essential oils and aroma-chemicals as commercial sources. Aromatic plants are classified into four broad groups for practical convenience. *i. e.*

1. Aromatic grasses: Lemongrass, palmarosa, citronella, vetiver etc.
2. Aromatic herbs and shrubs: Mints, Ocimum, patchouli, rosemary etc.
3. Aromatic trees: Sandalwood, eucalyptus, clove, camphor, cinnamon, nutmeg, linaloe etc.
4. Aromatic flowers: Rose, jasmine, tuberose, marigold, champak etc.

Aromatic grasses belong to the genus *Cymbopogon* and native to the tropics and subtropics of Asia, Africa and Australia. The name *Cymbopogon* derives from the Greek words 'kymbe' meaning boat and 'pogon' meaning beard that denotes the spike arrangement. Most oil grasses are perennials that are robust and densely tufted. It can prefer hot, humid tropics and can reach a height of 2 meters. They can bear long, flexible, narrow leaves. The genus *Cymbopogon* consists of approximately 50 to more than 100 numbers of species [2] under the Poaceae family. Aromatic grasses have traditionally been used in aromatherapy as an essential oil in Indian and Chinese medicine.

Lemongrass (*Cymbopogon flexuosus*) is tropical perennial grasses which possess a lemon-like odour. The name Lemongrass is justified by its lemon-like odour. It is belonging to the Graminae family[3] and native to many parts of tropical and subtropical South East Asia and Africa [4]. Aromatic oil is extracted from leaf and stalk of the plant. The main active principle is Citral (75-80%) which is extracted from leaves through the distillation process. East Indian lemongrass is largely exported from Cochin port; hence it is called Cochin oil[1]. Kerala shares the leading producer of this oil. India is the largest producer of lemongrass and about 80% of the produce is being exported. The essential oil is being traditionally exported to West Europe, U.S.A. and Japan. In India, the total cultivated area for lemongrass is estimated about 3000ha and largely grown in Kerala, Karnataka, Uttar Pradesh and Assam [5].

**Geographical Distribution**

Three types of lemon grasses are grown *i. e.* East Indian lemongrass or Cochin oil (*C. flexuosus*); West Indian lemongrass (*C. citratus*); and Jammu (*C. pendulus*) lemongrass. East Indian lemongrass is an Indian indigenous plant and commercially grown in Kerala, Assam, Maharashtra, Uttar Pradesh etc. West Indian lemongrass is native to Pakistan, India and Sri Lanka [6]. Then, it is widespread in many countries, such as West Indies, Guatemala, Brazil, Congo, Tanzania, Thailand, Bangladesh, Madagascar and China, etc. Jammu lemongrass is primarily restricted to the states of North India, including Jammu and Kashmir, Sikkim, Assam, Bengal and Madhya Pradesh. In India, lemongrass is commercially grown in the states of Kerala, Maharashtra, Karnataka and Tamil Nadu states [7].

**Uses of Lemongrass**

Lemongrass oil is being used as raw material for the preparation of important ionone such as  $\alpha$ -ionone for the preparation of perfumes, cosmetics as well as flavours, even as  $\beta$ -ionone is being used for the manufacture of synthetic vitamin A[8]. Lemongrasses are also used in many countries such as Java, Japan, China and India as flavouring in fruit, drink and tea or scented bathwater. The characteristic smell of oil makes use of soaps, detergents, insect repellent and formulations in the scenting process. From it is prepared a bio-pesticide with a nontoxic mode of action. It does have soil and water conservation properties. It can also be used as live mulch and cultivated along with the main crops. Spent gasses are also useful for the manufacture of cardboard and papers or as fuel. In India, it can be used as sedatives for the central nervous system [9]. Lemongrass oil is usually used in the preparation of

**Priyaranjan Koley**

many folk medicines for curing of digestive disorders, diabetes, nervous disorder, inflammation, fever [10] and also utilized as an antimicrobial agent for various pathogenic fungi [11].

**Morphology**

Lemongrass is tall, perennial grass that yields thick, glaucous, dense green leaves from a short rhizome. The culm is sturdy, upright, and grows up to 1.8 meters. It produces abundant flowering in South India. It is a short day plant and inflorescence is about a meter in length, with a long spike. Flowers are rarely produced from Panicle. Inflorescences are rosy in colour, growing up to 30 to 60 cm long.

**Species and Cultivars****Species**

Commonly lemongrass is categorized into three groups, such as

- East Indian lemongrass (*Cymbopogon flexuosus*): It is commonly termed Cochin grass or Malabar grass. It is a tall, perennial plant that grows up to 2 m tall and produces linear and lanceolate leaves. Plants consist of drooping panicles, as they are very long. Panicles are produced mainly in grayish colored leaves but are rarely shown in pinkish tinge. Two varieties are classified under this genus based on the colour of the stem. One of these is reddish or purple stem i. e. *C. flexuosus* var. *flexuosus*. It produces more Citral percentages (75-90 %) but poor yield. Another variety is the wild type, commonly referred to as white grass (*C. flexuosus* var. *albescens*) for its white stem colour. This grass produces less amount of Citral (60-75%) with a higher yield.
- West Indian lemongrass (*Cymbopogon citratus*): It is a smaller stem of perennial grass with numerous steep tillers arise from short rhizomatous rootstock. Leaf-blades are usually long, flat, glaucous and drooping. Inflorescences are reproduced very rarely.
- Jammu lemongrass (*Cymbopogon pendulus*): It is stemmed in white and has a small stature. The plant is frost resistant and suitable for northern India's Sub-Himalayan areas.

**Variety**

Some improved variety is developed for commercial cultivation like

**Sugandhi (OD-19):** This variety has originated from Research Station for Aromatic and Medicinal Plants, Odakkali. It can be cultivated in a wide variety of soil and climate conditions. Stem is typically reddish and expands 1 to 1.75 m long. It can yield approximately 80 to 100 kg/ha under rainfed conditions with a citral percentage varying from 85 to 88 percent.

**Pragati:** It is developed from CIMAP, Lucknow and suitable for Subtropical and tropical climatic conditions in the regions of North Indian Plains and Tarai Zone. It is a tall variety and produces dark purple colour leaf sheath. The Average oil content is 0.63 percent with a Citral content of 75-82 percent.

**Praman:** This variety was developed through clonal selection and belonging to species *C. pendulus*. It is a medium-sized variety with erect leaves and profuse tillering. The oil yield is high with 82 percent citral.

**Jama Rosa:** It is a hardy plant with vigorous growth that remains in the field for 16-18 months. This variety produces about 300kg oil in 4-5 cuts in peak growing period.

**RRL 16:** This variety was developed from RRL, Jammu. This variety's average annual herbage yield is 15 to 20 tonnes/hectare and yielding 100 to 110 kg of oil. The oil content varies from 0.6 to 0.8 percent on a fresh weight basis with a citral 80 percent.

**Priyaranjan Koley**

**CKP 25:** It is developed from a cross between *C.khasianum* X *C.pendulus* from RRL, Jammu. This variety is suitable for North Indian plains under irrigation conditions. It can produce 60 t/ha herbage and oil containing 82.85% citral. This variety can produce 50% and 140% more oil yield than RRL-16 and OD-19 respectively.

**Other Varieties**

**OD-408:** This variety has developed through selection from OD-19. It comprises a white stem and produces more oil and citral content.

**Kaveri:** This variety is suitable in the region with high soil moisture to produce luxuriant growth.

**SD-68:** This has been developed by CIMAP, Lucknow through selection.

**LS-48:** It is an improved variety developed at CIMAP, Lucknow are available for cultivation.

**Agro-climatic Requirements****Soil**

The plant is very hardy and it can be grown under a variety of soil conditions ranging from rich loam to poor laterite. However, it cannot tolerate Calcareous and water-logged conditions with poor drainage [12]. Lemongrass can be cultivated under well-drained sandy-loam soils with adequate incorporation of manure to obtain better yield and oil content. In the hilly region, it can be grown as a vegetative cover on an eroded land for its soil binding properties. It can prefer soil pH ranging from 5.5 to 7.5. In India, *C. flexuosus* is yielded more herb and oil under pH 7.5 [13]. It is also reported that electrical conductivity of 11.5, 10 and 5.5 mmhos/cm of soil was not affected the herb and oil yield of *C. flexuosus* in a pot trial where, Citral content was not decreased with increasing of Salinity level 15 mmhos/cm [14].

**Climate**

Lemongrass can be cultivated with ample sunlight in both tropical and subtropical conditions. It can grow up to the elevation of 900m above from MSL with uniformly distributed annual rainfall ranging from 250-280 cm. supplemental irrigation can be applied in the region where rainfall is poor. It is reported that *C. citratus* is more drought-tolerant [14] grass. In the hilly region, Citral production can be hampered with more rainfall per annum. It can prefer 20-30<sup>o</sup> C temperature with good sunshine throughout the year for better oil yield, but oil production can be reduced when the temperature goes to above 30°C.

**Field Preparation**

Lemongrass is a perennial crop and stands a minimum of 4 to 5 years in the field. So, initial land preparation is necessary for better growth and development. The land should be prepared by 2 to 3 ploughing and followed ridge and furrow beds. Land should be free from unwanted vegetation or Stones etc. Application of Phorate @ 10 kg neem @ 8-10 kg should be mixed on the soil at the time of last ploughing to control soil-borne disease.

**Propagation**

Lemongrass can be propagated through both sexually means seed and vegetative means Slips or root divisions. Seeds are most available but, vegetative propagation is preferable as seed causing a genetic heterogeneity resulting in degradation of oil yield and quality [15].

**Seed Production**

It is a perennial crop and produce flower during November-December. Seeds are collected from a healthy mother plant in the month of February-March. The healthy plant must be chosen by performance-based like average yield of about 100-200 g of seeds per plant. Seeds are collected from healthy plants by cutting off the whole inflorescence followed by dried under sunshine for 2-3 days. Again, seeds are threshed and re drying under Sunshine. After that,

**Priyaranjan Koley**

dried seeds are stored in gunny bags lined with polythene. But, it can lose viability under a long storage period line for more than one year.

**Rooted Slips**

Slips are also propagating materials for Lemongrass and it is more beneficial for commercial cultivation as compare to seed. Slips are separated from well-grown clumps and cut off at a height of 20-25cm. before planting; lower sheath should be removed for better exposure of roots.

**Nursery Preparation**

It is more advantageous to grow the plant through transplanting of seedlings rather than direct sowing as seeds lose their viability within a short storage period. In the case of broadcasting, about 25-30 kg/ha seeds are required for sowing, whereas, 3-4 kg/ha of seeds are required for transplanting. Nursery beds can be prepared by raised bed about 1m to 1.5m width. After bed preparation seeds are sown by hand on the month of April-May and covered with a thin layer of soil. The bed should be watered immediately after sowing and care should be taken to maintain adequate moisture in the soil. Seeds are germinated within 5-6 days after planting. Seedling is transplanting at 60 Days after planting when they are attaining a 6-7 leaf stage.

**Planting**

Planting is generally done at the beginning of monsoon maintain at a spacing of 40x40 cm, 40x30 cm, 40x60 cm [5] which is depends on soil fertility and Intercultural implements. Slips are planted on ridge and furrow beds at 15 cm deep. Generally, 2 -3 slips are recommended for one hole. Deep planting enhances root rot disease during the rainy season.

**Nutrient Management**

The fertilizers and nutrients should be applied in the field after knowing soil fertility status or soil testing. Generally, Farm Yard Manure can be mixed at the time of final land preparation at the rate of 8-10 MT/Ha. The recommended dose of fertilizer is 30 kg of each nitrogen, P<sub>2</sub>O<sub>5</sub> and K<sub>2</sub>O per ha as a basal dose and remaining 60-90 kg nitrogen [5] can be mixed as a top dressing in 3-4 split doses during the growing season has beneficial for proper growth and development. It is also recommended that spent lemongrass compost and Wood ash is obtained as a by-product of Grass distillation and applied at the time of final bed preparation [15]. Pest and disease do not generally occur on the lemongrass field but, some micronutrients like copper, iron, calcium and sulphur has been shown beneficial effect [5]. CIMAP, Lucknow was reported that a combination of Boron @ 2.5 ppm and Chloride Salts has been beneficial for lemongrass [12]. Citral production can be increased by the application of optimum fertilizer dose [16] and deduces with an excess dose of fertilizer [1].

**Water Management**

Irrigation is an important part of the cultivation of lemongrass. A supplementary application of irrigation is optimum for improved variety and frequent irrigation is requiring for newly bred grass. In the case of drought-prone areas, irrigation can be applied at an alternative day about a month. In general, 4 to 6 irrigations are required for optimum growth in February to June under North Indian conditions. In a rainfed condition, irrigation is supplied at 3 days intervals for the first month and 7-8 days interval on the subsequent month [17]. Irrigation can be supplied as a requirement by the plant depending on water holding capacity after establishment of plant

**Intercultural Operation**

Lemongrass is suitable as an intercropping crop in the orchards of fruit crops or plantation crops for utilization of land during the first 4 to 5 years before the establishment of main crops. Lemongrass cannot be suitable for shady areas as diffused light can reduce the oil yield [18]. Plants are suitable in the cinnamon plantation as compared to the coconut

**Priyaranjan Koley**

field as recommended by AMPRS, Odakkali. Distillation waste of the crop can be applied as an organic mulch @3 tonnes/ ha.

**Weed Management**

Weed management is an important operation for reducing crop-weed competition for the initial 3-4 months. After the establishment of a crop, it can able to compete with weed. Generally, 2-3 weeding are requiring in each after harvesting or 25 -30 days after planting. Hoeing is also done immediately after weeding. Weeding can be done with the help of tractor or hand weeding or by application of herbicides. Diuron @ 1.5 kg a.i. /ha and oxyfluorfen at 1.5 kg a.i./ha is effecting to control the weed in the field of lemongrass [15]. In rainfed condition, dried grasses are burnt on the field which is beneficial for controlling termites and also help to rejuvenation of old clumps.

**Pests and their Management**

This plant is not severely attracted by pests but, few pests are reported. Stem boring caterpillars are caused by *Chilotrea* sp. They are mainly feeds on a stem and causing drying up of leaf followed by whole plants. It can be controlled by spraying of Malathion @ 0.2%. Some plants are infected by nematode which is caused by *Tylenchorhynchus vulgaris*, *Rotylenchulus reniformis*, *Helicotylenchus* spp. and *Pratylenchus* spp.

**Diseases and their Management**

Red leaf Spot is one of the most important diseases which is caused by *Colletotrichum graminicola*. At first, a brown spot with concentric rings appear on the lower leaf surface. Then these spots are gradually increased and form big patches on leaf followed by drying of a leaf. This can be controlled by two spraying of Bavistin 0.1% at 20 days interval or spaying of Dithane M-45 (0.2%) at 10-12 days interval. Leaf bight also appears on the leaf margin or tip of the leaf. Older leaf is more susceptible than younger. Very small reddish-brown circular spots are appeared at the initial stage, later on, merge and causing premature drying of leaves. It can be controlled by spraying of Dithane Z-78 (0.2%) or 0.3% Copper oxychloride at an interval of 15 days. Little leaf or Grassy shoot is caused by *Balansia sclerotic*. The symptoms of this disease are stunting growth and little leaf formation instead of normal inflorescence. It can be controlled by foliar application of Dithane Z-78 (0.3%) just before the flowering stage at an interval of 10-12 days. It can also be controlled by planting healthy seedling and crop rotation.

**Harvesting**

Harvesting starts in May and continues to the end of January. Generally, lemongrass is cut by a sickle at a height of 10 cm above from the ground level and allowed to wilt in the field. Sunny days are preferable, as cloudy and misty conditions tend to deduce oil yield. Harvesting is also depending on some factors like temperature, rainfall, humidity and soil fertility level. Lemongrass is grown well under humid conditions [19]. First harvesting is done at 90 days after planting and subsequent harvest is done at 50-55 days interval up to consecutive 5-6 years [20]. Subramanyam and Gajanana (2001) [21] reported that three harvesting is done in the first year and 5-6 cuttings per year are recommended for the second year onward. On average, 25-30 tons of fresh herbage is obtained from 4-6 cuttings per year from one hectare of land, resulting in around 80 kg of oil. Under irrigated condition, improved variety can yield about 100-150 kg/ha of oil. Oil yields in the first year are lower but in the second year they increase and in the third year they reach a maximum; after this, yield declines. On average, the fresh herb contains 0.3-0.4 percent oil and thick stems are removed before distillation because these are oil-free.

**Postharvest Technology****Drying**

The essentials oils are found in different oil glands, oil sacks and glandular hairs of the plant. It can be lost through oxidation and resinification, therefore it must be store in a dry atmosphere before distillation. Plants are allowed to dry up to 30% moisture level for better oil yield. Plants are chopped into small pieces and immediately send to the distillation process to avoid oil loss. Small pieces of plants are dipped into 1 to 2 % sodium chloride solution for 24

**Priyaranjan Koley**

hours before distillation to maintaining the citral percentage. The recovery of oil from the grass ranges from 0.5 - 0.8 percent.

**Distillation**

Dried small pieces are inserted in the boiler made by stainless steel for steam distillation for around 3-4 hours at a vapor pressure of 18-32 kg / cm<sup>2</sup>. After completion of the process, it can produce yellow colour oil having 75-85% citral and other aroma compounds.

**Purification of Oil**

Other aroma compounds are removed by filtration methods. Oil is mixed with anhydrous sodium sulphate and kept in a dark room for 4-5 hours. Sometimes oil colour has changed due to rust then it should be overcome by the steam rectification process.

**Storage and Packing of Oil**

The better quality oil can be stored in a glass container in a dark condition. Sometimes, oil can also be stored in a stainless steel or aluminum or galvanized iron with a properly sealed and kept in a dark room.

**CONCLUSION**

Considering the above point it should be concluded that Lemongrass is utilized for various purposes like Aromatherapy, Flavoring industry, confectionary, preparation of perfume etc. Besides, it has many medicinal values and use against digestive disorders, diabetes, nervous disorder, inflammation, fever [10] etc. But, it is not so popularly cultivated in India as commercial. The purpose of this paper is to provide knowledge about Lemongrass cultivation and encourage cultivating this plant for more utilizing its phytochemicals in various treatments.

### ABSTRACT

Cotton cultivation provides livelihood security to millions of marginal and small farmers. The cotton enterprise is knowledge based and market driven. It evolved through innovations to better yields for meeting present and future national needs and attaining global competitiveness. Cotton yields in India are low due to various reasons such as inadequate inputs, rainfed cultivation, untimely field operations, and inefficient crop production practices. In India, 65% of the cotton acreage is dependent on rain. The annual variation in monsoon rainfall has an important role in cotton production in any particular year. Cotton is one of the profitable non-food crops in the world. Cotton production provides income for more than 250 million people worldwide and employs nearly 7% of all labour in developing countries. Half of all textiles are made of cotton. Although the global reach of cotton is wide, the current cotton production methods are environmentally unstable. This undermines the industry's ability to maintain future production. Developing cotton production technologies with even minimally acceptable environmental standards is a challenging task.

**Keywords:** livelihood, global competitiveness, income. Environmental standards

### INTRODUCTION

About 30% of all fibre used in textiles is contributed by cotton. Throughout the world around 30 million hectares, which is more than 2% of total arable land, are planted with cotton and 25 million metric tons of cotton is produced

24787

**Chitrasena Padhy et al.**

annually. It is grown in over 80 countries. Cotton supports the livelihood of 350 million people including 50 to 100 million farmers[1]. Maintenance of soil moisture levels in cotton fields is very challenging. It could bring pest attacks and diseases. Drip irrigation to maintain adequate moisture level is the best solution. Cotton farming that is mainly dependent on flood irrigation faces challenges with flowering, ball development, and ball opening. For good crop establishment and growth, high seed germination percentage and balanced nutrition are essential. To ensure this in cotton cultivation, precise irrigation is required [2]. The most common problems of unsustainable cotton growing systems include water quantity and quality issues, inappropriate and excessive use of pesticides and fertilizers, low incomes of small holder farmers, forced labour and child labour, soil erosion, adapting to land use pressure of the future, price volatility of an uncertain commodity market [1]. Cotton cultivation needs to be knowledge based, market driven and should meet the present and future needs of nations by accomplishing global competitiveness, as it is providing livelihood security to millions of marginal and small farmers[3].

## Precision Irrigation Requirement for Cotton [2]

### (1) Lower humidity for improved quality

Water should be supplied to the cotton crop root and not to the canopy. This ensures that humidity levels are unaffected. The lint quality is better when the humidity is lower.

### (2) Cultivating the right cotton plant

The application of measured water dosage in precision irrigation helps to control and create flexibility to develop mild stress during specific growth periods. This help for cultivating an ideal plant with several bolls.

### (3) More yield with less water

Drip irrigation can result in a 20% increment in the cotton yield per cubic meter of water despite diverse agro-ecological conditions and without affecting the lint quality.

(4) Fusarium wilt and Verticillium wilt are the major soil borne diseases affecting cotton cultivation. Precise fertilizer application along with fungicides prevents these diseases.

### (5) Managing EC and pH of irrigation water

Cotton plants respond well to optimum EC and pH of irrigation water. These factors help for increasing the yield through precision irrigation.

## Climatic Factors Affecting Crop Production

Sustainability of cotton production requires more precise water, mineral nutrition, and plant growth management. Fruiting of cotton plant is influenced by cultivars, climatic conditions, management practices, and pests. The effects of evaporation, sunshine duration, humidity, surface soil temperature, and maximum air temperature affect flowering and boll production of cotton. Applying specific cultural practices that minimize the deleterious effects of these factors leads to an improvement in cotton yield [4]. There were negative correlations of flower and boll production with evaporation and sunshine duration while correlations with minimum humidity were positive [5]. Climate change is one of the most important issues in the world. Increased number and severity of days with very high temperatures during the cotton season would have negative effects on cotton growth and development. These kind of events will reduce yields by decreasing daily photosynthesis, raising respiration at night, consuming stored assimilates leading to increase in squares and boll shedding and reducing seed numbers per boll [6].

Temperature is one of the most important climatic factors that affect cotton yield. The primary impact of heat stress in cotton results in reduction in fruit retention which can reduce overall lint yield, delay crop maturity, and reduce

**Chitrasena Padhy et al.**

lint quality [7]. Depending on cotton variety and environment, the effects of heat stress on cotton could be different [8]. At high temperatures, nutritional and water shortages were responsible for fruit loss [9] & [10]. Temperature played a role in fruit development. When the day and night temperatures were 30 C and 20 C respectively, maximum boll growth rates were observed [11]. Light duration is the key meteorological factor influencing the wheat cotton cropping pattern and position of the bolls, but temperature had an important function on upper node (7 to 9) and top (node 10) bolls, especially for double cropping patterns with early maturing varieties [12].

The farmers in India are unable to manage scientific transportation and storing facilities. Immediately after harvest they take cotton produce to the nearby market in open vehicles that leads to deterioration with dirt and dust. Manual picking leads to contamination of the cotton fiber with other trash materials. Cotton requires covered handling to protect from contamination. This is not available due to inadequate infrastructure at farms, markets, and ginning factories [13]. The enhanced production levels of cotton can only be maintained by the best package of practices and best management services. The main requirements are sustainable disease resistant, adverse weather tolerant, and high yielding varieties. At the picking time, transportation, storage, and handling cotton must be protected from contamination. By upgrading technology, it can be achieved. Due to small size on holdings in the country, the marketable surplus of the farmer is very less and it is uneconomical to use the required technology. Self help groups should be established with common mechanization processes to handle these activities in a scientific manner [13].

### **Risks of Cotton Farming [14].**

(1) In cotton cultivation, the prominent environmental impacts result from the use of agrochemicals mainly pesticides, consumption of water, and the change of habitat to agricultural use. The major impacts of diversion of water and its pollution are on major ecosystems such as the Aral Sea in Central Asia, the Indus Delta in Pakistan, and Murray Darling river in Australia.

(2) Due to cotton cultivation soil quality is degraded. Due to cotton production the soil is depleted in many areas although the global area is constant for the past 70 years. On well established fields cotton is grown, but due to exhaustion it leads to expansion into new areas and destruction of habitat.

(3) During conventional cultivation practices of cotton, the applications of substantial amounts of fertilizers and pesticides are involved. There is deterioration in the quality of soil and the health of biodiversity. Due to heavy use of pesticides, the health of farm workers and nearby populations is affected. The rivers, lakes, and underground aquifers are affected by runoff from the pesticides, fertilizers and minerals. So biodiversity is directly affected by immediate toxicity. These are affected indirectly through long term accumulation.

(4) Cotton uses more water compared to other agricultural commodities. Cotton production and processing requires large amounts of water. The surface and ground water are diverted many times to irrigate cotton fields. It leads to fresh water loss through evaporation and inefficient water management.

### **CONCLUSION**

Cotton yields are low in India due to inadequate input usage, rainfed cultivation, untimely operations on field and inefficient crop production technologies. Monsoon Rain plays an important role in India for production and yield in any particular year [15]. Cotton production provides income for more than 250 million people worldwide and employs nearly 7% of all labour in developing countries. Half of all textiles are made of cotton. Due to environmental instability in cotton production, it becomes a difficult task to achieve the target with minimum natural hazards [14]. Some quick primers on cotton are hard to pick, heavy use of pesticides and minerals, hard to control insect pests and diseases, hard to separate lint from seed, hard to control weeds, and difficult to grow

**Chitrasena Padhy et al.**

without adequate water [16]. There is focus on the cropping systems approach in the Cotton Development Programme of the Department of Agriculture, Cooperation and Farmers Welfare in 15 major cotton growing states. The emphasis from 2014-15 was on increasing production and productivity. The thrust was on transfer of technology to cotton growers through front line demonstrations, The scheme is being implemented by State Department of Agriculture and Indian Council of Agricultural Research from 2015-16 [17].

### ABSTRACT

In the present day society, farmers are facing multiple challenges, isolation, fatigue, and stress. They are experiencing serious mental health problems and are unable to confide in others and express their feelings. Some of the external factors are beyond the control of the farmers such as weather and commodity market prices. Prolonged droughts and extreme temperatures cause significant damage to crop yields. These add to the debt burden of farmers. Stress, mental health issues, and suicides are found more among people who work in agriculture than other occupations. Farmers are not able to manage stress due to uncertainty of economic and environmental conditions. Behavioral health is very much important for managing stress. Behavioral well being is important for increasing capacity building of the farmers. It can help for staying healthy and function efficiently. Social support systems can be helpful. Staying positive and communicating with trusted friends, relatives, fellow community members, and counselors is necessary and by these activities stress can be mitigated.

**Keywords:** Mental Health, Farmers, Stress, isolation.

### INTRODUCTION

Good communication skills are required for success in today's multiple generation farms. Communication breakdown is one of main reasons for farm families and that is the reason they have to seek help [1]. Farm life has its own set of challenges. Isolation, fatigue, and stress and there are some other factors that can lead to mental health

24791

**Chitrasena Padhy et al.**

problems [2]. Farm industry is now predominately male dominated. Mental health issues are not gender biased and traditionally men have been taught to put down their feelings and not to express their problems [3]. Destruction led by climate change is one of the world's leading health crises. Although it affects physical health, the effects on mental health are many times ignored. Extreme heat is directly associated with sleep loss, increased aggression and domestic violence. Heat strokes can lead to dementia, agitation, and confusion. These can be fatal. Changing weather patterns have impacted Agriculture by changing weather patterns.. Prolonged droughts and extreme heat cause significant damage to crop yields. In India more than 50% people are engaged in agriculture. Farmers face consecutive years of crop losses and worsening debt burden [4].

**Challenges Faced by Farmers**

Farmers want to get information from their innermost circle directly as per a recent research.. Limited mental health care facilities are available in rural areas. So it is difficult for farmers to manage stress arising from uncertainties of economic and environmental conditions [5]. External factors are responsible like weather and commodity market prices and are beyond the farmers' control. Financial difficulties and decreased market prices result in stress experienced by farm families. Open communication is required in farm operations in case of difficulties. Increased tension and worries may occur when information is not shared among family members and employees. Farm employees may be worried by losing the job. They can come through the difficult times if they maintain open communication and seeking social support [6]. Communication gives emphasis on agriculture related details among agricultural partners and between agricultural and non-agricultural partners. Agriculture includes farming, rural issues and natural resources [7]. Canadian Mental Health Association (CMHA), Ontario Division, and local CMHA branches say that mental health in agriculture industry is a rising concern. As compared to the general population, suicides due to stress and mental health issues are much higher among people who work in agriculture industry than in other occupations. Due to pressure and time constraints farmers put their work ahead of their well being [8].

Farmers face many challenges such as deviant weather, long hours, low commodity prices, self doubt and physical labour. Johnson [9] stated that farming is one of the dangerous occupations. Injuries can prevent farmers from completing their work in time. These can lead to depression. Occupational injuries lead to a seven times greater risk of depression in agriculture [9]. She reported that farmers face obstacles like accessibility to professional treatment and acceptance in their community who have mental health issues. She also added that many rural areas face shortage of mental health providers. Mental health problems are stigmatized in some small towns. Farmers and ranchers are facing many stressors in their lives. Many Nebraskans have experienced weather challenges and disasters that led to crop and livestock production losses. This has led to increased debt loads, machinery breakdowns, unstable markets, sleep deprivation, and changed regulations of multiple generations farm holdings. Farmers know the importance of planning and talk about their financial health to bankers and spouses. They do not realize how important it is to spend time on their mental well being [10]. Mental health affects the overall well-being as reported by Johnson [9] in a webinar on farm stress and mental health that was sponsored by Farm Credit Knowledge Center. Johnson told that the most common mental health disorders are anxiety and depression. The farmers faced some of the common stressors in U.S. These are financial pressures, debt load, unpredictable weather, unstable markets, extreme outdoor work conditions, fatigue, lack of personal time and time to talk through difficult problems, inter-generational differences and views of work and business philosophy, and excessive workloads that prevent their ability to maintain valuable relationships, health disorders, and disabilities connected to years of physical labour [11].

**Chitrasena Padhy et al.**

## **Remedial Measures**

Effective communication should be expected, maintained, routine, and rewarding. The communication barriers can be removed. Calmness in all situations should be maintained. By removing misconceptions about communication, the farm conditions can be improved [12]. Several tips are there on establishing effective operation meetings like establishing fundamental rules, including everyone connected, establishing regular meetings schedule, developing an agenda, alternating who leads the meetings, documenting minutes of the meetings, establishing decision making process, integrating fun into the meetings, providing a summaries of the meetings, and ending on a positive note [13].

With the abundance of multiple factors, farmers are getting limited platforms to connect with fellow farmers on a peer-to-peer level. Social outlets and local relationships are necessary for increasing the development of natural support systems. Natural support systems may come in different forms. It is necessary to connect with fellow farmers and the opportunity may come over coffee at a local elevator, weekly breakfast, and regular shop talk meetings. Staying connected with peers will develop local relationships. It can promote the development of natural support systems that create resiliency during difficult times [14]. The farming population experiences a high rate of anxiety and depression. So it is necessary to examine farm families' behavioral health, mainly during stressful times. A sociologist Michael R. Rosmann presented his professional knowledge on the matters of behavioral health. He said why suicide is unusually common among farmers in an AgriSafe webinar [15]. Key to healthy farming and ranching is behavioral well-being as studied by Rosmann. Behavioral health is extremely important for the farmers. To increase the capacity to function well and healthy, behavioral well being is important for agricultural producers. In the food chain, farmers are the most important asset. People can improve if farmers are healthier. The behavioral health of farmers has a positive correlation with their productiveness [15].

The active process of being aware of living a healthy and fulfilling life is well being. Well being is very essential in life. For being physically healthy, one can develop habits that can improve mental wellness. Mental well being and physical health are linked to each other. These kinds of skills should be developed and repeated in a balanced way. Rural communities and farmers are facing difficulty due to isolation or challenges in getting mental health providers and health care. The many uncertainties of farming can lead to added stress and financial difficulties. The five steps that help to become both physically and mentally healthy are doing regular exercises, good sleep, proper nutrition, community and relationships, and relaxation and recreation [16].

## **Positive Coping Strategies to Help Oneself or a Loved One Overcome a Traumatic Event [17].**

### **ACKNOWLEDGE FEELINGS**

Some emotional reactions and stress will happen around the anniversary of an event. One should acknowledge the feelings and allow oneself one to feel anger or sadness to relieve some of the stress.

### **Engaging in healthy ways to cope with stress**

Engaging in different activities can be different for every person. Some engage themselves in exercise such as running, taking a walk or doing yoga for coping with feelings, stress and emotions. Some people get involved in reading or writing a journal or being involved in a creative hobby that helps in relieving stress and provides a direction of healing.

### **Be gentle with Oneself**

Practicing sympathy is necessary. The same kindness and patience can be shown to oneself whatever one is showing to others. One should take time to celebrate his strength.

**Accepting kindness and help from others**

Allowing the people in one's life so that they can show their care and concern will help a lot. Inviting them for a cup of coffee or dinner for getting together will help for getting support and console. It is essential to get support from others for getting healing and recovery.

**Use social support system**

Depending on one's social support system can be useful. It is a positive way to talk with trusted friends, family or members of one's faith community. In the healing process expressing one's gratitude for support and assistance throughout the year is helpful.

**Help others**

A positive and healthy way to heal is volunteering. Finding time for helping the community by volunteering in some useful works. By donating one can provide a sense of satisfaction.

**CONCLUSION**

Indian agriculture is facing many problems. Farmers are greatly affected by these problems. Farmers consume lot of time and put efforts in farming practices and other activities of agriculture. People are storing grains and food throughout the year. They rarely think about the hard work and dedication of farmers. To contribute to the overall growth in the sector of agriculture, food crops are cultivated. The problems faced by farmers are unnoticed [18]. Depression in farmers and farming families is complex. It has its origin in stress. This includes economic, family, and traumatic stress. Agrichemical and pesticide stress contributes to higher than average level of depression [19]. Helping others, social support system, being connected with others, regular exercise, friendly and flexibility of approach can help coping with the farm stress.

### ABSTRACT

A The signal processing transforms such as S-Transform, Wavelet Transform are utilized for time frequency localization and feature extraction from non-stationary signals such as power quality signals, Electro cardiogram signals etc. due to the complex calculations involved in the S-Transform, a novel moving sum average filter for the detection and localization of power signal disturbances is proposed. The proposed moving sum average filter averages the number of input samples on a recursive manner and detects variations in the power quality signals. The moving sun average filter has been utilized to detect the fault locations in the power signals and utilized for feature extraction from the power quality signals. Further, the extracted features are inputted to a relevance vector machine (RVM) classifier for the classification of power disturbance signals. RVM is a machine learning method which represents a Bayesian extension of the Support Vector Machine (SVM). The result analysis shows the effective classification of power quality events and comparison results utilizing SVM and RVM are presented.

**Keywords:** Relevance Vector Machine (RVM), Non Stationary Power signal, Sparse Bayesian Kernel, Support vector.

## INTRODUCTION

Power quality is accredited due to the voltage “sag, swell, impulsive, and oscillatory transients” etc. The improvement of the quality of electrical power, unfortunately rely on visual inspection by the engineers. The wavelet transform [1-7] is monitoring the physical appearance of non-stationary signals. The characteristics of wavelet transform afford detection, localization of power quality fault waveforms. The well-organized classification of power signal faults shown by NN (Neural network) based classifiers [8],[9]. Using the WT [10-12], the features are extracted and fed as input to ANN algorithms for training and achieved classification. Wang [13] presented seven categories of PQ events detection and the classification by using wavelets and probabilistic neural network. S-Transform (ST) [14-16] searches the opportunity to have good representation in terms of time-frequency illustration of a signal. The S-transform comprises extraordinary computational complexity which involves long calculation time.

To avoid the computational complexity in S-Transform, a computationally simpler MSA (“Moving Sum Average Filter”) technique has been proposed, which makes all similar samples to zero by moving sample to sample. The features have been extracted by utilizing the moving sum average filter. The Support Vector Machines (SVM) [17-20] utilized for classification of power quality patterns. Also numerous fruitful presentations of SVM have been described in the case of information retrieval, speech recognition, and face recognition, etc. However, this generalization cannot compensate for nonstationary data streams where the signal parameters may change at random. On the other hand Relevance vector machine (RVM) [21] is a well-organized classifier in the field of machine learning. The RVM is based on “Bayesian formulation” of a linear model with sparse illustration and “Gaussian distributions” [22]. RVM offers an excellent trade-off between accuracy and sparsity, and become less sensitivity in selecting the parameters. The benefits of the RVM over the SVM are established on probabilistic predictions and shown faster performance against SVM. RVM uses a “linear combination of kernel functions centered on a subset of the training data” to mark classification. The RVM produces a much sparser estimate of the Bayesian kernel than the SVM. Thus the features extracted from the Cumulative average sum filter are used with the RVM classifier to recognize the power quality event.

This paper has three subsections as follows: section-2 presents Moving sum average filter and its mathematical operation, section-3 presents RVM operation and section-4 presents binary tree, section -5 presents results and discussion and section-6 shows conclusion and reference.

## MATERIALS AND METHOD

### Proposed MSA Filter for Detection of Power Quality Fault

For the signal  $Q(k)$ , the moving average filter[18] is given by

$$q_{SUM}(l) = \sum_{i=l-n+1}^L q(i) \quad (1)$$

$$q_{sum}(L) = q_{sum}(L-1) + q(L) - q(L-n) \quad (2)$$

Where L represents the number of sample per cycle.

Taking Z-Transform of the above equation, the following equation is obtained:

$$Q_{sum}(z) = Q_{sum}(z)z^{-1} + Q(z) - Q(z)z^{-n} \quad (3)$$

Thus on simplification equation (4) is obtained as

**Satyasis Mishra et al.**

$$\frac{Q_{sum}(z)}{Q(z)} = \left[ \frac{1-z^{-n}}{1-z^{-1}} \right] \tag{4}$$

Considering  $z = e^{j\omega}$

$$H(e^{j\omega}) = \frac{1-e^{-j\omega n}}{1-e^{-j\omega}} = \frac{1-e^{-j\omega n/2} \cdot e^{-j\omega n/2}}{1-e^{-j\omega/2} \cdot e^{-j\omega/2}} = \frac{e^{-j\omega n/2} [e^{j\omega n/2} - e^{-j\omega n/2}]}{e^{-j\omega/2} [e^{j\omega/2} - e^{-j\omega/2}]} \tag{5}$$

Dividing numerator and denominator by  $2j$  we get the modified equation as

$$H(e^{j\omega}) = \frac{e^{-j\omega n/2} \left[ \frac{e^{j\omega n/2} - e^{-j\omega n/2}}{2j} \right]}{e^{-j\omega/2} \left[ \frac{e^{j\omega/2} - e^{-j\omega/2}}{2j} \right]} = ne^{-j\omega(N-1)/2} \cdot \left[ \frac{\sin(\omega n / 2)}{\omega n / 2} \cdot \frac{\sin(\omega / 2)}{\omega / 2} \right] \tag{6}$$

On further simplification the amplitude response is obtained as

$$H(e^{j\omega}) = ne^{-j\omega(n-1)/2} \left[ \frac{\sin c(\omega n / 2)}{\sin c(\omega / 2)} \right] = ne^{-j\omega(n-1)/2} \cdot a \sin c_n(\omega) \tag{7}$$

Where  $a \sin c_n(\omega) \equiv \left[ \frac{\sin(\omega n / 2)}{n \cdot \sin(\omega / 2)} \right]$

For  $N \geq 1$ , and  $\omega = 0$ ,  $H(e^{j\omega}) = 1$ , and the phase response is given by

$$\phi(\omega) = e^{-j\omega(n-1)/2} \tag{8}$$

The right hand side of the equation (7) is termed as linear phase term and its plot is shown in Fig. 1.

As it is a low pass filter the nulls occur at  $\omega = \frac{\pi}{64}, \frac{3\pi}{64}, \frac{5\pi}{64}, \dots$

The values of occurrences of nulls are 0.04908, 0.09818, 0.1467 etc, respectively. The transfer function shows the maximum at  $\omega = 0$ . The moving sum average filter averages a number of input samples and produces single output sample.

### Model Equations for Generating Power Signal

The 50 Hz signal with a rate of 64 samples per cycle having “sampling frequency”  $f_s = (50 \times 64) = 3.2$  kHz. In case of voltage reduction (sag), twenty values have been taken between 0.3 and 0.8 per unit (normal voltage signal peak values 1.0 per unit) with dissimilar locations showing 10 types of sag and Nine classes of disturbances are taken and over-all 1800 signals are generated. Table-1 describes the mathematical formulas for generating synthetic power signal disturbances needed for the evaluation of the new approach presented in this paper.

**Satyasis Mishra et al.**

**Feature Extraction**

From Figs. 1 to 9, it is evident that the MSA filter focusses the concerned power signal event which can be used to extract the relevant features. Statistical feature values for different types of power disturbance signals are shown in Table-2. All the features calculated are normalized between zero and one for better stability. Normalization is made by dividing the individual feature and maximum of that feature set.

$$Std = \sqrt{\frac{1}{K-1} \sum_{i=1}^K (v_{sum}(k) - \overline{v_{sum}}(k))^2} \tag{9}$$

$$Variance \ \sigma = \frac{1}{K-1} \sum_{i=1}^K (v_{sum}(k) - \overline{v_{sum}}(k))^2 \tag{10}$$

$$E_i = \sum_{k=0}^{K-1} (v_{sum}(K))^2 \tag{11}$$

$$S_i[f_1, f_2, \dots, f_k] = - \sum_{i=1}^K KP_i(f_n) \log_2(KP_i(f_n)) \tag{12}$$

**RVM (Relevance Vector Machines)**

In the case of SVM, the vectors  $R = \{r_n\}_{n=1}^N$  fed as input having the "target values  $T = \{t\}_{n=1}^N$ ." In SVM the parameter 'C' requires cross validation to estimate the prediction where 'C' is the parameter which is controlling the tradeoff between the margin size and amount of error  $\mathcal{E}$ . To overcome the disadvantages, we illustrate our approach with a particular algorithm the 'Relevance Vector Machine' (RVM), a model which is identical to the 'support vector machine' (SVM).

For the "training points  $X = \{x_1, x_2, \dots, x_N\}$  and target" " $t = \{t_1, t_2, \dots, t_N\}$  the RVM model" with the "sigmoid function" given by  $\sigma(u) = \frac{1}{1+e^{-u}}$

The "probability" is can be written as

$$p_b(t_i = 1, w) = [\sigma(u(r_i; w))] = \frac{1}{1+e^{-\gamma(r_i; w)}} \tag{13}$$

with "Bernoulli distribution, the likelihood" is expressed as :

$$P(t_i|w) = \prod_{i=1}^N [\sigma[u(r_i; w)]^{t_i} \{1 - \sigma[u(r_i; w)]\}^{1-t_i}] \tag{14}$$

The "zero mean Gaussian prior distribution" is given by

$$P_b(w|\alpha) = \prod_{i=0}^N N(\omega_i|0, \alpha_i^{-1}) , \text{ and}$$

$$P_b(w|\alpha) = \prod_{i=0}^N \frac{\alpha_i}{\sqrt{2\pi}} \exp(-\frac{\alpha_i \omega_i^2}{2}) \tag{15}$$

**Satyasis Mishra et al.**

Where  $\alpha = [\alpha_1, \alpha_2, \alpha_3, \dots, \alpha_N]^T$ , and  $\alpha$  is a vector of "N+1 hyper parameter". With non-zero coefficients"  $\omega_i$  (relevance vectors)" will subsidize to the "decision function". The key feature of this learning method is responsible for its sparsity property.

(i) The probability  $P_b(t_i|w)$  is not a "normal distribution", and hence the approximation procedure based on Laplace's method is chosen.

Assuming  $\alpha$  the hyper parameters are known, the "probable weights"  $w_{MP}$  are found, and the data function  $p_b(w|t, \alpha) \propto P_b(t|w)p(w|\alpha)$ .

$$\begin{aligned} & \log \{P_b(t|w)p_b(w|\alpha)\} \\ &= \sum_i^N [t_i \log u_i + (1-t_i) \log(1-u_i)] - \frac{1}{2} w^T A w \end{aligned} \tag{16}$$

Where  $A = \text{diag}(\alpha_1, \alpha_2, \alpha_3, \dots, \alpha_N)$ ,  $u_i = \sigma[u(r_i; w)]$ , and equation (16) being a "regularized logistic log-likelihood function necessitates iterative maximization. Second order Newton methods is applied effectively" for this purpose as :

$$j = \nabla_w \log [P_b(t|w)p_b(w|\alpha)] = \psi^T (t - u) - A w \tag{17}$$

Where  $\psi$  is an "augmented kernel matrix" and is given by

$$\psi = \begin{bmatrix} 1 & \lambda(r_1, r_1) & \lambda(r_1, r_2) & \dots & \lambda(r_1, r_N) \\ 1 & \lambda(r_2, r_1) & \lambda(r_2, r_2) & \dots & \lambda(r_2, r_N) \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \lambda(r_N, r_1) & \lambda(r_N, r_2) & \dots & \lambda(r_N, r_N) \end{bmatrix} \tag{18}$$

Where  $\lambda(r, r_i)$  is the RBF kernel function and 1 in the first column indicating the use of bias in the Hessian matrix.

The kernel function is given by

$$\lambda(r_i, r_j) = \exp \left( - \frac{\|r_i - r_j\|^2}{2\sigma_k^2} \right) \tag{19}$$

where  $\|r\|^2 = \frac{1}{N} \sum_{j=1}^N r_j^2$

$\Delta w = -H^{-1} j$ , and

$$w_{MP}^{new} = w_{MP} + \Delta w \tag{20}$$

Where  $H$  is the Hessian matrix.

The following quantities are defined as follows:

$u = [u_1, u_2, \dots, u_N]^T$

$$B = \text{diag}(\beta_1, \beta_2, \dots, \beta_N) \tag{21}$$

$$\beta_n = \sigma[u(r_n)]\{1 - \sigma[u(r_n)]\}$$

The algorithm progresses with repeated application of (20), updating the covariance matrix until the suitable convergence criteria have been satisfied, and after which the last prediction function is obtained as:

$$u_{\bullet}(r_{\bullet}; w_{mp}) = \psi(r_{\bullet})w_{mp} \quad (22)$$

The next section provides the method of constructing a decision tree based on the extracted features of the power signal disturbance waveforms.

### Binary Decision Tree

Decision tree is a data mining classification algorithm for pattern classification. The importance of decision tree is to represent rules [23, 24]. For the classification a decision tree shown in Fig.19. The features are extracted and grouped and the total is first divided into two sections as 2,3,4,5,6,7,8 and section-1 which refers as transient(event-1) and section-2 as (2,3,4,5,6,7,8,9) refers to the rest disturbances. Again the features (2,3,4,5,6,7,8,9) are also subdivided into another section-1 as (event-2) and section-2 as (3,4,5,6,7,8,9). Section -1 represents harmonic and (3, 4, 5, 6, 7, 8, 9) represents the rest of the signals and the procedure progresses till two groups having two types of disturbances. The power quality disturbances such as “Transient, Harmonic, Voltage Notch, Voltage Sag, Voltage Spike, Sag+ Harmonic, Voltage Swell, Swell+ Harmonic, Flicker” have been considered for classification utilizing the “decision tree” which is shown in Fig.19.

## RESULTS AND DISCUSSION

### Results from Cumulative Sum Average Filter

Figs. 1 to 9 present the output of the Cumulative sum filter for different types power signal disturbance problems like the voltage sag, swell, harmonics, transients, spikes, and notch, etc

### Classification Results Using SVM and RVM

From the feature analysis, the classification is made using different statistical features for different events. The Hessian matrix generated in RVM according to the model given by equation (14), in which the “kernel function” need not “satisfy ‘Mercer’s condition’”. During the computation it gives less numbers of relevance vectors and the decision speed is higher in comparison to SVM. The classification follows the decision tree adopted for the classifier and classifies the power quality events. It is found that the RVM uses less numbers of relevance vectors (RVS) with higher decision speed as compared to SVM. “For the classification of transient” as 1<sup>st</sup> event the statistical feature standard deviation is assigned to data set x1 and the statistical feature energy is assigned to data set x2. Now the kernel function is designed with x1 and x2 and assigned into the Hessian matrix for classification. The program for the decision boundary is defined for the input vectors to separate the power quality event transient from the total feature vector which is shown in the Fig .8, and it is found that transient has been identified with triangles below the decision boundary.

Fig -11 to Fig-18 shows “Classification” results by utilizing RVM. It is observed that for the “classification triangles are assigned to a particular class and for rest of the classes are marked with star”. Fig-10 shows the classification result of transient from the total power disturbance signals. Feature combination F1F7 is used for transient that is standard deviation and energy. Transient has been assigned with triangles and rest of the signal with star mark. From the Fig-10 it is seen that the triangles are between the amplitude 0.1 and 0.2 below the decision boundary and within the contour. For harmonic feature combination F1F4 is used and shown in Fig-11. For notch feature combination F4F7 is utilized and presented in Fig-12. Fig-13 “shows classification” of sag. Spike is shown in Fig-14. Fig-15 shows the event sag+ harmonic is within the range 0.5 and 1. The event swell is nearer to the “decision

**Satyasis Mishra et al.**

boundary” and in the range 0.55 and 0.65 shown in the Fig-16 with F2F6. Fig-17 shows the classification of flicker and swell+harmonic with feature combination F2F7.

## CONCLUSION

In this paper, the moving sum average filter avoids complex calculations as compared to “wavelet transform” and “S-transform filters”. The filter has been utilized for extraction of features and presented in the table-2. The extracted features are inputted to the kernel based RVM for the purpose of classification. Further the decision tree is utilized to improve the performance of classification results. RVM offers good performance in accuracy comparing to the SVM. For SVM the “support vectors” are formed near by the “borderline” and classification becomes difficult. Further, the relevance vectors are formed which is more demonstrative of the classification, and are positioned away from the decision boundary. RVM shows good decision speed and the “kernel function” does not satisfies “Mercer Condition”. The accuracy reported by RVM as 98.82 percent. This can even better in ELM (Extreme learning machine) which is our future research.
