### ABSTRACT

2019 Novel corona-virus (2019-nCoV) also referred to as severe acute respiratory syndrome Corona-virus 2 (SARS-CoV-2) emerged as a global risk and put the entire globe into unrest. Unavailability of specific drug against the virus is more imperative. *In silico* Molecular Docking revealed that the Phytochemicals, Dopamine effectively binds at the active pocket of the SARS-CoV-2 main protease.

**Keywords:** 2019-nCoV, SARS-CoV-2, SARS-CoV-2 main protease, docking, Phytochemicals, Dopamine.

## INTRODUCTION

The pandemic situation caused due to the 2019-nCoV represents a severe public health calamity across the globe. The city of Wuhan was the epicentre where the outbreak of this human pathogen emerged, and resulted to human ailment, termed as COVID-19 [1, 2]. 2019-nCoV encodes at least 27 proteins, including 15 non-structural proteins, 4 structural proteins, and 8 auxiliary proteins. SARS-CoV-2 belongs to the beta corona-virus genus, closely related to the previously identified severe acute respiratory syndrome corona-virus (SARS-CoV) [3, 4]. Public Health Emergency of International Concern (PHEIC) was declared by the World Health Organization (WHO) owing to its fast rate of transmission within the humans [1, 5, 6]. Crystal structure of the Papain-like Protease of SARS-CoV-2 proves to be an exceptional ground for screening specific ligands [7]. Reportedly, M<sup>Pro</sup> and other known viral proteins are defining features paving the path of virus from entry to infection in the host cell [8, 9, 10].

## METHODS

### Viral Protein Structure and Phytochemical dataset collection

The 3D structure of Papain-like Protease of SARS-CoV-2 was accessed from Protein Data Bank accession 6W9C. The phytochemical, Dopamine was obtained and consequently both the protein and the ligands were used for *in silico* analysis.

### Molecular docking

For the *in silico* molecular docking, BIOVIA's Discovery Studio docking method [11] was used for molecular docking. The catalytic pocket of the Papain-like Protease of SARS-CoV-2 was specified and targeted for binding of the ligand. CDOCKER Energy and CDOCKER Interaction Energy signify the affinity of the ligands with the protein receptors. Basically, high positive values of the CDOCKER Energy, CDOCKER Interaction Energy and a diminutive difference between the CDOCKER Energy and CDOCKER Interaction Energy are considered to be the most favourable [12].

## RESULTS AND DISCUSSION

It was found that Dopamine; a common phytochemical specifically binds to the active pocket of the Papain-like Protease of SARS-CoV-2 as apparent from higher CDOCKER energy and CDOCKER interaction energy (Table 1). Since, simple active bio molecule like Dopamine effectively binds into the active pocket of the M<sup>pro</sup> under *in silico* conditions it is quite possible to design pharmacophore molecules based on the structural and functional identity of Dopamine and eventually can be used in the pharmaceutical sector.

## CONCLUSION AND FUTURE PERSPECTIVES

The current *in silico* molecular docking based study reveals that Dopamine can target the reported Papain-like Protease of SARS-CoV-2. It would be extremely noteworthy being confirmed *in vivo*. It is crucial to develop diagnostic tools, potential therapeutics and antibodies selectively for the COVID-19 proteins. Phytochemicals like Dopamine is commercially available and thus may be effectively prescribed to circumvent the current global scenario. Essentially, this study makes an attempt to reveal simple phytochemicals like Dopamine which can be employed for designing novel therapeutics.

### ABSTRACT

The consumption of fossil fuel increases day by day and it has been seen that the total utilization of fossil fuels globally is 10 million tons per day. These fuels are being emptied every day as these are present in finite quantity and it is anticipated that the future generation will face an intense energy supply collapse in the upcoming years. Again the use of these fuels causes environmental problems as it emits harmful gases. The use of nonedible oils such as karanja, Jatropha, Kusuma, Neem etc., to produce biodiesel mainly in tropical country like India is an added advantage due to their wide availability. Several research works is going on for use of the biodiesel to run diesel engine. In the present work, a diesel engine was run by using Mahua biodiesel and engine emission was analysed. The amount of exhaust gases present in engine emission were found to be reduced significantly that supports its use as an alternative fuel.

**Keywords:** biodiesel, engine, fossil, hydrocarbons

### INTRODUCTION

Air Pollution has become a crucial problem due to rapid growth in population and industrialisation. The combustion of fossil fuels produces many harmful gases like Carbon Monoxide (CO), Carbon Dioxide (CO<sub>2</sub>), Oxides of Nitrogen (NO<sub>x</sub>), and Hydrocarbon (HC) as well as some organic compounds such as monocyclic aromatic hydrocarbons, polycyclic hydrocarbons, aldehydes [1]. These poisonous compounds damage the temperature balance of the world, pollution, acid rain. Due to change in environment many human problems are seen such as cancers, respiration problems, heart disease etc. Hence it is imperative to find a possible source for fossil fuel which can be obtained from

23475

**Manas Ranjan Padhi and Sangram Keshari Samal**

biomass(from plant and animal fats) [2]. Now a day, to overcome all these problems biodiesel become one of the most interesting alternatives because biodiesel are biodegradable, non-polluting and has very similar physical characteristics with biodiesel. Biodiesel can be produce from non-comestible oils [3].

The use of comestible oil to produce biodiesel in India is not workable because of their high cost and India is self-insufficient in comestible oils. From the economy point of view non comestible oil can come up with best source for biodiesel production. India has great capability for the production of biodiesel from non-combustible vegetable oil seeds [4]. Biodiesel from vegetable oil have a favourable alternative fuel for diesel fuel because of its sustainability, better quality lighting, the approximate energy fulfilment and a higher safety without restriction of the energy. Madiwalea and Bhojwanib [5] presented an overview on Production, Properties, Performance and Emission Analysis of different biodiesels. Ismail et al. [6] studied the production of castor biodiesel from crude castor oil through transesterification method. Padhi and Singh [7] carried out their work towards the optimization of biodiesel from mahua oil. However they have not studied their emission characteristics.

Jena et al. [8] carried out their investigation on biodiesel preparation from mahua and simarouba oil. Ogunkunle and Ahmed [9] carried out their research on optimizing the biodiesel production from sand apple which is widely cultivated in Africa. Mahua is indigenous plant in India and can easily found in all over India. Hence Mahua oil was used as the raw material for biodiesel production. Transesterification is the common process to produce biodiesel from oils. However sometimes esterification is also follow to get better and purified biodiesel. Esterification is the reaction between the oil and alcohol in the presence of acid catalyst in which glycerol and methyl ester is produced. The esterified oil we get here is pure than crude Mahua oil. Transesterification is the reaction between the esterified oil with alcohol in the presence of alkali catalyst to produce glycerol and ester. The ester we get has molecular weight one-third less than the crude Mahua oil ratio was taken to get low viscosity. Sometimes high alcohol to oil ratio was taken to get low viscous biodiesel. Different characteristics of castor oil and castor biodiesel are determined. In this work, prepared Mahua biodiesel was blended with conventional diesel. Three different blends B10, B20 and B30 were prepared by mixing 10%, 20% and 30% of biodiesel with 90%, 80% and 70% of conventional diesel respectively. The prepared Mahua biodiesel blends were then tested in diesel engine and emission was observed and compared with the conventional diesel.

**MATERIALS AND METHOD**

The Mahua trees are fast growing and can grow easily in any kind of soils. Hence castor trees are shown all over the India and easy to collect castor seeds and oil directly. All the properties like acid value, viscosity, density of the crude Mahua oil were determined. In this study, the Mahua oil was converted to castor biodiesel by the two step transesterification process. Here in the first step the free fatty acid (FFA) in the Mahua oil was converted into methyl ester by acid-catalysed esterification and the second step was the base-catalysed transesterification using potassium hydroxide as catalyst. The transesterification was carried out to reduce the FFA of the oil. In the first step the temperature was maintained about 60-64°C with 200ml methanol and 10gm of concentrated H<sub>2</sub>SO<sub>4</sub>. After 3hour of heating process, excess alcohol with impurities was removed after pouring the product into a separating funnel.

After removing the impurities from the lower layer, the upper layer methyl ester was collected from the separating funnel for the base transesterification process. In the transesterification process, 10gm of KOH was dissolved in 200ml of methanol then poured in the flask. The mixture was heated at constant temperature about 62°C and stirred continuously for 3hour. After 3hour of heating the mixture was poured into a separating funnel for about 12hour where two layers were formed. The upper layer contained methyl ester and the lower layer contained glycerol, extra methanol, catalyst and other by products were removed. The upper layer of methyl ester or Mahua biodiesel was collected and washed several times with de-sterilized water until the washing water become neutral. The biodiesel layer was filtered to remove impurities and then heated up to 100°C to remove any remaining water. The biodiesel

**ManasRanjan Padhi and Sangram Keshari Samal**

was tightly sealed and kept for storage. The diesel engine was run three times using three different blends of Mahua biodiesel as fuel. The blending percentages of biodiesel with diesel were 10%, 20%, 30% and they were mentioned as B10, B20, and B30 respectively. The emission analysis was conducted by analysing the exhaust gas of diesel with the help of an exhaust gas analyser as shown in Figure 1.

**RESULT AND DISCUSSION**

The composition of exhaust gases which mainly consists four major pollutants such as CO, CO<sub>2</sub>, NO<sub>x</sub> and HC were recorded during testing of different blends of Mahua biodiesel. The comparison of exhaust emissions was shown in Table 1-4.

**Carbon Monoxide (CO) emission**

From Table 1, it is observed that the Mahua biodiesel has lower CO emission than conventional diesel. It is due to the complete combustion of various blends of Mahua biodiesel as compared to conventional diesel. Table 1: CO emission of conventional diesel and castor biodiesel at different load. From Figure 2, it is apparent that when load increases with increasing biodiesel ratio the CO emission of Mahua biodiesel blends decreases. This is mainly due to the complete oxidation process which was not happening in the case of diesel. At the time of biodiesel is burning the generation of CO<sub>2</sub> may be formed due to the presence of extra oxygen molecule in the biodiesel and this process aids in minimizing the CO emission.

**Oxides of Nitrogen (NO<sub>x</sub>) emission**

The NO<sub>x</sub> emission increases with the increase in percentage of biodiesel blends as shown in Table 2 and Figure 3. It is due to high oxygen content in the biodiesel which cause the formation of NO<sub>x</sub> in the emission chamber. The NO<sub>x</sub> emission is a function of the total oxygen inside the combustion chamber, temperature of combustion chamber, pressure, and compressibility of fuel. Again, the increase of NO<sub>x</sub> emission is due to the higher cetane number of biodiesel which will reduce the ignition delay. The increase of NO<sub>x</sub> emission is a result of the reduced ignition delay.

**Hydrocarbon (HC) emission**

Table 3 shows, the HC emission of Mahua biodiesel less as compare to conventional diesel. This may be due to effective combustion process inside the engine cylinder. When the load increases, the HC percentage also increases since amount of HC varies inversely with NO<sub>x</sub>. From Figure 4, it is observed that in B30 the HC emission is less as compare to B20, B10 and the conventional diesel because in B30 there is more biodiesel as compare to B20 and B10. As B30 contains more oxygen as compare to B20 and B10, it emits less HC.

**Carbon Dioxide (CO<sub>2</sub>) emission**

The CO<sub>2</sub> emission in conventional diesel is more as it contain less oxygen. It is shown from Table 4 that the CO<sub>2</sub> emission of B30 was more as compare to B20, B10. It is due to incomplete combustion process of higher blends of Mahua biodiesel in comparison lower blends. Figure 5 shows that the carbon dioxide emission increases with increasing biodiesel blends. However the emission is not so more than the diesel. Lower emission of biodiesel blends is due to high oxygen content than the diesel.

**CONCLUSION**

The prepared biodiesel from Mahua oil has good inherent properties than the conventional diesel and most of its properties resembles to that of diesel. From the above result it can be stated that the biodiesel can be used as the alternative fuel of diesel. The biodiesel contains more oxygen which promotes complete combustion in diesel engine and it led to lower emission. Due to high oxygen content, biodiesel emits lower CO and CO<sub>2</sub> as compare to diesel.

**Manas Ranjan Padhi and Sangram Keshari Samal**

The NO<sub>x</sub> emission emissions of biodiesel blends of Mahua oil has a scope to check the overall emission level of the blends by adapting engine modifications. As Mahua biodiesel has lower HC emission than the conventional diesel, the biodiesel pollutes less as compared to diesel and can be regarded as a green fuel. Hence it is a suitable fuel to be used as an alternative for diesel engine

### ABSTRACT

Commercial Banks plays the most important role in Indian financial Institutions. Competition is very high in the financial institutions and banks. Pressure is not only in Indian banks also from foreign banks and Institutions. So it is very important for the commercial banks to provide high quality service to their customers. Now the customers are using many banking products, which are offered by different banks. So the customer always wants the best product with high quality service. Because of globalization and liberalization the competition is very high within different banks. Now Indian customers are more educated and they have all the current information about the banks. As the buying power of the customers increasing, their expectations for high quality service are also increasing. Now it is the responsibility of the banks to satisfy their customers to increase their profits. This study will help in understanding the customer's expectation from commercial banks and their view regarding service quality maintained by banks.

**Keywords:** Service quality, financial services, Expectation & perception, Commercial Banks

### INTRODUCTION

Banks are the pillars of Indian financial system. Commercial banks play a major role in the collection and utilization of financial resources in the Indian economy. Now the service quality of these commercial banks plays the important role for the survival of these banks. There is always a visible difference between the customer's expectation and the service of banks. Private Banks are trying hard to meet the expectations of the customer. It is not only important for the customers but also equally important for the survival of the banks. But many of the public sector banks are not able to adopt the changes required in the service quality. Banks are providing different kinds of products to attract the customers. The banks which can provide best service, can only survive in the long run. So customer satisfaction is

**Girija Nandini and Alaka Samantaray**

one of the major factors for the banks and financial Institutions in India. So the banks have to understand the customer profile, their need and satisfaction from the services given by the banks. As the competition is very high, no bank can ignore the customer's satisfaction. Customers will choose other bank where they will get better service. So the study of service quality of commercial banks is one of the major researches in the present era.

**REVIEW OF LITERATURE**

Parasuraman. A., Zeithaml, V. & Bery, C. (1988) have used SERVQUAL model for their study. They tried to find out the customers satisfaction, customers perception and the banks perception to satisfy their customers. They evaluated the service quality by using the model. They have taken five different factors to measure the service quality. They have used different factors like tangibility, assurance, reliability, empathy and responsiveness for their study. Similarly Dhandabani (2010) has done the research to find the relation between quality of the administration and the customer's devotion in the Indian banking sector. He has used different factors like reliability responsiveness, knowledge for the study. He found that when the administration and service quality is good, it leads to high customer satisfaction and loyalty towards bank. Also Paul.M. k and Barman. A (2010) have studied the customer's loyalties towards bank in the state of Assam. They found that the banks are unable to retain their. Customers when they can't satisfy them with their service quality. It is also difficult for them to get new customers. So it is very much important for the banks to give good quality service to retain the existing customers and to get new customers. Abedniya.A and Zaeim. M. N. (2011) analysed on how the banks are doing the administration and how it is affecting the loyalty of the customers in the banks of Jordan. They have taken different devices like factor investigation, relapse examination for their research. They found that Administration quality is very important for the customer satisfaction and loyalty. Jani. A.S (2012) tried to find different factors which are affecting the customers. Future of E banking and different advances offered to the clients also analyzed in the study. The analysis disclosed that innovation gives a positive impact on the customer's satisfaction.

**Objectives of the study**

1. To find out the customers' expectations and perceptions of service quality provided by the commercial banks in India.
2. To assess customers' satisfaction towards the service quality of commercial banks in India.
3. To know which factor plays a vital role for choosing any bank.

**RESEARCH METHODOLOGY**

A descriptive field study was conducted for the research .The information required was clearly defined and data was collected through questionnaire based on a sample size of 100. A simple random sample has taken from India's top five commercial banks (SBI, Indian Bank, OBC, ICICI Bank and Axis Bank).

**H01:** - There is no significant evidence that satisfactory service quality will tend to be associated with outcomes equal to or above expectations.

**H02 :-** There is no evidence to indicate that service quality is more important in the selection of a bank by a customer than other factors, such as location, advertising, recommendation of others.

**DATA ANALYSIS AND DISCUSSION****Testing of hypothesis 1**

Table -1 shows that there is a positive gap and customers are not satisfied by the services given by the banks. Here paired t-test has been used for the analysis. It shows a statistically significant difference in all attributes used for the study. The biggest gaps ( $\geq 1.92$ ) were found in the following attributes; 6 "Employees should always be willing to

**Girija Nandini and Alaka Samantaray**

help customers" (-1.92 sig. <1.92), 13 "Employees should understand specific customer needs" (-1.72 sig. <1.72), 12 "Employees of a bank should give customers personal attention" (-1.68 sig. <1.68) and 9 "Employees should consistently be courteous" (-1.22 sig. <1.22). These are giving negative impact on the bank and require proper attention and administration in these areas. When the gap is more the service quality of the investors are bad according to the perception of the customers. Here the total gap 5 score is 1.02 which shows that the commercial are unable to satisfy the customers. Also the highest gap is 1.81 related to responsiveness followed by empathy (1.40), assurance (.91), tangibility (0.60) and reliability (0.55).

**Findings and managerial implication**

It is found from the analysis that the gap is 0.61 and 0.60 in physical facilities and professionalism of banks employees. Reliability dimension of service quality provide by the commercial banks like the problems solving of customer, services delivery and error-free records also analysed. The gap for these attributes is 1.01, 0.34 and 0.31. The gap related to responsiveness dimension of service quality provides by the commercial banks like the helping nature of banks employees and not too busy for respond is 1.92 and 1.70. It is also analysed the assurance dimension of service quality provide by the commercial banks like safe in all their transactions, courteous with customers and answering the customers' questions, in the sample size of 100. The result found the gap of 0.49, 1.22 and 0.57.

The analysis of empathy, dimension of service quality provide by the commercial banks like convenient operating hours, personal attention to the customers and understand specific customer needs by the banks employees shows a gap of 0.85, 1.68 and 1.72. Finally data analyzed overall combines scale of 13 attributes related service quality of commercial banks and found the gap mean differences between customers' expectations and perceptions of service quality in the commercial banks in India (n = 100) is 1.02.

**CONCLUSION**

So this study is a systematic study of the specific impact of relation between gender, age, income and education relating to the importance of service quality in the selection of a commercial bank. This study adds to the body of knowledge by establishing a means to test the relationship between or any significant evidence on impact of gender, age, education and income for selection of banks. The results from the test of this study will prove valuable to banks that are seeking to obtain and retain customers because it demonstrates that all of the outcomes can be measured and fall above the average level of satisfaction. The banks have to satisfy the customers by increasing their service quality to sustain in the long run.

### ABSTRACT

The United Nations' Summit on Environment and Development or the Earth Summit held in Rio in 1992 marked the rise of sustainable tourism development. The growing catastrophe of depletion of natural assets emphasized the need for resource conservation. Subsequently there has been a shift away from instrumental ethics as a basis of conduct for the use of nature to a more conservation based ethics in these countries. Ecotourism recognizes the principles of sustainable tourism. The Costa Rica Certification of Sustainable Tourism (CST) developed by the Costa Rica Institute of Tourism has also been successful in improving performance of the ecotourism destinations. Species richness generally increases with decreasing latitude. Due to this biogeographical phenomenon, majority of the species are located in developing countries (DCs).

**Keywords:** Service quality, financial services, Expectation & perception, Commercial Banks

### INTRODUCTION

The United Nations' Summit on Environment and Development or the Earth Summit held in Rio in 1992 marked the rise of sustainable tourism development (Butcher, 2006). With the growing popularity of ecotourism from 1992 onwards, the definitions of ecotourism have also been broadened to include other ethical dimensions rather than being confined to merely tourism trait (Blamey, 2001). Buckley (2004), for example, developed a framework of ecotourism based on four main dimensions: ecotourism being nature based; conservation supporting; sustainably managed; and environmentally educating. In 1996 the International Union for Conservation of Nature (IUCN) defines ecotourism as "Environmentally responsible travel and visitation to relatively undisturbed natural areas, in order to enjoy and appreciate nature that promotes conservation, has low visitor negative impact, and provides beneficially active socio-economic involvement of local populations".

**Madhumita Das**

Honey (1999) has emphasized the empowerment of local communities through equitable distribution of tourism benefits when she defines ecotourism as “small scale traveling to fragile, pristine and protected areas with the fundamental objective of educating travelers, providing funds for conservation, yielding direct benefits for the economic development and political empowerment of the local communities, as well as fostering respects for different cultures and human rights” (Cobbinah, 2015: 180). It is the International Year of Ecotourism (IYE) of 2002 that gave ‘ecotourism’ a plethora of possibilities on the basis of its ability to integrate development with conservation (Butcher, 2006). The Quebec declaration on ecotourism in 2002, the outcome of the IYE, recognizes the principles of sustainable tourism, concerning the economic, social and environmental impacts of tourism (Wood, 2002). The declaration says that ecotourism-

- contributes actively to the conservation of natural and cultural heritage
- includes local and indigenous communities in its planning, development and operation, and contributing to their well-being;
- interprets the natural and cultural heritage of the destination to visitors; and
- lends itself better to independent travelers as well as to organized tours for small size groups.

The accumulative impact of tourism development policies in developing countries are often guided by economic imperatives neglecting the environmental costs of resource usage. The growing catastrophe of depletion of natural assets emphasized the need for resource conservation. Subsequently there has been a shift away from instrumental ethics as a basis of conduct for the use of nature to a more conservation based ethics in these countries. Such a shift has given rise to ecotourism policies that applies green growth strategy in the ambit of tourism with an intention of sustainable use of exhaustible natural resources (Holden, 2003). Ecotourism gives the impression of a perfect policy particularly for the developing countries (DCs) in the sense that it generates much needed foreign currency and also provides a strong incentive for conservation (Kruger, 2005). The incentives for developing countries lie in the fact that it can aid in economic development, environmental protection, and preservation of cultural environments (Stone & Nyaupane, 2015).

The DCs are immensely fortunate to own a vast majority of species because of their biogeographical locations (Gossling, 1999). Yet the problems like poverty, rapid population growth, workforce-pressure, lack of capital and foreign debts etc., often lead to over-exploitation of natural resources and consequently loss of biodiversity (Burgess, 1993). The pursuit of achieving higher growth, prompted these countries to stress more on industrialization and in the process there has been more depletion of traditional sources of energy and raw materials, destruction of multitude of animal as well as plant species, large scale clearance of forests etc., leading to commotion of natural ecological balance and corrosion of environment. However, there is no consensus of the evidences about the benefits of ecotourism. There is a huge controversy and debate associated with the impact of ecotourism on local livelihood and conservation as well (Gezon, 2014; Cobbinah, 2015). Several studies have questioned the authenticity and the growing buzz of ecotourism. Ecotourism policies are designed to attract consumers’ preferences for recreation. In that process, revenue generation has become the prime consideration and protection of environmental assets has been kept aside. This is leading directly to environmental degradation.

The role and efficacy of ecotourism in conservation as well as the promotion of livelihood system of local people in and around the site are the areas that require further investigation due to the controversies and debates associated with ecotourism. Some of the addressable questions are: (1) whether the local indigenous communities get benefit from ecotourism? (2) can ecotourism be a successful conservation tool? These issues may be identified only through an impact analysis of ecotourism practices. A detailed and intensive study of a particular site can be of much help to understand the scenario. The present research is an attempt to assess the economic and environmental impact of ecotourism in some important sites of Odisha, India. Odisha with its rich natural and cultural heritage appear to be the ones amongst the most attractive tourist states in India. Two famous ecotourism sites from Odisha viz. Bhitarkanika Wildlife Sanctuary and Chilika Nalaban Sanctuary are considered for the study. The paper is organized

**Madhumita Das**

as follows. Section 2 reviews the literature. Section 3 discusses methodology, followed by results and discussion in Section 4. Section 5 concludes the paper.

## REVIEW OF LITERATURE

Libosada Jr. (2009) believes that ecotourism provides the tangible aspect of conservation as it has been helping save animals and fragile ecosystems. Particularly for developing countries, poverty and resource degradation are highly interlinked. Ecotourism provides jobs and opportunities for self-improvement and advancement which can help to break the vicious cycles of impoverishment, resource degradation, and migration (Durham, 2008). The findings of Hunt et al., (2015) corroborate the fact that through its commitment for improving local livelihood, ecotourism is helping in conservation. Reimer & Walter (2013) articulate that the financial benefits from ecotourism that come from park entrance fees, voluntary donations, environmental conservation levies etc., are targeted directly at conservation. Nyaupane & Poudel (2011) have finely interwoven the complexity of tourism and biodiversity conservation through their focus on Chitwan National Park, Nepal. They perceive that as people receive more economic benefits, they take more pride about their natural resources and tend to preserve these resources. The paper of Abbot et al., (2001) provides evidence drawn from Kilum-Ijim forest in North West Province, Cameroon. Adoption of Integrated Conservation and Development Projects (ICDP) has improved the income level and livelihood conditions of the people. This in turn has positive impact on conservation by changing the attitudes of the people in and around the forest area.

Ecotourism recognizes the principles of sustainable tourism. It (a) minimizes environmental impact and thus has a small ecological 'footprint', (b) contributes to conservation either through direct effort like reforestation, habitat restoration, or through financial benefits (Zambrano, Broadbent, & Durham, 2010). Development of forests through promotion of ecotourism in the reserve also helps in mitigating carbon which can reduce green-house gas emissions, which is really noteworthy (Badola, 2010). The Costa Rica Certification of Sustainable Tourism (CST) developed by the Costa Rica Institute of Tourism has also been successful in improving performance of the ecotourism destinations (Tepelus & Cordobci, 2005). Apparently, such practices have ensured that certain mammals and birds, which became extremely scarce, can now be observed by residents and tourists with greater frequency (Wunder, 2000).

Julianne & Thomas (2009) endeavor to test the relationship between economic growth, biodiversity loss and efforts to conserve biodiversity through Environment Kuznets's Curve (EKC) hypothesis with a combination of panel and cross section data. The EKC asserts that environmental damage increases initially and then after a certain point of time it falls with rising income resulting an 'inverted U' shaped curve. Nevertheless, a large number of articles posit ecotourism as not to be very effective in promoting conservation of biodiversity. Many authors consider ecotourism as an instrument for revenue generation. The word 'ecotourism' is to attract customers, and thereby generate more income. Many PAs in developing countries are found to be poorly planned, with the infrastructure and management inadequate, and even unsuitable for ecotourism. The following section depicts many problems of ecotourism that pose threat to successful conservation.

### Ecotourism as a business policy

Ecotourism is criticized by several researchers for its inability to insure the long term protection of environmental assets (Duffy, 2006). The critics claim that ecotourism is only a *proxy market* designed to attract customers. Ecotourism policies are designed to attract consumers' preferences for recreation. In that process, revenue generation has become the prime consideration and protection of environmental assets has been kept aside. This is leading directly to environmental degradation. Honey (2008) has therefore claimed in his book "Ecotourism and sustainable development- Who owns paradise?" that "much of what is marketed as ecotourism is simply conventional mass tourism wrapped in a thin veneer of green" (pp. 51). The author identifies that ecotourism is still in its 'infancy stage' and therefore a broad set of principles and practices are to be derived that will give a new direction to the so called ecotourism industry. Many ecotourism sites lack proper infrastructure to consider them as ecotourism sites.

23489

**Madhumita Das**

Scheyvens (2000) cites the case of Himalayan areas, where tourism has resulted in widespread deforestation in some areas as lodges use wood for heating water and rooms for tourists and cooking meals.

**Conflict between biodiversity conservation and ecotourism**

The proponents of ecotourism have failed to see the threat caused by such activities. Rise in the number of tourists, which exceeds the carrying capacity of the place, leads to the very erosion of natural resources for which tourists come (Drumm, 2008). The more elementary environmental critique against ecotourism is that it is usually based on extensive use of resources often including overseas transportation with large CO<sub>2</sub> emissions (Buckley, 2004). Lusseau & Higham (2004) have confirmed that there is a proliferation of tour operators in response to increased tourists' demand in the case of Doubtful Sound (New Zealand). This has brought tremendous pressures on the population of bottlenose dolphins the resident in the Sound. With the number of tourists increasing, there is increase in the number of boats. While many have permits, a large number of vessels do not have permission. It is so because there are significant commercial disadvantages associated with holding a permit because it ties operators to national responsibilities. As a result, these vessels venture into the critical zone hampering the habitat and population of dolphins.

Drum's viewpoint is awfully perplexing when he considers that conservationists at the 'Nature Conservancy' have identified "tourism as a threat in 78 international conservation area plans because of its effect over the past seven years" (Drum, 2008: 782). The author has also identified that if the current levels of investment continue, the tourism boom will simply destroy the biodiversity. Prime habitats will become degraded, wildlife will become scarce, the quality of the visitor experience will decline, and eventually ecotourism will fail completely as a policy. Even in the case of Whale watching, Orams (2000) finds that the industry by 1995 has expanded to 65 countries from 12 countries in 1983. The economic impact from such activities was estimated as more than US\$550 million. But the impact of this industry on the life of these endangered wild animals is very much alarming. The close proximity of the vessels to the whales, the noise and pollution of the vessels disturb their natural behavioral pattern. Martin's (2007) review paper also holds the same notion that the increase of whale shark-based ecotourism has serious impact on their behavior, habitat, and ecology.

Eijgelaar, Thaper & Peeters (2010) with the example of Antarctic cruise tourism have unfolded that the cruise passengers tripled from 2000 to 2007. The selling point of such tourism is claimed to create environmental awareness for the destinations before it disappears and are therefore termed as responsible tourism. However, no evidence of greater environmental awareness among the tourists after their visit to such places is found by the authors. In many places increased tourists cause a lot of unsustainable usage (Dixit & Narula, 2010). Moreover such trips produce higher green-house gasses and result in significant climate change. According to Eijgelaar, Thaper & Peeters (2010), total emissions per passenger are 7.8 t CO<sub>2</sub> per trip and 409 kg CO<sub>2</sub> per day. Dawson et al., (2010) view that the polar bear viewing industry is estimated to contribute 20,892t/CO<sub>2</sub> per season which is higher than average activity emissions. Tourists are more interested to see wildlife, including polar bears, beluga whales, walrus, seals, and penguins before they disappear completely and in the process also facilitate in the extinction of such endangered species.

Such paradoxical issues are becoming more important in certain cases as the focus point is more on tourism to generate revenues in the name of 'Responsible Tourism'. In the process, environment is getting compromised and the objective of environmental conservation through ecotourism policy is moving beyond our reach. Thus the role and efficacy of ecotourism in the conservation of biodiversity and the promotion of livelihood system of local people in and around the ecotourism spot is a question. The problem is more in a developing country like India where local communities are dependent on natural resources for their livelihood for ages together.

**Madhumita Das****The Study Area**

Bhitarkanika Wildlife Sanctuary (BKWS), and Nalabana (Chilika) Sanctuary of Odisha have been selected as the study regions owing to their significance within the ecotourism map of India and specifically in state of Odisha.

**Bhitarkanika Wildlife Sanctuary, Odisha**

BKWS is located in the *Kendrapara* District of Odisha in Eastern India (upper segment of the figure). The sanctuary (declared vide notification No.6958/FF AH Dtd. 22.04.1975) is spread over an area of 672 square kilometers and lies in the river delta of Brahmani, Baitarani, and Dhamra rivers.

The sanctuary is the second largest mangrove ecosystem in India after the Sunderbans of West Bengal. The park encompasses an area of 145 sq. km. and has been notified as Bhitarkanika National Park vide Notification No.19686/F & E dated 16.9.1998 of Forests & Environment Department, Govt. of Odisha. For its rich avi-fauna, it was declared as a "Ramsar Site" on 19.8.2002. The biodiversity of Bhitarkanika is unique and incomparable in the Country. Out of 72 mangrove and associated species found World over, Bhitarkanika houses 62 of them. The sanctuary in terms of mangrove vegetation occupies first position in India and second largest after Papua New Guinea. The faunal diversity in Bhitarkanika is represented by 42 species of reptiles, 5 species of amphibians, 280 species of birds, and 28 species of mammals. Salt water Crocodile (*Crocodilus porosus*) is the flagship species of Bhitarkanika. Recent report in Guinness Book of world records suggests that the largest living crocodile in the world is found in Bhitarkanika. Besides estuarine Crocodile, the Sanctuary is rich in avifauna, mammalian and reptilian population like King Cobra, Indian Python and Water Monitor Lizard. The avian diversity of Bhitarkanika is unique. As many as 280 species have been reported from the Sanctuary area. Both resident and migratory birds use this mangrove wetland in some part of the year or other. *Bagagahan*, the heronry is largest in Asia according to some sources. About 30,000 resident water birds nest in a compact area of 4 Ha. The Park attracts about 1, 00,000 migratory birds during winter. Bhitarkanika has recently made its way to the final list of heritage sites in 2014.(1)

**Nalabana (Chilika) Sanctuary, Odisha**

Just south of Puri, the sea mixes with the 1100 sq.km inland Chilika Lake to create the largest brackish water lake in Asia. These shallow waters enclose an immense area of marshes, lowlands, and islands. It abounds with a variety of fish, crabs, prawns throughout the year and migratory birds make it their home in winter (November through March). This brackish water lake attracts around 150 species of migratory birds every year during winter and hence is a bird-watcher's paradise. It is an interesting world of around 158 different species aquatic & wild life including insects, mollusks, fishes, prawns, amphibians, reptiles, birds and animals. Limbless skink, a rare reptile which was discovered for the first time from loose soil, attaches much significance to this place. The Lake is dotted with a number of islands. The Island of Nalabana, 8 km in circumference occupies a unique place in the vast expanse of Chilika Lake as it happens to be a sanctuary and the central refuge point for the migratory birds.

Kalijai Island is the abode of Goddess Kalijai, venerated by the local fisher folks. This island plays host to a huge fair on 'Makar Sankranti' held annually in the month of January. The large fishing community adds flavor to the lake. Rajhansa Island near the confluence of the lake and sea (New Mouth) offers a fantastic beach. The Irawady Dolphins can be seen playfully cavorting in the channels approaching the sea mouth near Satapada. Some of the Islands bear romantic names like Honeymoon Island and Breakfast Island.

**RESEARCH METHODOLOGY**

The study is exploratory in nature and is based on secondary data. Qualitative tools are used in the study for an elaborate investigation about the impact of ecotourism on the overall development of indigenous communities and conservation in all four sites. The study has relied on secondary source information for other three ecotourism spots.

**Madhumita Das**

Focus group discussions, thematic and content analysis, and case study methods are used to bring out the contrasts (if any) at each ecotourism site.

**RESULTS****A Case of Nalabana (Chilika) Sanctuary**

Nalabana (Chilika) sanctuary is one of the most important natural asset endowments of the State of Odisha. Managing Chilika entails ensuring conserving its rich biodiversity as well as sustainable livelihoods for communities dependent on the wetland resource for sustenance. The place was known for Poachers' place due to rampant poaching activities in the area. The Bird population dwindled to a great extent, but thanks to the efforts of the conservationists, Chilika has come a long way as narrated by Sharma & Pradhan (2).

The Government of Odisha created the Chilika Development Authority (CDA) in 1991 for under taking ecosystem restoration. With financial support of the state government and the Ministry of Environment and Forests, Government of India, CDA initiated several programs including treatment of degraded catchments, hydro-biological monitoring, sustainable development of fisheries, wildlife conservation, ecotourism development, community participation and development and capacity building at various levels. Even '*An Integrated Management Planning Framework for Conservation and Wise Use*, Kumar & Pattnaik (2012) emphasize on ecotourism for conservation of Chilika Lake and sustainable development of villagers.

Mangalajodi, a village on the banks of the Chilika Lake now hosts more than 150000 birds reported by Sharma & Pradhan (ibid). Mangalajodi is now not only home to birds but also represents a critical, one of its kind ecosystem whose protection is possible because of ecotourism. Through ecotourism, steps have been taken to convert poachers to conservationists through provision of employment opportunities. Poachers turned conservationists are involved in regular bird census, habitat management and other scientific studies conducted by State Forest Department and Other conservation organizations, which helped the locals to earn and also to know more about birds and their habitats. Protection has benefited not only the participants of ecotourism, but also has benefitted Mangalajodi's birds, aquatic biodiversity like fishes, snakes, monitor lizards and the elusive Fishing Cat.

Mangalajodi ecotourism aims to inspire, inform and enable communities to turn ecosystems into a sustainable source of livelihood through well managed tourism instead of exploiting them for short term profits. Project involved working in three key areas- Capacity Building of the local community through training in domains like Eco-Guiding, Hospitality and catering, Infrastructure Development and Marketing the venture through different mediums. This initiative involved establishing an other community based organization called Mangalajodi Ecotourism Society to cater to larger village needs and involving the youth from the village to manage ecotourism activities professionally. The institution is further divided into different teams taking care of different project domains. By protecting, reconnecting and restoring the life of the Mangalajodi Marshes, this community owned venture is giving a paradigm shift in conservation.

Mangalajodi ecotourism has tried to follow the principles of ecotourism, by making a positive contribution to economic betterment of the locals, ecology, and environment. Ecotourism is able to build partnership with different organizations to initiate development work in different areas. At present Mangalajodi ecotourism has evolved to support the continuous community conservation initiative. It is now a community owned and managed Ecotourism initiative started with a vision to support the livelihood of local community without hampering the fragile wetland Ecosystem. Very recently, Bird protection committee was bestowed with prestigious state "Biju Patnaik Pakhee Mitra" (Friends of Birds) Award for conservation and has been designated the status of 'Important Bird Area' by Birdlife International for its importance as a significant global waterfowl habitat (Kumar, Pattnaik & Pattnaik ; 2011). This shows how successfully ecotourism has been able to manage the nature and local community.

**Madhumita Das****A case of Bhitarkanika Wildlife Sanctuary**

According to a report of Das & Chatterjee (2015) Ecotourism as a policy has been introduced in the era of the 1990s, when the degradation of biodiversity and natural resources increased and intervention became critical. The major objective of ecotourism in BKWS is to conserve biodiversity through improved livelihoods of the villagers. After around two decades, the hotspot is doing really well now in terms of tourism business. The economy of the nearby villages of Bhitarkanika is characterized by remoteness, absence of electricity and industry, very little development in terms of infrastructure, communication, market and so on. Villagers have little occupational choice other than agriculture and fishing. Introduction of ecotourism has undoubtedly opened up different avenues of employment opportunities for the villagers in such a remote area. As per the authors, locals get an opportunity to work in hotels, restaurants, patrolling staff, plantation worker, gatekeeper, boat drivers at. Some skilled people work as eco-guides. Ecotourism has also created opportunity as temporary workers for park related construction and other development activities. With different job opportunities for the villagers, ecotourism has definitely come as an economic rescuer for many people who do not have a wide avenue of earning due to lack of infrastructure, resources, education, training and so on. This benefit has led to their dependence on natural resources.

**CONCLUSION**

Ecotourism aims at the conservation of natural resources through economic development of the indigenous communities. The protected areas such as wildlife sanctuaries and national parks are formed in remote areas where the locals depend on the natural resources for their sustenance. The policy measures of ecotourism of Bhitarkanika and Chillika need to be appreciated for the efforts to link conservation with local development. But there is more scope to make ecotourism an inclusive approach and therefore the study call for more stringent measures related to conservation.

### ABSTRACT

Capital structure is connected to corporate financing from various groupings of long term sources which comprise both insider funds in addition to outsider funds. Capital structure is the most important feature although measuring the corporate performance for any kind of firm. It is not only significant for the development of the firms' value but also it is obligatory to continue in the economic situation. Therefore the assessment of corporate performance of the organization should bring a sign on the way to exploiting stockholders wealth which is most vital from the investment decision during a particular time horizon. From the above it is clear that capital structure of an organization have an important impact on corporate's performance. Consequently, this study is connected to examine the impact of capital structure on corporate performance of six software companies in India for last five years from 2015-16 to 2019-20. The study considers four corporate performance measures as dependent variables two main capital structure ratios are as independent variables. The data has composed from secondary sources and composed data has been inspected by different tools like descriptive statistics, correlation and regression analysis for examining the impact of capital structure on corporate performance of six software companies in India for last five years from 2015-16 to 2019-20.

**Keywords:** Capital Structure, Corporate Performance, Capital Structure Ratio, Corporate Performance Ratios, Software Companies, Correlation, Regression

### INTRODUCTION

One of the most significant tasks of a finance manager is to make the finest capital structure; which will provide higher return with lower cost. Capital structure is connected to corporate financing from various sources of long

**Pramod Kumar Patjoshi and Girija Nandini**

term sources which comprise both insider funds in addition to outsider funds. Capital structure is the most important feature although measuring the corporate performance for any kind of firm. It is not only significant for the development of the firms' value but also it is obligatory to continue in the economic situation. Corporate performance is most important features, which recognize the corporate profitability as well as position from the company's investment. Consequently it is significant for the firm to perform better, earn more profit than cost in the competitive environment (Owolabi and Obida, 2012). The foremost problematic in framing capital structure is to realize various types of funds in addition to their proportion in the capital structure for achieving higher returns with less risk (Dada and Ghazali, 2016; Gambo et al., 2016). Subsequently, this study is connected to investigate the effect of capital structure on financial performance of six software companies in India for the last five years from 2015-16 to 2019-20.

**LITERATURE REVIEW**

Berger and Di Patti (2006) clarified that with the help of financial leverage in the firm cost of capital can be minimised. Higher debt will reduce the transactions cost in addition to this the firm can accomplish the objectives of shareholders wealth maximization. Conversely Efobi (2008) defined capital structure is mostly alienated into own funds in addition to borrowed funds. Firm sale ordinary shares and distributes profit to the owners of the firm. However Ihenetu, Iwo and Ebiware (2016) suggested that firms utilise borrowed fund and funds from the shareholders for the long term investment actions.

While, Owolabi and Obida (2012) analysed and mentioned that there are many measures used by the company to know the financial performance. Then again Lambe (2014); Odi (2014); Nirajini and Priya (2013); Salawu (2009) explained that debt ratio of the company can be taken to decide external financing. Company making profit but less growth opportunities can use moderate debt than issuing shares as debt is less costly than equity share. On the other hand Oyakhilome, Ibhaguia and Felicia (2018) in their research mentioned there is a positive impact of different capital structure on financial performance. Correspondingly, Hoang (2015) examined the 150 Vietnamese listed manufacturing companies and found that the impact of short term debt has positive significant effect on performance of firm whereas long term debt has insignificant effect on performance of firm. While, Olokoyo (2013) observed from 101 companies and found that financial structure has positive as well as significant relationship with firms' performance.

On the other hand Patjoshi and Nandini (2019) studied the trends of liquidity management and their impact on financial performance of CIPLA and SUN PHARMA. Similarly Patjoshi and Nandini (2019) examined the interrelationship between capital structure and financial performance of ACC while Patjoshi and Nandini (2019) examined the comparative financial performance of Hindustan Unilever and Nestle India. Whereas Patjoshi (2016) analysed the financial performance of HINDLCO and NALCO similarly Patjoshi (2018) analysed liquidity management and financial performance practices by ONGC and IOCL. Likewise Patjoshi (2014) investigated financing pattern and utilisation of fixed assets of fertilizer industries in India. While Nandini (2017) studied the impact of capital structure on financial performance of Tata Motor similarly Nandini (2013) examined the financing pattern and utilisation of fixed assets: case on Tata Steel and SAIL.

**Objectives of the Study**

The objectives of the study are To study the capital structure and corporate performance of six software companies in India for the last five years from 2015-16 to 2019-20.

- To analysis the impact of capital structure on corporate performance of software companies in India from 2015-16 to 2019-20.

## METHODOLOGY OF THE STUDY

For reviewing the stated exploration objectives the data has been collected from secondary sources. The data has been collected from the financial statements, available in different websites of six software companies in India for the last five years from 2015-16 to 2019-20. The research considers four corporate performance measures, including Net Profit Margin (NPM), Return on Equity (ROE), Return on Total Assets (ROTA), and Return on Investment (ROI) as dependent variables and two capital structure ratios including Total Debt Equity Ratio (TDER) and Long Term Debt Equity Ratio (LTDER) as independent variables. The sample six software companies for the study are HCL Technologies, Tata Consultancy Services, Infosys, Tech Mahindra, Mind tree and Mphasis.

## DATA ANALYSIS AND DISCUSSION

### Descriptive Analysis of Capital Structure Ratio and Corporate Performance Ratio of six Software Companies in India

From the table-I, it can observe that the two independent variables TDER and LTDER of six software companies have logged mean value of 0.42 and 0.05 and standard deviations of 0.13 and 0.05 respectively for the study period. Both TDER and LTDER variables are positively skewed. LTDER has recorded positive kurtosis value while TDER has recorded negative kurtosis value for the study period. From Table-I, it reveals among four dependent variables of six sample software companies that measure the firms' performance, NPM has the lowermost mean (0.16) but ROI has the uppermost mean (0.29). Conversely ROI has the higher volatility which equal to 0.12 while the volatility of NPM is the lower (0.05). All profitability ratios are positively skewed. ROE as well as ROI have much superior excess kurtosis than NPM in addition to ROTA.

### Analysis of Correlation of Capital Structure Ratio and Financial Performance Ratio of top six Software Companies in India

Correlation result does the association among capital structure and financial performance ratio of six software companies discussed in Table-II. It can find out that both capital structure ratios TDER and LTDER of software companies are negatively correlated to all corporate performance ratios (NPM, ROE, ROTA and ROI). While NPM (-0.79) correlation is found to be lowermost as compare to other corporate performance ratios for the study period.

### Regression Analysis Net Profit Margin and Capital Structure Ratio

Table-III shows the regression result considering NPM as dependent variable with the capital structure ratios as independent variables. The goodness of fit significances of standard linear multiple regressions through NPM as the dependent variable and various factors as predictors, the model result and model coefficients have shown in table-III. The R Square (0.64) in addition to adjusted R Square (0.61) indicate that there is moderate deviation in NPM is expressed by the independent variables involved in the model. The ANOVA result shows that there is a statistically significant association as the F value of 23.49 and a P-value < 0.05. TDER has a negative coefficient and P value of 0.00 (less than 5%) means that there is a negative but statistically significant relationship between NPM and TDER at 5% levels. Whereas LTDER has a negative coefficient and P value of 0.56 (more than 5%) indicates that there is a negative and statistically insignificant relationship among NPM and LTDER at 5% levels.

### Regression Analysis Return on Equity and Capital Structure Ratio

Table-IV shows the regression result considering ROE as dependent variable with the capital structure ratios as independent variables. The goodness of fit significances of standard linear multiple regressions through ROE as the dependent variable and various factors as predictors, the model result and model coefficients have shown table-IV. The R Square (0.26) as well as adjusted R Square (0.21) designate that there is very low deviation in ROE is formulated by the independent variables involved in the model. The ANOVA result shows that there is a statistically significant association as the F value of 4.86 and a P-value < 0.05. TDER has negative coefficient as well as P value of 0.52 (more than 5%) indicates that there are negative and statistically insignificant relationship between ROE and

**Pramod Kumar Patjoshi and Girija Nandini**

TDER. Similarly LTDER has a negative coefficient and P value of 0.24 (more than 5%) indicates that there is a negative as well as statistically insignificant relationship between ROE and LTDER at 5% levels

**Regression Analysis Return on Total Assets and Capital Structure Ratio**

Table-V shows the regression result considering ROTA as dependent variable with the capital structure ratios as independent variables. The goodness of fit significances of standard linear multiple regressions through ROTA as the dependent variable and various factors as predictors, the model result and model coefficients have shown table-V

The R Square (0.37) in addition to adjusted R Square (0.32) designate that there is low deviation in ROTA is expressed by the independent variables involved in the model. The ANOVA result shows that there is a statistically significant association as the F value of 7.94 in addition to a P-value < 0.05. TDER has a negative coefficient as well as P value of 0.51 (more than 5%) indicates that there is a negative as well as statistically insignificant relationship among ROTA and TDER at 5% levels. Similarly LTDER has a negative coefficient in addition to P value of 0.10 (more than 5%) indicates that there is a negative as well as statistically insignificant relationship between ROTA and LTDER at 5% levels.

**Regression Analysis Return on Investment and Capital Structure Ratio**

Table-VI shows the regression result considering ROI as dependent variable with the capital structure ratios as independent variables. The goodness of fit significances of standard linear multiple regressions through ROI as the dependent variable and various factors as predictors, the model result and model coefficients have shown table-VI.

The R Square (0.32) as well as adjusted R Square (0.27) show that there is low deviation in ROI is expressed by the independent variables involved in the model. The ANOVA result shows that there is a statistically significant association as the F value of 6.28 in addition to a P-value < 0.05. TDER has a negative coefficient as well as P value of 0.24 (more than 5%) indicates that there is a negative as well as statistically insignificant relationship between ROI and TDER at 5% levels. Similarly LTDER has a negative coefficient in addition to P value of 0.37 (more than 10%) indicates that there is a negative and statistically insignificant relationship between ROI and LTDER at 5% levels.

**CONCLUSION**

Capital structure is the most important feature for measuring the corporate performance for any kind of firm. Therefore, this study is connected to examine the impact of capital structure on corporate performance of six software companies in India for last five years from 2015-16 to 2019-20. The study considers four corporate performance measures as dependent variables two main capital structure ratios are as independent variables. The capital structure ratios TDER and LTDER of software companies are negatively correlated to all financial performance ratios (NPM, ROE, ROTA and ROI). It can observe from regression analysis for NPM with capital structure ratios designate with both TDER and LTDER have negative coefficient while TDER is statistically significant relationship with NPM and LTDER has statistically insignificant relationship with NPM at 5% levels. Whereas it can observe from regression analysis of ROE, ROTA and ROI with capital structure ratios designate that both TDER and LTDER have negative and statistically insignificant relationship with ROE, ROTA and ROI at 5% levels.

### ABSTRACT

Stock market plays significant role of economy development of the country. Investors use to invest in various financial securities in the Stock market by expecting a high return in future. Investment in stock market involves future uncertainties as well as unexpected risks. Irregularity in stock market also called as volatility. The stock market comprises maximum volatility which leads to maximum risk in the stock market. Consequently, this study mainly related to measurement of volatility pattern of the banking companies in Indian stock market. The study considers the daily closing price of different indices of Sensex as well as selected banking companies in India. For investigating the objectives the data has been self-possessed from secondary source (BSE website) over a period of 10 years from 1<sup>st</sup>January 2010 to 31<sup>st</sup>December 2019.

**Keywords:** Volatility, Sensex, Banking Companies, Beta, Correlation and Regression

### INTRODUCTION

Stock market plays significant role of economy development of the country. Investors use to invest in various financial securities in the Stock market by expecting a high return in future. Two most significant variables should consider while investing in the stock market are risk and return. Investment in stock market involves future uncertainties and unexpected risks. Irregularity in stock market also called as volatility. The stock market comprises maximum volatility which leads to maximum risk in the stock market. When the deviation between actual return and expected return is more volatility is more. So measurement of volatility is very important for the investors for

23503

**Girija Nandini Pramod and Kumar Patjoshi**

investment. In India Bombay Stock Market (BSE) in addition to National Stock Market (NSE) are two significant stock markets. Once there is arising or sliding drive in the Indian stock market the stock prices similarly displays up and down movements.

**REVIEW OF LITERATURE**

Samanta (2003) examined the volatility in Indian stock market over a period from 1993 to 2002. The study shows that historical prices of stocks affect the volatility in stock market. And while volatility is bigger the return is also higher during the study period. Although Chang-Jin, James and Charles (2004) studied the stock market volatility by considering from 1996 to 2000 and strained to discover whether there is any positive association among equity premium and volatility. Conversely Balaban and Bayar (2005) explored by investigating 14 countries. The study has taken stock market return as well as made the forecast of volatility during 1987 to 1997. Correspondingly Sarkar and Banerjee (2006) inspected the Indian stock market by considering the day wise stock prices in each five minutes break from NSE. They considered from 1<sup>st</sup> June 2000 to 30<sup>th</sup> January 2004 and used GARCH model for the analysis. While Tripathy, Prakash and Arora (2009) examined in the Indian Stock market by captivating data of BSE Sensex from January 2005 to June 2009. This research considered various variables like leverage, stock returns, trade and volatility for the investigation. Conversely Nicholas and Nicholas (2011) examined in European stock market for finding the variation of volatility in the disasters situation and found the stocks demonstrate negative as well as statistically insignificant leverage possessions. Whereas Gahan, Mantri, Parida and Sanyal (2012) examined the volatility in Indian stock market for both pre as well as post derivative period and found that the present news cast has additional effect in the volatility.

Conversely Patjoshi (2011) examined volatility in Indian stock market by taking various indices of BSE and NSE. Similarly Nandini, Patra, Mishra (2012) studied the volatility by finding month of the year effect and also day of the week effect. They have used statistical techniques and GARCH (1,1) model for the analysis. They found there is a significant difference in the return of the days of the week. Similarly Nandini (2013) analysed to find the volatility in the Indian stock market. She also found that there is a significance difference in the return of days of the week in different stock exchanges. Conversely, Patjoshi (2016) has done the research in Indian stock market. He has taken Sensex and banking stocks indices to find the risk and return for the analysis. Similarly; Patjoshi and Tanty (2016) analysed the stock market volatility in BSE and NSE of India while Patjoshi and Tanty (2017) scrutinizes the volatility of 30 companies of BSE SENSEX. They have taken daily return into consideration to find the volatility.

Alternatively Patjoshi (2016) investigated the issue and challenges faced by the Indian Stock Market while Patjoshi (2016), scrutinized suitable day in a week for investment, in the BSE. On the other hand Patjoshi and Nandini (2020) have done their research by taking the closing value of Sensex and different steel companies for the period from 2010 to 2019. They have used descriptive statistics, t test and correlation for the analysis. They found that Sensex average daily return is positive whereas all the sample companies return is negative. Also the volatility is more for the sample companies than Sensex. Similarly Patjoshi and Nandini (2020) analysed the day of the week effect in Indian stock market from the period 2000 to 2018 by taking the returns of Indices of BSE. They have used descriptive statistics and GARCH model for the study. They found a statistically significant return in the days of a week. Therefore, this study mainly related to measure measurement of volatility pattern of the banking companies in Indian stock market.

**Objectives of the Study:**

The study is based on the following objectives.

- a) To study the measurement of volatility pattern of the banking companies in Indian stock market.
- b) To analyse effect of volatility pattern of selected banking companies on Indian stock market.

Girija Nandini Pramod and Kumar Patjoshi

## Methodology and Tests Used in the Study

The main objective of the study theme asurement of volatility pattern of the banking companies in Indian stock market and their effect on Indian stock market. Sensex has been considered as an indicator of Indian stock market while ten selected banking companies i.e. HDFC Bank (HDFC), State Bank of India (SBI), ICICI Bank (ICICI), Axis Bank (Axis), Kotak Mahindra Bank (Kotak), Indusind Bank (Indusind), Yes Bank (Yes), Punjab National Bank (PNB), Bank of Baroda (BOB) and Bank of India (BOI) have been well-thought-out for the study of measurement of volatility pattern of the banking companies in Indian stock mark. The study considers the daily closing price of different indices of Sensex as well as selected banking companies in India. For investigating the objectives the data has been self-possessed from secondary source (BSE website) over a period of 10 years from 1<sup>st</sup> January 2010 to 31<sup>st</sup> December 2019. Different tools like Mean, Standard deviation, Skewness, Kurtosis correlation and regression are used to study the measurement of volatility pattern of the banking companies in Indian stock mark.

## Data Analysis and Discussion

### Descriptive Analysis of Sensex and Selected Banking Companies in India

Table-1 shows the descriptive analysis of Sensex in addition to selected banking companies in India. It can find out from table-1 that, out of ten banking stocks two banking stocks have positive mean returns although eight stocks have negative mean returns designed for the study period. It can be experiential that the mean return of Indusind bank (0.10) is upper most and mean return of PNB (-0.11) is bottommost compare to other banking stocks. Consequently top two better players in banking industry are Indusind bank (0.10) and Kotak bank (0.03). In contrast the bottom most two players in banking industry are PNB (-0.11) and SBI (-0.08). On the other hand, the standard deviation (volatility) logged maximum for SBI where as it is minimum for Indusind bank then other banking stock over the period under study. It also can be found from the table that the two larger volatile banking stocks are SBI (5.02) and Yes bank (4.48), however two slighter volatile banking stocks are Indusind bank (1.99) and Kotak bank (2.52). Although by examining the Sensex related to banking stock return, it can practical that Sensex has provided healthier return than all sample banking stock except Indusind bank and Kotak bank during the study period. Alternatively Sensex return include slesser volatile then as related to all sample banking stock over the study period.

### Analysis of Correlation between Sensex and Selected Banking Companies in India

Table-2 pronounces the correlation amongst Sensex and banking stocks in from 1<sup>st</sup> January 2010 to 31<sup>st</sup> December 2019. It can depict from table-2 that Sensex is positively correlated with all banking stocks' returns. The upper two banking stocks those are exceptionally correlated with Sensex are Indusind bank (0.58) and BOI (0.55). Whereas, the bottom two banking stocks those are less correlated with Sensex returns are SBI and (0.26) and HDFC (0.25).

### Analysis of Beta with Reference to Sensex

The betas (market volatility) of sample banking stock in India related to Sensex have explained in table-3. It found from table-3 that the two less risky banking stocks with smaller Beta are HDFC bank (0.99) and Kotak bank (1.05) whereas the two high risk banking stocks with maximum Beta are BOI (1.54) and Yes bank (1.55).

### Analysis of Regression Results for Returns on Sensex Dependent Variable and Various Banking Companies in India as Predictors

Table-4 replicates the regression study between Sensex returns as dependent variable with the sample banking stocks returns from Bombay stock market in India as independent variables. It reveals from table-4 that F-statistics value of 308.04 ( $P < 0.05$ ) demonstrate that the independent variables are jointly statistically significant at 5% level. The regression study specifies that the coefficients of Indusind bank, BOI and Kotak bank's stocks noted higher coefficients where as SBI, Yes bank, BOB and PNB stocks have noted smaller coefficients. Therefore the returns of Indusind bank, BOI and Kotak bank's stocks are really impact the Sensex return. Nevertheless SBI, Yes bank, BOB

**Girija Nandini Pramod and Kumar Patjoshi**

and PNB banking stocks return have slighter impact on Sensex return. The regression model discloses that all banking stocks' returns are statistically significant association amongst Sensex return (Sig. < 0.05) except PNB.

**CONCLUSION**

This study is associated to examine the measurement of volatility pattern of the banking companies in Indian stock market. The study considers the daily closing price of different indices of Sensex as well as selected banking companies in India. For investigating the objectives the data has been self-possessed from secondary source (BSE website) over a period of 10 years from 1<sup>st</sup> January 2010 to 31<sup>st</sup> December 2019. The descriptive consequence shows that the two better stocks in banking industry are Indusind bank and Kotak bank while the bottommost two stocks in banking industry are PNB and SBI. On the other hand the two larger volatile banking stocks are SBI and Yes bank; however two slighter volatile banking stocks are Indusind bank and Kotak bank. Sensex has provided healthier return than all sample banking stock except Indusind bank and Kotak bank also Sensex return includes lesser volatile then as related to all banking stock over the study period. Correlation result displays that Sensex is positively correlated with all banking stocks' returns. It found from beta anlysis that the less risky banking stocks are HDFC bank and Kotak bank whereas the high risk banking stocks with maximum beta are BOI and Yes bank. The regression study specifies that the coefficients of Indusind bank, BOI and Kotak bank's stocks noted higher coefficients whereas SBI, Yes bank, BOB and PNB stocks have noted smaller coefficients. Therefore the returns of Indusind bank, BOI and Kotak bank's stocks are really impact the Sensex return. Nevertheless SBI, Yes bank, BOB and PNB banking stocks return have slighter impact on Sensex return. The regression model discloses that all banking stocks' returns are statistically significant association amongst Sensex return (Sig. < 0.05) except PNB.

### ABSTRACT

From the review of extant literature, we came to believe that there are empirical evidences on the existing interrelationship between macroeconomic variables on international trade and movement of capital market. On the basis of movements in macroeconomic variables of any economy, we can actually predict the capital market. Now, in order to identify how macroeconomic variables in relation to international trade in this context, and explore relationship of these with capital market the present study has been undertaken.

**Keywords:** Indian Economy, Cointegration, Granger Causality

## INTRODUCTION

For many years, the focus of literature in the field of financial economics has been on the interrelationship between capital market and the macroeconomic variables in the economies. Every one of us knows it well that stock markets being a legitimate representative of the capital market in the country enhances liquidity and provides fund for industrialization which acts as the life blood of economic development. Stock market positions are essentially random which are generally believed to be affected by national and international news related to the economy. Consequent to the daily stock market positions, investors' daily gains or losses are determined and these are basically a variety of events which are not possible to anticipate those actually establishes the stock market positions.

It is however true that the stock index positions are determined by demand and supply of stocks listed in it. Price of a stock increases if its demand increases and conversely if people lose confidence on a particular stock, then its price declines. Hence, the price of a stock reflects its demand and peoples' confidence on it. Overall demand for stocks and confidence of people on them is determined by many factors including macroeconomic variables in the country. In

order to identify and measure the relationship between macroeconomic variables and stock market movement, usage of regression analysis by the technique of ordinary least squares (OLS) is not recommended because neither macroeconomic variables nor stock market positions are generally found to be stationary over time. In such a situation when we deal with non-stationary time series data sets, there is an extremely useful econometric tool developed by Granger (1986) that facilitates to analyze long-run relationships and that is popularly known as 'the cointegration approach'. Additionally, the vector error correction mechanism (VECM) which is generally accepted as a useful extension of the cointegration approach allows for examining the adjustments among cointegrated time series data sets those are happening in the short run while they are moving towards the long run equilibrium. Apart from it the implementation of Granger causality models gives insights about the cause and effect relationships between time series data sets in context.

### Research Objectives

The present study has been undertaken with the following objectives:

1. To identify the most useful macroeconomic variables on international trade in the context of present study; collect data on them and on stock indices of India.
2. To explore relationship between selected macroeconomic variables on international trade and the stock market movements in India.

### Research Hypotheses

The following null (H0) and alternative (H1) hypotheses have been formulated in the present study to be tested in this study:

1. H0: Time series return of the selected indices and macroeconomic variables on international trade follow normal distribution with skewness and kurtosis as zero and three respectively.  
H1: Time series return data of the selected indices and macroeconomic variables under consideration do not follow normal distribution with skewness and kurtosis different from zero and three respectively.
2. H0: The returns distributions of the selected indices and macroeconomic variables on international trade are not stationary i.e. mean, variance or both are not constant.  
H1: The returns distributions of the selected indices and macroeconomic variables are stationary i.e. mean, variance or both are constant.
3. H0: There is no co-integration between selected indices of India and macroeconomic variables on international trade.  
H1: There is co-integration between selected indices of India and macroeconomic variables.
4. H0: There is no causality between selected indices of India and macroeconomic variables on international trade.  
H1: There is causality between selected indices of India and macroeconomic variables.

### Variables on International Trade and Capital Market

After the review of extant literature, the following macro economic variables on international trade have been taken into account so that the cointegration between can be explored. The following are the meaning of the above listed macroeconomic variables as described by World Bank.

**Export value index (2000 = 100):** Export values are the current value of exports (f.o.b.) converted to U.S. dollars and expressed as a percentage of the average for the base period (2000). UNCTAD's export value indexes are reported for most economies. For selected economies for which UNCTAD does not publish data, the export value indexes are derived from export volume indexes (line 72) and corresponding unit value indexes of exports (line 74) in the IMF's International Financial Statistics.

**Sisir Ranjan Dash et al.**

**Import value index (2000 = 100):** Import value indexes are the current value of imports (c.i.f.) converted to U.S. dollars and expressed as a percentage of the average for the base period (2000). UNCTAD's import value indexes are reported for most economies. For selected economies for which UNCTAD does not publish data, the import value indexes are derived from import volume indexes (line 73) and corresponding unit value indexes of imports (line 75) in the IMF's International Financial Statistics.

**Lending interest rate (%):** Lending rate is the bank rate that usually meets the short- and medium-term financing needs of the private sector. This rate is normally differentiated according to creditworthiness of borrowers and objectives of financing. The terms and conditions attached to these rates differ by country, however, limiting their comparability.

Along with the above variables, as a representative of the stock market the BSE 500 has been taken. The period for which the analysis has been done is 20 years starting from 1999 and ending on 2018.

**Research Design**

For the test of normality of each of the above time series data sets the Jarque Bera (JB) Test has been implemented. Then in order to test the stationarity of the series in consideration Augmented Dickey Fuller (ADF) Test has been implemented. Further, in order to cross verify the results Philips and Perron (PP) Test has been implemented. After it, for detecting cointegration the technique developed by Granger (1986) has been implemented and then the Granger causality got implemented for knowing the cause and effect relationships.

**Key Findings**

The following is the data on the four variables considered in the present study. The JB Test results revealed that none of the time series under consideration are following a normal distribution. Hence, the first null hypothesis that Time series return of the selected indices and macroeconomic variables follow normal distribution with skewness and kurtosis as zero and three respectively has been rejected.

Then, the ADF Test and PP Test both revealed that the time series under consideration are integrated of order '1' i.e. I (1). It means the data sets are becoming stationary after taking their first difference while they are remaining non-stationary in their original forms. But, since all the data sets are found to be integrated of same order it is a green signal for going forward for a test of cointegration. Then, the test of cointegration by taking BSE 500 as dependent variable and individually the macroeconomic variables as independent variables one by one shown that there is cointegration between BSE 500 and Lending interest rate (%), export and import. And the Granger causality test results shown that lending interest rates granger causes the stock market positions.

**CONCLUDING REMARKS**

From the above findings, it is evident that there is a relationship between macroeconomic variables on international trade and capital market. It has been also found that stock market positions are affected by lending interest rates in Indian economy and not by the level of exports and imports. However, there is a limitation of this study which is that it has not considered much number of macroeconomic variables on international trade for analysis. This limitation is expected to be fulfilled in future researches.

### ABSTRACT

The purpose of the article is to carry out an in-depth analysis of career development theories and to know the practical implications in modern organizations. Content analysis method has been implemented for studying published literature on career theories. The outcome of the study shows that no single theory can be applicable to all situations and necessitates a combination of approach. Moreover, the factors emphasised by different theories that regulate a person changes very often with the changing organizational contours in this volatility, uncertainty, complexity, and ambiguity (VUCA) world. As a result, the organizations need to adapt with the changing scenario with an appropriate modified model to reap the benefit of career development. The study is limited to only five career development theories and the theories are analysed on the evidences collected from secondary sources. This study provides an insight into the changing professional world with individual coping strategies to the volatile work environment. It prescribes a path towards occupational growth and professional wellbeing for an individual. It also attempts to provide systematic steps to create a platform for career development of employees.

**Key words:** Career development, process theories, content theories, process-content theories

### INTRODUCTION

Career development theories show the various paths towards improving professional growth and the career trajectory followed by individuals for an overall job satisfaction and goal achievement. Understanding these theories is an essential step in determining the strengths, weaknesses, fundamental values, and desirable path that are operative while choosing a career. There are various types of career development theories that focus on different

**Lipsa Jena and Umakanta Nayak**

factors, and quite dissimilar to one another. Still all the theories recognise the importance of cultivating a positive emotional relation with work or work environment for developing and achieving a meaningful professional goal. Career development theories can be divided into four categories: by using trait factor, a proper match between individual traits to occupations is focused upon (like trait and factor theory by Frank Parson); it can be based on psychological structure, where the personality should correspond with the work environment (like Holland theory); it can be grounded on decision - situational factors (like social cognitive career theory); and it can be constructed on self-concept (like life span theory of Super). Besides this categorisation, another type of division can be noticed in the theories that are: process theories, content theories, and process-content theories. The process theories emphasise on communicating about the interaction and changes that occurs over a period of time. These theories deal with a sequence of stages through which people proceeds (example: Super's life-span, life-space approach to career development, Gottfredson's circumscription and compromise theory). The content theories are connected with the features of an individual and the environment they live in. The impact on career development are thought to be either intrinsic to the individual or it is initiated from the context or surrounding in which they live. For example: Theory of Work Adjustment. The content and process theories have been moulded in response to accommodate with the requirements of process theory and content theory. These theories embrace both the characteristics of context and individuals, and the advancement and dealings between them (example: Krumboltz's social learning theory of career decision-making, social cognitive career theory, Roe's theory of personality development and career choice).

**Objectives and Methodology of the Study**

The study is carried out to gain knowledge about the philosophy and theoretical underpinnings behind career development. Effort is also made to identify the various empirical research conducted by using these theories. As intrinsic as well as extrinsic factors impact career development, attention is provided to understand the same from existing literature. Finally attempt is made to understand the career path or stages adopted by the theories. Content analysis method has been implemented for studying published literature on career theories.

**Content Theories****(a) Theory of Work Adjustment or Person- Environment Correspondence Theory**

The Theory of Work Adjustment (TWA) is based on the difference of individuals and vocational behaviour (Dawis, 2002, 2005; Dawis & Lofquist, 1984). It views career choice as an unbroken process consisting of adjustment and accommodation. The theory declares two processes that an individual adheres to. In the first case, an individual or person (P) searches for a work environment (E) that can match with his requirement. In the second phase E searches for P having the skills that can tally with the needs of the organization. The amount of satisfaction of P depends on his needs and satisfactoriness of E is based on the operational skills of P helps to forecast the tenure of P. There are four types of adjustment maintained by person and environment (Dawis, 2005). The first one is flexibility that denotes to a person level of tolerance in environment. Next is activeness where P tries to modify E. The third is reactivity where P adopts a self-modification to the difficult situation without transforming E. The fourth is perseverance in which P determines to adjust before choosing to leave E.

The prime strength of TWA is that it measures many variables like satisfaction, satisfactoriness, needs and values, indexes of correspondence, skills and abilities (Dawis, 2005). TWA try to explain career development and satisfaction in terms of person-environment correspondence. Many international studies have been performed on this theory based on satisfaction/satisfactoriness, needs/abilities and work adjustment and tenure. Tziner, Meir, and Segal (2002) conducted a study on Israeli military officers on personality, vocational interest, and general ability; and similarity between interest and job were measured. The findings displays that extroverted personality and congruence were related to a greater level of performance, which was stable with TWA likelihoods. Feij, van der Velde, Taris, and Taris (1999) in their survey on Dutch young adults (ages stretched from 18 to 26) in two time points found connection between vocational interest and perceived skills with job satisfaction. The finding was in tune with TWA's affirmation that vocational interest becomes steady in adulthood, as the interest and skills among participants grew during the course of time and developed into a stable pattern of interest. Similarly, Griffin and Hesketh (2003)

**Lipsa Jena and Umakanta Nayak**

in their survey found that adaptive performance was linked with self-efficacy for adaptive behaviour. The work requirements and adaptability personality projects for the adaptive performance, which is similar with the notion of TWA. TWA can be tested to know career development and satisfaction in cross-cultural surroundings even if it was initiated in USA.

**(b) Holland's Theory of Vocational Personalities in Work Environment**

The theory of Holland can be applied in career counselling and career guidance. Holland expressed that vocational interest and personality is organised in hexagonal structure in the order of RIASEC and can be codified into Realistic (R), Investigative (I), Artistic (A), Social (S), Enterprising (E), and Conventional (C). Generally, this six types of interest and personality can take two type of forms by producing three-letter code e.g., RIA, SIA that symbolises one's career interest. The first letter of these two codes shows the chief interest of the person and the second and third alphabets denotes significant but secondary interest in the course of career choice. Holland used the word "congruence" to show the person-environment interaction where the personality and interest of the person and the work environment produces vocational stability and satisfaction and a low congruence causes vocational instability and dissatisfaction.

Many studies have been conducted on Holland hypothesis and its frame of vocational interests was effective through many cultures (e.g., Rounds & Tracey, 1996). Tak (2004) administered a survey and found good fit in the model of interest but the interest that was organised was not clearly hexagonal. Sverko and Babarovic (2006) conducted a research and supported the Holland hexagonal model. Leung and Hou (2005) directed a study and found six first order factors clustered into three groups Realistic-Investigative, Artistic-Social, and Social-Enterprising-Conventional. This cluster reproduces a definite cultural value and perception. There is a diversified support for Holland's structure of vocational interests found across the cultures.

**Process Theories****(a) Self-concept Theory of Career Development**

Among various theories of career development, the theory given by Super has received abundant attention in USA and other nations. Super established that career development and career choice is related with the self-concept of the person. A self-concept is a complex dealing among the mental and physical growth, environmental features, personal experience etc. (Super, 1990). Super (1990) established a framework for life stages consisting of growth, exploration, establishment, maintenance and disengagement. One has to manage development of vocation in the chronological age. The idea of "career maturity" represents the amount that an individual can achieve the vocational developmental task during each stage. Due to mixed results on career maturity, various studies have suggested to substitute the concept with adaptability (e.g., Herr, 1997; Savickas, 1997, 2002, 2005). The vocational stages are like a mini cycles that shows career transitions as compared with maxi cycles of other theories.

A sufficient number of international level of research have been made on Super's theory (Patton & Lokan, 2001). Patton et al., (2002) organised a study and found that those students having greater level of career maturity, proceeded to full time study, achieve more and fit in psychological balance as compared to other students. Creed and Patton (2003), and Repetto (2001) also studied on career development interventions where the results were regular with the developmental assumptions suggested by career maturity. Watanabe-Muraoka et al., (2001) stated that super theory has gained very widespread attention in Japanese academic and business surroundings.

**(b) Gottfredson's Theory of Circumscription and Compromise**

Gottfredson's theory of career development is a new input in the theory of career development. Gottfredson (1981, 1996, 2002, 2005) supposed that the process of career choice demands for a greater level of cognitive ability. Gottfredson's (2002, 2005) expounded on the interplay between the concept of genetic makeup and environment. Genetic features performs a vital role by influencing the attributes of a person like skills, values, and interest and

**Lipsa Jena and Umakanta Nayak**

these traits are moderated when one is open to an environment. Gottfredson informed that person is a dynamic agent who can modify the environment and hence viewed career development as a process of self-creation. Instead of the customary view that holds career choice as a method of selection, this theory viewed career development and career choice as a process of circumscription or eliminating occupations. There are four stages of circumscription that are, orientation to size and power, orientation to sex-roles, orientation to social valuation, and orientation to the internal, unique self. Another process of career development is compromise where an individual makes occupational choice that are truly achievable in the world. Here a person reacts to the numerous realities and restraints that are external in nature like labour market, family obligations, economic depression etc.

The theory have got little attention as it is problematic to test it empirically Swanson and Gore (2000) because (a) its variables like prestige, circumscription, compromise, sex type are tough to implement (b) the developmental process is suitable for longitudinal studies which requires ample time. But still the theory can be used for career guidance like gender stereotype found in the cultures of Asia, where a person chooses a profession which he consider suitable for his gender (Leung, 2002)

**Theory of content and process****(a) Social Cognitive Career Theory**

Social Cognitive Career Theory (SCCT) (Lent, Brown, & Hackett, 2002; Lent, 2005) proposed a model having three segments of career development that elucidates the vocational interest, career choices, and career performance and stability. This three sections emphasised on personal goals, self-efficacy, and outcome expectations. Personal goals is the intentional engagement in certain activity or to engender a particular outcome (Lent, 2005). Lent (2005) defined self-efficacy as “a dynamic set of beliefs that are linked to particular performance domains and activities” (p. 104). Lent et al., (2002) defined outcome expectations as “personal beliefs about the consequences or outcomes of performing particular behaviour” (p. 262). The theory considers that the development of career goals and career choices are the functions of the interface among interest, self-efficacy, and outcome expectations over time. The Career choice model suggested in the theory shows the interaction and influence between the person and the environment upon each other. The theory postulated that compromise in personal interests may be required during the career choice process due to factors that act as a barrier in choice making like contextual immediate to the person lack of support, social barriers, and cultural beliefs.

The theory has been used in many researches at international level (e.g., Arulmani et al., 2003; Hampton, 2005; Patton et al., 2004). Nota et al., (2007) used a SCCT structure and found a positive association between the career search self-efficacy of participants and family support, and a negative relationship between career search self-efficacy and career indecision. These findings were harmonious with the career choice models of general SCCT, and exemplified the prominence of social support for career decision and efficacy. Creed et al., (2006) used SCCT and their findings were dissimilar to the theoretical anticipation. They found that changes in career decision-making self-efficacy during a period of time were not related with parallel changes in career indecision, and vice versa.

**Analysis of the theories**

The theories of career development served a prominent role by encouraging research activity. By analysing the above mentioned theories of career development, it is found that most of them are related to the career behaviour of an individual. The theories are mostly descriptive in nature rather than explanatory even though they are tested by several researchers. Some theories has been applied much more (e.g. super theory of self-concept) as compared with other theories have got a mixed result (e.g. Holland theory). There exist some contrasting factors among the theories. Holland's theory (1959) identifies the factors that trigger the vocational behaviour of a person while other theories deal with the purpose and development of vocational behaviours. Trait factors associated with Holland's theory explains very little about vocational behaviour. This theory is also having certain limitations.

**Lipsa Jena and Umakanta Nayak**

The theory needs to settle up the inconsistencies of personality required for a proper operation in an occupation. The concept of role identification in career development has been approved by empirical evidences whereas the idea of psychic energy for vocational activity has acquired little support. A substantial amount of research on Super's theory has provided experimental confirmation of self-concept and career development task that is identified with a specific vocational decision. One of the noticeable limitation of the theory is related to its restricted range of use, when we compare the career of nursing that is having enormous amount of personal involvement for exercising the self-concept with that of the career of a clerk working in a dry clean store. Super theory interprets interest as a part of self-concept whereas Holland interest is related with the comparison of person occupation, which can be assessed but it is difficult to be analysed. Because an individual may be poor to judge his own talents and may opt for a career which may be challenging for him to carry out or too low in scope to practise his talents.

Generally all the theories have its origin in the theories of personality but its range varies from one extreme to other extreme as typified in Holland theory. Besides personality, the other area that has exerted impact on the theories of career development is developmental psychology. The effect of developmental notion can be found in Super's (1963a) concepts of vocational developmental task. Gottfredson theory and Super theory, we can find the importance of self-concept and how a work can provide meaning and purpose in an individual's life. Similarly, Social-cognitive career theory mentions the role played by personal, environmental, and behavioural factors that acts as a stimulus for a person through personal goals, self-efficacy, and outcome expectations with the impact of optimal adjustment (Lent, 2013).

The Theory of Work Adjustment is based on satisfaction and satisfactoriness of person and environment. But this theory does not shows what the individual learn during his work life. In the developmental theories like Holland theory, emphasis on the psychic nature of an individual that affects the career choice is shown. Besides the above mentioned theories there are other theories that play up a vital part in career development. There are numerous manifestations of career theories like Systems Theory Framework otherwise known as STF (Patton & McMahon, 1999, 2006), which delivers a structure for career counseling. Krumboltz's social learning theory to career decision, which elaborates that individual personalities and behaviour is the collection of learning experience rather than psychic process (Mitchell & Krumboltz, 1990). Task approach skills, environmental conditions and events, genetic endowment and special abilities, and learning experiences are the four factors that influence a person while making a career choice and career development. Another theory named as Tiedeman's Theory developed by Tiedeman and O'Hara (1963) considered that the process of career development takes place through a repetitive process of differentiation and reintegration. Differentiating is concerned with separating experiences; and integrating is related with structuring the experiences into an all-inclusive whole. Levinson theory developed by psychologist Daniel Levinson, shows the role performed by present circumstances of individual that is strictly regulated by age factor.

The dominant part of Levinson's Theory is that human being develops through specific stages of life irrespective of their background and occupation. If we compare this theory with the career stage model of Super's theory then we can find that in the Super theory people can recycle the career stages regardless of their age while Levinson theory considers career development to be a linear process that advances according to the individual's age. Levinson theory explains the behavioural intentions and individuals' attitudes that are external to work like promotional aims, preparedness to quit the company but Super model gives attentions on attitudes related to the work like job involvement and satisfaction. Roe's theory of personality development and career choice shows the influence of family on the personality of a child. The theory mentions the kind of profession a person chooses but doesn't clarifies the vocational development following the choice of occupation. It neglects the circumstance when the child is not treated in a similar way by either parent who may have two dissimilar ways of nurturing a child.

### Lipsa Jena and Umakanta Nayak

#### Findings:

- The theories generally focus on individual, environment and interrelation between the two.
- The study of theories shows that no particular theory can be suitable for every situation and every person.
- One type of theory cannot be applicable to all types of individuals or environment.
- A particular theory may not be applicable in long run. When the needs of a person changes or the requirement of an organization changes then the theory lacks its ability to influence.

#### Concluding Remarks

By studying the above mentioned career related theories, we can find that these theories discourses about the career related outcome (Chen, 2001; Dik, Duffy, & Eldridge, 2009). The study gives a detail vision into the various factors like personality, professional growth, self-concept, social situation etc. that sometimes performs as a source of encouragement and other time acts as barriers for an individual while choosing a career. The varied perspectives of career development theories offer valuable evidence that reflects employee development. These theories help to acquire knowledge about the ways by which an individual develops his career remaining in an organization and the methods that an individual adopts to adjust and achieves knowledge and skills accordance with various circumstances, needs, and social situations. It is suggested that while implementing a theory an organization should know about its employees' needs and should consider on the practicability of applying the theory.

This study complements with Super (1992) who advised that no single theory is sufficient enough to show the career progress of a person, rather each theory advocates certain idea and neglects the other part of individual career choice (Krumboltz, 1994). This study concludes that one particular theory may be operative for a person in a particular time but may be dysfunctional during other time. But still all the theories are valuable as they perform as an outline for dealing with several subject matters of a person related to his career.

### ABSTRACT

Medicinal plants have been used in human healthcare as a source of medicine. Assurance of the safety, quality, and efficacy of medicinal plants and herbal products has now become a key issue in industrialized and in developing countries. Medicinal Plants have been used for thousands of years to flavour and conserve food, to treat health disorders and to prevent diseases including epidemics. Active compounds produced during secondary metabolism are usually responsible for the biological properties of plant species used throughout the globe for various purposes, including treatment of infectious diseases. Products derived from plants may potentially control microbial growth in diverse situations and in the specific case of disease treatment, numerous studies have aimed to describe the chemical composition of these plant antimicrobials and the mechanisms involved in microbial growth inhibition, either separately or associated with conventional antimicrobials. Medicinal plants play vital roles in disease prevention and their promotion and use fit into all existing prevention strategies. These approaches present interesting and emerging perspectives in the field of medicinal plants. Recommendations are proposed for strategising the future role and place for medicinal plants in disease prevention.

### INTRODUCTION

The term "medicinal plant" include various types of plants used in herbalism ("herbology" or "herbal medicine"). It is the use of plants for medicinal purposes, and the study of such uses. The medicinal plants include a various types of plants used in herbalism and some of these plants have a medicinal activities. Medicinal plants are the "backbone" of traditional medicine, which means more than 3.5 billion people in the less developed countries utilize medicinal plants on a regular basis.[1]. The foundations of typical traditional systems of medicine for thousands of years that have been in existence have formed from plants. The plants remain to offer mankind with new medicines. Some of the beneficial properties ascribed to plants have recognised to be flawed and medicinal plant treatment is based on the experimental findings of hundreds to thousands of years.[2] The earliest reports

23524

**S. Sahoo and G.D. Pattanaik**

carved on clay tablets in cuneiform date from about 2600 BC are from Mesopotamia; among the materials that were used were oils of *Commiphora* species (Myrrh), *Cedrus* species (Cedar), *Glycyrrhiza glabra* (Licorice), *Papaver somniferum* (Poppy juice) and *Cupressus sempervirens* (Cypress) are still used today for the cure of diseases extending from colds and coughs to inflammation and parasitic infections [2]. The traditional medicine practice is widespread in China, India, Japan, Pakistan, Sri Lanka and Thailand. About 40% of the total medicinal consumption is attributed to traditional tribal medicines alone by China.[1] The use of traditional medicine and medicinal plants in most developing countries, as a basis for the maintenance of good health, has been widely observed by UNESCO, 1996[3]. Furthermore, an increasing reliance on the use of medicinal plants in the industrialized societies has been traced to the extraction and development of several drugs and chemotherapeutics from these plants as well as from traditionally used rural herbal remedies [4]

The therapeutic properties of medicinal plants are conditioned by the presence in their organs of active substances, such as alkaloids, flavonoids, glycosides, vitamins, tannins, and coumarin compounds, which physiologically affect the bodies of humans and animals or which are biologically active in relation to the causative agents of various diseases. A special group of medicinal plants are antibiotics [5] Medicine, in several developing countries, using local traditions and beliefs, is still the mainstay of health care. As defined by WHO, health is a state of complete physical, mental, and social well being and not merely the absence of disease or infirmity. Medicinal plants can make an important contribution to the WHO goal to ensure, by the year 2000, that all peoples, worldwide, will lead a sustainable socio-economic productive life [6]

Africa is a rich source of medicinal plants. Perhaps, the best known species is *Phytolacca dodecandra*. Extracts of the plant, commonly known as *endod*, are used as an effective molluscicide to control schistosomiasis [7]. Other notable examples are *Catharanthus roseus*, which yields anti-tumour agents such as vinblastine and vincristine; and *Ricinus communis*, which yields the laxative--castor oil. In Botswana, Lesotho, Namibia and South Africa, *Harpagophytum procumbens* is produced as a crude drug for export. Similarly, *Hibiscus sabdariffa* is exported from Sudan and Egypt. Other exports are *Pausinystalia yohimbe* from Cameroon, Nigeria and Rwanda, which yields *yohimbine*; and *Rauwolfia vomitoria*, from Madagascar, Mozambique and Zaire, which is exploited to yield reserpine and ajmaline[8]

**Role of medicinal plants in human health care**

Medicinal plants have been used as a source of drugs by mankind for several thousand years. Medicinal plants have played an essential role in the development of human culture, for example religions and different ceremonies. Many of the modern medicines are produced indirectly from medicinal plants, for example aspirin. Many food crops have medicinal effects, for example garlic.[9]

**Primary metabolites of plant**

Organic compounds produced in the plant kingdom have metabolic functions essential for plant growth and development produced in every plant. Include carbohydrates, amino acids, nucleotides, fatty acids, steroids and lipids

**Secondary metabolites of plant**

Organic compounds produced in plant kingdom Don't have apparent functions involved in plant growth and development. Produced in different plant families, in specific groups of plant families or in specific tissues, cells or developmental stages throughout plant development. Include terpenoids, special nitrogen metabolite (including, on-protein amino acids, amines, cyanogenic glycosides, glucosinolates, and alkaloids), and phenolics[10]

S. Sahoo and G.D. Pattanaik

### Diseases of the cardiovascular system

Plants used to treat diseases of the cardiovascular system include adonis, hawthorn, Erysimum, sea kale, lily of the valley, oleander, rauwolfia, Sal-sola Richtera, Strophanthus, cudweed, skullcap, *Eucommia*, and *Ephedra equisetina* [11]

### Diseases of the central nervous system

Plants used to treat diseases of the central nervous system include garden heliotrope, ginseng, Rhaponticum carthamoides, the Chinese magnolia vine, motherwort, nux vomica, Eleutherococcus, and the Japanese angelica tree (*Aralia mandshurica*). A small tree that grows wild, the Japanese angelica tree has roots that yield an infusion containing saponins (aralosides A, B, and C), which is used as a stimulant to treat hypotonia, exhaustion, asthenic syndrome, and other conditions [12]

### Respiratory diseases

Plants used in treating diseases of the respiratory organs include marshmallow, ledum, ipecac, milkwort, coltsfoot, juniper, licorice, and Thermopsis. A preparation from the roots of the wild herb elecampane (*Inula helenium*) is an expectorant for bronchitis and coughing and has antiseptic and anti-inflammatory properties

### Diseases of the gastrointestinal tract

Plants used to treat diseases of the gastrointestinal tract include aloe, marshmallow, buckbean, wild marjoram, Rhamnus, snakeweed, centaury, calendula, Sanguisorba, Frangula, sea kale, flax, alder, juniper, dandelion, plantain, sunflower, wormwood, Rheum, senna, polemonium, restharrow, cudweed, bald cypress, and whortleberry.

## CONCLUSIONS

Demand for a wide variety of wild plant species is increasing with growth in human needs, numbers and commercial trade. Plants have provided humans with many of their essential needs, including life-saving pharmaceutical agents. [15] However, medicinal plants are threatened as a result of human impact and that will enhance the effectiveness, efficacy and rational use of medicinal plants, especially through the integration into national, regional and local health policies and programmes.

### ABSTRACT

An attempt is made in this paper to ascertain the roles of community-based organizations (CBOs) in disaster risk reduction (DRR) in rural Odisha. A panchayat specific study was carried out in Alanda gram panchayat of Nimapada Block, Odisha which witnessed large scale devastation during the extremely severe cyclonic storm 'Fani' in the month of May 2019. Based on the data collected through focus group discussions and key informant interviews, the study highlighted the activities of CBOs in information dissemination, comprehensive understanding of the risk and risk assessment, resource mobilizing, support in evacuation, providing first-aid, assigning roles and responsibilities during crises, establishing connectivity and supporting district administration in distribution of relief materials. It also provides some suggestions as to how CBOs can be better leveraged to build more resilient communities.

**Key Words:** Community-based organizations, disaster management, disaster risk reduction, Fani

### INTRODUCTION

Disaster, whether natural or man-made, disrupts the normal progress of development and severely affects the community in the social, economic, psychological and needless to say the physical domain. The United Nations (UN) defines disaster as "a serious disruption of the functioning of society, causing widespread human, material or environmental losses which exceed the ability of affected society to cope using only its own resources" (UN 1992, 27). United Nations Office for Disaster Risk Reduction defines disaster as "a serious disruption of the functioning of a community or a society at any scale due to hazardous events interacting with conditions of exposure, vulnerability and capacity, leading to one or more of the following: human, material, economic and environmental losses and impacts" (<https://www.unisdr.org/we/inform/terminology>, 2017). India is prone to disasters due to its unique geo-

23528

**Umakanta Nayak**

climatic conditions and vast area and large population. Odisha an eastern Indian state on the Bay of Bengal is more susceptible to natural disasters like cyclones and tsunamis. This paper focuses on how community-based organizations of Alanda gram panchayat responded in the pre-cyclone, during cyclone and post-cyclone phases of Fani. The specific objective of this paper is to understand the role of CBOs in disaster risk reduction (DRR) and resilience. Further attempt is made to suggest ways for appropriate interventions to leverage the CBOs by planners, policy makers and administrators to reduce community vulnerabilities.

The remainder of this paper is organized in different sections as per the following order. Section 2 deals with the methodology followed by topography of India and Odisha in section 3. In section 4, focus is on cyclone Fani and its impact on Odisha. Section 5 covers preparedness and responses of Government. Section 6 highlights the studies on the role of community-based organizations on disaster risk reduction. Section 7 represents the role of CBOs in Alanda gram panchayat. Finally, conclusion provides suggestions to leverage CBOs for community resilience.

**METHODOLOGY**

This paper is built on a case study conducted in Alanda gram panchayat in Puri district. The methodologies engaged in this study are key informant interviews and focus group discussions. Besides collection of primary information, secondary sources were also referred to get insights and substantiate the arguments. Alanda gram panchayat of Nimapada block of Puri district, Odisha witnessed large scale devastation during the extremely severe cyclonic storm Fani in the month of May 2019. Alanda Gram Panchayat consists of 6 villages namely Alanda, Juanla, Kushikona, Manijanga, Porakana and Talatanla. The total geographical area is 225 hectares. According to 2011 census, there are 411 households residing in Alanda with a population of 1832. Out of which, there are 462 persons (25.22 %) belonging to scheduled castes. Alanda village has higher literacy rate compared to overall literacy rate of Odisha. As per the census 2011, literacy rate of Alanda village was 85.91 % compared to 72.87 % of Odisha. In Alanda village 672 persons are engaged in work activities. Among those, 65.63 % of workers describe their work as Main Work (Employment or Earning more than 6 Months). Out of the persons engaged in work 34.38 % are involved in Marginal activity providing livelihood for less than 6 months. Out of 672 workers engaged in Main Work, 230 are cultivators (owner or co-owner) and 120 are Agricultural labourers.

**Topography of India and Odisha****India**

India is vulnerable to various kinds of natural disasters due to its geographical location. In India, 58.6 per cent of the total landmass is prone to earthquakes (moderate to very high intensity). 12 per cent of land is prone to floods and river erosion (over 40 million hectares). Nearly 5,700 km of coastline is prone to cyclones and tsunamis. 68 per cent of the cultivable area is vulnerable to drought. Hilly areas are at risk from landslides and avalanches (National Policy on DM 2009). Besides the vulnerability to natural disasters, man-made disasters due to chemical, biological, radiological and nuclear (CBRN) origin also exist. Heightened vulnerabilities to disaster risks can be related to expanding population, urbanisation and industrialisation, environmental degradation and climate change (National Policy on DM 2009). The following vulnerability maps specify the zones prone to various natural disasters. It clearly indicates that the eastern region of the country is susceptible to flood, earthquake, wind, thunderstorm and cyclone hazards.

**Odisha**

Odisha is often referred to as the nation's capital of disaster (The Economic Times, May 03, 2019). The state of Odisha extends from 17°31'N latitude to 22°31'N latitude and from 81°03'E longitude to 87°02'E longitude. With a coastline of about 480.4 km on the Bay of Bengal, it is prone to natural disasters such as tropical cyclones, storm surges, lightning, tsunami and whirlwinds etc. "Geographically, the landmass between Puri to Bhadrak in the map of Odisha juts out a little into the sea, making it vulnerable to any cyclonic activity in the Bay of Bengal," opined by meteorologist Sarat Chandra Sahu (retired Director of the India Meteorological Department's Regional

**Umakanta Navak**

Meteorological Science Centre, Bhubaneswar). In October 2018, cyclone Titli had battered Odisha. In October 2013, cyclone Phailin had struck the state and caused extensive damage. Super cyclone in October 1999 with a wind speed of 260-300 km per hour and tidal surges of height 7 to 10 meters that reached upto 20 km inland caused 10,000 death, 1,500 orphaned, 25,00,000 marooned and 1.3 crore affected in some way or other (Times of India, Bhubaneswar, 3<sup>rd</sup> Nov 2019, p-5). IMD data reveals that out of 1,035 cyclonic disturbances that hit the Indian sub-continent in the last century, around 50 percent of cyclone hit the eastern coast. Out of those five hundred odd cyclones Odisha encountered 263 of them. This implies that one-fourth of the total disasters of the last century in India have battered Odisha. Odisha usually experiences storms/cyclones in post-monsoon phase, i.e. October-November. Out of 39 extremely severe cyclones that hit India in the last 52 years, 23 were (60 per cent) took place between October and December (IMD data). However, pre-monsoon cyclones are also not very unusual though the frequency was less. Cyclone Fani was a pre-monsoon cyclone which had been classified as an extremely severe cyclone (ESC). In the past 52 years, Fani is the tenth such cyclone that hit India in May. Last time the extremely severe cyclone that hit India in May was in 2004. After one and half decade Cyclone Fani as a pre-monsoon extremely severe cyclone hit India in the month of May.

**Onset of Cyclone Fani and its impact on Odisha**

On 3<sup>rd</sup> May 2019, Fani (Extremely Severe Cyclonic Storm) made a landfall in Puri district of Odisha and the devastation created havoc paralysing the normal life of the community for several weeks. A tropical depression that formed west of Sumatra in the Indian Ocean on 26<sup>th</sup> April 2019 was the source of formation of Fani. The environment became favourable to transform the depression into a storm only after 4 days, i.e. 30<sup>th</sup> April 2019. Fani reached its peak intensity on 2<sup>nd</sup> May 2019 as a high-end extremely severe cyclonic storm. It affected 14 districts of Odisha namely Angul, Balasore, Bhadrak, Cuttack, Dhenkanal, Ganjam, Jagatsinghpur, Jajpur, Kendrapara, Keonjhar, Khordha, Mayurbhanj, Nayagarh and Puri.

The numbers of affected blocks were 159, covering 51 urban local bodies (ULBs) and 18388 Villages. Number of casualties was 38 (64 is reported by Times of India, Bhubaneswar, 3<sup>rd</sup> November 2019) and number of people affected by Fani was 1,65,55,507. The impact of the cyclone damaged 5,08,467 number of houses, crops covering 181711.4 hectares of land and livestock casualty was 53,28,107 (Situation Report on Extremely Severe Cyclonic Storm- 'Fani', State Emergency Operation Center, Bhubaneswar, Odisha, 1.06.2019). Besides the above-mentioned damages, the cyclone caused severe damage to power supply and the state capital plunged into darkness for a week. Restoration of telephone and internet connectivity in the state capital took more than a fortnight.

**Preparedness and Responses of Government**

To mitigate the disasters effectively, Government of India promulgated The Disaster Management Act, 2005 which mandated establishment of disaster management authorities at national, state, district and local levels specifying the powers, functions and measures with funds. National Policy on Disaster Management (2009) aims at a holistic and integrated approach emphasising on building partnership at all levels. The themes highlighted in the policy are: community based disaster management aiming at integration of the policies, plans and executions at the last mile; capacity development of all the stakeholders in the relevant spheres of operation; consolidation of past initiatives as repository of knowledge highlighting best practices; cooperation with specialised agencies at National and International levels; and multi-sectoral synergy of efforts. The three major objectives are: promoting a culture of prevention, preparedness and resilience at all levels; encouraging mitigation measures based on technology, traditional wisdom and environmental sustainability; mainstreaming disaster management into the developmental planning process (National Policy on Disaster Management 2009). The National Disaster Management Plan (NDMP) 2016, provides a framework to be followed at various phases or stages of an impending disaster. It also provides relevant direction to the government agencies to be adhered to at all phases of disaster management cycle. It covers areas like disaster risk reduction, mitigation, preparedness, response, recovery, and better reconstruction. The

**Umakanta Navak**

NDMP incorporates an integrated approach that ensures the involvement of government agencies, numerous other relevant organisations, private sector and local communities.

The state of Odisha from zero preparedness for natural calamities has become a trailblazer in the sector and is constantly improving its manpower, technology and organizational structure to mitigate disasters. The state had established Odisha Disaster Mitigation Authority in December 1999, the first its kind in India. Established Disaster Rapid Action Force in 2001. From 21 cyclone centres with a capacity of 42,000 in 1999, the sector has now 879 cyclone shelters with a capacity of over 12 lakhs. Before Fani made a landfall in Puri, the Government could evacuate 11 lakh people and provided shelter to them in cyclone shelters and public buildings (safer places). The State is planning to build five lakh disaster resilient houses in the coastal districts (Times of India, Bhubaneswar, 3<sup>rd</sup> Nov 2019). The efforts are continuing on the part of the Government to mitigate the challenges posed by disasters. Cyclone Fani brought out the fact that there is shortage of skilled manpower and machinery to reduce the impact of cyclonic disaster. Keeping this in view, attempt has made to find out the role of Community Based Organizations (CBOs) in disaster risk reduction.

**Importance of Community Based Organizations (CBOs) in Disaster Risk Reduction: A Review**

CBOs are part of the civil society organizations that has a full range of formal and informal organizations. CBOs are mostly non-profit groups developed in the community to carry out voluntary activities for the development of the community and to improve the life for its residents. The members of CBOs are related to each other in a variety of ways like caste, profession, business, similar interests or purposes etc. Silverman defined that community based organizations grow at a local level within a community. These organizations remain close to the persons they serve. They primarily provide social services to the communities on a voluntary basis. Hence, CBOs are largely dependent on voluntary contributions of labour, material and financial support from the community members they serve and various donor agencies (Silverman, 2004). Nobel laureate Elinor Ostrom (1990) is of the opinion that community based organization are self-governed and generate resources on a sustainable and equitable basis at local level. According to Buxton and Prewitt (2003), a community based organization is comprised of a group of people with common interest living in a specific locality (contrary to an NGO that operates in a wider network). To Frank and Smith (1990), community based corporations [organizations] are locally based organizations whose explicit goal is to serve within communities that receive inadequate attention from government agencies and the private sector.

In the recent years, there is a renewed policy interest in community-based development initiatives (Mansuri and Rao, 2004). This interest is on the basic premises that community involvement in planning and implementation process ensures due consideration on available local resources, assured community support and ownership of the developmental activities by local community. It ultimately culminates in more effective and equitable development. In practice, such developmental initiatives are often channeled through Community Based Organizations (CBOs). CBOs often come into existence in local communities to provide public goods and resolve collective action problems where formal institutions fail or become inadequate (Putnam 2000, Coleman 1988, Ostrom 1990). Therefore, CBOs are gaining importance in the developing and underdeveloped countries where the government is unable to provide much needed social services, especially in rural areas (Edwards and Hulme 1995, Fafchamps 2006). Realising the importance of CBOs in disaster management, this study is carried out in Alnda Gram Panchayat of Puri District with following objectives.

**Role of CBOs in disaster risk reduction in Alanda**

Disaster risk reduction is a set of practices that are applied to preparedness, response, recovery, mitigation, and adaptation (UN-ISDR 2009). This section focuses on the activities of CBOs in the disaster risk reduction (DRR) in Alanda Gram Panchayat. The following CBOs played active role in disaster risk reduction (DRR) and resilience in Alanda Gram Panchayat.

**Umakanta Nayak**

- Women Self-help Groups
- Farmers clubs
- Caste groups
- Youth clubs
- Recreation clubs
- Village Level Disaster Resource Center

The early warning system provided by district administration and mass media culminated in action by the CBOs existing in the Alanda Gram Panchayat. The members of Women Self-help Groups (WSHGs), youth clubs including recreation clubs and Kishori clubs and members of village level disaster resource centers shared the information regarding dos and don'ts during the disaster. Information dissemination about onset of the cyclone Fani reached almost all the people in the Gram Panchayat. Information-sharing and shared awareness increased the efficiency and effectiveness of the operations both during and following the cyclone. The factual information disseminated by the CBOs about the cyclone helped people to get prepared for the disaster without getting panicked. The youth clubs and farmers' group took initiative in cutting down the trees posing threat to the housing structures.

Comprehensive understanding of the risk assessment was done by the CBOs which could reduce the impact of the cyclone. It resulted in less damage to the housing structures in the area. Houses of 13 families were completely damaged because of the wind speed of the cyclone. The CBOs in Alanda GP that took stock of resources were caste organizations, farmers' club and youth clubs during the cyclone. The family and caste groups accumulated and stored food grains and vegetables in safe places belonging to their relatives for consumption during cyclone. Families living in thatched houses shifted the essential and valuable belongings to the houses of their relatives for safe custody. Maa Dwarika youth club and Baba Budhanath youth club of Alanda village and farmers' clubs of Juanla, Porokona village helped the households to store food grains in common seed banks developed and operated by the farmers' clubs of their respective villages.

Caste based CBOs played a major role in the evacuation operations carried out by the state agencies. Large-scale relocation under time constraints was possible due to the activities of the CBOs. Families belonging to scheduled castes helped the households to move to the cyclone shelter with their essential commodities. The cyclone shelter was occupied by the scheduled caste as it is in the close vicinity (400 meters away) of the Harijan Sahi. The Swain community (agriculture caste) shifted vulnerable people from their community to the Gram Panchayat office and primary school of Alanda which is closer to their dwelling place. There was proper coordination among the members of these groups. Further, they ensure that there would be no casualty in the area.

During cyclone the youth groups particularly the members of Maa Dwarika Volleyball team, Kishore clubs of Alanda and Juanla, and youth club of Talatanla took the leadership in providing first-aid to the injured. The women associations particularly the members of SHGs in Alanda helped the district administration in preparation and distribution of food in the cyclone shelters, gram panchayat office and primary school. They also took care of the pregnant women and children in the cyclone shelters. Post-cyclone activities were mostly handled by youth associations and members of village level disaster resource centers (VLDRRC). In Alanda village, the members of volleyball team and VLDRRC helped in clearing the debris from the damaged houses, roads and other public places. The members of volleyball team disposed of the carcasses of animals in Alanda village. VLDRRC of Juanla, Kushikona, and Talatanla and youth club of Prokona and Talatanla cleared the debris from roads and other public places. Consequently road connection was restored which helped in smooth recovery operations carried out by different agencies.

The members of youth clubs and VLDRRC also helped in reconstruction of damaged houses by rendering voluntary labour in their respective villages. They along with the members of SHGs were also actively helping the officials of state government in distribution of relief materials aftermath of devastating effects of the cyclone. The youth clubs of the villages of Alanda gram panchayat were instrumental in collection of funds from the local communities to

**Umakanta Nayak**

establish temporary supply of electricity in the area. They helped electricians in establishing electric connection to the locality by rendering labour in fixing the electric poles and wiring of the poles.

**Concluding Remarks: leveraging CBOs for community resilience**

CBOs are an integral part of daily life of local communities. They practiced, tested, and reinforced across a diverse range of social, economic and cultural activities in a variety of contexts unlike many institutions that are specific to disaster management. These organizations due to their proximity to the community play the role of first responders to disasters. Their social capitals helped them in being accepted by the local communities. The knowledge about the topography assisted them in making appropriate context specific plans. The trust of the local communities on CBOs enabled them to mobilize resources from the local communities with ease. Being part of the community CBOs could able to carry out hassle free deliveries of the relief materials. Thus, CBOs in Alanda gram panchayat played a vital role in disaster management.

However, it was observed that the CBOs existing in Alnda panchayat had not received any training to handle the disaster mitigation activities in the last 7 years. Their traditional knowledge and attitude towards voluntary services could avert serious threat to the life of people in the locality. It is suggested that the gram panchayats should be the nodal body to keep information about CBOs existing in their locality. The data may be revised as the CBOs and their membership changes frequently. There is need to provide first-aid training, Cardiopulmonary resuscitation (CPR) training and Community Emergency Response training to the CBOs on a continuous basis to help the government machinery in handling the frequent disasters faced by the state. The VLDRCs existing already in the villages required training on pre-disaster preparedness, risk assessment, and post disaster responses. VLDRCs should be equipped with skilled man power to manage the disaster in effective and efficient manner.

### ABSTRACT

Today energy in the form of electricity has become an important dimension in country's economic growth. Every year 8 billion metric tones of carbon goes into our atmosphere, out of which 6.5 billion tones comes from fossil fuels and 1.5 billion tones results from deforestation. Renewable energy has pitch in about 19 percent to world energy consumption and 25 percent to the electricity generation in 2015 and 2016-17 respectively. Hence we need to focus on decentralized renewable energy solutions to settle a larger position in the core of "electricity to all" in our country.

**Keywords:** economic, atmosphere, Renewable, energy, solutions.

## INTRODUCTION

An end to the poverty and adopting sustainability are the major challenges in today's time. Energy is the solution to both. Today energy in the form of electricity has become an important dimension in country's economic growth. Hindrance to access to electricity creates bottlenecks to the development of livelihoods, employment, access to health, industries, education and negatively impacts economic development and standard of living. In recent era the demand of electricity has rose drastically. Today our country is the world's third largest producer and third largest consumer of electricity (BP Report, 2016). The gross electricity generation in our country was 1168 billion kWh during the year 2015-16 and having an annual growth rate of 5.81 percent (ibid). With increase in demand for power, and its generation from coal it has raised concerned of exhausting the reserves of coal, petroleum and other resources. In addition to it is also causing damage to the environment. Every year 8 billion metric tonnes of carbon goes into our atmosphere, out of which 6.5 billion tonnes comes from fossil fuels and 1.5 billion tonnes results from deforestation (Singh and Sood, 2002). India's energy sector had a major share in the country's green house gas (GHG) emission profile and is predominantly fossil fuel dependent (WWF, 2015). Both are not very compelling benchmarks in the context of providing quality electricity access to all. In order to sustain in future, there is a need to shift from the conventional sources of energy to renewable energy. Our country needs to increase its energy base for its population as well as a provision to increase the share of renewables in the overall energy mix. Renewable energy through the use of decentralised products are the solution to it (WWF, 2015). The objective of this paper is to give a

**Shiv Sankar Das**

snapshot on various renewable energy policies, schemes being framed in India for development of renewable energy. It has three sections. In the first section, focuses on a renewable energy access framework. Second section provides a snapshot on the global overview of renewable energy, later it speaks about the evolution of Indian power sector and the renewable energy development policies in our country. The last section focuses on the diffusion of solar lights across the districts of Odisha.

**Framework for Renewable Energy Access**

Access to renewable energy is an important aspect for human development. Here, an attempt has been made to develop a framework for renewable energy access. Many factors are responsible for renewable energy access, but majority of the factors can be categorised under finance, capacity building, infrastructure, technology and policy making which are necessary for energy access into the context of rural specific. For finance, it should cover access to the end user of the product. The presence of Self Help Group (SHGs) and cooperative society needs to support the end users to help them take up loans. These entities should also be linked to financial institutions so that the end users would get money for further lending. Presence of banks and micro credit agencies in the region and their capacity to disburse funds are important factors for process diffusion. For capacity building perspective the factors like awareness of the product, provision of technical training, providing support for operation and maintenance of the products will help in renewable energy access to the end-users. Other major factors include the government and private training institutions, support centres, presence of local NGOs, etc. helps in undertaking activities on generating awareness about the need and usage of renewable energy across household, livelihood and community levels are required for renewable energy access to the end-users. From infrastructural point of view, energy is required for infrastructural development in schools, community centres, health centres, etc. It can also help in leveraging the developmental aspect of communication networks, roads and other soft support entities. From technology aspect the presence of reliable local vendors, suppliers and the existence of a strong supply network with affordable good quality products, technologies, availability of spare parts and appliances will help in renewable energy access to the end-users. In addition a strong labour force with technical skills, can ensure smooth operations and functioning of the products as well. From policy aspect, it focuses on the current, potential targets, guidelines, schemes available, etc., will help in addressing the renewable energy access. From entrepreneurial perspective if the system components can be sourced locally, assembled and installed then it would create an ecosystem for adoption of the renewable energy products. It will help in employment generation, cost minimisation, faster service and building local capacity as well.

**Renewable Energy: A Global Overview**

Renewable energy has pitch in about 19 percent to world energy consumption and 25 percent to the electricity generation in 2015 and 2016-17 respectively. Energy consumption is further divided into 8.9 percent from traditional biomass, 4.2 percent from heat energy (modern biomass, geothermal and solar heat) 3.9 percent from hydro electricity and 2.2 percent from electricity, generating from wind, solar, geothermal, and biomass. Renewable energy consumption has grew by 14 percent in the year 2016-17, giving 7.5 percent of the world's electricity (BP Statistics Report, 2016-17).

Renewables have recorded for about 40 percent of growth in world power generation in 2016, and gave 31 percent of world primary energy growth (BP Statistics Report, 2016). Around 162GW of renewable energy was added in the year 2016-17 thus becoming the fatly annual increase, up by 9 percent when compared to 2015-16. Solar photovoltaics (PV) pacified with 47 percent of freshly installed renewable power capacity, while hydropower and wind accounted for about 16 percent and 34 percent respectively. Thus, renewables accounted for an estimated 62 percent of net additions to global power generating capacity in 2016-17 (Renewables India, 2017).By the close of 2017, global renewable generation capacity was enhanced by 167GW and reached around 2179GW worldwide (IRENA, 2017). Solar PV raised by 32 percent in 2017, followed by wind energy, rear by 10 percent. Underlying, this growth are substantial cost reductions, with the levelled price of electricity from solar PV diminished by 73 percent, and onshore wind by nearly one-quarter, between the year 2010 to 2017.

**Shiv Sankar Das**

### Market Review on Solar PV: World Wide

In the year 2016-17, the total solar PV installed capacity crossed 300GW, with China having 34.5GW, succeeded by USA with 14.5GW, Japan with 10.2GW and India with 5GW in fourth place. India, about 79GW capacity is expected to be added during the year 2017-18 (Bridge to India Report, 2017). In an attempt for a continuous growth, about 8.8GW of capacity addition (growth of 76 percent over 2016), was set to become the third largest PV market in 2017, overtaking Japan. Solar module prices continue to fall faster. Prices in India fell to less than 1 \$ which is equivalent to Rs 45 to 72/Wp in first quarter of 2017 depending upon the brand and company. Such breakneck fall has made solar PV the affordable new source of power in maximum countries and provided heave in emerging economies.

### India: Renewable Potential, Targets & Achievements

#### Renewable Energy Potential

India has the largest potential for production of energy from renewable sources. It records for about 4 percent of the world electricity generation and gives 4.43 percent to the world renewable generation capacity. As per International Energy Agency's (IEA) the renewable energy projects a growth of renewable energy supply to 4550GW by 2040 on a world basis.

By 2018, the total renewable power generation installed capacity in our country stood at 114.32GW, which is 33.23 percent of the total installed capacity of 344GW (CEA, IRENA, 2018). Installed renewable power generation capacity has increased with a CAGR of 9.29 percent from 2008 to 2018 (ibid). India added a record of 11788MW of renewable energy capacity during the year 2017-18. Power generation from renewable energy sources was 93.21 billion units in 2018. The GoI has set a target to achieve a total capacity of 175GW from other renewable energy sources by the year 2022. Out of 175GW, 100 GW is from solar power, 60 GW is from hydro power, 10GW from biomass power and 5GW from small hydro power has been. Solar installation in India is expected to increase by 360 percent by 2020. About 4.96 million household size biogas plants have been installed in India since the inception of National Biogas and Manure Management Programme (NBMMP) 15000 biogas plants were installed in 2017. Table 1 provides details on state-wise renewable energy potential in our country till December 2017. From the above table it is evident that Rajasthan is having the largest potential for renewable energy and solar energy, followed Jammu & Kashmir, Maharastra and Gujarat. Odisha stands at 10th position with a total renewable energy potential of 27727 MW in the year 2016-17 and 8th position with 25780 MW for potential of solar power.

#### Renewable Targets and Achievements

India has set a target to achieve 175GW by the year 2022 from renewables sources of energy. As most of the target is to be achieved from solar, 60GW is set from ground mounted, grid-connected, large solar projects and another 40GW is from rooftop solar (MNRE, 2017). On the basis of targets set on region specific, more targets have been assigned to southern region with 59GW, 54GW to western region and 46GW to northern region due to climatic conditions. Overall it is expected to install more than 90 percent of the total targets set while remaining is expected to be contributed from north-eastern and eastern regions (MNRE, 2017). If the target for 175GW is to be achieved then it would contribute to achieve 19.44 percent of the total renewable energy potential of 900GW (CEA, 2016). The state of Maharashtra in western India has set the richly target to achieve 22 GW followed by Tamil Nadu with 21.5 GW (CEA, 2017). Odisha has been set a target to achieve 2.3 GW from renewables by the year 2022. In total the installed capacity till March 2017 is set at 57.2 GW both from private and state sector.

#### Generation from Renewable Energy

The generation of electricity from renewables is increasing year by year. As of March, 2020 about 36 percent of India's installed electricity generation capacity is from renewables, which is generating about 21 percent of the total utility electricity in our country (All India Installed Capacity of Power Stations). Recently, a blueprint has been prepared which states that India aims to develop 275GW from renewable energy, 72GW from hydroelectricity, 15GW from nuclear energy and about 100GW from zero emission sources (Michael, 2016). India's total renewable electricity

23538

**Shiv Sankar Das**

capacity stands at 131GW, which represents about 36 percent of the total electricity generation capacity in the country which is approximately 366GW.

### **Off-Grid Decentralised Solar PV Program**

An off-grid decentralized or standalone mode, renewable energy is a perfect, scalable and viable solution for providing power to un-electrified, power deficient villages and hamlets in rural areas. Under the off-grid decentralized solar PV programme for the year 2017-18, the Ministry is providing Central Financial Assistance (CFA) to implementing agencies for diffusion of solar photovoltaic (SPV) home lighting systems, solar street lights, solar pumps, power packs and other solar applications to meet the electricity and lighting needs of the individual in the rural areas. State Nodal Agency (SNAs) are the primary implementing agency through which CFA of 30 percent is provided. NABARD is one of the implementing agencies for pumps and lighting systems through which CFA of 40 percent of the benchmark cost is provided. Below is the state wise installation of Off-Grid solar systems in India till Dec 2017. From the above table we find that maximum number of the solar home lights has been installed in Madhya Pradesh, followed by Rajasthan, Uttar Pradesh and Tamil Nadu. A total of 89961 solar lanterns, solar lamps and 5274 home lighting systems were installed in Odisha till Dec 2017.

### **Policy Landscape on Renewable Energy in India**

Electricity is an important requirement for all aspects of our life. It is a need. It is a captious infrastructure on which the socio-economic development of India hinges. Recognising that the electricity is one of the instrumental drivers for quick economic growth and poverty alleviation, our country had set a target to achieve full access to electricity to all households. In addition to it a target was also set of supplying a reliable and quality electricity at reasonable rate to rural India which is most essential requirement for overall development and growth. Below are the different policies being explained with reference to renewable energy.

### **Evolution of Renewable Power Sector and Renewable Energy Development Policies**

The evolution of renewable power took place mainly after 2003 with the introduction of Electricity Act 2003. Three major policies were introduced which laid the foundation for renewable energy development in our country. Policies were National Electricity Policy 2005, National Rural Electrification Policies 2006 and National Tariff Policy 2006. Electricity Act 2003 was further amended to create schemes like DeenDayalUpadhyaya Gram JyotiYojana (DDUGJY), Rajiv Gandhi GrameenVidyutikaranYojana (RGGVY) for making all villages electrified. National Tariff policy was introduced in 2006 to purchase a certain percentage of grid-based power from renewable sources. Further with the introduction of National Action Plan on Climate Change (NAPCC), it gave a pathway for the development of eight missions to deal with climate change adaptation and mitigation.

Energy policy came into existence through four phases: First is the Introductory phase which was introduced before 1956 where Electricity supply Act was introduced and establishment of semiautonomous State Electricity Boards (SEBs) were enacted. Second is the Nationalisation phase which was introduced between 1956-1991, where the ownership for generation and distribution of power came under state and their was focus on improvement on power losses, subsidies, infrastructure bottlenecks. Third is the Liberalisation phase which emerged between 1991 to 2003 where provision for private sector participation in generation, fast track clearing mechanisms of private investment proposals came into effect and finally the fourth phase where the Electricity Regulatory Commissions Act, was introduced in 1998 for establishing central and state electricity regulatory commissions and rationalisation of tariffs (MNRE and Corporate Catalyst India, IFLR, Aranca Research, 2017).

### **Electricity Act 2003**

This act gave a clear path on the development and integration of renewable energy into the grid. The broad objective was to acquaint competition, protecting consumer interests and provide power for all. This policy mandates the State Electricity Regulatory Commissions (SERCs) to take steps to promote renewable and non-conventional sources of

**Shiv Sankar Das**

energy within their area of jurisdiction. A percentage for purchase of power from these sources was made functional for the promotional tariffs to be determined by the each SERCs. Progressively the share of electricity from renewable energy sources was increased which is being prescribed by SERCs. Such purchase by distribution companies shall be through competitive bidding process.

### **National Electricity Policy 2005**

This policy recognises that electricity is an needful requirement for sustenance. The objective of this policy was to provide electricity to all people by 2010, meeting the demand fully by 2012 and to go for reserves after meeting the peak requirements. Increasing the per capita availability to over 1000 kWh per year by 2012 and ensuring a minimum lifeline consumption of 365 kWh per year per household by 2012 was the major targets under this policy.

### **National Rural Electrification Policies (NREP), 2006**

The objective of this policy was to have access to quality and reliable power supply at reasonable rates and have a minimum lifeline consumption of one unit/household/day by the year 2012. It was also put on that the villages/habitations where grid connectivity was not be feasible or low cost effective then off-grid renewable energy products, based on stand-alone renewable based systems was to be taken up for supply of electricity. Lighting technologies like solar photovoltaic to be adopted if it was not feasible, but these households shall not be designated as electrified. State Govt need to prepare the plan and will be linked to district level development plan involving the Gram Panchayat (GP). Village gram panchayat shall issue the first certificate at the time of the village becoming eligible for declaration as electrified. Subsequently, the gram panchayat shall certify and confirm the electrified status of the village as on 31 March every year.

### **National Tariff Policy 2006**

Under this act there was a provision that central and the state electricity regulatory commissions must purchase a certain percentage of grid-based power from renewable sources. State Electricity Regulatory Commissions will specify a Renewable Energy Purchase Obligation (RPO) by distribution licensees in a time-bound manner. Targets were assigned for each state for purchase obligations with 0.25 percent of power purchases by states by 2013 and 3 percent by the year 2022. Renewable Purchase Obligation targets can be achieved once the Green Energy Corridor (a transmission network to connect renewable energy rich states to lacking states) is complete, as it will provide for easy trade in renewable energy power. The new rooftop policy from MNRE is also expected to increase installation activity in the sector (helping with RPO obligations). Odisha has a lower solar RPO (of 0.15 percent in 2012-13) compared to the target as stipulated in the tariff policy of 0.25 percent in 2014-15. With increase in percentage of total energy consumption in Odisha the power to be harnessed from solar was increased from 44MU to 210MU, with a growth rate of 0.48 (48 percent) during the year 2015-16.

### **Off-grid, Decentralised Solar Power Schemes**

Under this programme, on technical aspect, both for off-grid, decentralised PV systems and minigrids for rural electrification upto a maximum capacity of 500 kWp per site was supported. This scheme was implemented through multiple implementing agencies for rapid up-scaling in an inclusive mode. Under this scheme, the financial assistance is provided by 30 percent capital subsidy to end-users and 90 percent to special category states for community projects and government departments for installation of solar PV systems. It also provided a credit linked capital subsidy scheme for solar lighting and pumping purpose through NABARD, other regional rural banks and commercial banks. Government provided 30 percent subsidy on the cost of the system ranging from Rs 21-105 per watt peak depending upon the capacity of the modules and configuration of the solar photovoltaic systems in different states of the country. For solar water pumping system the capital subsidy is ranged from Rs 27630- 57600 per HP depending upon the capacity.

**Shiv Sankar Das****Jawaharlal Nehru National Solar Mission (JNNSM)**

JNNSM was launched under India's National Action Plan on Climate Change (NAPCC) in 2008. It aims at establishing our country as a world leader in solar energy by creating a favorable policy environment for its deployment across the country. Under the original plan of 2010, the GoI sought to achieve total installed solar capacity of 20GW by 2022. Here the targets were divided into three phases, phase-I started from 2010 to 2013, phase-II from 2013 to 2017 and phase -III from 2017 to 2022. Each phase included three segments: solar rooftop, off-grid solar applications and solar collectors, targets for phase-I included 1100MW, 200MW and 7 million sq. meters respectively. Likewise for phase-II it included 10000MW, 1000MW and 15 million sq. meters respectively and for phase-III the targets assigned was 20000MW, 2000MW and 20 million sq. meters (MNRE, 2010). The Government again revised the solar target for 2022 from 20GW to 100GW. The revised targets were 5000MW, 17000MW, 32000MW, 48000MW, 65000MW, 82500MW and 100000MW for 2015-16, 2016-17, 2017-18, 2018-19, 2019-2020 and 2021-2022 respectively (MNRE, 2016).

**Diffusion of Solar Home Lights in Odisha**

Our state is making efforts for village electrification. Out of 51582 villages in Odisha (Census, 2011) 95 percent villages have been electrified by the end of 31 March, 2017. By the year 2022, Odisha envisages generation of 2200 MW of solar power, 200 MW of wind power, 180 MW of biomass power, 150 MW of small hydro power and 20 MW of Waste-to-Energy (WTE) power (Economic Survey, 2017). A total of 34216 numbers of solar lights were installed in Odisha (Census, 2011). During the year 2017-18, 14837 solar lights has been installed in the rural HH in our state by OREDA (OREDA, 2017).

**District wise Diffusion of Solar Home Lights across Odisha.**

The below table shows the district wise diffusion of solar lights across Odisha. From the above table we find that maximum number of solar lights were installed in Kalahandi district, followed by Sundargarh district and Kheonjhar district with 3420, 2442 and 2022 numbers respectively. Further we find that a maximum of 0.84% of solar lights were installed in Kalahandi district, followed by Malkangiri with 0.72%. From the above figure we find that in Kalahandi district has maximum number of solar lights with 9 numbers installed per 1000 rural household, followed by Malkangiri and Naupada with 7 numbers each.

**CONCLUSION**

Getting reliable, quality power remains a challenge and further extending it to the grid is more burdensome work at ground level. Although different policies are being implemented at ground level but still people are facing problems in getting unreliable power supply for which they are facing problem of drudgery, pollution, safety and health issues. Hence we need to focus on decentralized renewable energy solutions to settle a larger position in the core of "electricity to all" in our country. Currently the main challenge facing is the lack of strong foundation of various factors and actors that supports the functioning and provides a sustainability solutions. For the same there is a need to study the factors and actors that support in giving solutions for improving energy access to in the rural context.

### ABSTRACT

This paper attempts to make an exploratory study the conceptual approaches and practical information of Corporate Social Responsibility (CSR) activities in various paper industries in India. From the initial days of barter system to the recent trend of plastic money, the humankind has treated a long way. The theoretical concepts expounded by the deployment of current CSR practices in India. This paper examines how paper industries in India view and conduct the CSR, identifies key CSR practices and maps these against initiative standards by the Central Government of India.

**Keywords:** Paper Industries, CSR Practices

## INTRODUCTION

### Corporate social responsibility

(CSR) is a business approach that contributes to sustainable development by delivering economic, social and environmental benefits for all stakeholders. CSR is a concept with many definitions and practices. The evolution of corporate social responsibility in India refers to changes over time in India of the cultural norms of corporations' engagement of corporate social responsibility (CSR), with CSR referring to way that businesses are managed to bring about an overall positive impact on the communities, cultures, societies and environments in which they operate.[1] The fundamentals of CSR rest on the fact that not only public but even corporates should be responsible enough to address social issues. Thus companies should deal with the challenges and issues looked after to a certain extent by the states.

**P Kalyan Chakravarthy**

**Scope**

It is a way of integrating the economic, social and environmental imperatives of business activities.

**Why There Is A Need For Corporate Social Responsibility?**

A responsible corporate recognizes that its activities have wider impact on the society in which it operates. Therefore, it takes account of the economic, social, environmental & human rights impact of its activities on all the stakeholders.

1. Better Public Image:
2. Conversion of Resistances into Resources
3. Long Term Business Interest:
4. Avoiding Government Intervention:

**CSR Practices & Trends**

As businesses and professionals identify and define their CSR role, they may well look to their trade or professional associations for advice and support. Even if members don't actively seek input on CSR, their associations have an opportunity, even a responsibility, to reach out proactively to their members to provide a valuable service in the following areas:

**Education and awareness –**

As associations seek new ways to serve members in a tough economy, providing help with CSR may be an untapped avenue of opportunity. However, many associations may face questions from their members, the media or the public about whether the industry or profession they represent has a policy or program to promote CSR.

**Providing support**

If there is sufficient interest in CSR among members, consider providing assistance to members in getting educated, setting policy, and implementing CSR programs. Among the areas where advice and supporting material may be particularly helpful include:

- Policy
- Program ideas and support
- Greening
- Pitfalls.

**History and Evolution of Indian CSR**

India has the world's richest tradition of corporate social responsibility. Though the term CSR is comparatively new, the concept itself dates back to over a hundred years. CSR in India has evolved through different phases, like community engagement, socially responsible production and socially responsible employee relations. Its history and evolution can be divided into four major phases.

**PHASE 1 (1850 TO 1914)**

The first phase of CSR is known for its charity and philanthropic nature. CSR was influenced by family values, traditions, culture and religion, as also industrialisation. The wealth of businessmen was spent on the welfare of society, by setting up temples and religious institutions. In times of drought and famine these businessmen opened up their granaries for the poor and hungry.. During this period social benefits were driven by political motives.

**PHASE 2 (1910 TO 1960)**

The second phase was during the Independence movement. Mahatma Gandhi urged rich industrialists to share their wealth and benefit the poor and marginalised in society. His concept of trusteeship helped socio-economic growth. According to Gandhi, companies and industries were the 'temples of modern India'.

### PHASE 3 (1950 TO 1980)

This phase was characterised by the emergence of PSUs (Public Sector Undertakings) to ensure better distribution of wealth in society. The policy on industrial licensing and taxes, and restrictions on the private sector resulted in corporate malpractices which finally triggered suitable legislation on corporate governance, labour and environmental issues.

### PHASE 4 (1980 ONWARDS)

In this last phase CSR became characterised as a sustainable business strategy. The wave of liberalisation, privatisation and globalisation (LPG), together with a comparatively relaxed licensing system, led to a boom in the country's economic growth.

### Paper Industry in India

The paper industry in India is one of the most thriving industries in the country. The Indian paper industry accounts for about 1.6 per cent of the world's production of paper and paperboard. Indian paper industry is the 15th largest in the world and provides employment to 1.3mn people in country contributing Rs25bn to the government. The first paper mill was set up in India more than 100 years ago. In India, the first paper industry was developed in Kashmir, established by Sultan ZainulAbidin (Shahi Khan) of Kashmir in 1417-67AD. (<http://www.infinityfoundation.com>). Paper was observed in common use almost all over India at the close of Akbar's reign. The growth in paper is inevitable and is likely to contribute significantly to the government's target of achieving an overall growth of 12 per cent in manufacturing. Unfortunately, the rising costs of raw materials, primarily wood and wood products, are a big challenge facing the industry. The industry has recorded a volume growth of CAGR of 5.47 per cent over the last 3 years. In 2003-2004, it recorded a volume growth of 6 per cent in line with the GDP growth.

Newsprint mainly uses for newspapers, flyers, and other printed material intended for mass distribution.

The Rs. 25,000-crore Indian paper industry accounts for about 1.6 per cent of the world's paper and paperboard production even though the country accounts for nearly 16 per cent of the global population. The Indian paper industry's market size has been estimated at Rs.321 billion, growing at a CAGR of 10.5 per cent from around Rs. 195 billion in 2003-04 to Rs. 321 billion in 2008-09. In 2009-10, the country produced 9.18 million tons of paper, growing at an average 6-7 per cent compared with 2 per cent growth in developed countries.

### Information & Activities and By Paper Mills

ITC- Paperboards and Specialty Papers Division (ITC-PSPD), is amongst the leading names in the business worldwide. Our innovative solutions to meet a diverse cross-section of packaging and communication needs have helped us carve a unique niche for ourselves. With emphasis on harnessing state-of-the-art technology, we have emerged as the largest manufacturer of Packaging and Graphic Boards in South Asia. In the endeavour to move up the value chain, our portfolio of products and services has consistently grown over the years. Today, our products and pool of knowledge-based services are much sought-after by discerning customers, both in India and internationally, for sustaining and improving their competitiveness.

To implement the Company's CSR Programmes through Company personnel or through external implementing agencies or through ITC Education Trust, ITC Rural Development Trust, ITC Sangeet Research Academy, ITC Bhadrachalam Education Trust, Tribeni Tissues Education Society (and other Trusts, Foundations and Section 8 companies that may be established by the Company from time to time). In such cases, the Company will specify the CSR Programmes which may be undertaken by those Trusts in accordance with their Objects and administrative and accounting processes laid down in the respective Trust Deeds/ Memoranda and Articles of Association.

Tamil Nadu Newsprint and Papers Limited (TNPL) was established by the Government of Tami Nadu during early eighties to produce Newsprint and Printing & Writing Paper using bagasse, a sugarcane residue, as primary raw material. The Company commenced production in the year 1984 with an initial capacity of 90,000 tonnes per annum (TPA). Over the years, the production capacity has been increased to 2,45,000 tpa and the Company has emerged as the largest bagasse based Paper Mill in the world consuming about one million tonnes of bagasse every year. The activities conducting by the Industry are as follows

**i) Education**

- Scholarships for exceptionally talented children – based on merit
- Career Development
- Sports Development

**ii) Health Care**

- Disease Prevention
- Primary Health
- Help to Handicapped/ Disabled people
- Contribution to Hospitals and Medical Research
- Sanitation Infrastructure

**iii) Socio-Economic Development**

- Drinking Water facilities
- Community or Social Infrastructure \* Employment generation
- Vocational Training \* Integrated Farming
- Livestock and Animal Husbandry care
- Providing assistance for eradicating hunger and reducing poverty and malnutrition
- Road development
- Promoting gender equality and empowering women

**iv) Environmental Sustainability**

- Air pollution control
- TEWLIS related activities for improvement of land
- Water Shed Development
- Conservation of Flora, Fauna & Wild life

**V) Culture & Heritage promotion**

- Conservation of Heritage buildings, including places of worship and sites of historical importance
- Promotion of Literature/ Dance/Music/Theatre/ Arts, Architecture and Handicrafts.

West Coast Paper Mills Limited enjoys a pedigree standing over the past 61 years as premium brand in Paper industry,widely acknowledged both in India and abroad.The Company's commitment to its vision of constant up-gradation of its processes and technology to offer uniform quality of customized products and its sustained

### P Kalyan Chakravarthy

emphasis on achieving mastery over 'wood to paper product research' have enabled it to produce a wide portfolio of wood-free papers and boards of highest quality.

#### **Our CSR initiatives for the villages include the following:**

- Water supply projects.
- School uniform distributions.
- Subsidized notebook distributions.
- Cattle vaccination program.
- Distributions of medicines.
- Medical facilities such as mobile health care units.
- Drinking water arrangements.
- Drinking water arrangements for cattle.
- Organizing social awareness programmes.

Ballarpur Industries Limited (BILT), part of the US\$ 3 bnAvantha Group, is India's largest manufacturer of writing and printing (W&P) paper. More than 50% of India,s coated wood-free grades roll out of BILT's state-of-the-art plants. The company holds an impressive 85% share of the bond paper market and nearly 45% share of the hi-bright Maplitho market in India. BILT is the only Indian paper company to feature in the global top 100 list, with the recent acquisition of Malaysia's Sabah Forest Industries (SFI) having elevated BILT's global ranking to 87. In recent years, BILT has evolved as a knowledge driven and customer centric organization.

As of now the CSR programs of Bilt are carried out at the following levels

- Communities: Integrated Rural & Urban Community Development programmes with communities living in the periphery of our Mills
- Employee Volunteer Programme: employees are encouraged to volunteer time to work on social issues
- Workplace: HIV/AIDS prevention with employees, truckers and transporters
- Support to National Issues: Support to NGO's for Universalizing Primary Education and arresting school dropouts

#### **Community Development**

Out of all the stakeholders of BILT, the communities living around the manufacturing locations are the most marginalized and thus community development and upliftment of the marginalized have been identified as focus areas for CSR intervention. Today BILT's development programmes reach more than 2, 00,000 people living in more than 100 villages around the Mills.

#### **Employee Volunteer Programme (EVP)**

This programme covers employees at all levels and is an extension of the Company's sustained involvement with the communities at its various locations. This programme concentrates its efforts on volunteerism, allowing employees to participate in the process of social change. We have more than 300 employee volunteers who regularly volunteer their time for activities.

#### **Prevention of HIV/AIDS**

The prevention of HIV/AIDS programme was launched in the year 2005. The focus of the programme has been to create awareness about the disease. We have involved our own employee volunteers to deliver this prevention message.

International Paper APPM Ltd., is one of the largest integrated paper and pulp manufacturers in India. Established in 1964. The company produces writing, printing and copier papers for foreign and domestic markets. Our production facilities at Rajahmundry and Kadiyam have a total production capacity of 240,000 TPA. The company

23551

### P Kalyan Chakravarthy

employs around 2,500 employees and is headquartered in Hyderabad. International paper is highly committed to values such as respect for people, communities, cultures and environment while producing paper.

#### EDUCATION

IP India Foundation promotes literacy by developing, assisting and supporting educational institutions in order to impart quality education.

#### ENVIRONMENT

IP India Foundation promotes environmentally & socially responsible business practices by assessing and mitigating the environmental & social impacts on sustainable economic growth.

#### ENGAGEMENT

IP India Foundation has been initiating, encouraging and supporting various initiatives and engaging with the community. SPB is the flagship company of ESVIN Group. The headquarters of the group is at Chennai. The other companies belonging to the group are:

- ESVIN Advanced Technologies
- Ponni Sugars
- High Energy Batteries
- SPB - PC

The activities are

- Lift Irrigation
- Contract Farming
- Community Development

JK Paper Ltd. has two large integrated paper manufacturing units – JK Paper Mills, Rayagada, Odisha and Central Pulp Mills, Songadh, Gujarat with a combined capacity of 4,55,000 TPA. It is the market leader in Branded Copier paper segment and among the top two players in Coated Paper and high-end PackagingBoards. Its products are sold through extensive distribution network of 188 wholesalers, 10 depots & 4 regional marketing offices, and covering nearly 4,000 dealers. It offers a wide product range and its brands are synonymous with premium quality paper.

#### ENVIRONMENT INITIATIVES

- Continuously pursuing enriching the green cover through its Social Farm Forestry drive
- Till date in excess of 81000 Ha of land has been planted covering states of Orissa, Andhra Pradesh, Chattisgarh, Gujarat, Maharashtra & West Bengal
- On average it has added 7000 Ha annually to its plantation drive by distributing over 40 million saplings to farmers
- This farm forestry activity since 1990 has cumulatively provided income for over 45,000 farmers

#### EDUCATION

- Schools - Three schools providing education to over 3000 students with significant portion of them from SC & ST
- Adult Literacy Programme enabling - 3250 illiterate to become literate.
- Adoption/ Upgradation of Industrial Training Institute ( ITI), Ukai, Gujarat under PPP route:Providing training in line with industry requirements. Close to 425 students trained in various trades

**P Kalyan Chakravarthy**

**HEALTH CARE**

- Organising regular General/Disease specific Health Check up camps at the peripheral villages near the factory sites.
- Providing Financial assistance and support to District Administration for organising 'SwasthyaMela' (Health Fair)
- Helping tribal mothers to benefit from Janani SurakhyaYojana

**LIVELIHOOD INTERVENTIONS**

- To improve quality of life of rural poor in and around our Mills by helping them to organise self help group. Recognising the good work, Banks coming forward with loans to build confidence of SHGs & help them scale up their income generating activities.

**Government Norms on CSR activities of Paper Industries**

The Policy recognizes that corporate social responsibility is not merely compliance; it is a Commitment to support initiatives that measurably improve the lives of underprivileged by one or more of the following focus areas as notified under Section 135 of the Companies Act 2013 and Companies (Corporate Social Responsibility Policy) Rules 2014:

- Eradicating hunger, poverty & malnutrition, promoting preventive health care & sanitation & making available safe drinking water;
- Promoting education, including special education & employment enhancing vocation skills especially among children, women, elderly & the differently unable & livelihood enhancement projects;
- Promoting gender equality, empowering women, setting up homes & hostels for women & orphans, setting up old age homes, day care centres& such other facilities for senior citizens & measures for reducing inequalities faced by socially & economically backward groups;
- Reducing child mortality and improving maternal health by providing good hospital facilities and low cost medicines;
- Providing with hospital and dispensary facilities with more focus on clean and good sanitation so as to combat human immunodeficiency virus, acquired immune deficiency syndrome, malaria and other diseases;
- Ensuring environmental sustainability, ecological balance, protection of flora & fauna, animal welfare, agro forestry, conservation of natural resources & maintaining quality of soil, air & water;
- Employment enhancing vocational skills
- Protection of national heritage, art & culture including restoration of buildings & sites of historical importance & works of art; setting up public libraries; promotion & development of traditional arts & handicrafts;
- Measures for the benefit of armed forces veterans, war widows & their dependents;
- Training to promote rural sports, nationally recognized sports, sports & Olympic sports;
- Contribution to the Prime Minister's National Relief Fund or any other fund set up by the Central Government for socio-economic development & relief & welfare of the Scheduled Castes, the Scheduled Tribes, other backward classes, minorities & women;
- Contributions or funds provided to technology incubators located within academic institutions, which are approved by the Central Government;
- Rural development projects, etc.
- Slum area development.

Explanation: For the purposes of this item, the term slum area 'shall mean any area declared as such by the Central Government or any State Government or any other competent authority under any law for the time being in force.

**GAP ANALYSIS**

It has been found out that there is a difference between the actual and the standard performance by the Industries as

### P Kalyan Chakravarthy

per the Government norms. There is a gap found by this study between the two bodies which has mentioned below.

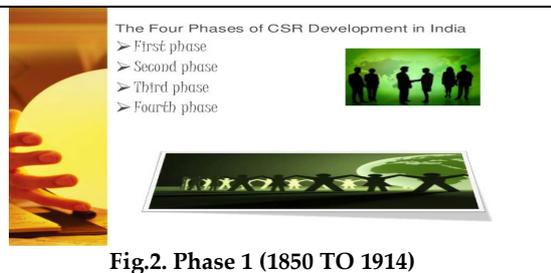

1. Industries should concentrate on Hunger, Poverty and Malnutrition
2. There should be a special focus on special education and also vocational skill education
3. Special focus should be on homes, hostels for orphans and also for old age homes
4. Some initiation towards public libraries
5. Observation on promoting activities on Regional/Traditional Arts and Handicrafts
6. Some benefits should be for War Widows, Armed Forces Veterans and their dependants
7. Special focus on semi urban development or slum area development

## CONCLUSION

The above mentioned statements are most necessary for concentration and implementation for the CSR activities by the paper industries as per the preliminary study. In addition, there should be a harmonious vision for the paper industries towards the implementation of more CSR activities.

### ABSTRACT

Indian retail industry is considered as the fifth largest one globally with huge growth potential. Retail contributes to 10% of India's GDP. India has highest retail density in the world with 15 million outlets. According to the Investment Commission of India, the retail sector in india is expected to grow almost three times its current levels to \$660 billion by the year 2015. Indian retail sector is one of the most sought after sectors that carry great potential for attracting FDI. The growth of retail, especially in 21st century is amazing and attracting the attention of retailers from all over the world. With the steady entry of top global single and multi-brand retailers such as Wal- Mart, Tesco, Carrefour, Nike, Ikea, Apple and many more in last couple of years despite conservative approach of the government, the sector has become more fascinating for the study. FDI is considered as an important tool in the economic development of the nation. Contribution of FDI through financial resources, technology and innovative techniques will raise the overall productivity of diverse sectors of economy. If properly navigated, FDI will truly acts as a catalyst for development of sectors such as agriculture, manufacturing, service, SME's and many more. The present paper attempts to outline the government's policy on FDI in Indian Retail Sector and tries to examine the advantages and adverse effects of FDI on various sectors of the Indian economy. A descriptive analysis is conducted to the present study.

**Keywords:** Foreign Direct Investment (FDI), FDI Policy, Indian Retail Sector, Multi-brand retail, Single-brand retail.

### INTRODUCTION

Indian retail industry is considered to be the fifth largest one globally with huge growth potential. Retail contributes to 10% of India's GDP. India has highest retail density in the world with 15 million outlets. According to the Investment Commission of India, the retail sector is expected to grow almost three times its current levels to \$660 billion by 2015. India is a land of retail democracy- hundreds of thousands of weekly haats and bazaars are located

**P Kalyan Chakravarthy**

across the length and breadth of our country by people's own self-organizational capacities and interests. Our streets are bazaars – lively, vibrant, safe and source of livelihood for millions (Deepali Moghe, 2012).

In 2004, The High Court of Delhi defined the term 'retail' as a sale for final consumption in contrast to a sale for further sale or processing (i.e. Wholesale) a sale to the ultimate consumer. Thus, retailing is the interface between the producer and the individual consumer buying for personal consumption. This excludes direct interface between the manufacturer and institutional buyers such as the government and other bulk customers. Retailing is the last link that connects the individual consumer with the manufacturing and distribution chain. A retailer is involved in the act of selling goods to the individual consumer at a margin of profit.

Indian retail sector is one of the most sought after sectors that carry great potential for attracting FDI. The sector is rightly projected as sunrise sector of India. The growth of retail, especially in 21st century is mind boggling and attracting the attention of retailers world over. With steady entry of top global retailers such as Wal Mart, Tesco, Carrefour and many more in last couple of years despite conservative approach of the government, the sector has become more fascinating for research study. The recent decision of Indian government of opening up the sector for FDI in single and multi brand retail has stirred up the heat with intense agitational activities witnessed all over India. The whole issue needs dispassionate review from all - intellegensia, corporate world as well as from government so that Indian retail sector benefits in its onward march of progress. Moreover, India ranked on 5th position in its Global Retail Development Index (GRDI) and second in Asia after China, by the US-based global management consulting firm, A T Kearney in its annual Global Retail Development Index (GRDI) 2012.

**Objectives of the Study:**

- (a) To study the present regulatory framework for FDI in Indian retail sector.
- (b) To study and analyze likely impact of FDI in single and multi brand retail on different components of Indian Economy.

**RESEARCH METHODOLOGY**

The descriptive research methodology has been used to collect the data. To evaluate the overall position of the entry of FDI in multi brand retail in India, secondary data has been collected from Various published sources and also from websites from the year 1999 to few assumptions for the future. Analysis and Interpretation of the data is more on qualitative terms than on quantitative terms.

**Retail Marketing – Indian Scenario**

The Indian retail market, the fifth largest retail destination globally, has been ranked as the most attractive emerging market for investment in the retail sector by AT Kearney's latest annual Global Retail Development Index (GRDI). At present, the retail industry in India is estimated at US\$ 400 billion industry. With rising consumer demand and greater disposable income, further the retail sector is expected to rise to US\$ 833 billion by 2013 and to US\$ 1.3 trillion by 2018, at a compound annual growth rate (CAGR) of 10 percent. In absolute terms, this figure is very commendable but the actual contribution to the GDP comes only in the form of organized retail. Organized retail segment grew at the rate of 42.4 % in and is expected to maintain a much faster growth rate in next three years. As of now, the organized part accounts for around 6.5% of the Indian retail market. Though, it is expected to maintain a faster growth rate in the coming years with an estimation of touching 13% by the end of 2013. Over the last few years Indian retail has witnessed rapid transformation in many areas of the business by setting scalable and profitable retail models across categories. Indian consumers are rapidly evolving and accepting modern retail formats. New and indigenized formats such as departmental stores, hypermarkets, supermarkets, speciality and convenience stores,

**P Kalyan Chakravarthy**

and malls, multiplexes and fun zones are fast dotting the retail landscape. Retailing in India is currently estimated to be a US\$ 200 billion industry, of which organized retailing makes up a paltry 3 percent or US\$ 6.4 billion. By 2013, organized retail is projected to reach US\$ 23 billion. For retail industry in India, things have never looked better and brighter. Challenges to the manufacturers and service providers would abound when market power shifts to organized retail and above all an experience that a consumer would like to repeat.

The retail sector has played a phenomenal role throughout the world in increasing the productivity of consumer goods and services. It is also the second largest industry in US in terms of numbers of employees and establishments (Chandu.K.L, 2012). There is no denying in the fact that most of the developed economies are very much relying on their retail sector as a locomotive of growth. The India Retail Industry is the largest among all the industries, accounting for over 10 percent of the country's GDP and around 8 percent of the employment. The Retail Industry in India has come forth as one of the most dynamic and fast paced industries with several players entering the market. But all of them have not yet tasted success because of the heavy initial investments that are required to break even with other companies and compete with them. The India Retail Industry is gradually inching its way towards becoming the next boom industry.

**Foreign Direct Investment in Indian Retail**

World Bank defined FDI as "Foreign direct investment (FDI) or foreign investment can refer to the net inflow of funds to acquire a long-term management interest in an enterprise operating in a foreign economy. It is the accumulation of equity, reinvestment of retained earnings, other long-term sources of capital, and short-term funds as presented in the balance of payments".

According to a recent survey by UNCTAD India is projected as the second most attractive destination for FDI (only after China) for multinational corporations during the years 2010- 2012. As per the data, the sectors such as telecom, services, infrastructure and computer hardware and software attract the FDI the most. The leading sources of FDI are from the economies such as the US, the UK, Singapore and Mauritius. The Indian retail market is currently unorganized and highly fragmented, with an estimated 13-15 million outlets countrywide. The overall retail market is expected to grow at a CAGR of about 11-13 percent by 2020-21, with the organized retail market expanding at 21-24 percent (Chandu.K.L,2012). Table 1 depicts the growth of the share of organized retail in the overall retail in India over years. From the table, it can be clearly understood that, in India, the growth of organized retail has been steadily rising since 1999 and is expected to continue in the years to come. This growth can be attributed to changes in FDI policy in retail trade.

**FDI in Single Brand Retail**

FDI up to 100 percent is now permitted in Single-Brand Product Retail Trading by only one non-resident entity, whether owner of the brand or otherwise, under the Government route subject to the terms and conditions issued by the Department of Industrial Policy & Promotion (DIPP), Ministry of Commerce & Industry, Government of India. The purpose for liberalizing FDI in single brand retail trading is to attract FDI in production and marketing, improving availability of goods to the consumer and increasing the competitive factor of the Indian enterprises by providing them access to global designs, technologies and management practices. Accordingly, in permitting such foreign investments, the Government of India has adopted a cautious approach and has made such permission for 100 percent FDI subject to certain terms and conditions explained herein below. FDI in single brand retail trading was permitted to the extent of 51 percent with the prior approval of the Government of India (Secretariat for Industrial Assistance) and was subject to the following conditions:

- Products to be sold should be of a 'Single Brand' only.
- Products should be sold under the same brand internationally i.e. products should be sold under the same brand in one or more countries other than India.
- 'Single Brand' product-retail trading would cover only products which are branded during manufacturing.

**P Kalyan Chakravarthy**

- The foreign investor should be the owner of the brand.
- In respect of proposals involving FDI beyond 51%, atleast 30% of the value of products sold would have to be mandatory sourced from Indian 'small industries/ village and cottage industries, artisans and craftsmen.

**Advantages of FDI in Single-brand retail**

Majority of the single brand retailers which are investing in India has already a sourcing base in the country and the trend is set to increase manifold. The consequential benefits, such as the integration of global best practices in management, along with global standards in quality, design, packaging and production, would help build capacities of local producers, by making it worthwhile for them to scale-up their production, thereby creating a multiplier effect on employment and income generation. This also would lead to up-gradation of technology, which, in turn, would have a further multiplier effect on the economy.

**FDI in Multi Brand retail - A welcome move**

The another landmark decision for the Indian retail industry is the cabinet approved the DIPP's proposal of permitting 51% FDI in multi brand retail in India on September 14, 2012. The decision to allow 51 percent foreign direct investment (FDI) in multi-brand retail clears the deck for multi-national chains such as Carrefour, Tesco and Walmart to set up shop in India, but with riders. It clearly says that approval should be taken from the Foreign Investment Promotion Board (FIPB) for investments. Further, it says the foreign investor should make a minimum investment of \$100 million, 50 percent of which should be invested in "back-end infrastructure". Also, 30 percent of the products must be procured from small-scale industries.

It also states that fresh agricultural produce, including fruits, vegetables, flowers, grains, pulses, fresh poultry, fishery and meat products, may be unbranded. For the purpose of FDI in multi-brand retail, the note describes small industries as units which have a total plant and machinery investment not exceeding \$250,000 (around Rs.1.25 crore). This investment refers to the value at the time of installation, without providing for depreciation. The foreign retail chains will be required to comply with self-certification. They have to keep all records, and the government will have the first right to procure agricultural produce.

Retail sales outlets can be set up only in cities with a population of more than 10 lakh as per the 2011 Census. In States/ Union Territories not having cities with population of more than 10 lakh, retail sales outlets may be set up in the cities of their choice, preferably the largest city. Other conditions include a minimum FDI amount of US \$ 100 million with a mandate that at least 50% of the total FDI be invested in 'back-end infrastructure' within three years of the first tranche of FDI. As for the back-end investment, it states that investments made towards processing, manufacturing, distribution, design improvement, quality-control, cold chain, warehouses and packaging, will constitute back-end. Retail chains will be allowed only in cities with a population of more than 10 lakh as per 2011 Census. There are 51 cities with a population of more than one million, based on 2011 Census.

**Multi-brand Retail Sector: Benefits accruing from FDI**

Accelerated urbanization in India has brought in drastic changes in the consumption pattern. Emergence of new social classes and expansion of middle and upper middle classes, substantial rise in the income of the people and growth of the nuclear family system have brought in a great deal of change in the attitude of consumers. India's population predominantly consists of youth who are more brand-conscious and are ready to pay a premium for quality, environment and brands.

People, now a days, are keen to spend on lifestyle. Today, the typical Indian consumer expects everything to be available under a single roof. All this makes India a very attractive destination for foreign investment in retail sector. It is opined that FDI in Multi-Brand Retail Sector can be considered appreciable as it may bring the latest cutting-edge technologies to India that would benefit a host of the sectors of the economy such as, the

**P Kalyan Chakravarthy**

retail traders, farming, cooperative, service sector in non corporate enterprises and end consumers. The face of the Indian Retail Industry will change with the entry of Global Retail Majors who are known for their quality, service, and technology of highest standards.

**Farmers – the Prime beneficiaries of the FDI Policy**

According to the FDI Policy, at least 50% of the Investment should be made in back end infrastructure such as investments in processing, manufacturing, distribution, warehouse, logistics, storage etc., which will help to reduce wastage of farm produce, improve livelihood of farmers, lower the prices of products and ease supply side inflation, food, safety, hygiene and quality. Direct farm initiatives shall also provide better remuneration to farmers. More investment is likely in farming sector. Since each retailer is expected to bring \$100 million, it will have notable investment in back end and logistics are likely to push employment further. Farmers have chances to gain greater market access, higher profits, better technology and linkages with consumers due to direct back end linkages. Key farmer issues can also be addressed which would help agricultural productivity.

**Real Estate sector likely to upscale their operations**

The decision to allow 51% in Multi brand retail is expected to prompt realtors to revive their plans to build malls and shopping complexes, which were shelved down in the past few years due to economic slowdown. As per Jones Lang Lasalle India, Global Consultant in real estate sector, Rs. 22,000 crores retail real estate market shall grow at CAGR of 25 % a year for the next five years, growing at 50- 100 %. With this, much needed capital too is expected to come into the country for retail which means more job creation in future.

**Consumers are going to be benefited the most**

The most advantaged section with the implementation of FDI policy would be the consumers. From the reduction in prices that would result from the supply chain efficiencies to the improvement in the quality of the products, the consumers are going to be benefitted the most. Along with this, food safety standards would also get better with improvised testing and aggregation facilities. The consumers would also have more choices to pick from. This policy measure is most likely to benefit the poorest sections of the society. Lowering of prices would arrest the erosion of real incomes and the current incomes of the economically disadvantaged sections would hence be able to buy more than before.

**Small Retailers Perspective**

Foreign direct investment in the retail sector would also incentivise the existing traders and retail outlets to upgrade and become more efficient. This would provide better services to the consumers, and also good remunerations to the producers from whom they source the products. A concern that the small retailers will get displaced by allowing FDI is completely misplaced. It is to be noted here that domestic organised retail services are already provided by entities like Big Bazaar, Shoppers Stop, Croma, Reliance Fresh among others in different parts of India. More interestingly, it constitutes only four percent of the retail trade and co-exists with small kirana stores and the unorganised retail sector.

There has been a strong competitive response from traditional retail to these organised retailers through technology upgradation. As a result, the organised retail chains have closed down in a number of locations, while others have reduced the scale and spread of their operations. Globally too organized and unorganized retail co-exist and grow. Small retailers would continue to be able to source high quality produce, at significantly lower prices, from wholesale cash and carry points. In countries such as China, Thailand, Indonesia, Brazil, Singapore, Argentina and Chile, where there are no caps on FDI and where there are no conditions, small retail stores have flourished, leading to more employment. Therefore, it is a white lie to state that FDI in multi-brand retail trade will force small retailers to shut down.

### **Advantages to SMEs**

Small and medium manufacturers are also going to be benefitted as 30 percent sourcing from these industries has been made mandatory. This would provide the necessary scales for these entities to expand their capacities in manufacturing, hence adding up to the employed population and also boosting the manufacturing sector of the country. These industries also stand to get added advantages of technology upgradation, which would give them an upper hand in productivity and local value addition, thereby raising the profitability and earnings of the small manufacturers. The 30 percent sourcing norm would also help the small enterprises to get integrated with the global retail chains. New manufacturing opportunities will also open for the country's micro, small and medium enterprises.

### **Opportunities for Rural Youth**

FDI in multi-brand retail trading will also help a large number of young people from rural areas to join the workforce. Youth from the villages spread across the country can engage themselves in activities ranging from backend to the frontend retail business, as also from the skills imparted to them by the prospective investors.

### **Provides Employment and Reduction in Inflation**

Investments in the organised retail sector will see gainful employment opportunities in agro-processing, sorting, marketing, logistic management, small manufacturing sector like textiles and apparel, construction, IT, and other infrastructure. The most important aspect of FDI in retail is that it will significantly increase the number of jobs in the front-end. According to a study conducted by the Indian Council for Research on International Economic Relations in 2011, as per the industry estimates of the employment of one person per 350-400 sq.ft. of retail space, about 1.5 million jobs will be created in the front-end alone in the next five years. Assuming that 10 percent extra people are required for the back-end, the direct employment generated by the organised retail sector in India over the coming five years will be close to 1.7 million jobs. The study also suggested that with direct buying from the farmers, improving supply chain inefficiencies, bettering storage capabilities to control supply/demand imbalances, inflation could also be tamed. It can thus be concluded that opening up multi-brand retail trading to foreign direct investment would have a multiplier impact on Indian economy. It would act as a strong catalyst for drawing investments in the food processing sector. This would also be a driver for economic growth by accelerating demand.

### **The other benefits of FDI in Multi –brand Retail are as follows**

#### **Long term cash liquidity**

FDI will provide necessary capital for setting up organized retail chain stores. It is a long term investment because unlike equity capital, the physical capital invested in the domestic company is not easily liquidated.

#### **FDI as a lead driver for the country's economic growth**

FDI in MBR would create a competition among the global investors, which would ultimately ensure better and lower prices thus benefiting people in all sections of the society. There would be an increase in the market growth and expansion. It will increase retail employment and suppress untrained manpower and lack of experience. It will ensure better managerial techniques and success. Higher wages will be paid by the international companies. Urban consumers will be exposed to international lifestyles.

#### **FDI opens new doors for Franchising**

Retail giants who are at their wings, seeking entry into foreign market look for other available alternatives. These restrictions on the global retailers regarding the inflow of Foreign Direct Investment, leads them towards acquiring the market entry through franchises. Thus, countries which offer promising market potentialities for retail growth offers substantial growth in the franchising sector as well.

**P Kalyan Chakravarthy**

**Various Myths about FDI in Multi-Brand Retail sector are as follows**

**Myth1: Impact on supply chain intermediaries**

It is feared that foreign retailers will directly impact existing supply chain intermediaries that are being fed by SME's. Since sourcing from domestic SME's is not mandatory, foreign retailers may source the products from countries like China which is known as manufacturing hub of the world and it may put Indian SME sector in great danger. There may be a possibility of large scale unemployment if not checked. The current provision of 30% sourcing from Indian SME's should be made mandatory and should be strictly monitored. Due to predatory pricing strategies, vast class of India's merchants may get affected directly.

**Myth 2: Fear of survival of Small and unorganized retailers in the environment of intense competition**

The local kiranas, small shopkeepers, hawkers, peddlers still form major section of Indian economy. Retail sector acts as a shock absorbing sector, providing opportunities for self employment in case of economic slowdown. The local shopkeepers in the vicinity of big retailers might find it difficult to compete. The prices will be determined by modern retailers and small shopkeepers may have to loose their profit margin due to predatory pricing strategy. The entry of large global retailers such as Wal-Mart would kill local shops and millions of jobs, since the unorganized retail sector employs an enormous percentage of Indian population after the agriculture sector; secondly that the global retailers would conspire and exercise monopolistic power to raise prices and monopolistic (big buying) power to reduce the prices received by the suppliers; thirdly, it would lead to asymmetrical growth in cities, causing discontent and social tension elsewhere.

**Myth 3: About consumer exploitation in the long run**

It is argued that consumers shall benefit due to variety, quality and availability of wide merchandise. However, it is feared that in the long run, consumers may have to face the risk of higher prices, substandard quality and limited options, once these big retailers settle down comfortably in Indian market.

**CONCLUSION**

With the new FDI policy in retail trade, India will significantly benefit in terms of quality standards since the inflow of FDI in retail sector is bound to pull up the quality standards and cost- competitiveness of Indian producers and marketers in all the segments. It will also help in integrating the modern Indian retail market with that of the global retail market. On the other hand, FDI in multi-brand retailing must be dealt cautiously as it has direct impact on a large chunk of population. Foreign capital, if unchecked, may widen the gap between the rich and the poor. Thus, the entry of foreign capital into multi-brand retailing needs to be anchored in such a way that it results in a win-win situation both for India and global players. For example FDI in multi –brand retailing can be allowed in a calibrated manner with social safeguards so that the effect of possible labor dislocation can be analyzed at regular intervals and policy fine tuned accordingly. To ensure that the foreign investors make a genuine contribution to the development of India's infrastructure and logistics, it can be stipulated that a percentage of FDI should be spent towards building up of back end infrastructure, logistics or agro processing units and the claims must be critically evaluated. It can also be stipulated that at least 50% of the jobs in the retail outlet should be reserved for rural youth. On regulatory front, more clarity is required and the same is possible only when retail is recognized as a separate and independent sector of Indian economy. Thus, the priority step would be accordance of industry status to retail sector. Secondly, uniform regulatory structure need to be set up with respect to taxes and duties as regards modern retail sector. Exclusive national policy pertaining to this sector should be formulated. Enactment of national shopping mall regulation act would help to regulate fiscal and social aspects of modern retail sector and create investor friendly environment in India that as regards FDI in retail sector. Along with existing legal and regulatory framework, strong enforcement mechanism is necessary to ensure that big retailers do not dislocate small retailers by unfair means and there is peaceful coexistence of both the arms of retail sector.

### ABSTRACT

New drug development is a series of lengthy and network of process, with maximum expenditure and minimum achievement rate. In current development years, there was major turn down in the number of finding the new lead candidate for approved clinical trial. The strategy of drug discovery programs is to improve the research and development process. Between all of the process the drug repurposing or, repositioning as a new area that involves clinical entreaty for already or existed approved drugs. This new method aimed to reduce cost and research time. So, repurposing is important, due to an area that has previously suffered from limited sources and an extensive urgency for effective therapies and offers advantages over traditional/ old approaches. Drug repurposing or repositioning find the new use of an already existing drug. Than the drug development process it provides affordable, cheap and faster treatment. However there are few barriers to drug repurposing which need to overcome to fasten for a new drug.

**Keywords:** Drug repurposing, Drug repositioning, Drug discovery, pharmaceutical development.

### INTRODUCTION

Drug repurposing is used for establishing other new medical usages for already known drugs including approved drugs. Drug repurposing or repositioning lies is the modification of an active pharmaceutical ingredient for a new indication that is already on the market. It is a new arena of success and is particularly appertain for the treatment of orphan hereditary condition and offers notable satisfaction to the field of pharmaceutical and medical sciences. At its simplest drug repurposing uses an existing drug and seeing whether it can be used as an effective treatment for another condition. Drug repurposing basically indicates to studying drugs or compounds that are already approved to treat one or more disease condition to check whether they are good, safe and effective enough for benefiting other disease condition. [1, 2, 3]. Therefore, in this mini review we discussed about how the drug repositioning serves as an important strategy for the development of new drug candidates.

### History

- In the year 2000, sildenafil which is used for treatment of angina was repositioned to treat erectile dysfunction and thalidomide which is used for treatment of morning sickness in pregnant women was repositioned to treat multiple myeloma. The success of these two drugs created a new environment for drug repurposing which evolved in the emergence of many repurposing engrossed leadoff pharmaceutical companies.
- Drug repurposing also since been extended and covers the active substances that cut out from clinical phase of their development due to the drugs toxicity, insufficient efficacy or withdrawn from the market
- In the year 1934, some company's uses chloroquine which is used as a known antimalarial drug was synthesized and was later on focused towards many other disease condition including parasitic disease, fever, lupus skin rashes and recently it is also being used for coronavirus affected patient. [4, 5, 6]

### Why go for Drug repurposing?

- The usual and traditional drug development process may detain the relocation of drug discovery of translational research.
- As the repurposing of old drugs involves the use of less risked compounds with potentially lower down overall drug development costs and minimizes development timelines thus it is an appealing postulation.
- With the expanding interest from pharmaceutical and clinical research organization and with the noticeable proof from different cheminformatics and bioinformatics centre findings, drug repurposing was initiated with huge investments.
- Out of all of the research nearly only 10% of repurposed drugs were get the approval from the regulatory bodies and 70% of repurposed drugs are there at various stages of clinical development. [3, 4]

### Drug discovery process

Researchers of various fields point out particular biogenetic, cellular and genetic factors which play a significant role in each of the disease condition. The drug discovery and development stages of new drug molecules or lead candidate includes lead compound identification (targets biogenetic, cellular and genetic markers analogous with a particular disease condition), lead compound upgradation/ standardisation/ validation (identify a existed developed molecule that have an ultimate effect on selected target), lead authentication (molecules that are being capable of treating the disease condition) and finally lead compound optimization (comparison of nature and properties of various lead compounds and selection of lead compound which is having the greatest prospective among all) [7, 8]

### Drug discovery and Drug repurposing

Preclinical study trail i.e, study of drugs on human candidate which always stick to the drug discovery process certify the safety of the drug candidate by laboratory and animal testing. After the preclinical study, investigational new drug (IND) application is being set forth to FDA as consent for conducting clinical trial testing. Clinical research/ trail phase includes phase I (human pharmacology and safety), II (therapeutic exploratory phase), and III (therapeutic confirmation) and is mainly deals with therapeutic safety and efficacy of drug in human subjects. In spite of the huge amount of investigation, the drug development process is time consuming process and the chances for the new drug candidate for clearing all the series of drug approval process are often negligible or minimal. So, the drug manufacturing companies mainly focus/ pivot on other types of feasible options for drug research and trail which defined and signifies drug repurposing process as examine the drugs that are already get the approval to treat/ prevent one disease condition to see if they are safe and effective enough for treating other disease condition. Thats why drug repurposing is the need for all and surpass the traditional method of development of drugs. [8, 3, 4]

### Pharmaceutical development

As an innovation stream/ science of pharmaceutical development and research, drug repurposing offers various advantages over traditional approach for drug developers/ scientist along with safer and effective medicines for patients. Several existing drug that have been successfully modified for repositioned to a new indication of use, with

**Lipsa Samal et al.**

the most distinguished of them being viagra and thalidomide, which have engender authentically of high revenues and expenditure. Drug repurposing can be seen as a business opportunity/ criteria for clinical research and pharmaceutical companies, serving both challenges and opportunities of drug repurposing. In addition to this, Drug repurposing can be extended to provide a lower risk of cost effectiveness repurposing model for clinical research and pharmaceutical companies and illuminate the novel cooperative business occasion that help drug repositioning of existed and marketed candidate. [2, 9]

### **Drug repurposing in India**

In India, Drug repurposing overlay various diseases like tuberculosis, Human Immune deficiency Virus- Acquired Immune Deficiency Syndrome, Malaria, Leprosy, Lymphatic disorder, Visceral Leishmaniasis known as kala- azar. Apart from these this process also covers some lifestyle orientated diseases like diabetes mellitus, hypertension and cancer. Various pharmaceutical companies are reluctant to eagerly invest in research and development of drugs for various infectious diseases in drug repurposing, even now in COVID- 19 cases. Now drug repurposing in India take over global initiatives based on public private partnership mod; medicine for tropical, orphan and neglected diseases. [1, 2, 9, 10]

### **Benefits of drug repurposing**

- Less risky- the chance of failure due to adverse side effect is reduced
- Faster – patients with terminal cancers, orphan diseases and other incurable conditions often do not have a decade to spare.
- Cheaper- more patients will have access to and be able to afford their medication.[10, 11]

### **Barriers to drug repurposing**

- Lack of financial incentives
- Undermines existing market
- Legal and intellectual property issue
- Still a risky business
- Scientists rewarded for originality content [10, 11]

## **CONCLUSION**

Now pharmaceutical and clinical research industries is look forward to explore their full potential for the lead compound at a much earlier stage of development of drugs, even if in late stage of preclinical development, it offers additional option and opportunities for these companies. Drug repurposing is expected and also provide value to the product development and securities of the drug research companies and maximize the ability to provide new and low cost treatment/ prevention options for a multitude of serious and neglected diseases. Since drug development involves series of multiple process, time and huge investment, thus this type of innovative and creative ideas and novel concepts definitely will speed up the drug discovery and development process.

## **ACKNOWLEDGMENTS**

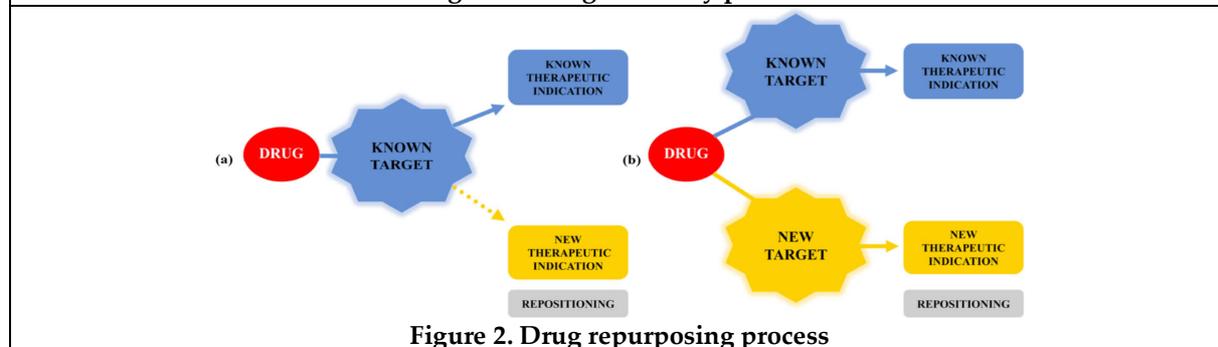

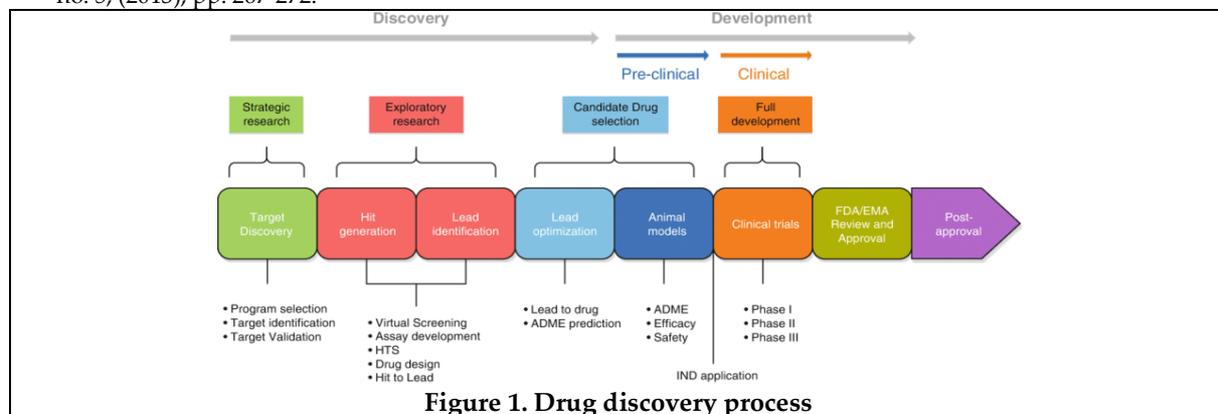

The authors would like to acknowledge Centurion University of technology and management, Odisha, India for encouraging to do some work in the recent advancement of drug repurposing.

### **ABSTRACT**

Plants have been widely used as herbal remedies due to the presence of many active phytoconstituents. Numerous plants have been used for years in daily life to treat diseases across the world. In the present study, our result showed antimicrobial activity of *Azadirachta indica* against gram negative pathogenic bacteria (*Escherichia coli*, *Salmonella typhi* and *Vibrio cholerae*) and gram positive bacteria (*Bacillus subtilis*). Leaves of *Azadirachta indica* were collected from the fields of Botanical Garden in school of pharmacy and life sciences, centurion university, Bhubaneswar and pure cultures of the test organisms for the antimicrobial study were procured from the Dept. of Microbiology, centurion university, Bhubaneswar. In our study all the micro organisms were screened for their antibacterial activity against leaf extract of *Azadirachta indica* by agar well diffusion method. Here we revealed that the leaves extract of *Azadirachta indica* showed more Zone of inhibition against *Vibrio cholerae* and *Bacillus subtilis*, as compared to *E.coli* and *S.typhi*. Our research confirms further need to explore the impact of neem leaves on antimicrobial activity.

**Keywords:** *Azadirachta indica*, Antimicrobial activity, pathogenic microorganism, leaf extract.

### **INTRODUCTION**

Various parts of neem tree were used in traditional medicine due to the presence of many pharmacological active constituents. Its twigs are commonly used as chewing stick and are widely used in the Indian sub-continent. Earlier studies confirm the numerous medicinal properties of various parts of neem (Maragatharavalli et al., 2012). Aqueous extract of neem leaf has effective against IDDM and NIDDM due to its antihyperglycemic activity (Mossadek and Rashid, 2008; Patil et al., 2013). Another study revealed that neem leaves could control the airborne bacterial contamination in the residential areas (Saseed iand Aslam, 2008; El-Mahmood et al., 2010). Alcoholic extract of neem

23569

**Jyoshna R. Dash et al.**

flower showed the antifertility activity due to its partial block in ovulation in sprague Dawley rats (Gbotolorun et al., 2008). Nimbin is the first bitter active compound isolated from neem oil and more than 135 compounds have been isolated from different parts of neem (Ganguli, 2002). Numerous medicinal properties of the plant *Azadirachta indica* were studied by several researchers. They were anti-pyretic (Okpanyi and Ezeukwk,1981; Khattakiet al.,1985), anti-malarial and anti-tumour effect(Fujiwara et al.1982), anti-ulcer effect (Pillai and Santhakumari, 1984), anti-diabetic effect(Patil et al., 2013), anti-fertility effect(Sinha et al.,1984), effect on central nervous system and antioxidant activity. Another study investigate the excellent antiseptic properties of boiled neem leaves to clean wounds, soothes, swellings and eases skin problems (Bonjar and Holland, 2004). Here we evaluate the antibacterial activity of neem parts against pathogenic bacterial strains.

## MATERIALS AND METHODS

### Collection of plant material and extract preparation

Leaves of *Azadirachta indica* were collected from the fields of Botanical Garden in school of pharmacy and life sciences, centurion university. The collected plant material was brought to the laboratory and shade dried and then blended into powder by mixture blender. The powder is then passed from the sieve to get the equal size particles. The powder should be kept in air tight container at the moisture free place in aseptic condition. About 30g of powder is accurately weighed and transferred to the conical flask containing 200mL distilled water and shaken well and powder mixed properly in water. Then kept the flask containing the mixture of powder and water is put on room temperature on aseptic condition for 7 to 8 days. Then extracted and filtered by using muslin cloth and Whatman filter paper. The filtered liquid is centrifuged at 4,000rpm for 5min and the pure extract was obtained in form of supernatant. This obtained extract was kept at 4°C for further experiments.

### Isolation of test organisms

The test organisms used for antimicrobial study were obtained from the Dept. of Microbiology, school of pharmacy and life sciences, centurion university, Bhubaneswar. Test organisms were cultured on nutrient agar slant medium. The cultures were maintained by sub-culturing periodically and preserved at 4°C prior to use.

### Antibacterial activity

The test organisms were screened for their antibacterial activity against leaf extract of *Azadirachta indica* by agar well diffusion method. The antimicrobial agent was allowed to diffuse out into the medium and interact in a petri plate freshly spreaded with the test organism. Antibacterial activity was performed by using Muller-Hinton agar.

### Preparation of stock solution

Stock solution of the extract was prepared to carry out the antimicrobial activities against selected cultures. For the preparation of the stock solution, 1g of the leaves extract was accurately weighed and dissolved in 10ml DMSO; giving concentration of the stock solution as 100 mg/mL. This solution was then centrifuged and supernatant liquid was collected in a separate test tube, covered with paraffin wax and stored at 4°C for further experiments.

### Agar well diffusion method

The Muller-Hinton agar plates were prepared for conducting the antibacterial activity of leaves extract of *Azadirachta indica*. About 0.1mL of the fresh 18h old broth culture was spread on the respective media. The wells were open with the help of sterile forceps. Then 100µL of original stock solution was added by using micropipette in each well. The final concentration in the well was 1mg/mL. The extract was allowed to diffuse and kept at room temperature for 30min and then 37°C for 24h.

Jyoshna R. Dash *et al.*

## RESULTS AND DISCUSSION

In our study the antibacterial activity of leaf extract of neem was evaluated against both gram positive and negative bacteria. Our investigation revealed that leaf extract of *Azadirachta indica* showed more zone of inhibition against *Vibrio cholerae* and *Bacillus subtilis*, as compared to *E. coli* and *S. typhi* (Table 1, Fig. 2a-d).

## CONCLUSION

In conclusion we have explored the antibacterial effects of neem leaves extracts against four different pathogenic bacteria. *Azadirachta indica* extract is an excellent source of active compounds having anti-microbial, anti-oxidant, anti-tumor, anti-malarial, anti-fungal, anti-inflammatory and anti-viral properties. In our study it provides the evidence that leaves extracts of neem can be used as antibacterial agents against various pathogenic bacteria. We can therefore affirm that in vitro studies provide mounting evidence that *Azadirachta indica* leaves extract may have beneficial effects to fight against various pathogenic bacteria.

## ACKNOWLEDGEMENTS

Authors are highly thankful to The Principal and Head, school of pharmacy and life sciences, Centurion University of Technology and Management, for providing laboratory facility and infrastructure.

### ABSTRACT

The key objective of this analysis was to compare & evaluate the feasibility of to prepare for oral disintegrating tablets of Valsartan using natural disintegrating agents like mucilage of *Cassia tora* and *Carica papaya* powder by direct compression method. *Cassia tora* mucilage and *Carica papaya* powder are extracted from raw seeds and tested separately using different concentrations (5 %, 10 %, 15 %, and 20 % w/w) for their physico-chemical properties in Valsartan tablets. The formulations obtained from above manner were evaluated for pre-compression, post-compression parameters and compared. According to the data acquired from the evaluated parameters the formulation F<sub>CM7</sub> (15% mucilage of *Cassia tora*) was found to be best and showed superlative disintegration and dissolution criteria. Accelerated stability studies on optimized formulation 40±0.50° C and 75±0.5 % RH were conducted for three months and analysed at 1, 2 and 3-month intervals of the physical parameters, disintegration time and drug content.

**Keywords:** Valsartan, *Cassia tora*, *Carica papaya*, Oral Disintegration Tablet, Comparative studies.

### INTRODUCTION

Owing to its convenience of self-administering, compactness and easy manufacturing, the route of administration through orally is measured as one of the most broadly recognized route. The oral disintegrant tablets (ODT) are designed to disintegrate or dissolve quickly when in contact with saliva, without the need for water, making them beneficial to traditional tablet formulations (1). ODTs are simply ingested by placing them on the tongue, thereby eradicating the need to chew the tablet, swallow an intact tablet or by help of water. New ODT technologies resolve numerous patient and pharmaceutical concerns such as improved lifecycle management, especially for pediatric, subconscious geriatric and psychiatric patients who have difficulty swallowing traditional tablets and capsules (2). It offers better stability, appropriate dosing, ease of manufacture, reduced packaging size; self-administration during

**Ladi Alik Kumar et al.**

the journey is possible, as no water is needed. However, the most noticeable limitation of widely used oral dosage forms such as tablets and capsules is difficulty in swallowing, leading to non-compliance with patients, and it also applies to people who are ill in bed and active working patients who are busy or traveling, particularly those without water. *Cassia tora* is a common annual herbaceous weed available in all over of India and belongs to the Leguminosae family. The seeds of the plant are suitable for tablet binder when comes in contact with water(4). *Carica papaya* plant is a large, single-stemmed herbaceous perennial tree having 20–30 feet height. Fruit of the *Carica papaya* possess carotenoids ( $\beta$ -carotene), lycopene, anthraquinones glycoside belongs to family Caricaceae (5).

## MATERIALS AND METHODS

Valasartan materials were collected from Hetero Laboratories, Baddi, (H.P.) Pearlitol SD 200, Croscarmellose Sodium obtained from Lotus chemicals, Vizag, Sorbitol, Magnesium Stearate obtained from Mumbai Fine Chemicals. *Cassia tora* and Papaya purchased from the local market. All the chemicals and reagents used in this experiment were analytical grade.

### Extraction of *Cassia tora* Mucilage

*Cassia tora* seeds were primarily immersed in enough water for a period of 10 hours. The resulting hydrated mucilage was then spread together with seeds onto the stainless steel tray as a thin layer and dried in an oven at 50°C for 4–5h. The dried mucilage was scraped from the tray by blade, and isolated from the seeds by passing 18 mesh sieve. The mucilage was further purified by winnowing to separate the seed husk.

### Extraction of *Carica papaya* Starch Powder

Unripe papaya bought from a nearby market, and the starch had been removed. The papaya pulp was extracted, dried, ground, and blended with a solution of 0.05 per cent w / v. The mass was then allowed for squeezed via muslin cloth and several times washed with saline solution to eliminate the present soluble substances, starch, and mucilage. The mass obtained was then repeatedly washed until the supernatant solution became clear. The starch from the sediment was washed with distilled water until neutral pH. It was then sieved, dried and milled to fine powder at room temperature. Extracted *Cassia tora* mucilage and *Carica papaya* starch powder studied for physico-chemical properties shown in Table 1.

### Formulation of oral disintegrating tablets [6]

In this investigation Valsartan ODTs were formulated by direct compression method using both isolated *Cassia tora* and *Carica papaya* starch powder at different concentrations of 5%, 10%, 15%, and 20% w/w. All the ingredients were passed through 60 mesh sieve before making formulation. Precise amounts of all the ingredients were weighed and combined carefully to produce a consistent mixture. 200 mg tablets were punched using Cadmach single station punching machine with 10 mm round flat punches. The composition of the formulations is shown in Table 2.

### Evaluation of Blend

#### Angle of Repose

Angle of repose was measured by using fixed funnel method. The funnel was fixed at height (h) where the tip of the funnel is secured above graph paper placed on the horizontal flat surface. The blend was forced through a funnel that can be lifted vertically until it obtained a full cone height (h). The heap radius(r) was determined, and the angle of repose was estimated.

$$\theta = \text{Tan}^{-1} \left( \frac{h}{r} \right)$$

Ladi Alik Kumar *et al.*

### Bulk Density and Tapped Density

An exactly weighed quantity of 10gm of powder from separately each formula, formerly evenly shaken to break if any agglomerates formed, was placed into a 20ml measuring cylinder. After the initial volume ( $V_0$ ) was observed, the cylinder was allowed to fall under its own weight onto a solid surface from the height of 2.5cm at 2sec intervals. The tapping was continued till no additional change in volume ( $V_f$ ) was noted. The bulk density and tapped density were evaluated by using the following equation.

$$\text{Poured density} = \frac{W}{V_0}$$

$$\text{Tapped density} = \frac{W}{V_f}$$

Where,

W = weight of the powder

$V_0$  = initial volume

$V_f$  = final volume

### Carr's Index

Carr's index is a significantly important phenomenon for determination of flowability of powder blend. It can be obtained by substituting the bulk density and tapped density values in the following equation.

$$\text{Carr's index (\%)} = \frac{\text{Tapped density} - \text{Bulk density}}{\text{Tapped density}} \times 100$$

### Hausner's Ratio

The ratio between both the tapped and bulk density indicates the flow properties of powder through Hausner's ratio [7].

$$\text{Hausner's Ratio} = \frac{\text{Tapped density}}{\text{Bulk density}}$$

### Evaluation of Oral Disintegration Tablets

#### Weight Variation

The weight variation test was carried out individually by weighing 20 tablets and by measuring average weight. By comparing individual weight with average by the following equation.

$$\% \text{ Weight Variation} = \frac{(\text{Average Weight} - \text{Individual Weight})}{\text{Individual Weight}} \times 100$$

### Hardness

The mechanical strength of the tablet is determined by the Monsanto hardness tester. Six tablets were taken randomly and kept between the jaws, and pressure is applied by screwing its base, which is connected to the lower jaw. The force required to break a tablet into pieces can be expressed in ( $\text{kg}/\text{cm}^2$ ) [8].

Ladi Alik Kumar et al.

### Friability

A sample of twenty pre-weighed tablets was taken in the plastic chamber of laboratory friabilator. These tablets are subjected to abrasion or shock, which was initiated by the rotation of the chamber at 25 rpm for 4 min. The tablets were dusted and weighed again for final weight. The percentage friability can be calculated by using the following formula [9].

$$\text{Percentage Friability} = \left[ \frac{(\text{Initial Weight} - \text{Final Weight})}{\text{Initial Weight}} \right] \times 100$$

### Disintegration test

One tablet from the each formulation was picked up and placed in each tube of disintegration apparatus without disk, containing 900ml of pH7.4 phosphate buffer at  $37 \pm 2^{\circ}\text{C}$ . The time required to disintegration of tablet was noted.

### Wetting Time

A simple procedure is carried out to determine the wetting time. A tissue paper of 10 cm diameter is placed in the petridish containing 10ml of water soluble dye. The tablet was carefully placed on the top of the tissue paper [10]. The required time taken by the water to reach the surface of the tablet is noted.

### Water Absorption time

Water absorption time can be measured by taking weight of the tablet before keeping in the petridish noted as ( $W_b$ ), the wetted tablet is taken out and reweighed and noted as ( $W_a$ ). The water absorption, R can be calculated by below equation [11].

$$R = 100 (W_a - W_b) / W_b$$

Where  $W_a$  = weight of tablet after absorption

$W_b$  = weight of tablet before absorption

### Dissolution rate study

*In-vitro*, drug release was studied in the USP (Electro-Lab TDT-06L) six station dissolution apparatus. 900ml of phosphate buffer pH 6.8 was taken as dissolution media maintained at  $37 \pm 0.5^{\circ}\text{C}$ . Paddles are inserted into dissolution media, which was rotated at 50rpm. 5ml of dissolution media was withdrawn through a filter  $0.45 \mu\text{m}$  at each time intervals. Samples are diluted with 1%w/v and assayed for Valsartan at  $\lambda_{\text{max}}$  209nm using UV spectrophotometer. Fresh fluid was replaced into the dissolution medium after withdrawn [12].

### Kinetic studies on dissolution rate

The drug release kinetic was studied with plotting cumulative % drug released vs. time, log % drug remained vs. Time as zero order and first order kinetic respectively. From the slopes of linear plots, dissolution rate constants (k), correlation coefficients (r) and half-lives were calculated [13].

### Stability study

The selected formulation  $F_{CM7}$  (15% *Cassia tora*) and  $F_{PM7}$  (15% *Carica papaya*) were subjected to stability studies. The ODT was stored at  $40 \pm 0.5^{\circ}\text{C}$  and  $75 \pm 0.5\%$  RH, for 3 months and analysed for their physical parameters, disintegration time and drug content at 1, 2 and 3 month interval [14].

Ladi Alik Kumar *et al.*

## RESULTS AND DISCUSSIONS (15-18)

In this present study, the effect of disintegration between the two disintegrants (*Cassia tora* and Carica starch powder) had compared. The both disintegrants selected for formulation are characterized and subjected to physico-chemical properties shown in table 2. Both mucilage and starch powder were showing good flow properties with % yield more than 30% and having well been swelling properties and soluble in water. As the both disintegrating agents were from natural sources might be contaminated from microorganisms, will significantly modify the properties of dosage form.

So the microbial load is a key issue for the appropriateness of the materials for the use as pharmaceutical excipients. The overall aerobic counts for bacteria and fungi were within the limit for both additives (as per IP aerobic count < 1000cfu/gm and fungi count < 100cfu/gm). Valsartan ODTs were prepared by direct compression method. In the formulations perlitol SD-200 was used as a direct compressible vehicle and sorbitol as diluents and humectants, whereas talc, aerosil were used as glidant and magnesium stearate as lubricant. Aspartame, Vanilla was used as sweetening agent and flavour respectively. The pre-compression parameters such as bulk density, tapped density, angle of repose and Carr's index were conducted. The poured density was in the range of 0.425 to 0.661(gm/cm<sup>3</sup>) and tapped density was in the range of 0.525 to 0.752(gm/cm<sup>3</sup>). Furthermore the angle of repose found in the range of 21.56 to 31.21 was below 40° indicates good flow properties. In addition, the Carr's index were in range of 11.23 to 25.69 respectively showing good flow properties of powder blend.

From the above results, it was concluded that the powder blends showed excellent flow properties and summarized in Table 3. The post compression parameters such as thickness, hardness, friability, wetting time, disintegration time were conducted and shown in Table 4. It is well known that hardness is directly proportional to disintegration time. Since the mechanical strength has a significant role in formulation of ODTs, the hardness of all formulations was found in the range of 2.9±0.52 to 3.3±0.11 (Kg/cm<sup>2</sup>) and this indicates good mechanical strength. Friability was observed in the range of 0.32 to 0.68% is below 1% indicates within the limits. The content uniformity was high (≤101.3±0.13) shows within the acceptable limits. Thickness of tablets was in the range of 3.0±0.27 to be 3.1± 0.71mm. The disintegration time values show an optimized formulation from both disintegrants at specific concentration, i.e. F<sub>CM7</sub> and F<sub>PM7</sub> provide less time to disintegrate, which is primary requirement of ODTs formulation.

The in-vitro dissolution study was conducted in phosphate buffer pH 6.8 for all formulations shown in Table 5 and Fig 3. The formulations F<sub>CM7</sub> and F<sub>PM7</sub> showed highest dissolution. The drug release of Valsartan follows first-order kinetics, which clearly shown linear graph on the plot between % drug released and time shown in Table 6 and Fig 4. In-vitro dissolution kinetics data was calculated and shown in Table.7. By the above data, F<sub>PM7</sub> was found to be optimized formulation for preparation of Valsartan ODT. The selected formulations F<sub>CM7</sub> (15% *Cassia tora* Mucilage) and F<sub>PM7</sub> (15% Caricastach powder) were subjected to stability studies. The ODT was stored at 40±0.5°C and 75±0.5% RH, for 3 months and analysed for their physical parameters, disintegration time and drug content at 1, 2 and 3 month interval shown in Table 8 and Fig 5. According to the stability data, formulation F<sub>PM7</sub> (15% *Caricapapaya* ) is subjected to in-vitro dissolution at 1, 2 and 3rd-month interval shown in Table.9.and Fig .6.

## CONCLUSION

From the present comparative study, finally it was concluded that formulation F<sub>PM7</sub> contains 15% *Caricapapaya* as a natural disintegrant has faster disintegration time and highest dissolution rate among all formulations. Stability studies showed better results in all parameters, studied at 40±0.50C and 75±0.5% RH, for 3 months. Therefore, F<sub>PM7</sub> was an optimized formulation for preparing Valsartan Oral disintegrating tablet.

### ABSTRACT

Nanoformulations (nanodrug) are superior to traditional medicine with respect to control release, targeted delivery and therapeutic effects. Such nanomedicine targeting capabilities are influenced by particle size, surface charge, surface modification, and hydrophobicity. Among these, it is important to determine the size and size distributions of nanoparticles for their interaction with the cell membrane and their penetration across the physiological drug barriers. The size of nanoparticles used to cross different biological barriers depends on the tissue, target site and circulation. For the cellular internalization of the nanoparticles, surface charge is important in determining whether the nanoparticles would cluster in blood flow or would adhere to, or interact with oppositely charged cell membranes. Persistence of nanoparticles is needed in systemic circulation of the body For the targeted delivery. But the fixed macrophages of the mononuclear phagocytic system organs rapidly opsonize and massively clear the conventional nanoparticles with hydrophobic surface. The surface of conventional nanoparticles are modified with different molecules to improve circulation time and persistence in the blood. Coating of hydrophilic polymers can create a cloud of chains at the particle surface which will repel plasma proteins. Finally, morphological characteristics, surface chemistry, and molecular weight influence the performance of nanoparticles in- vivo. Surface modified nanoparticles have anti-adhesive properties by virtue of the extended configuration on the particle surface which acts as steric barrier reducing the extent of clearance by circulating macrophages of the liver and promoting the possibility of undergoing enhanced permeation process. Release mechanism can be modulated by the molecular weight of the polymer used. Higher the molecular weight of polymer slower will be the in- vitro release of drugs. Nanoparticles are receiving considerable attention for the delivery of therapeutic drugs. The literature emphasizes the advantages of nanoparticles over microparticles and liposomes.

**Keywords:** Nanoparticle, ocular, current trends, drug delivery, controlled release.

## INTRODUCTION

In the delivery of ophthalmic drugs rapid elimination of the dosage form is the main problem thus reducing the residence time of drug product, for which frequent instillation dosage is required. Frequent instillation of dosage form may create systemic toxicity and side effects. Therefore a controlled and prolonged delivery is necessary. The idea for controlled drug delivery system, which was a bystander for a time being, paved the way for a nanoparticulate drug delivery system. To circumvent the complex anatomical structure of human body this type of drug delivery system can be a better way. As the human body or finely speaking the cell is concerned, is accustomed to take foreign matters in finest form as per the permeability is concerned. Drug to be delivered to a particular site is entrapped in a polymeric matrix as particulates. The particulate could be in nano form (nanocapsules, nanocrystals or nanoparticulate).

Albert Franks, an early promoter of nanotechnology, defined it as the field of science and technology in which dimensions and tolerances range from 0.1 to 100 nm (1). Drug delivery system containing nanoparticles have made a significant increase in targeting of drugs to organs having special pharmacokinetic properties and also nanoparticulate drugs have much more surface area, making the drug more bioavailable. With this concept in mind nanoparticulated drugs are playing a major role in ocular drug delivery system. Nanoparticles receive considerable attention when supplying therapeutic drugs. The literature highlights nanoparticles' advantages of over microparticles and liposomes. Nanoparticles submicron size offers a number of distinct advantages over microparticles, including relatively higher intracellular absorption compared to microparticles.

The surface of nanoparticle is also a very important consideration when it comes to targeting drug delivery. In fact, once in the bloodstream; the fixed macrophages rapidly opsonize and massively clear conventional nanoparticles (no surface modifications) and negatively charged particles. It is well known that the reticuloendothelial system, primarily the liver and spleen, is a major obstacle to active targeting due to its ability to identify these systems, eliminate them from systemic circulation and thus prevent the effective delivery of the nanospheres to organs other than those of the reticuloendothelial system. Surface modification of these hydrophilic polymers nanoparticulate systems is the most common way of controlling the opsonization process and improving the surface properties of the system, or coating modifications with polymers, such as the attachment of polyethyleneglycol (PEG) chains to biodegradable polymer such as polylactic acid (PLA) and polylactic-co-glycolic acid (PLGA). The hydrophilic PEG chains thus enable protein and peptide absorption to be controlled and, in addition enable regulation of cell behavior at the polymer surface (5).

These nanoformulations drugs (nanodrug) are superior to traditional medicine with regard to release control, targeted delivery and therapeutic effect. These nanomedicine targeting capabilities of are affected by particle size, surface charge, surface modification, and hydrophobicity. Among these, it is important to determine the size and size distributions of nanoparticles for their interaction with the cell membrane and their penetration across the physiological drug barriers. The size of nanoparticles used to cross various biological barriers depends on the tissue, target site and circulation. For the cellular internalization of nanoparticles, surface charging is important in determining whether the nanoparticles would cluster or adhere to blood flow or interact with cell membranes charged to the opposite end. Persistence of nanoparticles is needed in the systemic circulation of the body for targeted delivery. But the fixed macrophages of the mononuclear phagocytic system (MPS) organs are rapidly opsonizing and massively clearing typical nanoparticles with a hydrophobic surface. The surface of conventional nanoparticles is modified with different molecules to increase the circulation time and persistence in the blood. Coating of hydrophilic polymers at the particle surface can create a cloud of chains that will repel plasma proteins. Finally, morphological characteristics, surface chemistry, and molecular weight influence the performance of nanoparticles in- vivo. Surface modified nanoparticles have anti-adhesive properties due to the extended particle surface configuration that acts as steric barrier minimizing the degree of clearance by circulating liver macrophages

**Shubhashree Das et al.**

and promoting the possibility of enhanced permeation. The molecular weight of the polymer used can modulate the release mechanism. Higher the polymer's molecular weight slower would be drug release in- vitro (12). The development of hydrophilic drug delivery strategies emerges as an important research area for several reasons: (i) increasing interest in macromolecules, such as nucleic acids, peptides or proteins, for the treatment of a wide range of diseases such as cancer, infectious and inflammatory diseases, and (ii) the importance of small, hydrophilic drugs currently under production. It is clear that when macromolecules and small drugs are administered the problem is different. Therefore, although the discovery of macromolecules has opened up many perspectives in therapeutics, their use is often limited by low bioavailability due to their poor stability against proteolytic and hydrolytic degradation, low barrier permeability across and short biological half-life in the circulatory system, whereas the use of small, hydrophilic drugs such as anticancer agents is often associated with harmful side effects, or improper bio distribution. For several years, nanomedicines have been used for many years to encapsulate and target drugs to get through those crucial points. Drug encapsulation in colloidal systems offers many benefits, such as: (i) protecting the drug against in- vivo degradation, (ii) reducing the potential toxic side effects of direct solution administration, (iii) increasing patient comfort by avoiding repetitive bolus injections or using perfusion pumps, and (iv) achieving more favorable drug pharmacokinetics (2).

**Rationale**

The drug is applied to the surface of the eye for two purposes: to treat the outside of the eye for such infections as conjunctivitis, blepharitis, keratitis sicca and to treat diseases such as glaucoma or uveitis intraocularly via the cornea. The majority of ocular diseases are treated as eye-drops with topical application. For soluble drug eye drops require frequent instillations of highly concentrated solutions. The practical reasons for choosing solutions are the generally favorable cost advantage, the greater simplicity in the development and manufacturing of formulations and the patient's strong acceptance despite a little blurring (3). Upon instillation of an eye drop, usually less than 5% of the drug used penetrates the cornea and reaches intraocular tissues, whereas a large fraction of the instilled dose is often systemically absorbed through the conjunctiva and nasolacrimal duct (4). Therefore repeated formulation administration is needed. Prolonged dosage forms of action can modestly increased bioavailability and duration of activity, but patients have not gained broad acceptance. Even from the modified formulations the absorption of the ocular drug is restricted by the eye's corneal and conjunctival epithelial barriers.

Topical ocular drugs do not reach the drug targets of the posterior segment. High doses of drugs given intravenously or by intravitreal can be used to treat the posterior segment. There is currently a rapidly increasing interest in the posterior segment drug delivery. This is caused by the advances in understanding the retinal and choroid pathophysiological processes. Many posterior segment diseases (age related macular degeneration, retinitis pigmentosa, diabetic retinopathies and glaucoma-induced neural changes) cannot be effectively treated using current methods. Delivery of both small molecules and larger bio-organic compounds such as proteins and DNA in the posterior segment is problematic. Only drugs with large therapeutic index (such as antibiotics) can be administered to blood stream in massive doses for treatment of the posterior segment. On the other hand, intravitreal injection is an invasive procedure, and may even cause endophthalmitis. Hence, for large numbers of patients, it is not considered to be an ideal method of drug administration.

There is therefore an increasing interest in developing new, prolonged action dosage forms for subconjunctival and periocular administration. The residence time of the drug is much more important, which depend upon the property of the vehicle used in the formulation of dosage form. Furthermore, there is also possibility of over flowing of excess amount of drug through the nasal route and systemic circulation. Thus increasing the chances of systemic toxicity (5). It is known that for most of the drugs applied ocularly are having the elimination rate constant much greater than the absorption rate constant, thus, showing a flip-flop model. Reducing the dose volume from 25 microliter to 0 brings a fourfold improvement in bioavailability (6). But it is practically impossible to have zero dosing volume. It can be concluded that instead of adding much more volume of drugs, appropriate vehicle should be introduced so that drugs could be incorporated into it easily and show a sustained release profile.

**Shubhashree Das et al.**

As the name indicates, nanoparticles have more surface area than particles having nano size range. They also have a long shelf-life, safe materials, including synthetic biodegradable polymers, natural biopolymers, lipids and polysaccharides, and have the potential to overcome major mucosal barriers, such as the intestinal, nasal and ocular barriers (7).

**Findings of various workers**

Nanoparticles were revealed to be effective as ocular drug delivery systems by prolonging the duration of the drug action. The first experiment included piloplex systems using a poly (methyl methacrylate-acrylic acid) copolymer consisting of pilocarpine-loaded nanospheres (8). Piloplex has lowered the intra-ocular pressure in clinical trials (9). Wood et al. (1985) showed that after administration of poly alkyl cyanoacrylate (PACA) nanospheres labeled with [14]-C to rabbit, the degradation of nanoparticles in tears occurred at a relatively rapid rate for the first hour with a degradation of about 19 percent. It was interesting to note that in the cornea and conjunctiva, only 0.1 percent of the initial amount was found. However, after instillation, that concentration was relatively constant for 6 h. This result suggested that nanospheres adherence to the corneal and conjunctival surfaces was possible (10). Further research was carried out by Harmia et al. (1986), studying pilocarpine containing polybutylcyanoacrylate nanospheres.

Two formulations were tested: the first containing pilocarpine within the matrix of the particle, the second containing pilocarpine adsorbed onto the particle surface. For both formulations the intensity of miotic response was same. However, the formulation on the surface of the particle containing the drug retained the effect for a longer time. As described above, the result, which was not significant with pilocarpine included within the nanospheres, was associated with a slow and incomplete degradation of the polymer in tears (11). Diepold et al. (1989) made the same conclusions when pilocarpine nitrate loaded onto nanospheres (12). These results were confirmed in a poly butyl cyanoacrylate nanospheres study (13).

The lipophilic nature of the drug (progesterone) resulted in an encapsulation rate in the carrier of about 100 percent, but the drug's strong affinity for the polymer and the polymer's slow degradation did not provide an adequate release of the drug. Thus, the main problem with the use of alkylcyanoacrylate nanospheres appears to be very slow drug release out of the matrix compared to the particle's residence time in the precorneal area. The same experiment was carried out with the incorporation of a hydrophilic antibiotic, amikacin sulfate into poly-isobutylcyanoacrylate nanospheres (14). Increase the concentration of amikacin in the aqueous humor and cornea was statistically important with respect to the control solution for nanospheres. The matrix system used for hydrophilic drugs was limited due to a slow drug desorption from the polymeric nanospheres. Such findings are in line with the conclusion of Marchal-Heussler et al. (1990), which found that surface charge and the binding form of the drug to nanospheres were the most significant factors in enhancing another drug's therapeutic response, betaxolol (15).

The same authors compared the efficiency of nanoparticles in further studies as a function of the polymer that constitutes the drug delivery system. In various nano formulations, Marchal-Heussler et al. (1992, 1993) tested poly-ε-caprolactone, polylactic-co-glycolic acid copolymers and poly-isobutylcyanoacrylate polymer. The decrease in intraocular pressure of antiglaucomatous drugs such as betaxolol and carteolol has become more pronounced with poly-ε-caprolactone (nanospheres or nanocapsules) used by colloidal carriers. The hydrophobic the carrier seems to be, the higher the drug's ocular activity. The mechanism of action appeared to be directly related to the agglomeration in the conjunctival sac of the poly-ε-caprolactone nanoparticles. In addition, the nanocapsules showed a better effect for poly-ε-caprolactone than nanospheres, probably because the entrapped drug was unionized in the oily core of the carrier and could spread more frequently into the cornea.

It appears that diffusion of the drug from the oily phase to the corneal epithelium is more efficient than diffusion from the nanospheres internal matrix. This new method of dosage form provided an improved therapeutic effect with a much lower concentration of drugs, thereby reducing systemic effects (16, 17). Losa et al. (1991, 1992, 1993) proved this by integrating the ophthalmic administration of metipranolol in either poly-ε-caprolactone or

**Shubhashree Das et al.**

polybutylcyanoacrylate nanocapsules (18, 19, 20). In an ex-vivo study, Le Bourlais et al. (1997) showed that poly-isobutylcyanoacrylate nanocapsules increased bovine corneal absorption of cyclosporin (5.8%) compared to an oily vehicle as the control (2.5%) (21). They also found that there was minimal penetration of the drug into the cornea with a partitioning that was basically located on the epithelium's superficial layers and no complete penetration (22, 23, 24). Alonso et al. (1995) showed that poly-ε-caprolactone nanocapsules, nanospheres and nanoemulsions provided two lipophilic drugs (cyclosporin and indometacin) for corneal absorption.

They showed that compared to the oily solution, the corneal absorption of cyclosporine was five times superior with poly-ε-caprolactone nanocapsules (25). Calvo et al. (1996) compared corneal penetration through isolated cornea using encapsulated nanoparticles of indomethacin, poly-ε-caprolactone nanocapsules and emulsions of submicron indomethacin. The increased penetration for the three formulations examined during the 6 h of the study was more than 3-fold than that of the commercial eye-drops. The authors concluded that the principal factor responsible for indomethacin's favorable corneal transport was the colloidal character of these carriers, rather than their internal structure or composition (26). Most authors accepted that nanoparticles don't tend to be responsible for corneal toxicity or irritation. Some authors (Marchal- Heussler et al., 1992, 1993; Calvo et al., 1994; Zimmer et al., 1991), however found that PACA nanoparticles damaged the corneal epithelium by disrupting the cell membranes. However, they did not mention any toxicity to the corneal epithelium cells in their observations of PELC nanocapsules (16, 17, 27, and 28). In conclusion, the results of the various studies demonstrate the potential of colloidal systems as ocular drug delivery systems for either hydrophobic or hydrophilic drugs in liquid dosage forms that do not interfere with vision.

Keeping these things in eye novel nano particulate system have been developed enhancing the hosting capacity, targeting to the site etc. These are explained below briefly SLN (solid lipid nanoparticle), NLC (nanostructured lipid carrier), LDC (lipid drug conjugate) (29, 30). SLN This type of particulate form is having following advantages. Excellent physical stability, protection of incorporated labile drugs from degradation, controlled drug release, good tolerability, site specific targeting. Though some amount of novelty has been brought forward still some lacuna has been found out. They are insufficient loading capacity because incorporated drugs are located between fatty acid chain thus forming highly ordered crystal lattice, so less accommodation. Drug explosion after polymeric transition during storage (29).

NLC To overcome the above mentioned disadvantages NLC was introduced (31). The problem regarding the accommodation of drug molecules was solved by this particulate system. This particulate system denied the crystal lattice formation of the lipid outer layer. This was achieved by three methods like adding spatially different lipid glycerides composed of different fatty acids. Thus leading to an imperfect NLC. The best hosting was achieved by mixing the solid lipids with small liquid lipid. In the second formulation type the drug was dissolved in the lipid environment and it was entrapped in the solid lipid envelope the solid envelope provides a protecting environment around the lipid. This type is multiple NLC. Since drug explosion is caused by ongoing crystallization and transformation solid lipid. This paved the way for again modulation of the particulate system thus an amorphous type of NLC which was created by not adding hydroxyoctacosanylhydroxystearate and isopropylmyristate (60) (32).

LDC SLN are useful for lipophilic drugs incorporation. only highly potent hydrophilic drugs that are effective in low concentrations can be firmly incorporated into solid lipid matrix due to partitioning effects during the development process (33). The so called LDC nanoparticles with drug loading capacity of up to 33% were developed at the end of the millennium to overcome this limitation (30). An insoluble drug-lipid conjugate bulk is prepared either by formation of salt or by covalent bonding. The free drug base and fatty acid are dissolved in an appropriate solvent during the salt formation process. The solvent then evaporates under reduced pressure. The drug in the form of a salt and a fatty alcohol reacts in presence of a catalyst for the covalent linking and the LDC bulk is then processed with an aqueous surfactant solution to a formulation of nanoparticle using high pressure homogenization (HPH).

Most notably the interaction of the colloidal carriers with the phagocytes requires some serum components and then subsequently interaction with complement receptors.  $F_c$  receptors and sugar lecithin receptors on the macrophase, lymphocytes or other cells. Due to this type of peculiar drug delivery characteristics the nanoparticulate drug delivery system can be used for drug targeting in critical and special part of the body having peculiar anatomical characteristics. Mainly the drug formulations are administered in the cul-de-sac region of the eye, the drug is absorbed through the conjunctiva or corneal route as per the lipophilicity and hydrophilicity of the drug is concerned.

### Management and control of ocular diseases

The eye is a unique organ, being relatively unprotected as it is constantly exposed to atmospheric oxygen, environmental chemicals and physical abrasion. Anatomically human eye can be broadly divided into anterior segment and posterior segment. The major diseases affecting the eye include retinopathy, diabetic retinopathy, corneal neovascularization, keratitis, conjunctivitis, age-related macular degeneration (AMD), diabetic macular edema (DME), cataract, proliferative vitreoretinopathy (PVR), uveitis, cyto-megalovirus (CMV), and glaucoma. Various classes of drugs, such as antiviral, antibacterial, corticosteroids, sympathomimetics, antioxidants, antihistaminics, carbonic anhydrase inhibitors, angiotensin blockers etc. are widely used as therapeutic agents for the cure of these ailments (7).

### Role of nanoparticulate carrier to overcome the limitations

Prior to understand nanoparticle and its role in ocular drug delivery we should have a brief idea about ocular anatomy and drug transportation channels. The most prominent method of ocular drug delivery is to deliver the drug in to the cul-de-sac. Absorption may be corneal or non corneal at this site. The so called non corneal route of absorption involves penetration into the intra ocular tissues through the sclera and conjunctiva. This absorption mechanism is usually non-productive, as drug penetrating the surface of the eye beyond the limbus of the corneal sclera is taken up by the local capillary beds and added to the general circulation. In general, this non-corneal absorption prevents entry into the aqueous humour.

Non corneal absorption may be significant for drug molecules with poor corneal permeability. Studies with inulin, timolol maleate, gentamicin, and prostaglandin  $PGF_{2\alpha}$  suggest that these drugs gain intraocular access by diffusion across the conjunctiva and sclera. The noncorneal route of absorption may be significant for poorly cornea-permeable drugs; however, corneal absorption represents the major mechanism of absorption for most therapeutic entities. Topical absorption of these agents is considered to be rate limited by the cornea. The anatomical structure of the cornea exerts unique differential solubility for drug candidates. In terms of transcorneal flux of drugs, the cornea can be viewed as a trilaminar structure consisting of three major diffusional barriers: epithelium stroma and endothelium. The epithelium and endothelium contain on the order of 100-fold the amount of lipid material per unit mass of the stroma. Depending on the physicochemical properties of the drug entity, the diffusional resistance offered by this tissue varies greatly.

The outer most layer, the epithelium, represents the rate-limiting barrier for transcorneal diffusion of most hydrophilic drugs. The epithelium is composed of five to seven cell layers. The basement cells are columnar in nature, allowing for minimal paracellular transport. The epithelial cells, however narrow distal to Bowman's membrane, forming flattened epithelial cells with zonulae occludens interjunctional complexes. This cellular arrangement precludes paracellular transport of most ophthalmic drugs and limits lateral movement within anterior epithelium. Corneal surface epithelial intracellular pore size has been estimated to be about  $60\text{\AA}$ . Small ionic and hydrophilic molecules appear to gain access to the anterior chamber through these pores, however for most of the drugs paracellular transport is precluded by the interjunctional complexes to improve ocular bioavailability. This approach has however only met with moderate success and has the potential to severely compromise the corneal integrity.

**Shubhashree Das et al.**

Sandwiched between the corneal epithelium and endothelium is the stroma. The stroma constitutes 85-90% of the total corneal mass and is composed of mainly hydrated collagen. The stroma exerts a diffusional barrier to highly lipophilic drugs owing to its hydrophilic nature. There are no tight junction complexes in the stroma, and paracellular transport through this tissue is possible. The innermost layer of the cornea, separated from the stroma by Descemet's membrane, is the endothelium. The endothelium is lipoidal in nature; however it does not offer a significant barrier to the transcorneal diffusion of most drugs. Endothelial permeability depends solely on molecular weight and not on the charge or hydrophilic nature of the compound. Transcellular transport on the corneal epithelium and stroma is the major mechanism of ocular absorption of topically applied ophthalmic pharmaceuticals.

Nanoparticles provide controlled drug release and prolonged therapeutic effect. For this property the particles have to be retained in the cul-de-sac after topical administration, and the entrapped drug must be released from the particles at an appropriate rate. The utility of nanoparticle as an ocular drug delivery system may depend on optimizing lipophilic-hydrophilic properties of polymer drug system, optimizing rates of biodegradation in precorneal pocket and increasing retention efficiency in precorneal pocket. It is highly desirable to formulate the particles with bioadhesive materials in order to enhance the retention time of particles in the ocular cul-de-sac. Without bio adhesion could be eliminated as quickly as aqueous solution from the precorneal site. Bioadhesive systems can be either polymeric solutions or particulate systems. Several studies using natural bioadhesive polymers demonstrating improvements in ocular bioavailability, synthetic biodegradable and bioadhesive polyalkylcyanoacrylate systems were developed they may prove to be most promising particulate ocular drug delivery system in the future. Polyalkylcyanoacrylates gained popularity because of their apparent lack of toxicity and can be successfully used in surgery. This is from a toxicological view of referred pharmaceutical drug delivery system.

Efflux pumps have been identified and significant enhancement in ocular drug absorption was achieved following their inhibition. To maintain minimum inhibitory concentration the agent used to be frequently dosed resulting in poor patient compliance. Blood retinal barrier is selectively permeable to more lipophilic drugs or molecule this results in frequent administration of high amount of drug leading to systemic side effect. Intravitreal administration offer high concentration of drug in retina. This may cause various short term complication like retinal detachment, endophthalmitis (34). Periocular route has been considered as the most promising and efficient route for administration of drugs to posterior segment of eye. Injecting of drugs produces many complications rises in intra ocular pressure, cataract, hyphema strabismus and corneal decompensation.

An optimum ocular drug delivery system would be one which can be delivered in eye drops with no creation of blurred vision or irritancy and which would need no more than one to instillation each day. Owing to leakiness of the conjunctiva rich blood flow and large surface area, conjunctival uptake of a topically applied drug from tear fluid is typically an order of magnitude greater than corneal uptake. Physicochemical drug properties such as lipophilicity solubility molecular size and shape, degree of ionization affect the route and rate of permeation in cornea. Drugs penetrate across the corneal epithelium via transcellular and paracellular pathways. Lipophilic drugs prefer the transcellular pathways hydrophilic drugs prefer the paracellular path. Nanoparticles formed from bioadhesive polymers forms a covalent bond with the mucine coating. Covering the conjunctiva and corneal surfaces of the eye is the mucin coat. The mucous layer secreted by goblet cells of conjunctiva is multifunctional in role. It hydrates, cleanses, lubricates and serves as a defense against pathogens; ocular mucoadhesion relies on the interaction the polymer. Bioadhesive polymers are usually macromolecular hydrocolloids with numerous hydrophilic functional groups. Gellan gum a polysaccharide secreted by *Pseudomonas ebolain* aqueous solution forms a clear anionic gel. They have been studied for their ocular and percutaneous tolerability. Some commercial formulations hydrogels are widely accepted as tear substitutes because of their prolonged residence time on the eye surface. Gulsen et al. (2004) have recently developed a disposable soft contact lens of drug containing microemulsion dispersed in a poly-2-hydroxyethylmethacrylate (HEMA) hydrogel suitable for ophthalmic delivery, in an attempt to reduce drug loss and side effects (35). The use of water soluble polymer to enhance the contact time and possibly also the penetration of

**Shubhashree Das et al.**

drug was first proposed by Swan et al. (1945). Cyclodextrin a complexing agent entraps the hydrophilic and photo unstable drug molecule and enhances the stability. The hydrolytic stability of curcumin under alkaline condition was strongly improved by complex formation while the photo decomposition rate was increased compared to curcumin in organic solvent (effect of polymer in stability of curcumin). The cavity size and the charge and bulkiness of the cyclodextrin side chain influenced the stability constant for complexation and the degradation rate of curcumin molecule (36).

### Preparation technique

PNPs (polymeric nanoparticles) can be prepared conveniently either from preformed polymers or by direct monomer polymerization using classical polymerization (46). Methods such as solvent evaporation, salting-out, dialysis and supercritical fluid technology, which include the rapid expansion of a supercritical solution or the rapid expansion of a supercritical solution into liquid solvent, can be used to prepare PNP from preformed polymers. On the other hand, the polymerization of monomers can directly synthesize PNPs by using various polymerization techniques such as micro-emulsion, mini-emulsion, surfactant-free emulsion and interfacial polymerization. The method of preparation is chosen based on a number of factors such as the type of polymeric system, area of application, size requirement, etc. For instance, a polymeric system that is developed for use in the biomedical or environmental fields should be fully free from reactants such as surfactants or organic solvents traces. In this case it is possible to choose techniques such as RESS (rapid expansion of a supercritical solution) or RESOLV (rapid expansion of a supercritical solution into a liquid solvent) because they do not use any surfactant or organic solvent during the PNP preparation (polymeric nanoparticles preparation technique and size control method).

Solvent displacement and interfacial deposition are related methods based on the spontaneous emulsification of the internal organic phase, which includes the dissolved polymer in the external aqueous phase. Solvent displacement, however, forms nanospheres or nanocapsules, while interfacial deposition forms only nanocapsules. In the presence or absence of a surfactant, solvent displacement involves precipitation of a preformed polymer from an organic solution and diffusion of the organic solvent into the aqueous medium (59, 60, and 61). The polymer, usually PLA, is dissolved in an intermediate polarity water-miscible solvent which leads to the precipitation of nanospheres. This phase is injected into a stirred aqueous solution containing a surfactant like stabilizer.

The polymer deposition on the water and the organic solvent interface, caused by the rapid diffusion of the solvent, leads to the instant formation of a colloidal suspension. In order to facilitate the formation of colloidal polymer particles during the first step of the procedure, phase separation is done with a completely miscible solvent which is also a nonsolvent of the polymer. The solvent displacement technique allows the nanocapsules to be prepared while adding a small amount of nontoxic oil in the organic phase. In general, high loading efficiencies are reported for lipophilic drugs when nanocapsules are prepared, considering the oil-based central cavities of the nanocapsules. The usefulness of this simple technique is limited to water-miscible solvents, where the rate of diffusion is sufficient to produce spontaneous emulsification.

Then, although some water-miscible solvents produce certain instability when mixed in water, spontaneous emulsification is not observed if the rate of coalescence of the droplets formed is high enough. While, acetone/dichloromethane (ICH, class 2) are used for dissolving and increasing the entrapment of drugs, dichloromethane increases the mean particle size and is known to be toxic. Because of the miscibility of the solvent with the aqueous phase, this method is basically applicable to lipophilic drugs (Barichello et al., 1999) and it is not an effective way of encapsulating water-soluble drugs. Indeed, it seems impossible to select a drug/ polymer/ solvent/ nonsolvent system in which particles would be produced and the drug efficiently entrapped, since the solvent and the nonsolvent of the polymer must be mutually miscible. The gradual addition of the polymer solution to the nonsolvent generally results in the formation of nanospheres nearly 200 nm in size. A mechanism comparable to the diffusion and standing process found in spontaneous emulsification seems to form nanoparticles. Due to the mutual

**Shubhashree Das et al.**

diffusion of the third liquid, this phenomenon was explained by local variations of the interfacial tension between the two immiscible liquids.

This method was applied to different polymeric materials such as PLA, PLGA, PCL, and poly (methyl vinyl ether-co-maleic anhydride) (PVM/MA) (60). This method was well adapted to incorporate cyclosporin A, because entrapment efficiencies were obtained as high as 98%. Interfacial deposition is a process used to produce nanocapsules; however, this is not a technique for polymerization but a technique for emulsification/solidification. A fifth compound is introduced in interfacial deposition, of oil nature, miscible with the solvent of the polymer but immiscible with the mixture. The polymer deposits between the finely dispersed oil droplets and the aqueous phase on the interface, forming nanocapsules. An aqueous solution is used as the dispersing medium. The main difference is that polymers such as PLA dissolve in a solvent mixture (eg, benzylbenzoate, acetone, and phospholipids) along with the drug. This mixture is slowly injected into a stirred aqueous medium, resulting in the deposition of the polymer in the form of nanoparticles of about 230 nm in size. At the interface between water and benzoyl nanodroplets, polymer deposition occurs forming nanocapsules with a shell-like wall (54).

Emulsification-solvent evaporation involves two steps. The first step requires that of the polymer solution be emulsified into an aqueous phase. Polymer solvent is evaporated during the second step and induces polymer precipitation as nanospheres. Using a dispersing agent and high-energy homogenization [50], a polymer organic solution containing the dissolved drug is dispersed into nanodroplets in a nonsolvent or suspension medium such as chloroform (ICH, class 2) or ethyl acetate (ICH, class 3). The polymer precipitates in the form of nanospheres where the drug is finely distributed in the network of polymer matrixes. Subsequently, the solvent is evaporated by increasing the temperature under pressure or by stirring continuously (62).

The size can be controlled by adjusting the stir rate, type and amount of dispersing agent, organic and aqueous phase viscosity, and temperature (63). While different types of emulsions may be used, oil/water emulsions are of interest because they use water as the nonsolvent; this simplifies and therefore improves process economics, because it eliminates the need for recycling, facilitate the washing step and minimize agglomeration. However, this method can only be applied to liposoluble drugs, and the scale-up of the high energy requirements inhomogenization imposes limitations (62). PLA, PLGA, ethylcellulose (EC), cellulose acetate phthalate, poly(E-caprolactone) (PCL), and poly(h-hydroxybutyrate) (PHB). Drugs or model drugs encapsulated were albumin, texanus toxoid, testosterone, loperamide, praziquantel, cyclosporin A, nucleic acid, and indomethacin are frequently used polymers.

**Salting out technique**

Salting -out is based on salting-out effect separating a water miscible solvent from aqueous solution. The salting-out process can be considered as a modification of the emulsification/solvent diffusion. Initially, polymer and drug are dissolved in a solvent such as acetone, which is then emulsified into an aqueous gel containing the salting-out agent (electrolytes, such as magnesium chloride, calcium chloride, and magnesium acetate, or non- electrolytes such as sucrose) and a colloidal stabilizer such as polyvinyl pyrrolidone or hydroxyl ethyl cellulose. This o/w (oil/water) emulsion is diluted with a sufficient volume of water or aqueous solution to increase the diffusion of acetone into the aqueous phase, thereby inducing the formation of nanospheres. It is important to select the salting out agent, because it can play an important role in the drug's encapsulation efficiency. Cross-flow filtration then eliminates both the solvent and the salting-out agent. This procedure used in PLA, poly-(methacrylic) acid, and EC nanospheres preparation leads to high efficiency and is easily scaled up (64). Salting out has the main advantage of minimizing stress on protein encapsulants. Salting out does not need an increase in temperature and, hence, may be useful when processing heat sensitive substances (65). The main drawbacks are exclusive application to lipophilic drugs and the extensive washing steps of nanoparticle.

**Shubhashree Das et al.****Emulsification technique**

This is a technique where we can use natural sources to prepare nanoparticles. Chitosan nanoparticles were developed to encapsulate proteins such as bovine serum albumin, tetanus and diphtheria toxoid, vaccines (66), anticancer agents, insulin (67), and nucleic acids. Chitosan significantly improved the peptide (such as insulin and calcitonin) absorption across the nasal epithelium. The methods proposed for the preparation of chitosan nanoparticles are based on the spontaneous formation of complexes between chitosan and polyanions (68) or the gelation of a chitosan solution dispersed in an oil emulsion (70). Chitosan nanoparticles obtained through the formation of a spontaneous complex between chitosan and polyanions such as tripolyphosphate have small diameters (200–500 nm) and under transmission electron microscopy show a quasi spherical shape. Chitosan nanoparticles produced using an emulsification-based method by a promoting gelation, as illustrated above. Compared with the method described above, this technique has a main disadvantage when it involves organic solvents during the isolation of the particles; these are difficult to remove and may cause toxicity.

Similarly agarose nanoparticles can be prepared. These are prepared for the administration of therapeutic proteins and peptides (71). Agarose aqueous solution forms thermally reversible hydrogels when cooling below the gelling temperature (318–368C). Thermal gelation results from the formation of helicoidal structures responsible for a three-dimensional network in which large amounts of water can be entrapped. Hydrophilic, inert, and biocompatible, the hydrogel forms an appropriate matrix for proteins and peptides that can be entrapped in the gel during formation. Agarose nanoparticles were formed using a technology based on emulsion. This methodology requires the preparation of an agarose. Initially, peptides and proteins to be encapsulated are added to the agarose solution. Homogenization achieves the small size of the dispersed aqueous nano droplets. Gelation of agarose is then induced by diluting the emulsion under agitation at 58 °C with cold corn oil. The liquid nano droplets then gel to nanoparticles containing protein agarose hydrogel (69).

**Ionic gelation method**

In the presence of multivalent cations such as calcium, sodium alginate gels which is a water-soluble polymer. Drop wise extrusion of sodium alginate solution into calcium chloride solution usually results in alginate particles. The particle size of alginate depends on the size of the initial extruded droplet. The smallest formed particles, obtained by air atomization had a minimum size of 1 to 5 μm. Preparation of alginate nanoparticles was first achieved in a diluted solution of aqueous sodium alginate in which gelation was induced by the addition of a low calcium concentration. This leads to the development of invisible clusters of calcium alginate gels. In an additional advance, alginate particles were produced by using a modified method of emulsification/internal gelation as illustrated in. Preparing of alginate nanoparticles using this method requires no specialized equipment and can be done at ambient temperature. The major difficulty of this technique is the step of washing nanoparticles to remove the residual oil droplets, but new strategies have been devised (70).

**Recent development**

Increasing the retention time of the drug alone cannot increase the drug's permeability inside the ocular chamber. Administration of drugs neglecting the presence of the ocular barriers, which make the ocular system invincible and isolated from the foreign substances, makes the drug's fate nowhere to reach the target area. Blood ocular barrier is of two types a) blood aqueous barrier and b) blood retinal barrier. The former one makes permeation impossible for lipophilic drugs to pass through the aqueous humor. But trace amount of horseradish peroxidase was found in the aqueous humor chamber which made a sense of presence of trace amount of plasma proteins. But horse radish peroxidase cannot pass through the iris blood vessels; it can penetrate through the fenestrated capillaries of the ciliary process and reach the aqueous humor. Small and lipophilic drugs can enter the uveal blood circulation through the blood aqueous barrier also they are constantly eliminated more rapidly from the anterior chamber in contrast to the larger and more hydrophilic drug. The iris tissue is porous and makes it easy for the lipophilic drugs to permeate in to the uveal blood circulation. It was also observed that the lipophilic drugs get eliminated more rapidly than the larger hydrophilic drugs from the anterior chamber. Thus lowering the concentration of drug in the

**Shubhashree Das et al.**

anterior chamber. Blood retinal barrier resembles blood brain barrier so the paracellular and transcellular transport is restricted. Developing an efficient and accurate drug delivery system should be the matter of discussion. For this reason some formulas using well known pharmacokinetic relationship and a first order drug decay model for the tear film have been established. The time integration of the tear film concentration is then related to the ocular bioavailability. According to this it was found out that a) high corneal permeability with respect to lipophilic drugs produces the highest bioavailability b) drug volume does not play a major role in bioavailability of the drugs and c) making the dose volume relatively small the bioavailability increase by 4 fold (69). Using a lot of bioadhesive can decrease the drug's steady state. The permselectivity of cornea was investigated in vitro by measuring electrokinetic potential generated by ionic concentration gradient or hydrostatic pressure gradient (66).

This study suggested the dual permeability character of the cornea. At physiological pH above isoelectric point 3.2 the cornea behaves as it is negatively charged and allows positively charged ions to permeate through. It becomes the reverse in altered condition. Not only this has the transepithelial electrical resistance (TEER) played a key role in transportation of molecules across the cornea. Although these much constrains in ocular drug delivery still some development have been brought forward. They are as follows- A natural sourced cationic polymer chitosan is having unique biological characteristic in case of muco adhesion and biocompatibility so it has been extensively used in drug delivery. PEG along with chitosan sodium has a good compatibility with ocular structure. PEG is having good shielding effect so it can protect the drug molecule from the hydrolytic enzymes.

Poly- $\epsilon$ -caprolactone nano particles decrease the systemic absorption of ocular drugs. Polyalkylcyanoacrylate nano particles could also be used for anti-inflammatory drugs to target inflamed ocular tissue compared to healthy tissue (68). Pz-peptide (4-phenylazobenzoxycarbonyl-Pro-Leu-Gly-Pro-D-Arg) a hydrophobic collagens labile pentapeptide. Thus facilitating the opening of the tight junction in a reversible manner facilitating the paracellular transport (72).

**Future scope**

Finding effective treatment for ophthalmic diseases is a tremendous challenge for research scientists due to the nature of diseases and presence of the different ocular barriers. An ideal therapy should maintain effective levels of the drug following a single application for the desired period. Scientists have focused on designing a strategy with a multidisciplinary approach in recent years, e.g. microneedle, iontophoresis and MRI. Continued gene delivery research seems to be very exciting for a gamut of diseases. In ocular drug delivery systems, there are likely to be multiple applications of nanotechnology. Nanotechnology can be helpful in making nanodevices for complex eye surgeries, such as glaucoma, retinal vascular surgery, etc. In addition, it can be used in the development of new lens material to treat cataracts. This technology would also become useful in developing various delivery formats, such as parenteral, oral, implantable, transscleral, ect. Moreover, the development of different nanotechnology-based tools can be used to improve imaging, screening and research techniques, including nanolithography, nanoarrays, mass spectrometry, etc., that can be used in the field of discovery of novel ophthalmic drugs. Nanotechnology can also be used to solve the solubility problems associated with poorly soluble drugs and to increase the number of compounds available for potential development of formulations. Beside this, nanotechnology can also help to develop an effective and robust DNA nanoparticle therapy for the treatment blinding diseases based on genes.

It can aid in generation of scaffolds for tissue bioengineering, particularly for neural stem cells and can also be used to delivery growth factors and the stem cells. In the future, much of the emphasis will be placed on achieving non-invasive sustained drug release in both anterior and posterior segments for eye disorders. A clear understanding of the complexities of ocular tissues under normal and pathological conditions, physiological barriers and multi-compartmental pharmacokinetics would greatly enhance further development in the field. P-glycoprotein (P-gp) is a transport membrane protein that exists in many tissues of the human body. In the eye, P-gp is expressed in retinal capillary endothelial cells, iris and ciliary muscle cells and retinal pigmented cells (18), ciliary nonpigmented cells (50) corneal cells and conjunctival epithelial cells . P-gp is functionally active in the blood aqueous barrier. Studies

**Shubhashree Das et al.**

with Cyclosporine A, verapamil and dexamethasone which are some of the functional sub units of P-gp, were investigated to determine the presence of P-gp in the conjunctival epithelium (56). According to that study it was investigated that the efflux of Cyclosporine A was reduced in the presence of verapamil and P-gp inhibitors. Solubilizing agents often used in pharmaceutical formulation have been reported to have P-gp inhibitory activity (55). Another protein named multi drug resistance-associated protein is of same importance as that of P-gp. Only the main difference is that this type of proteins has high affinity toward compounds conjugated to glutathion, glucuronide and sulfate (29).

Development of nanotechnologies require better understanding of cell-surface interaction on the nanometer scale. Advances in nanometer scale patterning and detection have allowed the fabrication of appropriate substances and the study of cell surface interaction (1). Especially topographed nanosurfaces are more selective than the smooth surface ones. This can be a new direction for the development of nanoparticulate formulation for targeting to specific tissues. Surface resistance is also a main hindrance for drug penetration. Corneal permselectivity was investigated *in-vitro* by measurement of membrane electrokinetic potential generated either by ionic concentration gradient (diffusion potential) or hydrostatic pressure gradient (transport mechanism of cornea: characterization of barrier permselectivity). Studies on the effect of pH on these potentials indicate dual-selective character to passage of ions across the cornea. The cornea represents an isoelectric point (pI) at 3.2. At physiological pH and pH above pI, the cornea behaves as if it is negatively charged and allows preferential passage of positively charged ions with respect to negative ions. The reverse is valid below pI. Lowering the bathing solution's ionic strength results in increased ionic discrimination as well as membrane electric resistance. Validity and integrity of tissue, the two important properties of membrane involved in the overall transportation process.

It is useful to first investigate corneal tissue in order to understand the effect of charge type on corneal transport of peptides. The transport characteristics of L-(14C) lysine and L-(14C) glutamic acid were based on measurements of *in vitro* flux. Net L-lysine flux occurs via a co-transport mechanism that is dependent on sodium. L-lysine transport involves the Na-K-ATPase pump and requires a transportation system mediated by a stereospecific carrier. By blocking the carrier system, the lysine permeability co-efficient was lowered. However, it appears that L-glutamic acid was absorbed by a passive aqueous transport mechanism which was insensitive to ouabain. Overall the cornea was 2-3 fold more cation permeable than an anion. Additionally, salicylic acid which is charged negatively is 2-3 times less permeable than the cationic drug. Though anionic drugs having less permeability through the membrane, still it can be incorporated into the cationic nanoparticles, thus increasing its permeability.

### ABSTRACT

Drug development and approval is very long and complex process. For the approval of drug product we have to go through a series of guideline document and application procedure intended to aid applicants and sponsors making regulatory proposal and submission in computerize automatic or electronic submission format to the Center for Drug Evaluation and Research (CDER), Center for Biologics Evaluation and Research (CBER) and Food and Drug Administration (FDA). In some cases, guideline differs from CDER to CBER to FDA because of the differences in the procedure and expert review guideline and availability of computer infrastructure in the respective centers. Agency guidance and guideline documents on electronic submissions or computerize automatic format will be upgraded regularly to show the progressing nature of the technology and encounter of those using the same technology. This specific guideline discuss various issues resemblance to the computerize automated submission of the new drug applications (NDA) and modification to those submission to CDER.

**Keywords-** NDA, CDER, FDA, Drug development, Regulatory requirement.

### INTRODUCTION

For recent development years, in the United States the regulation and control of new drug product has been based on the guideline of New Drug Application (NDA). From 1938, each new drug product has been subjected to approval of NDA before U.S authentication and commercialization of drugs. The report gathered during the clinical studies and preclinical study of an Investigational New Drug (IND) became the part of NDA. In 1938, when Food, Drug and Cosmetic Act (FD & C Act) was enforced, NDA were only required to restrain information concerning to the safety of investigational drug. The Kefauver-Harris Amendment in 1962 modify the FD & C act required and provide guidance to NDA for providing evidence that a new drug was relatively safety and effective for its intended and that the given therapeutic application of the drug must overcome the risks. When the FDA completed a comprehensive revision of the regulation subjecting to NDA in the year 1985 the NDA was again the matter of change. This revision

**Prachi Rani Sahu Das et al.**

and modification commonly called the **NDA Rewrite**. It was mainly focused to rearrange the ways in which information, content and data are assembled and presented in the NDA to easily approach FDA reviews. [1, 3, 7] In this review we tried to explain about the process of approval and rejection of a new drug that is going to be marketed.

**Fundamentals of NDA Submissions**

The quantity and quality of content and data offered in NDA can vary remarkably, the key components of NDA are simple, uniform and given in Form FDA-356h. The application to Market a new drug for use in human or an antibiotic (biological) drug for human use contains basically of 15 parts i.e,

1. Index
2. Summary
3. Chemistry
4. Manufacturing and Control
5. Samples, Methods Validation, Package and Labeling
6. Nonclinical Pharmacology and Toxicology
7. Human Pharmacokinetics and Bioavailability
8. Microbiology (for anti-microbial drugs only)
9. Clinical Data
10. Safety update Report
11. Statistical
12. Case report Tabulations
13. Case report Forms
14. Patent Information
15. Patent registration certification
16. Other information (the previous marketing history of the drug inside and outside the U.S, approved discussion regarding the benefit and risk consideration and if any provided additional study or post marketing surveillance plans etc.) [2,7,8]

**NDA Format- Content and Requirements**

NDA guideline must provide all the relevant information and data that a sponsor or investigator has collected throughout the product research and development. The FDA also has various guidelines and guidance that are relate to NDA issue of content and format. These numerous guideline can be obtained from CDER website of Drug information branch (DIB).

1. New molecule entity
2. New Salt form of previously approved and existed drug ( not new molecule entity)
3. New formulation of already existed or approved Drug (not new salt form or, molecule entity)
4. New combination or rearrangement of two or more drug product
5. Already marketed drug Product – Duplication of product
6. New indication or claim for existed marketed drug
7. Already marketed drug Product - Not previously approved by NDA [7,8,9]

**Summary of application**

- According to the new or, present NDA regulation the application must be submitted in 2 copies,
- An archival copy- serves as a permanent record of the submission
- A review copy- by the scientific committee
- The review copy again is made up off a number of separate technical volume, each volume signifies the need of the discipline that is involved in the review.

**Prachi Rani Sahu Das et al.**

- Both the archival and review copies are submitted in the form of hard copy, but according to the guideline archival copy must be submitted as microfiche.

Generally the application form is supplied with detailed and technical guideline or guidance to improve the quality of submissions,

- The format and content of summary of an application
- Formatting, arranging and submitting new drug and antibiotic (biological) application
- The microfiche submission of archival copy
- The format, content and report of the human Pharmacokinetics and bioavailability section The format, content and report of the clinical and statistical section data
- The format, content and report of the chemistry, manufacturing and control section
- Post marketing surveillance and reporting of adverse drug reaction [1, 4, 7, 8]

The chemistry section because of its length, complex and highly detailed section basically deals with the manufacturing and control process, is required to be submitted between 90-120 days prior to the submission of the application for the identification of deficiencies in the application filed. Submission of proposal to the chemistry section earlier than 120 days and less than 90 days before the remainder of the application will not be accepted. The archival copy of the application should include a detailed index by volume and page number. It is always recommendable to prepare additional copies of the index and must be included with application form submitted to FDA for the NDA. This will aid in easily access the location of important parts of the submission which will be needed for meetings or, review by individual technical reviewers. It has been always recommendable that the summary consists of 50 - 200 pages. The summary should explain all the aspects of the application and needs to be written at ultimate level of detail required for publication and must meet the editorial board standard that applied by various referred scientific and medical journals. It is advantageous to provide the data in the summary in the form of table and graphic with clear explanation and distinction of all the terminology used in the table or graphics. The required safety and efficacy data must be submitted in same format that described under clinical data section of the NDA content and format. [5, 8, 10]

- **Chemistry, manufacturing and control summary-** provide a general and detailed overview of the drug substance and drug product
  - Drug substance: Description regarding physical and chemical characteristics and stability study.
  - Drug product: Description regarding composition and type of dosage form, manufacture, analytical methods, container/closure system, stability and investigational formulation.
- **Nonclinical laboratory studies-** include any in-vivo and in-vitro experiment with the test drug to determine its safety, activity or disposition. This section includes Toxicological effects of drugs on reproduction and the developing fetus, ADME animal experiments of the drugs. This section should provide a description, tabulation and graphics from Nonclinical laboratory studies of drug.[7, 8, 10]
  - First section: There should be an overall tabulated summary of all in-vivo biopharmaceutics studies carried out on the drug grouped by type of study.
  - Second section: The summary of bioavailability or pharmacokinetic data and overall conclusions ( $C_{max}$ ,  $T_{max}$ , AUC etc.)
  - Third section: List of all formulations used in clinical trials and in vivo bioavailability or pharmacokinetic studies together with each formulation used in studies.
  - Fourth section: Analytical methods used to measure the levels of drug and major metabolite (Bioanalytical)
  - Fifth section: Dissolution data on each strength and dosage form for which approval is being sought. A comparative dissolution study with the lot(s) used. In vivo biopharmaceutics studies should also be included.

**Prachi Rani Sahu Das et al.**

➤ **Statistics section** should include:

- A statistical evaluation of the clinical data
- A copy of the data given in the description and analysis of each controlled clinical study, along with the statistical analysis.
- A copy of the data included in the integrated summary of all available information about the safety of the drug. [7, 8, 10, 11]

**Review Time Frames of the NDA Application**

This time frame includes:

- Within 180 days of date of filing of an application, the FDA will review and issue an approval, approvable, or not approvable letter. This 180-day period is called the “review-clock”
- During the review period an applicant may withdraw an application and later resubmit it.
- The time period may be extended by mutual agreement between the FDA and the applicant or as the result of submission of a major amendment.

**Filing Time Frames of the NDA Application**

- Within 60 days after the FDA receives an application, a determination will be made whether the application may be filed.
- This will determine whether sufficient information is provided to proceed with an in-depth review of application.
- If FDA files the application, the applicant will be notified in written. The date of filing will be the date 60 days after the FDA received the application.
- The date of filing begins the 180-days period of the review. If FDA refuses to file the application, the sponsor will be given the opportunity to meet with FDA to discuss the reasons why the application is not fileable. [2, 6, 7, 10]

**APPROVAL OF NDAs BASED SOLELY ON FOREIGN DATA**

Clinical data will be considered on merit regardless of country of origin. Foreign Clinical data meeting U.S. criteria for approval may be approved if:

- The foreign data are applicable to the U.S. population and U.S. medical practice
- The studies have been performed by clinical investigators of recognized competence
- If an inspection is necessary, FDA is able to validate the data through an on-site inspection or other appropriate means or the data may be considered valid without the need for an on-site inspection by FDA.
- India is a signatory to an international agreement on "mutual acceptance of data" (MAD), the country is obliged to accept the results of such animal testing conducted in other countries and there is no need for the tests to be repeated.
- FDA will apply this policy according to the nature of the drug and the data being considered.
- The FDA is willing to explore all areas to remove the need to conduct repetitive clinical testing in U.S.
- When adequate foreign data have been generated a pre-NDA submission meeting is encouraged when approval being solely on foreign data is sought. [3, 8, 11]

**FDA DIALOGUE ON SCIENTIFIC & MEDICAL ISSUES**

- Approximately 90 days after the NDA is received, the FDA will provide applicants with an opportunity to meet with reviewers to discuss the general progress and status of the application
- Particularly for new chemical entities and major new indications of marketed drugs, this meeting will generally be held at the applicant’s option and may be held by telephone.
- With the issuance of an approvable/not approvable letter, an opportunity will be provided to applicants to meet with the FDA and discuss what further steps need to be taken before the applications can be approved. [7, 8]
- Priority for these meetings will be given to applications for new chemical entities and major new indications for marketed drugs.

Prachi Rani Sahu Das *et al.*

### NDA PRE-APPROVAL AND POST- APPROVAL SAFETY REPORTS

- CDER( the center for drug evaluation and research) provide guideline for the approval of NDA.
- The FDA details the necessity to periodically update a pending application with new safety information which affects the statements of contraindications, warnings, precautions and adverse reactions in the draft labeling.
- The safety update reports are required to include the same kinds of information from clinical or animal studies as well as other sources, and must be submitted in the same format as the previously described in integrated summary of safety.
- Safety update reports must be submitted at:
  - 4 months after the initial submission of an application
  - Following receipt of an approvable letter and
  - Any other times as requested by the FDA
- In case of any adverse drug experience, the surveillance system requires the reporting of such experience as soon as possible within 15 working days of initial receipt of the information.
- These 'alert reports' are required to be submitted on Form FDA 1639 (Drug Experience Report).
- All reactions subject to 15 day alert report require follow-up reports within 15 working days of receipt of new information
- Even if no such reports are reported, the follow up reports has to be submitted in separate cover and as a summary / tabular form to be presented in periodic report
- NDA holders must review periodically (quarterly for the first three years and yearly thereafter) the frequency of adverse drug experience reports that are serious and unexpected and report any significant increase in frequency (e.g. a doubling) within 15 working days to determine whether a significant increase in frequency exists or not
- Applicants must adhere to a reporting schedule that calls for submission of each quarterly and each annual report within 60 days of the anniversary date of approval of the application
- A 15-day alert report based on information from the scientific literature must be accompanied by a copy of the published article.
- These literature reports should be either case reports or the reporting of a formal clinical trial
- Applicants should not include in post-marketing adverse experience reports of any adverse experiences that occurred in clinical trials if they were previously submitted as part of the approved application. [7,8,9,10, 11]

### NDA approval process

CDER uses advisory committees to obtain outside advice and opinions from expert advisors so that final agency decisions will have the benefit of wider national expert input. Committee recommendations are not binding on CDER, but the agency considers them carefully when deciding drug issues. CDER may especially want a committee's opinion about:

- A new drug
- A major indication for an already approved drug
- A special regulatory requirement being considered, such as a boxed warning in a drug's labeling
- Advise CDER on necessary labeling information
- Help with guidelines for developing particular kinds of drugs
- May also consider whether a proposed study for an experimental drug should be conducted
- Whether the safety and effectiveness information submitted for a new drug are adequate for marketing approval

#### Notification of Easily Correctable Deficiencies

CDER communicates promptly inform about applicants of the need for more data or information, or for technical changes in the application needed to facilitate the agency's review. Major scientific issues are usually addressed in an action letter at the end of the initial review process. CDER makes every effort to grant requests for meetings that involve important issues and that can be scheduled at mutually convenient times. After the end of Review Conference there are three possible action letters:

**Prachi Rani Sahu Das et al.**

- Not Approvable Letter: Lists the deficiencies in the application and explains why the application cannot be approved.
- Approvable Letter: Signals that, ultimately, the drug can be approved. Lists minor deficiencies that can be corrected, often involves labeling changes, and possibly requests commitment to do post-approval studies.
- Approval Letter: States that the drug is approved. May follow an approval letter, but can also be issued directly
- “End of review conference”: Applicants get an opportunity to meet with Agency officials and discuss the deficiencies

An applicant may seek to augment the information provided in the original NDA during the review process. E.g. the applicant may submit a new analysis of previously submitted data or information needed to address a deficiency in the drug application. Any such information provided for an unapproved application is considered an “NDA amendment”. Result in an extension of FDA's time line for application review The review is likely to involve a reanalysis or an extension of the analysis performed by the sponsor and presented in the NDA. There is also extensive communication between review team members. If a medical reviewer's reanalysis of clinical data produces results different from those of the sponsor, for example, the reviewer is likely to forward this information to the statistical reviewer with a request for a statistical reanalysis of the data. Likewise, the pharmacology reviewer may work closely with the statistical reviewer in evaluating the statistical significance of potential cancer-causing effects of the drug in long-term animal studies. After reviews are completed, each reviewer develops a written evaluation of the NDA that presents their conclusions and their recommendations on the application. The division director or office director then evaluates the reviews and recommendations and decides the action that the division will take on the application. The result is an action letter and a justification for that recommendation. Each element of the proposed labeling, including indications, use instructions and warnings, is evaluated in terms of conclusions drawn from animal and human testing. All claims, instructions and precautions must accurately reflect submitted clinical result. [1, 2, 7,8,10, 11]

CDER comments can relate to almost any aspect of the proposed labeling For example, CDER can comment upon drug indications and warnings or suggest general changes in wording and format. The labeling "negotiation process," through which a drug's final approved labeling is agreed upon, can take a few weeks to many months. The length of the process depends upon the number of agency comments and an applicant's willingness to reach agreement. Sometimes a sponsor will submit several revisions of labeling before agreement with FDA on the labeling can be reached. The labeling is organized in the following sections:

- Description: Proprietary and established name of drug; dosage form; ingredients; chemical name; and structural formula.
- Clinical Pharmacology: Summary of the actions of the drug in humans; in vitro and in vivo actions in animals if pertinent to human therapeutics; pharmacokinetics
- Indications and Usage: Description of use of drug in the treatment, prevention or diagnosis of a recognized disease or condition
- Contraindications: Description of situations in which the drug should not be used because the risk of use clearly outweighs any possible benefit
- Warnings: Description of serious adverse reactions and potential safety hazards, subsequent limitation in use, and steps that should be taken if they occur
- Precautions: Information regarding any special care to be exercised for the safe and effective use of the drug. Includes general precautions and information for patients on drug interactions, carcinogenesis /mutagenesis, pregnancy rating, labor and delivery, nursing mothers, and pediatric use
- Adverse Reactions: Description of undesirable effect(s) reasonably associated with the proper use of the drug
- Drug Abuse/ Dependence: Description of types of abuse that can occur with the drug and the adverse reactions pertinent to them
- Over dosage: Description of the signs, symptoms and laboratory findings of acute over dosage and the general principles of treatment

**Prachi Rani Sahu Das et al.**

- Dosage/ Administration: Recommendation for usage dose, usual dosage range and if appropriate, upper limit beyond which safety and effectiveness have not been established
- How Supplied: Information on the available dosage forms to which the labeling applies [3,4,5,7,8]

Division may initiate a request for a preapproval inspection of the sponsor's manufacturing facilities and clinical trial sites. The FDA conducts inspections to:

- Verify the accuracy and completeness of the manufacturing-related information submitted in the NDA;
- Evaluate the manufacturing controls for the preapproval batches upon which information provided in the NDA is based;
- Evaluate the manufacturer's compliance with CGMPs and manufacturing-related commitments made in the NDA;
- Collect a variety of drug samples for analysis by FDA field and CDER laboratories. These samples may be subjected to several analyses, including methods validation, methods verification and forensic screening for substitution. [5, 6, 7, 8]

According to CDER policy, product-specific preapproval inspections generally are conducted for products:

- That are new chemical or molecular entities
- That have narrow therapeutic ranges
- That represent the first approval for the applicant;
- That are sponsored by a company with a history of CGMP problems or that has not been the subject of a CGMP inspection over a considerable period.[ 8, 9, 10]

CDER's preapproval inspection program is available from CDER's Compliance Program Guide.

- The results of the preapproval inspection may also affect the final approval decision
- When such inspections discover significant CGMP problems or other issues, the reviewing division may withhold approval until these issues are addressed and corrected.
- The division's response to such deficiencies is likely to depend on several factors:
  - The nature of the problem
  - The prognosis for the problem's correction
  - The potential effect of the problem on the safety and efficacy of the drug. [7,8,9]

Once a recommendation is reached by the reviewers and their supervisors, the decision must be evaluated and agreed to by the director of the applicable drug review division or office. For the director's review, the consumer safety officer assembles an "action package" that contains the action letter and any data, CDER reviews and memo, and other information supporting the reviewers' recommendation. Following the review of the action package, the division director may begin a dialogue with the reviewers and their supervisors. The division director generally serves as the final FDA ruling. The division director is said to have "sign-off" authority for such drugs. Once the division director (or office director, as appropriate) signs an approval action letter, the product can be legally marketed starting that day in the United States. [5, 9, 10]

## CONCLUSION

For many years, the regulation and control of new drugs in the United States has been based on the New Drug Application (NDA). Since 1938, every new drug or therapy has been the subject of an approved NDA before US commercialization. The NDA application is the vehicle through which drug sponsors, such as biotech and pharmaceutical companies, formally propose that the FDA approve a new pharmaceutical for sale and marketing in

**Prachi Rani Sahu Das et al.**

the US. The data gathered during the animal studies and human clinical trials of an Investigational New Drug (IND) become part of the NDA.

## ACKNOWLEDGMENTS

The authors would like to acknowledge Centurion University of technology and management, Odisha, India for encouraging to research in the field of drug repurposing.

### ABSTRACT

Oxidative damage is the key factor for initiation of various diseases which directly or indirectly related with immune system. Antioxidants have significant inhibitory effect on oxidative stress and free radical. Plant derived antioxidants may strengthen body's antioxidant defense mechanism to sort out various diseases. In this time of corona, human community can be safe guarded by boosting up their immunity so it is essential to take antioxidants which may rejuvenate the immune system and can be used for prevention of various diseases. This study aims to emphasis on natural antioxidants which prevent oxidative damage and strengthen immune system. This can be helpful in prevention of many diseases and for health benefits. This study also encourages investigating further in the field of natural antioxidants for less side effects.

**Keywords**-oxidative stress, free radicals, antioxidants, immunity

## INTRODUCTION

oxidative stress causes cellular and tissue damage, which means the change of free radicals or other reactive oxygen species (ROS) that can result direct or indirect damage to the body.[1] Creation of free radicals due to faulty mechanism of immune system, initiate a large number of diseases including AIDS,[2] carcinogenesis, liver damage, inflammatory diseases, cataract formation and Alzheimer's disease are recognized.[3,4] Antioxidant and radical scavenging compounds can be considered as essential dietary nutrients because these safe guard health from various sensitive disorders since they play a crucial role by preventing oxidative stress and restoring biological pathways and membrane function.[4] . Many studies has been carried out and reported that ROS mediates more than 100 disorders such as rheumatoid arthritis, hemorrhagic shock, cardiovascular disorders, cystic fibrosis, metabolic disorders, neurodegenerative diseases, gastrointestinal ulcerogenesis and AIDS etc. Some specific ailments

**Swagatam Sahoo et al.**

mediated by ROS include Alzheimers disease, Parkinson's disease, Atherosclerosis, Cancer, Down's syndrome and ischemic reperfusion injury in different tissues including heart, liver, brain, kidney and gastro intestinal tract. [5]

Intracellular protection of inflammatory stresses involve antioxidant enzymes, including superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GP) in tissues. It has been shown that faulty cellular antioxidant systems cause organisms to develop a series of inflammatory or malignant diseases and unhealthy conditions. [6]Objective of enzymatic antioxidants is to protect living things from excessive generation of oxidative stress during inflammation phase, which emphasise studies to focus on the role of natural products in suppressing the production of oxidation so as oxidative stress by increasing enzymatic antioxidants in tissues. [7]. Complex antioxidant immune system of body control the exceeding level of ROS under normal condition and maintains an equilibrium between ROS formation and oxidative damage.[5] Overproduction of ROS and/or inadequate antioxidant defence disturbs this equilibrium in favor of a ROS upsurge that results in oxidative stress. A deficiency in the body's natural antioxidant defense mechanisms is the key factor which induces several clinical disorders and It has the measure role on initiation of unhealthy conditions. This has led to scientific research focusing on identifying safe and effective sources of antioxidants. Plant extracts and plant-derived antioxidant compounds may potentiate the body's antioxidant and anti-inflammatory defence mechanisms. [5]

The mechanism behind cancer development involves the induction of three to seven mutations in the tumour suppressor gene and oncogenes. [8] These mutations created by free radicals that are produced during normal body metabolism and due to chronic oxidative stress and inflammation.[9]. In cell, mitochondrias are the primary source of oxidative stress which initiate several critical biochemical pathways involved in the pathogenesis of diabetic problems .The initial oxygen free radical produced by the mitochondria is superoxide, which then converted to other destructive species which may strengthen the primary serious effects of hyperglycaemia. [10]The detrimental effects of free radicals and reactive oxygen/nitrogen species are due to the removal of electrons from any biomolecule in their path. Due to this phenomenon as well as enzymatic and non-enzymatic glycation of the natural antioxidants, the antioxidant capacity of the body would be decreased. Such conditions lead to intracellular and extracellular accumulation of advanced glycation end products (AGEs), deactivation of enzymes, lipid peroxidation and eventually diabetes complication including coronary artery disease, nephropathy, neuropathy, retinopathy and stroke.[11]Fibroblast growth factor 21 (FGF21) an indigenous member of the FGF family mainly synthesized in the liver. It has a key role in diminishing oxidative stress.[12]

**Mechanism of antioxidant [13-15]**

- Agents that catalytically remove free radicals and other reactive species like SOD, CAT, peroxidase and thio specific antioxidants.
- Proteins that minimize the availability of peroxidase such as iron ions and copper ions.
- Proteins that protect biomolecules against oxidative damage example heat shock proteins.
- Low molecular mass agents that scavenge ROS e.g. ascorbic acid and tocopherol.

**Plants with antioxidant activity**

Some selected plants having antioxidant capacity of the traditional therapeutic applications under study are listed here so as to understand their medicinal importance.

**CONCLUSION**

Many antioxidants are consumed daily by knowingly or unknowingly in form of drugs or dietary supplements. Biomedicines contains antioxidant property protect the living organism against oxidative damage. Oxidative stress is

**Swagatam Sahoo et al.**

the key factor induces several serious ailments like cancer, diabetes, AIDS, Alzheimer's disease, inflammation associated with rheumatoid arthritis, osteo arthritis etc. Many drugs are disease oriented and specific for disease. Oxidative damage is not a disease but initiate many diseases so it is necessary to focus on antioxidants. This study aims to emphasis on natural antioxidant which prevent oxidative damage and strengthen immune system. This can be helpful in prevention of many diseases and for health benefits. This study encourage to investigate further in the field of natural antioxidants for less side effects. In this time of corona, human community can be safe guarded by boosting up their immunity so it is essential to take antioxidants which may rejuvenate the immune system and can be used for prevention of various disease.

Table1

Plant	Family	Common name	Parts used	Activities other than antioxidant	Reference number
<i>Acanthus mollis</i>	Acanthaceae	Bear's breeches	Leaves & root	Analgesic, Anti-inflammatory	[16]
<i>Acorus calamus</i>	Acoraceae	Sweet flag	Rhizomes	Anti-inflammatory Antiulcer, Bronchodilator	[17]
<i>Aegle marmelos</i>	Rutaceae	Bael,wood apple	Leaves	Antiulcer, Laxative	[18]
<i>Aloe vera</i>	asphodelaceae	Ghrit kumari	Leaves	Anti-diabetic, Laxative	[19]
<i>Andrographis paniculata</i>	Acantheaceae	Creast,green chireta	Whole plant	Anti-leprosy Anti-cancer	[20]
<i>Asphodelus tenuifolius</i>	Asphodelaceae	Jungle piyaz	Whole plant	Hypotensive, Antioxidant, Antibacterial	[21]
<i>Carica papaya</i>	Caricaceae	Papaw,pawpaw	Leaves	Laxative, Dyspesia, Anti-hypertensive	[22]
<i>Cassia fistula</i>	Fabaceae	Purging cassia	Bark	Laxative, Anti-leprosy, Anti-malaria	[23]

Swagatam Sahoo *et al.*

<i>Curculigo orchoides</i>	Hypoxidaceae	Golden eye glass	Rhizomes	Anti-asthma, Diuretic	[24]
<i>Cyperus rotundus</i>	Cyperaceae	Coco-grass	Rhizomes	Diuretics, Analgesic, Stimulant, anti-bacterial	[25]
<i>Dalbergia sisoo</i>	Fabaceae	Indian rose wood	Leaves and flower	Antipyretics, Analgesic, Anthelmintic	[26]
<i>Emblica officinalis</i>	Phyllanthaceae	Malaka tree, amla	Seeds	Antipyretic, Anti-inflammatory	[27]
<i>Ficus bengalensis</i>	Moraceae	Indian babyan, banyan fig	Aerial root	Antileprotic, Anti-inflammatory, Antipyretic	[28]
<i>Hemidesmus Indus</i>	Apocyanaceae	Ananta bel	Stem	Antileprotic, Antiasthma	[29]
<i>Lagopsis supina</i>	Lamiaceae	Bung	whole plant	Anti-inflammatory, Hepatoprotective	[30]
<i>Magnifera indica</i>	Anacardiaceae	Mango	Stem bark	Antiseptic, Antiasthma, antihypertensive	[31]
<i>Momordica charantia</i>	cucurbitaceae	Bitter apple, Bitter gourd	Fruit	Anticancer, Antipyretics	[32]
<i>Moringa olifera</i>	Moringaceae	Moringa, drums tick tree	Seeds	Anti-infective, Anticancer	[33]
<i>Ocimum sanctum</i>	Laminaceae	Holy basil, Tulsi	Leaf	Anti malaria Anti-inflammatory	[34]
<i>Petroselinum crispum</i>	Apiaceae	Parsley, Garden parsley	Seed	Hypotensive, Anti-inflammatory	[35]
<i>Plumbago zeylanica</i>	plumbaginaceae	Doctorbush	Root	Anti-inflammatory, Antidiuretic	[36]
<i>Psidium guajava</i>	Myrtaceae	Yellow guava, lemon guava	Leaves	Anti-hypertensive, Diuretic	[37]
<i>Solanum nigrum</i>	Solanaceae	Paneer phool	Fruit	Anti-hypertensive, Diuretic	[38]
<i>Syzygium cumini</i>	Myrtaceae	Malabar plum	Leaf	Antirheumatic	[39]

## Recent Development of Marketing Strategy in Pharmaceutical Industry

### ABSTRACT

The recent trends among pharmaceuticals firms of implementing marketing and integrating new mechanisms for upgrading the innovation process also a new challenge for integrating marketing inputs is one of the fundamental challenges for the pharmaceutical industry. At the same time it is expected that after 1 January 2005, when international patent Laws will be implemented, Indian pharmaceutical industry will undergo phenomenal changes. Indian domestic pharmaceutical industry experienced a significant increase in expenditure on research and development to be competitive on the world market. Although the Indian pharmaceutical market is very limited and has no enough funding for the development of new drugs. In order to remain competitive in this highly regulated field the primary purposes of this paper is to address the evolution of marketing strategies employed by pharmaceutical industries.

**Keywords:** Indian pharmaceutical industry, Business Strategies, Market Development Strategies, Pharmaceutical Branding.

## INTRODUCTION

The pharmaceutical business is the world's largest industry due to revenues of about US\$ 2.8 trillion worldwide. The pharmaceutical industry has been significant changes in the recent period that place new demands on the payers, the suppliers and the producers customers now-a-days thinking that the pharmaceutical industry having more convenient than other products deliver by a multitude of factors compression to other products Indian pharmaceutical industry is posed over the next few years for quick and steady growth. [1] Top Indian companies like Sunpharma, ZydusCadilla and Lupin have already established their presence, the Pharma industry is an industry powered by expertise that release heavily on research and production. It is also a time consuming and costly process because some basic research (discovering new molecules) where some multinational Indian companies are also involved. [2]

**Swagatika Das et al.**

Orphan drugs is another area that has become very popular in recent years. The shorter and less expensive regulatory path gives incentives particularly for smaller speciality pharmacies. However clinical studies on orphan medicines in many countries required a large network of clinical operations to recruit enough patients. [3]. Big Pharma works also on orphan drugs starting with a small initiative, hoping to enlarge the indication into a blockbuster status. [4]

Business awareness is still overlooked in science based enterprise management. Such kinds of companies belong to industries where the main investment is in basic and applied research. [5] Bengal Chemicals (1901) is the first Indian pharmaceutical industry comes into being; the company started its first operation in Kolkata and the pharmaceutical industry many stages over the next few decades. Starting with the repackaging and preparation of manufactured bulk drug formulations, the use of medical members for selling goods to physicians and the exercise of order is difficult. [6] The country has a developed domestic pharmaceutical industry with a large network of 3000 drug companies and approximately 10,500 production units of these, 1,400 production units are approved by Good Manufacturing Practice (GMP) the World Health Organisation (WHO), 1105 have European Certificate of Suitability (CEPs), more than 950 TGA guidelines, and 584 sites are approved by the US Food and Drug Administration (USFDA) In 2019, domestic pharmaceutical market turnover reached US\$20.03 billion, up to 9.3 percent from 2018, increasing as health insurance and pharmaceutical penetration rise. [7] The influence of decision makers has been a time tested tradition in the hierarchy. Revenue force spending usually accounts for an additional 15 percent to 20 percent of total business sales of the balance sheet item with the highest line item. Notwithstanding the extra cost still troubled by some very severe strategic and organizational issues, the organization has gone on to level become a net. [8]

**Evolution of Indian Pharmaceutical Industry**

Indian pharmaceutical manufacturing company began during private initiatives in the 1910s started Bengal Chemical and Pharmaceutical Works in Kolkata and Alembic Chemicals in Baroda and the establishment of tropical pharmaceutical research institutes. Chennai (in Tamil Nadu), King College of Preventive Medicine, Central Institute for Drug Research, Kasauli, Pastures Institute, Coonoor etc. through British initiatives. [9] The nascent industry has earned however post World War II losses resulting from new medical advances in tranquilizers, the Western countries causing natural transition of older medicinal products from the use of new medicinal products such as sulpha drugs, antibiotics, vitamins, hormone, and antihistamine, pharmacological substances, etc.

Company that wind up in local production of indigenous materials caused and the industry importing bulk drugs intended to be manufactured into formulation and for sale on domestic market. [10] We can divide the Indian pharmaceutical sector into four main stages. The pre 1970 era is the first stage in which foreign companies dominated the Indian market. The period between 1970 to 1990 is the second stage in which many domestic companies began operation. The third stage is between 1990-2010 in which the Indian companies lunch service in foreign countries. [11]

**Pharmaceutical Company Business Strategies**

The secret for achievement in business is always withstands by new concepts. Although best Indian firms concentrate on antibiotics and anti-infective drugs, Sun Pharma has concentrated on treating of cancer, depression and hypertension. The company has lunched whole product line and has owned more place of leadership in all these regions. [12] The company having a skilled role for the organization in any of these fields. The results for first quarter of FY02 justify this to some extension. Although the domestic sector was largely affected by a slowdown and, Sun Pharma posted sales growth of 26% over the years on the formulations market. Sun also used acquisitions and fusions to expand rapidly. This was acquired the bulk product facility to Knoll Pharma, Gujarat Lyka Organics, 51.5 percent. The Tamilnadu Dadha Pharma & Milmet Labs and acquired Natco's brands. Fax combining with Tamilnadu Dadha Pharma and acquiring the Natco's products, the firm has established presence in gynaecology and mergers with Tamilnadu Dadha Pharma segment Oncology. [13]

**Swagatika Das et al.**

### **Market or product development strategies:**

A plan for product or business growth includes the production of new products or the alteration of existing products and the sale of such goods to current or future customers. The four most common strategies in this category are

1. Entering into market
2. Market growth
3. Product enhancement
4. The Diversification. [14]

### **How are drugs promoted?**

The estimated cost of selling block-buster drugs is recently measured at \$895 million (EFPIA, 2002). Companies spending this money naturally need to recover their costs. Industry experts further point out that the pressure on Top Pharma Industry science less pipeline products to sustain present growth levels, by launching one new drug per year, companies will have to sell \$4.9 million.

Per 1-1.5% of the world's Pharmaceutical industry. [15] "A Company the size of recently combined Glaxo Wellcome Smith Kline Beecham needs 3 to 7 products per year, whereas one of the size of Astra Zeneca needs 2 to 4 products per year. The problem is that the quality of research productivity is declining. None of the top companies is nearer to the goal". [16] Nature of the marketing mission is different depending upon the drug category. There are generally two separate type of medications: self-medication or over the counter (OTC) medicine and prescribed drugs also called ethical medicine. [17]

### **Development of new drug and the therapeutically market place**

The motivation behind the pharma industry has been and will continue to be the discovery of new patentable molecular entities when registered and authorised person introduced into the market, significant profit can be made. [18] Overall however, the expense of research activities increases as their performance declines. It is difficult for large pharmaceutical companies to find new drugs at the rate required to continue the expected rise in profit. [19] This indicates that the issue of the cost of manufacturing products is starting to become More important following the recent mergers and acquisition activities, there is a push to cut costs by raising the number of research, development and production facilities. [20]

### **Marketing as a source of innovation:**

Marketing is the originator of new product ideas in many sectors and determines exact criteria of new products. Due to a very high degree of technological uncertainty, the entire development process focuses on developing innovations and requires a significant element of chance in pharmaceutical products, if marketing focuses on particular areas of study and product attributes serendipitous findings cannot be identified, acknowledged or followed. [21] Process of marketing: [22]

For several decades, product executives and marketing managers have used branding tactics to attain competitive advantage of consumer product and services. [23]. The Pharma industry has also prepared the fast moving consumer goods market (FMCG) where brands are seen like the main assets of a business, and where all sources are used to produce brands while the core concepts and techniques for branding a medicinal products are similar to any other product, marketing and sells difference have changed the pharmaceutical industry to develop new acceptable strategies. [24]

### **The key to branding**

1. In order to be effective customers, branding campaigns must be persuaded that Product or service Category has full sense of discrepancies between brands.
2. Consumers shouldn't believe all brands in this group are the same.
3. Perception=Value [25].

Swagatika Das *et al.*

### **Brand Management is the HUB of Pharmaceutical marketing: [26]**

#### **Maximising Brand Loyalty**

However in order for this approach to work it must be probable to distinguish the current version from the original medication or generics to offer a direct advantage to patients and Doctors. [27].

Promoting the reformulated anti-depressant Remeron by Oregano before patent expiry was unsuccessful as patients Receive Minimum incentives / benefits to switch. second generation or reformulation approaches may take time and expenditure for testing, approval and promotion and may not expand the patent in other countries. [28]. IN spite of challenges, market share may be maintained by brand loyalty if the enhanced product is launched still the original product is on the market. For example by launching extended release reformulation of their drug a few months before generic drug, they maintained success on the attention deficit hyperactivity disorder market. With sales down minimally, the brand has remained strong. [29]

#### **Important Industry Developments**

Significant developments on both the need and supply sides have influenced the development of the generic drug industry over the past 20 years. [30] One main event was the 1984 drug price competition and patent term restoration act, better known as the Hatch Waxman Act, which was passed through the establishment of an abbreviated New Drug Application (ANDA) procedure, which significantly minimised the entry cost and time for generic drugs. [31] Generic firms with an ANDA need only demonstrate that their products are bioequivalent to the branded product in order to obtain Federal Drug Administration (FDA) approval.

Furthermore, the law establish research exclusion so that generic firms could carry out their bioequivalence tests and obtain conditional FDA approval before the expiry of the brand product patents. The 1984 law also attempted to hit a balance between generic price rivalry and innovation by offering the prospect to brand name firms. [32]

#### **The process of new drug development**

New drug production is usually a continuous process. The decision must be focused on potential therapeutic advantages, expected incidence and harshness of adverse reaction, projected increased growth marketing, distribution and development costs and future reaction prediction. [34] The firm can start clinical testing 30 days after filing unless the FDA holds this application. Marketing clearance for clinical trials the sequence typically runs like the following chemists and biologists conduct extensive discovery work before synthesis to establish hypotheses for novel compound. [35]

Once a new compound has been used for drugs that make it all the way to synthesised FDA it will be Screened for pharmaceutical action and toxicity in vitro, and then in animals. [36] If the medication is still deemed to be potential candidate for further development at this stage the company must usually file an investigations still deemed to be a potential candidate for further development at this stage the company must usually file an investigation with the FDA in three separate stages each of which requires dissimilar quantities and forms of safety and efficacy information occur. [37]

Phase I experiments are carried out on a limited numbers of healthy volunteers. Such experiments are primarily performed to collect knowledge on human toxicity and appropriate dosing ranges. Data on the absorption and distribution of the drug in the body, its metabolic effects, and the way in which the drug is removed from the body are also collected Part II, the drug is given to a large number of people in the second step of human study. The selected groups include patients for whom the medication is accepted to be profitable. [38]

Swagatika Das et al.

### The Food Amendments of 1962:

The Drug and cosmetics Act 1938(FD and C) provides clear proof of the efficacy of the planned application of the medication before marketing authorisation can be given.

**Phase II** studies generally provide the first major evidence of their effectiveness when they are successful. Step III, the third and final step of pre-marketing drug research includes large –scale patient trials. During this phase additional evidence of the effectiveness is sought. [38]. The big sample size enhance the probability that statistically meaningful profit will be found to be true and after approval of the marketing several drugs will be used while comprehensive toxicology tests on animals occur during the preclinical period. [39] Typically, patients are enrolled in studies to detect teratological and carcinogenic effects, and Phase III testing is also useful in detecting adverse reactions rarely seen in patient populations. Furthermore, This test can approximate more closely how longterm animal testing is conducted by the concurrent with phases II and III. Long term stability checks and sometimes additional dosage formulation work and process improvement to manufacture the compound in sufficient amounts of the clinical trials also occur during the clinical era. After completion of various phases of clinical development, the company believes it has enough proof and acceptance it will send a New KE Mattson et al. (1988) for trend analysis of the number of INDs submitted by U.S. firms. [40].

## CONCLUSION

Through various base of marketing of a pharmaceutical industry can achieve success in the market. The relationship between three factors that is company, customer and competitors are always determine the growth and loss of a pharmaceutical industry at last the role of supply change also place an important in both acute and chronic therapy in the market. The company also have to plan release of new drugs and upgrading of old drugs is also as a major process in the market. We hope that our study create some light on present development of marketing strategies on pharmaceutical industry.

### ABSTRACT

Diabetes is one of the major health problems that affect a large number of human populations. Diabetic cataract is one of the most frequent ocular complications rising secondarily to the diabetes vanadium and its various coordination metal complex plays a significant role in reduction of diabetes as well as cataract. *Cinerea maritima* is one of the common herbal remedy used to manage diabetic cataract affecting the aldose reductase pathway. The current work had been done with the aim of comparing the role of *Cinerea maritima* and Vanadium Salicylic Acid Coordination Complex in Diabetic Cataract Induced *in vitro* in Goat Lens model. In the study it was concluded that the effect of *Cinerea maritima* is more effective in reducing the opacity of the goat lens as compared to the diabetic cataract.

**Keywords:** Diabetes, cataract, salicylic acid, *Cinerea maritima*, Coordination Complex.

### INTRODUCTION

Diabetes is one of the major health problems that affect a large number of human populations. Diabetic cataract is one of the most frequent ocular complications rising secondarily to the diabetes vanadium and its various coordination metal complex plays a significant role in reduction of diabetes as well as cataract. *Cinerea maritima* is one of the common herbal remedy used to manage diabetic cataract affecting the aldose reductase pathway. *Cinerea maritima* is also more effective in reducing the opacity of the goat lens as compared to the diabetic cataract.

Arin Bhattacharya and Vijaya Kumar Meher

## MATERIALS AND METHODS

### Chemicals and Reagents

Salicylic acid, VOSO<sub>4</sub> were purchased from Hi-media and other various chemicals and diagnostic kits were of analytical grade. *Cinreria maritima* was given as gift sample from Beckson Homeopathic, New Delhi.

### Synthesis of Metal Complex

Metal complex had been synthesized using the method given by Bhattacharya. Salicylic acid and 50% aqueous solution of VOSO is mixed in a molar ratio of 2/1 in 96% ethanol. The product formed was then stirred under nitrogen atmosphere. The pH was maintained at 3.5. The temperature was maintained between 0–8°C. The green oil was formed indicating formation of complex. Successive washings with bidstilled water produced a light green solid. The analytical data was as per the previous work of Bhattacharya *et al* [21], [22].

### Induction of in-vitro Cataract

Glucose at a concentration of 55 mM was used to induce cataracts, when there is high concentrations of glucose in the lens, it metabolizes through the sorbitol pathway leading to accumulation of polyols (sugar alcohols) which causes over hydration leading to oxidative stress. A total of 24 lenses were used for the study. These lenses were incubated in artificial aqueous humour with concentration of glucose 5.5 mM served as normal control and 55 mM served as toxic control for 72 hours. The lens were divided into three groups each group containing 6 lenses:-

\*Author for Correspondence E-mail: vijayakumar.meher@cutm.ac.in

Group I: Glucose 5.5 mM (normal control).

Group II: Glucose 55 mM (toxic control).

Group III: Glucose 55 mM + Vanadium-salicylic acid

Group IV: Glucose 55 mM + *Cinreria maritima*

### Morphological and Photographic Evaluation

Goat lenses were placed on a graph paper with its surface posterior part touching the graph. The lens were observed. Photographic evaluation was done using the Nikon-Cybershot Camera.

## RESULT

**Synthesis of complex** ; A green coloured complex was formed. [Figure 1]

### Induction of the Cataractogenesis and Treatment with the Synthesized Complex and *Cinreria maritima*

All lenses in normal group remained transparent whilst all lenses in diabetic cataract and nicotine developed dense opacities indicating cataract. The opacity gradually increased towards the centre with complete opacification by 72 hours indicating complete cataract formation. In the study it was observed that the toxic control group showed more opacity as compared to the normal group. The opacification is less in the *Cinreria maritima* group as compared to the diabetic control as well as the *Cinreria maritima* group. Figure 2: Opacity in the various treatment groups. Group I: Glucose 5.5 mM (normal control). Group II: Glucose 55 mM (toxic control). Group III: Glucose 55 mM + Vanadium-salicylic acid. Group IV: Glucose 55 mM + *Cinreria maritima*

## DISCUSSION

Opacification in the lens is one of the most common complications of the diabetes mellitus.[23,24] The current approach to manage the cataract is the surgical approach. The major drawback that was associated with the surgical approach is the complications arising from the surgical approach [25]. In a previous cross-sectional study it was conducted that the evidence that subject in one of the developing state of India had average income less than 10000

**Arin Bhattacharya and Vijaya Kumar Meher**

rupees per month. Most of the subjects were not very literate. The above evidence compels us draw conclusion that in a state where a large number of population had been not been educated, the awareness toward the health is very less and post-operative chances of complications arise due to lack of follow up visits after the surgery, an easy, patient compliance and economical system for diabetic cataract should be devised for maximum therapeutics effects with minimum obnoxious effects [21]. Development of the pharmacotheruputical approach is the best suited alternative to the surgical approaches. In the study it was observed that *Cinneria maritima* is more effective in management of lenticular opacity as compared to the synthesized complex in the toxic control group. The probable mechanism of action *Cinneria maritima* is well known homeopathic drug, this current work emphasis the scientific explanation to the homeopathic system of medicine which is always under the suspicion of a “fringe science”. The current work also emphasis the role of Vanadium-Salicylic acid coordination complex against the diabetic cataract. The current work had laid the impetus regarding the *In vivo* studies of Vanadium-Salicylic acid coordination, antioxidant parameters like GSH, MDA, GPx, SOD and CAT, the pathway it effects to show the biological actions, the structural elucidation of the complex formed. Thus it could be concluded in the nutshell that more homeopathic formulation and novel approaches should be explored to get a system with maximum benefits and minimum side effects.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and cis-isoprene composite were studied. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the parameters will increase with increase in mass fraction of acrylic acid. This study will help in determining pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** blend, polyacrylic acid, Cis-isoprene composite

## **INTRODUCTION**

Blends or composites are materials containing more than one component. The components do not lose their individuality in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire resistant materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments. Usually blends are primed by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have to focus on the use of Insilico approach [7] to develop new blends. This study intends to envisage the permeability related properties of polyacrylic acid and cis-isoprene composite.

Suchismita Dash et al.

## MATERIALS AND METHODS

For the analysis part “Materials studio module of Biovia software (Dassault Systemes of France)” was used. The structures of polyacrylic acid and cis-isoprene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. From Figure 1 we can find that, the heat capacity ( $C_p$ ) of the composite increases linearly with the increase in mass fraction of acrylic acid.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. Figure 2 shows that the thermal conductivity of the composite increases linearly with increase in mass fraction of acrylic acid.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. Figure 3 shows that the dielectric constant of the composite increases with increase in mass fraction of acrylic acid.

## CONCLUSION

The probable use of polyacrylic acid and cis-isoprene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicate that all the three parameters increased with increase in mass fraction of acrylic acid. This In-silico study will help to determine the components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The mechanical properties of the polyacrylic acid and cis-isoprene composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of acrylic acid. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blend, polyacrylic acid and cis-isoprene, Biovia Materials Studio

## **INTRODUCTION**

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error technique which helps it in reducing wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the mechanical properties of polyacrylic acid and cis-isoprene composite.

Suchismita Dash and Ankita Subhrasmita Gadtya

## MATERIALS AND METHODS

For the analysis of the experiment “Materials studio module of Biovia software (Dassault Systemes of France)” was used. The structures of polyacrylic acid and cis-isoprene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS & DISCUSSION

**Bulk Modulus:** “Bulk modulus is the measure of the decrease in volume with an increase in pressure”. From Figure 1 we can see that, the bulk modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Shear Modulus:** “It is defined as the ratio of shear stress and shear strain”. From Figure 2 we can see that, the shear modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Young's Modulus:** “It is defined as the ratio of stress and strain and compares relative stiffness”. From Figure 3 we can see that, the Young's modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Poisson Ratio:** “It is known as the ratio of lateral strain to longitudinal strain”. From Figure 4 we can find that, the Poisson ratio of the composite increases linearly with increase in mass fraction of acrylic acid.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”. From Figure 5 we can see that, the brittle fracture stress of the composite increases linearly with increase in mass fraction of acrylic acid.

## CONCLUSION

The possible usage of polyacrylic acid and cis-isoprene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to its mechanical properties. The results specified that the values of all the properties (bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture) increased with increase in mass fraction of acrylic acid. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and poly14aD-glucose composite were studied. The proportion of the blend was examined with respect to heat capacity, thermal conductivity and dielectric constant. The results show that all those parameters increased with increase in mass fraction of acrylic acid. This analysis will help to determine pairs without executing laboratory experiments saving materials, money and time.

**Keywords:** Blend, polyacrylic acid, poly14aD-glucose

## **INTRODUCTION**

Blends are the combination of more than one component. The components remain same their identity in the blend. They integrate and provide the property of the blend to improving the quality of the material. To develop a single material with the needed property requires notable research and time. A blend saves time to develop a new material with reducing the cost of development of products with needed properties. Polymer blends can be modified into nano material polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and poly14aD<sub>2</sub>glucose composite.

Asha Rani Dalai

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and poly14aD\_glucose were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. As shown in the Fig. 1 it is observed that the heat capacity ( $C_p$ ) of the composite increases linearly with increase in mass fraction of acrylic acid.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. As shown in the Fig. 2 it is observed that the thermal conductivity of the composite increases linearly with increase in mass fraction of acrylic acid.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. As shown in the Fig.3 it is observed that the dielectric constant of the composite increases with increase in mass fraction of acrylic acid.

## CONCLUSION

The possibility of use of polyacrylic acid and poly14aD\_glucose to form a blend was explored using Biovia Materials Studio. The proportion of the blend was examined with respect to permeability properties. The composition of the blend was examined with respect to heat capacity, thermal conductivity and dielectric constant. The results show that all the three parameters increased with increase in mass fraction of acrylic acid. This silico analysis will help to determine components of a blend without executing laboratory experiments saving materials, money and time.

## RESULTS AND DISCUSSION

**Molar Volume:** “It is the volume occupied by one mole of a substance”. As shown in the Fig 1 it is observe that the molar volume of the composite decreases linearly with increase in mass fraction of acrylic acid.

**Density:** “Density is mass per unit volume”. As shown in the Fig 2 it is observe that the density of the composite decreases linearly with increase in mass fraction of acrylic acid.

**Permeability of Gas:** “Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium”. As shown in the Fig 3 it is observe that the permeability of oxygen through the composite decreases with increase in mass fraction of acrylic acid.

As shown in the Fig .4 it is observe that the permeability of nitrogen through the composite decreases with increase in mass fraction of acrylic acid.

As shown in the Fig 5 it is observe that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of acrylic acid.

## CONCLUSION

The possibility of use of polyacrylic acid and poly14aD\_glucose to form a blend was explored using Biovia Materials Studio. The proportion of the blend was examined with respect to permeability properties. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results show that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. This silico analysis will help to determine components of a blend without executing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A complex is a combination of more than one component. The desired property of a blend is its homogeneity. The mechanical properties of the Acrylic acid-Oxymethelene composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The outcome signifies that the values of all the properties enhanced with increase in mass fraction of Acrylic acid-Oxymethelene. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blends, Biovia, Acrylic acid-Oxymethelene composite

## **INTRODUCTION**

Blends are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the mechanical properties of Acrylic acid-Oxymethelene composite.

Shiba Joshi et al.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of Acrylic acid-Oxymethelene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components

## RESULTS AND DISCUSSION

**Bulk Modulus:** “Bulk modulus is the measure of the diminish in volume with an boost in pressure”. Figure 1 shows that the bulk modulus of the blend increases with increase in mass fraction of Acrylic acid-Oxymethelene linearly.

**Shear Modulus:** “It is defined as the ratio of shear stress and shear strain.”Figure 2 shows that the shear modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Young's Modulus:** “It is defined as the ratio of stress and strain and compares relative stiffness”.Figure 3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Poisson Ratio:** “It is the ratio of lateral strain to longitudinal strain”.Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of acrylic acid.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”.Figure 5 shows that the brittle fracture stresses of the composite increases linearly with increase in mass fraction of Acrylic acid-Oxymethelene

## CONCLUSION

The possibility of use of Acrylic acid-Oxymethelene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The results point to the values of all the properties (bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture) improved with increase in mass fraction of acid-Oxymethelene. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the Acrylic acid and oxymethelene studied. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all those parameters increased with increase in mass fraction of acrylic acid. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blends, Biovia, Acrylic acid, oxymethelene

## **INTRODUCTION**

Composites are materials containing more than one component. The components intact their identity in the mixture. They unite and give to the property of the blend thereby enhancing the quality of the material. Development of a single material with the desired property involves significant research and time. A blend saves time to develop a new material thereby reducing the cost of development of products with desired characteristics. Polymer composites can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of Acrylic acid and oxymethelene composite.

Shiba Joshi et al.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of Acrylic acid and oxymethelene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. Figure 1 demonstrates that the heat capacity ( $C_p$ ) of the Acrylic acid and oxymethelene composite is increased with increase in mass fraction linearly.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. In Figure 2, it has been observed that the thermal conductivity of the composite increases linearly with enhancing the mass fraction of acrylic acid.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. Figure 3 exhibits variation of the dielectric constant of the composite. It signifies that dielectric constant increases with increase in mass fraction of acrylic acid.

## CONCLUSION

The possibility of use of **Acrylic acid and** oxymethelene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the three parameters increased with increase in mass fraction of Acrylic acid and oxymethelene.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the Acrylic acid-Oxymethelene composite were studied. The molar volume and density reduce with increase in Acrylic acid-Oxymethelene fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The outcomes presents that the permeability for all the gases decreased with increase in mass fraction of Acrylic acid-Oxymethelene composite

**Keywords:** Blend, Biovia, Acrylic acid-Oxymethelene,

## **INTRODUCTION**

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the superiority of the material. A blend save time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high potency for transportation industries [5], glass fiber reinforced polymers, latex polymer cementations composites [6] etc.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study propose to predict the permeability related properties of Acrylic acid-Oxymethelene composite

Pranabdatta Swain *et al.*

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of Acrylic acid-Oxymethelene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Molar Volume:** “It is the volume occupied by one mole of a substance”. Figure 1 exhibits that the molar volume of the composite diminish with increase in mass fraction of acrylic acid linearly.

**Density:** “Density is mass per unit volume”. Figure 2 shows that the density of the composite decreases linearly with increase in mass fraction of Acrylic acid-Oxymethelene.

**Permeability of Gas:** “Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium”. Figure 3 shows Acrylic acid-Oxymethelene composite at the permeability of oxygen through the composite decreases with augment in mass fraction of Acrylic acid-Oxymethelene.

Figure 4 shows that the permeability of nitrogen through the composite decreases with increase in mass fraction of Acrylic acid-Oxymethelene. Figure 5 shows that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of Acrylic acid-Oxymethelene.

## CONCLUSION

The possibility of use of Acrylic acid-Oxymethelene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density lessen with augment in Acrylic acid-Oxymethelene fraction. The permeability properties of the composite were analysed based on permeability of oxygen, nitrogen and carbon dioxide. The consequences state that the permeability for all the gases decreased with increase in mass fraction of Acrylic acid-Oxymethelene.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and 1,4-beta-D-glucose composite were studied. The composition of the blend was examined with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all those parameters are present, increased with increase in mass fraction of acrylic acid. This work will help determine pairs without performing laboratory and industrial experiments saving materials, money and time.

**Keywords:** Blend, biovia, polyacrylic acid, 1,4-beta-D-glucose composite

## **INTRODUCTION**

Blends or composites are materials containing more than one component. In the mixture, the components do not lose their identity. They combine and contribute to the material goods of the blend thereby civilizing the quality of the material. Development of a single material with the most wanted property involves significant research and time. A blend saves time to develop a new material thereby reducing the cost of expansion of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and 1,4-beta-D-glucose composite.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and 1,4-beta-D-glucose were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. Figure 1 display the performance that the heat capacity ( $C_p$ ) of the composite increases linearly with increase in mass fraction of acrylic acid.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. Figure 2 display the performance that the thermal conductivity of the composite increases linearly with increase in mass fraction of acrylic acid.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. Figure 3 display the performance that the dielectric constant of the composite increases with increase in mass fraction of acrylic acid.

## CONCLUSION

The prospect of use of polyacrylic acid and 1,4-beta-D-glucose to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The domino effect indicated that all the three parameters increased with increase in mass fraction of acrylic acid. This in silico study will help to determine components of a blend without performing any laboratory experiments saving materials, money and time.

## **INTRODUCTION**

Blends or composites are materials containing additional than one components. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby civilizing the quality of all the material. Development of a single material with the preferred property involves significant research and time. A blend saves time to develop a new material thereby reducing the cost of development of products with preferred properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the mechanical properties of polyacrylic acid and 1,4-beta-D-glucose composite.

Suchismita Dash and Debajani Tripathy

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and 1,4-beta-D-glucose were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Bulk Modulus:**“Bulk modulus is the evaluate of the decrease in volume with an increase in pressure”. Figure 1 shows that the bulk modulus of the compound increases linearly with increase in mass fraction of acrylic acid.

**Shear Modulus:**“It is defined as the ratio of shear stress and shear strain.”Figure 2 shows that the shear modulus of the compound increases linearly with increase in mass fraction of acrylic acid.

**Young's Modulus:**“It is defined as the ratio of stress and strain and compares relative stiffness”.Figure 3 shows that the Young's modulus of the compound increases linearly with increase in mass fraction of acrylic acid.

**Poisson Ratio:** “It is the ratio of lateral strain to longitudinal strain”.Figure 4 shows that the Poisson ratio of the compound increases linearly with increase in mass fraction of acrylic acid.

**Brittle Fracture Stress:**“Brittle Fracture is the sudden, rapid furious of a material under stress”.Figure 5 shows that the brittle fracture stress of the compound increases linearly with increase in mass fraction of acrylic acid.

## CONCLUSION

The possibility of use of polyacrylic acid and 1,4-beta-D-glucose to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The domino effect indicated that the values of all the properties (bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture) increased with increase in mass fraction of acrylic acid. This in silico study will help find out components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and 1,4-beta-D-glucose composite were considered. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the complex were considered based on permeability of oxygen, nitrogen and carbon dioxide. The outcome showed that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. This analysis will help to settle on pairs without performing any laboratory experiments saving materials, money and time.

**Keywords:** Blend, silico, polyacrylic acid and 1, 4-beta-D-glucose composite

## **INTRODUCTION**

Blends or composites are materials containing more than one component combine to make unique materials having significant properties. The components do not lose their identity in the mixture. Development of a single material with the desired property involves significant research and time. A blend saves time to develop a new unique material thereby dropping the cost of development of products with desired properties. Polymer blends can be nano material customized polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and 1,4-beta-D-glucose composite.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and 1,4-beta-D-glucose were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Molar Volume:** “It is the volume occupied by one mole of a substance”. Figure 1 looks that the molar volume of the complex decreases linearly with increase in mass fraction of acrylic acid.

**Density:** “Density is mass per unit volume”. Figure 2 looks that the density of the complex decreases linearly with increase in mass fraction of acrylic acid.

**Permeability of Gas:** “Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium”. Figure 3 looks that the permeability of oxygen through the complex decreases with increase in mass fraction of acrylic acid.

Figure 4 looks that the permeability of nitrogen through the composite decreases with increase in mass fraction of acrylic acid.

Figure 5 looks that the permeability of carbon dioxide through the complex decreases with increase in mass fraction of acrylic acid.

## CONCLUSION

The possibility of use of polyacrylic acid and 1,4-beta-D-glucose to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the complex were studied based upon permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. This in silico study will help find out components of a blend without performing laboratory experiments saving materials, money and time

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and silica composite were studied. The structure of the blend was analyzed with respect to the heat capacity, thermal conductivity and the dielectric constant. The outcome indicates that all those parameters increased with rise in mass fraction of acrylic acid. This study will help to determine the pairs without having laboratory experiments and saving materials, money and the time.

**Keywords:** Blend, silico, Biovia, poly acrylic acid, silica composite

## **INTRODUCTION**

Blends or composites are materials which have contain more than one component. The elements don't lose their identification in the mixture. They fuse and contribute to the belongings of the blend to improving the characteristics of the material. Evolution of a single material with the craving property involves major research and the time. A blend saves time to come about a new material thereby reducing the cost of development of products with preferred properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples based on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and silica composite.

Srabani Mishra *et al.*

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and silica were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. Figure 1 reveals that the heat capacity (Cp) of the composite rise linearly with rise in mass fraction of acrylic acid.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. Figure 2 reveals that the thermal conductivity of the composite rise linearly with rise in mass fraction of acrylic acid.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. Figure 3 reveals that the dielectric constant of the composite rise with increase in mass fraction of acrylic acid.

## CONCLUSION

The possibility of use of polyacrylic acid and silica to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The outcomes how that all the three parameters rise with increase in mass fraction of acrylic acid. This in silico study will help in determining components of a blend without having laboratory experiments and it will save materials, money and the time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The mechanical properties of the polyacrylic acid and silica composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The outcome indicates that the values of all the properties rise with the growin mass fraction of acrylic acid. This study will help to determine the pairs without having any laboratory experiments and it saves materials, money and the time.

**Keywords:** Blend, Biovia, poly acrylic acid and silica composite

## **INTRODUCTION**

Blends or composites are the materials which have contain more than one component. The components do not lose their identity in the mixture. They come together and contribute to the property of the blend for improving the quality of the material. Development of a single material with the required property involves major research and time. A blend saves time to develop a new material thereby lowering the cost of development of products with craving properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples lied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the mechanical properties of polyacrylic acid and silica composite.

Srabani Mishra et al.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and polyacrylochloride were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Bulk Modulus:** “Bulk modulus is the measure of the decrease in volume with an increase in pressure”. Figure 1 reveals that the bulk modulus of the compound grows linearly with increase in mass fraction of acrylic acid.

**Shear Modulus:** “It is described as the ratio of shear stress and shear strain.” Figure 2 reveals that the shearmodulus of the compound rises linearly with increase in mass fraction of acrylic acid.

**Young's Modulus:** “It is defined as the ratio of stress and strain and compares relative stiffness”. Figure 3 reveals that the Young's modulus of the compound increases linearly with rise in mass fraction of acrylic acid.

**Poisson Ratio:** “It is the ratio of lateral strain to the longitudinal strain”. Figure 4 reveals that the Poisson ratio of the composite increases linearly with increase in mass fraction of acrylic acid.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”. Figure 5 reveals that the brittle fracture stress of the composite grows linearly with increase in mass fraction of acrylic acid.

## CONCLUSION

The possibility of use of polyacrylic acid and silica to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The outcome shows that the values of all the properties (bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture) rise with increase in mass fraction of acrylic acid. This in silico study will help determine the components of a blend without having laboratory experiments which saves materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and silica composite were studied. The molar volume and the density will be low with increase in acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. This study will help determine the pairs without having any laboratory experiments and it saves materials, money and the time.

**Keywords:** Blend, poly acrylic acid and silica composite

## **INTRODUCTION**

Blends or composites are a kind of material which contains more than one component. The components do not lose their identity in the mixture. They come together and contribute to the property of the blend for improving the quality of the material. Development of a single material with the craved property involves major research and the time. A blend saves the time to develop a new material thereby lowering the cost of development of products with craved properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire resistance materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples lie on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and silica composite.

Srabani Mishra *et al.*

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and silica were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Molar Volume:** “It is the volume occupied by one mole of a substance”. Figure 1 reveals that the molar volume of the compound will be lower linearly with rise in mass fraction of acrylic acid.

**Density:** “Density is mass per unit volume”. Figure 2 reveals that the density of the compound lower linearly with rise in mass fraction of acrylic acid.

**Permeability of Gas:** “Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium”. Figure 3 reveals that the permeability of oxygen through the composite lower with increase in mass fraction of acrylic acid.

Figure 4 show that the permeability of nitrogen through the composite decreases with increase in mass fraction of acrylic acid. Figure 5 indicates that the permeability of carbon dioxide through the composite will decreases with rise in mass fraction of acrylic acid.

## CONCLUSION

The possibility of use of polyacrylic acid and silica to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to the permeability properties. The molar volume and density will decreased with increase in acrylic acid fraction. The permeability properties of the composite were studied based on the permeability of oxygen, nitrogen and carbon dioxide. The outcomes shows that the permeability for all the gases decreased with rise in mass fraction of acrylic acid. This in silico study will help to determine the components of a blend without performing laboratory experiments and it will save materials, money and the time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and polyvinyl amide composite were studied. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all those parameters increased with increase in mass fraction of acrylic acid. The study helps in finding pairs without undergoing laboratory experiments.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and polyvinyl amide composite

## **INTRODUCTION**

Blends contain more than one material. However, the constituents of the mixture do not lose their identity in the mixture. Again with combination they improve the quality of the mixture as compared to the single components. Blend or composite saves much time thus saving cost. The examples of polymer blends are nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6]. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and polyvinyl amide composite.

## **MATERIALS AND METHODS**

"Materials studio module of Biovia software (Dassault Systemes of France)" was used for analysis. The structures of polyacrylic acid and poly-vinyl amide were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

G. Padhan and B. Barik

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. Figure 1 shows that the heat capacity ( $C_p$ ) of the composite increases linearly with increase in mass fraction of polyacrylic acid.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. Figure 2 shows that the thermal conductivity of the composite increases linearly with increase in mass fraction of polyacrylic acid.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. Figure 3 shows that the dielectric constant of the composite increases with increase in mass fraction of acrylic acid.

## CONCLUSION

The possibility of use of polyacrylic acid and polyvinyl amide to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the three parameters increased with increase in mass fraction of acrylic acid.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The mechanical properties of the polyacrylic acid and vinyl amide composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of poly acrylic acid. This type of studies will help find pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and vinyl amide composite

## **INTRODUCTION**

A blend contains more than one material. But, these components do not lose their identity in the mixture. Blend saves much time [1]. It is biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6]. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the mechanical properties of polyacrylic acid and polyvinylamide composite.

## **MATERIALS AND METHODS**

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and polyvinylamide were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

G. Padhan and B. Barik

## RESULTS AND DISCUSSION

**Bulk Modulus:** “Bulk modulus is the measure of the decrease in volume with an increase in pressure”. Figure 1 shows that the bulk modulus of the composite increases linearly with increase in mass fraction of polyacrylic acid.

**Shear Modulus:** “It is defined as the ratio of shear stress and shear strain.” Figure 2 shows that the shear modulus of the composite increases linearly with increase in mass fraction of polyacrylic acid.

**Young's Modulus:** “It is defined as the ratio of stress and strain and compares relative stiffness”. Figure 3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of poly acrylic acid.

**Poisson Ratio:** “It is the ratio of lateral strain to longitudinal strain”. Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of polyacrylic acid.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”. Figure 5 shows that the brittle fracture stresses of the composite increases linearly with increase in mass fraction of polyacrylic acid.

## CONCLUSION

The possibility of use of polyacrylic acid and polyvinylamide to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The results indicated that the values of all the properties (bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture) increased with increase in mass fraction of polyacrylic acid. The in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and polyvinylamide composite were studied. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of acrylic acid.

**Keywords:** Blend, silica, polyacrylic acid and polyvinylamide composite

## **INTRODUCTION**

Blends are materials containing more than one component. The components do not lose their identity. The examples of blends are nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6]. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and polyvinylamide composite.

## **MATERIALS AND METHODS**

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and polyvinylamide were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

G. Padhan and B. Barik

## RESULTS AND DISCUSSION

**Molar Volume:** “It is the volume occupied by one mole of a substance”. Figure 1 shows that the molar volume of the composite decreases linearly with increase in mass fraction of polyacrylic acid.

**Density:** “Density is mass per unit volume”. Figure 2 shows that the density of the composite decreases linearly with increase in mass fraction of polyacrylic acid.

**Permeability of Gas:** “Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium”. Figure 3 shows that the permeability of oxygen through the composite decreases with increase in mass fraction of polyacrylic acid.

Figure 4 shows that the permeability of nitrogen through the composite decreases with increase in mass fraction of polyacrylic acid. Figure 5 shows that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of polyacrylic acid.

## CONCLUSION

The possibility of use of polyacrylic acid and polyvinylamide to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeability for all the gases decreased with increase in mass fraction of polyacrylic acid.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and dimethyl butane composite were studied. The composition of the blend was checked with respect to the heat capacity, the thermal conductivity and the dielectric constant. The results indicated that those entire variables increased with increase in mass fraction of acrylic acid. This study will help to determine pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blend, polyacrylic acid and dimethyl butene composite

## **INTRODUCTION**

Blends or composites are materials, those which contain more than one component. The components don't lose their specification in the mixture. They combine and contribute to the feature of the blend thereby improving the superiority of the material. Growth of a single material with the desired property involves significant research and time. A blend saves time to develop a new material thereby dropping the cost of development of products with desired properties. Polymer blends can be nano material tailored polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples lean on laboratory experiments.

Usually blends are equipped by trial and error method. Thus it involves in wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and dimethyl butene composite.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and dimethylbutene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. Figure 1 signify that the heat capacity ( $C_p$ ) of the composite increases linearly with increase in mass fraction of acrylic acid.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. Figure 2 clarify that the thermal conductivity of the composite increases linearly with increase in mass fraction of acrylic acid.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. Figure 3 elucidate that the dielectric constant of the composite increases with increase in mass fraction of acrylic acid.

## CONCLUSION

The possibility of use of polyacrylic acid and dimethyl butene to form a blend was searched using Biovia Materials Studio. The composition of the blend was analyzed with regard to permeability properties. The composition of the blend was examined with respect to the heat capacity, the thermal conductivity and the dielectric constant. The results demonstrate that all the three parameters increased with increase in mass fraction of acrylic acid. This in silico study will help to determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired possession of a blend is its homogeneity. The mechanical properties of the polyacrylic acid and dimethylbutenecomposite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The outcome indicated that the values of all the properties increased with increase in mass fraction of acrylic acid. This study will help to determine pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and dimethylbutene

## **INTRODUCTION**

Blends or composites are materials containing more than one component. The components don't lose their uniqueness in the mixture. They combine and contribute to the property of the blend in that way improving the quality of the material. Improvement of a single material with the desired property involves noteworthy research and time. A blend saves time to develop a new material thereby dropping the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composite [2], fire retardant/fire proof equipment [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Generally blends are geared up by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have all ears on the use of *in silico* approach [7] to develop new blends. This study intends to predict the mechanical properties of polyacrylic acid and dimethyl butane composite.

Leepsa Nanda and R. Sahu

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and dimethyl butane were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Bulk Modulus:** “Bulk modulus is the measure of the decrease in volume with an increase in pressure”. Figure 1 exhibits that the bulk modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Shear Modulus:** “It is defined as the ratio of shear stress and shear strain.” Figure 2 demonstrate that the shear modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Young's Modulus:** “It is defined as the ratio of stress and strain and compares relative stiffness”. Figure 3 display that the Young's modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Poisson Ratio:** “It is the ratio of lateral strain to longitudinal strain”. Figure 4 unveils that the Poisson ratio of the composite increases linearly with increase in mass fraction of acrylic acid.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”. Figure 5 elucidate that the brittle fracture stress of the composite increases linearly with increase in mass fraction of acrylic acid.

## CONCLUSION

The possibility of use of polyacrylic acid and dimethyl butene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with admiration to mechanical properties. The consequences indicated that the values of all the properties (bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture) increased with increase in mass fraction of acrylic acid. This in silico study will help to determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The preferred property of a blend is its homogeneity. Different properties of the polyacrylic acid and dimethylbutene composite were studied. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were premeditated based on permeability of oxygen, nitrogen and carbon dioxide. The consequences showed that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. This study will help to determine pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and dimethylbutene

## **INTRODUCTION**

Blends or composites are materials containing more than one component. The components do not lose their characteristics in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Expansions of a single material with the desired property involve major research and time. A blend saves time to expand a new material by this means reducing the cost of development of products with preferred properties. Polymer blends can be nano material customized polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Usually blends are geared up by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and dimethylbutene composite

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and dimethylbutene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Molar Volume:** “It is the volume occupied by one mole of a substance”. Figure 1 signify that the molar volume of the composite decreases linearly with increase in mass fraction of acrylic acid.

**Density:** “Density is mass per unit volume”. Figure 2 elucidate that the density of the composite decreases linearly with increase in mass fraction of acrylic acid.

**Permeability of Gas:** “Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium”. Figure 3 signify that the permeability of oxygen through the composite decreases with increase in mass fraction of acrylic acid.

Figure 4 clarify that the permeability of nitrogen through the composite decreases with increase in mass fraction of acrylic acid. Figure 5 that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of acrylic acid.

## CONCLUSION

The possibility of use of polyacrylic acid and dimethylbutene to form a blend was explored by means of Biovia Materials Studio. The composition of the blend was analyzed with admiration to permeability properties. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The consequences indicated that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. This *in silico* study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the acrylic acid and dichloro ethylene composite were studied. The blend was analyzed with respect to the properties like to heat capacity, thermal conductivity and dielectric constant. The result of this composition blend indicates that the above properties of this blend was increased with increase in mass fraction of acrylic acid. This study will help to reduce the laboratory experiment work, saving materials and time.

**Keywords:** Blend, silico, Biovia, acrylic acid and dichloroethylene composite

## **INTRODUCTION**

blends or composition are the materials that contain one or more than one components. The compositions or blend do not lose their identity in the mixture. They combine and contribute to the property of the blend for improving the quality of the materials. Development of a single material with the desired property involves significant research and time. A blend saves time to develop a new material thereby decreasing the cost of development of products with desired properties. Polymer blends can be nanomaterials that can be up to nano size modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experimental work.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of acrylic acid and dichloro ethylene composite.

Lokanath Meher

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of acrylic acid and dichloro ethylene were found to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. A graph was plotted between the mass fraction of acrylic acid taking along x-axis and heat capacity along y-axis. The figure 1 indicates that the value of heat capacity of solid at 298 was increases linearly with increase in mass fraction of acrylic acid.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. A graph was plotted between Mass fraction along x-axis and Thermal conductivity along y-axis. The figure 2 show that the value of thermal conductivity was increases very small with increase in mass fraction of acrylic acid.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. A graph was plotted between mass fraction along x-axis and dielectric constant along y-axis. The figure 3 indicates that the value of dielectric constant at 298 K was increases very little with increase in mass fraction of acrylic acid.

## CONCLUSION

The possibility of use of acrylic acid and dichloro ethylene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. From the above study of blend we concluded that the three parameters of the acrylic acid were increases with increases in mass fraction. This in silico study will help determine components of a blend without performing laboratory experiments work, saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The mechanical properties of the acrylic acid and dichloro ethylene composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The result of this blends indicate that the parameters like young modulus, bulk modulus and shear modulus were first decreases and then increases with increase in mass fraction of acrylic acid. And the properties like Poisson ratio and brittle fracture stress increases with increase in mass fraction of acrylic acid. This study will help determine pairs without performing laboratory experiments work, saving materials, money and time.

**Keywords:** Blend, silico, Biovia, acrylic acid and dichloro ethylene composite

### **INTRODUCTION**

Blends or composites are materials containing more than one component. The components do not hide their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend saves time to develop a new material thereby decreasing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

**Lokanath Meher**

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the mechanical properties of acrylic acid and dichloroethylene composite

**MATERIALS AND METHODS**

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of acrylic acid and dichloro ethylene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

**RESULTS AND DISCUSSION**

**Bulk Modulus:** “Bulk modulus is the measure of the decrease in volume with an increase in pressure”. A graph was plotted between mass fraction of acrylic acid along X-axis and Bulk modulus along Y- axis. The figure 1 indicates that the value of Bulk modulus was decreases first then increases linearly with increase in mass fraction of acrylic acid.

**Shear Modulus:** “It is defined as the ratio of shear stress and shear strain.” A graph was drawn between mass fraction along X-axis and shear modulus along Y-axis. The figure 2 shown that the value of shear modulus was first decreases for some time then increases linearly with increase in mass fraction of acrylic acid.

**Young's Modulus:** “It is defined as the ratio of stress and strain and compares relative stiffness”. A graph was plotted between mass fraction along X-axis and Youngs modulus along Y-axis. The figure 3 indicate that the value of Youngs modulus first decreases for some value of mass fraction then increases linearly with increase in mass fraction of acrylic acid.

**Poisson Ratio:** “It is the ratio of lateral strain to longitudinal strain”. A graph was plotted between mass fraction along X-axis and Poisson ratio along Y-axis. The figure 4 shown that the value of poission ratio was linearly increases with increase in mass fraction of acrylic acid.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”. A graph was plotted between mass fraction along X-axis and brittle fracture stress along Y-axis. The figure 5 indicate that The value of Brittle fracture stress was increases linearly with increase in mass fraction of acrylic acid.

**CONCLUSION**

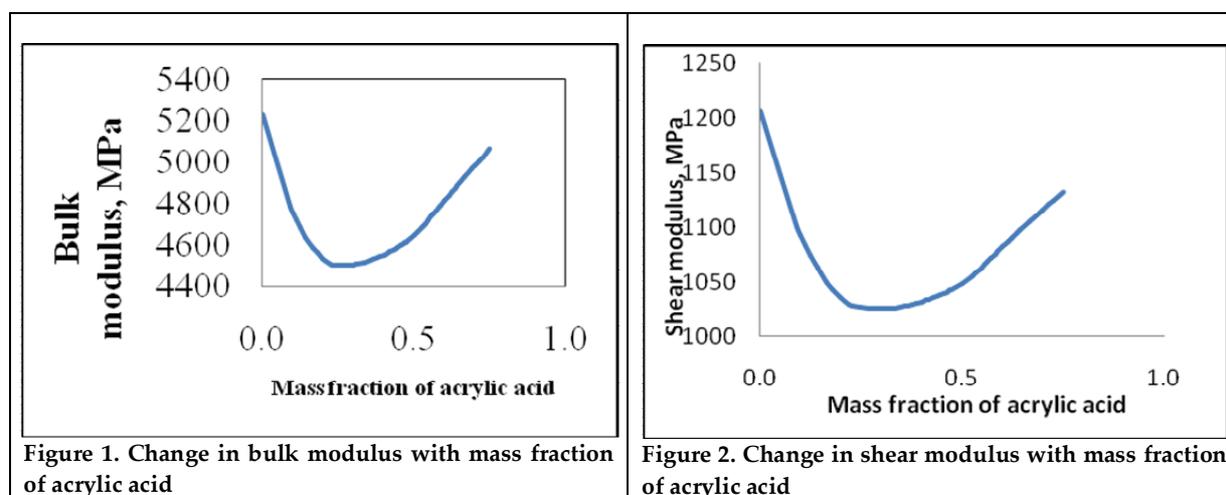

The possibility of use of acrylic acid and dichloro ethylene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The results indicated that the values of the properties like (bulk modulus, shear modulus, Young' modulus,) first decreases then increases with increase in mass fraction of acrylic acid. The property like Poisson ratio and brittle fracture stress increases with increase in mass fraction of acrylic acid. This in silico study will help determine components of a blend without performing laboratory experiments work, saving materials, money and time.

P. K. Dash and M.Palei

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of acrylic\_acid-tetmeth\_bisphen\_carbonate were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. Figure 1 shows that the heat capacity ( $C_p$ ) of the composite increases linearly with increase in mass fraction of acrylic\_acid-tetmeth\_bisphen\_carbonate.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. Figure 2 shows that the thermal conductivity of the composite increases linearly with increase in mass fraction of acrylic\_acid-tetmeth\_bisphen\_carbonate.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. Figure 3 shows that the dielectric constant of the composite increases with increase in mass fraction of acrylic\_acid-tetmeth\_bisphen\_carbonate.

## CONCLUSION

The possibility of use of acrylic\_acid-tetmeth\_bisphen\_carbonate to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the three parameters increased with increase in mass fraction of acrylic\_acid-tetmeth\_bisphen\_carbonate. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The mechanical properties of the acrylic\_acid-tetmeth\_bisphen\_carbonate composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of acrylic\_acid-tetmeth\_bisphen\_carbonate. It will help determine pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blend, silico, Biovia, acrylic\_acid-tetmeth\_bisphen\_carbonate composite

## **INTRODUCTION**

The properties of Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers , biodegradable polymers- natural fiber composites , fire retardant/fire proof materials , lightweight composite materials having high strength for transportation industries , glass fiber reinforced polymers, latex polymer composites etc. All above are mentioned examples relied on laboratory experiments

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the mechanical properties of acrylic\_acid-tetmeth\_bisphen\_carbonate composite.

P. K. Dash and M.Palei

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of acrylic\_acid-tetmeth\_bisphen\_carbonate was fed to the synthia menu of Materials Studio and run for different weight fractions of the components

## RESULTS AND DISCUSSION

**Bulk Modulus:** “Bulk modulus is the measure of the decrease in volume with an increase in pressure”. Figure 1 shows that there is a increase in bulk modulus of the composite with increase in mass fraction of acrylic\_acid-tetmeth\_bisphen\_carbonate.

**Shear Modulus:** “It is defined as the ratio of shear stress and shear strain.” Fig 2 this shows that the shear modulus of the composite increases linear with increase in mass fraction of acrylic\_acid-tetmeth\_bisphen\_carbonate.

**Young's Modulus:** “It is defined as the ratio of stress and strain and compares relative stiffness”. Fig 3 it shows that the Young's modulus of the composite increases linear with increase in mass fraction of acrylic\_acid-tetmeth\_bisphen\_carbonate.

**Poisson Ratio:** “It is the ratio of lateral strain to longitudinal strain”. Fig 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of acrylic\_acid-tetmeth\_bisphen\_carbonate.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”. Fig 5 this shows that the brittle fracture stress of the composite increases linearly with increase in mass fraction of acrylic\_acid-tetmeth\_bisphen\_carbonate.

## CONCLUSION

The possibility of use of acrylic\_acid-tetmeth\_bisphen\_carbonate to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The results indicated that the values of all the properties (bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture) increased with increase in mass fraction of acrylic acid. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the acrylic acid-tetmeth bisphen carbonate composite were studied. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of acrylic acid-tetmeth bisphen carbonate. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blend, silico, Biovia, acrylic acid-tetmeth bisphen carbonate composite

## **INTRODUCTION**

One of the finest property of Blends or composites are these components do not lose their identity in the mixture. And as named this material contains more than one component. They improve the quality of material by combining and contribute to the property of the blend. It involves significant research and time in development of a single material with the desired property. A blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Blends are usually prepared by trial and error method. It involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of acrylic acid-tetmeth bisphen carbonate composite.

P. K. Dash and M.Palei

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of acrylic acid-tetmeth bisphen carbonate were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Molar Volume:** “It is the volume occupied by one mole of a substance”. Figure 1 shows that the molar volume of the composite decreases linearly with increase in mass fraction of acrylic acid-tetmeth bisphen carbonate.

**Density:** “Density is mass per unit volume”. Figure 2 shows that the densities of the composite decreases linearly with increase in mass fraction of acrylic acid-tetmeth bisphen carbonate.

**Permeability of Gas:** “Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium”. Figure 3 shows that the permeability of oxygen through the composite decreases with increase in mass fraction of acrylic acid-tetmeth bisphen carbonates.

Figure 4 show that the permeability of nitrogen through the composite decreases with increase in mass fraction of acrylic acid-tetmeth bisphen carbonate. Figure 5 shows that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of acrylic acid-tetmeth bisphen carbonate.

## CONCLUSION

The possibility of use of acrylic acid-tetmeth bisphen carbonate to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in acrylic acid-tetmeth bisphen carbonate fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeability for all the gases decreased with increase in mass fraction of acrylic acid-tetmeth bisphen carbonate. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its. Different properties of the polyacrylic acid and poly-t\_butadiene composite were studied. The composition of the blend was analyzed with respect to thermal conductivity, heat capacity and dielectric constant. In this experiment the results is indicating that all those parameters increased with increase in mass fraction of acrylic acid. This study will help to determine pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and poly-t\_butadiene composit

## **INTRODUCTION**

Blends or composites are materials are containing more than one component. The components do not ever lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials are having high strength for transportation industries [5], glass fiber reinforced polymers and latex polymer cementitious composites [6] etc. All the above mentioned examples are relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and poly-t\_butadiene composite.

**Monalisa Joshi**

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systems of France)” was used for analysis. The structures of polyacrylic acid and poly-t-butadiene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. Here Figure 1 graph shows that the heat capacity (Cp) of the composite increases linearly with increase in mass fraction of acrylic acid.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. Figure 2 graph shows that the thermal conductivity of the composite increases linearly with increase in mass fraction of acrylic acid.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. Here Figure 3 graph shows that the dielectric constant of the composite increases with increase in the mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and poly-t-butadiene heat capacity to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the three parameters increased with increase in mass fraction of acrylic acid. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of material. Development of a single material with desired property involves the significant research and time. A blend saves time to develop a new material, thereby reducing the cost of development of the products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All of the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and poly-t\_butadiene composite.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and poly-t<sub>2</sub>butadiene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Molar Volume:** “It is the volume occupied by one mole of a substance”. Figure 1 graph shows that the molar volume of the composite decreases linearly with increase in mass fraction of acrylic acid.

**Density:** “Density is mass per unit volume”. Figure 2 shows that the density of the composite decreases linearly with increase in mass fraction of acrylic acid.

**Permeability of Gas:** “Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium”. Figure 3 graph shows that the permeability of oxygen through the composite decreases with increase in mass fraction of acrylic acid.

Figure 4 graph shows that the permeability of nitrogen through the composite decreases with increase in mass fraction of acrylic acid. Figure 5 graph shows that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and poly-t<sub>2</sub>butadiene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and t-neoprene composite were studied. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all those parameters increased with increase in mass fraction of acrylic acid. This study will help to determine pairs without performing in vivo experiments reducing the requirements for resources, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and t-neoprene composite

## **INTRODUCTION**

Blends or composites are defined as materials containing more than one component. These components present in blend do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property requires significant research and time. A blend to develop a new material is a great option as it saves time thereby cut back the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. The above mentioned examples are mainly categorized based on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and t-neoprene composite.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The mechanical properties of the polyacrylic acid and t-neoprene composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of acrylic acid. This in silico study will help one to determine blending pairs reducing the cost, materials and time without in-vivo study.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and t-neoprene composite

## **INTRODUCTION**

Blends or composites are mainly made up of materials containing more than one component and makes a mixture. In the mixture the components contained do not lose their identity. Further these components combine and contribute to the property of the blend hence, improving the quality of the material. The development of a single material with the desired property requires investment of significant research and time. Whereas a new material with desired properties can be developed by a blend at the same time by reducing the cost of development of products and also saves time. Blends are of various types but in this study only polymer blends has been considered for study. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. The above mentioned examples are reported from experiments conducted at laboratory.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the mechanical properties of polyacrylic acid and t-neoprene composite.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and t-neoprene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Bulk Modulus:** “Bulk modulus is the measure of the decrease in volume with an increase in pressure”. Figure 1 shows that the bulk modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Shear Modulus:** “It is defined as the ratio of shear stress and shear strain.” Figure 2 shows that the shear modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Young's Modulus:** “It is defined as the ratio of stress and strain and compares relative stiffness”. Figure 3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Poisson Ratio:** “It is the ratio of lateral strain to longitudinal strain”. Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of acrylic acid.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”. Figure 5 shows that the brittle fracture stresses of the composite increases linearly with increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and t-neoprene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The results indicated that the values of all the properties (bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture) increased with increase in mass fraction of acrylic acid. This in silico study will help to determine components of a blend without performing laboratory experiments cutting back the cost, resources, and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid polyacrylic acid-c\_butadiene composite were studied. The composition of blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results will indicated that all these parameters increased with increase in mass fraction of acrylic acid. This study will help to determine the pairs without performing any laboratory experiments.

**Keywords:** Blend, silico, Biovia, polyacrylic acid polyacrylic acid-c\_butadiene composite

## **INTRODUCTION**

Blends or composites are those materials which containing more than one components. The components will not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research.. A blend can saves time to develop a new material by reducing the cost of development of products with desired properties. Polymer blends can be a Nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by applying trial and error method. Thus it involves wastage of materials, time and money. Thus researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and poly acrylic\_acid-c\_butadiene composite.

Prativa Satpathy

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and poly acrylic\_acid-c\_butadiene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. Fig 1 shows that the heat capacity ( $C_p$ ) of the composite increases linearly with gradual increase in mass fraction of acrylic acid.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. Fig 2 shows that the thermal conductivity of the composite increases linearly with the increase in mass fraction of acrylic acid.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. Fig 3 shows that the dielectric constant of the composite will increase with increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and poly acrylic\_acid-c\_butadiene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results will give an idea that all the three parameters increased with increase in mass fraction of acrylic acid. This in silico study will help determine components of a blend without performing laboratory experiments.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The mechanical properties of the polyacrylic acid and polyacrylic\_acid-c\_butadiene composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties gradually increased with increase in its mass fraction of acrylic acid. This study will help to determine pairs without performing laboratory experiments saving materials.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and polyacrylic\_acid-c\_butadiene composite

## **INTRODUCTION**

Composites are materials those containing more than one components. The components will not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. so the researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the mechanical properties of polyacrylic acid and polyacrylic\_acid-c\_butadiene composite.

P.Satpathy and A. Patel

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and polyacrylic\_acid-c\_butadiene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Bulk Modulus:** “Bulk modulus is the measure of the decrease in volume with an increase in pressure”. Figure 1 shows that the bulk modulus of the composite increases linearly with increase in mass fraction of acrylic acid. From a certain point and after that it reaches some point and curve like graph have found.

**Shear Modulus:** “It is defined as the ratio of shear stress and shear strain.” Fig 2 shows that the shear modulus of the composite increases linearly with increase in mass fraction of acrylic acid for some specific point.

**Young's Modulus:** “It is defined as the ratio of stress and strain and compares relative stiffness”. Fig 3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Poisson Ratio:** “It is the ratio of lateral strain to longitudinal strain”. Fig 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of acrylic acid, but point fluctuate after achieving some fixed point.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”. Figure 5 shows that the brittle fracture stresses of the composite increases linearly with increase in mass fraction of acrylic acid.

## CONCLUSIONS

Polyacrylic acid and polyacrylic\_acid-c\_butadiene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The results shows that the values of all the properties (bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture) increased gradually with the increase in mass fraction of acrylic acid

### **ABSTRACT**

A blend is a mixture of one more than one components. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and polyacrylic\_acid-c\_butadiene composite were studied. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were studied based on oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. This study will help to determine pairs without performing laboratory experiments saving materials, efforts and times.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and polyacrylic\_acid-c\_butadiene

### **INTRODUCTION**

Blends or composites are materials containing more than one component. Those are combined and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend can save time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. That's why the researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and polyacrylic\_acid-c\_butadiene composite.

Prativa Satpathy and Alisha Rath

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and polyacrylic\_acid-c\_butadiene were fed to the synthia of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Molar Volume:** “It is the volume occupied by one mole of a substance”. Fig 1 shows that the molar volume of the composite gradual decreases linearly with its increase in mass fraction of acrylic acid.

**Density:** “Density is mass per unit volume”. Fig 2 shows that the density of the composite decreases linearly with increase in mass fraction of acrylic acid.

**Permeability of Gas:** “Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium”. Fig 3 shows that the permeability of oxygen with the composite decreases with increase in mass fraction of acrylic acid.

Fig 4 shows that the permeability of nitrogen through the composite decreases with increase in mass fraction of acrylic acid. Fig 5 shows that the permeability of carbon dioxide through the composite decreases with its increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and polyacrylic\_acid-c\_butadiene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density are decreasing with the increase in its acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeability for all the gases decreased with increase in mass fraction of acrylic acid.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and polyvinyl chloride composite were studied. With the increasing value of mass fraction of acrylic acid the molar volume and density of the composite decreases. Based on the permeability of oxygen, nitrogen and carbon dioxide the permeability of composite were studied. Results showed that when the mass fraction of acrylic acid increases the permeability for all the gases decreases. This study will be helpful because it is time, money, material savings and we did this experiment without performing any laboratory experiments.

**Keywords:** Blend, *in silico*, Biovia, polyacrylic acid and polyvinyl chloride composite

## **INTRODUCTION**

Blends or composites are materials which contain more than one component and the components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time while a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and polyvinylchloride composite.

Pritam K. Dash and T. Mishra

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and polyvinylchloride were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Molar Volume:** “It is the volume occupied by one mole of a substance”. Figure 1 shows that while the mass fraction of acrylic acid increases the molar volume of the composite also increases accordingly.

**Density:** “Density is mass per unit volume”. Figure 2 shows that with the increase in the value of mass fraction of acrylic acid the density of the composite decrease linearly.

**Permeability of Gas:** “Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium”. Figure 3 show that when the mass fractions of acrylic acid increase the permeability of the oxygen through the composite gradually decreases.

Figure 4 shows that the permeability of nitrogen through the composite decreases with increase in mass fraction of acrylic acid. Figure 5 shows that with the increase in the value of mass fraction of acrylic acid the value of permeability of carbon dioxide through the composite decreases gradually.

## CONCLUSIONS

The possibility of use of polyacrylic acid and polyvinylchloride to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume of the composite increases and the density of the composite decreases with the increasing value of mass fraction of the acrylic acid. Based on permeability of oxygen, nitrogen and carbon dioxide the permeability properties of the composite determined. The results indicated that the when the mass fraction of the acrylic acid increases the permeability of all the mentioned gases are decreases gradually. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and polyvinylchloride composite were studied. With the help of heat capacity, thermal conductivity and dielectric constant the composition of the blend was analyzed. Through this experiment we know that with the increase in mass fraction the above three parameters are increased as well. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and polyvinylchloride composite

## **INTRODUCTION**

Blends or composites are materials which contain more than one component and the components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time while a blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and polyvinylchloride composite.

Pritam K. Dash and T. Mishra

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and polyvinylchloride were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. Figure 1 show that with the increasing value of mass fraction the heat capacity also increase linearly to a certain instant.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. Figure 2 shows that with the increase in mass fraction of acrylic acid the heat capacity also increase.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. Figure 3 shows that with the increasing value of the mass fraction of the acrylic acid the dielectric constant of the composite increases and stop at some point.

## CONCLUSIONS

The possibility of use of polyacrylic acid and polyvinylchloride to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicates that with the increase in the mass fraction of acrylic acid the heat capacity, thermal conductivity and the dielectric constant of composite also increses. With the savings of money and time and without performing any laboratory experiment we find the component of the blend through computer based study.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and polyneoprene composite were studied. Thermal conductivity, dielectric constant, heat capacities are the parameters which are responsible for the synthesis of the composition of the blend. We concluded that these parameters are increased with increased in mass fraction of acrylic acid. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and polyneoprene composite

## **INTRODUCTION**

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and polyneoprene composite.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and polyneo-prene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. Image 1 indicates that the heat capacity ( $C_p$ ) of the composite increases linearly with increase in mass fraction of acrylic acid.

**Thermal Conductivity:** “a measure of the ability of a material to transfer heat. Thermal conductivity is the heat transfer per unit time & per unit surface area, divided by the temperature differences.” Image 2 shows that the thermal conductivity of the composite increases linearly with increase in mass fraction of acrylic acid.

**Dielectric Constant:** “It is defined as a material is its absolute permittivity expressed as a ratio relative to the vacume permittivity”. Image 3 shows that the dielectric constant of the composite increases with increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and poly neo-prene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. Thermal conductivity, dielectric constant, heat capacity are the parameters which are responsible for the synthesis of the composition of the blend. We concluded that these parameters are increased with increased in mass fraction of acrylic acid. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and polyacrylonitrile were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Molar Volume:** “It is the volume occupied by one mole of a substance”. Figure 1 indicate that the molar volume of the composite decreases linearly with increase in mass fraction of acrylic acid.

**Density:** “Density is mass per unit volume”. Figure 2 indicates that the density of the composite decreases linearly with increase in mass fraction of acrylic acid.

**Permeability of Gas:** “Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium”. Figure 3 indicates that the permeability of oxygen through the composite decreases with increase in mass fraction of acrylic acid.

Figure 4 indicates that the permeability of nitrogen through the composite decreases with increase in mass fraction of acrylic acid. Figure 5 indicates that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and polyneoprene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The mechanical properties of the polyacrylic acid and polyneoprene composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of acrylic acid. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and polyneoprene composite

## **INTRODUCTION**

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus; researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the mechanical properties of polyacrylic acid and polyneoprene composite.

P. P. Udgata and T. Mishra

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and polyneo prene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Bulk Modulus:** “Bulk modulus is the relative change in the volume of a body produced by a unit compressive or tensile stress acting uniformly over its surface.” Figure 1 shows that the bulk modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Shear Modulus:** “It is defined as the ratio of shear stress to the shear strain.” Figure 2 shows that the shear modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Young's Modulus:** “It is defined as the ratio of stress and strain and compares relative stiffness”. Figure 3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Poisson Ratio:** “It is the ratio of lateral strain to longitudinal strain”. Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of acrylic acid.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”. Figure 5 shows that the brittle fracture stresses of the composite increases linearly with increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and poly neo prene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The results indicated that the values of all the properties (bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture) increased with increase in mass fraction of acrylic acid. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and poly oxypropylene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Bulk Modulus:** “Bulk modulus is the measure of the decrease in volume with an increase in pressure”. Figure 1 shows that the bulk modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Shear Modulus:** “It is defined as the ratio of shear stress and shear strain.”Figure 2 shows that the shear modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Young's Modulus:** “It is defined as the ratio of stress and strain and compares relative stiffness”. Figure 3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Poisson Ratio:** “It is the ratio of lateral strain to longitudinal strain”. Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of acrylic acid.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”. Figure 5 shows that the brittle fracture stress of the composite increases linearly with increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and poly oxypropylene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The results indicated that the values of all the properties (bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture) increased with increase in mass fraction of acrylic acid. This is silico study will help to determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and poly oxypropylene composite were studied. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. This study will help to determine pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and poly oxypropylene composite

## **INTRODUCTION**

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All of the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and poly oxypropylene composite.

S. Naik and A Patel

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and poly oxypropylene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Molar Volume:** “It is the volume occupied by one mole of a substance”. Figure 1 shows that the molar volume of the composite decreases linearly with increase in mass fraction of acrylic acid.

**Density:** “Density is mass per unit volume”. Figure 2 shows that the density of the composite decreases linearly with increase in mass fraction of acrylic acid.

**Permeability of Gas:** “Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium”. Figure 3 shows that the permeability of oxygen through the composite decreases with increase in mass fraction of acrylic acid.

Figure 4 shows that the permeability of nitrogen through the composite decreases with increase in mass fraction of acrylic acid. Figure 5 shows that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and poly oxypropylene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and poly t\_isoprene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. Figure 1 shows that the heat capacity ( $C_p$ ) of the composite increases linearly with increase in mass fraction of acrylic acid.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. Figure 2 shows that the thermal conductivity of the composite increases linearly with increase in mass fraction of acrylic acid.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. Figure 3 shows that the dielectric constant of the composite increases with increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and polyacrylic\_acid-t\_isoprene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the three parameters increased with increase in mass fraction of acrylic acid. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The mechanical properties of the polyacrylic acid and polyacrylic\_acid-t\_isoprene composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of acrylic acid. This study will help determine pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and polyacrylic\_acid-t\_isoprene composite

## **INTRODUCTION**

Blends or composites are materials containing more than one component. The components do not lose their identity in the mixture. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the mechanical properties of polyacrylic acid and polyacrylic\_acid-t\_isoprene composite.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and polyacrylic\_acid-t\_isoprene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Bulk Modulus:** “Bulk modulus is the measure of the decrease in volume with an increase in pressure”. Figure 1 shows that the bulk modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Shear Modulus:** “It is defined as the ratio of shear stress and shear strain.” Figure 2 shows that the shear modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Young's Modulus:** “It is defined as the ratio of stress and strain and compares relative stiffness”. Figure 3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Poisson Ratio:** “It is the ratio of lateral strain to longitudinal strain”. Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of acrylic acid.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”. Figure 5 shows that the brittle fracture stress of the composite increases linearly with increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and polyacrylic\_acid-t\_isoprene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The results indicated that the values of all the properties (bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture) increased with increase in mass fraction of acrylic acid. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and poly vinyl alcohol composite were studied. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all those parameters increased with increase in mass fraction of acrylic acid. This study has been taken to attempt an in-silico study which will help to determine pairs in a blend without performing laboratory experiments saving materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and poly vinyl alcohol composite

### **INTRODUCTION**

Blends or composites can be defined as materials consisting more than one component. The components in the mixture do not lose their identity. The components in the mixture combine and contribute to the property of the blend hence improving the quality of the material. Development of a single material with the desired property involves rigorous and extensive research and time. Thus it can be said that a blend, saves time to develop a new material with desired properties reducing the cost of development of products. There are varieties of polymer blends. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above polymer blends mentioned examples are based on experiments done in laboratory. Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and poly vinyl alcohol composite.

**Bhattacharya S et al.**

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and poly vinyl alcohol were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. Figure 1 shows that the heat capacity ( $C_p$ ) of the composite increases linearly with increase in mass fraction of acrylic acid.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. Figure 2 shows that the thermal conductivity of the composite increases linearly with increase in mass fraction of acrylic acid.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. Figure 3 shows that the dielectric constant of the composite increases with increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and poly vinyl alcohol to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the three parameters increased with increase in mass fraction of acrylic acid. This *in silico* study will help determine components of a blend without laboratory experiments with less resources, cost and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The mechanical properties of the polyacrylic acid and polyvinyl alcohol composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that the values of all the properties increased with increase in mass fraction of acrylic acid. This insilico study will help determine pairs without performing in vivo experiments reducing requirements for materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and polyvinyl alcohol composite

## **INTRODUCTION**

Blends or composites are well defined as materials containing more than one component. The components in the mixture do not lose their identity. The components in the mixture combine and contribute to the property of the blend thereby improving its quality. A single material with the desired property is developed with significant research and time. A blend whereas saves time reducing the cost of development of products with desired properties to develop a new material. Blends specially Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above polymer blends examples are based on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the mechanical properties of polyacrylic acid and poly vinyl alcohol composite.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and poly vinyl alcohol were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Bulk Modulus:** “Bulk modulus is the measure of the decrease in volume with an increase in pressure”. Figure 1 shows that the bulk modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Shear Modulus:** “It is defined as the ratio of shear stress and shear strain.” Figure 2 shows that the shear modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Young's Modulus:** “It is defined as the ratio of stress and strain and compares relative stiffness”. Figure 3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Poisson Ratio:** “It is the ratio of lateral strain to longitudinal strain”. Figure 4 shows that the Poisson ratio of the composite increases linearly with increase in mass fraction of acrylic acid.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”. Figure 5 shows that the brittle fracture stress of the composite increases linearly with increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and poly vinyl alcohol to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The results indicated that the values of all the properties (bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture) increased with increase in mass fraction of acrylic acid. This in silico study will help determine components of a blend without laboratory experiments without wastage of materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and polyvinyl alcohol composite were studied. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results showed that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. This in silico study was taken to prove that it will help to determine pairs without experimental data of laboratory cutting back materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and polyvinyl alcohol composite

## **INTRODUCTION**

Blends or composites are defined as materials containing more than one component. The components in the blend do not lose their identity. They combine and contribute to the property of the blend improving the quality of the material thereby. To develop a single material with the desired property includes extensive research and time. Therefore a blend is a great option which saves time to develop a new material with desired properties reducing the cost of development of products. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above examples are based on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and poly vinyl alcohol composite.

**Bhattacharya S et al.**

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and poly vinyl alcohol were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Molar Volume:** “It is the volume occupied by one mole of a substance”. Figure 1 shows that the molar volume of the composite decreases linearly with increase in mass fraction of acrylic acid.

**Density:** “Density is mass per unit volume”. Figure 2 shows that the density of the composite decreases linearly with increase in mass fraction of acrylic acid.

**Permeability of Gas:** “Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium”. Figure 3 shows that the permeability of oxygen through the composite decreases with increase in mass fraction of acrylic acid.

Figure 4 shows that the permeability of nitrogen through the composite decreases with increase in mass fraction of acrylic acid. Figure 5 shows that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and poly vinyl alcohol to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with increase in acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The results indicated that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. From this study it can be concluded that in silico study will help determine components of a blend without performing laboratory experiments reducing materials, cost and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and difluoroethylene composite were studied. The composition of the blend was examined with respect to the heat capacity, thermal conductivity and the dielectric constant. The result indicates that those entire frameworks increased with increase in mass fraction of acrylic acid. This study will help to determine pairs without performing laboratory experiments saving the materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and difluoroethylene composite

## **INTRODUCTION**

Blends or composites are materials which contain more than one component. The components don't lose their identity in the mixture. They collaborate and contribute to the property of the blend thus improving the quality of the material. Development of a single material with the craving property involves remarkable research and time. A blend lay aside time to be born a new material thereby decreasing the cost of generation of the products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire-resistant materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementations composites [6] etc. All the above mentioned examples figure on the laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and difluoroethylene composite.

Srabani mishra and Lokanath Meher

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and difluoroethylene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. Figure 1 confirms that the heat capacity (Cp) of the composite boost linearly with raise in mass fraction of acrylic acid.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. Figure 2 reveals that the thermal conductivity of the composite expands linearly with rise in mass fraction of acrylic acid.

**Dielectric Constant:** “It is describe as the ratio of the electric permeability of the material to the electric permeability of free space”. Figure 3 reveals that the dielectric constant of the composite rise with the growth in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and difluoroethylene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The outcome indicated that all the three framework increased with rise in mass fraction of acrylic acid. This silico study will help to determine components of a blend without doing any laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The mechanical properties of the polyacrylic acid and difluoroethylene composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The outcome shows that the values of all the properties rise with increase in mass fraction of acrylic acid. This study will help to conclude pairs without performing laboratory experiments saving materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and difluoroethylene composite

## **INTRODUCTION**

Blends or composites are the materials which contain more than one component. The components don't lose their identification in the mixture. They come together and contribute to the property of the blend thereby improving the quality of the material. Improvement of a single material with the preferred property involves important research and time. A blend reduces the time to develop a new material thereby reducing the cost of development of products with preferred properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers-natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the mechanical properties of polyacrylic acid and difluoroethylene composite.

Srabani mishra and Lokanath Meher

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and difluoroethylene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Bulk Modulus:** “Bulk modulus is the measure of the decrease in volume with an increase in pressure”. Figure 1 shows that the bulk modulus of the composite grows linearly with rise in mass fraction of acrylic acid.

**Shear Modulus:** “It is defined as the ratio of shear stress and shear strain.” Figure 2 reveals that the shear modulus of the composite rise linearly with rise in mass fraction of acrylic acid.

**Young's Modulus:** “It is explain as the ratio of stress and strain and compares relative stiffness”. Figure 3 reveals that the Young's modulus of the composite grows linearly with increase in mass fraction of acrylic acid.

**Poisson Ratio:** “It is the ratio of lateral strain to longitudinal strain”. Figure 4 reveals that the Poisson ratio of the composite rise linearly with increase in mass fraction of acrylic acid.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”. Figure 5 indicates that the brittle fracture stress of the composite increases linearly with rise in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and difluoroethylene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The outcome indicated that the values of all the properties (bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture) grow with increase in mass fraction of acrylic acid. This silico study will help to determine components of a blend without having any kind of laboratory experiments and it saves materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. Different properties of the polyacrylic acid and difluoroethylene composite were studied. The molar volume and density decreased with rise in acrylic acid fraction. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. The outcome showed that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. This study will help to determine the pairs without having any laboratory experiments that will save materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and difluoroethylene composite

## **INTRODUCTION**

Blends or composites are materials which will contain more than one component. The components do not lose their identity in the mixture. They come together and contribute to the property of the blend for improving the quality of the material. Improvement of a single material with the preferred property involves major research and time. A blend saves time to develop a new material thereby reducing the cost of development of products with preferred properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples based on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and difluoroethylene composite.

Srabani mishra and Lokanath Meher

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and difluoroethylene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Molar Volume:** “It is the volume occupied by one mole of a substance”. Figure 1 reveals that the molar volume of the composite decreases linearly with rise in mass fraction of acrylic acid.

**Density:** “Density is mass per unit volume”. Figure 2 indicates that the density of the composite decreases linearly with rise in mass fraction of acrylic acid.

**Permeability of Gas:** “Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium”. Figure 3 reveals that the permeability of oxygen through the composite decreases with rise in mass fraction of acrylic acid.

Figure 4 indicates that the permeability of nitrogen through the composite decreases with rise in mass fraction of acrylic acid.

Figure 5 reveals that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and difluoroethylene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The molar volume and density decreased with rise in acrylic acid fraction. The permeability properties of the composite were studied lies on permeability of oxygen, nitrogen and carbon dioxide. The outcome indicated that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. This in silico study will help to determine the components of a blend without having any laboratory experiments and it saves materials, money and time.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (DassaultSystemesof France)” was used for analysis. The structures of polyacrylic acid and poly12butadiene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. In the given Fig1 it can be shows that the heat capacity ( $C_p$ ) of the composite increases linearly when mass fraction of acrylic acid increase.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. In the given Fig2 it can be shows that the thermal conductivity of the composite increases linearly with increase in mass fraction of acrylic acid.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. In the given Fig3 it can be shows that the dielectric constant of the composite increases with increase in mass fraction of acrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and poly12butadiene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results clearly indicated that when the mass fractions of acrylic acid increase then all the three parameters were also increased with increase in mass fraction of acrylic acid. In silico study it will help to determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The mechanical properties of the polyacrylic acid and poly12butadiene composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results indicated that all those parameters increased with increase in mass fraction of acrylic acid. This study will help us to determine pairs without performing any laboratory experiments it saves our materials, money and time.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and poly12butadiene composite

## **INTRODUCTION**

Blends or composites are mixture which containing more than one component. They combine and contribute to the property of the blend thereby improving the quality of the material. Development of a single material with the desired property involves significant research and time. A blend saves time to develop a new material thereby reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by hit and trial method. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the mechanical properties of polyacrylic acid and poly12butadiene composite.

A. Saraf and Sujata Acharya

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and polybutadiene were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Bulk Modulus:** “Bulk modulus is the measure of the decrease in volume with an increase in pressure”. In the below Fig1 it can be clearly shows that when the mass fraction of acrylic acid increases the bulk modulus of the composite increases linearly.

**Shear Modulus:** “It is defined as the ratio of shear stress and shear strain”. In the below Fig2 it can be clearly shows that when the mass fraction of acrylic acid increases the shear modulus of the composite increases linearly.

**Young's Modulus:** “It is defined as the ratio of stress and strain and compares relative stiffness”. In the below Fig3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of acrylic acid.

**Poisson Ratio:** “It is the ratio of lateral strain to longitudinal strain”. In the below Fig4 it can be clearly shows that when the mass fraction of acrylic acid increases the Poisson ratio of the composite decreases linearly.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”. In the below Fig5 it can be clearly shows that when the mass fraction of acrylic acid increases the brittle fracture stress of the composite increases linearly.

## CONCLUSIONS

The possibility of use of polyacrylic acid and polybutadiene to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The results indicated that the values of all the properties (bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture) increased with increase in mass fraction of acrylic acid. This in silico study will help determine components of a blend without performing laboratory experiments saving materials, money and time.

### **ABSTRACT**

A blend or composite is a mixture of more than one component. Homogeneity is a very unique property of a blend polyacrylic acid and polyoxyphenyl composite having many different properties, which can be studied. With respect to heat capacity, thermal conductivity and dielectric constant, the composition of the blend was analyzed. From this result it is clearly indicated that all those parameters increased with increase in mass fraction of acrylic acid. Without performing laboratory experiments, We can determine the pairs using this study. Since a laboratory experiment is not required hence we can save materials, money and time money and time.

**Keywords:** Blend, silico, Biovia, Polyacrylic acid and polyoxyphenyl composite

## **INTRODUCTION**

There are more than one components are present in blends or composites. In the mixture the components do not lose their identity. The components are combined and contribute to the property of the blend which improving the quality of the material. Development of a single material with the desired property involves significant research and time. A new material develops by blend which save time and reducing the cost of development of products with desired properties. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of *in silico* approach [7] to develop new blends. This study intends to predict the permeability related properties of polyacrylic acid and polyoxyphenyl composite.

**Tikina Mishra**

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and polyoxyphenyl were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Heat Capacity:** “It is the amount of heat required to raise the temperature of one unit weight of a substance by 1°C without change of phase”. From Figure 1 it is clearly observed that shows that the heat capacity ( $C_p$ ) of the composite increases linearly with increase in mass fraction of acrylic acid.

**Thermal Conductivity:** “It indicates the correlation between heat flux per unit area and temperature gradient”. Figure 2 shows that the thermal conductivity of the composite increases linearly with increase in mass fraction of acrylic acid.

**Dielectric Constant:** “It is defined as the ratio of the electric permeability of the material to the electric permeability of free space”. From Figure 3 it is clearly observed that the dielectric constant of the composite increases with increase in mass fraction of polyacrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and polyoxyphenyl to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to permeability properties. The composition of the blend was analyzed with respect to heat capacity, thermal conductivity and dielectric constant. The results indicated that all the above three parameters increased with increase in mass fraction of polyacrylic acid. Without performing laboratory experiments, We can determine the pairs using this study. Since laboratory experiments are not required hence we can save materials, money and time.

### **ABSTRACT**

A blend is a mixture of more than one component. The desired property of a blend is its homogeneity. The mechanical properties of the polyacrylic acid and polyoxphenyl composite were studied based on bulk modulus, shear modulus, Young' modulus, Poisson ratio and brittle stress fracture. The results show that all the above mentioned three parameters increases with increase in mass fraction of acrylic acid. This study saves our valuable time, money and material since it does not require performing laboratory experiments to determine pairs.

**Keywords:** Blend, silico, Biovia, polyacrylic acid and polyoxphenyl composite

## **INTRODUCTION**

Blends or composites are materials in which more than one component are present. In blends the components do not lose their identity. The components combine and contribute to the property of the blend which improves the quality of the material. To develop a single material with the desired property it requires time and significant. A new material with desired properties can be develop by blend which reducing the cost of development and save time. Polymer blends can be nano material modified polymers [1], biodegradable polymers- natural fiber composites [2], fire retardant/fire proof materials [3,4], lightweight composite materials having high strength for transportation industries [5], glass fiber reinforced polymers, latex polymer cementitious composites [6] etc. All the above mentioned examples relied on laboratory experiments.

Usually blends are prepared by trial and error method. Thus it involves wastage of materials, time and money. Thus, researchers have focused on the use of in silico approach [7] to develop new blends. This study intends to predict the mechanical properties of polyacrylic acid and polyoxphenyl composite.

Swapna Meher and Tikina Mishra

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and polyoxyphenyl were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Bulk Modulus:** “Bulk modulus is the measure of the decrease in volume with an increase in pressure”. From Figure 1 it is observed that the bulk modulus of the composite increases linearly with increase in mass fraction of polyacrylic acid.

**Shear Modulus:** “It is defined as the ratio of shear stress and shear strain.” From figure 2 it is clearly observed that the shear modulus of the composite increases linearly with increase in mass fraction of polyacrylic acid.

**Young's Modulus:** “It is defined as the ratio of stress and strain and compares relative stiffness”. Figure 3 shows that the Young's modulus of the composite increases linearly with increase in mass fraction of polyacrylic acid.

**Poisson Ratio:** “It is the ratio of lateral strain to longitudinal strain”. From figure 4 it is clearly observed that the Poisson ratio of the composite increases linearly with increase in mass fraction of polyacrylic acid.

**Brittle Fracture Stress:** “Brittle Fracture is the sudden, rapid cracking of a material under stress”. From figure 5 it is observed that the brittle fracture stress of the composite increases linearly with increase in mass fraction of polyacrylic acid.

## CONCLUSIONS

The possibility of use of polyacrylic acid and polyoxyphenyl to form a blend was explored using Biovia Materials Studio. The composition of the blend was analyzed with respect to mechanical properties. The results show that all the above mentioned three parameters increases with increase in mass fraction of acrylic acid. This study saves our valuable time, money and material since it does not require to perform laboratory experiments to determine pairs.. This study saves our valuable time, money and material since it does not require to perform laboratory experiments to determine pairs.

## MATERIALS AND METHODS

“Materials studio module of Biovia software (Dassault Systemes of France)” was used for analysis. The structures of polyacrylic acid and polyoxyphenyl were fed to the synthia menu of Materials Studio and run for different weight fractions of the components.

## RESULTS AND DISCUSSION

**Molar Volume:** “It is the volume occupied by one mole of a substance”. From figure 1 it is clearly observed that the molar volume of the composite decreases linearly with increase in mass fraction of polyacrylic acid.

**Density:** “Density is mass per unit volume”. From Figure 2 it is clearly observed that the density of the composite decreases linearly with increase in mass fraction of polyacrylic acid.

**Permeability of Gas:** “Permeability is the rate at which the gas can pass through the polymer membrane after the gas has come to equilibrium” From .figure 3 it is observed that the permeability of oxygen through the composite decreases with increase in mass fraction of polyacrylic acid.

From Figure 4 it is observed that the permeability of nitrogen through the composite decreases with increase in mass fraction of polyacrylic acid. From Figure 5 it is observed that the permeability of carbon dioxide through the composite decreases with increase in mass fraction of polyacrylic acid.

## CONCLUSIONS

By using Biovia Materials Studio the possibility use of blend of polyacrylic acid and polyoxyphenyl was explored. Permeability is a properties which is use to analyzed the composition of the blend. When acrylic acid mass fraction increases the molar volume and density decreased. The permeability properties of the composite were studied based on permeability of oxygen, nitrogen and carbon dioxide. From this result it is clearly indicate that the permeability for all the gases decreased with increase in mass fraction of acrylic acid. This study saves our valuable time, money and material since it does not require performing laboratory experiments to determine pairs.

### ABSTRACT

The stock markets play a significant role in the economic development of India. The focus of this work is to identify the statistically significant parameters related to share prices for Bank of Baroda. The parameters studied were “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization” and the effects were studied using correlation matrix. The results showed that six number of parameters were statistically significant and varied directly while two number of parameters were statistically significant and varied inversely.

**Keywords:** Bombay Stock Market, Bank of Baroda, r value, p value, correlation matrix

## INTRODUCTION

Share market plays a major role in Indian economy. A significant number of people invest in the share market. However, the ups and downs of the share market affects significantly common people. There are some studies [1,2] to understand the effect of various factors controlling the share price. Most of the trading in Indian stock market takes place through two major stock exchanges namely, Bombay stock exchange (BSE) and National stock exchange (NSE). The banks are the major pillars of the economy. Thus, there is a need to analyze the factors affecting their share prices. This study focusses on the effect of some BSE parameters on high stock price of Bank of Baroda.

## METHODOLOGY

Data from Bombay Stock Exchange was downloaded on 24 Apr 2020 at around 10 PM for the period 2 Mar 2020 to 23 Apr 2020 for Bank of Baroda. For each of the available dates “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization” were noted. The data were used to develop a correlation matrix using Mat lab 2014. The r values and p values were noted.

23815

KVD Prakash

## RESULTS AND DISCUSSION

Table 1 shows the r values and p values obtained from the correlation matrix. In the r value matrix, the parameters in red shows an inverse relationship while the ones in green shows a direct relationship. In the p value matrix, the parameters in green indicates p value less than 0.05 indicating statistically significant parameter. All the values have been taken with the precision upto two places of the decimal.

## CONCLUSIONS

In this study the statistically significant parameters related to share prices for Bank of Baroda were identified. Correlation matrix was used for the analysis. The parameters studied were “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization”. The results showed that six number of parameters were statistically significant and varied directly while two number of parameters were statistically significant and varied inversely.

### ABSTRACT

The stock markets contribute a large scope in economic development of India. The objective of this study was to identify the statistically significant parameters related to share prices for Bank of India. The parameters studied were “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization” and the effects were studied using correlation matrix. The results showed that six number of parameters were statistically significant and varied directly while two number of parameters were statistically significant and varied inversely.

**Keywords:** Bombay Stock Market, Bank of India, High Stock Prices, WAP, Spread, Deliverable Quantity

## INTRODUCTION

Share market plays a major role in Indian economy. A significant number of people invest in the share market. However, the ups and downs of the share market affects significantly common people. There are some studies [1,2] to understand the effect of various factors controlling the share price. Most of the trading in Indian stock market takes place through two major stock exchanges namely, Bombay stock exchange (BSE) and National stock exchange (NSE). The banks are the major pillars of the economy. Thus, there is a need to analyze the factors affecting their share prices. This study focuses on the effect of some BSE parameters on high stock price of Bank of India.

## METHODOLOGY

Data was collected from Bombay Stock Exchange on 23 Apr 2020 at around 10 PM for the period 2 Mar 2020 to 23 Apr 2020 for Bank of India. For each of the available dates “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization” were noted. The data were used to develop a correlation matrix using Mat lab 2014. The r values and p values were noted.

23818

KVD Prakash

## RESULTS AND DISCUSSION

Table 1 shows the r values and p values obtained from the correlation matrix. In the r value matrix, the parameters in red shows an inverse relationship while the ones in green shows a direct relationship. In the p value matrix, the parameters in green indicates p value less than 0.05 indicating statistically significant parameter. All the values have been taken with the precision upto two places of the decimal.

## CONCLUSIONS

This study focussed on identifying the statistically significant parameters related to share prices for Bank of India. Correlation matrix was used for the analysis. The parameters studied were “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization”. The results showed that five number of parameters were statistically significant and varied directly while two number of parameters were statistically significant and varied inversely.

There are some studies [1,2] to understand the effect of various factors controlling the share price. Most of the trading in Indian stock market takes place through two major stock exchanges namely, Bombay stock exchange (BSE) and National stock exchange (NSE). The banks are the major pillars of the economy. Thus, there is a need to analyze the factors affecting their share prices. This study focusses on the effect of some BSE parameters on high stock price of ACC Cement.

### METHODOLOGY

Data was collected from Bombay Stock Exchange on 23 Apr 2020 at around 10 PM for the period 2 Mar 2020 to 23 Apr 2020 for ACC Cement. For each of the available dates “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization” were noted. The data were used to develop a correlation matrix using Mat lab 2014. The r values and p values were noted.

23830

## RESULTS AND DISCUSSION

Table 1. shows the r values and p values obtained from the correlation matrix. In the r value matrix, the parameters in red shows an inverse relationship while the ones in green shows a direct relationship. In the p value matrix, the parameters in green indicates p value less than 0.05 indicating statistically significant parameter.

## CONCLUSIONS

This study focussed on identifying the statistically significant parameters related to share prices for ACC Cement. Correlation matrix was used for the analysis. The parameters studied were “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization”. The results showed that four number of parameters were statistically significant and varied directly while three number of parameters were statistically significant and varied inversely.

### INTRODUCTION

Share market plays a major role in Indian economy. A significant number of people invest in the share market. However, the ups and downs of the share market affects significantly common people. There are some studies [1,2] to understand the effect of various factors controlling the share price. Most of the trading in Indian stock market takes place through two major stock exchanges namely, Bombay stock exchange (BSE) and National stock exchange (NSE). The banks are the major pillars of the economy. Thus, there is a need to analyze the factors affecting their share prices. This study focusses on the effect of some BSE parameters on high stock price of Allahabad Bank.

### METHODOLOGY

Data was collected from Bombay Stock Exchange on 23 Apr 2020 at around 10 PM for the period 1Feb 2020 to 19Mar 2020 for Allahabad Bank. For each of the available dates “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high

**KVD Prakash**

and low, spread open and close and the high stock price of the organization” were noted. The data were used to develop a correlation matrix using Mat lab 2014. The r values and p values were noted.

**RESULTS AND DISCUSSION**

Table 1. shows the r values and p values obtained from the correlation matrix. In the r value matrix, the parameters in red shows an inverse relationship while the ones in green shows a direct relationship. In the p value matrix, the parameters in green indicates p value less than 0.05 indicating statistically significant parameter.

**CONCLUSIONS**

This study focussed on identifying the statistically significant parameters related to share prices for Allahabad Bank. Correlation matrix was used for the analysis. The parameters studied were “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization”. The results showed that zeronumber of parameters were statistically significant and varied directly while seven number of parameters were statistically significant and varied inversely.

## INTRODUCTION

Share market plays a major role in Indian economy. A significant number of people invest in the share market. However, the ups and downs of the share market affects significantly common people. There are some studies to understand the effect of various factors controlling the share price. Most of the trading in Indian stock market takes place through two major stock exchanges namely, Bombay stock exchange (BSE) and National stock exchange (NSE). The banks are the major pillars of the economy. Thus, there is a need to analyze the factors affecting their share prices. This study focusses on the effect of some BSE parameters on high stock price of HDFC Bank.

## METHODOLOGY

Data was collected from Bombay Stock Exchange on 23 Apr 2020 at around 10 PM for the period 2 Mar 2020 to 23 Apr 2020 for HDFC Bank. For each of the available dates “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization” were noted. The data were used to develop a correlation matrix using Mat lab 2014. The r values and p values were noted.

23845

**KVD Prakash**

**RESULTS AND DISCUSSION**

Table 1. shows the r values and p values obtained from the correlation matrix. In the r value matrix, the parameters in red shows an inverse relationship while the ones in green shows a direct relationship. In the p value matrix, the parameters in green indicates p value less than 0.05 indicating statistically significant parameter.

**CONCLUSIONS**

This study focussed on identifying the statistically significant parameters related to share prices for HDFC Bank. Correlation matrix was used for the analysis. The parameters studied were “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization”. The results showed that threenumber of parameters were statistically significant and varied directly while four number of parameters were statistically significant and varied inversely.

### INTRODUCTION

Share market plays a major role in Indian economy. A significant number of people invest in the share market. However, the ups and downs of the share market affects significantly common people. There are some studies [1,2] to understand the effect of various factors controlling the share price. Most of the trading in Indian stock market takes place through two major stock exchanges namely, Bombay stock exchange (BSE) and National stock exchange (NSE). The banks are the key drivers to the Indian economy. Thus, there is a need to analyze the factors affecting their share prices. This study focuses on the effect of some BSE parameters on high stock price of SAIL.

### METHODOLOGY

Data was collected from Bombay Stock Exchange on 23 Apr 2020 at around 10 PM for the period 2 Mar 2020 to 23 Apr 2020 for SAIL. For each of the available dates “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and

### KVD Prakash

low, spread open and close and the high stock price of the organization” were noted. The data were used to develop a correlation matrix using Mat lab 2014. The r values and p values were noted.

## RESULTS AND DISCUSSION

Table 1. shows the r values and p values obtained from the correlation matrix. In the r value matrix, the parameters in red show an inverse relationship while the ones in green shows a direct relationship. In the p value matrix, the parameters in green indicates p value less than 0.05 indicating statistically significant parameter.

## CONCLUSIONS

This study focussed on identifying the statistically significant parameters related to share prices for SAIL. Correlation matrix was used for the analysis. The parameters studied were “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization”. The results showed that five numbers of parameters were statistically significant and varied directly while two numbers of parameters were statistically significant and varied inversely.

### ABSTRACT

The stock markets contribute a largescope in economic development of India. The objective of this study was to identify the statistically significant parameters related to share prices for State Bank of India. The parameters studied were “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization” and the effects were studied using correlation matrix. The results showed that threenumber of parameters were statistically significant and varied directly while four number of parameters were statistically significant and varied inversely.

**Keywords:** Bombay Stock Market, State Bank of India, High Stock Prices, WAP, Spread, Deliverable Quantity

### INTRODUCTION

Share market plays a major role in Indian economy. A significant number of people invest in the share market. However, the ups and downs of the share market affects significantly common people. There are some studies [1,2] to understand the effect of various factors controlling the share price. Most of the trading in Indian stock market takes place through two major stock exchanges namely, Bombay stock exchange (BSE) and National stock exchange (NSE). The banks are the major pillars of the economy. Thus, there is a need to analyze the factors affecting their share prices. This study focusses on the effect of some BSE parameters on high stock price of State Bank of India.

### METHODOLOGY

Data was collected from Bombay Stock Exchange on 23 Apr 2020 at around 10 PM for the period 2 Mar 2020 to 23 Apr 2020 for State Bank of India. For each of the available dates “weighted average price (WAP), number of shares,

### KVD Prakash

number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization” were noted. The data were used to develop a correlation matrix using Mat lab 2014. The r values and p values were noted.

## RESULTS AND DISCUSSION

Table 1. shows the r values and p values obtained from the correlation matrix. In the r value matrix, the parameters in red shows an inverse relationship while the ones in green shows a direct relationship. In the p value matrix, the parameters in green indicates p value less than 0.05 indicating statistically significant parameter.

## CONCLUSIONS

This study focussed on identifying the statistically significant parameters related to share prices for State Bank of India. Correlation matrix was used for the analysis. The parameters studied were “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization”. The results showed that threenumber of parameters were statistically significant and varied directly while four number of parameters were statistically significant and varied inversely.

### ABSTRACT

The stock markets contribute a largescope in economic development of India. The objective of this study was to identify the statistically significant parameters related to share prices for VISA Steel. The parameters studied were “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization” and the effects were studied using correlation matrix. The results showed that fournumber of parameters were statistically significant and varied directly while three number of parameters were statistically significant and varied inversely.

**Keywords:** Bombay Stock Market, VISA Steel, High Stock Prices, WAP, Spread, Deliverable Quantity

## INTRODUCTION

Share market plays a major role in Indian economy. A significant number of people invest in the share market. However, the ups and downs of the share market affects significantly common people. There are studies to understand the effect of various factors controlling the share price. In most countries the stock exchange has two important functions. Most of the trading in Indian stock market takes place through two major stock exchanges namely, Bombay stock exchange (BSE) and National stock exchange (NSE). The banks are the major pillars of the economy. Thus, there is a need to analyze the factors affecting their share prices. This study focusses on the effect of some BSE parameters on high stock price of VISA.

## METHODOLOGY

Data was collected from Bombay Stock Exchange on 23 Apr 2020 at around 10 PM for the period 2 Mar 2020 to 23 Apr 2020 for VISA Steel. For each of the available dates “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and

### KVD Prakash

low, spread open and close and the high stock price of the organization” were noted. The data were used to develop a correlation matrix using Mat lab 2014. The r values and p values were noted.

## RESULTS AND DISCUSSION

Table 1. shows the r values and p values obtained from the correlation matrix. In the r value matrix, the parameters in red shows an inverse relationship while the ones in green shows a direct relationship. In the p value matrix, the parameters in green indicates p value less than 0.05 indicating statistically significant parameter.

## CONCLUSIONS

This study focussed on identifying the statistically significant parameters related to share prices for VISA Steel. Correlation matrix was used for the analysis. The parameters studied were “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization”. The results showed that four number of parameters were statistically significant and varied directly while three number of parameters were statistically significant and varied inversely.

### INTRODUCTION

Share market plays a major role in Indian economy. A significant number of people invest in the share market. However, the ups and downs of the share market affects significantly common people. There are some studies [1,2] to understand the effect of various factors controlling the share price. Most of the trading in Indian stock market takes place through two major stock exchanges namely, Bombay stock exchange (BSE) and National stock exchange (NSE). The banks are the major pillars of the economy. Thus, there is a need to analyze the factors affecting their share prices. This study focusses on the effect of some BSE parameters on high stock price of Kotak Mahindra Bank.

### METHODOLOGY

Data was collected from Bombay Stock Exchange on 23 Apr 2020 at around 10 PM for the period 2 Mar 2020 to 23 Apr 2020 for Kotak Mahindra Bank. For each of the available dates “weighted average price (WAP), number of shares,

**KVD Prakash**

number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization” were noted. The data were used to develop a correlation matrix using Mat lab 2014. The r values and p values were noted.

**RESULTS AND DISCUSSION**

Table 1. shows the r values and p values obtained from the correlation matrix. In the r value matrix, the parameters in red shows an inverse relationship while the ones in green shows a direct relationship. In the p value matrix, the parameters in green indicates p value less than 0.05 indicating statistically significant parameter. All the values have been taken with the precision upto two places of the decimal.

**CONCLUSIONS**

This study focussed on identifying the statistically significant parameters related to share prices for Kotak Mahindra Bank. Correlation matrix was used for the analysis. The parameters studied were “weighted average price (WAP), number of shares, number of trades, total turnover (in INR), deliverable quantity, percent deliverable quantity to traded quantity, spread high and low, spread open and close and the high stock price of the organization”. The results showed that twonumber of parameters were statistically significant and varied directly while five number of parameters were statistically significant and varied inversely.

### ABSTRACT

It is known that phytochemicals of different plants have antiviral property. *Curcumin* is one of the major phytochemical capable of fighting against virus. The effect of functional modification of *curcumin* molecule by amino group on deactivation of 6M3M protein of Corona virus has been studied. It was observed that the addition of functional groups at specific sites influence the activity of the ligand.

**Keywords:** antiviral, protein, amino group, *curcumin*

## INTRODUCTION

Corona virus has infected many people around the globe resulting in a pandemic situation [1]. Till date no drugs or vaccines has been developed. Medicinal plants are rich source of bioactive compounds which can be effectively used against this infection [2]. Efforts are going on to use medicinal plants due to their less harmful nature compared to the chemical formulations. Turmeric has medicinal properties and this can be used to prepare medicines. One of the major components of turmeric is curcumin. Usually curcumin is used directly. This study intends effect of modification of curcumin at various sites by amino group on a vital protein of corona virus.

## METHODOLOGY

Simulation module of Biovia Discovery studio was used to add amino groups to specific locations of curcumin thereby modifying the molecule. The list of molecules created through the functional modifications are presented in Table 1. A vital protein for corona virus is 6M3M. Molecular docking has been performed using CDock menu following Charmm algorithm.

Rukmini Mishra

## RESULTS AND DISCUSSION

Table1 shows the effect of amino group at 3 sites of curcumin. The molecules have been represented using SMILES code. The results presented in the table shows that the interaction of the compound with the 6M3M protein is influenced by the nature, size and position of the functional group.

## CONCLUSIONS

A study has been done to identify the effect of amino groups at specific sites of curcumin and evaluate the effectivity of the modified molecules. The results show that curcumin is the maximum effective formulation. COC1=C\C=C\C=C(/O)\[CH-]\C(=C\C=C\2/C=CC(=O)C(=C2)OCN)\O)\C=CC1=O and COC1=C\C=C\C=C(/O)\[CH-]\C(=C\C=C\2/C=CC(=O)C(=C2)OCN)\O)\C=CC1=O have effectivity against 6M3M protein of corona virus to some extent. Other formulation is not active.

### ABSTRACT

It is known that phytochemicals of different plants have antiviral property. Curcumin is one of the major phytochemical capable of fighting against virus. The effect of functional modification of curcumin molecule by methyl group on deactivation of 6M3M protein of Corona virus has been studied. It was observed that the addition of functional groups at specific sites influence the activity of the ligand.

**Keywords:** antiviral, ligand, methyl group, protein

## INTRODUCTION

Corona virus is a deadly virus and has threatened global health [1]. Till date there is no specific drug available for it. Thus, researchers are trying to formulate drugs using plant extracts from medicinal plants [2]. Medicinal plants are rich in bioactive compounds. Turmeric is well known due to its medicinal values. One of the major components of turmeric is curcumin. Usually curcumin is used directly. This study intends effect of modification of curcumin at various sites by methyl group on a vital protein of corona virus.

## METHODOLOGY

Simulation module of Biovia Discovery studio was used to add methyl groups to specific locations of curcumin thereby modifying the molecule. The list of molecules created through the functional modifications are presented in Table 1. A vital protein for corona virus is 6M3M. Molecular docking has been performed using CDock menu following Charmm algorithm.

Rukmini Mishra

## RESULTS AND DISCUSSION

Table 1 shows the effect of methyl group at 3 sites of curcumin. The molecules have been represented using SMILES code. The results presented in the table show that the interaction of the compound with the 6M3M protein is influenced by the nature, size and position of the functional group.

## CONCLUSIONS

A study has been done to identify the effect of methyl groups at specific sites of curcumin and evaluate the effectivity of the modified molecules. The results show that curcumin is the maximum effective formulation. CCOC1=C\C(=C\C=C(/O)\[CH-])\C(=C\C=C\2/C=CC(=O)C(=C2)OC)\O)\C=CC1=O has effectivity against 6M3M protein of corona virus to some extent. Other formulations are not active.

### ABSTRACT

Marine microorganisms continue to be a rich repository of structural and biologically active novel compounds with potential use in the Pharmabiotech industry. The unique physiochemical properties of the marine environment (such as pH, pressure, temperature, osmolarity) and uncommon functional groups (such as isonitrile, dichloroimine, isocyanate, and halogenated functional groups) are frequently found in marine metabolites. These facts have resulted in the production of bioactive substances with different properties than those found in terrestrial habitats. In fact, the marine environment contains a relatively untapped reservoir of bioactivity. Recent advances in genomics, metagenomics, proteomics, combinatorial biosynthesis, synthetic biology, screening methods, expression systems, bioinformatics, and the ever increasing availability of sequenced genomes provides us with more opportunities than ever in the discovery of novel bioactive compounds and biocatalysts. The combination of these advanced techniques with traditional techniques, together with the use of dereplication strategies to eliminate known compounds, provides a powerful tool in the discovery of novel marine bioactive compounds. This review outlines and discusses the emerging strategies of these bioactive compounds

**Keywords:** Biocatalyst discovery, Dereplication, Marine bioactive compounds, Metaproteomic, Omic approaches, Synthetic biology.

## INTRODUCTION

### Marine bio active compounds: Bioprospecting and its strategies

The advent of biotechnology has prompted researchers to attempt the synthesis of pharmaceutical compounds. Some success has been achieved with synthetic combinatorial chemistry and biosynthetic gene cluster manipulations. However, natural product discovery still proves to be one of the best sources for new bioactive chemicals. Nature's superiority in bioactive chemical production and the unknown number of undiscovered compounds provide poignant motivation to protect the aquatic environment from human alteration. The alteration of the delicate aquatic environment due to human pollution has unknown consequences for the undiscovered life forms. The vast diversity of undiscovered life in the aquatic environment affords many opportunities for increasing the arsenal of therapeutic chemicals used to treat human disease. With each new finding we can continue to marvel at nature's ability to produce such complex and beneficial structures.

French bacteriologist Vuillemin used the term antibiosis for the first time that means "against the life," in the year 1877, later Louis Pasteur and Robert Koch observations came in to light and the word antibiosis renamed as antibiotics by an American microbiologist Selman Waksman, in the year 1942. The idea of microorganisms as a new source of novel pharmaceuticals spurred an extensive search for microbial metabolites of medicinal value. Early efforts led to the discovery and development of several diverse classes of antibiotics which are believed to have added over a decade to man's life span. A majority of the antimicrobials in clinical use today are microbial products, products of microbial origin or are their synthetic/semi-synthetic analogs. However the last three decades have been disappointing as new classes of microbial metabolites worthy of commercialization as antibiotics have not been found. The main focus has been on the semi-synthetic, "me-too" compounds and on synthetic classes the fluoroquinolones and oxazolidinones. The widespread use of these various antimicrobial agents has resulted in the gradual emergence of multi-resistant pathogens. In response to the threat that these organisms now pose a search for novel agents lacking cross-resistance with the older compounds and perhaps possessing new modes-of-action has begun. Microorganisms from unique ecological niches are being explored, libraries of historical compounds are being reevaluated in the light of current needs and new sub-cellular targets discovered through bacterial genomics are being used for screening. These efforts may result to the discovery of new, more effective antibiotics that will meet current formidable challenges in the concerned field.

The effect of microbes in the environment has been recognized for centuries but until the accidental discovery of penicillin by Alexander Fleming in 1928 their true beneficial potential was not recognized. This fortuitous event seemingly provided the first scientific clue that microorganisms could be an enormous source of novel pharmaceuticals. Since then microbial products have been proven to be a rich source of novel compounds with diverse biological activities, (Davies 1999; Demain 1998 and 1999; Imada and Hotta, 1992; Berman et al.,) 1997. Although synthetic compounds have continued to play important role in our fight against various diseases (Table.1) The antibacterial and anticancer therapeutic agents currently in clinical use are dominated by either microbial products or one of their analogs, (Singh and Greenstein, 2000; Cragg et al., 1997). The Physicians' Desk Reference of 1999 lists a total of 403 antimicrobial formulations of which 211 are listed as antibacterial (Physicians' desk reference, 1999). This list includes 19 penicillins, 26 cephalosporins, 1 monobactam, 2 carbapenems, 6 aminoglycosides, 5 tetracyclines, 7 macrolides, 6 fluoroquinolones, etc.

Most of these new antibiotics were discovered through extensive screening of microbial fermentations from the year 1940 - 1960 which is also referred to as the 'golden' period of antibiotics. There after conventional screening became less productive and an upsurge in semi-synthetic and synthetic chemistry efforts expanded the number and quality of antibiotics derived from the known classes (Lawrence et al., 1999; Lee et al., 1999). In the year 1970's the discovery of the monobactams, carbapenems and clavulanic acid by three different microbial screening efforts re established the importance of microorganisms in the discovery of new antibacterial compounds (Christopher et al., 1991).

**Ravikiran Regeti et al.**

Continued chemical and microbiological efforts provided several superior analogs of various antibiotic classes for the antibacterial market and semi-synthetic approaches are still being pursued to further improve the activities of old compounds. In nature all organisms need to compete in order to survive in their habitats and this Biological task can only be achieved by the development of competitive mechanisms such as the production of toxins, enzymes and antimicrobial agents like antibiotics. The search for antibiotics began in the late 18<sup>th</sup> century with the growing acceptance of the germ theory of disease, a theory which linked bacteria and other microbes to the causation of a variety of ailments as a result scientists started to devote more time to search for drugs that would kill these disease-causing bacteria without causing any side or adverse effect to the host.

An antibiotic is a drug that kills or slows down the growth of bacteria. Antibiotics are one class of "antimicrobials" a larger group which also includes anti-viral, anti-fungal, and anti-parasitic drugs. They are relatively harmless to the host and therefore can be used to treat infection. The term originally described only those formulations derived from living organisms but now applied also to synthetic antimicrobials such as the sulfonamides. Antibiotics are labeled (magic bullets) drugs which target disease without harming the host. Antibiotics are not effective in viral, fungal and other non-bacterial infections and individual antibiotics vary widely in their effectiveness on various types of bacteria. Some specific antibiotics target either gram-negative or gram-positive bacteria and others are more wide-spectrum antibiotics. The effectiveness of individual antibiotics varies with the location of the infection and the ability of the antibiotic to reach the site. Oral antibiotics are the simplest approach when effective with intravenous antibiotics reserved for more serious cases. Antibiotics may sometime be administered topically as with eye drops or ointments.

The first widely used antibiotic compounds used in modern medicine were produced and isolated from living organisms such as the penicillin class produced by fungi *Penicillium*, streptomycin from *Streptomyces* but the actinomycetes are the group of prokaryotic filamentous soil microorganisms which are known as the top producers of antimicrobial agents especially *Streptomyces* (Osborne et al., 2000; Rondon M., et al 2000). Some of the antibiotics produced by *Streptomyces* are erythromycin, amphotericin, neomycin, streptomycin and rifamycin. Advances in organic chemistry led to contribute many synthetic antibiotics. Many antibiotics are relatively small molecules with a molecular weight less than 2000 Dalton, with different modes of action. Generally they interfere with biological processes such as replication, translation and cell wall synthesis. Some antibiotics like tetracycline interfere with protein synthesis by associating with the 30S ribosomal sub-unit penicillin, produced by *Penicillium notatum* prevent transpeptidation of N-acetyl-muramic acid resulting in a weakened peptidoglycan structure. The search for new natural products from aquatic microorganisms has already shown promising results by discovering compounds with possibly useful as anticancer and cardiovascular agents (Lei and Zhou 2002). With the worldwide sale of 45 billion dollars, anti-infective compounds represent the third largest therapeutics on commercial sale and is expected to increase by folds.

During the last three decades pharmaceutical companies have been searching for new antibiotics to counter the problem of increasing bacterial resistance. During this period use of new chemical derivatives of pre-existing antibiotics has been the only method available because no novel chemical class of antibiotics has been discovered. The oceans covers over the 70% of the earth's surface and roughly half of the biodiversity found on this planet is by the aquatic environment with 34 of the 36 phyla of life as represented by (Donia and Hamann 2003). Over the last 40 years aquatic natural product research has become a multi-disciplinary field touching on subjects within biology, chemistry, chemical ecology and pharmacology. During this brief period bacterial secondary metabolites with pharmacodynamic properties encompassing such diverse biological activities as antibiotics, antivirals, antimitotic and antineoplastics have already been documented. Other aquatic organisms such as blue green algae, seaweeds, horse shoe crabs, marine fungi and sponge metabolites have also yielded substantial natural products such as steroids, cytotoxic and antimicrobial agents as well as novel and biologically active peptides (Blunt et al., 2004).

**Ravikiran Regeti et al.**

The bacteria have long been the subject of scientific study due to their ability to cause disease in humans (Lederberg, 2000). One of the major advances in the health and well-being of human civilizations was the development of antibiotics. Although the introduction of antibiotics has had an enormous impact on the ability to treat bacterial infections bacteria continues to be the leading cause of deaths worldwide. Moreover the effectiveness of antibiotics has been eroded by the appearance of pathogenic strains that are resistant to nearly all classes of antibiotics coupled with the fact that only one new class of antibiotics has been introduced by the pharmaceutical industry since 1970 (Binder et al., 1999).

Soil microbial communities are among the most complex, diverse and important assemblages of organisms in the biosphere. They participate in various biological activities such as mineralization and decomposition of organic matter, biocontrol and antagonism (Hackl et al., 2004). It is said that bacteria that are found colonizing soil are ubiquitous since the chemical, physical and biotic characteristics present in such medium vary immensely. Recently Horner et al., 2003 postulated that microbial population can be various in a particle of soil due to oxygen concentration (Sprusansky et al., 2005). Postulated that soil bacteria display amazing versatility in their ability to use relatively poor sources of carbon, nitrogen and thrive on a mixture of complex carbohydrates and proteins that result from the degradation of organic material which demonstrates that soil microorganisms are an important source for the search of novel antimicrobial agents and molecules with various biotechnological importance. Some of the cultivable microbes that most commonly are isolated from soil samples belong to the genera of *Bacillus*, *Streptomyces* and *Pseudomonas*, (Belma et al., 2002; Stabb et al., 1994). *Streptomyces* are responsible for the production of over 70% of the antibiotics that have been isolated and reported (Dairi 1999, Lo C., 2002). The genus *Pseudomonas* is comprised of a gram-negative bacteria and is vastly involved in biological control of many plant pathogens.

Soil is a diverse medium composed of many minerals and substrates essential for metabolic pathways of prokaryotic and eukaryotic inhabitants (Dakora et al., 2002). The abiotic and biotic diversity present in this medium makes it difficult for the isolation of all the microbial community present therefore not even 1% of the entire soil microbial community has been identified (Courtis et al., 2003; Hackl et al., 2004; Rondon et al., 2000). There is great opportunity for discovering new microorganisms of industrial and clinical importance in soil. It is not possible to recreate all of the specific requirements that every soil microorganism needs. That is why standard microbiological techniques and innovative molecular and genetic technologies are being designed (Satoshi et al., 2004; Sprusansky et al., 2005; Zhou et al., 1996). Applying these techniques to a given environment one can obtain large quantities of genomic material and study a vast part of a given microbial community. Scientists have developed a new molecular strategies in the field of functional genomics which involves the construction of soil metagenomic libraries for the better understanding of microbial diversity and its possible applications in medical research (Rondon et al., 1999; Satoshi et al., 2004).

The irrational use of antibiotics has caused an increase in number of multiple drug resistant strains (MDR) of bacteria, fungi and many MDR strains are being reported from the genera *Pseudomonas*, *Streptococcus* and *Staphylococcus* (Chitnis et al., 2000). Some of these strains are resistant to most used antibiotics including methicillin, cephalosporins, and other beta-lactams that target peptidoglycan synthesis. Others have gained resistance toward neomycin and streptomycin which attack the bacterial ribosome. Antibiotic resistance got lot of attention in many forms including the recent developments in which the superbug NDM made lot of noise in news at global level there fore the hunt for the novel antibiotics from nature is the need of the day. NDM-1 is a newly-identified enzyme that makes bacteria resistant to a broad range of beta-lactam antibiotics. United Kingdom Health Protection Agency has stated that "most isolates with NDM-1 enzyme are resistant to all standard intravenous antibiotics for treatment of severe infections NDM-1 is known as New Delhi Metallo-Beta-Lactamase. This bacterium which was found recently is called the Superbug because of its efficiency to resist almost all antibiotics invented. NDM 1 has high resistance to survive against antibiotics such as carbapenems and beta-lactams which is its dangerous side. Though the investigations are on it has already effected India's medical tourism. Infact US President Obama has issued an advisory to US nationals not to go to the cheaper treatment in India to avoid the MDR. It is well understood that

**Ravikiran Regeti et al.**

antibiotic resistance is an evolutionary process that is based on selection for organisms that have enhanced ability to survive doses of antibiotics that would have previously been lethal; the underlying molecular mechanisms leading to antibiotic resistance can vary. Intrinsic resistance may naturally occur as a result of the bacterial genetic makeup. At the molecular level it is assumed that the bacterial chromosome may fail to encode a protein that the antibiotic targets or an acquired resistance may result from a mutation in the bacterial chromosome or the acquisition of extra-chromosomal DNA. The spread of antibiotic resistance mechanisms occurs through vertical transmission of inherited mutations from previous generations and genetic recombination of DNA by horizontal genetic exchange.

**Antagonism**

Antagonism may occur for space or for a common resource. (Nair and Simidu, 1987) hypothesized that antagonistic properties are linked to the trophic status of the habitats. Studies by the authors (Burgess et al., 1991) show that in shallow areas such as Tokyo Bay, organic nutrients derived from metabolic processes or death and decay of massive phytoplankton population and constant nutritional inputs from external sources assuage the necessity for bacterial populations to produce antibacterial substances to survive competition. Auto-inhibition acts as a controlling factor in maintaining species diversity by allowing the population to partially limit itself and co-exist with competitors. Many marine free-living and sediment-inhabiting marine bacteria have been shown to produce secondary metabolites that display antibacterial properties (Burgess et al., 1991).

Antibacterial activity has been widely exploited for the past 50 years and antibiotics have revolutionized Medical science by providing cure for formerly life-threatening diseases. Microbial populations have a resilient dynamic stability produced by biological buffering from competition. Microorganisms compete for nutrients, oxygen and favorable ecological niches and are selective for their tolerance towards ambient conditions i.e. pH, carbon dioxide, water and microbial toxins (Baker 1980). Microorganisms secrete metabolites some of which inhibit other microorganisms (antibiotics) while others stimulate other microorganisms to form essential stages of their life cycle.

A negative interaction can therefore directly inhibit a pathogen or inhibit a stimulatory microorganism there by indirectly inhibiting the pathogen. The aquatic environment harbors a wide range of microbes capable of exhibiting bacteriolytic and antibiotic activity. Bacteriolytic activities were found to be higher in the zooplankton than in sea water and the major group isolated were the gram negative bacteria in particularly the *Vibrio parahaemolyticus* followed by the gram positive strain, *Staphylococcus aureus* (Nair et al., 1985). There are reports on such bacteria from nutrient-rich algal surfaces (Jensen and Fenical, 1994; Bernan et al., 1997).

The bacteriolytic bacteria are mainly inhabitants of the places where the organic matter is high and contribute to its decomposition (Nair et al., 1985). A number of surface-associated marine bacteria have been found to produce antibiotics. (Trischman et al. 1994) isolated a species of *Streptomyces* from the surface of a jellyfish. Though the property of production of antimicrobial compounds is constitutive, (Patterson and Bolis 1997) observed that chemical signals received from potential competitor strains elicit an antagonistic response. However, this aspect still remains a little studied phenomenon (Mearns-Spragg et al., 1997; Mearns-Spragg et al., 1998). In contrast to antibiotics which promote interspecies antagonism, bacteriocins are responsible for intra specific antagonism. Colicin produced by *Eschereshia coli* has been studied extensively and similarly there are brevicin, nisin, pediocin produced by various groups.

Bacteriocin produced by *Halobacterium mediterranei* ATCC 33500 has been shown active against many other halobacteria (Meseguer et al., 1985). Bacteriocin -producing bacteria can change their strategy from anti- to pro-biotic depending on the environment. Therefore a brevicin producer could be skillfully used as probiotic to ward off unwanted microbes or to mitigate pathogenesis. A deep sea pigmented *Brevibacterium* sp has been shown to produce linocin-like compound that can be used as probiotic in aquaculture feeds. The extracts of this bacteria have not only been suggested to be useful in prolonging shelf-life of dairy products but the culture *per se* could be used as probiotics and also as feed additives in aquaculture (Loka Bharathi et al., 2003).

**Ravikiran Regeti et al.****16s rRNA sequencing & Metagenomics**

There are various methods to identify, characterize and exploit the microbes and the most accepted and popular technique of bacterial identification and classification is 16s rRNA gene sequencing in bacterial systematics. The rRNA is the most conserved (least variable) gene in all cells. Portions of the rDNA sequence from distantly-related organisms are remarkably similar. This means that the sequences from the distantly related organisms can be precisely aligned making the true differences required for easy measurements, therefore the genes that encode the rRNA (rDNA) have been used extensively to determine taxonomy, phylogeny and to estimate rates of species divergence amongst the bacteria. The comparison of 16s rDNA sequence can show evolutionary relatedness amongst microorganisms. This work was pioneered by (Carl Woese 1977) who proposed the three Domain system of classification - Archaea, Bacteria and Eucarya - based on such sequence information.

Prokaryotic microorganisms comprise the largest part of the earth's total biomass. This group contains a vast array of species, with enormous genetic, metabolic, physiological and behavioral diversity. However less than 1% of them have been cultured. Despite their ubiquity very little is known about their fundamental properties, range of diversity, interaction with the environment, evolution and the role they play in global biogeochemical cycles (Rodriguez-Valera, 2004). It is believed that progress towards filling these knowledge gaps will advance significantly when more whole genome sequences become available for the investigations. The current availability of bacterial genome information originated from molecular biology accomplishments and made available hundreds of protein-protein interactions based solely on sequence comparisons. Moreover genome sequence information can now be coupled with other experimental data (structures, domain shuffling, expression patterns, and gene adjacency in genomes) to allow new approaches to determine gene function. Nowadays genomics and especially metagenomic approaches contributing advancement in knowledge and understanding of microbiology, since it is not possible to transform a bacterial strain, delete gene information or manipulate any level of protein expression of non-culturable bacteria using traditional classical genetics techniques.

The information derived from whole-genome sequences following their comparative analysis can be used to study the novel aspects of biochemistry, physiology and metabolism of these organisms to investigate the role of microorganisms played in complex ecosystems and in global geochemical cycles, study their diversity and to predict the impact of microorganisms on the productivity and sustainability of agriculture, forestry and safety and quality of food supply. Simultaneously new genome sequences can be used to infer phylogenetic relationships among prokaryotes that deal with the organization and evolution of microbial genomes, mechanisms of transmission, exchange and reshuffling of genetic information (Koonin, 1997). The ability to culture a microbe certainly assists the sequencing of genomes. Some laboratories have already developed techniques to sequence organisms without ever culturing them (Kemmer and Fraser, 2002). This technique is important for those organisms that are not well understood or those live in very complex environments like extreme habitats, deep sea, rocks etc. (Nelson, 2003).

This technique allows scientists to discover new enzymes, antibiotics and other microbial products useful in various biotechnological applications including medicine and industry. Another application of sequencing directly from environment gives better understanding of the soil metagenome, metagenome of a healthy vs. diseased individuals (Nelson, 2003). The gene pools present in a prokaryotic species can be order of magnitude larger than that of the genome of a single strain. Contrasting with eukaryotic genomes the repertoire of genes present in a prokaryotic cell does not correlate stringently with its taxonomic identity. Therefore the gene catalogues from a particular environment may provide more meaningful information than the classical species catalogues. The industrial sector and researchers have employed great efforts searching for novel antimicrobial agents. They have screened many types of soils in order to culture antimicrobial agent producing microbes. One of the biggest problem that groups encountered is the rediscovery of the same antimicrobial agents. (Zachner and Fiedler 1995) stated that there is 99% of redundancy when searching for antimicrobial agents. The problem observed can be vastly related with the fact that 99% of the entire soil microbial population cannot be cultivated by conventional microbiological techniques.

**Ravikiran Regeti et al.**

Different approaches such as culture modification techniques in which culture media are prepared with ecological extracts and the use of density gradients for the separation of microbes based on cellular density are being used in order to culture the uncultivable, as mentioned above a limitation is that most of the time these methods render the same group of cultivable microbes resulting in the isolation of similar antimicrobial agents. In order to fulfill the need for novel antimicrobial screening methods significant contributions had been made by (DeLong 2002; Gillespie et al., 2002; Handelsman and Wackett. 2004, Martinez et al., 2004; Streit and Schmitz. 2004; Stevenson et al., 2004; Rondon et al., 2000) using metagenomic tools and techniques leading to the construction of many metagenomic libraries.

**Strategies for Marine Natural Compounds Discovery from Marine Microbial Communities**

Several screening approaches have been exploited in the discovery of novel natural compounds including conventional screening, genomics, metagenomics, combinatorial biosynthesis and synthetic biology. The repeated discovery of known compounds is a major limitation of existing assay methods, hence it is necessary not only to increase the availability of novel techniques to maximize the discovery of new compounds, but also to utilize dereplication strategies to avoid the discovery of known compounds. These strategies include the generation of antibiotic resistance markers and chemical profile analysis based on LC-NMR, LC-MS and HPLC-UV (Liu et al., 2012)

**Genome-Guided Bioprospecting**

Genomic sequencing of microorganisms in recent years has unveiled unprecedented insights into the biosynthetic potential of microorganisms, and thus the discovery of bioactive compounds has entered into the new postgenomic era. In recent years, the sequence data of microorganisms has been compiled into online databases such as Genomes on Line Database. The development of the Microbial Genome Sequencing Project resulted in the sequence, assembly and annotation of 182 marine bacterial genomes, which are available at CAMERA: Community CyberInfrastructure for Advanced Marine Microbial Ecology Research and Analysis. Available online: <https://portal.camera.calit2.net/gridsphere/gridsphere?cid=microgenome> (accessed on 22 January 2014). Due to these advances in bioinformatics, it is now possible to rapidly identify the gene clusters of bioactive compounds and predict their chemical structure *in silico* based on genomic information.

Along with advances in bioinformatics, genome sequencing has made it possible to rapidly identify the gene cluster of bioactive compounds and *in silico* predict their chemical structure based on genomics information. Development of software such as Antibiotics & Secondary Metabolite Analysis SHell (antiSMASH) (Figure 2), which allows the user to efficiently detect secondary metabolite gene clusters in the genomes of bacteria and fungi, has been a significant help to researchers (Medema et al., 2011; Blin et al., 2013). AntiSMASH allows for the detection of biosynthetic gene clusters of secondary metabolites such as type I, II and III PolyKetides (PKs), Non-Ribosomal Peptides (NRPs), phosphoglycolipids, oligosaccharide antibiotics, phenazines, thiopeptides, homoserine lactones, phosphanates, furans, terpenes, ectoines, bacteriocins, lantibiotics, nucleosides, aminoglycosides, aminocumarins amongst others. AntiSMASH also has the ability to partially predict types of compounds that can be produced if the gene cluster is completely functional (Blin et al., 2013).

**Gene-Guided Bioprospecting**

Gene-guided screening has been developed towards target genes associated with the biosynthetic pathways of bioactive compounds, such as those associated with the production of PKS (Engelhardt et al., 2010; Graça et al., 2013), NRPS (Engelhardt et al., 2010; Graça et al., 2013, bacteriocins Prieto et al., 2012) and dTDP-glucose-4,6-dehydratase (Wu et al., 2013). The combined strategy of gene and bioactivity based screens creates a more powerful tool which allows us to obtain valuable strains with the potential to synthesize new bioactive compounds. Marine sponge associated bacteria have been shown to produce a cocktail of secondary metabolites (Bhatnagar and Kim, 2010; Mondol et al., 2013).

**Ravikiran Regeti et al.****Metagenomics**

Metagenomics is the study of DNA from a mixed population of organisms and initially involves the cloning of either total or enriched DNA directly from the environment (eDNA) into a host that can be easily cultivated. Currently, function driven analysis and sequence-driven analysis are the two main approaches used for eDNA library screening (Figure 3) (Kennedy et al., 2010; Lee et al., 2010). More recently, advances in NGS technologies have allowed isolated eDNA to be sequenced and analyzed directly from environmental samples (via direct eDNA sequencing or shotgun metagenomics) (Figure 3) (Shokralla et al., 2012; Schofield et al., 2013). This is an effective strategy to access bioactive compounds encoded by the genomes of previously uncultured microbes through introduction of eDNA into a suitable host, bypassing the laborious step of library construction. This strategy has been used in human genome project and has also aided in the identification of novel biomass-degrading enzymes from cow rumen and compost (Schofield et al., 2013).

**Metagenomics: Functional Screening**

Functional screening has allowed for the identification of a large number of bioactive compounds and biosynthetic pathways including industrially important enzymes such as cellulases (Zhao et al., 2012), proteases (Biver et al., 2013; Waschowitz et al., 2009), lipases (Selvin et al., 2012; Hårdeman and Sjöling 2007), esterases (Jiang et al., 2012; Chu et al., 2008), glycoside hydrolases (Wierzbicka-Wos et al., 2013). For example, the isolation of clone-specific metabolites produced by eDNA clones identified from bacterial top agar overlay assays has led to the characterization of a wide variety of bioactive compounds. Among these compounds can be found long-chain *N*-acyl amino acid antibiotics, a novel isonitrile functionalized indole antibiotic, antibacterial active pigments such as violacein, indigo and turbomycin (Gillespie et al., 2002), terragines (Wang et al., 2000), fatty acid derivatives (Brady and Clardy 2002), and aromatic poliketides (Feng et al., 2011, all of which have been recovered from soil libraries. The cyclic peptides nocamide and patellamide D have also been isolated in this manner from soil and marine sponge libraries, respectively (Brady et al., 2009; Banik et al., 2010).

**Metagenomics: Sequenced-Based Screening**

Sequenced-based screening using homologous PCR or clone hybridization allows the identification of essential genetic components for cluster assembly. Sequenced-based screening has been used together with NGS technologies in the identification of PKS and NRPS clusters from a number of cultured strains (Johnston et al., 2012). Further to this, sequence-based analysis of marine metagenomic libraries has to date revealed the presence of a number of enzymes including peptidases (Cottrell et al., 2005), alkane hydroxylases (Xu et al., 2008, laccase Fang et al., 2011, and a fumarase Jiang et al., 2010).

**Novel Metagenomics Approaches**

In contrast with the conventional metagenomic approach, single cell genomics (Figure 6) begins with the isolation of the microbial cell fraction from an environmental sample and the separation of an individual prokaryotic cell through microfluidics, cytometry, or micromanipulation. Single cell genomics is dependent on multiple displacement amplification (MDA), which allows the generation of genomic DNA suitable for shotgun sequencing from unique microbial cells. Thereby, the entire biochemical potential of a single uncultured microbe can be evaluated from within a complex microbial community Stepanauskas and Sieracki 2007. Using this approach, microbial cells are firstly singularized by FACS, sorted, and individual microbial cells are then subjected to Whole Genomic Amplification (WGA). The amplified genome can then be sequenced, and the catalytic and metabolic potential of the genome analyzed. This approach has recently been employed by the Hentschel group, who used single cell genomics to characterize Poribacteria that form part of the microbial consortia of the Mediterranean sponge *Aplysina aerophoba* (Siegl et al., 2011). Using this approach, nearly 1.6 Mb of DNA sequence was obtained from the poribacterial genome that, following the annotation, allowed the identification of several enzymes, including several sulfatases and peptidases.

**Ravikiran Regeti et al.**

Substrate-Induced Gene-Expression screening (SIGEX), metabolite-regulated screening (METREX) and a technique based on subtractive hybridization magnetic bead capture. METREX involves the introduction of metagenomic DNA into a suitable host cell containing a biosensor plasmid to detect compounds of interest, for example, compounds that induce bacterial quorum sensing. Thereby, a sensor such as green fluorescent protein (GFP) is expressed by the cell either when gene (or genes) is introduced into the cell or when an exogenous quorum-sensing inducer is applied leading to the synthesis of an inducer. This can be identified using FACS or by fluorescence microscopy (Williamson et al., 2005). SIGEX has been developed to isolate novel catabolic genes from metagenomes which are particularly difficult to obtain using traditional gene cloning methods (Uchiyama and Miyazaki 2010). In SIGEX, digested metagenome fragments are ligated into an operon-trap vector containing a reporter protein such as GFP, and a metagenomic library is constructed in a liquid medium by transforming a suitable cloning host. This library is screened by a SIGEX assay, and positive clones are selected by detecting the activity of a co-expressed marker, in this case, the GFP fluorescence. (Uchiyama and Watanabe 2008). Another interesting approach that has been described is based on substrate hybridization capture involving the use of magnetic beads (Meiring et al., 2010). This involves the amplification of the internal portion of the gene of interest using degenerate primers, and the subsequent immobilization of the partial gene amplicons on streptavidin-covered magnetic beads. These beads are then used as hybridization probes to target full-length genes from metagenomic DNA. This method has been used to clone novel bacterial multicopper oxidases from soil but would clearly also have use in marine metagenomic samples (Meyer et al., 2007).

**Combinatorial Biosynthesis**

Combinatorial biosynthesis is a technology based on the genetic manipulation of biosynthetic clusters encoding bioactive compounds. Genetic manipulation techniques used include amino acid substitution, deletion or inactivation, swapping or borrowing of genes within a module, gene fusions, and assembly of these components, with the aim of producing novel structures in order to obtain new or altered structures that would be difficult to synthesize using other methods (Manzella and Reeves 2007). This approach has been used mainly in multi-modular enzymes such as PKS, NRPS and hybrid PKS-NRPS. The rapid advances in microbial genome analysis have not only enabled the identification of these gene clusters, but have also provided the necessary tools for engineering the biosynthesis of novel compounds by combinatorial biosynthesis (Walsh 2004; Manzella and Reeves 2007; Wong and Khosla 2012; Fisch 2013).

**Synthetic Biology**

Synthetic biology is a promising strategy to improve the production of known marine compounds or activate silent gene clusters by genetic manipulation of the biosynthetic machinery (natural or artificial) involved in the assembly of bioactive compounds. This approach is based on the development of genome manipulation techniques such as hierarchical Conjugative Assembly Genome Engineering (CAGE) (Isaacs et al., 2011) and Multiplex Automated Genome Engineering (MAGE) (Wang et al., 2009), as well as functional characterization of abundant genetic materials (e.g., controllable regulatory elements, synthetic RNA/protein scaffolds) (Khalil and Collins 2010). In addition to the efficient genome handling and transfer technologies, compatibilities between microbial hosts and all the necessary machinery to obtain the targeted product are very important for the choice of the most suitable host. This includes the proper expression of the genes responsible for the production of the target compound, compatibility with the enzyme activity and the availability of precursors. Nowadays, synthetic biology is used for the development of microbial cell factories for bioactive compound production (Keasling 2010) or to synthesize gene clusters enabling *in situ* therapeutic delivery (Khalil and Collins 2010). In recent years, many successful examples of bioactive compounds production with therapeutic interest through synthetic biology have been reported. Antibiotics such as aminoglycosides derivatives, which include neomycin, kanamycin and gentamicin (Park et al., 2013), as well as other natural products like PKS (Yuzawa et al., 2012; Gao et al., 2010; Zakeri 2013) and NRPS (Zakeri and Lu 2013) have been produced. In addition, the enzymes responsible for the production of these chemical compounds can be isolated and used as biocatalysts to synthesize bioactive compounds, their intermediates, and derivative compounds.

Ravikiran Regeti *et al.*

### Heterologous Production of Bioactive Compounds

In order to achieve the heterologous production of novel bioactive compounds, the development of marine-derived hosts such as cyanobacteria, actinomycete, and symbiotic fungi is key. Moreover, heterologous expression of genes or entire biosynthetic gene clusters involved in the synthesis of bioactive compounds is an important strategy in the identification of the function of these genes or genes clusters (Gomez-Escribano and Bibb 2014). Techniques such as natural product screening, compound chemical characterization, host isolation, gene cluster identification, sequencing analysis or synthesis, and metabolic and process engineering are necessary in the optimization of heterologous production (Zhang *et al.*, 2011).

### Omic" Integrated Approaches to Characterize Bioactive Compounds Biosynthetic Gene Clusters and Pathways:

Omics approaches utilize genomic, proteomic, metabolomic, and transcriptomic tools to bypass cultivation limitations by studying the collective material of organisms from environmental samples, thus enabling powerful new approaches to gene, genome, protein and metabolic pathway discovery (Schofield and Sherman 2013). Access to NGS and the development of bioinformatics tools is essential for the resolution of the tremendous databases generated from these technology applications.

### Dereplication Strategies

It is of the utmost importance that studies in the discovery of novel marine bioactive compounds, such as antimicrobial compounds, should be performed in parallel with a defined dereplication strategy to screen for previously known bioactive compounds. Dereplication itself is the process of screening samples for the presence of active compounds which have already been studied, thereby eliminating them from consideration. The identification of known molecules early in the marine bioactive compound discovery process minimizes time, effort and cost (Figure 6) (Liu *et al.*, 2013; Yang *et al.*, 2013).

## CONCLUSIONS

The discovery of novel bioactive compounds and biocatalysts is thereby hugely important and is still presenting a major challenge to researchers. Though metagenomic approaches have identified a number of novel genes encoding cellulolytic, pectinolytic, proteolytic, lipolytic enzymes, and so forth and many interesting novel enzymes have been discovered, the fact remains that the majority of biocatalysts are still uncharacterized. Further, since the functional heterologous expression of genes from unculturable microbes is not always successful, approaches like metatranscriptomics and stable isotope probing (SIP) could be adapted for the high resolution identification in the hunt for novel biocatalysts. Considering the wealth of opportunities offered by the ever-increasing sequencing power that allows studies ranging from community mining to elucidating expression circuitries and protein functional analyses, we can only expect an ever-increasing pile of information on known and novel antimicrobials. The interplay of bacteria with their environment, with other organisms and with hosts (e.g. gut microbiota, plant microbiota) will certainly involve antimicrobials of all sorts, and assessing their role in population dynamics will be an important area of research in the coming decade. Moreover, synthetic biology and novel chemistry approaches will enable the production of new-to-nature compounds to fight the increasing and important problem of antibiotic resistance in major human pathogens. A combination of mining approaches at all levels, followed by biochemical and pharmaceutical studies, will be greatly beneficial to find the solutions for major societal problems ahead.

### ABSTRACT

Early detection of cataract is considered as an important solution to prevent the vision loss. An automatic detection of cataract is proposed in this work with the help of machine learning algorithm such as Gradient Boosting algorithm and Support Vector Machine (SVM). The main aim is to examine the fundus images to detect whether an eye is healthy or affect with cataract. Histogram of gradient makes the job easy as it directly identify the white layer present in an eye, which is responsible for cataract. The cataract identification is carried out with image processing using python machine learning libraries. The classification of the input image verify the percentage of cataract affected area of an eye. This proposed system is modeled and tested with a dataset of 800 images with a ratio of 80:20 and has achieved an average accuracy of 95% using gradient boosting algorithm, this verify the usage of the system in real world scenario.

**Keywords:** Image processing; Augmenting; Pre-processing; classification; Gradient Boosting; Support Vector Machine (SVM).

### INTRODUCTION

A Cataract is a clouding of eye' lens that affects vision, blurry vision, trouble seeing at night and double vision in the affected eye. Most of the cataract is related to aging. A Cataract can affect either in one or both the eyes [1]. The current observation tests & cures are really high [2]. Cataract is detected by looking at the lens of the human eye, Computer processing of a Fundus image provide us with necessary detail such as affected areas & the overall percentage of affection [3]. There are a lot of causes of cataracts-smoking, an overproduction of oxidants, long-term use of medications & steroids, ultraviolet radiation & certain diseases, such as diabetes. Cataract can be divided mainly into 3 types- Nuclear cataracts, Cortical cataracts & Posterior capsular cataracts as shown in [figure-1]. Out of these Posterior capsular cataracts is the faster and affect the back of eye' lens.

**Mrutyunjoy Murmu et al.**

Nuclear cataracts form in middle of the lens. It colors the Centre (nucleus) of the eye. It affect vision leading to blurring of vision. A cortical cataract is wedge-like opacities that start to grow in the periphery of the lens and work its way to the center. This occurs in the lens cortex, which is the part of the lens that surrounds the central nucleus. Posterior capsular cataracts (PSC) are located in the most posterior cortical layer, back of the eye, under the lens capsule. This occurs to younger patients and affect vision and can live permanently. In this literature, An Automatic model is developed for detection of Cataract using machine learning and image processing techniques. To build the model a set of retinal images captured through a fundus image are taken as inputs. The classifier building procedure includes three parts pre-processing, feature extraction, and classifier construction. Preprocessing step, the RGB image is converted into green channel image and by applying image processing techniques, the contrast is enhanced and noise is removed. Then from the resultant image, features of retina are extracted by means of various operators and algorithms. Based on extracted features, classification step is carried out. Based on the degree of the image, the patient is classified into normal or affected. These set of extracted features are used to define the classifier by using 2 machine learning technique Support vector machine (SVM) & Gradient Boosting. This paper has been organized into five sections. Section-2 gives details about the related works that has been done in past, Section-3 demonstrates the proposed system and its methodology. Section-4 provides analysis of results. Finally, Section-5 concludes this study.

**Related Work**

Many works of literature have been done in the past, for the detection of cataract using diverse methodologies and techniques. Many model has been also done for not only just cataract but also for other eye diseases such as glaucoma [4]. Welfer D, Scharcanski J had written an article on A two-stage approach for automated optic disk detection for fundus image .The approach is very simple and is an easy to understanding of cataract detection as it only verify the presence of cataract and not the level of it [5]. J Nayak had developed an image processing model using SVM for normal and final stage of cataract detection [6]. Almost 180 images were taken for this experiment. Then used different machine learning methods to reduce mean intensity of the images. Features like small ring area were extracted and then provided to SVM model for classification.

They found an accuracy of 91%. M.Yang created a model for the cataract classification using back propagation neural network. A total of 504 images were obtained from real life patient and was used in this experiment. The green channel from the combination RGB was used for the clear contrast between regions of interest. The author used top-bottom hat transformation for more clear view of blood vessel and foreground .Author used a method known as trilateral filter to reduce noise in fundus images. The final categorization was done on the basis of severity. F.Wan developed a classification model having 4 Techniques for the best possible result. The paper was focus on PCA .Approx. 445 images were used. Here also top down hat transformation was used for the better extraction expectance He use SVM, Gradient boosting, Random forest and Logistic regression for the best outcome possible. Final classification was done into 2 category-, normal or Cataract [7].The best accuracy came from Gradient Boosting and SVM which was more than 90% [8]. J.J. Yang et al. presented a model .A total of 1239 images were used for this model. IN initial preprocessing stage all images were resized & green channel of RGB was consider for this model. Histogram equalization was used for the model. SET sketch, Wavelet and texture features were the consideration for the feature extraction they used trilateral filter for noise reduction [9].The author used SVM as well as back propagation for the model. The final accuracy came to be 93.2% [10].

**METHODOLOGY**

The Defined Model has four different phases.

**Assemblage and Selection of images:**

Total of 800 images were collected from various sources containing 500 cataract affected image and 300 normal images .Most of them were collected from kaggle and GitHub repository. The images are in JPG and PNG format.

Mrutyunjoy Murmu *et al.*

### Preprocessing of retina image using Open cv

Conversion of digital image into multiple segments pixels set, Image segmentation sorts pixels into larger components, eliminating the need to consider individual pixels as units of observation. Here we have used a histogram to group pixels based on “gray levels”. Simple images consist of an object and a background. The background is usually one gray level and is the larger entity. The RGB format is transformed to HSI (Hue, Saturation and Intensity). HIS conversion is based on set of parallel and sequential partially automated methods.

### Feature Extraction

In this stage, we have to extract some features from retinal fundus images to describe or detect the cataract diseases. A cataract condition consists of a whitish color that appears inside the pupil. This condition can be distinguished from normal condition that has not a whitish color inside the pupil, the feature extraction method uses statistical texture analysis from the extracted image will be distinguished normal and cataract condition affected by the exhibit of the whitish color inside the pupil. Extraction method that is proposed in this research uses GLCM (Gray Level Co-occurrence Matrix) method in getting the features.

### Building the Model

Finally the model is trained and tested with two well-known machine learning techniques.

### Gradient boosting

Gradient boosted trees utilize a *boosting* approach. Decision trees are usually used as that of random forest algorithm when doing gradient boosting. It uses a unit of models (decision trees) to reduce variance, boosting starts off with a high-bias, weak learner, and then uses the remaining from a defined objective function to repeating build trees which improve upon the loss of previous trees [11]. It can build a model on all of its input features. It is effective at classifying complex datasets having a lot of features to keep track on.

### SVM

SVM grant a high accuracy compared to other classifiers as decision trees. It is famous for the way it handle nonlinear input spaces using its kernel tricks. It is used in face detection, intrusion detection, classification of genes, and handwriting recognition. The classifier separates data points using a largest amount of margin by hyper plane. SVM finds an optimal hyper plane for the classifying new data points. It is able to easily handle multiple continuous and categorical variables. SVM generates optimal hyper plane in an iterative manner to minimize an error. The idea of SVM is to find a maximum marginal hyper plane (MMH) that best divides the provided dataset into different categories [12]. Classification is a final step of cataract identification process. After features selection process, we have to classify the obtained features as the degrees of affected areas [13].

## RESULT AND DISCUSSION

The two different models are tested with 200 test images out of which 150 are cataract affected and 50 are normal. The performance of the classifiers evaluated in terms of sensitivity, specificity, overall accuracy and F1 score as shown in [table-1]. The ROC curve shown in [Figure-7, 8] presenting the tradeoff between sensitivity and specificity. X-axis of the graph shows Specificity also known as False Positive rate and Y-axis shows the sensitivity known as True Positive Rate

## CONCLUSION

From the observed results generated by different models it is concluded that, Gradient boosting algorithm is fitting better with the underlying dataset in comparison SVM for detection of cataract with a high accuracy value 95%. In future this work can be extended to detect cataract along with its state using a multi class classifier.

### ABSTRACT

Experiment was carried out under induced flood stress to analyse the effect of fly ash on certain major pests of rice *viz.*, Brown plant hopper. The population of BPH were assessed at regular intervals on plants imposed with treatments including fly ash, Silicate Solubilizing Bacteria (SSB), Farm yard manure (FYM), and graded levels of soil test based potassium. The results revealed that the combination of Fly ash, SSB, FYM, with graded level of soil test based potassium significantly reduced the incidence of Brown plant hopper as compared to untreated plots. The silicon content was analysed in the leaf blade and leaf sheath cum stem and it was negatively correlated with the insect population. As the age of the plant increased, silicon content proportionately increased in the plants at different growth stages. The main cause for the death of insects due to fly ash application was wearing of mandibles and main feeding organs of insects which resulted in functionless mandibles so that the insects of paddy die without food. Further, the incidence of major insects was negatively correlated with yield. Application of fly ash as a source of silica and potassium with SSB, FYM with STBK reduced the incidence of Brown plant hopper, Green leaf hopper, Stem borer and increased the yield in rice.

**Key words:** fly ash, silica, Brown plant hopper, Green leaf hopper, Stem borer

## INTRODUCTION

Rice is known as Si accumulator, the plants benefit from Si nutrition thereby mitigate biotic (pests and diseases) and abiotic stress (flood) in rice. It is estimated that the rice crop producing a grain yield of 5 t ha<sup>-1</sup> will normally remove from soil of 230 to 470 kg Si ha<sup>-1</sup>. Salim and Saxena (1992) found that at higher levels of silicon, metamorphosis of plant hopper to nymphs to adult was reduced and there was a decrease in adult longevity a female fecundity. It has been reported that silicon suppresses insect pests such as the stem borer, brown plant hopper, green leafhopper, white backed plant hopper, and non-insect pests such as spider mites (Ma and Takahashi, 2002). Silica content in the plant is reported to play an important role in strengthening the cell walls of the plants and enhances resistance to both pests and diseases in the field (Qin and Tian, 2004). Chandramani *et al.* (2009) reported that the combination of FYM, biofertilizers, lignite fly ash and neem cake applied in splits reduced gall midge, stem borer and leaf folder and increased the content of Si and potassium in plants which induced resistance to pests in plants. Hence silicon content in rice plant was found to be negatively correlated with the incidence of brown plant hopper, green leaf hopper, and stem borer.

Fly ash is a major industrial waste in India. It is a by-product of thermal power station where electricity is produced by burning finely powdered coal. In India around 12.21 M t of fly ash is produced every year and for storing one tonne of fly ash, 0.35 m<sup>2</sup> area is required. This huge quantity of fly ash produced is dumped in ash disposal areas which are posing a great threat to the environment. Fly ash contains 0.2 to 3.0 per cent potassium and 15-60% SiO<sub>2</sub>. Silicon and K are considered most important nutrient elements in conferring resistance to biotic stresses *viz.* insect pests, nematodes and diseases and abiotic stresses *viz.* drought, lodging, salinity, water logging, and nutrient imbalances in soil. Potassium is also responsible for improving the quality of produce. In an attempt to effectively solve the disposal problem of the enormous solid industrial waste, some efforts have been made to use it as an amendment to improve soil fertility, reduce pest incidence and increase yield.

## MATERIALS AND METHODS

Field experiment were conducted under induced flood condition in split plot design with two replications. The plot size was 5x4 m<sup>2</sup> with 4 main plot treatments and 5 sub plot treatments. The main plot treatments, M<sub>1</sub> – Control (0 fly ash), M<sub>2</sub> – fly ash @ 25 t ha<sup>-1</sup> + silicate solubilizing bacteria (SSB) @ 2 kg ha<sup>-1</sup>, M<sub>3</sub> - fly ash @ 25 t ha<sup>-1</sup> + Farm yard manure (FYM) @ 12.5 t ha<sup>-1</sup>, M<sub>4</sub> - fly ash @ 25 t ha<sup>-1</sup> + (SSB) @ 2 kg ha<sup>-1</sup> + FYM @ 12.5 t ha<sup>-1</sup> were followed and subplot treatments were graded level of soil test based Potassium (STBK), S<sub>1</sub> - Control, S<sub>2</sub> - 25 % STBK, S<sub>3</sub> - 50 % STBK, S<sub>4</sub> - 75 % STBK, S<sub>5</sub> - 100 % STBK. The fly ash was applied before transplanting followed by incorporation of silicate solubilizing bacteria and farm yard manure. The rice variety BPT 5204 was selected for field experiment. The observations of pests were observed under natural condition. The incidence of brown plant hopper was recorded in 10 hills selected at random in each plots at 15 days interval and stem borers are measured as percentage of dead heart before flowering and percentage of white ear after flowering as below.

$$\text{Stem borer damage as dead heart/ white ear (\%)} = \frac{\text{Number of affected tillers/meter}^2}{\text{Total number of tillers/meter}^2} \times 100$$

The rice plant samples are randomly selected from each experimental plot and analysed for silicon content in different parts *viz.*, leaf blade, leaf sheath cum stem and ear head at tillering, panicle initiation and flowering stage.

### Estimation of Silicon in plant samples

The powdered samples of different parts of rice plant *viz.*, leaf blade, leaf sheath cum stem, ear head, were dried in an oven at 70 °C for 2-3 hrs prior to analysis. A 0.1 g sample was digested in a mixture of 7 ml of HNO<sub>3</sub> (62 per cent), 2 ml of hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) (30 per cent) and 1ml of hydrofluoric acid (46 per cent) kept in for 10-15 min for pre-digestion.

**Pedda Ghouse Peera et al.**

The samples were digested using microwave digester (Microwave reaction system Antonpaar Multiwave 3000 solv) with following program 500 watt for 17 minutes with a ramp at 10 °C per minute to reach the temperature of 150 °C, 500 watt for 10 minutes for holding the temperature of 150 °C and venting for 10 minutes. The digested samples were diluted to 50ml with 4 % boric acid (Ma et al., 2002).

The Si concentration in the digested solution was determined by transferring 0.1 ml of digested aliquot to a plastic centrifuge tube, added with 3.75 ml of 0.2 N HCl, 0.5 ml of 10 per cent ammonium molybdate and 0.5 ml of 20 per cent tartaric acid and 0.5 ml of reducing agent 1- amino -2- naphthol- 4- sulfonic acid (ANSA) and the volume was made up to 12.5 ml with distilled water and kept it for one hour. After one hour, the absorbance was measured at 600 nm with a UV- Visible spectrophotometer. Similarly, standards (0, 0.2, 0.4, 0.8, and 1.2 ppm) were prepared by using 1000 ppm, by following the same procedure. The stock standard of silica was obtained from Merk. The data obtained from field experiments were subjected to statistical scrutiny (Snedecor and Cochran, 1967) and the analysis was carried out in Agres Agdata. Square root transformation was followed for converting the population numbers. The treatment means were compared by Duncan's Multiple Range Test (DMRT) at p=0.05 for their significance (Gomez and Gomez, 1985).

**RESULTS**

The results (Table 1) on the incidence of important pests due to the application of fly ash + SSB +FYM+ STBK were represented below. The mean BPH population was low (0.15/ tiller) in the plots treated with fly ash with SSB and FYM with 100 % STBK which was on par with 75% STBK over control (0.4/ tiller) when compare to other treatments at tillering stage. At panicle initiation stage the plots treated with fly ash with SSB and FYM with 100 % STBK recorded the low mean BPH population of (0.1/ tiller) over control (0.35/ tiller) which was on par with 75% STBK. Similarly in flooded condition no BPH population was observed in the plots treated with fly ash with SSB and FYM with STBK over control (0.4/ tiller) when compare to other treatments. At panicle initiation stage the plots treated with fly ash with SSB and FYM with 100, 75, 50 % STBK recorded no BPH population whereas control recorded (0.45/ tiller).

**Silicon content in rice**

The results revealed that the application of fly ash increased the silicon content in rice. The mean Si content of 1.84 per cent in leaf sheath cum stem was recorded due to the addition of fly ash with SSB and FYM over control which recorded 1.64 per cent in leaf sheath cum stem in drought condition and in flood condition 1.63 per cent in leaf sheath cum stem was registered by the addition of fly ash with SSB and FYM. The control recorded the lowest content of 1.44 in leaf sheath cum stem.

Among the graded levels of STBK, the highest mean silicon content of 1.96 per cent in leaf blade and 1.76 per cent in leaf sheath cum stem was recorded due to the addition of 100 per cent K over control. At panicle initiation stage, the treatment effect of fly ash with SSB and FYM showed significant difference and recorded the mean Si content of 2.51 per cent in leaf blade and 1.96 per cent in leaf sheath cum stem over control which recorded 2.27 per cent in leaf blade and 1.77 per cent in leaf sheath cum stem. Among the graded levels of STBK, the highest mean silicon content of 2.40 per cent in leaf blade and 1.88 per cent in leaf sheath cum stem was recorded due to the addition of 100 per cent K.

**DISCUSSION**

The incidence of brown plant hopper was noticed during tillering, panicle initiation and flowering stage respectively. The treatment effect of fly ash with SSB and FYM with 100 % STBK on incidence of Brown plant hopper showed per cent reduction of 37.5 per cent at tillering and 22.2 per cent at panicle initiation stage in drought condition. (FIG 1 &

**Pedda Ghouse Peera et al.**

2). The pest incidence was reduced due to the soluble silicic acid present in the fly ash enhanced the Si uptake in plant which inhibits the feeding activity of BPH and also due to the antibiosis mechanism due to defensive chemicals like phenol (Meyer and Keeping, 2005)

The higher levels of silicon and phenolic compounds play important role in the metamorphosis of plant hopper to nymphs to adult was reduced and there was a decrease in adult longevity and female fecundity (Rajeshwari, 2000). The results of the present study revealed that the combination of fly ash with SSB and FYM with 100 % STBK significantly reduced the incidence of stem borer (46.7%) at flowering stage compared to control under drought condition whereas, under flooded condition stem borer incidence of 70 per cent at flowering stage was observed. This was due to the application of fly ash that enhances Si and K content results in the damage of mandibles of larvae of the rice stem borer. The results were in consonance with the findings of Djamin and Pathak (1967). Chandramani et al. (2009) reported that the main cause for the death of insects due to fly ash application was wearing of mandibles and main feeding organs of insects which resulted in functionless mandibles so that insect like leaf folder, stem borer die without food. Hence the application of fly ash with SSB and FYM significantly increased the silicon content at different growth stages and deposition of silicon in the leaf sheath cum stem reduced the incidence of brown plant hopper, green leaf hopper, and stem borer. In conclusion silicon is beneficial to plant growth and helps plants to overcome abiotic and biotic stresses and increasing resistance to pests and diseases, as well as other stresses.

**ACKNOWLEDGEMENT**

The authors pay gratitude to Dr. Vimal Kumar Scientist G and Head, Fly Ash Unit and Chairman and members Programme Advisory Committee and Project Monitoring Committee, Department of Science and Technology, Govt. of India for their, critical comments, suggestions and financial assistance during the period of investigation.

### ABSTRACT

Air pollution refers to harmful toxins into the atmosphere that are very much dangerous to human beings. Many living beings as well as non-living beings also get suffered due to this pollutant like it causes severe damage to crops, forests also. To take precautions of this problem, it is very much important to predict quality of air using machine learning techniques. Subsequently, assessment of air quality and prediction is most significant in research fields. Air quality dataset is preprocessed with respect to univariate, bivariate and multivariate analysis. Take care of missing values, data validation and data cleansing are also done. The performance of various machine learning algorithms is analyzed by comparing with Precision, Recall and F1 Score respectively. Decision Tree algorithm works very well and giving very good result for predicting air quality. This paper can be beneficial for the meteorological Department.

**Keywords:** Linear; Lasso; Decision Tree Regression

### INTRODUCTION

With economic development, population also increase in cities. Environmental pollution problems include air pollution, noise pollution and water pollution required a great attention. By these air pollutions, it directly impacts on human health through exposure to pollutants and has resulted to severe issues. So, public awareness should be increased all over the world regarding reduction of air pollution. Air pollution caused by power plants, residential heating, various manufacturing industries, fuel running vehicles, and also natural disasters. Human health suffered due to air pollution which is one of the major effects of air pollution, especially in urban areas. Anthropogenic greenhouse gas emissions lead to global warming which is a long-term consequence of air pollution. Perfect air quality forecasting can reduce the effect of rise in pollution in this ecosystem. Hence improving air quality prediction is a crucial goal.

Satya Ranjan Prusty et al.

“Air quality” in our surrounding means the quality of the air present our surrounding. Good air quality refers to cleanliness of air, free from pollutants such as smoke, dust and other gaseous impurities in the air. Air quality is determined by assessing a variety of pollution indicators. Good air quality is a requirement for preserving the exquisite balance of life on earth for humans, plants, animals and natural resources. Human health, plants, animals and natural resources are getting threatened when pollution in the air reach high concentrations. Poor air quality can affect and harm human health and to the environment. Air quality can be degraded by natural or man-made sources. Natural sources include volcanic eruption, windstorm dust. Man-made source include pollution from moving vehicles, toxic gases from industries, coal powered plants, burning wood or other material in open air. Both these sources can seriously affect the overall air quality and can lead to severe health problems for humans.

An air quality model is a numerical tool used to describe the causal relationship between emissions, meteorology, atmospheric concentration, deposition and other factors. It can give a complete deterministic description of the air quality problem. The most commonly used air quality models built upon regression. In this section, different models and their applications will be introduced. This paper is divided into five sub section i.e. 1. Introduction, 2. Related work, 3. Methodology, 4. Result Analysis for Model Evaluation and last section is 5. Conclusion.

### Related Work

Related Work is an import part to get referral from various existing paper. So, Some researched paper is studied and analyzed for this respective paper. [1] Air quality prediction in Milan: feed-forward neural networks, pruned neural networks and lazy learning by Corani and Giorgio. ### METHODOLOGY

There are four important stages that are proposed in this model: Data acquisition, Data processing and Model Building using Different ML Techniques like Linear Regression, Lasso Regression and Decision Tree Regression and at last Model Evaluation is done as shown in [Fig-2].

### Data Collection

For this respective model building data is acquired from Github repository which has a great collection of datasets for performing many machine learning analysis and model building. The dataset contains 9358 instances of hourly averaged responses from an array of 5 metal oxide chemical sensors embedded in an Air Quality Chemical Multisensor Device. The device was located on the field in a significantly polluted area, at road level, within an Italian city. Data were recorded from March 2004 to February 2005 (one year) representing the longest freely available recordings of on field deployed air quality chemical sensor devices responses. Ground Truth hourly averaged concentrations for CO, Non Methanic Hydrocarbons, Benzene, Total Nitrogen Oxides (NO<sub>x</sub>) and Nitrogen Dioxide (NO<sub>2</sub>) and were provided by a co-located reference certified analyzer. Evidences of cross-sensitivities as well as both concept and sensor drifts are present as described in De Vito et al., Sens. And Act. B, Vol. 129,2,2008 (citation required) eventually affecting sensors concentration estimation capabilities. Missing values are tagged with -200 value. This dataset can be used exclusively for research purposes. Commercial purposes are fully excluded.

### Preprocessing

The acquired data contain missing values, inconsistent data and repeated data. To avoid improper prediction result, data cleansing must be done, missing values must be taken care by filling mean values. Redundant data must be eliminated. Classification and clustering algorithms will work efficiently if all this preprocessing is taken care of.

### Construction of a Predictive Model

For making good predictive model, data pre-processing is most essential. Prediction fails due to raw data in the dataset. So, data cleansing is required before training and model is tuned with different parameters for better accuracy. Here are three types of algorithms used for different predictive models for comparison purpose and resultant in getting a better predictive model for air quality. These are

- Linear Regression
- Lasso Regression
- Decision Tree Regression

### Linear Regression

Linear equation takes combination of specific input values ( $x$ ) and the solution ( $y$ ) for the set of input values ( $x$ ) to predict output. As such, both the input values ( $x$ ) and the output value ( $y$ ) are numeric. One scale factor is assigned to each input value or column of linear equation, called a coefficient and represented by the capital Greek letter Beta ( $B$ ). Another coefficient is also added, giving the line an additional degree of freedom and is often called as the intercept or the bias coefficient. For example, in a simple regression problem (a single  $x$  and a single  $y$ ), the form of the model would be:

$$y = B_0 + B_1 * x \quad (1)$$

In higher dimensions when it has more than one input ( $x$ ), the line is called a plane or a hyper-plane. The representation therefore is the form of the equation and the specific values used for the coefficients (e.g.  $B_0$  and  $B_1$  in the above example). It is common to talk about the complexity of a regression model like linear regression. This refers to the number of coefficients used in the model. When a coefficient becomes zero, it effectively removes the influence of the input variable on the model and therefore from the prediction made from the model ( $0 * x = 0$ ). This becomes relevant if you look at regularization methods that change the learning algorithm to reduce the complexity of regression models by putting pressure on the absolute size of the coefficients, driving some to zero.

### Lasso Regression

Lasso regression is an example of regularized regression. Regularization is one approach to tackle the problem of over-fitting by adding additional information, and thereby shrinking the parameter values of the model to induce a penalty against complexity. The 3 most popular approaches to regularized linear regression are the so-called Ridge Regression, Least Absolute Shrinkage and Selection Operator (LASSO) and Elastic Net method. Suppose a regularized regression model on a dataset with  $n$  observations and  $m$  features. Lasso regression is an L1 penalized model where it simply adds the L1 norm of the weights to least-squares cost function:

$$J(w) = \sum_{i=1}^n (y_i - \hat{y}_i)^2 + \alpha \sum_{j=1}^m |w_j| \quad (2)$$

Where

$$\hat{y}_i = w_0 + \sum_{j=1}^m X_{ij} w_j \quad (3)$$

Satya Ranjan Prusty *et al.*

## Decision Tree Regression

A decision tree is a flowchart-like structure in which each internal node represents a test on a feature (e.g. whether a coin flip comes up heads or tails), each leaf node represents a class label (decision taken after computing all features) and branches represent conjunctions of features that lead to those class labels. The paths from root to leaf represent classification rules. Below Fig.3 is the diagram illustrate the basic flow of decision tree for decision making with labels (Rain(Yes), No Rain(No)). The above three figures Fig. 4, Fig. 5 and Fig. 6 are the representation for comparison between Linear Regression, Lasso Regression and Decision Tree Regression. The linear regression gives 0.9288505701939468 accurate value, Lasso regression gives 0.8424337687413078 accurate value and Decision Tree regression gives 0.9964315525768502 accurate value. Hence Decision Tree Regression gives more accurate result than both Linear and Lasso Regression. The below fig. 7 is the combination of all Linear, Lasso and Decision Tree Regression predictions.

## CONCLUSION

It began with information cleansing, record processing, detailed evaluation and then model construction and prediction is done. The best accuracy for test set is acquired by decision tree method by comparing with accuracy of other two regression methods. The future work is to automate the prediction result in web application or desktop application and also optimization of the work in Artificial Intelligence environment to be done".

### ABSTRACT

The Cauvery Delta Zone is a rice bowl of Tamil Nadu where the rice is being intensively cultivated season by season. Being silicicolous monocot rice exhausts large quantity of silicon from soil and accumulates in different parts led to decline in soil available Si year after year. Therefore an investigation was carried out to assess the status of plant available soil silicon in Cauvery Delta Zone of Tamil Nadu, South India. The surface soil samples have been collected from different locations of Cauvery Delta Zone using GPS coordinates. The soil properties viz., pH, EC, organic carbon, CEC were analysed and results were correlated with N NaOAc (pH 4.0) extractable Si. The results revealed that availability of Si is positively correlated with the soil reaction. Among the totally analysed samples (82) sample No.9 with pH 9.3 resulted higher availability of soil Si (324 ppm) and vice versa. The linear decreasing trend of plant available soil silicon has been arrived with decreasing soil pH. The soils of Cauvery Delta Zone revealed 62 per cent of samples as low in available soil silicon status and 21 per cent were high in silicon status. The organic carbon status of soils was 32.9 per cent as low, 32.9 per cent as medium and 34.1 per cent as high. The average organic carbon content was 0.68 per cent however no significant correlation was observed with available Si. On an average the soils of Cauvery Delta Zone where rice is a core crop showed N NaOAc (pH 4.0) extractable available silicon of 69.94 ppm (low). Hence depleted soil silicon status should be replenished to maintain the crop yield before the limit of abiotic and biotic stresses exceeds economic threshold level.

**Key words:** plant available soil silicon; Cauvery Delta Zone; intensive rice cultivation

## INTRODUCTION

Rice is a silicicolous plant that absorbs Si in the form of mono silicic acid ( $H_4SiO_4$ ) through active aerobic respiration and accumulates large amount that several fold greater than those of other macronutrients from the growing medium. Although Si is not an essential nutrient element, it is considered essential for rice, maize, sugarcane and other graminaceous plants. It is estimated that nearly 20 kg of  $SiO_2$  is removed from the soil by the rice for producing 100 kg brown rice. Total Si removed by rice grown in an inceptisol varied from 205–611 kg Si ha<sup>-1</sup> (Prakash 2002). Though the exact role-played by Si in the nutrition of crops remain still obscure, its efficiency for normal growth of rice plants cannot be ruled out. Japanese scientists have carried out intensive research activities on Si nutrition in order to establish its role for the normal growth of rice. Although Si fertilization is not a standard practice in India, the beneficial role for the application of Si in increasing the yield of rice was evident through such studies. In addition, Si depletion can occur in traditional rice soils from the continuous monoculture of high yielding varieties with intensive cultural practice especially if farmers are not replacing the Si removed by rice (Miyake, 1993). The amount of Si available to plants in soil is very small and varies with different soils. However, concentration of Si in the solution increases after flooding as well as with organic matter of the soil. (Ponnamperuma, 1984). Hence investigation has been carried out to delineate the status of plant available soil Silicon in intensively rice growing Cauvery delta zone of Tamil Nadu.

## MATERIALS AND METHODS

The soil samples from 82 locations were collected from different rice growing areas of Cauvery Delta Zone viz. Thanjavur, Thiruvarur, Nagapattinam, Trichy districts of Tamil Nadu using GPS coordinates for easier positioning. The soil samples were processed and analysed for available Si and other soil properties viz. soil texture pH, EC, Organic Carbon and Cation Exchange Capacity for their correlation with available Si. The pH and EC were determined by using Elico pH and EC meter. The soil organic carbon was estimated by Walkley and Black method as outlined by Jackson (1973). The CEC was determined by using  $NH_4OAc$  displacement subsequent distillation as per the procedure given by Jackson (1973). The soil available Si was estimated by using N NaOAc (pH 4.0) extractant colorimetrically.

## RESULTS

As a part of present investigation 82 samples were collected from intensively rice growing areas of Cauvery delta zone. The surface soil samples have been collected from different locations of Cauvery delta zone using GPS to find out the latitude, longitude and altitude of the location and enable to assess the soil available Si after certain year to find out the depleted level. The soil properties viz., pH, EC, organic carbon, CEC and soil texture were analysed and results correlated with N NaOAc (pH 4.0) extractable Si. The results revealed that availability of Si is positively and significantly correlated with the soil reaction. Among the totally analysed samples (82) sample No.9 with pH 9.3 resulted higher availability of soil Si (324 ppm) and vice versa. The linear decreasing trend of plant available soil Si has been arrived with decreasing soil pH. The soils of Cauvery Delta Zone revealed that 62 per cent of samples were low in available soil Si status. Out of 82 samples only 21 % were high in Si status. Significant correlation was found between soluble salts concentration ( $dSm^{-1}$ ) and N NaOAc (pH 4.0) extractable Si. The organic carbon status of soils revealed 32.9 per cent as low, 32.9 per cent as medium and 34.1 per cent as high. The average organic carbon status was 0.68 per cent. The maximum soil CEC of 37 meq lit<sup>-1</sup> was observed in sample No. 42 in which soil Si was low and vice versa. The soil exchange capacity was negatively correlated with soil Si status, however the correlation was statistically not significant (Tables 1, 2, 3, & 4).

**Pedda Ghouse Peera et al.**

Among investigated locations silty clay loam was prominent soil texture and occupied 52.5 per cent of soils followed by 18.3 per cent loamy sand, 15.8 per cent sandy loam and 13.4 per cent clay loam. The soil Si status was depleted in Cauvery Delta Zone due to intensive rice cultivation and long span of submergence in which sandy loam soils lies in first position with 69.2 per cent of low Si soils. Among silty clay loam, clay loam, loamy sand 67.4, 54.5 and 46.6 per cent soils were low soil Si status respectively. Among loamy sand soils 6.6 per cent registered the highest soil Si status followed by silty clay loam with 16.3 per cent. Irrespective of soil texture Si depletion was observed in Cauvery Delta Zone soils. On an average, soil in Cauvery delta zone showed N NaOAc (pH 4.0) extractable available Si of 69.94 ppm (low).

**DISCUSSION**

Delineation of soil silicon status in intensively rice growing areas of Cauvery delta zone revealed 62 per cent soil low in Si status which may be due to intensive rice cultivation (Lee, 2006). Among the totally analysed samples (82) sample No.9 with pH 9.3 resulted higher availability of soil Si (324 ppm) and vice versa. The linear decreasing trend of plant available soil silicon has been arrived with decreasing soil pH. Similar results were obtained by Korndorfer (2009). The pH was significantly correlated with N NaOAc (pH 4.0) extractable Si which may be due to rapid solubilisation of monosilicic acid at pH 8.0-9.0 from 2:1 clay as noticed by Goldberg and Glaubig (1986). Soils with pH range of 5.8-6.4 revealed low Si status which may due to additive impact of acidity and anions on Si release as showed by Wang (2004). As an exceptional case, sample No.2 though acidic in soil reaction showed medium soil Si status (108 ppm) which satisfies the results of Cheong (1982) and Jones and Handreck (1963) which may be due to decomposition of organic matter and production of mineral acids for solubilization of silica (Money, 1961).

Significant correlation was found between soluble salts concentration ( $dSm^{-1}$ ) and N NaOAc (pH 4.0) extractable Si which satisfies the results of Wickramasinghe and Rowell (2005) and Lin (1978). The average organic carbon status was 0.68 per cent which was slightly increased the soil Si status; however no significant correlation with soil Si was observed which satisfies the results of Money (1961). The soil exchange capacity was correlated with soil Si status, however the correlation was statistically not significant may be due to inherent soil Si has no significant effect on soil CEC but Si fertilization has been reported to induce soil exchange capacity (Matichenko, 2001). Soil texture greatly influenced the soil Si status (Mckeague and Cline, 1963). Among investigated locations silty clay loam was prominent in soil texture followed by loamy sand, sandy loam and clay loam. The silty clay loam, sandy loam, loamy sand soils were 69.7, 69.2 and 46.6 per cent low status of Si respectively which may be due to increase in sand content (Gontijo, 2000). Among loamy sand soils 26.6 per cent registered the highest soil Si status followed by silty clay loam with 16.27 per cent (Chinnaswamy and Chandrasekaran, 1978) which may be due to higher clay content with increase in pH improved the soil Si status (Meyer, 2001). Irrespective of soil texture Si depletion was observed in Cauvery Delta Zone soils. On an average, soil in Cauvery delta zone showed N NaOAc (pH 4.0) extractable available Si of 69.94 ppm (low) which coping with the results of low Si status in intensively rice growing soils (Lee, 2006).

**CONCLUSION**

The soils of Cauvery Delta Zone of Tamil Nadu, south India reveals 62 per cent of soil samples were low in plant available soil silicon status.

### ABSTRACT

Glaucoma is an incurable vision impairment disease and the vision loss due to this can't be restored in any case, early detection is the only way to prevent it. There are several automatic screening techniques exist for the determination of the disease still there is a scope for the improvement in accuracy of prediction. One of the way to improve the accuracy is by considering important artifacts present in the retina; those play a vital role in disease prediction. In case of glaucoma the important artifacts are Optic disc and blood vessels. In this literature, An Automatic model is developed for detection of glaucoma using image processing and machine learning techniques. To build the model a set of retinal images captured through a fundus camera are taken as inputs, which consists of the images of two types of retina healthy and glaucoma affected. From each input retinal image a set essential features are extracted like Optic disc and blood vessels, using two well-known predefined feature extraction techniques scale-invariant feature transform (SIFT) and speeded up robust features (SURF). These set of extracted features are used by Support vector machine (SVM) classifier for prediction of glaucoma. For a 210 set of test images the overall accuracy of the model is 96%.

**Keywords:** Optic disc; blood vessels; scale-invariant feature transform (SIFT); speeded up robust features (SURF); Support Vector Machine (SVM).

### INTRODUCTION

Glaucoma is the second most leading eye disease which causes irreversible vision loss. According to a survey conducted in 2019, 70 million people are affected by glaucoma [1]. It is a group of heterogeneous eye disease in which loss of retinal ganglion cells occurs. It's started with no pain and slowly from peripheral vision loss to permanent blindness. Glaucoma is the cause of 85% blindness all over the world [2]. Among the retinal diseases 13% of cases are affected by glaucoma. 0.5% of people aged 40 and 10% of people who are above 80 are affected by

23928

**Manoj Kumar Behera and S. Chakravarty**

glaucoma. In a healthy eye, a liquid called the aqueous humor is continuously produced by epithelium of the ciliary body to nourish the cornea and lens and drain out through a mess like a channel called canal of Schlemm. In glaucoma this fluid builds up which results in an increase in IOP (Intraocular Pressure) restricting the blood flow and severely damaging the optic nerve. IOP of normal eye range between 12 to 22 mmHg, but in glaucoma condition IOP is higher than normal [3].

Glaucoma mainly affects the optic nerve, major branches of the retinal vein, artery, ciliary body, and angle of the anterior chamber. It has been suggested that the diagnosis of glaucoma can't be certain until the progression has been demonstrated. Hence the correct diagnosis is required only at initial visits. There are different parameters to confirm that a patient has been correctly diagnosed with glaucoma or not [4] like Increase in IOP (Intraocular Pressure), definite visual field progression in at least one eye, Optic disc hemorrhage and Abnormal CDR. Many works of literature have been done in the past, for the detection of Glaucoma using diverse methodologies and techniques. The variation in model accuracy and average specificity depends upon the design of the algorithm and dataset. To classify the disorder related to the retina, different data mining, image processing, and Machine Learning algorithms have been suggested for feature extraction and classification. For automated Glaucoma detection, mostly used features are Intraocular Pressure (IOP) [5], Retinal Blood Vessel [6], papillary rim [6], and CDR and ISNT ratio [7]. Similarly different ML techniques such as, Neural Network is used for detection of glaucoma in article [5]. Decision tree algorithm was able to achieve 85% accuracy in glaucoma prediction, in article [8]. Naive Bayes classifier and k-nearest neighbor used and resulting an accuracy of 86%, in article [9]. In article [10], an automated Diagnosis of glaucoma using texture and higher-order spectra Features was developed, which produces an accuracy of 91%. In another article [11], the model is using the neuro retinal cup detection model and getting an average sensitivity and specificity of 97.2% and 98% respectively. But the dataset used for defining the model is very small (71 images).

In this literature, An Automatic model is developed for detection of glaucoma using machine learning and image processing techniques. to build the model a set of retinal images captured through a fundus camera are taken as inputs, which consists of the images of two types of retina healthy and glaucoma affected as shown in [Figure-1]. [Figure-2] shows the block diagram of the model, where each input image went through a preprocessing stage for getting more qualitative features. After the pre-processing, feature extraction is done using (SIFT) and (SURF) to capture the essential feature present in the retina. These extracted features are passed through the SVM classifier to predict the disease. This paper has been organized into four sections. Section-2 demonstrates the proposed system and its methodology. Section-3 provides analysis of results. Finally, Section-4 concludes this study.

## METHODOLOGY

### Assemblage and Selection Of images

The dataset for this paper is collected from deep blue data library [12]. The dataset consists of 3 different files: 1) MESSIDOR dataset file contains 460 Glaucomatous Retinal Images .2) Bin Rushed files contain 195 images 3) Magrabi Eye center file and contains 95 images. The total number of collected data from the above source is 750 which is of Glaucoma. The images are in JPG and TIFF format. 300 normal non-glaucomatous retina images are collected from different sources in JPG and PNG format.

### Preprocessing of retina image

Image processing is a method to perform different operations on an image, to get an enhanced image, or to extract some useful information from it. It takes the image as input however the output may be image or characteristics/features related to that input image. As we have Fundus retinal images as input, the accuracy of the model exclusively depends upon however we tend to preprocess the data. The supervised machine learning is employed for building the model that the RGB image dataset must undergo some basic image processing operations like compression to create it labelled for additional processes. The collected retinal images are of upper resolution

### Manoj Kumar Behera and S. Chakravarty

that will have an effect on the ultimate model accuracy. Consequently, all images are resized to a resolution of 512\*512. Then retinal images are filtered through layer separation techniques e.g. channel separation, image smoothing/blurring (Gaussian blurring, bilateral filtering) by convolving the image with a low-pass filter kernel that removes high-frequency content like extra noise and detecting required edges needed for further procedure. Contrast-Limited Adaptive Histogram Equalization (CLAHE) is employed to boost the contrast. Through this adjustment, the intensities are often higher distributed on the histogram [13]. This method allows a lower contrast region to achieve higher contrast.

#### Feature Extraction

There are many features involved for the detection of glaucoma as shown in [Figure-3], in this paper, two well-known predefined feature extraction techniques scale-invariant feature transform (SIFT) and speeded up robust features (SURF). Retinal Blood Vessels.

#### SIFT

The following steps are involved in SIFT.

- A. Scale-space Extrema Detection
- B. Key point Localization
- C. Orientation Assignment
- D. Key point Matching

#### SURF

SURF uses Wavelet responses in both parallel as well as perpendicular direction. A locality of size  $20s \times 20s$  is considered around the key point where  $s$  is the scope. Then it is distributed into  $4 \times 4$  sub-sections. For every sub-section, both parallel and perpendicular wavelet responses are considered and as a result a vector is made as equation ii,

$$V = (\sum dx, \sum dy, \sum |dx|, \sum |dy|) \dots\dots\dots(i)$$

This characterized as one vector that produces SURF features with total 64 dimensions. Lesser the dimension, higher the matching rate with better computational speed. This phenomenon provides better uniqueness of features.

#### Designing the Classifier

After feature extraction, we have two different feature sets one for SIFT and the other for SURF. The pixel matrix of both the features is flattened, and stacked horizontally. We keep track of the length of all the pictures taken to ensure a perfect feature matrix. The all above action is performed for the Normal and affected images. 1D Arrays for each sample are created and stacked vertically after grouping. This process yields a feature matrix of all the images. Now we create the target vector for the affected with the help of np.ones and for the unaffected np.zeros. The target vector is stacked horizontally with the feature matrix. Now we got the pixel values and label, which makes the dataset. Which is now ready to feed into the model. In this paper, the SVM classifier is used for the classification purpose.

SVM (linear) is a type of classifier that finds a hyper plane which, distinctly classify the given data into two chunks, positive and negative. The beauty of SVM is its powerful mathematical background. It classify the data more accurately as compared to other techniques in real-life applications. It immensely does well in case of high dimensional data like image. For example, Let the set  $D$  be  $\{(a_1, b_1), (a_2, b_2), \dots, (a_r, b_r)\}$ , is an input vector in  $A \subseteq R^n$  and  $b_i$  is its output value (class label),  $b_i \in \{1, 0\}$ . Where 1: positive class and 0: negative class. Then SVM finds a linear function in the form ( $w$ : weight vector)  $f(a) = \langle w \cdot a \rangle + k$

**Manoj Kumar Behera and S. Chakravarty**

$$b_i = \begin{cases} 1 & \text{if } \langle \mathbf{w} \cdot \mathbf{a}_i \rangle + k \geq 0 \\ 0 & \text{if } \langle \mathbf{w} \cdot \mathbf{a}_i \rangle + k < 0 \end{cases} \dots\dots(ii)$$

### Algorithm

#### MODEL FLOW

**STEP I:** Every input RGB image from the dataset goes through the following pre-processing techniques, such as (Resizing 512x512, Green Channel Extraction, Adaptive Histogram Equalization and Edge Enhancement).

**STEP II:** Two feature extraction techniques SIFT and SURF are implemented on each image simultaneously to capture the features present in it. The result of both techniques are appended and preserved in a single row of the feature table.

**STEP III:** After the completion of Step II each row in the feature matrix representing the features of individual input image is labeled with '0' or '1' depending on the type of image i.e. normal or affected.

**STEP IV:** This feature matrix generated in Step III used to train the Classifier.

**STEP V:** The Trained classifier applied on the test data set i.e. generated by a set of retinal images using Step I and II for generating the resultant matrix.

**STEP VI:** The generated result is compared with the actual to calculate the accuracy of the model.

### RESULT AND DISCUSSION

[Figure-4] shows the intermediate results produced after completion of each stage, in the proposed model. Where (a) and (b) indicates the original input image of Normal and Glaucoma affected eye. Figure (c) and (d) indicates the respective outputs after completion of preprocessing phase and finally figure (e) and (f) indicates the features captured using SIFT and SURF operator. Finally the model is evaluated using 210 test images out of which 150 are Glaucoma affected and 60 are normal images. The performance of the classifier evaluated in terms of sensitivity, specificity, overall accuracy are shown in [table-1].

### CONCLUSION

Glaucoma is an irredeemable disease, if it remains untreated may lead to permanent vision loss. This paper expresses effort concerning the automatic detection of Glaucoma disease using image processing and Machine Learning techniques. The well-known feature extraction techniques like SIFT and SURF are used for capturing the features and for modeling the classifier a very popular machine learning technique SVM is employed. The proposed model achieved an overall accuracy of 96% over 210 test images and has the potential to be additional sensitive for prediction of Glaucoma at its early stage. In future this work can be extended for detection of glaucoma at its various stages using a multiclass classifier.

### ABSTRACT

Agriculture production and productivity is constantly suffering from of threats created by various classes of plant pathogens leading to huge economic losses. To control the plant disease a huge amount of pesticide used for many year lead to the warning to environment and at the same time it is contribute the development of resistant pathogen races. So to maintain sustainability nano technology (Nanopesticide, Nanofertilizer etc.) introduced in modern agriculture. Among all the nano formulation tested for antimicrobial activity against plant pathogen silver and chitosan nano particle show significant effect.

**Keywords:** Nano-particle,Chitosan,Silver,Pesticide

### INTRODUCTION

Agriculture is the primary source of livelihood for about 58 per cent of India's population. The production and productivity is constantly suffering from of threats created by various classes of plant pathogens leading to huge economic losses. Among the total crop losses caused by different sources, 14.1 % are lost due to plant diseases alone and the total annual worldwide crop loss from plant diseases is about \$220 billion. (Agrios ,2005). To minimize loss caused due to the pathogen pesticides are used in huge amount for many years since mid-1950s.Due to the potential use of pesticide it start damage the environment and food as they are spread over the crop plant several times each year, at the same time it has contributed to the development of resistant pathogens (Lamsal *et al.*, 2011).

So for the maintain equilibrium between environment and food production innovative technologies are being introduced in modern agriculture to minimise such losses. Among such technological innovations, nanotechnology (nanopesticide, nanofertilizer etc.) is gathering noteworthy considerations due to its robust applications in agriculture (R nair 2010) ( Ghormade V *et al.*, 2011). In general, nanoparticles have attracted considerable attention in

**Abhinandita sahoo and Ria Mukhopadhyay**

the fields of medicine, pharmaceuticals, cosmetics and electronics due to unique physical, chemical and biological properties (Bakshi M *et al.*, 2014). In present day, the development and application of biosynthesized nanoparticles has opened new avenues in agricultural research oriented to developing ecofriendly and effective means of controlling plant diseases. Most importantly, biological synthesis of silver nanoparticles (AgNPs), Chitosan has offered a consistent, non toxic and ecofriendly approach for plant disease management due to their strong antimicrobial properties (Navrotsky A, 2000). This review evaluates the current literature on the effect of nanoformulation to inhibit the growth of plant pathogenic microorganism in *in-vitro* condition.

**Antimicrobial efficacy of Chitosan**

Chitosan is a naturally-occurring, linear polysaccharide produced from chitin by deacetylation in the solid state under alkaline conditions, or by enzymatic hydrolysis of chitin deacetylase. It is considered to be the second largest renewable biomaterial after cellulose in terms of utilization and distribution (Elgadir *et al.*, 2015). Now a days chitosan and its derivative biomaterials have a significant attention in the biomedical field, owing to their unique biological properties. Some of the most noted properties of chitosan are its non-toxicity, biodegradability, biocompatibility, and immunoenhancing, antibacterial and antimicrobial activity. Sudarshan *et al.* (1992) suggested that chitosan could penetrate fungal cell wall and bind to its DNA and inhibit the synthesis of mRNA and, in turn, affect the production of essential proteins and enzymes required for the infection. Rabea *et al.* (2003) explained chitosan chelates with metal ions, which has been implicated as a possible mode of antimicrobial action. Phaechamud and Ritthidej (2008) reported chitosan nanoparticles have got various applications in biology due to its biodegradable and nontoxic properties.

In acidic condition the free amino groups of chitosan protonates and contributes to its positive charge the inhibition mode of chitosan against fungi. García-Rincón *et al.* (2010) explained that positive charge of chitosan interacts with negatively charged phospholipid components of fungi membrane, which in turn alter the cell permeability of plasma membrane and causes the leakage of cellular contents, which consequently leads to death of the cell. Soleimani *et al.* (2011) reported that host resistance was an efficient and effective component in integrated management of plant diseases. The aim of this study was to test whether Acibenzolar-S-methyl (ASM), Chitosan, Heads-up and Acetyl Salicylic Acid (ASA), known to induce resistance against various diseases, can help protect potato crop against brown leaf spot. The effect of these inducers, on two potato cultivars, Goldrush and FL1879 against *Alternaria alternata*, causal agent of brown leaf spot at two different field sites were evaluated. To determine the effects of the application of inducers on disease resistance, the foliage of the potato cultivars was sprayed with appropriate concentrations of ASA, chitosan, and ASM. Heads-up was also applied as a pre-plant treatment on potato tubers. The results obtained from the both field experiments indicated the highest yield performance was achieved in plots treated with ASM, followed by Heads-up and chitosan treatments. However, no significant difference in terms of tuber yield production has been noted between ASA treated potato foliage, and the untreated control plants.

Results of experiments with detached leaves showed that there was a significant difference regarding disease index reduction between plots which been treated with defense inducers and untreated, inoculated plots. It was clear that on both potato cultivars, application of chitosan and ASM encouraged enhancement of the disease resistance compared to the ASA and Heads-up treatments. In the laboratory experiment, disease progress was recorded on leaves from three different heights of the crop canopy. The results indicated that disease severity was low in the apex, moderate in the middle and high in the lower parts of the crop, in both potato cultivars. These results suggest that chitosan and ASM may offer alternative methods for controlling brown leaf spot of potato. M. Sathiyabama *et al.* (2015) found that chitosan at the concentration of 1mg/ml inhibit the radial growth of *Alternaria solani* and protect the tomato plant from blight pathogen by enhancing the chitinase activity. Yadi Suryadi *et al.* (2017) explained that nano chitosan had an inhibitory activity to *Colletotrichum gloeosporioides in vitro* up to 85.7%.

**Abhinandita sahoo and Ria Mukhopadhyay****Antimicrobial efficacy of silver nanoparticle**

Silver was known as one kind of efficient disinfectors in the early 19th century. From then on, it was widely applied in the fields of bacteria inhibition, wound dressing, mildew preservation, etc. In the recent year, it was found that silver nanoparticle (AgNPs) were checked the growth of fungi, bacteria and virus. Becker *et al.* (1999) showed a nanosilver particle may or may not be charged on its surface or generate silver ions.

Like ionic silver, nano silver is a very potent killer of bacteria and has been shown to kill fungi, algae, and some viruses, including HIV. Park *et al.* (2006) explained that Silver in ionic or nanoparticle forms had a high antimicrobial activity and was therefore widely used for various sterilization purposes including materials of medical devices and water sanitization. Relatively few studies were reported on the applicability of silver in controlling various plant pathogens in a relatively safer way compared to synthetic fungicides. Min *et al.* (2009) observed in microscope that hyphae exposed to silver nanoparticles showed severe damage and resulted in the separation of layers of hyphal wall and collapse of fungal hyphae. Wei *et al.* (2009) reported that Silver has been used as an antimicrobial agent since ancient civilizations; it has been used extensively due to its broad spectrum and multiple modes of antimicrobial activity.

Young-ki Jo *et al.* (2009) examined the antifungal activity of silver ions and nanoparticles against two plant-pathogenic fungi, *Bipolaris sorokiniana* and *Magnaporthe grisea*. In vitro petri dish assays indicated that silver ions and nanoparticles had a significant effect on the colony formation of these two pathogens. Effective concentrations of the silver compounds inhibiting colony formation by 50% (EC50) were higher for *B. Sorokiniana* than for *M. grisea*. The inhibitory effect on colony formation significantly diminished after silver cations were neutralized with chloride ions. Growth chamber inoculation assays further confirmed that both ionic and nanoparticle silver significantly reduced these two fungal diseases on perennial rye grass (*Lolium perenne*). Particularly, silver ions and nanoparticles effectively reduced disease severity with an application at 3 h before spore inoculation, but their efficacy significantly diminished when applied at 24 h after inoculation. The in vitro and in planta evaluations of silver indicated that both silver ions and nanoparticles influence colony formation of spores and disease progress of plant-pathogenic fungi. In planta efficacy of silver ions and nanoparticles is much greater with preventative application, which may promote the direct contact of silver with spores and germ tubes, and inhibit their viability. Kumar *et al.* (2010) described that Metallic nanoparticles possess unique chemical and physical properties, small size, huge surface to volume ratio, structural stability and strong affinity to their targets. Lamsal *et al.* (2011a) showed the effective usage of silver nanoparticles instead of commercial fungicides.

They evaluated the effect of silver nanoparticles against six *Colletotrichum sp.* associated with pepper anthracnose under different culture conditions and found that, application of 100 ppm concentration of silver nanoparticles inhibited the growth of fungal hyphae as well as conidial germination in vitro when compared to the control. Silver nanoparticles showed significantly high inhibition of fungi in field conditions when applied on the plants before disease outbreak. Lamsal *et al.* (2011b) studied on *in vitro* and *in vivo* efficacy of silver nanoparticles against powdery mildew before and after disease outbreak in plants under different cultivation conditions, showed maximum inhibition of fungal hyphae and conidial germination with less concentration of nanoparticle on cucumbers and pumpkins. Hameed *et al.* (2012) studied that the secondary metabolites in plants have been used in the formulation of nanoparticles through increase the effectiveness of therapeutic compounds used to reduce the spread of plant diseases, while minimizing side effects for being: rich source of bioactive chemicals, biodegradable in nature and non-polluting (eco-friendly).

Particulate systems like Nanoparticles have been used a physical approach to alter and improve the effective properties of some types of synthetic chemical pesticides or in the production of bio-pesticides directly. Ing *et al.* (2012) explained that chitosan therefore could be formulated and applied as a natural antifungal agent in nanoparticles form to enhance its antifungal activity. Kim *et al.* (2012) reported the inhibitory effect of three different silver nanoparticles (WA-CV-WA13B, WA-AT-WB13R, and WA-PR-WB13R) against eighteen different commercially

### Abhinandita sahoo and Ria Mukhopadhyay

important plant pathogenic fungi on potato dextrose agar (PDA), malt extract agar, and corn meal agar. They found that inhibition of fungal pathogens with silver nanoparticles was concentration dependent and also on type of silver nanoparticles used. Most fungi showed a good inhibitory effect at 100 ppm concentration of silver nanoparticles on PDA, compared with others. WA-CV-WA13B showed the highest inhibition effect compared to other silver nanoparticles. Effect of silver nanoparticles on the growth of sclerotium-forming species *Rhizoctonia solani* and *Sclerotinia sclerotiorum*, revealed that silver nanoparticles effectively inhibit the hyphal growth in a dose-dependent manner.

## CONCLUSION

In the review cited above it observed that silver and chitosan nanoparticle is significant properties like its non-toxicity, biodegradability, biocompatibility, and immunoenhancing, antibacterial and antimicrobial activity. It potentially inhibit the mycellial growth, spore germination .

### ABSTRACT

A number of Epidemic diseases has been coming since a past years and a huge number of people and animals are coming in the clench of these deadly disease. More than 19 epidemic diseases have been reported by the WHO (World Health Organization). Those are Chikungunya, Cholera, Crimean-Congo hemorrhagic fever, Ebola virus disease, Hendra virus infection, Influenza, Lassa fever, Marburg virus disease, Meningitis, MERS CoV, Mokeypox, Nipah virus infection, Plague, Rift Valley fever, SARS, Smallpox, Tularaemia, Yellow Fever, Zika virus disease and now Novel Coronavirus. Before in the past years somehow spread of diseases were limited to affected countries only. But in this current era there are a certain reason which are responsible for the spread of disease globally like global trade, exchange of capital among the people of different geographic boundaries. It's becoming crucial to know the affected Coronavirus cases for future actions. Thus, machine learning techniques are applied to predict total number of cases affected by Coronavirus. In this Study, Data has been collected and interpreted for a number of analysis, how COVID-19 cases are reaching at a peak level, how death rates are increasing rapidly, the percentage of recovery cases and the mortality rate analyzed across the globe. Among all machine learning algorithm, linear regression is giving promising accuracy rate and suitable results in this proposed model. Therefore, this algorithm is chosen to prepare the model which will get trained by the previous cases and will predict the future cases.

**Keywords:** Coronavirus; Graph Visualization; Linear Regression

### INTRODUCTION

A perilous novel Coronavirus (COVID-19) which is pandemic all over the world emerged from a 'wet market' of Wuhan City in China in the year Dec, 2019. This contagious disease is caused by severe acute respiratory syndrome

23939

**Raj Kumar Sahoo et al.**

Coronavirus 2 (SARS-CoV-2). More than 108 countries are in the grasp of this deadly disease. Therefore, economy of these affected countries is drifting into troubles. Many initiative measures have been taken place such as informed the residents not to come outside of their mansion, wear masks and maintain social distance among people. Every day the cases are booming up and since it is a herculean task to control it and it's becoming significantly necessary to predict the total number of Corona affected people in coming days. So, that government can make future decisions and make arrangements such as to keep max units of ventilators, more number of doctors to be available, and be prepared to cope with the adverse situations.

The epidemic disease Novel Coronavirus which is since active in the date of writing this paper, need to be controlled. The disease is spread among people by indirect contact or direct close contact through coughing or sneezing by the affected persons. Symptoms such as cold, cough, tiredness, shortness of breath and fever develop in all these patients. People having these symptoms are required to be in quarantine and must do covid test in their respective testing centre. All countries should be ready to fight with this harsh situation. Before that, it is always required to predict the total number of Corona cases. For that quick prediction of total cases, a Machine Learning Technique is proposed which will predict the total Corona cases in near future and it will be helpful for great decision making by the countries to grapple this repugnant situation.

In this proposed model, at first confirmed cases of all the COVID-19 affected countries are visualized and analyzed by the trend line and growth rate. Country India is also analyzed. Future cases of India are predicted using machine learning algorithms. Total case of the world is analyzed and future case is predicted using machine learning model. Active cases, Death cases and Recovery cases are represented in a single scatter graph to interpret the highest growth trend. Mortality rate and recovery rate is interpreted. Top 10 affected Countries having highest percentage is evaluated and visualized in a pie chart. This paper is divided into five section i.e. 1. Introduction, 2. literature Survey, 3. Material and Methods, 4. Simulation Results and Discussion and 5. Conclusion.

## LITERATURE SURVEY

From existing machine learning models of Linear regression, some thoughts, understanding, ideas are acquired. [12] Corona Tracker: world-wide COVID-19 outbreak data analysis and prediction. [13] Modified SEIR and AI prediction of the epidemics trend of COVID-19 in China under public health interventions. [14] Prediction models for diagnosis and prognosis of COVID-19 infection: systematic review and critical appraisal. [15] Predicting the impacts of epidemic outbreaks on global supply chains: A simulation-based analysis on the coronavirus outbreak (COVID-19/SARS-CoV-2) case. From all of the above existing papers, knowledge is acquired from the analysis and predictions, how Linear Regression is used effectively and know different approach for the prediction of COVID-19 in various sector of medical field of science and technology.

Raj Kumar Sahoo et al.

## MATERIAL AND METHODS

### Data Acquisition

The main motive is to predict the total number of affected cases in upcoming dates. So, data is acquired from the popular GitHub repository. It contains a huge collection of datasets. i.e. [https://raw.githubusercontent.com / datasets/covid-19/master/data/time-series-19-covid-combined.csv](https://raw.githubusercontent.com/datasets/covid-19/master/data/time-series-19-covid-combined.csv).

### Data Preparation

The datasets describe about affected cases, number of recovery cases and number of death cases with respect to date. To eliminate any rise of error in quality of performance, the null values are replaced with mean values. But in this model of future prediction of affected cases, null values are replaced with 0, if no cases happened on that date. Active cases are calculated by subtracting the sum of death and recovery cases from the affected total cases.

### Feature and Target

Date is serialized by transforming it to numerical values. Then it is taken as input and total cases are taken as output before building the model. It's crucial to align the total cases with its respective dates.

### Linear Regression (LR)

Linear Regression is one of the machine learning algorithms comes under supervised learning approach. It is basically used for performing regression task. The main goal of linear regression is to find the variation in one variable (called dependent variable), based on the variation in one or more other variables (called independent variables). This means linear regression to find out relationship between variables and forecast data i.e. relationship between dependent and independent variables. The three major uses for linear regression analysis are

- (1) To determining the strength of predictors
- (2) To forecasting an effect
- (3) And to find the trend of forecasting.

Linear regression has many practical uses. Most applications fall into one of the following two broad categories [16]:

- i. If the aim is to make the prediction, forecasting or error reduction then the linear regression can be used to fit a predictive model.
- ii. If the goal is to find out the variation or error, the linear regression can be more skillful used to quantify the strength between the dependent and the independent variables. And to determine whether some independent variables may have no linear relationship with the dependent variables at all, or to identify which subsets of independent variables may contain redundant information about the dependent variables.

$$Y = B_0 + B_1 * X \quad (1)$$

The above equation (1) is of Simple Linear Regression. Y is dependent variable which represents the total cases of COVID-19 and X is independent variable which represents the dates as per respective total cases.  $B_0$  is constant or intercept term and  $B_1$  is coefficient for independent variable.

During training model, the process includes insertion of all training data(X) and labels to training data(Y). It finds the best fit line to predict the value for the given input data. Model finds the best regression by updating the intercept and coefficient of the input value by updating the intercept and coefficient of input value. With minimization of error, difference between the true value and the predicted value by using cost function best fit line is obtained.

### Proposed Algorithm

Now the normalize data is ready for modelling after the data cleansing phase is over. Splitting of the normalize data into training and testing data is a crucial part before model building. From the whole clean data, 80% percentage of

**Raj Kumar Sahoo et al.**

the data is assigned for training data i.e. signed to  $x_{train}$  and  $y_{train}$  respectively. The remaining 20% is assigned for testing where data i.e.  $x_{test}$  and  $y_{test}$  respectively.

Model is built by fitting the training and testing data by using Linear Regression algorithm. Linear regression is a very efficient algorithm which maps numeric inputs to numeric outputs in machine learning. Linear Regression makes the line which best fits to the data points. In this case, normalize is set to true and fit intercept is set to false of the parameter. Then the  $x_{train}$  and  $y_{train}$  is fitted to the model for training and  $x_{test}$  and  $y_{test}$  is fitted to the model for testing purpose. Score function is used to find the accuracy. The Completion of data fitting, resulting in 97% accuracy.

**SIMULATION RESULTS AND DISCUSSION**

Data is interpreted to predict total cases in upcoming future dates. At the very beginning, after adopting a certain procedure of data cleansing. Data is arranged in a structural manner as per usage model. Total cases of all affected countries are represented with interactive graph visualizations then analyzed and finally used for prediction.

At the time of writing this paper, highly affected countries by COVID-19 are US, Spain, Italy, France, United Kingdom, Germany, Turkey, Russia, Iran and Brazil. US is the most affected country and at the top among all the affected countries by this deadly disease.

Fig. 1 Represents the graph having total confirmed cases of India which has already crossed over 2,40,000 number of cases. Where as Fig. 2 show the graph having total confirmed cases of all over the world which has reached more than 6.5 million cases. The mortality rate is less than half of the global average as per as the information of Govt. Of India. Initially the rate of death is gradually increase up to April 2020 end. After the may 2020 first week the rate of mortality case through out the globe is decrease which shows in Fig.5. Similarly the recovery rate is proportionally increase with death rate across globe in Fig 6. India is a second highest populations after China in the world. Day by day the infection rate is increasing in India as well as all over the world. This model predict to the number of confirmed cases in very near future in India as well as the world by using linear regression algorithm. This model gives the prediction result 97% accuracy. Fig.7 and Fig.8 shows the number of confirmed cases for India and whole world.

**CONCLUSION**

Since past many years, a number of epidemic diseases have emerged in this world and grab a lot of human lives, made huge losses. But somehow, those ended. But now this Novel Coronavirus is booming up every day. Life of people are deceased without vaccine. But regardless of great achievements and developments in the field of medical research, no vaccine has yet prepared. Researchers, scientists of reputed medical organizations of various countries are under continuous research to prepare for antidote. It's a very critical situation for all the people to overcome this obstacle. All human beings have a great hope for proper vaccine to rescue this world. In COVID-19 period, it's very crucial to stay safe and keep all safe.

### ABSTRACT

Cyanobacteria belong to an ancient group of photosynthetic prokaryotes with pronounced variations in their cellular differentiation strategies, physiological capacities and choice of habitat [9]. The availability of complete genome sequences of some of the cyanobacteria occupying remarkably diverse ecological niches enabled to gain insights into their adaptive properties. The objective of this study was to analyze complete cobalt, nickel, zinc, cadmium, Mg<sup>2+</sup>, Mn<sup>2+</sup>, molybdate, chromate ion metal transporters (metal transportomes) from eleven representative *Cyanobacterial* species and to identify metal transporters which is associated with "Genomic Island".

## INTRODUCTION

Dataset cataloguing has been executed for the transition element metal ion transporters from all the selected eleven *Cyanobacterial* species using TIGR-CMR and Transport DB[5][6]. Metal transporters having "Genomic Island" associated features were identified using Island path analysis.

### Findings

#### Background

Cyanobacteria (also known as blue-green algae) are a group of extraordinarily diverse Gram-negative prokaryotes that originated 3.5 billion years ago. Their diversity ranges from unicellular to multicellular, coccoid to

23945

**Shanti Kumari Lunavat et al.**

branched filaments, nearly colourless to intensely pigmented, autotrophic to heterotrophic, psychrophilic to thermophilic, acidophilic to alkylphilic, planktonic to barophilic, freshwater to marine including hypersaline (salt pans). They are found both free living and as endosymbionts [1].

The transition metal ions including cobalt, copper, manganese, nickel and zinc are essential for the viability of Cyanobacteria as well as many other bacteria [2]. The transition metals like nickel and cobalt, essential components of many enzymes, etc. are taken up by specific transport systems of different types [18]. Biological systems have different types of transporters based on the different types of transport mechanisms, ATP dependent, ion channels, secondary transporters and unclassified transporters [6]. Three ATP-binding cassette (ABC)-superfamily multidrug efflux pumps are known to be responsible for chemoresistance [19]. These multidrug transporters provide resistance to the organism against different types of exogenous drug molecules along with some of the endogenous toxic compounds. Unlike metal ion transporters, multidrug transporters are nonspecific to the substrate, former one is more specific towards its substrate.

Cyanobacterial species are ecologically significant group of bacteria. In the post genomic era complete genome sequence of following eleven cyanobacterial species allowed us to understand the genomic organization of metal transporters (transition metals: Ni<sup>2+</sup>, Cu<sup>2+</sup>, Mn<sup>2+</sup>, Co<sup>2+</sup>, Cr<sup>2+</sup>, Mo<sup>2+</sup>; Poor metals: Zn<sup>2+</sup> and Cd<sup>2+</sup>; Alkali earth metal: Mg<sup>2+</sup> and multidrug transporters from *Prochlorococcus marinus* MED4 (CCMP 1378), *Prochlorococcus marinus* MIT 9313, *Prochlorococcus marinus* SS120 (CCMP 1375), *Synechococcus elongatus* PCC6301, *Synechococcus* sp. CC9311, *Synechococcus* sp. CC9605, *Synechococcus* sp. CC9902, *Synechococcus* sp. RCC307, *Synechococcus* sp. WH7803, *Synechococcus* sp. WH8102 and *Synechocystis* sp. PCC6803. Through analyzing their complete repertoire of metal transporters of cyanobacterial species, variety of metal transporters acquired through Horizontal Gene Transfer (HGT) are reported.

## METHODS

### Compilation of metal and drug transporter inventory

The genomic sequence information of the eleven sequenced Cyanobacterial sps *Scys*PCC6803, *Pmar*MED4 (CCMP1378), *Pmar*MIT9313, *Pmar*SS120 (CCMP1375), *Selo*PCC6301, *Synsp*CC9311, *Synsp*CC9605, *Synsp*CC9902, *Synsp*RCC307, *Synsp*WH7803 and *Synsp*WH8102 employed in this study were selected from TIGR-CMR database. Protein sequences were compiled using TransportDB; a relational database describing the predicted cytoplasmic membrane transport protein complement for organisms was used as a substrate for building the metal and drug transportomes [4]. From the compiled sequences phylogenetic trees were constructed for substrate specific transporters individually and through analyzing the aligned sequences conserved domains for individual metal ion and drug transporter were reported [7]. For some of the specific Nickel secondary transporter (slr 1796) and Cobalt transporters orthologous and paralogous sequences were obtained using KEGG database and phylogenetic trees were generated for them [8]. Transmembrane helix prediction for membrane transporters was performed using TMHMM version 2.0 [3]. Genomic location and gene organization were identified from TransportDB.

### Phylogenetic analysis

CLC main workbench has been employed to construct the phylogenetic tree for the compiled metal ion transporters and also for our intense interested multidrug transporters from *Scys*PCC6803 [7]. For the phylogenetic analysis, multiple sequence alignments (MSA) were produced using progressive alignment algorithm. The generated alignments were used for determining the evolutionary distance between the sequences. Thus the calculated sequence distance was used to create a phylogenetic tree- employing neighbour joining (NJ) algorithm with 1000 bootstrap replicates.

Shanti Kumari Lunavat et al.

### Sequence clusters and orthologous sequences

KEGG pathway database has been executed to identify sequence clusters for Ni<sup>2+</sup> transporter (slr0796) [8]. This database aids us to identify the clusters of genes those having the related functional annotation. Orthologous sequences having similar function in different species are also identified using KEGG pathway database for the same Ni<sup>2+</sup> secondary transporter (slr0796) (Fig 1).

### Island path analysis

Cyanobacterial sps are ecologically diversified organisms habituated to grow in different environmental conditions- freshwater ecosystems and marine water ecosystems are some examples to be named. Organisms to get acquainted to specific niche, they need to meet the requirements to survive in that conditions. Horizontal gene transfer mechanism is involved in the achievement of essential needs. Island path analysis was used for the detection of metal transporters acquired through HGT(islandpath). After generating the genomic sequences of eleven Cyanobacterial species with island path software (IPA version 1.0 tool) for the identification of the transporters located in GI's or exhibiting GI associated features like anomalous %G+C, dinucleotide bias above 1 STD DEV, presence of RNA genes (tRNA, rRNA genes) and mobility genes (transposons and insertion sequences).

### Protein sequence analysis

Metal and drug transporter proteins analysis has been carried out using CLC main workbench 6.9. The conserved motif in the ATP dependent transporter's membrane domain" LSGGQ" has been identified. This domain is the signature sequence for the ABC transporter proteins.

## RESULTS AND DISCUSSION

### From genome to metal and multidrug transporters in Cyanobacteria

Based on the global features of the eleven Cyanobacterial genomes we could draw a comparison among the genome size, number of genes, transporter proteins and total number of metal transporters and multidrug transporters from *ScysPCC6803*(Table 1). Among the eleven spp, *ScysPCC6803* has the largest metal transporter inventory (38 metal ion transporters) while *PmarMED4* (CCMP1378) has the lowest (16 metal ion transporters). *Prochlorococcus* spp has the less number of total transporters and metal ion transporters when compared to *Synechococcus*spp, while *Synechocystis PCC6803* has the largest genome size of 3.9mb, the highest total of 168 transporters and 38 metal ion transporters among the other organisms involved in this study [10]

Based on the TransportDB the metal transportomes were compiled for the metal ion complements of transition metals: Ni<sup>2+</sup>, Cu<sup>2+</sup>, Mn<sup>2+</sup>, Co<sup>2+</sup>, Cr<sup>2+</sup>, Mo<sup>2+</sup>; Poor metals: Zn<sup>2+</sup> and Cd<sup>2+</sup>; Alkali earth metal: Mg<sup>2+</sup> and multidrug transporters from *ScynPCC6803*. These transportomes furnish information for class/family/subfamily, protein name, orientation, length of the protein, TMD's substrate and the predicted role of the above metal transporters. A comparative analysis depicting the basic differences in the composition of transporter classes and metal transporter families from the eleven *Cyanobacterial* species is represented in Table 2. From the above analysis we were reported that *ScycPCC6803* has the highest no: of ATP dependent transporters (19 ATP dependent transporters) among the group and secondary transporters are distributed in uniform fashion in all the organisms and also the unclassified transporters are very less in number in all the group members.

### Salient features of Cyanobacterial transporters

Dataset cataloguing and multiple sequence alignment of the sequences helped to find the unique signature sequences in cobalt transporter along with regular signature sequences of ATP dependent transporter proteins (Fig 3). Most of the ion channel transporters contributed to MIT family Mg<sup>2+</sup>/Cobalt transporters. There are no records found related to Mg<sup>2+</sup>/Cobalt ion channel transporters from *Prochlorococcus* species.

**Shanti Kumari Lunavat et al.**

The major finding of our study is that there is only one Nickel transporter from *ScysPCC6803* found among all the organisms from the group and also the reported Nickel export transporter (slr 0796) is secondary transporter belongs to MFS superfamily. Analysis of the complete genome sequence of the cyanobacterium *Synechocystis PCC 6803* (henceforth referred to as *Synechocystis*) [12] led to the identification of a metal-regulated gene cluster involved in resistance against zinc, cobalt and nickel [13]. This 12 kb region consist of 11 open reading frames (ORFs) organized into six putative transcriptional units (Fig. 2): (i) *nrsBACD* operon involved in  $\text{Ni}^{2+}$  and  $\text{Co}^{2+}$  tolerance and regulated by the upstream *nrsSR* operon [14], (ii) *ziaA* encoding a putative  $\text{Zn}^{2+}$  efflux P-type ATPases and regulated by the product of the preceding ORF, *ziaR* [15], and (iii) *coaT* encoding a putative  $\text{Co}^{2+}$  translocating P-type ATPase under the regulation of the upstream *corR* product [16][11].

Various kinds of transporters related to different superfamily transporters were identified in the secondary transporters. CDF family  $\text{Cd}^{2+}/\text{Zn}^{2+}/\text{H}^{+}/\text{K}^{+}$  antiporter (*sync\_0686*), ZIP family Zinc ion (*sync\_0684*), Nramp family manganese/iron ion (*sync\_2773*), RND superfamily cobalt/zinc/cadmium ion efflux (HME subfamily) (*sync\_1510*) from *Synechococcus sp.* CC9311 and RND family cobalt/zinc/cadmium ion efflux (HME subfamily) (*syncRCC307*) from *Synechococcus sp.* RCC307 were reported. ABC transporters contain a specific motif, the consensus signature sequence LSGGQ/R/KQR, which is highly conserved and is specific to the ABC superfamily. This sequence is also known as the linker peptide or C motif and is located N-terminal with respect to the Walker B motif [17].

Multidrug transporters from *ScynPCC6803* were compiled and using CLC main workbench multiple sequence alignment was generated but there are no conserved domains were reported, being a multidrug transporter, substrate binding domain binds to various kinds of compounds Horizontal gene transfer effect plays an important role in the acquisition of the requirements to adapt to specific niche conditions. Island path analysis tool is used to analyze Genomic island associated features of metal ion transporters for 10 cyanobacterial spp and for PmarMED4 (CCMP1378) genomic island features are not available in the island path tool. Thus island path analyzer gave us the clear idea on the no. of metal ion transporters acquired through HGT mechanism in the Cyanobacterial spp. PmarMIT9313 showing 71% of metal ion transporters are acquired through HGT mechanism and SyncsWH7803, syncspWH8102 and PmarSS120 (CCMP1375) has the very less no. of transporters acquired through HGT mechanism.

## CONCLUSION

In this study a dataset cataloguing was performed for 184 transporter proteins including metal ion transporters from eleven *Cyanobacterial spp* and multidrug transporters from *ScynPCC6803*. This is the comprehensive genomic comparison of metal transporters, providing potentially important insights into the fundamental molecular aspects and novel facets of *Cyanobacterial* metal transporters.

### ABSTRACT

Churn prediction is a very important aspect in different private and public sectors all over the world. Customer's churn is very harmful for company's revenue and profit. Main step to avoid churn is to detect churn. Prediction of customer's churn helps company to apply various marketing strategies on the basis of whether the customer is about to leave or not. The objective of this paper was to predict the churn of banking sector by supervised classification using well known machine learning techniques like decision tree and Naïve-Bayes algorithm; the classification model to be built on historical data and then the model is used to predict the result for the current customers to identify the churn. The defined model is very effective for prediction of churn with the experimental dataset of an International Bank collected from kaggle repository and produced a prediction accuracy of 94.25%. Other than banking sector the model also can be useful in different sectors like telecommunication, online subscription, and online marketing field.

**Keywords:** Predictive models; Customer churn prediction; Performance metrics; Data sampling decision; Naïve-Bayes algorithm.

### INTRODUCTION

The key aspiration of every business is to build a loyal customer base and maintain that as well. However, the banking sector is characterized by stiff competition and also based on various marketing strategies. For a single dissatisfaction service, a customer does not churn [1]. So, customer churn can be defined as the loss of profit or revenue in the business sector [2]. The customer churn can be defined in other way also, like low switching cost, deregulation motivates a customer to replace the sector. The churn is also classified into two: voluntary and involuntary churn [3]. Voluntary churn is defined as the termination of services by the customer itself, whether involuntary churn is defined as the termination of services by the bank for fraud, non-payment services.

**Tamal Datta et al.**

The customer churn is very risky if it is not managed carefully, it may bring a company to its knees for poor maintain services. Cost of customer churn also includes loss of revenue, profit. Previous case study has shown that the cost of maintaining new customer is higher than the cost of maintaining the old one [4]. There are various banks who are suffering with this customer churn problem. So the most defined way is to deal with this problem is developing predictive model that can reliably and easily identify the possible churning. In the recent past most frequently used technique is data mining to develop such models with satisfactory results [5]. Day by day when this churn prediction problem get importance, much more research efforts generated towards improving churn prediction rates.

Most frequently used features that have been used previously includes credit score, geography, has credit card or not, is active member, estimated salary [6]. Due to business privacy and policy it is difficult to find and use public dataset for churn prediction. Tsai and Lu previously used two different hybrid model which can predict customer churn. To increase the prediction rate Kechadi and Buckley used attribute derivation process [4]. In this paper we present a new subset of features in order to improve the prediction accuracy. We performed experiments using Naïve Bayes classifier [7] and the result compared with decision tree [8], most frequently used algorithm in many classification and prediction work. This paper has been organized into five sections. Section-2 provides details of dataset and evaluation measures, Section-3 demonstrates the proposed system and its methodology. Section-4 provides analysis of results. Finally, Section-5 concludes this study.

### Data set details and Evaluation criteria

In this Study, a bank data is considered where a huge number of customer is leaving the bank. Almost 10000 records of the bank, collected from Kaggle repository is going to help the model to investigate and predict which of the customers are about to leave the bank soon. To test and evaluate the features the total dataset sliced into two subsets, training and testing dataset. Training dataset can be used to define the statistical model and the testing dataset can be used to predict the result and calculation of accuracy metrics for determining the model accuracy.

For validation of the model accuracy of the classifier is calculated on the basis of four output factors:

True positive (TP): correctly predicted positive cases.

False negative (FN): positive cases wrongly predicted as negative.

False positive (FP): negative cases wrongly predicted as positive.

True negative (TN): negative cases correctly predicted.

$$\text{Accuracy} = \frac{TP + TN}{TP + FP + FN + TN}$$

### METHODOLOGY

The defined model contains four different phases: data sampling, data pre-processing [9] and feature extraction, lastly model construction and model evaluation phase.

#### Data sampling

The dataset set containing 10000 costumers data in 24 columns, those are customerid, surname, credit score, gender, age, balance, geography, hasrcard, exited (the value indicates 1 when the customer churned).

#### Preprocessing

In this phase different preprocessing techniques like handling the missing values, data cleaning and feature extraction process has been performed. To identify the missing values in the dataset imputation technique will be used to impute the blank and null values. Noisy data, irrelevant attribute should be removed. Those variables those are not so much important can be removed in case of model building [10]. Finally for determining the performance of predictive model [11], feature extraction plays an important role for correct prediction. Here are some important features with description that can be useful for model construction as shown in [Figure-1].

Tamal Datta *et al.*

- Age: the age of the customer.
- Balance: the total bank balance of the customer.
- Is Active Member: how active the customer is/was in his service period.
- Tenure: defined by the length of service or duration, from the starting date to termination date. Plays an important role for prediction of churn.
- When it comes to the distribution of all data points over mean, box plots are used to identify the median and also respective qualities in well-structured manner.

### Building the Model

In this study, probabilistic algorithm Naïve Bayes algorithm is used on the proposed feature set for defining the model. Then the result is compared with the decision tree algorithm that most widely used algorithm for classification work. The two techniques are briefly discussed.

### Decision tree

Decision tree uses the most common method 'divide and conquer' to construct the model based on tree structure. The decision tree looks something like flowchart. The nodes of the tree represent the features. Main approach of this method is that it searches for the best attribute with the best information gain through the root node, then divide the tree into various sub trees. Similarly, those sub trees follow the same rule and separated recursively. When the leaf node is reached or there is no information gain, then the partitioning will be stopped.

### Naïve-Bayes algorithm

this is based on the Bayesian theorem. The approach instantly analyses the relationship between each feature as well as the class of each instance based on conditional probability. Assume that  $X$  is denoted as the vector of instance and also a random variable  $C$  denoted as the class of an instance. So now decide that  $X$  is a particular instance and  $C$  is a particular class. Now the training process shows that the computation of the probability of each class is defined by the how many times the class occurs in the training dataset. This is known as the prior probability  $P(C=c)$ . As well as the probability of the instance  $x$  given  $c$  is also computed by this algorithm. The advantage of this algorithm is that Naïve Bayes has achieved good result when the assumption and the considered class is violated. So, the Bayes formula is as follows:

$$P(C = c | X = x) = \frac{P(C = c) \prod_i P(x_i | C = c)}{P(X = x)}$$

The probability of an instance ( $x$ ) and a class  $c$  can be computed by the combination of prior probability and attribute density function.

Finally the block diagram of the proposed model is shown in [figure-2]

## RESULT AND DISCUSSION

The model is evaluated using two different machine learning algorithms decision tree and Naïve-Bayes algorithm by using a test data size 2000, which is 20% of the total dataset. The performance of the classifiers evaluated in terms of sensitivity, specificity and overall accuracy as shown in [table-1]. Based on the all pairs of TP and FP the ROC curves [12] were plotted as shown in [Figure-3] where X axis represents the false churn rate and Y axis represents the true churn rate. Each ROC curve represents actual pair of prediction rate (FP, TP). The ROC curve which is closer to the left top corner represent a better prediction rates. The difference between the Naïve Bayes and decision tree has shown from the upper curves. It is also shown that the sampling rate CHURN/ACTIVE decreases the number of ACTIVE increases through the Naïve Bayes model. This study shown that Naïve Bayes probabilistic classifier achieve higher growth that the decision tree.

**Tamal Datta et al.**

The gain of information is measured by the information theory, that also measure the information content on the attribute. The attribute we use to build the model is all about high information gain. Depending on the information gain of the attribute we use the top ranked attribute for model building purpose. It is defined that the selected attribute has the highest prediction rate through the Naïve Bayes model.

## CONCLUSION

Customer churn prediction plays an important role for predicting the churns in different sectors including banking. The defined model fits appropriately in identify the churners, with the underlying experimental dataset. The principal features were selected and evaluated by a powerful ML technique, Naïve Bayes algorithm and then the result is compared with Decision Tree algorithm. In future this work can be extended for prediction of churns in other sectors like sectors like telecommunication, online subscription, and online marketing field.

### ABSTRACT

Cyanobacteria can form dense eutrophic and harmful algal blooms (HAB). It can contribute towards atmospheric nitrogen fixation and influence the global nutrient cycles. Hence the study of their physiology, biochemistry and genetics is of much importance since last few decades. A cyanobacterial population provides an excellent model to identify the underlying molecular mechanisms which allow their success in water columns with higher intensities of light and extreme levels of nutrients. As cyanobacteria are primitive organisms, they provide novel insights into the genetic adaptations to their environmental changes happening due to global warming, high Photosynthetically Active Radiation (PAR) and UV-Radiation along with anthropogenic impacts. Comparing different types of species to different conditions enables better understanding of different physiological pathways linked to toxin production and bloom formations. The complete analysis of cyanotoxin biosynthesis-gene clusters (eg. Nodularin, Anatoxin, Microsporin, Cylindrospermopsin etc.) and the developments of their genetic manipulation techniques are of high importance in this area of research. However, toxin production depends on biological, physical and chemical factors encountered in the ecosystem. Genetic markers rather than traditional methods, presents a tremendous way to understand the interrelations, allelopathic

Shanti Kumari Lunavat *et al.*

influences and these are critical to understand the hidden secrets. In geographical distribution of cyanobacterial species, there is large information still to be explored to reveal the phylogenetic findings. In this review, few attempts were made to show possible solutions towards the above mentioned problems and are discussed in a general way emphasizing on genetic markers along with few other models.

## INTRODUCTION

### Connecting link between bacteria and plant

Cyanobacteria (blue green algae) form a diverse group of autotrophic bacteria, found in both aquatic and terrestrial environments. They evolved around 3 billion years ago (Knoll, 2008) and played an important role in the evolution of present day atmosphere oxygen, carbon, phosphorus, iron and nitrogen cycles - in short evolution of life on earth (Van den Hoek *et al.* 1995). It plays a key role in the functioning of onshore and offshore ecosystems, as they form the major constituent of phytoplankton communities and form dense mats of plankton blooms when favorable conditions prevail. These blooms are stimulated by high temperature, low CO<sub>2</sub> concentrations, high intensities of light, stratification of water body, a high phosphorus concentration and low inorganic N and P concentrations in the water column (Huisman *et al.* 2005). The important factor is, the cyanobacterial bloom once established, influences the internal phosphorus loading, light gradient, temperature, CO<sub>2</sub> depletion, which in turn stabilizes the bloom (Bicudo *et al.* 2007).

There are many species of cyanobacteria that produce hepato-, neuro-, gastrointestinal and cytotoxins along with some irritants i.e., Microcystis, Planktothrix, Anabeana, Aphanizomenon, Cyndrospermopsis that are highly toxic to some eukaryotes (Codd *et al.* 2005), causing health crisis in both fresh and marine ecosystems. Moreover, both global warming and eutrophication of waters have increased the frequency of formation of these blooms worldwide during last decade and it may continue (Jöhnk *et al.* 2008, Huisman *et al.* 2005). All these conditions prompt us to understand biodiversity of the species especially toxin producing ones. Genetic markers' gives us a scope to identify individuals and toxin producing species accurately. In ecological sense, genetic marker acts as a screening tool for ecological risk assessment and analysis. Several studies have shown that 16S rDNA are useful as molecular marker in taxonomic studies of cyanobacteria as in other prokaryotes. Hence, there is a need of thorough study of phylogenetics of cyanobacteria (Giovannoni *et al.* 1988, Otsuka *et al.* 1999).

Cyanobacteria can produce structurally diverse group of compounds called cyanotoxins which are synthesized via a nonribosomal pathway and are a product of the secondary metabolism (Pearson *et al.* 2008). Cyanotoxins have potential impact on aquatic ecosystems as well as on humans and livestock animals (Carmichael, 1992). Cyanotoxins are classified on the basis of their toxic effects and mode of action: hepatotoxins, neurotoxins and dermal toxins (Carmichael and Liu 2006). The production of cyanotoxin is not strain specific, for example, Cyndrospermopsin has been from nine different species (Moreira *et al.* 2012; Glenn *et al.* 2011). A family of multi-enzymatic complexes known as nonribosomal peptide synthetases and polyketide synthases, which are organized into repeated functional units are responsible for biosynthesis of cyanotoxins (Cane *et al.* 1996; Dittmann *et al.* 2011).

### Genetic diversity of cyanobacteria

Genetic markers provide valuable data which enables the detection of differentiation of species at DNA level. The suitability of the genetic marker depends on different characteristics, which include that the marker must be polymorphic, must show co-dominance, must be distributed randomly in the genome, must include simple and cost effective mechanisms and must be reproducible. They are useful in both basic studies like phylogenetic studies, searching of useful genes and applied studies like marker assisted selection, traceability testing.

**Shanti Kumari Lunavat et al.**

There are approaches which rely on DNA sequencing of cyanobacteria. In cyanobacteria, more than 80 genomes have been sequenced (Moreira *et al.* 2013). Genetic markers helped to determine the genetic diversity, population structure, phylogeographic structure and biogeographic pattern of the isolates ( Bittencourt-Oliveira *et al.* 2001; Moreira *et al.* 2011; Bahl *et al.* 2011). However, most phylogenetic analyses of nucleic acids as molecular markers for cyanobacteria have focused on *Synechococcus* and symbiotic filamentous *Anabaena* and *Nostoc* (Brett A. Neilan, 2002). The use of 16S rRNA genetic marker becomes an appropriate marker for cyanobacterial phylogenesis in recent years. The genetic polymorphism using 16S-23S ribosomal RNA transcribed spacer (RNA ITS) is able to define new horizons besides traditional methodology of classification (Brett A. Neilan, 2002). Genetic markers can be used to bring out the causes of hereditary diseases (Giovani, 1988). Procedures involving DNA transfer and probe hybridization have showed delineation of closely related and toxic cyanobacteria (Giovannoni, 1988, Douglas *et al.* 1988, Mazel *et al.* 1990, Wood *et al.* 1988, 1990).

There are many genetic markers identified which have wide application in phylogeny, taxonomy, phylogeography, evolution and biogeography studies of cyanobacteria (Moreira *et al.* 2013). Phycocyanin Intergenic spacer (PC-IGS) can be used as taxonomy, phylogenetic, phylogeography and biogeographical application while *ftsZ*, *glnA*, *glx*, *gyrB*, *pgi*, *recA*, *tpi*, 16S-23S ITS1-L, 16S-23S ITS1-S, *rpoC1*, *nifH*, 16 rRNA, 16S-23S ITS, *psbA*, *rbcL*, *rbcS*, *nifH*, 16 rRNA, 16S-23S ITS, *rbcLX* and *hetR*. From evolutionary point of view *nifH* and *rpoC1*, 16rRNA are important markers that find importance in phylogenetic studies only. Genetic markers which find application in taxonomy are *rpoB*, *rpoC1*, *nifH*, *nifD*, 16S-23S ITS, *rbcLX* and *hetR*. Genetic markers are useful tools to resolve taxonomic issues among genera or at species level, as well as to establish biogeographic patterns. There is a clear agreement between all the applied markers (Ballot *et al.* 2008; Gugger *et al.* 2002; Haande *et al.* 2007) in multi-gene analysis studies, though sometimes controversies may arise about the choice of best phylogenetic markers due to conflicting results (Dyble *et al.* 2002).

Multi-gene analysis requires more PCR reactions and DNA sequencing, which in turn, makes the procedure more expensive than to use a single genetic marker. In global perspective, we should consider different climatic zones tropical to temperate, high to poor levels of nutrients, high and low light gradient zones, all these different conditions influence the cyanobacterial blooms. Molecular markers are one of the proxies for detecting how environmental or biological factors are influencing the physiological and gene patterns of cyanobacteria. Such markers are the main source for indicating stress responses to low or high nutrient concentrations and changes in light intensities which can be detected at the gene transcription or protein level technologies (LaRoche *et al.* 1999), for example, the status of marine *Synechococcus* be assessed using a protocol expression of N regulatory gene *ntcA*. (Lindell *et al.* 2001) These responses may indicate species migrations and succession or suppression conditions. (Scanlan *et al.* 1997, 1999).

**Molecular approaches to study genetic diversity of cyanobacteria**

In early 1990s, research started on cyanotoxins and molecular markers of cyanobacteria. The studies were based on identification, detection, quantification, profiling, assembling of genetic diversity and phylogenetics of a particular taxa. Qualitative and quantitative studies of cyanotoxin were performed by HPLC and ELISA. In recent times, molecular tools DNA bar coding, Phylogenetic tree analysis, PCR, multiplex-PCR, Restriction Fragment Length Polymorphism (RFLP), Amplified Fragment Length Polymorphism (AFLP), Simple Sequence Repeats (SSR) / Microsatellites, Multilocus Sequence Typing (MLST), Random Amplified Polymorphic DNA (RAPD), Denaturing Gradient Gel Electrophoresis (DGGE), Fluorescence *in situ* Hybridization (FISH), Real-time PCR (qPCR) and DNA microarrays, CRISPRi technology are widely used.

All these methods are PCR based and the techniques used follows the same basic steps of using of Restriction Enzymes for digestion, Polymerized Chain Reaction (PCR) and finally Gel Electrophoresis. The methodology of genetic markers includes extracting proteins or chemicals from cells or tissues. Then different laboratory procedures will be applied and later blotting or staining techniques will be applied during which the information is formed in to a set of data. Analyzing these data sets, genetic diversity can be defined, measured and interpreted. The *in vitro*

molecular approaches based on Polymerized Chain Reaction showed significant advantages as screening tools for the identification of toxin releasing species because these systems enable potentially rapid as well as sensitive results. The type of technique selected is determined by the type of sample used and problems to be addressed.

- a) Restriction Fragment Length Polymorphism (RFLP):** The differences in DNA sequence of all organisms are genotypically distinct. This characteristic is the base for RFLP technique. Technique includes digestion of DNA fragment using digestive enzymes, gel electrophoresis and southern blotting. This technique is useful in identifying genetic diversity within and between species (Old *et al.* 1998). It shows a great co-inheritance but it takes long time and large amounts of DNA fragments which are the needs for this technique.
- b) Random Amplified Polymorphic DNA (RAPD):** Polymerized chain reaction (PCR) technique is being used in this technique along with gel-electrophoresis. It yields results in a short time. This technique enables to amplify a desired sequence of a DNA molecule, using a short primer and will be useful in phylogenetics. Its fast, high variability and relatively low cost characteristics made this technique a widely used one, but inability to give reproducible results made this technique replaced by other recent techniques.
- c) Amplified Polymorphic Length Polymorphism (AFLP):** This technique is a combination of both RFLP and RAPD techniques. Its good reproducibility, high levels of polymorphism and speed of analysis made this technique very popular now a day. These abilities enable one to utilize this technique for whole genome fingerprinting (Faccioli *et al.* 1999) and map expansion (Castiglioni *et al.* 1998).
- d) Denaturing Gradient Gel Electrophoresis (DGGE):** Black band disease (BBD) is a pathogenic, sulfide-rich microbial mat dominated by filamentous cyanobacteria that infect corals worldwide. We isolated cyanobacteria from BBD into culture, confirmed their presence in the BBD community by using denaturing gradient gel electrophoresis (DGGE), and demonstrated their ecological significance in terms of physiological sulfide tolerance and photosynthesis-versus-irradiance values. Twenty-nine BBD samples were collected from nine host coral species, four of which have not previously been investigated, from reefs of the Florida Keys, the Bahamas, St. Croix, and the Philippines. From these samples, seven cyanobacteria were isolated into culture. Cloning and sequencing of the 16S rRNA gene using universal primers indicated that four isolates were related to the genus *Geitlerinema* and three to the genus *Leptolyngbya*. DGGE results, obtained using Cyanobacteria-specific 16S rRNA primers, revealed that the most common BBD cyanobacterial sequence, detected in 26 BBD field samples, was related to that of an *Oscillatoria* sp. The next most common sequence, 99% similar to that of the *Geitlerinema* BBD isolate, was present in three samples. One *Leptolyngbya*- and one *Phormidium*-related sequence were also found. Laboratory experiments using isolates of BBD *Geitlerinema* and *Leptolyngbya* revealed that they could carry out sulfide-resistant oxygenic photosynthesis, a relatively rare characteristic among cyanobacteria, and that they are adapted to the sulfide-rich, low-light BBD environment. The presence of the cyanotoxin microcystin in these cultures and in BBD suggests a role in BBD pathogenicity. Our results confirm the presence of *Geitlerinema* in the BBD microbial community and its ecological significance, which have been challenged, and provide evidence of a second ecologically significant BBD cyanobacterium, *Leptolyngbya*.
- e) Microsatellites:** These are also known as Simple Sequence Repeats (SSRs), Short Tandem Repeats (STRs), Single Nucleotide Polymorphism (SNPs), Simple Sequence Length Polymorphism (SSLPs) etc. Generally there are many different microsatellite loci in organisms which are distinct genotypically. This technique is based on these loci. Microsatellites generally consist of less than 5 bp in length and show high variability, co-dominance and reproducibility which make them ideal for genome mapping besides population genetic studies.
- f) DNA microarrays:** Non-PCR based Methods: Non-PCR based approaches to identify and quantify cyanobacteria and cyanotoxin are based on DNA microarrays studies (Li *et al.* 2004). These studies are comparatively new to cyanobacteria field of research and limited to validation of methods related to detection of microcystin (*mcyE*) and

**Shanti Kumari Lunavat et al.**

nodularin (*ndaF*) cyanobacteria producers in both strains and environmental samples (Rantala *et al.* 2008). FISH studies is useful in identification of cyanobacteria in natural samples (Worden *et al.* 2000; Schönhuber *et al.* 1999) as well as for identification of the cyanotoxin microcystin (*mcyA*) in the cyanobacterium *M. aeruginosa* (Metcalf *et al.* 2009). In FISH, cells are made permeable to fluorescent labelled probes by a fixative. Probes are hybridized under stringent condition to rRNA and florescent signal determined by flow cytometry (Sekar *et al.* 2004).

- g) CRISPRi technology: Spatiotemporal Gene Repression System in the Heterocyst-Forming Multicellular Cyanobacterium *Anabaena* sp. PCC 7120:** The heterocyst-forming multicellular cyanobacterium *Anabaena* sp. PCC 7120 is often used as a model organism for prokaryotic cell differentiation. We recently demonstrated that heterocysts are suitable for photosynthetic production of valuable chemicals, such as ethanol, due to their active catabolism and microoxic conditions. We have developed gene regulation systems, including cell type-specific gene induction systems, to broaden this cyanobacterium's use. In the present study, a heterocyst-specific conditional gene repression system was successfully created by combining a cell type-specific gene induction system with CRISPRi technology. We targeted the *glnA* gene that encodes glutamine synthetase, an essential enzyme for nitrogen assimilation, to reconstruct metabolism in the multicellular cyanobacterium. Heterocyst-specific repression of *glnA* enhanced ethanol production. We believe that heterocyst-specific gene repression systems are useful tools for basic research on cell differentiation as well as for metabolic engineering of heterocysts.
- h) Photosynthetic capabilities of cyanobacterial isolates:** Photosynthetic growth rates of cyanobacterial cultures were determined experimentally by measuring the photo incorporation of [<sup>14</sup>C] NaHCO<sub>3</sub> over a 2-h period, using a photosynthetron, which generates a photosynthesis-versus-irradiance curve in a single experiment by using replicate samples over a range of light intensities (26). Light was supplied by a reflective fixture with four cool-white fluorescent bulbs (F40/ CW) and two very-high-output fluorescent bulbs (FR40T12/VHO). In each experiment, three replicate scintillation vials were incubated for each of 15 simultaneous light intensities (45 vials total), which were controlled by using neutraldensity filters to provide light in 7.1% increments from darkness to 100% light (150  $\gamma$ E m<sup>-2</sup> s<sup>-1</sup>). Light was measured using a biospherical Instruments Inc. (San Diego, CA) model QSL-100 averaging quantum meter. Experiments were conducted at a constant temperature of 30°C.
- i)** To measure oxygenic photosynthesis, an equal volume of cell suspension (1 ml) from a culture that was inoculated and incubated overnight was added to each experimental vial by using a sterile self-repeating syringe. This was accomplished by first dispersing the filaments by pumping with the syringe. Each of the 45 scintillation vials contained an equal volume (5 ml) of sterile ASN III medium. After inoculation, [<sup>14</sup>C]NaHCO<sub>3</sub> was added to a specific activity level of 0.05  $\gamma$ Ci m<sup>-1</sup> l. After the 2-h incubation, each sample was killed by the addition of formalin to a final concentration of 1.5%. The samples were filtered onto 934-AH glass fiber filters, washed with sterile ASN III medium, and rinsed with a solution of 2.0% HCl. Each filter was placed in 7 ml of Ecolume scintillation cocktail (MP Biomedicals, Solon, OH) to measure the photo incorporation of <sup>14</sup>C, using a Beckman LS-6500 liquid scintillation counter (Beckman Coulter, Fullerton, CA).
- j)** The amount of <sup>14</sup>C incorporated was expressed as CO<sub>2</sub> fixation per biomass by use of dry weight, which was obtained from three vials containing only ASN III medium (without [<sup>14</sup>C]NaHCO<sub>3</sub>) that were inoculated at the same time as the experimental vials, immediately filtered onto preweighted filters, dried, weighed, and averaged. Each experiment was performed in triplicate and included a dark aerobic control. Photosynthesis in the presence of sulfide was measured using the same experimental procedures as described above, with the following modifications. Anaerobic media were prepared by bubbling ASN III medium with a steady stream of reagent-grade N<sub>2</sub> gas for 30 min to remove the oxygen. In order to maintain anaerobic conditions, 7-ml scintillation vials with Hungate caps and septa were used. Sulfide was added from a stock solution of Na<sub>2</sub>S 9H<sub>2</sub>O through the septum of each vial to a final concentration of 0.5 mM. Each sulfide experiment included the following two controls: anaerobic without the addition of sulfide and anaerobic with sulfide and the addition of

**Shanti Kumari Lunavat et al.**

3-(3,4-dichlorophenyl)-1,1-dimethylurea (DCMU; final concentration of 10  $\mu$ M), which blocks electron transport to photosystem II. These controls were performed in triplicate at the highest experimental light intensity.

- k) **Photomicroscopy:** Photomicrographs were taken using a Leitz DMR microscope (Rockleigh, NJ) equipped with a Leica DC500 digital camera interfaced with a computer equipped with digital imaging software.

**CONCLUSIONS**

Application of genetic markers in combination with DNA amplification techniques into phylogenetic and toxicological studies of cyanobacterial system makes the system more accurate. Results of 16S rRNA genetic markers in cyanobacteria showed that morphological characters themselves are not appropriate for this system (Giovannoni *et al.*, 1988; Wilmotte, 1994). Species relatedness is determined by performing DNA-DNA hybridization procedures. More than 97% of in DNA-DNA homology technique resembles the species relatedness of a specific species. But still the same result always does not show same strain of the species. So we need a specific intraspecific genetic marker for several purposes. Then only we can conclude environmental, physiological, chemical and behavioral responses of different species of cyanobacteria. Along with the above we can conclude the harmful toxin producing abilities of different strains in relation to different nutrients, light gradients, temperatures etc in a global scale to minimize the detrimental effects and accidental effects. There is a great need of techniques to estimate the levels of cyanobacterial harmful toxins on global and regional scale to maintain the stocks, biodiversity of the species. Acquiring all these techniques and methodologies, scientific community must possess a duty to show some sort of solution mechanisms or strategies to the industries like aquaculture and tourism besides biodiversity.

### ABSTRACT

Now-a-days the numbers of vehicle accidents are increasing and a large portion of these is going on due to carelessness of driver. Drivers must watch out for the street, so they can respond to abrupt occasions right away. Driver weakness regularly turns into an immediate reason for some vehicle crashes. Consequently, there is a need to build up the frameworks that will identify and tell a driver of her/him terrible psycho-physical condition, which could fundamentally diminish the quantity of exhaustion related auto crashes. In any case, the advancement of such frameworks experiences numerous challenges identified with quick and appropriate acknowledgment of a driver's exhaustion manifestations. One of the specialized prospects to execute driver sluggishness recognition frameworks is to utilize the vision-based methodology. This article presents the as of now utilized driver laziness identification frameworks. Here the system is distinguishing the driver languor by evaluating vision arrangement of him. A convolution activity is performed on these layers utilizing a channel that performs 2D network duplication on the layer and channel.

**Keywords:** Haar Cascade Algorithm; OpenCV; Viola Jones Algorithm

### INTRODUCTION

Driver sleepiness recognition is a vehicle well being innovation which forestalls mishaps when the driver is getting sluggish. Different investigations have recommended that around 20% of all street mishaps are exhaustion related, up to half on specific streets. Driver weariness is a huge factor in an enormous number of vehicle mishaps. Ongoing insights gauge that yearly 1,200 passing and 76,000 wounds can be credited to weariness related accidents. The advancement of advances for recognizing or forestalling sluggishness in the driver's seat is a significant test in the field of mishap evasion frameworks. In view of the risk that sluggishness presents out and about, strategies should

Swagat Choudhury et al.

be created for checking its effects. Driver negligence may be the consequence of an absence of sharpness when driving because of driver languor and interruption.

Driver interruption happens when an article or occasion keeps a person from noticing the driving assignment. In contrast to driver interruption, driver sleepiness includes no activating occasion in any case, rather, is portrayed by a dynamic withdrawal of consideration from the street and traffic requests. Both driver laziness and interruption, nonetheless, might have similar impacts, i.e., diminished driving execution, longer response time, and an expanded danger of crash contribution shows the square chart of by and large framework. In light of Acquisition of video from the camera that is before driver performs constant handling of an approaching video stream so as to construe the driver's degree of weakness on the off chance that the sleepiness is estimated, at that point it will give the alarm by detecting the eyes. The system is used six steps to complete the project. Here this paper is divided into six sections i.e. Face Introduction , Related Work, Methodology , Result Discussion , Conclusion.

### Related Work

A few endeavors have been accounted for in the writing on the improvement of the not-meddlesome checking tiredness frameworks dependent on the vision [1]. build up a light-inhumane framework. They utilized the Haar calculation to recognize objects [2] and face classifier executed by [3] in OpenCV [4] libraries. Eye areas are gotten from the facial district with anthropometric components. At that point, they identify the eyelid to quantify the degree of eye conclusion [5] executes a framework to recognize side effects of driver tiredness dependent on an infrared camera. By abusing the wonder of brilliant students, a calculation for distinguishing and following the driver's eyes has been created. At the point when languor is distinguished, the framework cautions the driver with an alert message. The localization of the eye is done by locating facial landmarks such as eyebrow and possible face center. Morphological operation and K-means is used for accurate eye segmentation. Then a set of shape features are calculated and trained using non-linear SVM to get the status of the eye. This research paper characterizes a framework for recognizing the eye states progressively to recognize the driver sleepiness state.[4] The face area is recognized dependent on the improved Jones and Viola technique [2]. The eye region is acquired by a flat projection. At last, another multifaceted nature work with a powerful limit to recognize the eye state.

### METHODOLOGY

This section describes different aspects of the system considered in its implementation. The used algorithm processes the color information present in the image, First of all the original image is converted to grayscale image. Then to determine the face in the image, the image is divided in sub regions determining whether the sub region is a face or not. The gesture detection is done from the residual error that is modeled considering a linear combination of facial movement models. It includes a system that allows detecting facial gestures in the presence of head movement. Fig. 1 shows the flowchart of the system limitation of the algorithms, which camera content or features are very limited. There are some stages which are shown in flow chart. When the driver enters in to the vehicle and starts the engine at that time the camera is opened and observed the face and eyes. Then it separates and detected the face and eyes of driver. When the driver feels sleepy at the time of driving and his/her eyes closes for some second, then the alarm is rung and a warning is given through the alarm to the driver to stop the vehicle.

### Face Detection

OpenCV libraries use to classification of the images. When the face is in the front of camera it detects the face by making a rectangular on it. It detects the position of the face observe your moment of face.

Here is the equation for face detection:

$$SAD(x, y) = \sum \sum I(X+I, Y+j) - M(i, j) \quad (1)$$

The system is proposed to make a regular update of the reference model M to adjust it every time when light conditions change while driving, by making a tracking test:

$$\text{Tracking} \quad \left\{ \begin{array}{ll} \text{Good} & \text{if } SAD \leq Th \\ \text{Bad} & \text{if } SAD > Th \end{array} \right. \quad (2)$$

### Parameter Detection

At the time detection it make rectangle shape around the face and eyes and separate these.

### Eyes Tracking

It also tracks the eyes and according to the movement of eyes it gives warning to the driver. When the drowsiness level increases, it gives warning. The Hough transform for circles (HTC) is used on the image of the eye to detect the iris. For that, the system is applied the HTC to the edge image of the eye to detect the circles with defined rays, and at the end the circle which has the highest value in the accumulator of Hough for all the rays is taken. Then, the logical 'AND' logic is applied between edges image and complete circle obtained by the HTC by measuring the intersection level between them "S". Finally, the eye state "state eyes" is defined by testing the value "S" by a threshold:

$$\text{State}_{eye} = \text{Open} \quad \left\{ \begin{array}{ll} \text{if } S \geq Th \\ \text{Close} & \text{if } S < Th \end{array} \right. \quad (3)$$

### Driver state

The system is decided the driver state by estimating PERCLOS. In the event that the driver his eyes in any event 5 progressive edges a few times over a time of up to 5 seconds, it is viewed as drowsy.

Our system starts with the initialization phase, which is face and eyes detection to extract both face and eyes regions and take them as templates to track them in the following frames. For each tracking the system is tested if that tracking is good or bad? If the tracking is bad, the system is returned to the initialization step, else it is passed to the following steps which are: eyes states identification and driver state.

### Detection Model

- I. **Viola Jones Algorithm:** The proposed work uses Viola Jones algorithm for detecting the eyes, eyeblink using background subtraction, gradient based corner detection and it is capable of detecting common cases of fatigued behavior linked with prolonged computer use by tracking the eye blink rate.
- II. **Haar Cascade Algorithm:** Haar Cascade Algorithm for Face Detection and for image classification we used OpenCV libraries. To capture driver drowsiness, we use high resolution camera. When the drowsiness is detected the alarm rings and gives a warning to the driver.

### Alarm

The Alarm is used for giving warning to the driver at the time of driving, when drowsiness is detected.

## RESULTS AND DISCUSSION

Implementation of drowsiness detection with Python and OpenCV was done which includes the following steps: Successful runtime capturing of video with camera. Captured video was divided into frames and each frame was

Swagat Choudhury et al.

analyzed. Successful detection of face is followed by detection of eyes. If closure of eye for successive frames were detected, then it is classified as drowsy condition else it is regarded as normal blink and the loop of capturing image and analyzing the state of driver is carried out again and again. In this implementation during the drowsy state the eye is not surrounded by circle or it is not detected, and corresponding message is shown. This section presents the results on the detection of visual indicators of drowsiness. Collecting the data set to properly evaluate the system is a challenge; this is because dangerous drowsiness events are not guaranteed to occur during daily driving for application testing. Haar Cascade Algorithms is used for face and eye detection.

Table. 1 presents the results of the detection of somnolence considering the normal operation of the system in which the responses are obtained from each of the drivers that were submitted to the addresses issued by the co-pilot who recorded the results. The level of total hits on detection represents an average percentage of 92.23%. The above graph [Fig. 4] represents the drowsiness of driver in different condition. Table. 2 present the results obtained by placing additional objects on the clothes of the drivers, which in this case were the caps and glasses. The average percentage of hits is 84.33%. Above graph [Fig. 5] represents number of hits in two condition one is driver with glass and the driver without glass while driving. Table. 3 present the results obtained by considering the hair covering driver's face. The drivers were women and the average percentage of hits was 72%. The presented results indicate the efficiency of the system that is of higher level and even better than other systems referred to in this work. The lower levels of accuracy occur when users include elements that do not allow to correctly identify the face gestures, but despite that, their levels are satisfactory. The graph [Fig. 6] represents the hitting point of position of driver in two condition one is Hair cover by face and another one hairless face.

## CONCLUSION

This research paper represents the Drowsiness of the driver. Harr Cascade Algorithm is used for Face Detection and by it is applied to detect driver face and position of the face. Viola Jones Algorithm is used for detecting the eye and eye blink. By using this algorithm, the eye blink rate has been tracked. IDLE platform and python 3.8 version are used for this project. At the time of working on it, there is one problem has faced by us i.e in low beam of light it is not working properly.

### ABSTRACT

Transportation Engineering plays a vital role towards the progress of the nation. As the population is growing day by day, the demand for vehicles is also increasing accordingly and simultaneously the condition of the roads is getting deteriorated. It requires heavy maintenance costs and is even costlier if roads are constructed again. Flexible pavements are usually susceptible to rutting and cracking due to repeated application of heavy vehicle loads. Hence, this issue must be addressed in order to improve the life span and performance of the pavements. In this study, coir or coconut fibre is used as an reinforcement in bituminous mixes. Marshall method of bituminous mix design is adopted for the mixes. In this research work the bitumen content is taken is 5% and the percentage of coconut fibre is taken from 0.1% to 0.4%. Effort is made to find out how different percentage of coir fibre added to 5% Bitumen content enhances the durability of the pavement.

**Keywords:** Coconut fibre, bitumen, aggregate, eco-friendly, flexible pavement

### INTRODUCTION

A pavement consists of a mixture of asphaltic or bituminous material and aggregate placed on a good quality and compacted granular material is termed as flexible pavement. The pavement consisting of a Portland cement concrete slab is known as rigid pavement. Flexible pavements are preferred more than rigid pavements as they have self-healing properties, whatever deformation occurs in a flexible pavement due to heavier wheel loads, it is recoverable to some extent after some time but it is not so in case of rigid pavement. Flexible pavements are economical as compared to rigid pavements. Here, in this study, efforts are being made to find out the percentage of coir fibre which when added to bitumen gives satisfactory results. Coir fibre is commonly known as Cocunut tree. Cocunut fibre is mostly taken as a waste material. But According to some researchers in their previous studies, If Grounded cocunut powder is added to Bitumen, It not only proves eco-friendly but reduces the problem of disposal and also strengthens the pavement. It blends with Bitumen Easily. Therefore, In this project work, properties of aggregate and

**Minati Mohanty**

Bitumen are studied and an performance analysis is done with 0% addition of coconut fibre in bitumen and with different percentages of coconut fibre content added to 5% Bitumen content. The objective of the present work is to find out the percentage of coir fibre that increases the stability value of the bituminous concrete mix and to reduce the degradation of the environment by reutilizing the agricultural waste materials. Basically there are four types of tests on aggregate to test the quality of aggregates. These tests are required to be done for flexible pavement design. The results of the tests are tabulated below:

**TESTS ON BITUMEN:** Bitumen is a black colour viscous liquid which is obtained as a residue from petroleum distillation. It is used as a road paving material, road surfacing and also roofing. It is black in colour and highly sticky susceptible to climatic changes. The different properties of bitumen are studied and are presented in the following table:

**MARSHALL STABILITY TEST:** The procedure adopted for testing the specimens is Marshall method of Bituminous mix design. Here specimens are made adding bitumen percentage 5% and simultaneously adding the percentage of coconut fibre from 0.1% to 0.4%. Bitumen used here for testing is VG-30. In the Marshall method of Bituminous mix design two tests are done: Density-Void Analysis and Stability Test.

## RESULTS AND DISCUSSION

The Marshall Tests are done for all the specimens and the results obtained are tabulated below along with Graphs.

## CONCLUSION

After Testing all the Marshall samples , we are coming to a conclusion that after addition of 0.30% of coconut fibre content to 5% Bitumen content, observed stability values are increasing but after that point values are found to get decreased. The flow values are also showing an increasing trend at 0.30% fiber content and air content percentages are decreasing. Marshall stability value is maximum at 0.30% and minimum at 0% fibre content. The main reason behind it is excess addition of fibre content cannot bind with Bitumen as a result of which stability values are decreasing simultaneously. As fiber content increases, binding capacity of bitumen decreases as a result of which flow value increased simultaneously. VFB values are increasing as voids are getting filled with bitumen and some voids are filled up with fiber. VMA values are showing a decreasing trend as most of the voids are getting filled with fibres. Overall, from the results, we came up with a conclusion that 0.30% addition of fibre content with 5% Bitumen content increases the stability of the pavement along with other parameters. Definitely it is Sustainable, Eco-friendly, Economical and can be used for Road paving Purposes.

### ABSTRACT

One of the most dreadful disease is breast cancer and it has a potential cause for death in women. Early detection and diagnosis of breast cancer plays a significant role in the welfare of women. The mortality rate due to breast cancer is on an all-time high. As the diagnosis of this disease manually takes long hours and the lesser availability of systems, there is a need to develop the automatic diagnosis system for early detection of cancer. Machine Learning Techniques contribute a lot in the development of such system. For the classification of benign and malignant tumour we have used classification techniques of machine learning in which the machine is learned from the past data and can predict the category of new input. We have also implemented different machine learning algorithms for creating models like decision tree, logistic regression, random forest and gradient boosting which are applied on pre-processed data which gives greater accuracy for prediction.

**Keywords:** Logistic Regression (LR), Decision Tree Classifier (DTC), Random Forest Classifier (RFC), Gradient Boosting Classifier (GBC), Malignant, Benign

### INTRODUCTION

According to World health organization, Breast cancer is the most frequent cancer among women and it is the second dangerous cancer after lung cancer. In 2018, from the research it is estimated that total 627,000 women lost their life due to breast cancer that is 15% of all cancer deaths among women. In case of any sign or symptom, usually people visit doctor immediately, who may refer to an oncologist, if required. The oncologist can easily identify breast cancer by using Breast ultrasound, Diagnostic mammogram, Magnetic resonance imaging (MRI), Biopsy. Based on these test results, doctor may recommend further tests or therapy.

Early detection is very crucial in breast cancer. If cancer is predicted at early stage then the chances of survivability of patient may increase. An alternate way to identify breast cancer is using machine learning algorithms for prediction of abnormal tumour. Thus, the research is carried out for the proper diagnosis and categorization of patients into malignant and benign groups. There are two types of breast cancer tumours: those that are non-cancerous, or 'benign', and those that are cancerous, which are 'malignant'. When a tumour is diagnosed as benign, doctors will usually leave it alone rather than remove it. Even though these tumours are not generally aggressive toward surrounding tissue, occasionally they may continue to grow, pressing on organs and causing pain or other problems. In these situations, the tumour is removed, allowing pain or complications to subside. Malignant tumours are cancerous and aggressive because they invade and damage surrounding tissue. When a tumour is suspected to be malignant, the doctor will perform a biopsy to determine the severity or aggressiveness of the tumour.

Machine Learning, with its advancements in detection of critical features from the complex datasets is largely acknowledged as the method in the prediction of breast cancer. Application of data mining techniques in the medical field can help in prediction of outcomes, minimizing the cost of medicines, aid people's health, upgrade the healthcare value and to rescue lives of people. This process of classifying benign and malignant tumours can be best done by the application of Classification techniques of machine learning. Lot of research is being conducted in this area by the application of various machine learning and data mining techniques for many different datasets on Breast Cancer. Most of them show that classification techniques give a good accuracy in prediction of the type of tumour.

#### RELATED WORK

Lots of breast cancer research has been reported in the literature of medical data analysis, and most of them turn up with good classification accuracies. Some of such works are as follows. Liu Y-Q, Wang C and Zhang L.-2009 [1] used decision table (DT)-based predictive models for breast cancer survivability, concluding that the survival rate of patients was 86.52%. They Employed the under sampling C5 technique and bagging algorithm to deal with the imbalanced problem, thus improving the predictive performance on breast cancer. C.L. Chi, W. N. Street, W. H. Wolberg -2007 [2] used the ANN model for Breast Cancer Prognosis on two dataset. They predicted recurrence and non-recurrence based on probability of breast cancer and grouped patients with bad (<5 years) and good (>5 years) prognoses. Shomona G. Jacob, R. Geetha Ramani-2012 [3] have compared various classifier algorithms on Wisconsin Breast Cancer diagnosis dataset. They came across that Random Tree and SVM classification algorithm produce best result i.e. 100% accuracy. However they mainly worked on 'Time' feature along with other parameters to predict the outcome of non-recurrence or recurrence of breast cancer among patients. In this paper, "Time" feature has not been relied upon for prediction of recurrence of the disease. Here, prediction is based on "Diagnosis" feature of WBCD dataset.

Shajahaan, S.S; Shanthi, S., Chitra, V.M. -2013 [4] worked on the application of data mining techniques to model breast cancer data using decision trees to predict the presence of cancer. Data collected contained 699 instances (patient records) with 10 attributes and the output class as either benign or malignant. Input used contained sample code number, clump thickness, cell size and shape uniformity, cell growth and other results physical examination. The results of the supervised learning algorithm applied showed that the random tree algorithm had the highest accuracy of 100% and error rate of 0 while CART had the lowest accuracy with a value of 92.99% but naïve bayes' had the an accuracy of 97.42% with an error rate of 0.0258. D. Delen, G. Walker, A. Kadam -2005 [5] compared ANN, decision tree and logistic regression techniques for breast cancer prediction analysis. They used the SEER data of twenty variables in the prediction models. From the experiment the author found that the decision tree with 93.6% accuracy and ANN with 91.2% are more superior to logistic regression with 89.2% accuracy.

The study is based on multiple prediction models for breast cancer survivability using large datasets along with 10 fold cross validation method. It provides a relative prediction ability of different data mining methods. In future this work is extended by collecting real dataset in the clinical laboratory. Turgay Ayer, Jagpreet Chhatwal, Oguzhan

**Mamata Garanayak et al.**

Alagoz, Charles E. Kahn, Jr, Ryan W. Woods, Elizabeth S. Burnside -2010 [6] describes about Two models namely Logistic Regression and ANN which was implemented. They were used to compare prediction accuracy breast cancer in mammography. Their study says logistic regression performed well in prediction. Abdelghani Bellaachia, Erhan Guven-2006 [7] describes about using powerful machine learning classification algorithm Naïve Bayes, C4.5 which is usually used in data mining and ANN a neural network algorithm for the tumour classification of breast cancer in dataset. Their work shows C4.5 did a better job in classification. Diana Dumitru- 2000 [8] describes about Naïve Bayes algorithm which was implemented to test the classification accuracy of breast cancer dataset with specificity, sensitivity and mean accuracy. Cuong Nguyen, Yong Wang, Ha Nam Nguyen-2013[9] describes about Random forest classifier which was implemented in their project to find sensitivity, time consumed and mean accuracy of two data set WBCPD and WBCDD.

Rasool Fakoor, Faisal Ladhak, Azade Nazi, Manfred Huber-2013 [10] describes about Performance criterion of classifiers whose experimental results shows that SVM-RBF kernel produces an accuracy of 96.84% which is higher than other classifiers. Alireza Osarech, Bitu Shadgar-2011 [11] used SVM classification technique on two different benchmark datasets for breast cancer which got 98.80% and 96.63% accuracies. Nidhi Mishra, Naresh Khuriwal-2018 [12] took data from Wisconsin Breast Cancer database and worked on breast cancer diagnosis. The results of their experiments proved that ANN and Logistic Algorithm worked better and provided a good solution. It achieved an accuracy of 98.50%. Mandeep Rana, Pooja Chandorkar, Alishiba Dsouza-2015 [13] worked on the diagnosis and the prediction of recurrence of breast cancer by applying KNN, SVM, Naïve Bayes and Logistic Regression techniques, programmed in MATLAB. The classification techniques are applied on two datasets taken from UCI depository. A dataset of them is used for identification of disease (WDBC) and the next one is used for recurrence prediction (WPBC). Yeh WC, Chang WW, Chung YY-2009 [14] presented an innovative technique for breast cancer detection, by using statistical methods in combination with swarm optimization and reported the accuracy of 98.71%

Kaya Y, Uyar M-2013 [15] presented a hybrid approach for the detecting hepatitis disease by means of rough set and extreme machine learning algorithm. The selected hepatitis disease dataset was from UCI repository. 20 reducts containing three to seven attributes were produced by using rough set theory. The reducts are selected and then the records with missing value are removed from each reduct. Classification is done on selected reducts by using back propagation neural network and obtained the accuracy of 98.6%.

**PROPOSED APPROACH**

The Proposed Model is shown in Figure 1. In the suggested approach, we apply various supervised learning algorithms and classification technique to build a model which comes up with accuracy of Breast Cancer Prediction. The system is organized in following phases such as collection of information sets, pre-processing phases, selection of features and appealing different ML techniques such as Logistic regression (LR), Decision Tree Classifier (DTC), Random Forest Classifier (RFC) and Gradient Boosting Classifier methods.

**Collection of Data Sets**

The Data for the prediction of Breast Cancer is collected from the Wisconsin Breast Cancer diagnosis dataset from UCI repository. This dataset contains characteristics derived from digitized imaging of fine needle aspirates of a breast tumour cell mass. The goal of this analysis is to train a machine learning algorithms to accurately distinguish between a benign and malignant tumour to aid in clinical diagnosis. The data set used in this paper is breast cancer diagnosis data having the attributes like diagnosis, radius mean, texture mean, smoothness mean, compactness mean etc.

**Pre-processing step**

In machine learning, this phase is a very crucial phase. Pre-processing of the five data sets of five different crops consists of loading the missing values, the proper range of the data, and the functionality extraction. In this paper we

Mamata Garanayak et al.

have applied isnull () technique for checking null values and In Diagnosis Attribute, we have used Value labels in place of Numeric Values i.e. Benign Cells are coded as value "0" and malignant Cells are coded as value "1".

### Features Extraction

Feature extraction of breast cancer diagnosis data is about finding the subset of original features and simplifying the amount of data involved to represent a huge data set. The diagnosis data is divided into malignant and benign groups. Ten real-valued features having high entropy value which were computed as main feature for each cell nucleus for accuracy forecast of Breast Cancer Prediction are

- radius (mean of distances from centre to points on the perimeter)
- texture (standard deviation of grey-scale values)
- perimeter
- area
- smoothness (local variation in radius lengths)
- compactness (perimeter<sup>2</sup> / area - 1.0)
- concavity (severity of concave portions of the contour)
- concave points (number of concave portions of the contour)
- symmetry
- fractal dimension ("coastline approximation" - 1)

### Splitting the Dataset into Train Sets and Test Sets

This phase covers training and testing of input data. The loaded data of breast cancer is split into 2 sets, such as train sets data and test sets data, with a division ratio of 80% or 20% (0.8 or 0.2). In the training sets, a classifier is applied to build the obtainable input data. In this phase, we create the classifier's reinforce information. During the testing state, the data are tested and the concluding data are formed during pre-processing and is refined by the machine learning.

### Machine Learning Models

In this paper we have applied several supervised Machine Learning techniques such as Logistic regression (LR), Decision Tree Classifier (DTC), Random Forest Classifier (RFC) and Gradient Boosting Classifier methods for accuracy calculation of Breast Cancer Prediction which are as follows.

#### Logistic Regression (LR)

Logistic regression is a supervised learning classification algorithm used to predict the probability of a target variable. The nature of target or dependent variable is dichotomous, which means there would be only two possible classes. In simple words, the dependent variable is binary in nature having data coded as either 1 (stands for success/yes) or 0 (stands for failure/no). Mathematically, a logistic regression model predicts  $P(Y=1)$  as a function of  $X$ . It is one of the simplest ML algorithms that can be used for various classification problems.

#### Decision Tree Classifier (DTC)

In general, Decision tree analysis is a predictive modelling tool that can be applied across many areas. Decision trees can be constructed by an algorithmic approach that can split the dataset in different ways based on different conditions. Decision trees are the most powerful algorithms that falls under the category of supervised algorithms. They can be used for classification tasks. The Decision trees algorithm consists of two parts: nodes and rules (tests). A Decision tree is like tree structure, where node denotes a test on an attribute, Branch represents an outcome of the test, and each leaf node holds a class label. For detecting breast cancer, its leaf nodes are categorised as benign and malignant. And then certain rules are established to check tumour is benign or malignant

Mamata Garanayak et al.

### **andom Forest Classifier (RFC)**

Random forest algorithm is a supervised classification algorithm. In this classifier, the higher the number of trees in the forest gives the high accuracy results. Random forest algorithm can use for both classification and the regression task and can handle the missing values too. For this dataset, we have already handled missing values of attributes.

Random forest algorithm creates decision trees on data samples and then gets the prediction from each of them and finally selects the best solution by means of voting. It is an ensemble method which is better than a single decision tree because it reduces the over-fitting by averaging the result. It can also work on categorical values too. In this case, we had categorical data as B & M representing benign & malignant which is further converted to value labels as 0 & 1 respectively.

### **Gradient Boosting Classifier (GBC)**

Gradient boosting classifiers are a group of machine learning algorithms that combine many weak learning models together to create a strong predictive model. Decision trees are usually used when doing gradient boosting. Gradient boosting models are becoming popular because of their effectiveness at classifying complex datasets, and have recently been used to win many Kaggle data science competitions.

For detecting breast cancer, the leaf nodes of decision tree are categorised as benign and malignant. And then certain rules are established to check tumour is benign or malignant

## **EXPERIMENTAL RESULTS AND PERFORMANCE ANALYSIS**

### **Data Exploration**

From the Data Exploration, we came to know that, In Wisconsin Breast Cancer dataset, there are 569 instances in which 357 are benign and 212 are malignant. In addition, there are two classes malignant which contributes to 62.7% of dataset and benign 37.3%. The Heat Map of some of the top Correlation Features extracted from the Feature Extraction of the Wisconsin Breast Cancer diagnosis dataset are

### **Logistic Regression (LR)**

The predicted accuracy of Breast Cancer Prediction using Logistic Regression is shown in Figure 8.

### **Decision Tree Classifier (DTC)**

The predicted accuracy of Breast Cancer Prediction using Decision Tree Classifier is shown in Figure 9.

### **Random Forest Classifier (RFC)**

The predicted accuracy of Breast Cancer Prediction using Random Forest Classifier is shown in Figure 10.

### **Gradient Boosting Classifier (RFC)**

The predicted accuracy of Breast Cancer Prediction using Gradient Boosting Classifier is shown in Figure 11.

### **Performance Analysis**

The Accuracy for Some of the Machine Learning Models for predicting Breast Cancer are as shown in Table 2 and the graphical representation is shown in Figure 12.

## **CONCLUSION**

Medical dataset can not only be classified with the previously mentioned algorithms from machine learning, there are many algorithms and techniques which may perform better than these. Production of accurate classifier which perform efficiently for medicinal application is the main challenge we face in machine learning. In this paper, we

Mamata Garanayak et al.

have implemented different types of models and their accuracies are computed and compared with each other, so that the best cancer prediction model can be used in real life to identify breast cancer relatively faster than previous methods. Random Forest surpasses all the other algorithms with an accuracy of 97.90%. In conclusion, the Random Forest algorithm achieves the highest predicted accuracy which might be the best choice of algorithm for this problem and prediction of disease.

### ABSTRACT

Polycrystalline sample of  $\text{Na}_2\text{Ba}_2\text{Eu}_2\text{W}_2\text{Ti}_4\text{Nb}_4\text{O}_{30}$  is synthesized by high temperature solid-state reaction technique. X-ray structural analysis confirms the formation of compound in orthorhombic crystal structure at room temperature. The surface morphology of the sintered sample recorded by scanning electron microscope exhibits a uniform grain distribution. The frequency and temperature dependent impedance spectroscopy was carried out in order to investigate the conduction mechanism. The Cole-Cole plot shows depressed semicircle arc, which confirms the Non-Debye type relaxation in the material. The radius of the semicircle decreases with temperature indicating the reduction of resistance with temperature, which confirms the NTCR behavior in the material. The variation of bulk resistance of the material with temperature was obtained from the fitting of the equivalent circuit. The thermistor parameters with respect to temperature were calculated. The high value of parameters shows that the present compound is very much suitable for high temperature thermistor application.

**Keywords:** temperature, uniform, material, parameters .

### INTRODUCTION

The TB structure compounds belong to an important class of dielectric materials, having various properties [1, 2] at different temperature. The tungsten-bronze (TB) structure stands at intermediate positions between the perovskite and pyrochlore-type structures. The general formula of TB structured compounds is written as  $(\text{A}1)_2(\text{A}2)_4(\text{C})_4[(\text{B}1)_2(\text{B}2)_8]\text{O}_{30}$ , where the A-site is occupied by mono to tri-valence cations, the B-sites occupied by tetra to hexa-valent ions ( $\text{W}^{+6}$ ,  $\text{Ti}^{+4}$ ,  $\text{Nb}^{+5}$ ,  $\text{Ta}^{+5}$ ,  $\text{V}^{+5}$ ) and C site being small often remains empty, giving the general formula  $\text{A}_6\text{B}_{10}\text{O}_{30}$ . In the recent years, some new lead based TB type ferroelectrics of  $\text{A}_2\text{Pb}_2\text{R}_2\text{W}_2\text{Ti}_4\text{X}_4\text{O}_{30}$  (A=Li, Na, K; R= rare earth; X=V, Nb, Ta) have received much scientific attention due to their interesting ferroelectric

S.Devi et al.

properties [3-6]. However, the lead-based ceramics is eliminated due to the environmental, health and social aspects issues [7-9]. In view of the above, we have studied the structural, dielectric and electrical properties of  $\text{Na}_2\text{Ba}_2\text{Eu}_2\text{W}_2\text{Ti}_4\text{Nb}_4\text{O}_{30}$  [10].

Thermistor is special type of resistor, whose resistance varies more significantly with temperature than in standard resistors. The resistance of the thermistors decreases with the rise in temperature, for which it have been received considerable attention in house appliances, and aerospace as elements for suppression of in-rush current, temperature measurements and controlling, etc. As the resistance of thermistors depends on the temperature, they can be connected in the electrical circuit to measure the temperature of the body. Thermistors are mainly used as temperature sensors, inrush current limiters, self-resetting over-current protectors and self-regulating heating elements. Traditional NTC ceramic thermistors always contain transition-metal compounds with spinel structure such as Mn–Ni–O, Ni–Cu–Mn–O and Ni–Mn–Co–O systems, etc. [11–13]. However, the existence of the structural relaxation in those compounds leads to property degradation such as aging, and limits their applications at elevated temperatures ( $>300^\circ\text{C}$ ) [14]. Much work have reported to improve the electrical properties and ageing resistance of the thermistors with cation doping and microstructure modification [15–16]. The literature survey suggests that no attempt has been made to understand the impedance analysis of the above sample that the resistance of the material decreases with rise in temperature resulting NTCR behavior for the fabrication of highly sensitive thermistor. This factor motivated us to carry out a detailed characterization of the thermistor parameters of the above ceramic.

## EXPERIMENTAL

The Polycrystalline sample of  $\text{Na}_2\text{Ba}_2\text{Eu}_2\text{W}_2\text{Ti}_4\text{Nb}_4\text{O}_{30}$  (abbreviated as NBEWTN) was prepared using solid state reaction technique using high purity ingredients  $\text{Na}_2\text{CO}_3$ ,  $\text{BaCO}_3$ ,  $\text{Eu}_2\text{O}_3$ ,  $\text{WO}_3$ ,  $\text{TiO}_2$ , and  $\text{Nb}_2\text{O}_5$ . These ingredients, taken in suitable stoichiometry, were thoroughly mixed and ground in dry and wet (methanol) medium for 2h each in an agate mortar. Calcination was carried out in an alumina crucible at  $1150^\circ\text{C}$  for 4 h. The quality and formation of the compound were checked using X-ray diffractometer (Rigaku Ultima IV, Japan) with  $\text{CuK}\alpha$ ,  $\lambda = 1.5405 \text{ \AA}$  over a wide range of Bragg angles  $2\theta$  ( $20^\circ \leq 2\theta \leq 80^\circ$ ). The powder was then pelletized under the uniaxial pressure of 3.5 ton with polyvinyl alcohol (PVA) as binder. The pellets were then sintered at  $1200^\circ\text{C}$  for 6 h. The surface morphology of the sintered pellet was studied at room temperature using a scanning electron microscope (HITACHI SU3500). The sintered pellets were polished and electroded with silver paste and then dried at  $150^\circ\text{C}$  for 1 h. The dielectric and impedance parameters of the pellet were recorded as a function of frequency (1 kHz to 1 MHz) using a computer-controlled HIOKI 3532 LCR Hitester over a wide range of temperature.

## RESULTS AND DISCUSSION

### Structural study

Figure 1 shows the room temperature XRD pattern of NBEWTN on powder sample. The diffraction pattern consists of sharp and single diffraction peaks, which confirms the formation of single-phase of the compound [17]. Most of the observed peaks were indexed in different crystal systems with different unit cell configurations using a standard computer program package "POWD" [18]. The orthorhombic crystal system was confirmed on the basis of minimum error between observed and calculated inter planar spacing (d). The refined lattice parameters of the material are found to be very much consistent with those of reported compounds of similar structure. Figure 1(inset) shows the surface morphology of NBEWTN recorded on the bulk pellet sample. The nature and grain size of the sample suggests that the surface is highly dense due to uniformly distribution of grains. The average size of the grain is ranging from 4 to 5  $\mu\text{m}$ . In spite of sintering at high temperature some small voids of irregular shape and dimension are seen which may be due to background effect.

S.Devi et al.

### Complex Impedance analysis

Impedance spectroscopy is a powerful tool for analyzing the electrical properties of materials and results may be correlated with many complex materials. An equivalent circuit based on impedance spectra provides the physical processes occurring inside the sample. Most of the ceramics contain grains and grain-boundary regions, which individually have different physical properties [19].

Measurements of impedance and related parameters of the materials provide us some important data having both real (resistive) and imaginary (reactive) components. The basic formalism or equations of impedance and electrical modulus resistive and reactive components of the complex parameters have been reported elsewhere [10]. The frequency dependent of  $Z'$  at selected temperatures is shown in Fig. 2. It is observed that  $Z'$  decreases with rise in frequency at different temperature. At high frequency the value of  $Z'$  at the selected temperature coincides, which is due to the disappearance of space charge from the grain boundary. The value of  $Z'$  at lower frequency is high, which indicates the larger effects of polarization in the material. The value of  $Z'$  decreases with rise in temperature in low frequency region shows the negative temperature coefficient of resistance (NTCR) behavior in the material.

Figure 3 shows the complex impedance spectra (Nyquist plot) with fitted data [20] of the compound obtained at different temperatures ( $>200^\circ\text{C}$ ) over a wide frequency range (1 kHz to 1 MHz). At low temperature, (i.e up to  $300^\circ\text{C}$ ) complex impedance plots have single semicircular arc (not shown). The intercept of the semicircular arc along  $Z'$  axis gives the value of the bulk resistance, and it is observed that the value of  $Z'$  decreases with rise in temperature, due to which the dc conductivity in the material increases. However, at higher temperatures it shows two semicircles, where the high frequency semicircle can be attributed to the bulk property of the material arising due to the parallel combination of bulk resistance and bulk capacitance of the material. The low frequency semicircle is due to the grain boundary effect, which also can be confirmed by SEM micrographs in which polycrystalline grains separated by grain boundaries. The presence of two semicircular arcs due to grain interior and grain boundary is consistent with the "brick layer model" for polycrystalline materials [21] and it can be expressed as an equivalent circuit consisting of parallel combination of two resistance and capacitance connected in series. For non-Debye – like response, an equivalent circuit consists of parallel combination of (CQR) and (CR), where Q is known as constant phase element (CPE). The admittance of Q is defined as  $Y(\text{CPE}) = A_0(j\omega)^{-n} = A + jB$  with  $A = A_0 \cos(n/2)$  and  $B = A_0 \sin(n/2)$ , where  $A_0$  and  $n$  are frequency independent and temperature dependent parameters.  $A_0$  determines the magnitude of the dispersion, and  $0 \leq n \leq 1$  (for an ideal capacitor  $n=1$  and for ideal resistor  $n = 0$ ) [22]. From fitting curves, the calculated value of bulk resistance ( $R_b$ ) and grain boundary resistance ( $R_{gb}$ ) at different temperatures are plotted in fig. 3. It clearly shows that both the parameters decrease with rise in temperature, which confirms the negative temperature coefficient of resistance (NTCR) behavior of the material.

The relation between resistance and temperature for a compound exhibiting NTCR behavior is expressed as

$$R_T = R_N \exp [\beta(T_N - T)/TT_N],$$

Where  $R_T$  is the resistance at temperature  $T$ ,  $R_N$  the resistance at temperature  $T_N$  is known, and  $\beta$  is an NTC thermistor characteristic parameter.

The thermistor characteristic parameter can be expressed as

$$\beta = [TT_N / (T_N - T)] \ln R_T / R_N$$

The sensitivity of the thermistor  $\beta$  can also be defined by the temperature coefficient of resistance ( $\alpha$ ), which can be expressed as a function of  $\beta$  parameter according to the following equation

$$\alpha = (1/R)[d(R)/dT] = -\beta/T^2$$

**S.Devi et al.**

The various thermistor parameters are plotted against temperature. The observed  $\beta$  values in the ceramic are better compared to the values reported earlier by other researchers [23, 24]. Thus, the high value of  $\beta$  obtained endorsed, the sample as a good quality NTC material for the fabrication of thermistor devices.

## CONCLUSION

The polycrystalline material of  $\text{Na}_2\text{Ba}_2\text{Eu}_2\text{W}_2\text{Ti}_4\text{Nb}_4\text{O}_{30}$  has been prepared by a high-temperature solid-state reaction technique. Preliminary structural analysis confirmed the formation of a single phase material in an orthorhombic system at room temperature. Nyquists plots show both bulk and grain boundary effect and the resistance decreases with rise in temperature, which indicates the NTCR behavior of the sample.

### ABSTRACT

In the beginning of new millennium, the forensic science has practices to assess the identity of an individual from his handwriting. Character recognition has become one of the most researched work in the world of recognition and identification. Identifying a person through his handwriting is a biggest achievement for the handwriting experts. Handwriting recognition is one of a challenging task for academic circles, text recognition and also for forensic department. Handwriting is considered as the mirror of human character. Handwriting describes the human psychology. Starting from the love letters to the suicide letters the handwriting has explains the emotions of a person. Before we jump to the handwriting, we need to recognize the alphabets first. This research paper explains about the recognition of odia alphabets. The research paper presents the frame work for real time. These technologies are available in the library and methodology to implement them using Python in machine learning and artificial intelligence. For alphabet detection we have used edge histogram, and for alphabet recognition Genetic algorithm, ELM, PSO algorithm were used.

**Keywords:** Alphabet recognition; Machine learning; ELM; PSO; Histogram

### INTRODUCTION

Machine learning is a science that make the computers learn by itself and act like humans do, and improvise in their learning over time in a self-directed way, by collecting the information in the form of observation and real-world communications and feeding them. Technically we can define that machine learning is nothing but to train a model in such a way that in which we can fit our dataset. Alphabet Recognition is the capability of a computer to receive and construe intelligible handwritten input from sources such as paper documents, books, answer sheets, newspaper and other sources. Handwriting recognition traditionally is divided into two parts. One is offline recognition and other is online recognition [1-4].

23988

Stitiprajna Panda et al.

Handwriting recognition is nothing but to classify the alphabets according to their features. From a generation point of view, handwriting involves in several works. Handwriting recognition can be viewed as a particular instance of article class recognition. In object-class identification, the errand is to discover the areas and sizes of all articles in a picture that have a place with a given class. Like biometric, handwriting is also a key for all individuals. Handwriting differs from person to person. The main purpose of the step of pre-processing is to remove irrelevant information in the input data, which may affect the recognition accuracies [3]. It is practically equivalent to picture recognition in which the picture of an individual is coordinated a little bit at a time. A lot of variations can be found in alphabets during the recognition. These types of pictures are usually alluded as countenances in nature. A portion of these varieties incorporate head presents, alphabets in different angles, impediments, similarities between alphabets, and outward appearances. Customary techniques depended close by created highlights, for example, edges and surface descriptors, joined with machine. Fig. 1 shows typical variations found in alphabets. (a) Inclination of angle. (b) similarities between alphabets (c) curves in alphabets and (d) straight lines in alphabets. Alphabets representation is arguably the most important component of a handwriting. Recognition system and the focus of the literature review in Section II.

## LITERATURE REVIEW

Earlier researches about handwriting recognition looking for the methods that used image processing techniques to match simple features describing the geometry of the alphabets. Even though these procedures only worked under very constrained settings, they showed that it is possible to use computers to automatically recognize the alphabets. These methods are referred to as *all-inclusive* since they use the entire alphabet as an input. Though English alphabets are not so curved so it is quite difficult to recognize the alphabets of regional language. *Feature-based* approaches to alphabet recognition consist of matching these local features across images of the alphabets [8].

Moreover, whatever the techniques that have been implemented in the past have not yet provided a reliable output. Hence more refine methods need to developed for improved output. With many different types of algorithms present, it gave us an opportunity to study various feature extraction and image classification techniques [11-12]. Holistic and feature-based approaches were further developed and combined into *hybrid* methods. Handwriting recognition systems based on this hybrid approaches remained the up-to-the-minute until recently, when deep learning emerged as the leading approach to most computer vision applications, including the alphabet recognition. Picture of alphabets match with the picture stores in database. Any changes in the database will discredit the coordinating process.

The features like shape, size, colours are used to identify the alphabet first. Input or given alphabets will match with the images of alphabets that present in the datasets. After the identification the next step is to recognize whose handwriting it is. That means we need to reduce the percentage of error. Finding the minimum errors means that our alphabets are matching perfectly with the database. After various cycles, all the applicants with a high wellness esteem are chosen for additional confirmation. At this stage, it estimated and the presence of the distinctive highlights is confirmed for each alphabet images. Methods depended close by created highlights, for example, edges and surface descriptors, joined with machine. The rest of this paper provides a summary of some of the most representative research works on each of the above-mentioned types of methods. Fig. 2 shows alphabet recognition frame work

### Work flow

Alphabets recognition systems are usually composed of the following building blocks:

Stitiprajna Panda *et al.*

### Inputdata

In this research work we have taken datasets from UCI repository (<https://archive.ics.uci.edu/ml/index.php>). We have normalized our data and store in a file to extract a meaningful information from the dataset.

### Pre-Processing

In machine learning the processing of data means to fit our generalized datasets into a model. We have trained our datasets to our model. That stage is also known as train-test-spilt. In this phase model have learnt and given a prediction. This train-test-spilt is a random process. Because the model does not know from the dataset which are going to be trained and tested in every particular execution.

### Feature Extraction

At this stage, the pixel values of an image of an alphabet are transformed into a compact and discriminative feature vector, also known as a template. Ideally, all the alphabets of a same subject should map to similar feature vectors [8,12]. We have used edge histogram for extracting the features. We have predicted the shape of each alphabets. Though odia alphabets have a lot of curves.so, we have taken the shape of the edge.

### Training using ELM

Generally algorithm learns data from the dataset. Then after it will create a relation by understanding the data. It will classify the data and train itself for better performance. Classification is a process to predict that an object or task to which class it belongs to. In this stage the classifier will classify the alphabets according to their features.

### Testing using ELM

In testing data, the model used to test the data to get an expected result. Generally, the classifiers are used to represent the general categories. Here the classifier like ELM will classify the alphabets according to their features [12].

### Optimization using PSO

In this stage the algorithm will optimizes to get the best result. PSO or particle swarm optimization is a machine learning algorithm that helps to optimize the problem iteratively till it finds an optimum result. In handwriting recognition, the accuracy of matching the alphabets with the data set should be maximum. At that time the error should be minimum. This optimization algorithm will help to get the minimum error value.

### Output Results

After being optimized it will give the minimum error value. This research works consists of three major steps.

1. To recognize the alphabets- From the given images, it will recognize the alphabets by extracting the features. It will take the handwritten alphabets or from any source as its input.
2. To generate the labels for the training data- It will generate the labels and then it will train the classifier.
3. To predict the minimum errors- to predict the minimum error is equal to predict the maximum accuracy percentage of the matching of alphabets with the training images. In this step we have to find that how accurate our result is.

### Feature extraction

It is a process to reduce the dimensions of a raw data. Feature extraction is basically a method by which it extracts the important and meaningful information from a large dataset [1-2,5,11]. We have taken edge histogram to extract our features. In our dataset the alphabets are same in color. So, we took the edge histogram to extract the features on the basis of structure or shape of the alphabets. Though we know odia alphabets have a number of curves.

Stitiprajna Panda *et al.*

### Edge Histogram

Basically, Histogram is a graphical representation of repetition of pixels in a particular image or can be defined as histogram is the representation of frequency of pixels in an image. Similarly, the edge histogram is a graphical representation of repetition of pixels of an edge of an image. The figure 3 and 4 are the edge image of 15<sup>th</sup> number alphabet of odia language. Likewise, we have taken the edge histogram of each and every alphabet present in our dataset. Then after we will put all the extracted edge images in a CSV file.

### Multiclass Classification

Generally multi means more than one. So, the classification having more than one classes is known as multi class classification. Multi-class classification makes the assumption that each sample is allotted to one and only one label: By taking an example of English alphabets, an alphabet can be either a "A" or a "B" but not both at the same time. In a multiclass classification, we have trained a classifier using our training data, and use this classifier for classifying new examples. Similarly, the below alphabets are different from each other. The classifier classifies into different classes according to their features. Fig. 5: multiclass classification of different alphabets of different language. (from left "ka" of Hindi alphabets, middle one is "da" of Odia alphabets and the right one is "a" of English alphabets.) Fig. 5 shows multiclass classification of different alphabets of different language.

### ELME

LM is also known as Extreme Learning Machine is basically a machine learning algorithm. It is a single-hidden-layer Forward feed neural network. Generally, it is used for classification, regression etc. It is a rapid learning algorithm and avoids the unnecessary iterations [8,14]. The main advantage of elm is short training time. The number of hidden layer nodes can be randomly selected and analyzed to determine is to reduce the calculation time while learning speed fast [14-15]. However, ELM has some disadvantages such as over-fitting problem. This algorithm depends upon the number of neurons. This classifier because it takes less time to execute or can be said that ELM having the short training time [8]. We know that elm is depend upon the number of neurons. So, the only motive is to check whether it classifies properly or not. In elm the hidden nodes are chosen randomly (i.e. not only they are free of training data; but also independent of each other) and the parameters of the hidden nodes (i.e. input weights, bias for additive hidden nodes) need not be tuned manually. The output weights are calculated analytically.

### Activation Function

The activation function is the non-linear transformation in the weighted input signals and bias. The activation function is important in elm because it transforms the input data to a non-linear feature space which may help in the prediction of accuracy. This paper gives the approximated architecture of five different activation functions in elm.

### No. of Neurons

The number of neurons in the input layers equals to the number of input variables in the data to be processed and, the number of neurons in the output layers equals to the numbers of output associated with each input. This research paper will create a relationship activation function and number of neurons with the error. The only purpose of this paper to match the alphabets with the datasets and, find out the minimum error value. So, here it is going to prove that which activation function is giving the minimum error value. Two graphs have been plotted between the number of neurons and activation functions with the error to check the best activation function by which extreme learning machine is giving the minimum error value with a maximum prediction and also it will check that in how many particular number of neurons it is giving the minimum error. The figure 6 is the graph plotted in between error value and activation functions. Though the errors coming out from the execution is different each time of execution, here we have taken five executions and noted down in a table 1.

**Stitiprajna Panda et al.**

From the above table it is found that in 1<sup>st</sup> execution we found the minimum error .value at rbf\_12 function. In 2<sup>nd</sup> execution we found the minimum value at sigmoid function. In 3<sup>rd</sup> execution tanh has the minimum value. Linear function has the minimum value in 4<sup>th</sup> execution. In 5<sup>th</sup> execution sigmoid has the minimum error value. From this we can concluded that no specific activation function is giving the minimum error value because of randomness and complexity of the datasets. So, this classification algorithm (ELM) is independent of activation function. Fig. 7 depicts a graph between error and number of neurons.

We have plotted a graph between error Vs number of neurons. Though the errors coming out from the execution is different each time of execution, we have taken five iterations or executions and noted down in a table 2. From this table we have concluded that here also the values of the number of neurons also differs from execution to execution because of randomness and complexity of the datasets. So, this classification algorithm (ELM) is dependent of the value of number of neurons. After getting above disadvantages and randomness results ELM we have implemented PSO in this work.

**Optimization Algorithm**

An optimization algorithm is a method which is executed iteratively by comparing various solutions till an optimum or a satisfactory solution is found. Optimization is the procedure of improving a program's performance characteristics such as code size and execution speed. Traditional algorithm is a step by step procedure to follow in order to solve a given problem. We are taking the variable as  $x$  and calculating the  $f(x)$  for find out the global minimum value of a given graph. The purpose of optimization is to achieve the "best" design relative to a set of prioritized criteria or constraints. These include maximizing factors such as productivity, strength, reliability, longevity, efficiency, and utilization.

**Genetic Algorithm**

Genetic algorithm is a type of optimization algorithm that is based on the principle of genetics and natural selection or recombination theory to solve optimization problems. Genetic algorithms are commonly used to generate high-quality solutions to optimization and search problems by relying on bio-inspired operators such as mutation, crossover and selection.

**PSO**

Particle Swarm Optimization a type of optimization algorithm that is based on the examples of fish schooling and a flock of birds in searching their foods. All particles have fitness values which are evaluated by the fitness function to be optimized, and have velocities which direct the flying of the particles. The particles fly through the problem space by following the current optimum particles. It is shown in fig 8. PSO is initialized with a group of random particles (solutions) and then searches for optima by updating generations. In every iteration, each particle is updated by following two "best" values. The first one is the best solution (fitness) it has achieved so far. (The fitness value is also stored.) This value is called pBest. Another "best" value that is tracked by the particle swarm optimizer is the best value, obtained so far by any particle in the population. This best value is a global best and called gbest. By taking an example of flock of birds in searching their food we can explain the pbest of a bird is that it will compare its velocity and position from the initial point and how far it is from the particle. The gbest is to compare the velocity and position of the bird with every individual who is closer to the particle. In fig 8 example of particle swarm optimization is given. Though PSO is independent of number of neurons and activation function we have implemented in this work to find out the minimum error.

Stitiprajna Panda et al.

## SIMULATION RESULTS AND DISCUSSION

Machine learning is a science by which the machine learns by itself without any external help. It is all about to fit our dataset into the model. The model should train properly. Firstly, we have taken the datasets from UCI repository. Later on, we have used the customize datasets (handwritten alphabets). We can take genetic algorithm in this work but we know that genetic algorithm runs on the concept of recombination theory of scientist Charles Darwin. Though it has a number of steps, it will take more time to execute. In genetic algorithm the step size is necessary to find the best solution and these step sizes are not fixed. Every time we have to take a new one to get the optimum result. But in PSO there are no such recombination method is applied and also no need of step size in PSO. By comparing ELM classifier with PSO algorithm we found ELM depends on the number of neurons and activation function. The minimum error value is changing in every execution. No specific activation function is giving the minimum error value. Similarly, the minimum error value also changing if we are going plot against the number of neurons. PSO is independent of this number of neurons and also activation function. It will give result on the basis of gbest and pbest. As a result of testing the model, we got a minimum number of error value for the all activation function, that is 0.1. From this we concluded that no specific activation function is giving the minimum error value because of randomness and complexity of the datasets.

## CONCLUSION

In the beginning we have taken the datasets from UCI repository (<https://archive.ics.uci.edu/ml/index.php>). Later on, we have utilized the redo datasets of our own penmanship. We have taken twenty-six images of each alphabets for training. We got 0.1 of minimum error value. We have seen how handwriting recognition has surveyed the same evolution as many other computer visions applications. This describes the project for forensic science to match the handwriting, and in text recognition module. Next, it explains the technologies used in the project and the methodologies used. Finally, it shows the results, discuss the challenges. Utilizing Histogram calculation in picture preparing for highlights extraction worked amazingly well in any event, when the subjects have worn spectacles. Real time alphabet recognition has done by using ELM algorithm combined with PSO can be executed as a cost effective alphabet recognition platform. The computational models, which were implemented in this paper, were chosen after extensive exploration, and the successful testing results confirm that the choices made by the researcher were consistent.

### ABSTRACT

This study investigated the wound healing efficacy of silver/poly (lactic acid) nanocomposite (Ag/PLA-NC). Here silver nanoparticles (Ag-NPs) were amalgamated into PLA via chemical reduction method. Silver nitrate is used as silver precursor, while sodium borohydride is used as reducing agent. Poly (lactic acid), worked as a polymeric matrix and a stabilizing agent. The wound healing efficacy of the silver/poly (lactic acid) nanocomposite (Ag/PLA-NC) was examined in mice model. The results indicated that Ag/PLA-NC possessed a strong wound healing efficacy. To evaluate the role of poly (lactic acid) in wound healing, the wound healing efficacy of Ag/PLA-NC and silver nanoparticles were compared. The assessment of wound healing parameters showed no significant difference. This further indicated that the wound healing activity of Ag/PLA-NC was due to silver nanoparticles present in the composite and PLA can works as a suitable biocompatible matrix.

**Keywords:** silver, polymeric, method, chemical, healing, wound.

### INTRODUCTION

The limitation with conventional drugs is that it is not that target specific. Moreover, people started disliking conventional drugs because of its ineffective dosage formulations and unintentional side effects. Therefore, there is a surge in demand to design drugs with high specificity and minimal side effects. Nanotechnology addresses these issues amicably. Nanotechnology, engineering and manufacturing at nanometer ( $10^{-9}$  meter) scale is a new technology which is already present in many parts of industry and medicine, and the impact of it is being felt in everyday life. It uses nanoparticles of 1-100 nm and has revolutionized the field of medicine by using these particles for therapeutics and diagnostics. Clinical uses of silver as an antimicrobial agent is time tested and Silver nitrate is a

23997

**Anand Kumar and Jyoti Prakash Rath**

handy prescription for treating chronic wounds [1]. The noble metal works effectively killing broad spectrum of microorganisms ranging from viruses, bacteria, yeast and filamentous fungi [1, 6-10]. It targets the cytochromes present in the respiratory chain of microorganisms, thus impeding its function and ceasing the proliferation of microorganisms [2]. People also reported that it binds to DNA inhibiting replication of the master molecule [3-5]. There have been ripe evidences that ionic silver in exact proportion is a suitable agent for wound treatment [11-14]. This is being imperative by the loss of rubor in chronic wounds by colloidal silver. This is suggested to be because of the anti-inflammatory nature of the white metal [7].

Since silver nanoparticles have larger surface area therefore they have started replacing silver sulfadiazine for wound healing purpose [14-15]. The larger surface area of the nanoparticles may provide better bacterial interaction site thus working as a stronger antibacterial agent than metallic silver [16]. Similarly, study are there citing the enhancement of effectiveness of silver nanoparticles as wound healing agent when augmented with other materials. Therefore, several methods have been developed i.e. silver-doped hydroxyapatite [17]; polymer-silver nanoparticles [18]; and silver nanoparticles on TiO<sub>2</sub> [19] for studying the enhancement of antibacterial activity of silver nanoparticles when doped with other materials.

Silver nanoparticles when doped with biopolymers produce new antimicrobials. Several natural polymers like gum acacia, starch, gelatin and sodium alginate are being used to prepare biocompatible polymeric silver nanocomposite [20-22]. Though silver colloid based therapy is available in the market for wound healing. However, the bacteriostatic nature of poly (lactic acid) appeals to look for its utility in enhancing the wound healing efficacy of silver nanoparticles. Poly (lactic acid) (PLA) is a biodegradable thermoplastic polymer. It has got high melting point and better mechanical properties. The biodegradation, biocompatibility, superior thermal and mechanical properties make PLA a material of choice. [23-28]. Importantly, Poly (lactic acid) is an immunologically inert [29-30] and bacteriostatic polymer [31].

The crucial properties of poly (lactic acid) like bacteriostatic property, immunological inertness, biodegradability, and biocompatibility can be exploited in preparing a wound healing nanocomposite along with silver nanoparticle. The enhancement in wound healing efficacy of silver nanoparticles when blended with poly (lactic acid) can then be investigated. This study focussed to evaluate the enhancement of wound healing efficacy of silver nanoparticles when conjugated with PLA. The objective was met in two steps, in the first step silver/poly lactic acid nanocomposites were prepared by chemical reduction method followed by evaluating the wound healing efficacy of the prepared material in mice in second step.

## MATERIALS AND METHODS

### Materials

The reagents used in this work were of analytical grades and were used in their original form without any purification. Poly lactic acid (PLA) was supplied by Sigma-Aldrich, India. Silver nitrate (AgNO<sub>3</sub>) (99.8%) and tri sodium citrate dihydrate (99%) were obtained from RFCL limited, India. sodium borohydride (NaBH<sub>4</sub>) (95%), N, N-dimethyl formamide (DMF) (99%) and dichloromethane (CH<sub>2</sub>Cl<sub>2</sub>) (99%) were obtained from Sisco Research Laboratories, Mumbai, India. Double distilled water (DD-water) was used for making all the aqueous solutions.

### Synthesis of silver/poly (lactic acid) nanocomposites

Poly (lactic acid) was dissolved in a mixed solvent of dimethyl formamide (DMF) and dichloromethane (CH<sub>2</sub>Cl<sub>2</sub>) (1/9 v/v) to achieve a concentration of 10 wt % and certain amounts of silver nitrate (AgNO<sub>3</sub>) (0.08 g) powder was added to the solution. When stirred for 48 hours in an ice water bath a colourless solution of AgNO<sub>3</sub>/PLA was observed. To this 10 mL of sodium borohydride (NaBH<sub>4</sub>) aqueous solution (molar ratio of AgNO<sub>3</sub>/NaBH<sub>4</sub> 1:2) was added drop wise under vigorous stirring at the same temperature for 2 hours. The formation of the Ag-NPs started in the

**Anand Kumar and Jyoti Prakash Rath**

aqueous phase, but later the nanoparticles transferred to the organic phase due to the presence of van der Waals interactions between the hydroxyl groups of the PLA and the partial charges surrounded in the surface of the Ag-NPs. The organic phase containing stable Ag-NP colloid was separated from the aqueous phase and shaken with DD-water twice to remove any silver ions. It was then left for drying at room temperature; and form Ag/PLA-NC films [67].

**Synthesis of silver nanoparticles**

Silver nanoparticles were synthesized by chemical reduction method [68] by using sodium borohydride as a reducing agent and trisodium citrate as a capping agent. Here trisodium citrate (0.3 mM, 1 ml) was added to an aqueous solution of AgNO<sub>3</sub> (0.1 mM, 100 ml) and then NaBH<sub>4</sub> solution (50 mM, 1 ml) was subsequently added by drop-wise addition to the solution as a particle stabilizing agent with constant stirring in ice cold condition. This leads to the formation of yellow colour solution, which was the characteristic colour of the silver nanoparticle solution.

**Characterization methods and instrumentation**

The synthesis of silver nanoparticles and Ag/PLA nanocomposites were characterized using UV-visible (UV-vis) spectroscopy and Fourier transform infrared (FT-IR) spectroscopy. The size of the synthesized particles was determined using dynamic light scattering (DLS) technique. The UV-vis spectra were recorded over a range of 200-800 nm with a UV-1800 (SHIMADZU) UV-vis spectrophotometer. FT-IR spectra were recorded over the range of 400-4000 cm<sup>-1</sup> with an ALPHA (Bruker optics), FT-IR spectrophotometer. Particle size was determined using Zetasizer Nano (Malvern).

**Experimental animals**

Fifteen (for three experimental group, five in each group), five-six week old Swiss albino mice of either sex, weighing between 40 and 50 grams obtained from the animal house of CHRI (Chettinad Hospital & Research Institute), kelambakkam, Chennai, India, were used for *in vivo* studies. The experiments were conducted in accordance with the internationally accepted principles for laboratory animal use and approved by Institutional Animal Ethics Committee. The animals were housed in polypropylene cages in proper environmental conditions (20–25 °C), fed with standard rodent diet and water *ad libitum*.

**Excision Wound Model**

Animals were anaesthetized by open mask method with anesthetic ether. The hair on the back of each mouse was shaved and a predetermined area of 100 mm<sup>2</sup> full thickness outer skin was excised behind the neck. Group I (control) mice were left untreated, Group II mice were treated with silver nanoparticles colloid and Group III (test) mice were treated with Ag/PLA nanocomposites colloid. The wounds were applied with the appropriate agents daily.

**Doses of wound healing agents**

Group II mice were treated with 500 µL of 0.02 mg/mL silver nanoparticles and Group III mice were treated with 500 µL of 0.02 mg/mL Ag/PLA nanocomposites colloids daily for twenty days. This corresponds to a daily dose of 0.01 mg of silver nanoparticles and Ag/PLA nanocomposites for Group II and Group III mice respectively.

**Wound healing evaluation parameters****Measurement of wound contraction**

Excision wounds margins were traced following the progressive changes in wound area planimetrically, excluding the day of wounding. The size of wounds was traced on a transparent polythene sheet on day 5, 10, 15 and 20. The tracing were then shifted to a graph paper, from which the wounds surface areas were calculated. The evaluated surface area was then employed to calculate the percentage of wound contraction, taking initial size of wound, 100 mm<sup>2</sup>, as 100 %, by using the following formula:

$$\text{Wound contraction \%} = \frac{\text{Wound area day 0} - \text{Wound area day n}}{\text{Wound area day 0}} \times 100$$

### Epithelialization period

This was assessed by finding the number of days required for the Escher to fall off from the wound surface exclusive of leaving a raw wound behind.

### Statistical analysis

Results obtained from three wound models have been expressed as mean  $\pm$  SEM. Statistical differences were determined using t test. A p value of  $< 0.05$  was taken as statistically significant.

## RESULTS AND DISCUSSION

### UV-visible spectroscopy

The absorption spectrum (figure 1) of the yellow colour synthesized colloid showed a surface plasmon resonance around 400 nm with a plasmon peak at 425 nm indicating the presence of Ag nanoparticles in colloid. Similarly, the absorption spectrum (figure 2) of the dark brown Ag/PLA nanocomposites colloid showed the characteristic of the silver surface plasmon resonance band around 400 nm with a plasmon peak at 420 nm. This clearly indicates the formation of Ag nanoparticles in Ag/PLA nanocomposites.

### Particle size analysis

Dynamic light scattering technique was used to determine the size distribution profile of nanoparticles in colloids. Both in silver nanoparticles and Ag/PLA nanocomposites colloids most of the particles (98 %) were observed under a single peak area i.e. the colloids were almost monodisperse, indicating most of the particles in the colloids were of identical size. The mean hydrodynamic diameters of silver nanoparticles in silver nanoparticles and Ag/PLA nanocomposites colloid were found to be 80 and 109 nm respectively (figure 3, figure 4).

### FT-IR analysis

FT-IR spectroscopy was used to characterize the interaction between the Ag-NPs with PLA. Figure 5 shows FT-IR peaks for PLA and Ag/PLA-NCs. The peaks at 1264 (1091), 3055 (2936), and 3666  $\text{cm}^{-1}$  were assigned to the C–O, C–H (double) and O–H stretching of the –CH (CH<sub>3</sub>)–OH end group of PLA, respectively. The splitting of the C=O carbonyl stretching at 1669  $\text{cm}^{-1}$  might be due to the presence of –CH–CO–O– group. The peaks at 149, and 1387  $\text{cm}^{-1}$  were assigned to –CH<sub>3</sub>, and –CH– bending including symmetric and asymmetric bending. The interactions between PLA chain molecules and Ag-NPs were associated with the peak at 3489  $\text{cm}^{-1}$ . Broad peak was due to the presence of van der Waals interactions between the hydroxyl groups of PLA and the partial positive charge on the surface of the Ag-NPs.

### Evaluation of Wound healing efficacy

The progress of the wound contraction (expressed as percentage wound contraction) by day 5, 10, 15, and 20 in three experimental animal groups were shown in Table 1. It was observed (figure 6) that the wound contraction efficacy of Ag-NPs and Ag/PLA-NCs were significantly greater than that of the untreated group. Again, more than 95 % wound contraction was recorded in the Ag-NPs and Ag/PLA-NCs treated groups, as compared to 82 % wound contraction in the control (untreated) group by 20<sup>th</sup> day (figure 7). Throughout the experiment, the percentage wound contraction rate in the untreated group was significantly lower than those of Ag-NPs and Ag/PLA-NCs treated groups. It was observed that epithelisation has occurred on 20<sup>th</sup> and 19<sup>th</sup> day for Ag-NPs and Ag/PLA-NCs treated groups respectively, whereas no epithelization was observed till 20<sup>th</sup> day in untreated group. This indicates that Ag-NPs and Ag/PLA-NCs have high wound contraction efficacy and reduced epithelization time as compared

**Anand Kumar and Jyoti Prakash Rath**

to that of the untreated group. The wound healing efficacy of Ag/PLA-NCs treatment was not significantly different from wound healing efficacy of Ag-NPs treatment alone.

This further indicates that the wound healing activity of Ag/PLA-NCs is due to the antimicrobial and anti-inflammatory activity of silver nanoparticles present in the polylactic acid nanocomposites. Here polylactic acid nanocomposites acts as a matrix support for silver nanoparticles which releases the silver nanoparticles to the area of the wound. Moreover the biocompatible and biodegradable nature of poly (lactic acid) provides a strong support to use it as the matrix material for wound dressing. It is important to note that throughout the period of wound treatment, the nanocomposites did not cause irritation or pain to the animals as the mice neither show any signs of restlessness nor scratching/biting of wound site when the nanocomposites were applied. If animals were treated with silver nanoparticles on daily basis and silver-PLA nanocomposites on alternate day basis the enhancement in wound healing efficacy because of PLA can be better assured. Hence the role of PLA more than the matrix for control release of nanoparticles could have been fully pronounced.

**CONCLUSION**

Silver/poly lactic acid nanocomposite was synthesized. The average diameter of the silver nanoparticles in silver/poly lactic acid nanocomposite was 109 nm. The UV-visible absorption spectra show signature surface plasmon resonance peaks of the silver nanoparticles. FT-IR shows that interactions exist between molecules of poly lactic acid and silver nanoparticles. The wound healing efficacy of silver/poly lactic acid nanocomposite was demonstrated. Further it was confirmed that wound healing activity of silver/poly lactic acid nanocomposite was due to silver nanoparticles in the composite and PLA act as the supporting matrix in controlled release of silver nanoparticles.

### ABSTRACT

The present paper analyses the monthly rainfall data of various regions of India between 1901-2015. Multiple linear regression is used for training and testing the model to predict the average rainfall using the previous months' data from the equivalent time period. Prediction is done month-wise according to the sub-division and compared with the actual value. In this paper, the prediction model basically deals with steps such as data acquisition, data cleaning, feature extraction, prediction. In this experiment getting 0.99 accuracy after prediction the rainfall.

**Keywords:** Multiple Linear Regression (MLR); Rainfall Prediction; Historical Data

## INTRODUCTION

The Analytics which help us in solving many problems, Data analytics is collected from various statistical and analytical methods used to develop new techniques to predict future possibilities. In the current scenario forecasting the rainfall is measured to be an important and thought-provoker task, as it's closely associated with the agriculture, economy, and human life. Accuracy of a rainfall predicts has importance for countries like India whose economy majorly depends on agriculture. The rainfall prediction has to predict the state of the current weather conditions. The weather is dynamic in nature; statistical techniques are unsuccessful to provide thee decent accuracy of rainfall. Agriculture is the largest occupation in India, accounting for about 52% of employment. Because India is an agricultural country and its economy is largely based upon crop productivity. The occurrence of prolonged dry periods or heavy rain at the significant stages of crop growth and development may lead to significantly reduce crop yield.

Rainfall is important for food production plans, water resource management, and all activity plans in nature. Thus rainfall prediction becomes a major factor in agricultural countries. Rainfall prediction has been one of the most scientifically and technologically difficult problems around the world in the last century [1]. There is much

Poulomi Maji et al.

application that this system is used such as Air Traffic, Agriculture, Marine, Forestry, Navy, and Military, etc. The training of the data is done using a modified version of the linear regression method. The error percentage between the actual and predicted is used to improve the training set and train the data with the new inputs. Thus, with the advantages of this method; forecast the outcomes till there is no further improvement in the error percentage. This method can be used to forecast the rainfall and prevent the destruction caused by it to the life or property [2]. Indian Government has undertaken many research studies to analyze the impact of global warming and climate change on rainfall patterns in India. The analyses were made using experimental rainfall data from more than 3000 rain-gauge stations spread over the country for 115 years (1901-2015). In this field the major inferences from these studies based on the 115 years of rainfall data are as follows:

The analysis of 115 years of monsoon rainfall data suggest that there is no long term change in the monsoon rainfall averaged over the country. Even though there are no changes in the all-India rainfall, there are significant changes in annual rainfall in some meteorological sub-divisions. With this data with more variations of average rainfall, it is very difficult for a numerical model to predict the required data point. Here implement multiple linear regression to predict the average rainfall, the regression is used to create multiple features that help in predicting the data points with more seasonal variations. The rest of the paper is structured as provided below. In Section 2, the related work and plans for future research are introduced. Next, in Section 3, methodology, where explained how to predict the data. In Section 4, historical data collected for prediction. In Section this this paper is divided into five section i.e. 1. Introduction, 2. Related Work, 3. Methodology, 4. Dataset, 5. Result Discussion and Conclusion in Section 6.

### Related Work

Different scientists, researchers, and students doing prediction in different ways like Daniela Şchiopu [4] and his team in his publication used SPSS 13.0 tool and forecasted temperature from data collected from Hong Kong Observatory website. They used a factor analysis technique in the SPSS tool to reduce the complexity in calculations the temperature using correlation and regression. Samuel and Rajalakshmi [5] used multiple linear regression to predict the monsoon rainfall by using outgoing long wave radiations, global temperatures, and sunspots out of Tamil Nadu. They collected data from 110 years from the Indian Meteorological Department, Chennai. Hirani and Nitin [6] proposed different methods to estimate rainfall. The methods include Autoregressive Integrated Moving Average (ARIMA), Multiple Linear Regression (MLR), Genetic Algorithm, Support Vector Machine (SVM), Back-Propagation Neural Network (BPNN), Adaptive Splines Threshold Autoregressive (ASTAR) modeling and others. Paras and Sanjay [7] developed a forecasting model using mathematical regression.

The weather data is collected for a period of 3 years and this model can predict max and min temperatures for a period of 15 to 45 weeks into the future. Goutami [8] used Multiple Linear Regression to estimate average summer – monsoon rainfall on the data from 1871 to 1999. She analyzed the monthly rainfall of Indian summer monsoon months. Kannan, Ramachandran, and Prabhakaran [9] implemented Multiple linear regression and Karl Pearson coefficient. They made a short – term forecast over a particular state. They used fuzzy sets, neural networks to analyze the data. Returns and Delson [10] developed a weighted multiple regression model. They used a combination of time series analysis and regression to offer a powerful system for predicting annual rainfall. Timothy and Shukla [11] proposed the F-test and Screening procedure. a cross-validation procedure is used first to screens models out that are all likely to poorly perform on independent datasets, then the error of each model is compared with those all other models to determine a threshold of significance in error variance. Guhathakurta [12] used dynamic models on nonlinear equations that the atmospheric system governs. They implemented neural networks with three layers that works on one input, one output, and one hidden layer. The network training is carried out till the mean square error of 0.0005 to 0.001. Nikhil [13] proposed correlation and regression both linear and multiple linear regression. He estimated the rainfall by analyzing the atmospheric factors like precipitation, vapor pressure, average temperature and cloud cover.

Poulomi Maji et al.

## METHODOLOGY

### Algorithm

**STEP I:** In dataset the attributes are subdivision, year, month from jan-dec, jan-feb ,feb-mar and take the months as X attributes and predict the annual rainfall column(Y attributes).

**STEP II:** After imported all the modules panda, numpy, math, sklearn, seaborn and matplotlib, and need to do some data preprocessing such as removing null values or filling them with mean.

**STEP III:** Then checking the data types of the attributes.

**STEP IV:** Now grouping by subdivision and getting the co-variance and co-relation because Correlation, statistical technique which determines how one variables moves in relation with the other variable and co-variance indicates the direction of the linear relationship between variables.

**STEP V:** Apply the linear regression to train the model using train\_test\_split and test it using various performance measures like Mean Squared error(MSE),root mean squared error(RMSE). And modeling the classifier by using training dataset (80% of the data from the CSV.file).

**STEP VI:** Validating the model Using Testing dataset (rest of the 20% data) and Comparison of result  
There are six important stages that are proposed in this model: Data acquisition, Data preprocessing, Data selection, Reduction of explanatory predictor, Model design, and last Model validation as shown in [Figure.1].

### Multiple Linear Regressions (MLR)

In this article, use Linear Regression to predict the amount of rainfall. Linear Regression helps how many inches of rainfall expect. It is applied to the set of data and the coefficients are used to predict the rainfall based on the corresponding values of the parameters. The main advantages of this model are that it estimates the rainfall based on the previous correlation between the different atmospheric parameters.

It is a method used for defining the relation between a dependent variable (z) and one or more independent variables or explanatory variables, denoted by (x). For multiple explanatory variable, the process is defined as Multiple Linear Regression (MLR). The general equation for linear regression is given in equation (1) as  $z_i = \beta_0 + \beta_1 x_{i1} + \dots + \beta_p x_{ip} + \epsilon_i = x_i^T \beta + \epsilon_i$  (1)

where z denotes the dependent variable (rainfall) and  $x_i$  where  $i=1,2,\dots,n$ , denotes the explanatory or independent variables and  $\beta$  is called the intercept.

The Multiple linear regression equation used in this proposed system is given equation (2) as Rainfall =  $(\text{AvgTemp} * \beta_1) + (\text{Humidity} * \beta_2) + \beta_3$  (2)  
where  $\beta_1, \beta_2, \beta_3$  represents the different coefficients for different districts.

### Datasets

There are six important stages that are proposed in this model

### Data Acquisition

The data need for predict the rainfall. The data of rainfall prediction have been collected from kaggle repository the collected dataset has 115 years' time period from 1901 to 2015 sub division wise monthly data. Format of data is csv

Poulomi Maji et al.

file. It is historical data. This data is used to process in the system to predict the rainfall. Source: <https://www.kaggle.com/rajanand/rainfall-in-india-1901-2015>

### Data Pre-Processing

The Data Pre-processing is the next challenging task, the data obtained till now is noisy and there are some missing values and some unwanted data. The data have to clean by filling missing values and removing the irrelevant data.

### Data Selection

In this section to select the data which are relevant to analysis and left all other data use correlation to determine which are correlated or not.

### Reduction of explanatory predictor

After that the predictors which have high inter correlation with others are reduced because the presence of many highly inter correlated explanatory variables may significantly increase the sampling variation of the regression coefficients, and degrade the model predictive ability.

### Model design

The next step after the reduction explanatory predictors is the building model with the use of training data. Training/Testing is split in the ratio 80:20 randomly. The technique used here is linear regression technique.

### Model validation

After training the model with the training set, get the validating results and tuning the hyper parameters with the validation set till the reach a satisfactory performance metric. Once this stage is completed, then testing the model with the test set to predict and evaluate the performance.

## RESULT AND DISCUSSION

The experiments were performed to evaluate the accuracy of rainfall prediction using multiple linear regressions.

In this experiment data is collected for every state for a period of 115 years from 1901 to 2015 for all months i.e. from January to December. And visualized the data using various plots in the given below. These plots help to predict the future trend on the basis of current relationship between variables.

- In [Figure.3] Subdivisions with highest annual rainfall are "Arunachal Pradesh", "Coastal Karnataka" and "Konkan& Goa" with approximate annual rainfall of 3418.857143mm, 3408.409649mm and 2977.686087mm respectively.
- Subdivisions with lowest annual rainfall are "West Rajasthan", "Saurashtra& Kutch" and "Haryana Delhi & Chandigarh" with approximate annual rainfall of 292.673043mm, 495.161739mm and 530.496522mm respectively.
- In [Figure.4] Maximum overall rainfall (sum of all 36 subdivision) of 61815.6mm occurred in the year 1961
- Minimum overall rainfall (sum of all 36 subdivision) of 41273.6mm occurred in the year 1972
- Average (of all 36 subdivisions) overall rainfall (sum of all 36 subdivision) is 50182.832mm
- Highest average rainfall of 348.5675mm occurred in the month of July
- Lowest average rainfall of 19.1113mm occurred in the month of January

After train the model using `train_test_split`, and test it using various performance measures, Like mean squared error(MSE), root mean squared error(RMSE), mean absolute Error(MAE),  $R^2$  score. And also plot the scatter plot of expected vs predicted values shown in [Figure.6]. From get good results because Mean Absolute Error (MAE), Root Mean Squared Error(RMSE) are relatively less values, and scatter plot is pretty concentrated as straight line.

Poulomi Maji et al.

After that measure the classifier performance. F1-score is composite metrics that combine the precision and recall of a classifier. Precision is the fraction of true positives out of all positives; recall is the fraction of true positives out of all relevant elements. Higher precision and recall are, the better the classifier performs because it detects most of the positive data (high recall) and does not detect many data that should not be detected (high precision). In this experiment the higher precision and recall are, the higher F1-score is 1.00, and it proves that the better classifier of the model as shown in [Table.1]. And finally get the accuracy 0.9983805668016195. The true positive rates against the false positive rate at various cut points. It also demonstrates a trade-off between sensitivity as shown [Figure.7].

## CONCLUSION

Rainfall Prediction is the application of science and technology to predict the amount of rainfall over a region. Agricultural sectors can avail the benefits of knowing weather condition in advance and take precautionary steps accordingly. This directly helps in improvement of national economy as well. A rainfall prediction method has been proposed. This experiment used to multiple linear regression approach to predict the rainfall prediction because multiple linear regression has less error percentage and getting the accuracy 0.99. The model is robust and accurate as it trained and tested with a large size dataset for every state for a period of 115 years from 1901 to 2015 for all months i.e. from January to December. Rainfall over Kerala, East Madhya Pradesh, Jharkhand, Arunachal Pradesh, and Nagaland, Manipur, Mizoram, and Tripura show a decreasing trend. But, rainfall over coastal Karnataka, Maharashtra, and Jammu and Kashmir show an increasing trend.

There is a general tendency of increasing the frequency of extreme rainfall (heavy rainfall events) over India, especially over the central parts of India during the southwest (June- September) monsoon season. There is no fact of global warming on the observed changes in annual or seasonal rainfall over India. However, there is growing evidence suggesting that increasing the frequency of extreme rainfall is due to global warming. The climate change assessment made by the Intergovernmental Panel on Climate Change (IPCC) suggests that in the future, the frequency of extreme rainfall may increase over India due to increase in global warming. However, there are no other long term changes/trends in rainfall over India which can be attributed to global warming. The Indian Monsoon is found to be a stable system.

### ABSTRACT

With the spread of privatization, liberalization and globalization, economic activities are increasingly being de-controlled and de-regulated all across the globe. Forecasting plays a very important role in economic optimization of electricity usage. In the new competitive framework, short-term Price Forecasting is required by producers and consumers to derive their bidding strategies to the electricity market. This paper proposes an Extreme Learning Machine approach for forecasting short-term electricity prices. We evaluate the accuracy of the price forecasting attained with the proposed ELM approach. The proposed method is tested on Ontario Energy Market datasets. To overcome the limitations of the Artificial Neural Network model, ELM model is used for forecasting the short term electricity price of foreign electricity market. The results were showed that the proposed approaches are successful. Consumer and producers needs accurate price forecasting tools which are required for producers to maximize their profit and consumers required for maximize their utilities. The main objective is to predict the value or price of each unit so that consumers and producers get their benefits. Therefore, we evaluate the future price movements by adopting ELM. From result there is a close call between tribas and radbas but by considering both parameters processing time and accuracy tribas shows a promising result. The accuracy achieved is 92.506 with 10 numbers of hidden nodes.

**Keywords:** Price Forecasting; De-Regulated Energy Market; ELM; ANN

### INTRODUCTION

Market is the key aspect in every field of economic activities. And electricity market is no exception [1]. With an objective to restructure the electric power industry, different companies like generating companies and supplying companies need to meet in a market place to survey and evaluate the electricity price [2]. Nowadays, all over the

24012

**Satabdi Swain et al.**

world electricity forecasting provides a competitive frame work. There are a lot of researchers are engaged for developing algorithms and tools for load and price forecasting. Price forecasting tools are essential for all companies and consumers for their survival under new deregulated environment [3]. There are two different types of business strategy in the electricity market like the poll& bilateral contracts. In the poll, the producers and consumers submit their own bids. Then the next day market operator announced a set of accurate price. Bilateral contract is an agreement between seller & buyer. It is a tool for the companies to secure them against the price manipulation [4-5]. For both cases, predict the price of electricity for tomorrow or for next 12 month is most important for electric companies to adjust their daily bids and monthly schedules. Electricity has different characteristics from other commodities for e.g. electricity storage and supplying are more expensive [6]. The main objective of an electricity market is to decrease the cost of electricity through competition. Pricing mechanism can affect the competition, number of consumer, efficiency and strategy applied by the competitors in the electric market [7].

Producers and consumers depend on Price Forecast information to prepare their corresponding bidding strategies. If a producer has a good forecast of market prices it can develop a strategy to maximize its own benefit and establish a bidding techniqueto achieve its maximum benefit. More and more attention has been paid to price forecasting in the deregulation technique. Different forecasting techniques such as expert system, Artificial Neural Network, fuzzy logic, Extreme Learning Machine, wavelets have been developed for showing improving results [8]. Using ELM method the accurate electricity price has been calculated. In the proposed algorithm, the input weights and hidden biases are randomly chosen, and the output weights are determined analytically by using the Moore–Penrose (MP) generalized inverse. ELM surpasses the traditional gradient-based learning methods in terms of faster learning speed with a higher generalization and it also avoids many difficulties faced by gradient-based learning methods such as stopping criteria, learning rate, learning epochs, local minima, and the over-tuning problems [9-10]. Up to now, the ELM has been successfully applied in various areas such as classification, terrain reconstruction and protein structure prediction. The ELM technique has been applied for the case of electricity price forecasting in where the advantages of ELM over traditional ANN structures were highlighted and also the uncertainties related to prediction were quantified using the bootstrapping technique [11].

### Literature survey

In deregulated energy market, price of electricity has taken more importance. Accurate and efficient electricity price forecasting is more important factor. This topic provides us scope to enhance the methods used in it and gives us correct prediction in deregulated energy market.Using Artificial intelligence and Extreme Learning Machine (ELM) techniques to predict the monthly electricity prices and the day-ahead usage of electricity are proposed by VrushabGosalia and PradipAndhare[1-2]. Here using ANN model which is used for forecasting the behavior of the electricity market based on the different factors such as historical price, calendar date, occasions, and load. In this paper system will have gained high relevance and will represent one of the main sources of information that can bias one common base for system user for bidding in the electricity market. Such as for generator companies, forecasting of electricity price and consumption level can be used as possible value for finalizing the price level in this competitive market[3].Another topic on a detailed analysis on extreme learning machine and novel approaches based on ELM by Omer Faruk and Yilmaz Kaya has briefly discuss about ELM method[4-6]. In this paper accuracy of randomly selected input weights and biases was compared with new proposed approaches like ELM-P, ELM back propagation (ELM-B), single layer ELM (s-ELM), tuning ELM (t-ELM), ELM based on linear regression (ELM-r).

Another topic on a hybrid wavelet-ELM based short term price forecasting for electricity markets by N.A Shrivastava and B.K Panigrahi is used ELM technique coupled with wavelet technique to develop a hybrid model called as WELM (wavelet based ELM) to improve the forecasting accuracy as well as reliability [7-8]. The author concluded that the hybrid wavelet-ELM model can produce smaller predicting errors than the existing techniques.Using ELM and wavelet transform method and modified artificial bee colony (MABC) algorithm, a novel Short-term load forecasting method is proposed by Song Li, LalitGoel and Peng Wang [9-10]. Wavelet transform is used to decompose the load series into a set of different frequency components, which are more predictable. Moreover, a

**Satabdi Swain et al.**

modified ABC algorithm is proposed to choose the optimal set of input weights and hidden biases for ELM. The ELM-MABC algorithm has better convergence performance than the conventional Neuro-Evolution method, leading to a significant improvement in forecasting accuracy. The proposed method produce excellent forecasting result compared to other established methods [11]. In the paper by Rafał Weron [12-13] the author review an article of electricity price forecasting (EPF) to explain the complexity of available solutions, their strengths and weakness, and the opportunities and threats that the forecasting tools offer or that may be encountered. In this paper the author discussed all the methods, problems, suggestions to develop more efficient and better grounded models and techniques for electricity price forecasting area.

In the paper by Ling Tang, Wei Dai [14] the authors have use Extended Extreme Learning machine (EELM) and coupling complementary ensemble empirical mode decomposition (CEEMD) to predict the accuracy of crude oil price based on the principle of decomposition and ensemble". This novel CEEMD-based EELM model is actually an extension on existing ensemble models and the main contribution to literature is to introduce the current algorithms of CEEMD and EELM and to test their effectiveness in formulating the powerful decomposition and ensemble" learning paradigm. Another topic on what are Extreme Learning Machines? Filling the Gap between Frank Rosenblatt's Dream and John von Neumann's Puzzle by Guang-Bin Huang [15] has briefly discuss about ELM method. This paper wishes to clarify the ELM theories manage to address the open problem which has puzzled the neural networks, machine learning and neuroscience communities and compare ELM, SVM and LS-SVM tend to provide sub Optimal solutions.

This paper is composed of a total of four sessions. Session 1 is the current chapter and introduces the topic of thesis and describes the previous contributions in this dataset using Evolutionary Algorithm. Session 2 states the methodology of our research, where it showed the dataset which we obtained from Ontario energy market and describes the proposed model based on Extreme Learning Machine (ELM). Session 3 describes the result. Session 4 summarizes our research and also highlights the Future work.

## MATERIAL AND METHODS

### Data

The experimental data are obtained from Ontario, Energy markets. The Ontario data set consists of hourly electricity price from May 01, 2002 to December 26, 2006. The total numbers of samples taken from Ontario are  $(40824 \times 3)$  1, 22, 472.

### Extreme Learning Machine (ELM)

As compared to ANN which is time delay process due to the number of iteration, ELM is much faster to train. It provides no iterative training using generalization pseudo inverse operation. ELM is neural nets with a single hidden layer, where the 1<sup>st</sup> weight matrix is initialized randomly. This allows the output matrix to be estimated via least square, which is very quickly done [12-13].

ELM says "only learn the last layer" whereas ANN says "learn all the layers". 'Extreme' in ELM means to move beyond conventional artificial learning technology and to move towards brain alike learning. It is a feed-forward neural network for classification, regression, clustering, sparse approximation compression and feature learning with a single layer or multiple layers of hidden nodes. ELM aims to break the barriers between the conventional Artificial Learning techniques and biological learning mechanism. Extreme learning machine (ELM) represents a suite of machine learning techniques in which hidden neurons need not be tuned with the consideration of neural network generalization theory, control theory, matrix theory and linear system theory. In order to have clearer understanding of ELM, it is better to analyze ELM in the aspects of its philosophy, theories, network architecture, network neuron types and its learning objectives and algorithms [14-15].

Activation Functions: In ELM method different activation function is used to identify the accuracy for different hidden nodes. Basically 5 types of activation function are used such as hard limit, sigmoid, sine, triangular basis and radial basis function. The activation function is the nonlinear transformation of the weighted input signals and bias.

### Proposed Algorithm

The main puzzle in network, machine learning or neuroscience for many years, whether hidden nodes need to be tuned or not. It is generalized both for single hidden layer feed-forward network (SLFN) and multi hidden layer feed-forward network (MLFN) [10]. ELM is basically 2 types: multi layer ELM (MLELM) and hierarchical ELM (H-ELM). ML-ELM and H-ELM has a smaller training time than DBM (Decision boundary making) [16].

Extreme learning machine (ELM) is a learning method for training single hidden layer feed-forward neural network (SLFN), which generates input weights and biases randomly. Later, the output weights are computed analytically [17]. There are some basic differences between, ANN and ELM such as non-differentiable or discrete transfer functions can be used at ELM, ELM does not need the optimization parameters (such as momentum, learning rate), which are important for accuracy of ANN, ELM overcomes falling into local minima and also ANN is a slow method because of the need of tuning all network parameters. Where,  $x_i$  identifies input,  $y_k$  shows the output and network having  $n$  neuron in the hidden layer,  $n$  neuron in the input layer and  $k$  is the number of output. ELM is an emerging learning algorithm for SLFN, which randomly chooses the input weights and hidden biases and determines the output weights directly by a least squares method.

Consider a training set of  $N$  samples  $(x_i, t_i)$ , the SLFN can be modeled by

$$\sum_{j=1}^n g(w_j \cdot x_i + b_j) = o_i, i=1 \dots N \quad (1)$$

where  $x_i$  is the input vector,  $t_i$  is the output vector,  $n$  is the number of hidden nodes,  $g(x)$  is the activation function,  $w_j$  is the input weight vector,  $b_j$  is the hidden bias vector,  $\beta_j$  is the output weight vector and  $o_i$  is the actual network output.

If ELM fits all the training samples  $(x_i, t_i)$  with zero error, it can be said that there exist

$\beta_j, w_j$  and  $b_j$  such that

$$\sum_{j=1}^n g(w_j \cdot x_i + b_j) = t_i, i=1 \dots N \quad (2)$$

The compact form of (2) can be given by  $H\beta = T$ ,

where  $\beta = [\beta_1, \dots, \beta_n]^T$ ,  $T = [t_1, \dots, t_N]^T$  and  $H$  is called the hidden layer output matrix.

ELM cannot obtain the perfect zero error because the number of hidden nodes  $n$  is usually less than the number of training samples  $N$ . In ELM, the input weights  $w_j$  and hidden biases  $b_j$  are randomly initialized. For  $w_j$  and  $b_j$ , the SLFN becomes an over-determined linear system and the output weights  $\beta$  can be calculated by a least squares method. A special solution is given by  $\beta^* = H^+T$ , where  $H^+$  is the Moore-Penrose (MP) inverse of  $H$ . It is suggested that the singular value decomposition method is well-suited to compute the MP inverse of  $H$  in all cases. The special solution  $\beta^*$  is one of the least squares solutions of the linear system  $H\beta = T$ , which implies that ELM can reach the minimum error of the current system [18-19].

In SLFN a bias is used to absorb the system error along with activation function. But in case of ELM there is no need of bias. There are three levels of randomness in ELM:

- Fully connected, hidden node parameters are randomly generated.
- Connection can be randomly generated, not all input nodes are connected to a particular hidden node. Possibly only some input nodes in some local field are connected to one hidden node.
- A hidden node itself can be a sub network formed by several nodes.

**Satabdi Swain et al.**

The Hidden nodes of wide types of multi-hidden-layer networks (MLFN) do not need to be tuned. Although multilayer of ELM concepts have been given in ELM theories has not been used until recently.

## RESULTS

To develop a model, a number of case studies are performed and performance of the model under different conditions is investigated. The major advantage of ELM over traditional neural network models is that the parameters do not require any tuning in the former case thus eliminating the need for repetitive tuning and cross validation to come up with the best model [20]. The learning capacity of ELM is very fast and it gives excellent performance when the training data set is shown even once to the network. Price forecasting is computed using historical data of Ontario energy system for year 2002/01/May to 2006/26/ Dec. Data of Ontario electricity market has been obtained from their website. Due to the demerger of Ontario Hydro in early 1999, Ontario electricity prices may be assumed to have had no major impact on the load of interest. However, due to the large power exchange between Pennsylvania-New Jersey- Maryland (PJM) and Ontario, and the fact that PJM has operated a large energy spot market for a while, one may reasonably assume that these prices may have had a significant impact on the overall Ontario Hydro system for the period of interest. Thus, PJM electricity spot price data for the corresponding time period is used here as the price input for the forecasting process.

In this work, the requirement of a separate validation set is eliminated because the ELM model does not require any iterative tuning based on validation set. The trained model was directly validated using the testing data. In the first case study, a basic ELM network was tuned with a simple data without any decomposition and with different activation function to determine the most suitable activation function for the fixed number of hidden nodes. The performance with sigmoid, sinusoidal and hard limit, triangular, radial basics function was evaluated for the selection of activation function. Figure 7 shows the performance comparison and it was observed that Hard limit and sigmoid function gives a poor performance in comparison to radbas, tribas and sin. The performance of tribas activation function was still on the better side and is used as a default activation function in all the further analysis.

Above figure 7 represents accuracy of different activation functions with a fixed number of hidden nodes. As per the figure there is a close accuracy between tribas and radbas, whereas tribas is having high as compared to radbas.

The same result of previous Figure 7 has been represented in bar plot Figure 8 so as to distinguish the difference between different activation functions.

Once the activation function has been identified the robustness of the activation function has been analyzed for different number of nodes for all activation functions. And there is a remarkable difference between tribas activation function and rest of the activation functions. For different number of hidden nodes tribas activation function shows an average accuracy of 80% and with 10 numbers of hidden nodes the result is even better with an accuracy of around 98%. Though processing time is not that much to be considered as a decision making parameter for the application but even with selected number of hidden nodes and with selected activation function the result is very much encouraging. This execution time has been represented in above figure 10. Here radbas is faster as compared to tribas, but by considering both timing accuracy tribas is better. Above plot represents the same with a distinguishable difference between different numbers of hidden nodes for tribas activation function. Though there is little difference between 10 and 30 number of hidden nodes. 10 number of hidden nodes chosen considering both accuracy and time. Once the activation function, the number of hidden nodes and the training period duration is fixed for the ELM model as explained above, training and testing data sets corresponding to different markets are given to the model and next hour prices are predicted.

**Satabdi Swain et al.**

## CONCLUSION

In the present scenario where competition and globalization is overtaking all fields of life, electricity price forecasting plays a more and more prominent role in a decision support system of power market participants as well as consumers. Developing more accurate and timely price forecasting methods have become an important research topic. ANN technique has been proved as an effective methodology in forecasting of price in electricity market with minimum error. But the randomness of ANN and processing time makes it unusable while dealing with large datasets. In this research work we apply relatively novel neural network technique; we apply ELM powerful technique for electricity price forecasting. The work has been verified in two phases, first phase selects activation function with respect to accuracy and in second phase the timing has been analyzed. And of course to check the robustness of the selected activation function the result has been analyzed for all other activation function. From result there is a close call between tribas and radbas but by considering both parameters processing time and accuracy tribas shows a promising result. The accuracy achieved is 92.506 with 10 numbers of hidden nodes.

### ABSTRACT

Agriculture depends on many factors, soil is one of them. There are innumerable number of components present in the soil, which are important for different types of farming and its total production amount. This paper used a set of well-known Machine learning algorithms to remotely monitor soil and track parameters present in it. The objective of the paper is to determine the important factors that are present in the soil and their amount, which can be used to increase the productivity by choosing the appropriate fertilizers or manure for the particular soil. The proposed system has achieved an overall accuracy of 93% using Support Vector Machine for an underlying dataset containing 92,832 number of soil samples, collected by Karnataka State Government and available in Kaggle repository.

**Keywords:** Machine Learning; Support Vector Machine (SVM)

## INTRODUCTION

India is a country well known for its innumerable Agricultural products and where the majority of the population relies heavily on the agricultural sector. For agriculture, the soil is the basic component that is required. In soil there are many factors like pH, Electrical Conductivity, Organic carbon, Potassium, Phosphorus, Sulphur, Manganese, Zinc, Boron, Copper, and Iron, those have a high on amount and quality of farming. Agriculture land area in India spans around 159.7 million hectares which is the second largest in the world. Its gross irrigated crop area of 82.6 million hectares is the largest in the world. The Indian agricultural industry accounts for 18 per cent of India's Gross Domestic Product (GDP) and generates 50% of the country's workforce with employment. Soil is very essential for every human being and is a valuable resource. [1].

**Nitish Mahanand et al.**

There are a number of factors behind these soil variations. Soil health is a state of a soil linking the range of ecosystem functions to its environment. The health of soil arises from favourable interactions of all components of the soil that belongs together. Soil health monitoring is carried out as a status assessment but moves to be restricted to agronomic targets, for obvious reasons. Soil health depends on soil biodiversity and can be improved by proper management. Inorganic fertilizers do not necessarily damage soil health if it can be used in an appropriate quantity without excessive use. Soils differ considerably in their chemical and physical properties, depending on their age and the environments in which they are produced (parent material, atmosphere, topography and vegetation) [2]. Because of the climate conditions, the soils vary mainly from region to region. Visually observable data are difficult to decipher at a single glance, leading to many farmers making inaccurate assumptions about the soil [3].

As a result, sometimes it's harmful to the soil. Farmers lack some advice from the expert on how to deal with the soil's fertilizer. There has been insufficient knowledge regarding the deficiency of the parameters [4]. This is an underlying experience for the proposed methodology that aims to accurately detect the deficiency. The methodology suggested in the paper comprises the common deficiency of the parameters in the state of Karnataka and they are Phosphorus, Potassium, Zinc, Boron, Manganese, Iron, and Copper. The dataset used in this project contains 92832 rows, which are the data of different farmers of the different districts in Karnataka. Broadly, the proposed methodology consists of three major steps: data acquisition, pre-processing, and classification. The dataset is acquired by the Karnataka Government. In the next step, normalization of the dataset is required where NaN values were there. After that pre-processed the data including some visualization techniques. After that classification is done by dividing the dataset into correct and deficient one and by using deep learning Support Vector Machine.

Soil health can't be determined by only calculating crop yield, water quality, or any other single test. Soil health cannot be directly measured. Soil health requires knowledge its physical, chemical and biological properties [5]. And in this project, the chemical properties of the soil are included which will be taken by Machine Learning, and by the use of IoT it will take all the physical properties [6]. In this, biological indicators are not that much needed because it's hard to find the indicators from the soil [7]. We can find the biodiversity in the soil in different regions.

We have developed a soil quality index assessment method by taking into account soil texture, organic carbon, pH, water available, cation exchange capacity, bulk density, total porosity, saturated hydraulic conductivity, salinity, aggregate stability, and slope and soil depth [8]. They are Alluvial Soil, Black Soil, Red Soil, and Desert Soil. And basically, in the state of Karnataka, Red Soil and Black Soil is found. So, the soil is deficient in lime, phosphate, manganese, nitrogen, humus, potash, nitrogen, phosphorus, and organic matter. Basically in India, Rice-wheat system covers about 32% of the total rice area and 42% of the total wheat area in the Indo-Gangetic plains (IGP) and accounts for one quarter to one-third of the total rice and wheat production [9].

So, for farming people always busy for six months only. The identification of such components in the soil is very important in preventing any heavy losses in yield as well as the quantity of the agriculture field. Monitoring of the soil manually is a difficult task due to its complex nature and it's a time-consuming process. In addition, a soil rich in organic carbon and nutrients (commonly known as high-quality soils) cannot be considered a good soil if it causes harm to crops or supports large parasite populations [10]. Therefore, to reduce the manual effort this project has been designed. This project is useful in several fields whenever we need to monitor the soil. With that, this project can send a notification to the respective farmers and give some idea on which fertilizers will be the best for their field. Additionally, we could add IoT into it with which it can measure the humidity, moisture, temperature, water of the soil which are some environmental properties of the soil. This Soil Monitoring System based on Machine Learning and IoT can be accessed remotely by using a simple interface.

This paper has been organized into four sections. Section-2 demonstrates the proposed system and its methodology. Section-3 provides an analysis of results. Finally, Section-4 concludes this study.

## METHODOLOGY

The project approaches three important stages:

Data Acquisition, Data pre-processing, and Classification as shown in [Figure-1].

### Data Acquisition

The soil dataset consists of soil samples of different villages in Karnataka. The dataset was downloaded using from Kaggle repository. The acquired dataset consists of around 92832 rows belonging to 4 classes. The dataset includes data of different parameters (chemical properties) which are stored in different columns. This dataset includes 11 number of columns. Each of the data belongs to the different farmers of different districts of the Karnataka state.

### Data Pre-Processing

The acquired dataset consisted of rows with minimal NaN (Not a Number) values and to update the NaN values the average of each column was taken. The data in the dataset were normalized in order to speed up the training process and make the model training computationally. The process of standardizing both input and output variables moves to speed up the training process. We established a specific method for selecting the most representative indicators from the existing large data sets, merging indicators into location-specific indices of soil quality [11]. The improvement of the numerical data of the optimization issue is done through this. To visualize the data, the dataset is grouped by different districts of the state and find out the similarities in the components by which anyone can get those things easily.

### Classification

In this paper the support vector machine (SVM) algorithm is studied in detail. SVM is a common nonlinear technique and a theoretically powerful tool for the classification of all types of datasets [12]. Support Vector Machine (SVM) is a supervised machine learning algorithm that can be applied on classification or regression problems. It's mostly used in classification issues though. They're able to categorize the new class after giving an SVM model sets of named training data for each group. Enter Support Vector Machines (SVM): a simple and efficient classification algorithm with a limited amount of data that performs very well. In each class the closest points are denoted as support vectors. If other points are omitted in the training set the measured judgment boundary remains the same [12]. We extract the necessary functions and segment them into data for training and testing.

Eighty percent of the data is used for training and the remaining 20 percent for testing. The SVM model was constructed using the NumPy library. An  $\alpha$  (0.0001) is the learning rate and is set to 1 / epochs by the regularization parameter  $\lambda$ . Hence the regularizing value reduces the amount of increases in epochs. After classifying the dataset, we get the deficient data from which to apply the proposed model [13]. Various ML techniques like linear regression, Decision tree, Random Forest, and Support Vector Machine (SVM) are used to construct the classifier. Where is a strong complete method for building the model among all of SVM? SVM is used as a classifier in this methodology. It's mostly used in classification issues though. We map each data element in the SVM algorithm as a point in n-dimensional space (where n is the number of features you have) with each feature being the value of a particular coordinate. Then, by finding the hyper plane which differentiates the two classes very well, we perform classification.

## RESULT AND DISCUSSION

To analyze the performance of the defined models based on the input extracted feature set, Overall curacy has been considered and listed in [Table-2].

The best classification accuracy of 93.33% is achieved by the classifier model using SVM that is shown by GREEN color in bar graph [Figure-5]. The other models using Linear Regression and Naïve Bayes are also performing well on the underlying dataset and compared.

## CONCLUSION AND FUTURE WORK

In India, Agricultural sector is one of the most important sector over which majority of the population is relies on. Detection of deficiency in soil is critical for the growth of Indian economy. The proposed system has achieved an overall accuracy of 93% using Support Vector Machine for an underlying dataset containing 92,832 number of soil samples. In future the model can be remodeled to predict and classify soil samples on the basis of image data.

### ABSTRACT

Sentiment Analysis is one of the notable subjects in the discipline of opinion mining which falls under the category of Machine Learning domain where it deals with the recognition and exploration of sentimental texts available on the social media. Likely, Twitter is also one of a kind social platform where it streams millions and millions of tweets from users. The aim of this project is to compare different supervised learning methodologies for binary classifications of unknown live streaming tweets and find out their accuracy rate for correct results. These results will be helpful to conduct the survey on user's tone of the sentiment on various issues by the help of passing a keyword and it conducts search on tweets in relation to the keyword.

**Keywords:** Twitter Sentiment Analysis, Natural Language Processing, Supervised Binary Classification, Positive and Negative Tweets

### INTRODUCTION

The advent of social media such as Facebook, Twitter, Google Plus, etc. has attracted a massive number of active internet users who have found a very innovative, cheap and easy way to get themselves connected with their kith and kin.[9] Communication is not just restricted to personal grounds, people have used social media to start small businesses and reach out to the rest of the world to sell their products. Even firms who are not connected to the outside world through the Internet have found this way of marketing attractive and have extended their frontiers to the digital platform for the purpose of advertising and escalating their sales.

**Malini Patel et al.**

Social media has gained popularity on political grounds too, where the political parties put forward their propaganda on the social media sites and try to influence the mass through their slogans, promises and records of their past achievements of welfare. So, why are we discussing this? Over the last few years, sentiment analysers have gained huge popularity particularly among marketers, especially operating in the digital world. By analysing the tone of the people over the Internet, we can have a rough idea about the predications of a forthcoming outcome of any major event occurring in our nation or at any part of the world.

This is a very innovative way that substitutes the traditional method of collecting feedback from people that used to be very hectic and biased. But through the Internet, people can raise out their voices fearlessly against any odd, even anonymously if they don't want their identity to be revealed to the general public. Among all, Twitter has become very popular and precise when it comes to analysing the sentiments of the people on trending topics is its exclusive functionality. Retrieving data from social media has fascinated many researchers for working in text analysis. Insights of such work can be found in the works of Sandhu[3], who has proved the same. "Twitter Sentiment Analysis" is a simple implementation of a sentiment analyser which aims to classify the sentiment polarity of a tweet[13]. Our purpose is to fetch live tweets from the Twitter and apply machine learning techniques to predict the polarity of the tone of the people on any particular issue. There is an implementation of one of the Natural Language Processing model, i.e., TF-IDF Vectorizer for text vectorization. This is a very basic implementation and hence we have limited ourselves to predict if a tweet is giving a positive or a negative tone. In the rest of the paper, we have discussed about pre-processing, model building, training & testing, and finding the best result and implementing it on the Twitter data.

#### **RELATED WORK**

There has been a lot of work in this area that are published in the top machine learning platforms that are periodically updated with new functionalities for a better comprehension for the readers. Pang [6], in his work has made use of SVM and Naïve Bayes and concluded that in spite of their simplistic approach, these two algorithms do not work well in sentiment classifications and hence the problem becomes a more challenging task. Kotsiantis [1], has demonstrated all possible supervised learning algorithms, also providing a useful guide to the research work. Kharde [2], has provided insights on the surveys concerning twitter sentiment analysis. Another work, Mathews [4], on opinion mining shows analogy. Scikit-learn[7], helped a lot to understand the algorithms and the codes. The content is updated and easy to understand.

#### **DATASET**

For our work, we have used the Cornell Dataset that contains 1000 positive and 1000 negative tweets on movies. This dataset can be downloaded from the following site: <http://www.cs.cornell.edu/people/pabo/movie-review-data/> which is considered as training set for our model to find out the best supervised learning binary classifier to deploy it on testing set. This has been extensively exclusively for training in projects concerning opinion mining. A reference can be found in the work of Pang [6]. Using Twitter API, tweets fetched from Twitter are testing set used as corpus of text [10] posts for the model deployment for predicting the sentiment of the tweet to check the binary classifier gets the correct result or not which had the higher accuracy score than rest of the classifiers.

#### **PREPROCESSING TECHNIQUES OF DATA**

Data pre-processing is the most vital step followed by data gathering and collection in Machine Learning process. Our dataset includes raw data [12] which needs to be processed first for better analysis of sentiments. This technique is applied on both training and testing set. Therefore the proposed model uses these following techniques for pre-processing like

**Malini Patel et al.**

### Tokenization

Tokenization is the first step in pre-processing of the raw tweets which involves noise in terms of unwanted fuzzy words, junk characters and symbols and stopwords etc.[12]

There are two types of tokenization. They are:

- Firstly, sentence tokenization that breaks paragraph into sentences.
- Secondly, word tokenization that breaks paragraphs into words.

For example: “Where are you from? I am from India.” When we performed sentence tokenize operation on the paragraph, it yielded: ['Where are you from?', 'I am from India.']. When we performed word tokenize operation on the paragraph, it yielded: ['Where', 'are', 'you', 'from', '?', 'I', 'am', 'from', 'India', '.'].]

### Stopwords

Stop words are also referred to as noise in sentences. These need to be filtered out while performing sentiment analysis because they do not convey any sentiment and should hence be discarded. In the previous example (4.1), when the tokenized text, ['Where', 'are', 'you', 'from', '?', 'I', 'am', 'from', 'India', '.'] is given as input, it compares each word with the built in list of stopwords. Those words that do not match with the existing list of stopwords are appended into another list. The example yields an output, ['Where', '?', 'I', 'India', '.'].]

### Regular Expression

A Regular Expression is a text string that identifies a specific search pattern which is used to match or replace patterns inside a string with minimal code for removal of unwanted characters so as to generate the clean corpus. It comes with some pre-defined methods that help us achieve the task instead of going for loops. Special characters like “\$”, “#”, “%”, etc. can be removed using methods available in re module. Similarly, letters and punctuations that do not convey any meaning can be discarded using regular expression. For example '\s+' matches any whitespace character. The '+' notation on the end suggests a match with one or more spaces. Regular expressions are a relief when we are working on a huge amount of text data by reducing code size.

## METHODOLOGY

### TF-IDF Model

It is a numerical statistic feature extractor model that is intended to detect how important a word is to a document in a collection or corpus. The TF-IDF value is directly proportional to the number of times a word appears in the document intending the frequency of the word in the corpus. A reference to this model can be found in the works of Ramos[5]. This model is one of the many existing vectorizer models in equation (1).

$$\text{TF-IDF Model} = \text{TF} * \text{IDF} \quad (1)$$

Where TF (Term Frequency) = (Number of occurrences of a word in a document)/ (Total number of sentences containing the word)

IDF (Inverse Document Frequency) = log base (Number of sentences)/(Total number of sentences containing the word)

Example:

“Service is good today.”

“Ambience is really nice.”

“Today food is good and salad is nice.”

**Malini Patel et al.**

Demonstrating the above example on how to find the values for each word using TF-IDF Model to prioritize the words which will help in prediction the sentiment of the texts more than the other words, i.e., less the number of occurrences of words, higher the value. Table 1 evaluates the Term Frequency (TF) of each word of every 3 sentences as shown in example. Table 2 evaluates the Inverse Document Frequency (IDF) of each word same as TF. Table 3 evaluates the product of TF and IDF values taken from the results of above table. Table 4 demonstrates the word values from each sentences and it's clearly noticeable that the words which add meaning to the texts have values to them. These results are useful when it comes to pass the input texts through different classifiers to predict sentiment of the text.

**Logistic Regression classifier**

It is a binary classifier named after the logistic function, also called the sigmoid function which is an S-shaped curve that takes any real number as input and map it into a value in between the range of 0 and 1. Mathematically, this can be expressed in equation (2) as

$$y = 1 / (1 + e^{-x}) \tag{2}$$

where the x-axis represents input data and the y-axis represents the probabilistic output, ranging from 0 to 1, through a continuous set of values.

**Naive Bayes Classifier**

It is also a binary classifier probabilistic machine learning model which predicts the outcomes on the basis of the previous data records and follows the principle of Bayes Theorem. Mathematically, this can be expressed in equation (3) as

$$P(y|X) = \{P(X|y)P(y)\} / P(X) \tag{3}$$

where y represents the class variable given a previous condition. X represents the parameters or features and is a set.  $X = \{x_1, x_2, x_3, \dots, x_n\}$ . For example, if I need to visit a fair, I need to keep in mind some pre-defined conditions as in the weather, availability of a friend and the proximity of the fair from my house. These all conditions can be denoted as  $x_1, x_2$  and  $x_3$ . The probability of visiting the fair,  $P(y|Z)$  depends on these conditions.. A reference on the implementation of this algorithm can be found in Kharde [2].

**K-Nearest Neighbour Classifier**

It is a Machine Learning algorithm that can be used for both regression as well as classification problems. Classification problems, where K-Nearest neighbor is in effect, we go for voting of neighboring values with respect to the value under study. Mathematically, KNN makes use of the Euclidean distance formula for calculating the distance between the value under study and its neighbors. New cluster-head  $C_i$  of each cluster is calculated using following formula in equation (4):

$$C_i = \frac{1}{n_i} \sum_{d_j \in S_i} d_j \quad i = 1, 2, \dots, k \tag{4}$$

where  $d_j$  denotes the data points that belong to the cluster  $S_i$ ;  $n_i$  is the number of documents in cluster  $S_i$

**Decision Tree Classifier**

It a general, predictive modelling tool that is used in non-linear decision making with simple linear decision surface. It is a tree-like graph with nodes representing the place where we choose an attribute and ask a queries. The edges depict response to the queries and the leaves depict the actual outcomes or class label. For example, we need to find out if a person is physically fit, taking ideal criteria into consideration.

**Malini Patel et al.**

The [Figure-2] demonstrates the working of decision tree classifier as it suggests node represents the chosen attribute like this system projects texts or tweets to receive a response either 1 or 0, i.e, 1 represents positive tone and 0 represents negative tone are the outcomes at the leaves.

### Random Forest Classifier

It consists of a bunch of decision trees. Decision trees are very data sensitive. Hence, small changes in the training set makes dramatic changes in the tree structures, a process known as bagging. The principle this algorithm follows is that a tree is not behaviorally related to any other tree in the model. The chances of making correct prediction increases with an increase in the number of uncorrelated trees. General equation (5) of Random Forest Prediction for a classification problem:

$$f(X) = \text{majority vote of all predicted classes 1 over 0 or 0 over 1} \quad (5)$$

### Support Vector Machine

It is a linear model also for both classification and regression problems. The idea of SVM is simple: The algorithm creates a separator or a hyper-plane which separates the data into classes.

A reference on the implementation of this algorithm can be found in Kharde [2], whose work shows detailed use of SVM in sentiment analysis. The [Figure-2] illustrates support vectors falling on either side of the hyper-plane can be categorized into two classes 1 or -1.

### Passive Aggressive Algorithms

It is an umbrella term for a group of online learning algorithms for both classification and regression suggested by Crammer [8] et al. The objective of this algorithm is to train a model in an incremental manner while modifying the parameters only when needed and discarding the updates that might alter the equilibrium. Contextually, these are very similar to Perceptron. They make use of a regularization parameter(c).

### Perceptron Binary Classifier

It is an algorithm for supervised learning of binary classifiers. The idea of perceptron was inspired from information processing in a neuron. In a perceptron, the input data from the training set is combined and passed through a linear equation, that is, the activation function. Mathematically, this is expressed in equation (6) as activation = sum (weight<sub>i</sub> \* x<sub>i</sub>) + bias (6)

This value is then transformed into a prediction using the transfer function. Mathematically, this is expressed as prediction = 1.0 if activation  $\geq$  0.0 else 0. The [Figure-3] shows that let's suppose every single words are taken as inputs (x<sub>1</sub>, x<sub>2</sub>, x<sub>3</sub>, ..., x<sub>n</sub>) after the pre-processing of dataset and then put into binary classifier that makes prediction depending upon linear predictor function combining a set of weights with the feature vectors (Term Frequency and/or Inverse Document Frequency) and provides output y(1) or y(0).

## TESTS AND RESULTS

The machine learning algorithms were applied on the training set and accuracy was obtained for each case. The model that gave the highest accuracy was dumped in a pickle file for further implementation on the live streaming twitter data.[11]

Table 5 below presents the accuracy percentage of different classifiers in sentiment prediction of training set. Out of which Simple Perceptron for Binary Classification have highest accuracy percentage followed by Logistic Regression Classifier. These accuracy percentage becomes the deciding factor for which classifier to be used for predicting the tone of tweets fetched through Twitter in our proposed system.

**Malini Patel et al.**

The [Figure-4] illustrates the graphical representations of the accuracy percentage of the models used for analysing the sentiment of the texts in the form of bar charts. The [Figure-5] depicts the graphical representation of count of positive and negative tweets from the set of 1000 tweets fetched from Twitter on any matter.

## CONCLUSION

In this paper, we have applied eight different machine learning algorithms on the Cornell Dataset. We used the TF-IDF (Term Frequency – Inverse Documentation Frequency) vectorizer, a numerical statistic that helped us to find out how important a word is in a corpus. Among all the machine learning algorithms we have implemented, we found that SVM, Logistic Regression and Perceptron give the highest accuracy that is 83%, with very narrow deviations. So, in order to perform a sentiment analysis on the above data, we can choose any one of the algorithms. Twitter Sentiment Analysis is one of the topics that is widely worked upon by computer scientists, researchers, teachers, students and business analysts from all over the world. We have restricted our work to the utmost basic level that can be very well comprehended by people who are new in this field. Here, we have done a binary classification that is grouping the tweets into positive and negative sentiments. Further classifications can include tweets that intend racial or non-racial, sexist or non-sexist, neutral, happiness or sadness.

### ABSTRACT

Our daily life is connected with Data, where enormous data is generated and processed with modern computing techniques. Big data is not about enormous data but it is all about different sources of data in form of volume, Variety, velocity and value of data. Big data applications offer a wide range of business solutions based on business data such as education, health care, Finance, Banking and appropriate for real world data problems. This paper is predominantly focused on big data theoretical knowledge, big data analytics life cycle, applications, trends and research challenges.

**Keywords:** big data security, Smart Farming, Volume, Velocity, Variety.

### INTRODUCTION

In Today's competitive world, Data is the main resource for any business activity. Now day's organizations are facing problem in dealing with huge volumes of data challenges for their better business. Huge volumes data is being generated from different sources like networks, machines, social media, and business processes or business applications. Data is rapidly growing in terms of images, video, social media networks, collected and transmitted data. The most effective problems in traditional databases are not to handle huge data, in which huge data may not fit for current data database storage capacity, so in order to improve huge data storage, data processing and transmission of data from peer to peer communication, for all these problems the cutting-edge clarification is big data analytics. Big data name itself suggest that definition is huge data with limited storage capacity, that means Big data raises to immense and enormous data sets that may be in structured or unstructured format. Big data evolution starts in 21<sup>st</sup> century and every technology is making use of big data technologies. According to Gartner: Big data is huge-volume, fast-velocity and different-variety information assets that demand innovative platform for enhanced insights and decision making. The Big Data analytics is indeed a revolution in the field of Information Technology. The use of Data analytics by the companies is enhancing every year [1]. The best examples for big data is internet applications, Mobile internet, Google data, Facebook data, twitter data, movie reviews, product reviews etc. Big data structure defined in three ways: structured, unstructured and semi-structured data. Structured data defined as data is processed, stored and accessed in a fixed format. It follows a well-structured model and consistency, Ex: JSON, XML, CSV, TSV, and email. Unstructured data is defined by means of the collected data is not in consistent

24033

**P Annan Naidu**

order or it may not follow the standard data models, Web applications data like transaction history files, blogs are considered as examples of unstructured data. Finally semi-structured data, in which data may be in either structured data format or unstructured dataformat.

**Big Data Analytics Life Cycle**

Big Data Analytics (BDA) analysis process stays different from traditional analysis process because of its faces such as volume, variety, veracity, velocity and Value. In order to address requirements of the huge volumes of data analysis through BDA, a step- by-step procedure is required.

Big data analytics life cycle process is alienated into the following nine phases

1. Business CaseAssessment
2. Data Identification
3. Data Acquisition &Filtering
4. Data Extraction
5. Data Validation & Cleaning
6. Data Aggregation & Representation
7. Data Analysis
8. Data Visualization
9. Exploitation of AnalysisResults

**Business CaseAssessment**

Big data analytics life cycle starts with a well-structured business data for clear understanding, motivation and proper justification of analysis. In this stage business data will be created, accessed and approved for further data processing of BDA. Business case evaluation determined the business requirements like it helps to decision makers to understand business needs, it also helps to determine business assessment criteria. This is a first stage in which all the business requirements are well documented. The outcome of this stage is provides all budget matters in which it specifies about purchase of implements, hardware and exercise must be in advance.

**Data Identification**

In This stage, identifying a variety of data resources based on business development and nature of the business determination. The mandatory data sets may be collected either internal or external. In case of internal, data sets collected from internal resources, and this data is compiled and well-defined. In case of external, data sets collected from third party dataproviders.

**Data Acquisition & Filtering**

In prior stage, data is identified in various resources and identified in different formats. Once data is identified then data may be collected based on requirements, at this stage, collected data is filtered by removing error data or missing values in order to make sure that data is used to fulfill analysis objectives. Filtering applied on both internal data sets and external data sets, through this process data may be filtered based on the needs of analysis process.

**Data Extraction**

Whatever data sets are acquired as input for big data solution, that data might be not well-suitedthrough the actual requirement of big data result, data extraction stage remains focused on extracting distinct data and transforming data into suitable data for big data result then it can be used for analyticdetermination.

**Data Validation & Cleaning**

In big data solution data can be unstructured data or may be redundant data. When this data is considered for big data data analysis then invalid data can produce falsify data. So it is very much required the removing of redundant and invalid data from the given input. Data validation and cleaning is dedicated to validate data and removing invalid data.

P Annan Naidu

### Data Aggregation & Representation

Data collected for big data solution may be distributed across multiple data sets. Data aggregation and representation is focused on distributed data is represented group data through its common fields.

### Data Analysis

This stage carry out the data analytics task, in which the required data is analyzed depending on type of data set, Data analysis is an iterative process in which data is analysed until the proper data pattern covered. Data analysis can be two way process such as confirmatory analysis or exploratory analysis.

### Data Visualization

Data analysis stage provides clear insights of data as per the required pattern. But still it may not understand the data for business users. In order to elucidate the data analysis results, the results must remain representing in graphical representation with the data analysis outcome data. Data visualization is a visualize tool in which data can be represented in form of graphical representation like charts, graphs and plot for a better interpretation of business users.

### Exploitation of Analysis Results

This is the last stage of big data analytics life cycle, in which data analysis results used for decision making and further developments.

### Big Data Trends & Research Challenges

#### Big data Security

Big Data security provides strong protection for the deployed data where the big data is restricted to access by unauthorized persons. The main emphasis of big data security is unofficial users and interventions with firewalls, strong user authentication, end-user training, and intrusion protection systems (IPS) and intrusion detection systems (IDS). The following are identified as Data Security challenges [2]

- Vulnerability to fake data generation
- Potential presence of untrusted mappers
- Troubles of cryptographic protection
- Possibility of sensitive information mining
- Struggles of granular access control
- Data provenance difficulties
- High speed of NoSQL databases' evolution and lack of security focus
- Absent security audits
- Securing and protecting data in real-time

### Big data Analytics in the Cloud

In Current computing world, big data and cloud computing are center concern of IT. Both are available with own services for better business solution. Big data is deals with huge data in form of structured, unstructured and semi structured, cloud computing deals with services and infrastructure. Cloud computing provides on demand services with pay and use mode. Big data in cloud providing new business opportunities and supporting big data analysis

### Data Storage

Several solutions were proposed to store and retrieve large amounts of data demanded by Big Data, some of which are currently used in Clouds. Internet-scale file systems such as the Google File System (GFS) attempt to provide the robustness, scalability, and reliability that certain Internet services need [4]. Other solutions provide object-store capabilities where files can be replicated across multiple geographical sites to improve redundancy, scalability, and data availability. Example includes Amazon Simple Storage Service (S3), Nirvanix Cloud Storage, Open Stack Swift and Windows Azure Binary Large Object (Blob) storage. Although these solutions provide the scalability and

24035

### P Annan Naidu

redundancy that many Cloud applications require, they sometimes do not meet the concurrency and performance needs of certain analytics applications [5].

Big data security is the combined term for all the measures and tools used to safeguard both the data and analytics processes from attacks, theft, or other malicious activities that could harm or negatively affect them. Cloud computing involves Peer-to-peer network with decentralized network design on liberated nodes without any central control. When data is decentralized and distributed among different nodes, data may be exposed to other problems like security and privacy. Sensitive information in the perspective of cloud computing incorporates data from a wide range of different nodes and disciplines. Security and privacy remains one of the critical concerns of big data in cloud computing. Ensuring data security and protecting privacy has become extremely difficult as information is spread and replicated around the globe [6]. The major security challenges are data breach [10] and Multi-tenancy [9].

#### Big Data in Smart Farming

Smart Farming is an evolving growth that accentuates the use of modern technologies like IoT and Cloud technology for better productivity and optimized man power in farm management. Farming through technology, which requires huge value of data with wide variability of data that can be bagged, and analyzed for better result making. When this process starts with huge data then big data plays major role for storing, analyzing used for further process of farm management. Big data application in smart farming is mainly focused on social and economic challenges to be identified. Big data technologies are live an essential, common role in this development [7]. Life cycle process of Smart farming using Big data- access include the following steps; 1) Smart sensing and monitoring- to identify soil, water, light, humidity and temperature, 2) Smart control- mainly focused on data generation, data capture, data analysis, data processing and data transfer, 3) Smart analysis and planning- main role is to identify soil type, yield prediction, soil health and crop health. 4) Data storage- cloud based, hybrid data Storage, cloud-based warehouse. Big data in Smart farming [7]; the following key challenges are identified as big data applications in smart farming.

- Boosting productivity and innovation Managing environmental challenges
- Better supply chain management
- Cost savings and business opportunities

## CONCLUSIONS

Big Data has become important for both public and private organizations to manage their data, data processing in order to solve domain specific public and private problems. I understood and believe the importance of big data, based on that, I have present some important and relevant topics of big data and also described the role of Big data in different emerging fields like cloud computing, data security, smart farming. In my future work may be based on the above said challenges of big data.

**Table-1 5Vs of big data**

Characteristics	Definition	Example
Volume	Volume refers the huge amount of data, refers the size of ever increasing data of the computation world	Data is being generated in every second through internet applications or social media, for example Google generated data Gmail data, Google search engine data, YouTube data. Facebook data, Instagram data, WhatsApp data
Velocity	Velocity measures how fast data is produced, processed and modified. It refers high speed of growth of data	72 hours of video are uploaded to YouTube every minute[8]
Variety	Variety refers the type and nature of data, that means data available from various sources in various formats	Structured, unstructured and semi structured data
Veracity	Veracity signifies the quality then validity of the data files collected. It is basically the degree of credibility and reliability of collected data.	High speed Data processing in various computing applications
Value	It is not about the huge data collected, but it is all about amount of valuable, reliable and genuine data collected.	

**Table-2: Big data Applications**

Sl.NO.	Big Data Applications	Examples
1	Health Care	Clinical decision Support, Disease Pattern Analysis Electronic Health cards , Mobilized health record Disease Register data , Disease risk prevention Drug discovery development analysis
2	Telecommunication	Customer Call Record , Mobile user tracking Network analysis, Revenue analysis
3	Transportation Industry	Direction planning, traffic management road infrastructure
4	Financial &Investment Sectors	Mismanagement of credit/debit cards, User segmentation, Improves Cyber security, Efficient risk management, Trade surveillance
5	Government Sector	Welfare Schemes Cyber Security
6	Media	Predicting the interests of audiences sentiment analysis

**P Annan Naidu**

		of customer reviews, on-demand scheduling of media streams in digital media distribution platforms
7	Education	Customize Programs, Reduce dropouts, Improve Learning Possibilities, Grading Systems Career Prediction

### ABSTRACT

Medical Image plays an important role in medical field. In this context, this paper is predominantly focused on applying image segmentation techniques on medical image. Image segmentation is one of the basic requirements of image processing. Its objective is to determine a partition of an image into a finite number of semantically important regions. Image segmentation process aims to divide an image into various regions for better image processing, usually used in patter recognition. In this paper deafened different medical image modalities, also define segmentation techniques and its implementation based on a medical image.

**Keywords:** Segmentation, image modalities, threshold, edge based, clustering based.

### INTRODUCTION

The Key role of Medical images has worthy effect on medicine, diagnosis, and treatment. Medical imaging is the technique of producing visual representations of areas inside the human body to diagnose medical problems and monitor treatment. It has had a huge impact on public health. Medical imaging is performed in various modalities such as CT (Computer Tomography), MRI (Magnetic Resonance Imaging), Ultrasound, X-ray, ultrasound and positron emission tomography (PET), etc. The most important part of image processing is image segmentation. The increased availability and usage of modern medical imaging induced a strong need for automatic medical image segmentation. The aim of semantic segmentation is to identify common features in an input image by learning and then labelling each pixel in an image with a class (e.g. background, kidney or tumour) [1].

The most important part of medical image processing is image segmentation. Image segmentation is a procedure for extracting the region of interest (ROI) through an automatic or semi-automatic process. Many image segmentation methods have been used in medical applications to segment tissues and body organs [2]. Based on the recent studies or research, image segmentation widely used in medical image analysis in order to segment body organs, Automatic Liver Segmentation [3], Automatic Brain Tissue Segmentation [4], Automatic Tissue Image Segmentation

P. Annan Naidu

[5]. Segmentation is a process of partition an image into different regions containing each region with same attributes. To be meaningful and useful for image analysis and interpretation, the regions should strongly relate to depicted objects or features of interest. Meaningful segmentation is the first step from low-level image processing transforming a greyscale or colour image into one or more other images to high-level image description in terms of features, objects, and scenes. The success of image analysis depends on reliability of segmentation, but an accurate partitioning of an image is generally a very challenging problem. The Basic

### principles for Segmentation

1. All pixels have to be assigned to regions.
2. Each pixel has to belong to a single region only.
3. Each region is a connected set of pixels.
4. Each region has to be uniform with respect to a given predicate.
5. Any merged pair of adjacent regions has to be non-uniform.

### The main contributions of this paper is as follows

1. Defining different Image modalities
2. Discussed related work of image segmentation
3. Define and implements segmentation techniques.

### Image Modalities: MRI, CT, US

The imaging modalities used in biology and medicine are based on a variety of energy sources, including light, electrons, lasers, X-rays, radionuclides, ultrasound and nuclear magnetic resonance image [13]. Common Image Modalities includes CT (Computer Tomography), MRI (Magnetic Resonance Imaging), Ultrasound, X-ray. These modalities are very useful for patient follow-up, with regards to the progress of the disease state, which has already been diagnosed, and/or is undergoing a treatment plan [ref-1:16]. CT scans are a form of X-ray that creates a 3D picture for diagnosis. CT scans provide greater clarity than conventional X-rays with more detailed images of the internal organs, bones, soft tissue and blood vessels within the body [17].

CT scan combines a series of x-ray images taken from many different angles and computer processing to create cross-sectional images of the bones and soft tissues inside a body. The resulting image can be compared to a slice of bread. Each slice can be viewed individually from the whole "loaf" to get a better visualization of the body. CT scan images can provide much more information than plain X-rays [18]. MRI, Commonly used to examine internal body structures to diagnose strokes, tumours, spinal cord injuries, aneurysms and brain function. MR imaging of the body is performed to evaluate: [19]

- Organs of the chest and abdomen—including the heart, liver, biliary tract, kidneys, spleen, bowel, pancreas, and adrenal glands.
- pelvic organs including the bladder and the reproductive organs such as the uterus and ovaries in females and the prostate gland in males.
- blood vessels (including MR Angiography).
- lymph nodes.

**Ultrasound imaging (sonography)** uses high-frequency sound waves to view inside the body. Because ultrasound images are captured in real-time, they can also show movement of the body's internal organs as well as blood flowing through the blood vessels [20].

### Related Work

This section mainly focuses on different applications of segmentation on medical imaging. Medical imaging is one of the emerging research areas for decades, in past years there will be enough research already in progressed. One of the basic problems in medical imaging is to precisely segment structures of interest from a huge dataset, accurately

24040

**P. Annan Naidu**

represent them, efficiently visualize them, and perform measurements appropriate for diagnosis, surgery, and therapy guidance, or other applications [6],[7].LixuGu, *et al.* Propose a novel multistage method for three-dimensional (3-D) segmentation of medical images and a new radial distance-based segmentation validation approach. This approach is tested on 12 CT and 3 MRI images of the brain, heart, and kidney, to demonstrate the effectiveness and accuracy of this technique across a variety of imaging modalities and organ systems [8]. Automatic medical image segmentation is challenging task in which it extracts highly variable objects form images where image is low quality, lack of contrast, missing data in image to be segmented and difficult to determined edge and boundary of image. Olivier Ecabert et al. focused on Automatic Model-Based Segmentation for Heart CT images and using automatic image processing methods, where these methods are a prerequisite to efficiently analyze the large amount of image data produced by computed tomography (CT) scanners during cardiac exams [9]. Jing Wang et al. discussed texture-based segmentation to extracting descriptive characteristics of real world scenes based on image textures[10]. Watershed segmentation an image is regarded as a topographic landscape with ridges and valleys. The elevation values of the landscape are typically defined by the gray values of the respective pixels or their gradient magnitude [11],[12] Proposes a fast watershed segmentation algorithm which overcomes the heavy burden on computation and time consuming, but can't solve the problem of over-segmentation.[13] Proposes a neural network based supervised segmentation algorithm for retinal vessel delineation.

**Implementation of segmentation Techniques**

This section focused on implementation of segmentation techniques and image processing concepts based on a medical image using python libraries. The following figure describes different techniques followed by implementation. In order to implement the above techniques, the following are steps followed such as medical image collection and loading image using python programming. The following techniques are implemented based on the above said image using different python packages.

**Thresholding** Image thresholding is a simple form of image segmentation. Image thresholding is a simple and effective, way of partitioning an image into a foreground and background. Itsplits an image into a foreground pixels and background pixels. If pixel value is greater than a threshold value, it is assigned one value (may be white), else it is assigned another value (may be black). The function used is **cv2.threshold** in python programming to perform image thresholding.Thresholding converts grayscale images into binary images or distinguishes the lighter and darker pixels of a color image.

**K-means clustering.** In k-means clustering, it partitions a collection of data into a k number group of data an algorithm identifies groups in the data, with the variable K representing the number of groups. The algorithm assigns each data point (or pixel) to one of the groups based on feature similarity. Rather than analysing predefined groups, clustering works iteratively to organically form groups. Histogram-based image segmentationuses a histogram to group pixels based on “gray levels”. Simple images consist of an object and a background. The background is usually one gray level and is the larger entity. Thus, a large peak represents the background gray level in the histogram. A smaller peak represents the object, which is another gray level.

**Edge detection**

identifies sharp changes or discontinuities in brightness. Edge detection usually involves arranging points of discontinuity into curved line segments, or edges. For example, the border between a block of red and a block of blue.

**Image Gradients**

An image gradient is a directional change in the intensity or color in an image. The gradient of the image is one of the fundamental building blocks in image processing.The gradient of an image measures how it is changing. It provides two pieces of information. The magnitude of the gradient tells us how quickly the image is changing, while the

direction of the gradient tells us the direction in which the image is changing most rapidly. In Python Program used the following three functions `cv2.Sobel()`, `cv2.Scharr()`, `cv2.Laplacian()`.

### Smoothing Images

Image smoothing is used to reduce noise within an image or to produce a less pixelated image. Most smoothing methods are based on low pass filters. Smoothing is also usually based on a single value representing the image, such as the average value of the image or the middle (median) value.

### Gaussian and Median Filtering

Averaging is process of convolving the image with a normalized box filter. It simply takes the average of all the pixels under kernel area and replaces the central element with this average. This is done by the function `cv2.blur()` or `cv2.boxFilter()`. In Gaussian instead of a box filter consisting of equal filter coefficients, a Gaussian kernel is used. It is done with the function, `cv2.GaussianBlur()`. In Median Filtering the function `cv2.medianBlur()` computes the median of all the pixels under the kernel window and the central pixel is replaced with this median value.

### Image Segmentation Using Watershed Approach

Watershed transformation also called, as watershed method is a powerful mathematical morphological tool for the image segmentation. The watershed transformation is a powerful tool for image segmentation. It is a hybrid technique because it is the result of threshold based, edge and region based techniques using morphological watershed transform. The watershed transformation is popular image segmentation technique for gray scale images [14]. Computation complexity is one of the important criteria for image segmentation which should be considered carefully when real time image segmentation is required.

Watershed based image segmentation algorithms are less computational complex and provide very good segmentation results. If image is viewed as geological landscape, the watershed line determines boundaries which separate image regions. The watershed transform computes catchment basins and ridgelines (also known as watershed lines), where catchment basins corresponding to image regions and ridgelines relating to region boundaries [15]. The watershed based image segmentation produces mostly an over-segmentation of the image. Pre-processing and post-processing of an image is performed to overcome this problem. Pre-processing is mainly applied to the image before the watershed segmentation. The following steps are involved in pre-processing.

Input Image → Median Filter → Morphological Gradient → Thresholding → Output Image

## CONCLUSIONS

In this paper, I have discussed about image segmentation along with its techniques and also implemented those techniques using python programming. In order to implement segmentation techniques, I have taken one medical image for segmentation purpose and applied all segmentation techniques based on medical image.

### ABSTRACT

The main objective of present paper is to determine the impact of machine learning in medical diagnostic. Medical diagnostics are a kind of medical investigations designed to identify infections, conditions and diseases. In health care field, Medical Diagnostic is a process of collecting samples from patients to detect patient's health condition and diseases. Medical diagnostic provides technical health records to detect the disease and also identify the primary information of a patient. This paper aims to implement machine learning approaches to predict Heart disease, and also afford performance analysis based on accuracy.

**Keywords:** Machine learning, heart disease, KNN, Decision tree, Linear Kernel, Support Vector

## INTRODUCTION

According to WHO statistics, every year 17 millions people died of heart disease, one third of disease death are heart disease death. According to survey, heart disease is the leading cause of death in the world every year. Heart disease, which is usually called coronary artery disease (CAD), is a broad term that can refer to any Condition that affects the heart [1]. Heart disease is any illness that disturbs the structure or function of the heart. There are different types of heart diseases, such as Coronary artery and vascular disease, heart rhythm disorders (arrhythmias), Structural heart disease. Coronary artery and vascular disease occurs like heart attack, chest pain. Heart rhythm disorders cause the heart to beat too slowly, too quickly or in a disorganised fashion [20]. Structural heart disease refers to abnormalities of the heart's structure including its valves, walls, muscles or blood vessels near the heart [20]. In order to ensure the better cure results from treatment, it is very clear that the diagnosis electronic records plays major role. In this process, machine learning consider for medical filed, and also applied for reasons in medical filed, such as disease diagnosis, medical image analysis etc. Machine learning is one of the technology trendsetters in computing world, and also proved that machine learning used for decades in different research. Machine learning is an application of artificial intelligence (AI) that delivers classifications the ability to mechanically learn and improve from experience without being explicitly programmed [21]. Machine learning emphasizes on the advance of computer programs that can acquire data and used it learn for themselves through algorithms [21]. In Machine learning the learning process initiates with observations or data, such as examples, direct experience, or instruction, in order to look for patterns in data and make better decisions in the future based on the examples. The main objective is to allow the computers

24046

P. Annan Naidu

learn mechanically deprived of human intervention or support and modify actions therefore. Machine learning is purely creating healthcare smarter. Machine learning has proved really life-impacting prospective in healthcare, predominantly in the area of medical diagnosis. There are numerous difficulties deterring faster integration of machine learning in healthcare today. One of the biggest challenges is the ability to acquire patient data sets which have the essential size and quality of samples needed to train state-of-the-art machine learning models.

### ROLE OF MACHINE LEARNING IN HEART DISEASE DIAGNOSIS

This section presents existing research work of Heart Disease Diagnosis through Machine learning approach. Shashikant Ghumbre et al[2], projected a Decision Support System for the diagnosis of Heart disease by means of radial basis function network structure and Support Vector Machine and concluded that SVM with Sequential minimize optimization is equivalently good as the Radial basis function network in the diagnosis of Heart disease.

Haiyan Yang et al[3] focused on the application of support vector machine (SVM) approach based on the statistics-learning theory of structural risk minimization in heart disease diagnosis and also experimented with chaotic PSO's support vector machine algorithm for the diagnosis of heart disease in the sample data set on the basis of feature selection. My Chau Tu et al[4] proposed Bagging Approach to identify the warning signs of heart disease in patients and also to compare the effectiveness of the bagging algorithm with the decision tree algorithm and results shows that bagging algorithm has better performance and accuracy than the decision tree that is often used in medical data mining.

Proposed [5] SVM based on hybrid kernel function and apply the model to test the heart disease dataset and also used properties of kernel function is analysed, and the linear combinations of different kernels are to construct hybrid kernel function. In the process of the establishing model, PSO algorithm is used to optimize the parameters which are concerned, and classifier model of SVM recognize the heart disease data. Implemented [6] Extreme Learning Machine (ELM) and compared results with backpropagation ANN, Support Vector Machine (SVM), and decision tree and results stated that ELM model has potentially implemented to help medical professional diagnosing heart disease. Developed [7] effective alternating decision tree approach for early diagnosis of heart disease and also used Alternating decision trees are new representation for classification rule which are easy to implement, robust and interpretable, finally results stated that proposed approach achieved an accuracy of 91.66%. Described [8] an Health Decision Support System (HDSS) that combines Wearable Medical Sensors (WMSs) and Computer-based clinical decision support systems (CDSSs).

It incorporates a hierarchical and closed-loop multi-tier structure supported by robust machine learning ensembles. Proposed [9] model consists of two classification stages, three techniques composed of Support Vector Machine (SVM), K-Nearest Neighbor (KNN) method and Naïve Bayes approach are applied to combine into a mixture model based on multi-layer perceptron and back-propagation learning algorithm for solving heart disease problem. Used [10] the Least Squares Twin-Support Vector Machine, which unlike ordinary support vector machine, is based on a Non-parallel margin, investigated and compared several approaches such as: neural networks, SVM, Decision tree, and some improved SVMs in the accuracy for ECG Arrhythmia classification. Focused [11] on developing a fast and accurate automatic ischemic heart disease detection/localization methodology.

Methods: T wave was segmented from averaged Magnetocardiography (MCG) recordings and 164 features were subsequently extracted compared different machine learning classifiers including: k-nearest neighbour, decision tree, support vector machine (SVM), and XGBoost, to identify ischemia heart disease (IHD) case selected three classifiers with best performance and applied model ensemble to average results. Proposed [12] a hybrid Dynamic ant colony system three update levels, with wavelets transform, and singular value decomposition integrating support vector machine and the outcome of the proposed method seeks to minimize subset of features to attain a satisfactory disease diagnosis on a wide range of diseases with the highest accuracy, sensitivity, and specificity. Focused [13] on identifying optimum machine learning classifier among several different machine learning classifiers for heart disease

**P. Annan Naidu**

diagnosis and prototyping personal healthcare devices, use Bluetooth Low Energy for data transmission and development of iOS mobile application for integrating diagnosing and monitoring systems. Presented [14] an approach of utilizing machine learning to assist cardiac auscultation for heart murmur detection, compare the effectiveness and advantages of both supervised and unsupervised techniques in performing clustering and classification of selected sets of different heart murmur episodes. Proposed [15] development an Intelligent Heart Diseases Diagnosis Algorithm (IHDDA) which reads heart signals (e.g. ECG graphs etc.) and reaches on a flawless diagnosis in fraction of seconds. This paper [18] aims to improve the HF prediction accuracy using UCI heart disease dataset. For this, multiple machine learning approaches used to understand the data and predict the HF chances in a medical database and also provided result performance analysis.

### Comparison of Machine Learning methods for Heart disease Prediction

This section provides a level comparison between all the research papers described above. The comparison is made on the basis of evaluation which is presented in the existing work and can be seen in table.

### Machine Learning Approach

#### Data and Data Pre-processing

The dataset used in this paper is collected from Kaggle data domain, which is related to heart disease [19]. Dataset contains fourteen attributes and 303 records. The following details are related to dataset which provides information about used dataset. Used a variety of Machine Learning algorithms, implemented in Python, to predict the presence of heart disease in a patient. This is a classification problem, with input features as a variety of parameters, and the target variable as a binary variable, predicting whether heart disease is present or not. The following code provides the detail information about number of patients who have heart disease

```
df.target.value_counts()

1  165
0  138
Name: target, dtype: int64
```

Here 1 and 0 represents target value (have disease or not (1=yes, 0=no): 1-Yes, 0-No, that is 165 actually have heart disease. The following graph is represents the above data and also visualize gender wise.

From the above, the maximum heart rate occurs in between age 50–60 years. The following procedure is followed to implement KNN model, K-NN model is ready with K=4.

- Then the next step is label the data,
- After that dataset is divided into test data(25%) and train data(75%) respectively.
- Normalize the dataset by using StandardScaler() from sci-kit learn
- K-NN model and train it with the training data by considering K value.
- Confusion Matrix

```
[[25  8]
 [ 3 40]]
```

In the output, 25 and 40 are correct predictions, and 8 and 3 are incorrect predictions.

### Support Vector Machine

Support vector machine (SVM) is a classification method, used in different types of classification and regression problems. SVM can handle continuous and discrete variables. In SVM classification hyperplane line separates in multidimensional data points to separate different classes. SVM generates ideal hyperplane in a recursive manner,

**P. Annan Naidu**

which is used to minimize an error. The main idea of SVM is to find a maximum marginal hyperplane (MMH) that best divides the dataset into classes. SVM used basic terms defined as follows; Support vectors are the data points, which are closest to the hyperplane. These data points will define the separating line better by calculating margins. A hyperplane is a decision plane which separates between a set of objects having different class memberships. A margin is a gap between the two lines on the closest class points. This is calculated as the perpendicular distance from the line to support vectors or closest points. If the margin is larger in between the classes, then it is considered a good margin, a smaller margin is a bad margin. Working of SVM as follows, the main objective is to segregate the given dataset in the best possible way. The main objective is to segregate the given dataset in the best possible way. The distance between the either nearest points is known as the margin. The objective is to select a hyperplane with the maximum possible margin between support vectors in the given dataset. SVM searches for the maximum marginal hyperplane in the following steps:

Step1: Generate hyperplanes which segregates the data points in the best way.

Step-2: Select the right hyperplane with the maximum segregation from the either nearest data points.

The SVM algorithm is implemented in practice using a kernel. A kernel transforms an input data space into the required form. SVM uses a technique called the kernel trick. SVM supports the following kernel types: Linear, Polynomial, Radial basis function (RBF), Sigmoid. In order to implement SVM to predict heart disease, the above said dataset is used. In Data Processing, to work with categorical variables, dataset should break each categorical column into dummy columns with 1s and 0s. After applying Support Vector classifier based on the given dataset, the following are predicted. The score for Support Vector Classifier is 85 % with rbf and sigmoid kernel. The score for Decision Tree Classifier is 79.0% with [2, 4, 18] maximum features. The score for Random Forest (RF) Classifier is 88% with [200] estimators. The score for K Neighbours Classifier is 87.0% with 7 and 8 neighbours. The accuracy score achieved using XGBoost is 86%. By comparing the above results; results concluded that RF is the best model with 88% accuracy. Results generated based on data by using machine learning techniques. Results concludes that best performance techniques is Random Forest classifier, This performance may be increased by applying normalization on data and by using grid search approach.

## CONCLUSIONS

Machine learning models or approaches plays major role in current research studies. In this paper I have discussed about the importance of machine learning in medical field and also provide summary discoveries as a comparison table. This paper aims to describe machine learning models to classify heart disease dataset to diagnose heart disease based on the dataset and finally provides result analysis of different machine learning models.

### ABSTRACT

Natural Language processing (NLP) is a process of understanding data in natural languages through computer programs. NLP is used in sentiment analysis, speech recognition, call centres, to create chatbots, spell checking, machine translation etc. The main concern of this paper is the compressive study on NLP with its application. This paper presents NLP concepts and applications of NLP through python programming. In this paper, developed different applications based on website data and twitter datasets.

**Keywords:** Natural Language, Tokenization, Stemming, Morphology, Semantics

## INTRODUCTION

In 20<sup>th</sup> century, World is consolidated on computer applications and data. Social media networks generates huge amount of data through internet applications or services. This social media data available for business purpose, where data extracted, pre-processed ,apply different models or techniques and produce relevant results based on requirements then same results can be used for further decision making. In real world scenario, NLP is used in many applications, one such application is digital phone calls, generally when me make a call to any customer care service, we may experienced like "this call may be recorded for training purposes," in this case they will record our voice for training purpose, by using this database company can analyse customers views called sentiment analysis. Similarly NLP also used in chatbots, smart assistants, search results and email filters.

### Natural Language Processing

Data is one of the prominent requirements in today's business. In our day-to-day life huge amount of data is produced in various formats from different resources. One of biggest source of data is social media networks or internet applications like Facebook, Twitter, WhatsApp, Google etc. Conferring to industry assessments, only 21% of the available data is present in structured form and available unstructured data (approx.80).When the requirements demands the understanding of unstructured data for their business, In order to produce significant and actionable insights from text data, this type of issues can be solved by different computing methods, one such method is Natural Language processing (NLP).Natural Language processing is a sub filed of data science, linguistics, Artificial Intelligence, The main concern of NLP is the interactions between computer program and human languages.NLP is

24054

**P. Annan Naidu**

a systematic processes for analysing, understanding, and deriving information from the text data in a smart and efficient manner. By using NLP components and its techniques, one can perform various automated tasks like sentiment analysis, speech recognition, topic segmentation, relationship extraction. NLP means processing of human language automatically.

**Classification of NLP**

Phonology refers to the science of understanding sound, Morphology refers to word formation, and syntax refers to structure whereas Pragmatics refers to understanding.

When a person talks to each other, first other person understands the context then gives reply accordingly. So here natural language understanding refers understanding the context and natural language generation relate to response. NLP is used in the following common applications, such as

- Language Translation applications, Ex: Google Translate
- To check grammatical accuracy of texts, Ex: Word Processors
- Interactive Voice Response (IVR) applications Ex: Call centres
- Personal assistant applications, Ex: OK Google, Siri, Cortana, and Alexa.

“Natural Language Processing is a field that covers computer understanding and manipulation of human language, and it’s ripe with possibilities for news gathering,” Anthony Pesce said in Natural Language Processing in the kitchen [1]. While natural language processing used where the technology is rapidly advancing to an increased interest in human-to-machine communications, plus an availability of big data, powerful computing and enhanced algorithms. As a human, you may speak and write in English, but a computer’s native language known as machine code or machine language is largely incomprehensible to most people. At your device’s lowest levels, communication occurs not with words but through millions of zeros and ones that produce logical actions.

**Step-by-Step-by process flow of NLP**

**Step-1: Text collection:** Collecting data from various social media networks

**Step-2: Text Cleaning:** Removing links, urls and tags etc.

**Step-3: Tokenization:** Breakdown the text into meaningful words and terms

**Step-4: Word Stemming:** Reducing a word form to a base form or root form

Ex: Playing, Plays, Played are common root from ‘play’.

Ex: Likes, Likely, Liking, Liked are common root from ‘like’.

**Step-5: Stop word Removal:** Removing stop words like the, of, a, an, and.

**Step-6: Custom Dictionary Creation:** Creating domain specific dictionary with words used for different meanings in different context.

**Step-7: N gram analysis:** Check if sequences of words convey a different meaning than each word used separately.

**Step-8: POS tagging:** Part of Speech tagging helps in identifying whether a word is used as noun, Adverb or adjective.

**Step-9: Entity Recognition:** Entity Recognition based on location, organizations and places is performed.

**Step-10: Sentiment Scoring:** Score each document based on the sentiment associated with each word in a given text.

**Step-11: Sentiment Classification:** Based on the sentiment scoring the text is classified as positive, negative or neutral.

**Applications of NLP based on Web Page data and Twitter data****Case-1: Identifying what a web page content**

In this case, I have used web page [3] for identifying what this web page is speaks about by using python nltk package.

P. Annan Naidu

**Step- 1:**Take a webpage and analyze the text to observe what the page is about. This is possible by using import urllib.request, this package is used to read web page.

```
b'\n<!DOCTYPE html>\n<html class="client-nojs" lang="en" dir="ltr">\n<head>\n<meta
charset="UTF-8"/>\n<title>Health care -
Wikipedia</title>\n<script>document.documentElement.className="client-
js";RLCONF={"wgBreakFrames":!1,"wgSeparatorTransformTable":["",""],"wgDigitTransformTa
ble":["",""],"wgDefaultDateFormat":"dmy","wgMonthNames":["","January","February","Marc

**P. Annan Naidu**

A user-defined function (defremove\_ pattern (input\_txt, pattern)used to remove text outlineswhich are not carry much information from the tweets. It takes two arguments, one is the original dataset values and the other is the text pattern whichis eliminated from the string.The following code is used for the following actions, removing twitter handles through tidy\_tweet, removing Punctuations, Numbers, and Special Characters and removing short words.

```
# Eliminate twitter handles (@user)
c['tidy_tweet'] = n.vectorize(remove_pattern)(c['tweet'], "@[\w]*")
#Eliminate Punctuations, Numbers, and Special Characters
c['tidy_tweet'] = c['tidy_tweet'].str.replace("[^a-zA-Z#]", " ")
#Removing Short Words
c['tidy_tweet'] = c['tidy_tweet'].apply(lambda x: ' '.join([w for w in x.split() if len(w)>3]))
```

After applying the above steps,such as removing twitter handles, combined train and test data, removing short words, removing Punctuations, Numbers, and Special Characters.

id	tweet	label	tidy_tweet
0	31963 #studiolife #aislife #requires #passion #dedic... #passion #dedic...	NaN	#studiolife #aislife #requires
1	31964 @user #white #supremacists want everyone to s... everyone #birds #mov...	NaN	#white #supremacists want
2	31965 safe ways to heal your #acne!! #altwaystohe... #altwaystoheal #heal...	NaN	safe ways heal your #acne
3	31966 is the hp and the cursed child book up for res... already where w...	NaN	cursed child book reservations
4	31967 3rd #bihday to my amazing, hilarious #nephew... #nephew ahmiruncle ...	NaN	#bihday amazing hilarious

Compare the difference between the original tweets and the prepared tweets (tidy\_tweet) prettyvisibly. Only the important words in the tweets are remaining there in the tweets and the noise (numbers, punctuations, and special characters) has been removed.

**Step-3:Tokenization**

Tokenization is a process of break the senteces into individual words or terms.

```
0 [#studiolife, #aislife, #requires, #passion, #...
1 [#white, #supremacists, want, everyone, #birds...
2 [safe, ways, heal, your, #acne, #altwaystoheal...
3 [cursed, child, book, reservations, already, w...
4 [#bihday, amazing, hilarious, #nephew, ahmir, ...
Name: tidy_tweet, dtype: object
```

**Step-4: Stemming**

Reducing a word form to a base form or root form

Ex: Playing, Plays, Played are common root from 'play'.

Ex: Likes, Likely, Liking, Liked are common root from 'like'.

```
0 [#studiolif, #aislif, #requir, #passion, #dedi...
1 [#white, #supremacist, want, everyon, #bird, #...
2 [safe, way, heal, your, #acn, #altwaystoh, #he...
3 [curs, child, book, reserv, alreadi, where, wh...
4 [#bihday, amaz, hilari, #nephew, ahmir, uncl, ...
Name: tidy_tweet, dtype: object
```

P. Annan Naidu

id	tweet	label	tidy_tweet
0	31963 #studiolife #aislife #requires #passion #dedic...	NaN	#studiolif #aislif
1	31964 @user #white #supremacists want everyone to s...	NaN	#white #suprem
2	31965 safe ways to heal your #acne!! #altwaystohe...	NaN	safe wayhea
3	31966 is the hp and the cursed child book up for res...	NaN	curschildbo
4	31967 3rd #bihday to my amazing, hilarious #nephew...	NaN	#bihdayama

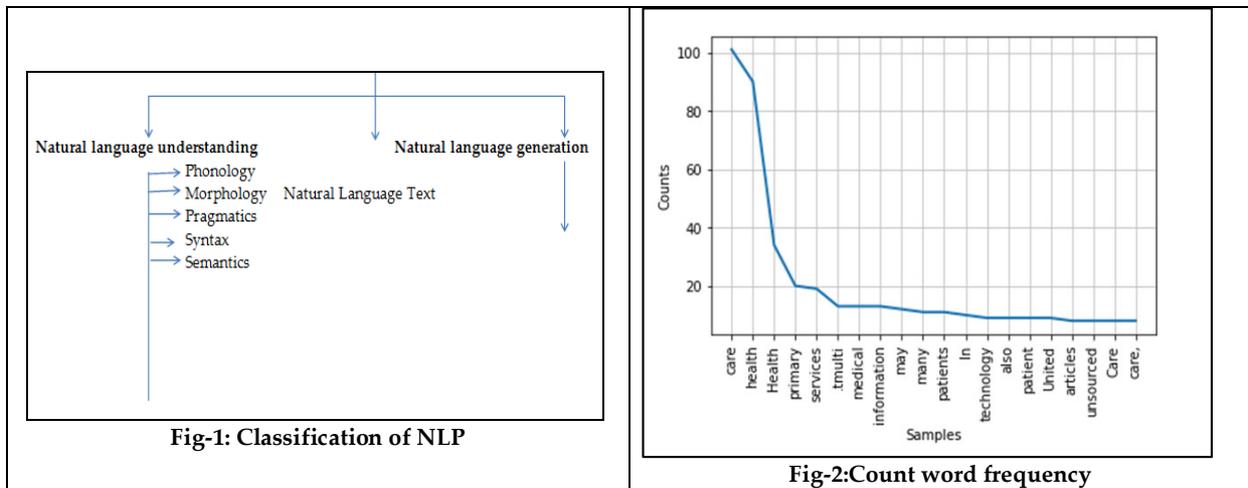

When compare the above result with the original dataset, the above results conclude that data presents without twitter handles, short words, numbers, punctuations, special characters. In this case, the process limited up to stemming.

### CONCLUSIONS

This study focused on the theoretical approach, step-by-step process flow of NLP and development of NLP applications based on web site data and twitter data.

### ABSTRACT

Healthcare is an essential diligence which offers value-based care to millions of people, while at the same time becoming top revenue earners for many countries. Today technology is allowing healthcare specialists develop alternate staffing models, provide smart healthcare and reducing administrative and supply costs. Machine learning in healthcare is one such area which is seeing gradual acceptance in the healthcare industry. This paper aims to provide the comprehensive study on Machine learning and its role in smart Healthcare.

**Keywords:** Machine learning, Healthcare, Drug Discovery, Imaging Diagnosis, Clinical Trial

## INTRODUCTION

### Machine Learning in Healthcare: Related Work

The healthcare sector has always been one of the greatest proponents of innovative technology, Machine Learning are no exceptions. Technology-enabled smart healthcare and Internet-connected medical devices are holding the health system [18]. Machine learning has virtually endless applications in the healthcare industry. Today, machine learning is helping to streamline administrative processes in hospitals, map and treat infectious diseases and personalize medical treatments [19]. Machine learning in medicine has recently made headlines. Google recently developed a machine-learning algorithm to identify cancerous tumours in mammograms, and researchers in Stanford University are using deep learning to identify skin cancer [20]. ML in healthcare helps to analyse thousands of different data points and suggest outcomes, provides timely risk scores, precise resource allocation, and has many other applications. This section briefly describes the role of machine learning in healthcare for last 10 years.

This study provides existing work of machine learning based on healthcare or medical field. In Machine learning, there are different types algorithms known as supervised learning, unsupervised learning and reinforcement algorithms. Most of the medical field or healthcare applications are developed by using machine learning techniques or algorithms. [1] The purpose of this research study was to compare the performance of various ML models for predicting surgical infection after neurosurgical operations. Implemented Supervised ML algorithms, evaluate

**P. Annan Naidu**

model with test data and also defined accuracy, sensitivity, specificity of the models. [2] In This paper, research work focused on the effect of diabetes on eye which leads to diabetic retinopathy by using Self Organizing Map and K-means algorithm, the results concluded that the SOM is able to show a 3D weighted map illustrating the noticeable difference between the normal and diabetic retinopathy images. In this work, authors [3] evaluated the performance of machine learning based techniques for Parkinson's disease diagnosis based on dysphonia symptoms by using by means of a tenfold cross validation protocol.

The results concluded the support vector machine classifier shows superior performance compared to the other classifiers. Objective of the present paper is to demonstrate the potential of Computational Intelligence in applications pertaining to the automatic identification categorisation of Cardiocograms using Machine Learning Algorithms and Artificial Neural Networks [4]. In this paper [5] author proposed adaptive ensemble voting method for diagnosed breast cancer using Wisconsin Breast Cancer database. The main contribution of this work to compare and explain how ANN and logistic algorithm provide better solution when its work with ensemble machine learning algorithms for diagnosing breast cancer even the variables are reduced.

Then main focus of this paper is to predict Interactive Thyroid Disease with help of different machine learning techniques and diagnosis for the prevention of thyroid. Machine Learning Algorithms, support vector machine (SVM), K-NN, Decision Trees were used to predict the estimated risk on a patient's chance of obtaining thyroid disease [6]. This paper presented the role of machine learning applications in early disease detection through different datasets like heart, breast cancer and diabetes and also implemented different machine learning algorithms [7]. The objective this work is carried out to choose the best tool for diagnosis and detection of Hepatitis as well as for the prediction of life expectancy of Hepatitis patients and also presented the comparison between different machine learning techniques. The performance of models evaluated based on accuracy and mean square error [8]. This paper aims at building a classifier model using WEKA tool to predict diabetes disease by employing Naive Bayes, Support Vector Machine, Random Forest and Simple CART algorithm and also projected a Decision Support System for the diagnosis of Heart disease by means of radial basis function network structure and Support Vector Machine [9].

**Machine Learning in Healthcare**

This section briefly explains about the role of machine learning in healthcare applications. As per the existing study, there is a lot of research has already implemented in health sector using machine learning approach. This section aims to provide healthcare applications through machine learning.

**Identifying Diseases and Diagnosis**

Machine learning methods are used in one of the important field in healthcare that is prediction of diseases and diagnosis. The machine learning can be applied on the following applications such as heart disease, Breast cancer, Cardiac Arrhythmia Diagnosis System, coronary heart disease, tongue disease diagnosis, Diagnosis of Diabetes Mellitus [10], Thyroid Disease Diagnosis. For the above said applications, machine learning techniques are applied based on dataset, and follow the following procedure: data pre-processing, data feature scaling, apply machine learning model, predict accuracy, evaluate model using evaluation metrics, comparing methods with its accuracy, sensitivity, specificity.

**Drug Discovery and Manufacturing**

Machine learning (ML), a branch of artificial intelligence for discerning patterns from complex data sets, has proven to be a valuable method in various fields of research over the past few decades [11]. ML algorithms have found great utility in several applications including drug discovery and manufacturing, exploring different material properties such as elasticity, plasticity, fatigue life, wear performance, and buckling [12]. The key areas of drug discovery process is ensuring drug safety, interpreting information of the known effects of drugs and envisaging their side effects. The

**P. Annan Naidu**

most of researchers and scientists are focused on obtained meaningful clinical data from clinical trials using machine learning techniques. In drug development the most expensive task is clinical trials, in order to reduce the cost effective of clinical trials, machine learning techniques are used to integrate with biomedical data and analysed interpreted clinical data to detect side effects of drug discovery.

**Medical Imaging Diagnosis**

Medical image analysis and processing has great significance in the field of medicine and clinical study. Medical imaging incorporates various imaging modalities and processes to image the human body for diagnostic and treatment purposes and therefore plays an important role in initiatives to improve public health for all population groups[13]. Machine learning techniques are applied on different medical image modalities to diagnose the disease or to prepare clinical health records. In medical imaging, diseases are identified through different medical images by using image processing techniques through machine learning techniques. Machine learning techniques in the following medical imaging research challenges such X-ray images, CT scan images and Ultrasound (US) images which includes brain related disease, bone related disease and human body internal organs related diseases. In this case, machine learning techniques follow the basic procedure that is image acquisition from CT or MR; apply image processing techniques, segmentation, detection and diagnosis.

**Personalized Medicine**

Personalized medicine represents a significant application for the health informatics community. The main objective of Personalized Medicine is to provide patients clinical history without appear drug data, design clinical database and optimize, clinical data analysis. The main challenges of Personalized Medicine through machine learning are as follows; Data representation of multiple relations, Data uncertainty, missing data and incomplete data.

**Smart Health Records**

Patient's clinical reports are plays major role in treatment, which is essential for disease detection to disease diagnosis. In order to understand the patient health condition, it is very much essential to predict the best values with respective their health condition from current and previous health records. In this concern, machine learning is a sophisticated approach to maintain and analyse patient health records, In order to create smart health records which includes modern computing processes such as data collection, data processing, data security, networking and computing techniques. The idea of a smart health system is that it uses all data coming from sensors on the patient body, smart homes, smart city infrastructure, and robots to help make better decisions and improve healthcare by providing emergency response and paging doctors, nurses, and technicians[14]. Electronic health records, digital health cards are best examples so far implemented.

**Clinical Trial and Research**

Clinical trial is a scientific experiments conducted to find best way to treat diseases and diagnosis. Clinical trials produce high quality health data for health care decision making. FDA's (Food and Drug Administration) Scott Gottlieb[15] says Real-world data gathered directly from EHRs and other data sources, paired with advances in machine learning, will be crucial for architecting the next generation of successful clinical trials. This paper describes MLBCD (Machine Learning for Big Clinical Data), MLBCD integrates techniques of fast pivoting, visual query building, efficient and automatic selection of machine learning algorithms and hyper-parameter values, and scalable machine learning.

**Scaled Up / Crowdsourced Medical Data Collection**

Crowd-sourcing has become a popular means of acquiring labelled data for many tasks where humans are more accurate computers, such as image tagging, entity resolution, and sentiment analysis [16]. Crowdsourcing refers to a large group of people collectively solving a problem or completing a task for an individual or an organisation. The

P. Annan Naidu

field of crowdsourcing has developed in information technology or business, but crowdsourcing can be a promising tool in health and in global health in particular [17].

### Future Applications/Challenges in Healthcare

- Robotic Surgery
- Automatic Treatment or Recommendation
- Autonomous Robotic Surgery
- Radiomics
- Augmented reality(AR)/ Virtual reality(VR) in the Future of Medical field
- Reforming drug development
- Nanotechnology in healthcare
- 3D-printing in healthcare

### CONCLUSIONS

Healthcare is one of the emerging fields, where it supports to doctors and patients for clinical treatments. Smart healthcare provides value added services depends on technology enabled services. In current scenario healthcare applications also developed by using various computing technologies. This paper presented the impact of machine learning in the developments of healthcare applications. Section-1 describes machine learning and its related work, section-2 discussed about different healthcare applications with support of machine learning and also presents future challenges(beyond 2020)of healthcare.

### ABSTRACT

Bioinspired eco-friendly Silver nanoparticles were synthesized by a green method from *Plumeria rubra* Flower Extract (PRFE) and *Plumeria alba* Flower Extract(PAFE). The use of two different concentration (1% and 5%) of PAFE resulted in two different sizes of two *Plumeria* SP as *Plumeria alba* Silver Nanoparticles (PASNPs1 and PASNPs2) and *Plumeria rubra* Silver Nanoparticles (PRSNPs1 and PRSNPs2). The controlled formation of silver nanoparticles was indicated by FTIR and XRD with increasing concentration of PAFE and PRFE. The antibacterial activity of PASNPs1, PRSNPs1 and PASNPs2. PRSNPs2 was tested against a nosocomial microbe, the small sized PASNPs1 and PRSNPs1 exhibited better antibacterial activity with highest 3.5cm zone of inhibition at a concentration of 200µg/ml. The PASNPs and PRSNPs shows great catalytic degradation activity against industrial dyes like Methylene blue (MB), Congo RED (CR), Methyl Orange (MO). The green synthesis of nanoparticles in bulk suggests the potential industrial applications.

**Key-words-** Silver nanoparticles, catalytic degradation, leaf, bark, flower, Green synthesis

### INTRODUCTION

*Plumeria rubra* and *Plumeria alba* belong to family Apocynaceae is a succulent, 2-8 mtr evergreen shrub having narrow elongated leaves, large and strongly perfumed white and pink flowers. Flowers are edible while heart of the wood used in medical preparation in form of vermifuge or laxative. Essential oil of *Plumeria* has antifungal efficacy and have potential for antimicrobial agents and also have pharmaceutical, anti-inflammatory, diuretic, emmenagogue, febrifuge, purgative applications and used as a tonic and expectorant [1].

Plant mediated synthesis of metal nanoparticles is more effective among green synthesis over microbial methods. Also this method is cost effective, improved stability, a wide range of biological activities and rapid synthesis due to

**Lopamudra Samantaray and Yashaswi Nayak**

active presence of many phyto-compounds. [2]. SNPs or Silver nanoparticles give different colors according to their aggregation ability and shape and size. Many previously reported data on the green synthesis of SNPs include the use of plants such as *Medicago sativa*, *Aloe vera*, *Pelargonium graveolens*, *Tamarindus indica*, *Cassia auriculata*, and *Coriandrum sativum*. Because the SNPs possess a high surface area and various sizes as well as shapes, they are also widely used in catalysis [3].

Dyes referred as principal pollutants for environment as it predominantly used in many industries like cosmetics, textiles, leather, plastic industries food, and also directly disposed into local river or other water reservoirs. These harmful dyes give toxic effects which negatively affect the aquatic life also result some mutagenic or carcinogenic effect to the nature, and the azo and nitro compounds of these harmful dyes take long times to degrade or for the deep soil accumulation and remain indefinitely in nature [4]. Many effective methods have been arisen to treat these dyes based upon adsorption, microwave-assisted degradation, photoelectric degradation and photocatalytic reduction. But all of these methods use the organic solvents which are cost effective and energy consuming. So as an alternative to this, many modern methods based on bio-green nanoparticles initiated to treat these harmful dyes which can be an alternative to those as the methods are operated under mild conditions and also uncomplicated [5].

This study reports a simple and green method for synthesizing silver nanoparticles using an aqueous extract of *Plumeria alba* and *Plumeria rubra* flowers (PAFE, PRFE). The PAFE and PRFE contains a mixture of phyto-compounds including amyriacetate, amyriins,  $\beta$ -sitosterol, scopotetin, the iridoid isoplumericin, plumieride, plumieridecoumerate, and plumieridecoumerate glucoside [6]. The synthesized P. alba P. rubra silver nanoparticles (PASNPs and PRSNPs) are characterized by particle size analysis, fourier transform infrared spectroscopy (FTIR), transmission electron microscopy (TEM), ultraviolet-visible (UV-visible) spectroscopy, energy dispersive X-ray spectroscopy (EDAX), and X-ray diffraction (XRD) analysis. The antibacterial potential of the PASNPs is analyzed against *Escherichia coli*. The catalytic property of PASNPs to degrade different organic dyes such as methylene blue (MB), methyl orange (MO), Congo red (CR) are analyzed.

## MATERIALS AND METHODS

### Collection and extraction

Leaves of *Plumeria* were collected from GIET Campus, Gunupur and authenticated by a botanist at the Plant Anatomy Research Centre (PARC), Chennai, Tamil Nadu, India. Leaf, Bark, Flower of *Plumeria* of different species of different month were collected. The collection were dried in shade for 15 days and then grinded to form powder.

### Preparation of flower extract

1 and 5 gm of flower powder was mixed individually with 100 mL of distilled water in 250 mL flasks. Then it was kept in an orbital shaker for 12 hours at room temperature. The supernatant was being filtered for thrice by a Whatman No. 1 filter paper and the collected extract was stored at 4 °C for future investigation.

### Green synthesis of silver nanoparticles

About 10 mL of 1% and 5% PAFE (*Plumeria alba* Flower Extract) and PRFE (*Plumeria rubra* Flower Extract) was added separately to 25 mL of AgNO<sub>3</sub> (1 mM) aqueous solution at room temperature, whereupon two minutes of incubation produced a noticeable color change in the reaction mixture from yellow to orange or blue, depending upon the concentration of flower extract. The color of the reaction mixture was changed which indicate of the formation of PASNPs and PRSNPs. The nanoparticles were further confirmed by UV-visible spectroscopy. These synthesized nanoparticles were collected by centrifugation (18,000 rpm) and then it washed with double distilled water followed by air dry and used for further investigation.

**Lopamudra Samantaray and Yashaswi Nayak****Characterization of Silver nanoparticles**

Bio-reduction and the formation of PASNPs and PRSNPs was monitored using a UV–visible spectrophotometer (UV-1700, Shimadzu, Japan) at wavelengths (350 and 700 nm), where the UV–visible spectrum of the PASNPs and PRSNPs at different time intervals was recorded. The average size and size distribution of the samples labelled PASNPs1 and PRSNPs1 (synthesized with 1% PAFE and PRFE) and PASNPs2 and PRSNPs2 (synthesized with 5% PAFE and PRFE) in liquid colloidal solution was measured by DLS instrumentation (Zetasizer Nano ZS, Malvern Instruments, UK). Morphology and the elemental composition of PASNPs1, PRSNPs1 and PASNPs2, PRSNPs2 samples were examined using TEM (Tecnai G2 30, FEI, USA) and an EDAX analyzer (SEM S-4500, Hitachi, Japan).

Samples were prepared by dropping the nanoparticle colloidal solution in methanol onto an aluminum-coated copper grid and placed at a 20 kV potential. Functional groups present in the PAFE involved in the formation of the PASNPs and PRSNPs were analyzed by FTIR (Thermo Nicolet Nexus 6700 spectrometer, Thermal Electron Corporation, USA) analysis. The nano-powder and PAFE and PRFE samples were uniformly mixed with potassium bromide (KBr) and compressed with a hydraulic press to prepare disks, which were then used for FTIR analysis.

**Antibacterial activity**

The antibacterial activity of the green-synthesized PASNPs1, PRSNPs1 and PASNPs2, PRSNPs2 samples was evaluated using nosocomial microbes of strain 1, 2 and 3 from R & D Laboratory via the modified disc diffusion method of Kirby–Bauer [7]. The antibacterial potential was screened using muellerhinton agar (MHA), where the MHA plates were prepared by pouring 20 mL of molten media into sterile Petri plates. The plates were solidified for 5 min, then 100  $\mu$ L of inoculum suspension was swabbed on the surface and allowed to dry for about 5 min. Three concentrations (400, 300, and 200 g/mL) of the PASNPs1, PRSNPs1 and PASNPs2, PRSNPs2 samples were loaded on 3 mm-diameter sterile individual discs, which were placed on the surface of the medium and the compound was allowed to diffuse for 5 min, after which the plates were kept for incubation at 37 °C for 24 h.

The growth inhibitory effect of the PASNPs1, PRSNPs1 and PASNPs2, PRSNPs2 samples in nosocomial microbes of R & D Laboratory was studied using three different PASNP and PRSNP concentrations like 400, 300, and 200 g/mL. In this study, the growth phase of the hospital microbes was being cultured with and without PASNPs1, PRSNPs1 and PASNPs2, PRSNPs2. The growth was measured at continuous time intervals using the UV–visible spectrophotometer (600 nm wavelengths), and growth curves were plotted.

**RESULT AND DISCUSSION**

The synthesis of silver nanoparticles was accomplished using two different concentrations (1% and 5%) of aqueous PAFE, PRFE and keeping the AgNO<sub>3</sub> (1 mM) concentration constant. The PASNPs1 and PRSNPs1 sample, synthesized with 1% PAFE and PRFE, exhibits an intense blue color while the PASNPs2 sample, synthesized with 5% PAFE, PRFE, manifests a pink color, and both of the samples were found to be stable for a period of three months. The PASNPs1, PRSNPs1 and PASNPs2, PRSNPs2 samples also show a pronounced difference in their UV–visible spectra, with their max located at 552 and 532 nm, respectively (Fig. 1(a) and (b)).

Also, the SPR peak intensity of PASNPs1, PRSNPs1 and PASNPs2, PRSNPs2 increased with the reaction time owing to the continued reduction of Ag ions and to the increased formation of nanoparticles, and the SPR peak location of the samples exhibits a blue shift with increasing PAFE concentrations. A possible explanation for the formation of smaller particles in PASNPs2, PRSNPs2 could be the presence of the increased number of nucleation sites for AgNO<sub>3</sub> – complexation with the increasing concentration of the PAFE. Whereas in PASNPs1, PRSNPs1, less nucleation sites were present this may lead to more reduction at one nucleation and formation of bigger particles. These investigations are indicating that the size of the nanoparticles can be controlled by changing the concentration of plant extracts in different variations.

**Lopamudra Samantaray and Yashaswi Nayak**

The TEM analysis of the PASNPs<sub>1</sub>, PRSNPs<sub>1</sub> and PASNPs<sub>2</sub>, PRSNPs<sub>2</sub>, enabling us to make accurate size measurements of samples found to be  $28 \pm 5.6$  and  $15.6 \pm 3.4$  nm, respectively. The morphology of the PASNPs, PRSNPs is spherical in shape, and the TEM data also illustrate the increased size of the PASNPs<sub>1</sub> sample compared to that of PASNPs<sub>2</sub>, which is in good agreement with the UV-visible analysis. To investigate the possible active groups present in the PAFE that are involved in the formation of the PASNPs, we performed FTIR spectral analysis on the samples. The IR spectrum of the synthesized PASNPs, PRSNPs sample is compared with pure PAFE and PRFE. The PAFE and PRFE displays intense vibrational stretching at  $3211\text{ cm}^{-1}$  (C H stretching),  $1685\text{ cm}^{-1}$  (C O stretching of carboxylic acids),  $1411\text{ cm}^{-1}$  (C C ring stretching of aromatics), and  $1046\text{ cm}^{-1}$  (C N stretching of aliphatic amines).

All of the peaks obtained with FTIR, therefore, confirm the presence of various phyto- components of the PAFE, PRFE. The IR spectra of the PASNPs, PRSNPs exhibit intense peak shifts from the locations observed for PAFE, PRFE sample, with shifts from  $3211$  to  $3348\text{ cm}^{-1}$  (N H stretching of  $1^\circ$  and  $2^\circ$  amines and amides) and from  $1046$  to  $1036\text{ cm}^{-1}$  (C N stretching of aliphatic amines), which may be owing to the reduction of  $\text{Ag}^{3+}$  to  $\text{Ag}^0$  and the capping of the PASNPs, PRSNPs by the phyto-compounds in the PAFE, PRFE. The other peaks observed in the IR spectra of the PASNPs, PRSNPs located at  $2900\text{ cm}^{-1}$  (C -H stretching of alkanes),  $1566\text{ cm}^{-1}$  (C - C ring stretching of aromatics), and  $1356\text{ cm}^{-1}$  (N- O symmetric stretching of nitro compounds) also are derived from the PAFE, PRFE and are involved in the formation of the PASNPs. The N H and C H (proteins or sugars) groups of the PAFE, PRFE may be involved in the formation of PASNPs, PRSNPs mainly.

Based upon the above results, the functional groups of PRFE, PAFE are involved in the formation and capping of PASNPs, PRSNPs. The thermal stability of the PASNPs, PRSNPs was studied by TG-DSC. The endothermic peak found at  $52^\circ\text{C}$  is owing to the transition temperature, as shown in. The TG plot of the PASNPs, PRSNPs exhibits initial 4% weight loss due to moisture loss in the temperature range ( $10\text{--}50^\circ\text{C}$ ), with a further weight loss up to 30% observed ( $50$  and  $350^\circ\text{C}$ ) that attributed to the degradation of the organic phase of the PASNPs, PRSNPs. No more weight loss was observed ( $800^\circ\text{C}$ ), which because the rest were PASNPs content which was only silver metal.

**Antibacterial activity**

The antibacterial activity of biosynthesized PASNPs<sub>1</sub>, PRSNPs<sub>1</sub> and PASNPs<sub>2</sub>, PRSNPs<sub>2</sub> samples are tested using different concentrations against a nosocomial via the modified disk diffusion method and the zone of inhibition obtained indicates that the PASNPs<sub>1</sub>, PRSNPs<sub>1</sub> and PASNPs<sub>2</sub>, PRSNPs<sub>2</sub> exhibit antibacterial activity in a dose-dependent manner. At  $200$ , the PASNPs<sub>1</sub>, PRSNPs<sub>1</sub> exhibit inhibition zones of  $1$  to  $3.5\text{cm}$  and the PASNPs<sub>2</sub>, PRSNPs<sub>2</sub> exhibit inhibition zone of  $1\text{ cm}$  to  $3.2\text{cm}$ . This work indicate that the antimicrobial activity of silver nanoparticles (SNPs) depends upon their size, that smaller the particle size inducing greater activity.

**Catalytic Degradation**

The catalytic activity of PASNPs<sub>1</sub>, PRSNPs<sub>1</sub> and PASNPs<sub>2</sub>, PRSNPs<sub>2</sub> is evaluated in the presence of  $\text{NaBH}_4$  on various dyes such as MO, CR, and MB. The addition of  $\text{NaBH}_4$  alone to vital dyes does not change the absorption intensity of the dyes, as shown in suggesting that the dye degradation does not take place in the absence of PASNPs<sub>1</sub>, PRSNPs<sub>1</sub> and PASNPs<sub>2</sub>, PRSNPs<sub>2</sub>. Methylene blue. PASNPs<sub>1</sub>, PRSNPs<sub>1</sub> were added independently to this aqueous solution causes degradation of MB, which displays a decreasing trend in the absorption intensity. The complete degradation of MB was done within  $70$  and  $40$  min by PASNPs<sub>1</sub>, PRSNPs<sub>1</sub> and PASNPs<sub>2</sub>, PRSNPs<sub>2</sub>, respectively. Of the two samples, PASNPs<sub>2</sub>, PRSNPs<sub>2</sub> exhibits a higher catalytic activity with Methylene Blue (MB). The effect of the smaller particle size was more in improving the catalytic properties. Congo red catalytically degraded by PASNPs<sub>1</sub>, PRSNPs<sub>1</sub> and PASNPs<sub>2</sub>, PRSNPs<sub>2</sub> in the presence of  $\text{NaBH}_4$ . The intensity of the absorption peak at  $490\text{ nm}$  is reduced significantly in the presence of the PASNPs, PRSNPs, and the PASNPs<sub>2</sub>, PRSNPs<sub>2</sub> sample exhibits superior catalytic activity, causing a complete reduction of MR by  $75$ .

**Lopamudra Samantaray and Yashaswi Nayak**

Methyl Orange found to be 40 and 60 min for PASNPs<sub>2</sub>, PRSNPs<sub>2</sub> and PASNPs<sub>1</sub>, PRSNPs<sub>1</sub> respectively and it seen that the PASNPs<sub>2</sub>, PRSNPs<sub>2</sub> exhibits better catalytic degradation of EB at 40 min, while the PASNPs<sub>1</sub>, PRSNPs<sub>1</sub> sample shown the same degradation at 60 min. This slower activity of the PASNPs<sub>1</sub>, PRSNPs<sub>1</sub> sample due to large particle size, which hinders the catalytic efficiency. The color degradation of all of the dyes used in this study in the presence of the PASNPs, PRSNPs is presented in Supplementary data. Of the two PASNP, PRSNP samples synthesized in this study.

Plumeria is of particular technological interest due to the synthesise and fixative capability of the plant parts like flower, bark and flower, but also to its protective or resistance to peculiar wood degradation agents. In this study, regular harvesting of Plumeria extract was readily obtained on monthly basis in 2016 as mother plants were stooled and pollarded. The air-dried extract subjected to mechanical and chemical extraction processes sequentially yielded appreciable quantity of  $5.67\% \pm 0.04$  ( $n = 4$ )  $\pm$  S.D. Storing of sample ensured fresh and sufficient quantity that can be explored for commercial use as Plumeria protectant.

**CONCLUSION**

Plumeria is an abundant resource that could provide a renewable alternative source of natural preservative. It imparted significant antimicrobial actions. Green silver nanoparticles were synthesized from Plumeria flower extract successfully by a methodology and they were added with catalytic and biological activities. Presence of phytochemicals were confirmed FTIR analysis that were involved in stabilization of nanoparticles. The green synthesized PASNPs and PRSNPs also displayed immensely powerful catalytic activity. A green-synthesis strategy was adopted in this study to avoid using hazardous chemical reducing agents. We synthesized silver nanoparticle samples of two different sizes, called PASNPs<sub>1</sub>, PRSNPs<sub>1</sub> and PASNPs<sub>2</sub>, PRSNPs<sub>2</sub>, using various concentrations of PAFE and PRFE. The size of the PASNPs controlled by varying within different concentrations of the sample extract, and thereby increasing their catalytic efficiency.

Among all July (leaf) PRSNPs<sub>1</sub>, October (leaf) PASNPs<sub>1</sub>, October (Bark) PRSNPs<sub>5</sub> and October (Flower) show best catalytic activity than others. PRSNPs<sub>1</sub> The green-synthesized silver nanoparticles exhibited size-dependent antibacterial activity where the small-sized leaf- PRSNPs<sub>1</sub>, bark-PASNPs and flower-PRSNPs<sub>1</sub> of displayed superior inhibition against microbes compared to that of PASNPs<sub>2</sub>, also shown significant size-dependent catalytic properties in carrying out the degradation of organic dyes. These simple biological procedures open new possible catalytic and biological models in material science with industrial applications. These simple ecofriendly silver nanoparticles can be considered in nanotechnology with promising catalytic and biomedical applications.

### ABSTRACT

The present investigation was carried out to determine the effect of music stimuli in laying performance and egg quality characteristics of duck (*Anas platyrhynchos*) and geese (*Ansercygnoides*). The study was conducted in the farm of CUTM campus from September 2019 to February 2020. The laying performance was assessed in both the bird species and egg quality was measured for internal and external parameters. A total of 90 ducks and geese were exposed to three types of treatments viz. Classical, Random and Control. Analysis revealed that geese and ducks exposed to classical music showed significant results with increased body weight than the control also the egg quality parameters. Although the results disclose comparable similar egg yolk weight and albumen with the weight of egg regardless of types of music consequences showed and proved that duck and geese barren with classical music significantly improved eating habits and increase the production rate with better egg quality which will help the normal management practices with good profit in those birds who are reared without music.

**Key words:** Classical music, Egg feed price ratio, External and internal egg quality characteristics, Feed conversion ratio, Random music

### INTRODUCTION

Music seems a more fundamentally human art form the most. The science of music's effect on animals and even plants reveals something startling. Music is therapeutic, it evokes memories and emotions of the birds as well as animals. The music specifically effect different reaction towards birds. These classical music tunes soothe and

**Priyanka Dash and Yashaswi Nayak**

alleviate anxiety which will help to smoothen the experiment. It is just an art form when animals are introduced into classical music and when they are listening to slow jam produce more eggs and improve egg production by reducing the stress stimuli of birds. Commotion is a potential stressor to animals and has an important psychological component which provides a source of potential fear of animals (Campo, 2005). Classical music definitely has a more calming effect on them than random music. On the other hand, the positive physiological and psychological effects of music on humans are well known (Standley, 1986; Snyder and Chan, 1999).

Various types of music influence the laying performance and economic of quail production (Retallack, 2008; Morell, 2013; Lokuta, 2013; poultry hub, 2006). Different type of music influences the performance, egg quality, behavior and economics of raising Japanese quails (Cabara, 2017). Sonic booms did not initiate abnormal behavior that would result in decreased productivity in wild turkeys (Lynch and Speake 1978). Classical music intensity the auditory stimuli and reaction of the birds towards the music stimuli which enhances the birds to be more relaxed in their environment and provide the birds to lay eggs comfortably and stimulates the reproductive system for better egg quality and production performance (Morell, 2013). The slow tunes increases in the baseline steroid level when exposed to the stimuli was observed in white leg horns (Borg, 1981). The quality, shape and size along with the rate of production of eggs are important for commercial point of view. Normal production performance during its reproductive age it lays 100-110 eggs. Earlier, there is no report on effect of music on duck and geese. So, the study was conducted on *Anas platyrhynchos* and *Ansercygnoides* which belong to the order Anseriformes and family Anatidae of phylum Chordata.

**MATERIALS AND METHODS****Birds and experimental design**

The ducks (*Anas platyrhynchos*) and swan geese (*Ansercygnoides*) were distributed separately into three treatments during the experiments conducted from September 2019 to February 2020. A total of ninety, one-month old birds of both the breed were randomly assigned into the treatments with three replications comprising of five birds each (3 females & 2 males). The birds were reared in grower and cages with sound proof materials, furnished with drinking water and feeding troughs.

**Music and light management**

They were given three treatments, viz. Control (without music), Random music and Classical music. There were nine cages with 1 meter in length, 1 meter in width and 40 cm in height. They were kept at a distance of 5 meter from each other. Cages used in the study were cleaned and disinfected thoroughly. During experiment period music was played for 12hrs with speakers as source of music. Classical music soothes the vibration of body by giving positive vibes. It is the magnificent form of art planted in the traditions of both eastern and western culture including both secular and sacramental music. Birds were treated with Hindustani vocal and Beethoven music as well as chants as classical music. Random music included heavy metal, reggae, jazz, rock music was given for the experiment. These are all popular distinctive music of the generation and it gives a soulful distraction. The cages were provided with 10 watts LED bulb as source of light. Bulbs were turned on at 06:00 pm and turned off at 10:00 pm to maintain light and heat.

**Feeds and feeding**

Ad libitum feeding for birds in all treatments was practiced. At the beginning of the study, all the birds were fed with starter feed. After 20<sup>th</sup> day grower feeding was given to all birds. Shifting of feed was done gradually by considering the adapting capability of birds, feed was gradually converted to grower feed. At the 6<sup>th</sup> week of the study, feeds were gradually converted to layer feed which was recommended as per the regulation of CPDO, Bhubaneswar. In addition, fresh and clean water were also given ad libitum. The birds were taken care for proper management in a hygienic manner with suitable environment. Proper cleanliness with sanitation of the cages was done in order to prevent diseases.

## Data Collection

### Egg Production

#### % Bird-day production

The average number of eggs produced by duck and geese was determined by getting the ratio of the number of egg produced and the number of birds per replication the day the birds start laying eggs. The % bird-day production was calculated using this following formula:

$$\% \text{ Bird-day production} \times 100 = \frac{\text{total number of egg produced}}{\text{total number of birds}}$$

### Feed consumption

Feed consumption was estimated by subtracting the amount of feed refused from the amount of feed offered per cage. In addition, total and average feed consumption per replication was also collected.

### Feed conversion ratio

Feed conversion ratio (FCR) was obtained after 80 to 90 days of rearing. Calculation was done by dividing the feed consumption (total feed consumed divided to the number of birds per replication) by the dozen of egg.

### Egg quality

The characteristics include egg length, egg breadth, egg weight, yolk length, yolk breadth, albumen length, albumen breadth, shell weight and egg shell thickness of eggs laid by both duck and geese exposed to different types of music was also considered. All eggs laid during experimental period were subjected to egg quality test.

### Fertility rate

All eggs collected between 20<sup>th</sup> to 24<sup>th</sup> week were set in the automatic incubator for incubation and fertility test. Fertility rate was analyzed by dividing the number of fertile eggs by the total number of eggs set in the incubator multiplied by 100 the formula is given below.

$$\text{Fertility rate} \times 100 = \frac{\text{total number of fertile eggs}}{\text{number of eggs set in the incubator}}$$

### Hatchability rate

All fertile eggs remained in the automatic incubator for hatching. Hatchability rate was calculated by dividing the number of hatches by the total number of fertile eggs in the incubator multiplied by 100. The formula is presented below.

$$\text{Hatchability rate} \times 100 = \frac{\text{total number of hatches}}{\text{no.of fertile eggs in the incubator}}$$

## Economics

### Egg Feed Price Ratio

EFPR is the ratio between the receipts from egg and expenditure on feed. This was computed using the following formula: EFPR

$$= \frac{\text{total value of egg produced}}{\text{total value of feed consumed}}$$

Priyanka Dash and Yashaswi Nayak

### Statistical Analysis

ANOVA (Analysis of variance) was used to analyze the significant differences in fertility, hatchability rate and egg quality characteristics. Data were estimated and analyzed by using PAST 3 software with one-way ANOVA and subsequently Tukey's Post hoc test.

## RESULTS AND DISCUSSION

The different parameters estimated in the performance of egg laying bird i.e. duck and geese during the growing and laying period including % bird-day production, feed consumption, feed conversion ratio (FCR) are presented in Table 1. External and internal parameters of eggs viz. egg weight, yolk length and breadth, albumen length and breadth, length and breadth of egg, shell width, shell thickness, fertility and hatchability rate exposed under different types of music are depicted in Table 2 and 3.

### Percentage Bird-day production

The average number of eggs produced by both the birds was determined by getting the ratio of the number of egg produced and the number of birds per replication the day the birds start laying eggs between 24<sup>th</sup> to 22<sup>nd</sup> weeks. Results showed significant ( $P < 0.05$ ) differences in the %bird-day production of duck exposed to random as well as classical music in comparison to the control. Ducks exposed to random music had significantly lower % bird-day production (73.3%) compared to the exposure to classical music (86.66%). The ducks which are not exposed to any kind of music was having 60% bird-day production and the difference was significant ( $P < 0.05$ ). Results revealed that geese which were exposed to classical music had significantly higher ( $P < 0.05$ ) % bird-day production with 66.66% compared to those geese which were exposed to random music with 33.33% and geese which are revealed to no music (control) is having 46.66%. Although birds exposed to random music showed less bird-day production than control the value was not statistically different. The higher egg production observed in the birds exposed to classical music than control may be attributed to their feed intake.

### Feed Consumption

Data presented in Table 1 revealed the feed consumption of both the birds to different types of music. In case of ducks the feed consumption for both random and classical music exposure was higher and highly significant over control ( $P < 0.05$ ) while the values for both types of music were at par. However in case of geese, listening to classical music resulted significantly more feed consumption (2842g/day) than control (2513g/day). These results were in line with the findings of Miclus (2011), Christopher (2011), Patricelli and Blickley (2006), and who mentioned that classical music results to regular eating and resting for a longer period without excessive movement which eventually lengthens the meal duration and more feed intake in comparison to the birds not exposed to any kind of music and noise. Similarly, Davila (2011) reported that layers provided with classical music reduces stress due to auditory enrichments, thus improves feed consumption.

### Feed Conversion Ratio

Feed conversion ratio (FCR) depends on the quantity of feeds needed to produce a dozen of eggs. The data revealed that random music was less efficient ( $P < 0.05$ ) in changing feeds into dozen of eggs compared to those exposed to classical in both the bird species. However, the values were statistically significant over control ( $P < 0.05$ ).

### Fertility and hatchability rate

In ducks the fertility (74.07%) and hatchability (80%) values for random music exposed birds were comparable to the control but significantly higher for classical music. However, in case of geese these values were significantly higher ( $P < 0.01$ ) for both types of music compared to the control. There is no direct study regarding the effect of specific music on the fertility and hatchability rate. Moreover, favourable background music helps like classical music cover

up loud noises keeping the birds more relaxed in their environment (Retallack, 2008) which helps the birds to comfortably lay eggs and activated the bird's reproductive system and made them lay eggs with thicker shell.

### External and Internal parameters of duck and geese

Table 2 presents the data on external and internal parameters of eggs in ducks. Result revealed that the external parameters viz. egg length, egg breadth, egg weight were significantly higher to control when exposed to classical music as well as random music in comparison to control. Egg shape index value and egg weight were at par for control and random whereas significantly higher in case of classical music ( $P < 0.001$ ). The yolk length, yolk height, albumen length values for both random and classical music were also significantly high in random and classical music. On the other hand although ANOVA revealed variation ( $P < 0.001$ ), albumen height was similar in all cases. Shell weight and thickness values were highly significant for both types of music ( $P < 0.001$ ) over control and there was difference between two types of music exposed birds. ANOVA revealed significant difference in all parameters among three types of treatments ( $F = 7.39$  to  $120.00$ ,  $P < 0.01$  to  $0.001$ ).

For geese there was significant difference in all parameters among three types of treatments ( $F = 5.23$  to  $80.443$ ,  $P < 0.05$  to  $0.001$ ). Classical music exposed geese excelled in all external parameters in comparison to control, while random music exposed birds showed intermediate values. In case of the yolk length, albumen length and height, there was clear difference among all the groups as they were separated by Tukey's LSD. There was no statistical difference between control and random music for albumen shape index while for other internal parameters both types of music significantly affected the geese for higher values. The shell weight and thickness were at par for both types of music and significantly higher over control ( $P < 0.01$ ). Thus exposure of classical music to both ducks and geese revealed positive effect on external and internal egg parameters.

### Economics

#### Egg Feed Price ratio (EFPR)

Egg-feed price ratio is used to indicate the relative profitability of egg production obtained by analyzing the relationship between egg prices and the cost of feed. This is calculated by dividing the total value of egg produced over total value of feed consumed, the EFPR of both duck and geese birds introduced to different types of music had relevantly higher ( $P < 0.05$ ) EFPR compared to birds not exposed to any kind of music. Results can be attributed to the significantly higher ( $P < 0.05$ ) egg production (i.e. % bird-day production), lower feed consumption and more efficient FCR of birds exposed to different types of music.

These findings was in line with Davilla, (2011), World poultry (2008) and Hopkins (2000) who reported that provision of music improved egg production and eventually improved the feed conversion efficiency compared to the normal management practices in egg laying birds reared without any supply of music. Observations made on egg laying, egg parameters and clutch size in Mallard *Anas platyrhynchos* (Mustafa shah, 2009). On the other hand studied the combined effect of music, environmental enrichment, and filial imprinting (Gvoryahu et al., 1989). (Ladd et al. 1992) reported that regular exposure to music (country or classical /jazz during 8h) reduce heterophil to lymphocyte ratio and grooming whereas it stimulate feeding and head shaking in laying hens. On the other hand exposure of meat type chicks to two different levels and kinds (rock and roll and dinner) of continuous music did not show any significant results on feed consumption (Christensen and Knight, 1975).

The study displays that classical and random music which is given to egg laying birds i.e. duck and geese are remarkably enhanced and upgraded in the average body weight. However the music helps in reducing the stress level and improved the psychological behaviour of egg laying birds so that the rate of production of eggs increases with its better egg quality. Increase in production and improved quality of eggs regain the economical status and return on investment. When the birds are revealed to musical environment gradually they become less aggressive as compared to when not introduced to any kind of music.

**Priyanka Dash and Yashaswi Nayak**

## ACKNOWLEDGEMENT

We are thankful to the HOD Zoology and to all my teachers and staff of the department and also the members of CPDO, Bhubaneswar for providing facilities to conduct the experiments. I also extend my sincere thanks to the people who all helped me in managing the birds during my experimental schedule.

### ABSTRACT

This paper provides a brief summary of information on growth performance of *P. monodon* under different feeding supplement. The nutritional requirements of *P. monodon* have been little known despite its importance in aquaculture. Recent findings indicate a noticeable difference between some important nutrient requirements of *P. monodon* and *P. japonicus*, the most studied shrimp species. For example, the thiamin requirement for *P. monodon* was estimated to be 14 mg/kg diet, while for *P. japonicus* it is 60-120 mg/kg diet for juveniles and 40-80 mg/kg diet for larvae. The same contrast was also observed in the requirements of riboflavin (22.5 mg/kg in juvenile *P. monodon* vs. 80 mg/kg in larval *P. japonicus*), niacin (6.4 mg/kg vs. 400 mg/kg) and vitamin C (2,000-2,500 mg/kg vs. 10,000 mg/kg). Research efforts to understand the lack of ability for shrimp to effectively use dietary crystalline amino acids have resulted in the development of a microencapsulated amino acid that can be assimilated by *P. monodon* which is incapable of utilizing the essential amino acid in crystalline form. This development enables the quantification of requirements of the amino acid and other essential amino acids for shrimp. A study using cellulose-acetate-phthalate encapsulated arginine indicated that the arginine requirement of postlarval *P. monodon* is 5.47 g/100 g protein (2.50 g/100 g diet). Other aspects concerning the importance of digestive enzymes, dietary requirements of protein, carbohydrate, lipid and vitamin, energy and larval feeding for *P. monodon* were reviewed.

**Key-words:** Substrate, *Penaeus monodon*, Periphyton, Brackishwater shrimp, Conventionally

## INTRODUCTION

Freshwater prawn culture has now occupied a significant position in inland aquacultural practices. Although India has marine water resources for aquaculture, these are generally being exploited for carp and other finfish culture that's too in a limited scale as discussed by Ramesh et al, 1991 [1]. Tiger shrimp, *Penaeus monodon*, were cultured in commercial ponds and fed diets with or without supplementations of a novel microencapsulated organic acid blend. Over 22 weeks, shrimp growth and various water quality parameters of the ponds were measured. At various intervals during the grow-out period, these farm-raised shrimp were transferred to the laboratory and two separate experiments were performed to determine nutrient utilization efficiencies and subsequent resistance to *V. harveyi*. With the incorporation of more controlled laboratory-based experiments using farm-raised shrimp, this helped provide a broader complement of data to the pond trial and a unique opportunity to assess the potential of dietary organic acids to the shrimp aquaculture industry. *Penaeus monodon* is found at depths from 0 to 110 m, inhabiting bottom mud and sand. Giant tiger prawn live in brackish, estuarine (juveniles) and marine (adults) environments. It is even grown commercially. *Penaeus monodon* appears to select muddy mangrove channels and often associates with marginal or floating vegetation *Penaeus monodon* are generally dark coloured, with the carapace and abdomen transversely banded with black and white. The rest of the body is variable, ranging from light brown to blue or red, while some smaller specimens show a dull red dorsal strip from the rostrum to the sixth abdominal segment.

## MATERIALS AND METHODS

### Experimental Ponds

Black tiger shrimp, *Penaeus monodon fabricus* was cultured for 110 days between December 2019, January, February and March of 2020 in twelve earthen ponds (0.5 ha or 5000 m<sup>2</sup> each) randomly selected in kasia shrimp farm (Basudevapur, Bhadrak, Odisha, India). Three ponds each were used to culture the shrimp for different feeding frequencies: (i) 3 times (T1), (ii) 4 times (T2), (iii) 5 times (T3), and (iv) 6 times (T4) day<sup>-1</sup>. Ponds were selected for each treatment following the random block design (RBD). All the experimental ponds were rectangular in shape with facility of both inlet and outlet structures with average of 1.2 meter water depth. Soil was clayey loam and aeration was maintained for all ponds during the culture period.

### Rearing in ponds

Similar pond management practices like sun drying, tilling, liming, and eradication of predators were performed once prior to water filling in all the experimental ponds during culture. Culture techniques and inputs were same for all ponds of four treatments. The ponds were ploughed conventionally and limed (1.5 ton ha<sup>-1</sup>) to improve the soil condition alkaline. Initial water filling in ponds was done directly with water pumped from Haldi rivercreek after being filtered by fine mesh bag net of 300 micron and chlorination (30 ppm with 60% active ingredients) was done for disinfection and killing of pathogens. After three days of dechlorination, organic fertilizers (poultry litter @ 250 kg ha<sup>-1</sup>) and inorganic fertilizers (urea @20 kg ha<sup>-1</sup>; single super phosphate @ 5 kg ha<sup>-1</sup>) were applied to improve the primary productivity of the cultured ponds. Routine application of urea @6 kg ha<sup>-1</sup> and single super phosphate @2 kg ha<sup>-1</sup> were performed twice a month to maintain development of natural food.

Agricultural lime and dolomite each were applied once a month @ 50 kg ha<sup>-1</sup> during production period. No water exchange was done during initial 20 days and later it was limited to 0-10% in every alternate days from pre-treated reservoir. During raining, only surface draining was maintained to retain salinity. Good quality and disease-free post larvae of 20 days old (PL) of *P. monodon* were procured from a private hatchery (Vaisakhi Hatchery, A.P., India), then acclimatized and stocked @ 20 pieces m<sup>-2</sup> in all the ponds where water quality were almost in same ranges within aquaculture standard (temperature 28.4-28.6°C, dissolved oxygen >4.0 mg l<sup>-1</sup>, pH 7.9-8.1, Secchi's disc transparency 35-45 cm and salinity 7-8 g l<sup>-1</sup>). Harvesting happened after 110 days of culture as per market demand and good quality of shrimps. A bag net was fitted on outlet canal with 20 # mesh (pore size) of width 1 meter and

**Raka Chandrika Panda and Yashaswi Nayak**

length of 4 meter. The water level in the pond was reduced to 60 -70 cm and outlet was opened and shrimp was caught at night, collected with ice and sold to processors on farm-gate price.

**Shrimp seed procurement and stocking**

A survey revealed that 93 percent of the farmers procured *Penaeus monodon* seed through a contract system whereby farmers purchase quality seed in bulk. The farmers enter into an agreement with a hatchery operator one month in advance of delivery. Seventy percent of the seed used in the traditional extensive farming systems were procured from commercial hatcheries, and rest were sourced from the wild as described by Ramaswamy et al 2013 [3]. In the modified extensive farming systems and the semi-intensive farming systems, the seed was sourced exclusively from commercial hatcheries. Farmers procure seed from local hatcheries that are in close proximity to their farms (<8 hrs transportation time). When the transportation time exceeds four hours, the PL are stocked directly into the ponds during the early morning hours. When the transportation periods are less than four hours, the PL are stocked during the late evening. After 45 days, survival estimates are made. These are based on feed consumption rates (using feed trays), and cast net sampling. Until the survival estimations have been made, 80 percent of PL are assumed to have survived, and feed rates are adjusted accordingly.

**Feeding management****Nutrient requirements**

Little is known about the nutrient requirements of *Penaeus monodon*. Like any other organism, however, prawns need nutrients or substances that will provide for normal growth, regulate body processes, and increase resistance to diseases. Shrimps were fed with standard commercial palletized feeds (crude protein-38.35%, Crude fat-7.75%, Crude fiber-3.36%, Total ash-14.25%, calcium-2.2-2.5% and phosphorus-1.5-1.8%) and applied as prescribed by feed company. The feeding regime (frequency, time of feeding and percentage ration) for cultured shrimp was presented in Table 1.

**Farm made feeds**

While twenty percent of the extensive farms reported using farm-made feeds, the study also revealed that 98 percent of the shrimp farmers used manufactured, sinking dry pellets in combination with farm-made feed. Only 20 percent of the extensive farms (<2 percent of the total farming area in the country) were using farm-made feeds; the other 80 percent of the extensive farmers, and all of the modified extensive farms and semi-intensive farms used manufactured, sinking pelleted feeds. The natural food was replenished by regular water exchange during high tide periods. On the smaller modified extensive farms, farm-made feeds were used and were primarily comprised of mixtures of boiled rice, maize and potatoes. During the first month of the production cycle, there was no feeding and the shrimp depended solely on natural pond productivity as discussed by Asaduzzaman et al 2010 [2]. In the second month feed was provided once per day, up to a maximum of 7.5 kg/ha. Groundnut, rice bran, wheat cake and egg yolk were used as ingredients. From the third month, feeding was based on the size of the shrimp, and a minimum of 7.5 kg/ha was fed per day.

**Industrially manufactured pelleted feeds**

India has a well-established capacity to produce shrimp aquafeeds. Prior to 1990, when the manufacturing aquafeed industry was in its infancy, the country relied on farmmade feeds. In the early 1990s, the large quantities of shrimp feeds were imported from Taiwan Province of China and Thailand. Over time, these imports had gradually been replaced by domestically produced feeds. Currently, the capacity of domestic shrimp feed production exceeds the demand.

**Raka Chandrika Panda and Yashaswi Nayak****Feed materials**

The manufactured aquafeeds which were reported during the survey, contain approximately 40 essential nutrients. About 20 to 40 percent of the total ingredients used in commercial shrimp feeds, are derived from marine capture fisheries, which include fishmeal, fish oil, shrimp/crustacean meal, squid meal and other miscellaneous products, such as fish, fish silage, fish/squid-liver meals and seaweed extracts. The principal classes of raw materials that are currently used in the shrimp aquafeeds can be classified as:

- Cereals and cereals by-products.
- Leguminous seeds.
- Vegetable oil residues.
- Animal by-products and oils.
- Miscellaneous ingredients, including vitamins and minerals.

**Diet development**

There are two categories of protein sources: animal and plant. Since prawns tend to be carnivorous, it is suggested that two-thirds of total protein come from animal sources and one-third from plant sources. Likewise, there are two sources of lipids: animal and plant. Of the animal fats, those from marine sources like fish liver oils are preferable. A pelletized artificial diet might be easy to prepare but whether or not the food is attractive and acceptable to the prawn is another problem to consider. Unlike fish that gulps on or swallows its food, *P. monodon* is a nibbler and hence requires a pellet that is stable in water for six or more hours. The effectiveness of a prepared diet is usually expressed in terms of food conversion ratio (FCR) or feed efficiency. This is the amount of dry feed that will produce a unit of wet weight gain.

The vitamin-mineral premix for poultry may not be the best combination but it can be utilized in the absence of concrete findings on the vitamin-mineral requirement of prawns under tropical conditions. The premix should contain Vitamin C which is good for prawn. The other vitamins needed in the mix were A, D, E, K, B1, B2, B6, B12, pantothenic acid, choline, inositol, and folic acid. The minerals calcium, phosphorus, potassium, iron, magnesium,

**Raka Chandrika Panda and Yashaswi Nayak**

It is advisable to have all feedstuffs chemically analyzed.

**RESULT**

For several decades, traditional farming has been practiced in Odisha. In February, ponds are filled during high tide, and PL that are either wild-caught or sourced from hatcheries are stocked at 15 000/ha. After two months of culture partial bi-weekly harvesting starts; 7 500 PL/ha are stocked immediately after each partial harvest and the final harvest takes place after approximately 10 months. The farmers procure seed from commercial nurseries that are supplied with PL from the hatcheries. The dependence on commercial nurseries for seed in Odisha is due to the small quantities that the farmers require to stock their ponds. Farmers feel it is not feasible for them to procure PL directly from the hatcheries because they would be required to purchase large numbers of animals. The production cycle in this system is approximately 10 months. The following tables bring the exact composition of needed supplements from both plants and animal sources as described by Ahmad Ali et al (1992) [4]

**Feeding regimes**

Artificial feeding could start immediately after stocking when natural food was lacking in the pond or when the pond was highly stocked (50,000 and above) as in intensive farming. When feeding, the suggested amount of feed was 10% of the total body weight.

### Raka Chandrika Panda and Yashaswi Nayak

The suggested feeding schemes and schedules at a stocking density of 25,000/ha were shown below;

1 – 30 days = 10% of body weight

31 – 60 days = 8% of body weight

61 – 90 days = 6% of body weight

91 – 120 days = 4% of body weight

#### Determination of growth and feed utilization efficiency

Cast net was used to measure the growth rate of shrimps during early hours. Shrimps were sampled every fortnight by cast net for monitoring the growth, survival and health conditions of shrimp and for estimation of production yield in the experimental ponds. During stocking average weight of post larvae (PL20) was 0.02 gm and the first sampling was taken after 15 days of grow out phase from four locations of each pond. The average body weight (ABW) was measured at fortnightly intervals till harvest. For measuring ABW, 100 samples of shrimp collected by cast net randomly & mean weight was calculated. For estimation of survival, measured cast net was thrown to ponds randomly 4 times and density calculated as per available shrimps in cast net and total pond area in relation to initial stocking density. FCR (Feed conversion ratio) is calculated as total feed utilized divide by total shrimp yield. Survival, FCR, yield were calculated from 45 days onwards as shrimps were smaller in size. Weight gain (WG), FCR and specific growth rate (SGR) was measured as per conventional method in every fifteen days. Protein efficiency ratio (PER) and feed efficiency ratio (FER) were estimated by routine methods and ABW, survival rate and production yield were calculated. Health conditions were recorded during same samplings for gut and abnormalities. Samplings of shrimps were regularly performed every 15 days until harvest. The formulae to calculate different parameters are as follows:

Average body weight (ABW) = Total weight of 100 shrimps (g) / 100

Weight gain (WG) = Final weight - initial weight

Food conversion ratio (FCR) = Total feed consumed (kg) divided by total yield (kg)

Survival rate = Average no. of shrimps taken/cast net area (m<sup>2</sup>) × pond area (m<sup>2</sup>) × 100/number of post larvae stocked

Specific growth rate (SGR) = 100 multiplied by (W<sub>f</sub> - W<sub>i</sub>)/ period (days) [W<sub>f</sub> = final weight; W<sub>i</sub> = initial weight]

Protein efficiency ratio (PER) = Weight gain (wet)/Protein fed

Feed efficiency ratio (FER) = Final weight - initial weight / total feed intake

Production yield = Survived shrimps number multiplied by ABW

#### RESULT

Feeding was administered according to their body weight and days of culture in a fixed quantity in all treatments (Table 2). Small post larvae were fed two times a day (1-15 days) for providing more availability of feed and they are accustomed to feed on natural foods; slowly increased to three times a day as it grows bigger (16-44 days). Later (45-110) feeding was followed as mentioned in Table. 2 for the experiment that was pallet feed with more quantity. Feed was broadcasted by rope method, i.e., floats tied and moved with rope in lines horizontally in all ponds. Aeration (4-10 hours as per biomass) was kept off for two hours during feed application.

#### DISCUSSION

Water quality parameters during the experimental period are presented in Table 2. The recorded water quality parameters were within the acceptable ranges for brackishwater shrimp culture. Comparatively lower level of total ammonia nitrogen (TAN), NO<sub>3</sub>-N, NO<sub>2</sub>-N and PO<sub>4</sub>-P were observed in substrate based system while no significant difference was noticed among the experimental ponds. This may be attributed to the fact that low stocking density in the present field trial might have kept the water nutrient parameters within the favorable limit in both the treatments. Provision of substrate increased the transparency (p<0.01) and reduced the turbidity (p<0.05) in

**Raka Chandrika Panda and Yashaswi Nayak**

treatment ponds compared to control. This is similar to our earlier findings where a lower turbidity level was noticed in substrate based system as substrate reduces turbidity by trapping suspended particles. Chlorophyll content in the water column is presented in Fig 1. Average chlorophyll a levels in water column were  $15.22 \pm 6.97$  and  $19.06 \pm 8.68 \mu\text{g L}^{-1}$  in substrate and control ponds respectively. Level of chlorophyll a in control ponds showed fluctuation throughout the culture period, and coincided with algal bloom and algal crashes. Similarly, comparatively lower gross primary productivity,  $235 \text{ mg C m}^{-3} \text{ h}^{-1}$  was recorded in substrate based system compared to control ponds ( $258 \text{ mg C m}^{-3} \text{ h}^{-1}$ ). The present findings are in line with the earlier reports where lower level of primary productivity, chlorophyll a and phytoplankton level in the water column were reported in substrate based culture ponds.

**Feed additives**

Seventy-five percent of the respondents were reported using probiotics and feed additives. The use of these additives was dependent upon stocking densities. There was an increase in the use of probiotics and feed additives as the stocking densities increased. No feed additives were used at stocking densities lower than 3-4 PL/m<sup>2</sup>.

**CONCLUSION**

From the above determination, it can be concluded that *P. monodon* reared in substrate based systems had higher biomass and lower FCR compared to shrimps grown in substrate free ponds. Periphytic community developed over the submerged substrate served as quality natural food for shrimps. Regression coefficient closer to isometric value and better Fulton condition factor observed in substrate based treatments reflects better feed utilization and suitable culture environment. Amount of utilization of periphyton by *P. monodon* at higher stocking density and utilization of periphyton at different life stages of black tiger shrimp is a subject of further research.

**ACKNOWLEDGEMENT**

I would like to express my deepest appreciation to all those who provided me the possibility to complete this report. A special gratitude I give to our final year Project Guide, Dr. Yashaswi Nayak whose contribution in stimulating and encouragement, really helped me to coordinate my project especially in writing this report.

### ABSTRACT

Calcium designated as supernutrient in human body by performing vital role. Many serious complications like porous and fragile bones, decay of tooth, cramps in muscle and osteoporosis are result of inadequate intake of calcium. Calcium source for humans is through diet. Therefore, this present study was undertaken for determination of "Calcium profile of locally and commonly consumed food stuff of Dhenkanal (Odisha)". Twenty five foods from five food groups were analysed for their calcium content by EDTA titration. Calcium content in different foods ranged from 8-1145 mg/100g. Pulses and fishes contained the highest calcium content while fruits had the lowest calcium content. Top five foods for Calcium were Puntius sophore (1145 mg/100gm), Marcotylomauniflorum (297mg/100gm), Labeocatla (182mg/100gm), Vigna radiate (152mg/100gm) and Cajanuscajan (145mg/100gm). These outcome results were compared with values reported in the literature.

**Keywords:** Calcium content, Calcium deficiency, EDTA Titration, Fish, Nutrition, Osteoporosis, Staple food

### INTRODUCTION

Minerals like calcium is an essential chemical element for animals to perform various functions of life which make up about 1-2% of body weight of an adult human being [1]. Calcium contribute in maintaining human body health by making the bone and teeth healthy and also act as a mediator of biological processes like muscle contraction secretion, glycolysis, gluconeogenesis, cell division, transportation of ion, cellular growth [2]. A natural tranquilizer is calcium as it calms the nerves of body. Body energy and immune system promoted by calcium. Calcium ion of blood affect the hormone level of body. Inadequate amount of calcium intake causes calcium level depletion and leads to thinning and weakening of bones and osteoporosis. This condition known as Dietary Calcium Deficiency [3].

**Lopamudra Samantaray and Yashaswi Nayak**

Every human being loses bone density between 30-40 age, mostly elderly women above 45 age group [1]. Tetany is initial stage of calcium deficiency, which may be identified by numbness in bones, cramps in muscle, arm and leg muscle tingling. The most common calcium deficiency sign seen in nails, skin, teeth and bones. Cramping during menstrual cycle or changes in menstrual flow indicate that woman suffering from severe calcium deficiency [4]. Calcium deficiency occurs when the bones become weakened or fractured which indicates towards osteoporosis. Osteoporosis is a condition where the bones are porous and fragile because of depletion of calcium level from them. Joint pains, increasing cholesterol level of body, impaired growth, numbness of fingers, arms and legs, joint pains, muscle cramps, irritability of nerves, insomnia, abnormal hormone regulation are common [5]. Good sources of calcium include dairy products, leafy green vegetables, certain fish, oatmeal and other grains, cabbage, summer squash, green beans, garlic, sea vegetables and calcium-fortified foods such as cereals and fruits. Other than that olive oil, soy beans, blueberries and foods rich in omega-3s, like fish oil and flaxseed oil may also have bone boosting benefits [6].

Many small, indigenous fish are important for nutrition because they can be eaten as whole, with bone, head and eye, so that it can provide sufficient calcium and other micronutrients required for human. Small indigenous fishes with a maximum length of 25-30 cm in mature or adult stage of their lifecycle can provide about 30% of total calcium content requirement of an adult human [7]. Fish bone fortification into the main food diet is effectively accepted as it is a cheaper way for providing the daily need for a range of vitamins and minerals that is mainly calcium [8]. The aim of this study is to examine the relationships of health beliefs to calcium intake of human especially women. Identification of amount and relationships of calcium concentration among the staple foods adds to existing calcium concentration knowledge concerning individuals that are at high risk for developing osteoporosis. This knowledge could be used by people in developing creative interventions to effectively modify complex lifestyle practices.

**MATERIALS AND METHODS**

**Collection of samples.** All samples were purchased in the open market in Dhenkanal, Odisha, India. They represent fruits and vegetables as bought by the ordinary consumer. No information about the genetic history of the fruits, vegetables, cereals, pulses and fishes could be obtained. Most of them are, however, not truly native, but were imported samples. Twenty five different food items were collected from local open market and retail stores of Dhenkanal, Odisha, India. **Sample preparation.** The samples investigated for calcium content at Dhenkanal Autonomous College, Dhenkanal. The samples were collected separately from market by clean polythene zipped bags through which contamination could be avoided during the transportation to the laboratory. The samples were stored in refrigerator in the laboratory at 4°C. These samples were digested and analysed within 15 days from the time of collection from local market. Ten staple fishes were washed and boiled separately in distilled water for 30 minutes. The flesh attached to fish was cleaned manually from fish bone and washed with water. Then they were dried in the oven at 100°C for 1 hour by the method of Amitha et al. 2019 [9]. Then samples were kept under direct sunlight for about 12 days. The sample bones were then powdered by using a pestle and mortar at laboratory. The sample fish bone powder was kept in container at room temperature. The calcium content was determined.

**Digestion of sample.** The samples were estimated for calcium content by using standard procedures reported by Lawani et al., 2014 [1]. All the samples were digested by a mixture of conc. nitric acid, sulphuric acid and Hydrogen peroxide. Five grams of each food stuff was put in heat-resistant conical flask. Conc. sulphuric acid (8ml) along with nitric acid (10ml) was added to that flask containing food stuff. The flask was placed in heater and warmed cautiously. **Preparation of solution.** After vigorous heating of the flask the solution began to darken or char. 2cm<sup>3</sup> aliquot of conc. nitric acid was added constantly to avoid charring of the solution at any time the solution began to darken. Addition of conc. nitric acid was continued until the solution stopped darkening on prolonged heating. At this point, the solution was made to cool down and diluted with distilled water (10ml) and boiled to fuming. This boiling to fuming was repeated twice with distilled water (5cm<sup>3</sup>). Addition of hydrogen peroxide (2ml) with drops of

**Lopamudra Samantaray and Yashaswi Nayak**

nitric acid allowed the persistent colour of solution were being cleared. Until there were no further reduction of pale yellow colour was obtained, the solution was heated to fuming state each time with hydrogen peroxide. The solution was allowed to be cool with distilled water (10ml) and made evaporated to fuming once again. Until there was no more fuming this step was continued, then the solution was made up to mark in 100ml volumetric flask. Estimation of calcium by trimetry. Each digested sample (50ml of aliquot) was pipetted into conical flask. pH was adjusted to 12 by 1M NaOH and then solochrome Dark Blue (4 drops) was added. After which the aliquot was immediately titrated against 0.01M EDTA solution to the end blue point.

**RESULT AND DISCUSSION**

The range of calcium content (mg/100g) of twenty five samples analysed are given in Table 1. Out of all staple food stuffs which Pool barb (*Puntius sophore*) (1145mg/100gm) (Figure-2) seen to contain highest calcium content and Banana (*Musa acuminata*) (8mg/100gm) observed to contain lowest calcium content among all. Pulses contribute more calcium than fishes, fruits and vegetables. The total calcium content contributed by pulses is 990mg/500g which make up 43% of total calcium content of all food items. Fishes contribute almost similar to pulses which is 980.5mg/500gm and make up 42% of total calcium content. Fruits contribute 90mg/500g of calcium content which is 4% of total calcium content. Whereas Vegetables contribute about 6% of calcium content which is 137mg/500g, showing in Graph 5. Table 1. Show that all the indigenous fishes contribute remarkable amount of calcium and out of which *Puntius sophore* (1145mg/100gm) contribute highest whereas *Rastrelliger branchy soma* (15gm/100gm) (Figure-5) contribute the lowest calcium content among all fishes and make up 41% and 0.5% in total calcium content respectively. Graph 1

Among pulses (Figure-7) *Marco tyloma uniflorum* contribute 297mg/g out of total pulse content, which is about 46% of the total pulse content, whereas among fishes *Puntius sophore* make up 60% of total fish calcium content with 1145mg/g of calcium. Among Fruits, *Citrus sinensis* contribute 38mg/g of total fruit calcium content which is 42 % of total fruit calcium content. In case of vegetables *Phaseleous coccineus* contribute about 29% of total vegetable calcium content. There were pulses and Cereals were taken into consideration which are two type of rice and three kinds of dal. The two type of rice are of almost same kind but only differ in the after cultivation processing method. Out of these two rice one is parboiled rice, which involves partial boiling of the paddy before milling to increase the nutritional value. White rice is the milled and polished rice which decrease the nutritional value. In that connection parboiled rice contain more calcium content than the white rice. So calcium content shows parboiled rice > white rice. Shows Table 1., but all dal items contain more calcium content than both the rice item. The present work elucidated on the calcium profile of some staple food stuff which are used commonly and has broadened our knowledge on the calcium content of food item like fishes, fruits, vegetables, cereals and pulses.

Lawani et al., 2014[1], investigated the calcium content nine staple food items of their locality and commonly consumed food items which was collected from six towns in North-Central Nigeria by titration. Their work shows much larger variation in calcium content of food items of vegetables and fruits like, *Phaseleous coccineus* and *Musa acuminata* (Table 2) whereas in our work it was 73.68% and 68% higher respectively. But other than cereals food items like parboiled rice show less variation. Their work evaluates calcium content of parboiled rice was evaluated 9.67% higher than our result. (Table 3) Saini and Devar, 2012[10], reported calcium content of locally and commonly consumed food analyzed for their calcium content by AAS of Kurukshetra (Haryana). The reported values of food items are not that much variable expect fruits like *Psidium guajava* and *Malus domestica*. The reported value of *Phaseleous coccineus* by Saini and Devar, 2012, was almost similar to the calcium content of this experiment, which means it is just 0.73% difference between these two content values.

In Table 3., Cunningham et al. 2001<sup>[11]</sup> reported mean calcium content in food samples. All the food samples studied by him contained lower percentage of calcium like *Pisum sativum* (28mg/gm), *Brassica oleracea* (23mg/gm), *Musa*

**Lopamudra Samantaray and Yashaswi Nayak**

*acuminata* (5mg/gm), *Malus dometica* (5mg/gm) in comparison to the calcium content of these respective work. Calcium content of studied food groups were quite similar with the calcium content reported by Longvah et al., 2017 [12] samples in present study calcium content results. The calcium content of *Phaseleous coccineus*(43.28mg/gm), *Pisum sativum* (28.24mg/gm), *Brassica oleracea* (25.16mg/gm), *Beta vulgaris* (17.28mg/gm), *Psidium guajava* (18.52mg/gm), *Vitis crinifera*(14.22mg/gm), *Musa acuminata* (8.73mg/gm), *Cajanus cajan* (139mg/gm) were nearly similar value. Among the similar food items *Cajanus cajan* (139mg/gm) show highest calcium content value whereas parboiled rice (8.11mg/gm) show the lowest value. Among all food items the calcium content of *Pampus argentus*, parboiled rice and white rice show great variation in the high calcium content in percentage than Longvah et al., 2017 [12]. Halevy. 1957 [13] studied on vegetables and fruits among which the calcium content of *Pisum sativum* (30mg/gm) and *Malus dometica*(9mg/gm) was exactly similar with the respective work, shows in Table 3.1.7. But many other food items show higher calcium content like *Brassica oleracea* (43mg/gm), *Beta vulgaris* (32mg/gm), *Allium cepa* (54mg/gm), *Psidium guajava* (49mg/gm) and *Musa acuminata* (18mg/gm). Among all reported food items only *Vitis crinifera*(12mg/gm) shows 55.55 percent lower calcium content.

Siong et al., 1989<sup>[14]</sup> and this respective work show only two similar food items like *Musa acuminata* (6.8mg/gm) and parboiled rice (7.1mg/gm) which had 17.64 percent and 294.36 percent more calcium content. Bogard et al., 2015<sup>[15]</sup> studied on nutrient composition of some important fish species in Bangladesh. The calcium content of *Puntius sophore*, *Oreochromis mossambicus*, *Pampusargentus* of this local work show rise under 30% in comparison to their work. The difference in calcium content of this respective study might have been attributed by different factors. The change could have been caused by anomalies of measurement of sampling, changes in agricultural practices or changes in varieties grown. Soil conditions including fertilizer application and storage and marketing conditions also influence mineral contents of vegetables, fishes, fruits, cereal and pulses. The plant state of maturation, genetic variance and environmental factors were also the possible for the differences observed

## CONCLUSION

Twenty five foods stuffs of 5 category were analysed for their calcium content. The calcium content values per 100g of fresh edible portion were tabulated. The determined average calcium content in present study was higher than the values reported by some other workers elsewhere. Pool barb had highest while banana had the lowest calcium content. Among food categories: Pulses and fishes had highest calcium content followed by vegetables, cereals and fruits respectively. Calcium content knowledge of staple foods and diets can allow an appropriate food selection and estimation of calcium concentration intake thereby improving intake of adequate mineral nutrition.

### Future Scope

Although staple food stuff available locally and commonly, although calcium content play vital role in maintaining skeletal health. Alternative warm possible area of this research relates to the use calcium by fortifying them in consumed foods and treatment of low bone mineral density, osteoporosis and osteomalacia.

## ACKNOWLEDGEMENTS

The author wish to thank Dr.Yashaswi Nayak and Dr.Siba Prasad Parida for guiding to conduct this work. The authors would like to acknowledge for providing necessary help and support provided by Centurion University of Technology and Management.

### Conflict of Interest

We declare that we have no conflict of interest.

### ABSTRACT

Cancer is disease caused by alterations of the genome as well as the proteome. These changes allow the cancer cell to evade normal cellular control mechanisms and to start growing uncontrolled. One of the fundamental features of cancer is tumor clonality, the development of tumors from single cells that begin to proliferate abnormally. The major goal of cancer research is to identify these molecular defects and use this knowledge to develop effective diagnostic, treatment and prevention regimens. The generalized loss of growth control exhibited by cancer cells is the net result of accumulated abnormalities is multiple cell regulatory systems and is reflected in several aspects of cell behavior. *Plumbagozeylanica*, commonly known as ceylon Leadwort or Doctrobush, is a species of *plumbago* is known to have anticancer effect. It causes pharmacological importance in medicine and employed clinically for their antifertility, germicidal, antileptotic and anti-inflammatory activities. Besides it possess central nervous system stimulatory, hepatoprotective, antioxidant, hypolipidaemic and anti-atherosclerotic properties. The root is used as laxative, expectorant, astringent, abortifacient, and in dysentery, the leaves are used as aphrodisiac and in scabies. *Plumbagin*(5-hydroxy-2methyl-1, 4-naphthoquinone) is a naphthoquinone and as the active ingredient Responsible for therapeutic effects. It exhibits effective cell growth inhibition by inducing cancer cells to undergo G2/M phase arrest and apoptosis.

**Divya Sankar et al.****Keywords:** Abnormalities, Anticancer, inhibition, Proteome, Mechanism.

## INTRODUCTION

Cancer is disease caused by alterations of the genome as well as the proteome. These changes allow the cancer cell to evade normal cellular control mechanisms and to start growing uncontrolled. One of the fundamental features of cancer is tumor clonality, the development of tumors from single cells that begin to proliferate abnormally.[24] The major goal of cancer research is to identify these molecular defects and use this knowledge to develop effective diagnostic, treatment and prevention regimens. The generalized loss of growth control exhibited by cancer cells is the net result of accumulated abnormalities in multiple cell regulatory systems and is reflected in several aspects of cell behavior that distinguish cancer cells from their normal counterparts. [1,16]. *Plumbago zeylanica*, commonly known as ceylon Leadwort or Doctrobush, is a species of plumbago is known to have anticancer effect. It causes pharmacological importance in medicine and employed clinically of their antifertility, germicidal, antileptotic and anti-inflammatory activities. Besides it possess central nervous system stimulatory, hepatoprotective, antioxidant, hypolipidaemic and anti-atherosclerotic properties.[20,21,22]The root is used as laxative, expectorant, astringent, abortifacient, and in dysentery, the leaves are used as aphrodisiac and in scabies. Plumbagin (5-hydroxy-2methyl-1, 4-naphthoquinone) is a naphthoquinone and as the active ingredient Responsible for therapeutic effects. It exhibits effective cell growth inhibition by inducing cancer cells to undergo G2/Mphase arrest and apoptosis [10,12,13]

## MATERIALS AND METHODS

### Sample Collection

*Plumbago zeylanica* was collected from the local areas of Thiruvananthapuram.

### Extraction of crude sample by using soxhaling apparatus

- 20 g of air dried roots of *P.zeylanica* was extracted with 300ml of methanol for 7-8 hours using soxhlet apparatus. This methanolic filtrate was dried and was used for further studies.

### Thin Layer Chromatography

- Preparative TLC silica gel plates are used for isolation and purification of alkaloid compounds using the solvent system chloroform: methanol in the ratio 5.5:1. to 20ml of the distilled water reliable amount of silica gel was added to form slurry. It was poured on the glass slide and then dried in the hot air oven. The crude sample i.e. methanolic extract of plumbagin was placed in the TLC plate with capillary tube and the slide was placed in the solvent. The chromatograms were air dried and the bands were viewed under the UV transilluminator.[2]

### Phytochemical Analysis

#### Alkaloids

#### Dragandroff's test

- 8g of  $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$  was dissolved in 20 ml  $\text{HNO}_3$  and 2.72g of potassium iodide in 50 ml  $\text{H}_2\text{O}$ . These were mixed and allowed to stand. When  $\text{KNO}_3$  crystals out the supernatant was discarded off and made up to 100ml with distilled water. The alkaloids were regenerated from the precipitate by treating with  $\text{Na}_2\text{CO}_3$  followed by extraction of the liberated base with ether.
- To 0.5ml of alcoholic solution of extract was added to 2.0 ml of HCL. To this acidic medium 1.0 ml of Dragandroff reagent was added. If orange red precipitate is produced immediately it indicates the presence of alkaloids.[9]

**Flavanoids**

**Test:** In a test tube containing 0.5 ml of alcoholic extract 5-10 drops of dilute HCL and a small piece of ZnCl<sub>2</sub> or Magnesium were added and the solution was boiled for few minutes. In the presence of flavonoids reddish pink or dirty brown color will be produced.

**Saponins**

**Test:** In a test tube containing 0.5 ml of aqueous extract, a drop of sodium bicarbonate was added. The mixture was shaken vigorously and kept for 3 minutes. If honey comb like froth was formed it shows the presence of Saponins.

**Phenols****Ferric chloride test**

To 1 ml of alcoholic solution of extract, 2 ml of distilled water followed by drops of 10% aqueous solution of FeCl<sub>3</sub> solution were added. Formation of blue or green colour indicated the presence of phenols.

**Steroids****Salkowski test**

To 200 µl of alcoholic solution of extract 800 µl of chloroform was added. 1ml of concentrated H<sub>2</sub>SO<sub>4</sub> acid was added carefully along the side of the test tube. A red colour was produced in the chloroform layer in the presence of steroids.

**Tannins**

**Test:** To 1ml of aqueous extract of sample, few drops of 5% aqueous FeCl<sub>3</sub> solution was added. Formation of bluish black colour which disappears on addition of a few ml of H<sub>2</sub>SO<sub>4</sub> indicates the presence of tannins.

**Carbohydrates****Benedict's test**

To 0.5ml of aqueous extract, 5ml of Benedict's reagent was added and boiled for 5 minutes. Formation of bluish-green precipitate showed the presence of carbohydrate.<sup>[8]</sup>

**Antimicrobial Activity****Preparation of inoculums**

Five colonies of single species i.e. *Pseudomonas*, *E.coli*, *Staphylococcus*, *Streptococcus* and *Klebsiella* were inoculated in separate test tubes containing LB broth and incubated for 24 hours at 37°C.

**Antimicrobial activity**

The Muller Hinton Agar plate was prepared. Five microorganisms (*Pseudomonas*, *E-coli*, *Staphylococcus*, *Streptococcus* and *Klebsiella*) were swabbed separately in different petriplates. Wells were cut in all plates, 50 µl of alcoholic plant extract, 25 µl of DMSO, 5 µl of penicillin were added in the wells and were incubated for 24 hours at 37°C.

**Evaluation of In Vitro Antioxidant Activity****Nitric Oxide radical Scavenging Activity**

5mg of extract was taken and was dissolved in 10µl methanol or dimethyl sulphoxide. The samples were allowed to get completely solubilize and different concentration of sample (50, 100, 200mg/ml) were taken. 50µl of 10µm sodium nitroprusside and 50µl of the test solution was added and finally the solution was made up to 3ml with phosphate buffer (pH 7.4) and it was mixed properly. The solution was incubated at 25-30°C for two and a half hour under fluorescence light. After incubation, 125µl of Griess reagent was added and incubated for 30 minutes at room temperature for color development (light pink color developed). The absorbance was read at 546 nm.

Divya Sankar *et al.*

### Hydroxyl Radical Scavenging Activity

Hydroxyl radical scavenging activity was carried out by measuring the competition between deoxyribose and the extracts for hydroxyl radicals generated from the Fe<sup>3+</sup>/ ascorbate/ ethylene diamine tetra acetic acid/ H<sub>2</sub>O<sub>2</sub> system. Attacks of the hydroxyl radicals on the deoxyribose led to TBARS (Thiobarbituric acid reactive substances) formation. The formed TBARS were measured by the method given by Oshawa *et al.* The different concentration of the extract (25 µl, 50 µl, 100 µl) were added to the reaction mixture containing 30mM deoxyribose, 1mM ferric chloride, 1mM EDTA, 1mM ascorbic acid, 20mM H<sub>2</sub>O<sub>2</sub> and 23mM phosphate buffer (pH 7.4) making a final volume of 1ml. 1ml of TBA (1%) and 1ml of trichloro acetic acid (2.8) were added to the tube and incubated at 100°C for 20 minutes. After boiling for 15 minutes, absorbance was measured at 532nm against a blank containing phosphate buffer.

### Reducing Power Activity

The reducing power of extract was determined by the method of YEN and DUH (1993). The different concentrations of the extract (25 µl, 50 µl, 100 µl) were taken and 2.5ml of phosphate buffer (pH 6.6) was added to the test tubes including control. 25ml of 1% potassium ferric cyanide was added and was boiled for 20 minutes at 50°C. To it 2.5ml of TCA was added and centrifuged for 10 minutes at 2000 rpm. 5ml of supernatant was collected and to it 1ml of distilled water and 250µl of 0.1% ferric chloride was added and the absorbance was read at 700 nm.

### Determination of *In vitro* Anticancer Effect of Plumbago Extracts

0.67g of Eagle's media was suspended in 25ml tissue culture grade water with constant stirring until the powder was completely dissolved. The water should not be heated. 0.187g of NaHCO<sub>3</sub> powder was added and stirred until dissolved. The pH was adjusted to 0.2-0.3 pH units below the desired pH (pH =7.4) using 1N HCl or 1N NaOH since the pH tends to rise during filtration. The final volume was adjusted to 50 ml with tissue culture grade water. The medium was sterilized immediately by filtering through a sterile membrane filter with porosity of 0.22 micron or less, using positive pressure rather than vacuum to minimize the loss of CO<sub>2</sub>. The sterile supplements were aseptically added as required and the desired amount of sterile medium was dispensed into sterile containers. The required medium was stored at 2-8°C and in dark till use.<sup>[17]</sup>

### Apoptotic Effect of Plumbago Extract on L929 And Sk-Mel Cell Lines

#### Passaging of L929 and Sk-MeL

Passaging (also known as subculture or splitting cells) involves transferring a small number of cells into a new vessel. L929 and Sk-MeL was used as the invitro system for assessment of anticancer activity. FBS is used to provide sufficient amount of nutrients for the proper growth of cell lines. The antibiotics present in the media (streptomycin and penicillin) prevent the contamination occurring due to growth of bacteria. In this medium Sk-MeL is grown properly. In order to access the anti-proliferative effect of *Plumbago zeylanica*, cancer cell lines i.e. L929 and Sk-MeL, were subcultured in Eagles Media supplemented with 10% heat inactivated FBS and antibiotics (penicillin and streptomycin). The flask was placed in CO<sub>2</sub> incubator (5% CO<sub>2</sub>) at 37°C for 3 to 5 days to obtain confluent growth.

### Trypsinization

It is the process of using trypsin, a proteolytic enzyme which breaks down proteins, to dissociate adherent cells from the vessels in which they are being cultured. The cell lines were washed with phosphate buffer saline. 500µl of trypsin was added in cultured cells lines for 3 minutes at 37°C. After disaggregation the cells are transferred to other flask and supplemented with media.

### MTT cell viability assay ((Deniel G)

MTT is a colorimetric assay that measures the reduction of 3-(4, 5dimethyl-thiazole-2-yl)-2,5diphenyl tetrazolium bromide (MTT) by mitochondrial succinate dehydrogenase. The MTT enters the cells and passes into the mitochondria where it is reduced to an insoluble colored formazan product. The cells are then solubilized with an

Divya Sankar *et al.*

organic solvent(DMSO) and the released, solubilized formazan reagent is measured by spectrophotometer at 540nm. Since reduction of MTT can only occur in active cells, the levels of activity is a measure of the viability of the cell. MTT cell viability assay is generally considered as a precise technique in determining the cell viability. To the cell culture suspension 30µl MTT was added and kept for incubation at 37°C for 3 hours. After incubation 200µl of DMSO was added to each culture plate, incubated at room temperature for 30 minutes until all cells get lysed and homogenous colour was obtained. After scraping the absorbance was read at 540nm using DMSO as blank and percentage viability was calculated.[10]

#### RPMI (Rosalin park memorial institute)

0.55g RPMI suspended in 25ml tissue culture grade water with constant stirring until the powder is completely dissolved. To this added 1.47g of NaHCO<sub>3</sub> powder and stirred until dissolved. Then added 5.5ml FBS, 100µl streptomycin, 100µl penicillin, 160µl PHA and stirred well. The pH was adjusted to 0.2-0.3 pH units below the desired pH (pH=7.4) using 1N HCl or 1N NaOH since the pH tends to rise during filtration. After that the final volume was made up to 55 ml with tissue culture grade water. Then the medium was sterilized immediately by filtering through a sterile membrane filter with a porosity of 0.22 micron or less. Positive pressure was used rather than vacuum to minimize the loss of CO<sub>2</sub>. Added sterile supplements as required and dispensed the desired amount of sterile medium into sterile containers and stored at 2-8°C.

#### Monocyte Isolation and Genotoxicity

A sterile centrifuge tube was taken and 50µl of heparin was added into it. 3 ml of blood was collected with a sterile syringe and transferred it into the tube containing anticoagulant and mixed gently to avoid coagulation of blood. Another centrifuge tube was taken and equal amount of Hisep was added to it. The blood was carefully transferred in to the tube without mixing it with the Hisep. It was then centrifuged at 2600 rpm for 30 minutes at room temperature. After that clear zone of monocyte was separated and transferred carefully into a new sterile centrifuge tube. The separated monocytes were added into RPMI medium and were kept in CO<sub>2</sub> incubator for 24 hour. After that methanolic extract of plumbagin was added in different concentration (5µl, 10µl and 20 µl) and placed in the CO<sub>2</sub> incubator for another 48 hours.

#### Tryphan Blue Assay

In vitro cytotoxicity testing was based on the effect of peptide on lymphocyte cell viability. A standard cytotoxicity dye elusion assay was employed to determine the effect peptide that reduce the lymphocyte cell viability. A cell suspension was prepared from the assay. A 1:1 dilution of cell suspension of 0.4% tryphan blue was prepared (1:1 dilution in PBS). The counting chamber of the haemocytometer was loaded with the duration. Then place it for 1-2 minutes. The cells were counted at 40x (Olympus CH 20). Dead cells were stained blue which was distinguished from transparent live cells from transparent live cells and the percentage of viability was calculated.[25]

#### Quantitation of DNA Fragmentation with Diphenylamine

This method is based on the notion that extensively fragmented double-stranded DNA can be separated from chromosomal DNA upon centrifugal sedimentation. The protocol includes the lysis of cells and the release of nuclear DNA, a centrifugation step with the generation of two fractions (corresponding to intact and fragmented DNA, respectively), precipitation of DNA, hydrolysis and colorimetric quantization upon staining with diphenylamine (DPA), which binds to deoxyribose.

## METHODOLOGY

After the incubation, the different concentrations of monocyte sample were centrifuged cells at 3500 rpm at 4°C for 10 min. Supernatants were transferred carefully into new tubes labeled S (supernatant). 1.0 ml TTE solution was added to the pellets in tubes B and vortexed vigorously. This procedure allows the release of fragmented chromatin from nuclei, after cell lysis (due to the presence of Triton X-100 in the TTE solution) and disruption of the nuclear structure (following Mg<sup>++</sup> chelation by EDTA in the TTE solution). To separate fragmented DNA from intact chromatin tubes B were centrifuged at 13000 rpm for 10 min at 4°C. Supernatants were transferred carefully into new tubes labeled T. To the small pellet in tubes B 1.0 ml TTE solution was added and mixed well.

Then 1.0 ml of 25% TCA was added into tubes T, B and S and vortexed vigorously. Precipitation was allowed to proceed overnight at 4°C. After incubation, precipitated DNA was recovered by centrifuging for 10 min at 13,000 rpm at 4°C. Supernatants were discarded by aspiration. DNA was hydrolyzed by adding 160 µl of 5% TCA to each pellet and heated for 15 min at 90°C in a heating block. A blank was prepared with 160 µl of 5% TCA alone. To each tube 320 µl of freshly prepared DPA solution was added, then vortexed. Color was allowed to develop for about 4 hours at 37°C (or overnight at room temperature). Optical density was measured at 600 nm, using 5% TCA as blank. The excitation wavelength of 600 nm is the optimal one, but wavelengths from 560 to 620 can be used as well. The percentage of fragmented DNA can be calculated using the formula:

$$: \% \text{ fragmented DNA} = \frac{S+T}{B} \times 100$$

Where, S, T and B are the OD<sub>600</sub> of fragmented DNA in the S, T and B fractions, respectively.

The fragmented DNA released by cells undergoing apoptosis and lysis during the experiment is recovered in the fraction S and should therefore be taken in consideration in particular circumstances. However, since many substances present in the fraction (serum proteins, components of the tissue culture medium, etc.) could heavily interfere with the OD measurement, it could be more convenient to disregard the S tubes (which most of the times contain only negligible amounts of DNA) and to apply the following formula:

$$: \% \text{ fragmented DNA} = \frac{T}{T+B} \times 100$$

### Preparation of Albumin Encapsulated Nanoparticle of Plumbagin

Bovine serum albumin (BSA) was chosen as the material for the particle matrix. BSA has great potential as a Nano carrier in food and pharmaceutical applications. BSA is non-toxic and degradable in vivo, so the nanoparticles generated by using it are easily adaptable to the human body.[3]Desolvation is a thermodynamically driven self-assembly process for polymeric materials. The addition of desolvating agents such as ethanol or acetone separates and coacervates the polymeric molecules in the aqueous phase [4]. The self-assembly of the polymer molecules occurs with electrostatic interactions, since the overall free energy in the system is minimised during desolvation. So, the polymeric molecules form particles of different shapes and sizes depending on the preparation conditions. Hence, a balance between attractive and repulsive forces is necessary for fabricating particles of an appropriate size. The suppression and expression of hydrophobic interactions provide a way to control the size of polymeric particles during desolvation.[5]

### Procedure

BSA nanoparticles were prepared using a desolvation method with minor modifications [3].1gm of BSA powder mixed 0.01mg of plumbagin and was added to distilled water; subsequently, pH and NaCl concentration were adjusted to 7 and 9 with 0.1 M NaOH. The solutions were stirred overnight at 500 rpm using a magnetic stirrer for complete hydration... A desolvating agent, acetone, was added dropwise at a rate of 1 ml/min into the BSA solutions until the solutions became just turbid. Finally, 0.01 ml of a 4% glutaraldehyde-ethanol solution was mixed to induce

Divya Sankar et al.

intra-particle cross-linking. The solution was stirred continuously at 500 rpm and room temperature for 3 h. the BSA nanoparticle solutions were centrifuged at 20000 rpm for 30 min. After the centrifugation, the pellets were redispersed to the original volume of absolute ethanol sonicated and were stored in absolute ethanol at 4°C. The size of particles were determined using Scanning electron microscopy.[6,7]

## Evaluation of Bcl-2 Expression in Sk-Mel Cell Lines

### Isolation of RNA

Total RNA was isolated using the total RNA isolation kit according to the manufactures instruction. Addition of RNA sol solution causes the disruption of cells and the release of RNA. Chloroform extraction following centrifugation, separates the mixture into a lower red phenol-chloroform phase, inter phase and the colorless upper aqueous phase. RNA remains exclusively in the aqueous phase whereas proteins are in the interphase and organic phase. On mixing with isopropanol RNA gets precipitated as a white pellet on the side and bottom of the tube.

1ml of SK-MEL cell suspension in a 1.5 ml vial was centrifuged at 10,000 rpm for 10 minutes. The supernatant was removed and the pellet was collected. 500µl RNA sol was added and mixed thoroughly. To this, 200µl chloroform: isoamyl alcohol mixture (24:1) was added. It was mixed well and centrifuged at 10000rpm for 5 minutes at 4°C. The clear upper aqueous layer was transferred into another vial, 3M sodium acetate (pH 5.2) was added 1/10<sup>th</sup> of the sample volume and isopropanol in the ratio of 1:1. The contents were thoroughly mixed and centrifuged at 1000rpm for 10 minutes at 4°C. The RNA pellets were collected and washed with 70% ethanol and centrifuged at 1000rpm for 5 minutes at 4°C. The pellet obtained were dried at 37°C and then suspended in 5µl TE buffer.

### Reverse Transcriptase PCR (RT-PCR)

Reverse transcriptase polymerase chain (RT-PCR) is a variant of polymerase chain reaction (PCR) laboratory technique commonly used in molecular biology to generate many copies of a DNA sequence, a process termed "amplification". In RT-PCR, however an RNA stand is first reversetranscribed into its DNA compliment (Complimentary DNA, or cDNA) using the enzyme reverse transcriptase and the resulting cDNA is amplified using traditional PCR or real time PCR. The RT-PCR technique was performed using primer designed specifically for amplified gene. [11,14]. All the components were thawed before performing the experiment. 5µl of control RNA template (suspended in 50µl of DEPC water and incubated at 65°C for 5 minutes) was mixed with 2µl of control reverse primer and 13µl of DEPC water was added to the RNA primer mix. The above mix was incubated at 65°C for 5 minutes and immediately chilled on ice. Control RT-PCR reaction was set up by adding the components in the following order. 2µl of reaction mixture, 20µl of chilled above sample and 2.5µl forward primer and finally 2µl of enzyme mix was added. The above reaction mix was placed in a thermocycler set to below mentioned conditions.

### Agarose Gel Electrophoresis

Agarose gel electrophoresis is a method for separating and visualizing DNA and RNA fragments. The fragments are separated by charge and size and which move through an agarose gel matrix subjected to an electric field. The electric field is generated by applying potential across an electrolytic solution (buffer). When boiled in aqueous buffer, agar dissolves and upon cooling solidifies to a gel. Agarose gel electrophoresis was performed to check the purity of the isolated RNA.[10,23]

### Procedure

1% agarose gel was prepared in 1xTE buffer. It was melted in hot water bath at 90°C, later cooled down to 45°C, 8µl of 0.5 mg/ml of ethidium bromide was added and poured into gel casting apparatus with gel comb. After setting, the comb was removed from gel. The platform with gel was placed into an electrophoresis tank with sufficient electrophoresis buffer (TBE) to immerse the gel. DNA sample was prepared with an appropriate amount of loading buffer and was loaded into well. The gel was allowed to run. The stained gel was then observed using transilluminator.

Divya Sankar et al.

### Determination of apoptosis by fluorescent staining

Apoptosis was determined morphologically after staining with acridine orange or ethidium bromide by fluorescence microscopy. The cell lines were subculture and incubated in carbon dioxide incubator (5% CO<sub>2</sub>) for three days at 37°C. After incubation, sample was added in different concentration (control, 4µg crude, 40µg standard). Again it was incubated at 37°C for 24 hours. Media was decanted; acridine orange and ethidium bromide was added in the ratio 1:1. After 10 minutes, it was washed with 1 ml PBS to remove the stain. The cellular morphology was evaluated by Olympus (CKX41) epifluorescent microscope. [9]

## RESULTS

### Thin layer chromatography

The alkaloid fraction was separated and identified by spraying with Dragandroff's reagent. When the TLC plate was viewed under UV-light, green colour fluorescence was observed. This confirms the presence of alkaloids. Chromatogram of *Plumbago zeylanica*, standard *Plumbago*

**Alkaloids:** Orange red precipitate was produced on addition of Dragandroff reagent which indicates the presence of alkaloids. the solution did not turn to bluish-black, so tannins are absent in the sample.

**Flavanoids:** No color was formed after boiling, so flavanoids are not present in the sample.

**Saponins:** On the addition of NaHCO<sub>3</sub>, no froth was formed, so saponins are not present.

**Phenols:** The color of the solution did not turn blue, so phenols are absent in the sample.

**Steroids:** Red color was not produced in the chloroform layer, so steroids are not present.

**Tannins:** The color of the solution did not turn to bluish-black, so tannins are absent in the sample.

**Carbohydrates:** Bluish-green precipitate was obtained after the addition of Benedict' reagent, which indicates the presence of carbohydrate.

### Antimicrobial Activity of *Plumbago zeylanica*

*Eschericea coli*, *Pseudomonas* (Gram negative) and *Streptococcus aureus*, *Staphylococcus aureus* (Gram positive) were used for the antimicrobial assay. Agar well diffusion assay was performed to evaluate the antimicrobial potential of *Plumbago zeylanica* extract. Penicillin was used as a standard for antimicrobial assay. From the results it can be concluded that *Plumbago zeylanica* contains potent antimicrobial agents than plumbagin. Plumbagin exert antimicrobial, antifungal and antiviral effects [2,14,15]

### Antioxidant activity

#### Nitric Oxide Radical Scavenging Activity

T1- Sample containing 0.1µg of plumbagin extract

T2 - Sample containing 0.2µg of plumbagin extract

T3 - Sample containing 0.4µg of plumbagin extract

Percentage of nitric oxide radical scavenging:

$$= \frac{(\text{Absorbance of control} - \text{Absorbance of sample}) \times 100}{\text{Absorbance of control}}$$

From the graph it was observed that increase in the inhibition efficiency increases the radical scavenging activity.

#### Hydroxyl Radical Activity

T1- Sample containing 0.025µg of plumbagin extract

T2 - Sample containing 0.05µg of plumbagin extract

**Divya Sankar et al.**

T3 - Sample containing 0.1µg of plumbagin extract  
Percentage of hydroxyl radical activity

$$= \frac{(\text{Absorbance of control} - \text{Absorbance of sample}) \times 100}{\text{Absorbance of control}}$$

Absorbance of control

From the graph it was observed that increase in the inhibition efficiency increases the radical scavenging activity.

### Reducing Power Activity

T1- Sample containing 0.025µg of plumbagin extract

T2 - Sample containing 0.05µg of plumbagin extract

T3 - Sample containing 0.1µg of plumbagin extract

Increase in absorbance of the samples indicates an increase in reducing power.

### MTT Assay for L929

T1- Sample containing 0.05µg of plumbagin extract

T2 - Sample containing 0.1µg of plumbagin extract

T3 - Sample containing 0.2µg of plumbagin extract

Percentage of viable cell =  $\frac{\text{Test} \times 100}{\text{Control}}$

Control

From the graph it was observed that increase in plumbagin concentration results in the decrease in the percentage of viability proportionally.

A maximum of 59.6% was observed in culture treated with 0.2µg of plumbagin.

### MTT ASSAY (SK-MEL)

#### MTT Assay for MONOCYTES

T1- Sample containing 0.05µg of plumbagin extract

T2 - Sample containing 0.1µg of plumbagin extract

T3 - Sample containing 0.2µl of plumbagin extract

From the graph it was observed that increase in plumbagin concentration results in the decrease in the percentage of viability proportionally.

A maximum of 40.9% was observed in culture treated with 0.2µg of plumbagin

### Tryphan Blue Assay for Monocytes:

A – Number of viable cells

B – Number of viable cells + number of dead cells

Percentage of viable cell =  $\frac{A \times 100}{B}$

B

1. In 0.05µg of cell sample, percentage of viable cell = 78.65%

2. In 0.1 µg of cell sample, percentage of viable cell = 62.5%

3. In 0.2 µg of cell sample, percentage of viable cell = 43.5%

From the graph it was observed that increase in plumbagin concentration results in the decrease in the percentage of viability proportionally.

A maximum of 43.5% was observed in culture treated with 0.2µg of plumbagin.

### DNA Fragmentation

- A<sub>600</sub> of supernatant 1(S1) from the samples containing 0.05µg, 0.1µg, 0.20µ of plumbagin is denoted as T.
- A<sub>600</sub> of pellet 1(P1) from the samples containing 0.05µg, 0.1 µg, and 0.2µg of plumbagin is denoted as S.

- A<sub>600</sub> of pellet (P2) from the samples containing 0.05µg, 0.1µg, and 0.2µg of plumbagin are denoted as B.

Percentage of fragmented DNA =  $B \times 100 / T + B$

- So, in sample containing 0.05µg of plumbagin extract, percentage of fragmented DNA = 49.30%
- In sample containing 0.1µg of plumbagin extract, percentage of fragmented DNA = 58.32%
- In sample containing 0.2µg of plumbagin extract, percentage of fragmented DNA = 78.7%

From the graph it was observed that increase in plumbagin concentration results in the increase in the percentage of viability proportionally.

### Agarose Gel Electrophoresis

The agarose gel showing the control, standard plumbagin and crude plumbagin loaded in lane 1,2 and 3 respectively.

### Double Staining

Acridine orange and ethidium bromide staining confirms the nuclear integrity of treated cells. Acridine orange selectively stain the living cells as green whereas ethidium bromide stains dead cell DNA as red. From the results it can be observed that crude *Plumbago zeylanica* extract has shown 35% increase in cell death which confirms the anticancer potential of crude extract. The fast growing L929 cell line was used to study the percentage viability by double staining.

## CONCLUSION

Herbal medicine in treatment of cancer as complementary and alternative therapy is one of the most extensively studied areas of recent research. The increased economic burden along with unintentional side effects limits the research and development of pure, novel phytochemicals as therapeutic drug against cancer. [18,19] As an alternative, purified crude extracts of significant plants as dietary supplements and botanical drug products are generating increased acceptance. Plumbagin (5-hydroxy 2 methyl 1,4-naphthoquinone) a quinonoid constituent isolated from *Plumbago* spp. is experimentally proven to inhibit phase arrest in cancer cells thereby promoting apoptosis. The accumulated toxicity of plumbagin to normal cells limits its wide spread application as a potent anticancer drug. In this aspect the current study was designed to compare the anticancer activity of crude and purified plumbagin in Breast cancer cell (MCF-7) and melanoma cell lines (SK-Mel 27). The crude ethanolic extracts (CEE) of *Plumbago zeylanica* was prepared, purified by Silca gel column and analyzed by Thin layer chromatography. In vitro studies using MTT shows significant reduction in cell viability in samples treated with crude extracts when compared with that of standard plumbagin. The study shows synergistic activity of phytochemicals present in crude alcoholic extracts (CEE) of plumbagin which exhibited decreased IC<sub>50</sub> values masking the possible toxicity generated by plumbagin alone. RT PCR analysis shows inhibition of Bcl2 gene by both plumbagin and extracts of *Plumbagozeylanica* in almost same manner.

## ACKNOWLEDGEMENT

I am highly grateful for the opportunity permitted by the Head of the institute of Biogenix, and also thankful to the director of Biogenix research institute Mr. Rajesh Ramachandran who gave the opportunity to work in an environment that a student should get his/her study period.

### ABSTRACT

Mycotoxins are secondary metabolites produced by toxigenic species of fungi, which can cause toxic effects in humans and animals. Food contamination by mycotoxins has been reported worldwide, mostly in foods that are susceptible to fungal growth, such as grains and cereals. Mycotoxins can lead to damage to health, and economic losses in agriculture. The most common mycotoxins found in routine food consumption and with consumption limits set by many countries, including Brazil, are: aflatoxins B1, B2, G1 and G2, ochratoxin A, zearalenone, deoxynivalenol, T-2 toxin and fumonisin. The contamination of foods and feeds with Mycotoxins can have serious consequences for human and animal health. Mycotoxin exposure is most likely to occur in the developing countries where food handling and storage processes are suboptimal, malnutrition is common, and where handful of regulations exist to protect the exposed populations. The better understanding of the biochemistry and metabolism of mycotoxins is necessary to avoid problems caused by them and minimize their negative effects on agriculture and health.

**Keywords:** Fungi, Mycotoxins, Secondary Metabolites, Toxigenic

## INTRODUCTION

Mycotoxins are produced mainly by the mycelial structure of filamentous fungi, or more specifically, the molds. They are secondary metabolites having no biochemical implication in fungal growth and development (Moss, 1991). Toxicogenic molds are reported to produce one or more of mycotoxins. It is already well-known that not all molds and not all secondary metabolites from molds are toxic. Some of the mycotoxins are of high significance in public health and agro-economy, for example, aflatoxins, trichothecenes, ochratoxins, zearalenone, fumonisins, ergot alkaloids, tremorgenic toxins. These toxins to be held responsible for loss of million dollars per annum worldwide in terms of human health, animal health, and condemned agricultural products (Shane, 1994; Vasanthi and Bhat, 1998).

Elements affecting the presence or production of mycotoxins in foods or feeds are storage condition, environmental, and ecological factors. Many of these secondary metabolites do have biological activity and may be toxic to microorganisms (antibiotics), plants (phytotoxins) or animals (mycotoxins) (Moss, 1996). Mycotoxins that are produced by fungi belonging to *Fusarium* and *Aspergillus* genera (fusariotoxins/ trichothecenes and aflatoxins, respectively) have received special attention, because they are most hazardous for humans and animals and are of economic significance. The terpenoid biosynthetic pathway is a characteristic of fusariotoxins (e.g., trichothecenes like toxin T2 and deoxynivalenol, the main precursors of which are mevalonic acid and farnesyl pyrophosphate).

A large group of mycotoxins, including aflatoxin B1 and zearalenone, are classified with polyketides, an important and large class of natural compounds, the initial stage of biosynthesis is the condensation of acetyl-CoA with several molecules of malonyl-CoA and subsequent multistage conversions of intermediate  $\beta$ -polyketones (Khomutov et al. 2011). Mycotoxins are commonly found in foods and feeds all over the world. It has been estimated that one fourth of the world's crops are contaminated with mycotoxins to some extent (Mannon and Johnson, 1985; Fink and Gremmels, 1999). Moisture, temperature, and insect damage are the most important environmental variables associated with aflatoxin contamination of agricultural commodities (Cast, 2003). Corn, peanuts, cotton, tree nuts, rice, figs, tobacco, and spices are among the most frequently contaminated crops (Detroy et al. 1971; Diener et al., 1987). In storage, the most important variables favoring mold growth are the water content of the substrate and relative humidity of the surrounding environment (Detroy et al. 1971; Wilson et al. 1994). Kuiper-Goodman, a renowned scientist in risk assessment studies, grades mycotoxins as the most significant noninfectious, chronic dietary risk factor. (Kuiper-Goodman, 1998).

In the last few decades, many pollutants have been detected in the surface water and marine environment, and these pose a potential threat to environmental integrity, biodiversity, and human health (Fleming et al. 2006; Hacon et al. 2005; Sherman, 2000). Marine mammals have been proposed as sentinels of marine environmental health, because these organisms are top predators and may accumulate great concentrations of pollutants in their tissues through bioaccumulation and biomagnification processes (Ross and Birnbaum, 2003; Siciliano et al. 2005). Drinking water sources contain different kinds of biological pollutants, such as bacteria, viruses, protozoa, and fungi. Recently, researchers have reported the presence of fungi in drinking water (Goncalves et al. 2006a; Pereira et al. 2010), and have observed that these fungi affect the taste and odor of the water. A wide spectrum of fungal species have been isolated from drinking water. Some of these species are known to be strongly allergenic (e.g., causing skin irritation), or may cause infections in immune-suppressed individuals (e.g., those suffering from AIDS, cancer, asthma or other respiratory diseases, or recovering from organ transplants) (Hageskal et al. 2009; Green et al. 2003). In addition, we describe the fungi that are known to be hazardous, and the nature of the risks they pose to human health, when consumed in contaminated water, food, or are inhaled. Finally, we review selected studies, in which efforts have been made to control fungi or their toxic metabolisms in aquatic environments.

## Major source of Mycotoxins

### Mycotoxins in Agriculture waste

Contamination of mycotoxin can occur at pre-harvest or post-harvest period, i.e., during processing, packaging, distribution, storage of food products. Most of the times, crops and cereals that are improperly stored under high temperature and humidity for a prolonged time, are prone to mold growth and mycotoxin contamination. Maize is most susceptible to mycotoxins contamination, while rice is the least. Mycotoxins can also come to the human plate via animal products such as meat, eggs, milk as the result of the animal eating contaminated feed. Most mycotoxins are chemically and thermally stable during food processing that includes cooking, boiling, baking, frying, roasting, and pasteurization. Mycotoxin Patulin Produced by *Penicillium*, *Aspergillus*, and other genera, patulin most commonly infects non-intact apricots, grapes, peaches, pears, apples, olives, cereals, and low-acid fruit juices (Sewram et al., 2000; Speijers, 2004). Apple juice has historically been a high concern for contamination. *P. expansum* is especially associated with a range of moldy fruits and vegetables. Although this is not a very strong toxin, a genotoxicity was detected in studies, i.e. there is a potential for a mutagenic and/or carcinogenic effect.

The fumonisins are found mainly corn crop, but several researches have reported the occurrence in other grains, such as rice (Park et al.2005), wheat and oat (Mallmann et al.2001). Fumonisin are structurally related molecules and 16 of which have been isolated and characterized: Fumonisin B1 (FB1), FB2, FB3, FB4, A1, A2, A3, AK1, C1, C3, C4, P1, P2, P3, PH1A, PH1B, however, fumonisin B1 and fumonisin B2 are the most important and constitute up to 70% of the fumonisins found in naturally contaminated foods and feeds (Seo et al.2001; Niderkon et al. 2009). Though several fungal genera are capable of producing trichothecene mycotoxins, most of them have been isolated from *Fusarium* spp. The presence of trichothecene mycotoxins in grains and other merchandises like corn, wheat, barley, oats, rice, rye, vegetables, are very common.

### Mycotoxins in Aquaculture waste

In intensive commercial aquaculture operations, the sources of wastewater are primarily from uneaten food and fish feces, which is 30 percent unconsumed dry feed and 30 percent consumed food egested as feces (Axleret al. 1996). The production of aquaculture waste in water can be estimated on the basis of several factors: growth, nutrients, energy gains, energy nutrient needs and excretory feed waste output by the systems in operation (Cho and Bureau, 1997). Aquaculture feeds are highly perishable,

The production of aflatoxins increases at temperatures above 27°C, humidity levels above 62 percent and moisture levels above 14 percent in the feed. Suitable conditions for fungal growth, in terms of warm temperature and moisture, promote mycotoxin contamination. For the main aquaculture producing regions of the world, notably Asia, these climatic factors increase the risk of such contamination. The extent of contamination will further be affected by ingredient and feed storage practices and processing methods. Additionally, long duration of transport under poor conditions and improper storage are crucial factors favoring the growth of aflatoxin-producing molds. Consequently, poorer aquafarmers in developing countries, where quality control of feeds may not be as high as in developed countries, are more likely to acquire contaminated feeds. Further, the Increase in prices of feed ingredients is likely to drive poor farmers to look for cheaper sources and run the risk of purchasing rejected or contaminated ingredients and feeds. Aflatoxin, a ubiquitous mycotoxin, which is produced primarily by the fungus *Aspergillus flavus* is a major concern because of its carcinogenicity, especially in warm and humid climates. Molds produce toxins that can be very damaging to the fish and shrimp. Molds certain species in the genus *Aspergillus* produce aflatoxins, which can cause liver damage to the shrimp. Occasionally feed will already have mold growing on it when it arrives from the feed mill, if the feed is hot condition or not been dried sufficiently.

The use of plant-based ingredients as substitutes for fish protein and oil in aqua feeds increases the risk of contamination by mycotoxins (fungal toxins produced by naturally occurring filamentous fungi or moulds). Several potent mycotoxins have been identified and those of serious concern, based on their toxicity and ubiquity, are

**Ravikiran Regeti et al.**

aflatoxin, ochratoxin A, the trichothecenes (DON, T-2 toxin), zearalenone, fumonisin, and moniliformin (Bhatnagar et al.2004).A survey of the conducted Food and Agriculture Organization of the United Nations in Andhra Pradesh state, India (FAO Fisheries and Aquaculture Technical Paper No. 578. Rome, FAO. 90 pp). Sinking pellets and mash uneaten feed cannot be collected, it may increase the organic loading of the pond waters and result in a deterioration in water quality and leads to contamination by fungal growth. The aquaculture industry has become an axis for criticism from environmental groups because of an apparent negative effect on the environment from the release of wastewater (Doupeet *al.* 1999).

### Detection Techniques

Numerous assay methods for detecting aflatoxins have been developed utilizing virtually all of the common tools of analytical chemistry including thin-layer chromatography, high-performance liquid chromatography, gas chromatography, mass spectrometry, immunoassays, capillary electrophoresis, and biosensors. Older methods rely on solvents for clean-up steps and chromatographic methods for quantification. Recent technologies include immunogenic assays that can be applied to samples with little or no cleanup (Chu,1998). Aflatoxins are considered as non-immunogenic but they can be conjugated to a protein carrier; a number of inexpensive antibody-based kits are now commercially available. Methods for assaying aflatoxins and other mycotoxins have been reviewed (Trucksess and Pohland,2001;Pohland,1993; Scott,1995).

For safety concern detection and quantification of aflatoxin in food,feed and water source is a very important. Different types of culture media have also been used to enumerate fungi; examples are Czapek-Dox Agar and Dichloran Rose Bengal Chloramphenicol (DRBC) (Pereira et al. 2010 ), and Sabouraud Dextrose Agar (Arvanitidou et al. 1999 ; Anaissie et al. 2003 ), although they required adding antibiotics to prevent bacterial growth (Sammon et al. 2010 ; Kanzler et al. 2007 ). Depending on what culture media or process is used, some fungi species may not be successfully isolated from water, even if present. Moreover, the method used for isolation of fungi may affect the frequency results recorded for the fungi. The filter membrane method is better than the direct plate-spread method for studying fungal occurrence in water than the other methods. The reason for this is that the volume of water in the filter membrane method is higher than that used for the plate-spread method. The swabbing method is best for studying the presence of biofilms in surface pipes.

Analytical methods for mycotoxins include Thin layer chromatography (TLC) is among one of the oldest techniques used for aflatoxin detection (Fallah et al.2011), while high performance liquid chromatography (HPLC), liquid chromatography mass spectroscopy (LCMS), and enzyme linked immune-sorbent assay (ELISA) are the methods most frequently used for its detection (Tabari et al.2011; Andrade et al.2013; Sulyok et al.2015). Aflatoxins immobilized on resin beads can induce RTP in the presence or absence of oxygen and heavy atoms (Costa-Fernandez and Sanz-Medel, 2000) and also have high sensitivity and specificity (Li et al.2003). Most patulin testing occurs via the use of HPLC (high performance liquid chromatography)-UV and/or liquid chromatography coupled to tandem mass spectrometry (LC/MS/MS) analyses within a laboratory. Patulin does not employ fluorescent properties and thus the use of UV detection is required. Moreover, several biosensors and immunoassays have been developed to detect ultra-traces of aflatoxins to ensure the food safety.

### Management and Control Strategies

#### TREATMENT AND CONTROL

Mycotoxins cannot be considered a group of toxicants on the basis of their mechanism of action because they are very chemically diverse. It would be impossible to develop one single control method that would ensure the reduction of every mycotoxin present in every agricultural commodity and aquaculture waste. Considering all these factors, it can be concluded that the development of food safety programs for mycotoxin control is not a simple issue (Park, 1993; Park and Liang, 1993).Prevention through pre-harvest management is the best. Pre-harvest, harvest and post-harvest processing minimize the risk (Lopez-Garcia and Park, 1998). Analysis and Critical Control Point

**Ravikiran Regeti et al.**

(HACCP) approach and should involve strategies for prevention, control, good manufacturing practices and quality control at all stages of production, from the field to the final consumer.

### Biological Methods

Biological methods have been explored as options for mycotoxin decontamination, Fermentation with yeasts has also been effective in destroying patulin and rubratoxin B (Lopez- Garcia and Park, 1998). Dimitrokallis et al. ( 2008 ) reported that many microorganisms including bacteria, yeasts, and molds are able to remove or degrade small amounts of aflatoxin in food and feed. The latest approach to mycotoxin control is mycotoxin deactivation. By means of enzymes (esterase, epoxidase), yeast (*Trichosporonmycotoxinvorans*) or bacterial strains (*Eubacterium*BBSH 797), mycotoxins can be reduced during pre-harvesting contamination.

### Chemical treatment

Numerous studies have evaluated the use of chemicals for the inactivation and hazard reduction of selected mycotoxins. Ammoniation is the chemical method that has received the most research attention. Extensive evaluation of this procedure has demonstrated that it is an efficacious and safe way of decontaminating aflatoxin-contaminated feeds. Nixtamalization, the traditional alkaline treatment of maize used to manufacture tortillas in Latin America, partially degrades aflatoxins and fumonisin, but the residual molecules can either be regenerated by digestive processes or become more toxic (Price and Jorgensen, 1985). The addition of oxidizing agents, such as hydrogen peroxide, has been shown to be an effective aid in nixtamalization. These chemicals degrade aflatoxins and fumonisin, thereby reducing toxicity (Lopez-Garcia, 1998; Burgos-Hernandez, 1998). Some recent studies have shown that hydrogen peroxide and sodium bicarbonate are effective for simultaneous degradation/detoxification of aflatoxins and fumonisin. Other chemical processes that have shown promise in controlling aflatoxins are the use of sodium chloride during thermal processing, sodium bisulphite at various temperatures and ozonation.

### Biocontrol agents

The biocontrol principle of competitive exclusion of toxigenic strains of *A. flavus* involves the use of non-toxigenic strains to reduce aflatoxin contamination in maize (Abbas et al., 2006). The use of biocontrol agents such as *Bacillus subtilis*, *Lactobacillus spp.*, *Pseudomonas spp.*, *Ralstonia spp.*, and *Burkholderia spp.* are effective at control and management of aflatoxins (Palumbo et al., 2006). Several strains of *B. subtilis* and *P. solanacearum* isolated from the non-rhizosphere of maize soil have been reported to eliminate aflatoxin (Nesci et al., 2005). Biological control of aflatoxin production in crops in the US has been approved by the Environmental Protection Agency and two commercial products based on atoxigenic *A. flavus* strains are being used (Afla-guard® and AF36®) for the prevention of aflatoxin in peanuts, corn, and cotton seed (Dorner, 2009). Good agricultural practices (GAPs) also help control the toxins to a larger extent, such as timely planting, providing adequate plant nutrition, controlling weeds, and crop rotation, which effectively control *A. flavus* infection in the field (Ehrlich and Cotty, 2004; Waliyar et al., 2013). Biological control is emerging as a promising approach for aflatoxin management in groundnuts using *Trichoderma spp.* and significant reductions of 20–90% infection of aflatoxin have been recorded (Anjaiah et al., 2006; Waliyar et al., 2015).

### Biotechnology approaches

Use of inbred maize lines resistant to aflatoxin has also been employed. Potential biochemical markers and genes for resistance in maize against *Aspergillus* could also be utilized (Chen et al., 2007). Additionally, biotechnological approaches have been reviewed for aflatoxin management strategies (Yu, 2012). Advances in genomic technology based research and decoding of the *A. flavus* genome have supported identification of the genes responsible for production and modification of the aflatoxin biosynthesis process (Bhatnagar et al., 2003; Cleveland, 2006; Holbrook et al., 2006; Ehrlich, 2009). In addition, Wu (2010) suggested that aflatoxin accumulation can be reduced by utilizing transgenic Bt maize with insect resistance traits as the wounding caused by insects helps penetrate the *Aspergillus* in kernels.

### UV irradiation techniques

(Nourmoradi et al. ( 2012 ) studied the effect of UV irradiation on selected *Aspergillus* spp. (Chun et al. (2010 ) studied the effect UV-C irradiation on inactivation of the food-borne pathogens population, and suggested that it can be useful for improving microbial safety of stored food, without impairing quality. (Begum et al. ( 2009 ) suggested that UV-C irradiation can effectively inactivate spores of *A. flavus*, *P.orylophilum*, *E. rubrum* , and *A. niger*, but the efficacy of UV-C radiation against fungal spores varied significantly among genera and method of irradiation exposure. *A. nigeris* more resistant to UV irradiation than other genera such as *A. flavus*, *Mucorspp.*, and *Penicillium*spp. Moreover, (Hijnen et al. ( 2006 ) showed that *Aspergillus* spp. are less sensitive to UV irradiation than are cells of vegetative bacteria species, such as *Campylobacter jejuni* and *Legionella pneumophia*; however, *Aspergillus* spp. are more sensitive than bacterial spore-forming species such as *Bacillus subtilis* and *Clostridium perfringens*. Xiong et al. ( 2010 ) investigated neutralized and acidic electrolyzed oxidizing water, and noted significantly different fungicidal treatment effectiveness against *Aspergillus flavus*, when targeting conidia; the normal cellular functioning of K<sup>+</sup> and Mg<sup>2+</sup> in *A. flavus* conidia was damaged. Similarly, Young et al. ( 2006 ) investigated the degradation of ten trichothecene mycotoxins from exposure to aqueous ozone. They discovered that all studied mycotoxins degraded readily; at pH 7–8 the degree of reactivity was dependent upon the carbon 8 oxidation state, whereas at pH 9, there was little or no reaction.

### Feed storage practices

A significant reduction in mycotoxin formation can be achieved by good agronomic practices. As the toxins are generally very stable, they can persist during storage, independent of storage conditions, and can hence reach the final feed. During storage mold growth and mycotoxin formation can be controlled successfully by controlling moisture content of the feed. If the moisture content is below 12%, molds become metabolically inactive, and no mycotoxins are produced. The incorporation of technical mold inhibitors such as Mold-Zap (Alltech, Inc.) further enhances stability of feed and ingredients during storage. Once any of the ingredients is found affected, complete removal of the contaminated ingredient is the logical solution. But it is often not practical to completely remove certain ingredients due to associated costs. In the feed and food industry it has become common practice to add mycotoxin binding agents such as Montmorillonite or bentonite clay in order to affectively adsorb the mycotoxins. The toxic effects of fumonisin, ochratoxin A, DON and T2 toxin are not mitigated by most sequestering agents. Since not all mycotoxins can be bound to such agents.

### Waste water treatment

Aflatoxins or other fungal toxins may be degraded by physical, chemical, or biological methods (Dimitrokallis et al. 2008 ). Also addressed in some studies is how drinking water can be processed in water treatment plants to reduce the danger of contaminating fungi. Wastewater treatment technology for land based aquaculture is adapted largely from municipal wastewater treatment. Sedimentation is one of the simplest methods to reduce the waste from the aquaculture industry. The basic principle in this system is to allow solid particles, mainly uneaten feed and feces, to settle out of the waste prior to release of effluent water into the environment. In this system, settleable substances can sink and floatable particles can collect on the water surface (Czyszet al. 1989). The separated wastes are removed from surface and bottom of the aquaculture chambers and may undergo further treatment before disposal. Sedimentation is widely applicable in commercial fish farming, as it requires no energy input and no specialized operation skills (Daniel and Trudell 1990). The basic principle in this system is to allow solid particles, mainly uneaten feed and feces, to settle out of the waste prior to release of effluent water into the environment.

Water treatment plants may serve to partially accomplish this, by first filtering the water and finally by adding disinfection, ammonia oxidation, chlorination and aeration treatments adequate to remove or mitigate fungi or their toxic metabolites. Sammon et al. ( 2010 ) showed that coagulation/flocculation, sand filtration, and chlorination was highly effective in removing microfungus contaminants from raw water, although recontamination will occur if supplementary chlorination of all water service reservoirs is not routinely carried out to prevent growth of fungi or

**Ravikiran Regeti et al.**

reduce fungal metabolites (e.g., geosmin, 2-methylisoborneol (2-MIB), and methyl tert-butyl ether (MTBE)) in drinking water. Lin et al. (2003) noted that the presence of chlorine substantially reduced concentrations of geosmin, 2-MIB, and MTBE. Similarly, Wilson et al. (2005) tested the effects of chlorine dioxide gas on growth of some fungi, and showed that it inactivated all organisms except for *C. globosum* colonies, although some Ascospores may also have been destroyed. Pereira et al. (2013) studied the effectiveness of free chlorine for deactivating some species of fungi, and established rate constants for such deactivation. Advances in bioengineering have tendered most methods of wastewater treatment technology effective in the aquaculture industry. The process of water cleaning evolved throughout time, including new techniques such as ultra-filtration. (Guidelines for Drinking Water Quality, 3rd ed.; World Health Organization: Geneva, Switzerland, 2004; p. 515.). Biofiltration is another technology recently being applied in aquaculture for the treatment of wastewater. The basic principle of this technology is the formation of a filter bed through the attachment and growth of beneficial bacteria that extract dissolved chemicals from the water and convert them to particulate biomass or harmless dissolved compounds (Geoffrey 2000).

**ECONOMICS, FOOD SAFETY, AND REGULATION**

The economic consequences of mycotoxin contamination are extreme. In developed countries, crops with high amounts of aflatoxins are either destroyed or diverted into animal feeds; aflatoxins lower the value of grains as an animal feed and as an export commodity (Smith and Moss, 1985). When susceptible animals are fed contaminated feeds it results in reduced growth rates, illness, and death; moreover, their meat and milk may contain toxic biotransformation products. Livestock owners often take farmers and feed companies to court; legal battles can involve considerable amounts of money (Pier et al. 1980).

Special committees and commissions have been established by many countries and international agencies to recommend guidelines, test standardized assay protocols, and maintain up-to-date information on regulatory statutes of aflatoxins and other mycotoxins. These guidelines are developed from epidemiological data and extrapolations from animal models, taking into account the inherent uncertainties associated with both types of analysis. Different national guidelines for safe doses have been established, and hence, there is a need for worldwide harmonization of regulations (Wilson et al. 2002). A compendium summarizing worldwide regulations for mycotoxins has been published by the Food and Agriculture Organization of the United Nations (FAO 1997). The websites for the various commissions and organizations that study mycotoxins are excellent sources for the latest information: see, e.g., the Council for Agricultural Science and Technology (CAST) ([www.cast-science.org](http://www.cast-science.org)); the American Oil Chemists Society Technical Committee on Mycotoxins ([www.aocs.org](http://www.aocs.org)); the Food and Agriculture Organization (FAO) of the United Nations ([www.fao.org](http://www.fao.org)); the International Union for Pure and Applied Chemistry section on Mycotoxins and Phycotoxins ([www.iupac.org](http://www.iupac.org)); and the US Food and Drug Administration Committee on Additives and Contaminants ([www.fda.gov](http://www.fda.gov)).

**CONCLUSION**

Worldwide Mycotoxins are a major source of disease outbreaks, due to consumption of contaminated water, food and feed due to a lack of knowledge. People are increasingly concerned about the safety of drinking water & food. Excessive levels of mycotoxins in food and water of non-industrialized countries are of major concern. Several effective physical, chemical, biological, and genetic engineering techniques have been employed for the mitigation, effective control and management of mycotoxins in food, feed and water. Post-harvest treatments to remove Mycotoxins such as alkalization, ammonization, and heat or gamma radiation are not generally used by farmers. Developing fungal resistant and insect resistant hybrids/crops to combat pre-harvest infections and their outcome is a major issue of concern. However, some of the microorganisms naturally present in soil have the ability to degrade and reduce the aflatoxin contamination in different types of agricultural products. Prevention is the recommended measure to avoid mycotoxins. Feeds should be stored in a cool and dry area. Regular testing is possible by inspecting visually the feed (with or without black light), or by the mean of commercial detection kits. When moulds are

**Ravikiran Regeti et al.**

detected in small quantities, a commercial inactivator can be purchased. However, heavily contaminated feeds and ingredients should be discarded (Royes&Yanong, 2002).

Many national and international public health and governmental authorities such as the US Food and Drug Administration (FDA), World Health Organization (WHO), Food Agriculture Organization (FAO), and the European Food Safety Authority (EFSA), are giving much importance to mycotoxin contaminated food and feed. They have pointed out this serious problem by adopting strict regulatory guidelines for major mycotoxin classes in food and feed. Currently, about 100 countries have established limits on the presence of major mycotoxins in food and feed. Worldwide comprehensive development plan is required for wastewater treatment technology in the aquaculture industry. Only a few countries have developed wastewater management plans for aquaculture for the protection of the environment and its natural resources. Technology for the treatment of wastewater in aquaculture is not only essential for the growth of the industry but also important for environmental sustainability.

### ABSTRACT

Rice (*Oryza sativa* L.) is one of the most important staple food crops for approximately 557 million people in Southeast Asia including India. In our state Odisha it is the staple food of 37 million people grown in 4.4 m ha of area. Submergence is one of main environmental stresses to rice growth and productivity in large rice-growing areas, especially in the flood-prone rainfed lowlands in South and Southeast Asia, where it regularly affects about 15 to 20 million hectares of rice land. Flash flooding can cover the entire plant for prolonged periods, and most rice cultivars die within 7 d of complete submergence. Complete submergence of rice leads to reduced growth and yield. Rice is a semi-aquatic species and has a reputation for growing well under flooded conditions however, it is also the case that rice is not well adapted to sudden and total inundation when this is sustained for several days the effect can be fatal. Many physiological and biochemical changes occur during submergence to sustain the plant in harsh condition.

**Keywords:** environmental, Rice, land, growth, yield, semi-aquatic

### INTRODUCTION

Rice (*Oryza sativa* L.) is a plant of Asian origin, widely cultivated in India and South East Asia. The Jeypore belt of Odisha is now considered as the origin of *Oryza sativa* L., the cultivated rice in India. Rice is the staple food for more than half of the world's population. Asia accounts for about 90% of the global rice production. India is the second largest rice-growing country after China, with a production of more than 100 million tonnes. In India, rice is mainly cultivated on tiny farms, primarily to meet the family demand. Marketable surplus for meeting the demand of urban

**Chandrasekhar Sahu and Udit Nandan Mishra**

populace comes from affluent farmers with large landholdings. Rice production and prices fluctuate widely with the occurrence of drought, flood and many more abiotic and biotic stresses.

Submergence is considered the third most important constraint for higher productivity in eastern India (Setter et al., 1996). Excessive flooding poses risks to human life and is a major contributor to the poverty and vulnerability of marginalized communities. During the past five decades, the flood-affected area in India has more than doubled in size from about 5% (19 million hectares) to 12% (40 million hectares) of the total geographic area (IPCC, 2007; World Bank Report, 2008). In addition, the climate projections suggest that temperatures, precipitation, flooding and sea level rise are likely to increase, with adverse impacts on crop yields and farm income. A spatial shift in the rainfall pattern towards the already flood-prone coastal areas is also projected. As an example of the implied magnitude of this shift, the discharge at the measuring station at Naraj on the Mahanadi River in Odisha, India is likely to rise dramatically from the current level of about 2% to over 10% under the climate change scenario (World Bank Report, 2008; INCCA, 2010). Rainfed lowlands constitute highly fragile ecosystem often prone to flash floods (submergence), with an average productivity of 1.2 t/ha in normal years and hardly 0.5 t/ha in case of the submergence.

Quiescence and elongation are two opposite strategies by which rice adapts to flood depending upon the nature of flooding (Luo et al., 2011). The ethylene response factors genes Snorkel1 (SK1) and Snorkel2 (SK2) allow rice to adapt to deep water whereas Submergence1A-1 (Sub1A-1) allows rice to acclimatize under flash flooding (Xu et al., 2006; Hattori et al., 2009; Nagai et al., 2010). Both SKs genes and Sub1A-1 are connected with gibberellin biosynthesis or signal transduction, yet deepwater and 2 submergence-tolerant rice seem to have opposite flooding response; namely, escape by elongation or remain stunted under water until flood recedes (Xu et al., 2006; Hattori et al., 2009; Sarkar and Panda 2009; Bailey-Serres et al., 2010; Bailey-Serres and Voisenek 2010). Introgression of SUB1 QTL into 'Swarna' greatly enhanced its survival under submergence, and plant productivity under flash flood conditions (Sarkar and Panda 2009). Rice plants that exhibit only limited elongation during submergence often show tolerance to complete flooding. Much of the injury to plants caused by abiotic stresses is associated with oxidative damage at cellular level. Damage to membrane integrity is a common effect of stress, especially in the case of low oxygen. Under anoxia, a decrease in membrane integrity is a symptom of injury, measured as changes in lipid content and composition, and also activation of lipid peroxidation (Blokina et al., 2003).

Plants have active oxygen-scavenging systems consisting of several antioxidant enzymes, and some low molecules of non-enzyme antioxidants, which can neutralize the free radicals and thus retard the progress of many injuries associated with oxidative stress and reactive oxygen species (ROS). ROS are common components of biochemical changes in the chloroplasts, mitochondria or in peroxisomes, when plants are subjected to harmful stress conditions and which can cause oxidative injury which includes super oxide (O<sub>2</sub><sup>-</sup>), hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) and hydroxyl radicals (OH<sup>-</sup>). Via oxidative damage of chlorophyll, DNA, proteins, lipids, nucleic acids and other macro molecules, Oxygen radicals can severely disrupts normal metabolism due to their cytotoxicity. To defend cellular membrane and organelles from injury, plants have developed a multifaceted anti oxidant system to mitigate oxidative damage created during anoxia condition of complete submergence. Antioxidative enzymes like catalase and peroxidase can easily overcome the injury effect (Boni Facio et al., 2011) suggested that H<sub>2</sub>O<sub>2</sub> detoxification followed by the activity of peroxidase.

Two important factors influencing rice plant survival during submergence are limitations to gas diffusion under water, and reduced irradiance that impair photosynthesis and efficient utilization of carbohydrates. Thus, survival during submergence may largely depend on accumulation of high carbohydrate concentration prior to submergence and a capacity for maintaining energy production through rapid alcoholic fermentation under oxygen shortage. During flash flooding, a third factor thought to affect survival is the aerobic shock during the post-submergence period when flood water recedes. Changes in the level of antioxidant and enzymes such as super oxide dismutase (SOD) suggest that tolerant rice cultivars develop protective systems to air after exposure to hypoxic or anoxic environment. These responses are similar to other wetland plants (Sarkar et al., 2006). The capacity to survive

**Chandrasekhar Sahu and Udit Nandan Mishra**

submergence depends not only on specific environmental factor, but also on the strategy that plants have evolved for adoption to particular flood-prone environments. In view of the above facts the present review is on Physiological and Biochemical changes in Rice under complete submergence.

**Effect of submergence on Morphological Characters****Plant Height**

Submergence increases the endogenous levels of GA1 (bioactive form) and GA20 (inactive form; an immediate precursor of GA1) in the intercalary meristem and elongation zone of inter node sections in deep water rice (Hoffmann-Benning, 1992). In deepwater and floating rice areas, water stagnates for longer duration, Most commonly more than a month, and varieties adapt to these conditions through shoot elongation to avoid complete inundation (Sarkar et al, 1996; Das et al, 2009; Kato et al,2014) Ethylene is a key regulator of the formation of lysigenous aerenchyma, at least in *Z. mays*, through programmed cell death, and stimulated shoot elongation mediated by cell-wall loosening in rice and *Rumex* (Voeselek & Bailey-Serres, 2013) thus affecting nutrients delivery to the shoot. On a shorter time scale, root growth is arrested immediately upon onset of hypoxia, while shoot growth still persists. Waterlogging/flooding treatment induces a “physiological drought”, reducing stomatal conductivity by several fold (Pang et al., 2004; Polacik and Maricle, 2013). The low energy status under hypoxic conditions results in a substantial depolarization of plasma membrane potential (Shabala, 2011). Rice varieties that exhibit limited or no elongation during complete submergence often show tolerance to flash flooding, whereas deepwater rice varieties adopt opposite strategy, displaying greater elongation of leaf and culm (Luo et al, 2011).

**Number of leaves**

R. K. Sarkar (2006) viewed that Low light intensity and hypoxia are the two key factors that limit the ability of rice plants to survive long periods of submergence, due to severe damage to old leaves and the failure of sensitive plants to develop new leaves.

**Number of Tillers**

The tillers of susceptible genotypes damaged due to anoxia stage under submerged condition and the energy required for survival was very less. The effective tillers contribute maximum for higher yield (Bisht et al, 2007). As per Ismail et al, (2009); Singh et al., (2009) modern high-yielding varieties are particularly sensitive to submergence even for a few days. Their yield can be severely reduced because of high mortality, low tillering and slow recovery. Age of tiller and number of tiller per hill were significant on crop growth rate (CGR), relative growth rate (RGR), net-assimilation rate (NAR), specific leaf weight (SLW), leaf area ration (LAR) and leaf area index (LAI) (Hossain et al., 1996).

**Leaf area**

Ali et al., (2003) reported that for maximum crop growth enough leaves must be present in the canopy to intercept most of the incident NAR. Therefore, growth is often expressed on leaf-area basis. According to Zhang et al., (2016) Leaf area in rice increases under submerged condition.

**Effect of submergence on Biochemical Characters****Chlorophyll and carotenoid content**

The chlorophyll content in leaf tissues varies with the age of the plant the species and the growing season. Chlorophyll content decreased proportionately with increase in submergence period (Deka and Baruah, 2000). Sarkar et al., (2006) during their study on physiological basis on rice under submergence, concluded that in complete submergence stress, the degradation of chlorophyll content occurs in susceptible cultivar compared to tolerant one which can be used as indication submergence tolerance. Chlorophyll content decreased proportionately with increase in submergence period (Das et al, 2005). Tolerant cultivars maintained a higher level of chlorophyll during submergence and the subsequent period of re-emergence. (Panda et al, 2008). Submergence resulted in significant

**Chandrasekhar Sahu and Udit Nandan Mishra**

reduction of chlorophyll content both in susceptible and tolerant cultivars (Panda et al, 2008). According to Rai et al., (2004) yellowing of leaves was found to be a symptom of submergence of seedlings with increase in carotenoid content.

**Proline content**

Suppressions of mitochondrial electron transport is the primary reason for stress induced proline accumulation in susceptible genotypes (Alia, 1993) 7 Under submergence normal growth of mitochondria is affected results in accumulation of proline. In tolerant variety proline accumulation is less than susceptible variety ( Shibasaka and Tsuji, 1988) Proline has also been referred as a supportive index for assuming osmotic deficits out of submergence as studied earlier (Mostajeran and Rahimi-Echi, 2009).

**Catalase and peroxidase activity**

Plants with a high level of antioxidants have greater resistance to this oxidative damage. Hence, monitoring the antioxidant content a few days after submergence could constitute an efficient technique to identify tolerant genotypes. (Rama Krishnaya et al., 1990). Plants have evolved defence mechanisms naturally to scavenge ROS by enzymatic and non-enzymatic antioxidant mechanisms. Several antioxidant enzymes have been evolved in detoxifying ROS. Among them, superoxide dismutase (SOD) is a major scavenger of O<sub>2</sub> – which dismutates O<sub>2</sub> – into H<sub>2</sub>O<sub>2</sub> (Bowler et al. 1992) H<sub>2</sub>O<sub>2</sub> is scavenged by ascorbate peroxidase (APX), glutathione reductase (GR), catalase (CAT), and some peroxidases (POX).

The activities of enzymes like catalase, peroxidase and super oxide dismutase expressed on a per g fresh weight of leaves basis, were higher in FR-13A (tolerant) than other cultivars (susceptible) (Sarkar et al., 2001). To minimize and eliminate oxidative damage, plants have evolved an antioxidant defence system comprising enzymes such as superoxide dismutase, catalase, peroxidase, the antioxidants remove, neutralize, and scavenge the ROS at different cellular locations. Previous studies have indicated that higher activity levels of antioxidant enzymes may contribute to better stress tolerance by increasing the protection capacity against oxidative damage (Sharma and Dubey, 2005). Plant adapted water logged condition, mechanism to cope with this stress such as aerenchyma formation, increase availability soluble sugar ,greater activity of glycolytic pathway, formation of enzyme and involvement of antioxidant enzyme to cope with the post hypoxia/anoxia oxidative stress.

**Lipid peroxidation**

A product of lipid peroxidation called malondialdehyde (MDA) is considered an indicator of oxidative damage. Blokhina et al., (2007) proposed that, reduction in membrane integrity under anoxia is an indication of injury and can be measured by variations in MDA content

**Carbohydrate and Sugar**

Complete submergence of rice leads to low concentration of carbohydrate, reduced growth and,finally death of tissues (Jackson and Ram, 2003). Complete submergence reduces level of carbohydrates up to 4–12 folds but in partial submergence the reduction depends on proportion of leaves below the water (Setter et al., 1997; Manzur et al., 2009). Maintenance of stored carbohydrate before the submergence of rice plant reserve large carbohydrate, is essential for better survival during submergence. Because flood tolerance is related to high carbohydrate supply. (Singh et al., 2009). A rice variety maintaining highest stored structural carbohydrate as well as carbohydrate constituents in the stem is supposedly proved more stress tolerant (Das et al., 2005; Nagai et al., 2010). Under complete submergence, photosynthesis is weakened, and plants exhaust the reserve carbohydrate and ultimately die (Das et al, 2005, 2009; Sarkar and Panda, 2009; Luo et al, 2014).

Some plants are able to sustain their basic metabolism by consuming reserve carbohydrates (Dixon et al., 2006). The reason of reduction of carbohydrate concentration under submergence may be due to the increase in carbohydrate

**Chandrasekhar Sahu and Udit Nandan Mishra**

consumption for cell division, cell elongation and maintenance of elongation growth (Voeselek et al., 2006). To continue life, exposure of leaf tip above the water surface is vital even for submergence tolerant varieties if flooding duration exceeds more than 2–3 weeks (Bailey-Serres and Voeselek, 2010; Sarkar and Bhattacharjee, 2011; Colmer et al., 2014). Rice genotype with higher deposition of structural carbohydrate on the tissue wall is set as a selective pressure of submergence tolerance (Nagai et al., 2010). The cellulose and hemicellulose undergo chemically turned over into soluble residues and contribute in extension of complex carbohydrate polymers for elongation of culm. Accumulation of carbohydrates and its metabolism happens to be the most crucial in plants under complete inundation and plants are forced to adopt alternative pathways of carbohydrate metabolism through fermentative reactions (Banerjee et al., 2015). Acquisitions of sugar is crucial for survival of plant under submerge condition. Reports suggested that in water logged condition rice plant could utilize sugar, mostly reducing type by hydrolyzing the sucrose and other storage carbohydrate on demand of respiratory substrate for better survival.

**H<sub>2</sub>O<sub>2</sub> and O<sup>2-</sup>**

Reactive oxygen species (ROS) are aggressive oxygen radicals, which can be enhanced by submergence stress in plants. These oxygen radicals are also known as active oxygen species (AOS) or reactive oxygen intermediates (ROI), which can cause oxidative injury which includes superoxide (O<sub>2</sub><sup>-</sup>), hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) and hydroxyl radicals (Cruz de Carvalho 2008). Via oxidative damage of chlorophyll, DNA, proteins, lipids, nucleic acids and other macromolecules, Oxygen radicals can severely disrupt normal metabolism due to their cytotoxicity (T. Colmer and O Pedersen 2008). To defend cellular membranes and organelles from injurious effects of ROS, Plants have developed a multifaceted antioxidant system to mitigate oxidative damage generated by reactive oxygen species. Antioxidative enzymes in combination with numerous peroxidases like ascorbate peroxidase (APX), peroxidase (POD) and glutathione reductase (GR), can ably overcome the activity of ROS (Bonifacio et al., 2011). Bonifacio et al., (2011) concluded that, Hydrogen peroxide detoxification is followed by the activity of an important ascorbate peroxidase (APX), which also catalyses the conversion of hydrogen peroxide to water by the reducing power of ascorbate.

**Effect of submergence on Yield and yield Attributes**

It has been revealed from the study that there is a positive correlation between yield and its component characters such as test weight, number of tillers/plant, number of spikelet/panicle and number of panicles/plant (Sadhu and Chattopadhyay, 2000). There is a positive correlation like plant height, panicle length, and 1000 grain weight, filled grain per panicle, biological yield and harvest index with grain yield. Great biomass accumulation occurs before or after anthesis (Peng et al., 2009; Yang and Zhang, 2006). Ram et al., (2002) reported that yield improvement in introgression lines in rice was observed due to increase in number of ear bearing tillers and number grains per panicle. According to Bisht et al., (2007) the greatest contributors to genetic diversity in grain yield were the flowering time, plant height and tiller number per plant.

The physiological character which is responsible for higher grain yield are high photosynthetic rate and slow leaf senescence revealed that the characters HI, biological yield, tillers per plant flag leaf width, test weight and spikelet per panicle exhibited high positive direct effect on grain yield per plant. Under submergence, rice plants have modulated pattern of partitioning dry matter for grain by enhancing remobilization of pre-stored carbohydrates from pre-flowering photosynthesis. Therefore, the slow and inadequate grain filling in submerged rice varieties might be compounded with lesser carbohydrates mobilization from pre-stored source (as in culm and leaf sheath before flowering and impairment of readily supplied grain filling materials through starch-sucrose metabolic pathway (Tang et al, 2009). Panicle number decreases due to the suppression of tiller growth or mortality of tiller either due to prevalence of less light below 50cm water depth or lack of sufficient supply of oxygen (Haque et al, 2015). In medium-deep water ecology, first elongation does not require, however, main requisite is to stagnant flooding tolerance with slow elongation so that plants can maintain appropriate yield and yield attributes for greater yield (Sarkar and Bhattacharjee, 2011). Genotypes having faster post submergence growth yield more. The decrease in rice yield can be controlled to 10% after the plants suffer from half, 2/3, and complete submergence for 1–3 d of

### Chandrasekhar Sahu and Udit Nandan Mishra

field water storage. Yield loss due to floods ranges from 10 to 100 % depending on flood duration, depth and floodwater conditions (Ismail et al., 2013). These Sub1 varieties can survive 2 weeks of complete submergence and they typically provide 1–3 t/ha yield advantage over the original varieties in flood-prone rainfed lowlands. (Ismail et al., 2013).

## CONCLUSION

Various morphological, biochemical and yield attributes changes occurs due to submergence in rice. Plant height, leaf area, days to 50% flowering, total biomass, proline content, catalase, peroxidase, lipid peroxidation content increases due to submergence in rice. Number of tillers, chlorophyll content, carotenoid content, protein, carbohydrate, sugar content, H<sub>2</sub>O<sub>2</sub> activity, O<sup>2</sup> activity, grain yield, grain per panicle and Harvest Index decreases because of complete submergence in rice.

### ABSTRACT

Dyadic communication plays a very important role in taking decision in farm families. It helps for passing informations among the family members, The research study indicates that tolerance and keeping patience is very important in dyadic communication between father and son. The direct communication is very much important for taking decision. Keeping faith between the dyads, father and son helps for better interaction in the farm situations. Faith has the highest contribution to predict the variable dyadic communication in case of father and son.

**Keywords:** Dyadic, communication, highest, farm

## INTRODUCTION

A dyad is smallest possible social group. It consists of two people. They can be linked by romantic interest, family relation, interests, work, partners (Dyad, Wikipedia, 2019). A person shares thoughts with another person in dyadic communication. The communicator can use charts, slides, graphs, own voice, body language, facial expressions for communicating with the person (Owlgen, 2020). The two-person group, dyad, is the most frequent of all social groupings (Coleman et al(1961), Fisher et al(1953), James et al(1951), American Sociological review(1953). The dyad is probably the most important of all social groups (Tagiuri et al(1958), Yablonsky, Lewis(1955). The two-or three-boy relationship was more valued than the relation to the larger gang as a whole. It is to the dyadic institution of marriage that most persons try to find emotional and physical fulfillment (Thrasher, 1927).

### Objective

- (1) To study the dyadic communication pattern between Family head and son
- (2) To find out the distance maintained while communicating in different dyadic situations.

### MATERIALS AND METHODS

The blocks Digapahandi and Chikiti of Ganjam district in Odisha were purposively selected for the study. Two villages Gadagovindapur and B-Nuapada were randomly selected under these two blocks.. Fifty farmers were taken from each village from the two blocks. purposive as well as simple random techniques were adopted for the study. For the selection of districts and blocks purposive sampling technique was adopted while in case of selection of villages and respondents simple random sampling technique was adopted. The total number of farm respondents were one hundred under the study. Dyadic communication among the farm family members with respect to the farming operations is the dependent variable of the study. The study was conducted in 2003.

### Analysis

The variable faith of the family head on his son shows a negative significant association with the dyadic communication between family head and son with respect to different farming operations and allied activities. It is due to the reason that their son's information endowment regarding agricultural technology is not at par with head of the family. The heads of the families (fathers) did not show significant faith on their sons regarding farming operations in dyadic communication situations.

Above table represents the multiple regression analysis between the dependent variable communication in case of dyad 2 and 18 predicted variables. It was observed that the variable tolerance and faith are significantly and positively effective to delineate the dependent one. Tolerance is an inherent quality to other farmers' information. To tolerate others is a good quality which influences the communication process. The  $\beta \times R$  value in case of the variable faith is 35.56% which indicates that the variable faith has the highest contribution to predict the variable dyadic communication in case of father and son. The  $R^2$  value being 0.247 indicates that 24% of the total variation of dyadic communication in case of dyad 2 is explained by 18 causal variables.

### CONCLUSION

Dyadic communication between family members is very important to take decision in farming situation. It plays a crucial role for maintaining group relationship, group solidarity and farmers do not feel alone. Better is the dyadic communication between the family members better is the coordination between them for ensuring any kind of decision at various stages of farming operations. Due to lack of dyadic communication between various farm families, farmers are facing lot of problems and feeling isolated and that leads to depression.

### ABSTRACT

At present farmers are facing several types of stresses. Earlier, people considered farming to be a pleasurable occupation but times have changed. Climate change, global warming, more insect pest and disease infestation in crops, exposure of farmers to continuous use of pesticides, commodity price fluctuations, and crop losses due to natural calamities such as drought, floods, and cyclones, are affecting the mental health of farmers. Farmers are showing various signs of stress, such as loss of memory, headache, body pains, lack of motivation, insomnia, irritability, and breathlessness. Possible remedial strategies include maintaining positive attitude, proper rest and sleep, doing regular exercises, humor and recreation, counselling, staying connected with others, being active, willing to learn, taking responsibility, and giving to others.

### INTRODUCTION

The physical, mental, and emotional response to a stress causing factor or 'stressor' is called stress. Stress makes one feel frustrated, angry, nervous or anxious, and can originate from any situation or thought. Each individual reacts differently to stressful situations. Some people manage a crisis or other stressful circumstances by focusing on the problem and putting everything else apart. Some of the signs that one may be under considerable stress are problems with concentration or memory, lack of motivation, lack of interest in activities like socializing, sleeping

24134

**Chitrasena Padhy et al.**

problems such as insomnia, early waking or over sleeping, change in appetite such as eating too little or too much or eating unhealthy foods, mood changes such as irritability, physical problems such as chronic headache and stomach ache, heart palpitation and breathlessness, and general ill health for long term (Better Health Channel, 2019). Financial difficulties, price and marketing uncertainties, farm transfer issues, production challenges, marital difficulties, and social pressure can be sources of stress for farmers and farm family members (Minnesota Department of Agriculture, 2020).

**Problems Faced by Farmers and Farming Industry**

The farming industry has many stress factors, which are imposing increasing pressure on workers and putting them at greater risk of mental health. These are long hours working in isolation, not making distinction between work and home life, and financial uncertainty (The Poultry Site, 2020). Several factors are responsible for depression and anxiety among farmers and their employees. Serious weather events can adversely affect finances by having extreme impact on a season's yield. As compared to other industries agricultural workers are rated as 46% more likely to face illness overall. They are facing physical illnesses like lung and musculoskeletal diseases higher than those for other workers. Many farm jobs are companionless and can go for longer duration without interaction with other people. This leads to depression (Morrison, 2020). Life is hard going for farmers. Farmers deal with unpredictability of weather, instability of markets, commodity supply trade disputes, global economic forces, estate and succession plans, family relationships, and natural disasters (Spangler, 2019).

Depression impacts one among five farmers. It is recognized by medical practitioners that whole health starts with mental health. The farm business owners may be stressed due to low commodity prices, debt load, family disagreement, and negative weather events. In the United States, farming is listed among the top ten stressful occupations as per survey. Accordingly, about 20% of farmers may suffer from depression and statistical data has indicated high suicide rates. Men on farms today commit suicide nearly twice as frequently as other men in the general population. The Centre for Disease Control and Prevention (2016) reported that the rates of suicides by occupation were highest in farming, fishing, and forestry. The report noted that farmers' chronic exposure to pesticides might affect the neuro-system and give rise to depressive symptoms. Other factors contributing to suicide are social isolation, financial losses, barriers to and unwillingness to seek mental health service, and access to lethal means (Mohr, 2017).

Depression is a common disorder that many people may experience sometime in their lives. In busy farming, it can be one of those stressed feelings that gets ignored. Depression interferes with mental health and it can affect physical health. Christensen, a therapist who farms near Rush Ford, Minnesota, said whole health begins with mental health. When we talk about mental health many are simply referring to the state of psychological or emotional well being. A healthy psychological state is the ability to successfully manage the ups and downs in life and to have a cheerful outlook (Mohr, 2017). A farmer may not admit that he or she is suffering from depression. Those kind of feelings of helplessness do not line up with the traditional image of farmer endurance and independence. There continues to be a significant stigma on those with mental health challenges as noted by Christensen. The emotion that goes with the stigma is often shame so that the farmer believes that there is something wrong with him that he cannot manage life the way others are dealing with. People who are struggling with emotion get good at emotional concealing, which is hiding one's true emotions and pretending that everything is fine when it is not (Mohr, 2017). National Institute of Health, USA reported that farmers breathe in pesticides while spraying and these are absorbed through their skin and can have neurological effects that can lead to depression and that farmers have more and easy way of access to lethal equipment (Countryfile, 2015).

**Warning Signs of Stress (Rural Mutual Insurance Company, 2020)**

- (1) Change in routine
- (2) Decline in the care of domestic animals
- (3) Increase in illness

- (4) Increase in farm accidents
- (5) Decline in appearance of farm stead
- (6) Signs of stress in children
- (7) Decreased interest

### Signs of Chronic Prolonged Stress

Table 1 indicates the various physical, emotional, behavioural, Cognitive and self-esteem signs of chronic stress. An Irish project found out research from across the world on proven actions that can help one to feel good and function well (Mental Health Ireland, 2020). There are simple actions of five ways of well being should be practiced daily to maintain or improve one's mental health.

- If there will be small improvements in well being, that can improve one's ability to lead a more fulfilling life.
- By doing each action in the five ways to well being can make a positive difference to one's life.
- The five ways to well being are free and easy to include into one's life.
- Someone may be probably doing some of these actions already without being aware of it.
- To get the most benefit from the five ways to well being, one should amalgamate all of them on a daily basis.

### Well being

Wellbeing is feeling good about oneself, the world around, and functioning well in everyday life. An important quality of well being is to be strong and coping with the normal stresses of life. Many things are there to influence one's well being. These include doing regular exercises, diet, and sense of belonging, relationship, career, self care, spirituality, money, where we live, and sense of purpose. Well being includes how satisfied one is with one's life, one's sense of purpose, and how in control one feels.

### Connecting

One should find time each day connecting with the people around like family, friends, colleagues, and neighbours, and at home, work, school or in a local community. By being connected and developing these relationships people feel happier and more secure, giving a better sense of purpose.

### Being Active

One should look for ways to be active every day and go for a walk or a run. One should step outside, cycle, play a game, garden or dance. One should find a physical activity one enjoys, which suits one's life style and level of mobility and fitness. Being physically active can improve one's mental health and well being.

### Taking Notice

One should be aware of the world around him, be curious and enjoy the beauty around. One should pay attention to changing seasons, savour the moment, eating lunch with friends, paying attention to one's present moment like thoughts and feelings.

### Keep Learning

One should try something new, regain an old interest, signing up for that course, cook a new recipe, and take a new responsibility, setting a new challenge and learning a new skill. These will increase one's confidence which can improve one's mental health and well being.

### Giving

One should give to others, do something good for someone. One should thank someone for the help and cooperation he is getting, volunteer time or join a community group. Linking one's happiness to the wider community can be extremely rewarding and creates connectedness with the people around.

**Five Steps to Help Someone at Risk** (Rural Mutual Insurance Company, 2020)

- (1) By asking others
- (2) Keeping others safe
- (3) Being there for others
- (4) By helping others connect
- (5) Following up on earlier events

**CONCLUSION**

With little human contact, farmers work in isolation for long hours in the fields. This can breed mental health problems and suicidal thoughts. According to the psychiatrist David Middleton when farmers do not seek help whenever stress comes, more serious and fatal consequences happen. Entire days without seeing anyone and social isolation can lead to mental illness symptoms (Countryfile, 2015). Visiting a doctor, family support, mental health services, and self help are necessary (NHS, 2019). Social activities are playing important role to support mental health. Getting off from the farm and taking breaks is very important. Practicing regular aerobic exercises will help for managing the stress. Giving attention to parents, daughters, sons, and friends has a positive impact on mental health (St Patrick's Mental Health Services, 2019).

### ABSTRACT

Farmers now face major problems, such as aberrant weather, low commodity prices, and trade wars. They are undergoing increasing mental stress and anxiety. The poor mental health of farmers may be ascribed to long working hours, lack of adequate rest and sleep, not enough time available for family and social gatherings, and less control on their emotions. Farmers often work continuously in isolation. They are under constant mental stress but are unable to express their feelings to others and seek counseling due to the social stigma attached to mental illnesses. Farmers do not feel comfortable talking of their psychological problems to friends or relatives. Farmers face several stressful situations in their profession. More mental health campaigns should be organized to create awareness among farmers and to motivate them to express their emotions and seek advice when facing any psychological problems.

**Keywords:** Farmers, problems, health, emotions, stress

## INTRODUCTION

Mental health of farmers is a growing concern. Agricultural Consumer & Environmental Sciences (ACES) expects to manage this problem by conducting workshops to increase awareness among farmers and improve access to mental health resources. A majority of farmers show symptoms of anxiety or depression as per a study by Josephine Rudolph, assistant professor in ACES( The Daily Illini, 2020).Among professions, farming was found to have very high suicide rate. This problem is due to substance abuse, social stigma attached to psychological illnesses, and perception of mental health treatment. Many rural areas are provided with inadequate services by the healthcare

24139

**Chitrasena Padhy and Pakalpati Satyanarayana Raju**

system overall as studied by Rudolphi (The Daily Illini, 2020). This problem was managed by organizing 'Agricultural Mental Health and Stress Management' programs. The goal of such programs is to connect local farmers with mental health resources and provide techniques making one stress-free and raising awareness about the problem (Caruso, 2020). Farmers have little control over problems with machinery, weather, labour, animal or plant diseases, commodity prices, and economics. The farmers can be provided with support when warning signs of stress are evident. Warning signs of stress include changes in emotions, changes in attitudes and cognitive skills, changes in behavior, and changes on the farm or ranch. The farmers can be helped by practicing active listening and empathizing (Sanguesa and Thompson, 2019).

**Causes of Poor Mental Health and Coping Strategies**

A recent study at the International Institute of Population Science found that in Vidarbha region of Maharashtra around 60% farmers needed help for mental illnesses and there is the need of trained rural counselors. Bombie and Hemkothang (Newslick, 2020) surveyed three hundred households in Vidarbha region and found that 34.7% farmers suffered from somatic symptoms, a mental illness that leads to neurological issues including body ache. In the survey, 55% farmers complained of anxiety, 7.3% showed symptoms of social dysfunction, and 24.7% showed signs of clinical depression. The farmers who had agricultural loans of more than Rs 25,000 had anxiety and depression (Newslick, 2020).

Large cover of cotton farmers in central India were the epicenter of a debt crisis that gripped the rural population. For years now it has propelled thousands of farmers to commit suicide. These suicides are a loss of human lives as well as weakening marks on a nation's development canvas. While debates continue on improving the agricultural sector to improve the economic conditions of the farmer, there has not been any attempt to focus on possible psychological problems arising out of economic stress that may be leading to suicides (Qazi, 2017). Mississippi's farmers, ranchers, and rural communities faced numerous adversities for the last two years including flooding, trade wars, and low commodity prices, creating a decline in the issue of mental health on farm and in rural areas. The already rising number of challenges these farmers and rural communities have experienced are expected to increase during and after the COVID 19 pandemic, doing it more important to have mental health research available according to Mississippi farm bureau federation president Mike McCormick. A recent survey (AFBF, 2019) showed that a large majority of farmers and farm workers said financial issues, farm or business problems, and fear of losing their farm negatively affected their mental health. In addition to that 48% of rural adults said they were personally experiencing more mental health challenges than they were a year ago. Almost one in three farmers does not feel comfortable talking to friends and family members about solution for a mental health condition (Lowery, 2020).

In the report entitled 'Healthy Minds Healthy Farms', most farmers reported unpleasant coping mechanisms that may contribute to poor mental health including working more hours and losing sleep, less attending the family and social gatherings, feeling less in control of their emotions. Stress is everywhere in farming. Over half of Canadian farmers were categorized in the mid stress scores, whereas 14% were identified with high stress. Three out of four Canadian farmers felt moderate to high stress about unpredictable interference, workload pressure, lack of time, and financial constraints. Women and young farmers felt more stressed. The report also recommended actions like doing awareness programs about the importance of farmer mental health, improvement of mental health literacy of farmers, delivering business management advice, tools and training that focus on risk management and preparedness as a means of facing uncertainty, and advocating farmer specific mental health services (Real Agriculture News Team, 2020). Studies show that farmers' suicide rates were nearly four times higher than those of the general occupational population. Calculating these rates is extremely difficult and unique to the agricultural profession. It is a challenge to study the farmers' suicide rates and also critical in determining ways to promote suicide prevention. Above all, after decades of mental illness awareness programs on stigmatism and suicides, farmers and agricultural workers are becoming more comfortable expressing their struggles and seeking professional helper (Raschke, 2019).

**Chitrasena Padhy and Pakalpati Satyanarayana Raju**

Farming is full of challenges that can take a charge on the mental health even under the best of circumstances. Presently in uncertain times of global COVID 19 pandemic which impact just about every aspect of life, emotional wellness is critically important for farmers. Few ideas that can help are taking care of oneself, developing a regular exercise routine, reading for pleasure, reconnecting with an old hobby, writing a list of relationships and things for which one is grateful, changing up listening routine, giving time to sit in silence, and meeting with a counselor or a therapist (Paff, 2020).

Nine in ten farmers and farm workers tell financial issues affect farmers' mental health. Nearly half of rural adults say they are experiencing more mental health challenges than they were a year ago, as per poll commissioned by the American Farm Bureau Federation. Kansas created a website offering research and support to individuals struggling with agriculture related stress. Research specific to different age groups and separate pages for men and women in agriculture is offered by the website. Resources include those related to financial counseling, legal assistance, substance abuse, gambling problem, and domestic violence. There is information in the site about the roots of farmers' stress and how to manage. It helps connect people to the services they need (Lenis, 2019). It is not a secret that farming life can be hard work. The most often quiet is the strain on farmers' mental health as a result as reported by Hicks (Farmers Guide, 2020).. Isolation for long hours for the farmers and financial pressures can be stressful enough, but sudden and uncontrollable factors like abnormal weather conditions, loss of vital chemical treatments and different political climate with an unstable trade system, their vulnerability is particularly apparent (Farmers Guide, 2020).

The Farm Stress Programme of the Michigan State University Extension is meant for farmers facing stress and mental health issues with online counseling. Farmers are connected with licensed mental health therapist by MSU Extension. Teletherapy provides mental health and counseling services through the internet rather than in-person. It is offered by video between mental health service providers and clients. It helps people to access behavioral health supports in their own environment. Farmers can access behavioral health services with the 'Stay Home, Stay Safe' executive orders, (Karbowski and Gross, 2020). The virtual mental health services are offered by Ontario government from May 2020 to thousands of Ontarions those who are experiencing anxiety and depression and it includes frontline health care workers during the COVID 19 outbreak. These Internet-based Cognitive Therapies were developed in partnership with Mind Beacon and Morneau Shepell . These would provided at no out-of-pocket costs to Ontarions across the province (Mental Health News, 2020).

Week-long mind your head campaign conducted by the farm safety foundation aims to raise awareness about mental health with stories and short films on social media. Recent research by the foundation charity found that that 81% of farmers under 40 believe that mental health is the biggest hidden problem facing farmers today. Other 92% believe that promoting good mental health is important. Lives can be saved and farmers are can be kept safe by promoting mental health (Hailstone, 2019). Suicide and mental disorder are major public health problems in India. Nearly 1000 farmers ended their lives every year in the Vidarbha region since 2001 according to the National Crime Records Bureau. Several experts mention higher as many cases do not even get reported. The report also indicated that the cause of suicide is varied, like gender disadvantage, caste discrimination, and debt. The most important at individual level determinant is mental disorder. The most common mental disorders that contribute to this risk are stress and depression. It can be a result of a range of social and health factors mainly in rural communities. A community initiative called Vidarbha Stress and Health Programme (VISHRAM) is an effective for bringing reduction in suicidal behavior and encourages people to seek professional help for depression (Pal, 2017).

**Chitrasena Padhy and Pakalpati Satyanarayana Raju****CONCLUSION**

There is an association between crop failure due to unexpected droughts and suicide attempts by farmers. Failure of a crop can lead to economic difficulties. When depending on low precipitation, the farmer might not be able to sustain the expenses of the family and becomes a victim of the debt trap to meet the expenses. The mental health risks among the farmers increase by climate change such as rise in temperature (Psychology Today, 2017). Agricultural networks such as farmers' unions or societies help the farmers to get together and share and discuss common problems. Farmers can get useful information on various farming issues such as good farming practices, health and safety, coping with issues etc. (Parry *et al*, 2005). Training and education are required for farmers to face uncertainties (Olesen and Bindi, 2002).

### ABSTRACT

The studies on the population dynamics of major pests of *Pongamia* were conducted during 2016-2018 in the agricultural fields of Bangalore, India. 20 species of pests were recorded on *Pongamia*. Nineteen species were recorded and found to be common both under nursery and field conditions. leaf webber, *Glyphodes negotialis* exclusively present only in nursery and flower gall inucer *Aspondylia pongamiae* was exclusively formed in field condition. The mite, *Aceria pongamiae* Channabasavanna, leaf blotch miner, *Acrocercops anthrauris* Fabricius, spiraling whitefly *Aleurodicus disperses* Russel and common banded awl *Hasora chromus* Cramer and web mite, *Schizotetranychus lespedezae* Beglyarov& Mitrofanov, were the major ones. Further, five species of insect pests were recorded on *Pongamia* under storage conditions.

**Key words:** Mite, *Aceria*, *Pongamia*, Leaf webber, Pests, blotch miner

### INTRODUCTION

*Pongamia pinnata*, commonly known as karanja is a leguminous oil yielding multipurpose tree. , it can tolerate a range of different conditions with mean annual rainfall between 500–2500 mm and temperatures of 0 – 16°C minimum and 27–50°C maximum where mature trees can cope with light frosts, but require a dry period of 2–6 months (Duke, 1983; Daniel, 1997). There are so many pests present on *Pongamia*, in that tree is attacked by a number of insect pests among the important insect pests, the common banded awl, *Hasora chromus* is one of the major defoliator causing heavy losses, the mite, *Aceria pongamiae* Channabasavanna, leaf blotch miner, *Acrocercops anthrauris* Fabricius, spiraling whitefly *Aleurodicus disperses* Russel and common banded awl *Hasora chromus* Cramer and web mite, *Schizotetranychus lespedezae* Beglyarov& Mitrofanov, were the major ones. However, leaf

webber, *Glyphodes negatalis* Walker, two tailed mealybug, *Ferisia virgata* (Cockerell), *Maruca amboinalis* Felder, *Euproctis* sp. Hubner, *Indarbela tetraonis* Moore, *Cyclopelta siccifolia* Westwood, *Nezara viridula* (Linnaeus), common cerulean *Jamides celen* Cramer, spherical mealybug *Nipaeococcus viridis* (Newstead), wasp moth *Amatapassalis* Fabricius, tree hopper *Oxyrachis* sp., *Chrysocoris stolli* (Wolff), cowbug, *Tricentrus bicolor* Distant are present.

## MATERIALS AND METHODS

### To record and document the pests and their natural enemies occurring on *Pongamia* under nursery, main field and storage condition

Studies to document the occurrence of major pests of *Pongamia* were carried out during 2016-17 and 2017-18 in nurseries, main field and storage. For this purpose surveys were conducted in *Pongamia* plots and the *Pongamia* nursery in UAS, GKVK, Bengaluru and Zonal Agricultural Research Station, GKVK and also in the surroundings of UAS, GKVK, Bengaluru.

### Location of plots for collection of pests

Frequent visits were made to both nurseries and plots of *Pongamia* for collecting the insect pests on *Pongamia* and their natural enemies in and around UAS, GKVK, Bengaluru from September 2016 - December 2017. The present study was based on random collection from time to time, covering different plants of *Pongamia*. In storage the pods which were collected from the *Pongamia* plants and also from godowns and were stored in containers like plastic boxes, polythene covers and cloth bags as well as in open conditions and observed on a daily basis to collect storage pests and to document them.

### Collection equipment

The basic equipment utilized for field and nursery collection comprised of forceps, scissors, vials containing 70 per cent ethyl alcohol, insect killing bottles, small boxes or containers of cardboard for storing specimens after their removal from killing bottles, small envelopes for temporary storage of delicate specimens or gel caps for tiny specimens, one or more aspirators, absorbent tissue for use in killing bottles and aspirators, field observation book, a strong secateur cutting twigs, white card board sheets for jarring, muslin cloth, rubber bands, soft camel brush, bags for storing plant material, hand lens etc.

### Collection of pests and their natural enemies on *Pongamia*

The insect pests present on *Pongamia* were collected both at their immature stages (eggs, larvae, pupae, maggots, grubs, nymphs, etc.) and also adults from *Pongamia* plants. The immature stages were collected alive from field in collection jars, collection tubes, paper bags or polythene bags, in order to carry them to laboratory for rearing them and their natural enemies, if any. The collection jars were thoroughly washed and sun dried prior to their use. Collection jars containing relevant insect material were covered with muslin cloth or cotton wool for aeration purpose. They were provided with absorbent paper to absorb extra moisture during carriage. The adult stage of the insects were collected and presented for identification. The predators devouring insect pests damaging *Pongamia* were raised by rearing their immature stages along with the host insects in the laboratory. Some coccinellids, preying mantids, spiders and hemipteran bugs were also collected as adults while they were preying on their host insects as per the methodology suggested by Lecker and Deay (1969) was adopted for this purpose. Various collection methods employed were:

### Hand picking

Based on keen visual observation this method was used for collecting caterpillars, grubs, maggots, blotch miners, galls, borers and mealybugs. Insects were picked by means of a forceps or by a camel hair brush and drawn into a collecting jar/ bags as suggested by Banks (1909).

D. Devika Rani et al.

### Beating / Jarring

This method proved efficient whenever the weather turned cold or early and late in the day, when normally insects seek shelter in vegetation and were otherwise difficult to detect. In this method a white drawing sheet was placed under a branch which was then hit with a stick, the insects that fell off on the sheet were picked by a moistened brush or with forceps. This method gave a good collection of bugs, and larval Lepidoptera which was as per the methodology suggested by Banks (1909).

### Aspirator

It was used to capture live tiny insects like thrips, white flies, etc. for further studies as suggested by Banks (1909).

### Flower gall inducer (*Asphondylia pongamiae* Mani)

To study the presence of different stages and to know how flower gall formation occurs, flower buds were collected in polythene covers and brought to the laboratory.

### Collection of flower buds

Visits were made every week when new leaves and flowering was observed on *Pongamia*. Fifty fresh flower buds were collected each day, dissected and viewed under a stereo zoom microscope to detect symptoms of oviposition by *A. pongamiae*.

### Dissection of flower buds

From the commencement of bud formation in *Pongamia*, 50 fresh buds/galls were plucked and brought to the laboratory at weekly intervals. Samples were dissected with a sharp blade and other required accessories. Care was taken to avoid any damage to the growing stages of *A. pongamiae* within the galls. The developmental stages were observed within the flower galls by periodical dissection.

### Methods of collection of pest mites

Samples of infested leaves of *Pongamia* were plucked and put in Zip-lock plastic bags for subsequent screening of pests harboured by them in the laboratory. Within the laboratory, individual leaf was thoroughly examined under a stereo zoom microscope for the recovery of pest mites. A small quantity of the sampled mites and insects were preserved in 70% ethyl alcohol for taxonomic studies.

### Clearing and mounting of specimens

The specimens of phytoseiid mites and pest mites which were preserved in 70% alcohol were then upgraded through 80 per cent, 90 per cent and absolute alcohol series and mounted in Hoyer's medium for identification.

### Preparation of mounting medium (Hoyer's Medium)

Hoyer's medium was prepared by careful and proper mixing of the following ingredients. The mixture was then filtered through two folds of thin cloth or glass wool and stored in a coloured bottle. Distilled water - 50 ml, gum-Arabic crystals - 30gms, chloral hydrate -200 gms, glycerine -20 ml.

## RESULTS AND DISCUSSION

### Insect pests recorded on *Pongamia* under nursery, main field, storage and their natural enemies

During the study, twenty pest species were recorded on *Pongamia* (Table 1), of which 20 pest species were present both under nursery and main field. However, leaf webber, *Glyphodes negotialis* exclusively present only in nursery and flower gall inucer *Asphondylia pongamiae* was exclusively present only under field condition. Further, five species of insect pests were recorded on *Pongamia* under storage (Table 1).

**D. Devika Rani et al.**

### **Pests recorded under nursery and field conditions**

Among the twenty species of insect pests recorded on *Pongamia* in nursery, the mite, *Aceria pongamiae* Channabasavanna, leaf blotch miner, *Acrocercops anthrauris* Fabricius, spiraling whitefly *Aleurodicus dispersus* Russel and common banded awl *Hasora chromus* Cramer and web mite, *Schizotetranychus lespedezae* Beglyarov & Mitrofanov, were the major ones. However, leaf webber, *Glyphodes negatalis* Walker, two tailed mealybug, *Ferisia virgata* (Cockerell), *Maruca amboinalis* Felder, *Euproctis* sp. Hubner, *Indarbela tetraonis* Moore, *Cyclopelta siccifolia* Westwood, *Nezara viridula* (Linnaeus), common cerulean *Jamides celen* Cramer, spherical mealybug *Nipaecoccus viridis* (Newstead), wasp moth *Amatapassalis* Fabricius, tree hopper *Oxyrachis* sp., *Chrysocoris stollii* (Wolff), cowbug, *Tricentrus bicolor* Distant and 20 species of pests were recorded on *Pongamia* (Table 2). Nineteen species were recorded and found to be common both under nursery and field conditions (Table 1).

### **Common banded awl, *Hasora chromus* Cramer (Lepidoptera: Hesperidae)**

Eggs were laid singly or in small groups of 2-3 on young shoots like a staple of the leaves or on the margin of the upper surface of young leaves. Eggs were bun shaped with ridges running from top to base. The eggs were flattened at the base which helped to be attached onto the substratum. The freshly laid eggs were whitish in colour but later turned pinkish and finally turned into silvery white colour, just before hatching. The larval head was blackish and they fed on the upper portion of the chorion and cut a hole to emerge out of the eggshell. After emergence larvae did not feed on the entire shell but fed only partly. The adult butterfly was brownish black in colour, the wings were completely covered with scales. The wings of a male butterfly were unmarked, whereas the female butterfly had two spots on both sides of the forewings and horizontal white band was present in both sexes, on the lower side of hind wings. *Hasora chromus* is dimorphic and the wings of a male being unmarked, whereas female having two pale yellow crescentic spots on the hind wing. The adult butterfly was very active. Antenna was enlarged gradually towards the tip with hook-like projection on the terminal segment. These results are similar to the findings of Harinath et al. (2012).

### **Spiralling whitefly *Aleurodicus dispersus* Russel (Hemiptera: Aleyrodidae)**

The white fly feeds on the underside of plant leaves by piercing their stylets into the phloem of plants, introducing toxic saliva and decreasing the plant vigour. Direct damage is caused by the piercing and sucking of sap from foliage by immature and adult stages. The majority of feeding damage was done by the first three nymphal stages. This feeding caused premature dropping of leaves. Indirect damage was due to the accumulation of honeydew and white, waxy flocculent material they produce. Subsequently they produce honeydew, which is sweet and watery excrement, often fed on by bees and ants, which in turn, may tend and offer protection to the whiteflies. The honeydew also serves as a substrate for the sooty mold growth, which blackens the leaf surface and decreases photosynthetic activity, decreases vigour and often causes disfigurement of the host and lessens the market value of the plant or makes it unmarketable.

The flocculent material produced by the nymphs was scattered by the wind and creates nuisance. Adults were similar in appearance to those of many other species of whiteflies. They were white and quite small in length and coated with a fine dust-like waxy secretion. They resembled tiny moths and both sexes were winged. Eyes of these whiteflies were dark reddish-brown. Wings were transparent after emergence from the pupal case, but developed a white powder (wax) covering after a few hours. Each forewing had two characteristic black spots. These results are similar to the findings of Paulson and Kumashiro (1985), Berlinger (1986) and Waterhouse and Norris (1989).

### **Bean pod borer, *Maruca amboinalis* (Felder & Rogenhofer) (Lepidoptera: Crambidae)**

*Maruca amboinalis* is a member of the subfamily Spilomelinae of the Crambidae family. The forewing of this species is dark brown, with a yellowish brown colour along the leading edge, a silvery white spot on the front end of the middle chamber; a white bottom on the hindwing, and a dark brown spot on the top corner extending to about half of the outer edge. The outer center line is a black wavy line. In addition to other species, there are also *M. vitrata*. The

**D. Devika Rani et al.**

fine-grained pods are similar to the pods damaged by the podborers and can be distinguished by the following characteristics: 1. The fore-wings have only white spots at the front end of the middle chamber and are only as wide as the middle chamber, and the latter is developed with white spots, and more than one piece; 2. The former hind wings are dark brown. The spot is rounder and the latter is longer. This species is rare compared to the pea pod borers that are considered to be pests. *Maruca amboinalis* represents one of the two *Maruca* species which could be distinguished from *Maruca vitrata*, the other *Maruca* species, by the following characters: 1. Only one undeveloped white spot on forewing; 2. Round dark-brown marking on the hindwing.

#### **Leaf webber, *Glyphodes negatalis* Walker (Lepidoptera: Pyralidae)**

Adults are white with several ragged pale brown submarginal bands outlined in dark brown. The hind wings are white with brown veins and brown margins. It is a defoliator of *Pongamia pinnata*.

#### **Leaf blotch miner, *Acrocerops antraulis* Fabr. (Lepidoptera: Gracillariidae)**

It is a very serious and common pest of *Pongamia pinnata*. The larvae make circular blotches on the upper (dorsal) surface of the leaves. Its damage reduces photosynthetic area of the leaves, thus hindering the growth and vigour of the plants. The full-grown larvae were slender, minute, and orange-yellow with a large black head.

#### **Hairy caterpillar, *Euproctis* sp.**

Hairy caterpillar, *Euproctis* sp. was noticed in very low numbers. Early instar larvae of a hairy caterpillar, *Euproctis* sp. fed on the green part of the leaves and skeletonized them but later instar larvae completely fed on the leaves along with soft apical shoots of plants.

#### **Flower gall inducer, *Aspondylia pongamiae* Mani (Diptera: Cecidomyiidae)**

It will affect the seed set, and causes reduction of the plant growth. Presence of strong needle shaped ovipositor, and the abdominal segments with combination of yellow black band, which differentiate females from males. The colour, body size and wing size of male and female *A. pongamiae* are as follows: Female: Brownish black, Male: Light brown in colour. Symptoms of infestation were evident within 10 - 15 days of egg laying. When flower buds were oviposited by the gall inducer, the freshly emerged larvae lacerate the developing ovary in a floret on oozing cell-sap. The buds turned into young sub globular galls due to the infestation within a month and petals towards the bulged portion of the infested ovary turned whitish green and coarse. After two months of gall development, the petals and sepals dropped from the gall and only the developed nut shaped galls were apparent on the trees. The fully matured galls were dull green in colour and had an average diameter of 1 cm.

#### **Metallic shield bug, *Chrysocoris stollii* (Wolff) (Hemiptera: Scutellaridae)**

The dorsum was metallic blue, green, or purple in colour abdomen of ventral region was yellow, broadly margined with purple laterad to spiracles, spiracles II-VII each surrounded by a rounded black spot; pro-, meso- and metepimeroids together with the supra coxal lobes yellow; coxae and trochanters pale yellow, femora with an apical annulus and longitudinal blackbands, tibiae and tarsi black. The pest feeds on plant sap of *Pongamia* plant due to which they cause extensive yield reduction.

#### **Common cerulean, *Jamides celen* Cramer (Lepidoptera: Lycaenidae)**

In case of the male upper side is pale bluish white. The forewing has the terminal margin narrowly edged with black that broadens very slightly towards the apex of the wing. The cilia are brownish black. Hind wing is uniformly coloured, except for an anteciliary black line faintly edged on the inner side by a white line within which and touching it is a row of black spots, the anterior spots are very faint, the spot in inter space 2 large and well-defined, two geminate (paired) spots in inter space 1 and a very small black lunular dot in inter space 1a; cilia brown, white at the base in the interspaces.

**D. Devika Rani et al.**

In the female adult the upper side colour is paler than in the male, often quite white; terminal black edging to forewing very much broader, broadest at apex, its margin there diffuse. Hind wing differs from that of the male with respect to costal margin broadly dusky black; a post discal transverse series of dusky-black connected lunules often more or less obsolescent; this is followed by a series of black spots each set in a background of the white ground colour; an anteciliary slender black line as in the male. The underside ground colour is paler than in the male, the markings however are identical. Antenna, head, thorax and abdomen are similar to that of male. It is a defoliator on *Pongamia*.

**Spherical mealybug, *Nipaecoccus viridis* (Newstead) (Hemiptera: Pseudococcidae)**

Adult female is oval; body segmentation is visible prior to oviposition and covered by wax. The body is dark green purple, or dark brown purple, beneath the white-creamy or pale-yellowish wax cover; it is 2.5-4 mm long and 1.5-3 mm wide, depending on the host plant and the specific feeding site. The adult male is brown-purple with well developed forewings, elongated more than body. The pest causes curling and dwarfing of young growth. Heavy infestations result in deterioration of the crown, which turns yellow, wilts and subsequently dies. The pest occurs on all plant parts causing injuries, It prefers to colonize fast growing tissues, contaminating them with honeydew, which results in a thick cover of sooty mold.

**Wasp moth, *Amata passalis* (Fabricius) (Lepidoptera: Amatidae)**

Adult moth can be broadly defined by the wing characteristics, forewings chocolate brown in colour with white spots. It feeds on the leaves of *Pongamia* plants.

**Metallic shield bug, *Scutellera perplexa* (Westwood) (Hemiptera: Scutellaridae)**

The bug is oblong elongate scutellerid with metallic green color and small or large spots of black on pronotum and scutellum. Body finely pilose. As is typical for Scutelleridae family, scutellum very long covering most of the body, wings not visible. Coloration of body underneath, rostrum and legs reddish, underside of head, lateral side of sternum, part of rostrum as well as lateral bands on abdominal segments are metallic bluish green. The adult suck the sap from the leaf petiole, stem, or on the pod surface. These bugs caused direct damage by sucking sap.

**Bug, *Tricentrus bicolor* Dist. (Hemiptera: Membracidae)**

The pest is recognized by the structure of pronotum which takes curious bizarre shapes in this, those have earned the name "Cow bugs" or "Horn bugs". Both nymphs and adults suck the plant sap and exude honeydew which attracts the black ant, *Camponotus compressus*. The damage caused is seldom severe resulting in drying of leaves/plant

**Leaf hopper, *Empoasca* sp. (Hemiptera: Cicadellidae)**

Their pronotum and scutellum are green. The green leafhopper, *Empoasca* sp., inserts its stylets into the plant and releases toxic substances present in the saliva into the plant vascular system, causing phytotoxicity.

**Pests recorded under storage conditions**

Totally five insect pest species were recorded on *Pongamia* under storage conditions, they were bruchid, *Caryedon serratus*, pulse beetle *Callosobruchus maculatus*, Saw toothed grain beetle *Oryzaephilus surinamensis* (Linnaeus), Rice moth *Corcyra cephalonica* (Stainton) and Mediterranean flour moth, *Ephesia kuhniella* (Zeller).

**Bruchid: *Caryedon serratus* (Olivier) (Coleoptera: Chrysomellidae)**

The adults were dark brown in colour, 4-7 mm long and show sexual dimorphism where, antennae are long and serrated in males than in females, whereas the pygidium (dorsum of the posterior abdomen) is more exposed in females than in males. The hind leg femur is serrated and 5 mm wide in both females and males. Grubs are pink in colour, 10 mm long and possess abdominal uromeres. Grubs inflict damage to both kernels as well as pods.

D. Devika Rani et al.

Infestation starts from the field where the adults lay eggs on exposed pods and it is carry forwarded to storage (Table 2). The first visual symptom is the exit hole of final instar larva before pupation.

**Pulse beetle: *Callosobruchus maculatus* (Fabricius) (Coleoptera: Chrysomellidae)**

The body of the adult is 3-4.5 mm long, reddish-brown, with black spots on the prothorax and elytra. The last segment of the abdomen extends out from under the short elytra and also with black spots. The females are sometimes larger and darker than the males. The larva is whitish in colour. The female attaches its eggs on the surface of seeds in the field or in storage. The larvae burrow into the seeds where their complete development occurs. The larvae cannot move among seeds; thus they are restricted to the seed that the adult bruchid has chosen for them (Table2). The larva makes tunnels through the pod until it is ready to pupate. Mature adults emerge from the seed, biting a neat circular exit from the seed.

**Rice moth, *Corcyra cephalonica* (Stainton)**

Hind-wings pale-buff, fore-wings mid- or greyish-brown with thin vague lines of darker brown along wing veins. Larva feed on *Pongamia* stored pods.

**Saw toothed grain beetle, *Oryzaephilus surinamensis* (Linnaeus) (Coleoptera: Chrysomellidae)**

It is adark brown beetle; it is unable to fly even small distances.Larval feeding results in shrinkage of the dry mass of the infested seeds.

### ABSTRACT

A field trial was conducted in a randomized block design with three replications at M.S. Swaminathan School of Agriculture, Centurion University of Technology and Management, Paralakhemundi, Gajapati district, Odisha, during the summer season 2020 to evaluate different bitter gourd genotypes. Observations recorded on eleven quantitative characters. Analysis of variance revealed that the genotypes evaluated differed significantly among all the eleven characters. The genotype Uchha Bolder has taken the minimum number of node bearing 1<sup>st</sup> pistillate flower (11.00) and the maximum number of fruits vine<sup>-1</sup> (39.00). Fruit diameter and average fruit weight were maximum in Priya (4.60 cm and 106.04 g, respectively). Among genotypes, Meghana produced maximum fruit yield vine<sup>-1</sup> (2.36 kg) followed by Green Long (2.10 kg) and Priya (2.00 kg). Meghana was found superior based on overall performance in terms of growth and yield under Paralakhemundi, Gajapati District agro-climate condition.

### INTRODUCTION

Bitter gourd (syn. Bitter melon; *Momordica charantia* L.) is an economically important vegetable crop belongs to the family Cucurbitaceae (De Wilde and Duyfjes, 2002). It is widely cultivated in India, China, Malaysia, Africa and South America (Raj *et al.*, 1993). The immature stage of fruits and seeds of bitter gourd possess medicinal properties

**K Mallikarjunarao et al.**

such as anti-diabetes (Chen *et al.*, 2003), anti-HIV activity (Lee *et al.*, 1995), charantin (Yeh *et al.*, 2003), momorcharin (Leung *et al.*, 1997), hypoglycaemic compounds (Jayasooriya *et al.*, 2000) and anti-carcinogenic and hypercholesterolemic (Ahmed *et al.*, 2001). Among the cucurbitaceous vegetable crops, bitter melon possesses a comparatively high concentration of ascorbic acid and iron. Even though India is a major producer of bitter melon in the world, the average productivity is very low. Most of the farmers are still cultivating nearby local cultivar. There is lack of appropriate cultivars in paralkhemundi region. So, there is need to find out the most suitable genotype in terms of yield and its attribute traits in this region.

## MATERIALS AND METHODS

The present study was carried out at Department of Horticulture, M.S. Swaminathan School of Agriculture, Centurion University of Technology and Management, Paralakhemundi, Gajapati district, Odisha during summer season 2020. The experimental materials of the present study comprised of 10 genotypes. Five plants were selected randomly for recording observations of eleven quantitative characters *viz.*, vine length (m), number of primary branches vine<sup>-1</sup>, days to 1<sup>st</sup> staminate flower appearance, days to 1<sup>st</sup> pistillate flower appearance, number of node bearing 1<sup>st</sup> staminate flower, number of node bearing 1<sup>st</sup> pistillate flower, fruit length (cm), fruit diameter (cm), average fruit weight (kg), number of fruits vine<sup>-1</sup> and fruit yield vine<sup>-1</sup> (kg). Data were statistically analyzed by following Panse and Sukhatme (1985).

## RESULTS AND DISCUSSION

Analysis of variance for eleven quantitative characters was studied for different genotypes of bitter melon are presented in Table 1. The analysis of variance showed that highly significant differences existed among the test genotypes for all the eleven quantitative traits. The mean performances of the genotypes in different characters are presented below as per Table 2. In respect of vine length, shortest vine length was observed in Arka Harit (2.50 m) followed by Pusa Aushadhi (2.62 m) and VNR 28 (2.75 m) while the 3 tallest genotypes were BBG 5 (4.40 m), Green Long (4.20 m) and Priya (4.11 m). The number of primary branches vine<sup>-1</sup> varied from 16.50 in Uchha Bolder to 8.10 in Pusa Aushadhi. The genotypes VNR28 (15.65) and Green Long (14.53) also recorded good number of primary branches vine<sup>-1</sup>. The early staminate flowering appeared in genotype Pusa Aushadhi (36.00 days) followed by VNR28 (36.50 days) and Arka Harit (37.50 days) and late staminate flowering was observed in genotype Pathapatnam Local (47.00 days). Days to 1<sup>st</sup> pistillate flower appearance ranged from 36.75 days in Pusa Aushadhi to 52.75 days in BBG-5. Other early genotypes are VNR28 (36.50 days) and Arka Harit (37.50 days).

Minimum number of node bearing 1<sup>st</sup> staminate flower recorded in VNR28 (8.50), followed by Pusa Aushadhi (8.75) and Uchha Bolder (9.00). The genotypes Uchha Bolder (11.00) and BBG-5 (25.00) had the minimum and the maximum number of node bearing 1<sup>st</sup> pistillate flower. The varieties Green Long and Uchha Bolder produced the longest fruits (21.50 cm) and shortest fruits (6.50 cm), respectively. The genotypes Meghana (17.25 cm) and Priya (17.00 cm) also had longer fruits. Variation in fruit diameter ranged from 3.20 cm in BBG-5 to 4.60 cm in Priya. The genotypes Meghana (4.50 cm) and Nobel Katahi (4.50 cm) also recorded maximum fruit diameter. The mean fruit weight varied from Uchha Bolder (30.00 gm) to Priya (106.04 gm). The genotypes Meghana (104.50 gm) and Green Long (101.25 gm) also produced reasonably heavy fruits. The mean number of fruits per plant varied from 16.00 in the variety Nobel Katahi to 39.00 in the genotype Uchha Bolder. The two genotypes VNR28 (30.00) and Meghana (23.25) also produced higher number of fruits plant<sup>-1</sup>. The fruit yield vine<sup>-1</sup> varied from 0.71 kg in the genotype BBG-5 to 2.36 kg in Meghana. The next two top yielders were Green Long (2.10 kg) and Priya (2.00 kg). These results agree with that of Yadagiri *et al.* (2017), Thakur *et al.* (2018), Adarsh *et al.* (2019) and Mounica *et al.* (2019). Among the evaluated genotypes, Meghana could be identified as the best genotype based on yield and its attribute traits.

### ABSTRACT

Yeast strains lacking mRNA decapping activation factors (*LSM1*), decapping factor (*DCP2*), cytoplasmic exosome function (*SKI2*) or cytoplasmic deadenylases (*CCR4* alone or double deletion of *CCR4* and *PAN2*) displayed apoptotic phenotype with typical markers of eukaryotic apoptosis such as cellular ROS generation, externalization of phosphatidyl serine, enhanced caspase gene (*YCA1*) expression and protein activity in mid-log phase cultures. In the present study, apoptotic yeast strains showed reduced gene expression for the key enzymes of TCA cycle (*Aco1*, *Cit1*, *Cit2* and *IDH1*) and *in-vivo* protein activity in mid-log phase cultures. Analysis of different Lsm1 C terminal deletion (CTD) mutants suggested strong association between mRNA decapping defects and apoptosis. Except in the *dcp2Δ* strain, all the strains undergoing apoptosis (*lsm1Δ*, *ski2Δ*, *ccr4Δ* and *ccr4Δpan2Δ* mutants) displayed clear-cut stabilization of protein A mRNA suggesting mRNA stability is not linked to caspase mediated apoptosis in strains compromised with *DCP2*.

**Keywords:** deadenylases, mRNA degradation, apoptosis, metacaspase, decapping, Real Time-PCR, flow-cytometer, yeast.

### INTRODUCTION

The condensation of acetyl-CoA and oxaloacetate to form citrate is the first reaction of the tricarboxylic acid (TCA) cycle and is catalyzed by the major mitochondrial citrate synthase (*Cit1*) in *S. cerevisiae*. Thus, *Cit1* functions as a rate-limiting enzyme of the TCA cycle [1]. *Cit2* is a peroxisomal citrate synthase involved in the glyoxylate cycle [1, 2]. Both *Cit1* and *Cit2* are involved in synthesis of citrate, which is expected to be converted into glutamate via  $\alpha$ -

**Kalidindi Krishnam Raju**

ketoglutarate. Thus, the absence of both Cit1 and Cit2 causes glutamate auxotrophy, whereas the presence of either Cit1 or Cit2 does not [3, 4, 5]. Yeast cells with *cit1* deletion showed much higher susceptibility to chronological aging-induced cell death accompanied by the typical hallmarks of apoptosis, such as reactive oxygen species (ROS) accumulation, phosphatidylserine externalization, nuclear fragmentation, and DNA breakage [5]. Aconitase (Aco1) is another important enzyme required for the second step of tricarboxylic acid (TCA) cycle and also independently required for mitochondrial genome maintenance [6, 7]. NAD(+)-dependent Isocitrate dehydrogenase (IDH) is an enzyme that is used during the third step of the citric acid cycle. Its main function is to catalyze the oxidative decarboxylation of isocitrate into alpha-ketoglutarate and consistent with its role in TCA cycle yeast strains compromised with IDH2 exhibits slow growth phenotype [8].

Two major mRNA decay pathways exist in eukaryotes. Both pathways are initiated by poly(A) shortening of the mRNA. In the 5' to 3' decay pathway, the Dcp1p/Dcp2p decapping enzyme complex can hydrolyze the cap structure following deadenylation by Pan2p and Ccr4p enzymes and the mRNA is subsequently degraded from the 5' end by Xrn1 nuclease [9, 10, 11]. In the 3' to 5' decay pathway, deadenylated mRNAs are degraded in a 3' to 5' exonucleolytic manner and require two multiprotein complexes: the exosome containing various 3'-exonucleases and the Ski complex consisting of RNA helicase Ski2p, Ski3p, Ski7p and Ski8p [12, 13]. The Lsm1-7-Pat1 complex is made up of the Pat1 subunit and the seven highly conserved Sm-like protein subunits, Lsm1 through Lsm7. The Lsm1-7-Pat1 complex promotes mRNA decay through the 5' to 3' pathway by facilitating mRNA decapping via an unknown mechanism [14, 15]. Yeast Lsm1 has extended N- and C-terminal domains (40 and 55 residues, respectively) flanking the Sm-domain, with C-terminal domain (CTD) being functionally indispensable both for both mRNA decay and 3'-end protection [16]. Infact CTD is able to support the function of this Lsm1-7-Pat1 complex in trans even when it is not contiguous with the Sm-domain of Lsm [17]. Mutagenic analysis of the C-terminal extension of Lsm1 revealed that C-terminal most residues are essential for RNA binding activity of Lsm1-7-Pat1 complex and deletion of C-terminal most 8 residues of Lsm1 results in clear, though moderate, defect in mRNA decay even when the C-terminal extension is contiguous with the Sm domain of Lsm1 [17, 18]. Analysis of CTD mutants of yeast Lsm1 suggests strong association between apoptosis and mRNA decay defects. The key enzymes of TCA cycle catalyzing the first three steps of TCA cycle (*CIT1*, *ACO1* and *IDH*) are rapidly declined in the apoptotic yeast strains defective in decapping (*lsm1Δ*) and deadenylation (*ccr4Δ* and *ccr4Δpan2Δ*mutants).

## MATERIALS AND METHODS

### Strains and Growth Conditions

Cells were grown in a mechanical shaker (220 rpm) at 26°C in minimal medium (0.5% ammonium sulphate, 0.17% yeast nitrogen base) containing 2% glucose (SD) supplemented with 0.079 % Synthetic Complete drop-out Medium Mix. Yeast strains used in this study are listed in Table 1. Inoculation was carried out by addition of a freshly revived colony of *Saccharomyces cerevisiae* to the medium, incubated at 26 ± 2°C under shaking conditions and yeast strains were harvested at mid-log phase OD≤0.5 for Quantitative RT-PCR and protein activity studies.

### Assessment of intracellular reactive oxygen species (ROS) by flow cytometry

Free intracellular ROS were detected with dihydrorhodamine 123 (DHR123) (Molecular Probes, Eugene, OR, USA). Multiple ROS convert DHR123 to the stable fluorescent derivative DHR with excitation and emission wavelengths at 500 nm and 530 nm, respectively. DHR123 was added from a 1 mg/ml stock solution in ethanol, to 5×10<sup>6</sup> cells/ml suspended in PBS, reaching a final concentration of 10 µg/ml. Cells were viewed without further processing through a rhodamine optical filter after 90 minute incubation at 28°C in the dark as described previously [19]. For flow cytometric analysis, the samples were labeled with DHR123 as described above except that 1×10<sup>6</sup> cells were washed with PBS prior to acquisition on a Guava easyCyte 8HT flow cytometer (Millipore). 488 excitation laser and 525/30nm bandpass filters were used to capture the emission of rodamine. For all the assays done, data was acquired

**Kalidindi Krishnam Raju**

with Express Pro software and analysed by FlowJo software (Version 7.6). 20,000 events were acquired at a flow rate of 0.59 $\mu$ L/sec per sample.

**In vivo caspase detection by Flow Cytometric Analysis**

Endogenous caspase activity was measured using Calbiochem® Caspase Detection Kit as described previously [20].

**Real-time PCR**

Total RNA isolation and real-time PCR was performed as described previously [20]. The different primers used in the study are listed in Table-2.

**Total cellular citrate synthase assay**

Citrate synthase activity was determined in whole cell extract using assay kit (705502; Cayman Chemical Company, USA). Yeast cells were harvested at mid-log phase ( $OD_{600} \leq 0.5$ ), washed once with PBS and cell wall digested with 40 U/ml lyticase (Sigma Chemical Co.) in assay buffer for 15 min at 30°C. For whole cell extracts, spheroplasts were treated with CellLytic M cell lysis reagent and the total protein was determined in triplicate by the method of Bradford, and the protein concentration of all samples equalized. Citrate synthase activity was measured by following the color of TNB (2-nitro-5-thiobenzoic acid) at a wavelength of 412 nm at 25°C on a spectrophotometer (Elico Systems, Hyderabad, India). In a 0.5 ml cuvette, 25  $\mu$ l of sample was added to a reaction medium containing 465  $\mu$ l assay buffer, 5  $\mu$ l of 30 mM acetyl coenzyme A and 5  $\mu$ l of 10 mM DTNB solution. The baseline assay solution absorbance was recorded, reactions were initiated by addition of 12.5  $\mu$ l oxaloacetic acid, and the change in absorbance measured after 1.5 min.

**Aconitase assay**

Aconitase activity was determined in whole cell extract using assay kit (CS0720; Sigma-Aldrich, USA). This assay measures the absorbance of NAD(P)H at 340 nm, which is generated in the coupled reactions of aconitase with isocitric dehydrogenase. The rate at which NAD(P)H is generated is proportional to the activity of aconitase. In a 0.5 ml cuvette, 100  $\mu$ l of sample was added to a reaction medium containing 10  $\mu$ l of assay buffer, 100  $\mu$ l of NADP<sup>+</sup> reagent, 100  $\mu$ l of isocitric dehydrogenase and 100  $\mu$ l of substrate solution. The reaction mixture was incubated for 30 minutes at 37°C and the absorbance measured on a spectrophotometer at 340 nm. The baseline assay solution absorbance was recorded in the absence of substrate solution.

**Isocitrate dehydrogenase assay**

Isocitrate dehydrogenase (IDH) activity is determined using the assay kit from Sigma-Aldrich (MAK062). In this assay, cellular isocitrate as the substrate in an enzyme reaction, which results in a colorimetric (450 nm) product proportional to the enzymatic activity present.

**RESULTS AND DISCUSSION****Quantification of cellular ROS levels in *lsm1* CTD mutants**

To understand the role of Lsm1 C-terminal domain (CTD) in apoptosis, CTD mutants *lsm1-27*, *lsm1-28* & *lsm1-29* that expressed truncated versions of Lsm1p having deletions of 55, 43, and 28 amino acid residues respectively from the very C terminus end, but carrying intact Sm-domain and N-terminal extension (i.e., residues 1–117), were analyzed (Fig 1a). Key event in apoptotic cells is generation of ROS. Previously reported that about 40% of *Kllsm4 $\Delta$ 1* cells displayed intense intracellular staining with dihydrorhodamine 123 [21]. Flow cytometric studies were carried to determine cellular ROS levels by incubation with DHR123. Intense cellular fluorescence was observed in *lsm1 $\Delta$* , *lsm1-27* and *lsm1-28* cells with  $44 \pm 2.12$ ,  $36.0 \pm 2.13$  and  $32.0 \pm 0.70$  median fluorescence intensity (MFI) respectively. Cellular ROS levels were perceptible in *lsm1-29* strain relative to wild type strain (Fig 1b).

**Kalidindi Krishnam Raju****In vivo caspase assay in yeast strains defective in decapping and degradation**

Yeast metacaspase (*YCA1*) plays an important role in regulating apoptosis triggered by oxidative stress, chronological ageing or stabilization of mRNAs [19]. caspase protein activation in vivo was quantitated with FITC labelled VAD-FMK by flow cytometry in strains defective in decapping activators (*lsm1Δ* strain as well as CTD mutants of Lsm1p such as *lsm1-27*, *lsm1-28* & *lsm1-29*). Based on median fluorescence intensity (MFI) values relative to untreated wild type control, *lsm1Δ* mutants display highest caspase activity with 76.05±2.12 MFI values followed by *lsm1-27* (69.8±0.99 MFI) and *lsm1-28* strains (36.55±2.05 MFI). *lsm1-29* (15.3±0.28 MFI) strain show noticeable caspase activity with 1.5-fold higher endogenous caspase activity than wild type strain with MFI 10.3±0.7 (Fig 2a & 2b).

**Quantification of cellular citrate synthase, peroxisomal citrate synthase, aconitase and iso-citrate dehydrogenase transcript levels in apoptotic and non-apoptotic cells**

Quantitative Real Time-PCR (qRT-PCR) was performed to analyze mitochondrial citrate synthase (*CIT1*), peroxisomal citrate synthase (*CIT2*), iso-citrate dehydrogenase (*IDH1*) and aconitase (*ACO1*) transcript levels in wild type (WT) as well as mutants defective in decapping (*lsm1Δ*) or cytoplasmic deadenylation (*pan2Δ*, *ccr4Δ* and *ccr4Δpan2Δ* strains). Based on median fluorescence intensity (MFI) values relative to untreated wild type control, *CIT1*, *CIT2*, *IDH1* and *ACO1* transcript levels showed highest reduction in *lsm1Δ* (0.2295±0.099, 0.216±0.0462, 0.163±0.063, 0.292±0.124 respectively) and *ccr4Δpan2Δ* mutants (0.307±0.0183, 0.231±0.004, 0.3845±0.044, 0.35±0.042 respectively) followed by *ccr4Δ* mutant. In *ccr4Δ* mutant the *CIT1*, *CIT2*, *IDH1* and *ACO1* MFI values relative to untreated wild type control are 0.808±0.115, 0.558±0.060, 0.483±0.066 and 0.7545±0.126 respectively. In *pan2Δ* mutant cells *CIT1*, *CIT2*, *IDH1* and *ACO1* mRNA levels were comparable to the wild type strain (Fig 3a & Fig 3b).

Based on median protein activity expressed in unit, non-apoptotic wild type and *pan2Δ* strains showed optimum citrate synthase activity (1 unit). Total citrate synthase activity was considerably reduced in *lsm1Δ* and *ccr4Δpan2Δ* mutants with 0.541±0.036 and 0.452±0.114 units respectively followed by *ccr4Δ* strain (0.791±0.086 units) (Fig 4a). Consistent with *ACO1* transcript levels, Aco1p activity was considerably reduced in *lsm1Δ* and *ccr4Δpan2Δ* mutants followed by *ccr4Δ* strain with 4.26±0.234, 3.93±0.152 and 6.47±0.282 nmoles/min/ml respectively. Wild type and *pan2Δ* strains showed comparable Aco1p levels of 8.35±0.199 and 8.33±0.245 nmoles/min/ml respectively (Fig 4b). Likewise cellular Isocitrate dehydrogenase activity of mid-log phase cultures were considerably reduced in *lsm1Δ* and *ccr4Δpan2Δ* mutants followed by *ccr4Δ* strain when compared to wild type and *pan2Δ* strains (Fig 4c).

**Stabilized mRNAs trigger caspase mediated apoptosis but not in *dcp2Δ* strain**

Previously reported that mutations in mRNA decapping activators such as *LSM4* gene leads to increased mRNA stability and caspase-mediated apoptosis [21]. Yeast strains defective in deadenylation (*ccr4Δ* and *ccr4Δpan2Δ* strains) accumulate all the mRNAs tested and also undergo caspase mediated apoptosis [20, 22]. In the present study, we used the construct expressing (from *GAL* promoter) the Protein A mRNA carrying tract of 12U residues at 3' end and GFP coding regions separated by the hammerhead ribozyme sequence. Stability of the protein A mRNA was determined from the steady-state kinetics of this cleaved 5' fragment of protein A mRNA with 12U tract in both apoptotic and non-apoptotic cells. Except in wild type, *pan2Δ* and *dcp2Δ* strains, the strains undergoing apoptosis (*lsm1Δ*, *ski2Δ*, *ccr4Δ* and *ccr4Δpan2Δ* mutants) displayed stabilization of protein A mRNA (Fig 5) [22].

Increased cellular ROS levels and cellular caspase activity were observed in *lsm1Δ* strain as well as CTD mutants of Lsm1p such as *lsm1-27* and *lsm1-28*. Relative to WT strain, *lsm1-29* strain displayed 1.5 fold higher caspase activity and increased ROS levels. Mutagenic analysis of CTD mutants of Lsm1 revealed the importance of C-terminal most 8 amino acid residues of Lsm1 in facilitating RNA binding of the Lsm1-7-Pat1 complex and deletion or mutation these C-terminal eight residues can result in clear, though moderate, mRNA decay defect even when the C-terminal extension is contiguous with the Sm domain of Lsm1[18].

**Kalidindi Krishnam Raju**

Minor but measurable cell death in *lsm1-29* strain having deletion of just 28 amino acids from the very C-terminal end suggest strong association between apoptosis and mRNA decay defects in yeast. *CIT1*, *ACO1* and *IDH1/2* are regulated by HAP complex in respiratory competent cells but are under the control of RTG genes in response to a reduction or loss of respiratory function [23]. Our studies demonstrate rapid decline of key respiratory enzymes (*CIT1*, *ACO1* and *IDH*) in the apoptotic yeast strains defective in decapping (*lsm1Δ*) and deadenylation (*ccr4Δ* and *ccr4Δpan2Δ*mutants) suggesting loss of mitochondrial respiratory chain function and consequent ROS generation [24]. But the intracellular increase in ROS in response to DNA damage is not directly related to cell death. Recent studies reveal autophagy contributes to caspase-mediated apoptosis in response to ROS generation and DNA damage [25, 26]. While mRNA stability is linked to caspase dependent apoptosis in yeast strains lacking mRNA decapping activation factors (*LSM1*), cytoplasmic exosome function (*SKI2*) or cytoplasmic deadenylases (double deletion of *CCR4* and *PAN2*), the lack of protein A mRNA stability in the apoptotic *dcp2Δ* strain suggest role of alternative pathways such as autophagy in cell death (Fig 5) [21]. The executioners of yeast apoptosis such as metacaspases (*Yca1p*) were shown to play important roles in autophagy [25, 26]. While autophagy is known to replenish key TCA cycle intermediates as a part of its pro-survival mechanism, its role in yeast apoptosis is complex and remains to be understood [25, 27].

**ACKNOWLEDGEMENTS**

The authors acknowledge DBT-OU-ISLARE for providing instrumentation facility for flow cytometer and central facilities for research and development (CFRD), Osmania University, for confocal microscopy. The authors thank Dr Roy Parker, University of Colorado at Boulder for providing yeast strains yRP1195, yRP1616, yRP1619, yRP1620 and Dr Tharun Sundaresan, Uniformed Services University of the Health Sciences (USUHS), Bethesda for providing yeast strains yRP840, yRP1365 and yST456.

### ABSTRACT

The messenger RNA decay pathways and decay factors are well conserved in all eukaryotes from yeast to humans. Two major pathways of mRNA decay exist in eukaryotes. Both pathways are initiated by poly(A) shortening of the mRNA. In the 5' to 3' decay pathway, the Dcp1p/Dcp2p decapping enzyme complex can hydrolyze the cap structure following deadenylation by Pan2p and Ccr4p enzymes and the mRNA is subsequently degraded from the 5' end by Xrn1 nuclease. Misregulation of apoptosis or mRNA turnover can result in many human diseases. Apoptotic studies in yeast suggested interconnecting mechanism between mRNA metabolism and apoptosis.

**Keywords:** Apoptosis, mRNA turnover, yeast, decapping complex, deadenylation.

### INTRODUCTION

mRNA turnover is an important control point in gene expression. Firstly, in assessing the accuracy of mRNA biogenesis. Second, in degradation of aberrant transcripts that contributes to disease development. Messenger RNA decay is therefore important for normal cellular physiology. The major mRNA surveillance pathways in mammalian cells include nonsense-mediated mRNA decay (NMD) and nonstop mRNA decay (NSD). Unlike NMD, NSD is activated only in the presence of mRNA transcripts missing a stop codon. In mammalian cells, eRF3-like factor Ski7 appears to detect the presence of stalled RNA-ribosome complex at the 3' end of RNA transcripts that lack a stop codon, targeting them to the RNA exosome for elimination. This NSD pathway, however, is not well characterized in humans. The phenomenon of nonsense-mediated mRNA decay (NMD) surveillance pathway was first described in

### Kalidindi Krishnam Raju

human cells and in yeast almost simultaneously in 1979 and mainly operates to reduce errors in gene expression by eliminating mRNA transcripts that contain both normal mRNAs (that includes alternatively spliced exons) and abnormal mRNAs with premature termination codon (PTC)[1]. Translation of aberrant mRNAs with premature termination codons (PTC) could, in some cases, lead to deleterious gain-of-function or dominant-negative activity of the resulting proteins and hence contribute to about one-third of human diseases [2].

#### Canonical NMD pathway

NMD is mediated by either the RNA exosome in the 3'–5' direction or by processing bodies (P-bodies) in the 5'–3' direction by the Xrn1 exoribonuclease after an initial removal of poly(A) tail by deadenylases followed by decapping by decapping complex (Dcp1/Dcp 2 complex). Decapping proteins participate in mRNA turnover and nonsense-mediated decay (NMD). A 7-kDa human microprotein called non-annotated P-body dissociating polypeptide (NoBody) interacts with mRNA decapping proteins, which remove the 5' cap from mRNAs to promote 5'-to-3' decay [3]. In the 3' to 5' decay pathway, deadenylated mRNAs are degraded in a 3' to 5' exonucleolytic manner and require two multiprotein complexes: the exosome containing various 3'-exonucleases and the Ski complex consisting of RNA helicase Ski2p, Ski3p, Ski7p and Ski8p (Figure 1)[4].

The major mRNA decay pathway in both yeast and human cells is the 5' to 3' decay pathway wherein the Dcp1p/Dcp2p decapping enzyme complex hydrolyze the 5' cap structure (5' m<sup>7</sup>GpppN cap where N is any nucleotide) following deadenylation by Pop2p and Ccr4p enzymes and the decapped mRNAs are subsequently degraded from the 5' end by Xrn1 exoribonuclease (Figure 2). The scavenger decapping enzyme, DcpS, hydrolyzes the cap structure generated by the 3' to 5' decay pathway. The initial event in mRNA decapping and degradation is the 3' shortening of poly(A) tail (A<sub>70</sub>) to oligo (A<sub>9-15</sub>) by the cellular Ccr4p and Pan2 deadenylases and recruitment of the decapping activator complex (Lsm1p-7p/Pat1p/ Dhh1p complex) to the oligo(A) tract. Therefore, mRNA A-tail is a critical determinant of the eukaryotic mRNA decay. Binding of this decapping activator complex may remodel the mRNA structure to allow the decapping enzyme (Dcp I/ Dcp2) to access the cap. The removal of the cap structure by the decapping enzyme may expose the 5' end of the mRNA to Xrn1 5' to 3' exoribonucleolytic activity (Figure 2) [5].

*In vivo* the heteroheptameric Lsm1p-7p complex (made of seven Sm-like proteins, Lsm1p through Lsm7p) physically interacts with Xrn1p, Dhh1p, MRT1 and Pat1p and colocalizes at cytoplasmic foci known as processing (P)-bodies. P-bodies are believed to be the site of decapping and 5'–3' mRNA decay. *In vitro* purified Lsm1–7–Pat1 complex, an activator of decapping, is able to bind RNA *in vitro* and exhibits a strong binding preference for RNA substrates with oligo(A) tail instead of unadenylated and polyadenylated RNA [6,7]. The Dhh1 protein is a DExD/H-box RNA helicase involved in both mRNA decapping and translation. Yeast genetic studies revealed that both Dhh1p, Edc1-3 proteins (Enhancer of Decapping), Scd6 and Pat1p act as inhibitors of translation and switches the mRNA from a translation-competent status to a degrading-competent form that requires an mRNP rearrangement involving removal of translation factors (such as cap binding complex elf4E/elf4G, and Poly(A) binding proteins) and recruitment of decapping factors for decapping to occur *in vivo* (Figure 3). The various enzymes that play a role in mRNA turnover were mentioned in Table-1 & Table-2.

#### Decay of Eukaryotic mRNA via Endonucleolytic Cleavage

Eukaryotic mRNAs can also be degraded via endonucleolytic cleavage prior to deadenylation. Evidence for this mechanism is based on the *in vivo* detection of 5' and/or 3' portions of the transcript such as mammalian 9E3, transferrin receptor, c-myc, insulin-like growth factor II, serum albumin, vitellogenin mRNA, and β-globin mRNA. For example, the endonuclease suggested to be responsible for β-globin decay appears to cleave at UG and UC dinucleotides, whereas decay of the eNOS pre-mRNA appears to occur by cleavage at CA repeats [5]. Endonucleolytic cleavage is also paramount in RNA-mediated gene silencing (RNAi). The process of RNAi appears to defend the genome against viruses and transposons as well as control gene expression of some endogenous mRNAs. MicroRNAs (miRNAs) is a small non-coding RNA molecule (20-25 nucleotides) found in plants and animals. Once made, miRNAs base-pair with 3' UTR region of specific mRNAs and reduce their translation or

**Kalidindi Krishnam Raju**

promote degradation by Xrn1/exosome [5]. The long miRNA precursors are synthesized by RNA polymerase II and are capped and polyadenylated. They then undergo a special type of processing by dicer-1 enzyme, after which the miRNA is assembled with a set of proteins such as argonaute to form an RNA-induced silencing complex or RISC. Once formed, the RISC seeks out its target mRNAs by searching for complementary nucleotide sequences. This search is greatly facilitated by the Argonaute protein, a component of RISC, which holds the 5' region of the miRNA so that it is optimally positioned for base-pairing to another RNA molecule. Once target mRNA has been bound by miRNA, several outcomes are possible. If the base-pairing is extensive (which is unusual in humans but common in many plants), the mRNA is cleaved by the Argonaute protein. Following cleavage of the mRNA, the RISC with its associated miRNA is released, and it can seek out additional mRNAs. Thus, a single miRNA can act catalytically to destroy many complementary mRNAs. These miRNAs can be thus thought of as guide sequences that bring destruction of specific mRNAs. If the base-pairing between the miRNA and the mRNA is less extensive (typically seven nucleotide pairs for most human miRNAs), Argonaute does not slice the mRNA; rather, translation of the mRNA is repressed and the target mRNA is shuttled to P-bodies where it eventually undergoes poly-A tail shortening, decapping and degradation. A single miRNA can control hundreds of different mRNAs. Several features make miRNAs especially useful regulators of gene expression. MicroRNAs and RNA binding proteins repress translation or degrade target mRNAs through recognition of cis-regulatory elements located primarily in the 3'UTR.

**Stabilized mRNAs trigger apoptosis in yeast**

In eukaryotes, programmed cell death (PCD) is a genetically regulated self-destruction process for the elimination of damaged or unwanted cells. It plays an important role in the development and maintenance of the integrity of organisms. The basic molecular machinery governing apoptosis in mammals has been very much conserved in yeast, including the yeast metacaspase Yca1p, the mitochondrially located proteins such as apoptosis-inducing factor 1 (Aif1p), HtrA2/Omi (Nma111p) and AMID (Ndi1p), and the anti-apoptotic proteins Cdc48p and Bir1p. Apoptosis in yeast may be initiated during physiological scenarios such as ageing and failed mating, or exposure to external stimuli such as lowdoses of H<sub>2</sub>O<sub>2</sub> or acetic acid.

Various morphological and biochemical events observed in apoptotic cells are chromatin fragmentation and its condensation (margination), externalization of phosphatidylserine to the outer leaflet of the plasma membrane, mitochondrial fragmentation, cytochrome *c* release, cytoskeletal perturbations and histone H2B[8]. Yeast strains lacking factors for 5' to 3' mRNA decapping and decay (*DCP2* and *LSM1*), mutants defective in 3' to 5' cytoplasmic exosome function (*SKI2*) or deadenylation (double deletion of *CCR4* and *PAN2*) were found to exhibit various biochemical and morphological features of apoptosis such as increased cellular reactive oxygen species levels, externalization of phosphatidyl serine, chromatin fragmentation, enhanced caspase gene (*YCA1*) expression and protein activity in mid-log phase cultures.

The characteristic feature of these strains apoptosis (*lsm1Δ*, *dcp2Δ*, *ski2 Δ*, *ccr4Δ* and double mutant *ccr4Δpan2Δ*mutants) is clear-cut stabilization of multiple mRNAs. Ccr4p is the predominant deadenylase subunit in yeast and *ccr4* mutants are known to exhibit accumulation of all mRNAs tested with 3' poly(A) tails of an intermediate length (~25–45 adenosines). Double mutants of *CCR4/PAN2* were reported to be deficient in cytoplasmic deadenylation and accumulate all mRNAs tested thus far with longer poly(A) tails (>55 adenosines) suggesting longer poly(A) tail length of the accumulated mRNAs contribute to enhanced cell death in *ccr4Δpan2Δ* strain than *ccr4Δ* strain. But the wild type strain and *pan2Δ* mutant do not exhibit cytoplasmic deadenylation defects as well as characteristic features of metazoan apoptosis [8]. RNA oxidation also dictates chronological life span. In mammals, RNA oxidation was described as an early event preceding cell death and neuronal deterioration, not merely a consequence of dying cells [9]. In the yeast decapping *Klism4Δ1* mutant, which accumulates oxidized mRNAs, has shorter life span than the wild type strain and undergoes regulated cell death. In addition, in this mutant the capacity to handle oxidised RNAs in yeast declines with aging. These phenotypes can be reversed to the wild type situation by the addition of antioxidants to cell cultures [10].

**Kalidindi Krishnam Raju**

## CONCLUSION

Moreover the cellular mRNA decay factors Pat1p, Lsm1p, and Dhh1p are required for the replication of wide range of positive-strand RNA [(+)RNA] viruses including the plant Brome mosaic virus (BMV), the animal Flock House virus, the human Hepatitis C virus (HCV) and the emerging West Nile virus (WNV) and therefore are potential targets for new antiviral drugs. The Lsm1-7-Pat1 hetero-octameric specifically binds to *cis*-acting regulatory sequences of Brome mosaic virus (BMV) RNA and the 1a protein in yeast to promote viral RNA translation and subsequent recruitment out of the host translation machinery to the viral replication complexes [11]. The upregulation of crucial mRNA decay factor Lsm1p contributes to human cancer making it a potential target for human cancers. It is not yet known how mRNA perturbations contribute to apoptosis in yeast and cancer, autoimmune and neurodegenerative disorders in mammalian cells. Beside defects in mRNA turnover, defects in the RNA synthesis and processing are associated with disease-specific alterations in RNA-binding proteins as well in miRNAs, tRNAs and lncRNAs that may represent potential diagnostic biomarkers [12]. *Saccharomyces cerevisiae* represents a well-established model system for understanding of the complex regulatory networks operating in higher organisms since RNA decay pathways and decay factors are well conserved in all eukaryotes from yeast to mammals. Dcp2 is the major mRNA decapping enzyme in eukaryotic cells and is regulated by interactions with several activators, including Dcp1, Edc1, and Edc3, as well as by an autoinhibition mechanism (Figure 4).

Deregulation of the Dcp1/2 activity, crucial for the quality control and turnover of RNA, may lead to the onset of serious diseases [13]. In mammalian cells, Dcp2 seems to be linked to the spinal muscular atrophy, the innate immunity pathway and the interferon response [14, 15]. With respect to this, Dcp2 inhibitors should be helpful in the study of RNA decapping and may provide novel therapeutic tools [16]. Yeast can be used to study the effects of the increase or decrease of mRNA stability through the modification of cap structures, an argument that has great potential for use in gene therapy and for the construction of new cap-based molecular probes [17]. Under nitrogen starved conditions, autophagy is induced, and the bulk RNA is first cleaved to 3' nucleotides by the vacuolar ribonuclease Rny1 [18]. A conserved process of stress-induced tRNA and rRNA cleavage exists in eukaryotes, possibly extending to prokaryotes. It is presumed that enhanced tRNA and rRNA cleavage during stress conditions are activation of a general cytosolic nuclease or stress-induced cytosolic release of vacuolar nucleases. The activation of endonucleolytic cleavage of tRNAs correlates with the progression of cancer and understanding the mechanism behind tRNA cleavage might provide a useful therapeutic target [19]. In addition, the frog-derived RNase known as Onconase has been shown to enter cells and trigger apoptosis in a manner correlated with tRNA cleavage and consequent translational inhibition and is currently in clinical trials as an anti-cancer therapy [20].

In addition, studies on yeast have shed light on human diseases such as prion biology, virus-host interactions, metabolic diseases, neurodegenerative disorders, cancer, or aging. Yeast apoptosis and its regulation is structurally and functionally conserved in yeast and yeast has even served to uncover pathways involved in apoptosis and other controlled cell death subroutines involving the AAA-ATPase Cdc48/VCP, the BAX inhibitor-1, the implication of metacaspases as cell death regulators, the role of cathepsin D in non-autophagic mitochondrial degradation. The understanding of yeast cell death and its putative modulation may improve industrial and biotechnological applications, provide insights into mRNA turnover, and help develop the fight against fungal and other diseases [21].

## Kalidindi Krishnam Raju

Table 1: Enzymes involved in mRNA decay

Protein	Properties	Function	Significant interactions
Pab1p	Contains four N-terminal RRM domains and a proline-rich C terminus	Major protein associated with poly(A) tail. Blocks mRNA decapping and stimulates translation. Primary coupler of deadenylation and decapping.	eIF-4G, eRF3, Pan2/3p
eIF-4E	Cap-binding protein	Component of the eukaryotic translational initiation complex, eIF-4F. Blocks mRNA decapping by competing with Dcp1/2p for access to the cap.	Lsm7p, eIF-4G, eIF-4A, eIF-4B, Pab1p
Lsm1-7p	Sm-like proteins	Required for the efficiency of decapping in vivo. Forms a heteroheptameric ring complex and interacts with the mRNA after deadenylation. May facilitate the assembly of the decapping complex.	Dcp1p, Dcp2p, Dhh1p, Pat1p, Xrn1p, Upf1p
Pat1p	88kDa protein with no recognizable sequence motifs	Interacts with both polyadenylated and deadenylated transcripts. Required for efficiency of both decapping and formation of P bodies in vivo. May "seed" the decapping complex on the mRNA.	Dcp1p, Dcp2p, Lsm1-7p, Dhh1p, Xrn1p, Crm1p
Dhh1p	Member of the ATP-dependent DExD/H box helicase family	Required for the efficiency of decapping in vivo. Homologs across species are required for translational repression during mRNA storage events.	Dcp1p, Dcp2p, Lsm1-7p, Ccr4p, Pop2p, Caf17p, Pbp1p, Edc3p
Edc1p, Edc2p	Small, basic proteins with weak homology to each other	Required for efficient decapping in vitro. Directly binds to the mRNA substrate.	Dcp1p, Dcp2p
Edc3p	Contains five conserved domains	A general and mRNA-specific regulator of decapping. Regulates the decapping of the RPS28a mRNA.	Dcp1p, Dcp2p, Dhh1p, Crm1p, Rps28ap, Nup157p, Lsm8p
Puf3p	Pumillo-like protein, contains eight PUF repeats	Messages specific activator of mRNA deadenylation and decapping. Homologs facilitate translational repression. Regulates the decapping of the COX17 mRNA.	
Upf1p, Upf2p, Upf3p	Upf1p is an ATP-dependent RNA helicase	Required for non-sense-mediated decapping.	eRF1, eRF3, Dcp2p, Upf2p, Lsm1p

Table 2: Enzymes involved in mRNA decay

Protein	Function	Features
<b>Deadenylation</b>		
Ccr4p	Catalytic subunit of the deadenylase	Homology to Mg <sup>2+</sup> dependent endonucleases
Pop2p	Regulator of deadenylation, may also have deadenylase activity	Homology to RNaseD
Pan2p/Pan3p	Minor deadenylases, required for poly(A) length control	Pan2p has homology to RNaseD
PARN	Mammalian deadenylase	Homology to RNaseD. Can bind to 5' cap, which stimulates deadenylase activity
<b>Decapping</b>		
Dcp1p	Major component of decapping holoenzyme	EVH1/WH1 domain
Dcp2p	Catalytic subunit of decapping holoenzyme	NUDIX motif, conserved Box A and Box B motif
<b>Exonucleases</b>		
Xrn1p	Major cytoplasmic 5'→3' exonuclease	
Rat1p	Nuclear 5'→3' exonuclease	
Rrp4, Rrp40p, Rrp41p, Rrp42p, Rrp43p, Rrp44p, Rrp45p, Rrp46p, Mtr3p, Csl4p	A complex of 3'→5' exonucleases termed the exosome	Domain organization similar to that of bacterial PNPase

Annu. Rev. Biochem. 2004. 73:861-890. Downloaded from www.annualreviews.org

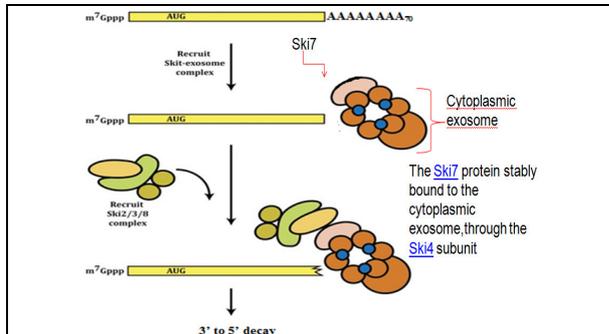

Figure 1: 3' to 5' decay mediated by exosome and Ski complex (Ski7 with Ski2/Ski3/Ski8). The Ski2/3/8 complex interacts with Ski7, and this interaction, which appears to occur between Ski7 and the Ski3 and Ski8 proteins, is required for 3' to 5' degradation of mRNAs.

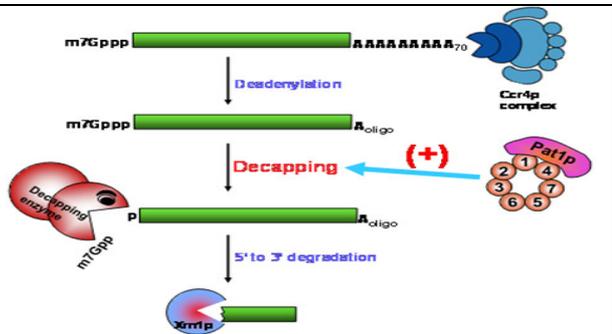

Figure 2: Lsm1p-7p-Pat1p complex is an activator of decapping *in vivo*. Deadenylation dependent decapping and 5' to 3' mRNA decay by Xrn1p is illustrated.

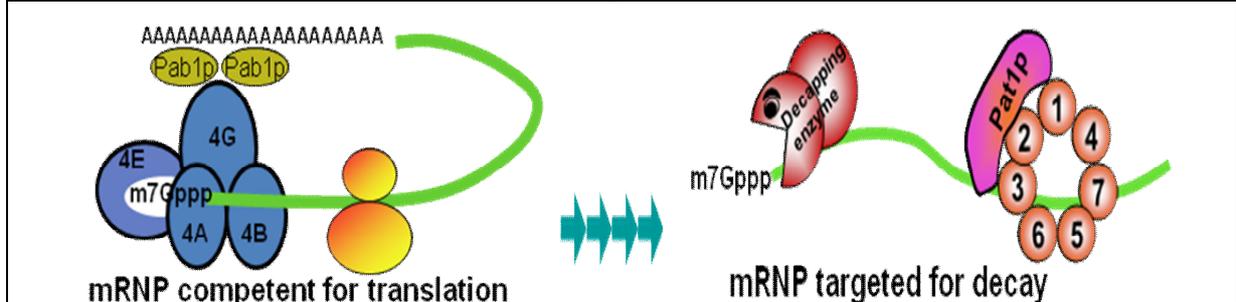

Figure 3: An mRNP transition from a translation competent status to degradation competent form.

### ABSTRACT

*Henosepilachna vigintioctopunctata* (Fabricius), commonly known as Hadda beetle, is a polyphagous pest of various economically important agricultural crops in India. It is a serious pest of cucurbit crops, especially, bitter gourd (*Momordica charantia*). The present study was carried out during June-July, 2019 and the studies on its biology indicated that a gravid female laid 182 to 356 eggs on an average in 6-7 batches during her life span. The duration of different stages of life cycle viz. eggs, larvae and pupa lasted for an average of  $4.1 \pm 0.33$  days,  $20.8 \pm 3.35$  days and  $3.2 \pm 0.72$  days, respectively. The adult male and female survived for an average period of  $29.8 \pm 3.10$  days and  $34.4 \pm 2.37$  days, respectively. The whole body of the adults is covered with fine short hairs. Adults are copper brown coloured mottled with black spots. The present study can help the researchers in understanding the biology and behaviour of this particular pest, which can help in taking proper management strategies.

## INTRODUCTION

Cucurbits, belong to Family Cucurbitaceae, constitute the largest group of summer vegetables grown all over the world. Bitter gourd is the most popular crop of the cucurbitaceae family grown in low and mid-hills of Jammu & Kashmir. Fruit juice of bitter gourd is used as a traditional medicine to cure diabetes and also used to treat acidity, indigestion, constipation and ulcers. Its seeds are also powerful antihelminthics. Bitter gourd is infested with a variety of insect pests right from the primordial stages of the crop to harvest of the products. Besides the direct damage, many pests act as vector for viruses. Insect pests of cucurbits of serious concern are Red pumpkin beetle, Fruit flies and Melon ladybird beetles. (Gupta, 2004).

*Henosepilachna vigintioctopunctata* (Fabricius) or melon ladybird beetle or spotted leaf-eating beetle, belongs to the Family-Coccinellidae or ladybird beetles, of Order- Coleoptera. *Henosepilachna* is an oligophagus, multivoltine, coccinellid beetle, infesting crops in mid-hills and plains of India (Kumar and Kumar 1998). Both grubs as well as adult beetles feed voraciously on the green matter of the leaf and skeletonize it leaving the upper epidermal tissue intact (Rath *et al.*, 2002; Mohasin and De, 1994).

## MATERIALS AND METHODS

In order to study the lifecycle of melon ladybird, the adults were collected from the fields of cucurbits, by using entomological nets, during the months of June-July, and were kept in rearing cage, under laboratory conditions. They were continuously fed on the leaves of cucurbits (bitter gourd). The adults were allowed to copulate and each pair was observed for pre-mating, mating and oviposition behavior and duration. The adult female laid eggs in batches. Eggs were counted and after hatching the grubs were reared and the morphometric measurements for each instar were recorded. Observations regarding the pre-pupal and pupal stages and adult longevity were also recorded. Data gathered during the experiment was analyzed statistically for calculating mean, standard deviation and standard error.

## RESULTS AND DISCUSSION

The results of present investigation presented in table1 revealed that the incubation period ranged from 3 to 4 days with mean duration of  $4.1 \pm 0.33$  days. showed complete metamorphosis with four different stages; Egg, Grub (Larva), Pupa and Adult (Beetle). The female laid as many as 182 to 356 eggs during the life span with an average of  $265.8 \pm 52.49$  eggs. Hatching % of the eggs were 56.60 %. Similar results were obtained by Indu and Chatterjee (2006). While 272.32 eggs were reported by Verma and Anandhi (2008) and 302.5 by Qamar *et al.*, (2009). Newly hatched 1st instar larvae were yellowish in color and had six rows of long branched spines. The duration of first instar larva ranged from 3-5 with a mean of  $5.8 \pm 0.62$  days. The range of second instar period varied from 4-6 days with mean duration  $5.6 \pm 0.41$  days. The third instar larva was 4-5 days ranged with a mean of  $4.3 \pm 0.45$  days. The fourth instar larva was observed 6-7 days ranged with the mean of  $7.2 \pm 0.63$  days. The total larval period ranged from 17 to 23 days with a mean of  $20.8 \pm 3.35$  days. The full grown 4th instar grub stopped feeding and roaming for 10-15 min to locate suitable site for pupation. The colour of the grub gradually faded and the body shrank. Verma and Anandhi (2008) observed the larval period as  $15.1 \pm 4.90$  days while  $14.9 \pm 0.43$  days was reported by Qamar *et al.*, (2009).

The full fed grubs spent 1 -3 days in the pre-pupal stage with an average of  $1.6 \pm 0.89$  days. The average pre-pupal length was  $5.32 \pm 0.42$  mm and breadth was  $3.26 \pm 0.32$  mm where as the mean pupal period was  $3.2 \pm 0.72$  days and ranged from 2 to 5days. Similar results were obtained by Verma and Anandhi (2008) and Qamar *et al.*, (2009). The average pupal length was  $6.15 \pm 0.24$  mm and breadth was  $3.73 \pm 0.38$  mm. The mean adult male beetle longevity was  $29.8 \pm 3.10$  with the range from 27 to 32 days. The mean lifespan of female beetle of *E. vigintioctopunctata* was observed  $34.4 \pm 2.37$  with the range from 31-39 days. The results further showed that the duration of life cycle varied from 49 to 75 days with mean duration of  $65 \pm 6.23$  days. The mean fecundity was recorded as  $56.8 \pm 6.62$  eggs/female with a range of 38 to 69 eggs/ female.

### Nature of damage

*Henosepilachna vigintioctopunctata* is a serious pest of cucurbits especially *Momordica charantia* (Bitter gourd). Both adults and larvae(grubs) are often found on the lower surfaces of the leaves, scrapping and feeding voraciously on the parenchyma and the lower epidermis between the veins and skeletonize it in a characteristic manner leaving intact the upper epidermis as well as the tougher tissues (veins, etc.) in the form of "window".

**Lipsa Dash et al.**

The affected leaves become translucent, take a grayish color and dry up. In cases of severe attack, the young plant can dry up completely and die. Adults are fliers can damage large crop areas during their peak activity (Nagia *et al.*, 1992).The adults are not responsible for as great level of injury as are the larvae

### ABSTRACT

In India, the matter of fish waste has concerned considerable attention to the food producers, processors, retailers, and consumers because the waste from fish generated during a huge amount from the fish processing industries, retail markets and also from the by-catch at the fishing harbour. The continuous increase in global fish resources leads to 25% of wastage among total fish catch annually. During 2006-07, an estimate of the, 02,750 tones of waste was generated from fish processing (both processing and pre-processing taken together) industries of India alone. Non-utilization or underutilization of those waste products not only cause negative externalities to society but also cause environmental pollution and ecological onus. To secure from pollution and to scale back waste, it's now become important to possess a comprehensive understanding about the recycle and/or conversion of those fish wastes into useful products of higher nutritive value and betterment of human society. Thus, the effective utilization of fish processing waste materials from the fish processing sectors has been reviewed here-in India, the problem of fish waste has concerned considerable attention to the food producers, processors, retailers, and consumers because the waste from fish generated during a huge amount from the fish processing industries, retail markets and also from the by-catch at the fishing harbour. Non-utilization or underutilization of these waste products not only cause negative externalities to society but also lead to environmental pollution and ecological onus. To secure from pollution and to scale back waste, it's now become important to possess a comprehensive understanding about the recycle and/or conversion of those fish wastes into useful products of higher nutritive value and betterment of human society. Thus, the effective utilization of fish processing waste materials from the fish processing sectors has been reviewed here.

## INTRODUCTION

Aquaculture is one of the fastest growing food sectors providing an ultimate livelihood option to a millions of peoples across the world. In the last three decades, capture fisheries production increased from 69 million to 93 million tons; during an equivalent time, world aquaculture production inflated from 5 million to 63 million tons. Globally, fish currently represents about 16.6 percent of animal protein supply and 6.5 percent of all protein for human consumption (FAO, 2012). The continuous increase in global fish resources results in 25% of wastage among total fish catch annually (FAO, 2012). Fisheries generate large amount of solid wastes such as whole fish waste, fish head, viscera, tails, skin, bones, blood, liver, gonads, guts and some muscle tissues and also liquid wastes consisting of wastewater used during fish processing.

Every year, enormous amount of these processing wastes are discarded from seafood processing plants and fish markets. Because of the specificity of certain raw material and its processing in relation to a specific product, surplus and waste food processing co-products are not readily used by the parent processors. During 2006-07, an estimate of 3, 02,750 tonnes of waste was generated from fish processing (both processing and pre processing taken together) industries of India alone. The maximum waste was generated from processing of shrimps followed by fin fishes and cephalopods. On the context of environmental pollution, waste generation from fish processing is of great concern today. This waste may be a superlative staple for the preparation of high value added products including proteinaceous foods. These are also a valuable source of raw material for recovery of bioactive compounds. Additionally, inappropriate disposal is a major cause of environmental pollution.

The utilization of fish waste succours to eliminate detrimental environmental aspects and revamp quality in fish processing. However, recent advances in industrial biotechnological processes have paved way for economical and highly serviceable utilization of these wastes for mankind. The recovery of chemical components from seafood waste materials & fish processing units, which may be utilized in other segments of the food industry, may be a promising area of research and development for the use of fish waste by-products. These wastes cause a serious problem of environmental pollution and make the environmental atmosphere unhygienic prone to various kinds of diseases. So there is a problem remains what to do with these wastes. One best alternative way is to convert these wastes to value-added bioactive and different products for the use of mankind and other animals. The valuable products that would be developed from of these fish processing waste materials are described below in short.

### Fish waste as a material for enzyme production

The major fish wastes usually found within the market are fish viscera, head, tail, scales etc. Fish viscera is consists of different types of food materials, have the property of enzymatic hydrolysis of different types of proteolytic enzymes that secreted to the gut. Enzymes and bioactive peptides are often attained from fish waste and used for fish silage, fish feed or fish sauce production. An alternative thanks to convert the fish processing wastes into more marketable products is to isolate and purify proteolytic enzymes which are abundant in fish viscera. Proteases or the proteolytic enzymes that are found within the gut might be helpful in fish protein hydrolysate production. Proteolytic enzymes like alkaline, a-chymotrypsin, neutralise, papain, pepsin, trypsin, pancreatin, flavourzyme, bromelain, pronase E, protamex, orientase, thermolysin, validase, protease A amano, protease N amano and cryotin F that derived from plant, animal, and microbial sources are successfully tested for the assembly of antioxidative peptides from fish protein sources.

Protease is a group of enzyme that makes proteolysis known as hydrolysis of the peptide bonds, which link amino acids together in the polypeptide chain forming the protein. Proteases represent one among the most important groups of commercial enzymes and are mainly derived from animal, plant, and microbial sources. Today, there's an increasing demand for fish proteolytic enzymes thanks to their wide selection of applications. Proteases play an

**Biswajit Mohanty et al.**

important role in industries due to their multifarious applications in leather and detergent industry, food and pharmaceutical industries and also in bioremediation processes.

### **Fish waste as a material for fish protein hydrolysates (FPH) production**

FPH is a liquefied product but different from silage. FPH may be defined as fish proteins that are broken down into peptides of various sizes. These products are produced by employing commercially available proteolytic enzymes for isolation of enzymes from fish waste. By selection of suitable enzymes and controlling the hydrolysis conditions, properties of the end product can be selected. Hydrolysates find application in milk replacers and food flavourings. According to the WHO's recommendation, fish protein also serves as a significant source of essential amino acids (about 30% by weight). That is the rationale why fish protein hydrolysates are getting more popular. The degradation can be carried out either chemically (using acid or alkali) or biologically (using enzymes).

Such processes not only maintain a high essential aminoalkanoic acid content but also generate many improved functions for food or pharmaceutical application. For example, improved capacities of oil-binding and emulsifying are required for meat products and spread texture food respectively. Similarly, natural anti-oxidants like FPH could be used for improved anti-oxidation and anti-hypertension activities and to control high blood pressure, in addition, to replace synthetic products which may have negative side effects. So the production of fish hydrolysates from fish processing waste will reduce the pollution due to the accumulation of fish waste in the environment from the fishery based industries [1]. Most hydrolysates are bitter in taste after the time of production. Therefore flavouring agents are like cocoa, and sugar should be used during the fortification in food preparation to mask the bitter taste [2].

### **Fish waste as a material for fish meal production**

Fish meal is that the most vital products obtained from fish waste, by-catch, and other abundant species. It is highly concentrated dry nutritious feed supplement consisting of high-quality protein (70%), minerals (10%), fat (9%) and water (8%). It can have different compositions and qualities, in terms of amino acid profile, digestibility, and palatability, depending on the raw material used for its production and the type of process employed for obtaining the meal. Fish meal is usually used as an ingredient in food for fish and crustaceans. Differences in organic quality can affect the expansion and feed efficiency ratios of the organisms fed. Fresh staple and rancid staple can produce significant differences within the content of biogenic amines like cadaverine within the organic and high-quality organic with low biogenic amine content.

These differences affect certain nutritionally important parameters within the organisms fed with those particular fish meals, like feed intake and feed efficiency, both being reduced within the case of the poor quality fish meal [3]. Traditionally fishmeal production was from the sundried fish collected from various drying centres and therefore the product was mainly used as manure, but now each day, the organic can be produced by two general processes like dry rendering and wet rendering. Process conditions also affect the meal quality. Superior quality fish meals are a prominent item of export from the very beginning of the industry. BIS has brought out the specifications for fish meal as livestock feed for facilitating proper quality control [4].

### **Fish waste as a material for fish silage production**

Viscera of fish include the digestive tissues (stomachs, pyloric caeca, intestines, liver, pancreas, etc.) and other organs like spleen and gonads. Viscera waste was used to obtain fish silages. Almost any low-cost species of fish can be used to make silage, though cartilaginous species like sharks and rays liquefy slowly. Fish silage are often defined as a product made up of whole fish or parts of the fish to which no other material has been added aside from an acid and in which liquefaction of the fish is brought about by enzymes already present in the fish [5]. The rate at which the liquefaction takes place depends upon the temperature and pH of the mixture. Fatty fish liquefy sooner than white fish and cannon fodder liquefy sooner than stale fish and previously chilled or frozen fish. Since the nutritional value of aquaculture, fish diet is decided basically by the aminoalkanoic acid composition of the feed and it's concluded

**Biswajit Mohanty et al.**

that silages made up of fish waste materials are adequate for use as an ingredient in balanced diets. So the ensilage can be used as for fish meal replacement for the production of feeds <sup>[6]</sup>.

**Fish waste as a material for fish oil production**

Fish oils are often extracted from the entire fish, skin or liver (in the case of some species). Fish oils are rich sources of polyunsaturated fatty acids, especially Eicosapentaenoic acid (EPA) and Docosa hexanoic acid (DHA). These two compounds have shown different interesting bioactivities. Among the properties of omega-3 fatty acids, the best known are the prevention of atherosclerosis, reduction of blood pressure and protection against arrhythmias. Squalene is a lipid found in large quantities in shark liver oil. The large by-catch of shark within the fishing industry round the world provides a useful source of fish oils whose value are often substantially increased by processing them to obtain fractions such as squalene. Squalene is interesting bio-active oil and their applications have been reported in the treatment of diabetes, cancer, and tuberculosis. It also has antifungal and anti-oxidative properties. At present, the medicinal values of fish oil are very well known <sup>[7]</sup>.

**Fish waste as a material for collagen and gelatin production**

Skin, bones, and fins represent around 30% of fillet processing waste and are produced as a consequence of the preparation of various fishery products like fillets and sashimi (sliced raw fresh fish). Fish skin, therefore, is a crucial by-product of the fish-processing industry, causing wastage and pollution. Collagen is the major structural protein found in the skin and bones of animals and gelatines are their degradation products. The collagen obtained has potential use for a spread of applications like edible casings for the meat processing industries, cosmetics (because it's good moisturizing properties) and biomedical materials or pharmaceutical applications, which include the production of wound dressings, vitreous implants or carriers for drug delivery. Some reports also show that collagen may evince high anti-radical activity. It is well established that the amount of gelatin used in the food industry worldwide is increasing annually. It has been also demonstrated that fish gelatin can stabilize emulsions, remaining moderately stable to droplet aggregation and creaming, even after being subjected to changes in temperature, salt concentration, and pH. Gelatin from marine source can be a possible alternative to bovine gelatin in future days <sup>[8]</sup>. The amount of gelatin obtained from fish and other species increased consistently from 2003 to 2005 with a growth of 0.7% to 1.3% of total world production <sup>[9]</sup>.

**Miscellaneous uses****Fish calcium**

Filleting waste of bigger fishes are very good sources of calcium which can be used for the pharmaceutical purpose.

**Pearl essence**
