ABSTRACT

In the process of becoming a highly mobile planet, a large number of Inequities has been caused due to Private Automobile Dependancy. Private Ownership of Automobiles ,has eventually increased the dispersion of Society, Sprawl and destruction of the Natural Areas. At the same time High Automobile Dependancy has minimized efficiency of Overall Resource Utilization, reduced live ability and degraded environment Consecutively. Whereas Sustainable transportation promotes efficient and healthier ways of commuting, in order to minimize disastrous effects on Public Realm. The frequent rise in private vehicle ownership has caused alarming rise in CO_2 emissions, increased demand for parking and an increase in road deaths. This research paper deals with the issues of private ownership of Automobiles, that have acted as a barrier to Sustainable Transportation.

Keywords: Sustainable Transportation, Automobile Dependancy, Private Ownership of Automobiles.

INTRODUCTION

The concept of automobile dependency emphasises automobility (based on one mode), whereas sustainable transportation focuses on plurality (multi-modality) and inter-modality. Talking of the scenario of India, it is the second most populated country in the world and has a steadily growing economy, which makes it a rapidly growing market for motorised vehicles. The total number of registered motor vehicles in India has increased by 157.5%, from 55.0 million in 2001 to 141.8 million in 2011 (Das, 2016). Rapid motorization in India and the growing inclination of its

79471

Poorva *et al.,*

people towards private transport modes have made the country the fourth largest petroleum-consuming nation in the world after the US, China, and Japan, with a total petroleum consumption of 3,426 thousand barrels per day in 2011 (Das, 2016). The challenge of shifting from private automobiles to sustainable transportation is great. It will eventually affect various aspects such as the viability of societies, access to jobs and services, and the transportation of goods. Private ownership of automobiles, especially car culture, has become a controversial topic. These are the most preferred modes of transport in developed countries. The conventional transportation system is inequitable or lacks access to transportation for all economic classes,especially transit and good walking and bicycling facilities. Conventional transportation has various impacts, such as social equity, economics, environmental, cultural, land use, and urban form. Many of these impacts are extremely harmful, such as pollution-related health impacts and even the survival of life on the planet. Sustainable transportation deals with meeting basic access and mobility needs in modes that do not harm the environment.

Comparative Analysis of Private Ownership of Automobiles and Sustainable Transportation
A comparative analysis of Private Ownership of Automobiles versus Sustainable Transportation has been depicted in Table 1 below. This comparison has been done giving weight age to different aspects such as Mobility, Accesibility, Connectivity ,use of modes ,sustainability considerations etc. The challenge of shifting from Private owned Automobiles to sustainable transportation is great. It affects various aspects of life such as health of Ecosystem ,livability of communities ,access to workspaces, costs of various stuffs. Private Owned Vehicles have increased the trip length, frequency and dispersion of trips. Sustainable Transportation can be considered as a better alternative than Private Owned Automobiles as it is enhancing the accessibility with quality. At the same time it is providing cost savings on fuel and vehicles .Taking public transportation reduces CO2 emissions by 45%,as well as decreases pollutants in atmosphere and hence improves Air quality. (Mead, 2021)

India's Scenario of Automobile Dependence
India is having the third largest road network, the number of private automobiles in India in FY 2022 stood at 326.3 million. (Sun, 2023) Commutation via Road was the preferred mode having about 60% people choosing this mode., The industrial commuting of goods through roads has also risen over the years with nearly 2.7 billion metric tons of freight transported through roads in financial year 2019.Figure 1 depicts the growth of Automobiles from Financial Year 1951-2022. The automobile sector of India currently contributes greater that 7% to India's GDP. It is aspired that India will reach to 12% via Automotive Mission Plan 2016–26 By 2030,due to rapid urbanization more than 500 million people in the country will live in cities – 1.5 times the current number of U.S population (Gupta, 2018). Higher incomes will play a significant role, as around 60 million families could move into the consuming class by 2025.At the same time,more people will be joining the workforce. Participation is expected to reach 67 percent in 2025, as more women and youth will be entering the job market, that will eventually raise the demand for mobility. Some portion of population would leap straight to four-wheeler segment, and others will evolve from two- to four-wheelers over time.About 44 percent of the consuming-class households will be in 49 growth clusters—for example, the Delhi cluster is expected to have the same GDP per capita at purchasing power parity as the entire country of Russia in 2025. Metro cities like Delhi are a hub for Automobile sector to flourish.(Sun, 2023)

Problems of Automobile Dependence
Considering the Scenario of India an insatiable demand for vehicles is expected for an economy that is expected to grow at an average rate of 7% for the next 20 years, the automobile industry of India will needlarge amounts of natural resources which will not only lead to implications of economic cost, but also considerable environmental and social impacts. The future growth will be closely associated with increased raw material extraction, pollution arising from production, processing of primary materials for production of auto components, GHG emissions during the manufacturing phase, use/operation phase, traffic congestion, etc(Bhattacharjya, 2016). The Urban Land use Transport cycle associated with High levels of Automobile Dependance ,brought variety of Environmental, Social and Economic problems that act as a barrier to sustainability of cities . These have been summarized in the Table 2 below.

Environmental Problems

The environmental problems arising due to Automobile dependance have been shown in Column 1 of Table 2 .Urban Areas having a high private automobile dependency have higher levels of Transportation Energy Use. Due to high energy use ,large quantities of Greenhouse gases and carbon emissions are released, which contribute to Photochemical Smog. Whereas Sulphur Di-oxide when comes in contact with precipitation leads to Acid smog and Acid rain ,which in turn degrades the environment by acidification of water bodies and kills Native forests. This makes Cities loose a large portion of productive areas. Covering of Large Urban lands with Roads, Pavings and Parking spaces and low density housing can lead to huge water runoff ,that can eventually cause Flooding. The most adverse problem create by private automobile dependancy and resultant Land use is the Decline of the Transit Systems.

Economic Problems

Most basic economic impacts is the Congestion Cost i.e in the terms of Cost of time and cost of extra mile travel for connecting to Infrastructure systems. Transit Systems is the Urban areas also have lower operating cost recovery ratio due to private automobile dependancy. Large economic costs are associated with Road accidents and deaths .The resultant Health related issues ,occurring as a consequence of Environmental impacts act as economic problems.

Social Problems

The discussed environmental and economic problems have resultant social problems, one such problem can be disastrous effect on the public realm. The social life of man is impacted due to private automobile dependency ,as he does gets to interact. The walk ability feature of the high density areas is replaced by Low density Areas of Suburbs, giving rise to lack of we feeling in the community, this further gives rise to lack to interactive and Child friendly Neighbourhoods. On the broader scale the above listed issues are affecting the Livability parameter of Cities.

The Concept of Automobile Cities

Automobile Cities are a resultant of the increasing car culture, that developed because of greater dependance on Automobiles, due to which cities started expanding into the suburbs. Automobiles have brought a enormous change in the pattern of Urban Areas. The concept of Automobile cities led to enormous expansion of the developed area in comparison to the walking and Transit cities. As the dependency on the Public transport and Non-motorized transport reduced ,as uninhibited outward expansion of city was caused. The development of the cities became foot loose and could easily occur anywhere. Automobile cities brought back the concept of Hypermobility and the Land use was segregated into zones. Cars eventually displaced public transit modes which gave rise to 80-95% modal share of Car in cities of America and Australia. A large number of transport deaths are caused as a resultant of Automobile cities. Due to high traffic congestion cities such as Bangkok are referred to as Automobile cities but these are more likely traffic saturated cities.

Some of the Consequences of Automobile Cities are summed below.

- Footloose Development.
- Expansion of cities without limits
- Arterials defined the mobility instead of Transit Network.
- Cater great mobility for a segment of Population ,where as inquity and mobility issues for others.

Automobile Dependency as a Barrier to Sustainable Transportation

Through the research paper it can be summed that Automobile dependency has given rise to a wide range of problems. It is is turn reducing the available transportation choices. The reasons why Automobile Dependency acting as a barrier to Sustainable Transportation are:

- Increased automobile dependency, makes cycling and walking Difficult and unpleasant on the streets.
- Service quality of public transit declines due to fall in demand.
- Affects the affordability, live ability, accessibility, and economic well-being of a region. serious issues i.e road accidents, increased carbon and greenhouse gas emissions, pollution congestion, and energy security.

- In order to achieve hypermobility, accessibility and quality have been compromised
- More polarization in the society and inequity caused.
- Enforced car ownerships for low-income households.

Initiatives by Indian Government towards Sustainable Transportation

India through the Automotive Mission Plan and the National Electric Mobility Mission Plan (NEMMP), and various alternatives tends to achieve two objectives—facilitate long-term sustainable growth in the industry and reduction of emissions and dependance on oil. Through the Automotive Mission Plan 2026, the automobile industry and government has basically set a target to triple the industry revenues to $300 billion, and expand exports sevenfold, to $80 billion. The primary aim would be improving manufacturing competitiveness and reduced emissions. Some of the key strategies are listed below:

- To bring Indian standards at par with global standards, which aims to leapfrog from BS-4 to BS-6 emissions (which is equivalent to EURO 6) by 2020.
- Corporate Average Fuel Efficiency norms through which the fuel efficiency has to be improved 10 percent between 2017 and 2021 and by 30 percent or more from 2022.
- In order to address pollution from old vehicles, Government is working on Scrappage or End of life policy.It plans to adoption of these policies with the help of lower taxes, discounts on purchase prices, and simple compliance processes.
- For reducing dependency on oil imports, the government is promoting adoption of alternative fuels through FAME2, which is an extension of the original FAME (Faster Adoption and Manufacturing of Hybrid and Electric Vehicles) initiative. "FAME1" was created to offer incentives for EV buyers. The initiatives taken by the government will eventually lead to more sustainable approach towards transportation by Reduction in carbon emissions and bringing the scenario at par with the global scenario.

Policy Recommendations for Mobilizing Sustainable Transport via SDG 11

The aim of SDG 11.2 is to By 2030, provide access to safe, affordable, accessible and sustainable transport systems for all, improving road safety, notably by expanding public transport, with special attention to the needs of those in vulnerable situations, women, children, persons with disabilities and older persons. The primary way of achieving this is by Avoid-Shift-Improve approach

- **Avoiding** the inefficient and needless trips, where possible, by the means of improved urban planning, compact city growth, management of travel demand, less complex and extended supply chains, and depending on E-communication options.
- **Shifting** transit to improvise the efficiency of the trip via efficient or environmentally friendly mode or multi-modal travel, capable of meeting the travel/transport needs, and/or shifting the travel from the peak hours.
- **Improving** the overall performance of transport by operational, technical, operational, or pricing, and/or infra led improvements to make transportation sustainably efficient. Design and implementation of policies aligned with the 'Avoid-Shift-Improve' guidelines will depend on following considerations:
- Cross-sector integration and institutional cooperation
- Intermodality
- Governance frameworks for effective policy making.
- Short- and long-term planning taking into account the business case for sustainable transport and development.
- Capacity Building in Developing Countries.
- Creation of Public Awareness and Stakeholder engagement.
- Effective funding.
- Creation of efficient framework.

The above listed Avoid-shift-improve model will lead to shift to a sustainable system,basically away from conventional Transportation Modes.

Poorva *et al.,*

Road Map to Sustainable Transport

"The main motive of sustainable transportation is to ensure that the three pillars of sustainability environment, social and economic considerations are incorporated into the framework of transportation planning."(Mead, 2021)

Some of Sustainable transport indicators are listed below:
• Level of Service of Roadway(LOS): a higher rating is preferred more.
• Average traffic speeds: Higher speeds are preferred
• parking convenience and price: Parking at lower price is preferred more
• crash rates per vehicle mile: Least crash rates are preferred.
• Fuel consumption and Emissions: lesser values are preferred .
• per capita motor vehicle mileage: Lower values are preferred.
• modal split: higher transit ridership is preferred
• Traffic injuries and deaths: less is better
• Transportation Land consumption in Landuse: less is better

CONCLUSION

Private ownership of Automobiles has affected Sustainable Transport on all parameters of Sustainability i.e Social, Environmental and economic. On a broader scale, it has increased dispersion of society, sprawl ,decreased social and cultural diversity and created more danger for people on roads. Sustainable Transportation can be achieved by shifting towards public modes of transportation..A shift towards Sustainable transportation   will favour the achievement of Millenium Development goals and SDGs. Sustainability can also be achieved by resource-efficient model for the automobile sector Design of automobiles should integrate design for environmental aspects, Shifting towards resource efficient technologies in automobile Manufacturing Industry ,Extending the lifetime of a vehicle, A regulatory environment conducive to promoting innovation for new mobility, Promoting clean fuel technology for motorized modes, Strengthening infrastructure and access for public transport, and Support energy efficient and green modes of transport.

**Table 1:Comparison of Private Ownership of Automobiles vs Sustainable Transportation**

Private Ownership of Automobiles	Sustainable Transportation
Emphasis on mobility and its quantity.	Emphasis on Accessibility and quality
Connection between different modes is acking.	Seemless connectivity between different modes(Inter-Modality).
Emphasis on One Mode.	Emphasis on Plurality.
Accepts and accommodates trends.	Reverses harmful trends.
Ignorance of Various Environmental and Economic costs.	Incorporates full costs,planning and provision.
Expansion of Road to meet Travel demand.	Manages mobility and transportation Demand.

ABSTRACT

The most prevalent kind of bone necrosis is a vascular necrosis (AVN) of the femoral head. The goals of AVN management include pain alleviation and the preservation of structure and function. Most affected people are between the ages of thirty and fifty. In Ayurveda there is no directly corelation with a vascular necrosis. *Asthimjjagata Vata, Ubhyashrita Vatarakta,* and *Asthi Majjakshya,* among other *Lakshanas,* are associated with the femoral headnecrosis. In contemporary medicine, treatments include total joint arthroplasty, bone grafting, core decompression, and NSAIDS, each of which has unique complications, an expensive affair, and a very bad prognosis. In present casethe goal of the current case was to assess the *Ayurvedic panchkarma* therapy effectiveness in the conservative management of AVN. *Matra Basti* and *Patra pinda sweda* therapy of *Panchkarma* were used in a case of AVN with right femoral head and early AVN of left femoral head. Throughout the whole course of treatment, the patient was monitored for problems; none were observed. Based on the questionnaire's assessment of the patient's graded signs and symptoms both before and after therapy, the patient's symptomatic improvements were monitored. The outcomes were positive. Pain, soreness, stiffness, and an improvement in gait were all significantly relieved by the therapy. Ayurvedic principles applied to conservative management of AVN result in significant relief in sign and symptoms and an improvement in quality of life.

Keywords: Pain, soreness, stiffness, and an improvement in gait were all significantly relieved by the therapy.

79477

INTRODUCTION

Avascular necrosis (AVN), is osteonecrosis (dead bone) and is also called Osteochondritis Dissecans/Chandler's Disease in young adults with 60% of the cases being bilateral. This condition is one of the most challenging problems faced by orthopedic surgeons. The objectives of the treatment include the preservation of structure, function and relief from pain.[1]Avascular necrosis (AVN) is a disorder in which the subchondral blood supply is cut off, resulting in the cellular breakdown of bone, especially in the epiphyseal area of weight-bearing joints. [2]There have been a variety of traumatic and atraumatic factors that have been identified as risk factors for ON, but the etiology and pathogenesis still remains unclear. The estimated frequency of the most frequent risk factors for ONFH in the United States is alcohol (20%- 40%), corticosteroid therapy (35%-40%), and idiopathic (20%-40%).[3]In Ayurveda AVN can be correlated to the *Asthi-Majja Gatha Vata*. Its symptoms are *Bhedoasthiparvanam* (breaking type of pain in bones and joints), *Sandhishoola* (joint pain), *Mamsakshaya* (muscular wasting), *Balakshaya* (weakness), *Sandhi Shaithilayam* (laxity of joints), *Aswapanasantat Ruk* (sleeplessness due to continuous pain), *Shiryantiva Cha Asthinidurbalani*(destruction of bony tissue causing generalized weakness).**[4]** Most people who are affected are in the age range of 30 to 50. Usually, the head of the femur is affected. The patient's only symptoms in the early stages will be a slight soreness around the hip joint. The hip, buttocks, groin, and thigh will all experience excruciating pain in the later stages, and all hip joint movements will be restricted. The goal of the treatment is to lessen the bone deterioration. Surgery is usually the last step in the treatment. In addition, the outlook is terrible and all therapies are expensive. The goal of the current instance was to treat femur head avascular necrosis conservatively through *panchkarma* therapy and *shaman Ausadh.*

MATERIALS AND METHODS

Case report
A 38 years old male patient with Registration no. 62160/2383 visited OPD of *Panchakarma,* at Dr. *Sarvepalli Radhakrishanan* Rajasthan *Ayurved* University, Jodhpur with complaints of Hip joints pain and pelvic region radiating through lower back to B/L lower limbs in the last 1.5 year. Pt had problem in difficulty in walking due to severe pain.

History of present illness
Patient was apparently alright before 1.5 years, after which he had a gradual onset of stiffness, dull ache in groin and thigh region. After that gradually pain increase day by day. The pain was so severe that it was associated with difficulty while doing any activity. Patient has taken allopathy treatment but did not get any relief. So that's why patient came Ayurvedic hospital for further management.

History of past illness
H/O allopathic medicine and NSAIDS

Personal History

Name: xyz

Age: 38 yrs.

Sex: male

Marital Status: Married

Occupation: Electricity dept.

Appetite: low

Bowel: mild constipation

Bladder: Clear

Pulse:70/min

BP: 114/70 mm/Hg

Respiratory Rate: 18/min

Temperature: 98.2^{0}F

Systemic examinations
Musculoskeletal System:
Inspection: no swelling on both hip joints.
Palpation: Tenderness present on Right hip joint more than left hip joint.
Range of Movements: Painful movements of hip joints present during examination.

Investigations
MRI: MRI of right hip joint given in figure 1
Avascular necrosis of right femoral head – Ficat and Arlet stage II
Early avascular necrosis of left femoral head – Ficat and Arlet stage I

Treatment Plan
After proper clinical examination based on sign and symptoms and diagnosed based on MRI reports as AVN of femoral head patient was advised for matra basti and patrapinda sweda as given as shown in table no.1. Shaman Aausadh were also given for 2 months continuous and upon follow up also given medicine as shown in table no.2

OBSERVATIONS AND RESULTS

Observation in Range of Movement of Hip joint by goniometer shown in table no.3. Changes in subjective criteria sign and symptoms as shown in table no 4.

DISCUSSION

The line of management of *Vatavyadhi* was adopted. *Snehana* (internal and external oleation), *Swedana* (sudation), *Basti* (medicated enema therapy), *Nasya* (nasal therapy), *Abhyanga* (massage), *Utsadana* (specific massage with medicated paste), *Parisheka* (sprinkling of medicated liquid), etc. are the line of management for any *Vatavyadhi* [5]. Administration of *Bahya* (external) and *Abhyantara* (internal) Snehana (oleation therapy) form may be the best treatment modality in this disease. *Snehana*in the form External administration is by *Abhyaṅga* (massage) with medicated oils. After *Abhyanga, Patra pinda sweda* can be applied to the affected part of the body, whichis *Sandhichestakara, Srotosuddhikara ,Agnideepaka,* and *Kapha-Vatanirodhana,* it decreased the *Stambha* (stiffness).By administrating proper Snigdha Swedana, It helps in alleviating vitiated *Vata Dosha. Patra Pinda Swedana* may increases the local blood flow to the affected tissues, and *Swedana,* might produce a hypoanalgesic effect by diverting stimuli and helps in releasing pain, helps in eliminating *Dosha* imbalances, strengthens the muscles of the affected area by the release of toxins and reducing inflammation.[6] whereas Swedana produces *Mriduta* with in body parts and relieves stiffness. *Shoola Shanti* is one of the Samyak *lakshana* of *Swedana Karma. Swedana* also having its vasodilation effect which helps in improving the blood circulation to the affected joint.[7] According to Acharya Vaghbhata, with the action of *Basti,* the *veerya* of *Basti* being conveyed to *Apana* to *Samana* vata which may regulate the function of *agni,* then to *Udana, Vyana* and *Apana,* thus providing its efficacy all over the body. At the same time this effect of *Matra basti* by specifying *vata,* restores the displaced *kapha* and *pitta* at their original seats. The control gained over *vata* leads to the *Samprapti Vighatana* of the disease. That's why *basti* is best treatment for *Vataja*disorders [8,9] . *Mahatiktaghrita* is indicated in the treatment of *Maharoga* (grievous disorders) and is thus helpful in mitigating the pathology of any *Vatavyadhi* like this disease [10]. *Ashwagandha* (*Withania somnifera* Dunal) possesses *Rasayana* and *Brahmana* (anabolic) properties, so it is useful in all types of *Dhatukshya* [11]. It is also reported to have an anabolic effect on bone tissue [12]. *lakshadiguggulu* as told by aacharya in baisjyaratnavliin bhagnadhikar 49/13-14 The content of *Laksha guggulu* include purified *guggulu, Laksha, Asthisanharaka, Arjun, Ashwagandha* and *Nagabala.* Most of these drugs have properties like.- *Vatakaphanashaka, deepana, balya, rasayana, tridoshanashaka, pachana, shothaghna, vedanashamaka & shoolaprashamaka.* Capsule *Gandha tailam* enriched with calcium riched ingredients like

sesame, *sarjarasa,* and milk. It helps to ease pain and gives relief from ligament injuries,sprains, spasms nourishes the weak bones.

CONCLUSION

Patient of AVN with the bilateral femoral head was treated with matra basti and patra pinda sweda. The therapy provide marked relief from pain, tenderness and stiffness. so therapy is very effective in management of AVN through ayurvedic principles.

ABSTRACT

In India at present the usage of Social Media Platforms (SMPs) amongst school and college going students has vastly increased and the usage of SMPs has extensive influence on these students in numerous ways, particularly on their interpersonal relationships. Social media platforms influence the interpersonal relationships of school students with their parents, friends, and teachers and with others in innumerable ways. The purpose of the study is to investigate the student's interpersonal relationships with their parents and teachers when SMPs is used for interaction, communication and educational purposes. The design of the study was descriptive in nature and the tool used by the researcher was self constructed. In the present study simple random sampling technique was employed for the selection of sample in which 86 were males and 84 were female's higher secondary school students from different Kendriya Vidyalaya schools of Jammu District. The main findings revealed that the usage of SMPs has influenced interpersonal relationships of students with their parents but not with their teachers. Students spend most of the time in the school mainly with the teachers, so teachers can help the students to use the social media platforms in such a way that it does not influence their relations with their parents, friends relatives etc. Teachers have to channelize student's usage of SMPs in constructive way that they don't effect student's interpersonal relations with others.

Keywords: Social media platforms, interpersonal relationships, school students, communication and technology

Juhi Gupta and Ritu Bakshi

INTRODUCTION

An incredible and unprecedented growth in ICT was seen around the world in the latter part of the 20th century, and in India in particular (Manjunatha, 2013). Today, people from all over the world can instantly connect with one another and share ideas, facts, and insights because to the widespread availability of the internet. Since then, other new mediums have emerged, most notably social media (Khatib and Khan ,2017). Many different types of social media have emerged recently, including Facebook, Twitter, WhatsApp, Instagram, and YouTube. The most widely used medium of communication nowadays is undoubtedly the various social media websites. Many different kinds of people from all walks of life are using it (Workie et al, 2021). Youth, and especially college and university students are avid users of social media owing to the widespread adoption of information and communication technologies. The use of social media has become so pervasive that it is essentially impossible to avoid; it has completely transformed the ways in which students communicate, connect, and socialise; and it has become deeply ingrained in their society and culture. As a result, students are devoting an increasing amount of time to online social networks (Akakandelwa and Walubita, 2018). Because of the rapid advancements in technology that have taken place over the past few years, the use of social media has exploded in popularity all over the world. These social networking websites have become extremely popular among users of all types, including celebrities and the ordinary public alike. With the increased penetration of smart phones and the internet in India, social media is becoming a fast-growing phenomenon as more people, particularly the youth, become engaged. India's youth are overly reliant on social media for networking, education, and pleasure. In millions, the number of social network users in India from 2015 to 2022 is depicted in the graph (Figure 2). More than 250 million people use social media in India, making it the second-largest country in the world. Millennials use social media in large numbers all across the world (Nayak et al. 2022). Social media is also heavily used by Indian youth to carry out their activities. Students now routinely use these interactive social media sites for fun and study, and the sites account for a large portion of their time online. Students are able to engage with their friends, teachers, peers, and professionals in any field, anywhere, and at any time by using the many social media platforms. This allows for the possibility of extended contact times as well as more effective communication. Through the use of social media platforms, they are able to obtain a limitless variety of data and material for their research and academic studies (Manikandan and Raja, 2017).

Students can also share lectures of different universities available on You-tube and can clarify their concepts in order to enhance their grades or academic achievement. Students also arranged online conferences, workshops in order to talk regarding the projects after the school hours. As a result, schools now recognise the importance of addressing pupils' easy access to social media. Some schools have fully integrated the use of laptops, tablets, and other electronic media into their instructional methodology (Mathew et al. 2017). The use of social networking sites has been the focus of a large number of research studies. The review of literature clearly indicates that adequate scientific investigations are not carried out on the impact of social media platforms on interpersonal relations of higher secondary school students. Hence, the study assumes profound academic and social significance. The use of social media platforms is a growing trend in India, which is highly concerning. Students from colleges and universities are becoming increasingly interested in these social networking sites that facilitate communication and entertainment. This provides the context for the study's attempt to delve deeper into this phenomena. Human growth and learning are built on interpersonal relationships. Analysis of how social media platforms affect interpersonal connections among secondary school students is therefore vital (Sudha and Kavitha, 2016). As an additional bonus, social media helps keep alive bonds that would otherwise suffer from people living too far apart. It makes possible communication that otherwise would have been impossible (Beniwal, 2018). A social media platform is like a drug to the current generation and is certainly affecting the interpersonal relationships among students. The time spent on social media platforms may cause distance or even conflict among interpersonal relationships, when spending time at home together as a family unit. Individuals may be physically present in the same room, but they may be so focused on the information they are scrolling through on the SMS, that they could be missing important nonverbal communication cues due to inattentiveness (Britt, 2017). When utilising Facebook for engagement, Liu, Yin, and

79484

Huang (2013) looked into how the teenagers interacted with their friends, parents, and teachers. One-way analysis of variance and the paired-samples t-test were used to analyse the data. The analysis's findings showed that adolescents who use Facebook frequently for social contacts, whether in real life or online, are better able to deepen their friendships than those who use it less frequently. However, if they utilise Internet technologies excessively for interactions, their real-life interpersonal relationships with their parents can suffer. Manjunatha (2013) studied SNS's impact on college students' relationships. The researcher used questionnaires and interviews to obtain data from 500 college students in Bangalore and Mysore. He observed that SNS enhanced communication between college students and their family members and friends. Ngonidzash (2016) looked into the effects of excessive usage of SMS and found that it has a major impact on the emotional relationships and physical presence within families. According to research conducted by Britt (2017), the use of short message service (SMS) decreases the quality of home-based relationships and decreases participants' overall happiness. It has been hypothesised that increasing one's SMS use at home will lead to less time spent in interpersonal, face-to-face discussion. Barriers to sharing one's views and opinions on a wide range of topics have been eliminated thanks to the rise of social media.

Students and experts are able to exchange and communicate with like-minded people and can ask for the insight and opinion on a certain topic. Furthermore, the present study has multiple direct uses to different sections of the society. To begin with, the research raises students' consciousness about the ways in which their use of social media affects themselves and their connections with others. It's a great way to teach kids how to use social media responsibly. Students' social lives benefit from more communication with adults in their lives, including instructors, parents, and friends. As social media is the new area of research and is the current or need-based problem, In the words of Ani DiFranco, "every tool is a weapon if you hold it right." Instead of letting social media use people, people should use social media. It should also be used in moderation, meaning only when the benefits outweigh the risks (Beniwal, 2018). The work in this field has been done in some developed countries like USA, UK and others and the researcher felt that less work has been done in our country especially in the state of J&K and the researcher felt that there is a great scope of research in this respective field. In addition, there are hardly any studies conducted in Jammu district, which helps in assessing the interpersonal relationship of school students in relation to specific dimensions i.e., parents, friends and teachers. Secondly, the present study is unique and differs from the rest of the studies in terms of variables, population and sample.

Objectives of the Study
The objectives of the study were:
1.   To study the main effect of gender on SMPs influenced Interpersonal Relations among Higher Secondary School students with their Parents.
2.   To study the main effect of various streams on SMPs influenced Interpersonal Relations among Higher Secondary School students with their Parents.
3.   To study the main interactional effect of gender and streams on SMPs influenced Interpersonal Relations among Higher Secondary School students with their Parents.
4.   To study the main effect of gender on SMPs influenced Interpersonal Relations among Higher Secondary School students with their Teachers.
5.   To study the main effect of various streams on SMPs influenced Interpersonal Relations among Higher Secondary School students with their Teachers.
6.   To study the main interactional effect of gender and streams on SMPs influenced Interpersonal Relations among Higher Secondary School students with their Teachers.

Hypotheses of the Study
1.   There will be no main significant difference of gender on SMPs influenced Interpersonal Relations among Higher Secondary School Students with their Parents.
2.   There will be no main significant difference of various streams on SMPs influenced Interpersonal Relations among Higher Secondary School Students with their Parents.

3. There will be no significant interactional effect of gender and streams on SMPs influenced Interpersonal Relations among Higher Secondary School students with their Parents.
4. There will be no main significant difference of gender on SMPs influenced Interpersonal Relations among Higher Secondary School students with their Teachers.
5. There will be no main significant difference of various streams on SMPs influenced Interpersonal Relations among Higher Secondary School Students with their Teachers.
6. There will be no significant interactional effect of gender and streams on SMPs influenced Interpersonal Relations among Higher Secondary School students with their Teachers.

Research Design
The descriptive survey method was utilized in the present investigation.

Population
In the present study the population of the study constituted the students of Kendriya Vidyalaya Sangathan of Jammu district. There are 11 Kendriya Vidyalaya Schools in Jammu district.

Sample
The total sample consisted of 170 students 84 females and 86 males' students studying in Kendriya Vidyalaya of Jammu district. Random sampling technique was used to collect the data.

Tool used
For the present study, self-constructed tool was used by the investigator i.e; Social Media Platforms influenced Interpersonal Relationship Opinionnaire. The validity of the tool was established by the investigator.

Statistical Technique used
The investigator used Two-way ANOVA for the analysis and interpretation of the data.

RESULTS AND INTERPRETATION

The tabulated data is meaningless unless and until it is examined and analyzed using a sophisticated statistical technique in order to reach a meaningful conclusion. Two-way ANOVA was used to interpret the numbers. Hypotheses-wise interpretations were given below. The table 1 shows that the value of F-ratio for the main factor gender has came significant as 5.8 which is higher than the table value at 0.05 level of significance at degree of freedom (1, 54) and the table values for significance are 4.03 and 7.17 at 0.05 and 0.01 level of significance. It means that there are significant differences found on SMPs influenced interpersonal relations among higher secondary school students with their parents in relation to gender. Thus the null hypothesis stating "there will be no main significant difference of gender on SMPs influenced Interpersonal Relations among Higher Secondary School Students with their Parents" is rejected. This finding is in agreement with the Liu, Yin and Huang (2013) and Ngonidzashe (2016), where as it is in disagreement with the Manjunatha (2013). From the table it comes to know that, the mean value of male students i.e. 29.6 is higher than female students i.e. 25.8 which means that male students interpersonal relations influenced by usage of SMPs with their parents. The table 1 shows that the value of F-ratio for the main factor Stream has came significant with interpersonal scores. The f-ratio value for the stream has came significant as 4.0 which is higher than the table value at 0.05 level of significance at degree of freedom (2, 54) and the table values for significance are 3.18 and 5.11 at 0.05 and 0.01 level of significance. It means that there are significant differences found on SMPs influenced interpersonal relations among higher secondary school students with their parents in relation to their streams. Thus the null hypothesis stating "there will be no main significant difference of various stream on SMPs influenced Interpersonal Relations among higher secondary school students with their Parents" is rejected. From the table it comes to know that, the mean value of non-medical stream students 28.6 is higher than commerce and medical stream students i.e. 27.7 and 25.7 which mean non-medical stream students

interpersonal relations influenced by usage of SMPs with their parents. The value of f-ratio for interaction between gender and stream on interpersonal scores has come out to be significant as 4.17 which is higher than the table value at 0.05 level of significance at degree of freedom (2, 54). It shows that these variables i.e. gender and Stream combined play important role in interpersonal scores influenced by usage of SMPs among higher secondary school students with their parents. Thus the null hypothesis stating "there will be no significant interactional effect of gender and streams on SMPs influenced Interpersonal Relations among higher secondary school students with Parents" is rejected. The value of f-ratio for the main factor gender has not came significant with interpersonal relation scores. The f-ratio value for the gender came 2.32 which is less than the table value at 0.05 against (1, 54) df. It means that there is no significance difference found on SMPs influenced interpersonal scores among higher secondary school students with their teachers in relation to gender. Thus the null hypothesis stating "there will be no main significant difference of gender on SMPs influenced Interpersonal Relations among higher secondary school students with their teachers" is accepted. The f-ratio value for the main factor stream is not significant with the interpersonal relation scores. The calculated value for the various stream came 2.02 which is less than the table value i.e. 3.18 at 0.05 level against (2,54)df. It means that there is no significant difference found on SMPs influenced interpersonal scores among higher secondary school students with their teachers in relation to their streams. Thus the null hypothesis stating "there will be no main significant difference of various stream on SMPs influenced Interpersonal Relations among higher secondary school students with their teachers" is accepted. The value of f-ratio for the interaction of gender and stream has not come significant with the interpersonal relations. The f-ratio value for the interaction of gender and stream came 1.48 which is less than the table value i.e., 3.18 at 0.05 level against (2, 54) df. It means that there is no significant difference found on SMPs influenced interpersonal scores among higher secondary school students with their teachers in relation to their gender and streams. Thus the null hypothesis stating "there will be no significant interactional effect of gender and streams on SMPs influenced Interpersonal Relations among higher secondary school students with their teachers" is accepted.

MAJOR FINDINGS

The main conclusions arrived at after investigating the data with regard to usage of SMPs influenced interpersonal relations is summarized below.
It may be concluded that
1.   There is main significant difference of gender on SMPs influenced Interpersonal Relations among higher secondary school students with their Parents.
2.   There is main significant difference of various streams on SMPs influenced Interpersonal Relations among higher secondary school students with their Parents.
3.   There is significant interactional effect of gender and streams on SMPs influenced Interpersonal Relations among higher secondary school students with Parents.
4.   There is no main significant difference of gender on SMPs influenced Interpersonal Relations among higher secondary school students with their Teachers.
5.   There is no main significant difference of various streams on SMPs influenced Interpersonal Relations among higher secondary school students with their Teachers.
6.   There is no significant interactional effect of gender and streams on SMPs influenced Interpersonal Relations among higher secondary school students with their Teachers.

From the results of the study, it comes to know that the non-medical stream students interpersonal relations influenced by usage of SMPs with their parents. It may be due to the reason that non-medical stream students make maximum use of social media as compared to medical and commerce students for their academic activities. The students also used SMPs to obtain knowledge and information from different scientists, experts and other communicators of science. They use SMPs for stay informed of events and news, update knowledge of technology, allow ideas exchange and meet students from other universities, post projects or models. They also used SMPs to research colleges, universities and company to get information about all the fields they are interested in. And gender also influenced student's interpersonal relations with parents and not with teachers because students spend most of

the time in the school mainly with the teachers. It is possible for educators to devise instructional methodologies that make use of social media for the purposes of teaching and learning. This, in turn, increases student-teacher contact, which contributes to improved academic performance.

Educational Implications

A growing number of college students spend a lot of time on social media platforms and for many of them it has become an inseparable part of their lifestyle, beneficial for education, communication, finding jobs, business and entertainment. Students need to be trained in the right use of social media for the all-round development of their personality. The implications of the study are stated as follows:

1. Students should be encouraged by teachers, parents and relatives to use these platforms carefully and utilize the innovative features for social interaction and collaboration.
2. Teachers with the help of SMPs gave live lectures, increased support to student queries, to expand and explore their own possibilities, skills and knowledge, variety of teaching aids and also by teaching blogs and write ups.
3. SMP use should be encouraged among children by parents, school officials, teachers, and guidance counsellors because of the positive effects it has on students' interpersonal connections.
4. If the students interpersonal relationship with their parents influenced by SMP then teachers can also guide the students about how to use SMPs without effecting their relationships.
5. Teachers should channelize their students" usage of SMPs in the right direction so that they benefit from the merits of social media rather than be caught up in the evils of social media usage.
6. Students should utilise SMPs not merely for amusement and recreation, but also as a means of communicating with elders in their lives such as parents and instructors.
7. 7. The usage of social media platforms should be encouraged for the sake of personal development; using these sites can help students improve their information technology abilities and maintain in contact with professionals.
8. Social media platforms (SMPs) are the most effective means of disseminating information and should be utilised to raise awareness of social concerns among members of a society and its interconnected communities.
9. Students can balance their time between studies and their usage of these social media platforms socially and particularly for academic purposes.
10. 10 Social media should be seen as an informal learning tool by both educators and learners because of the relaxed atmosphere it fosters for both.
11. Teachers, administrators, and policymakers in the field of education can all benefit from using social media as an additional teaching tool.
12. Institutions of higher learning create their own social media pages and groups on various platforms, inviting students to join in the hopes that they may provide a forum for students to discuss and find solutions to issues they are facing in the classroom.

CONCLUSION

Students in higher education cannot function properly without the use and features of social media, which are both needed and of the utmost importance. In the same vein, students might benefit from using social media to improve their learning performance, facilitate the exchange of information, and work together. Students have access to a learning platform in the form of social media, where they may readily communicate with one another, as well as with their lecturers and subject matter experts. In addition, the utilisation of social media platforms is beneficial to the improvement of collaborative learning among students (Khan et al. 2021). Because of their accessibility and convenience, social networking services now have millions of active members. Students in today's society rely on social networking websites for the majority of their real-time communication needs. Examples of such websites are Facebook, Twitter, and YouTube. According to the findings of the study, students' social media presence had an effect on their relationships with their parents and siblings. The gender of the user does not play a significant role in

the interpersonal relations that are influenced by the use of social media platforms that include parent and sibling dimensions. This holds true for both medical and commerce stream students' interpersonal relations that are influenced by the use of social media platforms.

ABSTRACT

Collagenase enzyme is a protein molecules made up of amino acids. It provides structural support to the extracellular space of connective tissues. Due to its rigidity and resistance to stretching, it is the perfect matrix for skin, tendons and also helps in the wound healing process. In the present study we worked on the isolation, production and optimization of collagenase enzyme from marine bacteria from different selected strains- Halomonas of sea water on Agar nutrient medium. Collagenase enzyme was collected from isolated Halomonas anticariensis and tested for enzyme activity through UV visible spectrophotometric analysis. The enzyme activity is optimized at 36^0C, PH-7, incubation period 48hrs and Moisture content 47% and study mainly concerned on the production of collagenase from solid substrate which have more high enzymatic activity.

Keywords: Enzymes, Extracellular collagenase, Cup assay, Biochemical assay

INTRODUCTION

Collagenase is an enzyme that breaks down collagen in damaged tissues within the skin and helps the body generate new healthy tissue. It is considered a virulence factor, facilitating the spread of gas gangrene. Collagen is a type of protein that connects and supports fibers in body tissues such as skin, tendons, muscles, and bone. Collagen, a key component of the animal extracellular matrix, is made through cleavage of pro-collagen by collagenase once it has been secreted from the cell. This stops large structures from forming inside the cell itself. Collagenase topical (for the skin) is applied to severe burns or skin ulcers to help remove dead skin tissue and aid in wound healing. It may also be used for other purposes not listed in this medication guide. The molecular and packing structures of collagen eluded scientists over decades of research. The first evidence that it possesses a regular structure at the molecular level was presented in the mid-1930s.[1,2] Research then concentrated on the conformation of the collagen monomer, producing several competing models, although correctly dealing with the conformation of each individual peptide chain. The triple-helical "Madras" model, proposed by G. N. Ramachandran ,1955, provided an accurate model of quaternary structure in collagen.[3,4] This model was supported by further studies of higher resolution in the late 20th century.[5,6] The packing structure of collagen has not been defined to the same degree outside of the fibrillar collagen types, although it has been long known to be hexagonal.[7] As with its monomeric structure, several conflicting models propose either that the packing arrangement of collagen molecules is 'sheet-like', or is microfibrillar.[8] The microfibrillar structure of collagen fibrils in tendon, cornea and cartilage was imaged directly by electron microscopy in the late 20th century and early 21st century.[9,10] The microfibrillar structure of rat tail tendon was modeled as being closest to the observed structure, although it oversimplified the topological progression of neighboring collagen molecules, and so did not predict the correct conformation of the discontinuous D-periodic pentameric arrangement termed microfibril.[11] collagen enzymes are able to effectively breakdown the peptide bonds found in collagen. Based on an increased interest in non-invasive therapeutic methods, collagenase enzymes are being studied for their ability to catalyze key chemical processes more specifically, collagen degradation. As seen in various in vivo and in vitro tests, injectable forms of collagenase have been shown to promote wound healing. With their unique ability to degrade collagen that is resistant to breakdown, collagenases can more effectively treat wounds, even those associated with third-degree burns. This is believed to be based on the fact that once collagen is degraded by collagenase, select inflammatory cells, including macrophages, are able to enhance migration and in turn, their efficiency. That is why ointments containing C. Collagenase are often applied to wounds, assisting in the removal of necrotic tissue. Since this type of dead tissue prolongs the inflammatory stage and enhances bacterial growth, collagenase supports proactive healing. While wound healing is imperative when aiming to reduce the risk of infection, the applications of collagenase enzymes are far-reaching in regards to scientific research and discovery.

Applications of Microbial Collagenase;
Enzyme Activity Reaction
The Collagenase are the enzymes necessary to initiate collagen turnover in normal connective tissue turnover and in diseases. Polyhydroxylated is a key enzyme in collagen synthesis acting by hydroxylation of proline residues in procollagen peptide, which is necessary for stabilizing collagen. More specifically, collagenase enzymes work by degrading the collagen found in the extracellular matrix. This collection of molecules is what essentially anchors cells to tissue, providing both biochemical and structural support. Depending on the class of collagenase, once the tissue is exposed to collagenase enzymes, it will bind to and cut either the ends of a collagen fibril or the middle of a collagen monomer. Once the structure of the triple helical is cut, they begin to unravel and denaturation takes place. At this point, it essentially becomes gelatin. From wound healing and scar contractures to research and disease prevention, collagenase enzymes will continue to play an important role within the scientific community, aiding and accelerating key.

Mechanism of action of collagenase

Collagenases are enzymes that break the peptide bonds in collagen. They assist in destroying extra cellular structures in the pathogenicity of bacteria such as clostridium. They are considering a virulence factor, facilitating the spread of gas gangrene. The normally target the connective tissue in muscle cells and other body organs. Collagen, a key component of the animal extra cellular Matrix is made through the cleavage of procollagen by collagenase once it has been secreted from the cell. The stops large structures from the forming inside the cell itself. In addition to being produced by the some bacteria. Collagenase can be made by the body as part of the it's normal immune response, this production is induced by the cytokines, which stimulates cells such as fibroblast and osteoblast, and can cause indirect tissue damage.

MATERIALS AND METHODOLOGY

Selection of Strains

The selected Halophilic strains were isolated from seawater, grown on Agar nutrition broth. The cultures were continuously maintained on petri plates. The cultures were every time cultured freshly on the Agar nutrients broth and incubated at 370c for 2 days before performing each experiment.

Raw Materials

Source: Sea Water collected from Machilipatnam, Krishna District; A.P.

Materials: Agar, Peptone, Meat extract, sodium chloride, was used to prepare Agar nutrition broth.

Preparation of Media
Preparation of Inoculum

The Sea water was inoculated in Agar nutrition broth with the help of loop and it was incubated in incubator for 48 hours. That supports the growth of Halomoans bacteria.

Preparation of Halomona. Anticariensis Production Media

The grown culture of Halomona.anticariensis was sub-cultured in the collagenase Enzyme rich media for increasing the production of enzyme.

Inoculum media Composition
Colleginase Enzyme Activity

After the 72 hrs of incubation period collect the culture broth and was centrifuged at 2000 rpm for 30 min and filter the solution for the separation of enzymatic fraction. The cell free supernatant was filtered through 0.45um cellulose acetate filter and the filtrate was considered as crude enzyme . The soluble protein content of the enzyme sample was measured at 520-540nm examined using UV.

Maintenance of Selected Strains

The organism in the present study Halomona.anticariensis was isolated from water and grown on Agar nutrition broth. The culture was continuously maintained on petri plates. The culture was every time cultured freshly on petri plates on the Agar nutrition broth and incubated at 37^{0}c for 2 days before performing each experiment.

Inoculum Media Components

Starch, Agar, Peptone, Yeast extract, Sodium chloride was used to prepare Agar nutrition broth.

Inoculum Media Composition

Starch-1gm, Agar-3g, Peptone-0.5gm, Yeast extract-0.3, Sodium chloridr 0.5gm, 1 litre of distilled water adjust the PH to 7.3 and autoclave the mixture for 25 min at 120^{0}c.

Preparation of Inoculum
The hallophlic culture bacteria was inoculated in Agar medium with the help of loop and it was incubated in incubator for 48 hours. Which supports the growth of Halomona. anticariensis bacteria.

Colleginase Enzyme Activity
Following incubation under optimized conditions, the culture was centrifuged at 2000 rpm for 30 min and filter the solution. The cell free supernatant was filtered through 0.45um cellulose acetate filter and the filtrate was considered as crude enzyme [Babashamsi]. The soluble protein content of the enzyme sample was measured at 520nm-54nm examined using UV.

Enzyme Activity Test
Weigh the 10ml of the water into the beaker and heat Weigh 2gm of gelatin add the above solution In this Solution , 5 ml of Ninhydrin solution is added.Finally Purple Colour is produced due to the Ninhydrin.
Observation: Collagenase activity is +ve

OPTIMIZATION OF COLLAGENASE ENZYME:
Results
Optimization of Collagenase Enzyme
a) Effect of Incubation Period on Enzyme Production:
5 gm of substrate was inoculated in mineral salt solution in 500ml Erlenmeyer flask and autoclaved. The suspended cultures were again inoculated as mentioned above and then incubated. The contents of flask were isolated and assayed at every 24 hrs; 48hrs and 72hrs of interval.

Enzyme Production
b) Effect of Temperature: The effect of temperature on the production of enzyme like collagenase was studied by incubating the culture at different temperatures ranging from 20oc-50oc.
c) Effect of Moisture Content: 5 gm of ground substrate was taken and dried at 60^0c for 6 hrs. cooled and weighed till a constant weight was obtained and moisture level was adjusted to 40%-80% by addition of required amount of salt solution and were sterilized.
d) Effect of pH: Substrate was mixed with mineral salt solution whose pH was adjusted; mineral salt solution was used as moistening agent which is used to adjust the pH. The pH was adjusted in the range of 2-7.5 with an increment of 0.5. The flasks which were prepared were sterilized, inoculated and incubated.

FORMULATION OF COLLAGINASE OINTMENT
Composition of Collagenase Formulation
Collaginase enzyme 0.5g;Arachis oil 1.5g;Methyl Salicylate 0.5g;Soft paraffin 10g.

Preparation of Ointment
Soft paraffin was taken and melted by heating process. After melting add arachis oil and mix well uniformly. And add methyl salicylate mix well finally add collagen enzyme followed by the tituration procedure. For this project we collected marine water for the isolation of halophillic strain and extraction of collagenase enzyme. For this firstly we prepared a nutrient media to that we inoculated sea water solution. And placed it in incubator until growth is observed.

Characterization of Isolated Halophilic Culture
After the growth of microorganisms enzyme is extracted by centrifugation process.
And the enzyme was assayed by biochemical tests. In that we got +ve results for staining tests, catalase test, motility test, and urease test.

CONCLUSION

The selected Halophilic culture showed more collagenase activity at an incubation period of 48hrs; temperature 55^0c and at pH 7. The collagenase as an enzyme with high therapeutic potential.

ABSTRACT

The human body uses glucose as its primary fuel, and diabetes, which is characterized by elevated blood glucose levels, can have major negative effects on our health. In this work, we examined the relationship between glucose levels in individuals who drink alcohol (drinkers) and those who do not (non-drinkers) using the five-state Markov model and a novel mathematical technique. Significant parallels and differences between the glucose levels of drinkers and non-drinkers are highlighted by this study. The five-state probability mass function was formulated based occurrence or non-occurrence of particular state. The transition probability matrix provides evidence that the state is likely to remain the same for the next fifteen minutes. Normoglycemia and mildhyperglycaemia was shown to be the most prevalent blood glucose state for non-drinker and for drinker normoglycemia has high chance. Comparing the two scenarios, there isn't much indication that drinkers may have major problems. Once diabetes is affected, the chances of hyperglycaemia and normoglycemia are practically equal for drinkers and non-drinkers in long term behaviour of the model; in fact, those who drink are less likely to experience serve hyperglycaemia.

Keywords: Markov model, continuous glucose monitor, alcoholic, non-alcoholic, probability distribution

INTRODUCTION

A blood sugar (glucose) level that is too high results in diabetes. It arises when the body isn't reacting to the effects of insulin appropriately or when the pancreas produces too little or no insulin at all. People of all ages are affected by

Tirupathi Rao Padi and Surnam Narendra

diabetes. All types of diabetes are treatable with medicine and/or lifestyle modifications, and the majority are chronic (lifelong). The primary source of glucose, or sugar, is found in the carbohydrate in food and beverages. It serves as the body's primary energy source. All of the cells in the body receive glucose from the blood to utilize as fuel. Once in the bloodstream, glucose need assistance a key to go where it needs to go. Insulin is a crucial hormone. Hyperglycemia, or elevated blood sugar, is brought on by an accumulation of glucose in the bloodstream due to insufficient insulin production or improper insulin utilization by the body. Consistently maintaining high blood sugar levels over time can lead to health complications like heart disease, nerve damage, and vision problems. India is the country most affected by diabetes worldwide, with an estimated 77 million Indians (1 in 11) officially diagnosed with the disease. This puts India second only to China. In addition, diabetes, hyperglycemia, Kidney failure, and other consequences of the disease claimed the lives of 700,000 Indians in 2020. India accounts for one in six (17%) of the global diabetes population. (As of October 2018, India accounted for roughly 17.5% of the world's population.) The International Diabetes Federation predicts that by 2045, there would be 134 million people with the condition. Worldwide, 537 million adult individuals suffer with diabetes. This number is expected to increase to 643 million by 2030 and 783 million by 2045, according to experts. A mathematical model that probabilistically depicts how a system evolves over time is called a stochastic process. Each random variable in the collection, is indexed by time or another parameter, represents the system's state at a certain moment in time. Numerous disciplines, including economics, engineering, physics, biology, and more, use stochastic processes extensively to model and evaluate systems that display uncertainty or randomness. If the future state of the system depends only on its current state and not on the preceding sequence of events, then a stochastic process possesses the Markov property. The process's modeling and analysis are made easier by this feature. A range of studies have explored the use of Markov models for understanding glucose levels among diabetes patients. Andreassen et al., (1994) implemented a probabilistic network model for predicting 24-hour blood glucose profiles with a mean error of 3.3 mmol/l[1]. Hovorka et al.,(2004) developed a nonlinear model predictive controller that uses a compartment model to maintain normoglycemia, with promising results [2]. Aibinu et al., (2010) suggested the use of artificial intelligent-based techniques for blood glucose level prediction, particularly the hybrid AI technique [3]. Stahl, (2012) investigated linear and Bayesian embedded models for short-term glucose prediction, focusing on low blood glucose detection [4]. Nath & Jain, (2012) proposed a hidden Markov model for predicting insulin charts, achieving positive results [5]. Varshney *et al.,* (2020) emphasized the higher risk of problems for patients with higher hemoglobin A1c levels by using an HMM to estimate transition probabilities between different diabetes states [6].

Zhou *et al.,* (2020) presents an improved deep neural network model that predicts diabetes with good accuracy in diabetes type classification [7]. Dey, (2020) introduced a novel neural network that outperformed other methods in terms of RMSE and adverse event detection [8]. S.Miyagi et al., (2021) speak about Moderate alcohol consumption contributes to impaired insulin secretion and glucose intolerance in lean/normal-weight non-diabetic Japanese men [9]. Dylag, (2023) found that a Hidden Markov Model can effectively predict glucose levels when used in conjunction with other machine learning models [10]. M.Ishohara et al., (2023) explores the relationship between habitual daily alcohol consumption and time-specific glucose levels in a non-diabetic population, revealing a time-dependent biphasic pattern in glucose levels associated with alcohol consumption [11]. Narendra & Padi (2024) discusses the use of Markov models to understand glucose levels in Type-1 diabetes patients, improvements in treatment, global diabetes prevalence, and the significance of stochastic models in various fields [12]. These studies collectively demonstrate the potential of Markov models and hidden Markov models for understanding glucose level. The goal of this work is to use a Markov model to understand glucose levels fluctuations at different times from drinker and non-drinker. It can be seen from the literature that most approaches for glucose levels rely on HMM and machine learning techniques to classify. However, very little work has been reported in the literature on speaking the holistic study mechanism by deriving the probability distributions of the specific state under study. In order to understand the overall behavior of the specific state of the diabetic patient, this study has given more focus on formulation of probability distribution's mass function. Their study has initiated with identification of appropriate stochastic processes by means of formulating the suitable Markov chains. Hence (i) deriving the probability mass function; (ii) developing the R-code from the derived mathematical relations; (iii) finding the statistical reports to the relative data; (iv) finding the statistical characteristics of Markov chain are the core activities of this study.

Markov model

A sequence of potential events where the probability of each event depends only on the state obtained in the preceding event is described mathematically as a Markov Chain. The process in question is stochastic and demonstrates the Markov property, which implies that the system's future state is contingent solely upon its present state and not on the preceding sequence of the events. The five state Markov chain model has developed based on glucose levels. The schematic diagram of the proposed Markov model is as follows. Consider the sequence of observations X_n where n is discrete time random process. In Markov chain X_{n+1} is conditional to the current state X_n and it is not dependent on $X_0, X_1, X_2 \dots X_{n-1}$. It is called memory less property. The chain behaviour that follows any state depends only on its current state, and this constraint is known as the Markovian assumption [11]. Let $O = \{o_1, o_2, \dots o_m\}$ be finite observable possible probabilistic state $X_n = o_i$ presents at discrete time t and $X_{n+1} = o_j$ at t+1 time, the Markov model written as, $a_{ij} = P(X_{n+1} = o_j | X_n = o_i)$ is the probability from moving $o_i \ to \ o_j$. The properties of Markov chain are: $\sum_{i=1}^{m} a_{ij} = 1 \ \& a_{ij} \geq 0$.

Probability mass function

In order to understand the model behavior, there is need of formulating the probability mass function for different states. The PMF formulated based on raw methods i.e. occurrence and non-occurrence of particular state in one step.

$$P(X_1(\omega) = x_1) = \begin{cases} \sum_{i=1}^{5} \sum_{j=2}^{5} \pi_i a_{ij} & x_1 = 0 \\ \sum_{i=1}^{5} \pi_i a_{i1} & x_1 = 1 \end{cases} \qquad P(X_2(\omega) = x_2) = \begin{cases} \sum_{i=1}^{5} \sum_{j=1, j \neq 2}^{5} \pi_i a_{ij} & x_2 = 0 \\ \sum_{i=1}^{5} \pi_i a_{i2} & x_2 = 1 \end{cases}$$

$$P(X_3(\omega) = x_3) = \begin{cases} \sum_{i=1}^{5} \sum_{j=1, j \neq 3}^{5} \pi_i a_{ij} & x_3 = 0 \\ \sum_{i=1}^{5} \pi_i a_{i3} & x_3 = 1 \end{cases} \qquad P(X_4(\omega) = x_4) = \begin{cases} \sum_{i=1}^{5} \sum_{j=1, j \neq 4}^{5} \pi_i a_{ij} & x_4 = 0 \\ \sum_{i=1}^{5} \pi_i a_{i4} & x_4 = 1 \end{cases}$$

$$P(X_5(\omega) = x_5) = \begin{cases} \sum_{i=1}^{5} \sum_{j=1}^{4} \pi_i a_{ij} & x_5 = 0 \\ \sum_{i=1}^{5} \pi_i a_{i5} & x_5 = 1 \end{cases}$$

In the PMF, x_1 represents hypoglycemia, x_2 represents normoglycemia, x_3 represents mild hyperglycemia, x_4 represents moderate hyperglycemia and x_5 represents serve hyperglycemia.

METHODOLOGY

Data collection

The data on two ShanghaiT2DM[13] individuals was taken from a secondary source. Of the 109 T2DM, 13 are drinkers and 96 are not. Thirteen samples were randomly selected from non-drinkers and thirteen from drinkers in order to preserve homogeneity. The average age of the 13 male drinkers is 62.76 years old, their height is 1.71 meters, their weight is 71 kg, their BMI is 24.23, and their duration of diabetes is 10.54 years. There are seven female and six male non-drinkers, with an average age of 59.54, height of 1.61 meters, weight of 60 kg, BMI of 22.97, and duration of diabetes of 7.23. The meal intake takes place three times a day, at 07:01, 11:01, and 17:16. Insulin is administered twice a day, at 06:05 before breakfast and 16:01 before dinner. For both drinkers and non-drinkers, the times are essentially the same every day with the occasional small change in minutes. The states represent different ranges of glucose levels they are: state-1: hyperglycemia (below 70); state-2: normoglycemia (70 to 130); state-3: mild hyperglycemia

Tirupathi Rao Padi and Surnam Narendra

(130 to 180); state-4: moderate hyperglycemia (180 to 250); and state-5: serve hyperglycemia (250+). The summary of the data given here. A fascinating result can be found in the summary statistics that contrast the glucose levels of drinkers with non-drinkers. Drinkers have a mean glucose level of 145, while non-drinkers have a higher mean of 151.1. The median blood sugar levels for the two groups are closer together, though, with drinkers at 133.2 and non-drinkers at 142.2. This implies that although the average glucose level is greater in non-drinkers, the middle values are more similar in the two groups. Furthermore, the standard deviation for abstainers is somewhat lower (49.0634) than for alcohol consumers (51.0738), suggesting that abstainers had less variation in their blood sugar levels. Positive skewness is seen in both groups, suggesting that the glucose distribution's tail extends towards higher values. The coefficient of variation (CoV) is 0.3247 for non-drinker and 0.3522 for drinkers. This suggests that drinkers' blood glucose levels are slightly more variable than non-drinkers', relative to their respective means. By putting the data spread in perspective and comparing it to the mean, the CoV makes it possible to compare group variability more meaningfully even when the means of the groups disagree. According on the kurtosis values, both distributions appear to be leptokurtic, which means that they are more peaked and have heavier tails than a normal distribution.

Limitations

The main limitation of the data is physical activity, stress levels, occupation and sleep hours are not given. Physical activity is not discussed of the patient and this is important for diabetes patients. The stress levels play a vital role in diabetes patients. If occupation is given then it will be more accurate to understand the fluctuation of the data. The alcohol consumption time period is not there. The sleep timing is assumed based on information available on google.

Numerical illustration

The numerical analysis performed for the proposed model from dataset[13]. The Markov modelnumerical results and probability distribution discussed here.

Drinker data classification

The drinker initial probability vector is calculated by average of the 13 patients. IPV= $\begin{pmatrix} 0.0162 & 0.4492 & 0.3256 & 0.1685 & 0.0405 \end{pmatrix}$ .The initial probability vector (IPV)indicates the probability of beginning in each state and provides important information about the model initial conditions and likely future paths. States like normoglycemia have a significantly greater likelihood, suggesting a strong tendency for the system to start in this state. On the other hand, states such as hypoglycaemia and serve hyperglycaemia have lower probability, indicating relatively smaller chances of commencement in these states. Predictive Modeling and analysis rely on the IPV as a fundamental component, which allows for a thorough understanding of the model evolution over time and helps with decision-making about the model future behaviour and possible state transitions. The transition probability matrix (TPM) is calculated by average of the 13 patients like IPV and standard error matrix

(SEM) calculated by the average of TPM using the straight forward formula $\dfrac{p_{ij}}{\sqrt{n}}$. The stationarity matrix (SM) or long-term behaviour calculated by multiplying TPM.

$$\text{TPM} = \begin{pmatrix} 0.841269841 & 0.15873016 & 0 & 0 & 0 \\ 0.005732302 & 0.93694468 & 0.05674979 & 0.0005732302 & 0 \\ 0 & 0.07908264 & 0.86081455 & 0.0597073942 & 0.0003954132 \\ 0 & 0 & 0.11773700 & 0.8539755352 & 0.0282874618 \\ 0 & 0 & 0 & 0.1238095238 & 0.8761904762 \end{pmatrix}$$

$$

The model complex dynamics are captured by the transition probability matrix (TPM), Markov chain is irreducible, all states are recurrent andaperiodic. The glucose level states are hypoglycaemia and serve hyperglycaemia show substantial propensities to self-transition, suggesting some stability in these states. On the other hand, states such as mild hyperglycaemia and moderate hyperglycaemia show a tendency to change into other states, indicating a more dynamic behaviour. Subtle interdependencies between states are also revealed by the matrix; certain transitions are more common than others, indicating underlying patterns of systemic advancement. In the next state prediction (after 15 minutes) there is a high chance for the same state, means there is a less chance for changing glucose levels in 15 minutes. The standard error matrix calculated from TPM. It shows that these estimates have different degrees of precision; certain transitions show high confidence because of their low standard errors, while other transitions are linked to higher levels of uncertainty because of their higher standard errors. As an example, changes from mild hyperglycaemiato itself show accurate estimations, indicating a steady trend, whereas changes from hypoglycaemia to normoglycaemia show a considerable level of uncertainty, indicating possible fluctuations in this evolution. The equilibrium distribution or long-term behaviour are the estimated percentage of time the system will spend in a specific state following an endless series of transitions is reflected in likelihood. The most stable condition is indicated by the steady-state probability of roughly 44.97%, indicating that the system is expected to primarily live in the normoglycaemia state. On the other hand, states such as mild hyperglycaemia and moderate hyperglycaemia have smaller but statistically significant steady-state probability, suggesting that they remain in the system throughout time. The likelihoods also reveal more nuanced details, like the relatively small but less significant existence of the hypoglycaemia and serve hyperglycaemia states.

Mean recurrent time$=\begin{pmatrix} 61.578750 & 2.223824 & 3.067981 & 5.931898 & 25.279698 \end{pmatrix}$

The discrete-time Markov chain (DTMC), mean first passage times (MFPT) matrix provides important new information on the temporal dynamics of state transitions. Every entry represents the anticipated time steps needed for the system to transfer from one state to another for the first time, offering a numerical assessment of pathway traversal and transition efficiency. Interestingly, shorter MFPTs: for example, from hypoglycaemia to normoglycaemia indicate more straightforward and effective transitions, whereas longer MFPTs: for example, from hypoglycaemia to serve hyperglycaemia indicate more intricate or uncommon paths. With the use of these insights, person can more effectively make decisions and manage systems across a variety of domains by being able to recognize crucial transitions, predict system behaviours, and plan actions to optimize transition pathways or reduce delays. The discrete-time Markov chain has a vector that shows the mean recurrence times for each state. This vector gives important information on how long the system typically stays in each state before going back to it. The internal dynamics and stability of the system inside each state are gauged by these mean recurrence times. As an illustration, mild hyperglycaemia shows a comparatively short mean recurrence time of about 3.07-time steps, indicating that the

system regularly returns to this condition. On the other hand, the hypoglycaemia and serve hyperglycaemia states show longer average recurrence periods, which suggests less occurrences of these states being returned to. By knowing these average recurrence times, person may assess the system's durability and resilience within each state, which helps guide interventions and decision-making processes targeted at controlling system stability or maximizing state transitions.

TPM non drinker

The non-drinker data analysis performed like drinker here we taken average of 13 patients, IPV=
$(0.006449764 \quad 0.383474273 \quad 0.386412498 \quad 0.177655153 \quad 0.046008313)$ Initial probabilities of various states in a model are represented by the initial probability vector. In this case, the vector's elements hypoglycaemia, mild hyperglycaemia, moderate hyperglycaemia, normoglycaemia, and serve hyperglycaemia each represent a distinct condition. These states probably relate to different categories or circumstances within a certain domain. For example, in a medical setting, they can stand for various illnesses or diagnoses. A state's initial probabilities are represented by the values allocated to it; hypoglycaemia has the lowest likelihood (0.006), and mild hyperglycaemia (0.386) has high chance. These probabilities provide insight into the initial distribution of states prior to any transitions or changes occurring inside the, and they can be used as the basis for additional research. The transition probability matrix (TPM), standard error matrix(SEM) and stochastic matrix (SM) are given.

$$TPM = \begin{pmatrix} 0.766666667 & 0.22222222 & 0.01111111 & 0 & 0 \\ 0.003925234 & 0.92728972 & 0.06841121 & 0.0003738318 & 0 \\ 0 & 0.06862018 & 0.87592730 & 0.0554525223 & 0 \\ 0 & 0 & 0.12182332 & 0.8354175071 & 0.04275918 \\ 0 & 0 & 0 & 0.1651090343 & 0.83489097 \end{pmatrix}$$

$$SEM = \begin{pmatrix} 0.0922958207 & 0.049690399 & 0.011111111 & 0 & 0 \\ 0.0008565562 & 0.013165302 & 0.003575911 & 0.000264339 & 0 \\ 0 & 0.003567393 & 0.012745565 & 0.003206902 & 0 \\ 0 & 0 & 0.007010144 & 0.018357499 & 0.004153138 \\ 0 & 0 & 0 & 0.016036807 & 0.036061797 \end{pmatrix}$$

$$SM = \begin{pmatrix} 0.006465637 & 0.3843462 & 0.3863166 & 0.1770261 & 0.04584542 \\ 0.006465637 & 0.3843462 & 0.3863166 & 0.1770261 & 0.04584542 \\ 0.006465637 & 0.3843462 & 0.3863166 & 0.1770261 & 0.04584542 \\ 0.006465637 & 0.3843462 & 0.3863166 & 0.1770261 & 0.04584542 \\ 0.006465637 & 0.3843462 & 0.3863166 & 0.1770261 & 0.04584542 \end{pmatrix}$$

Given the probability of transitioning between discrete states, the Transition Probability Matrix (TPM) is a tool for deciphering the dynamics of a chain. The possibility of changing from one state to another is indicated by each item in the matrix, providing detailed insights on the behaviour of the system over time. For example, a greater probability in a given transition denotes a higher frequency of that change occurring in the system. Through examining the TPM in conjunction with the initial probability vector, one may comprehend the complex patterns of state transitions and, as a result, obtain a thorough knowledge of the system's evolution and the relative importance of each state as it progresses. An indicator of the degree of uncertainty around the transition probability estimates in a Transition Probability Matrix (TPM) is the Standard Error Matrix. The standard error of the associated transition probability estimate in the TPM is represented by each entry in the matrix. A larger standard error, for instance,

denotes increased uncertainty in the estimated transition probability and raises the possibility that the real transition probability may differ more from the estimated value. On the other hand, a smaller standard error indicates more faith in the projected transition probability's accuracy. The robustness of the inferred dynamics inside the system and the accuracy of the transition probability estimations can both be evaluated by comparing the Standard Error Matrix with the TPM. The equilibrium distribution of states in a Discrete-Time Markov Chain (DTMC), which captures the model stability and long-term behaviour, every element in the final vector represents the percentage of time that the DTMC is expected to be in a particular state following a large number of iterations. As an example, a steady-state probability of roughly 0.0065 for hypoglycaemia indicates that, throughout time, this condition is predicted to remain present for about 0.65% of the system's existence. In a similar vein, the odds allocated to other states reveal information on their individual long-term prevalences

$$\text{Mean first passage time} = \begin{pmatrix} 0 & 5.377348 & 18.37958 & 54.175266 & 180.2279 \\ 657.4675 & 0 & 14.79856 & 50.582277 & 176.6349 \\ 680.3918 & 22.924316 & 0 & 36.035041 & 162.0877 \\ 690.7262 & 33.258754 & 10.33444 & 0 & 126.0527 \\ 696.7828 & 39.315358 & 16.39104 & 6.056603 & 0 \end{pmatrix}$$

$$\text{Mean recurrent time} = \begin{pmatrix} 154.663791 & 2.601821 & 2.588551 & 5.648884 & 21.812432 \end{pmatrix}$$

The resulting matrix captures the expected time, expressed in discrete time steps, for an average Discrete-Time Markov Chain (DTMC) represented by matrix to transition from one state to another. The mean first passage time (MFPT) between each beginning state and the target state is represented by each element in the matrix, providing detailed information about the temporal dynamics and effectiveness of state transitions in the model. A smaller MFPT, for example, indicates a relatively quick transition between two states, whereas a larger MFPT indicates a more complex or drawn-out journey. Analysts can identify significant transition patterns, evaluate the navigational effectiveness of the system, and make informed decisions about how best to maximize system performance or operational efficiency by determining these average passage times. The average time before a Discrete-Time Markov Chain (DTMC), represented by matrix returns to each state. These values provide information about the system's internal temporal revisitation patterns of states. For example, a mean recurrence time of roughly 2.59-time steps for mild hyperglycaemia shows that this condition is revisited frequently, but a larger time, like 154.66 for hypoglycaemia indicates longer stays between revisits. Determining these recurrence times helps evaluate the stability and cyclic behaviour of the system, which helps with resource allocation and system optimization decisions.

Probability Mass Function
The probability mass function was formulated based on occurrence and non-occurrence of state by raw method. For drinker and non-drinker similar but variation present in values. The data suggests that non-drinkers are significantly less likely to experience hypoglycemia compared to drinkers, hinting at a potential protective effect associated with abstaining from alcohol. The chance of normoglycemia has higher chance for non-drinker compare to drinker. Similarly mild hyperglycemia non-drinker has high chance. The highest likelihood state occurrence for drinker and non-drinker is moderate hyperglycemia and less chance for hypoglycemia. So, there is a high possibility to occur moderate hyperglycemia in both cases.

RESULTS AND DISCUSSION

In this work we examined the T2DM glucose levels of 26 patients in this study; 13 of them were drinkers and 13 were not. For comparison, the time series stochastic model Markov model was employed. hypoglycaemia, normoglycemia,

mild hyperglycaemia, moderate hyperglycaemia, and severe hyperglycaemia were the five states that were taken into consideration. By using a raw method, the probability mass function was created based on the likelihood that a specific condition would occur. According to the initial probability vector, drinkers are more likely than non-drinkers to experience normoglycemia. According to the transition probability matrix, there is a good likelihood that the subsequent state will occur within fifteen minutes. Drinkers have a higher risk of normoglycemia than non-drinkers, according to the stationarity matrix. The average first transit time indicates that there is a low probability of hypoglycaemia to normoglycemia, moderate to mild hyperglycaemia, and medium to moderate hyperglycaemia when moving from one condition to another in the drinker and non-drinker matrix. In both scenarios, the mean initial passage time is comparable, but there are steps that differ. The average return time indicates the duration of a state at a specific state; a short mean indicates the majority of mean state occurrences. In the drinker matrix, mild hyperglycaemia in non-drinkers is more common than normoglycemia. In the discussion, our study compares glucose levels between drinkers and non-drinkers using a Markov model. We found that non-drinkers have higher average glucose levels than drinkers, suggesting that alcohol consumption may impact glucose regulation. These results align with prior studies linking alcohol intake to impaired glucose metabolism. The Markov model provided a good framework for understanding glucose level transitions over time. However, the study's limitations include potential confounding factors such as diet and physical activity not accounted for in the model. Future research should incorporate these variables to validate and extend our findings.

ABSTRACT

Exploring the potential of herbal remedies as a viable solution to combat antimicrobial resistance (AMR) underscores the urgency for innovative strategies amid the diminishing effectiveness of traditional antibiotics. Herbal medicine, deeply rooted in diverse cultural traditions, offers a rich repository of bioactive compounds renowned for their antimicrobial efficacy, presenting a promising avenue in the battle against AMR. This review examines a selection of herbs known for their historical uses in traditional medicine and their emerging roles in modern healthcare. Notable examples include extracts from plants such as *Eucalyptus globulus*, and *Ocimum sanctum. L, Terminalia chebula, Curcuma longa, Morinda citrifolia*, and *Allium sativum*, which have demonstrated antimicrobial activity against a spectrum of pathogens. These herbs contain bioactive compounds, such as Eucalyptol, Eugenol, chebulagic acid and chebulinic acid, curcumin, and Scopoletin which exhibit antimicrobial properties and, in some cases, act synergistically with conventional antibiotics. Furthermore, the review explores the mechanisms these herbal compounds operate, including disruption of bacterial cell membranes, inhibition of essential enzymes, and modulation of immune responses. Additionally, we discuss the potential challenges and opportunities associated with integrating herbal remedies into mainstream healthcare practices, emphasizing the importance of rigorous scientific investigation and standardized formulations. The findings suggest that herbal remedies may serve as adjuncts or alternatives to conventional antibiotics, offering a sustainable and holistic approach to mitigate the escalating threat of AMR. Further research is warranted to elucidate the efficacy, safety, and optimal usage of these herbal interventions, paving the way for a more diversified and resilient arsenal against microbial infections. As we confront the complex

landscape of AMR, harnessing the therapeutic potential of herbs holds promise for developing novel strategies to combat infectious diseases and preserve the efficacy of existing antimicrobial agents.

INTRODUCTION

Antibiotics, whether naturally occurring or synthesized, are antimicrobial agents employed to address bacterial infections by either eradicating the bacteria or impeding their growth. Healthcare professionals frequently prescribe these compounds to counteract bacterial infections in human and animal subjects[1–3].The term "antibiotic" originates from the 1890 term "antibiose," coined by Paul Vuillemin to describe the hostile actions of microorganisms. Initially, it referred to antagonistic interactions between microorganisms like fungi against bacteria or bacteria vs protozoa. Over time, it evolved to include naturally occurring secondary metabolites with inhibitory or lethal properties against bacteria or fungi, now including engineered compounds.[4]Antibiotics have saved lives and significantly impacted medicine and surgery by preventing or treating infections in patients undergoing chemotherapy, dealing with chronic conditions like diabetes, end-stage renal disease, or rheumatoid arthritis, and recovering from complex surgical procedures like organ transplants or joint replacements [5].

Anti-Microbial Resistance (AMR)
It stands as a pervasive global health challenge, imperiling the effective prevention and control of bacterial, viral, parasitic, and fungal diseases.[6] This phenomenon unfolds as microorganisms, encompassing bacteria, viruses, fungi, and parasites, adapt and develop resistance to antimicrobial interventions, a consequence of misguided or excessive usage in both human and animal communities.[7–9]. To effectively address the threat of antimicrobial resistance, we must understand its causes and factors. While resistance naturally occurs in microorganisms, human activities in healthcare, agriculture, and the environment contribute to its emergence. [10]The spread of resistance is influenced by factors like infection control, sanitation, water quality, access to reliable antimicrobials, and travel patterns. Simply removing antimicrobial use may not be enough, as resistance doesn't always come with a fitness cost. To tackle this issue, a comprehensive approach is needed, considering resistance at various levels-mechanism, micro-organism, drug, (11)host, and context. This requires broad research spanning healthcare, agriculture, and the environment, with integrated strategies mindful of potential unintended consequences. The goal is to ensure global access to effective antimicrobials while minimizing resistance.[12,13].

Global Prospective on AMR
Antimicrobial resistance (AMR) is a global health threat causing 700,000 deaths annually due to overuse and misuse of antibiotics in human health, agriculture, and animal husbandry. It could increase to 10 million deaths by 2050 if not addressed. The economic burden of AMR is substantial, with estimates estimating costs of up to $100 trillion by 2050 if left unchecked.[14]Developing countries face increased vulnerability to resistant infections due to limited healthcare and sanitation facilities, and the emergence of multidrug-resistant pathogens like MRSA and XDR-TB, complicating treatment and increasing mortality risk.(15)The antibiotic resistance crisis requires a multifaceted approach, including improved surveillance, stewardship of antimicrobial use, development of new drugs and therapies, and investment in healthcare infrastructure. Collaboration between governments, healthcare providers, pharmaceutical companies, and the agricultural sector is crucial for effective strategies. Public awareness campaigns are also needed to educate individuals about responsible antibiotic use and infection prevention. Future research into novel antimicrobial agents, precision medicine, and innovative technologies is promising. Global efforts and sustained investment are needed to mitigate the threat.[16]

Causes of Antimicrobial Resistance

Overuse: Antibiotic abuse is common due to its widespread availability and unprescribed nature, compounded by online shopping. Incorrect prescriptions promote the formation of resistant bacteria. 30-50% of cases involve incorrect prescriptions for treatment indication, agent selection, or therapy duration. The Karolinska Institute in Sweden found a pathogen in 89% of CAP patients. Additionally, 30%-60% of antibiotics in ICUs are deemed unnecessary or inappropriate [11].

Agricultural Usage: Antibiotics play a vital role in agriculture, accounting for 80% of total use in the United States for cattle growth and prevention. They support animal health, boost yields, and enhance product quality. However, human consumption of cured meat can propagate antibiotic-resistant bacteria across the food chain. Genetic identification studies suggest that up to 90% of drugs are excreted and spread through urine, skin, and agricultural runoff. Personal hygiene solutions may decrease the immune system's reaction to environmental antigens.[17]

Limited Supply of New Antibiotics: The pharmaceutical industry's efforts to create new antibiotics have been delayed due to financial and regulatory obstacles. Major firms have stopped studying antibiotics, and mergers have reduced research staff. Academic funding for antibiotic research has also been reduced due to budget cuts and economic disincentives. Affordability, medical community recommendations for cautious usage, and concerns about drug resistance all contribute to the lack of economic attraction [18].

Regulatory Obstacles: Between 1983 and 2007, new antibiotic approvals fell due to regulatory changes, ambiguous regulations, and poor communication. The FDA has rigorous standards for designing clinical trials, including ethical restrictions on placebo research. Phase 3 clinical research is more complex and expensive, necessitating the involvement of smaller companies. In 2013, the Infectious Illness Society suggested a Limited Population Antibiotic Drug (LPAD) protocol and issued guidelines to improve clinical trials for acute bacterial skin and skin-structure illnesses.[2,11]

Herbs Used to Prevent Amr: The primary focus in treating respiratory, urinary tract, gastrointestinal, and biliary infections, as well as skin issues, has been on utilizing the essential oils of certain plants, rather than their extracts. For instance, *Melaleuca alternifolia*, commonly known as tea tree oil, is widely employed as a therapeutic remedy for skin problems, including acne and various infectious conditions [20].

Mechanism of Action of Herbs: which contain bioactive substances such as alkaloids, flavonoids, terpenoids, and essential oils, have antibacterial properties because they can disrupt cell membranes, impede cell wall formation, block protein and nucleic acid synthesis, and produce reactive oxygen species (ROS) within microbial cells. These antioxidant activities contribute to the antibacterial characteristics. Some herbs also have immunomodulatory properties, which improve the host's immunological response and aid in the successful battle against microbial infections [22].

METHODOLOGY

A comprehensive literature review was conducted using the search terms: antimicrobial antibiotic or antibacterial and synergy and plant or herb or natural. The search encompassed electronic databases such as Ebsco HOST, Pub Med, and Science Direct, as well as specific journals including Planta Medica and Phytotherapy Research. Inclusion criteria comprised studies on synergy between plants exhibiting antibacterial properties, either alone or in combination with antibiotics, published in peer-reviewed English-language journals between January 2000 and May 2023. Notably, this review excluded the extensive body of synergy research from Traditional Chinese Medicine and investigations into the antimicrobial efficacy of essential oils. Additionally, the reference lists of identified studies were manually scrutinized, and supplementary research was pursued online.

Eucalyptus globulus

Eucalyptus, originating from Australia, is renowned for its potent antimicrobial qualities [23]. Derived from its leaves, eucalyptus essential oil contains eucalyptol, a compound effective against bacteria, viruses, and fungi. In respiratory distress syndromes (RDS) like pneumonia or influenza, eucalyptus oil's antimicrobial attributes aid in symptom relief and combatting infections [[24,25]. Inhaling eucalyptus oil vapours or utilizing it in steam therapy helps clear airways, reduce inflammation, and alleviate breathing difficulties associated with RDS.(26) The innate antimicrobial properties of eucalyptus render it widely utilized in both traditional and alternative medicine for managing respiratory ailments.[27,28] A study involving E. globulus, also known as fever tree, found that chewing gum containing 0.6% E. globulus ethanolic leaf extract significantly improved several gingivitis outcome indicators.[29]The study explores the antibacterial properties of crude plant extracts against Porphyromonas gingivitis, a periodontitis-causing bacterium. The extracts from the *Eucalyptus globulus* leaf, *Azadirachta indica* leaf, *Glycyrrhiza glabra* root, and Rheum palmatum root showed MICs ranging from 64 to 1024 mg/L. The study also identified the anthraquinone rhein and its antibacterial activity. *P. palmatum* root extracts showed an extremely low MIC of 0.125 mg/L, suggesting further research for periodontitis treatment.[30]. *Eucalyptus globulus* essential oil, along with xylitol and papain compounds, effectively inhibited *Pseudomonas aeruginosa*, *Salmonella* sp., *Staphylococcus aureus*, *Proteus vulgaris*, *Escherichia coli*, and *Candida albicans in in vitro* tests. The oil showed better inhibition than chlorhexidine, while papain 10% had lower effectiveness against *Candida albicans* [31]. The study investigated the antimicrobial potential of *Eucalyptus globulus* essential oil (EOEG) against seven fish pathogenic bacteria from cultivated olive flounder. The disc diffusion method, minimum inhibitory concentration (MIC), and minimum bactericidal concentration (MBC) were used to evaluate the inhibitory effects. The results showed a concentration-dependent increase in the size of the inhibitory zone with increasing EOEG concentrations. EOEG's MIC ranged from 7.8 to 125 mg/mL, with MBC values ranging from 62 to 250 mg/mL. The study indicates that EOEG, a natural phenolic compound, exhibits antibacterial properties against all seven bacteria, indicating its potential as a potent antimicrobial agent for treating bacterial infections in aquaculture fish.[32]

Ocimum sanctum. L.

Ocimum sanctum, also referred to as Holy Basil or Tulsi holds a cherished place in traditional Indian medicine for its therapeutic qualities.(33) Originating from Southeast Asia, it is globally cultivated for its fragrant leaves, cherished in herbal preparations, teas, and culinary delights.(34) Holy Basil is esteemed for its potent antimicrobial attributes, attributed to its abundant reserves of essential oils, flavonoids, and diverse bioactive compounds.[35] Research indicates that extracts derived from *Ocimum sanctum* exhibit extensive antimicrobial efficacy against a spectrum of pathogens, encompassing bacteria, fungi, and viruses.[36] This remarkable antimicrobial potency has spurred considerable interest in both pharmaceutical and herbal medicine circles.[37,38]O. *sanctum* L. (Tulsi) gel, a plant extract, demonstrated significant antibacterial action against anaerobic oral microorganisms at concentrations of 20 and 25%. A higher concentration was effective in treating periodontitis, proving its potential as an efficient supplement. The study suggests that O. sanctum L. gel could be a promising traditional supplement for treating periodontal diseases, despite limitations and resistance of traditional treatments, highlighting its potential as a viable option in oral healthcare.[39]Cancer research is exploring alternative therapies, with around 30 natural substances being tested in clinical studies. Tulsi, also known as Holy Basil, is a cost-effective and religiously significant medicinal plant in India. Its essential oil contains bioactive components like camphor, eucalyptol, eugenol, alpha-bisabolene, beta-bisabolene, and beta-caryophyllene, linked to antibacterial effects. Tulsi, also known as the "queen of herbs" and "elixir of life" in Ayurvedic medicine, has anticancer properties in its leaves, high in eugenol. Clinical trials are ongoing to explore Tulsi's anticancer, chemo-preventive, and antioxidant properties.[40]The study tested the antifungal and insecticidal properties of *Ocimum sanctum* L. essential oil using a model involving hazardous organisms. Toxigenic and pathogenic filamentous fungi were used as exemplary fungal groups, while *Spodoptera littoralis, Culex quinquefasciatus,* and *Musca domestica* were chosen as model insects. The study found that *Ocimum sanctum* L. essential oil, containing linalool, t-methyl cinnamate, and estragole as phenylpropanoids, is an efficient botanical insecticide with significant environmental benefits [41]. Dental caries is a common issue involving Streptococcus mutants and Lactobacillus acidophilus, but their side effects are significant. *Ocimum sanctum L.*, a plant with a long history in traditional medicine, has potential as an alternative. Despite limited research on its

antimicrobial effects, an ethanolic extract showed a significant inhibitory effect against these microorganisms. The minimum inhibitory concentration (MIC) for Streptococcus mutants was 2.5%, while for Lactobacillus acidophilus it was 10%. This suggests *Ocimum sanctum* L. is a promising antibacterial agent.[42]

Terminalia chebula

Terminalia chebula, commonly referred to as "Haritaki" or "Black Myrobalan," holds esteemed status in traditional Ayurvedic medicine for its multifaceted healing attributes.[43] Originating from Southeast Asia, this botanical gem is renowned for its potent arsenal of antioxidants, tannins, and polyphenols, which underpin its robust antimicrobial efficacy. Scientific inquiry has revealed that extracts derived from Haritaki possess a wide-reaching antimicrobial spectrum, combating bacteria, fungi, and viruses alike.[44,45] Its antimicrobial prowess is rooted in its adeptness at disrupting microbial membranes, impeding enzyme function, and disrupting microbial DNA replication.[46] This comprehensive profile renders *Terminalia chebula* a cherished natural ally in the battle against infections while nurturing holistic well-being.[47] *Terminalia chebula,* an Indian herb, is a highly effective therapeutic agent with diverse applications. The fruit, dubbed the "King of Medicines," contains phytochemicals such as sterols, resin, amino acids, flavonoids, and tannins. The plant's primary polyphenols exhibit antibacterial properties against both gram-negative and gram-positive bacteria. T. chebula fruit extract contains antioxidants, anticarcinogens, antidiabetics, and anti-aging compounds. [48] *Terminalia chebula* Retz, commonly known as Haritaki/Myrobalan, is a traditional herbal remedy with roots in Unani, Tibb, Ayurveda, and Siddha. It has a wide range of medicinal uses, including antioxidant, antiproliferative, antibacterial, proapoptotic, antidiabetic, anti-aging, hepatoprotective, anti-inflammatory, and antiepileptic characteristics. It affects glucose and lipid metabolism, which reduces atherogenesis and endothelial dysfunction. Its constituents include bioactive compounds with antioxidant, antiaging, anti-inflammatory, antidiabetic, and cardioprotective activities.[49]Antibiotic resistance is caused by the misuse of antimicrobial medications for treating infectious diseases. Herbal medications like *Terminalia chebula*, known for their medicinal activity and Ayurvedic use, have emerged as a potential solution. A study found that solvent-free organic and aqueous extracts from *T. chebula* fruits inhibit microorganism development, lowering infection risks and aiding healing. The methanol extract demonstrated notable bactericidal effects and robust antioxidant activity, while the aqueous extract had lesser antibacterial efficacy but moderate antioxidant activity.[50]This study compared the antibacterial and antioxidant properties of ethanolic extracts from *Terminalia chebula* fruits and leaves. The ethyl acetate fraction showed higher levels of TPC and TFC in both fruits and leaves. It also displayed higher antioxidant properties in DPPH radical scavenging and FRAP experiments. The ethyl acetate fraction of fruit extracts outperformed other fractions in terms of antibacterial activity.The ethyl acetate portion of *Terminalia chebula* leaf extracts demonstrated significant antibacterial activity, supporting its historic folk medicine use and scientific evidence for its antioxidant and antibacterial properties.[51]

Curcumin longa

Turmeric, scientifically known as *Curcumin longa* and belonging to the ginger family, originates from Southeast Asia and is widely grown for its rhizomes, utilized both as a culinary spice and in traditional medicine.[52]. Its primary bioactive component, curcumin, demonstrates robust antimicrobial attributes against a spectrum of pathogens, encompassing bacteria, viruses, and fungi. Research illustrates its effectiveness against prevalent microbes such as Staphylococcus aureus, Escherichia coli, Candida albicans, and even certain drug-resistant strains. Curcumin's antimicrobial prowess arises from its capacity to disrupt microbial cell membranes, hinder enzyme function, and intervene in microbial signaling pathways, thus holding promise as a natural remedy against infections.[52,53] Curcumin, a plant-derived polyphenolic chemical, exhibits diverse antibacterial properties due to its unique structural characteristics and antioxidation products. It stops bacterial growth, suppresses virulence factors, interrupts biofilm formation, and prevents adherence to host receptors. Curcumin also acts as a photosensitizer, inhibiting growth when exposed to blue light. Its synergistic properties are demonstrated when combined with other compounds. This analysis provides a theoretical foundation for natural antibacterial agents.[54]. The work aims to improve curcumin by producing Nano curcumin nanoparticles (2-40 nm) by a wet-milling approach. Nanocurcumin demonstrated better water dispersibility and increased antibacterial effectiveness against a variety of bacterial and fungal species, including *Staphylococcus aureus, Bacillus subtilis, Escherichia coli, Pseudomonas aeruginosa*, Penicillium

notatum, and *Aspergillus niger.* It also shows greater antibacterial effects than antifungal properties.[55]. Curcumin, a bioactive compound in turmeric, has numerous therapeutic properties, including antioxidant, anti-inflammatory, antibacterial, antifungal, and antiviral activities. However, its effectiveness as an antimicrobial agent needs further investigation, particularly against clinical and multidrug-resistant (MDR) isolates. A study evaluated curcumin's effectiveness against over 100 strains across 19 species using the broth microdilution method. Gram-positive bacteria showed greater sensitivity, while MDR strains of certain bacteria displayed high MICs. Curcumin demonstrated selective antibacterial activity against specific species and strains, indicating its potential as a promising antibacterial agent.[56] Curcumin (CUR), a turmeric derivative, has antimicrobial properties and can be used as a photosensitizer in Photodynamic Therapy (PDT). However, its hydrophobicity, instability, and bioavailability limit its therapeutic potential. To address these issues, various drug delivery systems (DDSs) have been explored. The study evaluates various DDSs, including Colloidal formulations, metallic and mesoporous particles, graphene, quantum dots, and hybrid nanosystems. Both free and encapsulated CUR show broad-spectrum antibacterial action, low cytotoxicity, in vivo biocompatibility, and enhanced wound healing. Clinical trials are lacking, indicating the need for further research for practical infection clinical scenarios.[57]

Morinda citrifolia

Noni, scientifically known as *Morinda citrifolia*, is a tropical fruit-bearing shrub indigenous to Southeast Asia, Australia, and Polynesia. Revered in traditional medicine for its multifaceted health advantages, Noni boasts a nutritional profile brimming with vitamins, minerals, and antioxidants, which underpin its acclaimed therapeutic properties. [58] Studies indicate Noni's capacity to combat a spectrum of microbial threats including bacteria, fungi, and parasites, owing to its array of bioactive constituents such as anthraquinones, polysaccharides, and flavonoids. [59]. The antimicrobial prowess of Noni suggests promising avenues for infection management and holistic wellness, yet further investigation is essential to elucidate its mechanisms and clinical utility.[60] The study evaluated the antibacterial efficacy of extracts from *Morinda centifolia's* leaves, fruits, and seeds using the disc diffusion method. Five accessions were tested against five bacterial pathogens. The seed extract showed the most significant inhibitory effect (12.23 mm), surpassing leaf and fruit extracts. *E. coli* and Pseudomonas species were inhibited by all extracts, but Salmonella species, *Staphylococcus aureus*, and *Klebsiella* species did not. [61] The study investigates the prevention of bacterial spot, a major disease in passion fruit trees caused by *Xanthomonas axonopodis* pv. passiflorae, which leads to significant annual fruit production losses. Extracts and bioactive substances from endophytic fungus found in noni (*Morinda citrifolia*) are investigated. Nine fungi, including Guignardia mangiferae NF17, show the best inhibitory findings. Sydowinol and Sydowinin A, along with the acetonitrile extract from G. mangiferae NF17, show significant antibacterial action against X. axonopodis passiflorae strains.[62] *Morinda citrifolia,* a traditional Polynesian medicinal plant, was investigated for its antimicrobial potential. Extracts from dried and powdered leaves were prepared using solvents like benzene, chloroform, ethyl acetate, ethanol, and water. The antimicrobial activity was tested against *E. coli, Staphylococcus aureus, Candida albicans,* and *Aspergillus niger* using the disc diffusion method, showing inhibitory effects on all tested organisms.[63]Noni, a Pacific Island medicinal herb, has been shown to have strong antibacterial activity against *Escherichia coli* O157:H7 and *Salmonella Enteritidis*. The study extracted essential oil from ripe noni fruit using hydro-distillation and discovered a substantial inhibitory effect. The primary antibacterial components of noni EO were discovered by GC/MS analysis, with caprylic acid accounting for 82% of the volatile molecules. This study focuses on the antibacterial properties of noni EO.[64].

Allium sativum

Allium sativum, more commonly known as garlic, belongs to the onion genus and is esteemed not only for its culinary applications but also for its medicinal attributes.[65] Rich in allicin, a potent compound, garlic manifests remarkable antimicrobial characteristics upon crushing or chopping.[66] Allicin's release triggers antibacterial, antiviral, antifungal, and antiparasitic effects, as evidenced by studies demonstrating its efficacy against pathogens like E. coli, Staphylococcus aureus, and Candida albicans.[67] Garlic's widespread recognition as a natural remedy for diverse infections underscores its significance, although ongoing research endeavors persist in unraveling its complete therapeutic capacities.[68,69]Garlic is used as a medicinal plant by traditional practitioners in poor countries. The global drug resistance dilemma needs the search for alternative antibiotics, particularly those derived from natural,

plant-based sources. Allicin, a primary active component found in freshly crushed garlic, has numerous antibacterial effects. A study was done to determine garlic's antibacterial properties against typical strains of *S. aureus* and *E. coli.* Four solvents were utilized to extract the bioactive components from garlic. The highest inhibitory zone was discovered in chloroform, followed by water, ethanol, chloroform, and petroleum ether. E. coli was more susceptible to garlic extracts than *S. aureus*, showing garlic's potential as an efficient antibacterial agent against human pathogenic bacteria.[70,71] Garlic, a medicinal herb rich in sulphur compounds, is known for its antibacterial, anticancer, antioxidant, immunomodulatory, anti-inflammatory, and cardiovascular activities. The purpose of this study was to look into the in vitro antimycobacterial and antibacterial properties of several garlic extracts that had been enhanced with certain phytoconstituents. The extracts' activity was assessed using the Resazurin microtire plate test and the colony count method. The results showed that extracts rich in allicin and ajoene had significant antimycobacterial activity when compared to standard medicines. Garlic oil also shown strong antibacterial properties, particularly against methicillin-resistant *Staphylococcus aureus*. [73]An *in vitro* investigation on garlic extract's antibacterial effects on human dental plaque found that it suppressed all bacterial strains examined. The disk diffusion method was employed to test four different doses of garlic extract against *Streptococcus mutans*, *Streptococcus sanguis, Streptococcus salivarius, Pseudomonas aeruginosa*, and Lactobacillus spp. The results revealed that the 5%, 10%, and 20% doses produced similar inhibition zones that were much larger than the 100% extract. The study concluded that the 5% extract had equivalent effects, recommending more research into its potential benefits.(74)The study found that aged garlic has better antioxidant and antibacterial capabilities than fresh garlic. It exhibits higher total phenol and flavonoid content, increased DPPH, ABTS, FRAP, and H_2O_2 scavenging activities in the distilled water extract, and increased Fe_2 chelating activities in both fresh and aged garlic extracts.[75]

CONCLUSION

Exploring the realm of herbal remedies, which includes a variety of natural extracts such as *Terminalia chebula*, *curcumin* from turmeric, *lounga, eucalyptus, morinda citrifolia*, holy basil (*Ocimum sanctum*), and garlic (*Allium sativum*), reveals promising avenues for combating antimicrobial resistance. These botanicals have garnered attention due to their demonstrated antimicrobial efficacy in numerous scientific studies, coupled with their extensive historical use across diverse cultural settings. Despite the promising evidence, a comprehensive understanding necessitates rigorous scientific investigation, including thorough clinical trials. These trials are crucial for delineating the efficacy, safety profiles, and optimal dosages of herbal remedies against microbial infections, thereby addressing the growing challenge of antimicrobial resistance. This approach underscores the importance of evidence-based medicine in the development and deployment of herbal-based treatments. The fusion of ancestral knowledge with contemporary scientific methodologies represents a potent synergy that is poised to catalyze the emergence of ground-breaking herbal remedies. By integrating traditional wisdom with modern scientific rigor, researchers can unlock the full potential of herbal medicines in addressing antimicrobial resistance. Moreover, the augmentation of existing antimicrobial tactics with herbal remedies holds significant promise in global efforts to combat antibiotic resistance. Embracing this interdisciplinary synergy not only represents a transformative era for herbal solutions but also underscores the urgency of fortifying our collective response to the pressing issue of antimicrobial resistance. In essence, the exploration of herbal remedies as potential antimicrobial agents highlights the importance of evidence-based research, the fusion of traditional and modern knowledge, and the collaborative efforts needed to address the escalating challenge of antimicrobial resistance on a global scale.

ABSTRACT

Experimental pharmacology examines the impact of various substances on animal species, identifying therapeutic agents, assessing toxicity, and understanding drug mechanisms and effects in pre-clinical and clinical settings. The complexity of biological processes and limited access to in vivo systems make it difficult to evaluate chemical harmful effects and potential therapeutic benefits on human health. Scientists use model systems like animals and simpler organisms, but these models are expensive, challenging to manage, and often have poor translational value due to interspecies differences. Organ-on-a-chip technology offers potential for clinical translation, drug development, and personalized intervention, addressing current pharmacological challenges, as microfluidic systems have advanced from basic sample handling to bioanalytical apparatuses. This review discusses microfluidic cell culture platforms for engineered tissue constructs, aiming to create a physiologically relevant microenvironment for drug screening studies. Recent developments focus on liver, heart, and lung, with progress in reproducing complex mechanical environments and developing electrical signals. Future studies should focus on creating complex architectures using human cells.

Keywords: Organ-on-a-chip, experimental pharmacology, lung-on-a-Chip, heart-on-a-chip, skin-on-a-chip, kidney-on-a-chip.

INTRODUCTION

In the field of experimental pharmacology, the impact of diverse pharmacological substances on diverse animal species is examined. Identifying a therapeutic agent acceptable for human use, researching a drug's toxicity, and learning more about a drug's mechanism and site of action are the three basic goals of experimental pharmacology. Finding new drugs or examining the effects of ones that already exist is the goal of experimental pharmacology. This is done in two main stages: pre-clinical experimental pharmacology, which identifies and optimizes novel chemical lead structures and tests them for biological effects on animals, animal tissues, and animal organs; and clinical pharmacology, which tests drugs on volunteers and patients to determine their pharmacokinetics, safety, and efficacy in humans. Organ-on-a-chip (OoC) technology has promise for enhancing clinical translation of fundamental research, expediting the development of pharmaceutical drugs, and offering tailored intervention approaches. The discussion of individual OoC systems centers on pertinent applications and emphasizes their capacity to address contemporary pharmacological research difficulties. Microfluidic systems have advanced from basic chemical sample handling instruments to bioanalytical apparatuses and complex cell culture systems in the past thirty years [1]. Because of the intricacy of the biological processes involved and the limited experimental accessibility to informative *in vivo* systems, evaluating the possible harmful effects of chemicals and the potential therapeutic benefits of medications on human health remains difficult. Because of this, scientists use model systems, which may be anything from single cells to animals like rats, mice, dogs, or primates as well as simpler model organisms like the worm *Caenorhabditis elegans* and the fruit fly Drosophila melanogaster. Although the most widely used animal models are very beneficial for studying (Patho)physiology in an *in vivo* setting and for supporting the preclinical development of therapeutics, they are also relatively expensive, challenging to manage, and, in the case of pharmaceutical preclinical testing, often have poor translational value because of interspecies differences [2,3]. Because of this, this review provides an overview and critical evaluation of recent developments in the area of OoC technology, including both single and multi-organ models, with an emphasis on their potential uses in experimental pharmacology. Figure 1 shows a model on OoC technology.

How might organ-on-chip decrease the need for animals while enhancing safety prediction?
OoC models are shown themselves to be more helpful in offering regulated *in vitro* environments for the study of intricate biological systems. Obviously, OoC adds complexity when compared to straightforward single-cell type *in vitro* tests. Larger biological domains seen in OoC often include a greater portion of another network, making it easier to analyze the relationships between each in the network that are relatively distantly linked. OoC's comparatively poor throughput, the intricacy of their kinetics (volume, duration, interactions between cell types), and the challenge of inter laboratory standardization are drawbacks for their use in regulatory toxicology, which exacerbates validation problems [4]. Furthermore, OoC do not provide definitive answers on detrimental health impacts at the level of the intact individual, akin to basic 2D *in vitro* tests. When utilized for hazard and risk assessment, OoC data still need interpretation in the larger context of physiology and toxicology [5]. The evolutionary strategy is similar to the current practice of swapping out individual animal tests with a group of non-animal techniques that collectively anticipate the endpoint that the animal test was intended to evaluate [6]. When standardized and approved non-animal methods are available, the evolutionary approach is used one step at a time. Comparing an alternative strategy to reference animal data is still used to see how well it predicts or can be used. The ICH (for medicines), the OECD (for chemicals), and EU guidelines (like the EMA) have already approved and validated a number of non-animal methods for testing for toxicity endpoints, such as genotoxicity, corrosion and irritation, and sensitization. For more complicated outcomes, such as acute toxicity, repeated-dose toxicity, carcinogenicity, reproductive toxicity, and neurotoxicity, there aren't enough approved non-animal approaches. On the other hand, the innovative method begins with the discovery of significant metabolic or molecular pathways associated with human illness. The purpose of the tests is to find important rate-limiting stages in physiological systems (networks) that cause toxicity by messing up chemicals [7,8]. This technique establishes relevance based on physiological relevance, which is a measure of how well a test strategy or method covers the key molecular network events that generate toxicity. A test procedure's

prognostic power is its ability to forecast whether a chemical may disrupt this network to the point where it causes long-term negative consequences [8]. The goal of both the evolutionary and revolutionary approaches is to shift the focus of toxicology and pharmacology from mostly using animal experimentation to primarily using human physiology. OoCs have the remarkable ability to mimic human physiology, which is one of their main advantages. This is particularly important when using whole tissues rather than isolated cells since it allows for direct interaction between cells as well as between cells and external elements like the extracellular matrix. Comparing these interactions to a suspension culture where individual cells do not have direct touch should result in a pharmacologic or toxic response that more closely mimics the in vivo environment. Additionally, the ability to apply shear stress, drain waste products, and have a dynamic supply of nutrients should improve compatibility with the in vivo environment. Furthermore, ongoing reaction monitoring is made possible by the OoC's sensor integration. using a variety of methods to provide a complete picture of the pharmacologic or toxic response, such as concurrently evaluating the impact on cell metabolism [9]. Sensor technology allows for online electrochemical detection of several biomarkers, such as albumin and glutathione S-transferase, which are liver biomarkers, and creatine kinase, which is a cardiac biomarker, in addition to continuous monitoring of temperature, pH, and oxygen [11]. However, modest quantities and concentrations of signaling molecules, as well as their dilution, may provide difficulties for further analytics (dynamic range, background issue).

One of the main benefits of OoC over animal models is the ability to incorporate targets particular to humans, allowing for the identification of chemicals that have distinct pharmacological or toxicological effects exclusively in humans. The ability to combine (i) exposure/treatment, (ii) kinetics, and (iii) impact is another significant advantage of OoC. In a suspension cell culture, exposure and effect are immediately correlated, eliminating the need to assess kinetics. It is crucial that *in vitro* data be stated quantitatively in order to extrapolate the concentration response *in vitro* to the dose-response *in vivo* and provide quantitative predictions of dose-dependent unfavorable outcomes *in vivo*. This calls for a more thorough *in vitro* evaluation than the typical positive-negative chemical effect determination [10]. To translate *in vitro* exposures to *in vivo* exposures, kinetic modeling is also necessary. In addition to the compound's effects on the cells that make up the barrier, including any deleterious effects on the barrier function itself, the chemical or pharmaceutical's ability to flow across the barrier may also be assessed. Exposure, kinetics, and effect may all be combined in these models. Should the detrimental impact indeed transpire in a tissue other than the barrier, details on the kinetics beyond the barrier could be necessary. The tissue that makes up the barrier and the tissue where the negative impact occurs may mix in OoC [11].

Toward coordinated development and implementation of organ-on-chips
Human biology, engineering, and biotechnology are just a few of the fields that must be merged in order to imitate tissue, organ, or organ system structure and function for the creation of OoC. Many stakeholders must be included in order to fully realize the benefits of Outcome of Care (OoC) for toxicology and pharmacology, as well as to determine the next steps for the practical use of OoC in the safety testing of chemicals and the effectiveness and safety testing of medicines [11]. The European Union's Horizon (EUR) 2020 research and innovation program is supporting EUROoC, an interdisciplinary training network that aims to advance OoC technology in Europe. Its primary goal is to establish a network of application-focused researchers that are proficient in the creation and use of OoC technology [11]. By doing this, it hopes to foster creative research endeavors that, in turn, progress the creation of cutting-edge OoC systems. The development of OoC to more precisely anticipate medication safety and effectiveness in people is the program's main emphasis. To drive OoC toward acceptability and implementation in regulatory decision making, NCATS and other stakeholders, including FDA regulators and the pharmaceutical sector, developed public-private partnerships [11,12]. Talks about building trust in the technology's performance are required, since OoC is used to provide data that demonstrates safety. As a consequence, OoC technology may need to be modified to meet regulatory requirements. One benefit is that it will encourage conversation about updating toxicity and make room for new ideas.

Hisana Thasneem *et al.,*

Current and emerging methods in toxicology and regulatory pharmacology

Animal tests have been and continue to be the traditional method used to evaluate the safety of industrial chemicals as well as the safety and effectiveness of medications. When it comes to medications, thorough clinical testing on human volunteers in good health is often conducted after animal research, and then patient testing follows. Safety testing follows a methodical, tiered process. First-in-human trials employ the safety data from repeated-dose toxicity studies to determine the starting dosages. To provide a first indication of human relevance, exposure levels in animal studies are compared to human exposure at the estimated maximum recommended human dosage (MRHD). If you want to use a model, make sure it is pharmacologically relevant. This means that it expresses the drug target and changes downstream effects in a way that is similar to humans, that it is compatible with the drug's pharmacokinetics (having a similar metabolic profile and good bioavailability), and that it is safe for the test species. International Conference on Harmonization (ICH)highlights the need to consider product-specific factors such as the non-metabolization of monoclonal antibodies and the general restriction of the model of choice to non-human primates due to the target sequence. To enable longer and longer clinical studies, sub-acute and chronic toxicity testing is started later (i.e., phase 2 and 3 trials). It is generally accepted that for animals undergoing acute, subchronic, and chronic treatment, a dose selection limit of 1000 mg/kg/day is sufficient [13]. Mechanistic features have gained significance in assessing the safety of chemicals and pharmaceuticals for human use in recent years. In the past, adverse health effects and the exposure levels at which they were identified in animal studies have been the main basis for chemical hazard and risk assessment as well as pharmaceutical safety review. A deeper analysis of the differences between species and the application of findings from animal research to human situations are made possible by an understanding of the effects and processes of chemicals [14]. Pharmaceuticals are now used mostly for prescreening purposes in safety evaluation, in order to determine if a chemical is promising enough to proceed with animal safety research before being determined to have undesirable features. Furthermore, mechanistic studies for certain functional properties of substances and pharmacodynamic analyses for medications have been using in vitro research more and more [15]. To help with the creation of suitable in vitro models for both drug and toxicity testing, multi-OoC models that simulate the interactions between many organs have been created. When it comes to drug screening, OoCs may verify the efficiency of the medication in treating the desired target pathways as well as the lack of hazardous consequences (by evaluating, for example, liver, cardiovascular, or skin toxicity) [16].

Lung-on-a-Chip Systems: Enhancing Disease Models via Biomechanics

Inhaled air flows from the conducting zone (trachea, bronchi, bronchioles) to the respiratory zone (alveolar ducts to alveoli sacs) in the respiratory system for gas exchange [17].0 All things considered, the lung lobules are divided into segments, which are distinct functional units made up of an artery and a bronchus [18]. Lung and respiratory system pathologies include cystic fibrosis, bronchitis, lung cancer, chronic obstructive pulmonary disease (COPD), and asthma [19]. Preclinical models for lung disorders in humans are currently based on ex vivo lung tissue or in vivo rodent models, which can only partially replicate human pathologies [20,21]. Although tissue availability limits ex vivo approaches, they offer an interesting substitute for existing animal models by simulating the cellular architecture, structure, function, and dynamics of airway contraction relaxation in millimeter-thick lung slices of living lung tissue [22]. Moreover, the short experimental time frame of days to weeks for testing explant cultures poses a significant challenge for long-term research on chronic illness scenarios. Recent developments enable the in vitro reconstruction of human lung tissue and related disorders. Lung-on-a-chip models may stimulate epithelial development and physiologic functioning by simulating breathing movements using stretchy membranes [22].

The topic of "lung-on-a-chip systems," or micro-physiological models for human lungs, had its start in 2010 when Huh et al. created one of the first biomimetic microfluidic lung models that could subject alveolar cells to dynamic stretching. To make a copy of the alveolar-capillary interface, human alveolar epithelial cells are grown on top of a porous, flexible poly-dimethylsiloxane (PDMS) membrane, and microvascular endothelial cells are grown on the bottom. The gadget simulates breathing movements in the cell cultures by stretching them repeatedly and providing suction to pneumatic passages on each side of the membrane [23].

Valid Models for Pharmaceutical Screening

The liver is the biggest internal organ in humans and plays a role in detoxification, drug metabolism (first pass effect), and other metabolic processes that control blood sugar, bile formation, and the synthesis of several plasma proteins, including albumin. Anatomically speaking, the liver is composed of liver acini, which are the liver's functional units made up of liver sinusoids and linked to a sophisticated network system that includes the bile ducts, portal vein, hepatic artery, and central vein [24]. Pharmaceutical research focuses a lot of attention on the liver because of its general significance in drug metabolism [25]. The liver is an important organ that is highly regenerative and plays a crucial function in protein synthesis and xenobiotic metabolism. Notwithstanding, several factors such as medications, poisons, viral infections, cancer, and traumatic traumas may still cause irreversible tissue damage and reduction of liver function, ultimately culminating in end-stage liver disease or abrupt liver failure [26,27]. Human liver slices and mouse animal models have been utilized extensively up to this point in pharmaceutical research for drug screening, toxicity testing, and pathophysiology investigations on fatty liver disease, both alcoholic and non-alcoholic.For a variety of organotypic complexity, basic methods for recapitulating liver function utilizing liver on a chip devices may be identified. Kang et al. created an organotypic fusinusoid on a chip system to enhance biomimetic design. They did this by adding a simpler liver model taken from animals to study the propagation of the hepatitis B virus (HBV). The main features of the liver sinusoid, such as cellular architecture, biodynamic angiocrine stimulation, and parenchymal zonation, were demonstrated in a different study using a liver-like microfluidic device called "Exoliver culture." It also showed a different response to acute treatment with known hepatotoxic drugs than those observed in conventional culture platforms. Hepatocytes may also be co-cultured with other support cells, such as endothelial cells. Liver-on-a-chip platforms are organotypic models that recapitulate liver functions for basic science using a variety of cell types and co-culture techniques; however, because the biochips only have one or two individual liver units per chip, these biomimetic systems are not scalable for high-throughput experimental setups [28].

Heart-on-a-Chip: Determining the Positive and Negative Effects of Medicines in Health and Illness Heart

Maintaining cardiac physiological functioning is largely dependent on the biomechanical environment, structural complexity, and exposure to dynamic stimuli of the heart. We can carefully manipulate each of these parameters using microfluidic *in vitro* platforms, which allows us to investigate heart physiology and a variety of diseases such myocardial infarction, arrhythmia, or cardiomyopathy [29]. Nonetheless, the heart is a crucial target tissue for any drug development and interaction investigation because of the high morbidity of cardiac illnesses and the frequent side effects of medications. One of the main benefits of OoC technology over conventional *in vitro* systems is tissue for drug research and cardiac function monitoring utilizing on-chip and off-chip sensor techniques. Figure 2 shows a model of heart-on-a-chip platform.

Combined Epidermis Full Skin Thickness Models: Skin-on-a-Chip Systems

The skin, the largest organ of the integumentary system, is the body's first line of defense against external effects. *Ex vivo* skin models are used for drug testing due to their ability to represent the hierarchical structure of the barrier. However, their application is limited by tissue accessibility and short-term survival. To overcome these limitations, companies like StratiCELL, J-TEC, Cell Systems, Henkel AG, Biosolution KO, and Episkin have invested in creating full-skin and epidermis versions of these models. Additionally, significant progress has been made in the development of microfluidic skin-on-a-chip models, such as Alexander et al.'s skin-on-a-chip system that measures extracellular acidification rates and TEER in an air-liquid interface setting. Sriram et al. developed a mass-producible four-layer platform based on polymer polymethyl methacrylate (PMMA) to produce skin equivalents with minimal hydrogel shrinkage [30]. PEG-fibrin-embedded fibroblasts were used to generate dermal equivalents, followed by N/TERT-1 keratinocytes co-cultured on the apical side. It will be necessary for future on-chip skin models to take into consideration both the neurological and immunological systems in order to produce a miniature version that closely mimics physiological skin [31]. According to Lee *et al*. [32], organoid technology may be used to generate skin appendages such as follicles and glands, which should be taken into account when designing skin-on-a-chip systems from an anatomical perspective. The regulation of fluids, temperature, and external stress depends on these structures. Moreover, biomechanical cyclic strain should be taken into account for future models, much like the lung-

on-a-chip approach, because loading is essential for maintaining skin homeostasis and overuse may trigger fibrosis pathways [33,34].

Kidney-on-a-Chip: Assessing Drug Efficacy and Nephrotoxicity
The internal circulation's equilibrium is mostly maintained by the kidney. It controls blood pressure, preserves vital nutrients, keeps pH at a physiological level, and gets rid of waste products like medicines and their metabolites. As a result, the kidney experiences a high metabolic turnover rate, a big cardiac output volume, extended concentration abilities, and effective chemical trafficking, all of which may heighten the kidney's susceptibility to drug-induced unfavorable effects. Acute kidney damage occurs in a clinical context, and 20% of cases of acute kidney injury are brought on by kidney toxic medicines [35,36]. This indicates that the present protocols for evaluating drug toxicity need to be strengthened. Kidney dysfunction brought on by adverse drug reactions is still a crucial factor to take into account while developing new medications. It is crucial to note that because of the apparent differences in medication pharmacokinetics and pharmacodynamics between humans and animals, standard *in vivo* animal trials are especially restricted when it comes to assessing therapeutic effectiveness and nephrotoxicity. Human kidney-on-a-chip systems have recently been created in a number of forms that mimic the kidney tubule microenvironment and have shown similarities to *in vivo* medication nephrotoxicity outcomes. Researchers may assess and monitor different drug-induced biological reactions using kidney-on-a-chip systems [37], indicating possible advancements in disease modeling and drug lead optimization research. However, there are still some bioengineering obstacles, mostly related to recreating the intricate architecture, cellular makeup, and matrix composition required to accurately simulate kidney function at an organotypic level. Other kidney-on-a-chip technologies use milli fluidic systems to connect organoids while they are flowing to increase the body's supply of endothelial progenitor cells and build vascular networks with mural cells around perfusable lumens [38]. Compared to controls that didn't move, vascularized kidney organoids grown under flow had more mature podocyte and tubular compartments, as well as better adult gene expression and cell polarity. We can now study kidney development, illness, and regeneration in new ways because we can make kidney organoids much more vascularized and help them mature morphologically in a lab setting while they are flowing. Chemical substances are also eliminated via the kidney and/or biliary system, which is a factor that is often disregarded and affects the body's medication concentrations. Figure 3 discuss the active stimuli including fluid shear stress, compression and cyclic stretch that are incorporated into kidney-on-a-chip models.

Barrier Function, Transport Characteristics, and Neuroinflammatory Model: Blood-Brain- Barrier-on-a-Chip
A highly selective barrier, the blood-brain barrier (BBB) maintains the separation of the circulatory blood from the central nervous system (CNS). It is vital to preserve brain homeostasis by tightly regulating the movement of molecules and ions [39]. Nevertheless, the BBB is the largest barrier to cerebral medication delivery because of its complicated selectivity, which also prevents possible treatments from reaching their intended target in the brain [40]. Consequently, the goal of several investigations using OoC technology has been to decipher the BBB's Four different chip designs (sandwich, parallel, tubular structure, and vasculogenesis design) have been created for BBB-on-a-chip systems throughout the years. Using a porous membrane to divide the top and bottom channels, the sandwich design attempts to replicate the classic Transwell-type arrangement. Typically, astrocytes, pericytes, or other CNS cells are seeded in the bottom channel, while endothelial cells are sown in the top channel. Owing to its arrangement and the low transparency of porous membranes, only sophisticated confocal imaging methods are possible for imaging [40].

Multi-Organ on-Chip Models: Combining Tissue Models to Evaluate Pharmacokinetics, Pharmacodynamics, and Drug-Drug Interactions
Currently, over 70% of medication attrition and removal from the market are caused by drug-induced toxicities in the liver, heart, kidney, and brain. Off-target interactions or the medication's increased binding to toxicity-prone cells are common causes of adverse drug responses [41]. An effective method for examining the pharmacokinetic profiles of pharmacological molecules is the use of linked multi-tissue cell culture models, as deficient pharmacokinetics (PK) and pharmacodynamics (PD) are major contributors to therapeutic failure. For example, as described by Shinha et al

Hisana Thasneem *et al.,*

[42], drug-to-drug interactions were examined by combining the experimental data obtained from the Multi-OoC (MOoC) with a mathematical PK–PD model. The effects of CPT-11 metabolites, an anti-cancer prodrug, on lung cancer cells were studied in depth. The ability of simvastatin and ritonavir to block the metabolism of CPT-11 was examined in order to assess drug drug interaction and the ensuing changes in drug concentration and metabolic capacity. The MOoC that was shown had a lung cancer component (A549 cells), a stirrer-based micropump coupled via micro-channels, and a pro-drug metabolizing liver portion (HepG2 cells). In the end, it was indicated that the combination of the PK–PD model and the MOoC is a helpful technique to anticipate adverse effects of medications. Drug-specific parameters were obtained by a combination of a simulated PK–PD model and the experimental data, exhibiting similar results. The effects of the anti-cancer drug 5-FU and the two pro-drugs of 5-FU (CAP and tegafur) were assessed in terms of intestinal absorption, hepatic metabolism, and growth inhibition in cancer and connective tissue in a more sophisticated, pneumatic, pressure-driven, four-organ system made up of intestine, liver, cancer, and connective tissue models [43]. Additionally, to replicate in vivo absorption, distribution, metabolism, and excretion behaviors, Maschmeyer *et al*. incorporated skin biopsies in a four-organ system made up of a liver, gut, skin, and kidney model [44]. These tissue types are very important to evaluate multi-organ medication interactions since cardiac and liver toxicity are the main reasons for post-approval drug withdrawals [45]. A MOoC platform, for example, was reported by Oleaga *et al*. [46] and enabled the investigation of a long-term co-culture of hepatocytes and cardiomyocytes.

CONCLUSION

This review discusses microfluidic cell culture platforms for engineered tissue constructs, which aim to create a physiologically relevant cell culture microenvironment for drug screening studies. Recent developments focus on the liver, heart, and lung, with progress in reproducing complex mechanical environments and developing electrical signals for monitoring cardiac cells. Future studies should address creating a physical microenvironment with complex architecture, using human cells, and minimizing in vivo animal experiments. Microscale engineering technologies can combine multiple organ constructs on a chip, making systems more physiologically relevant than current in vitro models.

ABSTRACT

Fuel cells are an ingenuous environmentally friendly technology that has numerous uses across various fields and industries. These are electrochemical systems which convert chemical energy into electrical power in a way that is efficient and reduces emission. Fuel cells made of hydrogen are able to be used in a variety of application options ranging from portable energy sources to massive energy production. This makes hydrogen fuel cells excellent for use as mobile power sources as well as energy production in transport applications including zero-emission mobility vehicles that have a longer distance of travel. Fuel cells provide quick refueling time and less carbon dioxide emissions than conventional internal combustion engines. This makes they a cost-effective and greener alternative to the traditional engines. Technology for fuel cells is able to be used in a variety of applications in various industries and fields; it are a huge amount of writing on these technologies. This article provides a glimpse into certain of the key studies conducted in the development of fuel cells.

Keywords: Fuels Cells, Hydrogen, Regenerative, Bio, EV, PEMFC.

Nithish Reddy and Siva Reddy

INTRODUCTION

Fuel cells are the most cutting-edge, green technologies that have attracted significant attention because of their ability to change sectors and lead to the creation of a more sustainable energy future. Although traditional power generation using combustion methods generate emissions-intensive power generation, the fuel cells offer a green alternative to energy that has lower emissions output and are highly efficient in cost and emitting zero waste. This article provides an introduction and overview of what fuel cells are and their many uses across a variety of sectors and uses. They operate on the most simple of principles: changing the chemical energy of the oxidizer and fuel to electrical energy by electrochemical reactions. They are typically which are powered by hydrogen or oxygen in the air. Hydrogen serves as both the fuel source as well as an oxidizer. As hydrogen splits into protons and electrons, protons travel along proton-conductive electrolyte while electrons make their way out through external circuitry to form electrical current - until eventually reaching their cathode where these combinations will combine again to produce water and heat as byproducts of their reactions with protons/electrons/oxidizer combination as byproducts of their electrochemical reactions resulting in water and heat byproducts as byproducts of their combined actions. The fuel cells have proved their value in a variety of application areas due to their remarkable abilities: from marine transportation applications (ie propulsion for ships) and medical application to automotive and energy storage. Transport: Fuel cells have been leading the way in the transition to a zero-emissions transportation revolution.

Hydrogen fuel cells (FCVs) run on hydrogen fuel cells, which produce energy onboard to drive with electric motors that are driven through fuel cell technology. FCVs provide long driving distances and quick refueling time, as well as zero emissions from tailpipes, which makes them a desirable alternative to vehicles powered by internal combustion engines. Stationary power generation Fuel cells can be used in stationary power applications for producing electricity and heating for commercial, residential facilities, and industrial. Cogeneration systems that make use of CHP as well as cogeneration cells techniques improve efficiency of energy as well as providing useful heat for reducing the greenhouse gas emission. Backup Power Solutions The fuel cell technology are reliable power backup solutions for critical infrastructures such as data centers, data centers and other emergency operations. They are quick to start up and long-lasting operation makes the ideal tools for providing continuous electricity during grid interruptions. Fuel Cells for Off and Remote Energy: Fuel cells supply crucial electricity in areas that have access to electricity grid might be restricted or not available, such as telecom infrastructure remote monitoring devices as well as military equipment that requires continuous power 24 hours a day, 7 days a week. They are reliable sources of power that can provide vital solutions like monitoring the telecom infrastructure devices, as well as secure sources for power needs of military equipment. Manufacturing and Industry Fuel cells have been found to have wide-ranging applications in processes that need the highest temperatures to produce heat like the production of metals or chemical processing. The solid oxide fuel cell (SOFCs) as well as the molten carbonate fuel cell (MCFCs) are used in cogeneration as well as for process heating and process heating applications, respectively. Aerospace fuel cells are an integral part of aerospace technology, providing lightweight but energy efficient power to UAVs that are not piloted (UAVs) and spacecraft mission that require extended operation compared to combustion engines or batteries. Hydrogen Production A fuel cell plays vital roles in generating hydrogen which is a green and diverse energy source. Electrolysis that makes use of renewable energy breaks water down into oxygen and hydrogen, and any leftover is then put into fuel cells, or for future use. The fuel cells are an essential role in the transition to a low-carbon and sustainable energy sources, due to their flexibility, effectiveness as well as their low environmental footprint providing attractive alternatives across various sectors, and offering an opportunity for a sustainable and cleaner energy to come in the near future.

LITERATURE

Fuel Cell Vehicles incur higher expenses for capitalization as compared to Battery Electric Vehicles and also are susceptible to significant costs depleting in the future. When you distinguish the two types of Fuel Cell Vehicles and

Nithish Reddy and Siva Reddy

Battery Electric Vehicles. Battery Electric Vehicles can travel with greater speed ranges when compared with conventional automobiles and are fuel efficient with a brief fueling time, i.e. about three minutes[1].The idea behind this is to determine the specific area to particular resistance simultaneously using the solid Oxide Fuel Cell Interconnect issues in Fuel Cells, 2019, vol.19, no.5.This procedure supplies the complete method for working out the output of coatings as a specific area resistance. This method was supported by the 100 and 2000 hours of Area-specific resistance measurements of uncoated and coated 22 steel samples. It was intended to confirm the resistance perception and chromium capabilities, as well as the corrosion and coating of steel specimens coated with specified terms that replicate a realistic collection of a single structure[2]. It is widely known the fact that SOF cell systems are suggested for Ammonia applications. This study aims to study the operation and stability of Ammonia decomposition reaction using Nickel catalysts that are based on nickel and also the auto-thermal Ammonia cracker utilizing the Co-CeZr catalyst for composite oxides studied. It was found that direct NH3-fueled Solid Oxide fuel cell load was able to be regulated for 1,000 hours at 770°C, without major reductions[3].If the market expansion in micro-combined Heat power systems is examined, it could aid in achieving the energy goals of the strategy and meet atmospheric commitments. The research has shown that in the past and in the misperceptions given that the biological clock produces the greenhouse gas of a micro Combined Heat and Power systems can be found under a gas heat pump[4]. Production of power and the extended durability of solid oxide powered by ammonia fuel cell systems are studied using Solid Oxide Fuel Cell stacks comprised of 30 anode planar-powered cells. Three operating techniques are employed, which include direct ammonia, external decay, and auto-thermal decomposition. The result of auto thermal decomposition in conjunction with other methods using ammonia-fueled mass has an impressive strength when used in continuous methods and The efficiency of energy conversion is 57%[5]. Jacobson [6] conducted a study of components such as the solid oxide fuel cell that has an important function that demands operating temperatures between 500-800 degrees Celsius. Furthermore, it is important to know the type and characteristics investigated in this procedure. Fernandez et al.[7] studied the idea of carrying anode in H+-SOFC material that employs the triple conductor (H+/O2/e) oxide (TCO) for cathode for H+-SOFCs. The stability of single cells is demonstrated. Mermelstein *et al*. focused on the creation and demonstration of the reversible fuel cell. The extra grid energy, which is produced by renewable sources is delivered to the operating system via electrolysis, and it generates H2.Sunfire creates a variable element of the solid oxide cell with an efficiency of 50 kW for SOFC or 120 kW for the electrolysis process and generates 3.5 kg of H2 every hour. Wiebe in collaboration with [9] studied ways to increase the advantages of fuel cells in reducing hydrogen consumption.

This article outlines the functioning of electrochemical hydrocarbon compressors that facilitate the retransformation of hydrogen. It is found that installing an electrochemical blower that has hydrogen compressors can reduce the amount of hydrogen waste, removing approximately 95% of the waste and the production of a fuel cell can be increased. Debruijn et al.[10] have stated that with the modification of flow designs and stack design, voltage debasement is reduced to the minimum level that is possible. It is possible to achieve this by using those who have constant load conditions with fuel that operates at to evaporation of nearly 100 percent, as well as a temperature of a maximum of 75 degrees Celsius. The result will be greater profit and reduce your financial prudence as well as strength. the primary factor to figure out how to achieve profits. Pivac et al.[6] prove that it is possible to decrease the time spent in soak. Evaluation of the temperature of cells using Ice resulted in high-yielding and improved results. The outcomes of the increased stress test set-ups comprise the efficiency of voltage, followed by specific electro catalyst debasement, and returns each 2,500 voltage cycle for a previously-conditioned 50cm2 fuel cell. Varcoe et al.[11] have validated the use of radial approaches for making use of membranes that exchange anion with alkali to overcome the problems with direct methanol fuel cells. the advantages and disadvantages of the direct electrochemical oxidation process of the backup fuel are also discussed, as is the use of alkaline membranes in these fuel cells, which could improve effectiveness and productivity. This paper discusses the debasement mechanisms made up of nickel-yttria stabilized zirconia electrodes used in solid oxide cells, predominantly electrolysis cells of solid oxide. The investigation of the writing data reveals several different and at times, contesting the debasement status is a consequence of the cooperation between the and the loss contacts between Nickel and **particles of** Yttria stabilized zirconia electrodes as well as Nickel-Nickel particles[12-13[12-13]. Durability is the most important issue to be resolved before the materialistic proton exchange membrane-based fuel cells can develop. This article examines

79532

the techniques for debasement of membranes, electrodes, as well as bipolar plates[14and 14.Tai et al.[15] focused on the advantages and the approach to additive manufacturing that allows for an advantage in the output of fuel cells. Principally, the dares and assignments to improve performance are suggested. Taner et al.(16) attempted to make hydrogen gas energy by using innovative technology that charges reactions through electrolytic motions and to research a device that generates electricity using hydrogen. Viitakangas et al.[18] have demonstrated that the deficiency effects of toluene Proton Exchange Membrane Fuel Cell are ignored up to at least 20ppm. Then it goes up to 50ppm for toluene within hydrogen fuel. The principal goal of increasing the efficiency of fuel-cell electric vehicles is to increase their endurance. To allow for the development of Pt deposition, a process of debasement begins. The spaces between MPL and a catalyst layer saturated with water can be recommended to serve as the point from which to begin the Pt deposition[8].Energy balance in a Ballard proton exchange fuel cell membrane is examined in this study. A transient phenomenon occurs when the PEMFC stack loads when it is a result of warming up it is triggered when you connect the Proton Exchange Membrane Fuel Cell stack to a direct current or Alternate Current inverter. The results of experiments on a higher PEMFC stack's performance are also discussed[9]. The capability of MECs to react 0.9 million cubic meters of wastewater every day, to meet the European Standard for Chemical Oxygen Demand removal during winter temperature is being debated. The cathode's efficiency is below ten percent, and the hydrogen that is produced was generated for more than a hundred and twenty-seven days [20].Winkler et al.[21] described the creation of heat engines for fuel cell hybrids and combustors using different techniques being studied and developed. A combination of two subsystems creates hybrid fuel cells like fuel cells and heat engines. create hybrids from fuel cells[21]. Energy is a major component of human existence. is a key element as a factor, the need for energy rises and forms an integral part of energy generation.

Energy sources that are required include a fuel cell, which is a natural resource. This means that energy is generated at a lower cost than conventional electricity grids. In MATLAB, the modeling of fuel cells is carried out. The purpose of this research is to analyze and model the properties that the hydrogen fuel cells provide as well as the efficiency of the Product Identity controller for the fuel cell that uses hydrogen is the goal of this study[22].Tao *et al.* The study concludes the study by investigating the possibility of using liquid tin as a technique to lessen the harmful effects of pollution from coal, so if a method for reducing risks in a technological solution that directly converts coal by using fuel cells [23].Reinert et al.[24] presented a method to determine the use of fuel for a cell's load using the voltages of cells for different fuel types. The method used to determine the fuel usage in most of the tests isn't the same as that of the fuel used. Dimitrova et al.[25] examined the impression of electric vehicles equipped with range extenders that follow that allow the freedom of the vehicle to be expanded. Also, it examines the stability of the energy produced by different species of fuel cells that are charged with bioethanol. There are three ways to achieve the conversion of ethanol. These are Form 1: improvement of the bio-ethanol inside the outside refiners and hydrogen, as well as its transformation into an alkaline fuel cell. Form 2. : enhancing bio-ethanol within the refiner's outer layer to hydrogen and the transformation it undergoes in the fuel cell made of solid oxide Form 3: In the solid oxide fuel cell, you can see directly altering the bioethanol. As a result, we know that the most efficient design is form 3.The version 3 is more efficient in delivering power to the fuel cell. A fuel cell that is paired using a small quantity of oxidant and fuel is the ideal battery.

The fuel cell which is stationary from several angles is believed to last for 40,000 hours as a primary battery. They are employed for continuous tasks or work and are the most common type of battery used is used for short-term use. In the course of battery dispensing for a single cycle, debasement is not completely separated from the power generation. Debasement in a battery could be observed clearly, more than the process of processing. For the fuel cell, may be different from a battery, the process that causes debasement can't be controlled by the current efficiency of its density. The lifespan, as well as the capacity that a fuel cell loses capacity cell, is dependent on how the cell operates[26]. Three ways to define the manufacturing of fuel cells.1)thermal efficiency is a measure of the efficiency of exegetics, and 2)Area Specific Resistance is measured through the rate of variation of the exergetic efficiency.3)It is power density, which could be correlated with the potential economic value of the fuel cell [27].Wachsman et al..[28] observed that if hydrogen is considered a fuel cell, the majority of fuel cells increase in size and expand. Fuel cell machinery is now akin to hydrogen-related machinery from a general perspective. As a result of the study, the

development of equipment for fuel cells has risen as well as decreased in general an economy that is based on hydrogen which has restored the fossil fuel subordination. For this efforts are focused on the aggregation process of metal-supported cells, direct deposition including seal and stack technology, and low-temperature sintering low temperatures ceramic. The elements are being incorporated in low loads that are being developed at IFCI to help carry the power of materialistic technology. In the meantime, Direct deposition technology has been developed rapidly and has reached the point that 5x5 metal cells can be made with sintering temperatures that are below 800 degrees C. The outcomes of this work will be presented, along with the path of progress at IFCI [29].The purging control scheme of action as well as the thermal management mechanism for the fuel cell was proposed by Wei and al.[30] .We can now determine how fast the fuel cell can initiate the fuel cell in thirty degrees Celsius. Experimental results indicate that the power output of the fuel cell ranges between 42 to 75 percent of capacity, while the wasted heat usage accounts for 32 to 100 percent of total power. The fuel cell made of solid oxide was 10 micrometers thick, and also a Nickel Secondary Domain Controller anode that had a thickness of 15 micrometers. The thickness was reduced by screen printing, co-firing and casting. Cells that had a cathode surface of 16cm2 demonstrated the highest electrochemical capability at temperatures of 600°C and a maximum power density 0.9W/cm2 that was achieved with hydrogen fuel[31The thickness was replaced by co-firing, screening printing and casting. Narayana et al.[32] concentrated on three novel fuels for direct-oxidation-type fuel cells.

They are trioxane dimethoxyethane, and trimethoxymethane. The fuel cells by oxidation process uses carbon dioxide as well as Methanol. Modern fuels are utilized with no further process to direct-feed electrolyte fuel cell. Shanbhag et al.[33] focused on studying aspects that impact the production of the future as well as longevity of the fuel cell according to the different views of the present. Based on the research currently conducted that is conducted in the cells that produce fuel, variables like pressure, temperatures and other topics like corrosion fuel and oxidant insufficiency the chemical reaction, humidity and insufficient management of water are among the major factors that result in poor production. In the process of making fuel cells, there is to overcome the problems and methods that could increase the efficiency and longevity of fuel cells. Solid-state supporting metal oxide semiconductor-compatible glucose fuel cells, with carbon nano broadcasts with various ratios of Carbon-Nitrogen-Hydrogen and glucose solution were inquired in this paper. The fuel cell has been built using materials which are biocompatible with humans. It has OCVs of 442 mV as well as an CNH ratio of 3 weight percent. advancements in the manufacturing of fuel cells that are CMOS compatible are being made as well as the variables that impact the fabrication of these fuel cells have been identified[34]. The method is employed to investigate the openwork power output as well as the efficacy of various solid oxide fuel cell technologies. The results of this inspection are part of the investigation are the capacity to perform and the efficiency of Energy Conversion Networks of interest and the various liquid fuel cells made of solid oxide in multi-loop electrical networks, intelligent grids, and microgrids.

Energy Conversion Network topology is an important factor in determining the overall system efficiency of the solid oxide fuel cell which is why the technique used during this research is used. The process is an excellent instrument to analyze the primary role that of role that solid oxide fuel cells perform in the present [35-36].This research explores various kinds of micro-electro-mechanical Systems of microfluidic fuel cells as they demonstrate direct formic acids in microfluidic fuel cells which consume oxygen as an antioxidant. Three-dimensional micro-fluid fuel cell design was analyzed with Computational Modeling the transport and electrochemical processes were portrayed using the absorption media flow and hydrodynamic equations. Then, the electrochemical reactions, charge equation, and mass transport. The solid oxide fuel cell provide the most effective method to meet additional energy needs. Solid oxide fuel cells that operate in single chamber mode have shown various advantages over single-oxide fuel cells because of their complex, compact and sealed structure. This model is able to be employed to create a single-chamber system with solid oxide fuel[37].Single-chamber solid oxide fuel model is applicable to every. With the immense demands on energy, it's been recognized that scientists face global demands to answer the problem. Wind and solar energy is the primary source of fossil fuels' capability to be used as an alternative. The research has created models that could be considered as the largest engineered system that can reconstruct the temperature of fuel cells in addition to energy circulation. It was found how the energy density is dependent on the fuel cell's mode is as high as the flow rate of oxygen and hydrogen and hydrogen [38]. The simulation of proton exchange fuel cell are presented in this paper and

is applicable to various transport-related applications. The simulation was conducted by using MICROSIM PSPICE for modeling the fuel cell, thereby reducing costs of testing. The fuel cell has been paired with a converter that regulates the output voltage. Additional circuit ideas are proposed that can allow for the creation of a practical and efficient fuel cell vehicle[39].Proton Exchange Membrane fuel cells perform in a different manner unlike the phosphoric acid fuel cell. They function by making distinction between similar events and also to differentiate. The process of development is slow with Proton Exchange Membrane Fuel Cells. Insufficient membranes, as demonstrated in the Plans prevented the PEM device from being chosen for a successor to the space programme. In this piece we'll discuss the main debasement issues regarding Proton Exchange Membrane fuel cells and in particular the necessity of balancing the application of Phosphoric Acid Fuel Cells as well as those found that are used in Proton Exchange Membrane fuel cells[40]. Biotechnology research has shown that there are many opportunities for the production of gaseous and liquid fuels. Ethyl alcohol production was extensively conducted and studied using fluid fuels. This research focuses on the implementation of modern technology for the study of biotechnological methods and techniques that can be used to make liquid transportation fuels[41].Motwani et al.[41] devised an idea for the microbial production of 2,3-butanediol using water hyacinth the weed of nuisance that is composed of WH dried in sunlight which is then crushed, followed by the alkaline reaction at high temperatures as well as fermentation, and finally an enzyme-driven hydrolysis process. Vaccarino et al.[42] have demonstrated the use of the worn-out grape marc and vinasse, which is a hazardous waste of alcohol that results in grape marc.

A thorough and extensive analysis will be necessary to assess the viability of the entire process [43].Navarro et al.[44] examined research on Linear as well as quadratic equations to determine the relationships between carbon and organic matter and found that high r values, important at a 99 percent level, were found. Hydrocracking dimers are lignin-related to each other including benzyl-phenyl ether, 4hydroxydiphenyl diphenyl ether, and diphenyl ether. methane diphenylmethane biphenyl, dibenzyl, and 2-hydroxyphenyl in and out of catalysts. It was conducted at various temperatures. These results demonstrate the importance of the relationship between scented rings that have a catalyst or without one. catalyst that has phenolic hydroxyl collections that do not have biphenyl relationship availability. It is possible to split them in temperatures from 450 to 600 degrees Celsius[45].The principal goal of Felseghi et al.[46] research is to demonstrate the practicality factors and potential of using hydrogen as a substitute for energy sources to be used in applications, as well as to identify the possibility of expanding the use of hydrogen for stationary use. The research process was a SWOT analysis. cell that produces electric power through the chemical process of converting hydrogen and oxygen to water is called a fuel cell. It's a more eco-friendly and green alternative to energy, which is why it's an indispensable subject for study. This article offers a quick analysis of two types of fuel cells, as well in their connection to the sustainable management of resources i.e.,1) Electrolyte-based polymer membrane fuel cell 2.)Reversible Fuel Cell[47].This study was conducted in Libya which is also called" the Renewable Energy Authority of Libya created to help support the development of energy resources that are renewable in Libya in order to boost the use of renewable energy to between 6 and 10 percent over the next year. The research offers information for anyone who is looking for information on energy sources.

The research paper says that there's an abundance of progress in the development of alternative energy resources in Libya especially wind and solar[48] . WangaKen *et al.*The work [49] demonstrates the use of a polymer electrolyte membrane fuel cell, that converts the energy contained in hydrogen in an efficient and timely manner to electrical energy, with only one byproduct – water .A lot of effort has been taken to advance polymer electrolyte membrane fuel cell technology as well as basic research issues such as heat and water control. This analysis is (1)showcasing the current state of the development of PEM fuel cells and its applications to stationary, transportation, as well as portable/micro power generation fields with a comprehensive overview of current state of the art and latest technological developments; (2) to describe the necessity for research fundamental on this subject and provide a solution to the fundamental role that research plays on fuel cell technology as well (3) to identify the main issues in the field of the development of fuel cell technologies as well as the requirements to conduct fundamental research shortly, and before commercialization of fuel cell technology[49]. Reversible fuel cells, commonly referred to as unitized fuel cells are reversible electrochemical systems that are efficient in fuel cell technology for the production of electricity as well as electrolysis to produce hydrogen or chemicals production. This article discusses the principles

and the development of electrolysis and describes the working principles, components as well as materials used in various Reversible Fuel Cells [50]Jonathon *et al.* The work [51] demonstrates the possibility that Renewable energy could be the answer to reducing global warming by less than two degrees Celsius. This paper points out the problems by thermo-electrochemical modeling and simulation of reversible solid oxide fuel cells. The reasoning behind the release of gas by equilibrium reactors that utilize electrolysis was investigated. The research was conducted and showed that increasing working temperature, as well as pressure may enhance the efficiency. Therefore, the efficiency of the entire cell varies in relation to temperature, which is dependent upon the pressure that is optimal[5252.Mayyas et al.[53] research cites for an example cost of depository energy in reverse-reversible fuel cell. Sabato et al.[54] have presented the characteristics of a new Na-containing glass-ceramic sealant with excellent thermomechanical properties. Mortazavi et al.[55] have recognized the 2-phase liquid gas pressure drop as an official trademark which is utilized for small passages. Pressure drops that are sustained by research are assessed against three types of pressure drop that are both two-phase. Kdoddathimmaiah et al.[56] reviewed Regenerative Fuel Cells. Regenerative fuel cells are available in two forms: Discrete Regenerative Fuel Cells, as well in Unitized Regenerative Cells. An URFC is a unit gadget which can operate simultaneously in Electrolyzer as well as fuel cell modes. The configuration enables permanent swapping of liquids as well as gases and heat between the two piles. This is the reason PEM URFCs have been the focus of numerous studies. This research article focuses on URFCs.

The alkaline fuel cell electrodes carry porous nickel and Polytetrafluoroethylene They can also be used as anodes. Electrodes are assessed under a range of situations throughout this initial process by using X-ray photoelectronscopy, as well scan electron microscopy that includes energy-dispersive X-ray spectrum and nitrogen adsorption [57]and nitrogen adsorption[57].Fuel cells that convert the energy of chemical reactions into electricity tend to be arranged based on the guidelines set by the electrolyte's function. The five most common kinds of technology include membrane-based electrolyte polymer cells, Alkaline fuel cell fuel cells that contain sulfuric acid, molecular carbonate fuel cells as well as solid-oxide fuel cell [58].The fuel cell is a solid oxide. Mesoporous carbon-carrying Platinum nanocatalyst was identified as a cathode and anode catalyst in the Polymer Electrolyte Membrane fuel cell.Oxygen depletion was detected by rotating disk electrodes as well as the rotating ring electrode method within acid media. Membrane electrode assemblies were arranged with Platinum used on MP for cathode and anode activators as well as the effectiveness of fuel cells was assessed [59]. Chinda et al.[60]research focused on studying tiny replicas of the Solid Oxide Fuel Cell which incorporates electrochemical reactions as well as Mass conveyance, which was technologically developed. The replicas were then evaluated using a method of comparing previous expectations from the technical ones.For the ionic and electronic conductor particles, the optimal volumetric ratio has been as well recommended. Research results prove that the solid Oxide Fuel Cell excess potential may be reduced productively by manipulating temperatures and pressure. This research has revealed the working techniques of the solid oxide fuel cells on the smallest scale and helps increase their Solid Oxide Fuel Cell production.

CONCLUSIONS

The fuel cells have a lot of promise and have the potential to transform many key industries. Below are some general findings regarding their application: Fuel cells play an integral part in the current green energy revolution. Transportation Change: Hydrogen fuel cell vehicles (FCVs) are an emission-free alternative to cars with internal combustion engines with extended driving distances that allow for faster refilling and helping to reduce pollution within urban environments. Effective Stationary Power Generation In the field of stationary power generation fuel cells have swiftly been recognized for their reliability in power and heating delivery with incredible energy efficiency. They are used in the combined power and heat (CHP) systems allows factories and buildings to become more energy-efficient while still being eco-friendly. Resilience and Backup Power: Fuel cells play a crucial role in protecting vital infrastructures by providing stable energy backup during grid disruptions. Remote and Off-Grid Solutions in remote areas or those that are off grid fuel cells can provide stable power solutions to support communication services as well as remote monitoring devices and even military applications. They offer a variety of advantages for manufacturing industries which rely on high temperatures for production to increase productivity

and require very extreme temperatures for the production process. Aerospace Progress Fuel cells have also been able to make progress in the aerospace industry, by powering UAVs and spacecraft during extended missions by using renewable sources such as hydrogen. Hydrogen Production: The fuel cells serve two functions in the production of hydrogen, both as a source of energy to fuel combustion, and also to aid in the electrolysis of water to produce hydrogen gas. There are still challenges to overcome There are numerous benefits, however the advancement for hydrogen infrastructure cost-cutting strategies, as well as finding safe sources for hydrogen remain challenges to their use. Resilience and Sustainability Energy-efficient fuel cells can contribute to sustainable goals through reducing carbon dioxide emissions and wasting energy resources and increasing the resilience of grids. The fuel cells have the potential to change the energy sector, offering low-cost green solutions for many applications. As technology improves and investments are made in the field of research and development PEM fuel cells have the potential that they can lead to sustainable practices and reducing environmental impacts and enhancing the durability of infrastructures that are critical and advancing green practices for energy consumption and production.

ABSTRACT

Periodontitis, a chronic multifactorial inflammatory disease, is hypothesized to be produced by the colonization of dysbiotic plaque biofilms in a susceptible host, which gradually deteriorates the supporting periodontal tissues. Periodontitis, one of the world's most common dental disorders, is currently the main cause of adult tooth loss. When periodontitis develops, it is treated by scraping mineralized deposits and dental biofilm off the tooth surfaces. Several studies suggest that non-surgical therapy considerably improves clinical and microbiological indices in persons with periodontitis. Despite dramatic improvements in periodontal parameters, some bacterial reservoirs frequently remain on root surfaces even after regular periodontal treatment. Periodontitis was treated with local or systemic antibiotics, as well as scaling and root planing. Because there are few new antibiotics on the market, many researchers are focusing on developing other means of treating periodontal bacteria. There is a delay in a research on the issue of nanoparticle (NP) toxicity, which is particularly concerned with mechanisms of action, while the field of nanomedicine develops. Metal nanoparticles are the most promising because of their strong antibacterial properties. Metal nanoparticles can be used as effective growth inhibitors in a range of bacteria, making them valuable in the treatment of periodontitis. In this approach, the new metal nanoparticles helped greatly to the creation of effective anti-inflammatory and antibacterial platforms for the treatment of periodontitis. This paper summarizes the existing therapeutic efficacy of different metallic nanoparticles on periodontitis. This information might be utilized to develop NP-based therapeutic solutions for treating periodontal infections.

INTRODUCTION

Periodontitis is an inflammatory gum disease that damages the supporting tissue of teeth. It is characterized by the deterioration of periodontal ligaments (PDLs), the formation of periodontal pockets, and the resorption of alveolar bone. [1]This is frequently associated with a number of clinical conditions, such as gingivitis, loss of alveolar bone, PDL, and dental cementum degeneration. Gingivitis, the early stage of the disease, has the potential to progress into periodontitis, a more serious condition that causes cavities to form, a loss of clinical connection, and degradation of the alveolar bone.[2] Recent advancements in nanotechnology have made it possible to employ immunomodulatory nanoparticles (NPs) in regenerative dentistry techniques.[3]NPs' minuscule size allows them to infiltrate biological entities with great efficiency. Additionally, NPs are essential to antiviral therapy because they increase medication effectiveness and make it easier for hydrophobic medicines to be transferred.[4-6]Because of their tiny size (1–100 nm), NPs are able to enter tiniest lumen without difficulty and not killed, extending their duration of action and enabling greater progressive deliver of the medication.[5]NPs are used in a variety of applications, including as precise drug administration, sensors, antimicrobial agents in dentistry, antioxidants, larvicides, anti-cancer medications, mouthwashes, antibacterial agents in dentistry, and more.[7]Nanotechnology is used extensively in dental equipment, including enamel and dentin protection[8]. Metallic nanoparticles (NPs) initiate biomineralization by encouraging the remineralization of demineralized (caries-ridden) dental tissues[9]. Based on their capacity against inflammation of substances , metal nanoparticles have been shown in many studies to be an attractive new treatment option for periodontitis[10]. The use of metal nanoparticles (NPs) in the management of periodontitis was covered in this review article.

DEVELOPMENTAL FACTORS OF PERIODONTITIS
The main cause of periodontal disease is plaque biofilm on the dental and gingival surfaces. This condition is influenced by unhygienic behavioral factors, the oral cavity's internal environment, and the development of dental and gingival plaque. The primary keystone pathogen of the periodontal biofilm is *Porphyromonasgingivalis (P. gingivalis)*, which causes host immune responses that damage gingival tissues and resorb bone[11]. A person's response to a periodontal infection is heavily impacted by risk factors. Lifestyle factors that are distinct but modifiable risk factors for periodontal disease include things like drinking and smoking. Included are ailments like osteoporosis, metabolic syndrome, diabetes mellitus, obesity, and insufficient calcium and vitamin D consumption[12].

PERIODONTITIS TREATMENT METHODS
Opportunistic infections are the primary cause of periodontal disease in the majority of patients. The advantage of local delivery is that it can produce higher concentrations of drug at the intended site of action with lower doses, meaning fewer adverse effects. Syringes, irrigation equipment, dental gels, mouthwashes, and gentrifiers are a few examples. Individualized oral hygiene instructions, quit smoking initiatives, dietary changes, subgingival instruments for calculus and plaque removal, and local and systemic medication, and various surgical procedures are just a few examples of the strategies that fall under the category of therapeutic intervention[13].Another non-surgical periodontal treatment method is to control supragingival plaque with manual, sonic, and/or ultrasonic instruments. NPs can deliver specific drugs to certain tissues, cells, or pathogens inside periodontal pockets because of their small size. Moreover, they display antibacterial qualities by rupturing the membranes of bacteria, which eliminates the microbes [13,16].

NANOPARTICLES IN PERIODONTITIS
In general, smaller nanoparticles are more efficient in eliminating microbes. Metal nanoparticles (NPs) including gold (Au), silver (Ag), silver oxide (Ag_2O), titanium dioxide (TiO_2), silicon (Si), copper oxide (CuO), zinc oxide (ZnO), calcium oxide (CaO), and magnesium oxide (MgO) have been found to have antimicrobial action [17]. These NPs

produce reactive oxygen species (ROS), which can break down proteins, RNA, and DNA, making them harmful to microorganisms. Compared to other nanometals, Au NPs appear to be less hazardous to human cells due to their antibacterial effect not being dependent on reactive oxygen species[18]. Metal NPs eliminate the biofilm[19]. When it comes to metal nanoparticles, the negative membrane charges of the microbes interact with the positive metal ions. Bacterial membranes are permeable to metal ions, which can then penetrate the cells. They do this by interacting with the sulfhydryl group (-SH) on microbial proteins, preventing the synthesis of proteins and nucleic acids. The antibacterial efficacy of NPs is influenced by their surface charge and size[20]. They are also inexpensive and can be produced easily[21,22]. Fig. 1 [23]shows the effect of metals NPs on periodontitis

PROPERTIES OF GOLD NANOPARTICLES

Gold nanoparticles (AuNPs), a therapeutic carrier with exceptional bioavailability and functionality, range in diameter from 50 to 150 nm[24]. It is an excellent choice for usage as an antimicrobial[25]. AuNPs are added to other biomaterials to enhance their capabilities because of their antifungal and antibacterial characteristics. Because of these qualities, AuNPs are a common filler for biomaterials[26].

Gold nanoparticles in periodontitis

According to the findings, 45 nm AuNPs reduced discomfort and improved the periodontal inflammatory milieu by modulating the production of pro- and anti-inflammatory cytokines and macrophage polarization, which influenced the development of human PDL cells (hPDLCs).. It has been demonstrated that using 45nm AuNPs may significantly decrease the advancement of periodontitis and enhance the quantity of new cementum, bone, and periodontal attachment that forms in periodontal defects. 45nm AuNPs may directly affect hPDLCs with modifying the initial irritational symptoms of periodontium tissues via altering cell morphologies. This led to a milieu containing comparatively small levels of reparative and inflammatory cytokines, such as bone morphogenetic protein-2 (BMP-2), which induced the formation of periodontal tissue regeneration, PDLC, and the halting of the periodontitis[27].Fig. 2[23] shows various mechanisms of NPs to destroy microorganisms.

Gold nanoparticles as a photothermal agent in periodontitis

Due of its light-induced localized surface plasmon resonance (LSPR), AuNPs have attracted a lot of attention. Because of the strong instantaneous electric field present in the absorption band of photosensitizers in LSPR, the absorption rate of the photosensitizers is significantly increased. This process can therefore rising the photosensitizer excitation rate, ultimately increasing the ROS production. Au nanoparticles coupled with methylene blue(MB-AuNPs)were shown to be very efficient at photoin activating biofilms of methicillin-resistant Staphylococcus aureus (MRSA) that were four days old. After being exposed to radiation, the biofilm treated with MB-AuNPs showed a decrease of more than 5 log10, while the biofilm medicated with methylene blue alone showed a decrease of less than 1 log10. Therefore, photosensitizers on the surface of AuNPs turned out to be a very successful way to increase the effectiveness of antibacterial photodynamic treatment[28,29].

PROPERTIES OF SILVER NANOPARTICLES

AgNPs with a size range of 1 to 100 nm are made from pure crystalline Ag. They have recently gained popularity for a wide range of biological applications because to their enhanced and unique physical-chemical properties, such as reduced particle size, higher surface area, and quantum confinement effects . Because AgNPs prevent microbes from generating biofilms, hence used in the dental field[30,31].

Silver nanoparticles in periodontitis treatment

Researchers examined the biological effects of Oroxylum indicum (L) Kurz (OI) stem bark extracts as a reducing agent (OI/AgNPs) in biosynthetic process of AgNPs. The OI/AgNPs were stable spherical NPs with a size range of 21.49 0.32^ nm, and their biological and anti-oxidant capabilities were enhanced by biosynthesis. Biosynthesized OI/AgNPs have the potential to protect hPDLSCs from oxidative stress and inflammatory stimuli, stimulate osteoblastic growth, and not be cytotoxic. For these reasons, they can be used in the restorative therapy of peri-implantitis[32].AgNPs were utilized to make a novel mouthwash, which was tested for safety and efficacy. AgNPs

79542

Gunjan Aggarwal and Amit Bhardwaj

showed a 93.15% inhibition rate. The mouthwash containing AgNPs shown antibacterial effectiveness at a concentration of 100 L/mL[33]. Biosynthesized AgNPs were utilized in the current study to treat periodontal disease instead of topical antiseptics and antimicrobial agents; they may be combined with other antimicrobial agents to provide a synergistic effect and are also used to administer specific medications[34].*In vitro*, hydrogels doped with AgNPs and based on poly (2-hydroxyethyl methacrylate) have demonstrated encouraging antibacterial activity against S. aureus and E. coli. Ag ions have been demonstrated to affect bacterial cell structures in a number of ways, one of which being an increase in membrane permeability that leads to cell lysis[35].(Figure 3)

ZINC NANOPARTICLES

Zinc oxide nanoparticles (ZnONPs) are among the most widely used nanoparticulate materials worldwide due to their antibacterial properties. The antibacterial properties of Zn NPs also help to slow down the growth of biofilms[36].ZnNPs that are biofabricated from renewable resources are thought to be environmentally friendly. If brackets are covered in CuO and ZnONPs, they can be utilized to stop S. mutans from spreading while receiving orthodontic treatment[37]. A study by Rai et al., on 20 chronic periodontitis patients concluded that ZnONPs have been demonstrated to enhance ALT enzyme activity in people with periodontal illness, and those with chronic periodontitis had greater levels of ALT enzyme activity in their saliva when compared to healthy controls[60].Hence, more studies are needed to be done.

TITANIUM DIOXIDE NANOPATICLES

Titanium dioxide nanoparticles, or TiO2NPs, are smaller than 100 nm.Among metal oxide NPs, TiO2NPs are unique due to their widespread application in photocatalysis, antibacterial, and antiparasitic applications[38,39].Due to their remarkable chemical stability and photocatalytic activity, TiO2NPs are appropriate supplements to enhance the properties of polymer materials employed in periodontal therapy[40,41].Although there are very few reports of antibacterial photodynamic therapy utilizing nanomaterials, the nanosurface layer has demonstrated potential in reducing peri-implantitis. Ag, TiO2, and hydroxyapatite (HA) nanocoatings were prepared for implants by Ag plating, anodization, and sintering. The Ag-nHA nanocoating completely inhibited bacterial growth in the surrounding medium and reduced biofilm on the implant surface by 97.5%. This novel nano-coating for titanium alloy implants has the advantages of less infection risk, enhanced osseointegration, and accelerated bone repair[42].TiO2NPs boosted COX-2 mRNA and protein expression in PDL cells, and ERK1/2 and Akt were rapidly activated, perhaps upstream of NF. -B TiO2NPs also increased intracellular ROS generation in PDL cells, therefore halting the progression of periodontitis [63].

MAGNETIC NANOPARTICLES

In dentistry, NPs and magnetic forces have been used recently to transfer medications for the avoidance and therapy of dental conditions. Because MNPs are used in various dental medicine delivery systems, there has been a decrease in dental cavities as well as endodontic and periodontal illnesses. It has been demonstrated that dental composites and adhesives containing MNPs inhibit the formation of biofilm[43,44].

NICKEL NANOPARTICLES

It has been demonstrated that NiNPs have anti-microbial capabilities against S. aureus and E. coli.In dental compounds, nickel is frequently used to increase the success rate of root fillings[45].Numerous studies have demonstrated that the occurrence of adverse reactions, such as contact allergies therefore, its usage is less[46].

BISMUTH NANOPARTICLES

Bismuth NPs are bactericidal, antifungal and prevents biofilm formation [47,48]. According to a recent study, BiNPs' low MIC, strong effectiveness, and affordable price point make them a potential medicine substitute or mouthwash for oral infections [49]. One of the defensing properties of BiNPs is their capacity to prevent S. mutans, the bacterium that causes the majority of tooth decay, from forming biofilms[50].It was demonstrated that the primary dimensions of BSS-nano have a polygonal shape and range from 4 to 22 nm. Antimicrobial BSS-nano can be used to antiseptics and dental fillings[61].

COBALT NANOPARTICLES

During the evaluation of the synthetic Co oxide NPs' antibacterial properties, formation of investigated bacteria was considerably decreased. By chemically contacting Co oxide NPs, a beneficial antibacterial action against gram-negative bacteria is demonstrated[51]. By suppressing the expression of P. gingivalis survival genes, the substance has potential as a treatment for chronic periodontitis[52].

COPPER NANOPARTICLES

Copper (Cu) nanoparticles (NPs) have great biological activity, low cost, environmental safety, and promise as strong multipurpose antibacterial agents[53].Chitosan having CuNPs have the potential to treat periodontitis[54].When compared to bulk Co, oxytetracycline, and gentamicin, CoNPs were superior[62].

ADVANTAGES OF METAL NPsFOR DEVELOPMENT OF THERAPEUTIC METHODS

The advantages of employing metal nanoparticles is because of its potency for bacteria resistant to antibiotics, their adaptability to different types of microorganisms, and their use as efficient carriers of antibiotics. NPs have the ability to disperse and break apart bacterial biofilms[55].They also have the potential to eradicate periodontal bacteria enclosed in biofilms. *Prevotella intermedia, F. nucleatum,* and *P. gingivalis* are among the gram-positive and gram-negative bacteria responsible for periodontal diseases and NPs are effective against them [56]. In-vitro studies have demonstrated that AgNPs suppress the growth, adhesion, and biofilm generation of S. *mutans*[57].ZnO and TiO_2NPs might be employed as nano-antibiotics in the production of mouthwashes and dental pastes[58].Magnetic nanoparticles (NPs) may be remotely steered to specific areas by applying an external magnetic field[59]. More research is necessary to understand how metal nanoparticles (NPs) enter cells and how their antibacterial properties affect periodontitis patients.(Fig . 4 shows various effect of popular metal NPs in treating periodontitis)

DISADVANTAGESOF METAL NPSIN THERAPEUTIC METHODS

The high concentrations of the any metal can be fatal. The main mechanism underlying TiO_2NPs' potential for toxicity appears to be the generation of ROS, which can result in the development of cancer. The incidence of adverse responses such as contact allergies to nickel has also been shown. Many cases has shown even deaths linked to the use of Bi medicines throughout the past century. When Bi compounds are used at dangerous dosages, acute renal impairment results. Besides the biological toxicities the physical preparation of these nanoparticles requires a lot of high temperature and pressure while the chemical is dangerous so leaving us with the biochemical techniques of preparation only.

SUMMARY

Table 1 summarizes the effect of various NPs on periodontitis

CONCLUSION

There are several conventional therapies for periodontitis. Medication resistance and the onset of undesirable effects render established treatments ineffective. The NPs' small size allows them to potentially penetrate the biofilm matrix and come into direct touch with the bacterial cells, inhibiting the biofilm. It is anticipated that the broad use of research techniques and their commercial applications in the fields of medicine and healthcare will show to be extremely advantageous in the years to come.

Table 1: Summarizes the effect of various metal NPs on periodontitis

NPs	properties	Periodontitis effect	Type of study	references
AuNPs	45nm Anti-inflammatory effect Heals periodontal inflammation	AuNPs could produce a microenvironment with low levels of inflammatory cytokines and reparative cytokines like BMP-2 by directly modulating hPDLCsand indirectly and in vitro modulating macrophage phenotypes. This would induce PDLC differentiation, periodontal tissue regeneration, and the prevention of periodontitis progression.	In vivo	[27]
AgNPs	1-100nm Smaller size , larger surface area,	There is a window of opportunity for more research in the field when using AgNPs in place of topical antiseptics and antimicrobial agents, as well as when combined with other antimicrobial agents for a synergistic effect and local drug delivery during periodontal therapy.	In vitro	[34]
ZnONPs	Antimicrobial properties	ZnONPs have been demonstrated to enhance ALT enzyme activity in people with periodontal illness, and those with chronic periodontitis had greater levels of ALT enzyme activity in their saliva when compared to healthy controls.	20 patients with chronic periodontitis	[60]
MNPs	Less toxic more versatile	The antibacterial MNPs were able to remove bacterial biofilms in in vitro antibacterial investigations, resulting in a clearance rate that approached 80%.	In vivo and in vitro	[44]
NiNPs	inexpensive, safer, size is less	The study demonstrated that all clinical isolates of S. epidermidis were capable of producing biofilms. It has	In vitro	[45]

	than 25nm	been demonstrated that NiNPs inhibit the formation of biofilm.		
BiNPs	Bactericidal, fungicidal, antibiofilm agent	It was demonstrated that the primary dimensions of BSS-nano have a polygonal shape and range from 4 to 22 nm.	In vitro	[61]
CoNPs	Antibacterial, cheaper	By chemically contacting Co oxide NPs, a beneficial antibacterial action against gram-negative bacteria is demonstrated [51]. By suppressing the expression of P. gingivalis survival genes, the substance has potential as a treatment for chronic periodontitis [52].	In vitro	[62]
CuNPs	Cheaper, safer, antibacterial	Using CuNPs/chitosan gel nanocomposites.These compounds inhibited the growthof A. Actinomycetemcomitans. It has been used as a foundation for developing periodontitis therapies tailored to individual patients' needs.	In vitro	[54]
TiO₂NPs	Biocompatible cheaper safer	TiO2NPs boosted COX-2 mRNA and protein expression also increased intracellularROS generation in PDL cells.	In vitro	[63]

ABSTRACT

In this article Lucky labeling is coloring of vertices arbitrarily such that sum of labels of all adjacent vertices of a vertex is not equal to the sum of labels of all adjacent vertices of any vertex which is adjacent to it. The concept of lucky labeling has been used in transportation network, where pair wise connections are given some numerical values. And also in computational biology to model protein structures. In this research article concepts of different lucky labeling like square sum lucky labeling and 2-divisor lucky labeling have been observed for some algebraic graphs like zero-divisor graphs, identity graph and order prime of finite groups.

Keywords: 2- divisor lucky labeling, 2- divisor lucky number, Square sum lucky labeling, zero-divisor graphs, identity graphs, order prime graphs.
AMS Subject Classification: 05C25, 05C78.

INTRODUCTION

Graph labeling was introduced by Alexander Rosa in the year 1967[12]. Rosa identified three types of labeling which was later renamed by Solomon Golomb[8].Lucky labeling was studied by Ahai.et.al and Akbari.et.al[1][2]. Lucky labeling is coloring of vertices arbitrarily such that sum of labels of all adjacent vertices of a vertex is not equal to the sum of labels of all adjacent vertices of any vertex which is adjacent to it. It has been used in transportation network,

79550

Aruna Sakthi and Rajeswari

where pair wise connections are given some numerical values. And also in computational biology to model protein structures[6],[7].There are two variations of the zero-divisor graph. One is in the Beck definition in the year 1988, in which the vertices represent all elements of the ring [5]. In the year 1999, Anderson and Livingston slightly varied the graph, in which the vertices represent only the zero-divisor of the given ring [4]. A study on identity graph was studied in the book Groups as graphs[9].Order prime graph was introduced by M. Sattanathan and Kala R[13]. Inspiring d-lucky labeling[11] square sum lucky labeling and 2-divisor lucky labeling have been investigated in this paper for some algebraic graphs of finite group.

PRELIMINARIES

Definition2.1: [13]Order Prime Graphs: Let Γ be a finite group. The order prime graph(Γ)of a group Γ is a graph with V ((Γ)) = Γ and two vertices are adjacent in (Γ) if and only if their orders are relatively primein Γ.

Definition 2.2[4][5]: Zero-Divisor Graph: Let R be a commutative ring with identity 1 and let $Z(R)$ be its set of zero-divisors. We associate a $\Gamma(R)$ to R with vertices$Z^* = Z(R) - \{0\}$, the set nonzero zero-divisor of R, and for distinct $x, y \in Z(R)^*$, the vertices x and y are adjacent if and only if $xy = 0$. We denote their zero-divisor graph of R by $\Gamma_0(R)$ if we take vertex set as Z (R). In $\Gamma_0(R)$, the vertex 0 is adjacent to every other vertex. $\Gamma(R)$is a induced subgraph of $\Gamma_0(R)$.

Definition 2.3[9]: Identity Graph: Let g be a group. The identity graph $G = (V, E)$ with vertices as the elements of group and two elements $x, y \in g$ are adjacent or can be joined by an edge if $x.y = e$, where e is the identity element of g.

SQUARE SUM LUCKY LABELING FOR SOME ZERO-DIVISOR GRAPHS

Definition: Square Sum Lucky Labeling
A graph $G = (V, E)$ be a graph with n vertices and m edges. A graph G admits square sum lucky labeling if $f: V(G) \to \{1,2,\dots,n\}$ be a labeling of vertices of graph G from$\{1,2,3,\dots,n\}$. Define$c(u) = \lceil \sum_{v \in N(v)}(f(v))^2 \rceil$, where $N(v)$ is the neighborhood of v such that $c(u) \neq c(v)$ for every pair of adjacent vertices u and v in G.Thesquare sum lucky number is the least number from the set $\{1,2,\dots,n\}$ that has been used to label the graph G. It is denoted by η_{ssl}.

Theorem3.1: For the prime number $p \geq 3$, square sum lucky number of zero-divisor graph $\mathbf{\Gamma(Z_{2p})}$**,** is one.

Proof: Let graph $G = \Gamma(Z_{2p})$ and $p \geq 3$ be a prime number.
The vertex set of G is $V(G) = \{x_1, x_2, \dots, x_{p-1}, x_p\} = \{2,4,\dots,2(p-1), p\}$
The edge set of G is $E(G) = \{x_i x_p / 1 \leq i \leq p - 1\}$
$|V(G)| = p$; $|E(G)| = p - 1$
Define $f: V(G) \to N$ such that $f(x_i) = 1, 1 \leq i \leq p$
$c(x_p) = (f(x_1))^2 + (f(x_2))^2 + \cdots + \left(f(x_{p-1})\right)^2 = p - 1$
$c(x_i) = (f(x_p))^2 = 1$ where$1 \leq i \leq p - 1$
such that $c(x_p) \neq c(x_i)$ for all $1 \leq i \leq p - 1$.
Therefore graph G admits square sum lucky labeling. To label this graph only one label used and so the square sum lucky number of graph G is one i.e. $\eta_{ssl}(G) = 1$.

Theorem 3. 2: For prime number $p > 3$, the zero-divisor graph of $\mathbf{\Gamma(Z_{3p})}$ has square sum lucky number to be one.

Proof: Let graph G= $\Gamma(Z_{3p})$ and $p > 3$, be a prime number.

Aruna Sakthi and Rajeswari

The vertex set of G is $V(G) = \{t_1, t_2, x_1, x_2, x_3, \ldots, x_{p-1}\} = \{p, 2p, 3, 6, 9, \ldots, 3(p-1)\}$

The edge set of G is $E(G) = \{t_i x_j / 1 \leq i \leq 2, 1 \leq j \leq p - 1\}$

$|V(G)| = p + 1$; $|E(G)| = 2p - 2$.

Define $f : V(G) \to N$ such that $f(t_i) = 1$, $1 \leq i \leq 2$ and $f(x_j) = 1$, $1 \leq j \leq p - 1$

$c(t_i) = (f(x_1))^2 + (f(x_2))^2 + \cdots + \left(f(x_{p-1})\right)^2 = p - 1$ where $i = 1, 2$

$c(x_j) = (f(t_1))^2 + (f(t_2))^2 = 2$ where $1 \leq j \leq p - 1$

such that $c(t_i) \neq c(x_j)$ for all $1 \leq i \leq 2$ and $1 \leq j \leq p - 1$.

Therefore graph G admits square sum lucky labeling. To label this graph only one label used and so the square sum lucky number of graph G is one i.e. $\eta_{ssl}(G) = 1$.

Theorem 3.3: The square sum lucky number for the zero-divisor graph$\mathbf{\Gamma(Z_{5p})}$, $p \geq 3$ and $p \neq 5$ be a prime number is one.

Proof: Let graph $G = \Gamma(Z_{5p})$, $p \geq 3$ and $p \neq 5$ be a prime number.

The vertex set of G is $V(G) = \{t_1, t_2, t_3, t_4, x_1, x_2, x_3, \ldots, x_{p-1}\} = \{p, 2p, 3p, 4p, 5, 10, 15, \ldots, 5(p-1)\}$

The edge set of G is $E(G) = \{t_i x_j / 1 \leq i \leq 4, 1 \leq j \leq p - 1\}$

$|V(G)| = p + 3$; $|E(G)| = 4p - 4$.

Define $f : V(G) \to N$ such that $f(t_i) = 1$, $1 \leq i \leq 4$ and $f(x_j) = 1$, $1 \leq j \leq p - 1$

$c(t_i) = (f(x_1))^2 + (f(x_2))^2 + \cdots + \left(f(x_{p-1})\right)^2 = p - 1$ where $1 \leq i \leq 4$

$c(x_j) = (f(t_1))^2 + (f(t_2))^2 + (f(t_3))^2 + (f(t_4))^2 = 4$ where $1 \leq j \leq p - 1$

such that $c(t_i) \neq c(x_j)$ for all $1 \leq i \leq 4$ and $1 \leq j \leq p - 1$.

Therefore graph G admits square sum lucky labeling. To label this graph only one label used and so the square sum lucky number of graph G is one i.e. $\eta_{ssl}(G) = 1$.

Theorem 3.4: For the prime number $p, q \geq 3$ and $p < q$ and $p \neq q$ the zero-divisor graph $\mathbf{\Gamma(Z_{pq})}$ has square sum lucky number to be one.

Proof: Let graph $G = \Gamma(Z_{pq})$, $p, q \geq 3$ and $p < q$ and $p \neq q$ where p, q are prime numbers.

The vertex set of G can be partitioned in to two sets $V_1(G)$ and $V_2(G)$

$V_1(G) = \{x_1, x_2, x_3, \ldots, x_{q-1}\} = \{p, 2p, \ldots, (q-1)p\}$

$V_2(G) = \{t_1, t_2, t_3, \ldots, t_{p-1}\} = \{q, 2q, 3q, \ldots, (p-1)q\}$

The edge set of G is $E(G) = \{x_i t_j / 1 \leq i \leq q - 1 \text{ and } 1 \leq j \leq p - 1\}$

$|V(G)| = p + 3$; $|E(G)| = 4p - 4$.

Define $f : V(G) \to N$ such that $f(x_i) = 1$, $1 \leq i \leq q - 1$ and $f(t_j) = 1$, $1 \leq j \leq p - 1$

$c(x_i) = (f(t_1))^2 + (f(t_2))^2 + \cdots + \left(f(t_{p-1})\right)^2 = p - 1$ where $1 \leq i \leq q - 1$

$c(t_j) = (f(x_1))^2 + (f(x_2))^2 + \cdots + \left(f(x_{q-1})\right)^2 = q - 1$ where $1 \leq j \leq p - 1$

such that $c(x_i) \neq c(t_j)$ for all $1 \leq i \leq q - 1$ and $1 \leq j \leq p - 1$.

Therefore graph G admits square sum lucky labeling. To label this graph only one label used and so the square sum lucky number of graph G is one i.e. $\eta_{ssl}(G) = 1$.

Square Sum Lucky Labeling for Identity graph

Theorem: 4.1 The **identity graph of** $(\mathbf{Z_n}, \oplus_n)$ for $n > 3$ be an odd number then the square sum lucky number is two.

Proof: Let graph $G = Identity\ graph\ of\ Z_n$, $n > 3$ be an odd number.

The vertex set of G is $V(G) = \{0, 1, 2, \ldots n - 1\} = \left\{x_0, x_1, x_2, \ldots, x_{\frac{n-1}{2}}, x_{\frac{n+1}{2}}, \ldots, x_{n-1}\right\}$.

The edge set of G is $E(G) = \{x_0 x_i,\ x_1 x_{n-1}, x_2 x_{n-2}, \ldots, x_{\frac{n-1}{2}} x_{\frac{n+1}{2}}\}$, $1 \leq i \leq n - 1$.

$|V(G)| = n$; $|E(G)| = \frac{3n-3}{2}$

Define $f: V(G) \to N$ such that $f(x_0) = 1$, $f(x_1) = f(x_2) = \cdots = f\left(x_{\frac{n-1}{2}}\right) = 2$ and

$f(x_{\frac{n+1}{2}}) = f\left(x_{\frac{n+3}{2}}\right) = \cdots = f(x_{n-1}) = 1$.

$c(x_0) = (f(x_1))^2 + (f(x_2))^2 + \cdots + \left(f(x_{n-1})\right)^2$

$c(x_1) = (f(x_0))^2 + (f(x_{n-1}))^2$

$c(x_2) = (f(x_0))^2 + (f(x_{n-2}))^2$

.

.

.

$c\left(x_{\frac{n-1}{2}}\right) = (f(x_0))^2 + (f\left(x_{\frac{n+1}{2}}\right))^2$

.

.

.

$c(x_{n-1}) = (f(x_0))^2 + (f(x_1))^2$

such that $c(x_0) \neq c(x_1) \neq c(x_2) \neq \cdots \neq c\left(x_{\frac{n-1}{2}}\right) \neq c(x_{n-1})$.

Therefore graph G admits square sum lucky labeling. To label this graph two labels used and so the square sum lucky number of graph G is two i.e. $\eta_{ssl}(G) = 2$.

Theorem 4.2: The **identity graph of** $(Z_n, \oplus_n)$ for $n > 2$ be an even number then the square sum lucky number is two.

Proof: Let graph $G = Identity\ graph\ of\ Z_n$, $n > 2$ be an even number.

The vertex set of G is $V(G) = \{0,1,2,\dots n-1\} = \left\{x_0, x_1, x_2, \dots, x_{\frac{n}{2}}, \dots, x_{n-1}\right\}$.

The edge set of G is $E(G) = \{x_0 x_i, \ x_1 x_{n-1}, x_2 x_{n-2}, \dots, x_0 x_{\frac{n}{2}} / 1 \leq i \leq n-1\}$

$|V(G)| = n$; $|E(G)| = \frac{3n-3}{2}$

Define $f: V(G) \to N$ such that $f(x_0) = 1$, and $f(x_i) = \begin{cases} 1\ if\ n = odd \\ 2\ if\ n = even \end{cases}$

$c(x_0) = (f(x_1))^2 + (f(x_2))^2 + \cdots + \left(f(x_{n-1})\right)^2$

$c(x_1) = (f(x_0))^2 + (f(x_{n-1}))^2$

$c(x_2) = (f(x_0))^2 + (f(x_{n-2}))^2$

.

.

.

$c\left(x_{\frac{n}{2}}\right) = (f(x_0))^2$

.

.

.

$c(x_{n-1}) = (f(x_0))^2 + (f(x_1))^2$

such that $c(x_0) \neq c(x_n) \neq c\left(x_{\frac{n}{2}}\right)$.

Therefore graph G admits square sum lucky labeling. To label this graph two labels used and so the square sum lucky number of graph G is two i.e. $\eta_{ssl}(G) = 2$.

Theorem 4.3: For **identity graph of Klein-4 group** (K_4) under composition the square sum lucky number is one.

Proof: Let graph $G = Identity\ graph\ of$ Klein-4 group

The vertex set of G is $V(G) = \{x_0, x_1, x_2, x_3\} = \{e, a, b, ab\}$.

The edge set of G is $E(G) = \{x_0 x_i / 1 \leq i \leq 3\}$.

Define $f:V(G) \to N$ such that $f(x_0) = 1$ and $f(x_i) = 1$ for all $1 \le i \le 3$.

$c(x_0) = (f(x_1))^2 + (f(x_2))^2 + (f(x_3))^2$

$c(x_i) = (f(x_0))^2$ for all $1 \le i \le 3$.

such that $c(x_0) \ne c(x_i)$ for all $1 \le i \le 3$.

Therefore graph G admits square sum lucky labeling. To label this graph only one label used and so the square sum lucky number of graph G is one i.e. $\eta_{ssl}(G) = 1$.

Theorem :4.4 For the **identity graph of Quaternion group (Q_8)** has square sum lucky number to be two.

Proof: Let graph $G = Identity\ graph\ of\ Q_8$.

The vertex set of G is $V(G) = \{0,1,2,\dots 7\} = \{x_0, x_1, x_2, \dots, x_4, \dots, x_7\}$.

The edge set of G is $E(G) = \{x_0x_i,\ x_1x_7, x_2x_5, \dots / 1 \le i \le 7\}$

Define $f:V(G) \to N$ such that $f(x_0) = 1$, and $f(x_i) = \begin{cases} 1\ if\ n = odd \\ 2\ if\ n = even \end{cases} 1 \le i \le 7$

$c(x_0) = (f(x_1))^2 + (f(x_2))^2 + \cdots + (f(x_7))^2$

$c(x_1) = (f(x_0))^2 + (f(x_7))^2$

$c(x_2) = (f(x_0))^2 + (f(x_5))^2$

.
.
.

$c(x_4) = (f(x_0))^2$

.
.
.

$c(x_7) = (f(x_0))^2 + (f(x_1))^2$

such that $c(x_0) \ne c(x_n) \ne c\left(x_{\frac{n}{2}}\right)$.

Therefore graph G admits square sum lucky labeling. To label this graph two labels used and so the square sum lucky number of graph G is two i.e. $\eta_{ssl}(G) = 2$.

DIVISOR LUCKY LABELING

Definition: 2- Divisor Lucky Labeling

A graph $G = (V, E)$ be a graph with n vertices and m edges. A graph G admits 2-divisor lucky labeling if $f:V(G) \to \{1,2,\dots,n\}$ be a labeling of vertices of graph G from $\{1,2,3,\dots,n\}$. Define $c(u) = \lceil \sum_{v \in N(v)} \frac{f(v)}{2} \rceil$, where $N(v)$ is the neighborhood of v such that $c(u) \ne c(v)$ for every pair of adjacent vertices u and v in G. The 2-divisor lucky number is the least number from the set $\{1,2,\dots,n\}$ that has been used to label the graph G. It is denoted by η_{vdl}.

Theorem: 5.1: For the $OP(\Gamma(Z_n)), n = 2p, p \ge 3$ where p is a prime number under addition modulo n has $\eta_{vdl}(G) = 1$.

Proof: Let graph $G = OP(\Gamma(Z_n)), n = 2p, p \ge 3$ where p is a prime number

The vertex set of G is $V(G) = \{x_0,\ x_1,\ x_2, \dots, x_{\frac{p}{2}-1},\ x_{\frac{p}{2}},\ x_{\frac{p}{2}+1}, \dots, x_{n-1}\}$.

The edge set of G is $E(G) = \{x_0x_i, x_{\frac{p}{2}-1}x_{\frac{p}{2}},\ x_{\frac{p}{2}}x_{\frac{p}{2}+1} / 1 \le i \le n-1\}$

$|V(G)| = n$ and $|E(G)| = n + 1$.

Define $f:V(G) \to \{1,2,3,\dots,n\}$ such that $f(x_i)=1; 0 \le i \le n-1$

$c(x_0) = \left\lceil \dfrac{f(x_1) + f(x_2) + \cdots + f(x_{n-1})}{2} \right\rceil$

$c(x_i) = \left\lceil \frac{f(x_0)}{2} \right\rceil 1 \le i \le n-1$ except $i = \frac{p}{2}-1, \frac{p}{2}, \frac{p}{2}+1$

$c\left(x_{\frac{p}{2}-1}\right) = \left\lceil \dfrac{f(x_0) + f(x_{\frac{p}{2}})}{2} \right\rceil$

$$c\left(x_{\frac{p}{2}}\right) = \left|\frac{f(x_0) + f\left(x_{\frac{p}{2}-1}\right) + f\left(x_{\frac{p}{2}+1}\right)}{2}\right|$$

$$c\left(x_{\frac{p}{2}+1}\right) = \left|\frac{f(x_0) + f(x_{\frac{p}{2}})}{2}\right|$$

Such that $(x_0) \neq c(x_i) \neq c\left(x_{\frac{p}{2}-1}\right) \neq c\left(x_{\frac{p}{2}-1}\right) \neq c\left(x_{\frac{p}{2}+1}\right); 1 \leq i \leq n-1$

except $i = \frac{p}{2}-1, \frac{p}{2}, \frac{p}{2}+1$

Graph admits 2-divisor lucky labeling. Therefore 2-divisor lucky number is one i.e $\eta_{vdl}(G) = 1$.

Theorem: 5.2 : 2-divisor lucky number for the $OP(\Gamma(Z_n)), n = 3p, p > 3$ where p is a prime number under addition modulo n is two.

Proof: Let graph $G = OP(\Gamma(Z_n)), n = 3p, p > 3$ where p is a prime number

The vertex set of G is $V(G) = \{0,1,2,\ldots,n-1\} = \{x_0, x_1, x_2,\ldots,x_{n-1}\}$.

The edge set of G is $E(G) = \{x_0 x_i, x_p x_{\frac{j}{3}}, x_{2p} x_{\frac{k}{3}}/1 \leq i \leq n-1; \frac{pj}{3} \cong 0 \mod 3$ and $\frac{2pk}{3} \cong 0 \mod 3p\}$

$|V(G)| = n$ and $|E(G)| = n + 1$.

Define $f: V(G) \to \{1,2,3,\ldots,n\}$ such that $f(x_i)=1; 0 \leq i \leq n-1$ except

$j = $ multiples of p and $f(x_j) = 2; j = $ multiples of p

$$c(x_0) = \left|\frac{f(x_1) + f(x_2) + \cdots + f(x_{n-1})}{2}\right|$$

$$c(x_i) = \left\lceil\frac{f(x_0)}{2}\right\rceil \; 1 \leq i \leq n-1 \text{ except } i = \frac{p}{3}, \frac{2p}{3}, p, 2p$$

$$c\left(x_{\frac{p}{3}}\right) = \left\lceil\frac{f(x_0)+f(x_j)}{2}\right\rceil \frac{pj}{3} \cong 0 \mod 3p.$$

$$c\left(x_{\frac{2p}{3}}\right) = \left\lceil\frac{f(x_0)+f(x_k)}{2}\right\rceil \frac{2pk}{3} \cong 0 \mod 3p.$$

$$c(x_j) = \left|\frac{f(x_0) + f(x_{\frac{p}{3}})}{2}\right| \frac{pj}{3} \cong 0 \mod 3p$$

$$c(x_k) = \left|\frac{f(x_0)+f(x_{\frac{2p}{3}})}{2}\right| \frac{2pk}{3} \cong 0 \mod 3p.$$

Such that $(x_0) \neq c(x_i) \neq c\left(x_{\frac{p}{3}}\right) \neq c\left(x_{\frac{2p}{3}}\right) \neq c(x_j) \neq c(x_k); 1 \leq i \leq n-1;$

except $i = \frac{p}{3}, \frac{2p}{3}, p, 2p$

Graph admits 2-divisor lucky labeling. Therefore 2-divisor lucky number is one i.e $\eta_{vdl}(G) = 2$.

Theorem:5.3 The $OP(\Gamma(Z_n))$, $n \neq 2p$ and $n \neq 3p$ under addition modulo n has 2-divisor lucky number to be one.

Proof: Let graph $G = OP(\Gamma(Z_n))$, $n \neq 2p$ and $n \neq 3p$

The vertex set of graph G is $V(G) = \{x_0, x_1, x_2, \ldots, x_{n-1}\}$

The edge set of graph G is $E(G) = \{x_0 x_i/1 \leq i \leq n-1\}$

Define $f: V(G) \to \{1,2,3,\ldots,n\}$ such that $f(x_i)=1; 0 \leq i \leq n-1$

$$c(x_0) = \left|\frac{f(x_0) + f(x_1) + f(x_2) + \cdots + f(x_{n-1})}{2}\right|$$

$$c(x_i) = \left\lceil\frac{f(x_0)}{2}\right\rceil ; 1 \leq i \leq n-1$$

Such that $c(x_0) \neq c(x_i); 1 \leq i \leq n-1$

Graph admits 2-divisor lucky labeling. Therefore 2-divisor lucky number is one i.e $\eta_{vdl}(G) = 1$.

Theorem: 5.4 The $OP(\Gamma(K_4))$ under composition has 2-divisor lucky number to be 1.

Proof: Let graph $G = OP(\Gamma(K_4))$ under composition

The vertex set of graph G is $V(G) = \{x_0, x_1, x_2, x_3\} = \{e, a, b, ab\}$.

The edge set of graph G is $E(G) = \{x_0 x_i / 1 \le i \le 3\}$

Define $f: V(G) \rightarrow \{1,2,3,4\}$ such that $f(x_i)=1; 0 \le i \le 3$

$$c(x_0) = \left| \frac{f(x_0) + f(x_1) + f(x_2) + f(x_3)}{2} \right|$$

$$c(x_i) = \left\lceil \frac{f(x_0)}{2} \right\rceil ; 1 \le i \le 3$$

Graph admits 2-divisor lucky labeling. Therefore 2-divisor lucky number is one i.e $\eta_{vdl}(G) = 1$.

Theorem: 5.5 The $OP(\Gamma(Q_8))$ under composition has 2-divisor lucky number to be one.

Proof: Let graph $G = OP(\Gamma(Q_8))$ under composition

The vertex set of G is $V(G) = \{x_0, x_1, x_2, x_3, x_4, x_5, x_6, x_7\}$

The edge set of G is $E(G) = \{x_0 x_i / 1 \le i \le 7\}$

Define $f: V(G) \rightarrow \{1,2,3,4,5,6,7,8\}$ such that $f(x_i)=1; 0 \le i \le 7$

$$c(x_0) = \left| \frac{f(x_0) + f(x_1) + f(x_2) + f(x_3)}{2} \right|$$

$$c(x_i) = \left\lceil \frac{f(x_0)}{2} \right\rceil ; 1 \le i \le 7$$

Graph admits 2-divisor lucky labeling. Therefore 2-divisor lucky number is one i.e $\eta_{vdl}(G) = 1$.

CONCLUSION

In this paper square sum lucky labeling and 2-divisor lucky labeling and its numbers have been observed for some algebraic graphs like zero-divisor graphs of commutative ring, identity graphs and order prime graph of finite group. Further this work will be extended to some network related graphs.

ABSTRACT

Medicinal plants are vital sources of easily used in the countryside healthcare system. Survey of medicinal plants plays a pivotal role in the drug research programme of the Indian systems of medicine. In this study, we investigated the medicinal plants present in the campus of St. Ann's college for women, Visakhapatnam. We also analysed the measures that can be taken to protect these plants. Overall 144 plant species from 69 families were identified. Therapeutic uses of these plants provide basic information that can aid scientists to conduct additional research to conserve these species and pharmacological studies with the greatest significance.

Keywords: Survey, Medicinal plants, Healthcare and Therapeutic

INTRODUCTION

Slokam says "Na manthram aksharam nasthi, nasthi mulam anowshadham, ayogyaha purusho nasthi, yojakathathra durbalaha"Medicinal plants have been a vital source of both curative and preventive medical therapy preparations for human beings, which also has been used for the extraction of important bioactive compounds [1,2,3]. Health care which was a part of the traditions and culture of the people has been a profession in the modern industrial world. Synthetic drugs are giving side effects which are dangerous than the diseases which they care. Traditional medicines are usually cheaper than modern medicines, and probably the only natural remedies available and accessible in the remote rural communities in developing countries [4].The world's attention turned towards traditional medicines. The plant extracts are providing wonderful remedies against human diseases. Identifying the curing power of natural remedies. The plants contain natural sustainable and harmless substances which can cure various illnesses and promote health in a natural way without side effects. Indian climate, atmosphere and soils are very rich and can accommodate rich biodiversity. Indiscriminate trade of plant resources, uncontrolled collecting methods, habitat

79558

change, overexploitation, and climate change pose great threats to availability of plant medicine in most third world countries, thus, creating a pressing need for better methods of conservation and viable use of priority plant resources [5]. It is important to identify the healing power of extract of medicinal plants and their future use.

MATERIALS AND METHODS

Study Area
The Present survey of medicinal plants were done at campus of St. Ann's college for women, Visakhapatnam. Our campus all together 62,76,581 acres with about 180 trees around it(Fig 1).

Data Collection and Plant Identification
Ethnobotanical information were gathered from January 2023 to December 2023by interviewing, using methodological ways designed in ethnopharmacological in field data collection. The students were informed afore about the initiation of the survey and permission was allowed. Interviews, discussions, formal and informal conversations, as well as field visits were conducted. More information was sourced from literature studies including journal articles and books. The plants were identified with the help of floras. The species and family names are mentioned according to the APG 3 system of classification.

Preparation of herbarium specimens
The preparation of the specimens was followed by methods stated in Lawrence (1967), Jones and Luchinger (1987), Anonymous (1996) and Manilal and Kumar (1998)

Collection
The specimen material (plants) which you are interested in should be collected as whole (if they are herbs) or part of plant along with flowers and fruits/carpels. Before putting your specimens in the collection with carefully remove all the insects, spider-webs and foreign bodies attached to your specimens.

Pressing and Processing
Then the specimens mounted in 42 cm x 29 cm(16 ½" x 11 ½") size blotting paper. If the plant specimen larger than the specimen blotting paper they can mounted in V or N or M shape to accommodate the entire plant material in above size. Also the leaves mounted in dorsiventral position. The half-size of the regular newspaper can fit this size and economical. Put the mounted specimens in between cardboards/wooden-frames.

RESULT

Diversity of Medicinal Plant Use
This study was based on a review of the literature published in scientific journals, books, reports from national, regional and international organizations, theses, conference papers and other grey materials. This study compiled 144 plants herbs are 55, shrubs are 43, trees are 36 and climbers and stragglers are 10(Fig: 2).Out of these 69 families Asteraceae and Euphorbiaceae are the dominated families. After wards Fabaceae, Apocynaceae and Malvaceae are dominated (Fig: 3). The largest percentage of medicinal plants obtained belonged to the family Asteraceae(13), followed by Fabaceae (6), Apocynaceae (6), Acanthaceae (5), Lamiacea (4), Caesalpiniaceae (4), Liliaceae (4), Solanaceae (3), Oleaceae (3)and with the rest of the families treated less than 2 in number of the ailments (Table 1)

DISCUSSION

Now a days growing population and their health problems are demanding simple and alternate medicine along with allopathic medicines. People are now going for ayurvedic medicine. Ayurvedic medicine are prepared from various parts of plants to treat different local diseases. In India many plant species were used for this purpose. The study

shows that every plant species have medicinal importance. The climate conditions also favour for the growth of the herbs, shrubs and trees. Even though it is the industrial area, the pollutants are not inhibiting the growth of these plants and they require minimum herbal care. Local people use to collect various part of these plants for their purpose of use. Various plants parts like roots, stem, leaves, flowers, fruits and seeds used for different disorders. Many plants are useful to cure ailments like cough, cold, diabetes and skin problems. Even they can be used to cure poisonous effect of insect, rat, and snake bites. Some are useful to cure even cancer and HIV.

CONCLUSION

Many plants are useful to cure dysentery, diarrhoea, stomach disorders and kidney stones even. Simple direct oral intake is sufficient to cure many diseases. Important aim of this study is to collect the information of medicinal plants, and their medicinal uses and preservation of this information for future generations. This information may lead to the extraction of drugs from these plants may become easier and cheaper as they are abundantly available here. Traditional medicines still play an important role in meeting basic health care of local communities. There is a tremendous potential for the commercialization of these medicinal plants

Table:1 List of medicinal plants and their uses

S.NO	BOTANICAL NAME	IMAGE	MEDICINAL USES
1	*Ruellia tuberose.* Acathaceae		Diuretic, antipyretic, Analgesic, Antihypertensive, Abortifacient, Emetic, Kidney disorders, Bronchitis, Gonorrhea, Syphilis.
2	*Coleus ambonicus.* Asteraceae		antitumor, antibacterial, antifungal, antiprotozoal, anti-inflammatory, antioxidant, antidiabetic, wound healing analgesic, antirheumatic.

Adiseshu

3	*Gulphimia glauca.* Malpighiacae		Sedative, anxiolytic, anticonvulsant, antiasthma, antiallergic, nervous diseases, relieves coronary pains, anxiety, fear, phobia and stress.
4	*Jasminum officinale* Oleaceae		Liver diseases pains, relaxation, aphrodisiac, wounds, skin disease, cancer, ulcers in oral cavity.
5	*Ixora coccinea.* Rubiaceae		Dysentery, diarrhea, ulcers, gonorrhea, fever, hiccups, loss of appetite, nausea, antibacterial, gastroprotective, hepatoprotective, contosions.
6	*Pseudoranthemum reticulatum.* Acanthaceae		fever, headache, cold and back pain
7	*Plectranthus amboinicus.* Lamiaceae		cold, asthma, constipation, headache, cough, fever and skin diseases
8	*Terminalia catappa* Combretaceae		Scabies, leprosy wounds, skin diseases, diarrhea, fever, headache, hepatoprotective, antidiabetic, anticancer.
9	*Crossandra infundibuliformis* Acanthaceae		fever, headache, aperitisand pain

Adiseshu

10	*Croton bonplandianum* Euphorbiaceae				Liver disorders, skin Diseases including ringworm infection, Tourette swelling of body, bronchitis and asthma.
11	*Ficus religiosa* Moraceae				antiulcer, antibacterial, antidiabetic, in treatment of gonorrhea and skin diseases
12	*Gomphrena globose* Amaranthaceae				Antibacterial, antifungal, antioxidant, detoxifying, purifying properties, high blood pressure, diabetic, anti-inflammatory, leucorrhea.
13	*Clitoria ternatea* Fabaceae				Memory enhancers, nootropic, antistress, anxiolytic, antidepressant, anticonvulsant, tranquilizing, sedative agent.
14	*Tabernaemontana divaricata* Apocynaceae				Snake and scorpion poisoning, antiepileptic, anyimania, brain tonic, fever, pain, ringworms, antitumor saction.
15	*Acalypha lanceolata* Euphorbiaceae				Vermicide, carminative, jaundice, hypertension, fever, liver inflammation, asthma, pains, antimicrobial, diabetes, skin conditions.
16	*Tridax procumbens* Asteraceae				Wound healing, anticoagulant, antifungal, insect repellent, antianemia, antiinflammatory, antidiabetic, treats high blood pressure, malaria,
17	*Ocimum sanctum* Lamiaceae				coughs, asthma, diarrhoea, fever, dysentery, arthiritis, eye diseases, indigestion, gastric ailments.

Adiseshu

18	*Calotropis procera* Asclepiadaceae			Digestive disorders including diarrhoea, toothache, jointpains, parasitic infections, worms, cramps.
19	Hibiscus Rosa sinensis. Malvaceae			Treating wounds, Inflammation, coughs, diabetes, gastric ulcers, fever.
20	*Chlorophytum comosum* Asparagaceae			Antitumor, Anti-proliferative, indoor air purifier, Phytoremidative
21	*Chrysanthemum indicum* Asteraceae			Chest pain, high blood pressure, type 2 diabetes, fever, cold, headache, dizziness, swelling prostate cancer, anti bacterial, anti viral, cardiovascular health, inxiety improves, earing stress.
22	*Tagetus patula* Asteraceae			digestive poor problems, poor apetite, stomach pains, intestinal worms, dysentry to start menstruation, protect6s against miscarriage, sedative.
23	*Rosa indica* Rosaceae			Diarrohea, inflammation of mouth, dry skin, antibacterial, anti fungal, anti septic, anti inflammatory, cough.
24	*Tradescantia pallid* Commelinaceae			Anti oxidant, anti cancer, anti inflammatory, anti microbial, antifungal, antiviral, analgesic.

79563

Adiseshu

25	*Cosmos bipinnatus* Asteraceae			Antioxidant, antidiabetic, antihypertensive, anti-inflammatory, bone protective, antimicrobial.
26	*Lagerstromia indica* Lythraceae			Antiinflammation, ant analgesic, antipyretic, antioxidant, anticancer, antimicrobial, antialzheimers, antidiabetic.
27	*Nerium odorum* Apocynaceae			anthelmintic, adaptogenic, analgesic, aphrodisiac, anticancer, antiinflammation, emetic, asthma, epilepsy, painfulmenstrualperiods, malaria, ringworms ,causes
28	*Tithonia diversifolia* Asteraceae			Malaria, constipation, stamachpains, indigestion, sorethroat, liverpains, treatmentofbruises, liverfunctions, hepatitis, jaundice.
29	*Plumeria rubra* Apocynaceae			Antifertility, anti-inflammatory, antioxidant, hepatitisB,HIV.

ABSTRACT

Generally, stability studies are performed to comply with ICH guidelines, and in recent days there has been an increase in concern about the statistical approach. Pharmaceutical companies are also trying to adopt this statistical design in their research work. In this paper stability designs and statistical considerations to be followed during the sampling of drugs are discussed apart from this information regarding different sampling techniques like full design and reduced design are also mentioned. Conditions followed during the sampling of drugs for investigation of the expiry date included. In reduced design, there are two main designs i.e., bracketing and matrixing designs what are the parameters to be followed periods for sampling, and whether reduced design results are up to what extent accurate are also mentioned. The conditions that influence the sampling are also mentioned.

Keywords: Bracketing, Matrixing, Full design, Reduced design, Stability testing.

Karimulla Shaik *et al.*,

INTRODUCTION

The goal of stability testing is to determine recommended storage conditions, a retest period for a drug substance, and a shelf life for a drug product, by providing evidence on how the quality of a drug ingredient or drug product varies over time and responds to different environmental conditions, such light, humidity, and temperature. Every drug should be indicated with its shelf life on its label. Testing for stability is an essential step in product development. It does, however, take a lot of time and resources. A new product license often requires a minimum of 12 months of stability data, making it frequently on the vital path of development. Thus stability procedures must be effectively created to reduce the resources needed and guarantee regulatory approval. Reducing the number of stable samples may also result in cost savings in sample production and management, especially since the setup and upkeep of storage facilities are extremely expensive. Samples of stability have to be developed, labelled, and stored. Fortunately, there are ways of lowering the number of stability tests necessary, particularly B&M. When properly implemented, these techniques for lowering the number of product samples that are stability tested shouldn't significantly alter the anticipated shelf life or reduce the quality of the results. Although there are theoretically more presentations or batches evaluated for drug substance than there are for the product, the prospects and rewards are far more constrained. The FDA established detailed guidelines accompanied by suggestions for the Stability study design and analysis for human medications and biologics using statistics in 1987 [1]. As stated in this recommendation, It is crucial to look at the results of several variables, including the batch, strength, kind of packaging, length of storage, and storage environment. This results in a highly extensive and costly study design. The guideline suggests reducing stability testing using designs for matrixing and bracketing as an alternative. Since both designs are more affordable, it goes without saying that pharmaceutical corporations value them highly.

A stability schedule with a matrixing design was characterized as one where just a portion of the total number of samples was evaluated at each designated sample point [1]. Any subset of a full factorial design is how Chow [2] defined the matrixing design. Additionally, Helboe [3] added that a matrixing design only tests a portion of all potential factor combinations at any moment during a sample, but that the factor combinations' subgroups that were looked at different sample periods vary[3]. In general, this design assumes that the stability of the tested sample is indicative ofthe consistency of every sample. Natarajan et al. [4]have studied the influence of medicinal substances on the date of expiry of different matrixing designs regarding sampling time selection while taking reduced testing plans into consideration. By selecting the time-based vectors so that the layout is ideal concerning the greatest details on cost per unit, DeWoody and Raghavarao [5] also examined several ideal matrixing designs in stability experiments. According to FDA rules, all samples are analyzed at the beginning and end of the sampling process only the samples at the extremes of each factor. The extreme samples in this arrangement are thought to symbolize the samples' stability in the intermediate state. Additionally, the patterns of bracketing might be particularly useful if the composition of the strengths is closely connected, or if the container's material or closing type is consistent across the range of sizes. Instead of evaluating each of the three strengths.(20 mg, 30 mg, and 40 mg)of the medication product in three appropriate strengths. we might Test your strengths at both the lowest and greatest levels. (20 mg and 40 mg). In the present paper, we take into account an investigation of stability using a single factor at three levels, depending on whether the FDA allows matrixing or bracketing. We want to determine if a matrixing or bracketing design should be used If there is an annual maximum difference of δ between these values. To respond to this query, we take into account the provided sampling time points from Table 1. As suggested by the FDA, we employed three batches at each level, assuming that there were no slope changes across groups with the same factor levels. The optimal matrixing design and the bracketing design's FDA-recommended time points advised by Dewoody and Raghavarao[5] were also adopted by us. The matrixing design has 45 assays while the bracketing design has 42 assays. The FDA's guidance serves as the basis for the sample intervals used in bracketing design. The selection of time points in matrixing design is primarily concerned with the optimal matrixing design. from DeWoody and Raghavarao[5]

STABILITY STUDY DESIGN
A stability study's design aims to determine a retest duration or shelf life that will apply to all upcoming batches of the drug substance or product produced under similar conditions, based on testing a small number of batches of the drug substance or product. As a result, tested batches have to meet the drug product's quality standards and be reflective in every way, including formulation, production location, closure and container, manufacturing method, source, and bulk material quality. The stability research needs to be well thought out to estimate the product's shelf life with high precision and accuracy.
Types of stability design include the following

FULL DESIGN AND PARTIAL DESIGN
Full design:
Full designs, sometimes called complete factorial designs, have samples for every combination of all design elements tested as suggested at all times. ICH Q1A(R2)[6]. A minimum of 0, 3, 6, 9, 12, 18, 24, and annually thereafter for long-term testing; a minimum of 0, 3, and 6 months for accelerated testing. As was already indicated, ICH has published several guidelines for the planning and execution of stability studies. The drug material and product must be stored within the long-term guidelines indicated on the label of the container (e.g., 25∘ C ±2∘ C/60% RH ±5% RH or 30∘ C ±2∘ C/65% RH ±5% RH), except when drug substances or drug products are stored in the freezer conditions, they should also be kept in accelerated conditions for 6 months and tested at least once every 3 and 6 months. Additionally, if any "significant change" occurs at any point during the six-month testing period at the accelerated storage condition, the recommendation calls for additional testing at the intermediate storage condition to be conducted and evaluated if long-term studies are conducted at 25∘ C ±2∘ C/60% RH ±5% RH. An example of a stability protocol using a comprehensive design for a medicinal product made in is shown in Table 2, these drug products have three different container sizes, three different container closure systems, and three different strengths. This illustration demonstrates the need for 1188 test samples will be used for accelerated and long-term stability testing. Long-term studies conducted at 25°C ±2°C/60% RH ±5% RH will also need intermediate testing and need 1620 test samples if a "significant change" occurs at any time throughout the six months of testing under accelerated storage conditions.
The long-term condition could be 25∘C ±2∘C/60% RH ±5% RH or 30∘C ±2∘C/65% RH ±5% RH ∗∗If long-term studies are conducted at 25∘C ±2∘C/60% RH ±5% RH and ''significant change'' occurs at any time during 6 months' testing at the accelerated storage condition, then the intermediate testing is needed. Reference is taken from [7] A simple full design is demonstrated in Table 3. This example outlines a procedure for assessing a medicinal product's long-term stability at 25°C and 60% relative humidity. The product comes in three different bottle sizes (10, 50, and 100 ml) and three different strengths (25, 50, and 100 mg). Samples are always assessed for all potential combinations of strength, batch size, and kind of container. In this instance of a full factorial design, the total quantity of samples examined is
N = 3 × 3 × 3 × 8 = 216 . Table 3 shows that comprehensive testing of all factor combinations at every time is required for a full design, and this can be costly. As a result, pharmaceutical businesses want to use the reduced design. Can the reduced design, maintain enough accuracy for the specified shelf life without sacrificing too much data? What types of reduced designs are also applicable? Can it be said to be an effective way to lessen the number of samples tested?

Reduced design
A fractional factorial design, or reduced design, adheres to the ICH Q1D Guideline by evaluating some samples for each factor combination at a time rather than evaluating all of them[6]. A reduced design is any portion of a whole design. The two reduced designs that are most frequently utilized are bracketing and matrixing. Wright [8] first suggested using factorial designs in stability studies in 1989. In his 1991 presentation, Nakagasi [9] utilized the terms matrix and bracket. In articles published in 1992, Nordbrock [10], Helboe [3], and Carstensen [11] discussed several strategies for cutting the number of samples examined from the chemical and financial elements of stability studies. Nordbrock examined several fractional factorial design approaches and compared them based on their capacity to detect a noteworthy discrepancy between slopes. He concluded that power may be used to select the design with the smallest sample size and sufficient performance. Lin [12] examined the applicability of the bracketing and matrixing methodologies to stability studies. She concluded that the complete factorial design is the best option when the

Karimulla Shaik *et al.,*

accuracy of the shelf-life estimation is the most important element, but she also pointed out that matrixing designs could work well for pharmaceutical products that have less variation in strengths and container sizes. Fair weather [13], Ahn [14], Chen [15], and Yoshioka[16] have each suggested various methods for analyzing and categorizing stability data with many design elements concerning complex stability data.

Calculation of the expected expiration dating period via statistical modelling

The following is a representation of the statistical model for the deterioration profile;

$Y_{ij} = \alpha_i + \beta_i X_{ij} + e_{ij}$, i=1,2,3.   j= 1,2, . . ., n_i

where α_i and β_i denote the intercept and slope of the degradation line for level i, Y_{ij} = concentration of the ith level for a drug product at sampling time X_{ij}, and e_{ij} = random errors distributed as independent identically distributed (i.i.d.) N (0, σ^2). Based on the sample time points, the actual values of n_i are 21 for bracketing design and 15 for matrix design.

BRACKETING DESIGN AND MATRIXING DESIGN

When there are multiple designs to choose from, a reduced design may be a better option than a full design. The product under review has several contributing variables. It is important to think carefully before using a reduced design, However, accounting for potential risks associated with the ability to determine a precise and accurate shelf life or the consequences of accepting a shelf life that is shorter than intended. The two reduced designs that are most frequently utilized are bracketing and matrixing. Because there is less stability testing, a bracketing or matrixing design should be able to offer a sufficient degree of precision in shelf-life estimation without losing much information.

Bracketing design

Creating a stability schedule that only takes samples of specific design elements—like strength and packaging size—at their extremes and continually evaluates them, just as in a comprehensive design. The stability of any intermediate levels must be represented in the design. According to how frequently the tested extremes. Bracketing is appropriate when testing a range of strengths if the compositions are the same or closely related (for example, a range of tablets made with different compression weights of identical simple granulation, or a variety of capsules made by filling different plug fill weights of a single fundamental composition into different size capsule shells). Bracketing can be utilized for different container sizes or fills in the same container closing system.

Consider testing the null hypothesis

$H_0: \beta_1 = \beta_3$ against $H_1: \beta_1 \neq \beta_3$

Let $\hat{\beta}_1$ and $\hat{\beta}_3$ be the estimated slopes for levels 1 and 3 of the factors and let $SS_x = \sum_{j=1}^{n_i} (X_{ij} - 2 X_i)^2$, where $X_i = (1/n_i) \sum_{j=1}^{n_i} X_{ij}$. Assume that σ^2 is known. The key region for the test is

$$\left| \frac{\beta_1 - \beta_3}{\sqrt{\frac{2\sigma^2}{SS_x}}} \right| > z_{0.125}$$

Where $z_{0.125}$ = 1.15 is the highest 12.5 percentile of a standard normal distribution. The test's potency when $\beta_1 - \beta_3 = \delta/12$ is

$$Power_B = Power\left\{\beta_1 - \beta_3 = \frac{\delta}{12}\right\}$$

$$= P\left\{reject H_0 / \beta_1 - \beta_3 = \frac{\delta}{12}\right\}$$

$$= 1 - \left\{-1.15 - \frac{\frac{\delta}{12}}{\sqrt{\frac{2\sigma^2}{SS_x}}} < Z < 1.15 + \frac{\frac{\delta}{12}}{\sqrt{\frac{2\sigma^2}{SS_x}}}\right\}$$

$$= 1 - \Phi\left\{1.15 - \frac{2.115\delta}{\sigma}\right\}$$

Karimulla Shaik *et al.,*

Note that δ/12 is the deterioration rate of δ per year to be found in the slopes divided by 12 months.

Matrixing

The creation of a stability schedule that tests a predetermined portion of all potential samples for each factor combination at a given moment in time. For each combination of factors, an additional set of samples is analyzed. The stability of any sample subset under examination, as per the design, is equivalent to the constancy of every single sample at a given moment in time. It is important to note the variations between samples of the same medicinal product, such as those involving various batches, strengths, and sizes of the same container closing system and, under some circumstances, different container closure systems.

Consider testing the null hypothesis

H0: $\beta_1 = \beta_2 = \beta_3$ against H1: not all β_i are equal, for i = 1, 2, 3. Let $\hat{\beta}_1$, $\hat{\beta}_2$, and $\hat{\beta}_3$ be the anticipated slopes for the matrixing design for each of the three levels

Let $\overline{\hat{\beta}} = \sum_{i=1}^{3} \frac{\hat{\beta}_i}{3}$, and let $\chi^2 = \left(\frac{SS_x}{\sigma^2}\right) \sum_{i=1}^{3} \left(\hat{\beta}_i - \overline{\hat{\beta}}\right)^2$

Where SS_x is as defined earlier for the matrixing design. The critical region for the test is

$\chi^2 > \chi^2_{0.25}(2)$,

Where $\chi^2_{0.25}(2) = 2.773$ represents the highest 25th percentile of a central χ^2 distribution including a pair of freedoms.

Under H_1: $\chi^2 \cong \chi^2(2, \Delta)$, $\Delta^2 = \frac{SS_x}{\sigma^2} \sum_{i=1}^{3} \left(\hat{\beta}_i - \overline{\hat{\beta}}\right)^2$

Where $\chi^2(2, \Delta)$ is not centralized χ^2 a two-degree-of-freedom distribution with a non-centrality parameter Δ.

when $\beta_1 - \beta_3 = \delta/12$, Δ^2 is the minimum when $\beta_1 = \overline{\beta} - \frac{\delta}{24}$, $\beta_2 = \overline{\beta}$, $\beta_3 = \overline{\beta} + \frac{\delta}{24}$.

Thus, the minimum Δ^2 is $\Delta^2_{min} = \frac{2SS_x}{(24\sigma)^2} = \frac{3.9875\,\delta^2}{\sigma^2}$

Once the calculations are complete SS_x about the matrixing layout presented in Table 1. Consider that for large Δ,

$$\frac{\sqrt{2\chi^2(2,\Delta)} - \sqrt{2(2 + \Delta^2) - \frac{2+2\Delta^2}{2+\Delta^2}}}{\sqrt{\frac{2+2\Delta^2}{2+\Delta^2}}} = \frac{\sqrt{2\chi^2(2,\Delta)} - \sqrt{2\Delta^2 + 2}}{\sqrt{2}}$$

Z, the typical normal variable, is roughly distributed.[17][see Desu and Raghavarao (6), p. 88.] Consequently, the matrixing design's minimal power is

$Power_M = P\{\chi^2(2,\Delta) > \chi^2_{0.25}(2)\}$

$$= P\left\{Z > \frac{\sqrt{2\chi^2_{0.25}(2) - \sqrt{2\Delta^2 + 2}}}{\sqrt{2}}\right\}$$

$$= 1 - \Phi\left\{\sqrt{2.773} - \sqrt{\frac{3.9875\delta^2}{\sigma^2} + 1}\right\}$$

It should be noted that while H0 appears must be distinct between bracketing and matrixing designs, it is nearly the same for both designs, and there are no differences in the slope for the factor's values.

Expected expiry date

Since the FDA's 1987 guidance states that an expiration date may be achieved for a given slope and that minimum expiry dating should be used when slopes vary, the Expiry date can be calculated using the given formula.

$\beta_1 - \beta_3 = \delta/12$

The expected expiration dating, or E(ED), is determined as follows by combining all the samples when slopes aren't significant.

E(ED)=P * Smallest (ED)+(1-P) * Ave (ED)

where P is the ability to identify notable variations in slopes. The estimations of the theoretical expiration dating under the biggest and average degradation rates, respectively, are Smallest (ED) and Ave (ED). The FDA guidelines establish the potential dates of expiry; In particular, Smallest (ED) and Ave (ED) are the places at which the 95% one-sided lower confidence bound of the mean degradation curve crosses the lower specification limit of 90% if a pharmacological feature is expected to deteriorate over time.

BRACKETING VS MATRIXING
As mentioned before, there are two different ways to create a stability study: matrixing and bracketing. Every design has its presumptions, benefits, and drawbacks. The manufacturing method, stage of development, evaluation of supportive stability data, and additional elements listed in ICH Q1D [6] of the design stability research in question all have a significant impact on whether either study is applicable. The following details on use consideration can be given to a stability study's use of a bracketing or matrixing design. In a bracketing design, samples from a certain batch for a selected extreme of a factor are analyzed at every single time point. Because matrixing research often evaluates samples from a given batch at shorter intervals, In a bracketing examination, assessing the stability pattern is easier.If all of the tested selected strengths or container sizes display the same trend, it may be concluded with a high degree of certainty that the stability of all other strengths or container sizes is mirrored, or bracketed, by the selected extremes. In a matrixing design, the samples to be assessed are selected from all possible factor combinations. This approach could be less sensitive than bracketing to assess the stability pattern because of the shorter time intervals.Therefore, in the following situations, a matrixing design is more appropriate for evaluating a forecast or already available stability information: During production batch stability testing, In terms of annual stability batches, as well later on in the drug's development process, after sufficient supporting evidence is at hand. When conducting stability tests, matrixing has the advantage over bracketing in that all strengths and container sizes are considered. The literature has explored the general application of bracketing and matrixing (e.g., Chambers (1996), Chen (1996), Fairweather and Lin (1999), Helboe (1999), Lin (1994; 1999a, b), Lin and Fairweather (1997), Yoshioka (1999))[15,18–21]. From a statistical and regulatory perspective, the value of bracketing and matrixing depends on the kind of medicinal product, type of submission, type of factor, data variability, and product stability.

In a stability study, certain variables may be bracketed or matriculated, as described in ICH Q1D[6]. This ICH suggestion also covers, in brief, several additional considerations that need to be made when employing these sorts of designs. A bracketing or matrixing design may be preferred over a complete design to minimize the number of samples tested and, therefore, the cost; nevertheless, the ability of these types of reduced designs to precisely estimate the product shelf life should be carefully reviewed. If the preceding data demonstrate consistent product stability, a matrixing design is frequently acceptable. When there are only little patterns observed in the supporting data, matrixing variability. But in cases where the supporting data have a fair amount of variance; hence, the matrixing design should be confirmed by statistics. If a large variety is evident in the corroborating data, applying a matrixing design is not recommended. A statistical justification might be predicated on an evaluation of the proposed matrixing design's precision in the shelf-life estimate or its capacity to detect differences in the rates of degradation across different components. The amount of reduction that can be achieved from a complete design, if a matrixing design is thought to be applicable, depends on how many factor combinations are being assessed. The bigger the degree of reduction that may be taken into consideration, the more factors there are related to a product and the more levels there are in each element. Any simplified design, nevertheless, must be able to accurately anticipate the product's shelf life. Table 4 provides a bracketing design illustration. Similar to the whole design in Table 3, this example is based on a product that is available in three strengths and three container sizes.The 10- and 100-mL containers do represent the two extremes of container sizes, as this illustration should make evident. Furthermore, the extremes of the strengths must be illustrated by the 25 mg & 100 mg strengths. Just like in a

Karimulla Shaik *et al.,*

complete design, the batches for every selected combination should be checked at each time point. A total of samples will be examined.

N = 2 × 2 × 3 × 8 = 96

A matrixing-on-time-points design can be seen in Table 5. The drug product's description is comparable to those from the earlier examples. Two distinct designs each make use of three-time codes. As an example of a full one-third design, the time points for Batch B, which has a strength of 100 mg and a container size of 10 mL, are 0, 9, 24, and 36 months. For this full one-third design, there will be a total of samples examined.

N = 3 × 3 × 3 × 4 = 108.

Table 6 provides an instance of matrixing factors and time points using three-time codes, much like in the preceding example.These tests are conducted on Batch B at 0,6, 9, 18, 24, and 36 months using a 100 mg strength and a 10 mL bottle. For this case, a total of 36 samples will be evaluated.

N = 3 × 3 × 2 × 6 = 10

Power Comparison Between Bracketing and Matrixing Designs

Remember that the lowest power to detect slope changes is Power$_M$.

Power$_M$ >power$_B$, if and only if, is the minimum.

$\sqrt{2.773} - \sqrt{3.9875\delta^2/\sigma^2 + 1} < 1.15 - 2.115/\sigma$

or equivalently,

$0 < \delta/\sigma < (\cong 0.315)$

As it turns out, a matrixing design is more powerful than a bracketing design.

when $\delta/\sigma < 0.315$

Data evaluation

Data on stability from bracketed, matrixed, or both experiments should be handled similarly to data from nonreduced studies. If the visual evaluation of the data shows that there hasn't been a noticeable change in a parameter, then no statistical analysis is required. In case when Statistical evaluation is necessary, data from several batches and testing for the pool ability of presentations should come first. The smallest EP should be utilized rather than being applied to all demonstrations and groups if pooling is not necessary. All presentations are subject to the anticipated EP if combining is acceptable.

Stability protocol

Well-designed stability research is essential to the success of any stability program. The first stage in the program should be to create a stability protocol that explains the purpose of the research, structure, batches and packaging specifics, guidelines, points of time, needs for storage, sampling technique, statistical evaluation method, and other relevant information. The procedure itself must be carefully thought out and adhered to, and data gathering should be comprehensive and done by the process. To prevent the impression of picking a strategy to create the most acceptable conclusion at the time of data analysis, the protocol needs to describe the intended statistical analysis. Any alteration to the design complicates the interpretation of the collected data. Any changes made after the data has been analyzed or without changing the procedure should be clearly stated in the analysis or design plan. The following details have to be included in a stability procedure that is properly thought out:

- Number of Batches
- Containers and closures
- Orientation of storage of containers
- Sampling time points
- Test storage conditions
- Test parameters
- Test methodology
- Acceptance criteria

Karimulla Shaik *et al.,*

THE ESSENTIALS OF DESIGN
Effects of format elements on estimated duration of shelf-life:

There are multiple dosages and packaging choices available for a drug product. For long-term stability studies, the following design characteristics will be incorporated intostability designs: batch, strength, and container size. According to Nordbrock [10] and Chow [2], examining several possibilities is intriguing, including the following ones:

1. The rates of degradation for various container sizes are constant throughout the strengths.
2. The rates of degradation are constant across every container size.
3. The rates of degradation are uniform across all strengths.
4. All batches have the same degradation rates.

Consequently, during long-term testing, it is essential to examine how important effects (such as strength, batch size, and container size) and interaction effects impact the stability of the therapeutic product. When creating a design for stability, one must take into account how much data from various design variables may be pooled. For instance, if the interaction effect is statistically significant for container strength and size, then a distinct shelf life should be predicted depending on the container's dimensions and power. On the contrary, if the rates of degradation for every container size, batch, and strength are identical the combination's effect is not statistically important.The results should thus be combined, and only one shelf life should be calculated for all batch sizes, strengths, and container dimensions that were produced under the same circumstances. A design should be well thought out so that it can identify any potential major effects and interaction effects.

A simplified design is preferable to a comprehensive one since it requires fewer samples to be tested and, thus, less money. Nevertheless, it has the following drawbacks:

1. For some designs, it can be impossible to analyze certain interaction effects. For instance, two-factor effects for a24-1 fractional factorial layout are confused with himself, making it difficult to decide whether to pool the data.
2. If two factors interact, the data cannot be pooled to yield a single shelf life. such as the strength and container size. It is suggested that a distinct shelf life be mentioned for every strength combination and container size. The expected lifespan of the lacking component combinations, however, cannot be estimated.
3. The estimated shelf life might not be as accurate if there are a lot of unavailable component combinations. A design that reduces misleading and/or impact of interaction should be used to improve the accuracy of the expected shelf life. The features of the design should be considered in statistical analysis after design selection.

Concerns with sample quantity and selection

A stability study's overall number of samples evaluated should be sufficient to ascertain the medical product's stability characteristics and offer a fairly accurate estimate of its shelf life. The overall number of test samples required for stability research often depends on the study's goal and design. Limited design alternatives are available for a drug product with only one dosage and package size; samples must be examined every three months in the first year, every six months in the second, and once a year after that. For pharmaceutical items, a range of design types with several design aspects are offered., including complete, bracketing, and matrixing designs. In general, while selecting a design, the anticipated number of batches, variation in information within or between design factors, the expected product shelf life, and the planned variety of design elements for the research should all be considered. The stability data that is now available must also be evaluated, taking into account the variability in both the manufacturing and analytical procedures. The shelf life of a drug product is assessed by analysing a limited number of therapeutic product units. Thus, tested samples should be average in every aspect, as previously suggested.

Other issues

The goal of choosing a suitable stability design is to increase the precision and accuracy of the medication product's specified shelf-life. The design of stability research benefits from background knowledge, such as regulatory requirements, the manufacturing process, suggested specifications, and the findings of developmental studies. The formulation and manufacturing process should be taken into account while selecting a design for a stability study. For instance, a product created from a common granulation that comes in three strengths will have a different research design and statistical analysis than products made from several granulations with various formulas. The

79573

stability research strategy should be able to minimize variability and prevent bias. As a result, the design should account for differences from various sources. Variances can be caused through particular dose units, vessels within a batch, groups, techniques for analysis, analysts, labs, and batches. production facilities. Furthermore, lacking Values should be avoided, as well as the motivation to document the missing values is necessary. One cannot choose a matrixing design with the presumption that all drug products have the same shelf life. Design elements. If the statistical findings indicate a big difference between batch sizes and package sizes, one cannot depend on a statistical approach or specific batch and container size combinations to provide accurate data on the missing alternatives. Calculating the durability is necessary, given the observed batch and combo combinations, the size of a container, and the smallest shelf ever observed.

CONCLUSION

Generally, stability studies are to be necessarily performed for medical dosage forms so that the max time point up to which it remains (or) retains its therapeutic activity but previously companies used to perform stability studies for whole batches which requires a great amount of time and this method found to be expensive. As an alternative to this full design of stability studies reduced design was introduced which not only helped to lessen the time but was found to be economic by cutting expenses. In reduced design, there are mainly two techniques that are extensively used. These two techniques namely bracketing and matrixing. While sampling one should be careful and should consider different attributes like strength and container size. While considering these reduced design sampling should be done on statistical concerns. A part of this reduced design can have appropriate results that are quite reliable. So instead of a full design one can go with a reduced design in stability considerations.

CONFLICT OF INTEREST
The authors have no conflict of interest.

ABSTRACT

Fossil fuels like crude oil, coal, and natural gas have been around for millions of years. Their consumption has been increasing due to human needs. Crude oil is easy to extract and transport, while coal is cost-effective and produced in power plants. However, they also release CO2, which contributes to pollution and global warming. Also, emit harmful emissions and harm the environment and human health. They also cause acid rain and water pollution. Global summits aim for sustainable and renewable energy conversion to clean and green energies to combat these issues. The present study focused on sustainable and renewable energies in Asian countries like Bangladesh, India, Pakistan, and Sri Lanka. It compares fossil fuels and renewable sources like solar, wind, and hydropower. Renewable energy is clean and green and benefits natural resources. Renewable energy is cost-effective, pollution-free, and environmentally friendly. The present study overviewed the fossil fuel consumption and Rene energy consumption in Asian studies. This will be helpful as a glance picture for the policy makers and government to take necessary actions and right decisions for making sustainable environments.

Keywords: Renewable energy, Sustainable, Fossil fuel, Energy consumption, CO2 emissions

INTRODUCTION

Energy demand is increasing, diminishing conventional resources that pollute the environment. Non-conventional renewable energy resources (RERs) are limitless, abundant, and pollution-free. Several countries are moving toward RERs due to the diminishing supply of fossil fuels and increasing rate of Green House Gas (GHG) emissions. Renewable energy sources are inexhaustible and contribute to economic and social development goals. Fossil fuels remain the primary source of energy despite their disadvantages. Fossil fuels are the largest contributors to greenhouse gas emissions and climate change. Renewable energy sources have remained low compared to fossil

Lalitha

fuels. Renewable energy production world bank represents 17-18.5% of global energy production per person for the last 20 years. Non-hydro renewables share in global electricity portfolio was 7.9% in 2016. China, the US, and Germany produced 54.3% of renewable electricity. Japan, India, and Italy produced 14.1% of non-renewable electricity, while remaining countries produced 31.6% of renewable electricity globally. Renewable energy is crucial for sustainable and carbon-neutral energy needs. Increasing its share is critical.

RESEARCH STUDIES

[1]focused on attempts to assess the existing state, future strategies, and policies for hydropower development in India, with a particular focus on SHP. [2] given an overview of the renewable energy status in the Asian countries, and it includes an assessment of the region's renewable potential, current installed renewable energy capacity. In the context of energy scenario, the researchers explored about renewable energy potential and challenges in Asian countries. [3] looked into why Pakistan's hydropower sector has been slow to develop. To investigate the impending reasons, a combined strategy involving NVIVO analysis and Q methodology was used.

RESULTS AND DISCUSSIONS

Renewable Energy in Asian Countries
Asian current description unswerving including Afghanistan, Bangladesh, Bhutan, India, Maldives, Nepal, Pakistan, and Sri Lanka as the essential nations. It provides a comprehensive analysis of the fit volume of these types of energy in the region. This report covers the renewable energy market in Asian countries namely, hydro, wind, solar, and others. In 2021, the solar energy market is expected to grow at a significant rate. Asian is a significant contributor to the renewable energy market in the Asia-Pacific region due to the region's rapid emergence and growth. In 2021, India's government's efforts to encourage the expansion of policies and the execution of renewable energy projects were instrumental in the country's increasing 147.1 GW in 2021renewable energy capacity. In addition to government support, various financial instruments such as capital, concessional finance, and generation-based incentives have also been instrumental in India's renewable energy goals.

Need of Renewable Energy in ASIAN Countries
Over the past two decades, the ASIAN has successfully brought about half a billion people into the electricity supply. Unfortunately, many people still live in areas where electricity is not available. The major countries such as India, Pakistan, Bangladesh, and Sri Lanka were considered and highlighted need of renewable energy for electricity requirements of the countries. To meet the growing power consumption in the major countries in the region, the energy supply requirements to increase significantly. Conventional sources of energy are not able to keep up with the region's increasing demand, which is resulting in greater reliance on imported fuel. Renewable energy sources can help meet the region's energy needs.

Renewable Energy Potential in ASIAN Countries
Over the establishment of a regional clean energy development framework, the countries of Asian have been able to increase the renewable energy resources usage. This has also reduced the environmental impact of their energy usage. This strategy can help countries meet their international goals and reduce their greenhouse gas emissions. For instance, Sri Lanka, Afghanistan, and Maldives are expected to develop solar power.In addition, Bhutan and Nepal are also expected to benefit from the region's vast hydro resources. As for larger nations such as Bangladesh, India, and Pakistan, they can potentially increase their renewable energy mix by developing more balanced energy sources. The following table 2 shows the present generation measurements and peak demands of the different countries in the region. For instance, in Nepal and Afghanistan, the installed capacity of power plants is below the peak demand. The technology and country-wise breakdowns of renewable energy installations have been provided below. For instance, Nepal and Bhutan have traditionally been active in hydroelectricity. The other member states of the region, such as

India and Pakistan, have started catching up to their neighbours and are also investing heavily in wind and solar technologies.

CO2 Emission from Energy

Carbon dioxide emission of four countries India, Bangladesh, Sri Lanka, Pakistan from 2011 to 2021 and with comparison to world emission. The graphical representation of the above table mentioned in figure 6 clearly. India CO2 emission is high followed by Pakistan, Bangladesh and Sri Lanka. CO2 emissions from 2011 to 2021 world-wide, peak emissions observed in 2017-18 was displayed in fig 7. Growth rate and share of co2 emissions of 4 countries and world showed in Figure 8

Renewable Energy - Generation by Source (Wind, Solar, Hydro, Others)

Sources of generating renewable energy for India, Sri Lanka, Bangladesh, Pakistan and World were Wind, Solar, Hydro Power and other Renewables along with world data. The illustration showed in figure 9. Out of four countries India stands high in all sources of energy generation. Sources of generating renewable energy for India, Sri Lanka, Bangladesh, Pakistan and World were Wind, Solar, Hydro Power and other Renewables along with world data. The illustration showed in figure 9. Out of four countries India stands high in all sources of energy generation. The study focused on sustainable and renewable energies of major ASIAN countries like Bangladesh, Pakistan, Sri Lanka, India. The paper discusses about the energies like renewable and sustainable energy, non-renewables fossil fuels, CO2 emissions and greenhouse gases and their impact on nations.India's government's policies and financial instruments led to a 147.1 GW increase in renewable energy capacity in 2021. Majority of the renewable energy potential like solar, hydro, wind energy measured in Mega Watts among four ASIAN countries solar power was generated by Bangladesh. Hydro and Wind power. The consumption of electricity percapita in kilowatts is high for India 644 followed by Sri Lanka 636.6 and the population accessing the electricity was differ from 1990 to 2016 for the same. There is a huge difference in 1990 was 8.5% and 2016 was 75.9%To meet the growing power consumption in the major countries in the region, the energy supply requirements to increase significantly. Conventional sources of energy are not able to keep up with the region's increasing demand, which is resulting in greater reliance on imported fuel. Renewable energy sources can help meet the region's energy needs. Further peak demand of renewable energy generation capacity among four countries selected as installed in megawatt was high in India followed by Pakistan. For Installation of renewable energy Sri Lanka generates more in total as per pwc. India has the highest primary energy consumption among four countries (India, Sri Lanka, Bangladesh, Pakistan, and Sri Lanka) with 4.61% compared to the world's 4.4%.The total primary energy consumption in 2021 and its growth rate and share per annum from 2011 to 2021, with the highest consumption in 2019. The utilisation of primary energy across the world was illustrated in figure.8 the measurement expressed in exajoules. The data collected from 2011 to 2021. In India the consumption of energy is maximum in 2021 as 35.43 units followed by 34.15 EJ units in 2019. Among four ASIAN countries the least consumption of energy is Sri Lanka with 0.39EJ unit in 2019 but India is using 35.43 EJ units which is highest of 4 nations. Bangladesh utilizes less (1.65 EJ) energy compared with India (35.43 EJ). The data compared for 11 years from 2011 to 2021. Pakistan is second highest consumption nation of the study i.e., 3.86EJ in 2021 which scores maximum for 10 years of data. Asian's clean energy development framework has led to increased renewable energy usage and reduced environmental impact countries like Sri Lanka, Afghanistan, and Maldives are developing solar power, while Bhutan and Nepal benefit from hydro resources. Larger nations can potentially increase their renewable energy mix by developing balanced energy sources.

CONCLUSION

The fossil fuels consumption is high in the world, so there is significant scope and need of renewable energies. In Asia – Pacific region, Asian is significant contributor to the renewable energy market. The annual energy investment of Asian countries is quite less compared to global level investment comparatively from 2013 it has been increased. The potential of renewable energy, peak demand for production and consumption is high in India. In Carbon dioxide CO2 emission also, India ranked high to control and balance the environment there is a huge need of renewable

Lalitha

energies in the countries. India is the only country generate renewable energy by source hydro. In conclusion, reducing CO_2 emissions is urgent due to climate change threats. Transitioning to renewable energy sources like solar, wind, and hydropower is essential for a balanced environment. This shift demands concerted efforts from policymakers, industries, and individuals to adopt cleaner technologies. Investing in sustainable infrastructure and promoting energy efficiency will significantly cut emissions, fostering a resilient ecosystem. Additionally, this transformation offers economic benefits through green job creation. Ultimately, embracing renewable energy and reducing CO_2 emissions are critical for a sustainable and prosperous future for our planet.

ABSTRACT

Polycystic Ovarian Disease (PCOD) is a prevalent endocrine disorder affecting primarily women of reproductive age. It is characterized by biochemical or clinical evidence of hyperandrogenism, oligo-anovulation and polycystic ovarian morphology. This hormonal dysregulation leads to a range of symptoms, such as irregular menstrual cycles (less than 5-8 cycles per year), acne, hirsutism, hair thinning, obesity, acanthosis nigricans. It is associated with important reproductive morbidity, including infertility, endometrial cancer, metabolic and cardiovascular diseases, insulin resistance in obese and non-obese women. Homeopathy can be thought of as an alternative mode of treatment because its therapeutic approach is based on concept of individualization. As per Hahnemann "It is a man that is sick and needs to be restored to health and not his body or the tissues. Also, the true natural chronic disease arises from the chronic miasm and can only be treated by individualistic homeopathic constitutional medicine". "With this concept of the importance of the endocrine glands in maintaining health, and with the almost infinitesimal amount of some of these glandular secretions, we can hardly fail to see the important relationship the homeopathic remedy may hold to the manifestations of endocrine dysfunction and to the balance of the ductless glands themselves. Though there is a great clamor for information on treatment of endocrine conditions, the endocrinologist's findings are similar to the Hahnemannian philosophy that " The human being is a unit of mind, body and spirit - and these are so correlated as to act freely and without impediment when the vital principle, the spirit-like force, is in equilibrium; yet if this equilibrium of health be thrown out of balance by the dysfunction of one member." Citation : HERBERT A. ROBERTS: The principles and Art of Cure by Homœopathy; Chapter-XXXII- Homœopathic therapeutics in the field of endocrinology.

INTRODUCTION

The most common cause of secondary amenorrhea is PCOD,occurring in 5-10% of reproductive age women, also known as **Stein-Levanthal Syndrome.** It is a heterogeneous disorder of multifactorial aetiology in woman of reproductive age with the **ovarian expression** of various metabolic disturbances and of clinical features as **menstrual abnormalities**(Amenorrhea, Oligomenorrhea, Irregular bleeding), **Obesity, Hirsutism and Hyperandrogenism.**
The normal ovary is **3x4 cm** in size. In PCOD ovary there is multiple **small size follicles** which gives an appearance of **"Ring of Pearls"**. These follicles are arranged around the **periphery** of the ovary giving it a **Necklace Appearance.**There is presence of **20** or more follicles in either ovary measuring **2-9mm** in diameter or increased ovarian volume (**>10ml**). **According to ESHRE and ASRM conference held in 2018 the number of the follicles is updated from 12 to 20, and even if the one ovary is having this picture means more than 20 follicles is considered as PCOS.** Exact pathophysiology of PCOD is not clearly understood. The major causes for PCOD are hypothalamic pituitary abnormality and insulin resistance. These two factors further lead to androgen excess and chronic anovulation. The dysfunction in the hypothalamic pituitary axis leads to reduced rythmic, pulsatility of the GnRH pulse generator to progesterone suppression. Thus, ovarian steroid negative feedback that tightly regulates the Hypothalamic-Pituitary-Gonadal (HPG) axis is impaired, leading to hyperactive LH secretion. Higher frequency or constant exposure to LH gives rise to anovulation and amenorrhea. Variation in LH pulse frequency influence the ratio of LH and FSH levels. The other key factor that is resposible for the development of PCOD is insulin resistance which originally develops in the form of glucose intolerance. The insulin resistance at certain instances is termed as " the diabetes of bearded women". This insulin resistance manifests itself in different forms such as acanthosis nigricans, cental adiposity (mostly measured as increased hip-to-waist ratio and termed as male pattern obesity). Dyslipidemia is also evident in certain cases which also adds onto the disturbed hormonal levels. These dyslipidemia can also develop hypertension in long run cases. Another feature of hyperandrogenism and insulin resistance is hirsutism. It is defined as the presence of terminal hair in locations at which hair is not commonly found in women. It includes facial hair on the cheek, above the upper lip, on the chin and midline chest hair. The scoring system available for quantifying hirsutism are proposed by ferryman Gallway score. Visual methods are used to determine the density of terminal hairs at eleven different body sites- the lip, chin, chest, upper abdomen, lower abdomen, upper arm, forearm, thigh, lower leg; upper back and lower back- with scores ranging and the total score was calculated from 0-4, A maximum score of 36 is possible; but a score≥8; indicates hirsutism. Increased levels of androgen secretion induces over production of sebum causing desquamation of epithelial cells which lead to acne vulgaris. About 50% of the female suffer from facial acne, even neck, chest and upper back is also involved.

Objectives
1. To gauge the efficacy of homeopathic medicines in PCOD cases.
2. To determine the therapeutic strategy, evaluate the criteria for assessment, and analyze the treatment results of using homeopathic individualistic remedies in PCOD cases.

CASE REPORT

Case 1
A 28-year-old female consulted on 23/09/2022 for the treatment of menstrual irregularities (last 3-4 months menses not appeared), and abnormal hair growth on chin, back, upper lip and chest since 4 years. Menses with unbearable pain in hypogastrium and lumbar region (back). Menses lasts for only one day. Weight gain in last few years; it was 50 kg but now it is 65 kg. She was on gynecologist treatment but did not found quite effective. Menarche at the age of 13 yr,
Past History: recurrent pelvic inflammation, vaginitis, ganglion (operated 6 yr ago)
Family History: Father: High cholesterol, diabetes, Mother: hypertension

Shital C. Shah

Mental Generals

Born and brought up in Ahmedabad, studied B.com, housewife, husband works in a company. Stays with in laws. Normal in nature, not very sensitive, feels if husband can't give her enough time. Feel sad when mother in law scolds her or give advice repeatedly. Had a body image issues due to sudden weight gain. Lived in a joint family, had a strict grandfather who would not allow her to go out and he was very rigid and wanted things in a particular way. Had an incident in 7th std – a servant abused her sexually. That guilty feeling is still there and had a hard time, getting physical touch with her husband. Feels angry and weeps alone when remember the incidence

Physical general

Appetite: normal

Desire: oily food, junk food, onion,

Aversion: nothing specific

Thirst: 2 - 3 lit/day

Bowel: stool- hard, constipated

Urine: 6 -7 times/day

Perspiration: increased on genitals; slightly offensive

Sleep: restless,

Habit- tea/coffee/tobacco/smoking/alcohol-not any

Thermal: Hot

INVESTIGATION

Before treatment

After treatment

Shital C. Shah

First prescription

Thuja 1M single dose and sac lac ,TDS for one month is prescribed and advised for regular exercise for 30–35 min/per day with avoidance of junk/fast food and high-calorie diet.

Basis of prescription

Repertorisation was done of the following symptom:

Mind, delusion, imagination, ugly, is

Mind, anxiety, conscience of, as if guilty of crime

Female genitalia, menses, absent, amenorrhoea

Female, tumor, genitalia, ovary cyst

Skin, white spot, vitiligo

Food and drink, salty food, desire

Case 2

A 17-year-old female consulted on 24/12/2022 for the treatment of menstrual irregularities since menarche, menses every 2-2.5 months with abnormal hair growth on chin, back, upper lip and chest since 3 years. Menses with unbearable pain abdomen. Menses lasts for only one day. Weight gain in last few years; it was 50 kg but now it is 70 kg. She was on gynecologist treatment but did not found quite effective. Menarche at the age of 14 yr.

Past History: Dengue, typhoid.

Family History: Diabetes: mother, father, - grand mother

Mental Generals

Born and brought up in Mumbai, in a rich family, father is a businessman and mother works in a NGO. She always feels alone as her parents are busy in their life. Her mother always neglected me as she used to remain very busy with her meetings and work schedules. She had her first boyfriend at the age of 12yr, but it was just a crush and they broke up within sometime. Had another relationship for much longer than the previous one but they broke up because she needed more time and attention from the guy also the sexuality was higher. She felt that her needs were not fulfilled, so she parted her ways with him too. Recently she moved abroad to study and moved in with her new boyfriend within few months. She has a habit of masturbating quite frequently sometimes more than 5-6 times a day.

Physical general

Appetite: normal

Desire: meat, chocolate

Aversion: bitter gourd, coriander

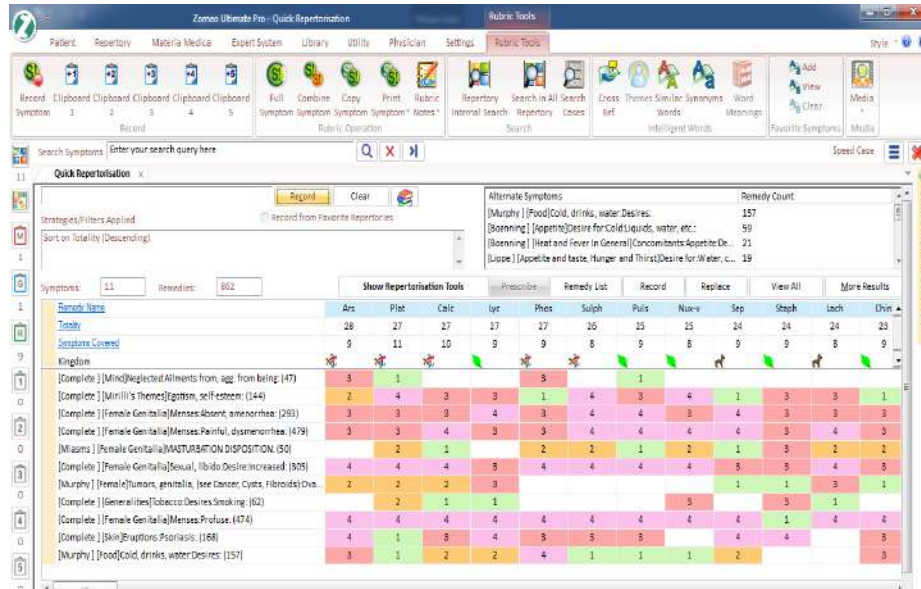
Thirst: 2 - 3 lit/day
Bowel: stool- hard , constipated
Urine: 6 -7 times/day
Perspiration: increase
Sleep: restless,
Habit- smoking and alcohol
Thermal: Hot

INVESTIGATIONS
Before treatment

After treatment

First prescription : PLATINA 10M single dose and sac lac ,TDS for one month is prescribed and advised for regular exercise for 30–35 min/per day with avoidance of junk/fast food and high-calorie diet.
Basis of prescription
Repertorisation was done of the following symptom:
Food, cold, drinks, water, desire:
Female, tumors, genitalia: ovary
Skin, eruptions: psoriasis
Female genitalia, menses, absent, amenorrhea
Female genitalia, menses, painful, dysmenorrhea
Female genitalia, masturbation, disposition
Female genitalia, menses profuse
Female genitalia, sexual, libido: desire, increased
Generalities, tobacco: desire: smoking
Mind, neglected: ailments from, agg. From being


Case 3

A case of 16-year-old girl came with PCOD on 16/9/2022 with complain of irregular menses since menarche. on investigation cysts were found in ovaries and also there was marked hyperandrogenism and a disturbed value of LH and FSH. She had extra hair-growth on chin and face. She had no visible weight gain which was contrary to the classical PCOD symptoms but had a marked biochemical changes.

Past History: recurrent stye.

Family History: Heart disease: Grandfather

Diabetes: grand mother

Mental Generals

Very shy in nature, always help mother in her household activity, father is strict, scolds me on a small matter without any reason, but I never back answer him. Even in a school my class mates tease me but I become quiet, always feel I slap him, but can't. loves to play badminton, and help teacher in extracurricular activity. Wants to go abroad for further studies. Scored 10 out of 30 in social studies. "I studied hard for the examination, but on that day not feeling well. The teacher scolds me badly and called my parents to show the result and complain about me, without knowing any reason, my father started abusing me verbally in school, he never understands me. He loves me and takes good care of me, but the way he scold me that affects me. My mother is mild and very caring in nature."

Physical general

Appetite: 2 times/ day

Desire: junk food +3

Aversion: rice

Thirst: 3-4 L/ day

Bowel: regular

Urine: 5-6 times / day

Perspiration: increased on face

Sleep: sound

Thermal: hot

INVESTIGATIONS
Before treatment

After treatment

First prescription: STAPHYSAGRIA 10M single dose and sac lac ,TDS for one month is prescribed and advised for regular exercise for 30–35 min/per day with avoidance of junk/fast food and high-calorie diet.

Basis of prescription

Repertorisation was done of the following symptom:

Food and drinks: Rice: Aversion

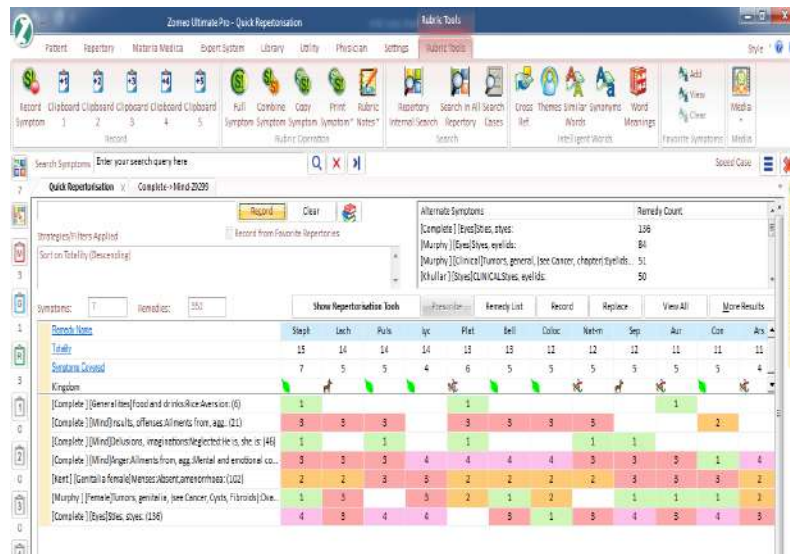
Mind: Insults, offenses: Ailments from, agg.

Mind: Delusions, imagination; Neglected: He is, she is

Mind: Anger Ailments from, agg.: Mental and emotional

Female genitalia: Menses : Absent, amenorrhoea

Female: Tumors, genitalia; Ova

Eyes: sties, styes


Case 4

Case of a 32-year-old female with irregular menses after the death of her husband with baldness appearing in her hairline. She also had fibroids in the uterus along with multiple cysts in ovaries. She also showed with increased hair growth on the face especially on chin, upper lip and chest.

History: -

Family History: Rheumatism: mother

Mental Generals

Bornand brought up in Ahmedabad. Studied B.com and she is housewife. Husband businessman. Stayed with joint family. She is very emotional and feels hurt when anyone says anything to her. She is taciturn, don't want to talk much. She never explains her feelings to other even she feel sad. Early years of mairrage, mother in law uses censorious words, but she just keep silent. Husband nature was good. He was loving and gives respect and even takes stand for me. But one day when she was at her parents home, and she had a news that he had done suicide, as he had lost everything in his business. Her life was totally changed. She was in depression for few years and had treatment for it. Now she stays with her parents. Her Bhabhi don't like that she stays with them. so fight with her on small matters , and her mother is suffering from initial stage of dementia, so she is controlling herself and not telling others that she had hurt or feel sad. She loved long and driving and risky activities like mountain climbing, diving, driving motorcycle, bungee jumping and parachuting feels attractive to them.

Physical general

Appetite: 3 times/ day

Desire: chocolate^{+2}

Aversion: bitter gourd

Thirst: 2-3L/ day

Bowel: regular

Urine: 5-6 times/ day

Perspiration: more on axilla and chest

Sleep: disturbed

Habit-:

Thermal: chilly

INVESTIGATIONS
Before treatment

After treatment

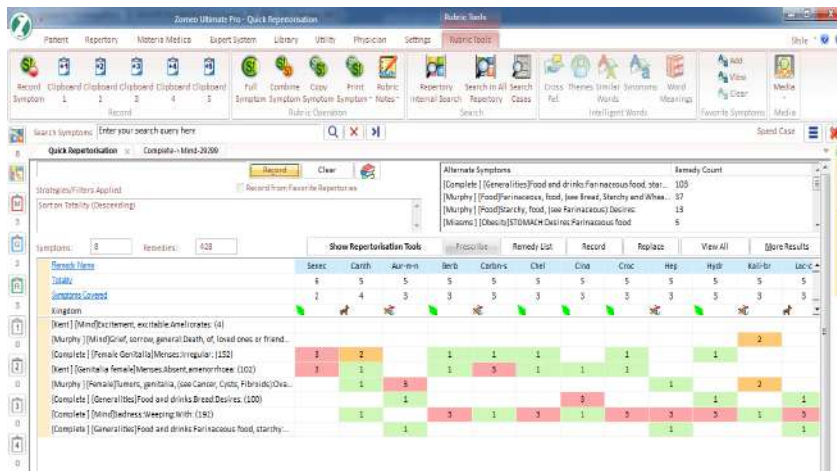
Repertorisation was done of the following symptom:
Mind, grief, sorrow, general: death of loved ones
Mind, sadness: weeping with
Mind, excitement, excitable, ameliorates
Genitalia female, menses: absent, amenorrhoea
Female,tumors, genitalia, :ovaries cyst
Generalities, food and drinks: bread, desires
Generalities, food and drinks: farinaceous desire

Shital C. Shah


DISCUSSION AND CONCLUSION

In § 5, Dr Hahnemann has mentioned, "the most significant points in the whole history of the chronic disease, to enable him to discover its fundamental cause, which is generally due to a chronic miasm. In these investigations, the ascertainable physical constitution of the patient (especially when the disease is chronic), his moral and intellectual character, his occupation, mode of living and habits, his social and domestic relations, his age, sexual function, etc. are to be taken into consideration."As PCOD is a condition of multisystem involvement, a multidisciplinary approach is pivotal to combat and overcome it. Our dynamic remedies arouse the individuals own immunity which fights the disease as an entity dynamically and re- establishes the health and harmony. Thus, a dynamic homoeopathic similimum clears hormonal imbalance, regularizes natural ovulation, restores menstrual normalcy, handles obesity, and treats as a whole positively. From the analysis of the above results obtained it is obvious that Homoeopathic treatment is effective in Polycystic Ovarian Disease especially where the patient is disturbed emotionally. We should consider mental general and constitution of patient for most similar homoeopathic remedy. Life style modification along with homoeopathic treatment is effective in reducing signs and symptoms of PCOD.

ABSTRACT

Financial literacy is important because it is only through being able to understand how money works that we can conquer it. Money may not be the only thing that matters but it does affect everything that matters: education, family, health, etc. Making money is a skill. And like most skills, it can be learned. If we want to become financially free the first steps to this is financial literacy. Become financially literate and start working on our way towards financial freedom. The lack of essential knowledge about financial products and services and their risk-return framework is one typical example of financial illiteracy that is regularly observed. The main objective of this paper is to analyze about the awareness about the financial knowledge among the students , channel of investment and savings. This paper also focuses on which factor plays a predominant role influences the student to invest in pattern of investment. Questionnaire have been framed to collect the data from the under graduate students. It is found that students were aware about the financial literacy and investment.

Keywords: Money, Investment, financial knowledge

INTRODUCTION

The creation, administration, and study of money and investments are collectively referred to as "finance" in this context. It comprises using projected income flows to fund ongoing projects via credit and debit, securities, and investments. Because the concept of financial literacy is complex, it is essential to comprehend its full relevance. Actually, our culture still hasn't fully grasped the need and potential of financial literacy. Financial literacy permeates every social group and economic level. Understanding and effectively utilizing different financial skills, such as

personal financial management, budgeting, and saving, are components of financial literacy. A person who is financially literate has the capacity to appropriately utilise credit, the assurance to manage their money and financial risks, an understanding of the long-term advantages of saving, and a positive outlook on financial planning. These are merely fundamental yet necessary qualities that each and every person and consumer demands. For the improvement of fundamental money management and personal success, the ability to function in a literate society extends specifically to financial competence. These initiatives have benefited from the national strategy for financial inclusion **(NSFI) 2019–2024**. The goal of the plan is to give under banked and underinsured people inexpensive access to formal financial services including banking and insurance. The other two significant goals, which include a comprehensive strategy for empowering end users, are promoting financial literacy and protecting consumers. These initiatives have made it possible to close the gap and include a significant portion of our population in financial services. Women currently own 56 per cent of PMJDY bank accounts. According to the **Economic Survey 2022–23,** India's life insurance penetration rate was 3.2 per cent in 2021, which is somewhat higher than the global average and nearly twice as high as that of emerging markets.

STATEMENT OF THE PROBLEM
The level of financial literacy is cause of concern in all sectors of the economy. The determination of financial literacy of college students in very critical because today's students can be tomorrow's investors. Here is the need of studying financial literacy of college students as there is a tenet that the Indian teenagers lack financial literacy. The development of every economy depends on healthy saving and proper allocation of funds. For that there is a constant need for good financial knowledge among the citizens of the nation. That proper allocation id dependent upon the financial literacy and skills that the individual have. Good financial knowledge will contribute to better savings. The awareness of various investment avenues, the preferences in investing, consideration of the opinion of friends and family members, financial position of family can all affect the financial literacy of a person. These factors may vary from one person to another. Participation of student in various classes should also be taken into consideration. A number of studies have been conducted in India and abroad regarding financial literacy and its importance in the day today life of every individual, lack of financial literacy is not a problem only in emerging or developing economics. Consumers in developed or advanced economics also fail to demonstrate a strong grasp of financial principles in order to understand and negotiate the financial landscape, manage financial risks effectively and avoid financial pitfalls. A study is needed to evaluate the level of understanding about the financial literacy.

REVIEW OF THE LITERATURE

Garg and Singh (gar 2018) Financial literacy among youth though out the world and found low literacy level among youth. The study also revealed that age, gender, income, marital status level of education plays an important role towards youth literacy level and interlink ages was found between knowledge, attitude and behaviour. **Jeyaram and Mustapha(2017)**The Relationship between financial literacy and demographic factor of university students in Malaysia. The results showed that students studying accounting and business administration found to have a better financial literacy than students in other branches. It was also found that there is a relationship between gender and level of financial literacy, as females students found to have lower levels of financial literacy than males. **Mani Goswami (2017)**The primary goal of her research paper, "A Study on Financial Literacy Among College Students in Delhi," is to analyse the degree of financial literacy among college students by evaluating the influence of various demographic factors, including gender, age group, discipline of study, level of study, annual household income, parent's occupation, and source of income to the students. The report also recommended that students be given access to personal finance courses on campus. All disciplines should be required to complete these. These classes ought to give students hands-on experience, encouraging participation and the transmission of knowledge and financial management skills. **Lazar , and Chandrasekar (2016).** A study was done to determine the impact of demographic parameters on financial literacy, including age, years of education completed, and personal income. Other demographic indicators are employed as independent variables, and financial literacy is used as a dependent variable. The survey took into account working women from Pondicherry who were professionals, salaried workers,

daily wage earners, registered business owners, and unregistered business owners. Financial literacy was found to be more strongly influenced by education than by age, and to be unrelated to personal income. **Mahammad Rizwan, Mahammad Sadhik, Kishan Kumar K S (2015).** The purpose of this study, "A Study on Financial Literacy Among the College Students," is to investigate how the Jnana Jyothi Financial Literacy Trust and its literacy initiatives have helped college students gain financial literacy. The study's primary goals are to evaluate the degree of financial literacy among college students, as well as the demand for financial literacy initiatives among present students, on college campuses. All of the respondents agreed that there was a critical need for financial education in both high schools and colleges, it was discovered. This is due to the students' ignorance of the financial services and products offered by banks. As a result, financial education is necessary. Their research also revealed a rise in deposits at the respondents' respondents' savings bank as well as savings. It demonstrates how trust has an impact on encouraging kids to save money. **Muhammad Albeerdy and Behrooz Gharleghi (2015).** "A study on Determinants of the Financial Literacy among College Students in Malaysia'' they tried to investigate the factors influencing the financial literacy among university students in Malaysia. Empirical results show that there is a significant relationship between independent variables of education, and money attitude towards the dependent variable of financial literacy, while there found no relationship between financial socialization agents and financial literacy. Conclusions: This study is important so as to understand how these independent variables affect the literacy rate of young adults. Efforts may be put to strengthen those variables in order increase the literacy rates of those university students. **Bedi, Sobti and Shankar(Bed2015)** a research study examined the relation among demographic characteristics and financial literacy, behaviour and assessment and also analysed the interconnection between the financial literacy and financial behaviour. The findings suggested that financial literacy varies across the level of education and incomes whereas the behaviour differs across "age, marital status, occupation, work experience and level of income of individuals". Lastly study established positive interrelation between financial behaviour and financial literacy.

OBJECTIVES OF THE STUDY:
- To know their financial knowledge towards saving and investment
- To analyze the money management skills possessed by the students.
- To know the financial literacy among the students.

LIMITATIONS OF STUDY
The following are the limitations of the study. The study covers only a sample 110 student respondents among the under graduate students. Due to time constraint the study has limited to a college in Coimbatore city. The result is based on the information collected from a sample of 110 students. So, No generalization is possible.

RESEARCH METHODOLOGY
In order to achieve the objectives of the study and to analyze the data collected, an appropriate methodology was developed. The present study is exploratory as well as descriptive. The collection of data and analysis are planned accordingly. The various aspects of methodology adopted in the present study are discussed below. The research design used in the study is descriptive research design. A descriptive study is undertaken in order to ascertain and be able to describe the characteristics of the variables, the research design reveals the study of facts existing. Primary data have been used by using questionnaire method to collect the response from the respondents. Simple percentage analysis and Chi square analysis have been used to analayse the collected data.

SAMPLE SIZE
Using the random sampling method, the data have been collected from 110 respondents.

SAMPLING METHOD
Convenient sampling method is used to select the respondents.

Hypothesis of the study
Hypothesis: The following Null hypothesis were framed and significant of these were tested with Chi – Square test with 5 percent level of significance.
Ho : There is no significant relationship between age and financial literacy of the respondents.
H1 : There is a significant relationship between age and financial literacy of the respondents.

ANALYSIS AND INTERPRETATION
FINANCIAL KNOWLEDGE TOWARDS SAVINGS AND INVESTMENTS.
Table 1 shows that Eatables gets the first rank with the mean score of 4.36, Stationery gets the second rank with the mean score of 4.345. Clothing, Books and magazines gets the third and fourth position with the mean score of 4.14 and 3.835 respectively. Since most of the student respondents are between 17-19 years they mostly spend their money on eatables, stationery and clothing rather than spending on books and magazines. Table II reveals that 88per cent of the student respondents are having savings bank account. 56 per cent of the student had the habit of keeping hundi at home. 35 per cent of the student have post office saving account. Only 27 per cent of them are availing education loan. This shows that students are aware of saving money by saving bank account or by hundi or by post office saving account and they show less interest in availing loan and insurance policy. Table III reveals that, Safety of principal amount gets the first rank with the mean score value of 3.735. Liquidity get the second rank with the mean score value of 3.085 followed by periodic return with the mean score value of 2.815. This reveals that most of the student respondents prefer saving money in bank thinking that it would keep their principal amount safe, rather than considering about the periodic returns or appreciation in capital value. Table IV shows that, life insurance policy occupies the first rank with the mean value of 3.695. Gold and silver occupies the second rank with the mean value of 3.41. Shares and Securities come in third position with the mean value of 2.78. Real estate and Mutual funds were in fourth and fifth position with a mean values 2.655 and2.595 respectively. This shows that the student respondents prefer to be in safer side by investing their money in low risk investment channels like life insurance policy, gold and silver. So, they avoid investing in high-risk channels such as shares and securities.

AWARENESS OF THE STUDENTS REGARDING THE FINANCIAL PRODUCTS
Table V reveals that the student respondents are having a knowledge about saving with high mean score value of 2.95 and low mean score value of 1. It implies that the students are more aware about savings is a part of our family life. and less aware in differencing the savings and investments. The students have knowledge on interest towards money lenders interest reveals a high mean score value of 2.55, a lesser knowledge of interest on saving towards bank with a mean score value of 2. Respondents believe that health insurance will covers hospitalisation expenses where it shows a higher mean score value of 2, a insurance which reduces financial risk with low mean score value of 2. It is also analysed that the user of e-shopping with credit card were more facilitated with a higher mean score value of 3, a lower usage of ATM card with the less mean score value of 1. From the improper use of credit card we understood that more spending with a high mean score value of 2 and financial trouble with a lower mean score value of 2. The respondents were very much knowledge and aware of educational loan is repayable with a mean score value of 2.5 and less aware of banks that are regulated by RBI with a low mean score value 2. Knowledge about financial literacy in day today life is higher with high mean score value of 2 when compare the knowledge about the slab rates that is with lower mean score value of 2. Table VI portrays that, 50per cent of the students view towards financial literacy, was savings and channels of investment. 26per cent stated that managing debt and financial security, is financial literacy. And 24per cent thinks that protection and accumulation of wealth is financial literacy. This table show that the student respondents had knowledge that saving and investment is financial literacy because most of them preferred to be in safer side by saving their money.

CHI-SQUAREANALYSIS
This analysis is used to determine the inter-relationship between the major and financial literacy.

RELATIONSHIP BETWEEN MAJOR AND FINANCIAL LITERACY

To determine the inter-dependency between the major and financial literacy, the following hypothesis is framed:

H1: There is significant difference between the major and financial literacy.

The above table reveals that the chi-square value was greater than the table value. Hence the hypothesis was accepted. It indicates that, the major and financial literacy depend on each other.

RELATIONSHIP BETWEEN AGE AND FINANCIAL LITERACY

To determine the inter dependency between the age and financial literacy, the following hypothesis was framed:

H2:There is significant difference between the age and financial literacy.

The above table reveal that the chi-square value was greater than the table value. Hence the hypothesis was accepted. Thus, the age and financial literacy depend on each other.

SUGGESTIONS

- It is found that the students respondents were willing to invest in safer modes like gold and silver, deposits in banks. Hence it is suggested to invest in shares and securities to attain hide returns.
- Students should know the importance of money and avoid spending unwantedly.
- It is suggested to the students that, they should be aware of their family budgets which influences their spending attitude.
- Encourage students to engage in part time jobs.
- To create an awareness about investing in other sources such as mutual funds, government bonds which may give higher rate of return.
- Creating awareness among the students about the fraudulent practices from unscrupulous people from southern part of Tamil Nadu.
- It is advised to the students to invest in high-risk investment to gain higher rate of return.

CONCLUSION

The students were willing to be in a safer side when it comes to investment of their principle amount, and they didn't give much importance for the capital appreciation. It is found that the students had the habit of saving either in bank or in post office or atleast by keeping hundi at home which shows that the students are having the knowledge of saving for future by knowing the value of money. We have analyzed that there is a connection between the age and financial literacy of the students. Thus, from the study of financial literacy we came to know that students had good knowledge in the field of finance. There is a long way for the students to know the depth in the field of financial literacy so it is better to teach the students about financial literacy from their early age. The knowledge of financial literacy should be inculcated for the students in their early stage itself preferably from the day of schooling.

ABSTRACT

The continents have experienced widespread disorder and tragedy as COVID-19 spreads rapidly. Under such circumstances, the indices measuring life satisfaction may decrease, while the likelihood of experiencing elevated mental stress is expected to increase. This study examines the stress levels and life satisfaction of 240 diabetic patients in our hospital during the COVID-19 pandemic. The average age of participants was 56.28 years, with 44.6% aged 50 or older. Results indicate that 50% of participants experienced moderate to high stress levels, with around 20% facing stress-related difficulties. This suggests a critical need for stress-reducing interventions, as stress may adversely affect blood sugar control in diabetic patients. Implementing stress-management strategies is crucial to prevent future complications associated with diabetes.

Keywords: COVID lockdown; Mental disorder; Daily life satisfaction; Diabetes; Stress.

INTRODUCTION

The Coronavirus Infectious Disease (COVID) pandemic has caused substantial distress for most of the human population [1]. In response to the COVID epidemic, the governments of several nations have implemented novel strategies to curb the spread of the disease [2, 3]. It has devastated one nation after another, annihilating all that our generation has ever seen [4]. Furthermore, apart from its adverse effects on an individual's physical and psychological well-being, it has led to a worldwide economic decline, joblessness, and international isolation measures [5]. The Indian government implemented the nationwide lockdown in March 2020, which imposed restrictions on the mobility of the nation's 1.3 billion residents, allowing only medical emergencies and crucial services [6]. The confinement zones remain subject to stringent lockdown measures, notwithstanding the progressive easing of restrictions after the conclusion of the lockdown in May 2020 [7]. As a consequence of the COVID epidemic, ordinary persons are experiencing mental health issues due to their exposure to extraordinary circumstances. For those employed in locations far from their residences, the lockdown has resulted in prolonged detachment from their families [8]. Furthermore, the loss of employment has resulted in financial adversity, which might potentially culminate in severe complications [9]. There are several forms of manifestations, including emotional issues like worry and depression, physiological effects like disrupted sleep and appetite, severe mental disorders, and drug misuse [10]. While the lockdown was essential for containing the epidemic, particularly to safeguard vulnerable groups like the elderly, diabetics, and cancer patients, the severe controls are expected to hurt the emotional well-being of the general population [11]. Individuals hailing from various regions of India encountered starvation, fatigue, law enforcement brutality, economic adversity, and joblessness [12]. Furthermore, they ought to have given more significant consideration to receiving appropriate medical care.

Regrettably, there is a lack of statistics about precise demographic information, such as the prevalence of diabetes among individuals. In recent years, researchers have postulated that stressful events may impact the regulation of diabetes and have shown a correlation between stressful events and the management of diabetes mellitus [13]. The hypothalamic-pituitary-adrenal (HPA) axis activates in reaction to psychological stresses related to feelings of defeatism or helplessness [14]. This activation leads to several hormonal imbalances, including elevated cortisol levels and reduced sex steroid levels, which oppose the effects of insulin. Self-care issues might also arise due to responses to external pressures, such as the anxiety and horror caused by COVID and the limitations on movement imposed by a lockdown [15]. It manifests as less physical activity, a worse dietary regimen, and a pervasive sense of melancholy, so impeding the ability to participate in self-care practices [16]. A lot of people in Puducherry have been getting psychological treatment from the government. Addressing the unique requirements of migrant workers, children with special needs, patients with mental disorders, and elderly people living alone is just one more way it has adopted an inclusive approach [17]. The state has provided psychiatric aid to around 1.2 million individuals out of its population of over 3.5 million. Psychiatric First Aid, which involves providing comprehensive assistance to those experiencing distress to promote a sense of calm and enhance their ability to cope, is crucial for preventing psychiatric issues [18]. It is imperative to prioritize the resolution of existing mental health disparities, particularly among the diabetic population, due to the detrimental impact that stress may have on diabetes care [19]. Because mental health services are already in a precarious position nationwide, the massive scope of the epidemic has only made matters worse. The purpose of this study is to examine the effect of COVID lockdown procedures on the psychological distress and subjective well-being of diabetic patients attending an endocrinology outpatient service clinic in Puducherry to obtain treatment.

METHODOLOGY

The study was done after obtaining clearance from the Institutional Ethics Committee of Medical College and Hospital, Puducherry. Patients who were undergoing ongoing follow-up therapy at the institution's Endocrinology Department were the subjects of this cross-sectional study. Amidst the countrywide lockdown, the patients were interviewed by telephone after the interviewer provided a formal self-introduction and obtained their consent to take

part in the research. The Perceived Stress Scale (PSS) and the Satisfaction with Life Scale (SWLS) were used to assess the subjects' stress levels and life satisfaction. The study included all adult individuals who had consistently made at least five visits to the Outpatient Department (OPD) over the previous year. Exclusion was applied to patients who chose not to participate in the survey. Two hundred and forty patients satisfied the criteria above and participated in the clinical study. The higher PSS scores reflect an elevated level of perceived stress, with individual values on the scale ranging from 0 to 40. According to the study, stress levels may be categorized as follows: scores ranging from 0 to 13 indicate mild stress, scores between 14 and 26 indicate moderate stress, and scores between 27 and 40 indicate high levels of perceived stress [12]. Individuals who indicated moderate to high-stress levels were categorized as feeling stress. A brief assessment tool, the Contentment with Existence Scale, was developed to evaluate an individual's overall cognitive happiness with their existence. In addition, a Likert Scale is used, which uses a rating system ranging from 1 to 7. A rating of "1" represents strong disagreement, while a "7" represents strong agreement. The whole outcome is quantified as a score of 35, with higher numbers indicating greater life satisfaction. Individuals who obtained a score of 20 or above were considered content with their lives, whilst those with a score of 20 or below were considered unsatisfied.

Statistical Analysis
The statistical analysis was conducted using SPSS version 29 after data input in Microsoft Excel [20]. The study used descriptive statistics and demographic features to evaluate the proportion of participants who reported high levels of stress and life unhappiness. Using the chi-square test, an investigation was conducted to analyze the correlation between life satisfaction and perceived stress.

RESULTS

The research included 240 participants who had diabetes. The average age of the study's participants was 56.28 ± 15.8 years. The oldest competitor was <=80 years of age, and the youngest was >=18 years old. 4% of the study participants were above 55. The study's participants consisted of more than 75% women. 25% of them have successfully finished their courses and obtained a diploma (Table 1). Based on the Perceived Stress Scale, precisely 50% of the people had moderate to high stress levels. While most individuals had favorable scores on the happiness with life measure, indicating their contentment with their lives, around 15% expressed dissatisfaction. The study found a strong correlation between age **(p = 0.036**) and life satisfaction (p = 0.001) in predicting stress while considering the associated features. Approximately 20% of the participants had difficulty in managing stress. The predominant strategies used to manage stress induced by the COVID lockdown were "Reliance on religious beliefs" and "Assistance from family members."

DISCUSSION

During the first phase of the lockdown, there was a widespread belief that the issue would be resolved swiftly. Nevertheless, with the uncontrolled spread of COVID and the lockdown, a significant number of individuals started encountering heightened levels of stress, melancholy, and sleep disturbances. Individuals may evaluate a stressful event differently based on past information, psychological factors, and social influences. The stress response, sometimes called the "fight-or-flight" response, is a specific series of physiological processes that occur when a perceived threat can harm an individual. When faced with the unprecedented COVID danger, our only recourse is to "respond with determination." Considering its ubiquitous nature, we are unable to evade it. Consequently, individuals may experience a range of stressors, such as anxiety about contracting COVID, inadequate or ambiguous information, monotony and discontentment, a shortage of social interactions, and financial hardships. Consequently, a significant number of individuals are susceptible to developing new mental health conditions, such as health-related anxiety, despair, discontent with Life, acute stress reactions, and emotional fatigue. Thus, it was imperative to assess the level of stress experienced by our community. Our analysis revealed that 50% of our diabetic patients reported stress. Undoubtedly, this proportion is concerning. Puducherry has a prevalence rate of around 20%, with

Durairaj Varalakshmi *et al.,*

over two-thirds of those aged 45 and above either having diabetes or being susceptible to its development. Studies indicate that several factors, including the quality of interactions with medical professionals, the impact of diabetes on daily life and work, and anxiety about the future, have a substantial role in stress-related or exacerbated diabetes. During the lockdown, diabetic patients were deprived of their regular monitoring and support from their reliable healthcare providers. Furthermore, due to the inability to engage in social activities or carry out professional responsibilities, all offices remained shut, perhaps leading to heightened stress levels. Research has shown that social support functions as a protective barrier against stress. Research suggests that stress might impede an individual's ability to self-manage diabetes. During periods of stress, individuals may have difficulties performing essential self-care tasks such as consistently monitoring glucose levels, planning meals, accurately preparing food, and remembering to take insulin or oral medications at the designated times. Hence, it is imperative to acknowledge that our populace is experiencing stress, and it is vital to acquire the ability to manage the negative responses to stress, particularly considering that the underlying factors, such as COVID, will last for an extended duration. Additionally, our research uncovered a significant association between age and stress. 62.2% of those between the ages of 36 and 55 reported experiencing stress. This demographic consists of employed individuals who may have been concerned about fulfilling familial responsibilities, raising their children, facing unemployment, or encountering financial hardships, all of which might have contributed to their elevated stress levels.

The contentment with life, which serves as a measure of well-being, has been associated with indications of mental health. Moreover, it predicts forthcoming behaviors such as suicide attempts. Based on our study, most participants expressed satisfaction with their lives. However, among the subset of individuals constituting 15% who expressed discontent with their lives, it was shown that stress levels were notably elevated, thereby establishing a distinct correlation between stress and unhappiness with life. Stress was found to be prevalent in 80.7% of those who indicated dissatisfaction with their lifestyles. Given the higher prevalence of depression in individuals with diabetes compared to the general population, healthcare providers must also differentiate between stress and depression. To assess for depression, it is necessary to use assessment methods. Research has also shown a significant association between feelings of grief and worry and the media coverage around the COVID outbreak. Media coverage of COVID might potentially have detrimental effects on an individual's emotional well-being. Implementing behavioral changes such as engaging in hobbies, exploring new interests, and limiting exposure to media reports on COVID may effectively reduce stress levels. Furthermore, it is crucial to acknowledge that individuals can effectively cope with this circumstance by cultivating emotional control, relying on their religious beliefs, engaging in regular daily tasks with their children, communicating with others through telephone or other technological means, and cultivating new hobbies or reviving old ones. Our investigation revealed that individuals mostly used family support and religious belief as coping mechanisms for stress. The enduring psychological ramifications of COVID need the continuation of therapy services during the lockdown period and for many months beyond. It is essential to recognize that if stress, depression, and anxiety are not accurately detected and treated, they may intensify into more severe distress. They have the potential to elicit suicidal ideation, emotions of powerlessness, and a sense of despair. During the pandemic, it is necessary to provide ongoing psychological crisis management for those at a higher risk. Under these conditions, helplines serve as vital sources of support. It is crucial to give enough treatment to the many individuals who are experiencing mental health issues because of the pandemic. Additionally, it is critical to cultivate resilience since it is essential for navigating these challenging circumstances.

CONCLUSION

Up to 50% of individuals in Puducherry with diabetes encountered stress. However, almost 85% self-identified as "Satisfied with Life." There was a strong correlation between stress and life satisfaction, and those dissatisfied with their circumstances were more prone to experiencing stress. 20% of the participants exhibited an inability to effectively cope with stress, even though most of them claimed to be doing their utmost effort to manage stress by relying on their religious beliefs and receiving support from their family.

ABSTRACT

Bengaluru is the third-most densely populated Indian city in terms of demography, and has adverse effects due to rapid urbanization. This study focuses primarily on determining the adverse effects of urbanisation by focusing on the effects on air, temperature, urban sprawl, and the lakes. The meteorological data was collected and analysed by using software like Google Earth Pro, AutoCAD Map 2000i, and Q-GIS. Within the last two decades, Bengaluru's population has increased by 88.10%, a total of 1955 new high-rise buildings have been built, the lake count has been reduced to 108 from 128 , the built-up area has increased by 87.33% while reducing greenery areas by 47.68%, and the AQI and temperature has also showed the variation as a result of increased urbanization. QGIS software is used to develop the maps representing the current environmental conditions, also a comparison is done with last ten years data

Keywords: Auto CAD Map 2000i, AQI, Google Earth Pro, Q-GIS, Urban Sprawl, Urbanization.

INTRODUCTION

Bengaluru's Urbanization

Bengaluru City capital of Karnataka, a state situated in southern India which falls under India's fifth-largest metropolitan area. Despite having a long history in manufacturing sector, the last couple of decades have seen it to transform into a global centre for Information Technology and services related with several domestic and international corporations locating offices here. During 1991, the Ministry of Electronics and Information Technology had set up the Software Technology Parks of India (STPI) in Bengaluru. In terms of demography, Bengaluru falls under the third most populated Indian city. Bengaluru's urban assemblage is called as the Bengaluru Metropolitan Region (BMR) and includes Bengaluru's urban & rural districts and Ramanagar district. Bengaluru's Metropolitan Region Development Authority (BMRDA), a regional development authority has jurisdiction over BMR and is functioning as per the provisions of Bengaluru Metropolitan Region Development Authority Act (BMRDA), 1985. The total extent of BMR is 8005 sq. km in terms of area. As of 2011, BMR had the total population count of 11.69 million. Between the years 2001–2011, nearly 38.9% population growth has taken place in the BMR and is primarily attributed to the inrush of IT employees in the city, compared to the prior decade, the population growth rate was 29.3%. Bengaluru is also one of the fastest changing city and growth of industrial and IT corridors are the major reason for this transition[1].However, it has resulted in unplanned growth and management especially in terms of infrastructure and services due to this rapid transition. During 1991-01, the area within the city limits recorded a significant increase by 92.1% and the population by 37.8% [2]. The spatial expansion of the urbanized area has increased to 710 sq. km from 226 sq. km in 1995[3].

Impacts of urbanization

The impacts of Urbanization have majorly considered in three sectors High Rise Building construction & Urban Sprawl (Land), AQI & Temperature (Air) and Lakes (Water).

High Rise Buildings

High-rise buildings are defined as the buildings having floor count more than 13 floors or above and their construction was only possible with the introduction of elevators in the buildings. Buildings with over 40 floors are Skyscrapers and are considered part of the high-rise category. In current scenario, the construction of the high-rise buildings is increasing which alongside arises a risk of eventually reaching a breaking point horizontally.[4]The studies show there's huge social and environmental risks arising due to these mega-structures construction and even having a negative impact on biosphere and human health as well.[5]

Urban Sprawl

The recent emphasis on urban growth and IT industries in Bengaluru is the primary cause of the land use change. There's a rapid land use change in and around city limits, as shown in fig. 1, resulting in geographical expansion and the rapid mushrooming of the population within the city limits. With 90.9 percent of its population residing in the city, Bengaluru is the most urbanised district. With unplanned and rapid urbanization, the city is characterised by high population density, more traffic congestion, a high pollution level, unaffordable housing, the creation of slums, urban crimes, expensive living costs, the degradation of the environment, sanitation issues, and water shortages. The district's area is 2196 sq. km., with 4381 people living in each sq. km[6]. As the cities enlarge, they expand around their outer city limits, but urban sprawl is defined as uncoordinated growth and is specific in nature, it occurs without considering the consequences of the expansion of a community on the environment. Urban sprawl is also identified by titles such as "distributed urbanization' or 'horizontal spreading'[7]. It's observed in both low-income and high-income countries. A variety of reasons are responsible for urban sprawl; among the main causes are lower house taxes, a lack of urban planning, improved infrastructure, lower land rates, rising living standards, increased population growth, and growing consumer preferences. The consequences include impacts on ecology, energy consumption, land consumption, atmospheric pollution, loss of farmland, loss of natural resources, the formation of

urban heat islands, and impacts on wildlife and the ecosystem.

Lakes

Lakes are one of the most essential parts of any ecosystem. In older times, lakes acted as the major water source for daily uses like drinking, washing clothes, etc. Apart from being a source of groundwater, it also serves as a recharge point for underground aquifers[8]. From historical data, in Bengaluru, the lakes are shrinking as a consequence of encroaching construction activities resulting from urbanisation .Lakes are also home to numerous bird, floral, and faunal species[9]. Conservation of the lakes should be done as soon as possible because losing any more time in initiating the process will just lead to skyrocketing the costs in the future to do the same work.

AQI and Temperature

The air quality index (AQI) for a given day is a number used for reporting the air quality: basically, it's the level of cleanliness of the air. It measures the particles and chemicals in the air that affect the health of people [8] The health effects of extreme pollution are severe, ranging from slight irritations to reduced endurance to respiratory problems. The consequence of urbanisation is observed in the form of an increase in the maximum daily temperature and the number of times it has exceeded the maximum limits, especially during the summer season, and results in the formation of urban heat islands and warmer air temperatures near urban centres.Air quality index standards are given in fig:2.

METHODOLOGY

Data Collection

The World Population Review is an independent organisation that turns the complicated demographic data of a country or city, presented in the format of Excel spreadsheets, APIs, etc., into easily understandable articles. Bengaluru's population data count is obtained from the "World Population Review" between the years 2005 and 2022. It is considered as the baseline for the computation of urbanisation and can be applicable as a comparative study for high-rise buildings, urban sprawl, and lakes over time. In India, the air quality and temperature data are monitored and stored by the Central Pollution Control Board (CPCB). The information gathered includes both live and recorded data and the data available can be downloaded in both Word and Excel format. For determining the air quality of Bengaluru, five places are taken into consideration, namely, Bapuji Nagar, Hebbal, Peenya, Silk Board, and the City Railway Station. And the required AQI of the collected data is then calculated using an AQI calculator, which takes into consideration three parameters of air quality. And finally, after overcoming all these steps, the required AQI is obtained. AQI Calculator, is generally used for the purpose of calculating the AQI with inclusion of three or more air pollutant or contaminant parameters.

Google Earth Pro

The required data (high-rise buildings, urban sprawl, and lakes) is first collected by using Google Earth Pro. Software "Google Earth Pro" is a user friendly and free programme that, allows visualization, assessment, overlay, and the creation of geospatial data. It provides options for viewing extremely high resolution satellite imagery, uploading or downloading the geospatial data in its native interoperable file format (KML), and also finding locations. This is a basic software package for students interested in learning about GIS, with basic tools and commands included.

Central Pollution Control Board

The Central Pollution Control Board was constituted under the Water (Prevention and Control of Pollution) Act in September 1974. This organisation is tasked with air quality monitoring and determining the present status and trends of air quality in order to regulate pollution from industries and meet the required air quality standards as per Air Act, 1981 The air quality and temperature data for Bengaluru were collected from this web portal.

Data Processing
Q-GIS
The data collected from Google Earth Pro is then further processed using "Q-GIS Software." QGIS, formerly known as "Quantum-GIS," is an open-source software that facilitates the user's ability to view, edit, and analyse geospatial data, to compose and export geographical maps. Both raster and vector layers are supported by QGIS; vector data is stored in the form of point, line, or polygon features. File formats, including shape files, coverages, dxf, personal geo-databases, Post-GIS, MapInfo, and others, are supported by QGIS as well and can also be used with SAGA GIS and Kosmo. To prepare maps, the Print Layout in QGIS is used, which allows you to add maps, labels, legends, directions, etc.

AutoCAD Map 2000i
AutoCAD Map 2000i is software that basically provides GIS analysis with precision mapping, property alteration tools and data querying, spatial analysis, and allowing access to multiple drawing files simultaneously or multiple-user access to the same drawing file. The data from this software can be exported and imported in just about any file format.

RESULTS AND DISCUSSION

Population
From the data obtained from the World Population Review, the population count in Bengaluru was approximately 6,786,000 in 2005, further, in 2010, it spiked to 8,296,000; thereafter, it reached 10,141,000 in 2015; and finally, in 2021, the count reached 12,765,000. Between 2005 and 2021, a significant population increase of approximately 188% was observed. The population of Bengaluru gradually increased as a result of the constant migration of the rural population and people from other states to Bengaluru as a result of the skyrocketing IT sector. The above graph shows People vs. Year data and is computed on the basis of a 5-year interval. It's crystal clear that the population skyrocketed during 2010–2021.

High Rise Buildings
From the obtained results, we can observe that, the high-rise building count was 185 in 2005, 381 in 2010, 1500 in 2015, and 2140 in the year 2021. Speaking in terms of percentage increase, from 2005 to 2010, it was 204.8%, 2010 to 2015 is 293.70%, and 2015 to 2021 is 42.66%. Here, the highest growth was observed between 2010 and 2015, when the count skyrocketed from 381 to 1500. The growth pattern of the high-rise buildings follows a gradual increase from the city centre to the outskirts of Bengaluru. In 2005, the buildings were in and around the core and on the outskirts, lying in the east of Bangalore (Whitefield).

Urban Sprawl
Spatial changes as the land cover changes from 2004-2020. They represent urban growth pattern in terms of built-up land for being constrained in the core due to lack of space and with rapid spatial expansion of urban areas in the city periphery a decrease in share that covers the agriculture land, land with dense vegetation (tree cover), wetland, and water bodies and simultaneously an increase in built-up land was observed. The percentage of built-up land has been increasing at an alarming rate and the land covering the green portion (trees, vegetation, etc.) has been decreasing as well.

Lakes in Bengaluru
Air Quality Analysis
The annual average Air Quality and Temperature data is obtained from the Central Pollution Control Board spanning from 2018 to 2021. There are majorly five points of interests from where the data is collected namely, Bapuji Nagar, City Railway Station, Hebbal, Peenya and Silk Board. These locations are selected on a criteria basis. Stating, Bapuji Nagar & Hebbal are one of the most densely populated residential areas in Bengaluru, furthermore, the City

Abhijeet Kumar Gautam and Geena George

Railway Station becomes a critical location as of it's a junction constituting Bus Stand, Railway Station, Metro Station & Vehicular Traffic, Peenya on other hand is the biggest Industrial Belt of Asia and on the bottom line is the Silk Board that houses India's worst bottleneck vehicular traffic. Finally, every location selected is crucial on its own and falls amongst the most polluted constituencies of Bengaluru.

CONCLUSION

The listed below conclusions can be drawn from the above study conducted: From being 6.78 million in 2005 to 12.76 million in 2021, the population of Bengaluru has almost skyrocketed about 6 million in past gone decades. Due to the growing population and land availability issues the demand and construction of High-Rise buildings increased consequently the count reached to 2140 in 2021 from just being 125 during 2005. As the construction accelerated, there was scarce in the land available to suit the purpose, and consequently resulted in Land-use change. This further had in numerous effects on Lakes, Forests, etc. as they were converted in order to be used for construction. The Urban sprawl data shows an increase of 60.79% in the built-up area, as the area cover reached to 620880 sq.km. in 2020 from just being 331420.9 sq.km in 2005 thereby, consequently reducing green cover by 62.60% from being 405140.2 sq.km in 2005 and reducing to 211961.1 sq.km in 2020. With increasing change in Land-use, the Lakes continued to vanish as they too were converted in order to facilitate urban growth and consequently resulted in reducing the count from 128 in 2005 to 108 in 2020. From the overall studies, we can conclude that, urbanization has impacted almost every key aspect of a vital running ecosystem and being the core reason behind all the ill effects experienced in Bengaluru, varying from change in land use, urban sprawl, air quality deterioration, increase in temperature, decreasing lakes count, level of underground water table, water scarcity to uneven climatic conditions.

ABSTRACT

Increasing population and growth of land use for agronomyhasseverely abused the regional groundwater resources. Intensive pumping has resulted in a rapid decline in the level of the water table as well as its quality. For better management practices, establishing sustainable groundwater resources thematic map of the lithology, geomorphology, Land use/ land cover, lineament density, drainage density, soil, slope and rainfall was used to identify the potential zones of the groundwater in the study area. This study adopted a weighted overlay methodology in the software ArcGIS 10.4.1. In the overlay analysis, the weight (for different thematic layers) and rating values (for sub classes) were assigned based on analysis of published literature. The thematic maps of the study area were categorized as four classes for groundwater potential zones and reveal the results such as poor (1%), moderate to poor (16%), moderate (59%), and good (24%).

Keywords: Groundwater, GIS,Lineaments, Potential zones,Remote sensing, Satellite image,Weighted overlay.

INTRODUCTION

One of the main sources of freshwater is groundwater, for human consumption as well as regional development. Potentiality of ground water depends upon location and additional abstraction wells to accomplish the growing water demand by the help of groundwater potential zones. Geological and hydro-geomorphological characteristics play a significant influence in the occurrence, distribution and movement of groundwater. The methods like geological and geophysical techniques can be used to conduct a comprehensive investigation of groundwater occurrences [1, 2] to observe groundwater potential zones and channels. These methods on the other hand, are dependent on time consuming and extensive ground measurements that are able to only be utilized for large scale mapping. Utilizing data from remote sensing in conjunction with a Geographic Information System is perfectly suiteddue to their high spectral resolutionand data collected from conventional and ground truth data can be simply merged for hydro-geological investigations [3] in remote sensing and GIS platform for identifying possible groundwater zones [4].In this study, satellite imageries are used to prepare various thematic layers such as the geology, geomorphology, soil, slope, lineament density, drainage density, land use, land cover and rainfall. These thematic layers are very useful in identifying the availability of groundwater resources.

The common strategies for determining groundwater possible exist are costly and it takes a long time and they necessitate a vast amount of data [5, 6]. An integrated system remote sensing and GIS research, on the contrary, can provide an effective forum for the study of data in a convergent manner in a relatively short amount of time. Remote sensing can provide a bulk amount of data for present scientific knowledge to better understand the hydrological framework [7]. Apart from its size, remote sensing gives data on locations that are inaccessible and saves time and money. Groundwater quality data has processed and integrated in GIS platform to understand the spatial distribution of thematic featureslike Geology (lithology), geomorphology, lineament density, porosity, slope, drainage density, drainage patterns, rainfall, and land use and land cover are only a few of influencing factors of groundwater occurrence and movement [8, 9, 10].

In the study area people are depended on groundwater for their agriculture practices and domestic uses because during the summer season, Bhima river irrigation canals are discontinued due to low rainfall and lack of water storage. This further add to the scarcity of water as the important available from this source is far less than required, whatever surface resources are obtainable and they either dry up by early monsoon or can only supply local demands for a short time. More number of the villages do not have any secured water supply. Hence, publics are stimulated to search around for alternative sources. Describing potential groundwater zones is therefore a significant undertaking (11, 12, 13). Water shortage can be caused by a number of issues, including uncontrolled groundwater management practices, a lack of rainfall, increased runoff, evaporation, climate change, the rapid rise of urbanization, and an uneven distribution of water resources (14, 15).

Hence, groundwater forms a valuable resource for agriculture also for domestic and drinking purposes in these areas. As a result, the current study was conducted to understand the spatial distribution of groundwater potential zones in Afzalpur taluk, which will suggest the proper management and development of groundwater resources, is essential in the study area.

Study area

Afzalpur Taluk situated in the northern part of Karnataka and western part of Kalaburagi. The research area covers 1050 sq.km. N-Latitudes 17° 03' 30"–17° 22' 40' and E-Longitudes 76°12'45"– 76°42'35".The whole southern boundary of the area is on the banks of River Bhima. Topographically the study area is very gentle slope (3 to 5%) towards southern direction. The entire study area comprises Deccan traps. This area has an arid and semi-arid climate, during the summer the temperature fluctuates from 30 to 46°C, during winter 28 to 35°C, monsoon occurs during June to October and annual rainfall is approximately 677 mm (CGWB 2011).

METHODOLOGY

The geomorphology, soil, slope, rainfall, lineament density, drainage density, and land use land cover maps were prepared using satellite imagery from the Indian Remote Sensing System Linear Imaging Self-scanning Sensor IV (IRS-1D LISS IV) data and Geological Survey of Indiatopo sheet (GSI 2001, 2005)in ArcGIS platform. Using rain gauge station data, rainfall circulation map was prepared and weighted overlay method was applied to combine all thematic layers by giving rank and weightage for every thematic layers. This technique is simple to analyze multi classification of maps based on the relative importance of every thematic layers. Many researchers have describedthe significance of numerous thematic layers that control the groundwater potential in an area. In the certain thematic maps weightage was given based on Saaty's scale [16, 17]for various thematic maps to describe groundwater potential zones. The individual layers and their classes are allocated a weightage and rank ranging from 0.10 to 0.25 and 1 to 4. High weightage and ranks are indicated, high groundwater potential in the study area. The study areas groundwater potential zones were divided into five categories viz, verygood, good, moderate, poor, and very poor. The Cumulative Score Index (CSI) was used to classify the data; the following equation was used to calculate CSI by multiplying the rank and weightage of each thematic layer. CSI= Σ (Geology = rank x weight + Geomorphology = rank x weight + Soil = rank x weight, Lineament density = rank x weight + Drainage density = rank x weight + Rainfall = rank x weight + Land use = rank x weight).

$$CSI= \int^n_{i=1}\int^m_{j=1}W_jX_i \quad (1)$$

Where, W_j= normalized weight of the jth factor, X_i = rank of the ith classes of a thematic layer, 'm' =total number of thematic layers, and 'n' = total number of classes in a thematic layer [18] and [19]. Using Statistical methods, the mean

and standard deviation of CSI was used to calculated the study area as very good (>Mean+ Standard deviation), good (Mean to Mean+ Standard deviation), Moderate (Mean- Standard deviation to Mean) and low (<Mean - Standard deviation).

RESULT AND DISCUSSION

Groundwater availability mainly depends on lithology, geomorphology, soil, slope, lineament density, drainage density, land use, land cover and rainfall. Hence, all the thematic maps pertaining to the study area were prepared using IRS-ID LISS IV satellite data. The salient aspects of these thematic maps are described below.

Lithology
Lithologicallythe area under study comprises dominantly of Deccan traps (Fig. 2). Various flows of Deccan trap overliesBhimagroup of rocks. The Deccan trap comprises numerous flows each of which might have erupted separately. During the interval until the next eruption took place, the weathering of the exposed flows continued, and sediments were deposited. The sedimentary beds were overlain by subsequent flows. These inter-trappings are generally porous and help in recharge of groundwater. The given weightage for this thematic layer while preparing ground water potential zone map is 0.20

Geomorphology
The geomorphological features of this area were prepared using IRS-ID LISS IV satellite data. The geomorphic map shows a gently rolling topography and vast stretches topped by black cotton soil. Broad valleys with intervening flat-topped country are by far the most predominant geomorphic feature in the area. In general, the area exhibits an undulating topography with table lands characteristics of Deccan traps in the north of the study area. The major geomorphological features are alluvial plains, pediments, Pedi plain, plateau highly dissected, plateau moderately dissected, plateau slightly dissected, plateau undissected, plateau weathered, river/stream, upper plateau and water body. And denudation hills are the prominent geomorphologic features (Fig. 3). The most part of the study area

comprises alluvial plains, which are expected to be zones with good groundwater potential. Hence higher weightage of 0.30 was assigned to this layer.

Soil

The study area contains of six types of soils such as fine, clayey, clayey skeletal, fine loamy, loamy, and loamy skeletal (Fig. 4). The soil map represents fine soil occupying most of the study area and covering 67 % of the area, clayey soils covering 21 % along eastern and central borders of the study area. Very fine to clay skeletal soil covered 5 % small portions of the area, fine loamy to loamy type soil covered 0 % (Table-2). The loamy, fine loamy and loamy skeletal soils have a high infiltration rate because it is a mixture of sand and silt and also favorite of maximum plants because it is usually richer in nutrients and humus and will hold water while allowing extra to drain away. It also has good groundwater potential zones. Whereas clayey soils have a low infiltration rate and less groundwater potential availability. Fine, very fine soil is made up of extremely small particles that stick together and obstruct the circulation of water and nutrients. As per result, given high rank and 0.15 weightage was assigned.

Slope

Four categories of slopes (Fig.5) were identified in the study area as nearly level 0-1 %, very gentle slope 1-3 %, gentle slope 3-5 % and moderate slope 5-10 % (Table-2). In the slope map it is observed that, about 56 % of the study area belongs to very gentle slopehaving good groundwater potential zones, 39 % belongs to nearly level slope having very good groundwater potentialdue to slow surface runoff of the rainwater. Gentle slope contains 3% having moderate potential zones due to moderate surface runoff and only 0.6 % of the study area is moderate slope having low potential zones due to high surface runoff for groundwater recharge is difficult and rated as weightage 0.15.

Lineament Density

Lineament density of the study area is categorized into three zones such as Low (0-1,000 km/km²), medium (1,000-1,500 km/km²) and high (>1,500 km/km²) (Table-2). In this study we observed that, most part of the area has low lineament density which indicates that only few areas have high and medium lineament density for groundwater resources (Fig.6) having medium lineament. Hence, it is considered as a moderate groundwater potential zone and given a weightage of 0.10.

Drainage Density

Drainage density is classified in to three classes like, low (<1,000 km/km²), medium (1,100-2,500 km/km²) and high (2,600-3,700 km/km²) (Table-2). Large part of the area falls under medium drainage density; therefore the infiltration of the water will be less in the study area. Since, the entire study area has moderate drainage density hence, this may be considered as good groundwater potential zones (Fig.7) and rated weightageof0.10.

Rainfall

Rainfall is main source of groundwater recharge. The study area comprisesfour rain gauge stations atAfzalpur, Atanoor, Karajagi and Gobbur. The rainfall dispersal map was prepared using the Kriging method in ArcGIS 10.4.1 software. Based on average Rainfall, the study area isdividedinto ten categories (Fig. 8). Highest Rainfall received in Karajagi Rain Gauge station in 2020 (64.21 mm) of the study area, and lowest rainfall received in Afzalpur Rain Gauge station in 2015 (28.95 mm). The study area received the highest mean annual rainfall of 770.55 mm in 2020. Increased rainfall encourages the occurrence of more groundwater. A weightage of 0.10 was given to this layer.

Land Use Land Cover

Land use land cover map (Fig. 9) describes the information about soil moisture, infiltration, surface runoff water cycle of groundwater and surface water. The study area comprises thirteen land use land cover classes such as gullied land, barren land, rabi crop, Rabi + kharif land, kharif land, fallow land, lake/tank, land with scrub, land without scrub, *prosopisjuliflora*, salt affected land, river/stream and town/cities. With respect to groundwater penetration inside the subclasses the lake and river have high weightage due to less runoff, settlement lands (included waste land, barren land, fallow land, gullied land salt affected land) have low weightage due to high

runoff, in agricultural land infiltration will be more, runoff will be less. Most of the study area comprises crop land (7 %) (Table-2). Hence, it is considered to have good groundwater potential and hence it is rated as weightage 0.10.

Groundwater potential zones

By adding all the thematic layers, the groundwater potential zones map were prepared (Fig.10 and fig.11) and four types of groundwater potential zones have been identified in the study area. The results indicated that the green colored area in the map is considered as a good potential zone (Rank-4) due to the alluvial Pedi plain along with the valley which cover about 24 % of the area. 59 % of the area covers a moderate potential zone which is indicated by sky blue in color (Rank 3) due to geologic units of Deccan traps, geomorphologic units of pediments, soil type, medium lineament and drainage density. The remaining 16 % of the area covers moderate to poor potential zone (Rank 2) which is indicated by pink color and it is due to clay patches, denudation hill, land use pattern, settlement areas, and higher drainage density. Poor potential zone (Rank -1) in the study area found is negligible indicated by brick red in color in the study area

CONCLUSION

The detection of groundwater potential zones in the study area by using geographical information system and remote sensing has proved to be powerful method by integration of thematic layers for the information to local authorities and planners about the areas suitable for groundwater exploration to meet the demands of agricultural and domestic uses.The groundwater potential zones were categorized in to four classes in the study area viz., good, moderate, moderate to poor and poor. The areaviz., Jewargi, Gour, Shirwad, Shirwal, Afzalpur, Havnoor, Nandarga, Chowdapur, Dannur was indicates "good" groundwater potential zones. The "moderate" groundwater potential zone wasdetected in the areas viz., Dixanga, Allagi, Hosur. "Moderate to poor" groundwater potential zones were observed in Udachan, Kallur, Chinmallietc and "poor" groundwater potential zones in the study areas were found nil. By this observation, available groundwater resources reveal the results as poor (1%), moderate to poor (16%), moderate (59%), and good (24%) of groundwater potential zones. These results may helpful for the effective planning and sustainable management of the groundwater recourses in the study area.

ABSTRACT

In this paper Advanced Fuzzy Filter (AFF) is developed. Objective of AFF is to minimize the Gaussian noise from a fuzzification image and to be obtained a clarity image. The t-test result on experiments using the developed AFF shows that AFF is more effective to reduce the noise comparing with the existing methods mean filter, median filter and modified fuzzy filter.

Keywords: Mean filter, Median filter, MFF, PSNR, AFF

INTRODUCTION

Zadeh's seminal paper on "Fuzzy sets", which investigated fuzzy sets and fuzzy logic, originally published in 1965. In his paper, Zadeh aimed to formulate a theory that could explain for the uncertainty and imprecision of specific forms of sets in human mind. Pattern recognition, communication, and abstraction are all examples of this. Basic principles of image processing and recognition using fuzzy theory is defined by Maria Somodevilla and Frederick E. Petry. Fuzzy filter has wide range of applications concerns with noise control, edge detection, segmentation and image enhancement. In this paper Advanced Fuzzy Filter (AFF) is developed. This AFF is used to minimize the Gaussian noise from a fuzzification image. T-test is applied on the experiments using the developed AFF and it is obtained that AFF is more effective to reduce the noise comparing with the existing methods [2-9] mean filter, median filter and modified fuzzy filter.

Mohamed Harif *et al.,*

Mean filter

Intensity variation between pixels can be reduced with mean filtering. Mean filtering wants to replace all pixel in a fuzzification image with the average (mean) frequency of its neighboring pixels. Corresponding pixel also replaced by itself. The result is to eliminate pixels with values that are non-typical of their environments. In general, mean filtering I considered a convolutional filter.

Median filter

Spatial filters with sliding windows are called median filters. The center value is modified by computing the median of all the image pixels in the pane.

Modified Fuzzy Filter

We define a modified fuzzy filter as
$$g(I_{u,v}) = \frac{\sum_{u=1}^{n}\sum_{v=1}^{m} I_{u-k,v-l}\chi_{u,v}(I_{u,v})}{\sum_{u=1}^{n}\sum_{v=1}^{m} \chi_{u-k,v-l}(I_{u,v})}$$

where $\chi_{u,v} = W(Membership\ function) * D(Distance\ function)$ is the modified fuzzy basis function and

its value $\chi(I_{u,v}) = \dfrac{\chi_{u-k,v-l}(I_{u,v})}{\sum_{u=1}^{n}\sum_{v=1}^{m} \chi_{u-k,v-l}(I_{i,j})}$.

PSNR

By using Peak Signal to Noise Ratio (PSNR), obtained mean square error (MSE) between the actual image (fuzzification image) and the resultant image. PSNR provide us to analyze a fuzzy filter design's efficiency.

Distance measure in proposed AFF

In RGB dimension, colours are represented by three dimensional space with Red, Green and Blue as the first, second and third elements respectively. A color image CI perform with a 2-D array of vectors where $(u,v) = I_{u,v}$ defines a position in CI called pixel and $CI_{u,v,1} = I_{u,v,1}, CI_{u,v,2} = I_{u,v,2}$ and $CI_{u,v,3} = I_{u,v,3}$ denotes the red, green and blue components respectively of CI. Let D be the Euclidean distance, RG-Red green, RB-Red Blue, N_{RG}- Neighbour Red Green and N_{RB}- Neighbour Red Blue.

Let $RG = (I_{u,v,1}, I_{u,v,2}), N_{RG} = (I_{u+k,v+l,1}, I_{u+k,v+l,2}), RB = (J_{u,v,1}, J_{u,v,2})$ and $N_{RB} = (J_{u+k,v+l,1}, J_{u+k,v+l,2})$. Then

$$D(RG, N_{RG}) = \left(\sqrt{\left(I_{u+k,v+l,1} - I_{u,v,1}\right)^2 + \left(I_{u+k,v+l,2} - I_{u,v,2}\right)^2}\right)$$

$$D(RB, N_{RB}) = \left(\sqrt{\left(J_{u+k,v+l,1} - J_{u,v,1}\right)^2 + \left(J_{u+k,v+l,2} - J_{u,v,2}\right)^2}\right)$$

Weight function of fuzzy noise reduction in proposed AFF

The weight function W for the proposed AFF is defined as the mean of the distinct distance functions D(RG,NRG) and D(RB,NRB).i.e, $Weight\ W = \dfrac{1}{2}(D(RG, N_{RG}) + D(RB, N_{RB}))$

Proposed Advanced Fuzzy Filter

The Advanced fuzzy filter (AFF) is defined based on the distance function D and weight function *W*. AFF is defined

as $h(I_{u,v}) = \left(\dfrac{\sum\limits_{u=1}^{n}\sum\limits_{v=1}^{m} I_{u-k,v-l}\psi_{u,v}(I_{u,v})}{\sum\limits_{u=1}^{n}\sum\limits_{v=1}^{m}\psi_{u-k,v-l}(I_{u,v})} \right)$, where $\psi_{u,v} = W * D$. The Advanced Fuzzy Basis Function is

$\psi(I_{u,v}) = \dfrac{\psi_{u-k,v-l}(I_{u,v})}{\sum\limits_{u=1}^{n}\sum\limits_{v=1}^{m}\psi_{u-k,v-l}(I_{u,v})}$.

Comparison of Modified Fuzzy Filter (MFF) and Advanced Fuzzy Filter (AFF) Result in PSNR of different noise removal methods

	Γ = 5	Γ =10	Γ =20	Γ =30	Γ =40	Γ =50	Γ =60	Γ =70	Γ =80	Γ =90
Noisy	33.10	29.07	23.18	17.88	15.05	13.09	12.04	11.02	10.24	9.58
Mean	29.01	26.03	20.12	14.90	13.02	11.05	10.20	8.79	7.91	7.75
Median	31.05	27.01	21.03	15.28	14.11	12.80	11.01	9.80	8.61	8.87
MFF	34.25	30.09	24.59	18.08	16.90	14.02	13.05	12.02	11.21	10.67
AFF	35.02	31.03	25.08	19.02	17.09	15.02	13.93	13.05	12.25	11.08

T-Test result

The statistical test is conducted on the alternative hypothesis "AFF gives better noise reduction comparing with other three filters" and the following result is obtained.

Case 1 : MFF and AFF. $t = 2.5669$,

The alternative hypothesis is accepted with 95% confidence level.

Case 2 : Median filter and AFF. $t = 14.852$

Case 3 : Mean filter and AFF. $t = 18.13025$

The result shows that AFF is more effective to reduce the Gaussian noise comparing with the existing methods Mean filter, Median filter and Modified Fuzzy Filter.

CONCLUSION

In this paper Advanced Fuzzy Filter (AFF) is developed. By using this AFF, we are able to optimize (Minimize) the Gaussian or white noise from an image. Using R-Software, T-test is applied used to reduce the Gaussian noise from an image signal. Using software R, T-test is applied on the experiments and it is obtained that AFF is more effective to reduce the noise comparing with the existing methods Mean filter, Median filter and Modified Fuzzy Filter.

ABSTRACT

In recent years, the application of flyash in geopolymer concrete has acquired significant focus because of its environmental benefits and possible uses in construction materials. The synthesis process involves the utilization of fly ash, an abundant industrial waste, as the primary material, thereby addressing both environmental concerns and the necessity of using sustainable building material. The synthesized fly ash geopolymer sand was subjected to comprehensive characterization studies, including physical, chemical, and mechanical properties. The characterization results gives information about the structural composition, microstructure, performance characteristics of geopolymer sand. The utilization of fly ash geopolymer sand not only reduces the environmental impact associated with fly ash disposal but also offers significant advantages in terms of strength, durability, and resource conservation. Overall, this research contributes to advancing the field of sustainable construction materials by offering a viable solution for the utilization of fly ash waste in geopolymer sand synthesis.

Keywords: Class F Flyash, Flyash Geopolymer Sand (FGPS), Conventional Fine Aggregate, Geopolymerization.

INTRODUCTION

The need for environmentally friendly building materials has been fueled by research efforts to identify substitutes that maintain performance requirements while minimizing environmental effect. Because of their remarkable qualities and sustainable nature, geopolymers have emerged as viable alternatives in this endeavor. Fly ash stands out among the variety of raw materials that are needed to make geopolymers because of its availability and potential

for value-adding. The novel method for creating fly ash geopolymer sand is presented in this research, along with an analysis of its viability and suitability for real-world building applications. Fundamentally, geopolymers are inorganic polymers that are created by alkali-activating aluminosilicate substances such as slag, fly ash, or metakaolin. In this technique, Si-O and Al-O bonds are dissolved, and then polycondensation processes with alkaline activators are used to generate a three-dimensional network structure. As an appealing substitute for conventional cement-based materials, the resultant material has outstanding mechanical strength, durability, and resistance to chemical assault. (Davidovits, J. 2014). Because of possible contamination and disposal problems, fly ash is a bi-product obtained from burning coal as a fuel in power plants, poses serious environmental risks. Fly ash, however, may be transformed into a useful building material by creating geopolymers, solving waste management issues and lowering dependency on the mining of natural sand. (Hardjito, D., et al. 2004).

A number of processing procedures, including material selection, formulation, mixing, curing, and grinding, are involved in the creation of fly ash geopolymer sand. Important factors influencing the final product's characteristics are fly ash's chemical makeup, the kind and quantity of alkaline activators used, the curing environment, and the grinding methods used. By adjusting these variables, geopolymer sand may be made to match the needs of certain applications, including workability, strength, and particle size distribution. Understanding fly ash geopolymer sand's microstructure, mechanical characteristics, and long-term performance requires characterization. The morphology, phase composition, and chemical bonding of the material may be understood by the use of experimental methods including Fourier-transform infrared spectroscopy (FTIR), X-ray diffraction (XRD) and scanning electron microscopy (SEM), Mechanical testing assesses the material's performance under various stress scenarios by measuring its compressive strength, abrasion resistance along with flexural strength. (Palomo, A. 2007). Assessments of environmental effect, commercial potential, and techno-economics are all included in a feasibility inquiry. Large-scale manufacturing and commercialization of fly ash geopolymer sand are feasible depending on a number of factors, including market demand, energy consumption, production costs, availability of raw materials, and greenhouse gas emissions. In order to evaluate the fly ash geopolymer sand's sustainability and economic feasibility, these properties are quantified and contrasted with regular sand and other alternative materials. (Provis, J. L. 2014). In summary, the production of flyash geopolymer sand offers a viable path toward the production of sustainable building materials. This work attempts to expand knowledge of fly ash geopolymer sand and its possible uses in the building sector by means of creative methods and thorough characterization.

MATERIALS AND PROCEDURES

The experimental procedure involved the usage of flyash which was sourced from thermal power plant situated in Raichur District of Karnataka, India. The physical and chemical properties of flyash is shown in Table 1, conforming to Class F specifications according to ASTM standards (2008). Notable concentrations of SiO_2 (57%), CaO (0.97%) and Al_2O_3 (26%) characterize its composition. Approximately 72% of fly ash material exhibit size lesser than 45μm. The synthesis of Fly Ash Geopolymer Sand (FGPS) employed laboratory-grade silica gel with particle sizes ranging from 0.12 to 0.25 mm, alongside sodium hydroxide as activators. For comparative analysis, Conventional Fine aggregate from Bangalore, locally sourced, was utilized.

Preparation of alkaline activator
To mitigate mineral interference, potable water is employed in the production of sodium hydroxide (NaOH) solution. NaOH pellets are dissolved in distilled water to create solutions of varying molarities: 8M, 10M, 12M, and 14M. These solutions are then left to cool overnight at room temperature following exothermic reaction that occurs upon mixing NaOH with potable water, during which heat is liberated.

Formulation of Flyash geopolymer Sand (FGPS)
Slurry was formed by blending 1 kg of fly ash with 172 ml of sodium silicate and 114ml of 8 M solution of NaOH, maintaining a solids-to-solution ratio of 3.5:1. The ratio of Na_2SO_4 to NaOH was maintained at 1.5:1. The resulting

slurry underwent initial curing in an oven at 100°C for 20 minutes, followed by a 10-minute cooling period. Subsequently, the sample was passed through a 4 mm IS sieve to separate the fine aggregate. These fine aggregates, identified as Fly Ash Geopolymer Sand (FGPS) particles, were further cured for two hours at 100°C in a temperature-controlled oven with an accuracy of ±2°C to facilitate complete geopolymer reactions.

Tests on FGPS and Conventional Aggregate

The pH values of FGPS and conventional aggregate were determined according to (IS) 2720. After mixing the specimens with potable water for one hour, the solid-to-water ratio (measured on a mass basis) was determined by centrifuging the suspensions. The suspensions were then centrifuged to determining Electrical conductivity(EC) of supernatant solutions after mixing the sample by potable water (solid:water=1:2) about an hour. The EC values obtained for FGPS and conventional aggregate specimens were then used to compute the Total Dissolved Solids (TDS) from the equation, 1 mg/L equals 7.28 µS/cm (Todd 1980). Specific gravities of FGPS along with conventional aggregate sample were found out using the IS 2720 (BIS 1980) method, while their particle size distributions were determined using the IS 2720 (BIS 1985) approach. Additionally, X-ray diffraction (XRD) patterns of fly ash, FGPS, and silica gel specimens were obtained using an X-ray diffractometer.

Mortar Specimen Preparation and Testing

According to IS 2250 (BIS 1981) guidelines, a mortar mixture was formulated by combining one part ordinary Portland cement with three parts conventional aggregate. The resulting Conventional Aggregate Mortar (CAM) specimens were prepared using water: cement of 0.45, kept as suitable for achieving workable consistency. However, observations were made that a higher water: cement ratio of 0.9 was necessary for a feasible blend of FGPS with cement. Both wet mixtures were compacted through static compaction until reaching 86.65cm^3 as a fixed volumne. During the Compaction process, FGPS- Cement blend achieved 1.94 Kg/m^3 which is a lower dry density compared to the Conventional Aggregate-cement mixture, which reached a dry density of 2.08 Kg/m3. Three compacted specimens were fabricated for each type of cement mixture (FGPS and Conventional Aggregate), resulting in a total of six compressed specimens. These specimens underwent a 24-hour curing period at room temperature in a laboratory, followed by immersion in tap water for 28 days. Later the immersion period, compression strength was measured at a strain rate of 1.2 mm/min. Triplicate assessments of both CA-M and FGPS-M specimens revealed that their respective strengths displayed variations from the mean of under 5%. Subsequently, pH and TDS levels were quantified in the failed CA-M and FGPS-M specimens using the outlined methods.

DISCUSSION AND FINDINGS

Graph 1 shows the particle size distribution of both FGPS along with Conventional fine Aggregate specimens. FGPS demonstrates fractions of fine aggregate ranging from 0.425 to 0.075mm, Mid Range (2 to 0.425 mm), and coarse (4.75 to 2 mm), constituting 7.59%, 81.38%, and 11.03%, accordingly In contrast, conventional aggregate primarily comprises mid range (64.49%) and fine (34.13%) particles, with a minor content of sand (1.38%). FGPS particles are categorized as poorly graded Fine Aggregate per IS 1498 (BIS 1970), evidenced by their coefficient of curvature (Cc) and uniformity coefficient (Cu) values of 1.55 and 3.25, accordingly, attributable to their higher water absorption property. Specific gravity measurements reveal values of 2.30 for FGPS and 2.62 for Conventional fine Aggregate, while fly ash exhibits a specific gravity of 2.15. The higher specific gravity of FGPS particles is attributed to the close packing of SiO─AlO units. FGPS particles exhibit a pH of 11.58, indicating strong alkalinity, expected to minimally impact mechanical properties when blended with cement for mortar or concrete production, as per IS 1498:1970. Both FGPS and Conventional Aggregate are classified as badly graded soil based on their Cu and Cc values. SEM patterns of fly ash and FGPS particles reveal distinctive features, with flyash showing wide lump inbetween 2θ values of 6 to 15 degrees, shows the presence of glassy materials. Peaks corresponding to mullite and quartz further characterize the fly ash pattern. Fly ash, especially Class F, exhibits pozzolanic qualities and can react with cementing agents or chemical activators like sodium silicate to form cementitious compounds or geopolymers, respectively. XRD analysis of the FGPS specimen indicates pronounced clarity in the shiny phase inbetween 6.n and 16 degrees, suggesting

heightened structural organization due to geopolymerization events. Graph 3 depicts the failure show of both conventional aggregate particles and FGPS, along with stress-strain curves from compression experiments conducted on CA- M and FGPS-M sample. Comparable 12.23 and 21.81MPa for 28-day compressive strengths were attained by CA-M and FGPS-M specimens, respectively. The initial tangent moduli (ITMs) of CA-M and FGPS-M specimens were also similar, measuring 0.5 and 0.495 GPa, respectively. The lower specific gravity observed may stem from various factors such as a high concentration of hollow cenospheres or alterations in the chemical composition, particularly in the iron content.

CONCLUSION

FGPS were synthesized through the geopolymerization process of blending fly ash and amorphous silica for four hours at 120°C in an 8 M NaOH solution. These FGPS particles primarily comprised medium-sized sand particles (2 to 0.425 mm). The grain size distribution properties, characterized by the coefficient of curvature and homogeneity coefficient, categorized as Sand Particles. The dissolution and subsequent poly-condensation of reaction Specimens gives the compact arranging of SiO_2AlO_2 units within the FGPS particles, resulting in a specific gravity of 2.30, comparable to conventional aggregate at 2.62. Upon dissolving in a high medium of alkaline, FGPS particles attained a markedly alkaline pH of 11.58, akin to the pH range observed in cement hydration processes, indicating their suitability for use in mortar and concrete production. Furthermore, the total dissolved solids (TDS) value of 478 mg/L for FGPS particles suggests their classification as suitable soil material. In direct shear tests, FGPS particles demonstrated a comparable high friction angle of 35.5 degrees despite their spherical grains. Similar specific gravity values and grain size distributions were found when FGPS and conventional aggregate were compared. Comparing FGPS particles to conventional aggregate, however, revealed that the former had a greater friction angle and much higher pH (8.0) and TDS (31.5 mg/L).

ABSTRACT

Although motor symptoms are part of the normal Parkinson's disease (PD) symptoms a variety of nonmotor symptoms, such as digestive problems, typically manifest before the motor symptoms. Through neurological, endocrine, and immune system pathways implicated in the microbiota–gut–brain axis, a variety of microbes that reside in the gastrointestinal tract can have a significant impact on the physiopathology of the central nervous system. Furthermore, a wealth of data points to be considered to correlate PD and the gut microbiome. The most recent research on microbial alterations in PD and its clinical significance is summed up in this review. Gastrointestinal symptoms may arise before motor symptoms in PD, a prevalent neurodegenerative condition. PD patients' gut microbiomes exhibit distinctive alterations that could be utilized as early disease indicators. Although the exact pathogenic pathways are unknown, changes in the makeup of the gut microbiota may have an impact on the development or manifestation of motor or non-motor symptoms. It has been proposed that the gut microbiota and its metabolites control neuro inflammation, barrier function, and neurotransmitter activity, which may play a role in the etiology of PD. The brain, gut, and microbiota axis may serve as a channel for the transfer of α-synuclein. Bidirectional communication exists between the enteric nervous system and the central nervous system. We discuss new findings about changes to the gut microbiota associated with PD. There is a wealth of research linking vitamin deficiencies and PD. One potential neuroprotective treatment approach is dietary supplementation of vitamins possessing antioxidant, anti-inflammatory, anti-apoptotic, and free radical scavenging qualities. The research that assessed the

79636

function of vitamins (A, B, C, D) in PD are compiled in this review. It may offer a framework for developing treatment plans to combat the illness and will direct future research into the possible therapeutic role of vitamins in disease pathogenesis.

Keywords: Parkinson's disease, gut microbiota, vitamins, neurodegeneration, neuroprotection

INTRODUCTION

Parkinson's disease (PD), the most prevalent movement illness worldwide, affects 1-2 people out of every 1,000. Many non-motor symptoms, such as sensory abnormalities, orthostatic hypotension, constipation, fatigue, depression, pain, and anhedonia, can even occur before the motor signs extend throughout the clinical spectrum in addition to the primary symptoms of motion (akinesia, tremor, rigidity, and postural instability [1],[2]. Based on epidemiological research, there is a lower chance of developing Parkinson's disease (PD) in those who drink green tea, coffee, and blueberries and don't consume dairy products [3]. The primary pathogenic alterations of PD include harm to dopaminergic neurons in the central nervous system's substantia nigra and development of Lewy body (LB), also known as Lewy pathology (LP). The etiology of PD is multifaceted and has been linked to oxidative stress, mitochondrial malfunction, and neuroinflammation [4].

GUT MICROBIOTA AND PARKINSON'S DISEASE
With over 100 million neurons, the Enteric Nervous System (ENS), also referred to as the "second brain," is a complex neural network. The distribution of enteric neurons is irregular in both plexuses. The ENS, which runs the length of the gastrointestinal tract, is made up of extrinsic innervation from the sympathetic and parasympathetic nervous systems and intrinsic innervation from the gastrointestinal wall. The ENS regulates GIT function, especially secretion and motility, independently of the central nervous system(CNS). At the autonomic nervous system level, however, the ENS and CNS form the so-called gut-brain axis (GBA) due to their bidirectional connectivity. Through bacterial metabolites or parts of the bacterial wall, the gut microbiome continuously interacts with the ENS, affecting neuronal transmission in the ENS [5]. The intestinal epithelium forms a barrier that prevents the passage of harmful content and at the same time allows the absorption and secretion of nutrients. By directing the expression of tight junction proteins including occludin, claudins, and zonula occludens-1 (ZO-1), the makeup of the intestinal microbiota influences the appropriate function of this barrier. Furthermore, lower L-DOPA absorption is linked to *Helicobacter pylori* infection, regardless of whether this is because of elevated stomach acid secretion or an inflammatory response that *Helicobacter pylori* causes in the guts of PD patients. The L-DOPA responsive motor issues improved in patients when *Helicobacter pylori* was eradicated [5]. Gut microbiota is intimately connected to the occurrence, development and progression of PD in its early stage. By adjusting the gut microbiota, it may be possible to monitor a person's health through an in-depth understanding of the microbiota-gut-brain axis in PD[6]. The relationship between neurological illnesses and the gut bacteria has been getting a lot of attention nowadays. Through metabolites, hormones, the immune system, and afferent nerves, among other channels, the gut microbiota connects with the CNS and ENS [2]. A variety of microorganisms, including bacteria, yeasts, and viruses, make up the gut microbiota. Firmicutes, Bacteroidetes, Actinobacteria, Proteobacteria, Fusobacteria, and Verrucomicrobia are the primary phyla of the human gut microbiota.In healthy people, the gut microbiota and host have a mutually beneficial relationship that can be broken by infections, viruses, fungus, and other parasites[2]. Recent research has shown that the Verrucomicrobiaceae family—which includes the genus Akkermansia—and Lactobacillaceae family are more abundant and decreased Prevotellaceae and Lachnospraceae families, which includes the genus Roseburia. The commensal mucin-degrading intestinal bacterium Prevotellaceae contributes to the creation of intestinal mucus and influences the regular fermentation of fiber to produce short-chain fatty acids (SCFAs). The host may consequently suffer increased intestinal permeability as a result of decreased intestinal mucus levels and the synthesis of microbe-derived SCFAs, which raises the possibility of local inflammation throughout the intestinal canal. Remarkably, it has been proposed that prevotellaceae may protect against the neurodegenerative process of PD by secreting ghrelin and

synthesizing mucin. Remarkably, the rise in Lactobacillaceae and fall in Prevotellaceae is connected to the decline in the gastrointestinal hormone ghrelin, which can preserve and safeguard the substantia nigra and striatum's normal dopamine function by altering the production of reactive oxygen species and mitochondrial respiration. Furthermore, a clinical investigation found that patients with PD had lower total and active levels of plasma ghrelin, suggesting that measuring this level could be a target for both illness diagnosis and treatment [2],[7]. Raised Enterobacteriaceae concentration in PD patients, which is correlated with the degree of postural instability and trouble with gait. Moreover, since the Lactobacillaceae family is known to have anti-inflammatory properties, the development of inflammatory processes is primarily linked to the markedly decreased levels of this family in PD patients. Given their capacity to lower levels of short-chain fatty acids (SCFAs), it is fascinating that certain bacterial families—like Prevotellaceae, Lactobacillaceae, and Lachnospiraceae—have decreased in PD patients [7] or ghrelin [8]. Due to the neuroprotective properties of both SCFA and ghrelin, it is possible that the lower levels of these two hormones in PD patients indicate both the severity of the disease and one of its key contributing components [9]. Pathological α-syn has been suggested in several recent investigations to have prion-like behavior. The ability of prions to interact with and change healthy proteins (PrPC) into their diseased version (PrPSC) and their transmissibility are the two factors that determine their classification [10],[11]. To summarize, individuals suffering with PD exhibit notable changes in their gut microbiota quantity and features. These changes could potentially serve as biomarkers or targets for therapeutic interventions. The precise mechanisms have not been fully understood, nevertheless, because of variations in research methodologies, living situations, and individuals, as well as the timing and kinds of altered gut microbiota.

Transmission of α-synuclein pathology
The food, the gut microbiome (GM), and its metabolites are among the many environmental elements that have drawn a great deal of scientific interest. In the 1980s, reports of Lewy pathology in the ENS began to surface, providing evidence of a malfunctioning gut-brain axis in PD. From that point on, both top-down and bottom-up models have been attempted to simulate the transfer of **α** -synuclein disease from the gut to the brain.

Bottom-up transmission of a-synuclein pathology:[12]
Braak [18] suggests that an invading pathogen that reaches the body through the stomach and nasal cavities causes sporadic PD. When α-synuclein in enteric or olfactory neurons is in contact with the invader, it causes α-synuclein aggregation. The olfactory bulb and vagus nerve allow the aggregated α-synuclein to enter the CNS, from which it finally travels to the SNpc. Furthermore, according to Braak's Parkinson disease staging, the pathology caused by α-synuclein first appears in the brainstem and olfactory bulb regions, then progresses to the cortical regions[13]. Regarding the many mechanisms that could lead to the start of α-synuclein pathology in the ENS in PD, Braak's idea is supported by multiple lines of evidence. LB illness is seen in the ENS and GI tract in humans, in rodent vasoactive intestinal polypeptide (VIP) and cholinergic neurons, and in neurons that produce VIP [14]. PD patients with ENS dysfunction (60–80%) might develop chronic constipation and other non-motor symptoms well before the onset of motor symptoms[15],[16]. PD patients are more likely than non-patients to experience ENS dysfunction, which may hasten the genesis of the disease by ten years before clinical symptoms appear [17]. The vagus nerve serves as a pathway for the transmission of α-synuclein pathology from the ENS to the CNS, according to postmortem investigations carried out on humans [18]. It is interesting to note that longitudinal human cohort studies from northern Europe have linked truncal vagotomy, as compared to controls, to a lower chance of developing PD. Asynucleinopathy may be transmitted from below up, as evidenced by the presence of α-synuclein aggregates in the ENS of α-synuclein transgenic mice, even before any known pathogenicity in the CNS.

Top-down transmission of α-synuclein pathology:[12].
It is crucial to look into whether the degeneration of dopaminergic neurons and the aggregation of α -synuclein in the brain can affect GI tract activity because of the bidirectional communication between the gut and the brain. The main nerve supply to the gastrointestinal system is the myenteric plexus, which controls GI motility via inhibiting neurotransmitters such as VIP and nitric oxide and excitatory neurotransmitters such as acetylcholine[9]. It might therefore act as a conduit for the transmission of aggregated α-synuclein from the brain to the intestines. Impairment

Prabha N Bhong *et al.,*

seen in the CNS that causes alterations to the GI tract or the brain-gut communication may be a manifestation of GI dysfunction linked to PD. The 6-Hydroxydopamine (6-OHDA) model of PD has been employed to rigorously analyze this hypothesis. In this model, injection of the neurotoxin in the substantia nigra or medial forebrain bundle (MFB) causes dopaminergic neuron deletion in the SNpc [19]. Observed intestinal irritation in rats given a unilateral 6-OHDA injection at two MFB locations. Increases in pro-inflammatory cytokine levels, oxidative stress, and colonic excitatory tachykininergic motility were linked to the intestinal inflammation. Similarly, in rats, bilateral injections of 6-ODHA at SNpc resulted in a decrease in acetylcholine levels, which typically increases gut motility, and an increase in the levels of inflammatory and colonic markers [20]. Because the human microbiome can be easily affected by external stimuli, the delicate balance between the microbiome and the development of psychopathologies is particularly noteworthy, such as diet, [21]exposure to antimicrobials [22]or disrupted sleep patterns [23].

VITAMINS

Vitamin A and Carotenoid:[24].

When free radicals cause damage to cells, including neurons, vitamin A functions as an antioxidant in the form of retinoic acid. It is thought that oxidative stress plays a role in the neurodegeneration observed in PD antioxidants have the potential to lessen this harm. Fish, meat, dairy products, and vegetables are rich sources of vitamin A, also known as retinol, which is a significant antioxidant in the diet. Vitamin A influences the expression of genes involved in brain development, neural tube patterning, and neuronal differentiation during the development of the CNS[25]. In vitro, it was previously shown that beta-carotene and vitamin A minimize the generation of alpha-synuclein fibrils and destabilize the ones that have already formed in a dose-dependent way. Retinoic acid (RA), which interacts with nuclear receptors to modify gene transcription, has a special precursor in vitamin A. Within the CNS, vitamin A and carotenoids serve a function in a complicated signal transmit that regulates neural tube patterning and neuronal differentiation in addition to gene expression throughout several organs, including the brain. Retinoic acid receptors have been shown to be crucial for the survival, adaptation, and equilibrium functioning of the dopaminergic system, and these further strengthens the role of retinoid signal transduction in regulating dopaminergic neurotransmission. The mesotelencephalic dopamine system has a substantial amount of retinoic acid-synthesizing enzymes. By encouraging cell survival and lowering inflammation, some research indicates that vitamin A and its derivatives may have neuroprotective effects. Neurons may benefit from this protection against PD-related degenerative processes. Due to its interactions with retinoic acid receptors (RARs) and retinoid X receptors (RXRs), vitamin A affects gene expression and cellular differentiation. A dysregulation of gene expression has been linked to PD and other neurodegenerative illnesses. Vitamin A may have an impact on pathways related to PD through its role in gene regulation. Keeping the immune system strong requires vitamin A. PD has been shown to progress due to immune system dysfunction and inflammation. Making sure you have enough vitamin A may help your immune system work better and control inflammatory reactions, which may change how your illness develops.

Vitamin B

A common cause of neurological damage and disability worldwide is a deficit in the B vitamin. More people with PD than in the general population have B vitamin deficiencies. Shortfalls in B1 are associated with increased homocysteine levels, whereas deficiencies in B12, B6, and folate are linked to neuroinflammation and dementia. Because homocysteine is a byproduct of the essential amino acid methionine cycle, there is research to support the crucial role of B vitamins in PD. In neurodegenerative diseases, such as PD, homocysteine exhibits a variety of neurotoxic pathogenetic effects. When compared to age-matched healthy individuals, those with PD had higher homocysteine levels. Through neurotoxic effects, elevated homocysteine levels may expedite the death of dopaminergic cells in PD, while decreased homocysteine in plasma may lower the likelihood of developing PD. B vitamins are needed as cofactors in the conversion of homocysteine to methionine. Elevated B vitamin consumption, thus, lowers plasma homocysteine levels and may offer protection against PD. The human substantia nigra has significant concentrations of vitamin B1. It has been shown that intrastriatal vitamin B1 administration increases dopamine release, and that striatal dopamine concentrations decrease in the presence of vitamin B1 deficiency [26]. High dosages of vitamin B1 reduce motor symptoms in PD patients who are not getting any other anti-Parkinson therapy, from 31.3% to 77.3% on the Unified Parkinson's Disease Rating Scale (UPDRS), according to clinical research

Prabha N Bhong *et al.,*

on PD patients [27]. There is evidence that taking supplements of vitamin B3 can help with a number of PD symptoms. Strong dietary supplements of nicotinamide, an active form of vitamin B3, have been demonstrated to alleviate motor impairments associated with PD and regulate aberrant mitochondrial activity in a Drosophila PD model. In the SNpc area of the brain, it has also been demonstrated that nicotinamide administration can stop DA depletion and dopaminergic cell death. Supplementing with vitamin B3 has also been shown in clinical studies to reduce neuroinflammation in PD patients by altering macrophage polarization from M1 (proinflammatory) to M2 (counter-inflammatory). Scientifically, vitamin B3 mediates the release of nicotinamide through poly-ADP ribosylation and encourages the manufacture of the traditional enzyme cofactor nicotinamide adenine dinucleotide (NAD). This results in an anti-inflammatory reaction that mitigates the neuroinflammation-induced dopaminergicneurodegeneration. According to these results, vitamin B3 intake may lessen neuroinflammation and oxidative stress, hence preventing the death of dopaminergicneurons [25],[28]. In small amounts, nicotinamide has antioxidant and neuroprotective properties; but, in large amounts, it causes toxicity, particularly dopaminergic toxicity. PD is linked to excessive nicotinamide use, and PD patients have higher levels of 1-methylnicotinamide (MNA), which can be produced excessively nicotinamide-induced overproduction. These findings were published by ZHAO [31] from several research. Griffin [36] discovered in an in vitro experiment that low-dose nicotinamide (10 mM) significantly influences the induction of neuronal differentiation from embryonic stem cells; but, larger doses (>20 mM) of nicotinamide cause cytotoxicity and cell death[28],[29]. Neurological function is one of the many physiological processes in the body that depend on vitamin B, specifically on B6 (pyridoxine), B9 (folate), and B12 (cobalamin). It has been demonstrated that vitamin B6 in particular has neuroprotective properties.

It aids in the manufacture of dopamine and other neurotransmitters. Due to its role in the synthesis of dopamine and its antioxidant properties unrelated to homocysteine metabolism, vitamin B6 may reduce the risk. In an open-label pilot research assessing the effects of 100 mg intramuscular vitamin B1 given twice weekly, 50 people with PD showed a sustained improvement in their motor and non-motor symptoms over the course of the 3-to 27-month follow-up period [30]. Status epilepticus and early-onset epilepsy are brought on by a vitamin B6 deficit in people with PD. Insufficient consumption of vitamin B6 in the diet is associated with a higher chance of PD, according to Japanese case-control research that included 249 PD patients and 368 healthy controls. Based on a population-based cohort study conducted in Rotterdam on 5289 participants over the age of 55, increased dietary consumption of vitamin B6 was linked to a considerably lower risk of PD. These findings are consistent with previous research [25].Research indicates that vitamin B12 deficiency in patients with PD is linked to neuropathy, impaired cognition and gait, and a fast decline in their ability to walk [31],[32]. Higher baseline levels of vitamin B12 at the time of PD diagnosis were linked to a lower risk of dementia, according to a population-based cohort research. Studies show that shortage in vitamin B12 can slow down the synthesis of S-adenosylmethionine, which can worsen apoptosis and result in Parkinsonian phenotypes in rats. Vitamin B12 enters the cell through the CD320 receptor-mediated transport mechanism, which prevents the degeneration of DA-ergic neurons and decreases oxidative stress, eases movement disorders, and restores mitochondrial function. Vitamin B12 also deconstructed pre-existing fibrils and prevented α-synuclein fibrillation, which decreased cytotoxicity. These data indicate that vitamin B12 is a nutritional source with promise for use in the treatment of PD. It may be explored as a potential functional food ingredient[25].

Vitamin C
It possesses anti-inflammatory, antiviral, anti-microbial, and antioxidant qualities. For PD patients, vitamin C can improve the absorption of levodopa, which can assist control "delayed on" or "poor on" responses [28]. Because it is essential for the sympathetic neurons to produce norepinephrine, ascorbic acid is also a promising target for treating orthostatic hypotension in PD [33]. Vitamin C deficiency and neurological diseases, including atypical Parkinsonism, have a close connection [34]. In addition, vitamin C supplementation has been demonstrated in the DJ-1 mutant fly model of PD to decrease protein oxidation, suppress H_2O_2 generation, and increase anti-oxidant enzymatic activity. The activation of microglia and astrocytes is linked to the inhibition of neuroinflammatory responses by vitamin C, which also modulates the TLR/NF-B/NLRP3/IL-1 pathway, thereby ameliorating PD-associated neuroinflammation, according to a study on MPTP-induced mice model of Parkinson's disease. According to a different in vivo study,

Prabha N Bhong *et al.,*

vitamin C prevents oxidative damage caused by MPP+, which in turn stops the loss of DAergic neurons in PD. Apoptotic signaling-mediated cell death is inhibited by vitamin C, which also prevents LB development in PD [25]. For two hours, the human neuroblastoma cell line SK-N-SH was incubated with ascorbic acid (100-500 mM), and Seitz [34] observed a dose-dependent overproduction of DOPA. Furthermore, after incubation with ascorbic acid (200 mM) for five days, the tyrosine hydroxylase gene expression increased thrice. Ascorbic acid may be useful in treating PD in its early stages, according to the experts' conjectures [35].

Vitamin D:[26]
Reduced verbal fluency, increased postural instability, motor severity, and poor memory have all been linked to vitamin D insufficiency. Vitamin D deficiency is substantially linked to a number of non-motor symptoms in PD patients in addition to the motor symptoms [25]. One crucial neurosteroid needed for proper brain development and operation is vitamin D. It has been proposed that vitamin D is linked to a number of neurological conditions, including multiple sclerosis, stroke, and neurodegenerative illnesses. Numerous brain regions have vitamin D receptors as well as the enzyme 1-alpha-hydroxylase, which is responsible for activating vitamin D. Research conducted on animals indicates that vitamin D could serve as a neurotrophic agent, boost antioxidant concentrations, and guard against excitotoxicity. It appears that the risk and severity of PD are negatively correlated with serum vitamin D concentrations. According to a meta study by Liang [28]PD patients had lower mean levels of 25-hydroxyvitamin D [25(OH)D] than healthy controls (weighted mean difference (MD), -16.9, 95% confidence interval (CI)], -33.5 to -0.2), PD risk was higher in patients with vitamin D insufficiency (25(OH)D level <75 nmol/l). PD risk was doubled in patients with vitamin D insufficiency (25(OH)D level <50 nmol/l). A higher risk of PD is linked to low vitamin D levels (36),(37). Compared to healthy controls, PD patients were shown to have decreased levels of 25(OH)D (38). The results of a randomized, placebo-controlled, double-blind experiment involving 114 PD patients provide evidence about the effectiveness of vitamin D in treating the disease. Specifically, individuals with the FokI TT or CT genotype may have a brief period of PD stabilization while taking 1200 IU of vitamin D3 daily (39).

In a variety of PD animal models, vitamin D3 has been reported to ameliorate behavioral abnormalities, lower oxidative stress, and lessen DA depletion and neuronal death. Tyrosine hydroxylase and the dopamine transporter are both overexpressed as a result of it, according to the molecular process. It suppresses the production of ROS that is mediated by inducible nitric oxide synthase (iNOS), MAO-B, and NADPH oxidase (NOX). In addition, vitamin D therapy causes PD neuroprotection by decreasing pro-inflammatory reactions and triggering anti-inflammatory ones. Mechanistically, vitamin D3 promotes the activation of M2 microglia for an anti-inflammatory response while inhibiting the pro-inflammatory activities of neuroinflammatory TNF-, TLR-4, iNOS, CD11b, MAO-B, IL-I, p47phox, and M1 microglia. In addition, vitamin D3 therapy increases brain-derived neurotrophic factor (BDNF) and glial-derived neurotrophic factor (GDNF) levels in PD animal models, which helps keep neurons alive. GDNF forms a complex with the proto-oncogene tyrosine-protein kinase receptor Ret after binding to the GDNF family receptor alpha 1. The neuronal survival-granting intracellular signaling is activated by this complex. GDNF is a potent antioxidant that promotes the synthesis of glutathione (GSH), SOD, and CAT in the striatum and helps dopaminergicneuron regeneration [25].

DAIRY PRODUCTS
The idea that consuming a lot of milk and perhaps other dairy products overall is linked to a higher risk of PD has received support from several researchers. A Hawaiian study discovered that consuming more than two glasses of milk a day was linked to a reduction in neuronal density in the SN at postmortem [40]. Using data from the American Cancer Society's Cancer Prevention Study II Nutrition Cohort, Honglei [41] prospectively examined the relationship between dairy consumption and PD risk in 57,689 men and 73,175 women." The follow-up period (1992–2001) revealed the identification of 138 women and 250 men with PD. PD risk was strongly correlated with dairy consumption. The likelihood of developing PD was positively correlated with dairy consumption [41]. A significant research of American men and women found that eating three or more servings of low-fat dairy products per day was linked to an increased chance of receiving a PD diagnosis [42]. There may be several mechanisms responsible to explain the association between PD progression and dairy consumption: (1) Dairy intake lowers uric acid [43]. Uric

acid quenches peroxynitrite in the CNS, and low uric acid levels are associated with greater PD incidence and faster PD progression. (2) Diary consumption is associated with insulin resistance. There is a growing body of evidence that PD and other neurodegenerative diseases are a form of "type III diabetes" (3) Lactose intolerance, occurring when the enzyme, lactase, that digests the milk sugar decreases with age, is especially common in individuals of African, Asian, Hispanic, and Native American decent. Consuming dairy in the absence of sufficient lactase may contribute to intestinal inflammation and intestinal permeability. (4) Presence of a neurotoxic component or contaminant, for example, pesticides, may be present in dairy. (5) Introduction of bovine microbiota, facilitating seeding of methanogenic organisms, leads to the development of methane-dominant small intestinal bacterial overgrowth (SIBO) and other forms of abnormal intestinal flora [3],[44]. A recent meta-analysis reported a combined risk of 1.4 for highest vs. lowest levels of dairy food intake, with a stronger association for men than for women [45].

COENZYME Q10 (UBIQUINONE)
PD has been shown to frequently result from mitochondrial malfunction, which is thought to contribute to the etiology of the illness. Coenzyme Q10, which is an antioxidant as well as an electron acceptor for complexes I and II of the mitochondrial electron transport chain (ETC), is an essential part of the chain [46]. When taken in daily doses ranging from 300 to 1,200 mg, coenzyme Q10 can reduce inflammation, motor neuron symptoms, finger dexterity, and visual color acuity [47]. Significantly less CoQ10 was found in the brain's cortex, according to research by Hargreaves [48], which suggest that the etiology of PD may be influenced by signs of a brain CoQ10 deficiency [48]. It was proposed by Hyung-Woo [49] that intrastriatal delivery of a modest dose of Coenzyme Q10 on a continuous basis could effectively prevent the degeneration of dopaminergic neurons. Although the dose of intrastriatal Coenzyme Q10 was 17,000 times lower than that of oral Coenzyme Q10, rats exposed to intrastriatal Coenzyme Q10 also showed less inflammation, more dopaminergic neurons, and higher expression of neurogenetic and angiogenetic factors. These effects were more pronounced than those of Coenzyme Q10 administered orally. Consequently, one efficient method of preventing neurodegeneration in PD may involve the continuous intrastriatal delivery of Coenzyme Q10, particularly in conjunction with implantable devices for convection-enhanced delivery or deep brain stimulation [49].

CONCLUSION

Research on the gut microbiota has made great strides because to high-throughput sequencing techniques. Although there is a lot of circumstantial evidence suggesting the microbiota may play a role in PD, definitive proof is still missing. Determining the exact biochemical pathways through which the microbiome contributes to the etiology of PD is a very challenging task.Notably, recent advancements in tissue culture technologies—most notably, the creation of organoids from human intestinal tissue and their incorporation into more complex organ-on-a-chip systems—offer excellent model systems for researching host-microbe interactions that have a high degree of clinical relevance [50]. Eating a nutritious, well-balanced diet can either reduce or eliminate the risk of PD. The start of PD has been linked to a number of vitamin deficiencies, including deficiencies in vitamins A, B, C, D. Consequently, consuming enough of these vitamins might be viewed as a vital prophylactic against PD. Numerous vitamin supplements can alleviate motor impairments and the clinicopathological changes associated with PD in the general population, as well as lower the prevalence of the disease. This has been shown in previous pre-clinical and clinical investigations. Vitamins may be helpful in treating PD due to their antioxidative properties and biological influence on different gene expressions linked to the disease. Therefore, more research on the neuroprotective vitamins and their active metabolites against PD is needed in the future to confirm vitamins as potent therapeutics against PD.

ABSTRACT

Oxidative stress is initiated by free radicals which seek stability through electron pairing with biological macromolecules such as proteins, lipids, and DNA in healthy human cells, therein causing protein and DNA damage along with lipid peroxidation. To prevent damage caused by free radicals, tissues possess an antioxidant defense system that includes enzymatic antioxidants, such as superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx) dietary non-enzymatic antioxidants such as reduced glutathione (GSH), vitamin C and vitamin E. In the present study was investigated the effect of different doses of *Ficus glomerata* on hydrogen peroxide induced oxidative stress in rat erythrocytes. The qualitative analysis of methanolic extract of *Ficus glomerata* leaves showed that tannin, phlobatannins, saponin, flavonoids, steroids, terpenoids, triterpenoids, carbohydrate, polyphenol, protein and glycoside while quantitative revealed total phenol (234 mg/gm) and flavonoids (142mg/gm). The increased content of MDA in group I as compared with other groups, indicates that the increase in oxidative stress and lipid peroxidation while treatment with *Ficus glomerata* decreased MDA content, based on dose dependent manner. The decreased activity of serum enzymatic antioxidant such as SOD, glutathione peroxidase (GPx) and catalase in erythrocyte were observed group I as compared with other groups. This may be indicating the increased free radical in aging attack on enzymes and inactivate them. Treatment with *Ficus glomerata* increased GPx and CAT activity, based on dose dependent manner. The decreased

level of erythrocyte GSH, vitamin C and vitamin E in group I compared with other groups, demonstrating the increased free radicals accumulation. Treatment with *Ficus glomerata* increased vitamin C and vitamin E content, based on dose dependent manner. The results obtained from the present study indicate that hydrogen peroxide enhance lipid peroxidation in the erythrocyte and influence the antioxidant enzymes of erythrocytes. The above results suggested that increased risk of oxidative stress related diseases such as cardiovascular diseases, diabetes, cancer, arthritis etc.

Keywords: Oxidative stress, Antioxidant activity, Phytochemicals, *Ficus glomerata*

INTRODUCTION

Stress is associated with increase in oxidant production and oxidative damage *via* imbalances of hormones, neurotransmitters, oxidants and other stress mediators, as well as the interactions of these stress-related substances, which result from stress-associated changes in metabolic rate/catabolic processes. The stress theory of aging suggests that aging is a result of the cumulative effects of stress experienced during an organism's lifespan. The increased accumulation of oxidative damage to biomolecules critically contributes to aging acceleration and age-related diseases, such as neurodegenerative diseases (Liu and Mori, 1999). Normal metabolism is associated with unavoidable mild oxidative stress resulting in biomolecular damage that cannot be totally repaired or removed by cellular degradative systems, including lysosomes, proteasomes, and cytosolic and mitochondrial proteases. Consequently, irreversibly damaged and functionally defective structures accumulate within long-lived post-mitotic cells, such as cardiac myocytes and neurons, leading to progressive loss of adaptability and increased probability of death and characterizing a process called aging, or senescence. Intralysosomal 'garbage' is represented by lipofuscin (age pigment)., an autophagocytosed materials, while extra-lysosomal 'garbage' involves oxidatively modified cytosolic proteins, altered biomembranes, defective mitochondria and other organelles. In aged post-mitotic cells, heavily lipofuscin-loaded lysosomes perform poorly, resulting in the enhanced accumulation of defective mitochondria, which in turn produce more reactive oxygen species causing additional damage (the mitochondrial–lysosomal axis theory) (Terman and Brunk, 2006b).

The oxidative stress theory of aging has become increasingly accepted, playing a role in the aging process. The intensity of oxidative stress is determined not only by the free radicals production but also by antioxidant (enzymatic and non-enzymatic). Defense (Beltowski *et al.,* 2000). Potential anti-aging strategies may involve the overall reduction of oxidative stress by the use of antioxidant and intralysosomal iron chelators hampering Fenton-type chemistry as well as the stimulation of cellular degradative systems (Terman and Brunk, 2006b). The exposure of aerobic organism to oxidative stress is an unavoidable consequence of their high capacity to produce energy from respiratory activity. Thus, to protect their own structures, organisms have developed several defense mechanisms with antioxidant activity. Because oxidative stress is considered to have a critical role in changes associated with senescence, it is conceivable that antioxidants are important antiaging agents (Mecocci, 2000). A broad class of protective agents termed antioxidants, which prevents oxidative damage by reacting with free radicals before any other molecules can become a target neutralizes the harmful effect of reactive oxygen species. The enzymatic antioxidant such as SOD, CAT, GPx etc., and non-enzymatic antioxidants are vitamin C, vitamin E ceruloplasmin, albumin and reduced glutathione play an important role in the protection of cells against free radical mediated damage (Halliwell, 1994). The balance between ROS production and antioxidant defense leads to 'oxidative stress'. Any compound, natural or synthetic with antioxidant properties might contribute towards the partial or total alleviation of this type of damage. Phytochemicals are biologically active, naturally occurring chemical compounds found in plants, which provide health benefits for humans further than those attributed to macronutrients and micronutrients (Hasler and Blumberg, 1999). They protect plants from disease and damage and contribute to the plant's colour, aroma and flavor. In general, the plant chemicals that protect plant cells from environmental hazards such as pollution, stress, drought, UV exposure and pathogenic attack are called as phytochemicals (Mathai, 2000).

Recently, it is clearly known that they have roles in the protection of human health, when their dietary intake is significant. More than 4,000 phytochemicals have been cataloged and are classified by protective function, physical characteristics and chemical characteristics (Meagher and Thomson, 1999). Medicinal plants are of great importance to the health of individuals and communities. The medicinal value of these plants lies in some chemical substances that produce a definite physiological action on the human body. Many of these indigenous medicinal plants are used as spices and food. Medicinal herb is considered to be a chemical factory as it contains a multitude of chemical compounds like alkaloids, glycosides, saponins, resins, oleoresins, sesquiterpene, locations and oils (essential and fixed) (Rajalkshmi *et al.*, 2013). Higher plants produce both primary and secondary chemical metabolites, the former being vitally important in normal development and reproduction of plants. On the other hand, secondary metabolites are known to play important roles in plant survival as defense mechanisms against adverse biotic and a biotic conditions. Plant chemicals to protect itself but recent research demonstrate that many phytochemicals can protect humans against diseases including cancer, cardiovascular and inflammatory diseases. Hence, the present study was investigate the antioxidant activity of *Ficus glomerata* on hydrogen peroxide induced oxidative stress in rat erythrocytes. *Ficus glomerata*. Roxb. is a popular medicinal plant in India, which has long been used in Ayurveda for the treatment of diabetes, liver disorders, respiratory, urinary diseases and inflammatory conditions.

MATERIALS AND METHODS

Plant materials and Preparation of extract
The leaf of *Ficus glomerata* was collected from Thamarankottai, Thanjavur district. The collected leaves were cut into small pieces and shade dried at room temperature and makes a fine powder using pestle and mortar. The powder materials of leaves were macerated with 70% methanol at room temperature for 24 hours. After 24 hours, the supernatant was transferred into china dish. The supernatant was completely removed by keeping the china dish over a boiling water bath at 45°C. A semi solid extract was obtained after complete elimination of alcohol. The obtained residue was kept in the refrigerator for further use.

Phytochemical screening
Chemical tests were carried out on the alcoholic extract and on the powdered specimens using standard procedures to qualitative identify the constituents as described by Sofowara (1993), Trease and Evans (1989) and Harborne (1973, 1984). Total phenols estimated by the method of Edeoga *et al.,* (2005). Flavonoid determine by the method of Bohm and Kocipai-Abyazan (1994).

Preparation of erythrocytes suspensions (Wu *et al.*, 1997)
Fresh blood samples from healthy volunteers (10–15ml) were collected and centrifuged at 3000 rpm for 15 minutes, plasma and pufy coats were removed. Red cells were washed with PBS (pH 7.00) for three times and erythrocytes were lysed with ice-cold distilled water. The antioxidant activities in erythrocytes were evaluated by the method of Sasikumar *et al.* (2015).

Experimental design
Erythrocyte suspensions obtained from healthy donor were divided into five groups.
Group I- H_2O_2 Control: [Erythrocyte suspension (750µl), 10mM H_2O_2 (50µl), PBS (950µl) and D.H_2O (250µl)]. **Group II Normal:** [Erythrocyte suspension (750µl), PBS (1000µl) and D.H_2O (250µl)]. **Group III-** *Ficus glomerata* **(100 µg/ml):** [Erythrocyte suspension (750µl), 10mM H_2O_2 (50µl), *Ficus glomerata* extract (500µl) and PBS (950µl)]. **Group IV-** *Ficus glomerata* **(250 µg/ml):** [Erythrocyte suspension (750µl), 10mM H_2O_2 (50µl), *Ficus glomerata* extract (500µl) and PBS (950µl)]. **Group V-** *Ficus glomerata* **(500 µg/ml):** [Erythrocyte suspension (750µl), 10mM H_2O_2 (50µl), *Ficus glomerata* extract (500µl) and PBS (950µl)].   These experimental groups were incubated at 37°C for 1 hour. Following the incubation, enzymic and non-enzymic antioxidant activity were determined.

BIOCHEMICAL ESTIMATION

Estimation of Malondialdehyde

Malondialdehyde was estimated by the thiobarbituric acid assay method of Beuge and Aust (1978). Reduced glutathione was estimated by method of Moron *et al* (1979). The level of ascorbic acid was estimated by the method of Omaye *et al* (1979). α-tocopherol was estimated by the method of Baker *et al* (1980). The activity of catalase was assayed by the method of Beers and Sizer (1952). The activity of mitochondrial glutathione peroxidase was assayed by the method of Rotruck *et al* (1973).

Statistical Analysis

Values are expressed as Mean ± SD for triplicates. Data were analyzed by one-way ANOVA followed by post-hoc Tukey HSD test, using SPSS ver. 20. Statistically significant variation was derived by comparing Group I versus Group II, Group III, Group IV and Group V. *$P<0.05$ statistically significant and NS= Non significant ($P>0.05$) compared with Group I (Negative control).

RESULTS AND DISCUSSION

Plants that having curing properties are known as medicinal plants or herbs. Herbs have been used in treating human diseases for thousands of years by tribal communities and ancient civilizations. They may be used directly as such, or in other extracted forms for their natural chemical constituents. They may also be used as constituents in different forms of medicines. Medicinal plants are not only a major source for the traditional medicine & herbal industry but also provide livelihood and health security to a large segment of Indian population. According to the World Health Organization (WHO), approximately 80% of the world's population currently uses herbal medicines in healing different ailments. Among the estimated 400,000 plant species, only 6% have been studied for biological activity, and about 15% have been investigated phytochemically (Pushpa Latha *et al.*, 2010). This shows a need for planned activity guided phyto-pharmacological evaluation of herbal drugs. This article is aimed to provide an overview of research work done on this plant which is helpful for further investigations and forms an important aspect of drug studies. The qualitative analysis of methanolic of extract of *Ficus glomerata* leaves showed that tannin, phlobatannins, saponin, flavonoids, steroids, terpenoids, triterpenoids, carbohydrate, polyphenol, protein and glycoside were present (Table 1). Quantitative analysis revealed that the plant has phenols, alkaloids, saponin and tannin. Rich amount of total phenol (234.28 mg/gm) and flavonoids (142.28mg/gm) was presented. This is because of the pharmacological activity of this plant is used to trace the particular compound.

Erythrocytes, the unique carriers of oxygen are highly susceptible to oxidative stress conditions. The rich polyunsaturated membrane lipids and iron, a potent catalyst for free radical reactions makes erythrocyte a good substrate for oxidative damages. Membrane oxidations do affect the intrinsic membrane properties as well, by altering membrane fluidity, ion transport and loss of enzymic activities of the cell (Chiu *et al.*, 1989). As cell membrane is an important target for radical damage, and blood can reflect the liability of the whole animal to oxidative condition, erythrocytes have been used extensively for determining the effect of aging in studies concerning the possible involvement of free radicals. The erythrocyte cell membrane has a total negative electric charge, which determines the correct course of many processes like transport of metabolic substrates and products through ionic pumps, carriers and membrane channels, for the transfer of information (Nalecz, 1989) and mainly to prevent aggregation of erythrocytes from each other (Jovtchev *et al.*, 2000). The aggregability of erythrocytes is mainly determined by glycocalyx on their membrane, in particular by the amount of the sialic acid residues bearing negative surface charge. Oxidative stress or other damaging effects to surface sialosaccharide may itself play role in aggregation of erythrocytes, increasing the adhesiveness to endothelial cells contributing for the development of various pathologies including diabetes mellitus, atherothrombotic complications (Wautier *et al.*, 1981) and sequestration of circulating erythrocytes by macrophages (Beppu *et al.*, 1995).

The vital function that blood cells perform, together with the susceptibility of this highly proliferative tissue to intoxication by xenobiotics, makes the hematopoetic system unique as the target organ. The various blood cells are produced at a turnover rate of about 1 to 3 million per second in a healthy human adult and this value could be altered in certain physiological or pathological states including hemolytic anemia or suppressive inflammation (Guyton, 1991). Erythrocytes are highly vulnerable to free radical induced LPO reactions due to rich content of polyunsaturated fatty acids (PUFAs)., presence of transition metals and continuous exposure to high concentration of molecular oxygen (Chiu *et al.*, 1982). Under normal conditions, the continuous production of free radicals is compensated by the powerful action of protective enzymes like superoxide dismutase, catalase and glutathione peroxidase that are believed as major antioxidant enzymes present in the human body that protect against the oxygen toxicity. As a result, a lipid peroxidation (LPO) process occurs. Therefore, antioxidant enzyme activities and lipid peroxidation levels are accepted as important parameters in the evaluation of oxidative stress in aerobic organisms (Abraham *et al.*, 2005). The present study was carried out to investigate the influences of hydrogen peroxide on the antioxidant status and lipid peroxidation (LPO) in erythrocytes. Table 2 represents the levels of MDA in experimental group. Group I hydrogen peroxide treated RBC showed a significant increased in the level of MDA when compared to Group II rats. Group III to V hydrogen peroxide exposed RBC treated with different doses (100, 250 and 500µg/ml) of *Ficus glomerata* significantly decreased in the level of MDA when compared to group I.

Among the various doses, 500mg/kg possess significant activity than other doses. Values are expressed as Mean ± SD for triplicates. Statistically significant variation was derived by comparing Group I versus Group II, Group III, Group IV and Group V. *$P<0.05$ statistically significant and NS= Non significant ($P>0.05$) compared with Group I (Negative control). Malondialdehyde (MDA) is the major aldehyde resulting from the peroxidation of biological membrane polyunsaturated fatty acid. MDA, a secondary product of lipid peroxidation is used as an indicator of tissue damage by series of chain reactions (Ray and Husain, 2002). The study of lipid peroxidation is attracting much attention in recent years due to its role in diseases process membrane lipids are particularly susceptible to lipid peroxidation due to the presence of polyunsaturated fatty acids. It has been implicated in the pathogenesis of a number of diseases and clinical conditions. These include atherosclerosis, cancer etc., Experimental and clinical evidence suggests that aldehyde products of lipid peroxidation can also act as bioactive molecule in physiological and pathological conditions. It is now generally accepted that lipid peroxidation and its product play an important role in liver, kidney, heart and brain toxicity (Lakshmi *et al.*, 2005). MDA is one of the indicators of oxidative stress. In the present study, the increased content of MDA in group I as compared with other groups, indicates that the increase in oxidative stress and lipid peroxidation. Treatment with *Ficus glomerata* decreased MDA content.

The decrease was observed dose dependent manner. Among the various doses, 500mg/kg possess significant activity than other doses. Table 3 represents the activity of SOD, Catalase and Glutathione peroxidase (GPx) in experimental group. Group I hydrogen peroxide treated RBC showed a significant decreased in the activity of SOD and Catalase when compared to Group II rats. Group III to V hydrogen peroxide exposed RBC treated with different doses (100, 250 and 500µg/ml) of *Ficus glomerata* significantly decreased in the activity of SOD and Catalase when compared to group I. Among the various doses, 500mg/kg possess significant activity than other doses. Group I hydrogen peroxide treated RBC showed a significant decreased in the activity of Glutathione peroxidase when compared to Group II rats. Group III to V hydrogen peroxide exposed RBC treated with different doses (100, 250 and 500µg/ml) of *Ficus glomerata* significantly increased in the activity of Glutathione peroxidase when compared to group I. Among the various doses, 500mg/kg possess significant activity than other doses. Values are expressed as Mean ± SD for triplicates. Statistically significant variation was derived by comparing Group I versus Group II, Group III, Group IV and Group V. *$P<0.05$ statistically significant and NS= Non significant ($P>0.05$) compared with Group I (Negative control). Glutathione is an important antioxidant that functions directly in elimination of toxic peroxides and aldehydes and indirectly in maintaining vitamins C and E in its reduced and functional forms. Vitamin C deficiency results in decreased plasma GSH and vitamin E supplementation increases plasma GSH. Both vitamin C and E concentrations in plasma decrease with age (Samiec *et al.*, 1998)., suggesting that GSH may also decrease in plasma with age diminished GSH status has been linked with normal aging as well as with neurodegenerative disease (Benzi and Moretti, 1997). The finding of our study showed decrease level of erythrocyte glutathione in group I as compared

with other groups. This may be due to increased utilization for detoxification of free radicals generated by hydrogen peroxide. Treatment with *Ficus glomerata* increased GSH content. The increase was observed dose dependent manner. Among the various doses, 500mg/kg possess significant activity than other doses. Ascorbate plays an important role with the lipophilic antioxidant α-tocopherol in protecting the membrane from oxidative stress. Recycling of ascorbic acid requires GSH, which reduces dehydroascorbate to ascorbate (Winkler, 1992). Ascorbate in turn is essential for the recycling of tocopherol radical to tocopherol (Packer *et al.*, 1997). The observed decline in glutathione level may contribute to the decrease in ascorbate as well tocopherol concentration in aged subject. Both vitamin C and E concentrations is decrease with age reported by Samiec *et al*. (1998). A variety of antioxidant defense systems is present in erythrocytes including α-tocopherol to detoxify pro-oxidants and scavenge free radicals to protect itself against oxidative damage. α-Tocopherol serves as a potent scavenger of peroxyl radicals to protect PUFA present in erythrocyte membranes against peroxidation (Mukai *et al.*, 1993). The significant decrease in erythrocyte α-tocopherol levels in aging subjects may be due to the scavenging of peroxyl and sanguinary induced production of ROS, as evidenced by increased peroxidation of erythrocyte. α-Tocopherol and ascorbate are well known non-enzymatic antioxidants, which play an important role by oxido-reductive mechanism in protecting biological membranes against toxicant induced oxidative damage by trapping ROS (McCay, 1985). In the present study, we also observed the decreased level of erythrocyte vitamin C and vitamin E in group I as compared with other groups, demonstrating the increased free radicals accumulation. Treatment with *Ficus glomerata* increased vitamin C and vitamin E content. The increase was observed dose dependent manner. Among the various doses, 500mg/kg possess significant activity than other doses.

CONCLUSION

The results obtained from the present study indicate that hydrogen peroxide enhance lipid peroxidation in the erythrocyte and influence the antioxidant enzymes of erythrocytes. The above results suggested that increased risk of oxidative stress related diseases such as cardiovascular diseases, diabetes, cancer, arthritis etc. Treatment with *Ficus glomerata* increased antioxidant activity. The increase was observed in dose dependent manner. Among the various doses, 500mg/kg possess significant activity than other doses. Antioxidant supplementation may be benefited to the free radical mediated diseases including diabetic, cancer, cardiovascular diseases etc.

ABSTRACT

"Oral and maxillofacial surgery encompasses the treatment of diseases affecting the head, neck, and face, particularly focusing on the oral cavity. This includes a wide spectrum of procedures ranging from routine teeth extraction to more complex interventions such as facial bone fracture reduction, oncological surgeries, and access osteotomies. Typically, both pre-operative and post-operative courses involve the administration of antibiotics and analgesics, albeit sometimes resulting in adverse reactions in patients. In India, alongside modern medicine, we have the AYUSH system, which offers treatments for various pathologies affecting the head, neck, and oral cavity, utilizing herbal remedies and therapies without the accompanying complications of conventional medication. The AYUSH system comprises Siddha, Ayurveda, Unani, and Sowrigba (Himalayan herbal medicine), all of which are rooted in herbal practices. Recognized by the World Health Organization (WHO) as a form of herbal medicine, AYUSH has gained significance, especially in the wake of the COVID-19 crisis, where herbal remedies have proven to be lifesavers. Herbal remedies, being a staple in Indian culture for centuries, are easily accessible and

affordable. They have been employed in treating both communicable and non-communicable diseases and can serve as effective alternatives for infection control and pain management in the field of oral and maxillofacial surgery (OMFS). This review highlights the potential of various AYUSH drugs, known for their minimal adverse effects, to contribute to the well-being of OMFS patients."

Keywords: AYUSH, Siddha, Ayurveda, Unani, maxillofacial surgery

INTRODUCTION

Diseases of the oral cavity primarily affect the teeth and surrounding tissues, spanning from common dental caries to pre-malignant lesions, conditions, and oral squamous cell carcinomas. Herbal remedies have been utilized for centuries in treating oral cavity diseases, boasting high success rates due to their interactions with specific receptors within the body. In light of the need for alternative treatments that are safe, effective, affordable, and devoid of side effects, the search for alternative herbal products persists. It is increasingly evident that plant extracts offer advantages over synthetic chemicals [1]. Traditionally, there were 18 Siddhars (Agasthiyar, Korakkar, Punnakkeesar, Pulasthiyar, Poonaikannar, Idaikkadar, Bogar, Pulikaiisar, Karuvurar, Konkanavar, Kalangi, Sattainathar, Azhuganni, Agappai, Pumbatti, Theraiyar, and Kudhambai) credited with the development of Ayush medicine, with Agasthiyar being particularly esteemed. Regarded as the originator of Siddha medicine, Agasthiyar holds a position akin to that of Hippocrates in modern Western medicine. The Siddha medicine system predominantly incorporates the use of metals, minerals, and chemical products, with the utilization of metals dating back to the period of Vagbhata (6th Century AD). While the exact dates of alchemy texts remain uncertain, they likely originated between the 9th and 18th Centuries AD, with the period between the 10th and 14th Centuries witnessing notable flourishing [2].

MATERIALS AND METHOD

This review checklist was followed in conducting the systematic review of the literature for the present study. To create a database of herbal product use in oral health literature from January 2000 to January 2020, a thorough search method was devised to find both published and unpublished citations. An automatic search of bibliographic databases, such as PubMed, Embase, Scopus, and the Web of Science database, was included in the search. These searches made use of proximity, phrases, truncation, and index terms from either the EMtree thesaurus or MeSH headings. Subject heading terms and keywords for oral disorders and herbal goods (e.g., "herbal medicine," "herbal extract," "herbal supplements," "plant extract," or "natural drug") were included in the search concepts.

Inclusion criteria and study selection
In order to determine if herbal products are beneficial in treating oral diseases, preliminary research encompassing cross-over studies, clinical trials, randomized controlled trials, and in vitro investigations was incorporated into this review. Editorials, commentaries, letters, review papers, and observational studies (such as case controls, cohorts, and cross-sectional studies) were not included.

Data extraction
Data were separately gathered from all included articles by two review authors, SS and GS. The study team created basic forms by extracting the characteristics of the included studies. The bibliographical data (title, authors, publication dates, and affiliations), patient data (age, gender, and oral disease subgroup), and methodological data (herbal product name, intervention group, control group, outcome assessment, and follow-ups) were some of these features.

Evaluation of the evidence's quality
Utilizing the Cochrane Handbook for Systematic Reviews of Interventions, the standard of the randomized trials included is evaluated. The Cochrane handbook lists five criteria—random sequence generation, allocation concealment, blinding, inadequate outcome data, and selective reporting—as a means of evaluating the quality of randomized controlled trials. The Health Gains Notation framework was utilized to evaluate the efficacy of the interventions.

Disease and Cause Concept in Siddha Medicine:
According to Siddha medicine principles, diseases occur when there is a disruption in the usual balance of the three components: Vatha, Pitha, and Kapha. Various factors such as environment, climate conditions, diet, physical activities, and stress contribute to this imbalance. In a healthy state, the ratio of these three components is typically 4:2:1.With the advent of modern medicine, there has been a decline in the use of traditional herbal medicine. However, the emergence of new diseases and the adverse effects associated with modern medicine have led to a resurgence of interest in Ayush treatments, which are known for their lack of adverse effects. Ayush medicine is not limited to a specific department but can be integrated into various specialties. As previously mentioned, Ayush is increasingly being utilized in oral and maxillofacial surgery (OMFS). Ayush medicine offers an alternative to modern medicine in various forms, including antibiotics, analgesics, antacids, antivirals, wound healing enhancers, anesthetics, and hemostatic agents. During the COVID-19 pandemic, many countries, including India, explored the use of indigenous medicines. In India, KabasuraKudineer was used to treat COVID-19, resulting in reduced mortality rates compared to conventional medicine. This serves as evidence that Ayush drugs can be comparable to modern medicine drugs [2].

Natural Remedies for Oral and Maxillofacial Surgery Conditions:
According to the WHO, 70-80% of people worldwide depend on native herbal medicine as their first line of treatment due to its high safety margin and availability [3]. Consequently, there is a crucial need for the development of evidence-based herbal medicine in modern dental practice. This article discusses the various diseases seen in oral and maxillofacial surgery and herbal-based treatments for these conditions based on existing Indian literature."

Ginger: The botanical name of Ginger is Zingiberofficinale
According to Indian literature, ginger has anticancer properties [4]. Zerumbone is a sesquiterpenoid and cyclic ketone extracted from the essential oil of ginger rhizomes. NurSyafinazZainal et al. demonstrated in their study that zerumbone, extracted from ginger, exhibits anticancer activity by inhibiting the activation of CXCR4-RhoA and PI3K-mTOR signaling pathways, thereby reducing the cell viability of ORAL SQUAMOUS CELL CARCINOMAcells. From this study, we conclude that zerumbone is a promising phytoagent for the development of new therapeutics for ORAL SQUAMOUS CELL CARCINOMAtreatment [5]."

Garlic: The botanical name of Garlic is Allium sativum .
According to Indian literature, garlic has anticancer and antifungal properties [4]. In epidemiological studies, the usage of garlic and garlic-based extracts has been associated with a lower risk of cancer. VoinPetrovic et al., in their study, examined the molecular and cellular activities of garlic extract and found that it enhanced the activities of chemotherapeutics, as well as MAPK and PI3K inhibitors. Furthermore, garlic extract affected hundreds of proteins involved in cellular signaling, including changes in vital cell signaling cascades regulating proliferation, apoptosis, and the cellular redox balance [6]. Polymicrobial biofilms are notorious for damaging intraoral tissues. Streptococcus sanguinis and Streptococcus mitis, which are commensals of the oral cavity, have been observed to coexist alongside C. albicans in resistant infections. There is an urgent need for alternate therapy choices. In their study, Ayesha Fahim et al., assessed the efficacy of garlic and bakuchiol combination against candida virulent genes and their subsequently secreted proteins. They found that ALS3 and SAP5 were significantly downregulated in the garlic and bakuchiol-treated polymicrobial biofilm. Therefore, garlic can be used against Candida albicans [7].

Arulsorubi *et al.,*

Turmeric: The botanical name of turmeric is Curcuma longa .
According to Indian literature, turmeric has anticancer and antifungal properties [4]. It belongs to the family of ginger and is a native plant of the Indian subcontinent. Phytochemical components of turmeric include diarylheptanoids, a class comprising numerous curcuminoids such as curcumin, demethoxycurcumin, and bisdemethoxycurcumin. Curcumin has been shown to possess anti-infectious, antioxidant, anti-inflammatory, and anticarcinogenic effects. The low bioavailability of curcumin has been overcome by numerous analogues and nanoformulations, including nanoparticles, liposome complexes, micelles, and phospholipid complexes. Curcumin's anticancer effects are mediated by its action on multiple molecular targets, including activator protein 1, protein kinase B (Akt), nuclear factor κ-light-chain-enhancer of activated B cells, mitogen-activated protein kinase, epidermal growth factor receptor (EGFR) expression, and EGFR downstream signaling pathways. These targets play essential roles in oral cancer development, hence curcumin is a promising adjuvant therapy approach [8]. FatemehForouzanfar et al. conducted a study on turmeric and its antibacterial effect over periodontal disease and found it to be equally or more effective when compared to chlorhexidine [9]

Tulasi: The botanical name of tulasi is Ocimum sanctum.
According to Indian literature, tulasi has anticancer properties [4]. The plant and its oil contain diverse phytochemicals, including tannins, flavonoids, eugenol, caryophyllenes, carvacrol, linalool, camphor, and cinnamyl acetate. Oral Submucous Fibrosis (OSMF) is defined as an insidious chronic condition of unknown etiology affecting the oral mucosa, characterized by dense collagen tissue deposition within the submucosa, occasionally extending to the pharynx and esophagus [10]. The condition is marked by trismus, a burning sensation, loss of tongue movement, loss of gustatory sensibility, and blanching and stiffness of the oral mucosa. The majority of these cases affect Indian people [11]. OSMF can be treated with tulasi, which is easily available and most recognized by Indians as the first line of medicine for sore throat and fever. AditSrivastava et al., in their study, used tulasi and turmeric for the treatment of OSMF and concluded that these herbs reduced the burning sensation and improved mouth opening [12]

Aloe vera: The botanical name of aloe vera is Aloe barbadensismiller .
According to Indian literature, aloe vera has antifungal properties [4]. Candida infection causes two types of infections: superficial infections such as oral and vaginal lesions, and systemic manifestations. Karina Nabila, in their study, determined the effectiveness of the antifungal nature of aloe vera by mixing aloe vera extract with 70% ethanol and dissolving it in DMSO into multiple concentrations (6.25%, 12.5%, 25%, and 50%). Candida albicans was cultured in Sabouraud dextrose agar for 72 hours, and the disc diffusion method was used to evaluate the inhibitory effect of each concentration compared to fluconazole. Zones of inhibition at 72 hours were measured and documented, then analyzed to obtain the mean inhibition zone (MIZ). Results: After 72 hours, all concentrations of Aloe vera ethanol extract showed inhibitory effects against C. albicans, with mean inhibition zones for each concentration. Aloe vera ethanol extract possesses concentration-dependent activity against Candida albicans that is comparable to standard antifungal agents. [13]

Large Caltrop: The botanical name of large caltrop is Pelladium murex.
According to Indian literature, Pelladium murex has lithiatic properties [4]. There is literature supporting the nephrolithiatic property of Pelladium murex. Petroleum ether, chloroform, ethanol, and aqueous extracts of the plant were prepared and evaluated for their anti-nephrolithiasis activity. Albino rats were treated with the prepared extracts. Thus, it may be concluded that P. murex possesses significant anti-nephrolithiatic activity. Moreover, it possesses antioxidant and anti-ulcer activity [14]. Hence, research should be conducted towards the lithiatic property of Pelladium murex in silolithiasis of the salivary gland.

Neem: The botanical name of neem is Azadirachtaindica .
According to Indian literature, neem has antibacterial, antiviral, antioxidant, and anticancer activities [4]. In primitive villages of India, people affected with chickenpox are treated with neem leaves for the blisters that appear on the body surface, and it has been shown to reduce blister formation [4]. Neem plays a role as a free radical scavenger due to its rich source of antioxidants. Azadirachtin and nimbolide showed concentration-dependent antiradical

scavenging activity and reductive potential in the following order: nimbolide>azadirachtin>ascorbate [16]. Neem ingredients show an effective role in the management of cancer through the regulation of cell signaling pathways. Neem modulates the activity of various tumor suppressor genes (e.g., p53, pTEN), angiogenesis (VEGF), transcription factors (e.g., NF-κB), and apoptosis (e.g., bcl2, bax) [15].

Neem also plays a role as an anti-inflammatory agent by regulating proinflammatory enzyme activities, including cyclooxygenase (COX) and lipoxygenase (LOX) enzymes [15].

Role of Neem in Oral Cancer

Nimbolide, extracted from neem, has demonstrated autophagy and apoptosis effects in hamster oral cancer study models. The exact mechanism of action is that nimbolide negatively regulates the PI3K/Aktsignaling pathway, resulting in an increase in p-GSK-3βTyr216, the active form of GSK-3β that inhibits autophagy. Downregulation of HOTAIR, a competing endogenous RNA that sponges miR-126, may be a major contributor to the inactivation of PI3K/Akt/GSK3 signaling by nimbolide. Analysis of key markers of apoptosis and autophagy, as well as p-AktSer473 during the sequential progression of hamster and human oral squamous cell carcinoma, revealed a gradual evolution to a pro-autophagic and antiapoptotic phenotype that could confer a survival advantage to tumors. From the above study, it was proven that nimbolide augments apoptosis by overcoming the shielding effects of cytoprotective autophagy through modulation of the phosphorylation status of Akt and GSK-3β as well as the ncRNAs miR-126 and HOTAIR. Therefore, neem may be the future oral anticancer drug.

DISCUSSION

The use of Siddha medicine, a form of herbal medicine, has persisted in treating certain non-curable and emerging diseases such as Covid-19. In India, the government has approved native herbal medicine as the first line of treatment and home remedial measure.[18]AnuragSrivastava conducted a double-blinded randomized control study to assess the efficacy of NilavembuKudineer and KabasuraKudineer alongside allopathic treatment in managing mild to moderate symptomatic patients with Covid-19. The study demonstrated that both NilavembuKudineer and KabasuraKudineer significantly reduced hospital stay time, viral load of SARS-CoV-2, and the time taken for patients to transition from symptomatic to asymptomatic. These findings indicate that traditional herbal medicine can be effective in treating novel infectious diseases. There is a global need for promising drugs that are effective and devoid of drug-induced complications. Similarly, in the field of Maxillofacial surgery, which is a sub-specialty of surgery, there is a desire for medicinal interventions that are highly effective without causing complications. Traditional therapies have been shown to be readily available, free of side effects, and effective in this regard. The concept of patient safety is paramount in healthcare as every stage of the healthcare delivery process carries the risk of error. This means that issues with practices, goods, processes, or systems of healthcare delivery may arise, potentially leading to unfavorable outcomes for patients, such as negative drug reactions.

The World Health Organization (WHO) defines a negative drug reaction as "a response to a drug that is noxious and unintended and occurs at doses normally used in man for the prophylaxis, diagnosis or therapy of disease, or for modification of physiological function." This underscores the importance of ensuring that medications are administered safely and effectively to minimize the risk of adverse reactions and enhance patient well-being.[19] There have been no reported side effects or complications associated with Siddha drugs used for the treatment of maxillofacial diseases. However, after tooth extraction, effective pain management is crucial for reducing patient discomfort, minimizing the risk of infection, and promoting faster healing. Due to safety concerns related to commonly prescribed medications like NSAIDs, there is a need for reliable and safe alternatives for pain relief. The use of natural products for pain management in dentistry has gained traction due to advancements in alternative medicine. Swapnil U Shinde conducted a study utilizing analdent, which is an AYUSH analgesic, for the treatment of post-extraction pain. The study demonstrated that analdent was nearly as effective as aceclofenac in reducing pain following tooth extraction, but with fewer adverse effects. These findings suggest the potential for developing modern drugs based on traditional herbal medicine, offering effective pain relief with improved safety profiles.[20] A

panel of ORAL SQUAMOUS CELL CARCINOMA(oral squamous cell carcinoma) cell lines was utilized to investigate the cytotoxic, anti-proliferative, anti-migratory, and anti-invasive properties of zerumbone. Through Western blotting analysis, the impact of zerumbone on the PI3K-mTOR and CXCR4-RhoA pathways, two crucial signaling pathways implicated in the spread and carcinogenesis oforal squamous cell carcinoma, was examined. These pathways are attractive targets for oral squamous cell carcinomatherapy due to their activation. Zingiberzerumbet (L.) Roscoe, also known as tropical ginger, produces rhizomes containing zerumbone, a bioactive monocyclic sesquiterpene with promising anticancer effects. Zerumbone has demonstrated the ability to affect several molecular targets involved in carcinogenesis. The study presented evidence suggesting that zerumbone may inhibit the activation of the CXCR4-RhoA and PI3K-mTOR signaling pathways, thereby reducing the survival capacity of oral squamous cell carcinoma cells. This indicates that zerumbone could be a promising phytoagent for the development of new therapeutics for oral squamous cell carcinoma treatment. Furthermore, ginger plays a significant role in iron metabolism and the absorption of oral iron supplements. The bioactive polyphenols present in ginger act as prebiotics for the gut microbiota, promoting gut health and reducing the undesirable side effects of iron tablets. Additionally, ginger has been shown to increase erythropoiesis, the production of red blood cells.

Therefore, ginger may have the potential to mitigate the negative effects and restore iron balance in cases of iron excess.[21]Further research is indeed necessary to delve deeper into the potential applications of ginger polyphenols. While existing studies have highlighted their beneficial effects on gut health, iron metabolism, and erythropoiesis, there may be additional therapeutic properties yet to be discovered. Regarding garlic, VoinPetrovic's research has shown that garlic extract reduces the proliferation of cancer cells by inducing increased endoplasmic reticulum (ER) stress. This finding underscores the potential anticancer properties of garlic and its potential role in cancer therapy.
Additionally, garlic has been the subject of research for its osteogenic capacity. The natural therapeutic effects of garlic compounds make them valuable additions to medicinal formulations used in bone scaffolds for targeted treatment aimed at stimulating tissue creation and promoting bone healing. When ginger and garlic extracts are incorporated into 3D-printed (3DP) bone tissue engineering scaffolds, they enhance osseointegration and promote osteogenesis, thereby facilitating bone tissue in-growth. This suggests that naturally obtained compounds from ginger and garlic could play a significant role in enhancing bone regeneration and improving outcomes in bone defect applications, particularly in low load-bearing bone and dental scenarios where 3DP scaffold biomedical devices are utilized.[22] Oral cancer poses a significant threat to public health due to its high morbidity and mortality rates, with squamous cell carcinoma being the most prevalent type in the head and neck region. Typically originating from the epithelium, oral cancer treatment options primarily include chemotherapy, surgery, and radiotherapy, either alone or in combination. While chemotherapy has demonstrated efficacy, it is often accompanied by serious side effects and the potential for tumor resistance and recurrence.To address these challenges and improve the effectiveness and safety of oral cancer treatment, there is a pressing need for the development of anticancer medications that are highly precise and have minimal adverse effects. Curcumin, a plant polyphenol extracted from the rhizome of the turmeric plant Curcuma longa, has emerged as a promising adjuvant therapy option.

Extensive research has demonstrated that curcumin possesses anti-inflammatory, anti-infectious, antioxidant, and anticarcinogenicproperties.Despiteits potential benefits, curcumin's therapeutic efficacy has been hindered by its low bioavailability. However, various analogues and nanoformulations of curcumin, including micelles, nanoparticles, liposome complexes, and phospholipid complexes, have been developed to overcome this limitation. These formulations enhance curcumin's bioavailability and improve its therapeutic potential.Studies have elucidated that curcumin's anticancer effects are mediated through its action on multiple molecular targets involved in the pathophysiology of oral cancer. These targets include nuclear factor κ-light-chain-enhancer of activated B cells, protein kinase B (Akt), activator protein 1, mitogen-activated protein kinase, expression of the epidermal growth factor receptor (EGFR), and downstream signaling pathways of EGFR. By modulating these targets, curcumin exhibits promising anticancer activity and holds potential as an effective adjuvant therapy for oral cancer.curcumin represents a valuable adjunct to conventional oral cancer treatment modalities due to its multifaceted pharmacological properties and favorable safety profile. Continued research and development of curcumin-based therapies, particularly in the form of optimized nanoformulations, hold promise for improving patient outcomes in

oral cancer management.[8] Clinical trials investigating the effectiveness of curcumin in treating various human diseases, including oral disorders, have been conducted extensively. One notable study focused on oral leukoplakia, a potentially malignant lesion of the oral cavity for which effective treatments are limited. Conducted by Kuriakose et al., this phase IIB clinical trial employed curcumin in a randomized, double-blinded, placebo-controlled manner among participants with oral leukoplakia. The results of the study demonstrated significant improvements in both histological and clinical responses with curcumin therapy. Particularly noteworthy was the sustained clinical response observed following treatment with curcumin at a dose of 3.6 g over a 6-month period. Importantly, the therapy was well-tolerated by the participants, indicating its safety profile in the management of oral leukoplakia.[23] Furthermore, recent studies have shown promising results regarding the use of topical curcumin in the treatment of oral mucositis, a common complication of cancer therapy characterized by inflammation and ulceration of the oral mucosa. These studies suggest that curcumin's anti-inflammatory and wound-healing properties make it an effective agent for managing oral mucositis and alleviating associated symptoms.[24] Overall, the findings from these clinical trials highlight the potential of curcumin as a therapeutic agent for various oral disorders, including oral leukoplakia and oral mucositis. Further research and clinical trials are warranted to fully elucidate curcumin's therapeutic benefits and optimize its use in clinical practice. The development of drug delivery systems at the nanoscale has been pioneered by nanotechnology. Because of the surface, small size, quantum size, and quantum tunnel effects of nanoparticles, hydrophobic compounds like curcumin can have enhanced bioavailability.[25] Several novel strategies have been developed to design curcumin nanoparticles as targeted drug-delivery systems, and these have been studied in various disease states, including cancer.[8]

Tulsi, referred to as "The Incomparable One," "Mother Medicine of Nature," and "The Queen of Herbs" in Ayurveda, is highly regarded as a "elixir of life" that is unmatched in its therapeutic and spiritual qualities.[26]According to these studies, tulsi possesses a special combination of properties, such as antimicrobial (including antibacterial, antiviral, and antifungal properties), antiprotozoal, antimalarial, anthelmintic), mosquito-repellent, anti-diarrheal, anti-oxidant, anti-cataract, anti-inflammatory, chemopreventive, radioprotective, hepato-protective, neuro-protective, cardio-protective, anti-diabetic, anti-hypercholesterolemia, anti-hypertensive, anti-carcinogenic, analgesic, antipyretic, anti-allergic, immunomodulatory, central nervous system depressant, anti-thyroid, anti-fertility, anti-ulcer, anti-emetic, anti-spasmodic, anti-arthritic, adaptogenic, anti-stress, anti-cataract, anti-leukodermal, and anticoagulant properties. [27-30] Tulsi also lessens DNA damage and causes precancerous and cancerous cells to undergo apoptosis, which helps to prevent malignancies brought on by hazardous substances. promoting survival and slowing the growth of experimental malignancies.[31,32] Contemporary scientific investigations on tulsi attest to the wisdom of the plant's numerous psychological and physiological advantages. intrinsic to AYUSH system of medicine , which honortulsi as a plant that can be consumed, worshipped, turned into tea, and used in daily life for both medical and spiritual purposes. With the objective to determine how well aloe vera and tulsi will they react to oral submucous fibrosis, Radha P. Dalai conducted a study , and found differences in the mouth opening and lessening of the burning sensation on the visual analog scale (VAS) were statistically analyzed.[33]

Nisha Singh conducted a study to compare the efficacy of Aloe vera with antioxidant when given along with physiotherapy in the management of OSMF and found significant Improvement in all the parameters was seen with the individuals receiving Aloe vera gel in comparison to antioxidants.[34]. When combined with appropriate habit limitation, aloe vera, a calming, easy-to-use, and safe kind of treatment, can be thought of as an effective regimen in the management of OSMF. Traditionally, neem leaves, blossoms, seeds, fruits, roots, and bark have all been used to cure fever, infections, inflammation, skin conditions, and dental issues. The therapeutic benefits of neem leaf in particular have been documented. Immunomodulatory, anti-inflammatory, antihyperglycemic, antiulcer, antimalarial, antifungal, antibacterial, antiviral, antioxidant, antimutagenic, and anticarcinogenic qualities have all been shown for neem leaf and its compounds.[35] After neem's anticancer qualities were assessed, it was shown that the plant's active ingredients have clear preventive and therapeutic potential against oral cancer.[36] Furthermore, research led by Shashank M. Patil revealed that neem functions as a natural contraceptive.[37] As of now, more than 400 substances have been identified from various neem components. These include significant bioactive secondary metabolites like gedunin, azadirachtin, nimbidin, nimbin, and nimbolide.[38] Nimbolide exhibited effectiveness

against H. pylori, with minimum inhibitory concentrations (MICs) and minimum bactericidal concentrations (MBCs) ranging from 1.25-5 µg/mL and 2.5-10 µg/mL, respectively, across the nine tested strains. Furthermore, both neem oil extract and nimbolide demonstrated efficacy against H. pylori biofilms.[39,40]

CONCLUSION

traditional herbal medicine offers a rich repository of therapeutic compounds with diverse pharmacological activities, making them valuable assets in addressing contemporary healthcare challenges. Further research and development efforts are warranted to harness the full potential of herbal compounds for improving patient outcomes and advancing medical treatments.

ABSTRACT

Diabetes is a standout amongst the most well-known non-transmittable diseases in the world. It is assessed to be the seventh leading cause for death. It is predicted that the diabetes rate in adults worldwide will become 642 million in 2040. Diabetes and obesity are associated with non-modifiable and modifiable risk factors. Non-alcoholic fatty liver disease (NAFLD) and type 2 diabetes (T2DM) are common conditions that regularly co-exist and can act synergistically to drive adverse outcomes. The presence of both NASH and T2DM increases the likelihood of the development of complications of diabetes as well as augmenting the risk of more severe NASH, including cirrhosis, hepatocellular carcinoma and death. Also cardiovascular disease is the most prevalent and detrimental complication of diabetes mellitus. Type 2 diabetes (T2D) is the result of interaction between environmental factors and a strong hereditary component. In this paper, summarised and critically evaluated the available data, with the aim of helping to inform the reader as to the most pertinent issues when managing patients with co-existent NASH, CVD, HEREDITY and T2DM and fit appropriate statistical distribution to the collected real data.

Keywords: Type 2 DM, NASH, CVD, Heredity, NAFLD, and Pascal Distribution.

INTRODUCTION

Type 2 diabetes (T2DM) is a complex metabolic disorder that has become a major public health problem worldwide in the past three decades. About one in 11 adults worldwide now have diabetes mellitus, of which 90% have T2DM. T2DM can cause injury not only to the pancreas and insulin system but also the liver, cardiac, kidneys, gut, muscle, fat cells and even the brain. Diabetes can affect many different organ systems in the body and, over time, can lead to serious complications, such as non-alcoholic fatty liver disease. The correlation between NASH and type 2 diabetes mellitus (T2DM) is complicated and bidirectional. NASH increases the risk of incident diabetes and is common in T2DM patients. Insulin resistance and type 2 diabetes mellitus are generally accompanied by low HDL cholesterol and high plasma triglycerides, which are major cardiovascular risk factors. This review describes abnormalities in HDL metabolism and reverse cholesterol transport, i.e. the transport of cholesterol from peripheral cells back to the liver for metabolism and biliary excretion, in insulin resistance and type 2 diabetes mellitus. Cardiovascular disease remains the leading cause of death in women. Both obesity and diabetes mellitus are important independent risk factors for the development of cardiovascular disease. Obesity is the leading risk factor for type 2 diabetes. Central obesity as well as obesity in general is associated with physiological changes that may cause the development of diseases like high blood pressure, heart disease, high blood cholesterol and type 2diabetes. Cholesterol is a waxy substance that's made by the body and found in some animal-based foods. Blood cholesterol levels describe a group of fats also known as lipoproteins (lipids) which include HDL-C, "good" cholesterol and LDL-C or "bad "cholesterol. Cholesterol is important to overall health, but when LDL-C levels are too high, it can contribute to narrowed or blocked arteries. Unfortunately, people with diabetes are more prone to having high cholesterol, which contributes to cardiovascular disease (CVD).In individuals who have diabetes, there are higher incidences of liver function test abnormalities than individuals who do not have diabetes. The most common liver function tests (LFTs) include the Serum Glutamic Pyruvate Transaminase (SGPT) activity, to measure the concentration of intracellular hepatic enzyme that has leaked into the blood and serves as a marker of hepatocytic injury. In this study we analyse the risk factors which affects type 2 diabetes mellitus and developing a predictive model with the aim to identify important risk factors for the development of NAFLD in patients with T2DM and try to fit appropriate statistical distributions to the collected real data.

REVIEW OF RELATED LITERATURE

AlaAmourah et al.,(2022) conducted study on Exploiting the Pascal Distribution Series and Gegenbauer Polynomials to Construct and Study a New Subclass of Analytic Bi-Univalent Functions to construct a new subclass of analytic bi-univalent functions defined on symmetric domain by means of the Pascal distribution series and Gegenbauer polynomials. Annabel Acs et al., (2018) studied Prevalence of cardiovascular disease in type 2 diabetes: a systematic literature review of scientific evidence from across the world in 2007–2017 and concluded that globally, overall CVD affects approximately 32.2% of all persons with T2DM. CVD was a major cause of mortality among people with T2DM, accounting for approximately half of all deaths over the study period. Coronary artery disease and stroke were the major contributors. Abraham TM et al., (2015) conducted a study on Trends in diabetes incidence: the Framingham Heart Study and established the result as the risk of new-onset diabetes continued to be higher in the 2000s compared with the 1970s. In the past decade, diabetes incidence remained steady despite the on-going trend of rising adiposity. Sarwar N et al ., (2010) explained in the study Diabetes mellitus, fasting blood glucose concentration, and risk of vascular disease: a collaborative meta-analysis of 102 prospective studies as Diabetes confers about a two-fold excess risk for a wide range of vascular diseases, independently from other conventional risk factors. In people without diabetes, fasting blood glucose concentration is modestly and non-linearly associated with risk of vascular disease. Fox CS, et al., (2008) proposed a study on Lifetime risk of cardiovascular disease among individuals with and without diabetes stratified by obesity status in the Framingham heart study and explained as the lifetime risk of CVD among individuals with diabetes is high, and this relationship is further accentuated with increasing adiposity. Van Hateren KJ et al., (2009) conducted a study on The lipid profile and mortality risk in elderly type 2 diabetic patients and stated as the lipid profile was not predictive in the overall group of elderly patients,

higher lipids were related to increased cardiovascular mortality in patients with diabetes of long duration. Muhammad AmmaarAslam et al., (2 019) proposed a study on prevalence of cardiovascular disease in type 2 diabetes- systematic literature review and concluded that CVD is one of the major cause of death in T2DM with coronary artery disease having the high prevalence. MarsoSPet al., (2016) studied Liraglutide and cardiovas- cular outcomes in type 2 diabetes and concluded that the rate of the first occurrence of death from cardiovascular causes, nonfatal myocardial infarction, or nonfatal stroke among patients with type 2 diabetes mellitus was lower with liraglutide than with placebo. Mills EPet al.,(2018) examined in the study Treating nonalcoholic fatty liver disease in patients with type 2 diabetes mellitus and reviewed that all reviewed treatment options are safe for management of NAFLD in patients with T2DM but long-term histological improvements are minimal. TZDs are efficacious for resolution of NASH and improvements in fibrosis but long-term use is required to maintain the results. Alessandro Mantovaniet.al., (2018) [16] studied "Non-Alcoholic Fatty Liver Disease and Risk of Incident Type 2 Diabetes: A Meta-analysis" and found that NAFLD is significantly associated with a twofold increased risk of incident diabetes. However, the observational design of the eligible studies does not allow for proving causality. Bhatt KN et.al., (2017) [17] conducted study 0n "Prevalence of Nonalcoholic Fatty Liver Disease in Type 2 Diabetes Mellitus and its Relation with Insulin Resistance in South Gujarat Region." The study revealed a high incidence of NAFLD in Type 2 diabetes patients stressing the need for early screening. Carrie R. Wong, et. Al., (2018) [18] conducted study on "The Association between Non-alcoholic Fatty Liver Disease and Cardiovascular Disease Outcomes" and concluded that the causal relationship of CVD and NAFLD remains under investigation, but the strong bidirectional association between CVD and NAFLD warrants clinical intervention in patients with NAFLD to modify metabolic risk factors, including T2DM, dyslipidemia, hypertension, and obesity. Claudio Tana et.al., (2019) [19] conducted study on "Cardiovascular Risk in Non-Alcoholic Fatty Liver Disease: Mechanisms and Therapeutic Implications" to conclude that all cardio-metabolic risk factors should be carefully and routinely screened among patients with NAFLD, and that disease management should be focused on both specific lifestyle modifications and aggressive risk factors modification, which would not only reduce the risk of liver disease progression, but may also provide benefits by reducing the risk of developing cardiac complications. Dharmalingam M, Yamasandhi P G (2018) [20] conducted a study on "Alcoholic Fatty Liver Disease and Type 2 Diabetes Mellitus" and concluded that T2DM and NAFLD have a common association. The increasing prevalence makes it a public health problem.

Targher G et. al., (2007) [21] conducted study on "Non-alcoholic Fatty Liver Disease is Independently Associated with an Increased Incidence of Cardiovascular Events in Type 2 Diabetic Patients." The findings suggest that NAFLD is associated with an increased incidence of CVD in type 2 diabetic patients, independent of traditional CVD risk factors and metabolic syndrome components. Dyson JK, et.al., (2014) [22] studied "Non-alcoholic Fatty Liver Disease: A Practical Approach to Treatment" concluded that lifestyle interventions aimed at weight loss and increased activity are essential for all patients with NAFLD and if sustained are effective in the treatment of NAFLD. Hagstromet.al., (2019) [23] studied "Cardiovascular Risk Factors in Non-alcoholic Fatty Liver Disease." The study concluded that patients with NAFLD are at an increased risk for CVD compared to matched controls, but histological parameters do not seem to independently predict this risk. Carrie et.al.,(2018) conducted a study on "The Association between Non-alcoholic Fatty Liver Disease and Cardiovascular Disease Outcomes and found that the causal relationship of CVD and NAFLD remains under investigation, but the strong bidirectional association between CVD and NAFLD warrants clinical intervention in patients with NAFLD to modify metabolic risk factors, including T2DM, dyslipidemia, hypertension, and obesity. Jonathan M. Hazlehurst, et.al., (2016) studied "Non-alcoholic Fatty Liver Disease and Diabetes and concluded Turkish Journal of Physiotherapy and Rehabilitation; that diabetes and NAFLD are reciprocal risk factors and when they occur together, an increasing body of data demonstrates that diabetes is more difficult to manage and that NAFLD is more likely to progress. Mathews et.al.,(2018) conducted a study on "Non-alcoholic Steatohepatitis, Obesity, and Cardiac Dysfunction." It summarises obesity as a major factor in the development of Nonalcoholic Fatty Liver Disease (NAFLD) and its progression to steatohepatitis. Patients with NAFLD have a significant increase in cardiovascular disease risk. For biopsy-proven NASH, Vitamin E and Pioglitazone are the recommended medical treatments in addition to lifestyle modification. NasrinAmiriet.al., (2017) conducted the study, "Type 2 Diabetes Mellitus and Non-Alcoholic Fatty Liver Disease: A Systematic Review and Meta-analysis." The findings indicated that the overall prevalence of NAFLD among type 2

diabetes mellitus patients is significantly higher. It can be concluded that type 2 diabetes mellitus patients should be managed to prevent NAFLD. Prasanth et.al., (2017) conducted a study on "Prevalence of NAFLD in Patients with Type 2 Diabetes Mellitus" and concluded that prevalence of NAFLD and NASH in our cohort of type 2 DM patients is high and increases with multiple components of metabolic syndrome. NASH and advanced fibrosis can occur in diabetic patients without any symptoms, signs or routine laboratory test abnormalities. Rashmee and Gagan (2017) studied "Non-alcoholic Fatty Liver Disease and Cardiovascular Risk and concluded that Non-alcoholic Fatty Liver Disease (NAFLD) is often associated with insulin resistance and is strongly associated with type 2 diabetes mellitus and obesity. NAFLD is now recognized as a risk factor for poor cardiovascular outcomes including mortality and morbidity from major vascular events. As a whole, NAFLD patients may benefit from more careful surveillance and early treatment interventions Shunquan Wu et.al., (2016) conducted a study "Association of Non-alcoholic Fatty Liver Disease with Major Adverse Cardiovascular Events: A Systematic Review and Meta-analysis." The main results of meta-analysis were NAFLD was not associated with overall mortality and CVD mortality. NAFLD was associated with an increased prevalence and/or incidence of other adverse cardiovascular events, including CVD, CAD, hypertension, and atherosclerosis; (3) NASH was not associated with overall mortality and CVD mortality but was associated with an increased incidence of CVD. Targher, et.al., (2005) conducted study on "Nonalcoholic Fatty Liver Disease and Risk of Future Cardiovascular Events Among Type 2 Diabetic Patients" and suggested that the metabolic syndrome predicts incidents of cardiovascular disease (CVD), so it is possible to hypothesize that NAFLD patients might portend a greater CVD risk and that NAFLD itself might confer a CVD risk above that associated with individual metabolic syndrome risk factors. Wenjie Dai et.al.,(2017) studied "Prevalence of Nonalcoholic Fatty Liver Disease in Patients with Type2 Diabetes Mellitus" and concluded that the high pooled prevalence of NAFLD in T2DM patients found in this study significantly underscores the need for early assessment of NAFLD and the importance of strengthening the management of NAFLD in T2DMpatients.

METHODOLOGY AND DATA ANALYSIS

The proposed study aims to summarize the evidence of the association with NASH and CVD with risk factors such as age, height, weight, waist circumference, blood sugar, cholesterol level, sgot, sgpt, TG, heredity, bmi, systolic pressure, diastolic pressure in childbearing diabetic women. 603 subjects were randomly selected from various hospitals in the two districts, Palakkad and Malappuram - at Kerala to make a real data analysis. Baseline information for this study was obtained via a questionnaire on general information, physical examination (height, weight, and blood pressure), laboratory tests (triglycerides, total cholesterol, blood glucose, aspartate aminotransferase (AST) or serum glutamic-oxaloacetic transaminase (SGOT) and alanine aminotransferase (ALT) or Serum glutamic pyruvic transaminase (SGPT)), Body mass index (BMI) and waist circumference (WC). Prevalence of T2DM patients is high and increases with multiple components of metabolic syndrome (Metabolic syndrome is a cluster of conditions that occurs together, increasing risk of heart disease, stroke and type2 diabetes. These conditions include increased blood pressure, high blood sugar, excess body fat around the waist, and abnormal cholesterol or triglyceride levels).

RESIDUAL STATISTICS
The residual is the vertical distance (or deviation) from the observation to the predicted regression line. Predicted values are points that fall on the predicted line for a given point on the x-axis.
The summary statistics of these variables are given in table.

ASSOCIATION OF BLOOD SUGAR, BMI AND WAIST CIRCUMFERENCE
Body mass index has a strong relationship to diabetes and insulin resistance. Overweight and obesity are defined by an excess accumulation of adipose tissue to an extent that impairs both physical and psychosocial health and well-being. The influence of obesity on type 2 diabetes risk is determined not only by the degree of obesity but also by where fat accumulates. Increased upper body fat including visceral adiposity, as reflected in increased abdominal girth or waist-to-hip ratio, is associated with the metabolic syndrome, type 2 diabetes, and cardiovascular disease.

Excess body weight has a well-established link with decreased insulin sensitivity which in turn is a correlate of cardiovascular risk factors and a defining characteristic of type 2 diabetes. An excessive BMI and visceral obesity are the most common and well-documented risk factors for NAFLD, also contributing to metabolic syndrome and other complications. In diabetes, individuals with excessive fat storage have been noted to have higher insulin levels and are said to have insulin resistance, which is described as the cause of T2DM. The entire spectrum of obesity, ranging from overweight to obese and severely obese, is associated with NAFLD. The correlations among the variables were positive; blood sugar and BMI have medium correlation. ANOVA indicates the model is also good for the data since $p < 0.05$. The graph of each data set shows that there is linear relationship. Linear Regression Model: 1
Blood sugar (PP) = 7.968517 bmi-0.7330wc+ constant

ASSOCIATION OF BLOOD SUGAR, SYSTOLIC AND DIASTOLIC PRESSURE
Hypertension and type 2diabetes are common comorbidities. Hypertension is twice as frequent in patients with diabetes compared with those who do not have diabetes. Moreover, patients with hypertension often exhibit insulin resistance and are at greater risk of diabetes developing than are normotensive individuals. The major cause of morbidity and mortality in diabetes is cardiovascular disease, which is exacerbated by hypertension. Accordingly, diabetes and hypertension are closely interlinked because of similar risk factors, such as endothelial dysfunction, vascular inflammation, arterial remodelling, atherosclerosis, dyslipidemia, and obesity. There is also substantial overlap in the cardiovascular complications of diabetes and hypertension related primarily to microvascular and macro vascular disease. Diabetes is associated with both macrovascular (involving large arteries such as conduit vessels) and microvascular (involving small arteries and capillaries) disease. Hypertension is an important risk factor for diabetes-associated vascular complications, because hypertension itself is characterized by vascular dysfunction and injury. Figure 2: Vascular processes whereby diabetes and hypertension predispose to cardiovascular disease. Common risk factors promote diabetes and hypertension, which are associated with atherosclerosis, vascular inflammation, endothelial dysfunction, and structural remodelling, which lead to macrovascular and microvascular disease. Vascular damage and endothelial dysfunction is amplified when diabetes and hypertension coexist. In this study also the correlation between blood sugar, systolic and diastolic pressure is positive and the linear regression model is Blood sugar (pp) = 0.099405 SP+1.037123 DP+ constant

ASSOCIATION BETWEEN BLOOD SUGAR, NASH AND CVD
Non-alcoholic fatty liver disease (NAFLD) and type 2 diabetes mellitus are common conditions that regularly co-exist and can act synergistically to drive adverse outcomes. There are many ways to image NAFLD and NASH, including abdominal ultrasound, CT scan, and magnetic resonance imaging (MRI) or MR spectroscopy. More recently, elastography performed with ultrasound or MR has gained traction in diagnosing different stages of NAFLD and NASH. Cardiovascular disease is the most prevalent and detrimental complication of diabetes mellitus. The incidence of cardiovascular mortality in diabetic subjects without a clinical history of previous cardiac events is as high as the incidence in nondiabetic subjects with a history of myocardial infarction. This inordinate increase in the risk of coronary events in diabetic patients is attributed to multiple factors, including glycation and oxidation of proteins and increased prevalence of classic risk factors of coronary disease, such as hypertension, obesity, and dyslipidemia.Chronic hyperglycemia leads to many long-term complications in the eyes, kidneys, nerves, heart, and blood vessels. Individuals with pre-diabetes, undiagnosed type 2 diabetes, and long-lasting type 2 diabetes are at high risk of all complications of macrovascular disease, coronary heart disease (CHD), stroke, and peripheral vascular disease. More than 70% of patients with type 2 diabetes die of cardiovascular causes. Therefore, the epidemic of type 2 diabetes will be followed by an epidemic of diabetes-related cardiovascular disease (CVD). Out of 603 children bearing diabetic women 373 (62%) had fatty liver or more risk for NASH. Majority of person's level of SGPT and SGOT are in normal range. Only countable number of persons was in the above risk level. While considering the cholesterol and triglyceride level of fatty liver diabetic patients nearly 50% persons higher cholesterol level. Graph of cholesterol level of fatty liver Diabetic patients is given below.

ASSOCIATION BETWEEN HEREDITY AND BLOOD SUGAR

Type 2 diabetes (T2D) is the result of interaction between environmental factors and a strong hereditary component. Hereditary factors clearly play a role in the development of diabetes; the actual genetic variants involved in this inherited risk were completely unknown prior to the advent of modern genetic technologies. The study reveals that the risk of developing type 2 DM increases with the   number of affected family members through parents or through influence of genetic factors. There is 62% of child bearing diabetic women have influenced by hereditary factors while the remaining were not influenced.

1. Dependent Variable: BLOODSUGAR(PP)
2. Predictors: (Constant), BMI
3. Predictors: (Constant), BMI, DIASTOLIC PRESSURE
4. Predictors: (Constant), BMI, DIASTOLIC PRESSURE, TG
5. Predictors: (Constant), BMI, DIASTOLIC PRESSURE, TG, CHOLESTROL
6. Predictors:(Constant),BMI,DIASTOLICPRESSURE,TG,CHOLESTROL,AGE

The model is perfectly significant for the predictor variables BMI, Diastolic pressure, TG, Cholestrol, and Age corresponding to the dependent variable Blood sugar(PP).

FITTING BEST PROBABILITY DISTRIBUTIONS TO THE DATA

In statistics and probability, distributions of random variables play a basic role and are used extensively to describe and model a lot of real life phenomena; they describe the distribution of the probabilities over the random variable values Some distributions are used in practice and have been given special names to clarify the importance of these distributions and the random experiments behind them. Appropriate distributions were derived using statistical tools; the collected data were fitted to four distributions named as Pascal Distribution, Poisson Distributions for two different means, discrete uniform Distribution. Using goodness of fit, Pascal Distribution is the best fitted distribution for the collected data. Comparison of fitted distributions were given below From the table it is clear that the p value is highest for Pascal Distribution. From the distributions considered, the best fitted distribution for the collected data is Pascal Distribution.

CDF OF PASCAL DISTRIBUTION FOR THE COLLECTED DATA

The best fitted distribution follows the Pascal Distribution. So CDF is also drawn for the best fitted distribution for the collected data.

CONCLUSION

The study supports the finding that diabetes development and obesity were positively and significantly associated. When it comes to type 2 diabetes mellitus patients who are childbearing, BMI and WC are more strongly linked to diabetes than other risk factors. The degree of connection with diabetes risk was drastically raised when BMI and WC were used. This shows that when determining the risk for diabetes, waist circumference should also be examined in addition to BMI. Therefore, preventing central obesity and being overweight at the same time has significant public health consequences for the prevention of diabetes. Also, it might be advisable to maintain blood pressure between 130-139/80-85 mm Hg, supported by other therapeutic and lifestyle interventions to improve cardiovascular outcomes in patients with diabetes. Patients with T2DM and NASH should be considered at high risk of CVD and could benefit from more intensive CV prevention. Additional long-term follow-up is needed to demonstrate that the treatment of NASH effectively reduces the risk of CVD. Type 2diabetes has a stronger link to family history and genetics play a very strong role in the development of type 2 diabetes. Here 62% of childbearing diabetic women have been influenced by hereditary factors. In fitting a distribution to a collected set of biological data, say, it is also important for the mathematical model underlying the theoretical distribution to have a reasonable biological meaning. The fitted Pascal Distribution offers interesting possibilities in this direction. This study is an exposure to medical science to predict different aspects of blood sugar in relation to its components.

ABSTRACT

Cowpeas (*Vigna unguiculata*), an important legume is a versatile crop, also commonly known as southern pea, black eye pea, crowder pea, lubia, niebe, coupe or Frijole. The establishment of this crop is poor due to poor germination. Seed priming technique helps to overcome this difficulty. There is only less research have been carried out to enhance seed germination in cowpea by seed biopriming technique. This research paper focuses on standardising seed biopriming technique in cowpea VBN 3 using *Trichodemaviridi*, Phospobacteria, Sea weed extract at three different concentrations viz., 10%, 20%, 30% and hydro priming all in 3 hrs and 6 hrs soaking conditions. The untreated seeds serve as control. The result from the present study revealed that the germination parameters viz., germination value, germination index, imbibition, co-efficient of variation of germination, seed length, root length, seedling length, vigour index were at its maximum for the seeds primed with *T.viridi* and sea weed extract concentration of 10 % whereas Phospobacteria at 20 %. Biopriming of seeds at lower concentration improves the seed germination thereby increasing the yield.

Keywords: *T.viridi* and sea weed extract concentration of 10 % whereas Phospobacteria at 20 %.

INTRODUCTION

Seed germination is a critical parameter for the successful development of sustainable agricultural practices [1]. Germination and seedling establishment are critical stages in the plant life cycle. The ability of crop to germinate under stress affect the crop establishment. However, if the stress effect can be alleviated at the germination stage, chances for attaining a good crop establishment would be high [2] Seed biopriming is an emerging technique to enhance seed germination under stress conditions [3]. It is a controlled hydration process that involves exposing seeds to low water potentials that restrict germination, but permits pregerminative physiological and biochemical changes [4]. It is the method of soaking of seeds in a solution of any priming agent followed by drying of seeds that initiates germination related processes without radical emergence [5].[6] reported that, seed priming is an effective seed in vigouration method to increase the rate and uniformity of emergence and crop establishment. Biopriming, a sub-category of seed priming, involves inoculation of seed with beneficial microorganisms. biopriming enhances nutrient and water uptake, boosts seedling vigour as well as induces systemic resistance to biotic and abiotic stresses [7], [8].In this method the seeds are primed in a solution containing bio-control agents like *T.harzianum*, *T.viride*, *Pseudomonas flourescens* etc. It has biological and physiological (seed priming) aspects of disease control. Except improvement in germination percent, uniformity of emergence and decrease the time to emergence like other priming methods, it also controls disease in plant [9]. Cowpeas (*Vigna unguiculata*), an important legume is a versatile crop, also commonly known as southern pea, black eye pea, crowder pea, lubia, niebe, coupe or Frijole. Cowpea grain contains, on an average, 23–25 % protein and 50–67 % carbohydrate. As in case of most legumes, amino acid profile of cowpea complements cereal grains. Presence of significant amounts of protein, calories and some water-soluble vitamins, makes cowpea a promising food ingredient [10].The establishment of this crop is poor due to poor germination. This results in the low yield and reduces per capita availability of the crop.Seed priming technique helps to overcome this difficulty. There is only less research have been carried out to enhance seed germination in cowpea by seed biopriming technique. This research paper focuses on standardising seed biopriming technique in cowpea VBN 3 using *T. viridi*, Phospobacteria, Sea weed extract at three different concentrations viz., 10%, 20%, 30% and hydro priming all in 3 hrs and 6 hrs soaking conditions. The untreated seeds serve as control.

MATERIALS AND METHODS

The study was conducted using genetically pure seeds of cowpea cv. VBN 3 obtained from Krishi Vigyan Kendra, Sandhiyur, Tamilnadu. The experiment was conducted at the Department of Genetics and Plant Breeding, Faculty of Agriculture, Annamalai University, Annamalai Nagar (11°24 N latitude and 79°44 'E longitude with an altitude of +5.79 m above mean sea level) with four replications in a Factorial Completely Randomized Block Design (FCRD) in three sets. The bulk seeds were first dried to below 9% moisture content, cleaned, and then graded with suitable sieves. The concentrations of the priming agents as factor 1 and factor 2 being the duration of soaking hours. Their treatment details are given in Table 1. Seeds were treated with their respective solutions for a specified duration. Following treatment, the seeds were extracted from the solutions, rinsed with water two to three times, air-dried in shade until they regained their original moisture content, and evaluated for various seed quality parameters,such as germination index, root length, shoot length, dry weight, seedling length (cm) [11], mean germination rate and time[12], imbibition rate [13], water content, speed of germination, germination percentage, peak value [14], germination value [14], days to 50 % germination,germination percentage and vigor index were recorded with hydroprimed seeds and control in each set. Germination test was carried out using glassplate and petri-plate method (ISTA, 1985) and calculated as Germination (%) = No. of normal seedlings germinated × 100/ Total no. of seeds placed for germination. Speed of germination was calculated according to the equation of [15]: MGT = $\sum(n \times d) / N$, where n = number of seeds germinated on each day, d = number of days from the beginning of the test, and N = total number of seeds germinated at the termination of the experiment . Root length and shoot length test was carried out by glassplate method. Vigor Index was also calculated by [16] as Vigor index-I = Germination (%) × Seedling length (cm). Vigor index -II= Germination (%) × Seedling dry weight (g). Data from the experiment underwent analysis using the 'F' test for significance, as outlined by [17]. In cases where necessary, percentage values were converted to

angular (arc-sine) values before analysis. Critical differences (CD) were determined at a 5 percent probability level. Non-significant results from the 'F' test were denoted by the abbreviation NS.

RESULTS AND DISCUSSION

Significant differences were observed in all the seed and seedling quality parameters in Cowpea VBN 3 due to the priming agents and duration of priming. The interaction effect between priming treatments and durations was also significant for germination characters, seedling length, dry matter production and vigour index. Between the soaking durations of 3 and 6 hours, three hours of soaking recorded the maximum physiological and morphological parameters of seed and seedling quality parameters compared to control. In the present study the seeds of VBN3 were hydroprimed and bioprimed using *T.viridi* Phospobacteria and seaweed extract at three different concentrations viz., 10%, 20% and 30%   along with hydropriming. Among all the treatments values for all the germination parameters were higher in the seeds soaked for three hours than for six hours. Water content and imbibition rate was higher in the seeds primed with priming agents *T.viridi and seaweed extract* at 10 percentage and phospobacteria at 20 %. Germination begins with the rapid imbibition of water by quiescent dry seeds to activate metabolic processes[18]. In unprimed seeds water content and imbibition rate is zero. Seed germination and seedling growth are two critical phases of the plant life cycle [19].Seed priming methods influenced the seed germination process by increasing the speed and reliability of germination. Increased germination, uniformity of germination, and sometimes greater total germination rate are widely reported in the primed seeds[20]. Many treatments for pre-hydration or priming have been used to improve the seed germination rate and synchronization of seeds [21]. The present study showed that, compared with the control group, the rate of hydration increased dramatically after seed primed by reagents. This implies that seed priming may improve seed germination of seeds by speeding up imbibition, which could contribute to facilitate emergence phage of seed after raining [22]. Similar results were also reported that priming improved germination of sunflower cultivars by accelerating imbibitions[23].The main effect of seed priming on germination and primary seedling establishment indicated by increased germination and other related indicators like mean germination time and vigor, root and shoot length, germination rate [24].

The seeds primed using biopriming agents *T.viridi*and seaweed extractat 10 percentage and phospobacteria at 20 % for 3 hours had nearly 90 percent germination which is the maximum than any other treatments. Hydroprimed seeds had 80 % germination and in control 75 percentage germination was achieved. [24]revealed that seed germination and seed quality of chickpea improved when seeds primed with *Tviridae*.[25] stated that the increment in germination percent ranged from 32.40 to 60.70 per cent in barnyard millet when seeds are treated with bioagent (Trichodermspp). Germination per cent ranged from 50 to 92 per cent in pearl millet was reported by[26] whereas[27] reported 79.15 percent germination in paddy seeds when seeds are treated with bio agents. All other germination parameters viz., peak value, germination value,time to 50 percent germination was higher for the seeds primed with bio priming agents *T.viridi*and seaweed extractat 10 percentage and phospobacteria at 20 % for 3 hours than all the other treatments. The stimulatory effect of seaweed extracts on seed germination has been widely recognized [28]; [29]. Seaweed extracts are predominantly high in phytohormones, which tend to play a major role in seed germination [30],[31]. Seaweed extracts enhanced plant growth attributes at low concentrations. The *germination index* (GI) [32] is defined as a weighted sum of the daily numbers of germinated seeds. Higher GI value denotes a higher percentage and a higher rate of germination. In the present study Germination index was higher for the seeds primed with bio priming agents *T.viridi* and seaweed extractat 10 percentage and phospobacteria at 20 % for 3 hours. The *coefficient of velocity of germination* (CVG) [33] gives an indication of the rapidity of germination. Its value increases when the number of germinated seeds increases and the time required for germination decreases. The seeds had maximum shoot length of 16.6 cm, root length of 12.2 cm, seedling length 28.8 cm, germination index 6.75 when primed with *T. viridi* at 10 % for three hours. The seeds primed with phospobacteria at 20 % for three hours had maximum shoot length of 16.8 cm, root length of 11.95 cm, seedling length 28.75 cm, germination index 6.15. The seeds primed with seaweed extract at 10 % for three hours had maximum shoot length of 16.4 cm, root length of 14.2 cm, seedling length 30.55 cm, germination index 6.04. The increase in shoot length with primed seeds might be due to

the fact that, priming induced nuclear replication in root tips of seeds [34] in bell pepper. The higher seedling length in bioprimed seeds might be attributed to enlarged embryos, higher rate of metabolic activities and respiration, better utilization and mobilization of metabolites to growing points and higher activity of enzymes. The unprimed seeds have the least values for the above germination parameters. Seed Vigor testing measures the percentage of viable seed in a sample and also reflects the ability of those seeds to produce normal seedlings optimum or adverse growing conditions. Priming often induces physiological and biochemical seed modifications during seed treatments[35] and increased amylase production enhances metabolic tasks, resulting in higher seed vigor[36]. Seed viability is the ability of the seed to germinate under optimal conditions, whereas vigour is its ability to emerge uniformly even under adverse environmental conditions in the field. These terms are often used interchangeably and incorrectly. In the current study the seeds primed with *T.viridi* and seaweed extract at 10 %, phospo bacteria at 20% had maximum seed vigour. Seed vigor is reflected by the rapid and uniform emergence of seedlings, field establishment, and plant performance [37],[38]. High seed vigor enhances the ability to obtain optimal plant densities and high crop yields [39]. In *Cucumis sativis* seed bio-priming agents *T.harzianum* (NBAII -THlO) and *P. fluorescens* enhanced the efficiency of biocontrol agents and increased the PGPR activity of beneficial microorganisms [40].Seeds primed with *T. viride* and *P. fluorescens* significantly improved seedling emergence of 96 and 98% respectively in chickpea [16]. From the above study it can be concluded that biopriming of seeds at lower concentration improves the seed germination thereby increasing the yield rather than by hydropriming.

ABSTRACT

This study compares different methods for assessing air quality, specifically focusing on the use of fuzzy VIKOR, TOPSIS with Entropy, and the CRITIC weight method. The goal is to assess and contrast the effectiveness of different approaches in calculating the air quality index based on a certain set of pollutant characteristics. The process includes gathering air quality 2020 data from the Tamil Nadu Pollution Control Board. The comparative analysis involves evaluating the efficiency, precision, and computational speed of fuzzy VIKOR, TOPSIS with Entropy, and the CRITIC weight method in measuring air quality. The initial findings show that each methodology has unique performance traits: fuzzy VIKOR is adept at handling fuzzy and imprecise data; TOPSIS with Entropy excels at managing uncertainty and decision-making with complex criteria; and the Critic Weight Method provides a structured way to include expert opinions and domain knowledge in the assessment process. This comparative study intends to analyze the strengths and limits of several air quality assessment approaches to assist in making informed decisions for environmental management and policy formation.

Keywords: Air quality evaluation, fuzzy VIKOR, TOPSIS, Entropy, CRITIC weight method, MATLAB, environmental supervision.

INTRODUCTION

Decision-making processes in today's environment sometimes include navigating between multiple conflicting objectives and criteria. Multi-factor Decision Making (MCDM) provides a structured approach to tackle challenges by considering multiple factors simultaneously. Multi-Criteria Decision Making (MCDM) offers a systematic method for evaluating choices and determining the best course of action across several domains like business, engineering, public policy, and personal decision-making. MCDM recognizes that decisions usually encompass many factors. They include several components such as cost, time, quality, risk, and sustainability, each with its own unique significance and trade-offs. Traditional decision-making methods that focus on a single criterion or rely on intuition may overlook crucial aspects and lead to suboptimal outcomes. Multiple Criteria Decision Making (MCDM) strategies aim to address this complexity by integrating various criteria, preferences, and uncertainties into a cohesive decision-making process. Multi-criteria efficiency entails determining the most suitable and feasible solution according to defined criteria. Practical issues often involve many incompatible and conflicting requirements, making it unattainable to discover a solution that accomplishes all criteria at the same time. The alternative comprises a collection of possibilities that are either equal or a compromise based on the decision-maker's preferences. [1] Several Multiple Attribute Decision Making (MADM) methods have been introduced in recent decades, including Simple Additive Weighting (SAW), the Analytic Hierarchy Process (AHP), VIekriterijumsko KOmpromisno Rangiranje (VIKOR), Technique for the Order of Preference by Similarity to an Ideal Solution (TOPSIS), Preference Ranking Organization Method for Enrichment of Evaluations (PROMETHEE), Elimination and Choice Translating Reality (ELECTRE), and Grey System Theory. These strategies try to identify answers for a collection of actions that are based on contradictory criteria. Standard Multiple Attribute Decision Making (MADM) procedures are ineffective in dealing with real-world challenges that contain imprecise and ambiguous information.

The VIKOR method is a potent tool used in multi-criteria decision analysis (MCDA). M. Zeleny's VIKOR is well-known for its capacity to handle choice issues involving multiple alternatives and conflicting criteria. The VIKOR technique excels at balancing conflicting objectives and determining a compromise solution that best meets all requirements. By combining elements of optimism and pessimism, VIKOR provides decision-makers with a holistic view, helping them traverse decision-making challenges with enhanced clarity and certainty. The VIKOR approach is commonly utilized for Multiple Attribute Decision MADM because of its ability to address conflicts across attributes and reach a compromise answer[2]. VIKOR offers the advantage of maximizing communal benefit and minimizing individual regret, increasing the likelihood of the compromise option being approved by decision-makers. The conventional VIKOR approach is limited to addressing MADM problems using attribute values represented as real numbers. Researchers have expanded the spectrum of applicability of the VIKOR technique. X.Han and X.Chen introduced a new VIKOR method using DNs[3]. L.Wang et al. developed a VIKOR method for picture fuzzy environments [4].Z.Tian et al.employed the VIKOR approach to ascertain the risk priority of failure modes [5]. The TOPSIS method is a widely acknowledged and often used technique in the field of MCDM. TOPSIS, created by Hwang and Yoon in the early 1980s, provides a structured method for assessing and ordering options by measuring their closeness to the best solution and their distance from the worst solution. The TOPSIS technique evaluates alternatives by comparing their proximity to the best potential outcome and distance from the worst possible consequence, aiming to identify the most suitable answer. TOPSIS offers decision-makers a comprehensive view by considering both the positive and negative elements of each alternative, helping them make clear and precise decisions amidst complications. We utilize the TOPSIS method to determine fuzzy states for all objects. Most studies focused on enhancing and advancing the TOPSIS approach for promotional purposes. Shen et al. [6] expanded the TOPSIS approach in intuitionistic fuzzy environments using a novel distance metric. Wu et al. [7] investigated the use of an interval-type-2 fuzzy TOPSIS model in social networks. Furthermore, certain researchers have significantly contributed to the fundamental concept of the TOPSIS technique. The fundamental concept of the TOPSIS approach is that the object performs better when it is closer to the positive ideal solution and farther from the negative ideal solution. Some researchers have conducted studies based on this premise. Opricovic et al. [8] conducted a

comparison between the TOPSIS approach and the VIKOR method. They highlighted that the correlation coefficient calculation in the original TOPSIS method did not account for the preference between the two distances. Doukas et al. [9] introduced a novel correlation coefficient formula that considers the preference between two distances. Kuo [10] demonstrated the validity and efficacy of the original correlation coefficient formula and developed a new correlation coefficient formula. Kuo developed a ranking situation for any two items based on positive and negative ideal distances in [10]. Overall, the decision-making approaches mentioned are enhancements and expansions of the TOPSIS method. Some techniques are adaptations of the TOPSIS approach for different simulation environments, while others are enhancements to the original TOPSIS method in real-valued information systems. This work aims to utilize TWD concepts to develop a new TOPSIS approach for real-valued information systems. Qingyong Wang, Hong-Ning, and Hao Wang have studied the influence of air pollution on urban economic development using TOPSIS[17]. Chen et al. (2018) identified coal-fired power stations and manufacturing emissions as the primary contributors to pollution through the utilization of the VIKOR approach[18]. Supriya Raheja and colleagues determined the most heavily polluted city in India in terms of many pollutants using CODAS[19]. Rashmi Bhardwaj and Shanky Garg analyze the detrimental effects of air pollution on human health, utilizing TOPSIS and DMCTM to determine and assess the factors of air pollution and its impact on health[20]. Mohsen, Tayebi and colleagues suggested creating a hybrid Decision Support System (DSS) by combining AHP, DAMATEL, and MULTIMOORA techniques, applied to three situations in Iran: a petrochemical plant, a gas refinery, and an oil refinery[21]. According to many evaluation techniques like WSM, VIKOR, TOPSIS, and ELECTRE [22], Hsing-Chen Lee and Chin-Ter Chang contend that hydropower is the best renewable energy source in Taiwan because of its cutting-edge technology and affordability. The method includes using entropic weights from Shannon's information theory to choose the material, along with critic approaches [23] and the Peng method for ranking preference functions that make use of composition enrichment technology [24].

METHODOLOGY

ENTROPY Method

An unbiased weighting, Entropy, method introduced by Shannon [26] in 1948, the technique employed involves the allocation of weights to choice criteria, taking into account their respective levels of relevance and variability.It measures the degree of uncertainty associated with each criterion and assigns higher weights to those with lower Entropy values, indicating greater consistency.

i) Calculate the projection value of each criteria is given by,

$$P_{kj} = \frac{f_{kj}}{\sum_{k=1}^{m} f_{kj}}, \text{k} = 1, 2, \ldots, \text{n}.$$

ii) Calculate the Entropy values are computed by using the following expression,

$$E_j = -c \sum_{k=1}^{m} P_{kj} \log (P_{kj}), \text{k} = 1, 2, \ldots, \text{m and j} = 1, 2, \ldots, \text{n}.$$

Where c = $(\log(m))^{-1}$ is a constant.

iii) Determine the degree of divergence d_j for each criteria

$$d_j = 1 - E_j, \text{j} = 1, 2, \ldots, \text{n}.$$

iv) Calculate the weight for each criteria are obtained as

$$W_j = \frac{d_j}{\sum_{j=1}^{n} d_\beta}, \text{j} = 1, 2, \ldots, \text{n}.$$

CRITIC Method

i) Normalize the decision matrix

$$\bar{X}_{ij} = \frac{X_{ij} - X_j^{-ve}}{X_j^{+ve} - X_j^{-ve}}$$

ii) Calculate the Standard deviation σ_j for each criteria

iii) The aim is to figure out the symmetric matrix of $n \times n$, where r_{jk} represents the linear correlation coefficient between the vectors $X_j \& X_k$

iv) Determine the scale of the conflict created by criterion j with respect to the

decision- making scenario established by the other criteria $\sum_{k=1}^{m} 1 - r_{jk}$

v) Analyzing the information's quality based on each criterion,

$$c_j = \sigma_j * \sum_{k=1}^{m}(1 - r_{jk})$$

vi) Determining the objectives weights $W_j = \frac{c_j}{\sum_{k=1}^{m} c_j}$

The VIKOR method

i) To find the optimal values of f_j^* and the minimum values of f_j^- for all criterion functions, j=1,2,...,n. When the jth function represents a benefit, the function f_j^* is defined as the $f_j^* = max_k f_{kj}$, indicating the desirable level. Conversely, the function f_j^- is defined as the $f_j^- = min_k f_{kj}$, indicating the lowest level.

ii) Compute the value S_k and R_k,k=1,2,...,m by the relations .

$$S_k = \sum_{j=1}^{m} wj \frac{|f_j^* - f_{kj}|}{|f_j^* - f_j^-|},$$

$$R_k = max\{\frac{|f_j^* - f_{kj}|}{|f_j^* - f_j^-|}\} \text{ k=1,2,...m, j=1,2,...,n.}$$

iii) Obtain the values Q_k, k=1,2,...,m by the relation

$$Q_k = \mho \frac{(S_k - S^*)}{(S^- - S^*)} + (1-\mho)\frac{(R_k - R^*)}{(R^- - R^*)} \text{ , k=1,2,...,m (alternatives).}$$

The variable $\mho$ is represented as the weight assigned to the strategy of "the majority of criteria" or "the maximum group utility," with a value of 0.5.

iv)Arrange the possibilities in descending order based on the values S, R, and Q. The outcome consists of ranking lists.

v) Suggest the alternative (μ') as a compromise option, which is ranked as the best according to the minimal measure Q, provided that the following two conditions are met.

C_1 : "Acceptable advantage "

Q(μ'')-Q(μ')≥ DQ

Where μ'' is the alternative with second position in the ranking list by Q^- ,DQ =$\frac{1}{(J-1)}$ and J is the number of alternatives .

C_2 : "Acceptable stability in decision making"

If any of the conditions are not met, a predetermined set of compromise solutions is suggested, which includes:

- The alternatives μ' and μ'' if only condition C_2 is unsatisfied, or
- The alternatives $\mu', \mu'', ..., \mu^{(n)}$ if condition C_1 is unsatisfied; and $(\mu^{(n)})$ is determined by the relation Q($\mu^{(n)} - Q(\mu')$)< DQ for maximum n
- The optimal options, denoted by Q, are those with the lowest value of Q. The "advantage rate" determines the primary outcome, which is the compilation of various options and the compromise solution.

The TOPSIS method

i) $r_{kj}(x) = \frac{x_{kj}}{\sqrt{\sum_{k=1}^{m} x_{kj}^2}}$, k=1,2,...,m; j=1,2,...,n

ii) For benefit criteria (large is better) , $r_{kj} = \frac{(x_{kj} - x_j^-)}{(x_j^* - x_j^-)}$

where $x_j^* = max_k x_{kj}$ and $x_j^- = min_k x_{kj}$

Then to calculate weighted normalized rating by $V_{kj}(x) = W_j r_{kj}(x)$, k=1,2,...,m; j=1,2,...,n.

Next the positive ideal point (PIS) and the negative ideal point (NIS) are derived as,

PIS =A^+ ={(max $V_{kj}(x)$)}

NIS=A^- ={($min_k V_{kj}(x)$)}

To proceed, it is necessary to compute the distance between the PIS and the NIS for each choice. The Euclidean distance, denoted as, can be utilized to quantify the separation values.

$A_k^* = \sqrt{\sum_{j=1}^{m}[\alpha_{kj}(x) - \alpha_j^+(x)]^2}$, k= 1, 2,...,m. ;j=1,2,...,n.

Sevanthi and Sivakumar

$$A_k^- = \sqrt{\sum_{j=1}^{m}[\alpha_{kj}(x) - \alpha_j^-(x)]^2}$$, k= 1 , 2,...,m;j=1,2,...,n.

The commonalities to the PIS can be derived as

$$C_k^* = \frac{D_k^*}{(D_k^* + D_k^-)}$$, k=1, 2,...,m

Ultimately, the optimal ordering can be derived based on the resemblances to the PIS(C_k^*) in a descending manner, with the aim of selecting the most favourable options.

STUDY AREA

This study attempts to evaluate air quality and determine the most polluted location during January, February, and March in the cities of Bangalore, Chennai, Mumbai, Delhi, and Kolkata. This study   different cities as potential alternatives for controlling metropolitan pollution. The air quality assessment using the MCDM method examines the characteristics of sulphur dioxide (SO_2), nitrogen dioxide (NO_2), carbon monoxide (CO), and particulate matter (PM_{10} and $PM_{2.5}$) as pollutants in the air. The pollutant concentration data for January, February, and March 2020 was acquired from the Tamil Nadu Pollution Control Board [27] and the graph is drawn using MATLAB are displayed in Figure 1. This study proposes that includes the Entropy weighting techniques and Criteria importance through inter criteria correlation to assign relative importance to each attributes. The VIKOR and TOPSIS approach is used to classify the alternatives to identify the most polluted state in India. The flowchart for the Entropy-CRITIC-VIKOR-TOPSIS approach is shown in fig.2

Numerical Example

Our health is directly influenced by the quality of our environment and the nourishment we consume. Air pollution is the introduction of gases, dust particles, fumes, or odour into the atmosphere in a manner that is hazardous to humans, animals, and plants. The presence of air pollution poses a threat to the well-being of both people and other living organisms on Earth. The emission of smog and acid rain results in the development of cancer and respiratory illnesses, the depletion of the ozone layer, and the exacerbation of global warming. The government has established and is continuously refining recommendations for air quality and regulations to limit emissions in order to manage air pollution. Individually, we can lessen our impact on pollution by utilizing public transit. This study attempts to evaluate air quality and pinpoint the most polluted region during January, February, and March in the cities of Bangalore, Chennai, Mumbai, Delhi, and Kolkata. The study assesses cities as potential alternatives for controlling metropolitan pollution. The air quality assessment using the MCDM method examines the characteristics of sulphur dioxide (SO_2), nitrogen dioxide (NO_2), carbon monoxide (CO), and particulate matter (PM_{10} and $PM_{2.5}$) as pollutants in the air. The pollutant concentration data for January, February, and March 2020 was acquired from the Tamil Nadu Pollution Control Board and then displayed [25]. Here the pollutants are taken as criteria and the states are taken as alternatives. The normalized decision matrix was created based on the obtained data and is illustrated in Table 1. The decision matrix is employed for the purpose of ascertaining the Entropy weights associated with the criteria., which are illustrated in Table 2. The CRITIC technique involves computing the normalized decision matrix, followed by determining the correlation matrix, calculating the amount of information c_j, and determining the criteria weights W_j as given in Table 3.

Comparing the Entropy – VIKOR and CRITIC – VIKOR

In this part, the decision matrix is used to identify the optimal and suboptimal values for each criterion. The values of optimal collective utility (S_k) and the limited personal remose of the opponents (R_k) are then determined. The value of Q_k can be computed and is displayed in Table 4. The options are arranged in ascending order by ranking the variables S_k , R_k , and Q_k. Consequently, three ranking lists are created based on the precise values of S, R, and Q, which are then used to provide a compromise option for the alternatives.

Comparing the Entropy – TOPSIS and CRITIC – TOPSIS

The decision matrix, which includes values for criteria against each choice, is initially normalized. The multiplication of the normalized decision matrix is performed using the Entropy and CRITIC weights derived from the techniques

employed for criteria weighting. The subsequent step involves the determination of the Positive Ideal Solution (PIS) and Negative Ideal Solution (NIS). It is necessary to compute the Euclidean distances between the points PIS and NIS. The ranks will be established using two sets, namely Entropy - TOPSIS and CRITIC-TOPSIS. Table 5 presents the results.

Comparison of Entropy –VIKOR-TOPSIS with CRITIC –VIKOR-TOPSIS methods
From the Table 4, the Entropy-VIKOR and CRITIC-VIKOR result indicates that Delhi is ranked as one of the five states in India, Chennai is ranked as two, Kolkata is ranked as three, Bangalore is ranked as four in Entropy method and five in CRITIC weight method, Mumbai is ranked as five in Entropy method and four in CRITIC method in 2020 respectively. And also from the Table 5 the Entropy- TOPSIS and CRITIC- TOPSIS result indicates that Delhi is ranked as one of the five states in India, Chennai is ranked as two, Kolkata is ranked as three, Bangalore is ranked as four in Entropy method and five in CRITIC weight method, Mumbai is ranked as five in Entropy method and four in CRITIC method in 2020 respectively. Figure 3 are drawn using MATLAB and represents the comparison of the ranks obtained by the VIKOR and TOPSIS method to assess their performance and effectiveness in ranking various states. The result for the year 2020 shows that the Entropy-VIKOR and Entropy-TOPSIS gives the same result when compare to the CRITIC-VIKOR and CRITIC-TOPSIS. Also the result shows that Entropy weight method gives the efficient result when compare to the CRITIC weight method.

RESULTS AND DISCUSSIONS

The VIKOR framework presents a well-balanced solution that effectively addresses the objectives of maximizing collective benefit and minimizing individual regret. TOPSIS focuses on the closeness of alternatives to the optimum answer, which is advantageous when there is a distinct reference point. The selection of VIKOR or TOPSIS relies on the unique attributes of the air quality evaluation issue and the preferences of the decision-maker. The entropy method offers a straightforward method for ascertaining weights by considering the diversity of criteria values. CRITIC examines inter-criteria correlations to offer a more detailed insight into the importance of criteria. Entropy is easier to apply, but CRITIC may provide more precise weights, particularly when criteria are interrelated. Examining the results of air quality analysis using VIKOR and TOPSIS methods along with entropy and CRITIC weights shows how important it is to use both methods. VIKOR and TOPSIS have unique benefits, and the selection between entropy and CRITIC relies on the decision problem's complexity and the data at hand. By combining these methodologies, a thorough assessment of air quality may be conducted, aiding in making well-informed decisions for environmental management and policy formulation. Fuzzification of numerical data can be accomplished by using the centroid technique along with the normalized decision matrix in Table 1. The target weight can be calculated using the Entropy and CRITIC method, as shown in Table 2 and Table 3. Algorithms are used on the dataset to analyze the regions and determine the most polluted state in India.

CONCLUSION

In conclusion, the comparison of air quality analysis utilizing fuzzy VIKOR and fuzzy TOPSIS approaches with weight Entropy and CRITIC methods provides useful insights for environmental management decision-making. Both fuzzy VIKOR and fuzzy TOPSIS are adept at managing the uncertainty and ambiguity present in air quality data, rendering them appropriate for such investigations. The addition of weight Entropy and CRITIC techniques promotes the robustness and accuracy of the decision-making process by dealing with the subjective nature of criteria weighting and identifying the best options. By comparing different methods, it is clear that using a combination of approaches can offer a thorough insight into air quality problems and help in choosing the best solutions. Integrating weight Entropy and CRITIC techniques enhances the objectivity and reliability of decision-making, enabling stakeholders to make well-informed choices to enhance air quality and reduce environmental risks efficiently. The comparative study emphasizes the significance of utilizing advanced decision-making approaches in

air quality analysis. It underscores the relevance of a rigorous approach that takes into account both the technical parts of methodology and the subjective elements of decision criteria. This comprehensive method facilitates the implementation of more efficient environmental management tactics and aids in the sustainable growth of global communities.

ABSTRACT

Abstract. Among women, breast cancer stands out as the prevailing type of cancer, with invasive ductal carcinoma (IDC) emerging as its most prevalent form. The precise identification and categorization of breast cancer subtypes represent crucial clinical responsibilities. Employing automated methods in this context not only saves time but also diminishes the likelihood of errors. Machine learning algorithms can be trained on extensive datasets, enabling them to recognize subtle patterns and features that might be challenging for human eyes. This enhances the accuracy and precision of breast cancer detection, potentially leading to earlier identification of tumors. This article outlines a comprehensive methodology aimed at detecting breast cancer in histopathology images, utilizing the concepts of preprocessing and hybrid CNN architecture. The data preprocessing is essential for ensuring the quality, reliability, and suitability of data for analysis or model training. Data preprocessing phase in this study applies Normalization, Resizing and Random sampling techniques to prepare the data for Modeling phase. Hybrid CNN architecture in this study involves integration ImageNet with custom-designed CNN layers or module tailored to specific tasks or datasets. The confusion matrix, used as a visualization tool, helps to understand how well the model is performing by showing the distribution of predicted and true class labels. It breaks down the model's predictions into categories such as true positives, true negatives, false positives, and false negatives. Python libraries like matplotlib and seaborn have been used for visual interpretation of model's predictions by generating heatmaps. This holistic approach strives to enhance

breast cancer detection by harnessing state-of-the-art techniques in pre-processing and leveraging deep learning-based methods for feature extraction and detection. The goal is to enhance diagnostic accuracy and interpretability, thereby contributing to advancements in the field of breast cancer detection.

Keywords: Breast cancer detection, Histopathology images, hybrid CNN, Normalization, Random Sampling, Confusion matrix, Seaborn, ImageNet, PreNet

INTRODUCTION

Cancer is a complex category of illnesses marked by the unregulated proliferation and dissemination of abnormal cells within the body. These aberrant cells have the capacity to create tumors, infiltrate adjacent tissues, and spread to distant parts of the body through a process known as metastasis. With more than 100 distinct types, each presenting unique features, risk factors, and therapeutic strategies, cancer exhibits considerable heterogeneity across its various manifestations [1]. Breast cancer stands as one of the prevalent forms of cancer and ranks as the second leading cause of death in women, following lung cancer. According to a surveillance study conducted by the American Cancer Society, approximately one in every eight women is affected by breast cancer during their lifetime [2]. As per International Agency for Research on Cancer (IARC) there are about 8.2 million deaths and are expected to increase by 27 million in 2030. The majority of breast cancers initiate in the milk-producing glands known as lobules or in the ducts, which are the tubes connecting these glands to the nipple. Early stage detection of breast cancer can reduce the death rate. The best combination of advanced technology, latest clinical research and efficient healthcare professional can make early stage detection feasible [3]. Breast cancer diagnosis typically involves a combination of imaging tests, clinical examinations, and biopsy procedures. There are numerous diagnostic methods available like Histology, Mammography, Clinical Breast Exam (CBE), Breast Ultrasound, MRI (Magnetic Resonance Imaging), Biopsy, Genetic Testing and Ductogram [4]. Now a days among all histology is considered a gold standard. Histology involves the microscopic examination of tissue samples and there by provides a definitive diagnosis of whether cancer is present and its specific type. More over Histopathology images also provide detailed information about the characteristics of a tumor, including its size, grade, and subtype. Thereby guiding healthcare professionals for further treatment plans. The procedure of histology entails applying specific dyes to the tissue samples, enhancing the visibility of cellular structures and abnormalities. Analyzing these stained tissues under a microscope enables the pathologist to discern irregular cell growth, detect the presence of tumors, and identify the distinctive characteristics of the cancer cells [5] [3]. This study has used dataset of Histopathology images taken from Kaggle for classification of breast cancer. The PreNet, which integrates ImageNet with customized CNN layers to create the hybrid CNN architecture, fed with the preprocessed data has been presented for this study. The Hybrid model approach allows leveraging the strengths of both pre-trained models and user defined architectures to achieve better performance, improved accuracy and facilitates enhanced interpretability. The structure of the paper is outlined as follows: section 2 explains literature review comprising recent publications. Section 3 is about proposed methodology. Section 4 includes the results obtained from the proposed method and compare with the other methods, and Section 5 concludes the article.

LITERATURE REVIEW

In 2016, Spanhol, et al., [5], have proposed CNN which has adapted AlexNet for classifying Breast cancer histopathological images. The BreaKHis database, consists of 7,909 microscopic biopsy images of benign and malignant breast tumors and collected at P&D lab, Brazil during Jan-Dec,2014, has been used as input for classification. It is observed that CNN based classification achieves better accuracy with compared to traditional machine learning algorithms trained on same dataset.

Priyanka Puvar and Bhagirath Prajapati

In 2018, V Gupta and A Bhavsar[6] conducted a study with the objective of delving deeper into the capabilities of fine-tuned pre-trained Convolutional Neural Network (CNN) models for the classification of breast cancer histopathology images. Their research introduced a sequential model that strategically amalgamates features from various layers, resulting in an enhanced performance in the classification of breast cancer histopathology images. In their study the outcomes reveal that the integration of multilayer deep feature fusion within the sequential framework of the proposed approach outperforms the performance of the baseline network.

In 2020, TG Debelee, et al., [7], have proposed a comprehensive review of articles published between 2004 and 2018 was undertaken to achieve the objectives like, Examine the Utilization of Imaging Modalities, Compare Breast Cancer Imaging Modalities, Identify Frequently Cited and Publicly Accessible Breast Cancer Databases, Evaluate Implementation of Deep Learning (DL) in Medical Image Analysis and Assess Application of DL in Histopathology-Based Breast Cancer Image Analysis. The findings of this comprehensive review contribute to the current understanding of breast cancer diagnostic methodologies, emphasizing the role of imaging modalities, database accessibility, and the evolving landscape of Deep Learning in medical image analysis, particularly within the context of breast cancer research.

In 2021, Demir [8] proposed an innovative and resilient approach for automated breast cancer diagnosis from histopathology images. The method leverages a convolutional-long short-term memory (CNN-LSTM) learning model, a pre-processing technique utilizing a marker-controlled watershed segmentation algorithm, and an optimized support vector machine (SVM) classifier. Unlike existing approaches where CNN-LSTM models are trained separately for classification tasks, the suggested method integrates them into a unified framework. The marker-controlled watershed segmentation algorithm (MWSA) is employed to delineate inherent small regions. However, a drawback of this approach is its dependence on powerful hardware, making it less practical for applications with large datasets, as it demands high-performance computing resources.

In 2021, Aswathy and Jagannath [9]proposed an automated method for breast cancer classification that relies on integrated features and employs a Support Vector Machine (SVM) classifier. The study suggests identifying the classifier that aligns most effectively with the task of breast cancer detection using histopathological images. An integrated feature extraction module was introduced to extract and combine three sets of biologically significant and clinical traits. The study included a statistical analysis to underscore the significance of different classifier performances. It's important to note that the proposed method did not integrate a real-time approach for breast cancer diagnosis, potentially limiting its application in dynamic, time-sensitive scenarios.

In 2022, D Muduli, et al., [10], have proposed A novel deep convolutional neural network (CNN) model for the automated classification of breast cancer using two distinct types of images: mammograms and ultrasounds. Their investigation revealed that Convolutional Neural Network (CNN) models exhibit unique attributes like automated feature extraction, high-level feature learning, and proficiency in transfer learning. When compared to alternative Computer-Aided Detection (CAD) models, those based on CNNs demonstrate superior accuracy in the detection of features, showcasing the efficacy of CNNs in enhancing detection performance.

In 2022, N Ranjan, et al., [3]introduced a methodology that involves the adaptation of Convolutional Neural Networks (CNNs) for the categorization of histopathology images. They developed classifiers that employ a hierarchical structure, utilizing multiple CNNs. The accuracy of this proposed CNN-based hierarchical classifier was examined using the BACH challenge dataset. To address the challenges posed by inter-class similarity and intra-class variability in histopathology images, a pre-trained CNN was modified for effective categorization. It's noteworthy that the evaluation of histopathological categorization was limited to a specific subset in this study.

Priyanka Puvar and Bhagirath Prajapati

Problem Statement

Breast cancer remains one of the most commonly diagnosed cancers globally, with millions of new cases reported each year. The incidence rates vary across regions, and lifestyle factors, genetics, and access to healthcare play significant roles [11]. Early detection through screening programs, including mammography, clinical breast exams, and self-examinations, continues to be a key focus. As a result of advancements in research, treatments and enhanced supportive care, a growing number of individuals diagnosed with breast cancer are now enjoying extended life expectancy and an improved quality of life [12]. The landscape of breast cancer continues to evolve with ongoing research and clinical trials, actively investigating novel treatment options, identifying biomarkers, and exploring potential interventions. The surge in popularity of deep learning in medical image analysis can be attributed to its intrinsic capability to autonomously acquire hierarchical features from intricate data, specifically within the domain of medical images. The worldwide scenario of breast cancer displays fluctuations, marked by continuous advancements in early detection methods, treatment approaches, and overall prognoses. It is imperative to recognize that the status of breast cancer is dynamic, susceptible to alterations over time. Consequently, staying informed and obtaining the most up-to-date information from reliable health sources or organizations through recent research is paramount [13]. As described in literature review a lot of research has been conducted on breast cancer detection by considering various attributes like different modalities, varieties of databases, various MLTs and it continues [14]. Nevertheless, several limitations are acknowledged across various studies, encompassing the requirement for robust hardware, challenges related to dataset generalization, and shortcomings in both segmentation and feature extraction and classification methodologies. Moreover, the utilization of histopathological images has been firmly established as the gold standard in research dedicated to breast cancer detection [15]. These aspects highlight areas that necessitate further exploration and enhancement of automated breast cancer diagnostic techniques.

PROPOSED METHODOLOGY

In recent years, image data classification using deep learning has propelled computer vision applications to unprecedented heights, empowering machines to discern and categorize visual information with remarkable precision. At the forefront of this transformative journey are Convolutional Neural Networks (CNNs), wielding their efficacy in diverse image classification tasks. The key facets of image data classification using deep learning are 1) Data Pre-processing through data augmentation techniques, such as rotation, flipping, and scaling to increase the diversity of the dataset, leading to improved model generalization, 2) Convolutional Neural Networks (CNNs) which are the backbone of image classification in deep learning. They are designed to automatically and adaptively learn spatial hierarchies of features from input images. The convolutional layers capture local patterns, and pooling layers help in down sampling and extracting essential information. 3) Model Architecture, is the architecture of a deep learning model for image classification typically consists of convolutional layers for feature extraction, activation functions (e.g., ReLU) for introducing non-linearity, pooling layers for spatial reduction, and fully connected layers for global patterns. 4) Transfer learning which involves leveraging pre-trained models on large datasets, such as ImageNet, and fine-tuning them for specific image classification tasks. 5) Loss Functions like categorical cross-entropy for multi-class classification and binary cross-entropy for binary classification are used for effective training. 6) Optimization Algorithms like Adam, SGD (Stochastic Gradient Descent), and RMSprop are employed to update the model parameters during training. These algorithms play a crucial role in converging the model to a solution efficiently. 7) Regularization Techniques such as dropout layers and batch normalization are used to prevent overfitting, ensuring that the model generalizes well to new, unseen data, Hyper parameter Tuning, Evaluation Metrics. 8) Hyper parameter Tuning: Adjusting hyper parameters, such as learning rate, batch size, and the number of layers, is essential for optimizing the model's performance on the specific image classification task [16] [17] [18].

The proposed methodology for breast cancer detection combines various techniques to improve accuracy and interpretability in histopathology images as shown in Fig:1. The process involves Random sampling, ReinhardColour Normalization for consistent color representation, Data Augmentation through elastic transformations, and median filtering for noise reduction during pre-processing. Adaptive thresholding is employed for segmentation to identify regions of interest. Feature extraction comprises texture features and color histograms, and a Variance Thresholding

technique is utilized for feature selection. The detection model, named PreNet, integrates a combination of ImageNet and a customized Convolutional Neural Network (CNN) architecture. This holistic yet succinct approach is designed to elevate the precision of breast cancer detection in histopathology images while facilitating a more understandable interpretation of the results.

Pre-processing

In the initial pre-processing phase of the breast cancer detection methodology, random sampling is utilized to randomly select a subset of images from an extensive dataset of histopathology images. Furthermore, Reinhard Colour Normalization is applied to ensure consistent color representation across all histopathology images, providing a standardized foundation for subsequent analyses. To address the variability in tissue structures, elastic transformations are employed, simulating deformations that augment the dataset. This augmentation strategy contributes to the model's resilience by exposing it to a broader range of variations in tissue morphology. In addition to these techniques, noise reduction is a crucial aspect of pre-processing. Median filtering is employed for this purpose, effectively diminishing noise in the histopathology images. This approach preserves structural information while enhancing the overall quality of the images, creating a more reliable foundation for subsequent stages of the breast cancer detection process[5] [18] [19].

Random Sampling

Random sampling in preprocessing is a technique where a subset of data points is chosen randomly from a larger dataset. Widely applied in machine learning and data analysis, this method is employed to create smaller, representative samples that encapsulate the essential characteristics of the overall dataset. The primary objectives of random sampling include reducing computational burden, expediting training processes, and, in certain cases, enhancing the generalization performance of a model. In the specific context of breast cancer detection or medical image analysis, random sampling is implemented to select a random subset of images from an extensive collection of histopathology images. This chosen subset serves various purposes, such as training a machine learning model, validating its performance, or conducting exploratory data analysis. The fundamental principle behind random sampling is to guarantee that the chosen subset is a representative sample of the entire dataset. This mitigates biases that might arise if only specific portions of the data were used, contributing to the creation of a diverse set of examples. Ultimately, this approach enhances the model's robustness and its ability to generalize effectively to unseen data in the domain of breast cancer detection or medical image analysis[5]. Mathematically, if you represent your dataset as $D = \{x_1, x_2, ..., x_N\}$, where x_i is an individual data point, and you randomly select indices $i_1, i_2, ..., i_n$, then your randomly sampled subset S would be $S = \{x_{i_1}, x_{i_2}, ..., x_{i_n}\}$.

Color Normalization through Reinhard's Method

Reinhard's Color Normalization is aTechnique for Consistent Histopathology Image Representation. Reinhard Color Normalization is implemented to standardize color variations, ensuring a uniform representation across histopathology images [20]. In this approach, the background color (and brightness) of the reference image is replaced with that of the color-normalized image. The mean and standard deviations of each color channel in both images are aligned through a linear transformation in the l $\alpha\beta$ color space. Additionally, an alternative global color normalization technique is chosen, involving the projection of the target image's mean color onto the source image. This technique guarantees the preservation of fluctuations in intensity from the source image. The resultant modified image closely mirrors the intended image, providing a processed picture with contrast matching the target image's contrast while preserving the structural characteristics of the original image. Despite these advantages, it's worth noting that stains in the l$\alpha\beta$ color space may not be evenly spaced.

Data Augmentation

By applying data augmentation to the original images, one can create new images with variations in appearance while retaining the same underlying concepts. This process helps enhance the model's robustness to various real-world conditions such as different lighting conditions, viewpoints, occlusions, and other environmental factors [7]. By exposing the model to a broader range of image variations during training, data augmentation can improve its

ability to generalize well and perform effectively when applied to unseen data in real-world scenarios. Elastic deformation is an effective augmentation method originally developed for image enhancement purposes. This technique involves generating a random displacement field, where the intensity is controlled by the elasticity coefficient σ and a scaling factor α. By applying this displacement field to the image, elastic deformation introduces realistic deformations that simulate the behavior of elastic materials. The following is a mathematical description of this deformation

$$I^{'}\big(x + \Delta x(x,y), y + \Delta y(x,y)\big) = I(x,y) \qquad (1)$$
$$\Delta x = G(\sigma) * \big(a \times Unif([-1,1,n,m])\big) \qquad (2)$$
$$\Delta y = G(\sigma) * \big(a \times Unif([-1,1,n,m])\big) \qquad (3)$$

In this method, Δx and Δy represent horizontal and vertical displacement grids of size n × m, respectively. $I^{\wedge'}$ and I denote the deformed and original images, respectively. The displacement values x and y are generated by convolving a Gaussian filter with a standard deviation of σ, applied to the product of a uniformly drawn value in the range [−1, 1] and α. This approach is particularly effective for capturing images of elastic objects, such as breast tissue, which may naturally undergo distortion due to factors like patient movement, breathing, or pressure from imaging devices. By simulating these deformations, the method can enhance the robustness of models trained on such images and improve their performance in real-world scenarios.

Noise Reduction through Median Filtering
Removing noise from input images is a fundamental step in image processing, crucial for improving the accuracy and reliability of subsequent analyses or visualizations. It's essential to apply noise reduction techniques while preserving the edges and details of the original image to achieve optimal results [16]. One widely used method for this purpose is median filtering. Median filtering is a common low-pass filtering technique used to remove noise while preserving image sharpness and clarity. Unlike traditional averaging filters, which calculate the output pixel value by averaging the intensities of neighboring pixels, median filtering replaces each pixel's value with the median value of the intensities within its local neighborhood. The size of the pixel neighborhood, also known as the filter size or kernel size, determines the extent of the median filtering effect. Larger filter sizes encompass more neighboring pixels, resulting in greater noise reduction but potentially causing blurring or loss of detail. Conversely, smaller filter sizes may preserve finer details but might not effectively suppress noise. One notable advantage of median filtering is its effectiveness in removing impulsive noise, such as salt-and-pepper noise, which can appear as random bright or dark pixels in the image. By replacing each pixel's value with the median value of its neighborhood, the median filter effectively eliminates these outliers without significantly affecting the underlying image structure. In practice, median filtering is applied as a preprocessing step to input images before further analysis or visualization. By replacing each pixel's value with the median value of its neighborhood, median filtering helps improve the image quality by reducing noise while maintaining important image features.

$$y_{(m,n)} = median\big(x_{i,j} : (i,j) \in \tau\big) \qquad (4)$$

Where τ represents the nearby neighbors in (m,n).

Segmentation through adaptive thresholding

Segmentation through adaptive thresholding is a technique used in image processing and computer vision to separate objects or regions of interest from the background in an image. Traditional thresholding methods use a fixed threshold value to binarise an image, where pixel values above the threshold are considered part of the object, and those below are considered part of the background. However, this approach may not be suitable for images with varying illumination conditions or uneven backgrounds. Adaptive thresholding addresses this limitation by dynamically adjusting the threshold value for each pixel based on its local neighborhood. This allows for more robust

Priyanka Puvar and Bhagirath Prajapati

segmentation, particularly in images with non-uniform lighting or varying contrast.Here's how segmentation through adaptive thresholding typically works: 1) Local Thresholding: Instead of using a single global threshold for the entire image, adaptive thresholding divides the image into smaller regions or windows. For each pixel in the image, a threshold value is computed based on the intensity distribution within its local neighborhood. 2) Threshold Calculation: The threshold value for each pixel is computed based on statistics such as the mean or median intensity of its local neighborhood. This calculation can also take into account factors like standard deviation to adaptively adjust the threshold based on the local image characteristics. 3) Binarization: Once the threshold values are computed for all pixels, each pixel's intensity is compared to its corresponding threshold. Pixels with intensities above the threshold are classified as foreground (object), while those below are classified as background. 4) Output Image: The result of adaptive thresholding is a binary image, where foreground pixels represent the segmented objects or regions of interest, and background pixels represent the surrounding areas. Segmentation through adaptive thresholding is particularly useful in applications such as document processing, medical image analysis, and object detection, where accurate delineation of objects against complex backgrounds is critical [9]. By adapting the threshold locally, this technique can effectively handle variations in illumination and contrast, leading to more accurate segmentation results.

Feature Extraction

Feature extraction in image analysis is a pivotal process that entails condensing raw image data into a condensed and informative feature set. These features are meticulously crafted to accentuate particular patterns, structures, or attributes within the image, thus facilitating various tasks such as classification, object detection, or image retrieval. This study considered texture features and color histograms for the same. Texture features in image processing encompass attributes that delineate the visual patterns, structures, or surface properties exhibited by textures within an image. Texture analysis plays a pivotal role in tasks like image classification, segmentation, and recognition, as discerning the nuanced texture details can offer invaluable insights [21]. An array of techniques and methodologies are utilized to extract texture features from images. Some texture feature extraction techniques considered in this study are LGPT (Local Gradient Pattern), GLDS (Gray Level Difference Statistics), and LTP (Local Ternary Pattern). LGPT (Local Gradient Pattern): LGPT is a texture descriptor that captures information about the local gradients in an image. It considers the magnitudes and orientations of gradients to represent texture patterns. LGPT is particularly useful for tasks where gradient information plays a significant role, such as edge detection or texture discrimination. GLDS (Gray Level Difference Statistics): GLDS is a set of statistical measures calculated based on the differences between neighboring pixel intensities in an image. It provides a way to quantify the variations in gray levels. GLDS can be employed for texture analysis, particularly in scenarios where the distribution of intensity differences is informative about the texture properties. LTP (Local Ternary Pattern): LTP is a texture descriptor that encodes information about local variations in pixel intensities. It categorizes each pixel based on whether its intensity is greater, equal to, or less than the average intensity of its neighbors. LTP is commonly used for texture classification tasks, especially when distinguishing between different types of textures based on local intensity patterns.

These techniques are part of the broader field of local texture analysis, where the focus is on capturing information within local neighborhoods of pixels in an image. Such techniques are beneficial for tasks like image classification, object recognition, and segmentation, where understanding the local texture patterns is crucial.

Feature Selection

Feature selection methods aim to choose a subset of relevant features from a larger set, improving the efficiency and effectiveness of machine learning models. This study considered Variance thresholding as a feature selection technique. Variance thresholding is a feature selection technique that involves removing features with low variance. The idea behind variance thresholding is that features with little variation in their values across samples may not provide much information for predictive modeling. Therefore, by setting a threshold on the variance, you can eliminate features with insufficient variability [22].

Priyanka Puvar and Bhagirath Prajapati

Here's how variance thresholding for feature selection typically works: 1) Calculate Variance: For each feature in the dataset, calculate its variance across all samples. Variance measures the spread or variability of values within a feature. Features with low variance have values that are close to each other, indicating little variation. 2) Set Threshold: Determine a threshold value for variance below which features will be considered low-variance and thus candidates for removal. This threshold can be chosen empirically based on domain knowledge or through experimentation. 3) Filter Features: Remove features from the dataset that have variance below the threshold. These low-variance features are deemed less informative and are unlikely to contribute significantly to the predictive power of a model. 4) Retain Informative Features: Keep the remaining features in the dataset, which have variance above the threshold. These features are expected to exhibit greater variability across samples and are more likely to contain useful information for building predictive models.

PreNet based detection

A comprehensive deep learning-based detection model integrating ImageNet, with customized CNN for capturing diverse features and temporal dependencies. ImageNet has played a crucial role in the advancement of image classification and object recognition [23]. Many deep learning models, especially convolutional neural networks (CNNs), have been pre-trained on ImageNet. These pre-trained models serve as powerful feature extractors and can be fine-tuned for specific tasks, allowing developers to leverage the knowledge gained from ImageNet for a variety of computer vision applications. The sequential model which constructs the PreNet for this study has incorporated the concept of ImageNet along with customized CNN. The architecture of customized CNN is named as BIA-CNN (Breast Image Analysis- CNN) which is show in Figure: 2 [24] [25] [26]. CNNs consist of multiple layers arranged in a hierarchical manner. The typical layers include: Convolutional Layers, Pooling Layers, Fully Connected Layers (also known as Dense Layers). Below is the explanation of each layer of CNN in details.

Input Layer

The input layer represents the raw input data, typically images in the case of computer vision tasks. Let's denote the input image as X, where X is a 3D array representing the image with dimensions (height, width, channels). For example, an RGB image would have 3 channels (Red, Green, Blue), hence   X can be represented as $X \in R\_{(H \times W \times C)}$, where H is the height, W is the width, and C is the number of channels.

Convolutional Layers

The core building blocks of CNNs are convolutional layers. These layers apply convolution operations to input data. Convolution involves passing a filter (also called a kernel) over the input data to extract features. The filter slides over the input, performing element-wise multiplication and summing up the results. This operation helps in capturing features like edges, textures, and patterns from the input images. Let's denote the output of the previous layer (input image or feature maps from a previous layer) as $A^{(l-1)}$. Convolution operation involves applying a filter $W^{(l)}$ (also called a kernel) to the input feature maps $A^{(l-1)}$. The output feature map $Z^{(l)}$ is obtained by convolving the filter over the input feature map using element-wise multiplication and summing up the results along with the bias term $b^{(l)}$ and applying an activation function f.

Mathematically,

$$Z_{i,j,k}^{(l)} = f\left(\sum_{c=1}^{C^{(l-1)}} \sum_{p=0}^{F-1} \sum_{q=0}^{F-1} W_{p,q,c,k}^{(l)} \cdot A_{i+p,j+q,c}^{(l-1)} + b_k^{(l)}\right) \qquad (5)$$

F is the filter size (both width and height), $C^{(l-1)}$ is the number of channels in the previous layer, i and j iterate over the spatial dimensions of the output feature map, and k iterates over the channels of the current layer.

Activation Function: After computing the convolution operation, an activation function is applied element-wise to the output feature map. The most commonly used activation function is the Rectified Linear Unit (ReLU), defined as:

Priyanka Puvar and Bhagirath Prajapati

$f(x)=\max(0,x)$ (6)

ReLU introduces non-linearity into the network and helps in capturing complex patterns in the data.

Pooling Layer: Pooling layers are interspersed between convolutional layers to reduce the spatial dimensions of the feature maps. Max pooling is a common pooling operation, where the maximum value within a certain region (e.g., 2x2 or 3x3) is retained. Let's denote the output of the previous layer as $A^{(l-1)}$, and the pooled feature map as $P^{(l)}$.

Mathematically (for max pooling):

$P^{(l)}_{i,j,k} = \max_{m,n} A^{(l-1)}_{2i+m,2j+n,k}$ (7)

(2i,2j) are the starting coordinates of each pooling region, and (m,n) iterate over the region.

Fully Connected Layer: After several convolutional and pooling layers, fully connected layers are used for making final predictions. The output of the last pooling layer is flattened into a vector and fed into the fully connected layer. Let's denote the flattened output as $F^{(l)}$ and the output of the fully connected layer as $O^{(l)}$.

Mathematically,

$O^{(l)} = f(W^{(l)} \cdot F^{(l-1)} + b^{(l)})$ (8)

$W^{(l)}$ is the weight matrix, $b^{(l)}$ is the bias vector, and f is the activation function (e.g., ReLU or softmax).

Dataset Description
As this is an eye catching application of AI, the varieties of datasets have been utilized in various study. The dataset used for this study is taken from kaggle database, which is widely utilized in study now a days. The dataset is comprised of 277,524 histopathology patches derived from 162 whole mount slide images of Breast Cancer specimens, captured at a magnification of 40x. Each patch is a 50 x 50 pixel image and is annotated based on the presence or absence of Invasive Ductal Carcinoma (IDC). Among these patches, 198,738 are categorized as IDC negative (Class 0), indicating the absence of IDC, while 78,786 patches are labeled as IDC positive (Class 1), signifying the presence of IDC. The patches are named using the convention u_xX_yY_classC.png, where: 'u' represents the patient ID. 'X' and 'Y' denote the x and y-coordinates of the patch's cropping location. 'C' indicates the class, where 0 corresponds to non-IDC and 1 corresponds to IDC. This nomenclature allows for easy identification and organization of the patches within the dataset.

This dataset is particularly valuable for tasks such as automatic grading and the development of machine learning models for the detection of IDC in breast cancer histopathology images. Pathologists typically concentrate on IDC regions for aggressiveness grading, underscoring the clinical relevance and significance of this dataset in advancing research and diagnostic capabilities in the field of breast cancer pathology [10].

RESULT AND DISCUSSION

In this section, the outcomes of the proposed model are juxtaposed with existing approaches. The input images are sourced from the Breast Histopathology Images dataset [27]. The implementation is conducted utilizing the Python programming platform. The dataset is partitioned such that thirty percent of the data is allocated for testing and validation, while the remaining seventy percent is earmarked for training. The model undergoes training exclusively on one subset, and its generalizability is subsequently assessed by evaluating its performance on the other subset. This division ensures a robust evaluation of the model's effectiveness and adaptability to unseen data.

Priyanka Puvar and Bhagirath Prajapati

In terms of performance evaluation, this study employs widely recognized metrics such as Accuracy (Acc), Sensitivity (Sn), Specificity (Sp), and Area Under the Curve (AUC) [28]. Accuracy (Acc) quantifies the percentage of samples accurately classified out of the total samples. Sensitivity (Sn) corresponds to the true positive rate, measuring the percentage of correctly classified abnormal samples. Specificity (Sp) represents the true negative rate, indicating the percentage of correctly classified normal samples. Area Under the Curve (AUC) is a prevalent metric used for model evaluation, particularly in scenarios where distinguishing between optimal and suboptimal models is crucial. The formulas for Accuracy (Acc), Sensitivity (Sn), and Specificity (Sp) are provided below [29]:

$$Acc = (TP + TN) /(TP + TN + FP + FN) \qquad (9)$$
$$Sn = (TP)/(TP + FN) \qquad (10)$$
$$Sp = (TN)/(TN + FP) \qquad (11)$$

Where TP: true positive, TN: true negative, FP: false positive, FN: false negative.

A Comparative Analysis: Evaluating the Proposed Breast Cancer Detection Model against Literature-Reviewed Approaches

This section depicts comparative analysis of proposed model and models considered in the studies presented in literature survey of this research study. The proposed PreNet model is contrasted with other currently employed models in considered articles, such as AlexNet CNN [30], DenseNet based sequential CNN model [6], Varieties of DCNN [7], a convolutional-long short-term memory (CNN-LSTM) learning model [8], Integrated feature extraction along with SVM classifier [31], Deep CNN [10], CNN-based hierarchical classifier [3]. Table 1 reflects the comparative analysis.

Here in the Table 1 it appears the description of a machine learning experiment comparing various techniques for a data classification task. The description includes information about evaluated metrics like accuracy, specificity and sensitivity to showcase the performance of different machine learning techniques [7] [32].

Among the various techniques assessed, the 'Proposed' method stands out with remarkable performance, consistently outperforming alternative approaches like AlexNet CNN, DenseNet based CNN, Varieties of DCNN, CNN-LSTM, SVM, Deep CNN and CNN-based hierarchical classifier across nearly all metrics [31] [33] [34]. Noteworthy is the 'Proposed' technique's outstanding accuracy at 96.13%, underscoring its proficiency in overall classification and precise identification of positive instances.

Accuracy
In the realm of machine learning algorithms, accuracy stands as a foundational metric for evaluating a model's performance in classification tasks. It quantifies the ratio of correctly predicted instances to the total number of instances within the dataset. The accuracy score offers a broad perspective on the model's capability to accurately assign instances to their respective classes. The following chart depicts comparison of proposed and reviewed methods with respect to Accuracy.

Specificity
Specificity refers to the extent to which a test accurately identifies individuals without a particular condition or disease. In medical diagnostics, specificity measures the ability of a test to correctly identify those who do not have a certain disease or condition among individuals who do not have the disease. It is essentially the proportion of true negative results among all individuals who do not have the disease. In the context of breast image analysis, specificity remains a crucial measure but is often applied to the performance of diagnostic tests or imaging techniques rather than traditional medical tests. Specifically, it assesses the ability of a breast imaging method to correctly identify images without evidence of a particular condition, such as breast cancer. The following chart depicts comparison of proposed and reviewed methods with respect to Specificity.

Priyanka Puvar and Bhagirath Prajapati

Sensitivity

Sensitivity, in the context of medical testing or diagnostic imaging, refers to the ability of a test or imaging method to correctly identify individuals who have a particular condition or disease. It is also known as the true positive rate or the recall. Sensitivity is a measure of how well a test can identify all the actual positive cases, minimizing false negatives. The following chart depicts comparison of proposed and reviewed methods with respect to Sensitivity.

A Comparative Analysis: Evaluating the Proposed Breast Cancer Detection Model with respect to different batch sizes

The comparative analysis of a proposed breast cancer detection model with respect to different batch sizes can be explained and understood through the lens of optimization and training dynamics in machine learning. Several theories and concepts in machine learning and deep learning can contribute to explaining the observed behavior [35] [36]. The choice of batch size is closely tied to the optimization algorithm being used. The batch size can affect the generalization capability of the model. Small batch sizes might introduce more noise into the training process, potentially leading to overfitting, while large batch sizes may result in a less noisy but less accurate gradient estimation. The study may investigate how different batch sizes impact the model's ability to generalize to unseen data. Larger batch sizes can lead to more efficient parallelization and GPU utilization, but they may come with trade-offs in terms of model performance. In brief, the choice of batch size is a critical hyper parameter that can significantly influence the training dynamics and performance of a deep learning model. Analyzing the proposed breast cancer detection model with respect to different batch sizes involves considering the interplay of optimization algorithms, learning rates, generalization, computational efficiency, and statistical efficiency. The following is the graphical presentations of outputs with respect to various batch sizes along with 60 epochs.

Graphical representation of proposed model's outputs with 60 epochs and 25 batch size.

From the figures 6 to 16, It can be noted that the choice of batch size has a noticeable impact on the performance metrics of the model. Specifically, when the batch size is set to 25, the model achieves a loss of 0.1798 and an accuracy of 0.9584. Increasing the batch size to 35 results in improved performance, with a lower loss of 0.1761 and a higher accuracy of 0.9613. However, using a batch size of 50 leads to a slightly higher loss of 0.1835 and a lower accuracy of 0.9579. Upon closer examination, it is evident that the combination of a batch size of 35 and an epoch value of 60 yields the optimal results. This configuration produces the highest accuracy of 0.9613 with a relatively low loss of 0.1761. Therefore, it can be concluded that, for this specific model and dataset, a batch size of 35 and 60 epochs provide the best balance between accuracy and loss.

CONCLUSION

In conclusion, this study presents a comprehensive and integrated methodology for breast cancer detection in histopathology images, incorporating various stages such as pre-processing, segmentation, feature extraction, and deep learning-based detection. The pre-processing phase employs techniques like random sampling, Reinhard Colour Normalization, data augmentation through elastic transformations, and median filtering, aiming at consistent color representation, focused region analysis, dataset augmentation, and noise reduction. The segmentation process utilizes adaptive thresholding for region identification. Feature extraction encompasses a diverse set of features, including deep learning-based, texture, color, and shape features, with the Variance Thresholding Algorithm aiding in effective feature selection.The PreNet detection model, a fusion of ImageNet architecture and a customized CNN, is a key component of this methodology. The overall objective is to advance breast cancer detection by leveraging state-of-the-art techniques, ultimately contributing to heightened diagnostic accuracy and interpretability in histopathology analysis. This holistic approach underscores the potential impact of combining advanced image processing and deep learning methods to improve the efficiency and effectiveness of breast cancer diagnosis.

ABSTRACT

A method for finding the generalized inverse of Centrosymmetric and k– Centrosymmetric Neutrosophic Fuzzy Matrices is provided in this paper. We discussed various g-inverse associated with a regular Neutrosophic Fuzzy Matrices and obtain characterization of set of all inverses by using Centrosymmetric and k–Centrosymmetric Neutrosophic Fuzzy Matrices. We proved sum, product and scalar multiplication oftwo Centrosymmetric Neutrosophic Fuzzy Matrices is again a Centrosymmetric Neutrosophic Fuzzy Matrices and also focusing on the fundamental principles and theorems of Centrosymmetric and k- Centrosymmetric Neutrosophic Fuzzy Matrices, as well as examples.

Keywords: Centrosymmetric NFM,k- Centrosymmetric NFM, Generalized inverse.

INTRODUCTION

Zadeh [1] first introduced fuzzy sets (FSs) in 1965. These are traditionally defined by their membership value or grade of membership. Assigning membership values to a fuzzy set can sometimes be challenging. Atanassov [2] introduced intuitionistic FSs to solve the problem of assigning non-membership values. Smarandache [3] introduced the concept of neutrosophic sets (NSs) to handle indeterminate information and deal with problems that involve imprecision, uncertainty, and inconsistency. Fuzzy matrices are used to solve certain kinds of issues. Many researchers have since completed numerous works. Only membership values are addressed by fuzzy matrices. These matrices cannot handle values that are not membership. The generalized inverse (g -inverse) deals withmatrix inverse generalization for both singular and non-square matrices Kim and Roush [8] have discussed Generalized fuzzy matrices. Pradhan and Pal [10] have studied The Generalized Inverse of Atanassov's IFM. Pradhan and Pal [11] have studied Some results on Generalized Inverse of IFM. The generalized inverse of matrices is applicable in many field, likely power, robotics, image processing and signal processing. Ann Lec [1] has introduced Secondary symmetric and skew symmetric secondary orthogonal matrices. Cantoni and Butler [2] have studied Eigenvalues and eigenvectors of symmetric centrosymmetric matrices. James Weaver [7] has discussed Centrosymmetric matrices their basic properties eigenvalues and eigenvectors. Punithavall [12] has studied Symmetric-Centro Symmetric Fuzzy Matrices. Elumalai and Rajesh kannan [3] have focused on k - Symmetric Circulant, s - Symmetric Circulant and s – k Symmetric Circulant Matrices. Elumalai and Arthi [4] have studied Properties of k - CentroSymmetric and k – Skew CentroSymmetric Matrices. Gunasekaran Mohana [5] have studied k-symmetric Double stochastic, s-symmetric Double stochastic , s-k-symmetric Double stochastic Matrices. Hazewinkel and Michiel [6] have focused on Symmetric matrix. Meenakshi [9] has studied Fuzzy Matrix: Theory and Applications. Anandhkumar [13,14] has studied Pseudo Similarity of NFM, On various Inverse of NFM and Reverse Sharp And Left-T Right-T Partial Ordering On NFM .Aim of this paper is to describe generalized inverse of Centrosymmetric, k– Centrosymmetric Neutrosophic Fuzzy Matrices and to discuss some basic principles and theorems of Centrosymmetric and k-Centrosymmetric matrices, as well as examples .

RESEARCH GAP

Punithavalli presented the concept of Centrosymmetric and K–Centrosymmetric Fuzzy Matrices. Here, we have applied the concept ofCentrosymmetric and K–Centrosymmetric 2×2 Neutrosophic FuzzyMatrices .We have examined some of the results and extended both concepts to NFMs. We discussed various g-inverse associated with a regular matrices and obtain characterization of set of all inverses by usingCentrosymmetric and K–Centrosymmetric NFM.

Preliminaries and notations

P^T is the Transpose of P if P is a Centrosymmetric NFM. Let k denote a fixed distinct transposition product in $S_n$and Krepresent the permutationNFM. Clearly K meets characteristics like K^T =K and K^2=I.

DEFINITIONS AND THEOREMS

Definition:1.1 Centrosymmetric NFM(CSNFM):A Square NFM which is symmetric about the centre of its array of elements is called CS,thus P= [p_{ij}]CS if p_{ij} = $p_{n-i+1,n-j+1}$.If K denotes the n×n IFM with <1,1,0> on the counterdiagonal and <0,0,1> everywhere else (i.e. $K_{i,n+1-i} = <1,1,0>;\quad K_{i,j} = <0,0,1>$ if $j \neq n+1-i$),then Pis CSNFM iff PK = KP.

Example:1 Let us consider the IFM

$$P = \begin{bmatrix} <0.7,0.2,0.4> & <0.4,0.2,0.3> \\ <0.4,0.2,0.3> & <0.7,0.2,0.4> \end{bmatrix} \text{and } K = \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix}$$

Murugadas and Shyamaladevi

Then $PK = \begin{bmatrix} <0.4,0.8,0.3> & <0.7,0.8,0.4> \\ <0.7,0.8,0.4> & <0.4,0.8,0.3> \end{bmatrix}, KA = \begin{bmatrix} <0.4,0.8,0.3> & <0.7,0.8,0.4> \\ <0.7,0.8,0.4> & <0.4,0.8,0.3> \end{bmatrix}.$

Definition: 1.2 If P Centrosymmetric Neutrosophic Fuzzy matrices (NFM) $P \in (NFM)_n$ is called k-Centosymmetric NFM if P = KP^{T}K

Definition 1.3 Suppose p and q are two NFM elements $p = <p_{ij\alpha}, p_{ij\beta}, p_{ij\gamma}>, q = <q_{ij\alpha}, q_{ij\beta}, q_{ij\gamma}>,$ are component wise addition and multiplication are described as,

$p + q = <\max \left\{ p_{ij\alpha}, q_{ij\alpha} \right\}, \max \left\{ p_{ij\beta}, q_{ij\beta} \right\}, \min \left\{ p_{ij\gamma}, q_{ij\gamma} \right\}>$

and $p.q = <\min \left\{ p_{ij\alpha}, q_{ij\alpha} \right\}, \min \left\{ 1 - p_{ij\beta}, 1 - q_{ij\beta} \right\}, \max \left\{ p_{ij\gamma}, q_{ij\gamma} \right\}>$

Definition1.4 (Transpose) The transpose P^T of an NFM $P = \left[p_{ij} \right]_{m \times n}$ is defined as $P^T = \left[p_{ji} \right]_{n \times m}$ where

$p_{ji} = <p_{ji\alpha}, p_{ji\beta}, p_{ji\gamma}>.$

Definition 1.5 (IFPM) If each row and each column contains accurately one <1,1,0> and all other entries are <0,0,1> in a square NFM, it is known as Neutrosophic Fuzzy permutation matrix .

Definition 1.6 A basis D of an Neutrosophic fuzzy vector space W is standard basis iff whenever $d_i = \sum_{j=1}^{n} a_{ij} d_j$ for

$d_i, d_j \in D$ and $a_{ij} \in [0,1]$ then $a_{ij} d_i = d_i$

Generalized Inverse
This section shows the g-inverse of an NFM. We also described a method for finding the g-inverse of a Centrosymmetric and k– Centrosymmetric NFMs.

Definition:2.1 For NFM P∈(NFM)ₘₓₙand another NFM K ∈(NFM)ₙₓₘ satisfies the given equation
1.   PKP = P   (g-inverse)
2.   KPK = K (2-inverse)
3.   (PK)^T =PK, (Least square g- inverse of P or P{1,3} inverses)
4.   (KP)^T =KP, (P{1,4} inverses).

Theorem:1 Let P be a Centrosymmetric NFM with a standard basis of non-zero rows. If P satisfies the equation PKP = P with the maximum and minimum process for some NFPMK, then K is a generalized inverse of P.

Proof: A standard basis is formed by the non-zero rows of an NFM P.
If KP = Z, Therefore the rows of Z and the rows of P rearranged.
Then Z is an idempotent NFM,
i.e., Z= Z², with the similar row space as P and non-zero rows forming a standard basis as well. Therefore the standard basis is unique,
$\Rightarrow$P = ZK, where K is permutation matrix.
Therefore,
PK^T P= ZKK^{T}ZK
= ZZK   (KK^T=I)
=ZK
=P
PKP=P (K^T=K)

Murugadas and Shyamaladevi

Therefore ,K is 2-inverse.

Example:2 Consider the NFM, $P = \begin{bmatrix} <0.6,0.2,0.4> & <0.8,0.2,0.3> \\ <0.8,0.2,0.3> & <0.6,0.2,0.4> \end{bmatrix}$, $K = \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix}$

$$KP = \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix}\begin{bmatrix} <0.6,0.2,0.4> & <0.8,0.2,0.3> \\ <0.8,0.2,0.3> & <0.6,0.2,0.4> \end{bmatrix} = \begin{bmatrix} <0.8,0.8,0.3> & <0.6,0.8,0.4> \\ <0.6,0.8,0.4> & <0.8,0.8,0.3> \end{bmatrix}$$

$$PKP = \begin{bmatrix} <0.6,0.2,0.4> & <0.8,0.2,0.3> \\ <0.8,0.2,0.3> & <0.6,0.2,0.4> \end{bmatrix}\begin{bmatrix} <0.8,0.8,0.3> & <0.6,0.8,0.4> \\ <0.6,0.8,0.4> & <0.8,0.8,0.3> \end{bmatrix}$$

$$PKP = \begin{bmatrix} <0.6,0.2,0.4> & <0.8,0.2,0.3> \\ <0.8,0.2,0.3> & <0.6,0.2,0.4> \end{bmatrix}$$

Theorem:2 For Centrosymmetric NFM $Q \in F_n$, if Q^+ exists $\Leftrightarrow (KQ)^+$ exists.

Proof : For Centrosymmetric NFM $Q \in F_n$, if Q^+ exits then $Q^+ = Q^T$

$\Rightarrow Q^T$ is a generalized inverse of Q , then $QQ^TQ = Q \Rightarrow Q^TQQ^T = Q^T$

Therefore , Q^T is a {2} inverse of Q.
Since both QQ^T and Q^TQ are symmetric.

Hence $Q^+ = Q^T$

Q^+ exists $\Leftrightarrow QQ^TQ = Q$

Q^+ exists $\Leftrightarrow KQQ^TQ = KQ$

Q^+ exists $\Leftrightarrow (KQ)(KQ)^T(KQ) = KQ$ where $K^2 = I$

Q^+ exists $\Leftrightarrow (KQ) \in (KQ)\{1\}$

$\Leftrightarrow (KQ)^+$ exists

Example:3 Consider the IFM , $Q = \begin{bmatrix} <0.8,0.2,0.4> & <0.6,0.3,0.4> \\ <0.6,0.3,0.4> & <0.8,0.2,0.4> \end{bmatrix}$, $K = \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix}$

Theorem:3 If $P \in (NFM)_n$ is k-Centrosymmetric NFM, then K is a least square g- inverse of P.

Proof : It is enough to show
1.   PKP = P
2. $(PK)^T = PK$
By theorem (1) ,(i) is easily verified
Let $P \in (NFM)_n$ is K-centrosymmetric NFM

$P = KP^TK$
$PK = KP^TK.K$
$PK = KP^TK^2$ $(K^2 = I)$
$PK = KP^TI = KP^T$
$(PK)^T = K^TP^T = KP^T$ $(K^T = K)$
$(PK)^T = KP^T$
Therefore, $(PK)^T = PK$

Example:4 Let us consider the NFM, $P = \begin{bmatrix} <0.8,0.1,0.4> & <0.6,0.3,0.4> \\ <0.6,0.3,0.4> & <0.8,0.1,0.4> \end{bmatrix}$

79718

$$,K = \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix}$$

$$PK = \begin{bmatrix} <0.8,0.1,0.4> & <0.6,0.3,0.4> \\ <0.6,0.3,0.4> & <0.8,0.1,0.4> \end{bmatrix}\begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix} = \begin{bmatrix} <0.6,0.9,0.4> & <0.8,0.7,0.4> \\ <0.8,0.7,0.4> & <0.6,0.9,0.4> \end{bmatrix}$$

$$(PK)^T = \begin{bmatrix} <0.6,0.9,0.4> & <0.8,0.7,0.4> \\ <0.8,0.7,0.4> & <0.6,0.9,0.4> \end{bmatrix}$$

Theorem:4 If $P \in (NFM)_n$ is k-Centrosymmetric NFM, then K is a {1,4} generalized inverse of P.

Proof : It is enough to show

1.   PKP = P
2. $(KP)^T = KP$

By theorem (1) ,(i) is easily verified

Let $P \in (NFM)_n$ is K-Centrosymmetric matrix

P=KP^{T}K

K = K.KP^{T}K

KP = K^2 P^{T}K (K^2=I)

KP = IP^{T}K=P^{T}K

$(KP)^T$ = P^{T}K^T=P^{T}K   (K^T=K)

$(KP)^T$=P^{T}K

Therefore,$(KP)^T$=KP

Example:5 Consider the IFM, $P = \begin{bmatrix} <0.5,0.1,0.2> & <0.4,0.1,0.7> \\ <0.4,0.1,0.7> & <0.5,0.1,0.2> \end{bmatrix}, K = \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix}$

Centrosymmetric Neutrosophic Fuzzy Matrix

This part, depicts the Centrosymmetric of an NFM.

Lemma: 1 If P and Q are Centrosymmetric NFM over a field F, then P + Q, PQ, and cP are Centrosymmetric NFM for all c in F.

Proof: By using definition:1

Example:6 Consider   the   NFM $P = \begin{bmatrix} <0.6,0.2,0.4> & <0.8,0.2,0.3> \\ <0.8,0.2,0.3> & <0.6,0.2,0.4> \end{bmatrix}$

$$,Q = \begin{bmatrix} <0.8,0.8,0.3> & <0.6,0.8,0.4> \\ <0.6,0.8,0.4> & <0.8,0.8,0.3> \end{bmatrix}$$

$$P+Q = \begin{bmatrix} <0.6,0.2,0.4> & <0.8,0.2,0.3> \\ <0.8,0.2,0.3> & <0.6,0.2,0.4> \end{bmatrix} + \begin{bmatrix} <0.8,0.8,0.3> & <0.6,0.8,0.4> \\ <0.6,0.8,0.4> & <0.8,0.8,0.3> \end{bmatrix}$$

$$= \begin{bmatrix} <0.8,0.8,0.3> & <0.8,0.8,0.3> \\ <0.8,0.8,0.3> & <0.8,0.8,0.3> \end{bmatrix}$$

Therefore ,P+Q is centrosymmentric

$$PQ = \begin{bmatrix} <0.6,0.2,0.4> & <0.8,0.2,0.3> \\ <0.8,0.2,0.3> & <0.6,0.2,0.4> \end{bmatrix}\begin{bmatrix} <0.8,0.8,0.3> & <0.6,0.8,0.4> \\ <0.6,0.8,0.4> & <0.8,0.8,0.3> \end{bmatrix}$$

$$PQ = \begin{bmatrix} <0.6, 0.2, 0.4> & <0.8, 0.2, 0.3> \\ <0.8, 0.2, 0.3> & <0.6, 0.2, 0.4> \end{bmatrix}$$

Therefore, PQ is centrosymmentric

$$cA = <0,0,1> \begin{bmatrix} <0.7, 0.2, 0.3> & <0.4, 0.6, 0.5> \\ <0.4, 0.6, 0.5> & <0.7, 0.2, 0.3> \end{bmatrix} = \begin{bmatrix} <0, 0.8, 1> & <0, 0.4, 1> \\ <0, 0.4, 1> & <0, 0.8, 1> \end{bmatrix}$$

Therefore ,cP is centrosymmentric

K-Centrosymmetric Neutrosophic Fuzzy Matrix
This part, depicts the K- Centrosymmetric matrices of an NFM.

Theorem: 5 Let $P \in (NFM)_n$ is k-Centrosymmetric NFM then $P^T = KPK$.

Proof: Let $P \in (NFM)_n$ is k-Centrosymmetric NFM

K PK = KP^TK where $P = P^T$
= P^TKK where $KP^T = P^TK$
= $P^TK^2 = P^T$

Example:7 Consider the IFM $P = \begin{bmatrix} <0.7, 0.2, 0.4> & <0.4, 0.2, 0.5> \\ <0.4, 0.2, 0.5> & <0.7, 0.2, 0.4> \end{bmatrix}$, $K = \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix}$

$$AK = \begin{bmatrix} <0.7, 0.2, 0.4> & <0.4, 0.2, 0.5> \\ <0.4, 0.2, 0.5> & <0.7, 0.2, 0.4> \end{bmatrix}\begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix} = \begin{bmatrix} <0.4, 0.8, 0.5> & <0.7, 0.8, 0.4> \\ <0.7, 0.8, 0.4> & <0.4, 0.8, 0.5> \end{bmatrix}$$

$$KAK = \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix}\begin{bmatrix} <0.4, 0.8, 0.5> & <0.7, 0.8, 0.4> \\ <0.7, 0.8, 0.4> & <0.4, 0.8, 0.5> \end{bmatrix} = \begin{bmatrix} <0.7, 0.2, 0.4> & <0.4, 0.2, 0.5> \\ <0.4, 0.2, 0.5> & <0.7, 0.2, 0.4> \end{bmatrix}$$

$$KAK = A^T$$

Theorem: 6 If P,Q are both k-Centro symmetric NFM , then PQ is as well.

Proof : P and Q are both k-Centro symmetric NFM if P = KP^TK and Q = KQ^TK.
We know that, P^T and Q^T are also k-Centro symmetric NFM then P^T = K PK & Q^T = KQK.
To prove PQ is k-Centro symmetric NFM
It's enough to show, PQ= K(PQ)^{T}K
Now K(PQ)^{T}K   = KQ^TP^TK
= K[(KQK)(KPK)]K   where , P^T = KPK and Q^T = KQK
= K^2 QK^{2}P K^2Properties of K- Centro Symmetric NFM,
=QP   Where K^2= I
=PQ Where, PQ=QP

Example:8 Consider the NFM, $P = \begin{bmatrix} <0.8, 0.2, 0.4> & <0.6, 0.4, 0.2> \\ <0.6, 0.4, 0.2> & <0.8, 0.2, 0.4> \end{bmatrix}$, $K = \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix}$ and

$$B = \begin{bmatrix} <0.6, 0.4, 0.5> & <0.7, 0.3, 0.6> \\ <0.7, 0.3, 0.6> & <0.6, 0.4, 0.5> \end{bmatrix}$$

$$PQ = \begin{bmatrix} <0.8, 0.2, 0.4> & <0.6, 0.4, 0.2> \\ <0.6, 0.4, 0.2> & <0.8, 0.2, 0.4> \end{bmatrix}\begin{bmatrix} <0.6, 0.4, 0.5> & <0.7, 0.3, 0.6> \\ <0.7, 0.3, 0.6> & <0.6, 0.4, 0.5> \end{bmatrix}$$

$$= \begin{bmatrix} <0.6,0.6,0.5> & <0.7,0.7,0.6> \\ <0.7,0.7,0.6> & <0.6,0.6,0.5> \end{bmatrix}$$

$$(PQ)^T = \begin{bmatrix} <0.6,0.6,0.5> & <0.7,0.7,0.6> \\ <0.7,0.7,0.6> & <0.6,0.6,0.5> \end{bmatrix}$$

$$(PQ)^T K = \begin{bmatrix} <0.6,0.6,0.5> & <0.7,0.7,0.6> \\ <0.7,0.7,0.6> & <0.6,0.6,0.5> \end{bmatrix} \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix}$$

$$= \begin{bmatrix} <0.7,0.4,0.6> & <0.6,0.3,0.5> \\ <0.6,0.3,0.5> & <0.7,0.4,0.6> \end{bmatrix}$$

$$K(PQ)^T K = \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix} \begin{bmatrix} <0.7,0.4,0.6> & <0.6,0.3,0.5> \\ <0.6,0.3,0.5> & <0.7,0.4,0.6> \end{bmatrix}$$

$$= \begin{bmatrix} <0.6,0.6,0.5> & <0.7,0.7,0.6> \\ <0.7,0.7,0.6> & <0.6,0.6,0.5> \end{bmatrix}$$

$$K(PQ)^T K = PQ$$

Theorem: 7 If $P \in (NFM)$ is k-Centrosymmetric NFM then PP^T is likewise k-Centrosymmetric NFM.

Proof : Let $P \in (NFM)_n$ is said to be k-Centrosymmetric NFM, then P= KP^{T}K

If P^T also k-centrosymmetric NFM then P^T = KPK
To prove that, PP^T = K(PP^T)^{T}K
 K(PP^T)^{T}K   = K[(P^T)^T P^T]K
                         =K[(PP^T)]K
=(PP^T)K.K
 =(PP^T)K^2 Where ,K^2 = I
=PP^T

Example:9 Consider the NFM, $P = \begin{bmatrix} <0.4,0.2,0.3> & <0.2,0.4,0.5> \\ <0.2,0.4,0.5> & <0.4,0.2,0.3> \end{bmatrix}, K = \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix}$

$$PP^T = \begin{bmatrix} <0.4,0.2,0.3> & <0.2,0.4,0.5> \\ <0.2,0.4,0.5> & <0.4,0.2,0.3> \end{bmatrix} \begin{bmatrix} <0.4,0.2,0.3> & <0.2,0.4,0.5> \\ <0.2,0.4,0.5> & <0.4,0.2,0.3> \end{bmatrix}$$

$$= \begin{bmatrix} <0.4,0.4,0.3> & <0.2,0.6,0.5> \\ <0.2,0.6,0.5> & <0.4,0.4,0.3> \end{bmatrix}$$

$$(PP^T)^T = \begin{bmatrix} <0.4,0.4,0.3> & <0.2,0.6,0.5> \\ <0.2,0.6,0.5> & <0.4,0.4,0.3> \end{bmatrix}$$

$$(PP^T)^T K = \begin{bmatrix} <0.4,0.4,0.3> & <0.2,0.6,0.5> \\ <0.2,0.6,0.5> & <0.4,0.4,0.3> \end{bmatrix} \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix}$$

$$= \begin{bmatrix} <0.2,0.6,0.5> & <0.4,0.4,0.3> \\ <0.4,0.4,0.3> & <0.2,0.6,0.5> \end{bmatrix}$$

$$K\left(PP^{\mathrm{T}}\right)^{\mathrm{T}} \mathrm{K} = \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix} \begin{bmatrix} <0.2,0.6,0.5> & <0.4,0.4,0.3> \\ <0.4,0.4,0.3> & <0.2,0.6,0.5> \end{bmatrix}$$

$$K\left(PP^{\mathrm{T}}\right)^{\mathrm{T}} \mathrm{K} = \begin{bmatrix} <0.4,0.4,0.3> & <0.2,0.6,0.5> \\ <0.2,0.6,0.5> & <0.4,0.4,0.3> \end{bmatrix}$$

$$\mathrm{K}\left(PP^{\mathrm{T}}\right)^{\mathrm{T}} \mathrm{K} = PP^{\mathrm{T}}$$

Note: If $P \in (NFM)_n$ is k-Centrosymmetric NFM then P^2 is also k-centrosymmetric NFM.

Theorem:8 If $P \in (NFM)_n$ is k-centrosymmetric NFM then $P + P^{\mathrm{T}}$ is also k-centrosymmetric NFM.

Proof : Let $P \in (NFM)_n$ is said to be k-Centrosymmetric NFM, then P= K P^{T}K

If P^{T} also k-centrosymmetric NFM, then $P^{\mathrm{T}} = KPK$
To prove that , $P + P^{\mathrm{T}} = K(P + P^{\mathrm{T}})^{\mathrm{T}}K$
$K(P + P^{\mathrm{T}})^{\mathrm{T}}K = K(P^{\mathrm{T}} + (P^{\mathrm{T}})^{\mathrm{T}})K$
$= K(P^{\mathrm{T}} + P)K$
$= (P^{\mathrm{T}} + P)K.K$
   $= (P^{\mathrm{T}} + P)K^2$ Where , $K^2 = I$
 $= (P^{\mathrm{T}} + P) = (P + P^{\mathrm{T}})$

Note: If $P \in (NFM)$ is k-centrosymmetric NFM then $A - A^{\mathrm{T}}$ is likewise k-centrosymmetric NFM.

Example:10 Consider the NFM, $P = \begin{bmatrix} <0.8,0.2,0.6> & <0.2,0.4,0.7> \\ <0.2,0.4,0.7> & <0.8,0.2,0.6> \end{bmatrix}, K = \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix}$

Theorem:9 If P and Q are k-Centrosymmetric NFM then P+Q is also k-Cetrosymmetric NFM.

Proof : If both P and Q are k-centrosymmetric NFM if P= $KP^{\mathrm{T}}K$ & Q= $KQ^{\mathrm{T}}K$
Since P^{T} and Q^{T} are also k-Centro symmetric NFM then $P^{\mathrm{T}} = KPK$ and $Q^{\mathrm{T}} = KQK$.
To show that P+Q is k-centrosymmetric NFM matrix
To prove that , P+Q= $K(P+Q)^{\mathrm{T}}K$
Now $K(P+Q)^{\mathrm{T}}K = K(P^{\mathrm{T}} + Q^{\mathrm{T}})K$
$= KP^{\mathrm{T}}K + KQ^{\mathrm{T}}K = P+Q$

Example:11   Consider   the NFM,   P $= \begin{bmatrix} <0.7,0.2,0.3> & <0.6,0.2,0.4> \\ <0.6,0.2,0.4> & <0.7,0.2,0.3> \end{bmatrix}$

$, B = \begin{bmatrix} <0.4,0.2,0.6> & <0.5,0.3,0.4> \\ <0.5,0.3,0.4> & <0.4,0.2,0.6> \end{bmatrix}$

$A + B = \begin{bmatrix} <0.7,0.2,0.3> & <0.6,0.2,0.4> \\ <0.6,0.2,0.4> & <0.7,0.2,0.3> \end{bmatrix} + \begin{bmatrix} <0.4,0.2,0.6> & <0.5,0.3,0.4> \\ <0.5,0.3,0.4> & <0.4,0.2,0.6> \end{bmatrix}$

$= \begin{bmatrix} <0.7,0.2,0.3> & <0.6,0.3,0.4> \\ <0.6,0.3,0.4> & <0.7,0.2,0.3> \end{bmatrix}$

Murugadas and Shyamaladevi

$$(A+B)^T K = \begin{bmatrix} <0.7,0.2,0.3> & <0.6,0.3,0.4> \\ <0.6,0.3,0.4> & <0.7,0.2,0.3> \end{bmatrix} \begin{bmatrix} <0,0,1> & <1,1,0> \\ <1,1,0> & <0,0,1> \end{bmatrix}$$

$$(A+B)^T K = \begin{bmatrix} <0.6,0.3,0.4> & <0.7,0.2,0.3> \\ <0.7,0.2,0.3> & <0.6,0.3,0.4> \end{bmatrix}$$

$$K(A+B)^T K = \begin{bmatrix} <0.7,0.2,0.3> & <0.6,0.3,0.4> \\ <0.6,0.3,0.4> & <0.7,0.2,0.3> \end{bmatrix}$$

$$K(P+Q)^T K = P+Q$$

Note: If P and Q are k-Centrosymmetric NFM then P-Q is also k-Cetrosymmetric NFM.

Theorem:10 If P is k-Centrosymmetric NFM and K is the NFPM , k=(1 2) then KP is also k-cento symmentric NFM.

Proof: An NFM $P \in (NFM)_n$ is said to be k-Centrosymmetric NFM if $P = KP^T K$

Since P^T is also k-Centrosymmetric NFM if $P^T = KPK$
To show that KP is k-Centrosymmetric NFM
It's enough to show , $KP = K(KP)^T K$

$$K(KP)^T K = K(P^T K^T) K$$
$$= KP^T \qquad (K^T K = I)$$
$$= KP$$

CONCLUSION

We introduced the concept of Centrosymmetric and k– Centrosymmetric NFMs. We also described a method for finding the g-inverse of a Centrosymmetric and k– Centrosymmetric NFM, which emphasis the fundamental principles and theorems of Centrosymmetric and k– Centrosymmetric NNFMs, as well as examples.

ABSTRACT

The characterization of interval valued secondary k- column symmetric Neutrosophic fuzzy matrices have been examined in this study with an example. It is discussed how interval valued s-k column symmetric , s- column symmetric, interval valued k- column symmetric, and interval valued column symmetric matrices relate to one another. We establish the necessary and sufficient criteria for IV s-k column symmetric Neutrosophic fuzzy matrices. The existence of several generalized inverses of a matrix in interval valued Neutrosophic fuzzy matrices. It is also established what are the equivalent criteria for various g-inverses of an interval valued $s-\kappa$ column symmetric fuzzy matrix to be an interval valued $s-\kappa$ column symmetric. The generalized inverses of an interval valued $s-\kappa$ column symmetric P corresponding to the sets P$\{1, 2\}$, P$\{1, 2, 3\}$ and P$\{1, 2, 4\}$ are characterized.

Keywords: Interval valued Neutrosophic Fuzzy matrix,Interval valued column symmetric Neutrosophic fuzzymatrix, s-k-column symmetric Interval valued Neutrosophic fuzzymatrix.

INTRODUCTION

Matrices are crucial in many fields of research in science and engineering. The traditional matrix theory is unable to address problems involving numerous kinds of uncertainties. Zadeh [1] has studied fuzzy set . The traditional fuzzy

sets are characterized by the membership value or the grade of membership value. Some- times it may be very difficult to assign the membership value for fuzzy sets. An intuitionistic fuzzy set introduced by Atanassov [2] is appropriate for such a situation. The intuitionistic fuzzy sets can only handle incomplete information considering both the truth membership (and simply membership) and falsity-membership (or nonmembership) values. It does not handle the indeterminate and inconsistent information which exists in belief system. Smarandache [3] introduced the concept of neutrosophic set which is a mathematical tool for handling problems involving imprecise, indeterminacy and inconsistent data. Fuzzy matrices are used to solve certain kinds of issues. Many researchers have since completed numerous works. Only membership values are addressed by fuzzy matrices. These matrices cannot handle values that are not membership. Khan, Shyamal, and Pal [4] have studied intuitionistic fuzzy matrices (IFMs) for the first time. Atanassov [5,6] has discussed IFS and Operations over IV IFS. Hashimoto [7] has studied Canonical form of a transitive matrix. Kim and Roush [8] have studied generalized fuzzy matrices. Lee [9] has studied Secondary Skew Symmetric, Secondary Orthogonal Matrices. Hilland Waters [10] have analyzed Onk-Realandk-Hermitian matrices. Meenakshi [11] has studied Fuzzy Matrix: Theory and Applications. Meenakshi andJayaShree [12] have studied Onk-kernelsymmetricmatrices. Meenakshi and Krishanmoorthy [13] have characterized On Secondary k-Hermitian matrices. Meenakshi and JayaShree [14] have studied On K -rangesymmetricmatrices. Jaya shree [15] has studied Secondary κ-Kernel Symmetric Fuzzy Matrices. Shyamal and Pal [16] Interval valued Fuzzy matrices. Meenakshi and Kalliraja [17] have studied Regular Interval valued Fuzzy matrices. But, practically it is difficult to measure the membership or non-membership value as a point. Anandhkumar [18,19] has studied Pseudo Similarity of Neutrosophic Fuzzy matrices and On various Inverse of Neutrosophic Fuzzy Matrices. Anandhkumar [20] has studied Kernal and k-kernal Intuitionistic Fuzzy matrices. Punithavalli and Anandhkumar [21] have studied Reverse Sharp and Left-T And Right- T Partial Ordering on Intuitionistic Fuzzy matrices. Pal and SusantaKha [22] have studied IV Intuitionistic Fuzzy Matrices. Vidhya and Irene Hepzibah [23] have discussed on Interval Valued Neutrosophic Fuzzy Matrices. So, we consider the membership value as an interval and also in the case of non-membership values, it is not selected as a point, it can be considered as an interval .Here, we introduce the IV Secondaryk-range Symmetric Neutrosophic FuzzyMatrices and introduce some basic operators on IVNFMs.

Research Gap

As mentioned in the above introduction section, Jayashri introduced the concept of k- RS Fuzzy Matrices and Meenakshi and Jayashri developed the notion of kernel symmetric in fuzzy matrices. Here, we have applied the concept of IV Secondary k-CS Neutrosophic FuzzyMatrices (IVNFM). This concept plays a significant role in hybrid fuzzy structure and we have applied the same in NFM and studied some of the results in detail. First we present equivalent characterizations of Secondary k-CSNeutrosophic fuzzy matrices. Finally we give the example of Secondary k- CS Neutrosophic fuzzy matrix.We discussed various g-inverse associated with a regular matrices and obtain characterization of set of all inverses by using Secondary s-k- CS Neutrosophic matrices.

Notations

IVNFM = Interval valued Neutrosophic Fuzzy Matrix,

IV =Interval valued, CS = Column Symmetric

$[P_\mu, P_\lambda, P_\nu]_L^T$ = Transpose of the IVNFM $[P_\mu, P_\lambda, P_\nu]_L$,

$[P_\mu, P_\lambda, P_\nu]_U^T$ = Transpose of the IVNFM $[P_\mu, P_\lambda, P_\nu]_U$,

$[P_\mu, P_\lambda, P_\nu]_L^+$ = Moore-Penrose inverse of IVNFM $[P_\mu, P_\lambda, P_\nu]_L$,

$[P_\mu, P_\lambda, P_\nu]_U^+$ = Moore-Penrose inverse of IVNFM $[P_\mu, P_\lambda, P_\nu]_U$,

$R\left([P_\mu, P_\lambda, P_\nu]_L\right)$ = Row space of $[P_\mu, P_\lambda, P_\nu]_L$

$R\left([P_\mu, P_\lambda, P_v]_U\right)=$ Row space of $[P_\mu, P_\lambda, P_v]_U$, $C\left([P_\mu, P_\lambda, P_v]_L\right)=$ Column space of $[P_\mu, P_\lambda, P_v]_L$, C $\left([P_\mu, P_\lambda, P_v]_U\right)=$ Column space of $[P_\mu, P_\lambda, P_v]_U$

Preliminaries and Definitions

Preliminary

If $\kappa(x)=(x_{k[1]}, x_{k[2]}, x_{k[3]},…, x_{k[n]})\in F_{n\times 1}$ for $x = x_1, x_2,..,x_n\in F_{[1\times n]},$ where K is involuntary, The corresponding Permutation matrix is satisfied using the conditions

$(P_{.2.1})KK^T=K^TK=I_n,$ $K=K^T, K^2 = I$

By the definition of V, and $R(x)=Kx$

$(P_{.2.2})$ $V=V^T,$ $VV^T=V^TV=I_n$ and $V^2=I$

$(P_{.2.3})C\left([P_\mu, P_\lambda, P_v]_L\right)= C\left([P_\mu, P_\lambda, P_v]_L\right)V, C\left([P_\mu, P_\lambda, P_v]_L\right)=C\left([P_\mu, P_\lambda, P_v]_L\right)K$

$\qquad C\left([P_\mu, P_\lambda, P_v]_U\right)=C\left([P_\mu, P_\lambda, P_v]_U\right)V, C\left([P_\mu, P_\lambda, P_v]_U\right)= C\left([P_\mu, P_\lambda, P_v]_U\right)K$

$(P_{.2.4})C\left([P_\mu, P_\lambda, P_v]_L V\right)^T = C\left(V[P_\mu, P_\lambda, P_v]_L{}^T\right), C\left(V[P_\mu, P_\lambda, P_v]_L\right)^T = C\left([P_\mu, P_\lambda, P_v]_L{}^T V\right)$

$\qquad C\left([P_\mu, P_\lambda, P_v]_U V\right)^T = C\left(V[P_\mu, P_\lambda, P_v]_U{}^T\right), C\left(V[P_\mu, P_\lambda, P_v]_U\right)^T = C\left([P_\mu, P_\lambda, P_v]_U{}^T V\right)$

Definition:2.1 IV Neutrosophic fuzzy matrix (IVNFM): An IV Neutrosophic fuzzy matrix P of order m×n is defined as P = $[x_{ij},<p_{ij\mu}, p_{ij\lambda}p_{ijv}>]_{m\times n}$ where $p_{ij\mu}$, $p_{ij\lambda}$ and p_{ijv} are the subsets of [0,1] which are denoted by $p_{ij\mu} = [p_{ij\mu L}, p_{ij\mu U}],$ $p_{ij\lambda}= [p_{ij\lambda L}, p_{ij\lambda U}]$ and $p_{ijv} = [p_{ijv L}, p_{ijv U}]$ which maintaining the condition $0\le p_{ij\mu U} + p_{ij\lambda U}+ p_{ijv U} \le 3,$ $0\le p_{ij\mu L} + p_{ij\lambda L}+ p_{ijv L} \le 3$, $0 \le p_{\mu L} \le p_{\mu U} \le 1, 0 \le p_{\lambda L} \le p_{\lambda U} \le 1, 0 \le p_{v L} \le p_{v U} \le 1$ for $i = 1,2,\cdots,m$ and $j = 1,2,\cdots,n.$

Example2.1 Consider an IV Neutrosophic Fuzzy Matrix

$$P = \begin{bmatrix} <[0,0],[1,1],[1,1]> & <[0.1,0.3],[0.2,0.4],[0.2,0.5]> \\ <[0.1,0.3],[0.2,0.4],[0.2,0.5]> & <[0,0],[1,1],[1,1]> \end{bmatrix}$$

Lower Limit NFM, $[P_\mu, P_\lambda, P_v]_L = \begin{bmatrix} <0,1,1> & <0.1,0.2,0,2> \\ <0.1,0.2,0.2> & <0,1,1> \end{bmatrix}$

Upper Limit NFM, $[P_\mu, P_\lambda, P_v]_U = \begin{bmatrix} <0,1,1> & <0.3,0.4,0.5> \\ <0.3,0.4,0.5> & <0,1,1> \end{bmatrix}$

and $Q = \begin{bmatrix} <[0,0],[1,1],[1,1]> & <[0.2,0.4],[0.3,0.5],[0.1,0.5]> \\ <[0.2,0.4],[0.3,0.5],[0.1,0.5]> & <[0,0],[1,1],[1,1]> \end{bmatrix}$

Then, $P+Q = \begin{bmatrix} <[0,0],[1,1],[1,1]> & <[0.2,0.4],[0.2,0.4],[0.1,0.5]> \\ <[0.2,0.4],[0.2,0.4],[0.1,0.5]> & <[0,0],[1,1],[1,1]> \end{bmatrix}$

$Q = \begin{bmatrix} <[0,0],[1,1],[1,1]> & <[0.1,0.3],[0.3,0.5],[0.2,0.5]> \\ <[0.1,0.3],[0.3,0.5],[0.2,0.5]> & <[0,0],[1,1],[1,1]> \end{bmatrix}$

$|P| = <[0,0],[1,1],[1,1]> <[0,0],[1,1],[1,1]> + <[0.1,0.3],[0.2,0.4],[0.2,0.5]> <[0.1,0.3],[0.2,0.4],[0.2,0.5]>$

$|P| = <[0,0],[1,1],[1,1]> + <[0.1,0.3],[0.2,0.4],[0.2,0.5]> = <[0.1,0.3],[0.2,0.4],[0.2,0.5]>$

Definition2.2. For IV Neutrosophic fuzzymatrix P is CS fuzzy matrix iff $C\left([P_\mu, P_\lambda, P_v]_L\right)=$

$C\left([P_\mu,P_\lambda,P_v]_L^T\right)$ and $C\left([P_\mu,P_\lambda,P_v]_U\right) = C\left([P_\mu,P_\lambda,P_v]_U^T\right)$.

Lemma2.1. For a matrix A belongs to F_n and a permutation fuzzy matrix P, R(A) = R(B) iff $R(PAQ^T)=R(PAQ^T)$.

Lemma2.2. For interval valued fuzzy matrix $P=KP^TK$ iff $KP=(KP)(KP)^T(KP)$, IV fuzzymatrix $\Leftrightarrow$ PK=(PK)(PK)^T(PK)IV fuzzymatrix.

Interval valued Secondary k-CS Neutrosophic fuzzy matrix

Definition3.1. For a Neutrosophic fuzzymatrix $P =< [P_\mu,P_\lambda,P_v]_L, [P_\mu,P_\lambda,P_v]_U > \in \mathrm{IVNFM}_{nn}$

is an IV s - symmetric fuzzymatrixiff $[P_\mu,P_\lambda,P_v]_L = V\left([P_\mu,P_\lambda,P_v]_L^T\right)V$ and $[P_\mu,P_\lambda,P_v]_U$

$= V\left([P_\mu,P_\lambda,P_v]_U^T\right)V$.

Definition3.2 For a Neutrosophic fuzzymatrix $P =< [P_\mu,P_\lambda,P_v]_L,[P_\mu,P_\lambda,P_v]_U > \in \mathrm{IVNFM}_{nn}$ is an IV s- CS fuzzymatrix iff

$$C\left([P_\mu,P_\lambda,P_v]_L\right) = C\left(V[P_\mu,P_\lambda,P_v]_L^T V\right),\ C\left([P_\mu,P_\lambda,P_v]_U\right) = C\left(V[P_\mu,P_\lambda,P_v]_U^T V\right).$$

Definition3.3. For a Neutrosophic fuzzymatrix $A =< [P_\mu,P_\lambda,P_v]_L, [P_\mu,P_\lambda,P_v]_U >$ is an IVs-k- CS fuzzymatrix iff

$$C\left([P_\mu,P_\lambda,P_v]_L\right) = C\left(KV[P_\mu,P_\lambda,P_v]_L^T VK\right),\ C\left([P_\mu,P_\lambda,P_v]_U\right) = C\left(KV[P_\mu,P_\lambda,P_v]_U^T VK\right).$$

Lemma3.1. For a Neutrosophic fuzzymatrix $P =< [P_\mu,P_\lambda,P_v]_L, [P_\mu,P_\lambda,P_v]_U > \in \mathrm{IVNFM}_{mn}$ is an IV s- CS Neutrosophic fuzzymatrix $\Leftrightarrow$ VA $=< V[P_\mu,P_\lambda,P_v]_L, V[P_\mu,P_\lambda,P_v]_U >$ IV CS Neutrosophic fuzzymatrix $\Leftrightarrow$ AV $=< [P_\mu,P_\lambda,P_v]_L V, [P_\mu,P_\lambda,P_v]_U V >$ is an IV CS Neutrosophic fuzzymatrix.

Proof. Let Neutrosophic fuzzymatrix $P =< [P_\mu,P_\lambda,P_v]_L,[P_\mu,P_\lambda,P_v]_U > \in \mathrm{IVNFM}_{nn}$ is s-CS fuzzymatrix

$\Leftrightarrow C\left([P_\mu,P_\lambda,P_v]_L\right) = C\left(V[P_\mu,P_\lambda,P_v]_L^T V\right)$ *[Definition3.2]*

$\Leftrightarrow C\left([P_\mu,P_\lambda,P_v]_L V\right) = C\left([P_\mu,P_\lambda,P_v]_L V\right)^T$

$\Leftrightarrow [P_\mu,P_\lambda,P_v]_L V$ is CS.   *[ByP.2.2]*

$\Leftrightarrow C\left(V[P_\mu,P_\lambda,P_v]_L VV^T\right) = C\left(VV[P_\mu,P_\lambda,P_v]_L^T V\right)$

$\Leftrightarrow C\left(V[P_\mu,P_\lambda,P_v]_L\right) = C\left(V[P_\mu,P_\lambda,P_v]_L\right)^T$

$\Leftrightarrow V[P_\mu,P_\lambda,P_v]_L$ is CS.

Similar manner

$\Leftrightarrow C\left([P_\mu,P_\lambda,P_v]_U\right) = C\left(V[P_\mu,P_\lambda,P_v]_U^T V\right)$

$$\Leftrightarrow C\left([\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_v]_U\,\mathrm{V}\right)=C\left([\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_v]_U V\right)^T$$

$$\Leftrightarrow [\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_v]_U\,\mathrm{V}\ is\ CS.$$

$$\Leftrightarrow C\left(\mathrm{V}[\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_v]_U\,\mathrm{V}\mathrm{V}^T\right)=C\left(VV[\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_v]_U{}^T V\right)$$

$$\Leftrightarrow C\left(\mathrm{V}[\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_v]_U\right)=C\left(\mathrm{V}[\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_v]_U\right)^T$$

$$\Leftrightarrow \mathrm{V}[\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_v]_U\ isCS.$$

Therefore, $\mathrm{VP}=<V[\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_v]_L, \mathrm{V}[\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_v]_U>$ is an IV symmetric.

Example3.1 Let us consider IV NFM

$$P=\begin{bmatrix} <[0,0],[1,1],[1,1]> & <[0.1,0.3],[0.2,0.4],[0.2,0.5]> \\ <[0.1,0.3],[0.2,0.4],[0.2,0.5]> & <[0,0],[1,1],[1,1]> \end{bmatrix}$$

Lower Limit NFM, $[\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_v]_L=\begin{bmatrix} <0,1,1> & <0.1,0.2,0,2> \\ <0.1,0.2,0.2> & <0,1,1> \end{bmatrix}$,

Upper Limit NFM, $[\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_v]_U=\begin{bmatrix} <0,1,1> & <0.3,0.4,0.5> \\ <0.3,0.4,0.5> & <0,1,1> \end{bmatrix}$

$$V=\begin{bmatrix} <0,0,0> & <1,1,0> \\ <1,1,0> & <0,0,0> \end{bmatrix},\ \mathrm{K}=\begin{bmatrix} <1,1,0> & <0,0,0> \\ <0,0,0> & <1,1,0> \end{bmatrix},$$

$$KVP_L{}^T VK=\begin{bmatrix} <1,1,0> & <0,0,0> \\ <0,0,0> & <1,1,0> \end{bmatrix}\begin{bmatrix} <0,0,0> & <1,1,0> \\ <1,1,0> & <0,0,0> \end{bmatrix}\begin{bmatrix} <0,1,1> & <0.1,0.2,0,2> \\ <0.1,0.2,0.2> & <0,1,1> \end{bmatrix}$$

$$\begin{bmatrix} <0,0,0> & <1,1,0> \\ <1,1,0> & <0,0,0> \end{bmatrix}\begin{bmatrix} <1,1,0> & <0,0,0> \\ <0,0,0> & <1,1,0> \end{bmatrix}$$

$$KVP_L{}^T VK=\begin{bmatrix} <0,1,0.2> & <0,0.2,0.2> \\ <0.1,0.2,0.2> & <0,1,0.2> \end{bmatrix}$$

$$KVP_L{}^T VK\neq P_L$$

Similarly, $KVP_U{}^T VK\neq P_U$

$$P_L=KP_LK$$

$$KP_LK=\begin{bmatrix} <1,1,0> & <0,0,0> \\ <0,0,0> & <1,1,0> \end{bmatrix}\begin{bmatrix} <0,1,1> & <0.1,0.2,0,2> \\ <0.1,0.2,0.2> & <0,1,1> \end{bmatrix}\begin{bmatrix} <1,1,0> & <0,0,0> \\ <0,0,0> & <1,1,0> \end{bmatrix}$$

$$KP_LK=\begin{bmatrix} <0,1,0.2> & <0.1,0.2,0.2> \\ <0.1,0.2,0.2> & <0.1,1,0.2> \end{bmatrix}\neq P_L$$

Similarly, $P_U\neq KP_UK$

N (P$_L$) = $N(KVP_L{}^T VK)=<0,0,0>$

Therefore P is symmetric NFM, Column symmetric NFM, kernel symmetric, but not both κ–symmetric and s-κ-symmetric NFM.

Example2.2. Let us consider IV NFM,

$$P = \begin{bmatrix} <[0.7,0.2],[0.3,0.4],[0.4,0.6]> & <[0.5,0.4],[0.3,0.3],[0.4,0.2]> \\ <[0.5,0.4],[0.3,0.3],[0.4,0.2]> & <[0.7,0.2],[0.3,0.4],[0.4,0.6]> \end{bmatrix} V$$

$$= \begin{bmatrix} <0,0,0> & <1,1,0> \\ <1,1,0> & <0,0,0> \end{bmatrix}, K = \begin{bmatrix} <1,1,0> & <0,0,0> \\ <0,0,0> & <1,1,0> \end{bmatrix},$$

Lower Limit NFM, $P_L = \begin{bmatrix} <0.7,0.3,0.4> & <0.5,0.3,0.4> \\ <0.5,0.3,0.4> & <0.7,0.3,0.4> \end{bmatrix},$

Upper Limit NFM, $P_U = \begin{bmatrix} <0.2,0.4,0.6> & <0.4,0.3,0.2> \\ <0.4,0.3,0.2> & <0.2,0.4,0.6> \end{bmatrix}$

$$KVP_L{}^TVK = \begin{bmatrix} <1,1,0> & <0,0,0> \\ <0,0,0> & <1,1,0> \end{bmatrix}\begin{bmatrix} <0,0,0> & <1,1,0> \\ <1,1,0> & <0,0,0> \end{bmatrix}\begin{bmatrix} <0.7,0.3,0.4> & <0.5,0.3,0.4> \\ <0.5,0.3,0.4> & <0.7,0.3,0.4> \end{bmatrix}$$

$$\begin{bmatrix} <0,0,0> & <1,1,0> \\ <1,1,0> & <0,0,0> \end{bmatrix}\begin{bmatrix} <1,1,0> & <0,0,0> \\ <0,0,0> & <1,1,0> \end{bmatrix}$$

$$KVP_L{}^TVK = \begin{bmatrix} <0.7,0.3,0.4> & <0.5,0.3,0.4> \\ <0.5,0.3,0.4> & <0.7,0.3,0.4> \end{bmatrix} = P_L$$

P is symmetric, CS, s-κ-symmetric and hences-k-kernel symmetric.

Example2.3. Let us consider IV NFM

Lower limit NFM, $[P_\mu, P_\lambda, P_v]_L = \begin{bmatrix} <0,0,0> & <0,0,0> & <1,1,0> \\ <0.5,0.3,0.4> & <1,1,0> & <0,0,0> \\ <0.4,0.2,0.6> & <0.5,0.3,0.4> & <0,0,0> \end{bmatrix}$

$$K = \begin{bmatrix} <0,0,0> & <1,1,0> & <0,0,0> \\ <1,1,0> & <0,0,0> & <0,0,0> \\ <0,0,0> & <0,0,0> & <1,1,0> \end{bmatrix}, V = \begin{bmatrix} <0,0,0> & <0,0,0> & <1,1,0> \\ <0,0,0> & <1,1,0> & <0,0,0> \\ <1,1,0> & <0,0,0> & <0,0,0> \end{bmatrix}$$

$$KV = \begin{bmatrix} <0,0,0> & <1,1,0> & <0,0,0> \\ <1,1,0> & <0,0,0> & <0,0,0> \\ <0,0,0> & <0,0,0> & <1,1,0> \end{bmatrix}\begin{bmatrix} <0,0,0> & <0,0,0> & <1,1,0> \\ <0,0,0> & <1,1,0> & <0,0,0> \\ <1,1,0> & <0,0,0> & <0,0,0> \end{bmatrix}$$

$$KV = \begin{bmatrix} <0,1,0> & <0,1,0> & <0,1,0> \\ <0,1,0> & <0,1,0> & <1,1,0> \\ <1,1,0> & <0,1,0> & <0,1,0> \end{bmatrix}$$

$$VK = \begin{bmatrix} <0,0,0> & <0,0,0> & <1,1,0> \\ <0,0,0> & <1,1,0> & <0,0,0> \\ <1,1,0> & <0,0,0> & <0,0,0> \end{bmatrix}\begin{bmatrix} <0,0,0> & <1,1,0> & <0,0,0> \\ <1,1,0> & <0,0,0> & <0,0,0> \\ <0,0,0> & <0,0,0> & <1,1,0> \end{bmatrix}$$

$$VK = \begin{bmatrix} <0,1,0> & <0,1,0> & <1,1,0> \\ <1,1,0> & <0,1,0> & <0,1,0> \\ <0,1,0> & <1,1,0> & <0,1,0> \end{bmatrix}$$

$$P_L{}^T VK = \begin{bmatrix} <0.5,0.8,0.4> & <0.4,0.8,0.6> & <0,0,0.4> \\ <0,0.7,0> & <0.5,0.7,0> & <0,0.7,0> \\ <0,0,0> & <0,0,0> & <1,0,0> \end{bmatrix}$$

$$KVP_L{}^T VK = \begin{bmatrix} <0,1,0> & <0,1,0> & <0,1,0> \\ <0,1,0> & <0,1,0> & <1,1,0> \\ <1,1,0> & <0,1,0> & <0,1,0> \end{bmatrix} \begin{bmatrix} <0.5,0.8,0.4> & <0.4,0.8,0.6> & <0,0,0.4> \\ <0,0.7,0> & <0.5,0.7,0> & <0,0.7,0> \\ <0,0,0> & <0,0,0> & <1,0,0> \end{bmatrix}$$

$$KVP_L{}^T VK = \begin{bmatrix} <0,0,0> & <0,0.2,0> & <0,0,0> \\ <0,0,0> & <0,0,0> & <1,0,0> \\ <0.5,0,0> & <0.4,0,0> & <0,0,0> \end{bmatrix} \neq P_L$$

$$P_L \neq KVP_L{}^T VK$$

Hence P is nots-k-symmetric and not RS. But s-k- kernel symmetric.
i.e) N(P_L)=N(KVP_L^T VK)= <0,0,0>

Theorem3.1. The following conditions are equivalent for $P \in \text{IVNFM}_n$

(i) $P = <[P_\mu, P_\lambda, P_v]_L, [P_\mu, P_\lambda, P_v]_U > \in \text{IVNFM}_{mn}$ is an IV s –κ CS.

(ii) $KVP = < KV[P_\mu, P_\lambda, P_v]_L, KV[P_\mu, P_\lambda, P_v]_U >$ is an IV CS.

(iii) $PKV = <[P_\mu, P_\lambda, P_v]_L KV, [P_\mu, P_\lambda, P_v]_U KV >$ is an IV CS.

(iv) $VP = <V[P_\mu, P_\lambda, P_v]_L, V[P_\mu, P_\lambda, P_v]_U >$ is an IV k- CS.

(v) $PK = <[P_\mu, P_\lambda, P_v]_L K, [P_\mu, P_\lambda, P_v]_U K >$ is an IV s- CS.

(vi)   P^T is an IV s-k CS.

(vii) $C([P_\mu, P_\lambda, P_v]_L) = (C[P_\mu, P_\lambda, P_v]_L{}^T VK), C([P_\mu, P_\lambda, P_v]_U) = (C[P_\mu, P_\lambda, P_v]_U{}^T VK)$

(viii) $C([P_\mu, P_\lambda, P_v]_L{}^T) = (C[P_\mu, P_\lambda, P_v]_L VK), C([P_\mu, P_\lambda, P_v]_U{}^T) = (C[P_\mu, P_\lambda, P_v]_U VK)$

(ix) $C(KV[P_\mu, P_\lambda, P_v]_L) = C(KV[P_\mu, P_\lambda, P_v]_L{}^T)^T, C(KV[P_\mu, P_\lambda, P_v]_U) = C(KV[P_\mu, P_\lambda, P_v]_U{}^T)^T$

As a conclusion (ii) $\Leftrightarrow$ (xiii) $\Leftrightarrow$ (x) is true

The above statement can be reduced to the equivalent requirement that a matrix be an IV s- RS for K = I in particular.

Corollary:3.1 The following statements are equivalent for $P \in \mathrm{IVNFM}_{nn}$

i. $P = <[P_\mu, P_\lambda, P_v]_L, [P_\mu, P_\lambda, P_v]_U > \in \mathrm{IVNFM}_{nn}$ is an IV s-CS.

ii. $VP = < V[P_\mu, P_\lambda, P_\nu]_L, V[P_\mu, P_\lambda, P_\nu]_U >$ is an IV CS.

iii. $PV = < [P_\mu, P_\lambda, P_\nu]_L V, [P_\mu, P_\lambda, P_\nu]_U V >$ is an IV CS.

iv. $P^T = < [P_\mu, P_\lambda, P_\nu]_L^T, [P_\mu, P_\lambda, P_\nu]_U^T >$ is an IV s – CS.

v. $C\left([P_\mu, P_\lambda, P_\nu]_L\right) = C\left([P_\mu, P_\lambda, P_\nu]_L^T V\right), C\left([P_\mu, P_\lambda, P_\nu]_U\right) = C\left([P_\mu, P_\lambda, P_\nu]_U^T V\right)$

vi. $C\left([P_\mu, P_\lambda, P_\nu]_L^T\right) = C\left([P_\mu, P_\lambda, P_\nu]_L V\right), C\left([P_\mu, P_\lambda, P_\nu]_U^T\right) = C\left([P_\mu, P_\lambda, P_\nu]_U V\right)$

vii. $C\left(KV[P_\mu, P_\lambda, P_\nu]_L\right) = C\left(V[P_\mu, P_\lambda, P_\nu]_L\right)^T, C\left(KV[P_\mu, P_\lambda, P_\nu]_U\right) = C\left(V[P_\mu, P_\lambda, P_\nu]_U\right)^T$

viii. $[P_\mu, P_\lambda, P_\nu]_L = V[P_\mu, P_\lambda, P_\nu]_L^T VH_1, [P_\mu, P_\lambda, P_\nu]_U = V[P_\mu, P_\lambda, P_\nu]_U^T VH_1$ for $H_1 \in IVNFM$

ix. $[P_\mu, P_\lambda, P_\nu]_L = H_1 V[P_\mu, P_\lambda, P_\nu]_L^T V, [P_\mu, P_\lambda, P_\nu]_U = H_1 V[P_\mu, P_\lambda, P_\nu]_U^T V$ for $H_1 \in IVNFM$

x. $[P_\mu, P_\lambda, P_\nu]_L^T = V[P_\mu, P_\lambda, P_\nu]_L VH_1, [P_\mu, P_\lambda, P_\nu]_U^T = V[P_\mu, P_\lambda, P_\nu]_U VH_1$ for $H_1 \in IVNFM$

xi. $[P_\mu, P_\lambda, P_\nu]_L^T = H_1 V[P_\mu, P_\lambda, P_\nu]_L V, [P_\mu, P_\lambda, P_\nu]_U = H_1 V[P_\mu, P_\lambda, P_\nu]_U V$ for $H_1 \in IVNFM$

Theorem 3.2. For $P = < [P_\mu, P_\lambda, P_\nu]_L, [P_\mu, P_\lambda, P_\nu]_U > \in IVNFM_{nn}$ then any two of the conditions below imply the other

i. $P = < [P_\mu, P_\lambda, P_\nu]_L, [P_\mu, P_\lambda, P_\nu]_U > \in IVNFM_{nn}$ is an IV κ- CS.

ii. $P = < [P_\mu, P_\lambda, P_\nu]_L, [P_\mu, P_\lambda, P_\nu]_U > \in IVNFM_{nn}$ is an IV s-κ- CS.

iii. $C\left([P_\mu, P_\lambda, P_\nu]_L\right)^T = C\left(VK[P_\mu, P_\lambda, P_\nu]_L\right)^T, C\left([P_\mu, P_\lambda, P_\nu]_U\right)^T = C\left(VK[P_\mu, P_\lambda, P_\nu]_U^T\right)$

Proof: (i) and (ii) implies (iii)

Let $P = < [P_\mu, P_\lambda, P_\nu]_L, [P_\mu, P_\lambda, P_\nu]_U > \in IVNFM_{nn}$ is an IV s –κ CS

$\Rightarrow C\left([P_\mu, P_\lambda, P_\nu]_L\right) = C\left([P_\mu, P_\lambda, P_\nu]_L^T VK\right), C\left([P_\mu, P_\lambda, P_\nu]_U\right) = C\left([P_\mu, P_\lambda, P_\nu]_U^T VK\right)$

[By Theorem 3.1]

$\Rightarrow C\left(K[P_\mu, P_\lambda, P_\nu]_L K\right) = C\left(K[P_\mu, P_\lambda, P_\nu]_L^T K\right), C\left(K[P_\mu, P_\lambda, P_\nu]_U K\right)$

$= C\left(K[P_\mu, P_\lambda, P_\nu]_U^T K\right)$ [By Lemma 2.2]

$\Rightarrow C[P_\mu, P_\lambda, P_\nu]_L^T = C\left(\left(VK[P_\mu, P_\lambda, P_\nu]_L\right)^T\right), C\left([P_\mu, P_\lambda, P_\nu]_U\right)^T = C\left(\left(VK[P_\mu, P_\lambda, P_\nu]_U\right)^T\right)$

(i) & (ii) implies (iii) is true

(i)& (iii) implies (ii)

$P = < [P_\mu, P_\lambda, P_\nu]_L, [P_\mu, P_\lambda, P_\nu]_U >$ is an IV κ- CS

$\Rightarrow C\left(K[P_\mu, P_\lambda, P_\nu]_L K\right) = C\left(\left([P_\mu, P_\lambda, P_\nu]_L\right)^T\right), C\left(K[P_\mu, P_\lambda, P_\nu]_U K\right) = C\left(\left([P_\mu, P_\lambda, P_\nu]_U\right)^T\right)$

Therefore, (i) & (iii)

$$\Rightarrow C\left([P_\mu, P_\lambda, P_\nu]_L\right) = C\left([P_\mu, P_\lambda, P_\nu]_L{}^T VK\right), C\left([P_\mu, P_\lambda, P_\nu]_U\right) = C\left([P_\mu, P_\lambda, P_\nu]_U{}^T VK\right)$$

$$\Rightarrow C\left([P_\mu, P_\lambda, P_\nu]_L\right) = C\left(\left(KV[P_\mu, P_\lambda, P_\nu]_L\right)^T\right), C\left([P_\mu, P_\lambda, P_\nu]_U\right) = C\left(\left(KV[P_\mu, P_\lambda, P_\nu]_U\right)^T\right)$$

$P = <[P_\mu, P_\lambda, P_\nu]_L, [P_\mu, P_\lambda, P_\nu]_U> \in \text{IVNFM}_{nn}$ is an IV s-k-CS   (By Theorem 3.1)

$\Rightarrow$ (ii) is true

(ii) & (iii) implies (i)

$P = <[P_\mu, P_\lambda, P_\nu]_L, [P_\mu, P_\lambda, P_\nu]_U> \in \text{IVNFM}_{nn}$ is an IV s- κ- CS

$$\Rightarrow C\left(K[P_\mu, P_\lambda, P_\nu]_L K\right) = C\left(K[P_\mu, P_\lambda, P_\nu]_L{}^T K\right), C\left(K[P_\mu, P_\lambda, P_\nu]_U K\right) = C\left(K[P_\mu, P_\lambda, P_\nu]_U{}^T K\right)$$

Therefore,(ii) and (iii)

$$\Rightarrow C\left([P_\mu, P_\lambda, P_\nu]_L\right) = C\left(K[P_\mu, P_\lambda, P_\nu]_L{}^T K\right), C\left([P_\mu, P_\lambda, P_\nu]_U\right) = C\left(K[P_\mu, P_\lambda, P_\nu]_U{}^T K\right)$$

$P = <[P_{\mu L}, P_{\lambda L}, P_{\nu L}], [P_\mu, P_\lambda, P_\nu]_U> \in \text{IVNFM}_{nn}$ is an IV κ- CS .

Therefore, (i) is true, Hence the theorem.

IV s −κ Column symmetric regular Neutrosophic fuzzy matrices

In this section, it was discovered that there are various generalized inverses of matrices in IVNFM. The comparable standards for different g-inverses of an IV s-k CS Neutrosophic fuzzy matrix to be IV s-k CS are also established. The generalized inverses of an IV s −κ CS P corresponding to the sets P{1, 2}, P{1, 2, 3} and P{1, 2, 4} are characterized.

Theorem 4.1: Let $P = <[P_\mu, P_\lambda, P_\nu]_L, [P_\mu, P_\lambda, P_\nu]_U> \in \text{IVNFM}_{nn}$, Z belongs to P{1,2} and PZ, ZP are an IV s- κ- CS.

Then P is an IV s- κ - CS iff $Z = <[Z_\mu, Z_\lambda, Z_\nu]_L, [Z_\mu, Z_\lambda, Z_\nu]_U>$ is an IV s- κ – CS.

Proof: Let $P = <[P_\mu, P_\lambda, P_\nu]_L, [P_\mu, P_\lambda, P_\nu]_U> \in \text{IVNFM}_{nn}$

$$C\left(KV[P_\mu, P_\lambda, P_\nu]_L\right) = C\left(KV[P_\mu, P_\lambda, P_\nu]_L Z[P_{\mu L}, P_{\lambda L}, P_{\nu L}]\right) \subseteq C\left(Z[P_\mu, P_\lambda, P_\nu]_L\right)$$

$$= C\left(ZVV[P_\mu, P_\lambda, P_\nu]_L\right) \subseteq C\left(ZVKKV[P_\mu, P_\lambda, P_\nu]_L\right) \subseteq C\left(KV[P_\mu, P_\lambda, P_\nu]_L\right)$$

Hence, $C\left(KV[P_\mu, P_\lambda, P_\nu]_L\right) = C\left(Z[P_\mu, P_\lambda, P_\nu]_L\right)$

$$= C\left(KV\left(Z[P_\mu, P_\lambda, P_\nu]_L\right)^T VK\right) \qquad\qquad [\text{ZP is IV s- κ-CS}]$$

$$= C\left([P_\mu, P_\lambda, P_\nu]_L{}^T[Z_\mu, Z_\lambda, Z_\nu]_L{}^T VK\right)$$

$$= C\left([Z_\mu, Z_\lambda, Z_\nu]_L{}^T VK\right) = C\left(\left(KV[Z_\mu, Z_\lambda, Z_\nu]_L\right)^T\right)$$

$$C\left(\left(KV[P_\mu, P_\lambda, P_\nu]_L\right)^T\right) = C\left([P_\mu, P_\lambda, P_\nu]_L{}^T VK\right)$$

$$= C\left(KV[P_\mu, P_\lambda, P_\nu]_L[Z_\mu, Z_\lambda, Z_\nu]_L\right) \quad [\text{ VP is s- κ − IV CS}]$$

$$= C\left(KV[Z_\mu, Z_\lambda, Z_\nu]_L\right)$$

Similarly,

Mageswari and Anitha

Hence, $C\left(KV[Z_\mu, Z_\lambda, Z_\nu]_U\right) = C\left(\left(KV[P_\mu, P_\lambda, P_\nu]_U\right)^T\right)$ (KVZ is an IV CS)

$\Leftrightarrow C\left(KV[P_\mu, P_\lambda, P_\nu]_L\right) = C\left(\left(KV[P_{\mu L}, P_{\lambda L}, P_{\nu L}]\right)^T\right), C\left(KV[P_\mu, P_\lambda, P_\nu]_U\right) = C\left(\left(KV[P_\mu, P_\lambda, P_\nu]_U\right)^T\right)$

$\Leftrightarrow C\left(KV[Z_\mu, Z_\lambda, Z_\nu]_L\right) = C\left(\left(KV[Z_\mu, Z_\lambda, Z_\nu]_L\right)^T\right),$

$C\left(KV[Z_\mu, Z_\lambda, Z_\nu]_U\right) = C\left(\left(KV[Z_\mu, Z_\lambda, Z_\nu]_U\right)^T\right)$

$\Leftrightarrow KVX = \left[KV[Z_\mu, Z_\lambda, Z_\nu]_L, KV[Z_\mu, Z_\lambda, Z_\nu]_U\right]$ is an IV CS

$Z = <[Z_\mu, Z_\lambda, Z_\nu]_L, [Z_\mu, Z_\lambda, Z_\nu]_U >$ is an IV CS.

Theorem 4.2:, Let $P = <[P_\mu, P_\lambda, P_\nu]_L, [P_\mu, P_\lambda, P_\nu]_U >$, $Z = <[Z_\mu, Z_\lambda, Z_\nu]_L, [Z_\mu, Z_\lambda, Z_\nu]_U > \in P\{1,2,3\}$,

$C(KV[P_\mu, P_\lambda, P_\nu]_L) = C\left(KV[X_{\mu L}, X_{\lambda L}, X_{\nu L}]\right)^T$,$C(KV[P_\mu, P_\lambda, P_\nu]_U) = C\left(KV[Z_{\mu U}, Z_{\lambda U}, Z_{\nu U}]\right)^T$ .Then

$P = <[P_\mu, P_\lambda, P_\nu]_L, [P_\mu, P_\lambda, P_\nu]_U > \in$ IVNFM$_{mn}$ is IV s-κ- CS $\Leftrightarrow$ $Z = <[Z_\mu, Z_\lambda, Z_\nu]_L, [Z_\mu, Z_\lambda, Z_\nu]_U >$ is IV s- κ – CS.

Proof: Given P$\{1,2,3\}$, Hence , $[P_\mu, P_\lambda, P_\nu]_L [Z_\mu, Z_\lambda, Z_\nu]_L [P_\mu, P_\lambda, P_\nu]_L = [P_\mu, P_\lambda, P_\nu]_L,$

$[Z_\mu, Z_\lambda, Z_\nu]_L [P_{\mu L}, P_{\lambda L}, P_{\nu L}][Z_\mu, Z_\lambda, Z_\nu]_L = [Z_\mu, Z_\lambda, Z_\nu]_L,$

$\left([P_\mu, P_\lambda, P_\nu]_L [Z_\mu, Z_\lambda, Z_\nu]_L\right)^T = [P_\mu, P_\lambda, P_\nu]_L [Z_\mu, Z_\lambda, Z_\nu]_L$

Consider, $C\left(\left(KV[P_\mu, P_\lambda, P_\nu]_L\right)^T\right)$ = $C\left([Z_\mu, Z_\lambda, Z_\nu]_L^T [P_\mu, P_\lambda, P_\nu]_L^T VK\right)$[By using P $=$ PZP]

$= C\left(KV\left([P_\mu, P_\lambda, P_\nu]_L [Z_\mu, Z_\lambda, Z_\nu]_L\right)^T\right)$

$= C\left(\left([P_\mu, P_\lambda, P_\nu]_L [Z_\mu, Z_\lambda, Z_\nu]_L\right)^T\right)$ $[By\ P._{2.3}]$

$= C\left([P_\mu, P_\lambda, P_\nu]_L [Z_\mu, Z_\lambda, Z_\nu]_L\right)$

$= C\left([Z_\mu, Z_\lambda, Z_\nu]_L\right)$

$\left[By\ using\ [Z_\mu, Z_\lambda, Z_\nu]_L = [Z_\mu, Z_\lambda, Z_\nu]_L [P_\mu, P_\lambda, P_\nu]_L [Z_\mu, Z_\lambda, Z_\nu]_L\right]$

$= R\left(KV[Z_\mu, Z_\lambda, Z_\nu]_L\right)$ $[By\ P_{2.3}]$

Similarly, we can consider, $C\left(\left(KV[P_\mu, P_\lambda, P_\nu]_U\right)^T\right)$ = $C\left([Z_\mu, Z_\lambda, Z_\nu]_U^T [P_\mu, P_\lambda, P_\nu]_U^T VK\right)$

$= C\left(KV\left([P_\mu, P_\lambda, P_\nu]_U [Z_\mu, Z_\lambda, Z_\nu]_U\right)^T\right) = C\left(\left([P_\mu, P_\lambda, P_\nu]_U [Z_\mu, Z_\lambda, Z_\nu]_U\right)^T\right)$ $[By\ P._{2.3}]$

$= C\left([P_\mu, P_\lambda, P_\nu]_U [Z_\mu, Z_\lambda, Z_\nu]_U\right)$ $\left[(PZ)^T = PZ\right]$

$= C\left([Z_\mu, Z_\lambda, Z_\nu]_U\right)$ [By using Z $=$ ZPZ]

$= C\left(KV[Z_\mu, Z_\lambda, Z_\nu]_U\right)$ [By $P_{2.3}$]

If KVA is an IV CS

$$\Leftrightarrow C\left(KV[\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_\nu]_L\right) \;=\; \mathrm{C}\left(\left(KV[\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_\nu]_L\right)^T\right),$$

$$C\left(KV[\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_\nu]_U\right) \;=\; \mathrm{C}\left(\left(KV[\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_\nu]_U\right)^T\right)$$

$$\Leftrightarrow C\left(KV[\mathrm{Z}_\mu,\mathrm{Z}_\lambda,\mathrm{Z}_\nu]_L\right) \;=\; \mathrm{C}\left(\left(KV[\mathrm{Z}_\mu,\mathrm{Z}_\lambda,\mathrm{Z}_\nu]_L\right)^T\right),\; KVX =[KV[\mathrm{Z}_\mu,\mathrm{Z}_\lambda,\mathrm{Z}_\nu]_L,KV[\mathrm{Z}_\mu,\mathrm{Z}_\lambda,\mathrm{Z}_\nu]_U]$$

is an IV CS.

$Z \;=< [\mathrm{Z}_\mu,\mathrm{Z}_\lambda,\mathrm{Z}_\nu]_L,[\mathrm{Z}_\mu,\mathrm{Z}_\lambda,\mathrm{Z}_\nu]_U >$ is an IV s-k CS.

Theorem 4.3: Let $P \;=< [\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_\nu]_L,[\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_\nu]_U >\in$ IVNFM$_{nn}$, Z $\in$ A {1, 2, 4}, $\mathrm{C}(KV[\mathrm{P}_\mu,\mathrm{P}_\lambda,\mathrm{P}_\nu]_L)^T$

Corollary 4.1: For $P = <[P_\mu, P_\lambda, P_\nu]_L, [P_{\mu U}, P_{\lambda U}, P_{\nu U}] > \in IVNFM_{nn}$, $Z \in$ P {1, 2} and

$PZ = <[P_\mu, P_\lambda, P_\nu]_L[Z_{\mu L}, Z_{\lambda L}, Z_{\nu L}], [P_\mu, P_\lambda, P_\nu]_U[Z_\mu, Z_\lambda, Z_\nu]_U>,$

$ZP = <[Z_\mu, Z_\lambda, Z_\nu]_L[P_\mu, P_\lambda, P_\nu]_L, [Z_\mu, Z_\lambda, Z_\nu]_U[P_\mu, P_\lambda, P_\nu]_U>,$ are is an IV s- CS. Then P is an IV s- CS iff

$Z = <[Z_\mu, Z_\lambda, Z_\nu]_L, [Z_\mu, Z_\lambda, Z_\nu]_U >$ is an IV s- CS.

Corollary 4.2: For $A = <[P_\mu, P_\lambda, P_\nu]_L, [P_\mu, P_\lambda, P_\nu]_U > \in IVNFM_{nn}$, $Z \in$ P {1, 2, 3}, $C(KV[P_\mu, P_\lambda, P_\nu]_L)$

$= C\left(V[Z_\mu, Z_\lambda, Z_\nu]_L\right)^T, C(KV[P_{\mu U}, P_{\lambda U}, P_{\nu U}]) = C\left(V[Z_\mu, Z_\lambda, Z_\nu]_U\right)^T.$

Then P is an IV s- CS iff $Z = <[Z_\mu, Z_\lambda, Z_\nu]_L, [Z_\mu, Z_\lambda, Z_\nu]_U >$ is an IV s- CS.

Corollary 4.3: For $P = <[P_\mu, P_\lambda, P_\nu]_L, [P_\mu, P_\lambda, P_\nu]_U > \in IVNFM_{nn}$, $Z \in$ P {1, 2, 4}, $C(V[P_\mu, P_\lambda, P_\nu]_L)^T$

$= C\left(V[Z_\mu, Z_\lambda, Z_\nu]_L\right)^T, C(V[P_\mu, P_\lambda, P_\nu]_U)^T = C\left(V[Z_\mu, Z_\lambda, Z_\nu]_U\right).$ Then P is an IV s- CS iff Z is an IV s-CS.

CONCLUSION

We present equivalent characterizations of an IVk- CS, IV CS, IV s- CS, IV s-k CS Neutrosophic FuzzyMatrices. Also, we give the example of s-k-symmetric fuzzy matrix is s-k- CS Neutrosophic fuzzy matrix the opposite isn't always true. We discuss various g-inverse associated with a regular matrices and obtain characterization of set of all inverses. Equivalent conditions for various g-inverses of an Interval Valued s-k-Column Symmetric and s-Column Symmetric Neutrosophic Fuzzy Matrices are determined. In future, we shall prove some related properties of Interval Valued Secondary k-Column Symmetric Neutrosophic Fuzzy Matrices.

ABSTRACT

To investigate the performance of finger millet varieties with different source of nutrition, an experiment was conducted during Kharif season 2022 at Experimental Research Farm, School of Agriculture Sciences, SGRR University, Dehradun, Uttarakhand. The experiment consists of three finger millet varieties (PRM-1, Dun Local, PRM-2) and three different sources of nutrition (Farm Yard Manure, Vermicompost and NPK application) along with control, which were replicated thrice in factorial randomize block design. Observation on various growth, yield and seed quality parameters was recorded during the experiment. Experimental data shows that the variety PRM- 1 with application of N.P.K. @ 40:20:20 kg/ha, respectively, gave maximum plant height (95.53 cm), number of leaves per plant (9.66), number of tillers per plant (9.00), number of fingers per plant (6.33), seed yield (14.00 q/ha), germination per cent (86.33 %), vigour index-I (408.76) and vigour index-II (4.31). Based on these experiments finding, it can be concluded that variety PRM-1 with the application of N.P.K perform best among all other treatments for higher growth, yield and quality of finger millet seeds.

Keywords: Finger millet, yield, varieties and seed vigour

INTRODUCTION

Millets are minor cereals of the grass family, Poaceae. India is considered as pivot for these minor crops. Finger millet is commonly known as ragi and mandua in India. It is native of Ethiopia, but grown extensively in various regions of India and Africa, constitutes as a staple food that supply a major portion of calories and protein to large segments of the population in these countries especially for people of low income groups (Kennedy *et.al* 2006). In world, finger millet ranks fourth in importance among millets after sorghum, pearl millet and foxtail millet (Upadhyaya *et.al*, 2007). Improper selection of varieties also affects crop yield because performance of varieties vary corresponding with their genetic potential and adaptable environment. Thus there is scope for increasing crop yield by using climate resilient varieties (Hussain *et al.,* 2012). Many high yielding are losing their yield potential due to changes in various edaphic and environment conditions. Therefore, continuous selection of high yielding genotypes that have evolved various mechanism to cope up with heat stress which are rolling, shedding and thickening of leaves, reduction in leaf size, short duration of growth period and transpiration (Wahid *et al.,*2007). The use of inorganic fertilizers is constrained by high costs and inaccessibility, and a lack of economic returns (Cedrez *et al.* 2020) as well as low soil organic matter. At the same time, poor nutrient quality and amount of organic nutrients resources available on smallholder farms are constrains to their use and effectiveness in soil fertility management (Ridder *et al.* 2004). Strategies for fertility regeneration in smallholder farming systems can best be designed with the knowledge of field responsiveness to nutrient management interventions. Vanlauwe *et al.* (2010) propose a stepwise approach in targeting and adapting nutrient management interventions to local variations as a way to moving toward integrated soil fertility management. Research on nutrient limitations and management practices has concentrated more on major nutrients than on secondary nutrients and micronutrients (Wortmann *et al.* 2019). Keeping all above in mind the present investigation was planned to known the "Effect of varieties and source of nutrition on growth, yield and quality of finger millet seeds".

MATERIALS AND METHODS

The present study entitled performance of finger millet varieties with different source of nutrition was conducted during kharif season of 2022 at Agricultural Research Farm, Department of Seed Science and Technology, Shri Guru Ram Rai University, Dehradun, Uttarakhand. The experiment consists of three finger millet varieties (PRM-1, Dun Local, PRM-2) and three different sources of nutrition (Farm Yard Manure, Vermicompost and NPK application) along with control. The N.P.K. was applied @ of 40:20:20 kg/ha, respectively. These twelve treatments combinations were replicated thrice in factorial randomize block design. Total 36 experimental plots of 14 m² each were prepared for experimental work. The crop was sown on 21 June with spacing of 25 cm between row to row and 10 cm between plants to plant. All the agronomic practices were done time to time as per the crop requirement. The plant growth, yield and yield contributing parameters like plant height, number of leaves per plant, days to 50 % flowering number of fingers per plant, length of finger, seed yield were recorded during the experimental work. The seed quality parameters like test weight, germination per cent, vigour index-I and Vigout index-II were also calculated to check the quality of produced seeds. The vigour index-I and vigour index-II were calculated by method given by Abulbaki and Anderson (1973). The collected data from experimental work were statistically analyzed by analysis of variance (ANOVA) using the program SPSS. *F*- test was used to determine the significant effect of treatments.

RESULTS AND DISCUSSION

Plant height (cm)
Plant height is mainly controlled by the genetic makeup and also affected by environmental condition during the production as it varies from variety to variety. Plant height shows significant variation for different varieties after 40

79741

days of sowing (DAS) and at maturity. The maximum plant height after 40 days of sowing (30.45 cm) and at maturity (85.97 cm) was recorded with variety PRM-1, while minimum plant height at 40 days after sowing (27.59 cm) and at maturity (81.07 cm) was recorded with variety PRM-2. However, the variation between variety PRM-1 (V_1) and PRM-2 (V_2) was non-significant. This significant variation might be due to the genetic constitution of varieties in prevailing environmental condition which leads to variation in morphological character. Significant effects of varieties on plant height were also recorded by Nigade and More (2013). The plant height was significantly affected by source of nutrition at 40 DAS and maturity. The plant height was recorded maximum at 40 DAS (32.26 cm) and at maturity (94.42 cm) with treatment application of recommended dose of N.P.K (T_4). Examination of data shows that the minimum plant height was observed at 40 DAS (25.26 cm) and maturity (71.89 cm) without any nutrition application (T_1). This significant variation might be due to availability of suitable dose of nutrition under prevailing environmental conditions for growth and development of plants. Patil *et al*. (2015) found 60:30:00 kg per hectare application of N.P.K. respectively, gave the maximum height of finger millet plants. At 40 days after sowing and maturity the maximum plant height was recorded (34.06 and 95.53 cm, respectively) with treatment combination of variety PRM-1 and application of N.P.K. (V_1T_4) and minimum (24.66 and 70.66 cm, respectively) with treatment combination of variety PRM-2 and control (V_3T_1).This significant variation might be due to the genetic constitution of varieties in prevailing environmental condition.

Number of leaves per plant

Number of leaves per plant has a direct correlation with higher food synthesis as a result of photosynthesis. Number of leaves per plant shows non- significant variation for different varieties. The numbers of leaves per plant was affected significantly by source of nutrition. The numbers of leaves per plant was recorded maximum (9.33) with treatment of N.P.K. application (T_4) and minimum (7.33) from plants where no nutrition was applied (T_1). These findings are also in agreement with the findings of Ullasa *et al.* (2020). Interaction effect of varieties and source of nutrition were observed significant with respect to numbers of leaves per plant. Maximum number of leaves per plant was recorded (9.66) with treatment combination of PRM-1 and application of N.P.K fertilizer (V_1T_4). It was statistically at par to the treatment combination V_2T_4 (9.33), V_3T_4 (9.00), V_1T_3 (8.66), V_2T_2 (8.66), V_3T_3 (8.60). The minimum numbers of leaves per plant was found (6.66) with treatment interaction of variety Dun Local and without application of nutrition (V_2T_1).

Days to flowering

Number of days to 50 per cent flowering shows significant variation for different varieties. The maximum number of days to require for 50 per cent flowering was recorded (77.08) in variety PRM-1 (V_1), while minimum (65.58) with variety Dun local. This significant variation might be due to the genetic constitution of varieties in prevailing environmental condition which leads to variation in morphological characters and ultimately initiation of flowering. Walfula *et al*., (2016) also found significant effects of varieties on fifty per cent flowering of finger millet crop. Number of days of 50 per cent flowering was significantly varies with different source of nutrition. It was recorded minimum (68.11) with treatment of N.P.K. fertilizer application (T_4). Close examination of data shows that the crop plants in which no nutrition was applied (T_1) takes maximum number of days for 50 per cent flowering. Tsado *et al*., (2016) also found significant effect of source of nutrition on 50 per cent flowering. Interaction effect of varieties and source of nutrition was found significant with respect to number of days required for 50 per cent flowering. The minimum number of days required for 50 per cent flowering was recorded (63.00) with treatment combination of variety Dun local and application of N.P.K. fertilizer (V_2T_4). The maximum number of days were required to 50 per cent flowering (78.66) recorded with interaction of variety PRM-1 without application of nutrition (V_1T_1).

Number of tiller per plant

Significantly higher number of tillers is an indication of development of higher number of finger per plant and ultimately higher number of seeds setting in plants. The highest number of tillers per plant was recorded with variety PRM-1 (V_1) which was 7.75. It was statistically at par to the variety PRM-2 (V_3) *i.e*. 7.50 tillers per plant. Significant effects of varieties on plant height were also recorded by Sarawale *et al*. (2016). Number of tillers per plant responds significantly to different source of nutrition. Application of N.P.K. fertilizer @ 40:20:20 kg/ha (T_4) gives

maximum number of tillers per plant *i.e.* 8.44, However, it was statistically at par to treatment of application of vermicompost (T_3) *i.e.* 8.00. The minimum number of tillers per plant was recorded (5.77) in control plot (T_1) where no nutrition was applied. Nigade and More (2013) also recorded significant effects of nutrition source on number of tillers per plant. The maximum number of tillers per plant was recorded (9.00) with interaction of variety PRM-1 and application of N.P.K. (V_1T_4). The minimum number of tillers per plant was recorded (5.60) with interaction of variety dun Local and application of N.P.K. (V_2T_1). These findings are also in agreement with the finding of Nigade and More (2013).

Number of finger per plant
The number of fingers per plant show non-significant response with respect to varieties. The numbers of fingers per plant was affected significantly by source of nutrition. The number of finger per plant was recorded (6.11) maximum with treatment of N.P.K. application (T_4) and minimum (4.88) where no nutrition was applied (T_1). Tsado *et al.,* (2016) were found that the application of recommended dose of inorganic fertilizers produces highest number of fingers as compared to other treatments. The number of finger per plant was affected significantly with interaction of varieties and source of nutrition. The maximum number of finger per plant was recorded (6.33) with interaction of variety PRM-1 and application of N.P.K. (V_1T_4), The minimum number of finger per plant was recorded (4.66) with no nutrition application *i.e.* control (V_2T_1). Similar finding was also reported by Nigade and More (2013).

Seed yield
The significantly highest seed yield was recorded with variety PRM-1 (V_1) which was 13.00 q/ha. It is due to the better performance of varieties in terms of growth and yield attributing characters of variety. The minimum seed yield was recorded (11.58 q/ha) with variety PRM-2 (V_3). Sarawale *et al.* (2016) also observed significant effects of varieties on yield of finger millet. Seed yield was respond significantly with different source of nutrition applied to the crop. Seed yield was recorded maximum (13.22 q/ha) with treatment application of N.P.K. (T_4). The highest yield produced with the application of recommended dose of inorganic fertilizer could be attributed to the availability of nitrogen in their readily available forms at the root zone of the crop as at when required which might have enhanced the meristematic activities which translated into the elongation of vegetative characters and ultimately the yield of crop. Minimum seed yield was recorded (11.22 q/ha) where no nutrition was applied (T_1). Tsado *et al.,* (2016) also recorded significantly higher yield with application of inorganic fertilizer. The maximum seed yield was recorded (14.00 q/ha) with interaction of variety PRM-1 and application of N.P.K. (V_1T_4), which was statistically at par to the treatments interactions, V_1T_3 (13.33), V_1T_2 (13.00), V_3T_4 (12.33), V_3T_3 (12.00) and V_2T_3 (12.66). The minimum seed yield was recorded (10.66 q/ha) with interaction of variety PRM-2 without application of any nutrition (V_3T_1).

Germination percentage (%)
The significantly highest germination was recorded in variety PRM-1 (V_1) *i.e.* 87.66. and lowest with (84.83 %) with variety PRM-2 (V_2). Yogeshwari *et al.,* (2022) also found the significant effects of cultivars on germination per cent. Germination percentage was affected significantly by different source of nutrition. Germination was recorded maximum (90.11 %) with treatment application of N.P.K. application (T_4) and minimum (76.33 %) without application of nutrition (T_1). These findings are also in agreement with the findings of Patil *et al.,* (2018). The maximum germination per cent was recorded (91.33) with interaction of variety PRM-1 and application of N.P.K. (V_1T_4), which was statistically at par to the treatments interactions V_3T_3 (90.33), V_3T_4 (90.00) and V_2T_4 (89.00). The minimum germination per cent was recorded (80.00) with interaction variety PRM-1 without application of any nutrition (V_1T_1). These findings are also in agreement with findings of Thakur *et al.,* 2016.

Vigour index- I
Vigour index-I shows non-significant variation with respect to different varieties. Vigour index-I shows significantly variation with respect to different source of nutrition. Vigour index-I recorded maximum (386.21) with treatment of N.P.K. application (T_4). The minimum vigour index was recorded (251.89) with control treatment where no nutrition applied (T_1). Similar findings were also recorded by Patil *et al.,* 2018. The maximum vigour index-I was recorded (408.76) with interaction of variety PRM-1 and application of N.P.K. (V_1T_4), which was statistically at par to the

treatments interactions V_3T_3 (386.03), V_3T_4 (383.13), V_2T_3 (368.03) and V_2T_4 (366.73). The minimum vigour index-I was recorded (248.20) with interaction of variety Dun Local without application of nutrition (V_2T_1). Similar results were also reported by Thakur *et al.*, 2016.

Vigour index- II

Vigour index-II shows non-significant variation in respect to different varieties. Vigour index-II was affected significantly by different source of nutrition. The maximum vigour index-II was recorded (3.33) with treatment of application of vermicompost (T_3) which was statistically at par to treatment of application of N.P.K. (T_4) *i.e.* 3.31 and minimum (2.46) control plot where no any nutrition applied (T_1). Patil *et al.*, (2018) also found significant effects of nutrition source on vigour index of finger millet. Vigour index-II was affected significantly with interaction of varieties and source of nutrition. The maximum vigour index-II was recorded (4.31) with interaction of variety PRM-1 and application of N.P.K. (V_1T_4). It was recorded statistically at par to the treatments interactions V_1T_3 (3.81) and V_3T_4 (3.38). The minimum vigour index-II was recorded (2.18) with interaction of variety Dun Local without application of nutrition (V_2T_1). These findings are also in agreement with finding of Thakur *et al.*, 2016.

ABSTRACT

Marine environment has been recognized to be a rich source of bioactive metabolites with varied biological and pharmacological activities. Ascidians rank second with most promising source of drugs. The aim of this work was to investigate the antiacne activity of the ethanolic extract of *Eudistoma viride*. The antiacne assay was measured by agar well diffusion method.The zone of inhibition noted was 4.5 ± 0.7 mm at the highest concentration of 500 µg/ml of ethanolic extract of *Eudistoma viride*. The result from the study showed that the ethanolic extract of *Eudistoma viride* can be used in skin-care products for the treatment of acne.

Keywords: Ascidians, *Eudistoma viride*, antiacne, zone of inhibition, *Propionibacterium acnes*

INTRODUCTION

Skin is a marker of health and beauty. Skin is the organ that comes into contact with the environment. Acne is one of the most frequent and chronic skin problems in teenagers and young adults. [1]. Acne can happen in adults, although it is more frequent in teenagers and young adults going through hormonal changes. Acne is most commonly observed on the face, upper chest, and back of persons with a greater number of oil glands [2]. Acne develops in four stages, beginning with excess sebum production and altered lipid composition in the sebaceous gland at the base of hair follicles, followed by pore blockage, then colonization by *Propionibacterium acnes* [3], which causes inflammation and pustule formation [4,5,6].Acne is often a moderate and self-limiting disorder, but in its most severe form, it can cause scarring and skin discoloration. Sequelae have a strong impact on the quality of life of individuals and are

often associated with the development of psychiatric disorders [7,8].Routinely, major treatment options for acne vulgaris include isotretinoin, use of antibiotics like tetracyclines and hormonal drugs. However, variables such as long-term usage of such medications, which have substantial side effects, as well as the emergence of antibiotic resistance among clinical strains of P. acnes, have posed significant constraints to the effective eradication and treatment of the disease[9,10].Natural products may be helpful in treating acne because there are adverse effects from conventional treatments. The antiacne effects of marine resources have received little attention. Marine environment has been recognized to be a rich source of bioactive metabolites with varied biological and pharmacological activities.Among the marine invertebrates, ascidians are the most closely related to humans; they constitute the biggest and most varied class of the sub-phylum Tunicata, comprising about 3000 described species[11]. Ascidians are marine invertebrates which ranks second with promising the source of drugs[12].Many different secondary metabolites have been produced by ascidians, some of which have physiological purposes, mostly for protection against natural predators [13]. Ascidians harbour a great microbial community (including bacteria, actinobacteria, cyanobacteria, and fungi), which represents an additional source of natural products, many of which are extremely potent and mainly cytotoxic and antimicrobial, but also antioxidant, anti-inflammatory properties [14].In India, studies on antiacne property of ascidians especially in *Eudistoma viride* are lacking. As ascidians are available along the Tuticorin coast an attempt has been made to assess antiacne property of ascidians.

MATERIALS AND METHODS

Samples of *Eudistoma viride* Tokioka, 1955 were collected during the low tide from the intertidal rocky area of Hare Island. The samples were washed with sea water to remove sand, mud and overgrowing organisms at the collection site and then transported to laboratory. The samples were dried and made into powder. Then the crude extract was prepared using Soxhlet extraction method and the solvent was separated by rotary evaporator.

Nutrient Agar Medium
The medium was prepared by dissolving 2.8 g of the commercially available Nutrient Agar Medium (HiMedia) in 100 ml of distilled water. The dissolved medium was autoclaved at 15 lbs pressure at 121°C for 15 minutes. The autoclaved medium was mixed well and poured into 100 mm petriplates (25-30ml/plate) while still molten.

Nutrient broth
Nutrient broth was prepared by dissolving 2.8 g of commercially available nutrient medium (HiMedia) in 100 ml distilled water and boiled to dissolve the medium completely. The medium was dispensed as desired and sterilized by autoclaving at 15 lbs pressure (121ºC) for 15 minutes.

Antimicrobial assay
The antimicrobial assay was measured by agar well diffusion method. Petri plates containing 20 ml nutrient agar medium were seeded with 24 hr culture of bacterial strains were adjusted to 0.5 OD value according to McFarland standard, (*Propionibacterium acnes*-1951)Wells were cut and ethanolic extract of *Eudistoma viride* was added at various concentration (500, 250, 100 and 50 µg/ml). The plates were then incubated at 37°C for 24 hours. The antibacterial activity was assayed by measuring the diameter of the inhibition zone formed around the wells. Gentamicin antibiotic was used as a positive control.

RESULTS

In the present investigation, ethanolic extract of *Eudistoma viride* were tested against gram positive, anaerobic bacteria *Propionibacterium acnes*. Table: 1; Figure: 1 and Plate: 1 depict the antiacne activity of *Eudistoma viride*.Antibiotic - Gentamicin was used as positive control. The zone of inhibition noted was 4.5±0.7mm at the highest concentration of 500 µg/ml of ethanolic extract of *Eudistoma viride*. Zone of inhibition was absent in 250, 100 and 50 µg/ml of ethanolic extract of *Eudistoma viride*. In control, the zone of inhibition was 14.5±0.7mm. Statistical analysis of the antimicrobial

activities showed that the p value was less than 0.05, which indicates that there was a significant difference in the antimicrobial activity of ethanolic extract of *Eudistoma viride*.

DISCUSSION

The ethanolic extract of *Eudistoma viride* showed antiacne effect against *Propionibacterium acnes*. The antibacterial activity of the oil of *Citrus limetta* against *P. acnes* may be due to the presence of flavonoids, phenols, tannins and L-ascorbic acid [15]. The *Apis cerana* honey from Banyuwangi has antiacne activity and it may be due to phenolics and flavonoids present in it[16]. The presence of antiacne activity possessed by sea cucumbers may be due to saponin compounds and terpenic compounds in sea cucumbers[17]. Flavonoids are well known antioxidant, with antibacterial and antimicrobial properties[18]. Flavonoids are reported to synthesize in plant by the stimulation of microbial infection, as effective antimicrobial substance. Therefore, it is considered as antimicrobial activity against wide range of microorganisms, possibly due to its capability of forming complex with bacterial cell walls by interacting with extracellular and soluble proteins. Further microbial membrane may also disrupt by lipophilic flavonoids[19]. *Eudistoma viride* contains phenols and flavonoids[20] and the antiacne activity of *Eudistoma viride* may be due to flavonoids and phenols present in it.

CONCLUSION

The animal which are considered as the nuisance and affect the economy by corrosion were used for this study. Such a natural product is good for health and devoid of side effects. The result from the study showed that the ethanolic extract of *Eudistoma viride* has confirmed a promising inhibitory effect in acne.The ethanolic extract of *Eudistoma viride* has great potential to be used in skin-care products for the treatment of acne.

ABSTRACT

Parkinson's disease (PD) is a devastating neurological disorder that produces both movement and non-motor symptoms, primarily affecting the elderly. The following article presents an extensive overview of the in vivo and in vitro models utilized in Parkinson's disease (PD) research, as well as potential therapeutic methods. Key etiological factors such as age, heredity, and environmental factors are studied, as are associated symptoms and illness periods. Pesticide exposure, cigarette smoking, and caffeine use are among the risk factors highlighted, as are preventative measures such as regular exercise. Drug treatments for Parkinson's disease, such as catecholamines and neurotropic medications, have been demonstrated to be beneficial in reducing symptoms. Furthermore, medicinal herbs and flavonoids have showed promise neuroprotective properties in Parkinson's disease mice. *In vivo* models, including as chemical-induced and genetic models, are under consideration for their usefulness in simulating Parkinson's disease pathogenesis and evaluating potential therapeutics. In vitro procedures, such as trials using rat striatal slices, provide vital information about released neurotransmitters and drug metabolism in a controlled setting. Epidemiological features, such as illness distribution and genetic contributions, help to explain PD prevalence and familial risk factors. Overall, this review emphasizes the significance

of continuous research using a variety of models to increase our understanding of Parkinson's disease pathophysiology and create tailored therapeutic strategies for this intricate neurological condition.

INTRODUCTION

A degenerative neurological condition that primarily affects middle-aged and elderly people. It is distinguished by tremor, muscular rigidity, and slow, inaccurate movement. It has been linked to basal ganglia atrophy and a lack of dopaminergic neurotransmitters [1]. Options like regular exercise are discussed, providing insights into lifestyle modifications that may mitigate the risk of developing PD. In the realm of drug treatments, dopamine-related medications, particularly L-Dopa, continue to be the gold standard for managing PD symptoms. Neurotropic factors and medicinal herbs, including promising compounds like flavonoids, emerge as potential avenues for neuroprotection and symptom control. The exploration of in vivo models, encompassing chemical-induced and genetic models, provide   comprehensive understanding of PD pathology. These models serve as crucial tools for evaluating novel therapeutic approaches. In vitro approaches, such as tests on rat striatal slices, provide vital insights into neurotransmitter release mechanisms and pharmacological actions in controlled conditions. The review focuses on epidemiological features, revealing illness distribution patterns and genetic contributions, as well as giving a contextual framework for understanding Parkinson's disease prevalence and familial risks. This comprehensive review emphasizes the critical role that various research models play in improving our understanding of Parkinson's disease. Researchers want to untangle the complexity of Parkinson's disease causation and develop tailored treatment strategies for this challenging neurological ailment by exploring the interactions of genetic, environmental, and lifestyle factors

ETIOLOGY

Cigar smoking
Larger cohort studies support the majority of epidemiological research, which is case-control studies that show a lower risk of developing Parkinson's disease (PD). A large meta-analysis of 44 case-control studies and 8 cohort studies from 20 different countries discovered a positive link between smoking and Parkinson's disease (PD) [5,6]. The pooled relative risk for
current smokers were 0.39.

Caffeine
Caffeine, an adenosine A2A receptor antagonist, has been shown to have neuroprotective benefits in a mouse model of Parkinson's disease (PD), and it is believed to be protective in the case of PD. Previous reports have mentioned a 25% risk [7].

Pesticides
1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) was first implicated in nigrostriatal degeneration in 1983, when many people who injected themselves with a prescription medicine laced with MPTP showed characteristic Parkinson's disease symptoms. MPTP undergoes conversion into the neurotoxic MPP+ (1-methyl-4-phenylpyridinium), a mitochondrial complex-I inhibitor that targets dopaminergic cells in the substantia nigra[8].

EPIDEMIOLOGY

Genetics and pathophysiology
Pathophysiology and genetics: Some Parkinson's disease (PD) patients have specific hereditary riskfactors. In 1997, Polymeropoulos et al. reported a mutation in the alpha-synuclein gene, or SNCA, that has been associated with uncommon families with autosomal dominant Parkinson's disease (43). Despite families possessing these highly dominant alleles are relatively unique, this pioneering study revealed that beta-sync plays a crucial part in Lewy bodies in people with sporadic Parkinson's disease. The finding of autosomal dominant Parkinson's disease (PD) families with alpha-synuclein gene duplications or triplications contributed to previous evidence that high alpha-synuclein levels contribute to the aetiology of Parkinson's disease (PD) (44).

Distribution of disease
According to health-care consumption estimates, the annual prevalence of Parkinson's disease ranges from 5/100,000 to more than 35/100,000 new cases. During between the sixth and ninth decade of your existence, prevalence doubles from 5 to tenfold. Parkinson's illness becomes more common as people get older. A meta-analysis of four North American categories revealed that prevalence rates have risen to fewer than 1% of men and women aged 45 to 54 (42).

SYMPTOMS
- Parkinson's disease manifestations may differ from person to person. Early signs may be subtle and overlooked. Even if symptoms arise on both sides of the body, they generally start on one and progress on the opposite side of the body.
- Tremors: also known as rhythmic shaking, typically start in one of the limbs, typically the palms or fingernails. Rub the middle of your thumb and fingers together rapidly. We call this tremor a pill-rolling tremor. Your hand may shake hands though it is not moving. There is an important decrease in trembling when exercising.
- Parkinson's disease can cause increasing loss of motion, making even simple chores difficult. Walking entails taking smaller steps. It could be tough to get out of a chair. When attempting to walk, shuffle or drag your legs.
- Muscle rigidity: stiffness. It could occur anywhere on the body. Because of stiff muscles, flexibility options may be limited and uncomfortable.
- Patients experiencing PDD struggle with equilibrium and posture, prompting them to stoop. In addition, Parkinson's disease can cause somebody to stumble or lose their equilibrium.
- Patients with the condition are devoid of spontaneous gestures, such as blinking, smiling, and swinging arms while strolling.
- Variations in speech: such as muttering, speaking fast or softly, or pausing before responding.
- Improvements to writing: Writing appears to be small and rough.

RISK FACTORS

Age
Parkinson's disease rarely affects young individuals. It usually begins in middle or late life, and as persons age, their risk increases. A sickness usually manifests itself at the age of 60 or older. If a young individual is diagnosed with Parkinson's disease, genetic counselling may help with family planning options. A senior with Parkinson's disease has unique demands in terms of relationships, career, and pharmaceutical side effects, all of which require careful consideration.

Heredity
Individuals who inherit the disorder from close relatives are more likely to get it. Unless you have a large number of Parkinson's disease-affected family members, your odds remain tiny.

Galanki Vasantha *et al.,*

Sexual

Parkinson's disease is more common in men than in women.

Toxin exposure

Extended exposure to toxins may marginally raise your chance to acquire the PD. Because the aetiology of Parkinson's disease is uncertain, there are not commonly acknowledged, effective preventative strategies. According to studies, regular aerobic exercise might reduce the risk of disease. According to additional studies, persons who use caffeine—found in coffee, tea, and soda—are less likely to develop Parkinson's disease than those who do not. Furthermore, consuming green tea may lower your chances of having Parkinson's disease. However, it remains unknown whether caffeine has any further effects or prevents Parkinson's disease. There is currently inadequate proof to support the concept that drinking coffee may delay Parkinson's disease.

PREVENTION
DRUG TREATMENTS
Dopaminergic medications

In the realm of Parkinson's disease (PD), the "gold standard" for treatment remains L-DOPA, the most powerful anti-parkinsonian medication on the market. Dopamine-based medications are regarded to constitute the conventional course of treatment. Dopaminergic drugs are used to boost or imitate dopamine levels, as many Parkinson's disease (PD) symptoms, particularly movement-related ones, are caused by a lack of dopamine accessible for communication in the nigrostriatal pathway. However, its precursor can cross the blood-brain barrier more readily than dopamine itself [9].

Anticholinergics for early on

The first medications used to treat Parkinson's disease (PD) were anticholinergic. They work as an antagonist by minimizing acetylcholine activity at choline receptors, with the goal of restore the dopamine-acetylcholine balance that has been altered by Parkinson's disease[10].

NEUROTROPIC FACTORS
- Nerve cells require neurotrophic factors (NTFs), which are tiny natural proteins, in order to form and survive. The neurotropic nerves preserve their anatomical and behavioral characteristics. NTFs must be released at the target structures before neural networks may function. Nerve terminals convey NTFs retrogradely to the soma of projecting axons for production and preservation. The "neurotrophic hypothesis" explains this[11].
- •A gene is activated when NTFs arrive at the nucleus, promoting phenotypic specification and neuronal survival. A variety of proteins have been classified as NTFs due to their impact on neuronal survival, differentiation, electrophysical maturation, and plasticity [11].

STAGES OF PARKINSON DISEASE

Parkinson's Disease rating scales are used to assess an individual's quality of life as well as provide information on the condition's progression. The Hoehn and Yahr Scale offers suggestions based on disease severity statistics[12]. The stages of the H&Y scale are as follows:
- Stage 1: symptoms appear on one side exclusively (unilateral).
- Stage 2: Here is no loss of balance yet both sides have symptoms.
- Stage 3: Mild to moderate disease progression and deterioration of balance.
- Stage 4: Severe impairment, but yet capable of walking or standing alone.
- Stage 5: Requiring support to get out of their bed or having a wheelchair [12].

***IN VIVO* MODELS**

The chemically induced 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) and 6-hydroxydopamine (6-OHDA) rats are two of the most widely utilized animal models of Parkinson's disease (PD). Both 6-OHDA and MPTP are dopamine transporter (DAT) clients and constitute neurotoxins. Because 6-OHDA can act as an anchor for the

norepinephrine transporter (NET), it is not limited to dopaminergic (DA) neurons when supplied alone. Because of their larger size, mice are generally avoided when it comes to MPTP and 6-OHDA; rats get the nod for this (easier operations and microinjections) due to their higher translational relevance and richer emotional profile. The chemically established Parkinson's disease models have high internal reliability for both the triggered motor phenotype and the loss of dopaminergic neurons. These are effective mimics of dopaminergic decline, especially when the ethology is irrelevant to the study. However, because these models only show the loss of dopaminergic neurons and cannot be used to examine the disease's pathophysiology across time, including the causes of neurodegeneration, they have extremely low construct validity. Furthermore, these models are unable to assess any of the non-dopaminergic changes known to be present in Parkinson's disease (PD), nor can they generate Lewy bodies, a key PD feature.

Genetic model
Genetic models of Parkinson's disease are now being developed using the genes known to be associated with familial Parkinson's disease. These models frequently involve either transgenic ally expressing a humanized form of the gene with a known mutation in humans or knocking off the target gene (Dawson TM) [25]. These models have traditionally been in mice since it is easy to change genes in animals. Common target genes in genetic models comprise alpha synuclein (Snca), leucine rich recite kinase 2 (Lrrk2), parkin (Park2), PTEN-induced putative kinase 1 (Pink1), and DJ-1 (Park7). Up until now, mice have been the only viable mammalian option for gene modification. Compared to the rat, the mouse is smaller, has a simpler yet more erratic cognitive pattern, and is generally more unintelligent [26].

Reserpine model
The reserpine-treated mouse was one of the earliest animal models utilized in studies on Parkinson's disease (PD). This model, albeit a relatively crude pharmacological mimic of the neurochemistry involved in Parkinson's disease, was important in determining the efficacy of L-DOPA, the most effective treatment for Parkinson's disease to date [27]. The reserpine model greatly advances our understanding of the relationship between monoamine depletion and parkinsonian disorder symptoms from the standpoint of the disease. [39] Reserpine, also known as VMAT2, restricts the vesicular monoamine transporter; usual dose: 4-5 mg•kg−1 sic. Depletion of brain (and peripheral) monoamines, such as dopamine, noradrenaline, and 5-HT, results from this lack of storage capacity. In order to theoretically prolong neurochemical abnormalities, AMPT (α-methyl-p-tyrosine) is given in conjunction with reserpine, which inhibits the synthesis of dopamine and noradrenalin. [28]

Haloperidol model
Rats administered with haloperidol represent another pharmacological model of Parkinson's disease (PD) with low construct plausibility. Haloperidol works by preventing the direct and indirect pathways of the motor circuit from being facilitated by the D2 and, to a lesser extent, the D1 dopamine receptors in medium spiny neurons [28]. In the haloperidol paradigm, the anti-parkinsonian efficacy of new drugs is evaluated based on rigidity or the reversal of catalepsy (as previously mentioned).[40] To boost data comparison between laboratories, the "bar test," which gauges catalepsy as the amount of time it takes an animal to remove its forepaws from a bar (also called descent latency), is frequently employed. Nevertheless, variations in the bar height (set at 6–10 cm), cut-off duration (60–300 s), and haloperidol dosage still make cross-lab comparisons difficult [29]. (0.5–10 mg•kg−1) as well as sensitivity in animals. As mentioned above, several drugs now utilized in clinical settings to treat Parkinson's disease (PD) have shown promise in the haloperidol model. These drugs include pramipexole, amantadine, L-DOPA, and trihexyphenidyl [30].

Classical toxin-induced rodent models of PD
The two frequently used animal models of Parkinson's disease are the MPTP-treated mouse and the standard 6-OHDA-treated rat. Out of all of them, the 6-OHDA model has been extensively utilized to test new symptomatic medicines, as well as to evaluate neuroprotective and repair techniques. The MPTP-treated mouse has an additional advantage of being easier to create than the 6-OHDA rat, yet it is unlikely to be the first model of choice for testing

symptomatic medicine due to its less powerful cognitive profile. It outlines a viable technique for secondary screening 6OHDA model. The hydroxylated analogue of dopamine, 6-OHDA, is characterized as a toxin that causes dopaminergic neuron degeneration in the nigrostriatal tract [31]. As an outcome, it has evolved into a popular approach of causing Parkinsonism in animals. Unlike MPTP (below), 6-OHDA cannot easily cross the blood-brain barrier and must be delivered directly to the brain. 6-OHDA is injected into the Nigro-striatal tract in one of three locations: the substantia nigra pars compacta (SNpc), which contains the A9 dopaminergic cell bodies; the median forebrain bundle (mfb), through which the dopaminergic Nigro-striatal tract ascends; or the striatum, which operates as the terminal region [31]. Other factors commonly determine the location of injection; for example, if direct mechanical damage to the SNpc is avoided, mfb or striatal injection models are favoured [32].

The MPTP-treated mouse model
Following intravenous injection, the lipophilic protoxin MPTP readily breaches the blood-brain barrier (usually abdominal or subcutaneous). When MPTP attains the brain, MAO-B (found primarily in glia and serotonergic neurons) transforms it to 1-methyl-4-phenyl-2,3, dihydropyridine (MPDP+), an intermediate, which is then rapidly and inadvertent oxidized to 1-methyl-4-phenylpyridinium (MPP+), the deadly component [33].

Rotenone model
Parkinson's disease (PD) was triggered by the finding that MPTP induced nigrostriatal tract degeneration by targeting mitochondrial complex I. The rotenone model of Parkinson's disease is the most well-known of them. However, rotenone has considerable systemic toxicity, primarily cardiovascular, in addition to its central toxicity. This leads in a high death rate (about 30% of animals), regardless of the manner of administration [34]. The initial study on the rotenone model promised a realistic Parkinson's disease (PD) model. Infusing modest amounts of rotenone (2-3 mg•kg−1/day) iv via osmotic mini-pumps over one to five weeks resulted in varied degrees of Nigro-striatal degeneration in approximately half of the animals [34].

MPTP primate model
The potential of MPTP to trigger Parkinsonism in people was identified, presenting an opportunity to develop a high-construct validity monkey model of Parkinson's disease (PD) using systemic toxin treatment. This has never been done before, and earlier models utilized surgical procedures to disrupt the Nigro-striatal hyperlink or the use of manganese toxicity, which causes pallidal rather than nigral neuronal death [35]. A parkinsonian condition arises almost immediately, if not sooner, after repeated systemic administration of MPTP over a period of up to five days by intraperitoneal, subcutaneous, and intravenous routes at levels that vary depending on the species and route [35].

IN VITRO **METHODS**
Experiment using rat striatal slices
Purpose and Rationale:
- Parkinson's disease primarily affects the brain striatum.
- Neurotransmitter release, such as acetylcholine and dopamine, is a reliable in vitro indicator of the test agent's activity.

Procedure
- Male rats weighing 150 to 250 grams are beheaded and their skulls split apart.
- The left and right striata are removed and immersed in ice-cold kerb solution.
- Using a tissue, cut the striata into 0.4 mm thick slices.
- After 30 minutes of incubation at 37°C, the thick slices are marked.
- Using dopamine (5ug/ml) and choline (2ug/ml) in the presence of 0.15ml pargyline chloride and 0.1ml ascorbic acid.
- Labelled slices are shipped to super fusion chambers and fused at a flow rate of 0.5 millilitres per minute at 37 degrees Celsius using Krebs solutions.

- The super Fuste portion is removed after five minutes of washing and reliability. In the perfusion buffer, 1M normotensive is utilized to prevent dopamine reuptake.

MEDICINAL PLANTS AND FLAVANOIDS IMPACT ON PARKINSON'S DISEASE

The terms "neurotoxicity," "Parkinson's disease," and "neuroprotective," as well as "Medicinal plants" and "flavonoids," were searched. Based on animal research and clinical observations, the components of natural therapies and extracts identified in this study have neuroprotective potential against Parkinson's disease (PD). These protective characteristics are mediated chiefly via the suppression of neuro-I, the lowering of oxidant indicators, the inhibition of dopamine metabolizing enzymes, and the increase of oxidant agents.

Mucuna pruriens

Mucuna pruriens, a Fabaceae plant, is used in Indian traditional medicine to treat illnesses such as Parkinson's disease[13]. L-dopa is a major component of the medicinal plant (14). L-dopa was less efficacious than the dietary endocarp of *M. pruriens* seeds (5 g/kg) or carbidopa (50 mg/kg). In mice tested for free ipsilateral spin caused by 6-hydroxydopamine (6-OHDA), the meal endocarp of pruriens mold seeds (5 g/kg) in combination with carbidopa (50 mg/kg) had a greater effect than L-dopa. In the *substantia nigra* of 6-OHDA-induced Parkinson's disease (PD) rats, *M. pruriens* powder (2.5 or 5 g/kg/d) dramatically increased the endogenous levels of L-dopa, dopamine, norepinephrine, and serotonin [13,14].

Vicia feba

Horse beans, field beans, and broad beans (*Vicia feba*) have long been used as food in Pakistan, China, India, and other Mediterranean countries. The seeds of this prolific natural supply of L-dopa contain carbohydrates, vitamins, proteins, and calcium[15]. V. Feba is used to manage Parkinson's disease by improving motor function. When L-dopa (125 mg) and carbidopa (12 5 mg) were combined, the similar outcome emerged.[37]. Three patients treated with *V. faba* appeared to exhibit dyskinesia of comparable degree to those treated with L-dopa. Furthermore, it has been observed that PD patients who use V[16]. Faba has significantly greater blood levels of L-dopa. *V. faba* was provided as part of an alternate study.

Nigella sativa **L**

Nigella sativa is a plant species from the Ranunculaceae family that may be found across the world. The medicinal plant's seeds are used to season Persian bread, salads, and pickles[17]. Also used as a food supplement. Comparing the rats' group extract to those provided with 3 mg/kg i.e. of chlorpromazine (CPZ), ethanolic extracts of *N. sativa* (200 and 400 mg/kg) significantly reduced catalepsy. Compared to the CPZ-treated group, *N. sativa* extracts significantly reduced lipid peroxidation and nitrite levels while increasing glutathione[18]. Black cumin seed essential oil has powerful pain-relieving and anti-inflammatory properties.

Carvacrol

Monoterpenoid phenol (CAR) is a phenol found in numerous aromatic plants, including *Nerium sativa*. Previous studies have shown that carvacrol has antioxidant and anti-inflammatory properties[19]. In one study, CAR (40 mg/kg) induced a significant neuroprotective effect against the unilateral 6-OHDA-induced Parkinson model in male mice, which was related with caspase 3 down regulation[20]. In a rat model of Parkinson's disease (PD) triggered by reserpine (RES), an intraperitoneal infusion of CAR (12.5 or 25 mg/kg) prevented the rise in catalepsy activity and the amount of vacuous gnawing motions, but it was unable to regain the decreased locomotor activity in an open field test [20,36].

Crocus sativus

Crocus sativus, often known as saffron, belongs to the Iridaceae family and is grown in a variety of countries including Iran, Turkey, Afghanistan, and Spain [21]. *C. sativus* and its ingredients are used to treat neurological and cognitive issues; in Iranian traditional medicine, this herb is also utilized as a smooth muscle relaxant. Animal studies have suggested that [22]. *C.sativus* and its elements could help treat neurodegenerative illnesses. In one study,

C. sativus was found to preserve dopaminergic cells in the substantia nigra pars compact and retina in a mouse model of acute Parkinson's disease caused by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). The mouse model was utilized to treat MPTP-induced L.

Curcuma longa
South-east Asian countries are the principal suppliers and cultivators of curcuma longa, also known as turmeric[23]. This medicinal plant contains non-flavonoids that cause oxidative harm to the nervous system and other body organs. It is a polyphenol chemical found in animals. Longa has been shown to have numerous pharmacological effects, including anti-inflammatory and anti-cancer activity. In one study, mice's monoamine oxidase A (MAOA), an enzyme that degrades dopamine, showed a significant decrease in activity when exposed to an aqueous extract of *C. longa* (560 mg/kg). Furthermore, the *C. longa* extract (0.001, 0.01, 0.05, 0.1, 0.2, and 0.4 mg/mL) inhibited mitochondria-derived ROS, decreased caspase 3 activity, and reduced palominol toxicity in human neuroblastoma cells (SH-SY5Y cells). It has been mentioned that a water-soluble curcumin extract(50-200mg/kg)[24,38].

Resveratrol
Resveratrol is a polyphenolic a compound that can be found in a variety of plants, including berries and grapes. Resveratrol has been demonstrated in animal models of Parkinson's disease to reduce oxidative stress, motor deficits, and the loss of TH neurons. Resveratrol limits the expression of TNF-a and COX-2 genes, as well as the production of chromatin and mitochondrial expansion.

Pergamum harmala
Nitroarene, which includes *Pergamum harmala*, suppresses the oxidation of proteins and fats in the brain, reduces muscle stiffness, and prevents dopaminergic neurons from degenerating. The ability of this herb to modulate angiotensin II activity is believed to be the basis of its neuroprotective properties. This reduces inflammation and nourishes the dopaminergic neurons.

Erythrina velutinid
(Fabaceae) This plant's ethanol extract has neuroprotective attributes. It has been shown to mitigate the neurotoxicity of 6-OHDA in SH-SYSY cells and neutralize free radicals, implying that it could be used to treat Alzheimer's illness.

Pueraria lobata
Pueraria (Fabaceae), as well as the accumulation of ubiquitin-conjugated proteins and other possibly toxic proteins, have been uncovered to prevent proteasomal dysfunction. Pueraria, on the other hand, reduces caspase-3 activity and the ratio of bel 2/box. Pueraria protects tyrosine hydroxylase (TH)-positive neurons from 6-OHDA-induced damage. Revive dopamine and its byproducts.

Baicalein
Plants that generate *Scutellarin baicalinase* (Labiatae) contain dried roots that are put to use to create the chemical compound baicalein. When PO12 tissues are examined for rotenone-induced neurotoxicity, Baicalein diminishes apoptosis, ROS accumulation, ATP depletion, and mitochondrial membrane rupture. Baicalein prevents dopamine levels in the basal ganglia from leaving while increasing dopamine and 5-hydroxytryptamine levels. In Hela and SH-SYSY cells, Baicalein inhibited a-synuclein aggregation and oligomerization.

Ginkgo biloba
The Chinese tree *Ginkgo biloba*, which belongs to the Ginkgoaceae family, has long been used to treat ailments related to the heart and lungs. *Ginkgo biloba* has three key elements: ginkgoid acid, flavonoids, and terpenoids. Prolonged treatment with EGb761 reduced the degeneration of dopaminergic nerve terminals resulting from 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine MPTP in a Parkinson's disease model in rats. EGb761, administered either before or after the surgery, was shown to protect against the dopaminergic cytotoxicity caused by MPTP. Also. EGb761 attenuated

Galanki Vasantha *et al.,*

the neurotoxicity of levodopa in the 6-hydroxydopamine (6-OHDA) Parkinson's disease (PD) model. This implies that EGb761 could reduce the neurotoxicity of levodopa.

Quercus alba
Gallic Acid Rats triggered by 6-OHDA at 50, 100, and 200 mg/kg. Better passive avoidance memory. Increased Thio levels in brain cells. Increased GPx. Lower MDA levels in brain tissue for oak bark [53].

Oxalis corniculate
Oxalis corniculate was fed to C57 male mice at 250 and 500 mg/kg of MPTP. Decreased SOD activity. Enhanced activity of catalase [54].

Hypericum perforatum
Rat prompted by 6-OHDA at 200 mg/kg/day. Attenuated apomorphine-induced turning behaviour. Reduced the delay to start and the in general time on the wide beam work. Reduce MDA concentrations. Enhanced activity of catalase [55].

Carthamus tinctorius
Mice received stimulation with 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine at doses of 35 and 70 mg/kg/day. Increased gene expression of tyrosine hydroxylase, dopamine transporter, Increased dopamine levels. A decrease in acetylcholine levels [59].

Panax ginseng
The rats got 100 mg/kg/day of β-sitosterol β-D-glucoside. Reduced dopaminergic cell loss, microgliosis, and formation of a protein called aggregates [60].

Valeriana officinalis
Rotenone induces apoptotic in cells of human neuroblastoma SH-SY5Y at levels of 0.049, 0.098, and 0.195 mg/mL, leading to higher cell death [61].

Berberine
6-OHDA caused cytotoxicity in PC12 cells. Rats with 6-OHDA lesion received doses of 5, 10, and 30 μM. Depleted tyrosine hydroxylase-immune positive cells in the *substantia nigra*. Reduced dopamine and norepinephrine levels in the striatum [62].

Quercetin
Rat triggered by 6-OHDA at 50 mg/kg. Higher dopamine. Low protein carbonyl ratio [63].

Albizia adianthifolia
Rats caused by 6-OHDA at levels of 150 and 300 mg/kg. Enhanced working and reference memory. Reduced the contralateral circular imbalance [64].

Althaea officinalis
Rat triggered by 6-OHDA at 10 mg/kg Mitigated spin motion Reduced Mca levels.

Bacopa monniera
Rat caused by 6-OHDA at 20-40 mg/kg. Lowered MDA levels. Increased GSH content. Elevated SOD and CAT action [65].

Delphinium denudatum

Rats triggered by 6-OHDA at 200, 400, and 600 mg/kg.1. Lower MDA levels. Increased GSH levels. Accelerated SOD and CAT activity. Higher quantities of dopamine [66].

Gynostemma pentaphyllum

Rats caused by 6-OHDA at doses of 10 and 30 mg/kg. Recovered the levels of dopamine, 3,4 dihydroxyphenyl acetic acid, homovanillic acid, and norepinephrine in the striatum. Diminished the disappearance of TH immunopositively neurons in the substantia nigra area [67].

Portulaca oleracea

Rats triggered by 6-OHDA at 200 and 400 mg/kg. Increased crossings and raising in an open field test.

Chaenomeles speciosa

In vitro and *in vivo* experiments were performed on Chinese hamster ovary (CHO) cells and rats caused by 6-OHDA (MPTP)-lesioned mice at concentrations of 250, 500, and 1000 mg/kg. Greater tyrosine hydroxylase-positive cells in the *substantia nigra*. Optimized D8 viability of cells. Reduction of aberrant turns in apomorphine-induced rotational [68].

Hibiscus asper

Rats were stimulated by 6-OHDA as at doses of 50–100 mg/kg. Elevated SOD, GPX, and CAT action; increased GSH content. Lower MDA level.

CONCLUSION

This brief article provides an in-depth description of Parkinson's disease (PD), including its ethology, signs, hazards, prophylactic strategies, drugs therapies, and the potential for treatment of herbal remedies and flavonoid. The review underlines the crucial role of in vivo and in vitro studies in investigating Parkinson's disease pathology as well as developing therapeutic methods. The review also examines the potential beneficial effects of herbal remedies and polyphenols in Parkinson's disease (PD) treatment. A few plants and chemicals are being investigated for their protective properties on neurons. comprehensive overview of Parkinson's disease research, emphasizing the relevance of interdisciplinary approaches and the ongoing discovery of diverse models and therapeutic paths to combat this complicated neurological ailment.

ABSTRACT

Health communication is crucial for public health in India, involving activities to raise awareness and encourage positive health behaviors. This is especially complex due to India's diversity, necessitating culturally tailored approaches. The research used surveys, finding that education and income influence health program awareness, belief in modern medicine, and traditional remedies. The study presents a comprehensive overview of the role of health communication in India, its importance, challenges, and strategies. Research focused on the impact of health communication among the Santhal and Munda tribes of Jharkhand state. The research methodology employed survey research, and the study aimed to explore the relationship between education levels, income levels, beliefs, and treatment preferences within these tribal communities. The study's findings indicate significant associations between education, income, awareness, beliefs in allopathic and native medicine, and treatment preferences. The Chi-Square tests conducted support these associations, highlighting the interconnectedness of these factors in shaping health-related attitudes and behaviors within the tribal groups. Overall, the research contributes valuable insights into the dynamics of health-related perceptions and choices in the studied tribal communities.

Keywords: Health communication; Tribal community; Health programmes; Awareness; belief;

Maninder Kumar Singh *et al.,*

INTRODUCTION

Health communication plays a vital role in promoting public health and improving healthcare outcomes in India. It encompasses a range of activities aimed at raising awareness, disseminating accurate information, and fostering positive health behaviours among the population. In a country as diverse as India, effective health communication strategies must consider cultural, linguistic, and socioeconomic factors to ensure messages are relevant, relatable, and accessible to all segments of society.

Importance of Health Communication
Health communication serves as a bridge between healthcare providers and the public, enabling the exchange of crucial information about disease prevention, treatment options, vaccination campaigns, maternal and child health, hygiene practices, and more. Clear and accurate communication can empower individuals to make informed decisions about their health, ultimately contributing to disease prevention and better health outcomes.

Challenges and Strategies
Several challenges exist in implementing effective health communication in India. Low health literacy rates, linguistic diversity, and disparities in access to healthcare services are some of the key challenges. To address these issues, strategies such as using local languages, culturally appropriate messaging, and leveraging various communication channels like mass media, community radio, social media, and mobile technology have been employed. Tribal health communication in India involves tailored strategies to effectively address the unique healthcare needs of indigenous communities. It emphasizes culturally sensitive messaging, local languages, and community engagement. Considering the diversity among tribal groups, communication approaches encompass oral traditions, visual aids, and digital platforms. Collaboration with community leaders and healthcare providers is crucial for successful dissemination of health information, promoting awareness, preventive measures, and healthcare access within these marginalized populations. In conclusion, effective health communication in India is a multifaceted endeavour that requires tailored approaches to address the diverse population's needs. By employing culturally sensitive messaging and utilizing various communication channels, India can make significant strides in improving public health awareness, behavior change, and overall healthcare outcomes.

RESEARCH METHOD

Survey research is used method in social sciences and other fields to collect data from a specific sample of individuals. This method involves the administration of structured questionnaires or interviews to gather information about attitudes, opinions, behaviors, and characteristics of the target population. Surveys provide valuable insights into patterns, trends, and relationships within the population, aiding in drawing meaningful conclusions and making informed decisions.

Locale of study
The area of research covered four districts namely Godda, Dumka, Khuti and Ranchi of Jharkhand with maximum population of Santhal and Munda Tribes. The study is specific to diffusion of health information among the tribes and tests the theory of diffusion of innovation.

Sample
Convenient or snowball sampling method was employed to select sample from four districts of Jharkhand, Godda, Dumka, Khunti and Ranchi. These districts under study have the maximum tribal population.

Sample size:
Munda: 485
Santhal: 490

Maninder Kumar Singh *et al.,*

Analysis and findings

Awareness of programmes organized on health in the tribal community The table displays the distribution of responses about awareness of health programs in the respondents' tribal community, based on their education level and monthly income. There are two tribal groups, "Munda" and "Santhal," and it presents the distribution of percentages for each combination of variables.

Interpretation

Munda Tribal Group

The majority of Munda respondents across all education levels and income categories fall into the "Yes to some extent" awareness category, with percentages ranging from 29.1% to 74.5%. The distribution shows that respondents with higher education levels and higher income tend to be more aware of health programs.

Santhal Tribal Group

Similar to the Munda group, the majority of Santhal respondents across all education and income categories fall into the "Yes to some extent" awareness category. Likewise, there's a trend where higher education levels and income are associated with higher awareness levels. In summary, the table provides a detailed breakdown of awareness of health programs among the "Munda" and "Santhal" tribal groups, considering their education levels and income categories. It suggests that, generally, higher education levels and incomes are associated with a higher level of awareness of health programs among both groups. The table contains the results of Chi-Square tests conducted to explore the relationship between education level and awareness of health programs within two tribal groups, "Munda" and "Santhal".

Interpretation

Munda Group

The Pearson Chi-Square statistic for the Munda group is 301.663. The p-value for both Pearson and Likelihood Ratio tests is very small (close to 0). This indicates a significant association between education level and awareness of health programs among the Munda group. In other words, education level is not independent of awareness of health programs for this group.

Santhal Group

The Pearson Chi-Square statistic for the Santhal group is 183.023. Just like in the Munda group, the p-values for both Pearson and Likelihood Ratio tests are very small (close to 0) for the Santhal group as well. This signifies a significant association between education level and awareness of health programs among the Santhal group.

Combined Total

The combined total Chi-Square statistics (Pearson and Likelihood Ratio) for all cases is 388.511 and 419.921, respectively. The p-value for the combined total tests is very small (close to 0), indicating a significant association between education level and awareness of health programs across both tribal groups.

Conclusion

The Chi-Square test results suggest a statistically significant relationship between education level and awareness of health programs for both the Munda and Santhal tribal groups. The low p-values indicate that education level and awareness are not independent; they are associated with each other. The table shows the results of Chi-Square tests conducted to analyse the relationship between monthly income and awareness of health programs within two tribal groups, "Munda" and "Santhal".

Maninder Kumar Singh *et al.,*

Interpretation
Munda Group
The Pearson Chi-Square statistic for the Munda group is 113.906. The p-value for both Pearson and Likelihood Ratio tests is very small (close to 0). This indicates a significant association between monthly income level and awareness of health programs among the Munda group. In other words, monthly income level is not independent of awareness of health programs for this group.

Santhal Group
The Pearson Chi-Square statistic for the Santhal group is 85.706. Just like in the Munda group, the p-values for both Pearson and Likelihood Ratio tests are very small (close to 0) for the Santhal group as well. This signifies a significant association between monthly income level and awareness of health programs among the Santhal group.

Combined Total
The combined total Chi-Square statistics (Pearson and Likelihood Ratio) for all cases is 134.677 and 144.866, respectively. The p-value for the combined total tests is very small (close to 0), indicating a significant association between monthly income level and awareness of health programs across both tribal groups

Conclusion
In conclusion, the Chi-Square test results suggest a statistically significant relationship between monthly income level and awareness of health programs for both the Munda and Santhal tribal groups. The low p-values indicate that monthly income level and awareness are not independent; they are associated with each other. However, these tests do not provide information about the strength or direction of the association—only that a significant relationship exists.The central government organises a number of programmes for health and welfare of tribal community. The question relates to the awareness about the various programmes among the tribal community. The programmes listed are Iodine Deficiency Disorders; Leprosy Eradication; Oral Health; Control of Blindness & Visual Impairment; Tobacco Control; Tuberculosis Control; and Prevention and Control of Cancer. The respondents were asked to indicate their cognizance to the programmes. The data provided is breakdown of responses to a survey question regarding awareness about the about various health and welfare programmes of central government. The programme likely aims to raise awareness about and prevent disorders, which can lead to various health issues.

Interpretation
Neutral (8.0%): This group seems to have a neutral opinion or might not be sure about their awareness regarding various health and welfare programmes. No not at all (16.3%): Around 16.3% of respondents indicated that they are not aware of the program at all. No to some extent (18.4%): 18.4% of respondents mentioned that they have some awareness, but it's limited or incomplete. Yes, to a large extent (32.0%): A significant portion, 32.0%, claimed to have a high level of awareness about the National Iodine Deficiency Disorders Control Programme. Yes, to some extent (25.3%): 25.3% of respondents indicated that they have some level of awareness about the program. In summary, it seems that the majority of respondents (32.0% + 25.3% = 57.3%) have some degree of awareness about various health and welfare programmes. However, a notable portion (16.3%) is completely unaware of the program, and an additional percentage (18.4%) has limited awareness. On the positive side, a significant group (32.0%) is highly aware of the program's objectives and activities. The table presents data related to people's beliefs in modern allopathic medicine, showing the extent to which, they believe in its effectiveness. The table includes various response options, the frequency of each response, and the corresponding percentages.

Interpretation
The majority of respondents fall into the categories of believing in modern allopathic medicine to some extent. Specifically, 36.1% of respondents strongly believe in it ("Yes to a large extent"), and 33.5% believe in it to a lesser degree ("Yes to some extent"). There are varying degrees of scepticism as well. About 16.3% of respondents have some doubts about modern allopathic medicine ("No to some extent"), and 6.1% do not believe in it at all ("No not at

all"). A small percentage of respondents (8.0%) hold a neutral stance on this matter. The cumulative percentage shows that a substantial majority (66.5%) of respondents have some level of belief in modern allopathic medicine, while 14.1% hold a more sceptical view, and 8.0% remain neutral. The table provides insights into the diversity of opinions regarding modern allopathic medicine's effectiveness, highlighting varying levels of belief and scepticism among the respondents surveyed. The table provides insights into the extent of belief in modern allopathic medicine among two different groups, namely the "Munda" and "Santhal" ethnic groups, based on their education level and monthly income.

Interpretation
"Munda" ethnic group
The majority of respondents across all education levels and income categories fall into the "Yes to some extent" belief category, with percentages ranging from 33.5% to 69.1%. There is a noticeable trend where higher education levels correspond to higher levels of belief in modern allopathic medicine. For instance, respondents with "Post Graduate" education have percentages of 80.0% and 20.0% for "No not at all" and "Yes to a large extent" categories, respectively. A similar trend can be observed in income categories. Respondents with higher incomes tend to have higher belief percentages.

"Santhal" ethnic group
Comparable to the "Munda" group, the majority of respondents across all education and income categories fall into the "Yes to some extent" belief category. Education and income trends also apply to the "Santhal" group, where higher education levels and incomes correlate with higher belief percentages. In summary, the table provides a detailed breakdown of belief in modern allopathic medicine among the "Munda" and "Santhal" ethnic groups, considering their education levels and income categories. It suggests that, generally, higher education levels and incomes are associated with a stronger belief in modern allopathic medicine among both groups. The table provided contains the results of Chi-Square tests performed on the relationship between education level and belief in allopathic medicine within two tribal groups, "Munda" and "Santhal".

Munda Group
The Pearson Chi-Square statistic for the Munda group is 171.777. The p-value for both Pearson and Likelihood Ratio tests is very small (close to 0). This indicates that there is a significant association between education level and belief in allopathic medicine among the Munda group. In other words, education level is not independent of belief in allopathic medicine for this group.

Santhal Group
The Pearson Chi-Square statistic for the Santhal group is 147.804. The p-value for both Pearson and Likelihood Ratio tests is again very small (close to 0). This signifies that there is a significant association between education level and belief in allopathic medicine among the Santhal group.

Combined Total
The combined total Chi-Square statistics (Pearson and Likelihood Ratio) for all cases is 257.995 and 320.953, respectively. The p-value for the combined total tests is very small (close to 0), indicating a significant association between education level and belief in allopathic medicine across both tribal groups.

Conclusion
Overall, the Chi-Square test results indicate a statistically significant relationship between education level and belief in allopathic medicine among both the Munda and Santhal tribal groups. The low p-values strongly suggest that education level and belief are not independent; they are associated with each other. However, the tests themselves do not reveal the direction or strength of the association—only that it exists. The table contains the results of Chi-Square tests that were conducted to assess the relationship between income level and belief in allopathic medicine within the two tribal groups, "Munda" and "Santhal".

Maninder Kumar Singh *et al.,*

Munda Group:

The Pearson Chi-Square statistic for the Munda group is 96.364. The p-value for both Pearson and Likelihood Ratio tests is very small (close to 0). This indicates that there is a significant association between income level and belief in allopathic medicine among the Munda group. In other words, income level is not independent of belief in allopathic medicine for this group.

Santhal Group

The Pearson Chi-Square statistic for the Santhal group is 107.062. Just like in the Munda group, the p-values for both Pearson and Likelihood Ratio tests are very small (close to 0) for the Santhal group as well. This suggests that there is a significant association between income level and belief in allopathic medicine among the Santhal group.

Combined Total

The combined total Chi-Square statistics (Pearson and Likelihood Ratio) for all cases is 140.790 and 197.101, respectively. The p-value for the combined total tests is very small (close to 0), indicating a significant association between income level and belief in allopathic medicine across both tribal groups.

Conclusion

The Chi-Square test results suggest a statistically significant relationship between income level and belief in allopathic medicine for both the Munda and Santhal tribal groups. The small p-values indicate that income level and belief are not independent; they are associated with each other. However, these tests do not provide information about the strength or direction of the association—only that a significant relationship exists.

The table presents data regarding individuals' beliefs in native medicine and the extent to which they hold those beliefs. Cumulative Percent: This column shows the cumulative percentage up to a certain response option. For instance, the "Cumulative Percent" for the "Yes to a large extent" group (197 respondents) is 66.5%, indicating that 66.5% of respondents believe in native medicine to some degree or more.

Interpretation

The majority of respondents fall into the categories of believing in native medicine to some extent. Specifically, 40.2% of respondents strongly believe in it ("Yes to a large extent"), and 33.5% believe in it to a lesser degree ("Yes to some extent"). There are varying degrees of scepticism as well. About 12.2% of respondents have some doubts about native medicine ("No to some extent"), and 6.1% do not believe in it at all ("No not at all").A small percentage of respondents (8.0%) hold a neutral stance on this matter. The cumulative percentage shows that a substantial majority (66.5%) of respondents have some level of belief in native medicine, while 14.1% hold a more doubtful view, and 8.0% remain neutral. The table provides insights into the diversity of opinions regarding native medicine's effectiveness, highlighting varying levels of belief and disbelief among the surveyed individuals. The table displays the distribution of responses about the extent of belief in native medicine among two different tribal groups, "Munda" and "Santhal," based on their education level and monthly income. The table presents the percentage distribution of responses for each tribal group and income category.

Interpretation

Munda Tribal Group

The majority of Munda respondents across all education levels and income categories fall into the "Yes to a large extent" belief category, with percentages ranging from 39.0% to 66.7%. There is a noticeable trend where higher education levels correspond to higher levels of belief in native medicine. For instance, respondents with "Post Graduate" education have percentages of 40.0% and 20.0% for "No not at all" and "Yes to a large extent" categories, respectively. A similar trend can be observed in income categories, where respondents with higher incomes tend to have higher belief percentages.

Maninder Kumar Singh *et al.,*

Santhal Tribal Group

Like the Munda group, the majority of Santhal respondents across all education and income categories fall into the "Yes to a large extent" belief category. Comparable education and income trends are observed for the Santhal group as well. In summary, the table provides a detailed breakdown of belief in native medicine among the "Munda" and "Santhal" tribal groups, considering their education levels and income categories. It suggests that, generally, higher education levels and incomes are associated with a stronger belief in native medicine among both groups The table contains the results of Chi-Square tests conducted to analyse the relationship between education level and belief in native medicine within two tribal groups, "Munda" and "Santhal".

Interpretation

Munda Group

The Pearson Chi-Square statistic for the Munda group is 165.577. This value represents the extent of discrepancy between the observed distribution of responses and the distribution that would be expected if the variables (education and belief) were independent. The p-value for both Pearson and Likelihood Ratio tests is very small (close to 0). This indicates that there is a significant association between education level and belief in native medicine among the Munda group. In other words, education level is not independent of belief in native medicine for this group.

Santhal Group

The Pearson Chi-Square statistic for the Santhal group is 111.980. Similar to the Munda group, this statistic measures the association between education and belief in native medicine for the Santhal group. As in the other groups, the p-values for both Pearson and Likelihood Ratio tests are very small (close to 0) for the Santhal group. This indicates that there is a significant association between education level and belief in native medicine among the Santhal group.

Combined Total

The combined total Chi-Square statistics (Pearson and Likelihood Ratio) for all cases is 175.031 and 196.760, respectively. The p-value for the combined total tests is very small (close to 0), indicating a significant association between education level and belief in native medicine across both tribal groups.

Conclusion

The Chi-Square test results imply a statistically significant relationship between education level and belief in native medicine for both the Munda and Santhal tribal groups. The low p-values indicate that education level and belief are not independent; they are associated with each other.

The table y shows the results of Chi-Square tests conducted to explore the relationship between monthly income (PM) and belief in native medicine within two tribal groups, "Munda" and "Santhal".

Interpretation

The Pearson Chi-Square statistic for the Munda group is 158.471. The Likelihood Ratio statistic is 161.573 for the Munda group. The p-value for both Pearson and Likelihood Ratio tests is very small (close to 0). This indicates a significant association between monthly income level and belief in native medicine among the Munda group. In other words, monthly income level is not independent of belief in native medicine for this group.

Santhal Group

The Pearson Chi-Square statistic for the Santhal group is 97.626. This statistic assesses the association between monthly income and belief in native medicine for the Santhal group. Just like in the Munda group, the p-values for both Pearson and Likelihood Ratio tests are very small (close to 0) for the Santhal group as well. This signifies a significant association between monthly income level and belief in native medicine among the Santhal group.

Combined Total

The combined total Chi-Square statistics (Pearson and Likelihood Ratio) for all cases is 199.761 and 227.451, respectively. The p-value for the combined total tests is very small (close to 0), indicating a significant association between monthly income level and belief in native medicine across both tribal groups.

Conclusion

In conclusion, the Chi-Square test results suggest a statistically significant relationship between monthly income level and belief in native medicine for both the Munda and Santhal tribal groups. The low p-values indicate that monthly income level and belief are not independent; they are associated with each other. The represents the distribution of treatment methods used in the case of a health issue. The respondents were asked about the type of treatment they prefer or use for addressing health problems. The two options mentioned are "Allopathic" and "Native. Allopathic (70.0%): This group indicates that 70.0% of the respondents use or prefer allopathic treatment methods when dealing with health issues. Allopathy is a conventional medical approach commonly practiced by medical doctors and involves using drugs or interventions to counteract symptoms or diseases. Native (30.0%): The remaining 30.0% of respondents mentioned using or preferring "Native" treatment methods. This term is often used to describe traditional or alternative treatments that may have cultural or traditional roots and could include practices like herbal medicine, homeopathy, acupuncture, Ayurveda, or other non-conventional approaches. In summary, the data suggests that a significant majority of respondents (70.0%) prefer or use allopathic treatment methods for addressing health issues. However, a substantial minority (30.0%) opt for "Native" or traditional treatment methods. This breakdown provides insights into the distribution of treatment method preferences among the surveyed population for dealing with health problems.

SUMMARY AND CONCLUSION

The research findings revolve around awareness, beliefs, and treatment preferences related to health programs and medicinal approaches within the "Munda" and "Santhal" tribal communities. The data has been analyzed using Chi-Square tests to explore the relationships between variables.

Awareness of Health Programs

The data suggests that within both the "Munda" and "Santhal" groups, there exists a moderate level of awareness regarding health programs. Higher education and income levels are associated with increased awareness. The Chi-Square tests reveal a significant relationship between education level and awareness, as well as between income level and awareness, in both tribal groups.

Belief in Allopathic Medicine

A significant majority of respondents across both groups hold some level of belief in modern allopathic medicine. The degree of belief varies, with a considerable portion expressing strong belief, followed by moderate belief. The Chi-Square tests indicate a strong and significant relationship between education level and belief in allopathic medicine, as well as between income level and belief, for both "Munda" and "Santhal" groups.

Belief in Native Medicine

The research reveals that a majority of respondents have varying degrees of belief in native medicine, with a substantial proportion expressing strong belief and moderate belief. A smaller percentage expresses doubt or skepticism. The Chi-Square tests demonstrate a significant relationship between education level and belief in native medicine, as well as between income level and belief, within both tribal groups.

Treatment Preferences

In terms of treatment preferences for addressing health issues, the data shows that a significant majority of respondents (70.0%) prefer or utilize allopathic methods, while a substantial minority (30.0%) opt for traditional

"Native" methods. This provides insight into the distribution of treatment preferences among the surveyed individuals. Overall, the research underscores the connections between education levels, income levels, beliefs, and preferences for health programs and treatment methods within the "Munda" and "Santhal" tribal communities. Chi-Square tests consistently reveal significant associations, indicating that these factors are not independent of each other and are interconnected in shaping health-related attitudes and behaviors within these groups. However, while the Chi-Square tests establish the presence of relationships, they do not provide insights into the strength or direction of these associations. To sum up, the research findings provide a comprehensive analysis of awareness and beliefs related to health programs and treatment methods within the "Munda" and "Santhal" tribal communities. The data reveals significant insights into the connection between education levels, monthly income, and these aspects. Across both tribal groups, a moderate level of awareness is observed regarding health programs, with higher education and income levels associated with increased awareness. Similarly, belief in modern allopathic medicine and native medicine shows a similar trend, with higher education and income levels corresponding to stronger belief. The Chi-Square tests conducted further strengthen these associations, indicating a statistically meaningful relationship between education level and awareness, as well as belief in both allopathic and native medicine. The tests highlight the non-independence of education level and income with these factors, emphasizing their interconnectedness. Furthermore, the data sheds light on the distribution of treatment preferences, showing that a significant majority of respondents favor or utilize allopathic treatments, while a substantial minority opt for traditional or "Native" methods. This distribution reflects the diverse perspectives and choices within the surveyed population when addressing health issues. In conclusion, the research findings provide valuable insights into the dynamics of awareness, beliefs, and treatment preferences within the "Munda" and "Santhal" tribal communities. The data underscores the influence of education levels and monthly income on these aspects and highlights the intricate relationships that exist among these variables. This information contributes to a deeper understanding of health-related perceptions and choices within these tribal groups.

ABSTRACT

Using bio-enzyme in agriculture supports sustainable farming while also reducing the environment impact of traditional farming practices. These enzyme improve soil health, reduce chemical inputs because they use as fungicide, insecticide and also used as detergent. Bio-enzyme also promotes the healthy ecosystem. The effect of citrus-banana Bio-enzyme on biochemical of Flat bean seedlings leaves was determined. After 2 days of germination Flat bean were treated with different concentration (2%, 4%, 6%, 8%, 10%) of bio-enzyme. An assess the effect of this bio-enzyme on biochemical like Phenol , Protein , Starch , Reducing sugar , Total sugar content of Flat bean seedling leaves. Highest amount of Phenol and Protein were found in 6% treated flat bean seedlings leaves. More amount of starch were found in control untreated seedlings leaves. Highest amount of Reducing sugar and Total sugar were found in 8% and 4% respectively.

Keywords: Flat bean, Seedling, Citrus-banana Bio-enzyme, Biochemical, Estimation.

INTRODUCTION

The United Nations Environment Programmer's Food Waste Index Report 2021 shows that about 50 kg of food is thrown away annual per person in Indian homes. In India, daily near 7.5 tons of food were wasted; this food is disposed of in trash cans alongside sewage, which increase its overall waste production. There's a shortage of awareness of food waste. Food waste is often disposed of in landfills, which adds to the overall volume of garbage there and increase greenhouse gas emission and other forms of pollution. Additionally, chemical herbicides and fertilizer are widely used in agriculture cultivation, which reduces the soil's ability to bind nutrient [7]. An alternative way to chemical based and solid based natural fertilizer is bio-enzyme. It is natural, easy to use for plant's

79778

Divya B. Sadhu *et al.,*

absorption, biodegradable, cheap, recycle the waste products and non-toxic to environment. There are various names are found for Bio-enzyme such as Garbage enzyme, eco-enzyme, fruit enzyme, Terrazyme and Flower enzyme [6]. First to develop the bio-enzyme from solid waste was Dr. Rosukon Poompanvong [7]. A mixture of jiggery/molasses, fruits and vegetable peels, kitchen waste and water is work as raw material for fermentation process to make bio-enzyme. Some microorganism also helps to form a bio-enzyme [8].

MATERIALS AND METHODS

Soil preparation
75% soil and 25% fertilizer were mixed in ratio of 3:1 and six pots of was equally filled with prepared soil mixture.

Plant growing
Seed of flat bean was grown in six pots in January month of 2024 and equal amount of water was sprinkled in each pots after one day of time interval.

Bio-enzyme treatment
Citrus and Banana Bio-enzyme was used to treat the seed of flat bean after germination. One of grown flat bean seedling pot was not treated with bio-enzyme, remain untreated called as control. Remains five pots treated with respective different concentration of bio-enzyme such as 2%, 4%, 6%, 8%, 10%. And this treatment repeated after 8 days of time interval for 16 days and also labeled the pots.

Biochemical test
After 16 days leaves of control and treated seedling with concentration of Bio-enzyme 2% , 4% , 6% , 8% , 10% collected for an estimation of Phenol , Protein , Starch , Reducing sugar and Total sugar.

Estimation of Phenol
Phenol estimation Folin-Ciocalteu reagent method was performed. 100 milligram fresh leaves of flat bean from control and treated seedling with various concentration of bio-enzyme was taken. Separate grind it with 10 ml 80% boiling ethanol in mortal pastel. Centrifuge it at 5000 rpm for 10 min and take supernatant I in other test tube. Now, add 10 ml 80% ethanol in residue and again centrifuge at 5000 rpm for 10 minutes. Take supernatant II and mix the supernatant I & II and discard the residue. Take 1 ml aliquot and 1 ml 20% Na_2CO_3 in test tube and add 0.5 ml 1 N Folin-Ciocalteu reagent. Now boil the mixture in water bath for 10 min and cool it. Make the final volume of 20 ml with distilled water. Check Absorbance at 600 nm for Phenol estimation[2].

Estimation of Protein
Estimation of Protein in flat bean seedling leaves was performed using Bradford's method. Take 1 gram fresh leaves of flat bean control and treated seedling with various concentration of bio- enzyme. Future separate grind it in 10 ml phosphate buffer (pH-7.2) using mortal pestle. Now centrifuge it at 10,000 rpm for 15 min. Take 0.2 ml supernatant and discard the residue. Add 5 ml Bradford reagent in the mixture. Now check absorbance at 595 nm [1].

Estimation of Starch
Starch estimation in flat bean seedlings leaves was done using Hedge's method. Separately Take 100 milligram fresh leaves of flat bean from control and treated seedling. Grind it with 10 ml 80% boiling ethanol in mortal pestle. Now centrifuge it at 5000 rpm for 10 min and discard the supernatant. Add 10 ml 80% ethanol in the residue and again centrifuge at 5000 rpm for 10 min. discard the supernatant. Put residue in water bath for drying. Now add 5 ml water and 6.5 ml 52% $HClO_4$ in the mixture. Put it in 0°C for 20 min. centrifuge it. Take supernatant II and mix it with supernatant I, discard residue. Make 100 ml of final volume by adding distilled water and add 0.2 ml aliquot. Add water make volume up to 1 ml. now add 4 ml anthron in them. Boiling for 8 min and cool rapidly. Green color appearance in the mixture. Check absorbance at 630 nm [3].

Divya B. Sadhu *et al.,*

Estimation of reducing sugar
Somogayi's method was performed to estimate reducing sugar in leaves of flat bean seeding. Take 100 milligram fresh leaves of flat bean from control and treated seedlings. Separate grind it with 10 ml 80% boiling ethanol in mortal pestle. Centrifuge it at 5000 rpm for 10 min and Take the supernatant I in other test tube. Add 10 ml 80% ethanol in residue. Again centrifuge it at 5000 rpm for 10 min. take supernatant II in other test tube and mix both supernatant I & II and the discard residue. Now take 1 ml aliquot in test tube and add 1 ml nelson somogayi reagent boil the mixture at 100 °C for 10 min. add 1 ml arsenomolybdate in them. Check absorbance at 680 nm [5].

Estimation of Total sugar
Estimation of total sugar Nelson's method was performed. Take 100 milligram fresh leaves of flat bean from control and treated seedlings. Separate grind it with 10 ml 80% boiling ethanol in mortal pestle. Centrifuge it at 5000 rpm for 10 min. take supernatant I in other test tube and add 10 ml 80% ethanol in the residue. Centrifuge it again at 5000 rpm for 10 min. take supernatant II in other test tube and mix both supernatant I & II, discard the residue. Now take 1 ml aliquot and incubate it for 30 min at 49 °C. Add 1-2 drop methyl red indicator in the mixture. Add 1 M NaOH drop wise till color change Pink to Yellow). Now add 1 ml Nelson somogayi reagent and incubate it for 20 min in water bath. Add 1 ml arsenomolybdate and make final volume of 20 ml with distilled water. Check absorbance at 620 nm [4].

RESULTS

After 16 days, plant growth was found more in various concentrated bio-enzyme treated flat bean seedlings than controlled flat bean seedlings.

Estimation of Phenol
Table 1 and Graph 1, show the highest amount of phenol 5.38 µg/ml was reported in 6% treated leaves of flat bean seedling with bio-enzyme which was greater than 4.03 µg/ml phenolic content in control leaves of flat bean seedling. 4.21 µg/ml and 4.13 µg/ml phenolic content respectively founds in 4% and 10% treated seedling's leaves. In 2% and 8% treated flat bean seedling's leaves respectively shows the less amount of phenolic content 3.78 µg/ml and 2.55 µg/ml.

Estimation of Protein
Table 2 and Graph 2, show the highest amount of protein 0.298 mg/ml was reported in 6% treated leaves of flat bean with bio-enzyme which is greater than 0.266 mg/ml in untreated control seedling's leaves. 0.264 mg/ml and 0.263 mg/ml protein contain respectively found in 2% and 4% treated leaves of flat bean. 0.288 mg/ml and 0.279 mg/ml respectively reported in 8% and 10% treated leaves of seedling.

Estimation of Starch
Table 3 and Graph 3, show highest amount of 0.0994 mg/ml starch was reported in untreated control leaves of flat bean seedling. 0.0984 mg/ml, 0.0982 mg/ml respectively found in 2% and 4%, lowest amount of starch 0.0974 mg/ml found in 8% treated leaves of flat bean with bio-enzyme. 6% and 10% treated leaves shows the same 0.0979 mg/ml starch contain.

Estimation of reducing sugar
Table 4 and Graph 4, show highest amount of 0.505 mg/ml was reported in 8% treated leaves of flat bean seedling. Which is greater than 0.279 mg/ml reducing sugar in control. 0.267 mg/ml, 0.334 mg/ml and 0.398 mg/ml reducing sugar respectively found in 2%, 4% and 10% treated leaves of flat bean seedling. Treated leaves of flat bean with 6% bio-enzyme shows the 0.469 mg/ml reducing sugar.

Estimation of Total Sugar

Table 5 and Graph 5, show the more amount 1.409 mg/ml and 1.359 mg/ml total sugar are respectively found in 4% and 10% treated leaves of flat bean seedling. Which was greater than 0.801 mg/ml in control leaves of flat bean seedling. 0.680 mg/ml, 0.788 mg/ml and 0.870 mg/ml total sugar respectively found in 2%, 6% and 8% treated leaves of flat bean seedling.

DISCUSSION

Phenolic content, Protein Content, reducing sugar and total sugar founds more in citrus and banana's Bio-enzyme treated leaves of flat bean seedlings. Starch content founds more amount in untreated control leaves of flat bean seedling than treated flat bean seedling's leaves. Phenolic and protein content found more in 6% treated leaves of flat bean seedling with bio-enzyme. Reducing sugar and total sugar respectively found more in 8% and 4% treated leaves of flat bean. Protein content gradually decrease after 6% treated leaves of flat bean seedlings and treated leaves with 2% and 4% concentration of bio-enzyme shows minute change in protein content with untreated leaves of flat bean seedling. For more accumulation of protein in flat bean seedling's leaves 6% concentration of citrus banana's bio-enzyme would be beneficial. Reducing sugar gradually increase in flat bean seedlings as concentration of citrus-banana's bio-enzyme increases. For total sugar content 4% concentrated, for reducing sugar 8% concentrated, for phenolic content 6% concentrated citrus-banana's bio-enzyme would be beneficial to leaves of flat bean seedling.

CONCLUSION

A present study concluded that leaves of flat bean seedling treated with bio-enzyme shows more concentration of total sugar , reducing sugar , protein and phenolic content that untreated control leaves of flat bean seedling. Where starch found in more amount in control untreated leaves of flat bean seedling. In flat bean seedling the phenol and protein shows the higher concentration in 6% treated leaves of flat bean with citrus banana bio-enzyme. Reducing sugar shows higher concentration in 8% and total sugar shows higher concentration in 4% treated leaves of flat bean seedling.

ABSTRACT

This research proposes a novel approach to enhance the security of Play fair and Polybius ciphers by improving the 10x10 Polybius Square Key Matrix using K-Means Clustering. The extended key matrix has historically suffered from low entropy when using short keys, leading to potential vulnerabilities. By applying K-Means Clustering, this study aims to increase the complexity and entropy of the key matrix, thereby improving the security of the ciphers. The results demonstrate a significant enhancement in the average avalanche effect, ensuring a more robust encryption process, especially in scenarios where an unmodified key matrix would yield a minimal avalanche effect.

Keywords: Cryptography, Playfair cipher, Polybius cipher, Key matrix, K-Means Clustering, Encryption, Avalanche effect

INTRODUCTION

From classical to modern ciphers, cryptography has remained one of the most powerful and oldest techniques for ensuring information security. Ciphers have been used as a reliable means of protecting sensitive information from prying eyes. To keep up with today's state of encryption, many of these ciphers need to be improved due to their inherent insecurity. (1). One of the first encryption methods ever documented is the Polybius Square Key Matrix,

Janvi Sanjaykumar Patoliya *et al.,*

which is also regarded as one of the most popular encryption techniques used in ciphers. The key matrix was initially employed in the Polybius Cipher, which bears its name. Subsequently, it was refined and expanded upon by various ciphers that are still in use today(10). Modernization of the algorithm has benefited from improving the Polybius Square key matrix from a 5 by 5 matrix to a 10 by 10 matrix. This expansion greatly increased the number of characters that could be used for encryption and decryption, from 26 characters of the alphabet to 100 characters x, usually in ASCII(8). Modernizing the algorithm has benefited from expanding the Polybius Square Key Matrix from its original 5x5 matrix to a 10x10 matrix. This expansion has greatly increased the number of characters that can be used for encryption and decryption, from the 26 letters of the alphabet to 100 characters, usually in ASCII(11). This study proposes securing an enlarged 10x10 square of the key matrix using k-means clustering. This enhancement improves efficiency, security, and usability. To protect information, data is converted to an obfuscated format using a variety of ciphers and encryption technologies. The Polybius cipher is believed to be one of the most widely used among them. Polybius created one of the earliest known encryption methods. The Polybius square is among the first techniques created for fractionating letters to replace numbers in unencrypted communications. Based on classical to modern ciphers, one of the most powerful and oldest techniques for assuring information security has been cryptography. Throughout time, classical ciphers have been utilized as an accurate means of protecting valuable data from unauthorized others. It is important to take measures and pass information from the sender to the receiver to ensure that a third party can't find it. The encryption-decryption procedure, in which the sender encrypts the message using a secret key that the recipient of the message just understands, is one technique for protecting data. Using the same secret key, the message is decoded once it reaches the recipient. Symmetric encryption is the name for this kind of encryption. Cryptography is a Greek word that means secret writing. Today this term refers to the science and art of transforming messages to make them secure and immune to attacks(3). The Polybius Square Key Matrix has expanded largely because of the increasing number of available characters and the enlargement of the matrix. However, when using shorter keys, the increased 10x10 Polybius square matrix shows little to no avalanche effect. Small changes in the short key have little to no effect on the outputted ciphertext, as demonstrated by testing the avalanche effect of the augmented matrix by flipping the bits of each key while increasing the array of characters and converting the Polybius square key matrix into a 10x10 matrix. Cryptographic techniques play a significant role in any communication network's security design. Symmetric key algorithms are a type of these algorithms that employ one key to encode and translate data. The stream cipher, in which the encryption rule is developed based on a plaintext symbol's position in the stream of plaintext symbols, and the block cipher, which encrypts several plaintext symbols at once in a block, are essential techniques ways to create a stronger cipher(8).

LITRATURE SURVEY

Maintaining the Integrity of the Specifications(1). The original 5x5 matrix Playfair cipher is modified to a 7x4 matrix Playfair cipher in this paper. The symbols "*" and "#" are included in the matrix, resulting in a one-to-one connection between the plaintext and the ciphertext. As an outcome, the procedures for decryption and encryption are clear and simple. The suggested method differs in that it may be applied to any language by simply selecting an appropriate matrix that will accommodate all alphabets of that language(3). The traditional Playfair cipher's basic drawback is that plain text can contain only 25 capital characters. After decoding, one letter must be omitted and cannot be reassembled. Also, lowercase letters, white space, numbers, and other printable characters cannot be handled by the traditional cipher. This signifies that this cipher cannot handle entire sentences. In plaintext, a space between two words is not considered one character. When the plaintext word has an odd number of characters, a spare letter X is appended. In this study, we examined the advantages and disadvantages of the original Playfair cipher. The modified Playfair cipher with a 10 x 9 matrix was then discussed. We utilized all alphanumeric characters as well as some special characters in this matrix. Six distinct keys and six iteration stages are utilized in this modified Playfair cipher to make the encrypted message stronger than the conventional Playfair cipher(4). The proposed algorithm outperforms current 8 x 8 matrices. It improves security, using increasing complexity to hack the original text. This algorithm uses different types of keys for the Four-square encryption process. When using a symmetric key cryptosystem, the keys are utilized to modify the plaintext, converting the 5x5 matrix into an enhanced format of

Janvi Sanjaykumar Patoliya *et al.,*

10x10 matrixes(7). We analyzed any modifications made to the Playfair cipher. To solve the problems using the traditional Playfair cipher, the first modification is to implement an 8*8 matrix(12). This study modifies the 5x5 Polybius square by dynamically shifting the elements in the grid determined through the keys' ASCII code. Simulation results revealed that the proposed method is more secure against the unmodified Polybius cipher(15). The Playfair cipher is a well-known multiple-letter encryption cipher. The plaintext diagrams are treated as single units and transformed into corresponding cipher text diagrams. However, because of the drawbacks inherent in the 5*5 Playfair cipher which adversely affects the security we proposed an 8*8 Playfair cipher(17). Researchers have expressed a strong desire to develop and adapt the Playfair Cipher algorithm to address its shortcomings. The previous decade saw a surge in cryptographic research for the Playfair cipher. While the classic Playfair Cipher is incapable of encrypting numeric characters, the technique is incompatible with many current technologies. The encryption of spaces between words is required because post-processing of the decrypted message is confused without it. This paper presents a Playfair Cipher modification that can encrypt both alphanumeric letters and spaces. The study achieves its aim by increasing the dimension of the key matrix from 5 by 5 to 6 by 6 and presenting a mechanism for replacing gaps in the reduced key matrix with configurable digraphs(18). However, due to a few flaws in the original 5 × 5 Playfair cipher, a recently enhanced version of the Playfair encryption, known as the Extended 88 Playfair cipher, has been developed. To conceal the presence of any such communications, an extended Playfair cipher with the Least Significant bit of steganography is used in this study. The primary goal of this effort is to create a secure system for sending and receiving communications. The results suggest that combining the extended 8 × 8 Playfair cipher with steganography improves message security over the existing standard Playfair ciphers(20). Drawbacks of Traditional Playfair Cipher: The original Playfair is a 5*5 grid of 25 letters that can only be uppercase and cannot encrypt lowercase letters, whitespaces, or different printable characters. Furthermore, one letter will be eliminated due to the 25 squares. Because this is the major disadvantage, various new approaches have been considered.

PROPOSED METHOD

Polybius Square-based ciphers apply different encryption algorithms, but all use the Polybius Square as the key matrix upon which the encryption is built. In the 10x10 expansion of the square matrix, there are 100 ASCII characters within the square, with 95 legible ASCII characters and 5 extended ASCII characters. It uses a key to initialize the square matrix's characters and is encoded into each cell of the square from top left to right row by row, ignoring the key's repeated characters. Once all of the key's characters have been encoded into the square, all additional square matrix characters not contained in the key are added to the remaining cells in the 10x10 square's default sequence of characters(21). The 10x10 Polybius Square Key Matrix base system, the K-Means augmented 10x10 Polybius Square Key Matrix, and the ciphers and performance metrics used to assess the key matrices were all created in Python for this study using Google Colab, with dependencies on NumPy and PIP. The 95 readable ASCII characters and the 5 special characters from the expanded ASCII are used to encode a 10x10 2D array. Next, entropy is added to the square using a user-supplied keyword. Under PIP, the model is set to 128 bits, and the taps are configured to output the maximum number of bits in an 8-character keyword. The k-Means Cluster is imported from pylfsr(14). The binary output is transformed into a collection of ASCII characters using the same keyword that served as the LFSR model's seed. The distinct characters are then encoded into a brand-new 10x10 2D array. The five unique extended ASCII characters are added after all 95 distinct ASCII characters have been encoded into the array by repetition of this operation. The Polybius, Bifid, and Playfair ciphers will be the main subjects of the investigation. The numerous literatures cantered on each cipher will serve as the foundation for the mechanics of these ciphers(21).

RESULTS AND DISCUSSION

The avalanche effect test will be used to quantify the improvements of the new algorithm compared to the current method. The baseline will be the initially expanded 10x10 Polybius Square Key Matrix. Both the baseline and the suggested encryption methods will employ three ciphers, and each performance metric will be applied to a different

cipher. The Polybius Cipher and the Playfair Cipher will be the ciphers utilized. To measure the power of a cryptographic method, the avalanche effect is tested using the least amount of keyword changes. The "avalanche effect" in cryptography refers to the property where even a small alteration in the input, such as one bit, would have a significant impact on the output[11]. Ten keywords for each cipher would be used to encrypt one plaintext in order to evaluate the avalanche effect. The same keywords would then be utilized to encrypt the plaintext, with one letter modified for each keyword. The original keyword's ciphertext and ciphertext to depict the avalanche effect, different keywords will be clustered together by computing the percentage difference between the two ciphertexts. The average avalanche impact of the cipher will next be evaluated by computing the percentage average of these ten results. The average avalanche impact of every used cipher is significantly improved by the cluster-enhanced key matrix as compared to the base key matrix. Some of the base matrix's keywords exhibit moderate gains, while others exhibit a 0% avalanche effect, which indicates that the ciphertext of the two distinct keywords is the same. These keywords are significantly improved by the cluster-enhanced key matrix. The findings demonstrate that the k-means cluster augmentation may be able to lessen the avalanche impact of other Polybius Square-based ciphers, which in some cases may also exhibit a 0% avalanche effect.

CONCLUSION

According to the study's findings, ciphers can enhance the avalanche effect of the extended 10x10 Polybius Square Key Matrix by utilizing the K-means Cluster as a key stretching function to simulate a longer key for short keys. This is particularly true in situations where the avalanche effect of the base 10x10 key matrix would otherwise result in 0%. For future work, the researchers recommend further examination of the K-Means Clustering to utilize a model with higher bits to increase the probability of entropy. Additionally, the researchers suggest applying the K-Means-enhanced 10x10 Polybius Square Key Matrix to other Polybius Square-based ciphers that were not more thoroughly covered in the study, such as the Two-Square cipher and Four-Square cipher. Further studies in these areas could provide valuable insights into the effectiveness and applicability of the proposed methods.

Table1.Indexed Polybius cipher modifications

Sr. No.	Title	Authors/ Year	Methods	Purpose	Significant Results
1	An Extended Version of the Polybius Cipher	Kondo & Mselle (2013)	Modified the Polybius cipher with the introduction of 8x8 Polybius square grid	To improve cipher capabilities, enlarge the usual 5x5 grid Polybius square.	Plaintext comprising numerals, special symbols, and alphabets may now be encrypted using the expanded Polybius square. Furthermore, the letters I and j are now separated, reducing uncertainty during the ciphering process.
2	A Modified Version of Polybius Cipher Using Magic Square and Western Music Notes	Maity (2014)	Modified Polybius Cipher with the introduction of a 6x6 magic square and musical notes	To bring variation into the classic Polybius cipher substitution process using the magic square theory, and to construct a music sequence from ciphertext.	The suggested approach provides a unique substitution process since the arrangement of alphabets is dependent on the unique magic squares created, making cracking challenging. In this study, no two characters are housed in the same cell.
3	A Hybrid Polybius-Playfair Music	C. Kumar, Dutta, &	Hybrid Polybius and Playfair	To include music cryptography into	The research has cleared the door for the

	Cipher	Chakraborty (2015)	ciphers with a secret key	ciphertext generation utilizing a key matrix for safe encryption and decryption using a hybrid Polybius-Playfair technique.	development of musical sequences utilizing a dual encryption approach. The hybrid approach provides suitable musical sequences without jeopardizing the security of the secret information. Characters In this proposed strategy, I and J continue to share the same cell
4	Development of Modified Polybius Technique for Data Security	P. Kumar & Rana (2015)	Modified the Polybius cipher with the introduction of a 6x6 Polybius square grid following a different arrangement of characters	To enhance the cipher's capacity by employing a 6x6 Polybius square and to provide a new technique of letter arrangement.	The study introduces a new character sequencing in the grid. The cipher may accommodate additional characters to be encoded and decoded with the addition of digits. Furthermore, because there are ample places for all letters and numerals, the characters I and J are split into different cells.
5	Design of a Modified AES Algorithm for Data Security	P. Kumar & Rana (2016)	Modified the Polybius cipher with the introduction of 6x6 Polybius square grid	To convert the Polybius square into a 6x6 matrix for use in the key generation process of another cryptographic system.	The suggested change enables the processing of all letters and integers. As a result, the AES algorithm's key generation process has become safer and more advanced.
6	A Novel Structure of Advanced Encryption Standard (AES) with 3-Dimensional S-box, RSA-based Key Scheduling, and modified 3-Dimensional Polybius Cube Encipherment	Rahman et al., (2017)	Modified the Polybius cipher with the introduction of 9x9x9 Polybius cube	To provide a novel 3-dimensional Polybius cube for the key scheduling algorithm (KSA) that can accommodate letters, integers, and symbols.	The work presents a novel key generation procedure for the AES algorithm that employs a 3D dynamic substitution box with a ciphertext output of a trigram rather than a bigram. The cipher can handle capital letters, lowercase letters, digits, and most special characters with a larger capacity.
7	A Modified Polybius Square-Based Approach for	Manikandan, Rajendiran, Balakrishnan,	Modified the ciphertext generation	To present several transmutation techniques for the	The modified Polybius cipher offers diverse ciphertext generation

ABSTRACT

The rapid proliferation of online communication platforms has magnified the prevalence and impact of hate speech, posing significant challenges for content moderation. This research aims to enhance the accuracy and sensitivity of hate speech detection systems by integrating advanced natural language processing techniques that can more effectively discern the subtleties and complexities of language.This paper introduces the MSADCR model, an advanced version of the BERT framework enhanced with Semantic Multi-level Augmentation (MSA) and Dynamic Context Refinement (DCR). MSA enriches the model's word embeddings with external semantic knowledge, providing deeper insights into the meanings of words and phrases. DCR dynamically adjusts the context windows during the model's attention phases, focusing on the most relevant textual elements. The model was trained and validated on several high-quality datasets, including Davidson-ICWSM, Waseem-EMNLP, and Waseem-NAACL, which contain diverse examples of hate speech. When compared to baseline models like Naive Bayes and SVM, MSADCR achieved superior performance metrics, with increases in accuracy (91%), precision (90%), recall (89%), and F1-score (89%) on the Davidson-ICWSM dataset. Similar gains were observed on other datasets, confirming the model's robustness and effectiveness. The novel integration of MSA and DCR into the BERT architecture represents a significant advancement in the field of hate speech detection.

Keywords: Hate Speech Detection, Semantic Augmentation, Context Refinement, Natural Language Processing, MSADCR.

Solomon Praveen Kumar and Mythili

INTRODUCTION

The increasing complexity of online communication has made it clear that more sophisticated solutions are necessary. This has led researchers and technologists to delve into advanced natural language processing (NLP) techniques designed to accurately interpret the intricacies of human language. The development and implementation of such technologies are vital for enhancing content moderation systems, maintaining discourse standards, and protecting users from harmful content on digital platforms. Against this backdrop, this paper explores innovative methods that could fundamentally transform how online hate speech is detected and managed. The motivation behind enhancing hate speech detection technology stems from the need to address the limitations of current systems in moderating online platforms effectively. Traditional methods, which often rely on straightforward keyword searches and basic language patterns, frequently misunderstand the context or miss subtle cues, leading to incorrect classifications. This can either unfairly censor innocent communications or fail to prevent the spread of genuinely harmful content.

Given the vast and diverse nature of online interactions, there is a critical need for a system that not only understands words and phrases but also grasps the nuances of context, intent, and cultural differences. Such a system would significantly improve the accuracy of content moderation, reducing the burden on human moderators and limiting the exposure of users to potentially damaging speech. The growing impact of online hate speech on society, including its potential to incite violence, discriminate against marginalized groups, and influence public opinion negatively, underscores the urgency for more advanced and effective detection methods. By focusing on improving hate speech detection technologies, it aims to contribute to safer online environments and more respectful and constructive discourse on digital platforms.

This model aims to address the current challenges faced by traditional content moderation systems by enhancing the accuracy, efficiency, and adaptability of hate speech detection across various digital platforms. Specifically, the research is designed to achieve the following goals:

- *Enhance Linguistic Understanding:* Implement MSA to enrich the semantic processing capabilities of the MSADCR model, allowing it to grasp deeper meanings and subtle nuances in language that are often indicative of hate speech.
- *Improve Contextual Sensitivity:* Integrate DCR to dynamically refine the context in which words and phrases are analyzed, ensuring that the model considers relevant linguistic surroundings that can alter the intent and meaning of speech.
- *Reduce False Positives and Negatives:* By improving semantic and contextual analysis, the model is expected to more accurately differentiate between true hate speech and non-hateful content that may contain similar words or phrases, thereby reducing errors in content moderation.

The organization of this paper follows a systematic structure designed to present the research on the MSADCR model for hate speech detection comprehensively. The paper begins with an Introduction, setting the stage by discussing the significance of the problem and the motivations behind the study. This is followed by a detailed Literature Review that contextualizes the research within existing works. The Methodology section delineates the theoretical framework, the model's architecture, and the specific algorithms employed, providing a deep dive into the technical aspects. In the Results and Discussion section, the findings are presented and compared against baseline models. The paper concludes with the Conclusion, summarizing the study's contributions and suggesting directions for future research.

Solomon Praveen Kumar and Mythili

LITERATURE REVIEW

The exponential growth of digital platforms has transformed the landscape of communication, allowing individuals worldwide to share ideas, opinions, and information instantaneously (Gawer, 2022). While this advancement in connectivity has numerous benefits, it has also given rise to significant challenges, one of the most pressing being the proliferation of hate speech (Mathew et al., 2020). Hate speech poses severe social, emotional, and psychological impacts on individuals and communities (Castaño-Pulgarín et al., 2021). As digital platforms continue to grow, the volume and velocity of online content make it increasingly difficult for traditional moderation systems to monitor and manage hate speech effectively (Zuo et al., 2024). These systems often rely on keyword-based filters or simple machine learning models that fail to capture the contextual subtleties and cultural nuances essential for identifying hate speech accurately (Al Maruf et al., 2024). The result is a high rate of both false positives, where benign content is incorrectly flagged as hate speech, and false negatives, where actual hate speech goes undetected (Fenza et al., 2024).

Moreover, the dynamic nature of language, with constantly evolving slang and new colloquialisms, adds another layer of complexity to the detection process (Sundaram et al., 2024). Perpetrators of hate speech frequently use coded language, sarcasm, and context-dependent phrases to evade detection, further complicating the moderation efforts (Gandhi et al., 2024). Davidson et al. (2021) demonstrated the effectiveness of context-aware learning models in distinguishing nuanced expressions of hate speech across diverse online platforms, emphasizing the need for models that dynamically adapt to evolving linguistic contexts. Additionally, Waseem and Hovy (2016) explored the role of multimodal data integration, utilizing both textual and visual cues to enhance the detection accuracy of potential hate speech instances. Their work illustrates the benefits of combining multiple data sources to better understand the context and intent behind user-generated content. Deep learning frameworks like BERT have been particularly noted for their superior performance in processing complex language patterns (Vidgen and Derczynski, 2020).

METHODOLOGY

Theoretical Framework
Semantic Multi-level Augmentation (MSA)

Overview of MSA
MSA represents a key innovation in enhancing the semantic processing capabilities of natural language processing models, particularly in the domain of hate speech detection. MSA aims to enrich the model's embeddings by incorporating external semantic knowledge, which provides a deeper understanding of the context and subtleties associated with language use in social media. This augmentation facilitates a more nuanced interpretation of potential hate speech by bridging the gap between surface-level text features and underlying semantic meanings. MSA is grounded in the need to deepen the semantic interpretability of embeddings within NLP models, particularly those engaged in the complex task of hate speech detection. Traditional embeddings efficiently capture syntactic relationships but often lack the semantic depth required to discern subtle nuances in language that differentiate benign discourse from hate speech. The foundation of MSA is the enrichment of base model embeddings through the integration of semantic layers from expansive knowledge bases such as WordNet. These databases provide detailed semantic networks, encompassing relationships like synonyms, antonyms, hypernyms (broader terms), and hyponyms (narrower terms), crucial for a nuanced understanding of language.

Example of MSA
Consider the application of MSA to the word dog in different contexts:
1. Pet Context: The dog played in the yard.
2. Derogatory Context: You are a dog.

Solomon Praveen Kumar and Mythili

In a traditional embedding setup, dog would maintain a consistent vector across both sentences. However, MSA modifies this approach by dynamically augmenting the vector based on context-specific semantic relationships:

- In the Pet Context, MSA enriches the word dog with semantic associations like 'animal' and 'pet', aligning with benign meanings.
- In the Derogatory Context, the process involves adjusting the semantic vector to associate dog with terms such as 'insult' or 'slur', reflecting its pejorative use, which could be sourced from lexical databases detailing non-literal and culturally specific meanings.

During preprocessing, the context of each instance of dog is analyzed. A context-specific semantic vector is generated for the term:

- For the Pet Context, the vector is weighted towards positive and neutral connotations.
- For the Derogatory Context, the vector shifts towards negative connotations, emphasizing the derogatory usage detected based on the semantic relationships in the knowledge base.

Implementation of MSA

The implementation begins by identifying the base embeddings E generated by the pre-trained BERT model. Each word or token w in the vocabulary is associated with an embedding vector e_w $from$ E. To augment these embeddings with semantic information, an external knowledge base is queried to retrieve semantic relationships for each word. For each word w, retrieve related semantic concepts such as synonyms, hypernyms, and antonyms from a semantic database. Each semantic concept s related to w is represented by its embedding e_s, which can be sourced from the same initial embedding model to maintain consistency in vector space. The augmentation of the base embedding e_w with its related semantic embeddings e_s is performed using a weighted combination. Mathematically, the augmented embedding e'_w for word w is given in the equation 1:

$$e'_w = \alpha e_w + \sum_{s \in S(w)} \beta_s e_s \ \text{............................ (1)}$$

where:
- α is the weight for the original embedding $\boldsymbol{e_w}$.
- β_s are the weights for each semantic embedding $\boldsymbol{e_s}$, which are adjusted based on the relevance of each semantic relationship to the context of use.
- $S(w)$ represents the set of all semantic concepts related to w.

The weights α and β_s are crucial as they determine the influence of the original word embedding versus the semantic augmentations. These weights can be learned through training on a development set, optimized to enhance performance on specific tasks like hate speech detection. Alternatively, they may be set manually based on empirical observations or expert linguistic input. Once the augmented embeddings e'_w are prepared, they replace the original embeddings in the MSADCR model. This replacement ensures that during the model training and inference phases, the model uses embeddings that are rich in semantic content, enhancing its ability to understand and process complex language patterns typical of nuanced hate speech. MSA equips the MSADCR model with an advanced capability to understand not just the literal meaning of words but also their contextual implications. For instance, words that might typically appear neutral or benign can take on aggressive or derogatory connotations based on their usage in specific social or cultural contexts. MSA helps to capture these nuances by providing a richer semantic representation of each word. Let's consider a text sample X composed of words $w_1, w_2, \ldots, w_n$. The traditional BERT embedding for each word w_i is e_{w_i}. With MSA, the embedding is augmented to e'_{w_i} as given in the equaiton 2:

$$e'_{w_i} = \alpha e_{w_i} + \sum_{s \in S(w_i)} \beta_s e_s \qquad \text{..................... (2)}$$

The output vector y from the MSADCR model, which predicts whether text X is hate speech, is influenced by these augmented embeddings:

$$y = f\left(e'_{w_1}, e'_{w_2}, \ldots, e'_{w_n}\right) \qquad \text{..................... (3)}$$

Solomon Praveen Kumar and Mythili

where f represents the model's classification function, which could involve multiple layers of neural network processing. One of the direct impacts of integrating MSA is the reduction in false negatives, where hate speech might previously have been missed. This improvement occurs because the model now better understands contexts where certain terms or phrases are used with hateful intent, despite possibly appearing benign in isolation. Similarly, the model also reduces false positives by recognizing when seemingly harsh words are used in non-hateful contexts.

Dynamic Context Refinement (DCR)
DCR is a sophisticated technique designed to enhance the contextual processing capabilities of NLP models, particularly in the MSADCR framework. This methodology focuses on dynamically adjusting the contextual window around each word or phrase, enabling the model to better capture and interpret the surrounding linguistic environment, especially in complex scenarios like hate speech detection.

Overview of DCR
DCR operates by refining how context is utilized within the transformer architecture of BERT. Unlike static approaches that consider a fixed contextual range, DCR adapts the contextual focus based on the semantic importance and relevance of surrounding words. This adaptation allows MSADCR to pay more attention to contextually significant words that influence the meaning of the target phrase. Consider a sentence S with words $w_1, w_2, \ldots, w_n$. In a standard BERT model, the context window for each word w_i is static. DCR modifies this by introducing a variable context window size c_i for each word, influenced by its semantic and contextual importance. The refined embedding e'_{w_i} for each word w_i in the context of DCR can be represented as:

$$e'_{w_i} = \sum_{j=i-c_i}^{i+c_i} \gamma_{ij} \, e_{w_j} \qquad\qquad \ldots\ldots\ldots\ldots\ldots\ldots (4)$$

where e_{w_j} is the embedding of the j-th word in the window and γ_{ij} are the attention weights dynamically computed based on the relevance of each word w_j to the central word w_i.

Dynamic Adjustment of Context Windows
The size of the context window c_i and the weights γ_{ij} are determined by a combination of factors including the part of speech, semantic roles of the surrounding words, and their contributions to the overall sentence meaning. Techniques like attention mechanisms or reinforcement learning can be used to learn these parameters effectively during the training phase.

Example of DCR
Sentence Example: He threw a stone at the dog in jest.
In a typical static context model, equal importance might be given to all words around stone. However, with DCR:
- The words threw and at the dog are more contextually relevant to understanding the action involving the stone than in jest.
- Hence, DCR would dynamically increase the attention weights γ for threw and at the dog, while decreasing it for in jest.

This dynamic adjustment allows the model to focus more on the part of the sentence that conveys the main action and intent, aiding in more accurately determining the tone and context of the action described.

Model Architecture
The main model is based on multi-layer transformer encoder and the text input is transformed using self-attention and feed-forward sub-mappings. Every layer of the transformer helps in the understanding of linguistic relation between the elements of the input text. MSADCR consists of 12 transformer blocks, all of which have a hidden size of 768 units. This configuration is the same as in BERT-base and it is sufficient to provide the model with a rather large representational capacity, which allows it to learn a wealth of language phenomena effectively. Each

Solomon Praveen Kumar and Mythili

transformer block within the BERT-base model includes two main components: The design of the transformer consists of a multi-head self-attention mechanism and a position-wise fully connected feed-forward network. The actual size of 768 in each transformer block to accommodate input sequences is hidden, and the feed-forward networks of each of these blocks have a hidden size of 3072 units. These dimensions are important when the model has to train on often huge amount of textual data.

MSA is implemented at the embedding layer, where each input token's embedding is dynamically enhanced with additional semantic information derived from external databases. This enhancement enriches the input representations with broader linguistic and contextual awareness before they are processed by subsequent transformer layers.DCR is integrated within the attention mechanisms of the transformer layers. It modifies the self-attention operation to weight the importance of different words within the input sequence dynamically. This is achieved by adjusting the attention scores based on the contextual relevance of each word, allowing the model to focus more on significant contextual cues and less on irrelevant information. To integrate the enhancements from MSA and DCR, additional dense layers may be incorporated into the model architecture. These layers typically align with the hidden size of 768 units to ensure that the augmented semantic and contextual information is effectively synthesized within the existing BERT architecture. The output layer, tailored for the classification task, is designed to output probabilities across the designated classes (hate speech, offensive but not hate speech, and neither), facilitating precise and actionable predictions.

MSADCR Algorithm
The algorithm is structured to preprocess text data, enrich word embeddings with additional semantic information, refine these embeddings based on contextual relevance, and ultimately classify the text into appropriate categories. By formalizing this process through specific computational steps and mathematical notations, it aims to provide a clear and systematic understanding of how the MSADCR model processes and analyzes text for detecting hate speech effectively.

Algorithm: MSADCR Model for Hate Speech Detection
Input: Set of documents $D = \{d_1, d_2, \dots, d_n\}$
Output: Set of classifications $C = \{c_1, c_2, \dots, c_n\}$, where $c_i \in \{HateSpeech, Offensive, Neither\}$

Procedure:
Preprocess each document d_i:
        Convert to lowercase: $d_i' \leftarrow \text{lower}(d_i)$
        Tokenize: $T_i \leftarrow \text{tokenize}(d_i')$
        Clean tokens: $T_i' \leftarrow \text{clean}(T_i)$
        Lemmatize: $T_i'' \leftarrow \text{lemmatize}(T_i')$
Augment tokens using MSA:
        For each token $t \in T_i''$:
                Retrieve semantic info: $S_t \leftarrow \text{semantic\_lookup}(t)$
                Augment token: $e_t \leftarrow \alpha e_t + \sum_{s \in S_t} \beta_s e_s$
Refine context using DCR:
        For each token $t \in T_i''$:
                Define context window: $W_t \leftarrow \text{context\_window}(t)$
                Compute contextual embedding: $e_t' \leftarrow \sum_{w \in W_t} \gamma_{tw} e_w$
Feed into transformer:
        Construct sequence embedding: $E_i \leftarrow \text{concat}(e_t' \mid t \in T_i'')$
        Compute transformed embedding: $H_i \leftarrow \text{transformer}(E_i)$
Classify:
        Compute logits: $L_i \leftarrow \text{dense\_layer}(H_i)$

Solomon Praveen Kumar and Mythili

Apply softmax: $P_i \leftarrow \text{softmax}(L_i)$
Classify document: $c_i \leftarrow \text{argmax}(P_i)$

Return:

Return classifications: $C \leftarrow \{c_1, c_2, \dots, c_n\}$

End.

RESULTS AND DISCUSSION

Experimental Setup
Training the MSADCR model involves specific settings to optimize performance:
- Learning Rate: 2e-5.
- Batch Size: The model is trained with batch size32.
- Epochs: The training generally extends over 5 epochs.

The Adam optimizer is employed to handle the optimization of this model, which is particularly suited for these tasks due to its handling of weight decay, improving training stability. A dropout rate of 0.1 is used within the transformer blocks to enhance the model's generalization capabilities by mitigating the risk of overfitting through the random omission of units during training.

Datasets
The experimental setup for evaluating the MSADCR model's performance in hate speech detection utilizes multiple datasets, sourced from a variety of contexts to ensure robust testing across different types of language use and social media platforms. The following datasetsprovide a comprehensive basis for training and testing the model, encompassing a wide range of linguistic expressions, demographic variations, and types of hate speech. The datasets are as follows: Davidson-ICWSM Dataset(Davidson et al., 2017), Waseem-EMNLP Dataset(Waseem & Hovey 2016) and Waseem-NAACL Dataset(Waseem & Hovey 2016). The use of these datasets allows for rigorous evaluation of the MSADCR model under varying conditions and across different types of hate speech. The datasets are split into training, validation, and testing sets, with typically 70% used for training, 15% for validation, and 15% for testing. This split ensures that the model is trained on a substantial amount of data while also allowing for frequent evaluation and testing to monitor and optimize its performance throughout the training process.

RESULTS

The results section presents a comprehensive comparison of the MSADCR model's performance, with and without the integration of MSA and DCR, across the various datasets mentioned. Additionally, the performance of MSADCR is compared against several baseline methods traditionally used in hate speech detection. The following table 1, 2 and 3 summarize the performance metrics of the MSADCR model under different configurations and against baseline models. The graph in the figure 1 illustrates the performance of various models on the Davidson-ICWSM dataset. It is evident that the MSADCR model, which integrates both Semantic Multi-level Augmentation (MSA) and Dynamic Context Refinement (DCR), outperforms all other configurations across all metrics. Notably, the model achieves a peak accuracy of 0.91, which highlights its efficiency in correctly identifying hate speech. The progression from basic models like Naive Bayes and SVM to more sophisticated configurations underscores the benefit of integrating advanced NLP techniques. The incremental improvements seen from MSADCR (No MSA, No DCR) to MSADCR (MSA Only) and MSADCR (DCR Only) suggest that each component MSA and DCR contributes uniquely to enhancing the model's sensitivity. In Figure 3, the data from the Waseem-EMNLP dataset showcases a similar trend, where the fully enhanced MSADCR model demonstrates superior performance, reaching an accuracy of 0.90. This dataset, known for its complexity due to nuanced expressions of hate speech, provides a robust platform for testing the efficacy of the SMART-BERT enhancements. The results here reinforce the observation that the combined application of MSA and DCR significantly enhances model capabilities, which is critical for practical applications

Solomon Praveen Kumar and Mythili

where diverse and subtle language use must be accurately interpreted. Finally, Figure 4 focuses on the Waseem-NAACL dataset, revealing that the MSADCR model maintains high performance, with an accuracy nearing 0.89. This dataset, incorporating various forms of hate speech, challenges the models to differentiate between closely related categories of speech. The graph reflects that while standalone applications of MSA or DCR yield substantial improvements over baseline models, the synergy between these two enhancements in the full MSADCR model provides the most effective approach for managing the complexities of hate speech detection across linguistically diverse datasets.

Baseline Models: Naive Bayes and SVM show lower performance metrics across all categories when compared to MSADCR configurations. These models, while effective in simpler text classification tasks, struggle with the complexity and subtleties of hate speech. MSADCR Variations: The version of MSADCR without MSA and DCR already outperforms the baseline models, indicating the strength of the underlying BERT architecture in handling complex linguistic tasks. Impact of MSA and DCR: Incorporating either MSA or DCR individually improves the performance, with MSA generally showing slightly higher effectiveness than DCR alone. This suggests that semantic augmentation plays a critical role in enhancing model sensitivity to nuanced language.
Combined Effect: The combination of both MSA and DCR provides the highest scores inall metrics, underlining the synergy between semantic enhancement and dynamic context adjustment. This configuration effectively captures both the overt and subtle expressions of hate speech, significantly reducing both false positives and false negatives.

CONCLUSION

The deployment of the MSADCR model, enhanced with MSA and DCR, has demonstrated substantial improvements in hate speech detection across various datasets. The integration of MSA and DCR has effectively increased the model's accuracy, precision, recall, and F1-score, notably achieving an accuracy of up to 91%, precision of 90%, recall of 89%, and an F1-score of 89% on the Davidson-ICWSM dataset. Similar improvements were observed on the Waseem-EMNLP and Waseem-NAACL datasets, where the combined enhancements led to top performance metrics, significantly surpassing those of baseline models like Naive Bayes and SVM. These results underline the efficacy of incorporating advanced semantic and contextual analysis techniques into NLP models, significantly elevating their ability to discern complex and subtle linguistic cues associated with hate speech.

Future research could focus on optimizing the computational efficiency of models like MSADCR, possibly through more sophisticated model compression techniques or more efficient training algorithms. Further exploration into multilingual capabilities and the incorporation of more diverse semantic resources could enhance the model's applicability across global platforms. Additionally, investigating the impacts of different types of bias in training data and developing methodologies to mitigate these biases will be crucial for ensuring the fairness and neutrality of automated content moderation systems.

ABSTRACT

A young man named Shanjamo Jungi left his home in Nagaland, a remote state in the mountainous northeast corner of India, and traveled to the United States in 1905.He studied at Port Norris Public School under the tutelage of a missionary couple who had returned to Port Norris, New Jersey. Demonstrating remarkable promise as a scholar, Shanjamo established his life's work as an educator among his fellow natives of the Naga Hills. His commitment to this goal inspired those around him at Port Norris, garnering their support. Additionally, he attended Northfield Mount Hermon School in Massachusetts and Trendon Junction Public School in Massachusetts. After completing his studies, Shanjamo returned to Nagaland with a wealth of knowledge and enthusiasm, embarking on a career in teaching and Christian missionary work. As the first Naga to attend an American school, Jungi's story embodies a remarkable voyage of tenacity, fortitude, and the transformational power of education. His steadfast dedication to diversity and high standards of education has rewritten the history of cultural representation in American schools, leaving a lasting legacy that continues to uplift and empower future generations.

Keywords: Missionaries, Education, American Baptist Missionaries, Nagaland, Impur, Wokha Baptist, Church.

INTRODUCTION

The story of Shanjamo Jungi, the first Naga to receive an education in America, is a profound narrative of bravery, tenacity, and the transformative power of education. Born on January 2, 1882, in Yikhum Village, Wokha, Nagaland, Shanjamo embarked on a remarkable journey that would bridge the traditional and modern worlds through the lens of education. In 1905, amid the American Baptist Missionaries' endeavors in Nagaland, Shanjamo was brought to the United States by Reverend Samuel Alden Perrine and his wife, Rose Ermina Perrine, to pursue advanced studies. His educational journey spanned across various institutions, including Port Norris Public School in New Jersey and Northfield Mount Hermon School in Massachusetts, where he was exposed to cutting-edge educational technologies and methodologies of the time. Shanjamo's quest for knowledge was not merely an individual endeavor but a pioneering path that illustrated the profound impact of educational science in bridging cultural divides. His experience in America was characterized by an immersion in scientific pedagogy and technological advancements that were unparalleled in his homeland. This exposure to diverse educational tools and techniques empowered Shanjamo to return to Nagaland with a wealth of knowledge and enthusiasm, which he channeled into his career as a teacher and Christian missionary. The study explores the scientific and technological aspects of Shanjamo Jungi's educational journey, how his experience in American schools not only expanded his own horizons but also served as a catalyst for educational and cultural transformation in Nagaland. Through his story, we explore the intersection of traditional indigenous knowledge with modern educational practices, underscoring the enduring legacy of Shanjamo Jungi in the realm of education. The study employs a historical-analytical methodology, utilizing primary sources such as letters, missionary records, and school documents, alongside secondary sources including books, articles, and oral histories. By examining these diverse materials, the study reconstructs Shanjamo Jungi's educational journey and its impact on educational practices in Nagaland.

ORIGIN OF YIKHUM VILLAGE

One of the oldest settlements in the Lotha is Yikhum, which is part of the Wokha region. Although the exact date of the village's founding is unknown, oral traditions suggest that it was established somewhere in the 12th century A.D. First, the village was formerly known as Khumyanpan, which translates to "place of worship or village of worship." Before beginning to settle, the ancestors of those times explored the area, performed certain rites, and worshipped the location; for this reason, the area was known as Khumyanpan. Later, though, the name was altered to Yikhum (Yikhum), which means "believe in word." The terms Oyi, which means word, and Khuma, which means faith or worship, are combined to form the name Yikhum. Numerous academics and authors have proposed that these people first moved, most likely from Manchuria, in the eleventh or twelfth century AD, traveling over the Himalayan foothills. They left the Mongoloid race and moved here. They continued to migrate from one location to another. They travelled via Manipur and Burma before settling in Yikhum.

THE PERRINES

On February 19, 1859, Rev. Samuel Alden Perrine was born in Greensburg, Indiana. On June 9, 1891, he took Rose Ermina Lamb in marriage. Lucile and Linden LaRue were their two children. The American Baptist Missionaries sent the Perrines to work in the Naga Hills on March 28, 1892. Since there were no written languages for the Naga tribes, the Perrines put a lot of effort into creating texts that would educate the youth of the Naga people. Shanjamo was brought to study in the United States by Rev. Samuel Alden Perrine and Rose Ermina Lamb Perrine.

EARLY LIFE

On January 2, 1882, Shanjamo Jungi was born in Yikhum Village, Wokha, Nagaland. He was born in Nagaland into the Lotha Naga tribe. He was Sichio Jungi's second son. When he was a small boy, his mother died. His uncle Pvuchinyimo Jungi, the village's Assistant GB at the time, reared him following the death of his mother. Shanjamo was taken to Dr. Clark's School in Impur by his older brother Nkhao Jungi when he reached 16 in 1898 in order to pursue a better education. He studied here from 1898 to 1904, passing class 5 (the fifth grade) with success. Shanjamo was baptised by Rev. W.F. Dowd on January 4, 1899, and thereafter became a member of the Impur Baptist

Church.Dr. Clark thought highly of Shanjamo, a brilliant student, and advised Rev. and Mrs. Perrine to send him to the United States for additional education. It seems that Dr. Clark was a planner, a visionary who saw the importance of keeping the ministry going. Consequently, he decided to completely prepare Shanjamo for ministry by sending him to the United States for education. Shanjamo was found at the Impur School, which Dr. Edward Winter Clark founded, and his wife Mary Mead Clark, the first American Baptist Missionaries to the Naga Hills.

FOREIGN EDUCATION

On the advice of Dr. Clark, Rev. and Mrs. Perrine took him to the United States to further his education. On December 27th 1904, Rev. and Mrs. Perrine and Shanjamo started their journey to America from Impur via Guwahati, Calcutta, Delhi, Jaipur, Bombay, Egypt, Joppa, Palestine, Italy, Germany, Belgium and London taking six months to reach America. Shanjamo studied in three schools in America. In 1905, he studied in Trendon Public School, Port Norris Public School in New Jersey in 1906 and Northfield Mount Hermon School in Massachusets in 1907, and successfully passed class 8 becoming the first Naga to obtain foreign education.

MINISTRY IN THE NAGA HILLS

On September 10, 1908, Shanjamo departed from the United States and landed in Guwahati, Assam, on November 21. On November 27, 1908, he reached Impur, Naga Hills. He preached the message of Jesus Christ to the native tribes upon his return to Nagaland. He had exceptional abilities as a teacher, evangelist, preacher, and linguist. After coming back to the Naga Hills from the United States, Shanjamo was deeply interested in ministry. In 1909, he was invited back to Impur to help the American Baptist missionaries, and he became a mission center teacher there. In future years, he provided his services as a pastor in various communities, including Changtongya Baptist Church (Ao tribe), Yikhum Baptist Church (Lotha tribe), ancient Changsu Baptist Church (Lotha tribe) and Litami Baptist Church (Sema tribe). In addition, he started working as a teacher at the Vankhosung Mission Center, where he did so from 1930 until 1937. He contributed Rupees 100 towards the establishment and purchase of the center, along with Dr. Bailey, who was one of the school's founding leaders. After spending a few years returning to his hometown of Yikhum, he was asked to return and continue teaching at the Vankhosung Mission Center until 1948. From 1909 till 1910, Shanjamo was the pastor of Changtongya Baptist Church (Ao Tribe). In 1910, according to the Houstons (American Baptist Missionaries), Shanjamo was appointed as the pastor of Okotso Baptist Church's (Lotha Tribe) temporary associate. From 1912 to 1913, Shanjamo was also the pastor of Changbang Village Baptist Church, which belonged to the Lotha Tribe. In 1914, he spent a year preaching at Yikhum Village Baptist Church as the pastor. He went back to Impur Mission Center (Ao Tribe) in 1915–1917 to serve as the American Baptist Missionaries' assistant to conduct the choirs. Shanjamo commanded the Naga Labour Corps to France in March 1917 as part of World War I. He returned in 1918 and settled in Kohima, where he collaborated closely as an accounts clerk and interpreter with the deputy commissioner of the British Colonial government, filing accounts and records and distributing money to veterans of the war. He returned to serve as the pastor of Yikhum Village Baptist Church (Lotha Tribe) from 1919 to 1920. Shanjamo was a native of Yikhum village, where he held two terms as the church's pastor. From 1921 to 1922, he is the pastor of Old Changsu Baptist Church, which belongs to the Lotha Tribe. Yikhum Village is not far from Old Changsu Village

FAMILY LIFE

On Sunday, April 11, 1909, Shanjamo wed NoksanglemlaLemtur, an Ao woman from Longpa village. There were no kids raised by them. Since there was no internet, cell phones, telephones, or other form of communication back then, it was frequently impossible to communicate with loved ones. With the Naga Labour Corps, Shanjamo departed for France on March 1, 1917, and he didn't return to Kohima, Naga Hills, until June 17, 1918. Because of this, his wife fled for her village when Shanjamo departed for the war, purely out of fear that he might not return. Shanjamotraveled to his wife's village to bring her home once he got back. Sadly, he learned that she had already married again.Following that, in 1919, Shanjamo got married to Chomoni, a Lotha girl from the village of Riphym. They adopted three children instead of having children of their own: Mr. Yanrenthung from Old Riphym, Ms. Sumalmvu from Old Riphym, and Mr. Sathungo Jungi from Juti village, who was given the name Moses.

Mr. Sathungo's account
Sathungo Moses had a single son and was married. His wife was rather eloquent and upbeat.

Ms. Sumlamvu's account
Sumlamvu never got married and took on the role of taking care of her father from the time of his death till his later years. Before he passed away, Shanjamo told his daughter Sumlamvu that his time on earth was running out and asked to God to take him home before something terrible happened. The Indian Army arrived shortly after his death on February 28, 1956, and on July 29, 1956, they destroyed the village of Yikhum.

Mr. Yanrenthung's Account
Yanrenthung wed and gave birth to a son. Along with being the church's long-term caretaker, he was a member of the Yikhum Baptist Church choir. He resided in Wokha with his son, daughter-in-law, and grandchildren. The last gasp he made was in February 2019.

Shanjamo Memorial Baptist High School
Following a thorough deliberation, the executive members of the Lotha Baptist Association convened on November 22, 1968, and resolved to rename the Baptist English School in Wokha Town in honor of Shanjamo's efforts to the evangelization of the Naga people, specifically the Lothas. Back then, there were only two Christian private schools, one of which was the Shanjamo Memorial Baptist English School. The Catholic Don Bosco School was the other private establishment. The community's children are still served by the school.

CONCLUSION

Shanjamo Jungi's experience as the first Naga in American education is a motivational example of the strength of willpower, resiliency, and the quest for knowledge. Shanjamo has not only made a name for himself in academia or mission work but has also created opportunities for people from marginalized areas by shattering down obstacles and forging new routes. Shanjamo Jungi, the first Naga in American school, has made a lasting impression and encouraged numerous others to follow their dreams in the face of overwhelming challenges.His story also serves as a reminder of how diversity enhances our educational institutions and how every person's distinct experiences and viewpoints add to a livelier and more dynamic classroom. His legacy will inspire future generations since his story is a celebration of bravery, perseverance, and the unwavering pursuit of knowledge.

ABSTRACT

In this research, a novel approach to the design of a folded printed quadrifilar helix antenna (FPQHA) is described. A dual band antenna with exceptional gain and circular polarization is developed for the L1/L2 Global Positioning System application. This research work's main objective is to reduce antenna size in comparison to traditional PQHA. The second objective of this work is dual band operation, which typically results in distinct issues when using several frequencies. By describing a multiple arm technique with a novel design strategy, a multi band PQHA may be obtained. The third objective of this research is to incorporate several techniques to attain a good band width in the axial mode. A multiband printed quadrifilar helix antenna design and optimization proposal is given. With the advancement of GPS and satellite navigation systems, increasingly demanding applications now require an antenna that can cover dual or even triple frequencies. The difficulty of using traditional FPQHA at several frequencies is one of its current issues. This work describes several ways that would allow this antenna to operate in two frequency bands. Because of its low cost, good axial ratio, circular polarization, hemispherical radiation, and good axial ratio, the folded printed quadrifilar helix antenna (FPQHA) is a particularly appealing choice for many applications, including global positioning systems, broadcasting satellite systems, and mobile satellite communications. However, for certain applications, a traditional PQHA's bandwidth might not be adequate. As a result, the method for boosting an FPQHA's bandwidth by using meandering line approaches is provided. The goal of the novel folded printed quadrifilar helix antenna (FPQHA) is to attain a good axial-mode bandwidth. Furthermore, the production of FPQHA requires relatively little space, money, or effort because the arms are printed on a single substrate face.

Keywords: Printed quadrifilar helix antenna, circular polarization, axial ratio

Jesavath Kiran Naik

INTRODUCTION

The use of satellite communication systems, such as GPS and broadcasting satellite systems, has increased significantly in the twenty-first century in response to urgent needs. Since the polarization rotation of the ionosphere won't influence circular polarization antennas, they are a good choice for signal transmission in these systems. More specifically, the GPS requires hemispherical radiation patterns with strong circular polarization in the bandwidth between terrestrial antenna receivers and satellites. For these purposes, the Folded Printed Quadrifilar Helix Antenna is a particularly appealing antenna. The many noteworthy qualities of Folded Printed Quadrifilar Helical Antennas (FPQHA), such as their low cost, light weight, hemispherical coverage, and strong circular polarization, have drawn a lot of interest in recent years in a variety of applications, including GPS and mobile communication. Numerous authors have employed meandering techniques to minimize the dimensions of wire antennas, including monopole and loop antennas. They include the use of continuously folded wire antennas, which have a tendency to resonate at frequencies far lower than those of a regular antenna of the same length. There are numerous techniques in the literature to shrink the printed QHA while it operates in a single band and has an integrated feeding network utilizing various pitch angles.

As it is unaffected by anomalies in the ionospheric atmosphere, the folded printed quadrifilar helix antenna (FPQHA) is typically employed in mobile satellite communication. Systems requiring great radiation performance and good beam width over the frequency band include satellite mobile communication and position-based services. The folded printed quadrifilar helix antennas' (FPQHA) radiating pattern makes them ideal for satellite mobile communications. In order to feed four helical weaponry with the same power and a 90° phase shift between ports, a large low frequency band conventional PQHA is needed. As a result, small-scale FPQHAs using a straightforward feeding network are needed. An integrated compact feeding network-equipped folded printed quadrifilar helix antenna (FPQHA) is presented in this letter. A 50% reduction in the axial length of FPQHA can be achieved by appropriately folding the helix arms into several identical pieces.

An antenna with a folded printed quadrifilar helix has a small profile and is lightweight. It is a wide beam antenna that is easily produced using printed circuit technology. For example, a continuous metallic layer serves as the ground plane on one side of the substrate and a metallic layer in a certain shape is bonded to a dielectric substrate to form a radiating element. Any continuous shape can be utilized as the radiating patch; it's not just limited to basic shapes. The mechanically robust, low-profile FPQHA antenna is easily fabricated on both planar and coplanar surfaces. FPQHA has a size of l / 2. Because these antennas are utilized at very high frequencies below microwave frequencies, the FPQHA is used above microwave frequencies.

Problem statement

Many researchers have employed meandering approaches to minimize the size of wire antennas, including monopole and loop antennas. Compared to a regular antenna of the same length, they have continuously folded wire that tends to resonate at lower frequencies. As GPS and satellite navigation systems have developed, more demanding applications now need an antenna that can span dual or even triple frequencies. The difficulty of using traditional PQHA at several frequencies is one of its current issues. In published work, numerous techniques that will increase the antenna's capability to dual frequency bands have been explained. Circularly polarized (CP) waves are used by the majority of satellite communication and navigation systems to send signals over large distances through the atmosphere with favorable propagation characteristics. Then, you need circularly polarized (CP) antennas with a suitable axial ratio spanning both the desired beam width and the operational frequency spectrum. Antennas with strong axial ratio throughout a multiband and wide beam width are especially needed for navigation applications that use Global Navigation Satellite Systems.

Jesavath Kiran Naik

Existing System

It is possible to create an FPQHA in a novel approach. The helix is spiral-shaped when printed. The antenna is smaller than it was with PQHA. A dual band antenna with exceptional gain and circular polarization is created for use in L1/L2 Global Positioning Systems applications. The suggested antenna is offered in order to produce a printed quadrifilar helix antenna with many bands. With the advancement of GPS and satellite navigation systems, increasingly demanding applications now require an antenna that can cover dual or even triple frequencies. The difficulty of using traditional PQHA at several frequencies is one of its current issues. This work explains a number of techniques that will enable the antenna to operate in two frequency bands.

Because of its low cost, strong axial ratio, circular polarization, hemispherical radiation, and good axial ratio, the PQHA is a better antenna for a variety of applications, including GPS, satellite mobile communications, and broadcasting systems. However, for certain applications, a traditional PQHA's bandwidth might not be adequate. Consequently, this method of adding a shorted parasitic helix to a PQHA increases its bandwidth. The goal of the novel folded printed quadrifilar helical antenna (FPQHA) is to attain a good axial-mode bandwidth. Furthermore, the FPQHA production is very easy, inexpensive, and requires little space because the arms are printed on a single substrate face.

RESEARCH METHODOLOGY

1. The traditional printed quadrifilar helical antenna is made smaller with a superior radiation pattern across many bands by using the meander line approach.
2. Looked at a cutting-edge multiple arm technique design approach to create a multiband.
3. The folded (FPQHA) printed quadrifilar helix antenna has been suggested; it provides a good axial ratio over a broad beam width and a big frequency bandwidth, making it more appropriate for use in navigation systems.

Proposed System

- The size reduction is obtained for the overall axial lengths of the PQHA structure, to satisfy require space limitations of a satellite mobile terminal with good performance.
- The proposed antenna to cover the L1/L2 frequency bands of GPS.

ELEMENT FOLDING AND MEANDERING METHODS

This method combines two miniaturization techniques: meandering of the helical elements and element flop, which was previously utilized for FPQHA miniaturization. Two segments are produced by folding the helical parts of an FPQHA: the straight segment (SS) and the meandering segment (MS). Figure 1 shows an illustration of a folded PQHA (FPQHA) and its unwrapped structure.

The folded FPQHA structure's dimensions, the length of the helical elements is separated into five components, a, b, c, d, and e, to facilitate the design process of an FPQHA. The length of a mean segment is equal to the total of the lengths of b, c, d, and e, whereas the length of a straight segment is represented by a. In this technique, the helical elements' turn was altered to maintain the same pitch angle as the standard FPQHA, in contrast to the previous element folding method that used the same number of turns after the helical elements were folded. Consequently, determining an FPQHA's axial length which is based on the value of a can be done by using the following steps:

SIMULATION OF PRINTED QUADRFILAR HELIX PATCH ANTENNA

With the specifications listed in section 4.2, the printed quadrifilar helix monopole patch antenna is virtually realized in antenna magus [--]. The first design is typically entirely optimized, and it is standard procedure to make model adjustments to further fine-tune the dimensions. The antenna's final dimensions are shown in Figure 5.1.The patch is built on a high-frequency laminate board made of FR4 material with a thickness of 2 mm, a relative permittivity of 4.4, and a 20 □m copper metallization layer. The patch antenna substrate's diameter (ground plane) is 18.01 mm, its

length (ground plane) is 132.5 mm, with 1.068 turns. The printed quadrifilar of the helix antenna has a width of 4 mm. Patch thickness and the thickness of the ground plane 0.2 mm and 2 mm respectively. The width of the feed element (FL) is 2 mm.

SIMULATION RESULTS OF THE PROPOSED FOLDED PRINTED QUADRIFILAR HELIX ANTENNA

With Antenna Magus Software, a folded printed Quadrifilar Helix patch antenna is simulated. Plots of many characteristics, including as return loss, impedance, and VSWR as functions of frequency, can be obtained with this software. Figures 5.1 and 5.35 display prototypes of the suggested antenna, while table 5.1 provides specific dimensions. The diameter plane and helix patch are essential for achieving a broad bandwidth in the suggested printed quadrifilar helix patch antenna. In order to obtain the best outcomes, a mender line analysis is performed by adjusting the diameter beginning at 16 mm. The impedance bandwidth of an 18 mm diameter patch antenna ranges from 1.22 GHz to 1.575 GHz, with a return loss that varies from -10 dB to -10 dB by reaching minimum levels of -28 dB and -27 dB.

 This analysis shows that when the diameter increases from 16 mm to 18 mm, there is a monotonic increase in the impedance bandwidth and a decrease in the lowest amount of return loss. The minimum level of return loss increases and the impedance bandwidth decreases beyond 18 mm in diameter. Hence, the printed quadrifilar helix patch antenna's 18 mm diameter is its ideal configuration. It is evident that this antenna radiates in an unidirectional manner. The gain of the antenna improves monotonically from 3.5 dBi to 4.25 dBi. Below is a display of the simulation results that Antenna Magus Software calculated.

The return loss of the FPQHA is plotted in Figure 4 from which, it is shown   that return loss of the antenna is below -10 dB for the frequencies in the range of 1.22 GHz and 1.575 GHz. The simulated return loss attained in this case is -28 dB and -27 dB only.

The VSWR of the FPQHA with 18 mm diameter is plotted in Figure 5 from which, it is shown that VSWR of the antenna is below 2 for the frequencies in the range of 1.22 GHz and 1.575 GHz. The maximum VSWR attained in this case is 0.9833 and 0.9917 only.

The Figure 6 shows real and imaginary parts of the impedance for the frequency range of 1.22 GHz and 1.575 GHz. The antenna possesses the enough impedance (36 – 70 Ohm) in this frequency range. These impedance values are apt for the FPQHA patch with good performance

Figure 7 shows the simulated LHC polarized gain components of the FPQHA with an innate ground plane, of which the main beam is scanned to different angles. This illustrates the good axial ratio that is achieved over most of the hemisphere.

CONCLUSION

It is possible to design a compact folded PQHA in a new approach. A highly desirable option for numerous applications, including global positioning systems and mobile satellite broadcasting systems, is the folded printed quadrifilar helix antenna (FPQHA). The FPQHA's axial-mode design aims to achieve a good bandwidth. The Folded Printed QHA design requires very little space, money, or effort.

ABSTRACT

Dysmenorrhea is one of the gynaecological disorder prevailing in the women. Dysmenorrhea means painful menstruation .It has two types. (a) Primary (b) secondary. Primary dysmenorrhea is one where there is no identifiable pelvic pathology. Clinical features include the pain which is spasmodic and confined to abdomen which may radiate to back and medial aspect of thighs. Core stability exercise is beneficial intervention for management of several medical problems. The study aims to see the effectiveness of core strengthening with physio ball or without physio ball in patients with the primary dysmenorrhea. Total 40 female students were taken for participating in the study from Ahmedabad Physiotherapy College. After the initial assessment with the outcome measures(Visual analogue scale, Mc gill core endurance test, Biering Sorensen test), patients were explained about both the interventions, exercise with physio ball and without physio ball. The subjects were divided into two equal groups; group a core strengthening with physio ball and group b core strengthening without physio ball. Significance tests for difference in means was done using paired t tests. According to the results the study concludes that both the groups, are effective in reducing menstrual pain and strengthening of core muscles but group A was more effective than group B.

Keywords: primary dysmenorrhea, core strengthening, physio ball, menstrual pain intensity, *VAS.*

INTRODUCTION

Dysmenorrhea is one of the gynaecological disorder prevailing in the women[1]. The name "dysmenorrhea" comes from the Greek word "dys" which means "difficult, unpleasant, abnormal," "meno" which means "month," and "rhea" which means "flow"[6].   Although primary dysmenorrhea is rarely life threatening, it does have certain socioeconomic consequences, such as increased sick leave, higher health-care costs, disruption of everyday activities, and social isolation[1]. The prevalence rate of primary dysmenorrhea ranges between 67-90% among the 17-24 aged girls[7]. According to the International Association for the Study of Pain, about 10-15% of women are unable to work for 1-3 days during their menstrual period[7]. Dysmenorrhea means painful menstruation .It has two types. (a) Primary (b) secondary[3]. Primary dysmenorrhea is one where there is no identifiable pelvic pathology[3].The causes of pain in primary dysmenorrhea may be due to psychosomatic factors like tension and anxiety[3].It may be due to the abnormal anatomical and functional aspect of myometrium, imbalance in the autonomic nervous control of uterine muscle , more synthesis and release of prostaglandins , increased vasopressin release , platelet activating factor and endothelins stimulating myometria contractions[3].Clinical features include the pain which is spasmodic and confined to abdomen which may radiate to back and medial aspect of thighs [3]. Discomforts like nausea, vomiting,fatigue,diarrhea, headache and tachycardia may be associated[3].In the medical treatment the drugs used are prostaglandin synthetase inhibitors and oral contraceptives[3]. The pain begins with onset of menstrual bleeding and can last for 12 hours – 72 hours[4].The pain is often described as cramped and intermittent[4].The pain mainly experienced in inguinal region, lower back, posterior thigh . Extroverted uterus, lack of exercise, psychological and social stress are the factors which worsens the pain6.Cramping pain results due to hypoxia in primary dysmenorrhea[6]. Many therapies are used to treat dysmenorrhea, including medicines, acupuncture, local application of heat and massage, herbal therapy, TENS, vitamins and minerals such vitamin B1, B6, E, and magnesium[1]. For primary dysmenorrhea, nonsteroidal anti-inflammatory medications (NSAIDs) and prostaglandin inhibitors are the first-line treatments[1].Physical exercise has been suggested as a non-medical approach for the management of symptoms and also effective in reducing the frequency and severity of dysmenorrhoeal syndrome[5]. Life style factor are responsible for primary and hence improving it can reduce the severity of primary dysmenorrhea[6]. Core stability exercise is beneficial intervention for management of several medical problems[1].

Core stability exercise strengthen the abdominal, lumbar, pelvic region muscles[1]. With the help of core strengthening, little intrinsic muscle surrounding the lumbar spine is conditioned for increased performance[5]. The goal of core training is to integrate the principles of lumbar stabilisation and core strengthening since instability can lead to injury and suffering, especially when the female body is under stress, and dysmenorrhea is one of those stressful times[2]. If a section of the lumbar spine becomes weak at any moment, its ability to handle functional stress is impaired, which can cause pain in the abdomen, low back, or thighs[2]. Core strengthening causes the muscles surrounding the lumbar spine to strengthen and become stronger, allowing them to manage daily demands of normal biomechanics even when the body is stressed by the menstrual cycle[2]. Improved metabolism aids in the alleviation of dysmenorrhea symptoms[2]. Menstrual discomfort is thought to be exacerbated by uterine muscular contractions, which are derived from the neurological system and innervated by the sympathetic nerve. As a result of the sympathetic nervous system's hyperactivity, stress causes uterine muscle contractility to rise, resulting in menstruation symptoms[2]. Exercise with physio ball is effective in stabilization of torso[9]. Movements with gym ball increase activity of other muscles and also stimulate other body parts, so it is effective on pain relief and blood flow smoothness[9].Exercise with physio ball helps to strengthen gluteus muscles, abdominal muscles, and back muscles[8]. It aids in the development of lower back, gluteus, and hamstring strength and stability [8]. It aids in the reduction of menstruation discomfort by boosting blood flow to core muscles following core muscle stretching and strengthening[8]. It also helps to lessen menstruation discomfort by improving balance, stability, and blood supply.[8]

MATERIALS AND METHODS

Source of data– Ahmedabad Physiotherapy College, Bopal, Ahmedabad
Study Design– Comparative study
Sampling method – convenient random sampling
Sample-young females
Sample size – 40
Study duration– 8weeks of study (3 session per week)
Materials used in the study areLow mat / yoga mat, Plinth,Pencil, Consentform, Paper, Physio ball,60^0 wedge

INCLUSION CRITERIA
- Written consent for participation in the study.
- Having regular menstrual cycles
- Females having primary dysmenorrhea
- Age criteria :18 to 25 years

EXCLUSION CRITERIA
- Pregnancy
- Known genital diseases
- Chronic diseases (heart disease, respiratory, kidney, blood pressure, asthma, diabetes, epilepsy, migraine, thyroid, anaemia, nervous disorders)
- Participation in other sports program

METHODOLOGY

Total 40 female students were taken for participating in the study from Ahmedabad Physiotherapy College. Subjects were selected on the basis of inclusion criteria and exclusion criteria and questionnaire(modified moos menstrual distress questionnaire) that was filled by the subjects .After the initial assessment , patients were explained about both the interventions , exercise with physio ball and without physio ball and their consent was taken for the same. The subjects were divided into two equal groups by simple random sampling namely Group A CORE STRENGTHENING WITH PHYSIO BALL and Group B CORE STRENGTHENING WITHOUT PHYSIO BALL. Before the treatment given to each group, the intensity of pain experienced by the subject was measured with the help of pain rating scale (Visual analogue scale) and Abdominal flexors was assessed with mc gill core endurance test (60^0 trunk flexor test), side flexors with mc gill core endurance test (right and left bridge test) and extensors were assessed with the Biering Sorensen test.

GROUP – A (CORE STRENGTHENINGWITH PHYSIO BALL)
In this group total 20 young females were taken. After the subjects have rated their level of pain on VAS and assessment of core muscles with endurance test. The group received core strengthening with physio ball for 8 weeks for three time in a week Each session lasted 45-60 minutes, beginning with a 10-minute warm-up, followed by 25-40 minutes of the main programme, and concluding with a 10-minute cool-down. In this group exercises included were (1)Ball crunch,(2) Crunch with feet on the ball,(3) Leg curl on the ball,(4) Ball bridge fall off,(5)Ball pendulum,(6)Bridging,(7)Oblique ball crunches,(8)Wall squat,(9)Ball squat , sideways , single leg,(10)Ball hip adduction,(11)Ball squeeze,(12)Back extension,(13)Knee tuck from plank,(14)Opposition raise

GROUP B(CORE STRENGTHENING WITHOUT PHYSIO BALL)
In this group also total 20 young females were taken. After the subjects have rated their level of pain on VAS and assessment of core muscles with endurance test. The group received core strengthening without physio ball for 8 weeks for   three time in a week Each session lasted 45-60 minutes, beginning with a 10-minute warm-up, followed

by 25-40 minutes of the main programme, and concluding with a 10-minute cool-down. In this group exercises included are; (1)Pelvic bridge,(2) Plank,(3) Cat and camel,(4) Single leg abdominal press,(5) Double leg abdominal press,(6) Curl up

OUTCOME MEASURE
1. VAS(Visual analogue scale)
2. Mc gill core endurance test
3. Biering Sorensen test

RESULTS AND TABLES

Total   43 female students were taken with primary dysmenorrhea as subjects in this study in which 3 students not completed the study, so finally 40 were included for the study. These 40 subjects were randomly divided into two group ,20 subjects in group A (Exercise with physio ball) and 20 subjects in the group B(Exercise without physio ball).The data taken from Ahmedabad physiotherapy college was entered and analysed by using SPSS (statistical package for social sciences) software version 25. Significance tests for difference in means was done using paired t tests. The test was applied as the data followed the condition of normality. Table1.1: table shows within group comparison of vas, 60^0 trunk flexor endurance test , biering sorensen test ,right side bridge endurance test Left side bridge endurance test in group a Table 1.2 table shows within group comparison of vas, 60^0 trunk flexor endurance test, biering sorensen test ,right side bridge endurance test, Left side bridge endurance test in group b Table1.3 table shows between groups comparison of group a and group b Graph1.1:showsbetween groups comparison intervention of 60^0 trunk flexor endurance test , biering sorensen test ,right side bridge endurance test, left side bridge endurance test of group a   and group b Graph 1.2graph shows VAS between groups comparison of group a and group b As shown by the results for group A and group B both have significant effect on decreasing pain intensity and increasing core strength. But when comparing both group A and group B, group A has more effect on pain intensity and increasing core strength. Hence alternative hypothesis in favour of exercise with physio ball and without physio ball is accepted and null hypothesis of no difference is rejected.

DISCUSSIONS

The present study was designed to find the effect of core strengthening exercise with physio ball and without physio ball in primary dysmenorrhea on pain and strengthening of core muscle. This was conducted on 43 female students of primary dysmenorrhea with age 18-25 years according to the inclusion and exclusion criteria. They were divided into two groups and both the groups underwent core strengthening protocol one with physio ball and second without physio ball. Due to 3 dropouts from the study, there were total 40 female students remaining at the end. Both the groups were assessed before and after the treatment to measure the level of reduction of pain as well as strength of muscle with the help of VAS and mc gill core endurance test and biering Sorensen test. At the end of 8 weeks, the female students in both the groups showed significant improvement in reduction of pain and increase in strength of core muscle. But the strengthening exercise with physio ball group showed more significant improvement than core strengthening exercises without physio ball. According to a study done by shahnaz shahrjerdi et al (2019), in journal of modern rehabilitation. The goal of this study was to see how core stability exercises affected pain severity, pain duration, and drug intake in adult females with primary dysmenorrhea. The study was done on 34 girls divided into two groups experimental group and control group in which experimental group was given core stability exercises 3 session per week for 8 weeks. In primary dysmenorrhea, core stability exercises were found to be useful in lowering pain severity, duration, and the use of pain relievers[1]. Hence, in this literature they have mentioned that 18 to 25 years aged girls have primary dysmenorrhea and for that they take analgesics. The core stability exercises are beneficial in reducing pain severity and duration during menstruation, and the need of painkillers is reduced greatly. It appears to be linked to the overall health benefits of physical activity, such as stress reduction, reduced sympathetic irritation, and increased endorphin production. So reduction in sympathetic system activity and stress

reduction can decrease the symptoms of primary dysmenorrhea[1]. Core stability exercise leads to conditioning of core muscles via neural drive increment and effective contraction and conditioning of core muscles might increase the circulation and metabolism in pelvic region and hence results in improvement of primary dysmenorrhea. One more study done by himani parikh et al (2021) in journal of Indian journal of physiotherapy and occupational therapy aimed to compare the effect of heat application and core strengthening exercise on relieving pain of primary dysmenorrhea among young females. This study was done on 50 girls divided into two groups core strengthening exercise group and moist pack application group. The intervention was continued for three consecutive months. The study concluded that core strengthening exercise group was effective in reducing pain of dysmenorrhea as compared with moist pack application. Hence it can be said that there are positive effect of core strengthening exercise in the treatment of primary dysmenorrhea[11]. Due to insufficient core musculature, the body is unable to bear the stresses required for regular movement and function during menstruation, resulting in inappropriate biomechanical function of tissues close to the lumbar spine[7].The pain in the abdomen, low back, and thighs could be caused by a lumbar spine that is weak or incapable of handling functional stress. The body is supported by the inert structures against any external forces. The muscles operate as dynamic guy wires, supplying counterforces to gravity torque and body stability, preventing loads from being put on inert structures[10]. Hence with the strengthen musculature we can reduce the stress on the body provided by external forces   As shown in table 1.1 and 1.2, the pain intensity reduced from 5.050 to 1.760 in group A and 4.930 to 3.055 in group B. This finding is consistent with the report by Sandeep Kaur where pain reduction was found to be from 9.09 to 4 in 4 weeks to 0.97 in 8 weeks measured by using NPRS[7]. Physio ball helps to strengthen the muscles around abdomen, legs, arms and back region and it also improves stability, balance, blood supply which helps to case menstrual pain[8]. Thus core strengthening with physio ball or without physio ball helps to reduce the menstrual pain intensity and strengthen the core muscle to manage the primary dysmenorrhea.

CONCLUSION

According to the results the study concludes that both the groups, group A-core strengthening with physio ball and group B- core strengthening without physio ball are effective in reducing menstrual pain and strengthening of core muscles but group A was more effective than group B. Hence core strengthening with physio ball can be a very useful adjunct in female students with primary dysmenorrhea. The limitation of the study is Mid-term (0-4 week) follow up not taken, Long term follow up is not done. The future recommendations areto find out effect of exercise on quality of life in such populations,the study can be done on young from 18 years age of females. As the present study conclude that core strengthening with physio ball is more effective when compared with core strengthening without physio ball in female students with primary dysmenorrhea. Hence core strengthening with physio ball can be an effective adjunct to a management program to females with primary dysmenorrhea and can be used in clinics.

ABSTRACT

Conventional methods for hypothesis testing are insufficient for tackling ambiguous data. The emergence of the concept of fuzzy sets has resulted in endeavors to address the difficulty of evaluating hypothesis to deal with such ambiguous data. A method to determine crisp and fuzzy hypotheses is provided for natural fuzzy observations. The fuzzy test statistic is computed using crisp or fuzzy hypotheses as well as fuzzy data. During testing hypotheses, we might come across situations where data is taken as fuzzy, rather than crisp. In such cases, standard methods of hypothesis testing are inadequate and must be modified. In the challenge of evaluating hypotheses with data that is uncertain, an IPL match's run rate is fuzzy rather than precise. The paper, we focus data on fuzzy rather than data on crisp, along with we provide an approach for hypothesis testing with vague information that employs interval type -2 specialized hexagonal numbers that are uncertain.

Keywords: Hypothesis testing, Generalized hexagonal fuzzy number (Interval Type-2)
Mathematical Subject Classification: 62F03

INTRODUCTION

Preface
Basic statistical testing of hypotheses requires that the basic hypothesis and the offered data are clear. Furthermore, testing statistical hypothesis is an effective technique meant for drawing conclusions in whole-world scenarios.

79819

Typically, the core information is expected to be accurate numbers; however, it is significantly more practical to investigate fuzzy numbers, known as non-precision records. From this case, the statistical test will produce inaccurate results. Numbers of authors have explored statistical hypothesis testing in fuzzy contexts, employing fuzzy set theory notions proposed by Zadeh [10] in 1965. Arnold [1, 2, 3] described a method for assessing fuzzily expressed hypotheses using unambiguous evidence. S.M.Taheri et.al [9] investigated the problem of testing fuzzy hypothesis, in which the hypothesis are uncertain but the data are unambiguous. Kalpanapriya and Pandian [8] suggested a one-sample t-test for interval numbers that uses triangular unclear figures. A.Hari Ganesh and N.Jaimaruthi[4,5,6,7] presented a test of statistical hypothesis testing under fuzzy environment and interval using interval type 2 hexagonal fuzzy numbers. It's structured as follows: Section 2 covers the fundamental principles and definitions related to interval type-2 hexagonal numbers that are unclear and their alpha cut. Section 3 discusses the fundamentals of the T20 format as well as the run rate. Section 4 demonstrated how the data (run rate) of an IPL match is examined using a particular sample t-test for unique interval data. Section 5 provides an example of an IPL run rate evaluated with a particular sample t-test for unique interval data, based on the process of employing alpha cut of ITHFN [4].Finally, Section 6 concludes this study.

PRELIMINARIES

Fuzzy Number (**Definition**)

A set $\tilde{M}$ is fuzzy a term for a set that includes numbers in real. R is considered to be a fuzzy number if the membership of its functions exhibits the following properties.

(i) $\tilde{M}$ is convex, i.e., $\tilde{M}(\lambda t_1 + (1-\lambda)t_2) = \min\{\tilde{M}(t_1), \tilde{M}(t_2)\}$, for all $t_1, t_2 \in R$ and $\lambda \in [0,1]$.

(ii) $\tilde{M}$ is normal, i.e., there exists an $t_0 \in R$ such that $\tilde{M}(t_0) = 1$

(iii) $\tilde{M}$ is piecewise continuous

Hexagonal Fuzzy Number (Definition)

A fuzzy number $\tilde{M}$ is a hexagonal fuzzy number denoted by $\tilde{M} = (m_1, m_2, m_3, m_4, m_5, m_6)$, where $m_1 \leq m_2 \leq m_3 \leq m_4 \leq m_5 \leq m_6$ are real numbers satisfying $m_2 - m_1 \leq m_3 - m_2$ and $m_5 - m_4 \leq m_6 - m_5$, if its membership functions $\mu_{\tilde{M}}(t)$ is given by

$$\mu_{\tilde{M}}(t) = \begin{cases} 0 & t < m_1 \\ \dfrac{1}{2}\left(\dfrac{t-m_1}{m_2-m_1}\right) & m_1 \leq t \leq m_2 \\ \dfrac{1}{2} + \dfrac{1}{2}\left(\dfrac{t-m_2}{m_3-m_2}\right) & m_2 \leq t \leq m_3 \\ 1 & m_3 \leq t \leq m_4 \\ 1 - \dfrac{1}{2}\left(\dfrac{t-m_4}{m_5-m_4}\right) & m_4 \leq t \leq m_5 \\ \dfrac{1}{2}\left(\dfrac{m_6-t}{m_6-m_5}\right) & m_5 \leq t \leq m_6 \\ 0 & t > m_6 \end{cases}$$

Definition (Interval Type-2 Hexagonal Fuzzy Number)

A number $\tilde{M}$ that is fuzzy is a type-2 hexagonal uncertain quantity defined by

$$\tilde{M} = \left[\tilde{M}^L, \tilde{M}^U\right] = \left[(m_1^L, m_2^L, m_3^L, m_4^L, m_5^L, m_6^L), (m_1^U, m_2^U, m_3^U, m_4^U, m_5^U, m_6^U)\right],$$

where $(m_1^L \le m_2^L \le m_3^L \le m_4^L \le m_5^L \le m_6^L), (m_1^U \le m_2^U \le m_3^U \le m_4^U \le m_5^U \le m_6^U)$ are real numbers satisfying

$m_2^L - m_1^L \le m_3^L - m_2^L, \quad m_5^L - m_4^L \ge m_6^L - m_5^L, m_2^U - m_1^U \le m_3^U - m_2^U$ and $\quad m_5^U - m_4^U \ge m_6^U - m_5^U$, if its

membership functions $\mu_{\tilde{M}^L}(t)$ and $\mu_{\tilde{M}^U}(t)$ are given

by

$$\mu_{\tilde{M}^L}(t) = \begin{cases} 0 & t < m_1^L \\ \frac{1}{2}\left(\frac{t - m_1^L}{m_2^L - m_1^L}\right) & m_1^L \le t \le m_2^L \\ \frac{1}{2} + \frac{1}{2}\left(\frac{t - m_2^L}{m_3^L - m_2^L}\right) & m_2^L \le t \le m_3^L \\ 1 & m_3^L \le t \le m_4^L \\ 1 - \frac{1}{2}\left(\frac{t - m_4^L}{m_5^L - m_4^L}\right) & m_4^L \le t \le m_5^L \\ \frac{1}{2}\left(\frac{m_6^L - t}{m_6^L - m_5^L}\right) & m_5^L \le t \le m_6^L \\ 0 & t > m_6^L \end{cases}$$

2.4.

$$\mu_{\tilde{M}^U}(t) = \begin{cases} 0 & t < m_1^U \\ \frac{1}{2}\left(\frac{t - m_1^U}{m_2^U - m_1^U}\right) & m_1^U \le t \le m_2^U \\ \frac{1}{2} + \frac{1}{2}\left(\frac{t - m_2^U}{m_3^U - m_2^U}\right) & m_2^U \le t \le m_3^U \\ 1 & m_3^U \le t \le m_4^U \\ 1 - \frac{1}{2}\left(\frac{t - m_4^U}{m_5^U - m_4^U}\right) & m_4^U \le t \le m_5^U \\ \frac{1}{2}\left(\frac{m_6^U - t}{m_6^U - m_5^U}\right) & m_5^U \le t \le m_6^U \\ 0 & t > m_6^U \end{cases}$$

Definition (α - cut of an Interval Type-2 Hexagonal Fuzzy Number**)**

The form of an α - cut Interval Type-2 Hexagonal fuzzy set is

$${}^{\alpha}\tilde{M} = \left[\begin{cases} \left[\tilde{M}_\alpha^U, \tilde{M}_\alpha^L\right], \alpha \in [0, \lambda) \\ \left[\tilde{M}_\alpha^U, \tilde{M}_\alpha^L\right], \alpha \in [\lambda, 1] \end{cases}, \begin{cases} \left[\tilde{M}_\alpha^L, \tilde{M}_\alpha^U\right], \alpha \in [\lambda, 1] \\ \left[\tilde{M}_\alpha^L, \tilde{M}_\alpha^U\right], \alpha \in [0, \lambda) \end{cases} \right]$$

$${}^{\alpha}\tilde{M} = \left[\begin{cases} \left[2\alpha(m_2^U - m_1^U) + m_1^U, 2\alpha(m_2^L - m_1^L) + m_1^L\right], \alpha \in [0, \lambda) \\ \left[2\alpha(m_3^U - m_2^U) - m_3^U + 2m_2^U, 2\alpha(m_3^L - m_2^L) - m_3^L + 2m_2^L\right], \alpha \in [\lambda, 1] \end{cases}, \right.$$
$$\left. \begin{cases} \left[-2\alpha(m_5^L - m_4^L) + 2m_5^L - m_4^L, -2\alpha(m_5^U - m_4^U) + 2m_5^U - m_4^U\right], \alpha \in [0, \lambda) \\ \left[-2\alpha(m_6^L - m_5^L) + m_6^L, -2\alpha(m_6^U - m_5^U) + m_6^U\right], \alpha \in [\lambda, 1] \end{cases} \right]$$

TWENTY -TWENTY CRICKET FORMAT

Cricket has approximately 500 years of history, with the International Cricket Council serving as its regulating council since 1909. The ICC now recognizes three worldwide formats: Test, ODI, and T20I, and has 104 associated nations that are members to International Cricket Council. Only twelve elite nations compete in all three formats, while the rest are limited to playing a single-day and Twenty20 cricket internationally. The essential regulations for all three variants are the identical and have some similarities to the actual game of softball. The game is carried out by two squads of eleven teammates each one, with the team that bats seeking to get in numerous runs as feasible

opposing the team that fields till their innings is over. In the subsequent innings, the batting and bowling sides adopt opposing positions. A defending side bowler "bowls" in six-delivery sets referred to as "over's." Over's are delivered periodically from both ends of the wicket. At any given point, two batters from the team that is batting occupy the two extremes of the pitch, often referred to as the "creases." Striker batters try for scoring runs by hitting the bowling ball with their bats. Runs are obtained by going across the two stumps on opposite sides of the pitch. Runs are determined by the volume of repetitions the player who strikes and non-striker exchange ends, which might vary from zero to three. If a hitter can hit the ball out of the boundaries, he gets four or six runs for completing the outer boundary without a bounce within. An inning concludes when all 10 batsmen are lost (one hitter is 'not out' since no one is at the opposing end of the field). A test game lasts five days, with each day permitting 90 over's of bowling and each squad striking for two innings respectively. At last, after two innings, the side with the most runs wins.

In contrast, limited over's formats such as ODI and T20I take place through one inning per side, with 50 and 20 over's, respectively. Test performances are the ultimate test of skills, determination, patience, tenacity, and endurance over five days, and they can occasionally provide a vivid picture of effort, sorrow, ecstasy, strategy, and, above all, skill. But test matches seem to have lost their appeal in this era of lightning-fast short-over's cricket, notably T20I. With fewer over's, the shorter game has evened out the playing the field, which makes it more difficult and unexpected. This has resulted in a tremendous lot of enjoyment and excitement for those who see it while involving very little time input. High viewership generated significant media rights and sponsorships, resulting in ballooning player pay and a bustling industry surrounding the game. The promise of big money enticed cricketers of all levels to this shortened format. Even experienced players are leaving Test cricket to pursue longer T20 careers.

RUN RATE

In cricket, the run rate (RR), also referred to as runs per over (RPO), is the mean number of runs secured by a batting side in each over. It includes all of the runs secured by the batting side in the innings leading up to that point in the match, as well as any additional runs conceded by the bowling team. What constitutes a good run rate varies according to the quality of the pitch, the kind of match, and the level of play. A five-day Test match often has a lower run rate than a limited-over's game, as batters take a more conservative approach. In the past few years, the mean Test run rate has been between 3 and 3.5 runs per over, sometimes considerably lower, but in short-format cricket, batters must take a more enthusiastic attitude in order to get the required total to win. The mean run rate in One Day International (50-over) cricket has risen from approximately four when the format was originally introduced in the 1970s to more than five in recent years. Only England has ever achieved more than 9 runs per over; scoring 8 or 7 is a reasonable run rate given the 50 over's, and dropping wickets is always a concern. In 20-over Twenty20 International cricket, the mean run rate is 8 to 9 runs per over. This is the quickest format of the game, and hitting out is essential. The maximum run rate ever recorded was about 13-14. Excluding extras and overthrows, the greatest conceivable run rate is 36 - if every ball is struck for six, which has never happened in an entire match and only occurs in a single over extremely seldom. The primary usage of run rate in limited over's cricket is for comparing the batting team's run rate (runs scored per finished over) to the run rate necessary to win the game. Teams typically strive to enhance their run rate in the last over. Cricket officials utilize fielding limitation restrictions, also referred to as Power plays, to promote speedier scoring in the early stages of the innings.

RUN RATE PREDICTION

The run rate will be change are depends upon the batsman skills, bowler, fielding and etc.,
The run rate will change from the following condition:

BATSMAN VIEW

i.   If a batsman can hit both pace and spin bowlers. (strike rate is high)
ii. If a batsman struggle with spin or with pace bowler.(strike rate is medium)
iii. If a batsman struggle to get score in the both spin and pace bowler.(strike rate is low)

BOWLER VIEW

i. If a bowler can take wicket and not to allow batsman to hit boundaries. (Economic rate is low).
ii. If a bowler can give batsman to hit boundaries.(Economic rate is medium)

iii.   If a bowler not to get wicket and allow the batman to hit boundaries and give extras.(economic rate is high)

FIELDING VIEW
i.   If a team has a fielding set up very strong, the batsman struggle to hit a run or boundaries.
ii.   If a team has a fielding set up very moderate the batsman can easily hit run or boundaries.
iii.   If a team has a fielding setup very low, the batsman easily hit run or boundaries and they won't get run out.

The run rate will define in the following method:
(i) All balls are fair delivery and all balls scored one run.
(ii) All balls are not fair delivery and all balls scored one, two, three and less boundaries.
(iii) All balls are not fair delivery and all balls scored high runs.

ALL BALLS ARE FAIR DELIVERY AND ALL BALLS SCORED ONE RUN:
RUN RATE IS CRISP: 6.0

ALL BALLS ARE NOT FAIR DELIVERY AND ALL BALLS SCORED HIGH RUNS:
RUN RATE IS FUZZY AND RUN RATE POSSIBILITY:
The run rate of a cricket match will be possible only by the batsman hits from 1 run to maximum 36 runs.

Example: In an IPL match a team scored in the 5th over is 63 runs of having run rate as 12.6. If the next over (6th over) possibilities
(i)In the 6th over no run will be scored. (Maiden over)
(ii) Only one run will be scored. (Economic rate≤1)
(iii) Scored 2, 3, 4 ... And maximum run will be scored is all balls hits as 6 runs(Economic rate≥ 1)

Hypothesis testing for Interval data (special)

Let $\left\{\left\{\left[q_{1i}, r_{1i}\right]\left[q_{2i}, r_{2i}\right]\right\}, \left\{\left[q_{3i}, r_{3i}\right]\left[q_{4i}, r_{4i}\right]\right\}\right\}, i = 1,2,\ldots\ldots n\right\}$ be a random sample with size n (<30) such that

$\left\{q_{1i}, i = 1,2,3,\ldots\ldots n\right\}, \left\{q_{2i}, i = 1,2,3,\ldots\ldots n\right\}, \left\{q_{3i}, i = 1,2,3,\ldots\ldots n\right\}, \left\{q_{4i}, i = 1,2,3,\ldots\ldots n\right\},$

$\left\{r_{1i}, i = 1,2,3,\ldots\ldots n\right\}, \left\{r_{2i}, i = 1,2,3,\ldots\ldots n\right\}, \left\{r_{3i}, i = 1,2,3,\ldots\ldots n\right\}, \left\{r_{4i}, i = 1,2,3,\ldots\ldots n\right\}$ are the eight selected at random from normal individuals, and the population of the mean of the collection be

$\left[\left\{\left[\psi_1, \upsilon_1\right]\left[\psi_2, \upsilon_2\right]\right\}, \left\{\left[\psi_3, \upsilon_3\right]\left[\psi_4, \upsilon_4\right]\right\}\right]$

Right now, the null hypothesis will be checked for the population's mean of the provided sample

$\left[\left\{\left[\psi_1, \upsilon_1\right]\left[\psi_2, \upsilon_2\right]\right\}, \left\{\left[\psi_3, \upsilon_3\right]\left[\psi_4, \upsilon_4\right]\right\}\right]$ is equal to a specific interval

$\left[\left\{\left[\psi_{1o}, \upsilon_{1o}\right]\left[\psi_{2o}, \upsilon_{2o}\right]\right\}, \left\{\left[\psi_{3o}, \upsilon_{3o}\right]\left[\psi_{4o}, \upsilon_{4o}\right]\right\}\right],$ that is, $\psi_1 = \psi_{1o}, \psi_2 = \psi_{2o}, \psi_3 = \psi_{3o}, \psi_4 = \psi_{4o}$ and

$\upsilon_1 = \upsilon_{1o}, \upsilon_2 = \upsilon_{2o}, \upsilon_3 = \upsilon_{3o}, \upsilon_4 = \upsilon_{4o}$.

Take into consideration a random sampling of fewer values from the provided special interval data.

$S_{L1} = \left\{q_{1i}, i = 1,2,3,\ldots\ldots n\right\}, S_{L2} = \left\{q_{2i}, i = 1,2,3,\ldots\ldots n\right\}, S_{L3} = \left\{q_{3i}, i = 1,2,3,\ldots\ldots n\right\},$

$S_{L4} = \left\{q_{4i}, i = 1,2,3,\ldots\ldots n\right\}, S_{U1} = \left\{r_{1i}, i = 1,2,3,\ldots\ldots n\right\}, S_{U2} = \left\{r_{2i}, i = 1,2,3,\ldots\ldots n\right\},$

$S_{U3} = \left\{r_{3i}, i = 1,2,3,\ldots\ldots n\right\}, S_{U4} = \left\{r_{4i}, i = 1,2,3,\ldots\ldots n\right\}.$

Now, the sample mean of $S_{L1}, S_{L2}, S_{L3}, S_{L4}, S_{U1}, S_{U2}, S_{U3}$ and S_{U4} are $\overline{q}_1, \overline{q}_2, \overline{q}_3, \overline{q}_4, \overline{r}_1, \overline{r}_2, \overline{r}_3$ and $\overline{r}_4$ correspondingly and sample standard deviations (S.D) of $S_{L1}, S_{L2}, S_{L3}, S_{L4}, S_{U1}, S_{U2}, S_{U3}$ and S_{U4} are $s_{q_1}, s_{q_2}, s_{q_3}, s_{q_4}, s_{r_1}, s_{r_2}, s_{r_3}, s_{r_4}$ and s_{r_4} respectively.

Test statistics:

79823

Jaimaruthi and Hari Ganesh

$$t_{L_1} = \frac{(\bar{q}_1 - \psi_1)\sqrt{n}}{s_{q_1}}, t_{L_2} = \frac{(\bar{q}_2 - \psi_2)\sqrt{n}}{s_{q_2}}, t_{L_3} = \frac{(\bar{q}_3 - \psi_3)\sqrt{n}}{s_{q_3}}, t_{L_4} = \frac{(\bar{q}_4 - \psi_4)\sqrt{n}}{s_{q_4}} \text{ and}$$

$$t_{U_1} = \frac{(\bar{r}_1 - \upsilon_1)\sqrt{n}}{s_{r_1}}, t_{U_2} = \frac{(\bar{r}_2 - \upsilon_2)\sqrt{n}}{s_{r_2}}, t_{U_3} = \frac{(\bar{r}_3 - \upsilon_3)\sqrt{n}}{s_{r_3}}, t_{U_4} = \frac{(\bar{r}_4 - \upsilon_4)\sqrt{n}}{s_{r_4}}$$

The refusing zone of an alternative hypothesis for the α level is shown below:

Now, if $\left| t_{L_i} \right| < t_{\alpha, n-1}, i = 1,2,3,4$ (one -tailed test) and $\left| t_{U_i} \right| < t_{\alpha, n-1}, i = 1,2,3,4$ (one -tailed test), the difference between $\left[\{ [\psi_1, \upsilon_1 \| \psi_2, \upsilon_2] \}, \{ [\psi_3, \upsilon_3 \| \psi_4, \upsilon_4] \} \right]$ and $\left[\{ [\psi_{1o}, \upsilon_{1o} \| \psi_{2o}, \upsilon_{2o}] \}, \{ [\psi_{3o}, \upsilon_{3o} \| \psi_{4o}, \upsilon_{4o}] \} \right]$ is not important at this α level. Following this, the population mean for the given sample $\left[\{ [\psi_1, \mu_1 \| \psi_2, \mu_2] \}, \{ [\psi_3, \mu_3 \| \psi_4, \mu_4] \} \right] = \left[\{ [\psi_{1o}, \upsilon_{1o} \| \psi_{2o}, \upsilon_{2o}] \}, \{ [\psi_{3o}, \upsilon_{3o} \| \psi_{4o}, \upsilon_{4o}] \} \right]$. That is, the null hypothesis is accepted. Otherwise, the alternative hypothesis is accepted.

Now, if $\left| t_{L_i} \right| < t_{\alpha/2, n-1}, i = 1,2,3,4$ (two- tailed test) and $\left| t_{U_i} \right| < t_{\alpha/2, n-1}, i = 1,2,3,4$ (two -tailed test), the difference between $\left[\{ [\psi_1, \upsilon_1 \| \psi_2, \upsilon_2] \}, \{ [\psi_3, \upsilon_3 \| \psi_4, \upsilon_4] \} \right]$ and $\left[\{ [\psi_{1o}, \upsilon_{1o} \| \psi_{2o}, \upsilon_{2o}] \}, \{ [\psi_{3o}, \upsilon_{3o} \| \psi_{4o}, \upsilon_{4o}] \} \right]$ is not important at this α level. Following this, the population mean for the given sample $\left[\{ [\psi_1, \upsilon_1 \| \psi_2, \upsilon_2] \}, \{ [\psi_3, \upsilon_3 \| \psi_4, \upsilon_4] \} \right] = \left[\{ [\psi_{1o}, \upsilon_{1o} \| \psi_{2o}, \upsilon_{2o}] \}, \{ [\psi_{3o}, \upsilon_{3o} \| \psi_{4o}, \upsilon_{4o}] \} \right]$. For us, the fact that the null hypothesis has been accepted. Nevertheless, the alternative hypothesis is acceptable.

Right now, the 100(1-α)% confidence level for the population mean $\left[\{ [\psi_1, \upsilon_1 \| \psi_2, \upsilon_2] \}, \{ [\psi_3, \upsilon_3 \| \psi_4, \upsilon_4] \} \right]$ corresponding to the given below:

$$\left[\left\{ \begin{array}{c} \left[\bar{q}_1 - t_{\alpha/2,n-1}\left(\frac{s_{q_1}}{\sqrt{n}}\right), \bar{r}_1 - t_{\alpha/2,n-1}\left(\frac{s_{r_1}}{\sqrt{n}}\right) \right] \\ \left[\bar{q}_2 - t_{\alpha/2,n-1}\left(\frac{s_{q_2}}{\sqrt{n}}\right), \bar{r}_2 - t_{\alpha/2,n-1}\left(\frac{s_{r_2}}{\sqrt{n}}\right) \right] \end{array} \right\}, \left\{ \begin{array}{c} \left[\bar{q}_3 - t_{\alpha/2,n-1}\left(\frac{s_{q_3}}{\sqrt{n}}\right), \bar{r}_3 - t_{\alpha/2,n-1}\left(\frac{s_{r_3}}{\sqrt{n}}\right) \right] \\ \left[\bar{q}_4 - t_{\alpha/2,n-1}\left(\frac{s_{q_4}}{\sqrt{n}}\right), \bar{r}_4 - t_{\alpha/2,n-1}\left(\frac{s_{r_4}}{\sqrt{n}}\right) \right] \end{array} \right\} \right]$$

$$< \left[\{ [\psi_1, \upsilon_1 \| \psi_2, \upsilon_2] \}, \{ [\psi_3, \upsilon_3 \| \psi_4, \upsilon_4] \} \right] <$$

$$\left[\left\{ \begin{array}{c} \left[\bar{q}_1 + t_{\alpha/2,n-1}\left(\frac{s_{q_1}}{\sqrt{n}}\right), \bar{r}_1 + t_{\alpha/2,n-1}\left(\frac{s_{r_1}}{\sqrt{n}}\right) \right] \\ \left[\bar{q}_2 + t_{\alpha/2,n-1}\left(\frac{s_{q_2}}{\sqrt{n}}\right), \bar{r}_2 + t_{\alpha/2,n-1}\left(\frac{s_{r_2}}{\sqrt{n}}\right) \right] \end{array} \right\}, \left\{ \begin{array}{c} \left[\bar{q}_3 + t_{\alpha/2,n-1}\left(\frac{s_{q_3}}{\sqrt{n}}\right), \bar{r}_3 + t_{\alpha/2,n-1}\left(\frac{s_{r_3}}{\sqrt{n}}\right) \right] \\ \left[\bar{q}_4 + t_{\alpha/2,n-1}\left(\frac{s_{q_4}}{\sqrt{n}}\right), \bar{r}_4 + t_{\alpha/2,n-1}\left(\frac{s_{r_4}}{\sqrt{n}}\right) \right] \end{array} \right\} \right]$$

The computation example below illustrates the solution approach.

Illustration

In IPL the run rate of the CSK matches between one opponent team is between {[6.1, 7.1][6.8, 7.3]} and {[8.2, 10][9.5, 10.5]} that is, first power play and middle over between 6.1 to 7.1 run rate and 6.8 to 7.3 run rate respectively as well as middle over and dead over between 8.2 to 10 and 9.5 to 10.5 respectively. Only ten matches from the IPL are chosen at random. The run rate between the first ten over's and the last ten over's is therefore expressed in the following unique interval form:

[{[6.3, 6.2][6.4, 6.7]}, {[8.1, 9.0][9.5, 9.3]}],   [{[5.5, 7.2][6.1, 7.4]}, {[7.4, 9.5][9.3, 10.0]}]
[{[6.4, 6.4][6.9, 7.0]}, {[8.8, 9.2][10.8, 9.1]}],   [{[3.5, 7.9][7.8, 7.5]}, {[8.0, 10.2][8.4, 9.9]}] [{[6.7, 6.8][7.3, 6.9]}, {[8.3, 9.8][9.6, 9.8]}],   [{[4.0, 7.3][6.6, 7.1]}, {[8.1, 10.9][9.9, 10.1]}]
[{[5.1, 6.0][7.4, 6.8]}, {[7.9, 10.1][10.8, 9.4]}],   [{[6.4, 7.0][7.2, 7.4]}, {[8.7, 10.1][8.2, 10.7]}]

[{[3.5, 6.5][7.0, 7.1]}, {[6.9, 9.5][9.5, 10.7]}],   [{[6.9, 7.6][6.3, 7.8]}, {[8.0, 10.7][9.5, 10.6]}]

Presently, we will consider testing the hypothesis

H_0 : $\left[\left\{\left[\psi_1, \upsilon_1\right]\psi_2, \upsilon_2\right\}, \left\{\psi_3, \upsilon_3\right]\psi_4, \upsilon_4\right\}\right] = \left[\left\{\left[\psi_{1o}, \upsilon_{1o}\right]\psi_{2o}, \upsilon_{2o}\right\}, \left\{\psi_{3o}, \upsilon_{3o}\right]\psi_{4o}, \upsilon_{4o}\right\}\right]$

H_A : $\left[\left\{\left[\psi_1, \upsilon_1\right]\psi_2, \upsilon_2\right\}, \left\{\psi_3, \upsilon_3\right]\psi_4, \upsilon_4\right\}\right] \neq \left[\left\{\left[\psi_{1o}, \upsilon_{1o}\right]\psi_{2o}, \upsilon_{2o}\right\}, \left\{\psi_{3o}, \upsilon_{3o}\right]\psi_{4o}, \upsilon_{4o}\right\}\right]$

Then consider the sample size, n = 10 and the population mean is $\left[\left\{\left[\psi_{1o}, \upsilon_{1o}\right]\psi_{2o}, \upsilon_{2o}\right\}, \left\{\psi_{3o}, \upsilon_{3o}\right]\psi_{4o}, \upsilon_{4o}\right\}\right]$ =
[{[6.1, 7.1] [6.8, 7.3]}, {[8.2, 10][9.5, 10.5]}] with an undefined standard deviation. We utilize the 5% level of significance.

Right now, the mean value of the lower and higher interval values are $\overline{q}_1 = 6.0,\ \overline{q}_2 = 6.9,\ \overline{q}_3 = 8.0,\ \overline{q}_4 = 9.6$, $\overline{r}_1 = 7.0,\ \overline{r}_2 = 7.2,\ \overline{r}_3 = 9.9,\ \overline{r}_4 = 10.0$ respectively and the sample standard deviation of the lower and upper interval values are $s_{q_1} = 0.81, s_{q_2} = 0.30, s_{q_3} = 0.31, s_{q_4} = 0.72,\ s_{r_1} = 0.47, s_{r_2} = 0.12, s_{r_3} = 0.38, s_{r_4} = 0.34$.

Now, the table shows that the value of t for 9 degrees of freedom at the 5% level is 1.833.

The current lowest values are $\psi_{1o} = 6.1, \psi_{2o} = 6.8, \psi_{3o} = 8.2, \psi_{4o} = 9.5$ and the current upper values are $\upsilon_{1o} = 7.1, \upsilon_{2o} = 7.3, \upsilon_{3o} = 10, \upsilon_{4o} = 10.5$.

Test statistics:

$t_{L_1} = \dfrac{(\overline{q}_1 - \psi_1)\sqrt{n}}{s_{q_1}} = -0.390, t_{L_2} = \dfrac{(\overline{q}_2 - \psi_2)\sqrt{n}}{s_{q_2}} = 1.054, t_{L_3} = \dfrac{(\overline{q}_3 - \psi_3)\sqrt{n}}{s_{q_3}} = -2.040,$

$t_{L_4} = \dfrac{(\overline{q}_4 - \psi_4)\sqrt{n}}{s_{q_4}} = 0.439, t_{U_1} = \dfrac{(\overline{r}_1 - \upsilon_1)\sqrt{n}}{s_{r_1}} = -0.673, t_{U_2} = \dfrac{(\overline{r}_2 - \upsilon_2)\sqrt{n}}{s_{r_2}} = -2.636,$

$t_{U_3} = \dfrac{(\overline{r}_3 - \upsilon_3)\sqrt{n}}{s_{r_3}} = -0.832, t_{U_4} = \dfrac{(\overline{r}_4 - \upsilon_4)\sqrt{n}}{s_{r_4}} = -4.650$

Now, since $\left|t_{L_1}\right| < t_{0.05}, \left|t_{L_2}\right| < t_{0.05}, \left|t_{L_3}\right| < t_{0.05}, \left|t_{L_4}\right| < t_{0.05}, \left|t_{U_1}\right| < t_{0.05}, \left|t_{U_2}\right| < t_{0.05}, \left|t_{U_3}\right| < t_{0.05}, \left|t_{U_4}\right| < t_{0.05}$, the null hypothesis H_0 is accepted and the 95% confidence limits for the population mean

$$[\{[5.53, 6.7][6.73, 7.13]\}, \{[7.82, 9.68][9.18, 9.80]\}] < \left[\left\{\left[\psi_1, \upsilon_1\right]\psi_2, \upsilon_2\right\}, \left\{\psi_3, \upsilon_3\right]\psi_4, \upsilon_4\right\}\right] <$$
$$[\{[6.47, 7.27][7.07, 7.13]\}, \{[8.18, 9.68][10.01, 10.20]\}]$$

Hypothesis testing for Interval valued type-2 Hexagonal fuzzy Numbers

Interval valued type-2 hexagonal fuzzy number $\left[(m_1^L, m_2^L, m_3^L, m_4^L, m_5^L, m_6^L), (m_1^U, m_2^U, m_3^U, m_4^U, m_5^U, m_6^U)\right]$ can be expressed as a specific interval value by utilizing the α - cut method as follows:

$$\left[(m_1^L, m_2^L, m_3^L, m_4^L, m_5^L, m_6^L), (m_1^U, m_2^U, m_3^U, m_4^U, m_5^U, m_6^U)\right]$$

$$= \left[\begin{cases} \left[2\alpha(m_2^U - m_1^U) + m_1^U, 2\alpha(m_2^L - m_1^L) + m_1^L\right], \alpha \in [0, \lambda) \\ \left[2\alpha(m_3^U - m_2^U) - m_3^U + 2m_2^U, 2\alpha(m_3^L - m_2^L) - m_3^L + 2m_2^L\right], \alpha \in [\lambda, 1] \end{cases}, \right.$$
$$\left. \begin{cases} \left[-2\alpha(m_5^L - m_4^L) + 2m_5^L - m_4^L, -2\alpha(m_5^U - m_4^U) + 2m_5^U - m_4^U\right], \alpha \in [0, \lambda) \\ \left[-2\alpha(m_6^L - m_5^L) + m_6^L, -2\alpha(m_6^U - m_5^U) + m_6^U\right], \alpha \in [\lambda, 1] \end{cases} \right]$$

- (5.1)

Assume that the supplied sample is type 2 fuzzy data with values of type 2 hexagonal fuzzy numbers, and we need to test the hypothesis regarding the population mean. Using the connection (5.1) and the provided test strategy for special interval data, we may test the hypothesis by converting type 2 fuzzy data to special intervals. The solution process is shown using the following example.

Illustration

The sports department wishes to declare that the lowest and highest run rates in the IPL for the specific team are 5.5 and 10.5 respectively. Only 12 matches from the IPL were documented. The lowest and greatest run rates recorded in the IPL for a specific team were around a certain figure. As a result, the lowest and greatest run rates were calculated using interval type 2 hexagonal fuzzy numbers, as shown below.

[(5.09, 5.17, 5.31, 5.43, 5.50, 5.59), (10.25, 10.29, 10.42, 10.45, 10.49, 10.54)]
[(5.29, 5.37, 5.38, 5.50, 5.57, 5.65), (10.03, 10.08, 10.12, 10.16, 10.20, 10.25)]
[(5.20, 5.28, 5.42, 5.54, 5.62, 5.69), (10.48, 10.54, 10.55, 10.60, 10.64, 10.73)]
[(5.18, 5.26, 5.39, 5.51, 5.58, 5.65), (10.14, 10.19, 10.34, 10.38, 10.69, 10.78)]
[(5.40, 5.47, 5.61, 5.74, 5.81, 5.89), (9.96, 10.04, 10.22, 10.29, 10.33, 10.39)]
[(5.57, 5.65, 5.78, 5.90, 5.97, 6.05), (10.61, 10.67, 10.78, 10.83, 10.87, 10.91)]
[(5.38, 5.47, 5.61, 5.73, 5.80, 5.88), (10.10, 10.15, 10.69, 10.73, 10.79, 10.82)]
[(5.34, 5.42, 5.57, 5.69, 5.76, 5.85), (10.04, 10.10, 10.12, 10.17, 10.73, 10.79)]
[(5.68, 5.76, 5.90, 6.03, 6.10, 6.18), (10.16, 10.22, 10.41, 10.46, 10.51, 10.57)]
[(5.41, 5.49, 5.63, 5.74, 5.81, 5.89), (10.06, 10.13, 10.32, 10.38, 10.44, 10.52)]
[(5.29, 5.37, 5.51, 5.64, 5.71, 5.78), (9.99, 10.06, 10.17, 10.23, 10.29, 10.36)]
[(5.39, 5.47, 5.61, 5.73, 5.79, 5.88), (10.14, 10.20, 10.34, 10.39, 10.44, 10.53)]

Now, we are considering the testing hypotheses $\tilde{H}_o : \quad \tilde{\upsilon} \approx \tilde{5.5} \text{ to } \tilde{10.5}$ and $\tilde{H}_A : \quad \tilde{\upsilon} \succ \tilde{5.5} \text{ to } \tilde{10.5}$

where $\tilde{5.5} \text{ to } \tilde{10.5}$ is recognized as linguistic data. Hence, we may process the hypotheses.

$\tilde{H}_o :$ The lowest and highest run rate is around 5.5 to around 10.5.

$\tilde{H}_A :$ The lowest and highest run rate is approximately greater than around 5.5 to around 10.5.

We may suppose that the membership function of

$\tilde{5.5} \text{ to } \tilde{10.5}$ = [(5.1, 5.2, 5.3, 5.4, 5.5, 5.6), (10.1, 10.2, 10.3, 10.4, 10.5, 10.6)]

Presently, the sample measures 12, and the population mean is

$\tilde{\upsilon}_o$ = [(5.1, 5.2, 5.3, 5.4, 5.5, 5.6), (10.1, 10.2, 10.3, 10.4, 10.5, 10.6)] with an undetermined sampling standard deviation.

Now, applying the relation (5.1), we transform the type 2 fuzzy interval data, and subsequently, we find that the average of the lowest and higher interval estimations of the special interval

$\overline{q}_1 = 0.1178\alpha + 10.164$, $\overline{r}_1 = 0.1610\alpha + 5.3498$, $\overline{q}_2 = 0.3017\alpha - 10.373$, $\overline{r}_2 = 0.2593\alpha + 16.421$,

$\overline{q}_3 = -0.1410\alpha + 5.8213$, $\overline{r}_3 = -0.2262\alpha + 10.648$, $\overline{q}_4 = -0.1610\alpha + 5.831$, $\overline{r}_4 = -0.1242\alpha + 10.597$

accordingly, and the sample standard deviation of the mean value of the smallest and higher interval values is

$s_{q_1} = \sqrt{0.0137\alpha^2 - 0.0016\alpha + 0.0388}$

$s_{r_1} = \sqrt{0.0001\alpha^2 + 0.0002\alpha + 0.0264}$, $0 \le \alpha < \lambda$

$s_{q_2} = \sqrt{0.0758\alpha^2 - 0.0529\alpha + 0.0453}$

$s_{r_2} = \sqrt{0.0054\alpha^2 + 0.0137\alpha + 0.2447}$, $\lambda \le \alpha \le 1$

$$s_{q_3} = \sqrt{0.0001\alpha^2 - 0.0003\alpha + 0.0296}$$

$$s_{r_3} = \sqrt{0.1021\alpha^2 - 0.1536\alpha + 0.0957}, \qquad\qquad 0 \le \alpha < \lambda$$

$$s_{q_4} = \sqrt{0.00006\alpha^2 - 0.00034\alpha + 0.02964}$$

$$s_{r_4} = \sqrt{0.0014\alpha^2 + 0.0023\alpha + 0.0429}, \qquad\qquad \lambda \le \alpha \le 1$$

We apply the 5% level of significance to the table value of t for 11 degrees of freedom.

$t_{0.05} = 1.796$.

Now, the interval representation of $\tilde{\upsilon}_0$, $\qquad [\tilde{\upsilon}_0] = \left[\left\{ \left[\psi_{1o}, \upsilon_{1o} \right] \left[\psi_{2o}, \upsilon_{2o} \right] \right\}, \left\{ \psi_{3o}, \upsilon_{3o} \right] \left[\psi_{4o}, \upsilon_{4o} \right] \right\} \right]$

where

$$\psi_{1o} = 0.117\alpha + 10.1, \ \upsilon_{1o} = 0.16\alpha + 5.34$$

$$\psi_{2o} = 0.3\alpha - 10.3, \ \upsilon_{2o} = 0.25\alpha + 5.3$$

$$\psi_{3o} = -0.14\alpha + 5.82, \ \upsilon_{3o} = -0.22\alpha + 10.6$$

$$\psi_{4o} = -0.1\alpha + 5.83, \ \upsilon_{4o} = -0.12\alpha + 10.5$$

Now, let $\lambda = 0.5$, we have the test statistics

$$t_{L_1} = \frac{(\bar{q}_1 - \psi_1)\sqrt{n}}{s_{q_1}} = \begin{cases} 1.1176, \alpha = 0 \\ 1.0439, \alpha = 0.49 \end{cases}, t_{L_2} = \frac{(\bar{q}_2 - \psi_2)\sqrt{n}}{s_{q_2}} = \begin{cases} 1.3544, \alpha = 0 \\ 1.3610, \alpha = 0.49 \end{cases},$$

$$t_{L_3} = \frac{(\bar{q}_3 - \psi_3)\sqrt{n}}{s_{q_3}} = \begin{cases} 0.9365, \alpha = 0.5 \\ 0.8654, \alpha = 1 \end{cases}, t_{L_4} = \frac{(\bar{q}_4 - \psi_4)\sqrt{n}}{s_{q_4}} = \begin{cases} 1.4147, \alpha = 0.5 \\ 1.4754, \alpha = 1 \end{cases},$$

$$t_{U_1} = \frac{(\bar{r}_1 - \upsilon_1)\sqrt{n}}{s_{r_1}} = \begin{cases} 1.2800, \alpha = 0 \\ 1.2723, \alpha = 0.49 \end{cases}, t_{U_2} = \frac{(\bar{r}_2 - \upsilon_2)\sqrt{n}}{s_{r_2}} = \begin{cases} 0.7120, \alpha = 0 \\ 0.7902, \alpha = 0.49 \end{cases}$$

$$, t_{U_3} = \frac{(\bar{r}_3 - \upsilon_3)\sqrt{n}}{s_{r_3}} = \begin{cases} 0.6672, \alpha = 0.5 \\ 0.0522, \alpha = 1 \end{cases}, t_{U_4} = \frac{(\bar{r}_4 - \upsilon_4)\sqrt{n}}{s_{r_4}} = \begin{cases} 0.8429, \alpha = 0.5 \\ 0.6320, \alpha = 1 \end{cases}$$

Since for α, $0 \le \alpha < 0.5$, $t_{L_1} < t_{0.05}$, $t_{L_2} < t_{0.05}$, $t_{U_1} < t_{0.05}$ and $t_{U_2} < t_{0.05}$ and for α, $0.5 \le \alpha \le 0.92$, $t_{L_3} < t_{0.05}$,

$t_{L_4} < t_{0.05}$, $t_{U_3} < t_{0.05}$ and $t_{U_4} < t_{0.05}$. Therefore, $\tilde{H}_o$: The lowest and highest run rate is around 5.5 to around 10.5 is allowed depending on the specified fuzzy data and criteria

$0 \le \alpha \le 0.92$.

CONCLUSION

In this study, we addressed the challenge of evaluating statistical hypotheses for cricket run rate using interval valued type-2 Hexagonal fuzzy numbers. The key advantage of this method is that it allows the statistical hypothesis to be tested when the available data falls within the interval of fuzzy numbers. Finally, numerical examples are provided to show the practicality of the suggested technique.

ABSTRACT

Systems like intrusion detection, fraud detection, and system monitoring depend heavily on anomaly detection. Regrettably, false positives are a common problem with these systems, which can lead to alarm fatigue, diminished effectiveness, and lowered system confidence. This abstract will examine several strategies for handling false positives in anomaly detection. We will talk about strategies that can help reduce the false positive rate and increase the accuracy and robustness of the system, like semi-supervised learning, ensemble methods, and threshold tweaking. By putting these strategies into practice, you may lessen alert fatigue, boost productivity, and boost user confidence in anomaly detection systems—all of which can make them useful for a variety of applications.

Keywords: Accuracy, robustness, efficiency, confidence, alert fatigue, semi-supervised learning, ensemble techniques, intrusion detection, fraud detection, system monitoring, and threshold tweaking.

INTRODUCTION

In response to the widespread misuse of computers by individuals, network intrusion has become a major worry for enterprises in recent years. Malicious assaults can still happen even with encryption, VPNs, and firewalls installed, which is why having a monitoring system in place is essential. Intrusion detection is an important technology that, through the analysis of hostile data and counterattacks, offers dynamic protection to companies. One such system is the Network-Based IDS (NIDS), which keeps an eye on network traffic to spot possible threats coming from outside the network. Three types of intrusion detection systems (IDS) exist: signature-based, anomaly-based, and protocol modelling-based. All three approaches are combined by most IDS systems to improve security.

Pankhuri Goyanka *et al.,*

Categories of Intrusion Detection System [2]
Detection Systems based on Signature
Comparing network traffic or system behavior to a database of predefined attack signatures is a technique for identifying known assaults. The patterns that match the distinctive qualities of a known attack are known as attack signatures. There are two primary stages to the process:

Signature Generation
Creating an attack signature database is the first step in the signature-generating process. Usually, to do this, patterns in network traffic or system logs are identified by examining the behavior of known assaults. The intrusion detection system uses the generated signatures to identify upcoming assaults by adding them to the database.

Signature Matching
When using signature-based intrusion detection, the system searches network traffic or computer system behavior for patterns of known attacks. It alerts you if it discovers a match. While this is a quick method for identifying known assaults, it is ineffective against undiscovered ones. Attackers can modify their strategies to avoid being discovered. More recent intrusion detection systems utilize machine learning and other cutting-edge methods to learn from previous attacks and recognize strange behavior to uncover these new attacks.[8]

Detection System based on Anomaly
An instrument that searches a computer network for anomalous activity is called an anomaly-based detection system. After establishing a profile of what is typical, it keeps an eye out for deviations. This system is capable of identifying anomalous behaviors or denial-of-service attacks. It locates these items with intelligent technologies. This system's ability to identify previously unseen assault kinds is one of its advantages. However, if the system changes or if it is unaware of what normal is, it may also make mistakes. It is crucial to define normal clearly and to change it as necessary to improve the functionality of this system. To keep things safe, it's also critical to employ additional security measures like passwords and virus scans.

Protocol Modelling
Computer network protocols can be analyzed using a technique called protocol modeling. It models the protocol, mimicking its actions and spotting potential security risks. This model's behavior is controlled by a variety of states and messages. Testing the protocol's resilience to various attacks and identifying its vulnerabilities are beneficial. Researchers and experts in network security utilize protocol modeling to make networks more secure and to ensure that new protocols are developed with performance and security requirements in mind.

LITERATURE SURVEY

V. chandola et al, employed several clustering strategies and data processing methods. The Hybrid Detection Framework provides the foundation for this [1]. Francesco Mercaldo, specialized in anomaly identification utilizing data processing methods such as classification trees and support vector machines. Based on the 1999 KDD Cup data, the trials showed that the algorithm C4.5 is superior to SVM in terms of identifying false alarm rates and network anomalies[2]. Symbolic dynamic filtering (SDF), a feature-derived algorithm, is used by the D. Denning algorithm [3]. Probabilistic finite-state automata (PFSA), which are features for pattern classification, can be generated by dividing the information into symbolic sequences in SDF [4]. Ugo Fiore et al, in this paper, initially noticed how the learning process worked as noise levels increased and how it could affect the method's ability to extract accurate rules. Three criteria are used to measure this method's effectiveness: "Max rule confidence," "Precision," and "Recall" [5]. Cluster analysis is used by T. Bhavani et al. to detect anomalies. Our method preferred for K-mean clustering is a straightforward and widely recognized technique. Compared to many other algorithms, it requires less computing power, which makes it more appealing for bigger datasets [6]. S. Lina et al, these user-provided fixed cluster counts are not an acceptable estimate for high-dimensional datasets since they cause different deviations or inappropriate

data distribution[7]. B. Thuraisingham, Network intrusion detection systems employ data mining or signature-based techniques that rely on labeled training data. Principal Component Analysis (PCA) is used in the anomaly network intrusion detection conduct to minimize data, and Fuzzy Adaptive Resonance Theory (Fuzzy ART) can be utilized for the classifier[8]. S. wu et al, A novel hybrid intrusion detection system incorporates simplified swarm optimization for intrusion data classification and intelligent dynamic swarm-based rough set (IDS-IR) for feature selection[9]. B. Singh et al, through simulation, the technique is thoroughly improved and then used in an industrial case study. The results point to a productive application of decision-making in production management. Work order data is the foundation for the algorithms used for developing a dynamic network[10]. For IDS, M. Xue et al. employed a hybrid strategy based on data mining. By strengthening the detection rate, the clustering analysis method attempts to lower the false alarm rate[11]. K.Wankhede et al, in this paper, Support Vector Machine (SVM) and Entropy of network features-based anomalous traffic detection systems are examined. Furthermore, a hybrid approach that combines support vector machines and network feature entropy is contrasted with freestanding methodologies[12]. Samad, A. focuses on an extensive examination of many different anomaly detection frameworks for various types of network intrusion detection[13]. J. Jonathan proposed a "new density-based and grid-based clustering algorithm" that is suitable for the detection of unknown abnormalities[14].

PROBLEM IDENTIFICATION
An intrusion detection system (IDS) guards and safeguards a network. It has the automated ability to identify unusual activities. An intrusion detection system handles intrusions. The need to defend computer networks and systems against attacks and security breaches is the primary issue that intrusion detection systems (IDS) [9] attempt to address. Specifically, intrusion detection systems (IDS) are made to identify and counteract any efforts to jeopardize the availability, confidentiality, or integrity of network resources.The following are some particular issues that intrusion detection systems handle:

Identifying Attacks
Reliability in real-time attack identification is one of the primary obstacles in intrusion detection. This calls for the capacity to discern between benign and malevolent network traffic as well as the ability to spot attacks as they happen.

False Positives
False alarms or alerts from IDS may result in resource and time waste. Numerous things, such as incorrect setups, unusual network activity, or genuine traffic that seems suspicious, might result in false positives.[11]

False Negatives
Additionally, IDS may be unable to identify assaults, leaving networks open to security risks. Attacks that are intended to avoid detection or flaws in the detection methods the IDS uses can result in false negatives.

Scalability
IDS needs to be able to manage high network traffic volumes and evolve with the traffic on the network. To identify and analyze network traffic, this calls for scalable and effective algorithms.

Adaptability
IDS needs to be flexible enough to react to new and developing security threats as well as changing network settings. This necessitates constant observation and upgrading of the IDS's detection rules and algorithms.
There are two categories of procedures used in the identification of aberrant activity: -

Predefined Normal Behavior
The term "predefined normal behavior" in intrusion detection refers to a standard that is established for the typical behavior of a computer network or system. This standard is based on the typical operation of the system or network. Before setting this standard, we observe the system and network for a while to determine what is typical. Next, we

create a set of guidelines that specify what constitutes appropriate behavior. Upon obtaining this information, we can deploy tools to monitor the network and system for any non-compliant activity. As a result, the IDS can identify possible security threats or assaults and notify security staff of them [10]. This aids in the detection of potential issues. Having predetermined normal conduct offers several advantages, such as:

Improved accuracy
IDS can more precisely detect deviations from typical usage patterns by setting up a baseline of usual activity, which can lower the number of false positives and false negatives.

Increased efficiency
By streamlining the detection process, predefined usual behavior enables intrusion detection systems to concentrate on questionable activity that deviates from typical usage patterns.

Better scalability
IDS can better manage high amounts of network traffic and scale to meet the demands of expanding networks by creating a baseline of typical behavior. It examines normal conduct in accordance with the stored pattern after first storing the pattern of the user's typical behavior in the database. A sufficiently large deviation may indicate the presence of unusual activity. A high detection rate, accuracy, and low false alarm rate are necessary for an intrusion detection system (IDS). Typically, the effectiveness of an IDS is assessed using the following formula, which takes into account the detection rate (DR), accuracy (AC), and false alarm rate (FAR): In general, one of the most crucial methods for spotting security risks and defending computer networks and systems against infiltration is the use of specified usual behavior in intrusion detection.

Predefined Intrusion Behavior
It is a collection of well-known attack patterns or signatures that security professionals have recognized and categorized. To find potential security threats and attacks, intrusion detection systems (IDS) might make use of predetermined intrusion behavior. IDS are designed with a collection of policies or rules that specify how an intrusion behaves in response to recognized attack patterns. These rules can be used to keep an eye out for indications of intrusion on system activity and network traffic. Numerous attack types, including port scanning, password guessing, buffer overflow, and many more, can be included in predefined intrusion behavior. Security specialists can develop rules or policies that enable intrusion detection systems (IDS) to promptly identify and address potential security issues by classifying and recognizing these incursion patterns. There are some restrictions attached to the usage of specified incursion behavior, though. Adversaries are always coming up with new and cutting-edge ways to get around security measures and evade detection. Therefore, predetermined intrusion behavior may not identify new or developing threats over time and may become outdated. Anomaly-based detection, which focuses on spotting odd or unexpected activity that deviates from typical usage patterns, is another tool that IDS can employ to get around this restriction.IDS can offer a more thorough method of intrusion detection and improve network security by combining both specified intrusion behavior and anomaly-based detection. [6] It initially records the pattern of malevolent activity associated with intrusion and then assesses the likelihood of intrusion based on the pattern discovered. Its detection accuracy is good and its false alarm rate is minimal. Its primary drawback is that it can only identify intrusions using specified patterns.

1. Detection Rate = (TP) / (TP+FP)
2. Accuracy = (TP+TN) / (TP+TN+FP+FN)
3. False Alarm Rate = (FP) / (FP+TN)

Actual	Predicted Normal	Predicted Attack
Normal	TN	FP
Intrusions	FN	TP

An attack has been identified in the attack data.

Pankhuri Goyanka *et al.,*

True negative (TN): Occurs when normal data is identified as negative.

False-positive (FP): Occurs when normal data is mistakenly identified as malicious.

False-Negative (FN): Normal detection was made of the attack data.

This research uses the KDD Cup 1999 dataset to assess several intrusion detection techniques. MIT Lincoln Labs developed and oversaw the dataset in 1998 as a component of the DARPA Intrusion Detection Evaluation Program. This study aims to investigate and assess several intrusion detection methods. This study addresses the issue of detecting intrusions when regular data is mistakenly labeled as such. There was no plagiarism in the original material. The KDD Cup 1999 data, which was created by MIT Lincoln Labs for the DARPA Intrusion Detection Evaluation Program in 1998, is the dataset that was used in this study. It's a military network environment with both regular data and incursions for assessment. The dataset has become a standard for examining intrusion detection systems. There are 41 attributes used in this dataset to determine whether the input belongs to a normal or anomaly class. These attributes include duration, protocol type, service, flag, source bytes, destination bytes, and various rates such as error rates and same server rates. The class is either normal or anomaly. 41 attributes are :- Attribute 1, represented as P1, is the duration while Attribute 2, P2, is the protocol type. Attribute 3 is the service represented as P3, and Attribute 4, P4, is the flag. The amount of source bytes is represented as P5 while P6 represents the amount of destination bytes. The attribute P7, land, indicates whether the connection is from/to the same host/port. P8, wrong_fragment, represents the number of wrong fragments received. P9, urgent, indicates the number of urgent packets received. P10, hot, represents the number of "hot" indicators in the content. P11, num_failed_logins, is the number of failed login attempts. P12, logged_in, indicates whether the user is logged in. P13, num_compromised, represents the number of compromised conditions. P14, root_shell, represents whether the user has root access. P15, su_attempted, represents whether the user has attempted to escalate their privileges. P16, num_root, represents the number of root accesses. P17, num_file_creations, represents the number of file creations. P18, num_shells, represents the number of shell prompts. P19, num_access_files, represents the number of operations on access control files.

P20, num_outbound_cmds, represents the number of outbound commands in an FTP session. P21, is_host_login, indicates whether the login is a host login. P22, is_guest_login, indicates whether the login is a guest login. P23, count, represents the number of connections to the same host as the current connection. P24, srv_count, represents the number of connections to the same service as the current connection. P25, serror_rate, represents the percentage of connections that have "SYN" errors. P26, srv_serror_rate, represents the percentage of connections that have "SYN" errors to the same service as the current connection. P27, rerror_rate, represents the percentage of connections that have "REJ" errors. P28, srv_rerror_rate, represents the percentage of connections that have "REJ" errors to the same service as the current connection. P29, same_srv_rate, represents the percentage of connections to the same service. P30, diff_srv_rate, represents the percentage of connections to different services. P31, srv_diff_host_rate, represents the percentage of connections to different hosts. P32, dst_host_count, represents the number of connections to the same destination host as the current connection. P33, dst_host_srv_count, represents the number of connections to the same service as the current connection to the same destination host. P34, dst_host_same_srv_rate, represents the percentage of connections to the same service to the same destination host. P35, dst_host_diff_srv_rate, represents the percentage of connections to different services to the same destination host. P36, dst_host_same_src_port_rate, represents the percentage of connections to the same source port to the same destination host. P37, dst_host_srv_diff_host_rate, represents the percentage of connections to different hosts to the same service as the current connection to the same destination host. P38, dst_host_serror_rate, represents the percentage of connections that have "SYN" errors to the same destination host. P39, dst_host_srv_serror_rate, represents the percentage of connections that have "SYN" errors to the same service as the current connection to the same destination host. P40, dst_host_rerror_rate, denotes the proportion of connections encountering 'RE

For example, four data points from the KDD Cup 1999 dataset can be analyzed using these attributes.

The 41 qualities play a critical role in identifying any malicious activity when it comes to recognizing unusual behavior. The trick, then, is to identify these behaviors effectively without raising the false alarm rate. A way to improve efficiency is to minimize the amount of characteristics, but remember that accurate detection is the ultimate aim. By comparing values to the mean, these 41 properties may be used to detect potentially abnormal behavior, with

variations from the mean suggesting possible anomalies. The count characteristic can be removed as one solution to the false positive issue in IDS, but timely attack detection is still a concern. Effective intrusion detection ultimately comes down to striking the correct balance between accuracy and efficiency.

PROPOSED METHODOLOGY
An increase in false-positive rates has been attributed to the count property. Two performance metrics—detection rate and false alarm rate—are the main focus of system modifications. To calculate the false alarm rate, divide the total number of normal instances that were mistakenly identified as intrusions by the total number of normal instances. Similarly, to calculate the detection rate, divide the total number of intrusion patterns in the dataset by the number of correctly identified intrusion patterns. The percentage of intrusions the system can accurately detect and the number of detection errors made are the two measures of successful execution. On sample data, these values can be computed to assess performance. The count attribute can be deleted and replaced with a one-time password (OTP) given to the user's phone number or email address to solve authentication issues. OTP is a dependable fix for this issue.[1]

Algorithm 1: Registration
1.   Begin
2.   Enter details in a registration form and complete all mandatory fields.
3.   If all mandatory information is not filled in the registration form.

Algorithm 2: Login
1.   Begin   // (i represent how many times the user can attempt to complete   CAPTCHA or I am not a Robot checkbox Repeat steps 1 and 2.
2.   Fill in the username and password field and also log in)
3.   If both the details are valid then login successfully.
4.   Else (for i=1 to i=5)
5.   One-time password is generated and sent to the user's email address
6.   If OTP match then repeat step 1 and 4.

EXPERIMENT AND RESULTS

Figures 5.1–5.4 display the clustering methods' outcomes. The output of the Simple K-mean clustering procedure with the count attribute added is displayed in Figure 5.1, it reveals that the clustering time was 0.42 seconds. With the count property removed, Figure 5.2 shows the output of the same technique with a 0.26-second faster clustering time. Figures 5.5–5.8 display the clustering methods' outcomes. The output of the Canopy clustering procedure with the count attribute added is displayed in Figure 5.5, and it reveals that the clustering time was 0.32 seconds with the count attribute. Figure 5.6 shows the clustering time was 0.12 without the count attribute, Figure 5.7 shows the output of Fastest first with the count attribute which is 0.05 seconds and Figure 5.8 displays the clustering time was 0.04 seconds without the count attribute.

CONCLUSION

People struggle to remember all the passwords for their accounts on multiple platforms, thus it has become a regular problem these days. This frequently leads to several tries to access an account; in the case of banks, the user's account is blocked for a whole day by the bank website following three unsuccessful attempts. This study suggests removing the count characteristic to enhance system performance to overcome this problem. The simple K-mean value dropped from 0.42 to 0.16 and the filter clustered value dropped from 0.16 to 0.11 wherease Fastestfirst value

Pankhuri Goyanka *et al.,*

dropped from 0.05 to 0.04 and Canopy Clustering value dropped from 0.32 to 0.12. These enhancements lower the false alarm rate by increasing efficiency and cutting down on the amount of time needed for detection. Since a breach is less likely to occur with faster discovery, this enhancement may contribute to an increase in security. Rapid detection and response are essential for system maintenance because delayed detection can compromise the system.

ABSTRACT

This present investigation evaluated the phytochemistry, and anti-bacterial potential of *Punicagranatum*Peel extract. Phytochemical analysis of pomegranate fruit peel extracts in methanol, ethanol, diethyl ether, and water showed the presence of glycosides, alkaloids, tannins, saponins, glycosides, flavonoids, quinones, and flavonoids; steroids, terpenoids, and phenols were exclusionary. The in-vitro agar well diffusion method was used to test different concentrations of methanolicPGP extract (three different concentrations) against pathogenic bacterial strains. A standard medication was employed as a positive control, and all of the formulations demonstrated good action.

Keywords: *Punicagranatum*, phytochemical analysis, and anti-bacterial, gentamycin**.**

INTRODUCTION

Eighty percent of the global population uses some form of complementary or alternative medicine, therefore there has been a huge uptick in research into the potential medicinal benefits of plants in the last several decades. Phytoplants have emerged as viable substitutes for synthetic chemical antimicrobials and antibiotics, which pose significant risks such as resistance to these drugs, the development of new, rare infections, and the occurrence of harmful side effects[1]. Clinicians should caution patients about side effects such as urticaria, changes in taste, increased calculus formation, tooth and mucous membrane staining, and, in rare cases, desquamation of the oral mucosa and swelling of the parotid glands before prescribing chlorhexidine mouthwash as an antimicrobial. Of the 250,000–500,000 species of plants and animals on Earth, hardly 1% have had their medicinal potential investigated. The effects of native Iranian plant extracts have been documented in manuscripts[2-3]. A member of the Lythraceae

79847

family, the pomegranate tree or shrub (*Punicagranatum* L.) is a popular fruiting plant grown in many parts of the world, including South Africa. Due to its various health benefits, all components of the plant, including fruit juice, are highly sought for. The fruit's peel is the most valuable yet wasted part, making up about 49% to 55% of the fruit's weight[4]. Its antibacterial, free radical scavenging, and anticancer properties are unparalleled by any other component of the pomegranate plant. The chemical makeup of pomegranate peel, especially the phenolics, is intimately linked to these biological activities since it includes numerous bioactive compounds, including ellagitannins, flavonoids, and phenolic acids, among many others. Even though there are a lot of different kinds of pomegranates available and more are being grown all the time, the "Wonderful" kind is still the most popular in South Africa due to its high yields and exceptional qualities. The pomegranate, or PGP, is a natural fruit of the area between Iran and northern India. However, it is currently grown extensively in certain regions of Africa, Mexico, Arizona, and Southwest America. Even ancient Greek and Egyptian writings make reference to the pomegranate's pharmacological benefits. Some of the many possible effects of pomegranate have been discovered in recent investigations[5-7]. These include: anthelmintic, stimulant, vermifuge, antifungal, antiviral, immunological modulation, styptic, astringent, stomachic, laxative, diuretic, and bacteriocidal. The cultivars 'Acco' and 'Herskawitz,' which together account for 9% of the market, are the second most prevalent. Several studies have shown that the beneficial compounds in pomegranate skin might differ across cultivars[8].

In addition, it helps lessen the negative effects of cardiovascular illness, vaginitis, denture stomatitis, erectile dysfunction, obesity, Alzheimer's disease, and baby brain ischemia are among the many medical diseases that it helps alleviate [9]. The pomegranate's seed oil, peels, and juice retain its numerous cancer-fighting and therapeutic characteristics. The plant also contains estriol, testosterone, 17-alphaestradiol, stigmasterol, campesterol, gamma-tocopherol, estriol, punicie acid, and coumesterol. Because of its many beneficial medicinal properties, the pomegranate deserves investigation from various branches of medicine [10]. In spite of this, a study is documented that aims to investigate the antibacterial characteristics of PGP peel extracts against four distinct pathogenic microorganisms. Additional objectives of this research include analyzing the peel extracts' phytochemical composition and determining which of the most promising extracts include biologically active components. To investigate the phytochemical properties (varieties of extracts) and antimicrobial investigation, we employed a suite of analytical tools.

MATERIALS AND METHODS

Preparation of Plant Extract
Getting the plant extract ready to start, fresh pomegranates (500 gr) were bought from a market in the city of Tiupattur so that fresh extraction could be made. The peels of pomegranates were separated and dried for 7 days at 33°C in an oven. An electric grinder was used to turn the dried peels into a powder, which was then put in plastic bags and kept for the next step. 200 ml of methanol (99.9%) was mixed with 100 grams of powder in an electric mixer for 30 minutes. For 30 days, this solution was filtered three times a day. It was always a new methanol dissolvent that was used. The methanol was then taken away in a rotating evaporator to make a dry powder[11]. The samples were then sent to the Institute of Biological Science to be tested for phytochemicals and antibacterial activity.

Preparation of Extracts for Phytochemical Constituents
Before being chopped into bits and allowed to dry in the shade at room temperature, the selected medicinal plants were rinsed with distilled water after being cleaned with clean water. We crushed and sieved the dry samples before putting them in plastic bags to make sure they weren't contaminated. Using organic solvents instead of water is the optimal method for extracting bioactive chemicals, according to multiple research[12]. In this study, the powder was extracted from the peel of PGP using 80% methanol alcohol. Following that, there was a mixture of ethanol, diethyl ether, and water. This solvent triumphed due to its expanded extraction capabilities and higher yields of secondary bioactive chemicals. Two thousand milliliters of plant extract and one hundred grams of powdered material made up each reagent vial. Then, we filled each bottle with 1000 mL of methanol. Using an orbital shaking machine, the bottles

79848

were shaken after being left at room temperature for 24 hours. The leftover liquid was then filtered using a Whatman No. 1 strainer. Following filtration, the procedure was carried out twice using new solvent. Under reduced pressure and 40 ◦C, the methanol filtrate was concentrated using a rotary evaporator. Then, to remove any residual organic solvents, it was moved to beakers & dried in a water bath set at 40 ◦C. A final step was to keep the samples at 2-8 ◦C until they could be analyzed further.[13].

Phytochemical Analysis of PGP Extract
Initial phytochemical evaluation
The presence of secondary metabolites was investigated through a first phytochemical screening using standard, well-established methods[14].

Alkaloid detection
The presence of alkaloids was confirmed by the use of Mayer's test reagent in precipitation processes. Along the inside of a test tube, a couple of drops of Mayer's reagent were delicately applied to a little amount of plant extract. When alkaloids are present, a white, creamy precipitate will occur.

Polyphenol detection
The ferric chloride assay, as employed before by Peter et al., was utilized to determine if the extracts contained total polyphenols or not. A 5% ferric chloride solution was added to 1 mL of the crude extract in a volume of 2 mL. If you notice a blue-green hue, it means that phenols are present.

Saponin detection
The presence of saponins could be detected using the foaming test. The process began with forcefully mixing about 3 milliliters of plant extracts with 3 milliliters of distilled water. A favorable sign of saponin presence was the observation of steady and persistent foam production.

Identifying Terpenoids
Two milliliters of chloroform, three milliliters of sulphuric acid, and five milliliters of plant extracts were used in a chemical method to identify terpenoids. It was thought that terpenoids were present when a reddish-brown color was present.

Detection of steroids
Steroids were identified using the Salkowski test. About 2 milliliters of the sample solution and 5 milliliters of chloroform were mixed. Then, while being careful to add it all the way along the inside of the test tube, 1 mL of sulphuric acid that was 98% concentrated was added to the previously indicated mixture. Steroids are present when a reddish-brown ring appears at the interface of the two layers.

Flavour compound identification
The plant extracts were tested for flavonoids using an alkaline reagent assay. As part of this experiment, a 10% sodium hydroxide solution was mixed with 3 milliliters of plant extract. One way to tell if flavonoids were present was when a bright yellow hue developed.

Detection of Tannins
Finding tannins required the use of the gelatin test. A 1% w/v gelatin solution containing 10% sodium chloride was used to treat a sample solution. The presence of tannins was confirmed by the presence of a white precipitate.

Tested Bacterial Species
We tested their antimicrobial properties on four reference strains of bacteria from the American Type Culture Collection (ATCC). Bacillus subtilis ATCC 6633, Staphylococcus aureus ATCC 10876, Pseudomonas aueogenisa, and Escherichia coli ATCC 10536 were the bacterial strains that were evaluated. The SAIDAL group's microbiology unit

in Media (Algeria) generously supplied them. Sacred Heart College (Autonomous), Tirupattur'sPomegranate and Research Microbiology lab, which is a part (TMMRD), kept the germs at a temperature of -78∘C[15].

Inoculum Preparation
To ensure uniformity, a suspension was prepared by combining three or five test organism colonies from a pure culture with nutrient broth. Afterwards, a UV-Visible spectrophotometer was used to test the suspension's absorbance at 625 nm. The light path was 1 cm. The measurement was repeated until an absorbance range of 0.08-0.1 was reached. This measurement is indicative of a bacterial concentration of 1×10^1 CFU/mL. Following that, enough broth was added to these suspensions in a 1:10 ratio until a concentration of approximately 1×10^1 CFU/mL was reached. This concentration was used to evaluate the extract's antibacterial activity by comparing it to positive and negative controls.

Antibacterial activity of Methanolic extraction of PomegranatePeel extract
In accordance with the methodology described earlier by Degu et al. [21], the antibacterial effectiveness of crude extracts obtained from particular medicinal plants was evaluated by means of the agar well diffusion. The selected organisms for testing were inoculated into Mueller Hinton agar plates after being prepared in a sterile saline solution. The 8 mm diameter circular holes were bored using a cork borer. Next, 100 μl of methanol extracts from PGPP Peel were added to each well, with concentrations of 50 mg/mL, 100 mg/mL, and 150 mg/mL respectively. The same was true for Gram-positive and Gram-negative bacterial strains; standard benchmarks such as Tetracycline (5 μg), Streptomycin (5 μg), Erythromycin (5 μg), and gentamycin (5 μg) were used. The Petri plates were then incubated at 37 ∘C for 24 hours[16]. Afterwards, a measuring equipment was used to assess the inhibitory zones. An equal number of trials were carried out.

RESULTS AND DISCUSSION

Phytochemical screening of PGP Extract
Important therapeutic properties are provided by secondary metabolites for the benefit of human health. Some of these chemicals, in particular, show promise as cancer preventives and suppressors. For the treatment or prevention of a wide range of diseases, people turn to dietary supplements and pharmaceuticals containing compounds from the carbohydrate, alkaloids, quinones, and steroid families. After being washed with running tap water, the chosen fruits of the peel were carefully rinsed in distilled water. They were then let too dry at room temperature for approximately one month in the open air. The dried fruit was ground into a powder and placed in a sterile container for future use. The four solvents—ethanol, methanol, water, and diethyl ether—were used in 100 mL increments to extract the PGP powder from storage. Using air drying and an evaporator set at 40°C, the solvents were removed to get crude extract after the extraction step. Following the standard protocol, the phytochemical screening of the peel extract was conducted. Phytochemical analysis of plant sources in aqueous, methanolic, and ethanolic extracts showed the presence of a wide range of phytochemicals, including carbs, tannins, saponins, alkaloids, flavonoids, quinones, and glycosides; however, steroids, terpenoids, and phenols were not detected[17-18]. Table 1 lists the phytochemical components of the *Punicagranatum* peel extracts that are suggested.

Antibacterial Activity
Using the conventional zone of inhibition assay, we assessed the antibacterial activity of the PGP methanolic extract that was produced. Utilizing a sterile cotton scrub, a pathogenic organism culture was swabbed from a new culture of 1.5×10^8 CFU/mL of the bacterial species on a Muller Hinton Agar plate. A 1 mg/1 mL stock solution of PGP extract was produced in sterile distilled water. The sterile disk was filled with varying volumes of PGP extract, ranging from 50 to 100 μL. The discs containing the drugs were then placed on top of the swab culture plate. The mille meter was used to measure the zones of inhibition after incubating the plate for 24 hours at 37ºC[19]. Because of this, it hinders the system's normal functioning, which in turn causes the bacteria to die because it disrupts their respiration mechanism. In order to analyze the surface morphological alterations of the test pathogens, all of the

photos were captured (Figure 1). Traditional medicinal plants in Tirupattur District had high informant consensus factor values; antibacterial tests were done to confirm their therapeutic effects. The results showed that almost all of the therapeutic plant extracts tested had antibacterial effects against at least one of the Gram-positive and Gram-negative bacteria. From Table 2 showed that the concentrations of 100 and 150 mg/ml, the crude PGP extract exhibited a much larger mean zone of inhibition against *Pseudomonas aeruginosa* than the positive control, *streptomycin.* Likewise, against *Bacillus subtilis*, the Peel extract of Escherichia coli showed the largest mean zone of inhibition at a dosage of 150 mg/ml. No previous research has ever looked at the effects of PGP extract like this one. This precludes any meaningful comparisons between the results of this study and those of related studies carried out in the same or similar locations around the world.

CONCLUSION

Based on the results of this investigation, pomegranate peel extract outperformed the other plant sources in terms of yield.The recommended Peel extracts showed promise in antibacterial activity testing and preliminary phytochemical analyses of different extractions. Selected extracts from the peel of the Pomegranate tree were discovered to be extremely sensitive to four different bacterial strains, one each of Gram positive and Gram negative. According to the study's findings, *Punicagranatum* peel extracts had greater mean zones of inhibition against a number of harmful bacteria, including *Staphylococcus aureus, Escherichia coli, Bacillus subtilis,* and *pseudomonas aeruginosa. Staphylococcus aureus, bacillus subtilis*, in comparison to the conventionally prescribed medications. Therefore, in order to create antimicrobial agents that are more effective against harmful microbes, it is necessary to undertake extensive research. Alkaloids, polyphenols, saponins, terpenoids, steroids, flavonoids, and tannins were also identified through phytochemical study. The abundance of these secondary chemicals may explain why extracts from peel are so efficient against bacteria, whether they are gram-positive or gram-negative. Consequently, in order to create new antibiotics, it is crucial to undertake more in-depth research to extract the bioactive secondary components from PGPpeel and identify them. But scientists should look into the phytochemical and antibacterial properties of these plants in vitro before they isolate and characterize the bioactive components.

ABSTRACT

Diabetic Retinopathy (DR) is an ocular disorder that primarily impacts patients with diabetes and is a significant contributor to adult blindness. Diabetic Retinopathy (DR) is a condition that occurs due to Diabetes Mellitus, leading to the formation of many abrasions on the retina of the human eye.These lesions obstruct vision and in severe situations, they might result in permanent vision loss.Diabetic retinopathy (DR) affects 80% of long-standing diabetes patients. Manual diagnosis is cumbersome, unreliable, and resource-intensive. Deep learning, specifically Convolutional Neural Networks (CNNs), minimizes human intervention. Researchers used PyTorch to identify DR, aiming to enhance patient care.Our objective is to utilize Deep Learning Algorithms to create a model capable of analyzing retinal imagery and accurately categorizing them according to the level of Diabetic Retinopathy. The objective of this project is to develop a computerized and effective method to aid healthcare practitioners in the diagnosis and classification of diabetic retinopathy. The ultimate goal is to enhance patient care and minimise the likelihood of vision impairment. The research involved training and testing the enhanced CNN model using two datasets, namely IDRiD and Kaggle. The suggested model attained a training accuracy of 93% for IDRiD datasets and 95% for Kaggle datasets. The proposed model using the Kaggle dataset has demonstrated superior accuracy compared to their state-of-the-art approach in diagnosing diabetic retinopathy using retinal fundus images.

INTRODUCTION

Individuals with diabetes are more susceptible to severe ocular complications. It can result in profound visual impairment and potentially lead to complete loss of eyesight. However, diabetic eye disease can frequently be addressed prior to the onset of vision impairment. Diabetic retinopathy is the leading cause of vision impairment in adults in the United States. The illness is caused by changes in the blood vessels of the retina, which is the light-sensitive layer of the eye. During the initial phase of diabetic retinopathy, the blood vessels develop minute enlargements known as microaneurysms. Microaneurysms have the ability to release fluid and blood. In the event of this occurrence, the cells in your retina are deprived of the necessary oxygen and nutrients for their survival. This leads to the formation of neovascularization on the retinal surface, which is characterised by the growth of fragile blood vessels that frequently experience leakage. This stage of retinopathy, known as proliferative retinopathy, is responsible for the impairment of vision and eventual blindness. Individuals with diabetic retinopathy may be unaware of their condition. This implies that your retina can sustain significant damage prior to any noticeable alteration in your vision. Occasionally, you may experience visual blurring or see the presence of strings, cobwebs, or particles floating in your field of vision. While it may not be possible to completely avoid diabetic retinopathy, you can reduce the likelihood of developing it by undergoing an annual eye examination. Glaucoma and cataracts are two more ocular complications associated with diabetes. Glaucoma is a medical disorder characterised by the impairment of the optic nerve due to increased pressure within the eyeball. As a result, there is a loss of vision. Individuals with diabetes have a higher likelihood of experiencing glaucoma compared to those without the condition. Typically, glaucoma-induced damage to the optic nerve does not result in noticeable symptoms. A cataract is the condition in which the transparent lens of the eye turns opaque. Clouding obstructs the transmission of light rays through your lens, impeding their ability to focus on your retina. The light-sensitive tissue lining located at the posterior part of your eye is referred to as the retina. The clouding of the lens occurs due to the aggregation of certain proteins, resulting in impaired vision. Individuals with diabetes have a higher likelihood of developing cataracts compared to those without the disease. One is more prone to developing them during early stages of life. The symptoms of cataracts can vary from person to person. Possible symptoms encompass hazy or indistinct vision, the presence of glare or halos around lights, or lights appearing excessively bright, impaired vision in low light conditions, the occurrence of multiple or double vision, diminished colour perception, frequent alterations in eyeglass or contact lens prescriptions, and visual distortion in either eye. A CNN technique has been devised to expedite the procedure and provide accurate forecasts. CNN has been successfully utilised for accurate predictions in many domains such as healthcare [1,2] and intelligent automation [3].This work utilises CNN to diagnose diabetic retinopathy and effectively identify eye images based on their severity, by comprehending its robustness. This technology will automatically diagnose diabetic retinopathy without any input or action required from the user. The suggested models are evaluated using the Kaggle and IDRID datasets [4], which contain a vast collection of high-resolution retinal images taken under different imaging settings. A healthcare practitioner has evaluated the existence of Diabetic Retinopathy in each image and given a score on a scale from 0 to 1, which corresponds to the following classifications:

0-> Diabetic Retinopathy
1->No Diabetic Retinopathy

This research presents a technique for identifying diabetic retinopathy by employing transfer learning. The authors optimise a pre-trained Inception-ResNet-v2 model by incorporating supplementary proprietary CNN layers. The model is assessed using the Messidor-1 diabetic retinopathy dataset and the APTOS 2019 blindness detection dataset from Kaggle. The test accuracy obtained for Messidor-1 is 72.33%, whereas for APTOS it is 82.18% [1].This research provides a comprehensive analysis of transfer learning techniques used for detecting diabetic retinopathy. The authors conduct a comprehensive analysis of the current literature and provide a concise summary of the many transfer learning approaches employed in this particular situation. Instead of concentrating on a particular dataset, they offer valuable information about the broader scope of transfer learning research for diabetic retinopathy [2].This research presents a methodology that utilises transfer learning to diagnose and identify diabetic retinopathy. The

authors employ a Convolutional Neural Network (CNN) architecture based on InceptionV3, utilising transfer learning. However, the dataset lacks specific specifics. The evaluation encompasses many parameters including accuracy, AUC, F1 score, and other metrics [3].Using deep learning and transfer learning to diagnose diabetic retinopathy. Five phases of DR (0-4) are completed. The hybrid convolutional Neural Network (CNN) incorporating DenseNet architecture has been identified as the optimal model for automated detection of diabetic retinopathy (DR) [4].This paper examines new research on the identification of diabetic retinopathy utilising effective deep learning methods, particularly convolutional neural networks (CNN) and AlexNet. These models are exceptionally efficient at identifying the characteristics of diabetic retinopathy in retinal pictures. The study highlights the significance of precise classification of diagnosed photos by utilising related images as input in convolutional semantic networks. The Django web framework demonstrates the results of the suggested methodology [5].Diabetic retinopathy (DR) is a significant global contributor to human vision impairment. Early intervention is crucial in order to mitigate the deleterious effects of this condition. While there are affordable options for ophthalmologists to treat individuals with diabetes, diagnosing diabetic retinopathy remains a significant barrier for medical professionals. This study examines new studies on the detection of diabetic retinopathy utilising extremely efficient deep learning algorithms, including convolutional neural networks (CNN) and ALEXNET.

These methods are widely employed to identify features of diabetic retinopathy from images. The CNN and ALEXNET methods for detecting diabetic retinopathy offer the advantage of time and cost efficiency. Furthermore, it is also more efficient. Therefore, it is more advantageous for the detection of diabetic retinopathy [6].This study centres on the identification and categorization of fundus images associated with diabetic retinopathy through the utilisation of advanced deep learning methodologies. The suggested methodology utilises a Convolutional Neural Network (CNN) algorithm to identify and categorise fundus images according to the stage of the disease. The method attains a precision of 92.26% and a mean squared error (MSE) of 0.06281 [7].This study utilises deep learning techniques to automatically detect diabetic retinopathy (DR). The suggested method attains a peak accuracy of 80% in contrast to conventional machine learning techniques, which only obtain a maximum accuracy of 48% on the identical IRDiR Disease Grading Dataset [8].The proposed approach accurately detects hard exudates. The method employs a fusion of background removal and de-correlation stretch techniques. When evaluated using the DiaretDB database, it demonstrates superior performance compared to current cutting-edge methods [9].This study utilises a combination of Convolutional Neural Network (CNN) for identifying lesions and Long Short-Term Memory (LSTM) for creating descriptive words from retinal fundus images. The suggested model successfully correlates images with phrases and attains a precision level of approximately 90% when evaluated on the MESSIDOR dataset. The user's text is "[10]."Diabetic retinopathy (DR) is a significant consequence of diabetes and a primary factor in adult blindness. This work presents a novel method for detecting blood vessels in retinal pictures. The strategy is based on regional recursive hierarchical decomposition using quadtrees, followed by post-filtration of edges. This approach offers insights into the structure of retinal blood vessels, facilitating the early identification of diabetic retinopathy [11].

The main aim of the paper is to classify diabetic retinopathy and normal retinal images using Convolutional Neural Networks (CNN) and Support Vector Machines (SVM). However, the abstract [12] lacks specific performance metrics. This survey examines techniques for segmenting magnetic resonance imaging (MRI) and computed tomography (CT) pictures of brain tumours. The article addresses the difficulties in segmenting brain pictures caused by the similarities in characteristics between hard and soft muscle tissue [13]. The study examines the utilisation of deep convolutional neural network methodology to automatically categorise diabetic retinopathy using colour fundus images. The suggested model has a 94.5% accuracy on their dataset, outperforming conventional approaches[14]. The abstract lacks precise performance measures. The research concentrates on employing data augmentation methods to improve the diagnosis of proliferative diabetic retinopathy in eye fundus images[15].This research presents an automated method for identifying and categorising diabetic retinopathy (DR) using retinal fundus pictures. The technique employs a Convolutional Neural Network (CNN) methodology, attaining a precision of 92.26% on three distinct datasets: Kaggle, a self-generated custom dataset, and an improved custom dataset[16].Prior to this, other models were suggested for the detection of Diabetic Retinopathy by utilising deep learning models in conjunction with image analysis. This study employed the CNN-based Efficient CNN pre-trained

Mahalakshmi Sampath *et al.,*

deep learning model to accelerate the identification of intensity levels in Diabetic Retinopathy. The model acquired features from the retinal images[17].This study investigates the application of transfer learning in the analysis of medical images. Transfer learning differs from traditional deep learning methods such as convolutional neural networks in terms of its simplicity, efficiency, and minimal training expenses. It efficiently tackles the problem of little datasets. Medical image processing is indispensable for both scientific investigation and clinical diagnosis. However, the act of categorising medical pictures with labels is restricted and insufficient. Transfer learning is a method that leverages pre-trained models built on large datasets unrelated to medicine to improve the accuracy of medical picture analysis. This article presents a comprehensive analysis of the structure of Convolutional Neural Networks (CNNs), the fundamental knowledge of transfer learning, various methods of transfer learning, the application of transfer learning in various areas of medical image analysis, and the potential future developments of transfer learning in this field[18].This research examines the use of transfer learning in the processing of medical images. The text emphasises the benefits of transfer learning, particularly for limited medical imaging datasets. The paper discusses the architecture of Convolutional Neural Networks (CNNs), provides background information on transfer learning, explores alternative transfer learning algorithms, and examines their applications in diverse sub-fields of medical picture processing. This article offers valuable information for novices and decision-makers regarding the future potential of transfer learning in this domain [19].This study provides an overview of different evaluation criteria employed in the classification of medical images. This text offers a comprehensive summary of research studies focused on the application of convolutional neural networks (CNNs) in the field of medical image processing. The report provides a concise overview of current patterns and potential future advancements in deep learning techniques used to the analysis of medical images[20].This review paper examines the most advanced deep learning methods currently used in the field of medical image processing. The main focus is on CNN-based approaches and how they are applied in medical imaging. The report offers valuable insights into the latest advancements and emerging trends in this particular subject [21].

MATERIALS AND METHODS

Proposed System
This project uses PyTorch, a well-liked deep learning framework, to use Convolutional Neural Networks (CNNs) for diabetic retinopathy identification. Our goal is to create a model that can categorize retinal images accurately according to the severity of diabetic retinopathy by utilizing the capabilities of deep learning algorithms. In order to improve patient care and lower the risk of vision loss, this project aims to develop an automated and effective method to help medical professionals diagnose and grade diabetic retinopathy.Our suggested model is made up of a Deep Learning Convolutional Neural Network (CNN) that was trained on a set of 4,231 images of the fundus. A different test dataset with 487 fundus images was used to test the model. There are images of two types of diabetic retinopathy (DR) in both the training and test collections. To see how well they work, the dataset of interest is used to train and test each DL model individually. There are different training and evaluation values for the suggested model, and it shows how these models behave in a logical order. A goal size of (255 × 255), the built-in preprocessing of the CNNs, a batch size of 32, and fully connected classification layers with the softmax activation function are used to train the DL models. As part of their 60-epoch training process, the deep learning models also use the cutting-edge Adam optimizer, which has a learning rate of 0.0001, and the category cross entropy loss function.

Experimental Environment
The proposed framework employs a 64-bit operating system, an x64-based processor, Windows 10 Pro, the DL package torchvision from Pytorch, Python 3.10, Pytorch version 2.1.1, 64GB RAM, and an Intel(R) Xeon(R) W-2155 CPU @ 3.30GHz 3.31 GHz.

Image Dataset Acquisition
The performance of the DL architectures in this model is evaluated using a sizable dataset of fundus images. It is a highly disproportionate model that makes use of the IDRiD and Kaggle datasets [14]. The Kaggle dataset contains

541 images out of 2155 images, which are used by the model to be validated using 2076 images obtained during training. The dataset has a long tail distribution is described in Figure 4. and Fundus image label with DR and No_DR in Figure 5.

RESULTS AND DISCUSSION

The image preprocessing module is a component of the convolutional neural network (CNN) that follows the image dataset acquisition process and is responsible for making the image data more suitable for analysis. The fundus images are original high-resolution images that need to be downsampled to meet the compatibility requirements of various CNN architectures. The image is downsampled to a size of 255 × 255 pixels. This enhances the model's ability to accurately understand the image. Moreover, there is uncertainty in identifying high-intensity structures such as EXs and Optic Disc (OD), as EXs suggest a lesion while OD represents the normal anatomical structure of the retina.An atypical optical density (OD) might result in inconspicuous lesions that go unnoticed because of their high brightness. Hence, the utilisation of image preprocessing techniques is crucial in order to accurately identify and distinguish between artefacts and lesions, thereby enhancing the detection of the disease. Furthermore, it is crucial to identify lesions that result in intermediate phases of diabetic retinopathy (DR) in order to detect DR at an early stage. The suggested approach utilises the CNN's inherent pre-processing capabilities to extract specific details from images through convolution and pooling. This involves applying various filters and kernels, as well as employing picture striding and padding. Nevertheless, these deep learning convolutional neural network (CNN) models possess an opaque character, and the process of improving images occurs in real-time. Consequently, it is not feasible to observe the enhanced image output. However, it is possible to extract only the gradient details and edges during the process of feature extraction for classification.

Features Extraction and classifications

Convolutional neural networks (CNNs) are neural networks that make use of non-linear activation functions. The next phase in the proposed system involves the extraction of features and classification using CNN-DL. The DL models include many layers of convolution and pooling, as well as normalisation and activation techniques, to carry out feature extraction. These models have the ability to learn and generate new features based on existing features through representation learning. These features can include lines, borders, points, edges, corners, vascular structure, and so on. This process helps to simplify detection.By utilising high-performance computation and Graphical Processing Units (GPUs), it becomes possible to smoothly transition from encoding with modest feature dimensions to deeper Convolutional Neural Networks (CNNs). These networks have seen significant changes, investigated various patterns of connectedness, and extracted features at multiple levels using skip-connections, inception modules, and dense blocks. In addition, the utilisation of cross-layer connections and architectural advances involves the incorporation of small multi-layer perceptrons into the convolutional layer kernels to extract intricate information. In addition, auxiliary classifiers are used to supervise the inner layers. This helps to strengthen the gradients that are expected from previous layers in highly supervised networks. It also allows for the integration of transitional layers from different base networks or the expansion of networks with paths that minimise reconstruction losses.

Convolutional Neural Network Model

Each input image has dimensions of (3, 255, 255). Torch typically operates on photos in fixed-size batches. Therefore, an additional dimension is incorporated for this specific objective. As the batch size is considered a variable, its value varies based on the size of the dataset. -1 stands for the size. Consequently, the shape of the input is transformed to (-1, 8, 253, 253). Applying convolution to an image of size 253x253 with a filter of size 2x2, using strides and a dilation rate of 1, and 'same' padding, yields an output of size 253x253. Due to the presence of 16 filters, the resulting shape becomes (16, 124, 124). The MaxPooling layer, with a stride of 2, receives the output of the convolution layer as its input. The pooling layer reduces the dimensions of the image by a factor of 2, resulting in an output shape of (32, 60, 60). This pattern can be applied to all Conv2D and MaxPooling layers. The flattening layer transforms the pixels into

Mahalakshmi Sampath *et al.,*

a single-dimensional vector. Thus, when the input dimensions are (64, 28, 28), the input is flattened to (128, 12, 12), resulting in a total of 18496 parameters. The equation (1) provides the formula for calculating the number of parameters in a Conv2D layer.

Parameter = (Kernel height * kernal width * input channel * output channel) + (output channels that use bias) (1)

The CNN model is trained for 70 epochs using the Kaggle dataset and 60 epochs using the IDRiD dataset, with observations in each. The accuracy and loss are computed for each epoch. Once the training procedure is complete, the model is evaluated using the test images. A confusion matrix is generated, which includes the counts of true positives, true negatives, false positives, and false negatives. The confusion matrix obtained is displayed in Figure . The CNN model demonstrates higher accuracy on the Kaggle dataset in comparison to the IDRiD dataset.

Comparison of Performance

Diabetic Retinopathy can be predicted utilising advanced techniques such as deep learning, machine learning, and image processing algorithms. A variety of functional classifiers were utilised. Image processing and augmentation techniques were employed to enhance the brightness and contrast of the photographs. The performance is compared and analysed by tabulating the accuracy achieved through the implementation of different approaches. Applying transfer learning approaches to deep learning classifiers improves the accuracy of predicting diabetic retinopathy, even with a small dataset. The table displays the accuracy achieved in comparison to existing research efforts.

CONCLUSION

The objective of this study is to analyse several machine learning algorithms and deep learning techniques in order to accurately diagnose and classify diabetic retinopathy, including its stage. The use of advanced image processing techniques has effectively enhanced the visibility of exudates, blood vessels, and cotton wool patches. After analysing and comparing different methodologies, it can be inferred that deep learning algorithms, along with transfer learning, have significant potential for predicting diabetic retinopathy. Conventional machine learning classifiers such as Support Vector Machine (SVM), Decision Tree (DT), Naïve Bayes (NB), and Random Forest (RF) have not been successful in reliably classifying images. While CNN outperformed classical algorithms, the requisite accuracy without overfitting was only attained by employing transfer learning methods such as ResNet and DenseNet. So, using a custom CNN model along with pre-trained models and the right image processing methods, such as image enhancement, made it possible to accurately predict the presence of diabetic retinopathy. The hybrid Convolutional Neural Network (CNN) incorporating DenseNet achieved a superior accuracy of 95%, surpassing the performance of existing models. By utilising the established model, physicians can propose proactive interventions at an earlier stage, effectively preventing vision loss in patients.

Future Enhancement

In the future, there will be technological improvements in the realm of medicine. Currently, individuals are unable to access timely medical intervention and care. Automating disease prediction will reduce the time required, enabling individuals to proactively take preventive steps. In the future, the algorithms' parameters can be meticulously adjusted to get superior outcomes, and the model's accuracy can be enhanced through the utilisation of additional effective optimisation strategies. Furthermore, there are plans to utilise similar techniques for forecasting additional ailments such as brain tumour or breast cancer identification, which likewise necessitates professionals to analyse the scanned brain or breast report. It is possible to incorporate these advanced deep learning algorithms into electronic health record systems used in clinics. This would alleviate the workload of the doctors. The project can be improved by implementing a user interface, which will allow real-time access for users.

ABSTRACT

In *BM*-algebra, we have utilized the notion of Lukasz logic theory in Intuitionistic *fuzzy* set theory to make a way for the creation of Lukasz Intuitionistic *fuzzy* subalgebra. In which the properties and characterizations of Lukasz *fuzzy* subalgebra are discussed and the relation among them are illustrated with some examples.

Keywords: BM-algebra, Intuitionistic $\mathcal{F}uzzy$ set, Lukasiewicz Intuitionistic $\mathcal{F}uzzy$ set, Lukasiewicz Intuitionistic $\mathcal{F}uzzy$ subalgebra.

INTRODUCTION

BCI and BCK algebra were introduced by Y. Imai, K. Iseki and S. Tanaka in 1966. The term BCK was taken from C.A. Meredith's BCK system. These are algebraic structures of universal algebra which describe fragments of propositional calculus. Apart from the two algebraic structures BCI and BCK algebras, there were various algebraic structures which were attempted for the generalizations. In 1983, Atanassov gave an extension of Zadeh's notion of *fuzzy* set, which is commonly called as Intuitionistic Fuzzy sets. The elements in the set have the degree of both membership and non-membership value. Jan Lukasiewicz was a logician and Philosopher. He gave rise to the improvement ofproportional logic. Lukasiewicz or Lukasz logic is an unconventional and exceedingly valued logic, which is of Lukasz t-norm.[9]The concept of Lukasz *fuzzy* subalgebra in *BCK/BCI*-algebras was built by Jun using the

Gokila and Mary jansirani

thoughts of Lukasz t-norm. Later, he extended it to Lukasz *fuzzy* ideal in BCK/BCI-algebras in 2023[8].Their capacity to handle partial truth values, include *fuzzy*principles and integrate them into the decision-making process leads to a variety of applications. To build an advanced algorithm for the solution of real-life problems, we can explore various algebraic structures. In this study of BM-algebra, we apply the concept of Lukasiewicz logic in Intuitionistic *fuzzy* set which give rise to the introduction of Lukasiewicz Intuitionistic *fuzzy* sub algebra in BM-algebra and investigated some of their properties and relations with some examples.

PRELIMINARIES

Definition 2.1
The set $\mathfrak{G}$ be a non-empty set.The**BM-algebra**satisfies the given axioms under binary operation $" * "$ with a constant element "0".
$(BM_1)p * 0 = p$
$(BM_2)(r * p) * (r * q) = q * r, \forall p, q, r \in \mathfrak{G}$

Proposition 2.2
Every BM-algebra satisfies
1. $p * p = 0$
2. $0 * (0 * p) = p$
3. $0 * (p * q) = q * p$
4. $(p * r) * (q * r) = p * q$
5. $p * q = 0 \Leftrightarrow q * p = 0$ for all $p, q, r \in \mathfrak{G}$.

Definition 2.3
A $\mathcal{F}$uzzy set $U$is called $\mathcal{F}$**uzzy sub algebra** of a BM-algebra $\mathfrak{G}$if it satisfies:
$(FA_1)U(p * q) \geq min\{U(p), U(q)\}, \forall p, q \in \mathfrak{G}$

Definition 2.4
An **Intuitionistic** $\mathcal{F}$**uzzy**set$H$ in BM-$algebra$$\mathfrak{G}$ is of the form,
$$H = \{(p, \alpha_H(p), \beta_H(p))| p \in \mathfrak{G}\}$$
where the functions $\alpha_H: \mathfrak{G} \to [0,1]$ and $\beta_H: \mathfrak{G} \to [0,1]$ denote the degree of membership and the degree of non-membership respectively, and $0 \leq \alpha_H(p) + \beta_H(p) \leq 1$, $\forall p \in \mathfrak{G}$. The set can also be denoted as $H = (\alpha_H, \beta_H)$.

Definition 2.5
An Intuitionistic $\mathcal{F}$uzzy set $H = (\alpha_H, \beta_H)$in a set $\mathfrak{G}$ of the form
$$\alpha_H(q) = \begin{cases} u \in (0,1] & if \ q = p \\ 0 & if \ q \neq p \end{cases} \text{ and } \beta_H(q) = \begin{cases} v \in [0,1) & if \ q = p \\ 1 & if \ q \neq p \end{cases}$$
is said to be **Intuitionistic** $\mathcal{F}$**uzzy point** with support p and membership value u and non-membership value v. It is denoted by $[p/u]$and $[p/v]$ respectively.

Definition 2.6
For an Intuitionistic $\mathcal{F}$uzzy set $H = (\alpha_H, \beta_H)$ in a set $\mathfrak{G}$, we say that an Intuitionistic $\mathcal{F}$uzzy membership point $[p/u]$ and non-membership point $[p/v]$ is
(i) **contained** in H, denoted by $[p/u] \in \alpha_H$ and $[p/v] \in \beta_H$, if $\alpha_H(p) \geq u$ and $\beta_H(p) \leq v$.
(ii) **quasi-coincident** with H, denoted by $[p/u]q\alpha_H$ if $\alpha_H(p) + u > 1$ and $[p/v]q\beta_H$ if $\beta_H(p) + v < 1$.

Definition 2.7
An Intuitionistic $\mathcal{F}$uzzy set $H = (\alpha_H, \beta_H)$ in BM-$algebra$$\mathfrak{G}$ is called an **Intuitionistic** $\mathcal{F}$**zzy subalgebra** of $\mathfrak{G}$ if it satisfies:

$(IFA_1)\alpha_H(p*q) \geq min\{\alpha_H(p), \alpha_H(q)\}$

$(IFA_2)\beta_H(p*q) \leq max\{\beta_H(p), \beta_H(q)\}, \forall\, p, q \in G$

Lukasiewicz Intuitionistic $\mathcal{F}uzzyBM\text{-}algebra$

Definition 3.1

An $\varepsilon - \boldsymbol{Lukasz\ Intuitionistic\ \mathcal{F}uzzy}$ **Set** of an Intuitionistic $\mathcal{F}$uzzy set $H = (\alpha_H, \beta_H)$ in $\mathfrak{G}$ is of the form,
$L_H^\varepsilon = \{(p, \alpha_{L_H^\varepsilon}, \beta_{L_H^\varepsilon})|\, p \in \mathfrak{G}\}$,
where $\alpha_{L_H^\varepsilon}: \mathfrak{G} \to [0,1]$, $p \mapsto max\{0, \alpha_H(p) + \varepsilon - 1\}$ denote the degree of membership　　and $\beta_{L_H^\varepsilon}: \mathfrak{G} \to [0,1]$,
$p \mapsto min\{\beta_H(p) + \varepsilon, 1\}$ denote the degree of non-membership respectively.

Definition 3.2

An ε-Lukasz Intuitionistic $\mathcal{F}uzzy$ set L_H^ε in $\mathfrak{G}$ is called an $\boldsymbol{\varepsilon\text{-}}$ **LukaszIntuitionistic $\mathcal{F}uzzy$ subalgebra** of $BM\text{-}algebra\mathfrak{G}$
if it satisfies
$(LFS_1)[p/u_a], [q/u_b] \in \alpha_{L_H^\varepsilon} \Rightarrow [(p*q)/min\{u_a, u_b\}] \in \alpha_{L_H^\varepsilon}$　　　　　　　　(3.1)
$(LFS_2)[p/v_a], [q/v_b] \in \beta_{L_H^\varepsilon} \Rightarrow [(p*q)/max\{v_a, v_b\}] \in \beta_{L_H^\varepsilon}$　　　　　　　　(3.2)
for all $p, q \in \mathfrak{G}, u_a, u_b \in (0,1]$ and $v_a, v_b \in [0,1)$

Example 3.3

Let $\mathfrak{G} = \{0, h_1, h_2, h_3\}$ be a set with binary "$*$" given by Table 1,

$*$	0	h_1	h_2	h_3
0	0	h_1	h_2	h_3
h_1	h_1	0	0	h_2
h_2	h_2	0	0	h_1
h_3	h_3	h_2	h_1	0

TABLE 1 Cayley table for the binary operation "$*$"
Then $\mathfrak{G}$ is a $BM\text{-}algebra$.
Defining an Intuitionistic $\mathcal{F}uzzy$ set $H = (\alpha_H, \beta_H)$ in $\mathfrak{G}$ as follows:
$\alpha_H: \mathfrak{G} \to [0,1], p \mapsto \begin{cases} 0.86\ if\ p = \{0, h_1\} \\ 0.65\ if\ p = h_2 \\ 0.31\ if\ p = h_3 \end{cases}$ and $\beta_H: \mathfrak{G} \to [0,1], p \mapsto \begin{cases} 0.09\ if\ p = \{0, h_1\} \\ 0.25\ if\ p = h_2 \\ 0.65\ if\ p = h_3 \end{cases}$.

If it is taken that $\varepsilon = 0.62$, then the Lukasz Intuitionistic $\mathcal{F}uzzy$ set L_H^ε of H in $\mathfrak{G}$ is provided as follows:
$\alpha_{L_H^\varepsilon}: \mathfrak{G} \to [0,1], p \mapsto \begin{cases} 0.48\ if\ p = \{0, h_1\} \\ 0.27\ if\ p = h_2 \\ 0.00\ if\ p = h_3 \end{cases}$ and $\beta_{L_H^\varepsilon}: \mathfrak{G} \to [0,1], p \mapsto \begin{cases} 0.71\ if\ p = \{0, h_1\} \\ 0.87\ if\ p = h_2 \\ 1.00\ if\ p = h_3 \end{cases}$
Typically, it is verified that L_H^ε is a Lukasz Intuitionistic $\mathcal{F}zzy$ subalgebra of $BM\text{-}algebra\mathfrak{G}$.

Theorem 3.4

Every Lukasz Intuitionistic $\mathcal{F}uzzy$ set L_H^ε is a Lukasz Intuitionistic $\mathcal{F}zzy$ subalgebra of$BM\text{-}algebra$ of $\mathfrak{G}$ iff it satisfies:

(i) $\forall\, p, q \in \mathfrak{G}, \alpha_{L_H^\varepsilon}(p*q) \geq min\{\alpha_{L_H^\varepsilon}(p), \alpha_{L_H^\varepsilon}(q)\}$　　　　　　　　(3.3)
(ii) $\forall\, p, q \in \mathfrak{G}, \beta_{L_H^\varepsilon}(p*q) \leq max\{\beta_{L_H^\varepsilon}(p), \beta_{L_H^\varepsilon}(q)\}$　　　　　　　　(3.4)

Proof
Let H be an Intuitionistic $\mathcal{F}uzzy$ set in$BM\text{-}algebra\mathfrak{G}$.

Gokila and Mary jansirani

Assume that L_H^ε is a Lukasiewicz Intuitionistic $\mathcal{F}zzy$ subalgebra of $BM\text{-}algebra\mathfrak{G}$.

Let $p, q \in \mathfrak{G}$ and it is clear that $[p/\alpha_{L_H^\varepsilon}(p)] \in \alpha_{L_H^\varepsilon}$ and $[q/\alpha_{L_H^\varepsilon}(q)] \in \alpha_{L_H^\varepsilon}$ It follows from (3.1) that $[(p * q)/min\{\alpha_{L_H^\varepsilon}(p), \alpha_{L_H^\varepsilon}(q)\}] \in \alpha_{L_H^\varepsilon}$, and hence $\alpha_{L_H^\varepsilon}(p * q) \geq min\{\alpha_{L_H^\varepsilon}(p), \alpha_{L_H^\varepsilon}(q)\}$ for all $p, q \in \mathfrak{G}$. Similarly note that $[p/\beta_{L_H^\varepsilon}(p)] \in \beta_{L_H^\varepsilon}$ and $[q/\beta_{L_H^\varepsilon}(q)] \in \beta_{L_H^\varepsilon}$ for all $p, q \in \mathfrak{G}$. It follows from (3.2) that $[(p * q)/max\{\beta_{L_H^\varepsilon}(p), \beta_{L_H^\varepsilon}(q)\}] \in \beta_{L_H^\varepsilon}$, and hence $\beta_{L_H^\varepsilon}(p * q) \leq max\{\beta_{L_H^\varepsilon}(p), \beta_{L_H^\varepsilon}(q)\}$ for all $p, q \in \mathfrak{G}$. Conversely, suppose that L_H^ε satisfies (3.3) and (3.4). Also let $p, q \in \mathfrak{G}$ and $u_a, u_b \in (0,1]$ be such that $[p/u_a] \in \alpha_{L_H^\varepsilon}$, $[q/u_b] \in \alpha_{L_H^\varepsilon}$. Then $\alpha_{L_H^\varepsilon}(p) \geq u_a$ and $\alpha_{L_H^\varepsilon}(q) \geq u_b$, which imply from (3.3) that

$$\alpha_{L_H^\varepsilon}(p * q) \geq min\{\alpha_{L_H^\varepsilon}(p), \alpha_{L_H^\varepsilon}(q)\} \geq min\{u_a, u_b\}.$$

Thus $[(p * q)/min\{u_a, u_b\}] \in \alpha_{L_H^\varepsilon}$. Similarly, $\beta_{L_H^\varepsilon}(p) \leq v_a$ and $\beta_{L_H^\varepsilon}(q) \leq v_b$,

which imply from (3.4) that

$$\beta_{L_H^\varepsilon}(p * q) \leq max\{\beta_{L_H^\varepsilon}(p), \beta_{L_H^\varepsilon}(q)\} \leq max\{v_a, v_b\}.$$

Thus, $[(p * q)/max\{v_a, v_b\}] \in L_H^\varepsilon$.

Therefore L_H^ε is a Lukasiewicz Intuitionistic $\mathcal{F}zzy$ subalgebra of $BM\text{-}algebra\mathfrak{G}$.

Theorem 3.5

Show that ε-Lukasz Intuitionistic $\mathcal{F}uzzy$ set L_U^ε in $\mathfrak{G}$ is an ε-Lukasz Intuitionistic $\mathcal{F}uzzy$ subalgebra of $BM\text{-}algebra\mathfrak{G}$, if H is an Intuitionistic $\mathcal{F}uzzy$ subalgebra of $\mathfrak{G}$.

Proof

Assume that H is an Intuitionistic $\mathcal{F}uzzy$ subalgebra of $\mathfrak{G}$.

Let $p, q \in \mathfrak{G}$ and $u_a, u_b \in (0,1]$ be such that $[p/u_a] \in \alpha_{L_H^\varepsilon}$, $[q/u_b] \in \alpha_{L_H^\varepsilon}$.

Then $\alpha_{L_H^\varepsilon}(p) \geq u_a$ and $\alpha_{L_H^\varepsilon}(q) \geq u_b$.

Similarly, $v_a, v_b \in [0,1)$ be such that $[p/v_a] \in \beta_{L_H^\varepsilon}$, $[q/v_b] \in \beta_{L_H^\varepsilon}$.

Then $\beta_{L_H^\varepsilon}(p) \leq v_a$ and $\beta_{L_H^\varepsilon}(q) \leq v_b$.

Thus

$$\begin{aligned}
\alpha_{L_H^\varepsilon}(p * q) &= max\{0, \alpha_H(p * q) + \varepsilon - 1\}[\because by\ defn\ (3.1)]\\
&\geq max\{0, min\{\alpha_H(p), \alpha_H(q)\} + \varepsilon - 1\}[\because (3.3)]\\
&= max\{0, min\{\alpha_H(p) + \varepsilon - 1, \alpha_H(q) + \varepsilon - 1\}\}\\
&= min\{max\{0, \alpha_H(p) + \varepsilon - 1\}, max\{0, \alpha_H(q) + \varepsilon - 1\}\}\\
&= min\{\alpha_{L_H^\varepsilon}(p), \alpha_{L_H^\varepsilon}(q)\}[\because by\ defn\ (3.1)]\\
&\geq min\{u_a, u_b\}.
\end{aligned}$$

So, $[(p * q)/min\{u_a, u_b\}] \in \alpha_{L_H^\varepsilon}$.

Similarly,

$$\begin{aligned}
\beta_{L_H^\varepsilon}(p * q) &= min\{\beta_H(p * q) + \varepsilon, 1\}[\because by\ defn\ (3.1)]\\
&\leq min\{max\{\beta_H(p), \beta_H(q)\} + \varepsilon, 1\}[\because (3.4)]\\
&= min\{max\{\beta_H(p) + \varepsilon, \beta_H(q) + \varepsilon\}, 1\}\\
&= max\{min\{\beta_H(p) + \varepsilon, 1\}, min\{\beta_H(q) + \varepsilon, 1\}\}\\
&= max\{\beta_{L_H^\varepsilon}(p), \beta_{L_H^\varepsilon}(q)\}[\because by\ defn(3.1)]\\
&\leq max\{v_a, v_b\}.
\end{aligned}$$

So, $[(p * q)/min\{v_a, v_b\}] \in \beta_{L_H^\varepsilon}$.

Hence L_H^ε is a ε-Lukasiewicz Intuitionistic $\mathcal{F}uzzyBM$-algebra of $\mathfrak{G}$. The following example demonstrates why the converse portion of Theorem 3.5 is false.

Example 3.6

Suppose the set $\mathfrak{G} = \{0, h_1, h_2\}$ be a $BM\text{-}algebra$ and Table 3.2 shows binary operation $" * "$ in $\mathfrak{G}$

$*$	0	h_1	h_2
0	0	h_2	h_1
h_1	h_1	0	h_2
h_2	h_2	h_1	0

TABLE 3.2 Cayley table for the binary operation " $*$ "

Defining an Intuitionistic $\mathcal{F}uzzy$ set $H = (\alpha_H, \beta_H)$ in G as follows:

$$\alpha_H: \mathfrak{G} \to [0,1], p \mapsto \begin{cases} 0.76 \ if \ p = 0 \\ 0.32 \ if \ p = h_1 \ and \ \beta_H: \mathfrak{G} \to [0,1], p \mapsto \begin{cases} 0.16 \ if \ p = 0 \\ 0.65 \ if \ p = h_1. \\ 0.59 \ if \ p = h_2 \end{cases} \\ 0.40 \ if \ p = h_2 \end{cases}$$

Provided that $\varepsilon = 0.41$, then the ε-Lukasz Intuitionistic $\mathcal{F}uzzy$ set $L_H^\varepsilon = (\alpha_{L_H^\varepsilon}, \beta_{L_H^\varepsilon})$ of H in $\mathfrak{G}$ is formed as follows:

$$\alpha_{L_H^\varepsilon}: \mathfrak{G} \to [0,1], p \mapsto \begin{cases} 0.17 \ if \ p = 0 \\ 0.00 \ if \ p = h_1 \ and \ \beta_{L_H^\varepsilon}: \mathfrak{G} \to [0,1], p \mapsto \begin{cases} 0.57 \ if \ p = 0 \\ 1.00 \ if \ p = h_1 \\ 1.00 \ if \ p = h_2 \end{cases} \\ 0.00 \ if \ p = h_2 \end{cases}$$

Typically, it is verified that L_H^ε is an ε-Lukasz Intuitionistic $\mathcal{F}uzzy$ subalgebra of BM-$algebra\mathfrak{G}$. But H is not an Intuitionistic $\mathcal{F}zzy$ subalgebra of $\mathfrak{G}$ because of

$\alpha_H(0 * h_2) = \alpha_H(h_1) = 0.32 \not\geq 0.40 = min\{\alpha_H(0), \alpha_H(h_2)\}$ and

$\qquad \beta_H(0 * h_2) = \beta_H(h_1) = 0.65 \not\leq 0.59 = max\{\alpha_H(0), \alpha_H(h_2)\}$.

CONCLUSION

In Society, Decisions are taken based on incomplete and uncertain insights, such as risk management and financial marketing. The application of BM-algebra within Lukasz Intuitionistic $\mathcal{F}uzzy$ logic operation can improve the robustness of decision-making process using the degree of hesitancy and scepticism. This study give rise to the notion of Lukasz Intuitionistic $\mathcal{F}uzzy$sub algebra along with the investigation some of their properties. In addition to the characterization of Lukasz Intuitionistic $\mathcal{F}uzzy$ subalgebra algebra, the relations of Intuitionistic $\mathcal{F}uzzy$ sub algebra and Lukasz Intuitionistic $\mathcal{F}uzzy$ subalgebra are discussed. Some examples are provided based on those relations. In future, we will construct an algorithm for the improvement of robustness by making use of the ideas and results of this study.

ABSTRACT

Animal waste can be managed biologically through the process of vermicomposting. The current study provides examples of how to make vermicompost from biogas plants by mixing the leaves litter and *Eisenia festida*. The biogas plant has two crucial functions. Through outlet sludge, it indirectly supports organic farming while also directly supplying energy. For vermicomposting, two distinct types of vermin beds were constructed in the following ratios: 3:1 for leaf litter plus cow dung and 3:1 for leaf litter plus biogas plant slurry. They were given the labels "control" and "test," in that order. After 15 weeks, the vermicompost material was examined for several chemical parameters, and *Phaseolus vulgaris* was used in the pot experiment to assess the material's potential for growth. In the test tank, a drop in pH, organic carbon, and the C: N ratio, as well as an increase in N availability, exchangeable K, and P, were noted in comparison to the control. Vermi compost's final material's C: N ratio fell between 20 to 30 percent, which is considered agronomically acceptable. The application constructed from biogas plant slurry improved root length, shoot length, and number of leaves, according to the results of the pot experiment. In the two treatments, *E. festida* reproduction biology was also observed, and the results revealed outstanding biomass of microbial flora and earthworms in the test tank compared to the control. The findings unequivocally showed that vermin technology might be a viable means of transforming household biogas plant byproducts into certain value-added goods.
Keywords: Vermicompost, vermibed, *P.vulgaris*, bio digested slurry, *E.festida*

INTRODUCTION

Interest in enhancing overall soil quality through the addition of organic matter has increased as a result of the reduction in soil fertility and productivity brought on by excessive soil erosion, nutrient run-off, and loss of soil organic matter [1]. In natural systems, the addition of organic matter from falling leaf litter and root mortality over time maintains the soil's fertility level and organic structure [2].The conversion of organic wastes, such as sewage sludge, green waste, industrial sludge, urban community wastes, and livestock excreta, to compost or vermicomposting is one of the many techniques that is becoming more and more popular worldwide. This reduces the amount of waste that is added to landfills and the need for artificial fertilizers [3]. It's noteworthy to note that 38 billion metric tons of organic wastes are produced year worldwide by humans, animals, and crops. This trash could be a useful source of organic matter for soils [4]. Vermicompost, a nutrient-rich biofertilizer, may be made from this enormous amount of organic waste that is produced from many sources for use in sustainable and restoration operations [5]. Earthworms and microbes work together to create vermicompost. Earthworms play a crucial role in conditioning the substrate and modifying biological activity, which in turn drives the biochemical breakdown of organic materials by microorganisms [6]. Thus, earthworms were used by farmers in India to create manure in their crops more traditionally and conventionally [7]. In terms of nutrient availability, vermicomposting produces a higher-quality product than regular composting [8]. The Indian government has been encouraging the generation of biogas at the individual and community levels from cow dung and other organic wastes for the past few decades. A high-quality manure that is utilized as a soil conditioner in agricultural areas is the slurry left over from the biogas plant [9]. Because earthworms are biofilters, they can be utilized to increase crop yields and manage cattle dung and biogas plant slurry without causing pollution [10]. Vermicomposting technology can be effective for managing cow manure and biogas plant slurry, according to a literature review [11]. The requirement for food and water is increased due to the world's population growth and increased energy consumption, which promotes the creation of agricultural waste [12]. The community is paying close attention to issues such as excessive chemical fertilizer use, agricultural waste generation, and proper waste disposal techniques [13]. Nonetheless, utilizing agricultural residues combined with vermicompost for biogas technology is a sustainable way to address the needs of energy recovery, reducing pollution and global warming, replacing artificial fertilizers, and providing wholesome food security [14]. Therefore, this study was conducted to determine the effectiveness of vermicompost in promoting plant development utilizing biogas plant slurry and cow manure [15].

MATERIALS AND METHODS

The bioconversion process was carried out with the help of earthworm (*E.festida*) in Biocompoting pits of A.P.C Mahalaxmi College for Women, Thoothukudi, Tamil Nadu, India. The experimental details, materials used, and analytical methods employed for the characterization of the materials are presented below.

Preparation of vermibeds and composting trial
For vermicomposting, two distinct types of vermibed were created in the following ratios: 1:3 (leaf litter + cow dung) and 1:3 (leaf litter + bio-digested slurry). They were labeled as control and test pits. Water was routinely sprayed to regulate the temperature and moisture content. Following three weeks of pre-composting, 250 adult *E. festida* individuals were placed into pits. On the sixty-fifth day, the physio-chemical characteristics of the vermicompost were assessed using conventional techniques.

Germination of *P.vulgaris*
 P. vulgaris was chosen as the field crop to assess plant development using decomposed materials. Two sets of plastic containers were selected, each measuring 45 cm in diameter and 25 cm in depth. There were four containers in each set. The control group's composted materials were used in the first set, and the test compost was added to the pots in the second set. Fifteen seeds were planted in each container.

Earthworm collection

Earthworm *E. festida*, which is used for composting, was acquired from Killikulam Agriculture University in Killikulam, Tamil Nadu, India. On cow manure that had partially decomposed, stock earthworms were raised. The biomass, growth, and reproduction of earthworms are trustworthy markers of the quality of the vermimanure. When comparing the test feedstock group to the control, the largest number of *E.festida* was discovered.

Chemical analysis

A digital pH meter (manufactured by Systronics) was used to determine the pH. The partial-oxidation approach [16] (Hartenstein and Hartenstein 1981) was used to determine the amount of organic carbon. Jackson's (1975) method was used to determine total Hjeldahl nitrogen (TKN). The amount of available phosphorus was measured using the technique outlined by Anderson and Ingram. After the material was extracted using ammonium acetate, exchangeable K was calculated [17].

Statistical Analysis

The average (mean) and standard deviation of all the experimental data were calculated as mean±SD by using Microsoft Excel. Then the N, P&K values were tested by Students't' test analysis of in vermicomposting.

RESULTS AND DISCUSSION

If not handled appropriately, the biogas digesters' slurry turns into a breeding ground for insects that carry disease. Earthworm culture could benefit greatly from the usage of biogas slurry. Figure 1-3 displayed the physico-chemical properties of the "control and test" vermicompost pits. Figures 4 and 5 showed the rate of plant growth and earthworm multiplication, respectively. The vermicompost unit's average temperature was measured and found to be 27°C, falling within 0 and 35° C according to Dominguez and Edwards (2011) classification. According to the humidity result, the unit was moist to wet (85%), falling between 80 and 90 percent for rapid growth. Only after the slurry period were the pH values of the vermicompost taken in all treatments. In the test, the pH dropped in comparison to the control (fig 1). The involvement of microorganisms in the decomposition process during vermicomposting may be the cause of the overall pH reduction. The pH drop was caused by the microbial breakdown that occurs during vermicomposting, which produces CO_2 and organic acids. According to Suther (2009), the final pH range of the vermicomposted material was 7.4±0.01 to 8.0±0.05. In the final compost, the soluble salt concentration (expressed as electric conductivity) was 3.71 mS/cm and 3.00 mS/cm, respectively. Earthworms' intake and subsequent excretion of inorganic chemicals from organic compounds resulted in a high EC in the test.

The total organic carbon has significantly decreased in the treated when compared with the control. A decrease is an indication of enhanced decomposition. The total organic carbon was 18.53% and 21.02%. The significant percentage change indicated that the earthworms accelerated the decomposition of the organic matter. The total nitrogen was 1.46% in the test vermicompost and 1.88% in the control. The C: N ratio in the vermicompost of control is 11:1 and the test is 13:1. The total phosphorus was 0.58% and 0.26%. The total potassium was 0.56% in the test vermicompost and 0.48% in the control. From the results, it was clear that there was a significant increase in NPK values of the test when compared to the control (fig 3). The nitrogen level increased because the earthworms enhanced the nitrogen cycle which attributed to the increased levels of nitrogen in vermicompost [16]. When compared to the control, the test compost showed the highest plant growth on day 20 in terms of shoot length, root length, leaf length, number of leaves, and root length. There are more macro and micronutrients in the test. They were easily assimilated by the plants for growth and development (fig 4). This might be caused by certain of the worms' and their associated bacteria' secretions, which, in addition to other nutrients, function as growth boosters [20]. In the test and control groups, earthworm counts rose to 487 and 396, respectively. The study concludes that cow dung blends and biogas plant sludge promote earthworm proliferation (fig 5). The present investigation indicated that biogas plant slurry and cow dung could be used as raw material in the vermicomposting process. It concluded that biogas plant slurry contributed to increasing NPK, macro, and micronutrients.

Ho: There is significant difference between N,P&K in the control and in the experimental vermicomposting..
Unpaired *t* test results
P value and statistical significance
The two-tailed P value equals 0.5509 By conventional criteria, this difference is considered to be not statistically significant.

Confidence interval
The mean of Group One minus Group Two equals -0.2367
95% confidence interval of this difference: From -1.2470 to 0.7736

Intermediate values used in calculations:
t = 0.6504
df = 4
standard error of difference = 0.364

ABSTRACT

Prime distance is a measure of the connectivity of a graph based on the concept of prime numbers. The Gaussian prime distance (GPD) graph G is defined as any graph with two relatively prime vertices. The Gaussian neighborhood prime distance (GNPD) graph G along with each vertex v, with neighboring vertices being relatively prime numbers. It is formed by dividing G into n separate Gaussian numbers such that adjacent vertex numbers are relatively prime numbers. The order in the XY plane was structured linearly by means of Gaussian integers to create a spiral structure and demonstrate that certain graph family has a finite Gaussian prime distance with the Gaussian integers.

Keywords: Finite Gaussian Prime distance, Neighborhood Gaussian Prime Distance, Spiral order, Gaussian integers.

INTRODUCTION

Labeling in the realm of graph theory has found application across diverse research domains. For instance, within social network analysis, labeling serves to pinpoint influential nodes or communities. Moreover, in the field of bioinformatics, graph labeling has proven instrumental in scrutinizing protein structures and DNA sequences. The advent of complex numbers and their inherent properties has catalyzed numerous breakthroughs in various disciplines. The impression of prime labeling for graphs was initially formulated by Roger Entringer, gaining prominence with its publication in a work by Tout et al. [1] during the early 1980s. Then, it has evolved into a widely explored subject among scholars, with Gallian [2] serving as a comprehensive resource detailing prime graph results.

Kavitha and Jayalalitha

This document introduces the novel concept of neighborhood-prime labeling utilizing Gaussian integers, inspired by the exploration of prime labeling in Gaussian integers. We anticipate that this will emerge as a captivating area of research for academics in the future. Finite Gaussian prime distance graphs and neighborhood prime distance graphs exhibit vertices with significantly prime distances. The vertices in neighborhood graphs are relatively prime, ensuring that each vertex of a graph G can be labeled by n distinct numbers. Various graph families, such as walks, trails, paths, double star trees, caterpillars, spider webs, snake graphs, fans, and others, are recognized for permitting prime distance labeling [3]. In this study, the concept of finite Gaussian prime distance is extended to Gaussian Integers [4], commonly referred to as Gaussian integers. Neighboring vertices of a vertex v in a GNPD graph are relatively prime Gaussian integers. By splitting the GPD graph into discrete Gaussian numbers and making sure that neighboring vertex numbers are substantially prime, the graph is created. To illustrate specific graph families with finite Gaussian prime distance, the ordering of the Gaussian integers in the XY plane is usually arranged linearly, frequently in a spiral pattern. This paper initiates its exploration by delving into the first n Gaussian integers, subsequently turning its focus towards the finite Gaussian prime and neighborhood prime distance graph for Gaussian integers. The ensuing analysis encompasses a presentation of the graphs' outcomes, unveiling their properties and characteristics. These results provide important new information about the distribution and behavior of prime numbers in the Gaussian integer domain. Section 2 delves into the concept of Gaussian integers, elucidating various aspects of their nature. The XY plane spiral order is introduced, preserving numerous known properties observed in the natural number ordering of N. Additional features within this spiral sequence are highlighted in this section. Moving on to Section 3, the paper demonstrates how the spiral ordering lends itself to facilitating prime distance labels [5] with Gaussian integers for certain tree families. Moreover, it explores snake graph families that are amenable to neighborhood prime labeling. An alternative graph is also discussed, showcasing its capacity to accommodate both prime distance and neighborhood prime distance labeling.

GRAPH LABELING WITH GAUSSIAN INTEGERS AS PRIMES

There will be no loops or numerous edges in our graphs. The goal of our study is extended to Gaussian integers in the finite Gaussian prime distance labeling. To establish the concept of the first n Gaussian integers [6], it is necessary to provide a definition for "the first n Gaussian integers." This exploration serves to demonstrate that Gaussian numbers share similar properties with real numbers. Outlined below is our proposed ordering.

Definition 2.1

Using recursive definitions of the Gaussian integers, we can recursively order them in spiral order. As with, the spiral ordering denotes the nth Gaussian integer by τ_n. Equation 1 states that the spiral is ordered from $\tau_1 = 1$ to base on the nth integer in the spiral. See Fig.1 for an illustration. The first 10 Gaussian integers are ordered according to this ordering $1, 1+i, i, -1+i, -1, -1-i, -i, 1-i, 2-i, 2 \ldots \ldots \ldots$

In the spiral ordering, we write $[\tau_k]$ to represent all the kth Gaussian integers.

$$\tau_{k+1} = \begin{cases} \tau_k + i & if \ |\mathrm{Re}(\tau_k)| > |\mathrm{Im}(\tau_k)|, \ \mathrm{Re}(\tau_k) > 0 \ and \ -(\mathrm{Re}(\tau_k)-1) \le \mathrm{Im}(\tau_k) \le (\mathrm{Re}(\tau_k)-1) \\ \tau_k - 1 & if \ |\mathrm{Re}(\tau_k)| \le |\mathrm{Im}(\tau_k)|, \ \mathrm{Im}(\tau_k) > 0 \ and \ -\mathrm{Im}(\tau_k) \le \mathrm{Re}(\tau_k) \le \mathrm{Im}(\tau_k) \\ \tau_k - i & if \ |\mathrm{Re}(\tau_k)| \ge |\mathrm{Im}(\tau_k)|, \ \mathrm{Re}(\tau_k) < 0 \ and \ \mathrm{Re}(\tau_k) < \mathrm{Im}(\tau_k) < -\mathrm{Re}(\tau_k) \\ \tau_k + 1 & if \ |\mathrm{Re}(\tau_k)| \le |\mathrm{Im}(\tau_k)|, \ \mathrm{Im}(\tau_k) < 0 \ and \ \mathrm{Im}(\tau_k) \le \mathrm{Re}(\tau_k) \le -\mathrm{Im}(\tau_k) \end{cases}$$

Gaussian integer spiral ordering leads to finite Gaussian prime distance labeling of other Gaussian integer graphs.

Definition 2.2

Let G be a simple graph. A finite GPD labeling graph of Gaussian integers G is a injective labeling $\varphi : V(G) \to Z[i]$ such that if $uv \in E(G)$, then $\varphi(u)$ and $\varphi(v)$ are relatively prime to each other. So G is called a finite Gaussian prime distance graph if there exists a finite Gaussian prime distance labeling exists. Prime distance labeling requires distinct labels at each vertex of G.

AN OVERVIEW OF SPIRAL ORDERING PROPERTIES

An order of Gaussian spiral is defined here in several pieces. Spiral corners occur when spirals move from one direction to another direction. Spirals have branches when they travel in a straight line north, south, east, or west.
Our first objective is to decide the ordinal numeral of an inconsistent Gaussian whole number, $a + bi$ in the winding request in light of which kind of branch or corners it lies on. Let $O_{GI}(a + bi)$ be used to mean the ordinal numeral of $a + bi$ in the twisting requesting. The points lie on the axes is

On X axis, either $\mathrm{Re}(z) > 0 \, or \, < 0 \, and \, \mathrm{Im}(z) = 0$

On Y axis, either $\mathrm{Im}(z) > 0 \, or \, < 0 \, and \, \mathrm{Re}(z) = 0$

I and III quadrant corners are the Gaussian integers such that their real and imaginary parts are equal and of same in signs. II quadrant corners are having equal real and imaginary part and are of opposite signs. IV quadrant corners are of opposite in signs and $\mathrm{Re}(z) = |\mathrm{Im}(z)| + 1$

Lemma 2.3

Ordinal numerals of four types of points lie on X – axes, and Y-axes and are found as follows:

$$O_{GI}(a + bi) = \begin{cases} 4a^2 - 3a & if \ a > 0 \ and \ b = 0 \\ 4b^2 - b & if \ a = 0 \ and \ b > 0 \\ 4a^2 - a & if \ a < 0 \ and \ b = 0 \\ 4b^2 - 3b & if \ a = 0 \ and \ b < 0 \end{cases}$$

Proof

The ordinal numerals of a GI are the number of points in its path. First, we'll examine the points on the positive side of the X-axis. We started with the very first integer $1 + 0i$, and its ordinal numerals are 1. The second point in the axis is $2 + 0i$, it finally crosses a 3 x 3 grid of points having three columns of three points each, and it may cross another point to reach its ordinal numerals. For our convenience in the calculation, we include point zero and exclude point $2 + 0i$. The third point in the axis is $3 + 0i$, which crosses a grid of five columns of five points each, and it may cross another two points to reach its position. By progressing in this fashion, the point $a + bi, b = 0$ on the positive real axis is crossed by "$2a - 1$" columns of "$2a - 1$" a point each and it may crosses another "$a - 1$" points. It crossed completely $(2a - 1)(2a - 1) + (a - 1) = 4a^2 - 4a + 1 + a - 1 = 4a^2 - 3a$ points. So, its ordinal numerals are $4a^2 - 3a$ Second, we'll look at the points on the positive side of the Y axis. We started with the first point $0+i$ in the Y axis, which ordinal number is 3. The second point in the axis is $0+2i$, from which crosses three columns with four points each and it may cross another two points to reach its place. We use the current y-axis as the point instead of zero as the center point. $0 + 3i$, The Y axis third point crosses five columns of six points each and it may cross another three points. In general, the positive side of Y axis point $0 + bi, b > 0$ is crossed by "2b-1" columns of 2a points each by continuing in this manner.
It entirely crossed $(2b - 1)(2b) + b = 4b^2 - 2b + b = 4b^2 - b$ points. So, their ordinal numerals are $4b^2 - b$
Similarly, we get the indices of the points on the negative sides of the X and Y axes.

Lemma 2.4
Ordinal numerals of the corners lie on the four quadrants are found as follows:

$$O_{GI}(a+bi) = \begin{cases} 4a^2 - 2a & \text{if corners lie in I quadrant} \\ 4a^2 & \text{if corners lie in I quadrant} \\ 4a^2 + 2a & \text{if corners lie in III quadrant} \\ (a-b)^2 & \text{if corners lie in IV quadrant} \end{cases}$$

Proof
First, let's explore the corner points of the first quadrant in the XY plane. Initiating with the initial corner integer 1+i, the second corner point in the first quadrant, 2+2i, spans three rows of four points each. Meanwhile, the third corner point, 3+3i, traverses seven rows, each containing eight points. Progressing systematically, the corner points a+bi in the first quadrant, where a equals b, intersects "2a-1" rows, each with 2a points. This results in a total intersection of $4a^2-2a$ points. Moving on to the second quadrant's corner points, we commence with -1+i, which intersects two columns, each with two points. The second corner point, -2+2i, crosses four columns with four points each, while the third corner point, -3+3i, extends across six columns of six points each. Continuing this pattern, the corner point -a+ai in the second quadrant, with a=b, intersects "2a" columns, each comprising 2a points. This yields a complete intersection of $4a^2$ points. Next, we turn to the third quadrant's corner points. Starting with -1-i, this first corner integer crosses two rows, each containing three points. The second corner point, -2-2i, spans four rows with five points each, and the third corner point, -3-3i, traverses six rows of seven points each. Following the established trend, the corner point -a-ai in the third quadrant, with a=b, intersects "2a" rows, each with 2a+1 points. This results in a total intersection of $4a^2+2a$ points. Finally, examining the corner points of the fourth quadrant, we initiate with the first corner integer, 2-i, which crosses three columns, each comprising three points. The second corner point, 3-2i, spans five columns with five points each, while the third corner point, 4-3i, extends across seven columns of seven points each. In a similar manner, the corner point a+bi in the fourth quadrant, with a>b, is intersected by "(a-b)" columns, each with "(a-b)" points. This leads to a complete intersection of (a-b)(a-b) = $(a-b)^2$ points.

Finite Gaussian Prime Distance Results for Graph Families
Definition 3.1
A lattice graph is a type of graph that represents a structure consisting of points or nodes arranged in a regular, grid-like pattern. It is commonly used in physics and mathematics to model crystal structures and other regular arrangements of particles.

Theorem 3.2
Every grid graph is a finite Gaussian prime distance graph.

Proof
The set of Gaussian integers we are considering here is already on a grid system in the XY plane, and we know of consecutive Gaussian integers in the system that differ by a unit difference and unit distance points having the gcd of 1. Thus, every Lattice graph is a finite Gaussian prime distance graph
Example: A 2x2 grid graph.

$$5 + 3i = (1)(4 + 3i) + (1)$$

$$4 + 3i = (1)(4 + 3i) + (0)$$

$$\text{Thus, gcd}(4 + 3i, 5 + 3i) = 1$$

Similarly,

$$4 + 3i = (1)\,(4 + 2i) + (i)$$
$$4 + 2i = (i)\,(2 - 4i) + (0)$$
$$Thus, \gcd\,(4 + 3i, 4 + 2i) = i$$

$$5 + 3i = (1)\,(4 + 2i) + (1 + i)$$
$$4 + 2i = (1 + i)\,(3 - i) + (0)$$
$$Thus, \gcd\,(5 + 3i, 4 + 2i) = 1 + i$$

Theorem 3.3
Every path graph is a finite Gaussian prime distance graph.

Proof
A square grid graph is a particular kind of graph that has edges joining adjacent vertices and vertices arranged in a s quare grid pattern.We can say that the square grid graph is a composition of multiple path graphs if we assume of the vertical and horizontal lines of the grid as path graphs, which implies that they enhance the property of finite prime distance. It therefore proves.

Definition 3.4
Grid graphs are bipartite, meaning that all edges have its end points in two different vertex sets.

Theorem 3.5
Bipartite graphs admit finite Gaussian prime distance labeling.

Proof
If we color the vertices of the grid graphs in a checkerboard fashion, it can be verified easily. (Fig 4)

Definition 3.6[6]
The star S_{2n} with central point v_0 and leaves through v_{2n}, with an edge connecting each subsequent pair of vertices v_{2k-1} and v_{2k} where $1 \le k \le n$, is the Dutch windmill graph D_n or friendship graph. As a result, D_n has n copies of C_3 joined at v_0 [7]. D_5 is seen in Figure 5.

Theorem 3.7
Any Dutch windmill graph $D_n, n > 1$ admits a finite Gaussian prime distance labeling.

Proof
The Dutch windmill graph is a simple graph consisting of a central vertex v_0, and n blades, each containing m vertices[8], where every vertex in the ith blade is adjacent to v_0 and to the equivalent vertex in the (i+1)[th] blade. Let us start with vertex $v_0 = \alpha + \beta i, v_0 \in Z[i]$, the center vertex of the Dutch windmill graph [9]. Assign a vertex value in the blade neighboring to v_0 such that $v_0 \ and \ v_i$ are relatively prime Gaussian integers [10, 11].
Hence, every adjacent vertex in the Dutch windmill graph is relatively prime and admits a finite prime distance.

Theorem 3.8

Any star graph S_n, $n > 1$ is a finite Gaussian prime distance graph.

Proof

If we start with a star graph, we have one central vertex connected to several peripheral vertices. Labeling the central vertex v_0 with $\alpha + \beta i \in Z[i]$ and labeling all other peripheral vertices with the Gaussian integers relatively prime [12] to v_0. Hence, every adjacent vertex in the star graph is relatively prime and admits a finite prime distance.

Definition 3.9

The (n, r, s)-double star tree, where n, r, s be integers with $r \leq s$ then $DS_{n,r,s}$, is the graph with $V(DS_{n,r,s}) = \{v_1, \ldots, v_n, v_{n+1}, \ldots, v_{n+r-1}, v_{n+r}, \ldots, v_{n+r+s-2}\}$, and
$E(DS_{n,r,s}) = \{v_j v_{j+1}: 1 \leq j \leq n-1, v_1 v_{n+j}: 1 \leq j \leq r-1, v_n v_{n+r+j}: 0 \leq j \leq s-2\}$

Theorem 3.10

Any (n, r, s) −double star tree admits a finite Gaussian prime distance labeling.[13]

Proof

A path graph is characterized by a linear sequence of vertices, where each vertex is connected to its adjacent ones. In contrast, a star graph features a central vertex linked to all other vertices. In a double star tree, there exists a path of distance end to end with end vertices and v_1 and v_2 serving as the middle vertices for stars having r and s vertices. Theorems 3.3 and 3.8 assert that both path graphs and star graphs have a finite Gaussian prime distance, categorizing them as finite Gaussian distance graphs.

Definition 3.11

A tree with at least one vertex with a degree of three and all other vertices with degrees of one or two is called a spider graph. (Fig.8)

Theorem 3.12

Any spider tree admits finite Gaussian prime distance labeling.

Proof

Let T be a spider tree and assume the center vertex v_0 has degree n. Label the any vertex v_k, $1 \leq k \leq n$ with the Gaussian integers relatively prime to v_0 and continue the process to the adjacent vertices of v_k, $1 \leq k \leq n$.

NEIGHBORHOOD PRIME DISTANCE RESULTS FOR GRAPH FAMILIES
Definition 3.13

The neighborhood of a vertex v in Graph G is defined as the set of all vertices in G that are adjacent to v, denoted by the set N(v).

Definition 3.14

Consider a graph G = (V(G), E(G)) with n vertices. If, for every vertex v ∈ V(G) with degree greater than 1 (deg(v) > 1), the greatest common divisor of the set {f(u): u ∈ N(v)} is equal to 1, then the function f: V(G) → Z[i] is referred to as a neighborhood-prime labeling[14].

Definition 3.15

A triangular cactus is a linked graph that only consists of triangles as its building blocks.

Remark

A prime graph may or may not also be a neighborhood-prime graph and vice versa [15]. This independence between the words "prime graphs" and "neighborhood-prime graphs" refers to their flexibility.

Theorem 3.16

Every path graph P_n admits neighborhood prime labeling.

Proof

Let v_i be any Gaussian integer in P_n where $v_i = \alpha + \beta i \in Z[i]$. Already we say that every grid graph (Theorem 3.2) and every path P_n (Theorem 3.3) admits finite prime labeling. If we take the neighborhood of v_i as v_{i-1} and v_{i+1} belongs to the set$\{(\alpha - 1) + \beta i, (\alpha + 1) + \beta i, \alpha + (\beta - 1)i, \alpha + (\beta + 1)i\}$, Clearly, v_i, v_{i-1} and v_{i+1} are relatively prime to each other.

Theorem 3.17

Every triangular cactus graph is a neighborhood prime labeling graph.

Proof

Identifying a path as the cactus graph's basis is the first step in proving the theorem. According to Theorem 3.16, the path that is derived from the grid graph allows for neighborhood prime labeling [16]. Since their differences in the path alternative are *2i*, it follows that their gcd is *-i*. Gaussian integers are relatively prime in this case. Thus every triangular cactus graph admits neighborhood prime labeling. [Fig.9]

CONCLUSION

The study of Gaussian prime distance and Gaussian neighborhood prime distance graphs has provided a unique perspective on graph connectivity, combining the principles of number theory with the intricate structures of graph theory. The Gaussian neighborhood prime distance graph, with vertices representing Gaussian numbers and edges connecting vertices with relatively prime numbers, presents a visually compelling spiral structure that showcases the beauty of interconnectedness and underlying mathematical principles. The delineation of a finite Gaussian prime distance within this graph family reinforces the potential for finite patterns in graph theory. This exploration deepened our understanding of graph structures and underscored the versatility of mathematical concepts in diverse fields. The study of Gaussian prime distance graphs and their variants contributed to the rich tapestry of mathematical research and exemplified the beauty that emerges when seemingly disparate concepts converge.

ABSTRACT

Strong synthetic glucocorticoids like dexamethasone are increasingly used in many medical specialities, including anaesthesia. Its antiemetic, immunosuppressive, and anti-inflammatory qualities make it a useful perioperative care adjunct. This narrative review aims to provide an overview of the available data on the application of dexamethasone in anaesthesia practice. We review its pharmacokinetics, mechanisms of action, and clinical uses, including how it helps minimize pain and inflammation, lessen airway oedema, and prevent postoperative nausea and vomiting. We also discuss the possible side effects and controversy related to its use, including immune suppression and hyperglycaemia. We also highlight new directions in research and recent advancements in the use of dexamethasone to improve perioperative outcomes. Dexamethasone is a useful tool in anaesthesiologists' toolbox, but cautious application and understanding of its potentialrisks are essential for safe and effective perioperative management.

Keywords: dexamethasone, anaesthesia, perioperative care, antiemetic, anti-inflammatory, immunosuppressive

INTRODUCTION

Due to its many different pharmacological characteristics, the powerful synthetic glucocorticoid dexamethasone has attracted a lot of interest in the field of anaesthesia. Dexamethasone was first identified as having anti-inflammatory and immunosuppressive properties, but its use in perioperative settings has expanded to include anaesthesia. Its ability to lessen inflammation, lower postoperative nausea and vomiting (PONV), and possibly improve postoperative analgesia is the reason for its widespread use [1]. Dexamethasone has become a useful addition to anaesthesia protocols in recent years due to its capacity to control the stress response during surgery, improve hemodynamic stability, and help patients recover more smoothly. Dextamethasone's pleiotropic effects have prompted its investigation in a variety of surgical specialities, from neurosurgery to orthopaedic procedures, among others [2]. This narrative review aims to present a thorough summary of the available data regarding the perioperative administration of dexamethasone in anaesthesia practice. Through the integration of results from observational studies, meta-analyses, and clinical trials, we aim to clarify the medication's safety profile, efficacy, ideal dosage schedules, and possible directions for future investigation [3]. This review aims to provide insights into the complex role of dexamethasone in perioperative care by critically analyzing the body of existing literature and addressing its effects on outcomes like immune function, wound healing, glycemic control, and surgical site infections. We will also look at new developments, debates, and paths forward for the use of dexamethasone in anaesthesia management procedures [4]. Anesthesiologists, perioperative teams, and healthcare professionals need to comprehend the changing landscape of dexamethasone utilization in anaesthesia practice. Given its potential to improve patient care, optimize perioperative outcomes, and refine anaesthesia strategies, anesthesiologists, perioperative teams, and other healthcare providers must comprehend the changing landscape of dexamethasone utilization in anaesthesia practice [5].

Mechanism of Dexamethasone

Administration of Dexamethasone
|
Binds to glucocorticoid receptors (GR) in the cytoplasm
|
Formation of GR-Dexamethasone Complex
|
Translocation of the complex into the nucleus
|
Binding of complex to DNA (GREs) in promoter regions of target genes
|
Activation or repression of gene transcription
|
Anti-inflammatory effects and immunosuppressive effects
|
Reduction of inflammation and Immune responses in the body
|
Clinical effects: reduction in swelling, inflammation, immune responses, and associated symptoms
|
Overall improvement in patient condition

Komal Yadav *et al.,*

Dexamethasone in Postoperative Nausea and Vomiting

In perioperative care, postoperative nausea and vomiting (PONV) continue to pose major challenges. It is associated with increased healthcare costs, delayed recovery, and patient discomfort. Many pharmaceuticals have been used to reduce PONV, and because of its antiemetic qualities, dexamethasone has become a promising adjunct [6]. Synthetic glucocorticoids such as dexamethasone have anti-inflammatory and immunosuppressive properties, but they are not the only ways in which they help manage PONV. Dexamethasone has been the subject of numerous studies that have examined its safety and effectiveness in lowering the incidence and severity of post-operative nerve injury (PONV) in a variety of surgical populations [7]. The purpose of this review is to present a thorough summary of the available data on the application of dexamethasone in the treatment of PONV. By critically analyzing meta-analyses, systematic reviews, and randomized controlled trials, Our objective is to assess the effectiveness of dexamethasone in treating and preventing PONV, as well as how well it works in comparison to other antiemetic medications [8]. In addition, the safety profile of dexamethasone will be covered in this review along with its implications for managing PONV, taking into account possible side effects like hyperglycemia, immunosuppression, and difficulties with wound healing. The best time to administer dexamethasone, dose-response relationships, and patient-specific factors affecting its safety and effectiveness will all receive particular consideration [9]. Perioperative healthcare providers must comprehend the role of dexamethasone in PONV management to better tailor multimodal antiemetic strategies and enhance patient outcomes. Through a comprehensive analysis of the existing literature, our review seeks to support clinical judgment and encourage additional investigation to enhance PONV prevention and therapy approaches [10].

Role in Prospective Pain

Inflammation, nerve injury, or direct tissue damage are the causes of postoperative pain. Of these, acute inflammation brought on by tissue damage is the main contributing factor. By blocking peripheral phospholipase and thereby lowering cyclooxygenase and lipoxygenase, dexamethasone reduces pain. Several reactions, including inflammatory, metabolic, hormonal, and immune responses, are triggered as soon as a surgical incision is made. Dextamethasone's anti-inflammatory and immunosuppressive properties may reduce these responses, demonstrating the drug's role in pain management [11].

Dose and Administration of Dexamethasone

Depending on the type of surgery, the patient, and the intended results, several variables can affect the best dose and timing of dexamethasone administration in the context of different perioperative applications, such as pain management and the prevention of postoperative nausea and vomiting (PONV)[12]. Nonetheless, based on the information at hand, a few broad recommendations, and widely accepted regimens have been developed:

Prevention of postoperative nausea and vomiting (PONV):
- To lower the frequency and severity of PONV, dexamethasone is commonly used as a preventive antiemetic medication.
- The usual intravenous dose is between 4 and 10 milligrams. Although the exact timing of administration varies, common practices include: - Giving dexamethasone at the time of induction of anesthesia.
- Giving dexamethasone to the patient after the procedure, before their awakening from anesthesia.
- Giving high-risk patients or procedures dexamethasone at both the beginning and the end of the surgical procedure. Research indicates that most of the time, a single dose of dexamethasone is sufficient for PONV prophylaxis; however, in cases of prolonged surgery or high-risk patients, additional doses may need to be considered [13].

Pain Management: - Dexamethasone can also be used to lessen the need for opioids and improve postoperative pain control.
- For this purpose, intravenous administration of a dose of 4 to 8 mg is typically advised.
- Although the exact timing of administration varies, common practices include: - Giving dexamethasone at the onset of anesthesia to prevent inflammation and pain.

Komal Yadav *et al.,*

- Giving dexamethasone to help with postoperative pain management following surgery.
- Adding dexamethasone to multimodal analgesic regimens or regional anesthesia techniques may help improve pain management and decrease opioid-related side effects [14].

Other Perioperative Uses

Dexamethasone can also be applied in other perioperative situations, like lowering airway edema, avoiding stridor after extubation, and speeding up recuperation following specific surgical procedures. For these applications, the dosage and schedule of administration ought to be customized according to particular clinical circumstances and patient requirements [15]. Healthcare professionals should take patient comorbidities, drug interactions, and possible side effects into account when deciding on the right dosage and schedule for dexamethasone administration. Optimizing perioperative management strategies can also be achieved by adhering to the most recent evidence-based recommendations and consulting institutional guidelines [16].

Role of Dexamethasone in Neuromuscular Block

Synthetic glucocorticoids like dexamethasone have been studied for their possible effects on neuromuscular function and how they affect neuromuscular blocking agents (NMBAs) in different clinical settings. Although dexamethasone is best known for its anti-inflammatory and immunosuppressive qualities, its impact on neuromuscular transmission has drawn interest in the field of anesthesia [17]. The function of dexamethasone in the neuromuscular block is summarized as follows:

Strengthening of Neuromuscular Blockade

- Research indicates that dexamethasone may strengthen the effects of non-muscular blockade agents (NMBAs), resulting in a longer period of neuromuscular blockade and possibly influencing the extent and length of muscle relaxation during surgery.
- By improving neuromuscular blockade, dexamethasone may improve operating conditions, ease surgical exposure, and lessen the need for volatile anesthetics. These effects could have an impact on intraoperative management [19].

Diminished Neuromuscular Blockade Reversal:

- Research suggests that dexamethasone may postpone the restoration of neuromuscular function after reversal medications, like sugammadex or neostigmine, are administered.
- To guarantee sufficient recovery of respiratory function and muscle strength, modifications to postoperative monitoring and extubation protocols may be necessary due to the delayed reversal of neuromuscular blockade by dexamethasone [20].

Possible Mechanisms

- Although the exact processes underlying dexamethasone's effects on neuromuscular transmission are unclear, they could include interactions with neuromuscular junction receptors, changes in muscle membrane excitability, or modulation of neurotransmitter release.
- Dexamethasone's complex interactions with neuromuscular signaling pathways may be attributed to its broad pharmacological profile, which includes effects such as anti-inflammatory and metabolic [21].

Clinical Implications and Considerations

- When using dexamethasone in perioperative management strategies, healthcare providers should be aware of the possible effects it may have on neuromuscular function.
- Optimizing patient outcomes and reducing the possibility of side effects require tailored dosing schedules and close observation of neuromuscular function [22].

Komal Yadav *et al.,*

When using dexamethasone in anesthesia practice, healthcare providers should be aware of its potential impact on perioperative neuromuscular function, even though more research is required to clarify the exact mechanisms and clinical implications of this medication's effects on the neuromuscular blockade[21,22].

Role of Dexamethasone in Shievering

Postoperative shivering can have a major impact on patient care, so treating and preventing it should be a top priority. Increased oxygen consumption, increased carbon dioxide production, or sympathetic stimulation can all result from shivering. Dexamethasone reduces shivering by lowering the difference in temperature between the skin and the body's core. The effects of shivering were compared between dexamethasone and pethidine in a randomized double-blind study. According to the study's findings, dexamethasone outperformed pethidine in preventing postoperative shivering[23]. However, in patients undergoing transurethral prostatectomy under spinal anesthesia, there was no discernible difference in the incidence of shivering between intrathecal pethidine and intrathecal dexamethasone[24].

Concerns Associated with Dexamethasone Usage

Issues with dexamethasone use in anesthetic practice include poor wound healing, hyperglycemia, and an increased risk of infection. Dexamethasone taken alone does not appear to raise the risk of infection or slow the healing of wounds. Furthermore, there is no proof that a single dexamethasone dosage will cause hyperglycemia. The most recent trial confirming dexamethasone's safety is the PADDI trial [25].

Role of Dexamethasone in Quality of Recovery

Dexamethasone is an effective tool for enhancing the standard of recovery following surgery. It improves patient comfort and satisfaction by lowering pain, decreasing inflammation, and preventing postoperative nausea and vomiting (PONV). Furthermore, by lowering the chance of complications like hypersensitivity reactions and airway edema, its immunomodulatory qualities may aid in quicker recoveries. But it's important to dose carefully and take possible side effects into account. Healthcare providers must work together to make decisions to maximize benefits and minimize risks. To improve the quality of recovery, more research is required to define its role and create standardized protocols for its application [26].

Mechanism of Action

Dexamethasone most likely works as an anti-inflammatory through both nongenomic and genomic mechanisms. Postoperative pain results from tissue injury and inflammation caused by surgical procedures. The strong anti-inflammatory qualities of corticosteroids like dexamethasone lessen these effects. The processes include lowering the concentration of bradykinin in tissues, stabilizing neuronal membranes, and inhibiting the cyclooxygenase and lipoxygenase pathways. Moreover, dexamethasone inhibits the release of neuropeptides following tissue damage from nerve endings [27].

CONCLUSION

To sum up, dexamethasone has a variety of uses in the field of anesthesia and is advantageous in a range of clinical situations. Its versatility makes it a useful adjunct in perioperative management, from reducing pain and inflammation to mitigating postoperative nausea and vomiting. Its immunomodulatory properties may also be useful in reducing side effects like hypersensitivity reactions and airway edema. Potential negative effects, however, must be carefully considered, especially in more susceptible patient populations [28]. To maximize patient outcomes while lowering risks, anesthesiologists, surgeons, and other healthcare professionals must collaborate when making decisions. To clarify its exact mechanisms of action and improve dosage schedules for particular surgical procedures, more research is necessary [29].

ABSTRACT

The banking industry has played a significant role in the economic progression of a country since time immemorial, especially in terms of preserving capital and granting credit to both people and enterprises. The banking concern in India has experienced an evolutionary change, particularly in the last two decades. The quality of the assets, technology, and laws have all changed substantially. Branchless banking enabled by modern and contactless technologies has replaced traditional physical banking, which required client walk-ins and in-person interactions. Digitization in the financial sector has revolutionised the banking landscape. Therefore, the foremost purpose of this paper is to explore the various approaches in the banking sector as digitization resulted in paradigm change from traditional banking processes to digital operations using new technologies. It can be concluded that banking can be reformed and redesigned through technological advancements and will continue to drive the economy forward by integrating various financial sector components. This paper serves as a learning guide to the future researchers as it provides a comprehensive outlook of the various developments the banking sector has undergone over the years.

Keywords: Banking industry, Information Technology, Digitization, Digital banking

INTRODUCTION

Banking industry which is amongst the main pillars of the financial system plays a crucial part in the economic progression of any country. The rapidly evolving economy is bringing with it rapidly evolving technologies, a greater need for expertise in all facets of business, and new ways to provide services to customers, like e-banking (Chandrasekharan & Narayanan, 2019). The business operations of the banking concern have undergone remarkable transformation in the last few years. Following the economic crisis of 2007–2008, financial controllers reinforced

79893

Nisha Sunil and Anitha s Yadav

governance of the banking industry by executing new rules and reinforcing those that already existed (Romanova &Kudinska, 2016). The e-banking revolution is one of the few breakthroughs that has altered the banking industry so swiftly. E-banking has offered banks the potential to cross potential frontiers, amend their entrepreneurial behaviour, and open new possibilities. With the advent of e-banking, real-world banking practices are now more in line with neoclassical economic ideas of how markets operate. Customers are better able to evaluate the services of different banks because of the market's complete transparency (Nitsure, 2003). Furthermore, the advancement of Fintech has boosted the necessity for increased creative banking solutions. As a result of growing competition from nonbank financial entities, banks today have begun to compete outside the realm of traditional financial services (Romanova &Kudinska, 2016). Thus, over a period the banking industry has transformed from a product centric approach to customer centric approach. Internet technologies have a significant potential to profoundly alter banks and the banking sector. Banks are influenced to outline, expand, and operate their own e-banking techniques. The e-banking services and technologies provide the banking industry with an opportunity to fulfil the demands of prospective customers and attract new potential consumers (Angelakopoulos & Mihiotis, 2011). The Banking Regulation Act of 1949 (BR Act), which governs banking, explicitly states the importance of the money-saving industry in India. In accordance with Section 5 (c) of the BR Act, a banking firm is an entity that conducts banking operations in India. Furthermore, according to Section 5(b) of the BR Act, banking is defined as "accepting, with the intent of providing or assuming, from the people, repayable with interest or generally, and withdrawal, with check, draft, order, or otherwise" (Abhijit Roy, 2012). The Indian banking sector is currently experiencing an IT revolution.

To keep up with the top global competitors who offer a broad range of sophisticated services, Indian banks are evolving and becoming more powerful by investing heavily in digital technologies. A quickly expanding digital community is being created at the same time by current innovations and prospective banking developments in India. The significance of complete Indian banking automation is rising due to a mix of competitive and regulatory factors (Chittabbai et al., 2015). Dhanwani (2014) opines that information technology has reformed and redesigned banking and it will be able to offer more enhanced amenities in the future with further product and process improvements. As a result, the sector is transitioning from a seller's to a buyer's market, which ultimately has an impact on bankers' methods, causing them to switch from traditional banking to convenience banking and mass banking to class banking. Gupta & Shrivastava (2018); Bansal et al., (2022) concludes that communication and business process re-engineering are two different ways that information technology is utilized in banking. Considering the enormous global expansion of financial operations, the information technology transformation has created an environment for addressing the problems the new economy is facing. Kumar & Pavithra (2017) emphasises that due to the newly enhanced and cutting-edge services provided by banks, India's banking industry is advancing along with the rise in its customer base. The country's economic expansion is a sign that the banking industry will expand as well. Priyanka (2020); Sujatha et al., (2017) states that the development of the economy is greatly aided by technological advancements in banking. The "next level of banking" is now operational in the Indian financial sector.

The banking industry is certain to experience transformation as a result of ICT innovation combined with the cashless economy vision. Yadav (2019); Gupta et al., (2017) opines that banks are anticipated to have considerable expansion in the years ahead. Banks can implement universally accepted accounting methods, improve risk management systems, and increase openness and transparency due to innovation and IT systems utilized in the banking industry. The analysis outlines the ways in which information technology has impacted the Indian banking industry, including its advancements, transformations, and possible future developments. A possible research gap that the assessment highlights is the need for a more thorough examination of the challenges and risks connected to the banking sector's growing use of information technology. In particular, the assessment emphasizes the benefits, like improved services, economic growth, and expansion, but it skips over any potential negative effects or difficulties banks may encounter as a result of this technological revolution. Hence the main objective of the paper is to explore the past approaches of the Indian banking system and to explore the recent trends that have taken banking in India to an advanced level. This paper serves as a learning guide to the future researchers as it provides a comprehensive outlook of the various developments the banking sector has undergone over the years.

METHODOLOGY

The study uses secondary data in the form of research articles published in various databases, newspaper articles and government websites.

OBJECTIVES

The main aim of this study is:

1. To analyse the banking approaches in the past.
2. To explore the recent approaches in the Indian banking system.
3. To explore the various challenges and risks that banks encounter for being reliant on information technology.

DISCUSSIONS

History of the Indian banking industry

Indian banks are the country's first generation of financial facilitators. Due to its unique geographic and socioeconomic features, the Indian banking industry stands apart from the rest of the global financial system (Bhosale, 2015). The Indian banking system can be categorised into three periods namely, pre-independence (1786 – 1947), post-independence (1947 – 1991) and liberalisations period (1991 – till date). The Bank of Hindustan, which had its headquarters in Kolkata and was founded in 1770, was the first bank of India. However, this bank was a failure and stopped operations in 1832. A number of other banks were formed in India after the Bank of Hindustan such as The general bank of India (1786-1791), Oudh commercial Bank (1881-1958), Bank of Bengal (BoBe) (1809), Bank of Bombay (BoB) (1840), Bank of Madras (BoM) (1843). The BoBe, the BoB, and the BoM were three banks that the East India company founded during the British era of rule in India and known as presidential banks. In 1921, these three banks were ultimately combined into a single institution known as the Imperial Bank of India (IBI). The IBI was later nationalised in 1955 and renamed as the State Bank of India (SBI), which is presently the biggest public sector bank. On the advice of the Hilton Young Commission, RBI was established on April 1st, 1935. All the main banks during independence were autonomous, which raised issues as rural population still depended on financiers for funding. The administration decided to nationalise the banks to confront this issue.

These banks were nationalised in accordance with the Regulation Act of 1949, while the RBI was nationalised the same year. SBI was founded in 1955, and 14 additional institutions were nationalised between 1969 and 1991. The 14 banks that were nationalised in 1969 included Allahabad Bank, Bank of India, Bank of Baroda, Bank of Maharashtra, Central Bank of India, Canara Bank, Dena Bank, Indian overseas Bank, Indian Bank, Punjab national Bank, Syndicate Bank, Union Bank of India, United Bank, and Uco Bank. These banks had national deposits that totalled more than 50 crores. Six additional banks were nationalised in the year 1980. These institutions included Vijaya Bank, Punjab & Sindh Bank, New Bank of India, Oriental Bank of Commerce, Andhra Bank and Corporation bank. State Bank of India subsequently merged with some of the banks, including State Bank of Patiala, State Bank of Hyderabad, State Bank of Bikaner & Jaipur, State Bank of Mysore, State Bank of Travancore, State Bank of Saurashtra, and State Bank of Indore, in 2017. The banks needed to be regularly monitored and regulated during the liberalisation phase. The government decided to establish a commission under the chairmanship of Shri. M Narasimhan to oversee the major developments in the Indian banking sector to provide consistency and profitability to the nationalised Public Sector Banks. The introduction of private sector banks in India was the biggest advancement. Global Trust Bank, ICICI Bank, HDFC Bank, Axis Bank, Bank of Punjab, IndusInd Bank, Centurion Bank, IDBI Bank, Times Bank, and Development Credit Bank were some of the financial institutions. Other measures taken included establishing foreign bank branches in India, introducing payments banks in response to technological and banking advancements, allowing small finance banks to open branches throughout India, and progressing a significant portion of Indian banking online with internet banking (Kumar, 2021).

Nisha Sunil and Anitha s Yadav

Banking innovations in the past

Society For Worldwide Interbank Financial Telecommunications (Swift)

SWIFT was founded as an intergovernmental organization in May 1973 and currently has 239 affiliated organizations from 15 different nations. The headquarters is in Brussels. The RBI, along with 27 other public sector banks and 8 foreign banks, became members of SWIFT in 1977. SWIFT offers a quick, safe, dependable, and affordable way to send financial messages across the globe. SWIFT was upgraded in the 1980s to accommodate the increase in message volume; this form is known as SWIFT-II. Indian banks are connected to the SWIFT-II network. A reputable international means of advanced message transportation is SWIFT. This kind of money transfer is reliable, safe, and cost-effective. Additionally, this network makes it convenient for messages about fixed deposits, interest payments, inflow-outflow statements, foreign currency, etc. to be transferred. This is offered 365 days a year, around-the-clock (Kumar & Pavithra, 2017).

Automated Teller Machine (ATM)

It is a type of electronic device that a consumer uses to deposit, withdraw, and perform other financial transactions (Deolalkar, 1998). The ATM facility is accessible 24/7. This card bears the customer's name. The magnetically recorded data on this card can be accessed by the device. Each cardholder receives a personal identification number (PIN) that is kept confidential. The customer must insert his card in the machine's slot and follow the instructions to withdraw the money (Indian Banking, 2004).

Electronic Clearing Service (ECS)

A committee was established by the RBI in 1994 to examine the electronic clearing service as well as the mechanization of banks. The committee suggested in its report that all business bodies and government institutions should have access to electronic clearing services and credit clearing facilities for processing frequent small-value payments including dividends, interest, refunds, salaries, pensions, and commissions. The committee also suggested that pre-authorized debits for payments of utility bills, insurance premiums, and instalments to leasing and financing businesses be made through the Electronic Clearing Service-Debit clearing (Kumar & Karthik, 2013).

Telebanking

Another technological advancement that provided customers the facility of 24-hour banking was telebanking (Lakshmi et al., 2009). Telebanking relies on the voice recognition capability found on a bank's system and provides the caller with an appropriate response. The user can check the transaction details whenever he/she calls the bank (Lakshmi et al., 2010). In this method, a modem is used for linking the bank's computers to a telephone line. Some banks also utilize telephone answering machines; however, these are only used for a few limited activities (Venkataganesan et al., 2016).

Chip card

The bank issues a specific kind of credit card to each of its customers that bears their name, code, and other information. The customer account's credit balance is magnetically recorded on the card. These magnetic dots may be read by the computer (Kanniga& Sundararajan, 2013). From the moment a customer uses the card, the credit amount reflected on it starts to decline. The cardholder is required to put cash into his account before making any additional card purchases. Once more, the credit amount is written on the card using a magnetic method (Venkatesh & Ramachandran, 2014).

Internet Banking

The ability to do monetary transactions online through a bank's website is known as internet banking (Suganthi & Senthilkumar, 2015). It is a method of using a computer to access accounts and basic details about bank's offerings while being at the comfort of home (Thooyamani et al., 2014). While in the conventional banking system a customer had to visit the bank branch physically for cash withdrawals, cash deposits, account statement requests and so on

Nisha Sunil and Anitha s Yadav

(Nivethitha & Brindha, 2014). All these types of transactions can now be performed by anyone using the bank's website and a computer. These transactions employ advanced multi-layered security framework, including firewalls and filters, and are encrypted (Mathew & Brindha, 2014).

Recent trends in banking
In India, banking has undergone significant developments. Banking has been at the forefront of advancements brought about by the newest technology and swift actions taken by the industry and the administrators, from the cash withdrawals at counters to now 24X7 accessibility of all bank services, to Fintech's redefining payments and loans. Banks have changed from being a place to store cash to a platform for financial services. They provide for practically all a person's direct and indirect requirements by providing them with financial goods or services that improve their quality of life. The industry has advanced farther and more quickly during the last two years. Banks are increasingly concentrating on experience-driven, platform-based banking, utilizing the bigger ecosystem, for the routine financial services experience to transition to a totally virtual environment. The prospects of digital banking in India have effectively gained an entirely novel aspect because of Covid-19. The usage of digital technology in India grew rapidly during the pandemic.   Transition was facilitated at the local level by the introduction of new digital engagement from other financial firms (Bank of Baroda, 2022).

Digitisation
Digitizing processes and reinventing digital technologies are today's top strategic banking priorities as banks aim to increase efficiency and modernize their infrastructure across the board. Processes like customer onboarding have already seen a change from paper-based to digital onboarding. Today's customers, however, look for customized service designs that are interesting and in line with what Internet businesses are delivering. To meet the customer's expectation, banks must therefore speed up the digitisation process. It will result in fundamental process changes that will lower costs, increase employee productivity, and facilitate smooth customer interactions.

Growth of banking as a service (BaaS) Model
As banks permit other partners to utilize their core infrastructure, which includes technology and regulatory licenses, to expand their products and services to a larger market, the idea is emerging as a game-changer for many of them. Banks profit greatly from this since downstream organizations like FinTechs, NBFCs, NEO Banks, and others use their services to access novel markets and clientele. With the use of BaaS, banks can act as a market for financial products due to their regulatory arbitrage.

Modernising payments
The backbone of the Indian economy is its payment and settlement systems. The pandemic has been crucial for the digital payments sector specifically since it has ushered in new advances, which have been supported by regulatory assistance, technological breakthroughs, and industrial transformation. This expansion has largely been facilitated by UPI. However, upgrading the infrastructure to support digital payments is necessary to create a strong payments ecosystem. Due to the expanding adoption of e-commerce and the growing number of physical acceptance points, Cards—namely credit, debit, and prepaid—are currently one of the reliable drivers to the expansion of digital payments.

The proliferation of Super apps
The days of using an app to access a specific service are long gone. For instance, many apps that initially served a single purpose have evolved to offer a variety of services in order to increase their portion of the user's pocket. For its consumers to be able to utilize their apps for all their daily requirements, banks must put in a lot of work and money. In order to anticipate what the user will need next, banks will need to rethink their customer journeys and point of encounter, leveraging data to inform logical recommendations and ideas. These are all essential elements of how banks can increase their users' wallet shares. Fintech's are helpful partners in the transition from a single-use case

Nisha Sunil and Anitha s Yadav

interface to a daily use app since they not only operate as integrators of such complementary services but also have a keen understanding of how to use data to create a truly wonderful customer experience.

Collaboration with FinTech

The future lies in partnership-based growth in a disruptive environment. Due to historical issues and a complicated decision-making process, banks are less adaptable and sensitive to shifting market conditions. For instance, many banks struggle to expand their card business despite possessing lucrative retail franchisees. Banks need the ability to introduce card schemes that are tailored for a consumer with all the characteristics that such a customer demands because cards (including credit, debit, and other types) are significant income generators. On the contrary, FinTech's are designed to be incredibly adaptable and sensitive to markets. Currently, banks and fintech companies work together to open accounts, manage balances, carry out transfers, invest in savings products, and provide access to prepaid/multi-currency instruments as well as on-demand short- and long-term credit products. They can support banks in expanding their clientele, broadening the market for financial services, particularly lending, and boosting GDP. Overall, this can lead to reduced transaction and acquisition costs, faster processing times due to digitization, the use of multiple media like mobile, and increased consumption among consumers, particularly young people through influencing their choices (BFSI, 2022). According to the RBI, the banking institutions in India are well-funded and subject to tight regulations. India has much superior monetary and economic standing than any other country in the world. Recently, cutting-edge banking methods like payments and small finance banks have been established. India has recently focused on enlarging the reach of its banking system through several programs, including the Pradhan Mantri Jan Dhan Yojana and Post Payment Banks. Such initiatives have notably accelerated financial inclusion in India and quickened the country's credit cycle along with extensive banking sector reforms including neo-banking, digital payments, the expansion of Indian NBFCs, and fintech. The Immediate Payment Service (IMPS), the only payment method ranked at level five in the Faster Payments Innovation Index (FPII), has experienced the fastest growth in its digital payments' infrastructure among the 25 nations. In recent years, India's Unified Payments Interface (UPI) has functioned to broaden its universal reach and transformed real-time payments (Indian Brand Equity Foundation, 2023).

Risks, challenges and potential vulnerabilities associated with the integration of IT in the banking sector

The integration and significant dependence on information technology (IT) in the changing terrain of modern banking has created numerous opportunities and breakthroughs. But there are challenges and dangers along this path to transformation. A number of risks, difficulties, and vulnerabilities arise when banks digitize their operations more and more; these need to be carefully considered and strategically mitigated. As researchers like Kumar et al., (2021) indicate, the field of cybersecurity becomes increasingly important due to dangers ranging from sophisticated cyber-attacks to data breaches. There are numerous operational concerns, including the possibility of interruptions, outages, and difficulties during data migration while implementing new IT systems (Acharya et al., 2019). The complex world of regulatory compliance is explored by He et al., (2020), who highlight the legal repercussions that may arise and the delicate balancing acts that must be performed in order to adjust to rapidly changing technology landscapes. The intricate obstacles that banks have in navigating this digital frontier include vendor and supply chain risks, customer privacy issues, the threat of technological obsolescence, and the human element in IT security. In order to maintain the advantages of technological integration and strengthen the resilience of the banking industry, it is critical that banks have a thorough awareness of the risks and challenges associated with the rapidly changing financial technology landscape.

Cybersecurity risks

A major risk for the banking industry is cybersecurity. Banks are susceptible to a range of cyberthreats, including malware, phishing, and hacking (Kumar et al., 2021). The likelihood of cyberattacks and data theft has increased as banks depend more and more on digital channels for consumer communications and transactional processes.

Nisha Sunil and Anitha s Yadav

Operational challenges

The deployment of new IT systems may encounter operational issues that result in service delivery interruptions, system outages, and challenges with data migration management (Acharya et al., 2019). The general effectiveness and dependability of banking operations may be impacted by these difficulties.

Regulatory compliance and legal risks

The banking industry is subject to stringent regulatory systems. Technology advancements may make compliance more difficult, and breaching regulations may have legal repercussions (He et al., 2020). To minimize legal concerns, IT systems must be in compliance with regulations.

Customer privacy concerns

The gathering and processing of large volumes of consumer data by banks for tailored services raises the possibility of privacy violations. Consumer mistrust of financial institutions might be worsened by anxieties about data privacy and possible exploitation of personal information (Kshetri, 2020).

Vendor and supply chain risks

Banks frequently depend on outside suppliers for IT solutions. Because of this reliance, there are dangers related to these suppliers' security policies. Significant risks can arise from problems like supply chain vulnerabilities and relying on outside parties for essential services (Schneier, 2021).

Technology obsolescence

Existing IT infrastructure may become outdated as a result of rapid technological improvements. According to Mohanty et al., (2016), banks may encounter difficulties in keeping up with the rapid advancement of technology and may encounter difficulties in upgrading their legacy systems.

Human factor risks

Mistakes committed by employees, deliberate wrongdoing, or ignorance of cybersecurity procedures can all be serious hazards. Internal risks could be caused by inadequate programs for awareness and training (Safa et al., 2019).

Financial fraud and identity theft

A greater dependence on digital transactions puts banks and their clients at risk of identity theft and financial fraud. Cybercriminals could take advantage of flaws in online systems to commit fraud (Jang-Jaccard et al., 2019).

CONCLUSION

A phenomenal talent pool is driving the banking and financial technology change in India. Innovation in digital banking will open possibilities for client inclusion if there is a willingness to adapt, parallel effort on the part of the government, and close monitoring by the RBI. The size and complexity of the Indian banking system will continue to increase as it drives the nation's economy forward and integrates various financial sector components. It follows logically that both domestic dynamics caused by continued returns and international trends in the financial sectors will affect how Indian banking develops in the future. With the aid of information technology, banking has been reformed and reengineered, and it is certain that, as product and process advancements continue, individuals will receive enhanced amenities from banks in the future. On a whole, banks must use a diverse and proactive approach to overcome the risks and difficulties associated with the integration of information technology. Strong cybersecurity measures must be put in place, operational difficulties must be addressed with careful planning and phased implementation, and regulatory compliance must be seen as a chance for creativity. Clear communication with

clients about data protection, robust vendor due diligence, and a commitment to continual innovation can jointly mitigate possible weaknesses. Establishing a robust and customer-focused digital banking ecosystem is facilitated by industry collaboration, alliances with cybersecurity specialists, and the integration of cutting-edge technology like artificial intelligence. Banks can ensure the security of their operations and position themselves for long-term success in the changing financial landscape by adopting these measures and navigating the challenges of technology integration.

ABSTRACT

A computer vision approach, which helps in locating various elements in an image/video can be called as object detection. Various CNN models can be built for processing the input, with efficient accuracy score. In this paper, an approach of Deep Learning, known as Transfer Learning is used for measuring the performance of various pre-trained models for detecting objects from fruit images. Fruits360 dataset is used for testing and training the pretrained models. Performance metrics of various pretrained models like VGG16, VGG19, MobilenetV2, GoogleNet, InceptionV3, ResNet18, ResNet50, DenseNet121 and Alexnet are evaluated and compared using Fruits360 dataset for object detection.

Keywords: Object Detection, Performance Metrics, Pretrained Models, Fruits360 dataset, Transfer Learning

INTRODUCTION

Computer vision has been recognized as one of the most important applications of Deep Learning concepts, which has its primary focus on extracting the metadata of the image or video input to the convolutional neural network. This extraction is possible with the help of certain detection techniques like detecting objects from the image/video, motion detection, cluster based detection, detection based on features like color, shape, etc.[1][3] In this paper, one of

79902

Dishita Mashru and Vithalani

the techniques of metadata extraction, i.e. object detection is used to detect the objects from the images. This approach can be implemented by creating a convolutional neural network and providing the set of training images as an input to it, or by using the concept of Transfer Learning, which gives the provision of using the predefined CNN models, and hence one doesn't need to create a CNN model from the scratch [2]. The concept of Transfer Learning improves the performance of object detection application by reducing the training and testing time of the model while the larger datasets are provided for input to the neural networks. Also, unlike common CNN models, the models defined by the Transfer Learning approach, also known as Pretrained Models, doesn't require the training and testing dataset to be mutually dependent on one another.[2]As discussed, the transfer learning approach for object detection, using various pre-trained models is used in this work. The models used are namely VGG16, VGG16, VGG19, MobilenetV2, GoogleNet, InceptionV3, ResNet18, ResNet50, DenseNet121 and Alexnet. These models are trained using Fruits360 dataset [4], which contains 131 classes of fruits, with 90,483 sample images [5], out of which 67692 images (one fruit or vegetable per image) are used for training and 22688 images (one fruit or vegetable per image) are used for testing [4]. In this paper, various performance metrics like training and validation accuracy, Kohen's Kappa Value, F1 Score, Precision Score, Recall, etc.[6] have been evaluated to compare the pre trained models mentioned above. In the present work, the values of the parameters used to evaluate the performance of the pretrained models, apart from those mentioned above, have been kept fixed for each and every model. For instance, the number of classes in the dataset is 131, batch size for training the model is 128, number of epochs for training the pretrained model is 5, learning rate for the model is set to 0.01 and the mean and standard deviation values set to [0.485, 0.456, 0.406] and [0.229, 0.224, 0.225] respectively.

Pretrained Models

Using pretrained models in the deep learning applications has been considered one of the dominant approach in the transfer learning methodology. This approach is useful in advancing the model performances where there is a presence of subsequent amount of noise in the input dataset. [7]. Some of the applications of pretrained models include: Natural Language Processing, Computer Vision, Content Creation and Virtual Assistants [7]. The VGG16 model is the simplest of all the models available in Keras Library. The architecture is divided into two parts- Convolution Base which is being developed from a sequence of connecting layers, also known as MaxPooling2D and convolution layers, i.e. Conv2D. The other part of the architecture is the classifiers are densely connected and situated at the latter part of the network. This architecture is found suitable for classification problems used in image processing. The important point to note about this architecture is that the outputs produced by this model is based on the tested dataset of image classes on which the model was trained.[13]VGG19 is CNN model which has 19 layers in its architecture. This pre-trained model is capable of classifying the images belonging to almost 1000 categories, which is the result of its training over millions of images from the ImageNet dataset[12]. The 19 layers of this model consists of 16 convolutional layers and three layers which are fully connected [14]. The GoogleNet architecture has been considered to be the first application of the modern neural networks architectures, which uses the Inception model, and isdoes not consist only sequential convolution as well as pooling layers. There are around 7 million parameters in this architecture.[15].The presence of inception modules, this architecture becomes complex structurally, and also utilizes more memory and power. This might also result in increase of memorization.[16].

Resnet18 and Resnet50 are collectively a part of a transfer learning approach known as Residual Network. This network is more deeper than the normal artificial neural networks. Hence, it increases the accuracy and eases the training of the architecture.[17]. The residual networks come in may variants, based on the number of layers it consists, viz. 18 layer, 34 layer, 50 layer, 101 layer, 152 layer. The Densenet121 architecture inculcates the coupling of each layer in a feed forward manner. Suppose there are X layers in the model, then the number of direct connections will be $X(X+1)/2$. The model merges the output features with the input features, and hence, it becomes important for each layer to gain the collective knowledge of its previous layers.[18] .This architecture is best suitable for the models of the neural networks where it is necessary to reduce the gradient problem, keeping the minimum number of parameters, and feature reusability.The only drawback of this architecture is the excessive usage of memory due to the concatenation of the tensors. For InceptionV3 architecture, there is a sequence of layers which are used to divide and bunch the relationship statistics of the last layer with high connections. These bunches are used to shape the

79903

units of the past layer. It has been defined previously that every unit from the former layer will be compared with some portion of the input image and then the bunch of these units would be assembled together into filter banks. [18]. The MobileNet architecture is being designed considering the convolutions that can be separated on the basis of the depth of the network architecture. This results in a lightweight deep convolution network that shrinks the overall size of the network and as a result, reduces the computation time for training and validation. This architecture has its core applications in detecting objects from images, face detection algorithms, classification and other computer vision applications.[19]. The last pretrained model used, AlexNet, is able to handle multiple GPUs , and the network is designed to handle larger images of the dimensions 224x224x3. It has a capacity to train 62 million parameters in total.[20].

Comparison of the pretrained models

The performance of the above mentioned pretrained models was measured using the metrics like Training and Validation Accuracy/Loss to train the model, Accuracy, Precision, Recall, F measure, Coheran's Kappa value, discussed in this section.

Training and Validation Accuracy

The model was provided the Fruits360 dataset to classify the fruit images, belonging to 131 predefined classes. The number of epochs to be processed were limited to 5, and the learning rate set to 0.01. From this, we had tried to obtain the training accuracy, as well as validation accuracy, depicted in the following:

Accuracy

To evaluate any deep learning model, it is necessary to get the number of correct and incorrect predictions/classifications. This may be classified into True Positive (i.e. predicted and actual values are same and positive), False Positive (predicted values are positive but the actual outcomes are negative), False Negative (predicted values are negative but the actual outcomes be positive), and True Negative (both the predicted as well as actual values are negative). For any pre-trained model used for classification of images, the accuracy of the model can be observed by dividing the total number of correct classifications by the total number of classifications possible. From the above description of the possible classifications, we can obtain Accuracy of the model using the following formula:[6]

$MODEL\ ACCURACY = \frac{TP+TN}{TP+FP+FN+TN}$ ……………………………………………….(1)

In this work, the observed accuracies of all the pretrained models used are as depicted in the following chart:

Precision

The precision parameter of a pretrained model gives the proportion of the classification values which are actually true positive. This value indicates how reliable a model is to classify the correct class of interest. The value of precision can be obtained using the following equation: [6]

$PRECISION = \frac{TP}{TP+FP}$ ……………………………………………………(2)

The following graph depicts the precision values of the pretrained models used:

Recall

This metric gives the observed values of true positive cases with respect to the total positive cases. For example, in our dataset, the proportion of the total objects detected as kiwi which were classified correctly is defined by Recall. One can calculate the recall value using the formula:

$RECALL = \frac{TP}{TP+FN}$ …………...……………………………………………(3)

The following graph shows the observed values of recall for the pretrained models used.

F-Measure

This gives the harmonic mean of the precision and recall values, which is calculated as

$F\ MEASURE = \frac{2 X PRESCISION X RECALL}{PRECISION\ + RECALL}$ ………………………………………….(4)

Cohen's Kappa

It may happen in certain cases that both True Positive as well as True Negative values may happen together coincidentally. This causes the accuracy value to rise drastically, but ideally this should not happen. The Cohen's Kappa value is calculated as below:

Kappa Value (k) $= \frac{P(a) - P(p_r)}{1 - P(p_r)}$ …………………………………………(7)

P(a)=proportion of observed argument between actual and predicted in overall dataset

$= \frac{TP + TN}{TP + FP + FN + TN}$

$P(p_r)=$ Proportion of expected agreement between actual and predicted data both in case of class interest as well as the other classes.

$= \frac{TP + FP}{TP + FP + FN + TN} X \frac{TP + FN}{TP + FP + FN + TN} X \frac{TN + FN}{TP + FP + FN + TN} X \frac{TN + FP}{TP + FP + FN + TN}$

Observing the values obtained for the above mentioned performance metrics, we can summarize the observations in the following table:

CONCLUSION

This paper observed the performance of the pretrained models used for object detection using the Fruits360 dataset. The performance metrics for measuring the same has been described in detail. From the observations, we can say that AlexNet Model gave the maximum accuracy for object detection in lesser amount of time taken, as compared to the other pretrained models. DesnseNet and GoogleNet had near about 95% accuracies respectively, which can also be considered remarkable, but DenseNet took more amount of time than AlexNet and GoogleNet both. ResNet also had 95% accuracy but took the maximum training time. Hence, observing all the performance metrics, AlexNet model was found to be the most efficient pretrained model for object detection.

ABSTRACT

Plithogenic Cognitive Maps (PCM) are attribute centric, robust and flexible decision-making models that facilitate in investigating the relational impacts between the factors of the study. PCM models are a generalized form of cognitive maps discussed with various representations of sets. This paper introduces an alternate decision approach to PCM integrating with Extended PlithogenicSociogram (EPSo). In this newly designed integrated approach, both the dominant and the recessive attributes are considered to make comprehensive decisions. The proposed blended approach is advantageous as it facilitates to study the extent of the relational impacts between the factors subjected to significant attributes of the factors. This method also assists to determine the most influential factor which will benefit the decision-makers to strategize and devise suitable policies and framework as further course of action. The efficacy of the model is illustrated by applying to make decisions on the factors promoting green industries.

Keywords: Plithogenic Cognitive Maps, PlithogenicSociogram, Green Industries

INTRODUCTION

Plithogenic theory is purely attribute based and it is considered to be the generalization of all types of set representations The inclusive nature of Plithogenic sets of the form (P,a,V,d,c) has drawn the attention of researchers to develop Plithogenic based decision models. This quintuple Plithogenic sets is more concerned on the dominant attribute values subjected to each of the attributes. A decision instant which is primarily concerned over the

significant attributes values facilitates in accepting the ideal alternatives. However, it is equally essential to consider the recessive attribute values also to make decisions on eliminating the alternatives. Sudha et al [1] discussed the notion of Extended Plithogenic sets (EPS) which includes the concept of recessive attributive values. The extended version of Plithogenic sets is a seven tuple of the form (P, a, V, dD,cD,dR,cR) where d, the degree of appurtenance and c, the degree of contradiction considered with respect to both the dominant and recessive attributive values. Researchers have developed several Plithogenic based decision models, however, the models based on extended Plithogenic sets are very limited in literature. A few decision models integrating Extended Plithogenic sets with Plithogenicsociogram, Plithogenic multi-criteria decision making and Plithogenic cognitive maps are constructed. Plithogenic Cognitive Maps are developed to study the interrelational impacts between the factors using Plithogenic theory. The PCM models developed by Martin and Smarandache [2]are more generalized in nature to accommodate any kind of representations. Researchers have formulated many Plithogenic based PCM models such as New Plithogenic sub cognitive maps, Induced Plithogenic Cognitive Maps, Plithogenıc Combined Disjoınt Block Fuzzy Cognitive Maps, PCM with Linguistic Contradiction Degree Representations. PCM models are also applied in several domains of medical, spiritual intelligence and many other. Martin and Smarandache[9] jointly worked on the theoretical arguments of PlithogenicSociogram. Sudha et al [1] discussed PlithogenicSociogram with extended Plithogenic sets and evolved the notion of Extended Plithogenic Sociogram. The decision approach based on EPS is applied as an alternative to Plithogenic based multi-criteria decision making. PlithogenicSociogram is integrated with Plithogenic Cognitive Maps to devise a novel decision-making method. Plithogenic Cognitive Map models basically investigate the interrelational impacts between the factors of the decision problem and the integrated Plithogenicsociogram based Plithogenic Cognitive Map approach facilitates in identifying the most influential factors. Based on this integrated approach, in this research work, a similar kind of blended decision approach is formulated with extended PlithogenicSociogram. The efficacy of the proposed hybrid approach is measured by applying to find the most influential factor contributing to the promotion of green industries. On investigating the need of such a hybrid model, the following research gaps are identified,

(i)   The PCM model in general facilitates only in determining the interrelational impacts between the factors of the study

(ii)   PCM based PlithogenicSociogram decision model helps in identifying the most influential factor using the interrelationships only with respect to the dominant attribute values. However, the above-mentioned decision models do not consider the recessive attribute values and this lacks the holistic approach of making optimal decisions. This has motivated the authors to develop a more holistic model by including both the dominant and recessive attribute values. The remaining contents of the paper are presented in the following sections. The methodology of the integrated approach is presented in section 2. The application of the proposed approach is discussed in section 3. The results are discussed in section 4 and the concluding remarks with future directions are presented in section 5.

Methodology of Integrated Approach of PCM and EPSo

This section presents the steps followed in the newly introduced integrated approach of PCM and EPSo.

Step 1: The problem definition is the first step in which the problem to be resolved is considered with therelated core factors say F1,F2,..Fm (Attributes) and the sub-factors (Attribute values) say F11,F12,….F1j, F21,F22,…,F2k, ……, Fm1,Fm2,…Fmy. The decisive factors day D1,D2,..,Dn whose interrelational impacts are to be investigated are also determined together with the choices the of dominant and recessive attribute values.

Step 2: Based on the domain experts, the proximity between the decisive factors or the associational impacts between the factors are determined with respect to the dominant attribute values pertaining to each of the attributes. Let us consider an expert E1 using the representations of the form {D2((F1j)(dβj),F2k(dβk),… Fmy(dβy)), D3((F1j)(dαj),F2k(dαk),… Fmy(dαy)), … Dn((F1j)(dμj),F2k(dμk),… Fmy(dμy))} to state the decisive factors such as D2, D3,..Dn having proximal relation with the decisive factor say D1 with respect to the dominant attribute values. The values dβj, dβk,.. dβy are the degrees of appurtenance stating the proximal relationship between the decisive factors.

Step 3: The above step is repeated with respect to the recessive attribute values to determine the deviations between the decisive factors. In this case, the degrees of appurtenance state the deviance in relationship between the decisive factors.

Step 4 : The Evaluation matrix with respect to each of the dominant attribute value and recessive attribute value is formulated to and the combined evaluation matrix is also determined by considering the weight of the attribute values (both dominant and recessive) and the weightage given to the experts.

Step 5 : The Plithogenic amicability degree with respect to dominant attribute value say tD_{gh}, is calculated using $\frac{2}{tD_{gh}} = \frac{1}{fD_{gh}} + \frac{1}{fD_{hg}}$ and the Plithogenic non-amicability degree with respect to recessive attribute value say tR_{gh}, is calculated using $\frac{2}{tR_{gh}} = \frac{1}{fR_{gh}} + \frac{1}{fR_{hg}}$, Where fD_{gh} presumes the associational impact between the factors g and h and fD_{hg} represents the associational impact between the factors h and g in proximal sense, also, fR_{gh} presumes the deviational impact between the factors g and h and fR_{hg} represents the deviational impact between the factors h and g in deviance sense. The values say tD12 with respect to dominant attribute value and tR12 with respect to the recessive attribute value determines the range of values stating the extent of associational impacts.

Step 6 : The most influential factor shall be determined with respect to the dominant attribute value using $\frac{\sum_h tD_{gh}}{\sum_g \sum_h tD_{gh}}$. The extent of diminishing the possibilities of ranking the influential factors shall be determined with respect to the recessive attribute values using $\frac{\sum_h tR_{gh}}{\sum_g \sum_h tR_{gh}}$.

Step 7: The final ranking of the factors is determined by finding the differences between the score values with respect to the associational and deviational impacts considering equal and unequal weightages.

Application of the Integrated Approach in Decision making on Promoting Green industries
In this section, the novel integrated approach proposed in section 2 is applied to make decisions on the factors influencing the promotion of green industries.

Problem Definition
Industrial sectors are mostly contributing to the economic growth of every nation and equally contributing to the environmental deprivation. The onset of several industries has been drawing the end of the natural resources and puts the future generation to a large disarray. It is quite inevitable for the industrial sectors to minimize their production as such course of actions will certainly affect the functioning of the populace resulting in shortages. This is the vantage point where the industries are compelled to be eco-friendly and this is the origin point of Green Industries. In the context of Green industries, the industrial sectors are expected to practice green initiatives in all its activities of pre-production, production and post production. But, how does these industries shall promote green environment or the sustainable environment. What are the aspects should these industries consider in promoting eco-sustainability? Which action-based initiative shall be concentrated more or which factor shall be implemented based on their flexibility? These are some of the practical problems faced by the industrial sectors on promoting green industries. To resolve this, the proposed approach is applied as follows

Literature review on the attributes of Green industries
The green industries are the need of the hour and the attributes or the characteristics of the green industries are to be identified to decide the decisive factors. The following table 1 presents the state of art with respect to some characteristics of green industries and they are determined as the core attributes.
The above table clearly explicates that the environmental researchers have strongly favoured the above-mentioned characteristics of green industries and henceforth they are considered in the further modelling procedure.

Expert's Opinion on Attributes, Attribute Values, Decisive Factors, Dominant and Recessive Attribute Values.
The experts chosen from the environmental domain have given their expertise in making initial decisions on the following:

Decision on Attributes

The attributes considered for modelling are presented in Table 2 and they are determined with the assistance of expert's opinion and the literature review of the work mentioned in Table 1.

Decision on Sub Attribute Values

Since the model is embracing the theory of Plithogeny, the sub attribute values of each of the attribute is determined and presented in Table 3.

Decision on the Decisive Factors proposed for promoting Green Industries

The following factors are considered as the decisive factors based on the Expert's opinion and the intention is to find the most influential factor.

F1: Establishing collaboration with the stakeholders to evolve green practices

F2: Integrating eco-friendly technologies to create carbon neutral communities

F3: Formulating policies and strategies backing renewable energy and sustainable practices

F4: Exercising corporate social responsibility endeavours.

F5: Developing products with eco-consciousness and societal concerns

Decision on Dominant and Recessive Sub Attribute Values

The dominant and recessive sub attribute values are decided based on the opinion of the experts and it is presented in Table 4.

Determination of the Influential Decisive Factor using the integrated approach

Case (i) Proximity Between the Factors with respect to the Dominant Attribute Values

The expert's opinions are considered in determining the factors proximal to one another based on the dominant sub attribute values and are presented in Table 5.

The Evaluation matrices Mi, (i = 1,2..5) for each of the dominant sub attribute values are presented in Table 6.

Case (i a) Sub Attribute Values with Equal Weightage. In this case, the sub attribute values are assumed equal weightages of 0.2 each and the combined evaluation matrix is computed using step 4 and it is presented in Table 7. The amicability degree is determined using the step 5 and it is sketched out in Table 8. The respective score values of the decisive factors with respect to equal sub attribute weightages are presented in Table 9

Case (i b) Sub Attribute Values with Unequal Weightage

In this case the sub attribute values are assumed different weightage values based on the expert's opinion. (AT11 = 0.1, AT21 = 0.2, AT31 = 0.3, AT41 = 0.2, AT51 = 0.2)

The amicability degree is computed as follows and it is presented in Table 11. The respective score values of the decisive factors with respect to unequal sub attribute weightages are presented in Table 12

Case (ii) Deviance Between the Factors with respect to the Recessive Attribute Values

The expert's opinions are considered in determining the factors deviant to one another based on the recessive sub attribute values and are presented in Table 13.

The Evaluation matrices Ni, (i = 1,2..5) for each of the recessive sub attribute values are presented in Table 14.

Case (i a) Sub Attribute Values with Equal Weightage

In this case, the sub attribute values are assumed equal weightages of 0.2 each and the combined evaluation matrix is computed using step 4 as in Table 15. The non-amicability degree is determined using the step 5 and it is presented in Table 16. The respective score values of the decisive factors with respect to equal sub attribute weightages are presented in Table 17

Case (i b) Sub Attribute Values with Unequal Weightage

In this case the sub attribute values are assumed different weightage values based on the expert's opinion. (AT13 = 0.2, AT23 = 0.3, AT33 = 0.2, AT43 = 0.1, AT53 = 0.2).The combined evaluation matrix is presented in Table 18.

The non-amicability degree is computed as follows and it is presented in Table 19. The respective score values of the decisive factors with respect to unequal sub attribute weightages are presented in Table 20. The ranking of the factors is determined by finding the difference in the score values obtained with respect to both dominant and recessive attribute values. The final ranking of the factors under two cases of equal and unequal weightages are presented in Table 21.

Comparative Analysis
This section compares the efficacy of the proposed approach of Plithogenic Cognitive Maps with Extended PlithogenicSociogram with the extended plithogenic cognitive maps. The former ranks the factors considering both the associational and deviational impacts whereas the latter represents the associational impacts between the factors with respect to both dominant and recessive attribute values. The extended plithogenic cognitive analysis of the factors is determined as follows:

Formulation of Plithogenic Connection Matrix
The Plithogenic connection matrix is developed which state the expected associational impacts between the factors in terms of fuzzy values and it is presented in Table 22.

Contradiction degrees of the Factors with respect to the Dominant and Recessive Attribute Values
The impact between the factors is determined using the contradiction degree presented in Table 23
The associational impacts between the factors are determined using the approach discussed by Angel et al and the results are presented in Table24

Inferences
The rankings of the factors presented in Table 13 facilitates in identifying the most crucial factor in promoting the green industries. The rankings obtained with respect to equal and unequal weightages of the attribute values result in an almost similar manner. It is evident that the factor F1 is more significant and it is more influential amidst other factors in both the cases of equal and unequal weightages. Moreover, the inter associational impacts are presented in Table 15 which shows the relational impacts between these factors with respect to each of the dominant and recessive attribute values. This will facilitate the decision makers to identify the influence of each of the factors with respect to specific attribute values. However, the Extended Plithogenic cognitive map approach assists only in determining the associational impacts between the factors but not in identifying the influential factor. This is resolved with the integrated approach proposed in this work. The amicability and non-amicability degrees with respect to the attribute values states the relational impacts and the ranking of the factors identifies the influential factor.

CONCLUSION

This research work presents a hybrid decision making method integrating Plithogenic cognitive approach with extended Plithogenicsociogram approach. The proposed approach facilitates in identifying the influential factor in addition to the relational impacts between the factors. The validity of the decision-making model is determined by applying it to the context of finding the most influential factor that the business people or the policy makers shall implement to promote green industries. This integrated model shall be further developed and extended by embracing different kinds of Plithogenic representations.

Environmental Conservation	Ho.,2014 [28], Dhull and Narwal.,2017 [29], Xu et al., 2021 [30], Zhou et al., 2023 [27]

Table 2. Description of the Attributes

Attributes of Green Industries	Description
Resources Utilization (AT1)	Optimal utility if the resources
Carbon Neutrality (AT2)	Minimization of carbon emissions
Sustainable Technology Interface (AT3)	Use of eco-friendly technology in production
Waste Management (AT4)	Management of different types of wastes
Environmental Conservation (AT5)	Preservation of natural resources and biodiversity

Table 3. Attribute Values

Attributes	Sub Attribute Values		
Resources Utilization (AT1)	High Efficiency (AT11)	Intermediate Efficiency (AT12)	Low Efficiency (AT13)
Carbon Neutrality (AT2)	Minimal Emissions (AT21)	Moderate Emissions (AT22)	High Emissions (AT23)
Sustainable Technology Interface (AT3)	Advanced (AT31)	Basic (AT32)	Non-basic (AT33)
Waste Management (AT4)	Effective (AT41)	Average (AT42)	Ineffective (AT43)
Environmental Conservation (AT5)	Strong (AT51)	Medium (AT52)	Weak (AT53)

ABSTRACT

Oral health is important for overall health of the body. We are what we eat. We should be aware of the nutrition and balanced diet we take. Numerous oral health disease are a result of lack of knowledge, care and poor diet. Diet should be rich in micro as well as macro nutrients. In this article we have discussed various factors associated with the common oral diseases. It's causes and role of nutrition. The role of sugars in dental caries is well known but still it's prevention is not controlled due to it's multifactorial behaviour. Periodontal diseases which are accumulated over the years and present late in life has many risk factors which are discussed at length.

Keywords: Oral Health, Sugars, Caries, Periodontitis, xerostomia, Nutrition

INTRODUCTION

Oral health depends on the same nutritional factors as the overall bodily health. It includes routine maintenance, a healthy non sedentary lifestyle and nutritional food. Healthy nutrition influence the progression and development of oral diseases and conditions such as enamel erosion, gingivitis, periodontal disease and dental caries.1 Impact of nutrition on oral health-

CARIES
The standard classification of sugars by Committee on Medical Aspects of Food Policy (COMA) is based on the location of sugar molecule within the food or drink.

Total sugars
Intrinsic Sugar: Sugar molecules inside the cell e.g. fresh fruit & vegetables.
Extrinsic Sugar: Sugar molecules outside the cell. This is of two types

MILK SUGARS
E.g. lactose in dairy products.

NON-MILK EXTRINSIC SUGARS (NMES)
e.g. table sugar, confectionery, honey fruit juice. According to Rugg Gunn 1993 NMES are highly cariogenic. Milk extrinsic sugars are virtually non cariogenic. Non- sugar sweeteners are non cariogenic. According to the recommendations on diet and caries the amount of NMES must be reduced and should be taken with meals in less frequency. Consumption of intrinsic sugars such as fresh fruits, vegetables, should be increased to 5 pieces/ portion of fruit or vegetable / day. According to Department of Health 1989; WHO 1990 the energy provided by Non milk extrinsic sugar (NMES) should not exceed 10% of total energy in diet.2 Various types of sugars available in eatable products

Coupling Sugar
When a mixture of starch & sucrose are allowed to act upon by enzyme cyclodextrin glucosyltransferase, derived from Bacillus megaterium, a mixture of glycosylsucrose, maltosylsucrose, monosaccharide & oligosaccharides is formed which is termed coupling sugar. The acid production by fermentation of this sugar is much less than obtained with glucose & sucrose. Very little insoluble glucans are produced for adherence of S mutans.

Sucrose
it is a non reducing disaccharide. It has a positive optical rotation & can be readily hydrolyzed. Sucrose being fermentable resists bacterial decomposition at higher concentrations. Sugar cane & sugar beet are the main industrial sources of sucrose. Sucrose serves in the formation of insoluble extracellular polysaccharides & enhances plaque formation & microbial aggregation on tooth surface. The adhesion of S. mutans is promoted by the glucans which is the most important determinant of virulence of them on smooth surface.

Invert sugar
The resulting mixture of glucose & fructose is known as invert sugar which has a negative optical rotation. It is slightly sweeter than sucrose.3 Plaque pH

Stephans curve
Robert Stephans 1940 was the first person to demonstrate changes in plaque pH after every consumption of food items which was responsible for demineralization procedure. In his experiments he demonstrated that after a rinse with sucrose solution (10 ml of 10% sucrose solution for 10 seconds). The mixed bacteria in dental plaque are responsible for uptake of sucrose and acid production and rapid drop in pH. pH in the range of 5-5.5 was termed critical pH as at this pH the saliva stops to get saturated with mineral such as calcium and phosphates. Initially there is drop in the plaque pH and it takes almost 20 minutes for the pH to attain its resting value. Depending upon the other factors influencing the drop in pH such as microbial composition of plaque, the type of carbohydrate consumed and rate of diffusion of substrate in plaque it may take even longer 40 minutes for the plaque to achieve the resting pH.20

Buffering System
The buffering agents are bicarbonates, the phosphates and the protein buffer systems. Bicarbonates are most important because it can buffer rapidly by losing carbon dioxide. Its pK is close to that encountered in plaque & therefore it is more effective. As flow rate increases bicarbonate concentration increases dramatically whereas phosphate falls slightly. After removal of bicarbonate by a current of CO_2-free air at pH 5, the buffering capacity of saliva is markedly reduced. Sialin is an argenine peptide which rapidly clears glucose from plaque, increases base

79924

formation and increases pH. The human saliva are supersaturated with calcium and phosphates which is mediated by salivary proteins egstatherin, the acidic Prolin rich proteins, cystatins and histatinshistatins. 3,4

Trace elements
Zinc
Zinc helps in arresting demineralization of tooth LYNCH RJ. Studies indicate role of zinc in prevention of dental caries UCKARDES .Lower level of zinc systemically was associated with high caries prevalence ATASOY, however few studies do not support the utility of zinc in the prevention of dental caries.5, 6,7

Strontium
The deficiency of strontium may help form caries. The role of strontium in preventing dental caries was much studied in 1970s and 80s but till date the results of studies are inconclusive.8, 9

Iron
Iron interferes with the sucrose metabolism of streptococcus mutans thus reducing the production of extracellular polysaccharides and inhibits enzyme glucosyl transferase. 10

Saliva
Saliva is a mixture of major and minor salivary glands secretions. Saliva contains inorganic molecules such as electrolytes, mucin, immunoglobulins and various enzymes. Salivary antioxidant system is made of peroxidase, catalase, superoxide dismutase glutathione, peroxidase and small molecules, uric acid, Vitamin E & C. Immunoglobulins acts as defence against bacteria, viruses, fungi and promotes mucosal healing and enzymes. Antioxidants are helpful in prevention and progression of dental caries.15,16,There is a possible connection between dental caries & mucin(MUC1 & MUC5B) in saliva.17The main oral innate defence factors are the peroxidase systems,Lysozyme,Lactoferrin and histatins. they limit bacterial or fungal growth, intereference with glucose metabolism of bacterias, promote aggregation and elimination of bacteria.11

Lactoferrin
Iron binding basic protein.Tends to bind and limit the amount of free iron which is essential for microbial growth, this salivary protein is an active host defense mechanism.

Igs
They could bind to salivary pellicle blocking glucan-induced irreversible adherence or they could agglutinate bacteria. IgGs opsonize bacteria permitting phagocytosis by polymorphonuclear leukocytes or possibly macrophages.

Lysozyme
Small highly positive enzyme- catalyzes the degradation of the negatively charged peptidoglycan matrix of microbial cell wall. Binds to hydroxyapetite and maintains its activity after binding. Strong ionic interactions with bacterial cell walls and with the mucin in saliva.

Lactoperoxidase
Kills microorganisms- catalyzing the hydrogen peroxide mediated oxidation of a variety of substances in the microbes. High affinity for enamel surface and it forms an important defense mechanism limiting early microbial colonization of tooth surfaces. 12,11

Fluoride dentifrices
Tinanoff N 2005 in a CDE program in Chennai in 2005 pointed out the fluoridated dentifrices as the single most important factor for the global decline of caries. Downer reviewed caries prevalence in UK in the 20 yrs from 1973-93 and observed a 53% reduction of caries experience in 5 yr old children. He attributed this to the widespread use of

79925

fluoridated dentifrices. Brown regarded widespread use of fluoridated tooth pastes in reduction of dental caries prevalence in NZ. Changing levels of dental caries experience (DMFT) among 12-year-olds in developed and developing countries

Increased dental awareness

As stated by the joint working group of FDI and WHO in 1985, the increased dental awareness and the organized oral health education programmes may be few of the most probable reasons for dental caries decline. Adoption of preventive approach by the practitioner. The criteria for filling the teeth have changed over time with the advent of Minimal Intervention Dentistry (MI), smart restorative materials, Nanotechnology, etc. Increased use of professionally applied fluorides. Advent of sealants and preventive resin restorations in the routine dental practice.

NUTRITIONAL RISK FACTORS FOR PERIODONTITIS

Nutritional factors

vitamin deficiency, protein deficiency, starvation: Refined carbohydrate
Leads to Scorbutic, Rachitic, non-detergent diet gingivitis. Vitamin C deficiency leads to bleeding gums. Gastrointestinal disorders, syphilis, nephritis, liver disease, tuberculosis show signs in the mouth.

Physical disabilities

physical disabilities makes a person affected with it with lower neuromotor skills and thus poor maintenance of oral hygiene and thus rendering him more prone to gingival and periodontal disease.

Xerostomia

Xerostomia will lead to retention as well as lower clearance of food particle from mouth and reduced ability of natural oral clearance of food by the action of tongue, lips and cheeks thus increased chances of periodontitis.13
Drug induced disorders: Dilantin sodium used in treatment of epilepsy leads to gingival inflammation & enlargement. Chronic bismuth intoxication shows ulcerative gingivostomatitis.

Psychological or emotional factors

In such conditions a person is high strung and due to emotional upheaval salivary changes such as xerostomia or excess salivation can occur, lack of proper personal care can lead to poor oral hygiene and hence periodontitis or altered gingival conditions. Psychological factors has important role in necrotizing ulcerative gingivitis. Psychosomatic disorders exert their effect on periodontitis by the development of habits that are injurious to the periodontium.14

Metabolic conditions

pregnancy, puberty, menopause: Endocrine adjustments takes place during this time. There is generalized tissue enlargement with discoloration. Bleeding and mulberry like swelling and papillae become bulbous. There is adverse effect on periodontal structure during the course of pregnancy.

Endocrinal disturbances

diabetes mellitus, hyperparathyroidism and hyperthyroidism: The glucose level of saliva and blood in diabetic patients is more than normal which has the potential to alter the microflora towards more pathogenic bacterias. Due to polymorphonuclear leucocytes deficiencies in diabetes which results in impaired chemotaxis, defective phagocytosis thus making the diabetic individual more susceptible to periodontal infection. Most of the studies show statistically significant relationship between severe gingival inflammation and loss of attachment in diabetic group as compared to normal individuals which is more when there is increase in glucose level. Periodontal disease in diabetics presents with very severe gingival inflammation, deep periodontal pockets, rapid bone loss, frequent periodontal abscesses, greater loss of attachment, increased bleeding on probing and increased tooth mobility. 15

Revant H Chole and Swati Balsaraf

1,25(OH)2D3 has an important role in maintaining calcium and phosphate level in blood. Its deficiency leads to increased secretion of parathyroid hormone leading to rickets and osteomalacia. In Mice, vitamin D receptor (VDR)-mediated induction of osteoblast RANKL may account for enhanced bone resorption. Osteoporosis results in lowered density in jaw bones leading to altered trabecular bone pattern and rapid alveolar bone resorption followed by invasion of periodontal pathogens. Periodontal infection increases the systemic release of proinflammatory cytokines, which accelerate systemic bone resorption. Hypopitutarism exhibits with crowding of teeth, enlarged gingiva, delayed resorption of deciduous teeth, delayed formation and eruption of teeth. Hyperpitutarism exhibits spacing of lower teeth-jaw size. Thus people with poor metabolic control have higher frequency of gingivitis and periodontitis.16

Hematologic disorders
There is occurrence of hemorrhagic gingival overgrowth with or without necrosis as a common early manifestation of acute leukemia. Chemotherapy associated with bone marrow transplantation also adversely affect gingival health. Immune system disorder: leukocyte disorder, antibody disorders, HIV infection, persons on immunosuppressive drugs: Bacterial infections acts as a stimulus for systemic acute phase response resulting in increased production of acute phase proteins like C Reactive protein(CRP), macroglobulin and Serum amyloid. The bacterial endotoxins also stimulate the local host inflammatory mediators which finally results in serum antibody response to bacteria. Thus if the immune system is compromised it will be a risk factor for developing periodontitis. HIV infected patients exhibit Kaposi's sarcoma, necrotizing ulcerative gingivitis, necrotizing ulcerative stomatitis, necrotizing ulcerative periodontitis which results in inflammation and enlargement of gingiva.17

Stress
stress, depression and anxiety are considered potential risk factors to affect periodontal condition as these factors are risk indicators to take up health impairing habits such as smoking, tobacoo chewing, alcoholism, poor oral hygiene status and the pathophysiological factors that lead to higher glucocorticoid and catecholamine level which affects the immunological profile thus making the individual susceptible to periodontitis.10 stress related habits such as pencil biting are detrimental to periodontal health.17

Obesity
stress has been marked as a potential risk factor for uptaking unhealthy lifestyle which includes uptake of unhealthy food habits such as refined carbohydrates, fast food, which promotes plaque retention and thus periodontal and gingival diseases.18

Cardiovascular disorders
There is increase in C-reactive proteins and fibrinogen in periodontitis. Furthermore there is an increase in level of systemic markers of inflammation such as C-reactive protein and IL-6 in cardiovascular disease. Bacteremia from periodontitis and dental disease is known to be the primary cause of infective endocarditis.SALIVA: several inorganic and organic factors in saliva are important for bacteria and their products in oral environment. Saliva like GCF contains antibodies that are reactive with indigenous oral bacterial species. Salivary enzymes such as hyaluronidase , lipase, beta-glucuronidase, chondroitin sulfatase are present in increased concentrations in periodontal disease. Proteolytic enzymes in the saliva are generated by both host and oral bacteria which are contributors to the initiation and progression of periodontal disease.To combat these enzymes saliva contains antiproteases that inhibit cystine proteases such as cathepsins and antileucoproteases. Saliva contains coagulation factors that hastens blood coagulation and protects wound from bacterial invasion. Saliva exerts a major role in plaque initiation, maturation and metabolism. Calculus formation, periodontal disease and caries are dependent on salivary flow. An increase in inflammatory gingival disease, rapid tooth destruction are a consequence of decrease salivary gland secretion.19

CONCLUSION

Oral health is a gateway to overall health. Mouth is the entry point which decides what a person will become as the adage goes we are what we eat. Oral diseases are preventable if proper lifestyle is adapted. A few changes in eating habits can save oral and overall health.

ABSTRACT

Let p and q denote respectively the number of vertices and edges of a finite, simple and undirected G. A graph G with p vertices and q edges is called a *mean graph* if it is possible to label the vertices $x \in v$ with distinct elements $f(x)$ from $0,1,2,\dots,q$ in such a way that when each edge $e = uv$ is labeled with $\frac{f(u)+f(v)}{2}$ if $f(u) + f(v)$ is even and $\frac{f(u)+f(v)+1}{2}$ if $f(u) + f(v)$ is odd, then the resulting edge labels are distinct f is called a *mean labeling* of G. A graph which admits mean labeling is called a *mean graph*. An injective map $f: V(G) \to \{\pm1, \pm2, \pm3, \dots, \pm p\}$ is said to be *pair mean labeling* if the induced edge function $f_{em}: E(G) \to Z\{0\}$ defined by

$$f_e(uv) = \begin{cases} \frac{f(u)+f(v)}{2} & \text{if } f(u) + f(v) \text{ is even} \\ \frac{f(u)+f(v)+1}{2} & \text{if } f(u) + f(v) \text{ is odd} \end{cases}$$

is one-one $f_{em}(V(G))$ is either of the form $\left\{\pm k_1, \pm k_2, \pm k_3, \dots, \pm k_{\frac{q}{2}}\right\}$ or $\left\{\pm k_1, \pm k_2, \pm k_3, \dots, \pm k_{\frac{q-1}{2}}\right\} \cup \left\{k_{\frac{q+1}{2}}\right\}$ according as q is even or odd.. A graph with a pair mean labeling defined on it is called a *pair mean graph.* Motivated by the above two works, we introduce here a new pair mean labeling called distance pair mean labeling.

Keywords: Mean labeling**,** Pair mean labeling, DPML, comb graph, ladder graph, star graph.
2010 Mathematics Subject Classification: 05C78.

Muthuselvi and Saratha Devi

INTRODUCTION

The concept of mean labeling was introduced by R. Ponraj[4] and investigated the existence of such labeling on path, cycle, complete graph K_n for $n \leq 3$, the triangular snake and some more special graphs and also proved that the complete graph K_n and complete bipartite graph $K_{1,n}$ for $n \geq 3$ are not mean graph. Inspired by the labeling, R. Ponraj[5] defined and discussed the concept of pair mean labeling and studied $P_n, C_n, n > 3$, admit pair mean labeling. Also proved the complete graph is a pair mean graph iff $n \leq 2$. The Cartesian product $G \times H$ of two graphs G and H is a graph such that the vertex set of $G \times H$ is the Cartesian product $V(G) \times V(H)$ and two vertices (u, v) and (u', v') are adjacent in $G \times H$ iff either $u = u'$ and v is adjacent to v' in H or $v = v'$ and u is adjacent to u' in G. The ladder graph L_n is defined by $L_n = P_n \times K_2$ where P_n is a path with n vertices and x denotes the Cartesian product and K_2 is a complete graph with two-vertices. The corona $G_1 \odot G_2$ of two graphs G_1 and G_2 defined as the graph by taking one copy of G_1 (with P_1 vertices) and P_1 copies of G_2 and then joining the ith vertex of G_1 to all the vertices in the ith copy of G_1. The comb graph is represented by $P_n \odot K_1$ where P_n is a path graph with $(n-1)$ edges and n vertices. The graph is constructed by connecting each vertex in the path with a pendant edge. There are 2n vertices and 2n-1 edges in the comb graph.

Distance pair mean labeling of a graph G

Definition 2.1. An injective map $f: V(G) \to \{\pm 1, \pm 2, \pm 3, \ldots, \pm p\}$ is said to be distance pair mean labeling, if the induced vertex weight function $w(v): V(G) \to Z \setminus \{0\}$ defined by $w(v) = \left\lceil \dfrac{\sum\limits_{u \in N(v)} f(v)}{|N(v)|} \right\rceil \neq 0$ is one-one, where

$N(v) = \{u \epsilon V: uv \epsilon E\}$ is the open neighborhood of v and $w(V(G))$ is either of the form $\left\{\pm k_1, \pm k_2, \pm k_3, \ldots, \pm k_{\frac{p}{2}}\right\}$ or $\left\{\pm k_1, \pm k_2, \pm k_3, \ldots, \pm k_{\frac{p-1}{2}}\right\} \cup \left\{k_{\frac{p+1}{2}}\right\}$ according as p is even or odd. A graph which admits distance pair mean labeling is called a distance pair mean graph or just a DPML graph.

Example2.2

    An example for a distance pair mean graph of C_5 is given below. Here, the vertex labels are in *usual font* and weight are in *bold font.*
Figure:1 C_5 is distance pair mean graph.

Observation 2.3. If G contains two vertices u and v such that $N(u) = N(v)$, then G is not a distance pair mean graph. For, Let $u, v \epsilon V(G)$ and $N(u) = N(v)$. Then $w(u) = w(v)$. Hence G is not a distance pair mean graph. The following figure shows the P_3 and C_4 are not distance pair mean graphs.

Muthuselvi and Saratha Devi

From this observation, we can conclude that the *star graph*, denoted by $K_{\{1,n\}}$, is not a distance pair mean graph.

Main Results

**Theorem 2.1.1.** Anypath P_n is distance pair mean graph for $n \neq 3$.

Proof.

Let $V = \{v_1, v_2, \ldots, v_n\}$ be the vertex set of P_n.

By definition, P_2 is obviously a distance pair mean graph and P_3 is not a distance pair mean graph by observation **2.3.**

Take $n \geq 4$. We consider the following two cases:

Case(i): n is even.

For $n \geq 4$, define the labeling $f: V(P_n) \to \{\pm1, \pm2, \ldots, \pm n\}$ by

$$f(v_1) = -1; f(v_2) = 2; f(v_i) = \begin{cases} -\left\lceil \dfrac{i+2}{2} \right\rceil, & \text{if } i \geq 3 \text{ and } i \text{ is odd} \\ \dfrac{i+2}{2}, & \text{if } i \geq 4 \text{ and } i \text{ is even} \end{cases}$$

The induced vertex weights labeling are

$$w(v_i) = \begin{cases} \left\lceil \dfrac{i+2}{2} \right\rceil, & \text{if } i \text{ is odd} \\ -\left(\dfrac{i+2}{2}\right), & \text{if } i \text{ is even} \end{cases} \Rightarrow w(v_i) = -w(v_{i+1}), \text{for all } i = 1,2,\ldots,n.$$

Hence, f is a distance pair mean labeling of P_n, if n is even.

Case(ii): n is odd.

Define the labeling $f: V(P_n) \to \{\pm1, \pm2, \ldots, \pm n\}$ by

$$f(v_1) = 1 = -f(v_2), and \ f(v_3) = 2,$$

$$f(v_i) = -\left\lceil \dfrac{i+1}{2} \right\rceil = -f(v_{i+1}), if \ i \geq 4 \text{ and } i \text{ is even.}$$

The induced vertex weights labeling are $w(v_1) = -1$

$$w(v_i) = \begin{cases} \dfrac{i+2}{2}, & \text{if } i \text{ is even} \\ -\left\lceil \dfrac{i}{2} \right\rceil, & \text{if } i \text{ is odd} \end{cases}$$

Clearly f is a distance pair mean labeling of P_n, if n is odd.

Hence P_n is distance pair mean graph for $n \neq 3$.

Theorem 2.1.2. Anycycle C_n is distance pair mean graph if $n \geq 5$.

Proof.

Let $V = \{v_1, v_2, \ldots, v_n\}$ be the vertex set of C_n. Consider the following two cases:

Case(i). n is even and $n \geq 6$.

Consider the following two subcases.

Subcase (i). $n = 4m + 2$, where $m = 1,2,3,\ldots$

Muthuselvi and Saratha Devi

Define $f: V(C_{4m+2}) \to \{\pm 1, \pm 2, \ldots, \pm n\}$ by

$$f(v_i) = \begin{cases} i, & if \ i = 1,3,5,\ldots,n-1 \\ -(i-1), & if \ i = 2,4,\ldots,n \end{cases}$$

The induced vertex weight labeling are

$$w(v_i) = \begin{cases} -(i-1), & if \ i = 3,5,\ldots,n-1 \\ i, & if \ i = 2,4,\ldots,n-2 \end{cases}$$

Hence f is a distance pair mean labeling of C_{4m+2}, if $m \geq 6$

Subcase (ii). $n = 4m$ and $m \geq 2$

Figure:2 C_8 is a distance pair mean graph.

If $m = 2$, clearly from the above labeling C_8 is a distance pair mean graph.

If $m \geq 3$, we define $f: V(C_{4m}) \to \{\pm 1, \pm 2, \ldots, \pm n\}$ by

$$f(v_i) = \begin{cases} i+1, & if \ i = 1,3,5,\ldots,2m-1 \\ -i, & if \ i = 2,4,6,\ldots,2m \end{cases}$$

$$f(v_{n-i}) = \begin{cases} n - \left(\dfrac{i+1}{2}\right), & if \ i = 1,3,5,\ldots,2m-3 \\ -\left(n - \dfrac{i}{2}\right), & if \ i = 2,4,6,\ldots,2m-2 \end{cases}$$

$f(v_n) = -n, f(v_{2m+1}) = 3m.$

Then induced vertex weight labeling are

$$w(v_i) = \begin{cases} i+1, & if \ i = 2,4,6,\ldots,2m-2 \\ -i, & if \ i = 3,5,7,\ldots,2m-1 \end{cases}$$

$$w(v_{n-i}) = \begin{cases} n - \left(\dfrac{i}{2}\right), & if \ i = 2,4,6,\ldots,2m-2 \\ -\left(n - \left(\dfrac{i+1}{2}\right)\right), & if \ i = 1,3,5,7,\ldots,2m-3 \end{cases}$$

$w(v_1) = -(2m+1) = -w(v_n); w(v_{2m}) = \left\lceil \dfrac{5m}{2} \right\rceil = -w(v_{2m+1}).$

Hence f is a distance pair mean labeling of C_{4m}, if $m \geq 2$.

Case (ii). n is odd and $n \geq 5$.
We consider the following two subcases.

Subcase (i). $n = 4m + 1$, where $m \geq 1$.
If $m = 1$, clearly from the figure 1, C_5 is a distance pair mean graph.
If $m \geq 2$, we define $f: V(C_{4m+1}) \to \{\pm 1, \pm 2, \ldots, \pm n\}$ by

$$f(v_1) = 1, f(v_2) = -2, f(v_3) = 2$$

$$f(v_i) = \begin{cases} -(i-1), & if \ i = 4,6,\ldots,\dfrac{n-1}{2} \\ i-2, & if \ i = 5,7,\ldots,\dfrac{n+1}{2} \end{cases}$$

$$f\left(v_{\frac{n+1}{2}+i}\right) = \begin{cases} \dfrac{n+1}{2} + (i-1), & if \ i = 1,3,5,\ldots,\dfrac{n-3}{2} \\ -\left[\dfrac{n+1}{2} + (i-2)\right], & if \ i = 2,4,\ldots,\dfrac{n-1}{2} \end{cases}$$

79932

Muthuselvi and Saratha Devi

Then induced vertex weight labeling are

$$w(v_1) = -\left(\frac{n-1}{2}\right) = -w(v_n),$$

$$w(v_2) = 2 = -w(v_3), w(v_4) = 3,$$

$$w\left(v_{\frac{n+1}{2}}\right) = 1 = -w\left(v_{\frac{n+1}{2}+1}\right),$$

$$w(v_i) = i - 1 = -w(v_{i+1}), \text{for } i = 5,7,\dots,\frac{n-1}{2}$$

$$w\left(v_{\frac{n+1}{2}+i+1}\right) = \frac{n+1}{2} + i = -w\left(v_{\frac{n+1}{2}+i+2}\right), i = 1,3,5,\dots,\frac{n-7}{2}$$

Hence f is distance pair mean labeling of C_{4m+1}.
Subcase (ii).$n = 4m + 3$ and $m \geq 1$.
Figure:3 C_7 is a distance pair mean graph.

If $m = 1$, clearly from the above labeling C_7 is a distance pair mean graph.
If $m > 1$, we define $f: V(C_{4m+3}) \to \{\pm 1, \pm 2, \dots, \pm n\}$ by

$$f(v_1) = 1, f(v_2) = -2 = -f(v_3)$$

$$f(v_i) = -(i-1); i = 4,6,\dots,\frac{n-3}{2}$$

$$f(v_i) = (i-2); i = 5,7,\dots,\frac{n-1}{2}$$

$$f\left(v_{\frac{n-1}{2}+i}\right) = \frac{n-1}{2} + i - 1; i = 1,3,\dots,\frac{n-1}{2}$$

$$f\left(v_{\frac{n-1}{2}+i}\right) = -\left(\frac{n-1}{2} + i - 2\right); i = 2,4,\dots,\frac{n+1}{2}$$

Then induced vertex weight labeling are

$$w(v_1) = -\left(\frac{n-1}{2}\right) = -w(v_n), w(v_2) = 2 = -w(v_3), w(v_4) = 3,$$

$$w(v_i) = -(i-1) = -w(v_{i+1}), i = 5,7,9,\dots,\frac{n-5}{2},$$

$$w\left(v_{\frac{n-1}{2}}\right) = 1 = -w\left(v_{\frac{n+1}{2}}\right)$$

$$w\left(v_{\frac{n+1}{2}+i}\right) = \frac{n+1}{2} + i - 1 = -w\left(v_{\frac{n+1}{2}+i+1}\right), i = 1,3,5,\dots,\frac{n-5}{2}.$$

Thus f admits distance pair mean labeling and hence C_n is a distance pair mean graph for $n \geq 5$.

Theorem 2.1.3. The Ladder graph $P_n \times P_2$ is distance pair mean graph for $n \geq 3$.

Proof.
Let $V(L_n) = \{u_i, v_i : 1 \leq i \leq n\}$;
$E(L_n) = \{u_i u_{i+1}, v_i v_{i+1} : 1 \leq i \leq n-1\} \cup \{u_i v_i : 1 \leq i \leq n\}$.
Define $f: V(L_n) \to \{\pm 1, \pm 2, \dots, \pm n\}$ by
For $1 \leq i \leq n$,

$$f(u_i) = -f(v_i) = \begin{cases} 2i, & \text{if } i \text{ is odd} \\ -2i, & \text{if } i \text{ is even} \end{cases}$$

Then the induced vertex weight labeling are as follow:
$w(u_1) = -3 = -w(v_1)$
For $1 \leq i \leq n$,

$$w(u_i) = -w(v_i) = \begin{cases} 2i, & if\ i\ is\ even\ and\ i \neq 1, n \\ -2i, & if\ i\ is\ odd\ and\ i \neq 1, n \end{cases}$$

$$w(u_n) = -w(v_n) = \begin{cases} -(2n-1), & if\ i\ is\ odd \\ 2n-1, & if\ i\ is\ even \end{cases}$$

$$\Rightarrow w(u_i) = -w(v_i)\ for\ all\ i.$$

Thus f admits distance pair mean labeling and hence, $P_n \times P_2$ is a distance pair mean graph.

Theorem 2.1.4. Any comb graph $P_n \odot K_1$ is distance pair mean graph if $n \geq 3$.

Proof. Let G be a comb $P_n \odot K_1$ obtained from the path $v_1, v_2, \ldots, v_n$ by joining a vertex u_i to v_i for each $i = 1,2, \ldots, n$. Then G is of order $2n$ and size $2n - 1$.

We consider the following two cases:

Case(i). n is odd.

Define $f : V(G) \rightarrow \{\pm 1, \pm 2, \ldots, \pm 2n\}$ by

$$f(u_i) = \begin{cases} i, & if\ i\ is\ odd \\ -i, & if\ i\ is\ even \end{cases}$$

$$f(v_i) = \begin{cases} -i, & if\ i\ is\ odd\ and\ i < n \\ i, & if\ i\ is\ even\ and\ i < n \\ -(n+1), & if\ i = n \end{cases}$$

Case(ii). n is even**.**

Define $f : V(G) \rightarrow \{\pm 1, \pm 2, \ldots, \pm 2n\}$ by

$$f(u_i) = -f(v_i) = \begin{cases} i, & if\ i\ is\ odd \\ -i, & if\ i\ is\ even \end{cases}$$

In both cases the weight of the vertices are

$$w(u_i) = -w(v_i) = \begin{cases} -i, & if\ i\ is\ odd \\ i, & if\ i\ is\ even \end{cases}$$

Thus f admits distance pair mean labeling and hence $P_n \odot K_1$ is distance pair mean graph.

RESULTS AND DISCUSSIONS

Investigation of mean labeling on graph families are given in [4]. Pair mean labeling has been defined by R. Ponraj, J. Vijaya Xavier Parthipan in 2011 and studied the labeling on certain graph such as path, complete graph, star graph, complete bipartite graph and $P_n \odot 2K_1$. And also the one-one map f admits pair sum labeling iff it is pair mean labeling has been observed. Further for a pair mean labeling, any two adjacent vertices of G never have the labels of the form $x, -x$ and $x, -x - 1$ has been observed. The various results on various mean labeling[7,8] and pair sum labeling[3,6] motivated us to extend the concept and define the DPML and characterize the labeling for some graph families.

CONCLUSION

In this paper the distance pair mean labeling of a simple undirected graph is defined and contributed some results by investigating distance pair mean labeling on certain families of graphs such as path, cycle, comb, ladder and observed that the star graph is not a DPML graph.

ABSTRACT

In the quest for educational excellence, this paper presents a pioneering approach to student evaluation. This paper explores the paradigm shift from traditional assessment methods to a comprehensive, learner-centered framework that recognizes the multifaceted nature of student development. The proposed holistic assessment model integrates cognitive, emotional, and social competencies, offering a more accurate reflection of a student's learning journey. The research underscores the limitations of conventional testing, advocating for assessments that encapsulate the full spectrum of educational experiences. By incorporating diverse evaluation tools, including portfolios, peer reviews, and self-assessments, the model fosters an environment where feedback is constructive and learning is personalized. The paper also delves into the challenges of implementing such a transformative system, including teacher training, curriculum adaptation, and stakeholder acceptance. It presents case studies of successful integrations of holistic assessment in various educational settings, highlighting the positive outcomes on student engagement and achievement. Finally, the paper proposes strategies for scaling this innovative assessment approach, emphasizing the role of policy reform and community involvement. It calls for a collective effort to redefine success in education, ensuring that every learner embarks on a distinctive journey that prepares them for the complexities of the modern world.

Keywords: Holistic Evaluation, 360-degree Holistic Assessment, Education, Evaluation Tools

Parinka Sharma and Baliya

INTRODUCTION

Historically, education has often relied on standardized tests and narrowly defined metrics to assess student performance. While these assessments have their merits, they often fail to capture the full spectrum of students' abilities and potential. Innovative holistic assessment, however, takes a broader view, encompassing not only academic achievements but also personal growth, social-emotional development, creativity, critical thinking, and collaborative skills. Holistic assessment recognizes that every learner is unique, with diverse strengths, interests, and learning styles. It seeks to provide a more comprehensive and nuanced understanding of student progress, enabling educators to tailor instruction and support to individual needs. By moving beyond one-size-fits-all evaluations, holistic assessment celebrates the richness of student diversity and promotes inclusive learning environments.

By embracing innovative holistic assessment, educators unlock new possibilities for nurturing well-rounded individuals poised for success in the 21st century. A distinctive learning journey emerges—one that is characterized by:

- Personalized Growth: Students receive personalized support and feedback tailored to their unique needs and aspirations, fostering a sense of agency and empowerment.
- Cultivation of Lifelong Learners: Holistic assessment cultivates a culture of continuous learning and growth, instilling in students the value of lifelong learning beyond formal education.
- Preparation for the Future: By developing a comprehensive skill set and a growth mindset, students are better prepared to navigate complex challenges and seize opportunities in an increasingly interconnected global society.

Concept of Holistic Education

Beyond the fundamentals of academics, the notion of holistic education aims to educate the whole person. Many educational institutions understand that providing pupils with a solid foundation in a core curriculum is not enough. This method is learner-centered. a thorough method of teaching in which instructors work to meet students' intellectual, social, emotional, and ethical requirements through an integrated learning environment. Positive school climates and attending to kids' academic and non-academic needs are prioritized. The curriculum would incorporate, among other "traditional" disciplines, dancing, games, role play, stage performances, painting, photography, and debates. This method is oriented toward play-based learning. In addition to learning how to take lessons from their local and global communities, students are also taught to reflect on their actions and how they affect those communities. Instructors make an effort to get students involved in projects that use critical thinking abilities to solve practical issues. A developing child'smoral, physical, spiritual, emotional and psychological qualities are nurtured through the holistic education method. Personalized learning experiences that take into account a kid's abilities and emotions are essential to addressing the full child. Students can make use of their skills in a supportive learning atmosphere where lessons are taught. A holistic learning culture may be established via the use of a variety of techniques and tactics. (Dutta, 2022).

RESEARCH OBJECTIVES

- To study the role of technology in facilitating 360-degree holistic assessment and its integration into the curriculum.
- To explore the different tools used in 360-degree holistic assessment in a teaching-learning environment.
- To propose a framework for the continuous improvement of the teaching-learning climate through iterative feedback and assessment cycles.

NEP 2020's Holistic Approach

The National Education Policy (NEP) 2020 in India emphasizes the importance of holistic development and assessment of students. The policy proposes a shift towards a more comprehensive and continuous evaluation

system, moving away from rote learning and high-pressure exams. Regarding the concept of "360-degree holistic evaluation," the NEP 2020 emphasizes the following principles:

1. **Comprehensive Assessment**: The policy advocates for a shift from summative assessment (focused on end-of-year exams) to formative assessment (which includes a range of tools like quizzes, projects, and activities throughout the academic year). This approach aims to provide a more comprehensive understanding of a student's progress.
2. **Multi-dimensional Evaluation**: The NEP emphasizes assessing students not only on academic achievements but also on their skills, interests, attitudes, and values. This multi-dimensional evaluation is intended to capture a student's overall development.
3. **Life Skills and Values Assessment**: The policy suggests incorporating assessments that measure life skills such as critical thinking, creativity, communication, collaboration, ethical reasoning, and digital literacy. Additionally, it emphasizes the assessment of values like empathy, respect, and responsibility.
4. **Flexible Board Exams**: NEP 2020 suggests reforms in board examinations to test core competencies rather than memorized facts, providing students with flexibility in choosing subjects and the mode of examination.
5. **Technology Integration**: The policy encourages the use of technology for assessment, including adaptive testing methods that adjust to a student's level and style of learning.
6. **Continuous Professional Development**: NEP 2020 emphasizes the need for continuous professional development of teachers to ensure the effective implementation of holistic evaluation practices. Thus, the NEP 2020 promotes a shift towards a more holistic, continuous, and multi-dimensional assessment system that aims to foster overall development in students beyond academic achievements. This approach aligns with the intention to nurture well-rounded individuals capable of thriving in various aspects of life.

Concept of 360-Degree Evaluation

In NEP 2020, 360-degree evaluation is a novel technique for assessing each learner's progress and distinctiveness across all domains of learning. It includes feedback from a variety of sources, including self, peers, instructors, and parents. It aspires to give a holistic, multifaceted, and comprehensive report card that represents each student's strengths, areas for progress, and interests. The report card will also highlight students' accomplishments in other co-curricular and extra-curricular activities such as athletics, arts, social service, and so on. Rather than ranking or labeling students, the goal of this assessment is to support their learning and development. 360-degree feedback is a procedure that collects comments from teachers, peers, supervisors, and parents as well as a self-evaluation by the students themselves. It is also referred to as multi-source feedback or multi-source assessment. The participants are encouraged to continue studying thanks to the efficient 360-degree feedback. They may become better learners simply by hearing feedback, but this transformation must occur internally. It is crucial to first "unfreeze" the participant's self-view in order to encourage improvement or behavioural change. The greatest method to break the self-view out of its ice is to give the participant factual information from several angles and to urge them to be open to receiving criticism. 360 Degree Holistic Assessment of students is a new approach to evaluating the learning and development of students in different domains and contexts. It is based on the idea that students can benefit from receiving feedback from multiple sources, such as themselves, their peers, their teachers, and their parents. This way, they can get a comprehensive and holistic view of their strengths, weaknesses, opportunities, and challenges. According to the National Education Policy 2020, 360 Degree Holistic Assessment is one of the key features of assessment reform in India. It aims to shift the focus of assessment from certification to improvement in learning and to test higher-order skills such as analysis, critical thinking, and conceptual clarity. It also involves using a Holistic Report Card (HRC) that reflects the progress and uniqueness of each child in the cognitive, affective, and psychomotor domains. The HRC will also provide valuable information to teachers and parents on how to support each child in and out of the classroom(NEP, 2020). The new report cards are going to be "a holistic, 360-degree, multidimensional report that reflects in great detail the progress and the uniqueness of each learner in the cognitive, affective, and psychomotor domains". The progress report will contain self-assessment, peer assessment, and instructor evaluations.

Benefits of 360 Degree Holistic Assessment

- It helps students to become more aware of their own learning process and goals and to develop self-regulation and metacognition skills.
- It encourages students to collaborate with their peers and learn from each other's perspectives and experiences.
- It provides teachers with a rich and diverse data source to monitor student learning and adjust their teaching strategies accordingly.
- It fosters a culture of continuous feedback and improvement among all stakeholders involved in student learning.
- It reduces the stress and anxiety associated with high-stakes examinations and promotes a more positive attitude towards learning (Extramarks, 2023).

Difference Between Traditional Assessment Techniques & 360-Degree Holistic Assessment

- Traditional assessment techniques measure students' knowledge and understanding, while 360-degree evaluation measures each learner's development and individuality across all learning domains. These are some of the primary contrasts.
- Unlike 360-degree evaluations, which incorporate feedback from a variety of sources, including peers, teachers, parents, and self, traditional assessment techniques rely on feedback from a single source, typically the teacher.
- Unlike 360-degree evaluation, which uses a variety of informal tools including portfolios, projects, and observations, traditional assessment methods use standardized and formal tools like tests, quizzes, and essays.
- While 360-degree evaluations are utilized for learning and growth, traditional assessment methods are employed for grading and reporting.

Different Domains Assessed in 360-Degree Holistic Assessment

These domains are interrelated and influence each other in the learning process. Therefore, 360 Degree Holistic Assessment aims to capture the holistic and multidimensional nature of student learning and development. The different domains are assessed using various methods and tools that are aligned with the learning outcomes and competencies of each domain. Some of the methods and tools are:

- **Self-assessment:** This method involves students reflecting on their own learning process and goals, and evaluating their own performance and progress in different domains. Self-assessment can be done using tools such as checklists, rubrics, journals, portfolios, etc. Self-assessment helps students develop self-regulation and meta cognition skills, and to identify their strengths and areas for improvement.
- **Peer assessment:** This method involves students giving and receiving feedback from their classmates on their work and behavior in different domains. Peer assessment can be done using tools such as peer review, peer editing, peer feedback, etc. Peer assessment helps students to collaborate with their peers and learn from each other's perspectives and experiences.
- **Teacher assessment:** This method involves teachers observing, monitoring, and evaluating students' performance and progress in different domains. Teacher assessment can be done using tools such as quizzes, tests, assignments, projects, observations, interviews, etc. Teacher assessment helps teachers provide timely and constructive feedback to students and to adjust their teaching strategies accordingly.
- **Parent assessment:** This method involves parents or guardians providing feedback on their children's learning and development in different domains. Parent assessment can be done using tools such as parent-teacher meetings, parent surveys, parent reports, etc. Parent assessment helps parents to be actively involved in their children's holistic education and development, and to support them in and out of the classroom. These methods and tools are used in a balanced and integrated way to create a 360-degree holistic report card that reflects the progress and uniqueness of each child in the cognitive, affective, socio-emotional, and psychomotor domains. The report card is descriptive and analytical rather than numerical and provides valuable information to teachers and parents on how to support each child.

Tools Used In 360 Degree Holistic Assessment Are
This table provides an overview of various tools used in 360 Degree Holistic Assessment for students in education, covering aspects related to data collection, academic progress, social-emotional development, skill development, technology integration, feedback/reflection, collaboration, and data analysis. These tools are essential for assessing students comprehensively and supporting their overall growth and learning experiences. The description of these tools is given below:

Data Collection
- **Surveys**: Surveys can be designed to gather feedback from students about their learning experiences, interests, and challenges.
- **Interviews**: One-on-one interviews with students can provide in-depth insights into their perceptions, strengths, and areas for improvement.
- **Observations**: Teachers and assessors can observe students in various learning settings to assess their behavior, engagement, and interaction with peers.

Academic Progress
- **Portfolios**: Students compile portfolios showcasing their work, achievements, and reflections over time to demonstrate academic progress.
- **Projects**: Project-based assessments allow students to demonstrate their knowledge, skills, and creativity through extended assignments.
- **Exams/Assessments**: Traditional exams and assessments measure students' understanding and mastery of academic content.

Social-Emotional Development
- **Self-Assessment Tools**: Tools like self-assessment questionnaires or reflections help students evaluate their own social-emotional skills and growth.
- **Peer Feedback**: Peer assessment encourages students to provide feedback to each other on teamwork, communication, and social skills.

Skill Development
- **Rubrics**: Rubrics outline specific criteria for assessing student performance across various skills and competencies.
- **Performance Assessments**: Assessments that require students to demonstrate skills through presentations, simulations, or practical tasks.
- **Skill Inventories**: Inventories assess students' skills and abilities in areas like problem-solving, critical thinking, and creativity.

Technology Tools
- **Online Platforms**: Learning management systems (LMS) and assessment tools provide digital platforms for administering and managing assessments.
- **Interactive Apps**: Apps and tools that facilitate interactive learning experiences, quizzes, and simulations to assess student understanding.

Feedback and Reflection Tools
- **Feedback Forms**: Structured forms or templates for providing and receiving feedback on academic work or projects.
- **Reflection Journals**: Journals where students record their reflections on their learning progress, challenges, and achievements.

Collaboration Tools

- **Collaborative Platforms**: Using online collaboration tools like Google Workspace or Microsoft Teams to facilitate group projects, peer collaboration, and shared document editing.

Data Analysis Tools

- **Data Analytics Software**: Analyzing assessment data using tools like Microsoft Excel or Google Sheets to identify trends, student performance patterns, and areas needing intervention or improvement. These tools are integrated into the educational process to create a comprehensive picture of students' academic performance, social-emotional development, and overall growth. They enable educators to tailor instruction and support based on individual student needs and promote a holistic approach to student assessment and development.

Role of Technology in 360-Degree Holistic Assessment

Technology plays an important role in 360-degree holistic Assessment, as it can facilitate the collection, analysis, and reporting of data from multiple sources and domains. Technology can also enhance the quality, efficiency, and accessibility of assessment tools and methods. Some of the ways that technology can support 360 Degree Holistic Assessment are:

➢ Technology can enable the use of appropriate and flexible software that allows and enables children to work at their own pace, with personalized and adaptive curricula that leverage each child's strengths and interests.

➢ Technology can help create an ecosystem for appropriate assessment and certification, by providing online platforms, digital portfolios, e-certificates, etc. that can document and showcase the learning and development of each child in different domains.

➢ Technology can assist teachers in designing and implementing various assessment tools and methods, such as quizzes, tests, assignments, projects, observations, interviews, etc. that can test higher-order skills and competencies of students in the cognitive domain.

➢ Technology can empower students to engage in self-assessment and peer assessment, by using tools such as checklists, rubrics, journals, feedback forms, etc. that can help them reflect on their own learning process and goals, and provide constructive feedback to their classmates in the affective and socio-emotional domains.

➢ Technology can enable parents to be actively involved in their children's holistic education and development, by using tools such as parent-teacher meetings, parent surveys, parent reports, etc. that can provide them with valuable information on how to support their children in and out of the classroom in the psychomotor domain.

➢ Technology can integrate with artificial intelligence and machine learning algorithms that can enhance data analysis, improve accuracy, and provide even more valuable insights for individuals and organizations. Technology can thus play a vital role in transforming the culture of assessment from certification to improvement in learning, and from summative to formative and competency-based. Technology can also help create a 360-degree holistic report card that reflects the progress and uniqueness of each child in the cognitive, affective, socio-emotional, and psychomotor domains(Recruitment, 2022).

PARAKH for Holistic Evaluation

PARAKH, which stands for Performance Assessment, Review, and Analysis of Knowledge for Holistic Development, is India's first national assessment regulator established by the NCERT. It was set up to align with the National Education Policy (NEP) 2020, focusing on four key areas:

1. Capacity Development in Competency-Based Assessment: PARAKH aims to bridge gaps in competency-based learning and teaching through initiatives like Project Vidyasagar, which involves workshops to disseminate learning competencies at various educational levels.

2. Large-Scale Achievement Survey: It conducts large-scale surveys to monitor and assess the educational standards of the country. For instance, an assessment covering approximately 8.5 million learners across grades 3, 6, and 9 was conducted to gauge competencies in foundational literacy and numeracy, language, and mathematics.

3. Equivalence of School Boards: PARAKH works towards examination reforms and equivalence across all school boards in India. This includes developing recommendations and conducting workshops to collect data for analysis and report preparation.
4. Holistic Progress Cards: These are designed for foundational, preparatory, middle, and secondary stages to provide a comprehensive view of a student's progress. PARAKH's approach to assessment is competency-based, focusing on the development and demonstration of skills, knowledge, and abilities rather than solely relying on traditional standardized testing. This regulator plays a crucial role in setting norms, standards, and guidelines for student assessment and evaluation across all recognized school boards in the country. With PARAKH, education will progressively shift toward a more scientific methodology. It would take care of academic requirements such as a child's cognitive growth and social and physical awareness. The efficient method of assessment and evaluation for the comprehensive, growth of the kids will undoubtedly improve the country's future, and the PARAKH will be implemented successfully to make this happen (Sharma & Baliya, 2023).

CONCLUSIONS

In conclusion, the research on evolving teaching-learning climate through 360-degree holistic assessment highlights the transformative potential of comprehensive evaluation methods in education. This study has underscored the importance of moving beyond traditional assessment practices towards a more inclusive, multifaceted approach that considers various dimensions of student development and teacher effectiveness. Through a thorough analysis of the literature and empirical findings, it is evident that embracing 360-degree assessment can foster a supportive and dynamic learning environment. By incorporating feedback from diverse stakeholders including students, peers, and supervisors, educators can gain valuable insights into their teaching methods and areas for improvement. Similarly, students benefit from a more personalized and well-rounded educational experience that nurtures their holistic growth. Moreover, the research underscores the need for educational institutions to adapt and evolve in response to changing pedagogical demands and student expectations. The implementation of 360-degree assessment requires institutional commitment and investment in professional development to ensure its successful integration into teaching practices. In essence, this study advocates for a paradigm shift towards continuous improvement and student-centered learning approaches facilitated by comprehensive assessment frameworks. By embracing the principles of 360-degree assessment, educators can create a more inclusive, engaging, and effective teaching-learning climate that better prepares students for the challenges of the modern world. This research serves as a catalyst for further exploration and implementation of innovative assessment strategies aimed at enhancing educational outcomes and fostering a culture of lifelong learning.

ABSTRACT

Retention time (RT) prediction stands as a cornerstone in analytical chemistry, pivotal for upholding the accuracy of identification and quantification while streamlining method development. In this review paper, we delve into the intricate realm of the Quantitative Structure-Retention Relationship (QSRR) technique, an invaluable tool for forecasting retention times (RTs) in chromatography. By examining the historical progression and amalgamation of diverse statistical and computational methodologies, we elucidate the pivotal role these approaches have played in various pharmaceutical applications, encompassing quality control and drug discovery among other critical sectors of the industry.Drawing upon the rich tapestry of QSRR applications, we uncover its multifaceted utility in pharmaceutical endeavors, showcasing its efficacy in drug development and quality assurance. QSRR, with its systematic framework, orchestrates a symbiotic relationship between chemical structures and chromatographic behavior, establishing mathematical correlations that underpin precise RT predictions.The evolution of QSRR owes much to the synergy of statistical and computational techniques, harnessing their prowess to achieve extraordinary precision in RT prognostication. Through meticulous analysis and synthesis, this review underscores the transformative impact of QSRR on the pharmaceutical landscape, paving the way for enhanced efficiency and accuracy in analytical methodologies.

Keywords: Retention time prediction, Quantitative Structure-Retention Relationship, Pharmaceutical analysis, Chromatography, Statistical and computational techniques.

Harini Rachamallu *et al.,*

INTRODUCTION

Analytical chemistry stands as a cornerstone within various industries, including pharmaceuticals, food, biotechnology, and forensics, where its primary focus lies in the precise identification and quantification of substances, as well as the intricate analysis of complex compound mixtures[1]. Its significance resonates across diverse sectors, aiding in determining the purity and quantity of chemical entities amidst compound mixtures found in realms like natural products, clinical chemistry, and forensic science [2] A plethora of techniques and instruments are employed by analytical chemists to accomplish these tasks effectively. Among the most prominent are UV-visible spectroscopy, Infrared (IR) Spectroscopy, Nuclear Magnetic Resonance (NMR), Mass Spectrometry, and various Chromatography techniques such as Gas Chromatography (GC), Liquid Chromatography (LC), and High-Pressure Liquid Chromatography (HPLC). These instruments serve as pillars in the analytical arsenal, each offering unique capabilities tailored to different analytical challenges [3]. The selection of equipment is a critical decision influenced by several factors, including the specific analytical objectives, the characteristics of the sample under investigation, and the requisite sensitivity and accuracy demanded by the analysis. From elucidating the molecular structure of a pharmaceutical compound to identifying trace evidence in forensic investigations, analytical chemistry tools are indispensable in unraveling the complexities of chemical composition and behavior. As technology advances, so too does the breadth and depth of analytical methodologies, ensuring that analytical chemists remain at the forefront of scientific inquiry and innovation [4].A key aspect of analytical chemistry is the estimation of RTs, which plays a crucial role in the separation of analytes and their subsequent identification. QSRR is a powerful tool that links the chemical structure of analytes to their RTs, allowing for predictive modeling and optimization in various analytical techniques [5]. This review offers an in-depth overview of QSRR in retention time (RT) estimation, focusing on applications in gas chromatography (GC), liquid chromatography (LC), and related techniques[6-8]. It covers QSRR principles, model development, influencing factors, challenges, and future prospects. Software like ChemDraw, MarvinSketch, and RDKit are used for chemical structure drawing, while tools like Dragon and PaDEL compute molecular descriptors. QSRR models are developed using statistical methods in R, Python (scikit-learn, TensorFlow), MATLAB, and JMP. Cheminformatics libraries like RDKit, Open Babel, and ChemPy aid in model development using algorithms like linear regression, SVMs, and neural networks[9,10].

Scope and objectives of QSRR in Chromatography
Chromatography's versatile, precise, and highly sensitive capabilities enable researchers to analyze complex mixtures, optimize methods, and achieve precise separations across a wide range of compounds[11]. This makes chromatography an essential tool in scientific research, quality control, and numerous industrial applications, as illustrated in Figure 1. Its ability to dissect intricate compositions with high accuracy and reliability underscores its critical role in advancing both scientific discovery and practical applications across multiple fields.

Predictive Capability
QSR Renables the anticipation of retention durations for compounds based on their chemical structure. This predictive power is instrumental in identifying and quantifying individual components within complex mixtures, a common challenge in chromatographic analysis [12].

Method Optimization
QSRR models play a pivotal role in optimizing chromatographic methods. Understanding how structural variations in analytes influence RTs allows researchers to fine-tune chromatographic settings for enhanced separation, resolution, and analytical efficiency [13].

Reduced Expenses and Time
QSRR models offer a cost-effective and time-efficient approach to method development in chromatography. By providing insights into the relationship between molecular structure and chromatographic behavior, these models minimize the need for extensive experimental trials to identify optimal conditions [14]. This not only conserves

resources but also accelerates the pace of research and development in industries reliant on chromatographic analysis.

Environmental Analysis

QSRR in chromatography plays a vital role in predicting the behavior of pollutants and contaminants in complex environmental samples such as water. By extrapolating RT data, QSRR models aid in assessing environmental risks and ensuring regulatory compliance [15]. This capability is indispensable for monitoring and mitigating the impact of contaminants on ecosystems and human health.

Structural Clarification

QSRR facilitates the elucidation of unknown substance structures by comparing expected RTs times with experimental data. By leveraging computational tools to correlate retention behavior with molecular properties, researchers can make informed hypotheses about the chemical structure of unidentified analytes [16]. This contributes to the comprehensive characterization of complex mixtures and accelerates the process of compound identification.

Understanding Molecular Interactions

QSRR sheds light on the intricate molecular interactions occurring between analytes and chromatographic phases. By elucidating the mechanisms underlying separation processes, QSRR enhances our understanding of chromatographic phenomena and guides the development of novel separation techniques [17]. This fundamental knowledge paves the way for innovation in chromatography, enabling the design of more efficient and selective analytical methods.

Adaptability to Diverse Chromatographic Methods

QSRR can be applied across various chromatographic techniques including GC, TLC, and HPLC. This versatility underscores the utility of QSRR in diverse analytical scenarios, making it a valuable tool for researchers across different fields and industries [18].

Quality Assurance and Control

QSRR enhances quality assurance in industrial and medicinal settings by predicting retention times (RTs) under varying conditions, ensuring consistency in chromatographic analyses and safeguarding product integrity [19]. It aids in seamless method transfer between labs or equipment by minimizing validation efforts and promoting standardization [20]. By integrating computational chemistry for molecular descriptor calculations, QSRR strengthens predictive models, improving accuracy and providing deeper insights into chromatographic behavior across analytical platforms [21].

Factors influencing RT

RT refers to the duration a solute spends traversing through a chromatographic column, influenced by various parameters associated with both the mobile and stationary phases [22]. Alternatively, it can be defined as the duration between the injection of a sample combination and the appearance of its peak in the chromatogram. Several factors impact RT, including stationary phase, temperature, column length, analyte properties, mobile phase composition, flow rate, etc shown in Figure 2.

Stationary Phase

The choice of stationary phase significantly affects RT in chromatography. Different stationary phases interact with analytes distinctively, leading to varying RTs [23-25].Here are examples of different stationary phases and their effects on RT.

Silica Gel

Widely used in normal-phase chromatography, silica gel is a polar stationary phase that strongly retains polar analytes, resulting in longer retention times (RTs).

Harini Rachamallu *et al.,*

C18 (Octadecylsilane)
A common reversed-phase stationary phase with hydrophobic alkyl chains. C18 columns retain non-polar analytes strongly, allowing polar analytes to elute faster compared to silica gel columns.

Cyano (CN)
Moderately polar, cyano stationary phases provide intermediate retention for both polar and non-polar analytes, offering distinct selectivity influenced by specific functional groups.

Amide
Polar stationary phases with carbonyl groups that interact via hydrogen bonding, extending RTs for polar compounds like carbohydrates and amino acids.

Chiral Stationary Phases (CSPs)
Designed for separating enantiomers, CSPs contain chiral selectors like cyclodextrins that influence RTs based on analyte stereochemistry.

Ion Exchange Resins
Charged stationary phases used in ion chromatography separate analytes by charge properties, with RTs dependent on mobile phase pH and ionic strength.

Size-Exclusion Columns
These separate analytes by size, where larger molecules elute quickly, bypassing pores, while smaller molecules infiltrate the beads, prolonging RTs.

Mobile Phase
Components of the mobile phase, such as solvent polarity, play a crucial role in RT. Adjustment of mobile phase composition alters analyte-stationary phase interactions, consequently affecting RT. Various mobile phases and their effects on RT

Aqueous Mobile Phases
Water
A fundamental constituent of aqueous mobile phases in chromatography, water's innate polarity fosters interactions with polar analytes. Consequently, polar analytes tend to exhibit prolonged RTs in aqueous environments. [25-27]

Buffer Solutions
Buffer solutions, such as phosphate or ammonium acetate buffers, are frequently employed to regulate pH in chromatography. These buffers wield the power to modulate analyte interactions with the stationary phase, thereby influencing RTs based on pH-dependent properties.

Organic Mobile Phases
Methanol
A prevalent organic solvent in chromatography, methanol offers distinct selectivity owing to its lower polarity compared to water. Consequently, non-polar analytes may experience abbreviated RTs when subjected to methanol-based mobile phases.

Acetonitrile
Another widely utilized organic solvent, acetonitrile presents intermediate polarity and offers differential selectivity compared to methanol or water. RTs of analytes may fluctuate depending on the composition of acetonitrile in the mobile phase.

Mixed Mobile Phases

Water-Methanol Mixtures
Blending water with methanol in varying ratios enables precise tuning of solvent polarity. Mobile phases with higher methanol content tend to favor non-polar analytes, leading to reduced RTs, while those skewed towards higher water content favor polar analytes, resulting in elongated RTs.

Water-Acetonitrile Mixtures:
Analogous to water-methanol mixtures, adjusting the ratio of water to acetonitrile allows for modulation of solvent polarity and selectivity. Mobile phases with elevated acetonitrile content may expedite elution of non-polar analytes, whereas those with a higher water content may protract RTs for polar analytes.

Ionic Mobile Phases
Incorporating salts like sodium chloride or ammonium sulfate into the mobile phase can modulate the ionic strength, thereby influencing analyte retention. Ionic interactions between analytes and the stationary phase are augmented or perturbed by the presence of salts, thereby exerting a pronounced effect on RTs.

pH-Modified Mobile Phases
Manipulating the pH of the mobile phase using acids (e.g., formic acid) or bases (e.g., ammonium hydroxide) facilitates alterations in analyte ionization and polarity. This transformative adjustment can significantly impact RTs, particularly for ionizable compounds.

Column Temperature in Chromatography
Column temperature plays a crucial role in chromatography by influencing analyte interactions with the stationary and mobile phases. Understanding its effects allows for optimizing chromatographic conditions and improving separation efficiency and retention time (RT) control[28,29].

Gas Chromatography (GC)
In GC, temperature increases enhance analyte volatility and vapor pressure, reducing RTs. Higher temperatures expedite the analysis of volatile organic compounds (VOCs) by shortening elution times[30].

Liquid Chromatography (LC)
In reversed-phase LC (RPLC), increased temperatures reduce hydrophobic interactions, decreasing RTs for non-polar analytes. In normal-phase LC (NPLC), higher temperatures improve analyte solubility in the mobile phase, weakening interactions with the stationary phase and lengthening RTs for polar compounds[31,32].

Size-Exclusion Chromatography (SEC)
Temperature influences macromolecule mobility in SEC. Higher temperatures increase the mobility of large molecules, shortening RTs, as seen in protein separations.

Ion Chromatography (IC)
Temperature affects ion mobility and ionization in IC. Elevated temperatures enhance ion mobility, reducing RTs and speeding up the analysis of inorganic ions [33].

Chiral Chromatography
Temperature changes influence the enantio selectivity of chiral stationary phases (CSPs). Adjusting temperature alters interactions with enantiomers, impacting RTs and enantiomer resolution[34,35].

Harini Rachamallu *et al.,*

Analyte Properties

The size, chemical structure, and polarity of analytes play a pivotal role in determining RT in chromatography. Generally, more polar analytes demonstrate shorter RTs in reverse-phase chromatography. Molecular properties significantly impact retention times (RTs) in chromatography. Larger molecules typically exhibit longer RTs due to increased interactions with the stationary phase, while in size exclusion chromatography (SEC), they experience prolonged RTs by being excluded from stationary phase pores.[36] Complex chemical structures, like aromatic compounds, engage in π-π interactions, extending RTs in reversed-phase liquid chromatography (RPLC). Polarity and hydrophobicity influence RTs based on interactions with stationary phases in normal-phase (NPLC) and RPLC, respectively.[37] Additionally, ionization state affects RTs depending on mobile phase pH, while functional groups, especially in chiral analytes, determine RTs through stereochemical interactions.[38]

Flow Rate

The flow rate in chromatography directly influences retention time (RT). Higher flow rates result in shorter RTs due to reduced interaction time with the stationary phase, while lower flow rates prolong RTs by increasing analyte interaction. Optimizing flow rates balances analysis speed with adequate separation and resolution, ensuring reliable results.[39]

Pressure

In HPLC, pressure significantly affects RT and overall performance. Higher pressure enhances column efficiency and mass transfer, leading to shorter RTs. However, excessive pressure may compromise column stability and resolution. Proper pressure management is crucial for achieving accurate, reproducible outcomes.[28,35,40]

Column Length

Longer columns increase analyte interaction with the stationary phase, extending RT and improving resolution, albeit with longer analysis times and higher costs. Balancing column length with RT, resolution, and efficiency is key to optimizing chromatographic performance.

Analyte Concentration

Higher analyte concentrations typically extend RT due to intensified interaction with the stationary phase. Variations in concentration can affect peak shape, detection sensitivity, and quantification accuracy, influencing overall chromatographic results.[41]

Significance of predicting RT

Predicting RT is a crucial task in analytical chemistry, offering several advantages that enhance efficiency and accuracy in identification and quantification processes.

Technique Development Facilitation

Predicted RT aids in technique development by assisting in the selection of optimal stationary phases, mobile phases, and column temperatures for chromatographic separations. [42]

Identification Capability

Each compound exhibits a distinct RT, enabling the identification of unknown compounds by comparing their RTs with those of known standards. [43]

Quality Control Assurance

Comparison of RTs between test and standard samples facilitates quality control, aiding in the detection of contamination, impurities, and adulteration in various fields. [44]

Harini Rachamallu *et al.,*

Sample Identification
RT comparison between known and unknown samples allows for easy identification of unknown compounds, utilizing known RTs as benchmarks for detection.[44]

Cost Savings
Predicting RTs leads to increased accuracy and reduced trial and error, resulting in cost savings by minimizing unnecessary experimentation and analysis. [45]

Time Efficiency
Prediction of RTs contributes to shorter chromatographic analysis durations, thereby reducing the overall duration of the analytical process. [46] While the benefits of RT prediction are substantial, achieving them requires adherence to complex procedures and strategies rooted in principles of chromatography. Various approaches and techniques, including statistical and computational methods utilizing precise datasets, have been extensively employed by researchers to forecast RT accurately.

Quantitative Structure-Retention Relationship (QSRR)
Quantitative Structure-Retention Relationship (QSRR) is a predictive approach used to estimate compound retention times (RTs) in chromatographic systems based on structural and physicochemical data. [47]. This review explores QSRR principles, methodologies, and recent advancements, focusing on data sources, model development strategies, and applications in analytical chemistry. Additionally, it addresses challenges and future prospects, emphasizing QSRR's significance in predicting RTs and enhancing chromatographic analyses.

Theoretical foundation
The theoretical foundation of QSRR lies in the principle that a compound's retention time (RT) is determined by its chemical structure and physicochemical properties. This relationship can be mathematically represented as: tR = f(Structure, Physicochemical Properties), where tR is the RT. "Structure" includes molecular descriptors like chemical formula, connectivity, and molecular weight, while "Physicochemical Properties" cover polarity, hydrophobicity, and acid-base characteristics. QSRR models quantitatively link these factors to RT using statistical methods, machine learning, or quantum chemical calculations.

Descriptors and Molecular Representation
An integral facet of QSRR lies in the meticulous selection of pertinent molecular descriptors and the accurate representation of chemical structures. Descriptors serve as numerical representations of chemical attributes, adept at capturing both the structural intricacies and physicochemical properties of compounds such as size, shape, polarity, electronic properties, and other pertinent characteristics.[48] These descriptors play a crucial role in various fields including computational chemistry, cheminformatics, and drug discovery, facilitating investigations such as QSAR, QSPR, and QSRR[23,49] shown in Figure 3.By mathematically capturing the essence of chemical compounds, molecular descriptors essentially create molecular fingerprints, providing deeper understanding of their characteristics and functions. They are particularly invaluable in disciplines like material science and pharmaceutical research. In recent times, molecular fingerprints have garnered attention due to their efficacy in encoding the presence or absence of specific substructures within a molecule. These fingerprints facilitate the efficient management of extensive datasets and facilitate the development of robust machine learning modelsand enhances the efficiency and precision of analyses in diverse scientific endeavors.

Zero-dimensional (Topological) molecular descriptors
Zero-dimensional (0D) molecular descriptors constitute a foundational class of descriptors that offer essential molecular information independent of spatial arrangement or connectivity. Although they appear simplistic in contrast to higher-dimensional descriptors, they yield valuable insights into fundamental properties critical across chemical and biological domains. Nonetheless, their simplicity inherently imposes limitations on the breadth and depth of information they convey when compared to descriptors of higher dimensions. [50]

Molecular Formula and Atom Information

The molecular formula provides the elemental composition of a molecule, indicating the types and numbers of atoms present. Atom information includes the identification and counting of different atom types (e.g., carbon, hydrogen, oxygen) and their connectivity. Bond information involves the types of chemical bonds (e.g., single, double, triple) connecting atoms.

Ionization Potential

This descriptor measures the energy required to extract an electron from a molecule or atom, reflecting its stability and reactivity.

Electronic Charge Distribution

Describes the distribution of electrons within the molecule, providing insights into its electronic structure and reactivity.

Constitutional Descriptors

These descriptors are based on the chemical makeup of the molecule, providing fundamental information about its composition like molecular weight, number of atoms, and rotatable bonds etc.

These foundational information about molecules, essential for various applications such as drug design, chemical synthesis, and property prediction. While they offer simplicity and ease of computation, they may lack the detailed structural information provided by higher-dimensional descriptors.

One dimensional (1D) molecular descriptors

One-dimensional molecular descriptors characterize structural fragments such as fingerprints, functional groups, and substituents, offering key insights into molecular structure.[48] Molecular fingerprints, widely used in similarity searches and virtual screening, are binary or hashed representations indicating the presence or absence of specific substructures. Chemical fingerprints encode structural substructures, [51] while circular fingerprints capture circular substructures around atoms for detailed representation. These descriptors are valuable tools in drug discovery, chem. informatics, and computational chemistry, providing concise numerical representations of molecular structure for efficient analysis and prediction of molecular properties and behaviors.[52]

Two dimensional (2D) molecular descriptors

Two-dimensional molecular descriptors provide key insights into molecular structure and properties essential for predicting retention times (RTs) in QSRR. These descriptors, calculated from a molecule's 2D representation, capture connectivity, functional groups, and topological indices. Common descriptors include molecular volume, shape indices, atom and bond counts, and topological measures like the Wiener and Zagreb indices. Molecular volume, reflecting atom spatial distribution, informs on size, reactivity, and solubility, impacting chromatographic behavior. This approach is valuable in fields like analytical chemistry, pharmaceuticals, and biochemistry, where chromatography is crucial for compound analysis and separation. [53]

Three-dimensional (3D) molecular descriptors

3D molecular descriptors are crucial for predicting retention times (RTs) in chromatography by capturing the spatial arrangement of atoms. These descriptors model interactions between analytes and the stationary phase, improving RT accuracy. Chirality descriptors are essential in chiral separations, reflecting how stereochemistry affects retention behavior, critical in pharmaceutical analysis for enantiomeric purity. Additionally, 3D pharmacophores highlight key spatial features influencing molecular interactions, aiding RT predictions. By identifying structural elements for effective binding, pharmacophore descriptors support designing optimized chromatographic methods for specific analytes, enhancing separation efficiency and analytical performance. [52, 54]

Harini Rachamallu *et al.,*

Four-dimensional (4D) molecular descriptors

4D molecular descriptors enhance QSRR models for predicting retention times (RTs) by offering deeper insights into molecular properties and interactions. Beyond traditional 1D, 2D, and 3D descriptors, 4D descriptors incorporate time-dependent properties and environmental variations, capturing dynamic molecular behavior. This comprehensive portrayal improves RT predictions by considering factors like molecular dynamics and temporal changes that influence chromatographic separations. Integrating 4D descriptors into QSRR models increases accuracy and reliability, driving advancements in pharmaceuticals, environmental science, and chemical analysis by enabling more precise chromatographic analyses and better method optimization. [52,54]

Modeling Statistics

Following the selection of relevant descriptors, a variety of statistical and machine learning models are employed to establish the quantitative relationship between these descriptors and RT.50 Regression analysis serves as a pivotal tool in elucidating the link between descriptors and specific molecular characteristics or behaviors. By employing regression analysis, we can discern the contributions of individual descriptors to the property of interest, unveiling their relative importance and influence. This analytical approach finds applications across diverse sectors such as drug discovery, materials science, and chemical engineering, shedding light on fundamental factors governing molecular behavior. [55]

Linear Regression Models

Linear regression models, including simple linear regression and regression with multiple linear variables, form the cornerstone of regression analysis. In simple linear regression, the relationship between two variables is represented as a linear combination of descriptors and corresponding coefficients. Regression with multiple linear variables expands upon this basic framework by incorporating multiple descriptors simultaneously. [56] Previous research has demonstrated the effectiveness of combining genetic algorithms with multiple linear regression for handling both constrained and unconstrained problems. [57]

Nonlinear Regression Models

Nonlinear regression techniques, such as polynomial regression and spline regression, enable the modeling of nonlinear relationships by incorporating polynomial terms or piecewise polynomials for the descriptor. [58] Kernel regression further extends this capability by leveraging kernel functions to capture intricate nonlinear relationships by transforming data into a higher-dimensional space.

Machine Learning Models

Machine learning models offer powerful tools for capturing complex relationships between descriptors and RT. Support Vector Machines (SVMs) identify hyperplanes that maximize the margin between data points, effectively capturing intricate relationships. [59]. Ensemble techniques, such as Random Forest, are particularly adept at capturing complex relationships between descriptors. Deep learning models, such as Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), [60] with multiple layers, excel at depicting intricate, nonlinear functions and can be adapted for QSRR tasks.[61] Additionally, methods like K-Nearest Neighbors (KNN) and Gradient Boosting, including Light GBM and XG Boost, demonstrate exceptional prediction accuracy and are frequently employed for QSRR tasks, especially in processing high-dimensional descriptor spaces and capturing complex patterns in data. [62]

Chemometric Approaches

Chemometrics, a multidisciplinary field combining statistics, mathematics, and chemistry, offers invaluable techniques for modeling and processing chemical data in QSRR. [63]

Principal Component Analysis (PCA)

PCA reduces the dimensionality of the dataset by transforming descriptors into a new set of uncorrelated variables known as principal components. This facilitates data visualization and highlights significant structural elements. [64]

Harini Rachamallu *et al.,*

Partial Least Squares (PLS)

PLS combines multiple linear regression and PCA, identifying latent variables that capture the most variance in RT and descriptors. It is especially useful in cases with multicollinearity and many descriptors [65]. Integrating regression analysis, machine learning, and chemometric approaches in QSRR provides a robust framework for predicting RT, advancing research, and discovering compounds with desired properties.

QSRR Model Evaluation

Performance Metrics

Performance metrics are fundamental tools for evaluating the efficacy and precision of QSRR models developed for prognosticating RT in chromatographic methods. [66] Widely utilized metrics encompass

Root Mean Square Error (RMSE)

RMSE gauges the root of the average squared deviation between predicted and observed RTs. Reduced RMSE values signify enhanced model performance.

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}$$

Where n denotes the number of observations, y_i represents the observed RT, and $\hat{y}_i$ signifies the predicted RT.

Coefficient of Determination (R²)

R^2 delineates the ratio of the variance in RT elucidated by the model. Augmented R^2 values, nearing unity, indicate superior model fit to the data. [67]

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2}$$

Where $\tilde{y}$ denotes the mean of observed RTs.

Cross-validated Coefficient of Determination (Q²)

Q^2 assesses the predictive capability of the model via cross-validation. Elevated Q^2 values connote enhanced predictive performance. [67]

$$Q^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2}$$

Where $\hat{y}_i$ represents the predicted RT from cross-validation.

Mean Absolute Percentage Error (MAPE)

MAPE delineates prediction errors as a percentage of observed values, offering insight into the relative precision of the model.

$$MAPE = \frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right| \times 100\%$$

These metrics serve as indispensable benchmarks for scrutinizing the fidelity and efficacy of QSRR models, ensuring their applicability and reliability in chromatographic method prediction and refinement.

Bias-Variance Trade-off

The bias-variance trade-off is critical in QSRR model development. High bias results in underfitting, oversimplifying the RT prediction, while high variance leads to overfitting and poor generalization. Balancing both requires choosing the right model complexity. Techniques like cross-validation and regularization help mitigate overfitting by penalizing overly complex models[68].

Harini Rachamallu *et al.,*

Model Robustness and Reliability

Ensuring QSRR model robustness and reliability is crucial for accurate RT predictions in chromatography [69]. Techniques like cross-validation, bootstrapping, and external validation with independent datasets assess model performance and generalization [70]. Validating predictions against varied experimental conditions, including column types and temperatures, ensures consistency and accuracy across diverse scenarios.

Overfitting and Underfitting Assessment

Overfitting and underfitting are key challenges in QSRR model development. Overfitting occurs when a model captures noise in the training data, leading to poor performance on new data, often due to excessive complexity or inadequate regularization. Underfitting happens when a model fails to capture the data's underlying patterns, resulting in low accuracy. Cross-validation helps identify these issues by comparing performance on training and validation sets. High training accuracy with low validation accuracy suggests overfitting, while poor performance on both indicates underfitting. Regularization methods like ridge and lasso regression help mitigate overfitting by penalizing excessive complexity, improving model generalizability.

Interpretability of the Model

Interpretability is crucial in QSRR models for RT prediction, as it allows researchers to understand how molecular descriptors influence retention behavior. This insight aids in optimizing compounds and designing effective chromatographic methods. Linear regression models like multiple linear regression (MLR) and partial least squares (PLS) regression are inherently interpretable, providing clear coefficients that show the impact of each descriptor on RT. Advanced techniques such as feature importance analysis also help identify key descriptors, even in complex models [71]. Prioritizing interpretability enhances the practical utility of QSRR models, fostering trust and enabling better decision-making in chromatographic research.

DISCUSSIONS

Analytical chemistry serves as a cornerstone across various industries, from pharmaceuticals to forensics, providing invaluable insights into the identification and quantification of substances. Within this domain, QSRR stands out as a powerful tool, particularly in chromatography, aiding in the precise estimation of RTs (RT) of compounds. By establishing a mathematical correlation between the chemical composition of compounds and their RTs, QSRR enables predictive modeling and optimization in chromatographic techniques such as gas chromatography (GC) and liquid chromatography (LC). The scope of QSRR in chromatography is vast and multifaceted, offering numerous benefits across different analytical challenges. One of its primary advantages lies in its predictive capability, allowing for the anticipation of RTs for compounds based on their chemical structure. This predictive power is instrumental in identifying and quantifying individual components within complex mixtures, facilitating method optimization and reducing expenses and time associated with method development. Furthermore, QSRR plays a crucial role in environmental analysis by aiding in the prediction of pollutant behavior and structural clarification of unknown substances. The theoretical foundation of QSRR is rooted in the intricate relationship between a compound's chemical structure, physicochemical properties, and its RT. By leveraging molecular descriptors to mathematically represent these factors, QSRR models provide a quantitative framework for understanding and predicting RTs. These descriptors, ranging from zero-dimensional to four-dimensional representations, capture essential structural and physicochemical characteristics of compounds, essential for accurate RT predictions. Modeling statistics, including linear regression models, nonlinear regression models, machine learning models, and chemometric approaches, are employed to establish the quantitative relationship between descriptors and RT. These models undergo rigorous evaluation using performance metrics such as Root Mean Square Error (RMSE), Coefficient of Determination (R^2), Cross-validated Coefficient of Determination (Q^2), and Mean Absolute Percentage Error (MAPE). Additionally, the bias-variance trade-off, model robustness and reliability, overfitting and underfitting assessment, and interpretability of the model are critical considerations in QSRR model development.

Harini Rachamallu *et al.,*

CONCLUSION

QSRR holds immense potential in advancing chromatographic analysis by providing a systematic approach to predict RTs based on compound structure and physicochemical properties. Its application spans across various industries, offering cost-effective and time-efficient solutions for method optimization, environmental analysis, structural elucidation, and quality assurance. As technology continues to evolve, QSRR remains at the forefront of analytical chemistry, driving innovation and pushing the boundaries of scientific inquiry.

ABSTRACT

1-Naphthol picrate has been synthesized and characterized, and its third-order nonlinear optical properties were investigated via Z-scan studies. It demonstrates reverse saturable absorption, as indicated by a positive absorption coefficient β, which is of the order 10^{-12} m/W. Closed aperture data indicate positive refractive nonlinearity due to self-focusing, with nonlinear refractive index n_2, third-order susceptibility $\chi^{(3)}$ and second-order hyperpolarizability γ in the order of 10^{-19} m²/W, 10^{-13} esu and 10^{-34} esu respectively. Additionally, it exhibits an optical limiting property with a threshold of 18.66J/cm². Optical limiting is crucial for protecting sensitive optical sensors and human eyes from damage caused by intense laser beams. Therefore, 1-naphthol picrate is highly recommended for optical limiting applications due to its effective third-order nonlinear optical properties and low threshold for limiting.

Keywords: Z Scan, Third-Order Nonlinear Optical (NLO) Properties, Optical Limiting

INTRODUCTION

Nonlinear optics plays a crucial role in modern photonics, encompassing various phenomena such as second-order and third-order nonlinearities [1-3]. Among these, third-order nonlinearities are particularly important due to their ability to facilitate processes like third-harmonic generation, self-phase modulation, and the optical Kerr effect, which

are essential for manipulating light in advanced optical systems[4-5]. These third-order effects enable precise control over light propagation, phase, and intensity, allowing for the development of sophisticated optical devices such as all-optical switches, modulators, and signal processors. Additionally, third-order nonlinearities are pivotal in creating new frequencies of light through processes like four-wave mixing, expanding the versatility and functionality of optical technologies [6-8]. The significance of third-order nonlinearities extends to their crucial role in optical limiting, where they protect sensitive equipment and human vision from high-intensity laser beams, ensuring safety and reliability in various applications [9-10].In today's era of rapidly advancing laser technologies, optical limiting is increasingly relevant for safeguarding delicate optical sensors and human eyes from accidental exposure to high-power laser pulses. This protection is vital not only in industrial and scientific research settings but also in consumer electronics and medical devices, where the prevalence of laser use continues to grow. Organic molecules with aromatic rings are highly promising for third-order nonlinear optical applications due to their exceptional nonlinearity, high tolerance to optical damage, and rapid electronic response [11-12]. Among these, picric acid derivatives stand out as compelling candidates, owing to their readily accessible charge transfer interactions, which confer strong nonlinear optical (NLO) activity [13-15]. Despite the potential of picrates, 1-naphthol picrate remains relatively unexplored regarding its nonlinear optical behavior. Therefore, this study aims to conduct a comprehensive investigation into the third-order nonlinear optical responses and optical limiting properties of 1-naphthol picrate through z-scan studies.

MATERIALS AND METHODS

The reagents used for the synthesis were of AR grade. Solvents were purified and dried according to standard procedures. 1-Naphthol and picric acid were purchased from Merck and used without further purification. Purity of the product was checked by TLC and melting point determination (BUCHI, B540). Characterization was done using FT-IR (Bruker Alpha-E FT IR).

Synthesis of 1-Naphthol Picrate
1-Naphthol Picratewas synthesized by slow evaporation of methanolic solution containing equimolar amount of 1-naphthol and picric acid. Solution of equimolar amounts of naphthol and picric acid in Methanol were prepared separately. After mixing the two solutions, the resultant solution is stirred well. Within two days, bright yellow crystals of 1-naphthol picrate were formed. The obtained crystalline material mixed with methanol and allowed to evaporate at room temperature. Good morphological yellow-coloured crystals were grown within one week.Purity was checked by TLC and melting point determination. Melting point for the title compound is obtained as 191.1˚(Methanol).

Z-scan Studies
The Z-scan technique holds significant relevance for investigating third-order nonlinear optical properties and optical limiting characteristics due to its ability to accurately measure nonlinear absorption, nonlinear refraction, and third-order nonlinear optical susceptibility. By traversing the sample along the focal point of a lens, the technique provides insights into the material's response to intense light, distinguishing between reverse saturable absorption and saturable absorption mechanisms. This thorough characterization enables the identification of materials with desirable optical limiting properties, crucial for the development of effective laser safety measures and advanced photonic devices [16-17]. The open aperture Z-scan technique involves measuring the transmission of a sample while keeping the aperture fully open, allowing the entire beam to pass through the sample. This setup is useful for investigating nonlinear absorption processes such as reverse saturable absorption (RSA), where the intensity-dependent transmission is observed due to nonlinear absorption mechanisms within the material [18].In contrast, the closed aperture Z-scan technique involves partially blocking the beam using an aperture, allowing only a fraction of the beam to pass through the sample. This configuration is employed to study nonlinear refraction effects such as self-focusing or self-defocusing, where changes in the beam's phase and focal length occur due to nonlinearities in the refractive index of the material[19].In summary, open aperture Z-scan measures nonlinear absorption processes,

while closed aperture Z-scan assesses nonlinear refraction effects, providing complementary information about the third-order nonlinear optical properties of the material. Indeed, for a molecule to effectively exhibit optical limiting properties, it must possess both reverse saturable absorption behavior and positive nonlinear refractive properties. Reverse saturable absorption (RSA) allows the material to absorb more light as the intensity increases, effectively limiting the transmission of high-intensity light through the medium. Additionally, positive nonlinear refractive properties indicate that the material exhibits self-focusing behavior, where the refractive index increases with increasing light intensity, leading to the defocusing of intense light and thereby contributing to optical limiting capabilities. Together, these characteristics enable the molecule to efficiently mitigate the effects of high-intensity light, making it suitable for optical limiting applications in various fields such as laser safety and photonics. Z-scan measurement was carried out using Q-switched Nd-YAG laser having 5 ns pulses at a repletion rate of 10 Hz giving second harmonic at 532 nm. The laser beam was focused by a lens of 10 cm focal length. In this technique sample is mounted on the translation stage and translating the sample between +Z and –Z position along Z-direction. The radius of the beam waist ω_0 was calculated to be 35μm. The Rayleigh length, was calculated as 7.42 mm, is greater than the thickness of the sample cuvette (1mm), an essential requirement for Z-scan experiments. The third- order nonlinear refractive index n_2 and nonlinear absorption coefficient β, third order NLO susceptibility $\chi^{(3)}$, second hyperpolarizability γ(third order effect) of 1-naphthol picrate in acetone having 0.5 mM concentration and intensity at 1.08 GW/cm2 were evaluated by closed and open aperture Z-scan techniques.

RESULTS AND DISCUSSIONS

Characterization using FT-IR

FT- IR spectrum of 1-naphthol picrate is given in Figure 1.The O-H stretching vibrations are sensitive to hydrogen bonding. The non-hydrogen-bonded or free hydroxyl group absorbs strongly in the 3600–3550 cm^{-1} region, whereas the existence of an intermolecular hydrogen bond can lower the O-H stretching wave number to the 3550–3200 cm^{-1} region with the increase in IR intensity. The O-H stretching vibration appears as a weak band in IR at 3120 cm-1 which reveals the presence of intramolecular hydrogen bonding and a strong band corresponds to the OH vibration. The characteristic infrared absorption wavenumbers of carbonyl group in cyclic ketones are present. The C=O stretching mode can be easily identified from IR spectra and because of the degree of conjugation, the strength and polarizations are increased. The carbonyl stretching vibrations in ketones are expected in the region 1715–1680 cm^{-1}. Peaks around 1300-1500 cm^{-1} are attributed to aromatic C=C stretching vibrations, characteristic of the naphthalene ring in 1-naphthol. Furthermore, peaks in the region of 1000-1200 cm^{-1} indicate the presence of C-O stretching vibrations, likely originating from the ether linkage in the molecule.

Third Order Nonlinear Optical Studies of 1-Naphthol Picrate
Open Aperture (OA) Z-Scan Plot

Nonlinear absorption characteristics of 1-naphthol picrate have been obtained from open aperture Z-scan plot. Figure 2 shows the open aperture (OA) Z-scan curve of 1-naphthol picrate at 0.5 mM concentration in acetone and 1.08 GW/cm2 intensity. The obtained OA curve shows decrease in transmittance (a dip) as the sample passes through the focal point of the lens (z = 0). This dip occurs because the absorption increases with the light intensity at the focus, resulting in less transmitted light. It is the characteristic feature of reverse saturation behavior where the material absorbs more light as the light intensity increases. Hence the absorption coefficient β is positive. A material with reverse saturable absorption property shows increase in absorption when increase in laser intensity. From the following curve, it is clear that open aperture plot of 1-naphthol Picrate shows excellent agreement with theoretical fit.

Closed Aperture (CA) Z-Scan Plot

Closed Aperture (CA) Z-Scan Plot of 1-naphthol picrate at 0.5 mM concentration in acetone and 1.08 GW/cm2 intensity have been recorded and is shown in Figure 3.In the closed aperture Z-scan data of 1-naphthol picrate, the presence of a valley followed by a peak in the normalized transmittance curve indicates positive nonlinear refraction.

Anju Linda Varghese *et al.,*

This pattern signifies that as the sample approaches the focal point (z = 0), the refractive index increases with light intensity, causing the beam to focus more tightly. This self-focusing effect leads to a reduction in transmittance (valley) because the beam becomes more concentrated within the aperture. As the sample moves past the focus, the beam diverges, resulting in an increase in transmittance (peak). This characteristic valley-peak sequence is a clear indicator of positive nonlinear refractive behavior, confirming the self-focusing nature of 1-naphthol picrate.

The normalized transmittance T(z) is given by

$$T\left(z,\Delta\phi_0\right) = 1 - \frac{4\Delta\phi_0 x}{(x^2+9)(x^2+1)}$$ ---------------- **(1)**

Where, $\Delta\phi_0$ is the on axis nonlinear phase shift and x is z/z_0. The nonlinear refractive index n_2 and real part of third-order nonlinear susceptibility, Re $\chi^{(3)}$ were calculated by the following relations[20].

$$n_2 = \frac{\Delta\phi_0 \lambda}{2\pi I_0 L_{eff}}$$ ---------------- **(2)**

$$\mathrm{Re}\,\chi^{(3)} = 10^{-4}\frac{\varepsilon_0 n_0^2 c^2}{\pi} n_2$$ ---------------- **(3)**

The imaginary part of the third order susceptibility (Im$\chi^{(3)}$) was calculated from β through the relation

$$\mathrm{Im}\,\chi^{(3)} = 10^{-2}\frac{\varepsilon_0 n_0^2 c^2 \lambda}{4\pi^2}\beta$$ ---------------- **(4)**

Where, ε_0 is the permittivity of free space, c is the velocity of light in vacuum and n_0 is the linear refractive index.

The third-order nonlinear susceptibility, $\chi^{(3)}$ was calculated from the relation

$$\chi^{(3)} = \left[(\mathrm{Re}\,\chi^{(3)})^2 + (\mathrm{Im}\,\chi^{(3)})^2\right]^{1/2}$$ ---------------- **(5)**

The second order hyperpolarizability, γ of the sample is related to the third-order susceptibility through the equation

$$\gamma = \frac{\chi^{(3)}}{\left[\frac{1}{3}\left(n_0^2+2\right)\right]^4 N}$$ ---------------- **(6)**

Where, N is the molecular number density in cm^{-3}.

The third order nonlinear refractive index n_2, nonlinear absorption coefficient β, third order NLO susceptibility $\chi^{(3)}$ and second order hyperpolarizability γ of 1-naphthol picrate in acetone having 0.5 mM concentration and intensity at 1.08 GW/cm^2 were evaluated by the measurements of closed and open aperture Z-scan techniques and are enlisted in Table 1.The values presented in Table 1 highlight key nonlinear optical properties of the material under study, which have significant implications for various applications in photonics and optoelectronics. The nonlinear absorption coefficient β (m/W) is of the order of 10^{-12}. This coefficient indicates the material's ability to absorb light in an intensity-dependent manner, which is crucial for applications such as optical limiting and the protection of sensitive optical components from high-intensity light. The nonlinear refractive index n_2 is of the order of 10^{-19} m^2/W which measures the intensity dependent change in the refractive index. This property is essential for applications in all-optical switching, modulation, and the development of advanced photonic devices that leverage light. Additionally,

the third-order susceptibility $\chi^{(3)}$ and second-order hyperpolarizability γ are of the order of 10^{-13} esu and 10^{-34} esu, respectively. $\chi^{(3)}$ is a fundamental parameter describing the third-order nonlinear response of the material, indicating its ability to interact with high-intensity light in a non-linear fashion. γ further elucidates the strength of the nonlinear interaction, providing insights into the efficiency of various nonlinear optical processes within the material. These parameters collectively underscore the material's potential for integration into advanced optical systems, enabling innovations in optical limiting, signal processing, and other photonic applications.

Optical Limiting Properties of 1-NaphtholPicrate
Figure 4 illustrates the optical limiting curve of 1-naphthol picrate, where the normalized transmission is plotted against the input power for a 0.5 mM solution. At a threshold value of 18.66 J/cm², a self-focusing effect occurs, significantly reducing the beam intensity that reaches the detector. This self-focusing effect causes a notable decrease in the transmittance recorded by the detector. The importance of this behavior lies in its application potential for optical limiting devices, which are essential for safeguarding sensitive optical sensors and human eyes from high-intensity light sources. The ability of 1-naphthol picrate to clamp transmitted intensity through self-focusing makes it a promising material for developing advanced optical limiters, ensuring protection against laser-induced damage.

CONCLUSION

1-Naphthol picrate has been synthesized and characterized and found to be third order NLO active from Z-scan study. The Z-scan technique reveals its reverse saturation behavior, characterized by a positive absorption coefficient β of the order 10^{-12} m/W. This behavior is crucial for optical limiting, which protects sensitive optical sensors from damage by intense light pulses. The positive nonlinear refractive index n_2 of the order 10^{-19} m²/W, indicates self-focusing properties, essential for beam control in optical systems. The third-order nonlinear optical susceptibility $\chi^{(3)}$ and the second-order hyperpolarizability γ are of the order of 10^{-13} esu and 10^{-34} esu, respectively, confirm the picrate's strong nonlinear response. The optical limiting threshold of 18.66 J/cm² indicates its effectiveness in limiting high-intensity light, ensuring its applicability in protecting optical devices. These properties underscore 1-naphthol picrate's potential in optical limiting applications, where controlling light intensity is crucial for device safety and performance.

ABSTRACT

Sorghum is a versatile grain with promising agricultural, industrial, and nutritional applications. Sorghum production in India stands at 8.71 million tonnes. It is grown on 4.01 lakh hectares in Tamil Nadu, with a yield of 612 kg/ha. The output is 4.6 lakh tonnes. Technical efficiency of sorghum farmers in Namakkal district, with a focus on factors influencing productivity. A study was carried out in Namakkal district to investigate the technical efficiency of sorghum production as well as the constraints that sorghum farmers face. The study included a sample of 120 respondents chosen at random and analyzed using stochastic frontier analysis and the garret ranking technique. This study concluded the efficiency level of sorghum production in a selected study area and investigated the problems encountered by sorghum farmers. The mean technical efficiency of the study area obtained 0.82. Because selected variables like seed, plant protection measures, chemical fertilizer, irrigation and machinery usage are high significant at positive nature.

Keywords: Productivity, Stochastic frontier production, Technical Efficiency, Constraints, Garret Ranking.

INTRODUCTION

Sorghum a drought-tolerant crop grown by small farmers in rainy regions. Sorghum is a popular food among high-income individuals due to its high nutritional value. Efficient production is systems benefit agricultural growth, nutritional security, and rural livelihoods in countries such as India and Nigeria, where sorghum is a major crop [1]. Improving the use of existing technologies by all households, rather than introducing new technology, can increase sorghum output. Smallholder households growing sorghum lack technical efficiency, which can be improved by addressing important policy variables that impact their level of technical inefficiency [2]. The extension support system should work towards awareness building in terms of improving economic and technical efficiency of inputs [3]. Comparing Technical efficiency and productivity across farming systems, methods, and locations, including periurban and rural areas [4]. Consider the profitability, employment generation, and technical efficiency of various cropping systems, rather than a single enterprise. There is a growing emphasis on doubling farmers' income and eliminating hunger. Farming systems have the potential to reduce production risks, increase profitability, optimize resource utilization, and generate sustainable income in today's agricultural policy context [5]. The marginal value productivity analysis revealed that all variables, except farm yard manure, were used inefficiently in sorghum farms. Maize farms used all variables inefficiently. Farmers of sorghum and maize faced significant challenges such as pest and disease outbreaks, high labor costs, lack of value-added awareness, and limited processing options [6]. Sorghum production by smallholder farmers in the county is inefficient in terms of resource utilization [7]. Sorghum is a high-yield crop in the area under investigation. In this focus the current study which examines technical efficiency and production constraints faced by the sorghum farmers based on the study area.

MATERIALS AND METHODOLOGY

Tamil Nadu offers a plethora of studies. The area under cultivation of sorghum crop ranks first in Namakkal district in overall Tamil Nadu [8]. A predetermined interview schedule was used to collect primary data. The data for the 120 sample farmers respondents was collected using the random sampling method. In this section, I examined the technical efficiency of frontier stochastic production function analysis, as well as the constraints that sorghum farmers face when using the Garrett Ranking Technique.

Technical Efficiency

The stochastic frontier production function for estimating farm level technical efficiency is specified as

$$Y_i = f(X_i \beta) + e_i \qquad\qquad \text{......................... (1)}$$

Here i is the nth observations, Y_i is output, X_i is denotes the actual input vector of production function and β is the vector of parameters of production function and e is the error term is divided of two elements, that is

$$e_i = V_i - U_i \qquad\qquad \text{................. (2)}$$

Here, V_i is the symmetric disturbances assumed to be identical, independently and normally distributed as $N(0, \sigma_{vi}^2)$ given the stochastic structure of the frontier. Next U_i is a one side error term that is independent of V_i and is normally distributed as $(0, \sigma_{ui}^2)$. The farm specific technical efficiency is defined in terms of observed output (Y_i) to the corresponding frontier output (Y^*_i) using the available technology derived which is defined as follows:

$$TE_i = \frac{Y_i}{Y_i} = \frac{E\left(Y_i / u_i \, X_i\right)}{E\left(Y_i / u_i = 0, \ X_i\right)}$$

$$= E\left[exp^{-U_i / e_i}\right] \qquad\qquad \text{.............................(3)}$$

In measuring the technical efficiency this study assumed that yield of sorghum production (Kg) is dependent on farm size (ha), quantity of seeds (kg), labor (man day), plant production measures (lit), chemical fertilizer (kg), irrigation (no.) and machinery usage (hr). The stochastic model was specified as,

$$\ln(Y) = \beta_0 + \beta_1 \ln X_1 + \beta_2 \ln X_2 + \beta_3 \ln X_3 + \beta_4 \ln X_4 + \beta_5 \ln X_5 + \beta_6 \ln X_6 + \beta_7 \ln X_7 + V_i - U_i \qquad \text{..................... (4)}$$

Where,

Sujith Sankar and Ramanathan

Y = sorghum yield

X_1 = farm size (ha)

X_2 = quantity of seeds (kg)

X_3 = labor (man day)

X_4 = plant production measures (lit)

X_5 = chemical fertilizer (kg)

X_6 = irrigation (no.)

X_7 = machinery usage (hr)

β_0 = constant

$\beta_0 - \beta_7$ = Coefficient of independent variable $X_1 - X_7$

v_i = random error team which is assumed to be independent and normally distributed as N $(0, \delta^2)$

u_i = technical inefficiency which is assumed to be independent and a truncated normal distribution at zero with mean μ_i and variance δ^2_u, N (μ_i, δ^2_u)

Garret Ranking Technique

Garret ranking technique is widely used to rank the qualitative judgements and opinion about a phenomenon. The technique was used to rank the reason for constraints faced by sorghum farmers. The respondents were asked to rank the factors or problems and the ranks were converted into percent position using following formula.

$$\text{Percent Position} = \frac{100\,(R_{ij} - 0.5)}{N_{ij}}$$

Where,

R_{ij} – Rank given for the ith attribute by the jth individual

N_{ij} – number of items ranked by j^{th} individuals

RESULTS AND DISCUSSIONS

MLE estimators of stochastic frontier function of sorghum farmers

The technical efficiency of sorghum farmers was estimated by using the stochastic frontier production function. The Maximum Likelihood Estimates (MLE) of the parameters of Cobb-Douglas stochastic frontier function were obtained and using maximum likelihood procedures through FRONTIER 4.1 package and the results are presented in Table 1. The variance of parameters γ and σ^2 were 0.99 and 0.082 in sorghum production. The sigma squared denoted that the goodness fit and correctness of the distribution form assumed for the composite error team while the gamma indicated that systematic influence was un-explained by the production and also, the mean technical efficiency was estimated at 82 percent. It represents the estimated coefficient of seed, plant protection measures, chemical fertilizer, irrigation and machinery usage were influenced positively and significantly. Labor was negatively significant. The estimated coefficient of the seed and plant protection measures was positive and significant with the value of 0.5155 and 0.1224 in respectively, implied that one percent increases in the expenditure on seed and plant protection measures would increase sorghum yield by 0.51 per cent and 0.12 per cent in respectively. The coefficient of the chemical fertilizer and machinery usage was positive and significant with the value of 0.6811 and 0.5638 in respectively, implied that one percent increases in the chemical fertilizer and mechanization would increase the yield by 0.68 per cent and 0.56 per cent in respectively. The estimated coefficient of the irrigation was positive and significant with the value of 0.0273, implied that one percent increases the no. of irrigations it could influence the yield at 0.02 per cent.

Level of efficiency in farmers

Table 2. represent the technical efficiency ranges from 0.98 to 0.50 with a mean efficiency of 0.82. For the average efficiency to achieve the technical efficiency level of most efficient farmers could only bring about a 16.32 percent increase in production. The least efficient farmers can increase their production by 43.2 percent to achieve the required technical efficiency of the most efficient farmers. Among the farmers, 35 percent efficient level. Mostly we

can see that 66.67 per cent sample respondent of sorghum farmers which shows the efficiency level is above 80 per cent.

Production constraints faced by the sorghum farmers

Table 3. represent that the problem faced by the user respondents of the sorghum farmers used to Garret ranking tool and analyzed to given the ranking of that problems. Lack of high-quality seeds were in first ranked and that garret mean score is 57.7. Lack of capital is a second rank of that garret mean score is 47. Irrigation problems is an occupied third rank of the respondents and it state the score on 41.01. Price fluctuations is a fourth rank of the respondents and it state the score is 38.31. Inadequate transport is a fifth rank of the respondents and it is state that the score is 29.96.

CONCLUSION

The study concluded that the technical efficiency level of sorghum farmers and constraints faced by the sorghum farmers in the research area. Independent variables in quantity of seed, plant protection measures, chemical fertilizers, irrigation and machinery usage were found to influence the production of sorghum positively and significantly. Farmers increasing one percent quantities of raw materials would increase the co-efficient of output. To maintain proper collaboration with nearby farmers to overcome the constraints. It provides valuable insights for policy makers and adaptation of new technologies to increase the sorghum productivity.

ABSTRACT

The existing literature has revealed that the children who have enriching early educational experience will utilize future experiences more efficiently. The previous studies have further highlighted that investing in early years will create a strong foundation for higher education. The children success in higher education greatly relies on the attainment of foundational skills such as literacy and numeracy in the early years of life. Therefore, there is a great need to provide early financial support to the children for the subsequent attainment of higher educational success. The present study explores the pivotal role of early financial support in fostering higher educational success, shedding light on the varied aspects that shape the learning pathway of the children. Recognizing that financial barriers can significantly impede educational opportunities, this research inquire into the multifaceted ways in which securing essential features, such as scholarships, grants, and financial aid, plays a decisive role in fostering academic achievement. Drawing on a comprehensive review of existing literature, empirical studies, and case analyses, the research investigates the impact of early financial support on students' access to quality education, persistence in academic pursuits, and eventual graduation rates. It elucidates the varied patterns between socio-economic factors, financial accessibility, and educational outcomes, emphasizing the potential long-term consequences of insufficient early financial support on individual academic orientation. Furthermore, this research explores the exquisite effects of financial support on diverse student populations, including underrepresented minorities, first-generation college students, and those facing additional socio-economic challenges. By understanding the critical connection between early financial support and higher educational success, this study offers insights that can inform policy development, intervention strategies, and the allocation of resources, ultimately working towards fostering an inclusive and supportive educational system for all students.

Keywords: Early Investment, Financial Accessibility, Financial Barriers, Foundational skills, Financial Support, Higher Education

Poonam Pandita *et al.,*

INTRODUCTION

The formative years of a child's education serve as the bedrock upon which the edifice of their academic journey is constructed. The journey from early learning to higher education is a continuum (Aunola, 2004) where the seeds of success are sown in the fertile soil of early educational experiences. Early learning experiences are instrumental in cultivating foundational skills such as literacy and numeracy, fostering a love for learning, and preparing students for the challenges and rigors of higher education (Slaby et.al., 2005). These experiences further help children adapt to a structured learning environment, setting the stage for a smooth transition to formal schooling (Slaby et.al., 2005). This preparation contributes to a positive attitude towards learning and academic success in the later years. The research studies also indicate that the quality early education impacts the adulthood, influencing educational attainment, employment opportunities, and even physical and mental health outcomes (The State of Global Learning Poverty report: 2022). National Scientific Council for the Developing Child (2012) has further highlighted that sound early educational experiences enhance children Foundational literacy and numeracy skills, alleviates the risk of drop-out and failures and consequently leads to a higher educational success. (Slaby et.al., 2005) has also stated that quality early education helps the individuals to accomplish more academically in higher grades. Moreover, early learning serves as the incubator for language acquisition and communication skills cultivated in the early years (The State of Global Learning Poverty Report: 2022). These skills are the keystones of higher education success, where effective reading, writing, and communication form the backbone of academic engagement.

Beyond academics, early learning environments play a pivotal role in socialization and emotional development (The report on state of foundational literacy and numeracy, 2023 and Braak et al., (2022). The interpersonal skills and emotional intelligence nurtured during these formative years are integral for navigating the collaborative and diverse landscapes of higher education. Students who emerge from quality early learning experiences are often better equipped to build meaningful relationships, collaborate with peers, and handle the social complexities inherent in advanced academic settings (Henningham, 2014). Furthermore, children who receive quality early education are more likely to stay in school, graduate, and pursue higher education. This sets the stage for better career opportunities and increased economic mobility in the long run. Therefore, investing in the early years of children's education is crucial and has long-lasting positive effects on their overall development and moreover it provides higher returns in future (Bhalotra & Zamora, 2006 and Lloyd et al., 2000). Investing in early childhood education can lead to cost savings in the long run (Rolnick & Grunewald, 2007). Studies have shown that children who receive quality early education are less likely to require remedial education, special education services, or encounter behavioral issues that may result in costly interventions (Rolnick & Grunewald, 2007). Several studies have further highlighted the significant economic benefits associated with investing in early childhood education (Karoly, 2016). Position Paper on Early Childhood Education, 2006 and Heckman, 2006 have highlighted that high-quality early childhood education enhances cognitive and social development, preparing children for success in school and later in the workforce which consequently contributes to economic productivity and innovation.

Additionally, the existing studies has also highlighted the positive ripple effects of early education on society, as a highly educated workforce is essential for innovation, productivity, and economic growth (report on tracking Progress on Foundational Learning: Findings From The Rapid 2023 Analysis). There is a critical connection between early financial support and higher educational success underscores the profound influence that financial resources wield on a student's academic journey. The ability to access resources and support in the early stages of education can significantly impact a student's trajectory, shaping their educational experiences and setting the stage for higher learning achievements. This connection highlights the importance of recognizing and addressing financial barriers at the onset of a student's educational pathway, paving the way for a more equitable and empowering educational system. This paper highlights the connection between early financial support and higher educational success and the ways in which financial investments during a student's formative years can serve as catalysts for academic excellence, laying the groundwork for a future enriched by educational opportunities and achievement.

Poonam Pandita *et al.,*

Objectives of the Study

The objectives of the study are delineated as follows:

- To explore the long term impact of insufficient financial support provided during the early years of children's education.
- To highlight the positive impact of adequate financial support provided during the early years of children's education.
- To understand the significance of early financial support for underrepresented minorities, first-generation college students, and individuals facing socio-economic challenges.
- To highlight various strategies that educational stakeholders can employ to offer financial support to children's in their early years, ensuring their success in subsequent educational stages.

Long term Impact of Insufficient Early Financial Support

Insufficient early financial support can have profound and lasting consequences on an individual's academic trajectory

Difficulty in Meeting Basic Needs

Insufficient early financial support can create a ripple effect, hindering the ability to cover basic needs. Difficulty in meeting basic needs during early childhood education can have lasting effects on higher education. Moreover, lack of access to proper nutrition, healthcare, and a supportive environment can hinder cognitive development, impacting academic readiness (Kobayashi, 2021). This early disadvantage may lead to academic challenges in later years, potentially limiting opportunities for higher education due to gaps in foundational knowledge and skills. Therefore, it is significant to address the basic needs during early childhood for laying a solid educational foundation and fostering future academic success.

Educational Attainment Gap

Insufficient early financial support can perpetuate an educational attainment gap, limiting opportunities for those facing economic challenges. Limited financial support may hinder access to quality educational resources, tutoring, and extracurricular activities, leading to a potential gap in educational attainment. This disadvantage often persists, contributing to a gap in foundational skills, confidence, and readiness for further education (Duncan & Magnuson, 2011). This early setback can create a lasting impact on educational attainment, widening the disparity between those with and without adequate support (centre for education statistics and evaluation, 2001). Thus, it is important to address these disparities for fostering a more equitable education system.

Psychological Impact

Insufficient early financial support can create stress and limit opportunities, impacting one's overall well-being. Financial instability during the formative years of education can contribute to long-term stress and anxiety, impacting mental health and overall well-being (The report on state of foundational literacy and numeracy, 2023 and report on tracking Progress on Foundational Learning: Findings from the Rapid 2023 Analysis). This may lead to lower academic achievement and self-esteem, impacting future career prospects. Therefore, seeking support from related organisations and developing financial literacy among parents can help to alleviate from these challenges.

Lowered Aspirations and Confidence

Insufficient financial support in early years of child education may lead to lowered aspirations and reduced confidence in one's ability to succeed in higher education and career pursuits. Lower aspirations and confidence may stem from limited resources and opportunities. When children experience a lack of opportunities and resources, they may develop a sense of inadequacy or lower self esteem. Kobayashi (2021) has highlighted that children who receive high quality learning in their early are more likely to have higher educational and career aspirations later in life. Adequate resources and encouragement are vital for fostering positive future outlook.

Poonam Pandita *et al.,*

Potential Dropout Risk

Insufficient early financial support can force students to juggle work and studies, impacting academic performance. This may lead to increased stress, fatigue, and a higher likelihood of dropping out due to the inability to meet both financial and academic demands. Moreover, as student's progress through the education system with these disadvantages, they may find it increasingly challenging to meet the academic expectations of higher education. In extreme cases, financial strain may lead to the inability to continue education, resulting in dropping out of higher academic programs (The report on state of foundational literacy and numeracy, 2023). In summary, insufficient financial support in early childhood education creates a domino effect, impacting various aspects of a child's development and setting the stage for potential challenges in higher education. Addressing these financial disparities is crucial for fostering an environment that promotes equal opportunities and sets the stage for lifelong success.

Impact of Adequate Early Financial Support on an Individuals Academic Trajectory

Early financial support can have a significant impact on mainly students' access to quality education, persistence in academic pursuits, and eventual graduation rates

Access to Quality Education

Financial support provides students with the means to access quality education, including enrolment in reputable institutions, access to well-qualified faculty, state-of-the-art facilities, and up-to-date educational resources. Quality education at the elementary level builds a strong foundation for future academic success (The report on state of foundational literacy and numeracy,2023). Financial support in early years can ensure a stable environment for a child's development, covering basic needs such as nutrition, healthcare and a conducive living space. This support fosters overall development, laying a strong foundation for their educational journey.

Enhanced Persistence in Academic Pursuits

Early financial support can positively impact academic persistence by alleviating financial barriers that might otherwise hinder a student's educational journey. It reduces the likelihood of students dropping out due to financial constraints (Kumar et al., 2023). Moreover, students who receive early financial assistance are more likely to persist in their academic pursuits, even when facing challenges, as they have the necessary resources to overcome obstacles. Early financial support not only removes financial hurdles but also enriches the overall academic experience, promoting persistence and dedication to educational goals.

Improved Graduation Rates

Early financial support contributes to higher graduation rates by reducing financial barriers and allowing students to focus on their studies without excessive financial stress. Students who have the financial means to navigate their academic journey are more likely to complete their programs successfully and graduate. Furthermore, improved graduation rates are often linked to early intervention programs, mentorship, and tailored academic support, ensuring students receive the assistance they need to overcome challenges and successfully complete their degrees (Kumar et al., 2023).

Strengthen the Foundational skills

Early childhood is a critical period of cognitive development, where children are particularly receptive to learning experiences. Quality early education programs provide enriching environments that stimulate intellectual curiosity and encourage exploration, fostering the development of essential language and mathematical concepts (Slaby et.al., 2005) . Moreover, early education investment supports the recruitment and retention of qualified educators who are trained to implement evidence-based instructional strategies tailored to the diverse needs of young learners. By investing in early education, societies can ensure that all children, regardless of socioeconomic background, have equitable access to the resources and support necessary to build a strong educational foundation, setting them on a pathway towards academic achievement and future success. In summary, early financial support has a cascading effect on various aspects of a student's educational journey, from initial access to quality education to successful graduation and beyond. It plays a crucial role in shaping the trajectory of students' academic and professional lives.

Furthermore, this can benefit the diverse student population including underrepresented minorities, first-generation college students, and individuals facing socio-economic challenges.

Significance of Early Financial Support for Diverse Student Population
Early financial support plays a crucial role in shaping the educational trajectories of underrepresented minorities, first-generation college students, and individuals facing socio-economic challenges

Underrepresented Minorities
Early financial support plays a pivotal role in shaping the educational trajectories of underrepresented minorities. For many individuals from these groups, financial barriers pose formidable obstacles to accessing higher education. When provided with early financial support, such as scholarships, grants, or subsidized educational programs, underrepresented minorities experience increased opportunities for academic advancement. This support not only addresses immediate financial needs but also fosters a sense of belonging and equity within the educational system. It enables individuals to pursue higher education without the burden of overwhelming financial constraints, empowering them to focus on their studies and engage more fully in extracurricular activities. Additionally, early financial assistance often contributes to building a supportive community, as it sends a message of inclusivity and investment in the success of underrepresented minorities. Overall, early financial support is a catalyst for breaking down systemic barriers, promoting diversity in academia, and empowering underrepresented minorities to thrive in their educational pursuits.

First-Generation College Students and Individuals facing Socio-Economic Challenges
Early financial support plays a pivotal role in shaping the academic trajectories of first-generation college students and those facing socio-economic challenges. For individuals who are the first in their families to pursue higher education, financial assistance can be a transformative factor. It not only addresses the economic barriers that may hinder their access to college but also establishes a foundation for academic success. By alleviating the burden of tuition, textbooks, and other educational expenses, early financial support empowers first-generation students to focus on their studies, fostering a sense of belonging in the academic environment. Additionally, it provides a pathway for these students to explore extracurricular activities, internships, or research opportunities that might otherwise be financially out of reach. Similarly, for students facing socio-economic challenges, early financial support becomes a lifeline, enabling them to overcome obstacles and pursue education without compromising their basic needs. This support not only enhances their academic persistence but also contributes to breaking the cycle of generational educational disparities, opening doors to broader opportunities. In essence, early financial support for first-generation college students and those facing socio-economic challenges is instrumental in creating an equitable educational landscape, offering them the resources and encouragement needed to thrive academically.

Strategies that Educational Stakeholders can Employ to offer Financial Support to Children's in their Early Years
Educational stakeholders, including governments, schools, communities, and non-profit organizations, play a crucial role in providing financial support to children in their early years to ensure their success in later educational stages. Here are several strategies and initiatives that can be implemented:

Early Learning Grants
The early learning grants doesn't only means providing free education to the children but it also means allocating funds for teacher training, professional development, curriculum development, and facility improvements. Furthermore, for covering the basic needs of children in their initial years, a system of child allowances or grants should be implemented that provide direct financial assistance to families based on the number of children they have. This can help cover basic needs and create a foundation for a child's development.

Early Intervention Services
Early childhood interventions focus on building essential skills, fostering a love for learning, and enhancing school readiness, setting the stage for future academic achievements. The educational stakeholders should invest in early

Poonam Pandita *et al.,*

intervention services for children with developmental delays or special needs, ensuring they receive the necessary support and resources from an early age. Early intervention programs in early childhood education play a crucial role in ensuring higher education success by laying a strong foundation for cognitive, social and emotional development. These programs help to identify and address developmental delays or challenges early on, promoting a positive learning trajectory.

Parental Education and Support Programs
The educational stakeholders should develop programs that educate parents about the importance of early childhood education and provide support in navigating educational resources. Empowered parents can create a more conducive learning environment for their children (Kobayashi, 2021). These programs should aim to provide parents with knowledge and skills to create a positive learning environment. They should be encouraged to do long-term financial planning and should be provided incentives for consistent contributions. Additionally, they should be informed about the compounding effect of starting early and the ability to cover future educational costs. The programs should be organized to provide clear information to parents on savings and investment options, showcasing potential returns and the security they offer and share success stories of individuals who have benefitted from such programs, making it relatable for parents. Additionally, offer resources or workshops to enhance financial literacy, making them more confident in committing to long-term savings for their children's education.

Long-Term Savings and Investment Programs
The educational planners and stakeholders should introduce savings and investment programs for families, allowing them to set aside funds for their child's future education. They should be encouraged to do long-term financial planning and should be provided incentives for consistent contributions. Additionally, they should be informed about the compounding effect of starting early and the ability to cover future educational costs. The programs should be organized to provide clear information to parents on savings and investment options, showcasing potential returns and the security they offer and share success stories of individuals who have benefitted from such programs, making it relatable for parents. Additionally, offer resources or workshops to enhance financial literacy, making them more confident in committing to long-term savings for their children's education.

Healthcare Support
Healthcare support in early childhood education is crucial as it lays the foundation for a child's overall well-being and can significantly impact their later success in higher education. Moreover, a healthy child is more likely to attend school regularly. Regular health check-ups and prompt medical attention contribute to reduced absenteeism (Health policy snapshot, 2016). Health check-ups on regular basis ensure that any health-related barriers are identified and addressed promptly for supporting children learning. The educational stakeholders should ensure access to affordable healthcare for children, covering preventive care, vaccinations, and medical treatments. They should implement programs to address nutrition and well-child checkups. Investing in health care support for early childhood education can have long-term economic benefits by reducing health-related barriers to learning, leading to a more skilled and productive individuals.

CONCLUSION

In conclusion, the research undertaken in this paper sheds light on the pivotal role that early financial support plays in shaping the educational trajectories and, consequently, the futures of individuals. The critical connection between early financial assistance and higher educational success is evident through a comprehensive analysis of various factors, including access to resources, academic performance, and long-term outcomes. Our paper underscore the significance of fostering a supportive financial environment from the early stages of education, as it has the potential to break down barriers and pave the way for academic achievement. The present study highlights a direct correlation between adequate financial support and increased access to educational opportunities, leading to improved academic performance and, ultimately, higher educational success. Furthermore, this research study emphasizes the

need for policymakers, educators, and stakeholders to recognize the long-term impact of early financial support on an individual's educational journey. Moreover, the research underscores the need for collaborative efforts among stakeholders to design and implement effective financial support mechanisms. Initiatives such as scholarships, grants, and targeted financial aid programs are essential tools in ensuring that students have the resources they need to pursue higher education without the burden of financial constraints. By investing in initiatives that ensure equitable access to resources, scholarships, and financial aid, society can contribute to breaking the cycle of educational disparities and empower individuals to reach their full potential. As we navigate the complex landscape of education and the challenges that students face, it is crucial to acknowledge the role of financial support as a catalyst for securing brighter futures. By prioritizing and expanding efforts to provide early financial assistance, we can collectively contribute to a more inclusive and equitable educational system, fostering a generation of individuals poised for success in higher education and beyond. In securing futures through targeted financial support, we pave the way for a society that thrives on the principles of equal opportunity, achievement, and the realization of individual potential.

ABSTRACT

This research paper presents a comprehensive investigation into solving fuzzy transportation problems using MATLAB. The fuzzy transportation problem is an extension of classical transportation problems, where the demand and supply values are uncertain and represented by fuzzy numbers. Fuzzy set theory offers a robust framework to model and analyze such uncertain systems. In this study, we investigate the application of fuzzy set theory to the transportation problem, specifically focusing on the Northwest Corner (NWC) method, which is a widely used technique for initializing the transportation matrix. We propose a fuzzy version of the NWC method and develop a MATLAB code to solve fuzzy transportation problems. The MATLAB implementation allows us to explore various scenarios and analyze the impact of uncertainty on transportation decisions.

Keywords: Fuzzy set theory, Transportation problem, Northwest Corner method, MATLAB, Uncertainty, Optimization.

INTRODUCTION

The transportation problem is a classical optimization problem that arises in various domains, including supply chain management, logistics, and distribution planning. Its primary objective is to determine the most cost-effective

79981

Nathiya *et al.,*

way to transport goods from suppliers to consumers, given the available supply, demand, and transportation costs. Traditional formulations of the transportation problem assume precise and deterministic data, which may not accurately reflect real-world conditions characterized by uncertainty and imprecision. Fuzzy set theory, introduced by Zadeh, provides a mathematical framework for modeling and handling uncertainty, vagueness, and ambiguity in decision-making processes. By allowing elements to belong to a set to a degree between 0 and 1, fuzzy set theory enables the representation of vague or imprecise information more accurately. In recent years, there has been growing interest in applying fuzzy set theory to optimization problems, including the transportation problem, to address the limitations of traditional approaches. The Northwest Corner (NWC) method is a heuristic approach commonly used to initialize the transportation matrix in classical transportation problems. It starts by allocating shipments from the northwest corner of the transportation matrix and then iteratively adjusts the allocations until all supply and demand constraints are satisfied. While the NWC method is straightforward and easy to implement, its deterministic nature may not be suitable for scenarios where data uncertainty is prevalent.In this study, we propose a fuzzy version of the NWC method to address the limitations of traditional approaches in handling uncertain transportation data. We develop a MATLAB code to implement the fuzzy NWC method and conduct a comparative analysis to evaluate its performance against conventional techniques.

Mathematical Formulation

The fuzzy transportation problem deals with finding the optimal allocation of goods from multiple sources to multiple destinations, considering uncertain or vague parameters such as demand, supply, and transportation costs. The traditional transportation problem assumes crisp (precise) values for these parameters, whereas the fuzzy transportation problem allows for fuzzy sets to represent these parameters.

Existing Method for finding optimal solution

Step 1: In the cell located in the upper left (north-west) corner of the transportation table, the initial assignment is made. It allots the highest amount that can be. In other words,$x_{11} = \min\{a_1, b_1\}$.

Case (i): Put $x_{11} = a_1$, reduce b_1 by a_1, and go vertically to the second row (that is, to the cell (2,1) cross out the first row if $\min\{a_1, b_1\} = a_1$.

Case (ii): Put $x_{11} = b_1$, reduce a_1 by b_1, and proceed horizontally right (i.e., to the cell (1,2) cross out the first column if $\min\{a_1, b_1\} = b_1$.

Case (iii): Put $x_{11} = a_1 = b_1$ and proceed diagonally to the cell (2,2) cross off the first row and the first column if $\min\{a_1, b_1\} = a_1 = b_1$.

Step 2: Continue the process until all rim specifications have been met.

CONCLUSION

In this study, we have presented a comprehensive analysis of solving fuzzy transportation problems using the Northwest Corner method and MATLAB code. Our findings highlight the advantages of incorporating fuzzy set theory into transportation optimization, particularly in handling uncertain data. The proposed fuzzy NWC method offers a promising approach to address real-world challenges in logistics and supply chain management, where uncertainty is prevalent. Future research directions may include extending the methodology to other optimization problems and integrating advanced fuzzy techniques for improved performance.

ABSTRACT

This study aims to evaluate the concurrent validity of the St. George's Respiratory Questionnaire (SGRQ) by comparing it with the Chronic Respiratory Questionnaire (CRQ) and the Medical Outcomes Study Short Form 36 (SF-36), which are considered gold standard measures for assessing health-related quality of life (HRQoL) in patients with lung cancer—a condition characterized by respiratory diseases with airflow limitation. A cross-sectional study design was employed. The correlation between the domains of the SGRQ and CRQ was assessed, as well as the correlation between the SGRQ and SF-36. The analysis revealed a high to moderate correlation between the SGRQ and CRQ domains ($r = -0.826$, $p < 0.05$) and a moderate correlation between the SGRQ and SF-36 domains ($r = -0.697$, $p < 0.05$). The SGRQ, a disease-specific questionnaire, showed a strong alignment with the CRQ, while demonstrating moderate correlation with the generic SF-36. The findings suggest that the SGRQ is a valid tool for assessing HRQoL in lung cancer patients, with excellent concurrent validity when compared to the CRQ and moderate validity relative to the SF-36. This supports the use of the SGRQ in clinical settings to effectively measure HRQoL in this population.

Keywords: Bronchogenic carcinoma, Chronic Respiratory Questionnaire, Health-Related Quality of Life, Lung Cancer, St. George Respiratory Questionnaire,

Mohammedsohel Quadri *et al.,*

INTRODUCTION

Lung cancer (LC), also known as bronchogenic carcinoma, is the leading cause of cancer-related deaths globally (Leiter et al., 2023). In 2020, it was the most commonly reported cancer, with an estimated 2.2 million new cases and 1.8 million deaths worldwide (Leiter et al., 2023).In Bharat, lung cancer represented 11.4% of all cancer cases and caused 18% of cancer-related deaths in 2020 (Mathur et al., 2022). The estimated number of cancer cases in Bharat for 2022 was 1,461,427, with a crude incidence rate of 100.4 per 100,000 people (Sathishkumar et al., 2023). Lung cancer arises from tumors in the lung parenchyma or bronchi (Street et al., 2023) and includes any cancer originating from the airways. Common symptoms are dyspnea, cough, wheezing, blood-stained sputum, and hoarseness (Ralston et al., 2018).Dyspnea is a prevalent and distressing symptom among lung cancer patients, affecting about 80% of individuals and significantly impairing their quality of life. It can limit physical endurance and make daily activities increasingly difficult (American Cancer Society, 2004). Quality of life (QoL) is a measure of overall physical and social well-being as perceived by individuals or groups. Health-related quality of life (HRQoL) assessments typically include physical, emotional, and social dimensions, with some also considering cognitive aspects. Although HRQoL tools are used in various settings, a specific instrument for lung cancer patients has not been validated (Sell et al., 1992).The St. George's Respiratory Questionnaire (SGRQ) is designed to assess health status in patients with chronic airflow limitations and has been validated for diseases such as COPD, cystic fibrosis, bronchial asthma, bronchiectasis, and pulmonary tuberculosis (Carolyn et al., 1997). However, its use in lung cancer patients has not been studied. The SGRQ comprises three components: "symptoms," "activity," and "impacts." The Chronic Respiratory Questionnaire (CRQ) evaluates physical and emotional function through four dimensions: dyspnea, fatigue, emotion, and mastery. The Medical Outcomes Study Short Form 36 (SF-36) is a general HRQoL tool used to evaluate various chronic conditions, demonstrating strong validity and reliability.Despite the SGRQ's established effectiveness in respiratory diseases, it has not yet been used to assess HRQoL in lung cancer patients. This study aims to determine the concurrent validity of the SGRQ in evaluating HRQoL in this population, in comparison with the CRQ and SF-36.

AIMS AND OBJECTIVES
Aim
To determine the concurrent validity of SGRQ in the LC population.

METHODOLOGY

Study Design
Cross-sectional study design

Source of data
The participants with LC in this study were recruited from the following hospital
- Vinus Institute Of Physiotherapy, Gandhinagar
- Vidhyadeep Institute of Physiotherapy, Kim Permission for the ethical clearance was obtained from the Institutional ethical clearance committee of Madhav University, Sirohi-Rajsthan and above mentioned respective centres.

Sampling Technique
Since the study was done on LC patients subjects were chosen based on the selectivity criteria. Hence purposive sampling was done.

Sample Size
A total 59 number of cancer subjects were selected for the study. Out of 59 subjects 34 were included in the study as 17 subjects were not willing to participate and 8 did not meet the inclusion criteria.

Mohammedsohel Quadri *et al.,*

Criteria for selection
Inclusion Criteria
- Patient with histopathological diagnose daslung cancer.
- Age more than eighteen years.

Exclusion criteria
Subject with history of
- Psychiatric disorders.
- Neurological impairments.
- Muscula dystrophies.
- Cognitive impairments.
- Medically unstable.

PROCEDURE
The participants who fulfilled the inclusion& Exclusion criteria were explained to sign an informed consent form approved by the institution. Pre-participation data was taken for each subject beforethe study which included Name, Age, Sex, Socioeconomic status, Concurrent disease, and Type of LC. Subjects were asked to fill out the questionnaire which was designed to measure their level of health-related quality of life by using SGRQ, CRQ and SF-36 respectively. The participants, who did not know how to read and write, were explained about the questionnaire in their mother tongue and response was noted by the person interviewing.

Data Recording and Tabulation
Data was collected in hard copies of all questionnaires, and then the data for SGRQ was entered in the SGRQ Microsoft Excel-based calculator as recommended by the developer, while for the CRQ the scoring was done on a 7-point Likert scale higher the score better the quality of life as suggested by developer and for SF – 36 the same MicrosoftExcel-based calculator as recommended by the developer.

Statistical Analysis
Basic characteristics of the subject's age, gender, height, weight and BMI were analyzed by Descriptive statistics. The concurrent validity of SGRQ with CRQ and SF-36 was validated with Spearman's correlation test. Statistical analysis was done by using SPSS Version 14.0.

RESULT

Table 1 shows the descriptive statistics i.e. mean and Standard Deviation of SGRQ, CRQ and SF-36 score(x = 54.25 SD = 17.68, x= 75.23 SD =18.35 and x = 46.55 SD = 18.76 respectively). Table 2describes the descriptive statistics for subject age and all the domains of SGRQ,CRQ andSF-

DISCUSSIONS

The assessment of lung function alone does not fully capture the complex impact of lung cancer (LC) on patients, necessitating the use of quality-of-life (QoL) questionnaires to provide a more comprehensive evaluation. Health-related quality of life (HRQoL) measures are essential for capturing both the personal and social aspects of a patient's experience. The integration of HRQoL assessments in clinical research has grown significantly over the past two decades, reflecting advancements in the development of psychometrically robust tools to evaluate a range of health conditions (Chan et al., 2002). In this study, we found a strong correlation (r = -0.826, p<0.05) between the St. George's Respiratory Questionnaire (SGRQ) and the Chronic Respiratory Questionnaire (CRQ), and a moderate correlation (r = -0.697, p<0.05) between the SGRQ and the Medical Outcomes Short Form 36 (SF-36). This variation can be attributed to SF-36 being a generic HRQoL questionnaire, whereas CRQ is specifically designed for chronic respiratory diseases.

Mohammedsohel Quadri *et al.,*

Previous research by Molken et al. demonstrated a good correlation (r = -0.725, p<0.001) between the SGRQ and CRQ, consistent with our findings (r = -0.826, p<0.001). This underscores the strong alignment between the total scores of both questionnaires and their respective domain scores (Wilson et al., 1997). Our study also revealed a moderate to strong significant correlation between the SGRQ domains and the CRQ total score (p<0.05), corroborating findings from earlier studies. Furthermore, our results align with prior research indicating moderate to high correlations between SGRQ and SF-36 across different health conditions. Notably, SGRQ scores were more strongly associated with the Physical Component Summary (PCS) of the SF-36 than with the Mental Component Summary (MCS). This is likely due to the fact that the Impacts component of SGRQ shares similarities with the PCS and MCS components of SF-36, highlighting the overlap in measuring physical and emotional impacts (Roberts et al., 1993). The moderate significant correlation observed between the SGRQ domains and the SF-36 total score (p<0.05) suggests that the SGRQ is a valid instrument for assessing HRQoL in respiratory diseases, comparable to the CRQ. The SGRQ encompasses a broader range of HRQoL aspects compared to the CRQ, offering a more detailed understanding of the disease's impact on patients' daily lives. This comprehensive assessment is particularly valuable in clinical trials, as it facilitates the evaluation of treatment benefits, side effects, and costs. Moreover, the SGRQ is available in 48 languages, including 11 Indian languages, enhancing its applicability for assessing HRQoL in diverse populations. In contrast, the CRQ is available in only 8 languages, with no Indian languages included, making the SGRQ a more suitable tool for use in Indian contexts.

LIMITATIONS
- Smaller sample size.
- To precisely know HRQOL, and how longits impact remains longitudinal study should bed one.

FURTHER RECOMMENDATIONS
- Further research should be focused on specific types of local language-adapted questionnaires.
- Further research should be done with Cancer cancer-specific questionnaire along with the HRQOL questionnaire.
- The SGR Q emerges as an excellent discriminative and a good evaluative instrument for LC subjects, and its use should be encouraged in the routine assessment of patient's health status.
- Psychometric properties of the Questionnaire should be done in Lung cancer.

CONCLUSION

This study establishes that the St. George's Respiratory Questionnaire (SGRQ) is a valid and reliable tool for assessing health-related quality of life (HRQoL) in patients with lung cancer. Our findings demonstrate a strong concurrent validity of the SGRQ when compared with the Chronic Respiratory Questionnaire (CRQ) (r = -0.826, p<0.05) and a moderate correlation with the Medical Outcomes Short Form 36 (SF-36) (r = -0.697, p<0.05). These results indicate that the SGRQ effectively captures key dimensions of HRQoL related to respiratory symptoms, activity limitations, and impacts, comparable to established measures like the CRQ and SF-36. The high correlation between SGRQ and CRQ underscores the SGRQ's robustness as a disease-specific instrument for evaluating respiratory health. Additionally, the moderate correlation with SF-36 highlights its relevance in assessing broader HRQoL aspects, particularly the physical component. The SGRQ's broad linguistic availability, including in several Indian languages, enhances its applicability in diverse populations and settings, making it a valuable tool for both clinical practice and research. In summary, the SGRQ provides a comprehensive and nuanced assessment of HRQoL in lung cancer patients, offering insights that extend beyond traditional lung function metrics. Its effectiveness in capturing the multifaceted impact of lung cancer on patients' daily lives supports its use in clinical trials and routine evaluations, contributing to more informed treatment decisions and improved patient care.

ABSTRACT

Increased globalization and industrialization over the last few decades have undoubtedly boosted the global economy and led us towards development but have contributed to a huge upsurge in environmental pollution. The discharge of industrial wastewater flooded with various pollutants like heavy metals, organic pollutants, pharmaceuticals, textile dyes, and other contaminants into surface water bodies has considerably depleted the groundwater quality, raising several concerns over the usage of such polluted water for animal and human usage. This has fueled the research to look for safer alternatives to ameliorate the groundwater quality, restoring it to a level fit for human and animal consumption. In this regard, the field of phyto-nanotechnology, involving the usage of biosynthesized green nanoparticles for removal of wastewater toxicants appears to be a promising tool, owing to the non-toxic and biodegradable nature of the biosynthesized nanoparticles. The current review summarizes the recent studies conducted in the last few years, showcasing the usage of green nanoparticles in amelioration of wastewater quality by heavy metals removal and other wastewater pollutants.

Keywords: Phyto-nanotechnology, green nanoparticles, heavy metals, wastewater bioremediation

INTRODUCTION

The last few decades have witnessed the implementation of an increasing number of nanomaterials for ameliorating the environmental quality by alleviating the problems associated with the deteriorating quality of soil as well as groundwater due to the noxious toxicants infiltrating them. However, one crucial aspect that needs to be considered while utilizing the agents to ameliorate the environmental quality is that the so-called "ameliorative agents" do not end up becoming pollutants themselves. Therefore, this concern has been dealt with by the usage of biodegradable materials ameliorative agents for restoration of environmental quality owing to their inability to persist in the environment and eco-friendly nature. Nanomaterials are an excellent choice when it comes to usage in various applications owing to their exceptional physic-chemical properties in the form of a high surface area to volume ratio, which makes it amenable to nanoengineers by introducing several functional groups on their surface. Furthermore, several other attributes associated with green nanomaterials include [1] their non-toxic nature and biodegradability, low economic cost associated with manufacture and maintenance, target specific nature, and potential to recover, and recyclable nature. All these benefits outweigh the demerits associated with the use of metallic nanoparticles such as high recovery cost, toxicity problems associated with byproducts of metallic nanoparticles, and implementation of a special fabrication process coupled with limited stability. Keeping in mind the above-stated facts, it is asserted that a thorough understanding of the biosynthesis process along with optimization of the performance and usage of material platforms are some of the points that need to be kept in mind while biosynthesizing nanomaterials. The usage of different plant extracts as capping agents for the biosynthesis of green nanomaterials has given rise to an altogether new branch of science, termed Phyto-nanotechnology. Phyto-nanotechnology can be best defined as an approach to phytochemical mediated synthesis of metallic nanomaterials to address several existing environmental issues [2]. Several other sources such as different bacteria and fungi are also being used at an increasing scale for the greensynthesis of nanoparticles owing to the availability of several phytochemicals in them. However, the current review article only talks about the applications of plant-synthesized green nanomaterials and their applications in wastewater remediation.

TYPES OF TOXIC EFFLUENTS PRESENT IN WASTEWATER
Heavy Metals
Heavy metals such as Ni, Zn, Co, Cd, Cu, Fe, Cr, Pb, Cr, Hg, and Mn may enter the water bodies from effluents released from several industries such as mining waste, natural gas, plastic, coal, dye, vehicular emissions, and several other anthropogenic activities. Exposure to heavy metals present in water may lead to innumerable deleterious effects on plants, animals, and humans. Exposure of aquatic animals to heavy metals may lead to retarded growth and development, alteration in feeding as well as swimming patterns, and induction of oxidative stress owing to the production of ROS, which may have detrimental effects on DNA, proteins, and other organs of aquatic animals. Certain heavy metals such as Arsenic may lead to fish death due to asphyxiation, and alteration in the number of B and T cells, thus making the aquatic animals immune compromised and susceptible to infections. Consumption of heavy metal-contaminated water has been visualized to induce several detrimental effects in humans including irritation of the lining of lungs and stomach, decreased erythrocyte production, reproductive disability, and other fatal consequences. Exposure of plants to heavy metal-contaminated water has been seen to trigger a whole cascade of malicious events, evident in the form of increased oxidative stress, decreased photosynthetic efficiency, inhibition of plant signaling leading to compromised plant immunity and several other fatal consequences [3].

Dyes
Anionic and Cationic dyes used in various industries such as paper mills, textile industry, plastic industry, leather industry, food, printing, and pharmaceutical industries are major sources of water pollution. Nearly 15% of the dyes used for coloring the fabrics are discharged into water bodies after being used up. Discharge of these dyes triggers a series of malicious events in the water bodies including augmentation of turbidity of the water bodies, an increase in turbidity further curtails the penetration of sunlight and a consequent reduction in photosynthetic efficiency of aquatic plants, an increase in lipid peroxidation activity, necrosis, chlorosis, and impaired root system in aquatic

plants, decrease in dissolved oxygen content of water, leading to increased BOD and COD. Exposure to several textile dyes has been observed to trigger several haemotoxic and genotoxic traits in aquatic animals, evident in the form of RBC lysis, increased mortality, alteration in shape and size, decreased amount of carbohydrates, lipids, and proteins, alteration in enzyme activity, decreased haemoglobin, impaired liver activity, respiratory distress, kidney dysfunction and several other debilitating metabolic disorders [4].

Organic pollutants
Organic pollutants present in the water bodies include fertilizers, phenols, pesticides, pharmaceuticals, biphenyls, hydrocarbons, and other waste products. Discharge of organic pollutant-laden water may disturb the ecological balance in several ways such as Nitrogen and phosphorus present in fertilizers may lead to algal bloom and lead to eutrophication in water bodies, Exposure to pesticides may trigger several genotoxic and cytotoxic effects in aquatic animals, The presence of biodegradable organic pollutants may deplete the oxygen content of the water bodies and may cause eutrophication and the presence of pharmaceutical products such as antibiotics in wastewater may lead to the selection of antibiotic-resistant bacterial strains, followed by their proliferation, leading to the emergence of drug-resistant strains[5].

Pathogens
The effluents released from hospitals, medical laboratories, and municipal wastes may be rich in many potentially harmful pathogenic organisms such as *E. coli, Staphylococcus aureus, Bacillus subtilis, Pseudomonas aeruginosa, Salmonella typhi, Vibrio cholera, Enterobacter aerogenes,* and several other harmful pathogens. Exposure to pathogen-containing water may lead to the spread of infections and other outbreaks of communicable diseases in the community [6].

PROCESSES USED FOR WASTEWATER TREATMENT
For the treatment of wastewater conventional and non-conventional approaches have been used. Conventional approaches include the use of activated carbon, activated sludge process and microalgae reactor, while non-conventional methods include constructed wetlands and membrane bioreactors. Besides these two methods, chemical (coagulation, ozonation, advanced oxidation process, photocatalysis) and physical processes (microfiltration/ultrafiltration, nanofiltration, and reverse osmosis) are also being used for the treatment of wastewater. Currently, scientists are taking an interest in developing strategies for adsorption-based water treatment which includes the use of various nanomaterials, composites with activated carbon, activated hydrochar, biochar, activated carbon, metal-organic framework, organic soils, zeolites, carbon nanotubes, graphene and mesoporous nanocomposite of polymer and clay.

INTRODUCTION TO GREEN NANOPARTICLES, THEIR SYNTHESIS AND THEIR APPLICATIONS
Green synthesis of nanoparticles using plant extracts is carried out by mixing the plant extracts with the optimum concentration of desired metal ions to be incorporated in the nanoparticle. The ions ofmetal are further reduced and stabilized by several phytochemicals that are there in the plants that include secondary metabolites such as alkaloids, phenolics, terpenes, flavonoids, and other secondary metabolites. This is followed by filtration of the obtained nanoparticle and a series of other processing steps. The shape and size of synthesized nanoparticle can be manipulated at various steps by optimizing the concentration of the plant extracts. The green nanoparticles synthesized from plant extracts can be used for a number of applications such as:

Agriculture and Environment
The biosynthesized nanoparticles can be used for the alleviation of environmental pollutants and bioremediation of polluted soil and wastewater.

Biomedical
The green biosynthesized nanoparticles have been used for several biomedical applications such as immunotherapy, regenerative medicine, antibacterial, antifungal, and anticancer properties, wound healing, and bio-sensing.

Besides these, these are also used in Food science and technology, the cosmetic and textile industry, and the electronics industry. The current review discusses the usage of nanoparticles for environmental bioremediation by their usage in the removal of heavy metals from contaminated wastewater. This is achieved by exploiting the ability of green nanoparticles to act as super-adsorbents to adsorb contaminants from water. The green biosynthesized nanoparticles possess extremely large surface area to volume ratio along with the presence of several functional groups, specified pore size and surface as well as short diffusion distance. All these attributes contribute to the usage of green nanoparticles as potential bio adsorbents capable of adsorbing heavy metals that are found in polluted water [7],[8]. The nanoparticles biosynthesis and their use in the removal of heavy metals from wastewater is shown in the figure 1.

REMOVAL OF HEAVY METALS FROM WATER USING GREEN SYNTHESIZED NANOPARTICLES
Effluents released from different industries and research labs are rich in heavy metals and their release into the wastewater causes heavy metal accumulation invarious forms of water reservoirs. Increased buildup of these obnoxious heavy metals into the ecosystem has been a menacing problem for scientists, in response to which a number of approaches have been used to alleviate this heavy metal accumulation. Generally, heavy metals like copper, lead, chromium, iron, and cadmium are the major toxicants that are present in the water bodies. The studies enlisted in the section underneath as well as Table 1 highlight research studies to ameliorate the effect of heavy metal accumulation in wastewater using green nanomaterials. A recent study by [9] showed the biosynthesis of ZnO green nanoparticles from leaf extract of *Zizyphus jujuba* using microwave irradiation, followed by the characterization of the synthesized nanoparticles and further demonstrated the unparalleled efficacy of the green nanoparticles to eliminate Pb from wastewater. Furthermore, the researchers also highlighted the crucial role of various physic-chemical parameters such as the mass of synthesized ZnONPs, pH of the solution, contact time, ionic strength of the solution, and temperature in determining the absorption efficacy of the nanoparticles to adsorb heavy metals from wastewater. In yet another study by [10], the researchers synthesized silver nanoparticles using leaf extract of *Prosopis juliflora,* followed by characterization of the biosynthesized nanoparticles by FTIR, SEM, and XRD. Furthermore, the biosynthesized silver nanoparticles were demonstrated to exhibit potent cleansing action in the removal of several obnoxious pollutants from wastewater including *E coli*, heavy metals as well as Rose bengal dye (Table 2). Another study by [11] demonstrated thebiosynthesis of silver nanoparticles from an agro-industrial byproduct, walnut husk. Furthermore, the synthesized nanoparticles were characterized using different biochemical techniques followed by a demonstration of the ability of the green silver nanoparticles to ameliorate the quality of petroleum wastewater by removing several heavy metal toxicants including Pb. Cr and Cd.

Another recent study by [12] showed the green biosynthesis of silver nanoparticles using leaf extract of *Piliostigma thonningii* followed by characterization of the biosynthesized nanoparticles using FTIR, XRD, UV-visible spectroscopy, Zetasizer, and TEM techniques. Furthermore, the researchers demonstrated the ability of silver nanoparticles to eliminate heavy metal toxicants from laboratory-simulated wastewater, with the best adsorptive performance of the nanoparticles at pH of 6.5, temperature 65°C, 1.25 mM of silver nitrate, and 5 ml of plant extract. The researchers further proceeded to demonstrate the safety of the biosynthesized nanoparticles by orally administering the nanoparticles to experimental laboratory rats and showing a lack of any adverse histopathological alterations in the rats in response to nanoparticle exposure. A recent study by [13] showed the biosynthesis of silver nanoparticles using leaf extract of *Ficus Benjamina* followed by characterization of the synthesized nanoparticles using FTIR, UV-visible spectroscopy, and SEM. Furthermore, the researchers demonstrated excellent efficacy of the synthesized nanoparticles to eliminate cadmium from wastewater; with increased efficacy of the nanoparticles with an increase in the concentration of the biosynthesized adsorbent nanoparticles, increase in pH from 1 to 6 and increase in contact duration between the wastewater and the biosynthesized nanoparticles. In a study conducted by [14], the researchers showcased the green biosynthesis of silver nanoparticles from the seed extract of *Moringa oleifera.* Furthermore, the researchers demonstrated excellent efficacy of the biosynthesized nanoparticles in eliminating different types of pollutants in wastewater including both gram-negative and gram-positive bacterial strains (*Staphylococcus aureus, , Salmonella enterica typhimurium, Escherichia coli*and *Pseudomonas aeruginosa)*, organic dyes (methylene blue, orange red and 4-nitrophenol) as well as Pb heavy metal, therefore unveiling the powerful

antimicrobial as well as disinfecting ability of the biosynthesized nanoparticles in the cleansing of effluents released from dyeing units. A recent study by [15] demonstrated the biosynthesis of iron nanoparticles from green tea extract, followed by the characterization of the nanoparticles using XRD, TEM, and UV-Visible spectroscopy and showcasing the unparalleled efficacy of the biosynthesized iron nanoparticles to eliminate Cr contamination from wastewater.
A recent study by [16] demonstrated the biosynthesis of green iron nanoparticles from the leaf extract of the barberry plant followed by the characterization of the nanoparticles using XRD, TEM, and UV-visible spectroscopy.

Thereafter, the researchers showcased the ability of the biosynthesized nanoparticles to remove the heavy metals pollutants (Cr) from industrial wastewater. Another study by [17] showcased the biosynthesis of green zero-valent iron nanoparticles from aqueous tea extract followed by characterization of the nanoparticles using XRD, HRTEM, FESEM zeta-sizer, BET surface area, and UV-visible spectroscopy. Furthermore, the researchers highlighted the microbicidal activity of the synthesized nanoparticles and their ability to eliminate Cu metal ions from polluted industrial effluent. In addition to this, the researchers also highlighted the crucial role of several physicochemical parameters such as pH of the solution, dose of the adsorbent nanoparticle, and concentration of the contaminant in controlling the efficacy of the biosynthesized nanoparticles. A study by [18] showcased the biosynthesis of titanium dioxide nanoparticles from lemon peel extract, followed by SEM analysis and EDS mapping of the biosynthesized nanoparticles. In addition to this, the researchers also showcased the ability of the biosynthesized titanium dioxide nanoparticles to eliminate nickel ions from industrial wastewater. [19] demonstrated the green biosynthesis of bimetallic FeNi nanoparticles from straw waste followed by a demonstration of the excellent ability of the biosynthesized nanoparticles to ameliorate the quality of industrial effluents by removal of Cr heavy metal contamination. A series of studies by [20], [21], and [22] showcased the green biosynthesis of bimetallic FeNi nanoparticles, palladium nanoparticles, and zirconium hydroxide nanoparticles from green tea extract, rice residue and plant extract of *Konjac glucomannan.* Furthermore, the efficacy of these nanoparticles to ameliorate the quality of industrial effluents by eliminating heavy metal pollution in the form of Sb, As, and Cr was demonstrated in the studies by [20],[21] and [22] respectively.

CONCLUSION

The discovery of nanoparticles has revolutionized the entire field of science and technology, however, there are several concerns surrounding the use of synthetic nanoparticles as they are known to exhibit malicious effects on the environment as well as other components of the ecosystem. This has contributed to increased impetus in the biosynthesis of green nanoparticles using plants and other sources, which are biodegradable, non-hazardous, and relatively safe to use with increased efficacy in comparison to their bulk counterparts. The current review sheds light on the recent studies showing the usage of green nanoparticles in environmental bioremediation by removal of pollutants, particularly heavy metals from wastewater released from various industries and other domestic as well as municipal units. The current field of phyto-nanotechnology to ameliorate environmental pollution by performing wastewater remediation using phyto-nanoparticles appears to show promising results. Nevertheless, several concerns need to be addressed before the full-fledged usage of green nanoparticles for wastewater bioremediation, monitoring the influence of physic-chemical attributes such as pH, solvent concentration, temperature, and reaction time in controlling the shape and size of the biosynthesized green nanoparticles. Green synthesis of nanoparticles has only been performed at the laboratory level so far; therefore, performing this humongous task at the industrial level while also controlling the physico-chemical attributes of the biosynthesized nanoparticles would be a daunting task.In-depth research is needed to study the mechanism of action of green nanoparticles before using them at the commercial level.Despite these concerns and issues, the biosynthesis of green nanoparticles for environmental bioremediation appears to showcase promising results in a sustainable way.

ABSTRACT

Due to the increased environmental pollution in recent times, the contamination of the food chain by heavy metals is a plausible concern. The aim of this research was to investigate how heavy metal contamination affects the antioxidant capabilities of three different *Glycine max* L. cultivars (JS:335, JS:80-21 and JS:75-46). The study evaluated various antioxidant parameters such as total antioxidant capacity, ferrous reducing antioxidant capacity, DPPH radical scavenging activity and hydroxyl radical scavenging activity after harvesting. Results indicate that exposure to normal concentrations of lead (Pb) and chromium (Cr) did not produce visible toxic effects in *Glycine max* L. plants. However, at higher concentrations (200mlKg^{-1}), both Pb and Cr caused a significant decrease in antioxidant activities across all parameters except for the ferrous reduction assay. These findings highlight the negative impact of elevated heavy metal concentrations on antioxidant activities in soybeans. Consequently, there's a need for strategies to mitigate heavy metal toxicity in agricultural soils. Additionally, further investigation into the molecular mechanisms underlying heavy metal toxicity in plants is warranted.

Keywords: Heavy metal, chromium, lead, Glycine max, JS:335, JS:80-21 and JS:75-46

INTRODUCTION

"Heavy metals" refers to metals and metalloids with a density exceeding 5 g/cm3, a term commonly used to describe these elements. While some of them serve as micronutrients, they also pose environmental risks as pollutants. Over recent centuries, human actions have resulted in the pollution of land and water with heavy metals (Nagajyoti *et al*., 2010).The escalating issue of environmental pollution due to heavy metals is a significant concern. Factors such as

Gazala Bashir and Sartaj Manzoor

rapid urbanization, industrialization, unsustainable agricultural methods, combustion of fossil fuels, and extensive mining activities are primarily responsible for the substantial release of heavy metals into the environment. This contamination severely affects water, air, and soil quality(Li, *et al.*, 2019).The proliferation of heavy metal contamination poses a significant threat to both the environment and food security. This is largely due to the rapid advancements in agriculture and industry, as well as the disruption of natural ecosystems caused by the substantial growth in the global population (Sarwar *et al.*,2016).Heavy metals infiltrate the agricultural ecosystem through both natural means and human activities. Several studies suggest that, in comparison to human-induced activities, the contribution of natural sources to heavy metal presence in the environment is typically minimal (Dixit *et al.*,., 2015).Chromium, positioned in group VI B of the periodic table as a transition metal, exhibits various oxidation states, with the trivalent and hexavalent forms being the most stable and commonly encountered. Despite being the 7th most abundant element on Earth and the 21st in the crustal rock, chromium has become a significant pollutant of air, soil, and water due to its extensive use in leather tanning, pigment production, electroplating, and alloy manufacturing. It is classified as a hazardous heavy metal due to its detrimental effects, which include membrane damage, alterations in organelle structure, disruptions in metabolic processes, and inhibition of growth (Vazquez,1987). Chromium has been shown to promote the generation of free radicals (FR) and reactive oxygen species (ROS) like superoxide radicals (O2), hydrogen peroxide (H2O2), and hydroxyl radicals (OH). This can occur through direct electron transfer involving metal cations or as a result of chromium-mediated interference with metabolic reactions(Stohs and Bagchi, 1995). The presence of these radicals leads to oxidative damage to biomolecules such as lipids, proteins, and nucleic acids (Kanazawa *et al.*, 2000).Lead, a hazardous heavy metal pollutant in the environment, arises from multiple sources including lead ore mining and smelting, coal combustion, emissions from storage battery industries, vehicle exhausts, metal plating and finishing processes, fertilizers, pesticides, and additives in pigments and gasoline (Eick *et al.*,1999).

To counteract oxidative damage, plants possess an antioxidant defense system consisting of enzymes such as catalase, peroxidases , and superoxide dismutases, along with non-enzymatic components including alpha-tocopherol, ascorbate, and reduced glutathione. These elements work together to eliminate, neutralize, and scavenge reactive oxygen species (Shah *et al.,* 2001).Food intake has been recognized as the primary source of metal exposure in humans (Alam, *et al.*, 2003). Furthermore, research on the transference of heavy metals from soil to crops (Lavado, 2006) has indicated that soybeans have the potential to accumulate higher levels of potentially harmful elements compared to other crops. Soybean (*Glycine max*) is globally recognized as one of the most extensively cultivated crops and serves as a crucial protein source. Argentina stands out as a significant producer of the genetically modified Roundup Ready variety of *Glycine max* L. with soybean being its foremost crop in terms of production volume (INTA). The considerable demand for soybean has led to its cultivation in areas adjacent to busy roads with heavy vehicular traffic and in regions near human activities such as industrial manufacturing (Rodriguez, *et al.,* 2011). Currently, there is a shortage of toxicological studies regarding the food safety of soybeans cultivated near industrial areas (Murakami2009, Zheng *et al.*, 2007). Therefore, the objectives of this study were: (i) to determine the impact of heavy metal contamination on antioxidant activities of three different varieties of *Glycine max* L.

MATERIALS AND METHODS

Plant material and experimental setup
Certified seeds of three cultivars i.e. JS:335, JS:80-21, and JS:75-46 of *Glycine max* L. varieties were bought from MFP PARC (Vindhya Herbals) in Barkhera Pathani, Bhopal, Madhya Pradesh, India. The experiment took place in pots at the Department of Botany, Government Motilal Vigyan Mahavidyalaya, Bhopal, from 2021 to 2022.The soil was dried naturally and then combined with vermicompost and sand. Each plastic pot was filled with around 4 kg of this soil mixture, following the method outlined by (Kumar et al., 1993). Solution of Four different concentrations i.e., 50 ml, 100 ml, 150 ml and 200 ml Kg^{-1}(01mM/ml concentration) of two heavy metals Lead (II) nitrate and Potassium dichromate was sprayed and mixing continuous to homogenize properly. Three pots were filled with soil without treatment and labeled as control. Seeds were surface sterilized with 0.1% HgCl$_2$ for two minutes, then washed with

Gazala Bashir and Sartaj Manzoor

distilled water twice and air dried. Seeds were sown at 2-3cm depth in pots and watering was done once every two days. All experimental pots were placed outdoor for growing.

Determination of Total Antioxidant Capacity (TAC)

This experiment was performed by following the method of (Prieto *et al.*,1999) with some modifications. A crude sample of 0.5 ml was combined with 3 ml of a reaction mixture (0.6 M sulphuric acid, 28 mM sodium phosphate and 1% ammonium molybdate)in a test tube and left to react at 95°C for 10 minutes. Afterward, the absorbance was gauged at 695 nm using a spectrophotometer against both a blank and catechin as a standard at room temperature. Higher absorbance in the sample mixture compared to the standard and blank indicated a heightened overall antioxidant capacity.$\text{TAC} = \frac{Ac - As}{Ac} \times 100$

Ferrous Reducing Antioxidant Capacity Assay

The ferrous reducing antioxidant capacity was evaluated following the methodology described by Oyaizu 1986. 0.25 ml of the sample along with standard solutions at various concentrations were mixed with 0.625 ml of 0.2 M potassium buffer and 0.625 ml of 1% potassium ferricyanide (K3Fe(CN)6) solution into test tubes. Afterwards, the reaction mixture was allowed to incubate at 50°C for 20 minutes to ensure completion of the reaction. Subsequently, 0.625 ml of 10% trichloroacetic acid (TCA) was introduced, followed by centrifugation at 3000 rpm for 10 minutes. Following centrifugation, 1.8 ml of the supernatant was transferred to a test tube. To this, 1.8 ml of distilled water and 0.36 ml of 0.1% ferric chloride (FeCl3) were added. The absorbance of the resulting solution was measured at 700 nm using a spectrophotometer against both a standard and a blank. A higher absorbance of the sample mixture compared to the standard and blank indicated an increased reducing capacity: % Inhibition $= \frac{Ac - As}{Ac} \times 100$

DPPH Radical Scavenging Assay

The assay test was conducted following the procedure outlined in (Choi *et al.*,2000) and (Desmarchelier *et al.*, 1997). Reaction mixtures (2.4ml of 0.1mM DPPH in methanol and sample/standard (butylated hydroxytoluene) were vortexes and incubated in dark at room temperature for 30minutes. Absorbance was measured at 817nm using a spectrophotometer. The percentage of DPPH was determined as follows:% Inhibition $= \frac{Ac - As}{Ac} \times 100$

Hydroxyl Radical Scavenging Activity

This was determined using the procedure outlined in (Klein *et al.*, 1981).Reaction mixture: 1ml of Fe-EDTA solution, 0.5ml of 0.018% EDTA, 1ml of 0.85% DMSO and 0.5ml of 22% ascorbic acid were added in a test tube. This was act as blank. Similar mixture was made for different sample concentration and standard by adding 0.5 ml of samples or standard. The reaction mixture tubes were tightly capped and heated at 85°C for 15 minutes in a water bath. After cooling to room temperature, the tubes were uncapped, and 0.5 ml of ice-cold 17.5% TCA was added to each tube. Then, 3 ml of Nash reagent (prepared by mixing 7.5gm of ammonium acetate, 300 μl of glacial acetic acid, and 200 μl of acetyl acetone and making up to 100 ml) was added to all tubes and incubated at room temperature for 15 minutes. Absorbance was measured at 412 nm using aa UV-spectrophotometer. The percentage of hydroxyl radical scavenging activity (% HRSA) was calculated using the following equation: % HRSA $= \frac{Ac - As}{Ac} \times 100$

Data analysis

Data were analyzed statistically by analysis of variance (ANOVA) using SPSS 16.0 software. The values are mean (±SE) of treatments (n=3) at P<0.05 significant level. The least significant difference (LSD) was calculated for mean separation for significant differences among treatments at p < 0.05 levels.

RESULTS

The effect of different concentrations of Heavy metals (Lead and Chromium) on Antioxidant activities of three Cultivars i.e JS: 335, JS: 80-21 and JS:75-46 of *Glycine max* L.as shown in table 1. The treatments were categorized as

Gazala Bashir and Sartaj Manzoor

follows: A = JS: 335; B = JS: 80-21; C = JS: 75-46; L = Pb; C = Cr. Additionally, numerical values were assigned to represent volume: 1 = 50 ml; 2 = 100 ml; 3 = 150 ml; 4 = 200 ml. The abbreviation "Ctrl" stands for Control.

JS:335 Cultivar

Total antioxidant capacity (mg E AA/g dw), Ferrous reducing antioxidant capacity assay (μmol Fe2+/g FM), DPPH radical scavenging assay (% inhibition) and Hydroxyl radical scavenging activity (% inhibition) were performed on leaf extracts of *Glycine max* L. treated with two different heavy metals i.e. Pb and Cr in four concentrations, i.e. 50 ml, 100 ml, 150 ml and 200 mlKg^{-1} with control. Maximum reduction of Total antioxidant capacity, DPPH radical scavenging activity, Hydroxyl radical scavenging activity parameters was observed in 200ml Kg^{-1}concentration in both pb and cr treated plants whereas minimum reduction was observed at lowest concentration i.e 50 ml Kg^{-1}when compared to control group. At the highest concentrations, there is an observed rise in ferrous reducing antioxidant activity.

JS:80-21 Cultivar

Leaf extracts were subjected to various antioxidant assays after treatment with two different heavy metals, Pb and Cr, at four concentrations, alongside a control group. The maximum reduction in total antioxidant capacity, DPPH radical scavenging activity, and hydroxyl radical scavenging activity was observed at the highest concentration (200 ml Kg^{-1}) for both Pb and Cr treatments, while the minimum reduction was noted at the lowest concentration (50 ml Kg-1) compared to the control group. Additionally, an increase in ferrous reducing antioxidant activity was observed at the highest concentrations.

JS:75-46 Cultivar

Highest reduction in total antioxidant capacity, DPPH radical scavenging activity, and hydroxyl radical scavenging activity was observed at the concentration of 200 ml Kg-1 for both Pb and Cr treatments, while the lowest reduction was observed at the lowest concentration (50 ml Kg^{-1}) compared to the control group. Additionally, an increase in ferrous reducing antioxidant activity was observed at the highest concentrations.

Comparative influence of lead and chromium on antioxidant Potential of different cultivars of Glycine max L.
Total Antioxidant Capacity

The study investigated the impact of varying doses (50ml, 100ml, 150ml, 200mlKg^{-1}) of lead and chromium on the total antioxidant capacity of different cultivars of *Glycine max* L. compared to a control group after harvesting. The highest decrease in total antioxidant capacity was noted in the JS:80-21 cultivar at the highest dose (200mlKg^{-1}) of lead treatment, while the lowest reduction was observed in the JS:75-46 cultivar at the same dose. Conversely, in chromium treatment, the maximum decrease in total antioxidant capacity occurred at the 200ml dose in the JS:75-46 variety, while the minimum reduction was seen at the 200ml concentration in the JS:335 variety compared to the control, as illustrated in Figure 4.

Ferrous reducing antioxidant capacity assay

In higher concentrations (i.e., 200ml) of both lead and chromium, the Ferrous reducing antioxidant capacity showed an increase. The greatest enhancement was observed in the JS:335 variety, followed by JS:75-46 and JS:80-21, compared to the control, as illustrated in the figure 5.

DPPH radical scavenging assay

At higher concentrations (200ml) of lead and chromium treatment, the DPPH radical scavenging activity exhibited a decrease. The most significant reduction was observed in the JS:80-21 variety, while the smallest decrease was noted in the JS:75-46 variety compared to the control, as depicted in the figure 6.

Gazala Bashir and Sartaj Manzoor

Hydroxyl radical scavenging activity

The greatest decrease in hydroxyl radical scavenging activity occurred at the 200ml concentration in JS:80-21 cultivar, followed by JS:75-46 and JS:335, in both lead and chromium treated plants compared to the control group as shown in fig 7.

DISCUSSIONS

Heavy metals pose both immediate and long-term health risks to humans and various organisms. Plants act as a conduit for heavy metal accumulation, which can then be transferred to humans through the food chain. These metals in soil can impede plant growth and development by disrupting the absorption and movement of essential nutrients (Massoud *et al*., 2018; Kaya *et al*., 2022). Research indicates that *Glycine max* L., commonly known as soybean, has the capacity to accumulate heavy metals (Bojinova *et al*.,., 1994). A study by Reddy and Dunn (1984) investigated soybean plants and observed the accumulation of heavy metals such as Cd, As, Cr, and Zn in various plant parts. In this research, three varieties of *Glycine max* L. (JS:335, JS:80-21, JS:75-46) were subjected to treatments with different concentrations of lead and chromium. The effects of these heavy metal treatments on antioxidant parameters were investigated, including Total Antioxidant CapacityFerro,us reducing antioxidant capacity, DPPH radical scavenging activity, and Hydroxyl radical scavenging activity. The data presented in Table 1 indicates that following exposure to lead and chromium at concentrations of 50ml, 100ml, 150ml, and 200ml, there was a notable decrease in the antioxidant activities of the *Glycine max*L. plants compared to the control group. The harmful effects of heavy metals on plants stem from an imbalance between the productions of reactive oxygen species (ROS) and antioxidants within plant cells. Exposure to heavy metals can lead to heightened ROS production, including superoxide anion (O_2), hydroxyl radical (OH), and H_2O_2, resulting in oxidative stress (Devi and Prasad, 2005; Pradedova *et al*., 2011). Heavy metals, such as chromium (Cr), are particularly notorious for inducing oxidative stress in plants. Studies have indicated that elevated levels of Cr can disrupt antioxidant activities in response to Cr stress (Adhikari *et al*.,2020). In the current investigation, the total antioxidant capacity, DPPH radical scavenging assay, and Hydroxyl radical scavenging activity exhibited significant reductions at higher doses of heavy metals, while Ferrous reducing antioxidant capacity increased. Consequently, the study's findings suggest that escalating concentrations of supplementary elements lead to diminished antioxidant activities.

CONCLUSION

Our findings indicate that Cr and Pb have distinct impacts on various parameters of our experimental plants. Significant variations in the concentrations of Cr and Pb were found to affect antioxidant activities differently. Both Pb and Cr led to a notable decrease in antioxidant activities across all parameters except for the ferrous reducing antioxidant capacity assay. Among the tested varieties, JS:335 showed the least reduction, while JS:80-21 displayed the highest reduction in all parameters. Pb treatment exhibited greater toxicity compared to Cr treatment. Given the escalating issue of Pb and Cr accumulation in agricultural soils, it is imperative to devise strategies and mechanisms to mitigate their toxicity in crops. Further exploration of molecular mechanisms is necessary to understand the signaling pathways of heavy metal toxicity exhibited by treated plants.

Declaration of Competing Interest

The author declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

ABSTRACT

Azolla serves as a biofilter during wastewater treatment. Phytoremediation using *Azollapinnata* is ecologically sound and economically viable and it is an attractive alternative to the current cleanup methods. The effluent after phytoremediation is suitable for reuse and recycle along with a yield of *Azollapinnata.* This yield can be used to increase productivity. Hence the present study was planned to study the Phytoremediation potential of *Azollapinnata* with diary, municipal and domestic wastewater. Microbial population was also determined. This effluents after phytoremediation can be used for irrigation and agricultural purposes .The physicochemical parameters of wastewater were analyzed before and after treatment with *Azollapinnata*. Compared to dairy, municipal waste water Phytoremediation of domestic wastewater with *Azolla* decreased the pH from 7.8 to 7 to and the colour of the liquid waste was changed from greyish black to brown colour. The turbidity (0.04NTU),electrical conductivity (0.30dsm-1), COD (0.31mg/L, Nitrogen (0.56ppm) and   Phosphorus(69.7ppm) content was decreased respectively. Heavy metals like Cadmium (Cd)1.76 mg/l, Lead (Pb)0.21 mg/l, and Zinc 14.46 mg/lare potentially hazardous in combined or elemental forms. Heavy metals are profoundly solvent in the aquatic environments and accordingly they can be retained effectively by living organisms. Therefore the further study has remedial approach to treat wastewater for irrigation purposes in developing countries.

Keywords: *Azollapinnata* , Phytoremediation, pH ,COD, BOD , Nitrogen, Phosphorus

INTRODUCTION

Wastewater is water generated after the use of freshwater, raw water, drinking or saline water in a variety of deliberate applications or processes Frankin *et al*., (2016) One more meaning of waste water is "Utilized water from any mix of duman business or developing works out, surface flood storms water, and any sewer inflow interruption". (Tiley *et al*. 2014) in everyday usage, wastewater is commonly a synonym for sewage (also called sewerage, domestic wastewater, or municipal wastewater, which is wastewater that is produced by a community of people. *Azolla Azolla* is a free drifting new water plant having a place with the family *Azollaceae* and request Pteridophyta. It is a typical bio-manure in rice crop. It develops in relationship with the blue-green. *Anabaenaazollae*, is considered to be the most promising because of the case of cultivation, high productivity and good nutritive value (Singh *et al*., 1978, The higher crude protein content above 20%) furthermore, presence of fundamental amino acids (high lysine content),vitamin A precursor beta-carotene, vitamin B^{12} and minerals like Iron calcium, phosphorous, potassium and magnesium made *Azolla* valuable feed supplement for livestock, poultry and fish, rural poultry integrated with in situ *Azolla* cultivation was able to provide sustainable livelihood security as well as income for diversifying the livelihood of the farmers. Therefore the present study was aimed to analyze the Phytoremediation potential of *Azolla*. Lusing different wastewater.

MATERIALS AND METHODS

Collection of wastewater
The source of wastewater were collected from (dairy ,domestic, Municipal) sample was collected from the area of Mannargudi, Thiruvarur district ,Tamil Nadu, ,India, and collected water samples were sealed in air tight polythene containers (5litres capacity)

Sample
Dairy waste water: The colour of dairy wastewater is initially thick white and highly turbid nature.
Domestic waste water: The colour of domestic wastewater is initially greyish black turbid nature.
Municipal waste water: The colour of municipal wastewater is initially blackish and turbid nature.

Analysis of physico-chemical parameters of the water samples before treatment
The collected wastewater was undergoes for the analysis of parameters such as pH, dissolved oxygen, electrical conductivity, nitrogen, phosphorus, oil and grease content.

Determination of pH (Misra,1968)
In a clean conical flask, 20 ml of dairy, domestic, municipal wastewater was taken, and 100ml of distilled water was added for making 1:5 suspensions .It was shaken for one hour at regular intervals. After shaking, the suspension was filtered through Whatmann no.1 filter paper . The pH of the sample was determined using a pH meter.

Dissolved oxygen (Winkler Method, 2021)
The Winkler Strategy is a method used to dissolved oxygen in freshwater frameworks. Dissolved oxygen is used as an indicator of the health of a water body, where higher dissolved oxygen concentrations are correlated with high productivity and little pollution. This test is performed nearby, as deferrals between test assortments and testing might bring about an adjustment in oxygen content.

Estimation of electrical conductivity (Smith and Doran, 1996)
1ml of distilled water was added with 1g of dairy, domestic, municipal wastewater sample was mixed which is a 1:1 suspension. The suspension was filtered using suction. A circular Whatmann no. I filter paper was put in the Buchner funnel, and the filtered paper was moistened with marine water and made sure that it was tightly attached to the bottom of the funnels so that all holes are covered. The vacuum pump was started. The suction was opened, and the

suspension was added to the Buchner funnel. The clear filtrate was transferred into a 50 ml bottle and the conductivity cell was immersed in the solution and the readings were noted.

Estimation of Nitrogen (Subbaiah and Asija, 1956)

The nitrogen was estimated by the dairy ,domestic , Municipal wastewater sample was wrapped in aluminium foil and was put in a kjeldhal flask the catalyst mixture was added and digestion was carried out. The sample was heated on flame for 10- 30 min till charred. The flask was rotated until the natural matter obliteration and tilled grey color solution was obtained. The digested sample was then diluted 10 mi of distilled water and 5 ml in flask. Flask was then heated till the solution boiled. The titration was carried out with 0.1 ml HCL by adding a phenolphthalein indicator. Endpoint purple to pink was noted for calculating the nitrogen content

N-(A-B) 1.4/wt, of the sample

A =ml of the HCL used, B-ml of HCL used for blank

Estimation of Phosphorus (Jackson, 1973)

1ml of wastewater sample taken and 200ml of 0.002 N H_2SO,N H_2SO^4, was added in its mixture was stirred for half an hour. The solution was then filtered through No.1 Whatmann filter paper 42.5 ml Filtrate was taken and 2 ml of ammonium molybdate along with 5 drops of SnCl was added to the total volume of the mixture was made to 100ml with distilled water and absorbance was taken at 690nm standard graph was plotted and reading were extrapolated calculation. %Available phosphorus= mg p/L. of the sample.

Turbidity

Turbidity water becomes fixed, the heavier and bigger suspended particles settle down rapidly and the lighter and finely separated particles settles gradually and even requires months. Ground water is less turbid in light of low speed of water. Turbidity might be useful for controlling development of agnosticisms by not permitting legitimate daylight to water which is important for their development then again it is destructive as the creatures are dealing with to the suspended particles. When water becomes stationary, the heavier and larger suspended particles settle down quickly and the lighter and finely divided particles settles very slowly and even takes months. Ground water is less turbid due to low speed of water. Turbidity may be helpful for controlling growth of paganisms by not allowing proper sunlight to water which is necessary for their growth on the other hand it is harmful as the life forms are dealing with to the suspended particles. The turbidity of the wastewater was analyzed by using spectrometer and difference in turbidity was recorded.

Cultivation of *Azolla* in different wastewater
Collection of *Azolla*

The *Azolla* were collected from agricultural land around Melanatham, Thiruvarur district, Tamil Nadu, India.

Cultivation of *Azollapinnata*

Several methods of *Azollapinnata* production had been explored such as plastic trays, *Azolla* beds, here concert plastic trays was used to cultivate *Azollapinnata* which contains 4 trays and it's was made as bed .It located in shady place , preferably under a tree , with sufficient sunlight should be chosen for cultivation. Direct sunlight should be avoided. Each bed was having the dimensions 2m×2m (4 m 2) with 0.3 m depth. About 1 kg two to three day old cow dung was dissolved in 6litres of water was added into each bed with thorough mixed such that mixture was spread evenly throughout the area .The collected water samples was filled up in the trays .All corners of the tray should be of the same level so that the water level can be kept uniformly .Each bed was inoculated with 5 gm of fresh and pure culture of *azollapinnata* and water was sprinkled over it.pH of the bottom organic matter and top water were tested regularly. After 15-20 day. 1 kg of *azollapinnata* can be harvested from each bed. To avoid nutrient deficiency 20 gm of super phosphate and 1 kg cow dung was mixed once in every month.About 30 percent water was replaced with fresh water once every 15 days to prevent excess nitrogen accumulation. Replacement of water and soil should be followed by fresh inoculation of *Azollapinnata*, once in six months.

Collection and storage of *Azollapinnata*

After 15-20-day *Azollapinnata* multiplied rapidly and filled the beds within 7 days. Every fortnight about 10 *Azollapinnata* samples were collected from beds. Harvested *Azollapinnata* was washed thoroughly in clean water, weighed and dried for 2 to 3 days under shed with the goal that it becomes firm while green variety actually held in the dried *Azolla.* Dried *Azolla* was collected, packed in air tight bags and stored until further use.

Isolation of bacteria from wastewater
Serial dilution technique (Avishai Ben-David 2014)

Microbiological analysis of dairy, domestic, municipal wastewater sample was also carried out to analyse the soil quality. Serial dilution was performed by using the collected sample to isolate the bacteria and fungi .1 gm of soil sample was diluted in the tube containing 9ml of sterile distilled water and mixed thoroughly to make a 1:10 dilution. 1ml of diluted sample was transferred to the next test tube and serially diluted into the series of the test tubes having 9ml of water, sterile pipettes using up 10^7dilution.

Preparation of Sorbitol MacConkey Agar (SagarAryal 2022)

Sorbitol MacConkey Agar 50.03gramsof the powdered was mixed with in 1litre   of purified/distilled or deionized water. Blended completely and heat with regular tumult and bubble for 1 moment to disintegrate the powder totally.Avoid overheating and do not autoclave Leave for cooling to 45-50°C. The medium was poured into petriplates leave plates on the sterile surface until the agar was solidified .The plates were stored in a refrigerator at 2-8°C.

Gram Stain for *E.coli*(Chris Hayhurst 2004)
Gram staining was done by picking colonies from plating technique.

The smear was covered with crystal violet and allowed it to stand for one minute. The smear was flushed again tenderly under regular water. The smear was decolorized with 95% alcohol. The smear was flushed again delicately under regular water. The smear was covered again gently with safranin for one minute. The smear was rinsed again gently under tap water and airs dry it. The smear was first observed, under the low power (10X) objective, and then under oil immersion (100X) objective.

Inoculation of *Azolla* in wastewater

Azollapinnata inoculated with wastewaters such as Dairy, Domestic, Municipal wastewater. Healthy manure *Azollapinnata* plants obtained from the cultivation tanks were rinsed with tap water in order to remove adhering mud particles and epiphytes and used to test for the phytoremediation property. .

Analysis of *Azolla* treated wastewater:

The *Azolla* treated wastewater was undergoes for the parameters such as pH, dissolve oxygen, electrical conductivity, nitrogen, phosphorus, oil and grease content.

Heavymetal analysis in *Azolla* treated wastewater:

The collected water samples were prepared by diluting the respective stock solutions of 6 ppm concentration. Salts of every one of the weighty metals with 6 ppm focuses were combined as one out of 1000 ml refined water, isolated the combination arrangement into two equivalent segments of each having a final volume of 500 ml. An additional beaker with 500 ml freshwater without metals was also set up for comparing the growth rate and characteristics of *Azollapinnata* in comparison with the metal contained habitat. Healthy and developed *Azollapinnata*plants were chosen, washed with refined water, and smudged on channel papers to eliminate disciple water, and 2 g of the water fern were laid on the outer layer of one of the measuring beaker added with metals and the other with fresh water. The third beaker with metals was kept as a control for the experiments. All of them were run for a 9 day period.On the 9th day of the experiments, water samples were filtered with whatmann No.1 filter papers and analyzed by Atomic absorption spectrometer for Zn, Cd, and pb.

RESULTS AND DISCUSSIONS

Phytoremediation is such a strategy where the capacity of plants to get by in dirtied water and to work with contaminations expulsion from the environment is exploited. The main advantage of phytoremediation is that it is very economic and eco friendly method of treatment when compared to other physical and chemical methods of wastewater treatment. The capacity of aquatic plants to fill in supplement rich water and to proficiently eliminate supplements and metals from wastewater make them an appealing choice for coordinating into wastewater treatment plants. Also, they have very high growth rates and hence produce potentially valuable biomass which can be used for the production of a variety of liquid and solid bio fuels. The focus on the use of biomass as an alternative feedstock to fossil fuels is intensifying due to: its role in reducing CO_2 emission (Sreelakshmi *et al.*,2020) Our findings similar with Murali *et al.*, (2022) he was carried to test the *Azolla* (*Azollapinnata*) as bioremediation agent for dairy farm liquid waste and to find out the effect of feeding *Azolla* obtained from bioremediation on growth of Nellore lambs Eighteen Nellore lambs having uniform body weights were selected and randomly divided into 3 groups TD (0% *Azolla*).T (10% Conventional *Azolla),* and T2 (10% Phytoremediation *Azolla* obtained from dairy farm liquid waste) of 6 lambs in each group in a completely randomized design. The exploratory eating diets were proposed to the lambs for a period of 90 days. Bioremediation of dairy farm liquid waste with *Azolla* decreased the pH from 7.96 to 738 and the colour of the liquid waste was changed from greyish black to brown colour.The turbidity, COD, BOD. Nitrogen and Phosphorous substance was diminished to 48.14, 0.74, 0.43, 30.76 and 7.44%, respectively.The present review reasoned that Azolla can be utilized for bioremediation of dairy ranch fluid waste in an eco-friendly manner.

CONCLUSIONS

The present study concluded that *Azolla* can be used for Phytoremediation of domestic wastewater in an eco-friendly manner. Experimental results show that *Azolla* can be used differently for wastewater treatment, such as nutrient remover and heavy metal absorber. But most researchers haven't been forced into real situations and have studied only laboratory scale. Some practical problems will occur in real cases because *Azolla* may not grow well in deep tanks, such as treatment tanks used in wastewater treatment. *Azolla* needs a large surface area for its growth;Providing a large surface area may not be a practical situation in wastewater treatment. This economical wastewater treatment is related with low energy utilization, low capital expense and in certain circumstances, low mechanical innovation prerequisites. Hence this project step forward a lead to mutually beneficial system for treatment of wastewater with a yield of *Azollapinnata*. Further study is to be planned that increase the usage of *Azolla* species as Phytoremediation agent to treat the wastewaters at low cost .

ABSTRACT

To be competitive in a time of technological upheaval and shifting consumer tastes, banks must innovate their operations. With a thorough examination of process innovation projects and how they affect competitive advantage, this study seeks to provide empirical understandings of tactics that improve banks' positions in the market. This empirical study explores the relationship that exists between competitive advantage and process innovation in the banking industry. By examining the dynamics of process innovation and its consequences for competitive advantage in the banking sector, this empirical study seeks to close this gap. Through a survey methods approach, we examine the extent and nature of process innovation initiatives adopted by banks, the impact of process innovation on various dimensions of competitive advantage including cost efficiency, service quality, and market share, and the mediating factors influencing this relationship. Leveraging both quantitative and qualitative methods, this study investigates the relationship between process innovation and competitive advantage, shedding light on key drivers, challenges and outcomes. The findings provide actionable insights for banking executives and policymakers aiming to navigate the evolving landscape of financial services.

Keywords: Innovation Process, Consumer preferences, Competitive advantage, Employee empowerment.

Afsar Ali *et al.,*

INTRODUCTION

The primary component of the financial system is the banking industry, whose activities have an impact on every facet of the economy (Davies, 1996; Bhosale, 2012). Like other businesses, the banking sector suffers from dynamic conditions, such as intense competition in the financial systems (Khedr, 2008; Kwan, 2010), and it is particularly susceptible to employee malfeasance (Childress, 2014). Compared to other sectors, the banking industry is more prone to instability (Northcott, 2004). Consequently, this industry begins to innovate its administrative system by maintaining moral leadership (Sandra and Johnt, 2015) and knowledge process competence (Bidmeshgipour et al., 2012; Abualloush et al., 2016). The Indian banking sector plays a crucial role in the country's economic development. With a diverse mix of public sector banks, private banks, foreign banks, and cooperative banks, the sector serves the needs of various segments of the economy (Reserve Bank of India, 2021). The regulatory environment, primarily governed by the Reserve Bank of India (RBI), has undergone significant reforms in recent years. Initiatives such as Basel III implementation, asset quality reviews, and the Insolvency and Bankruptcy Code (IBC) have aimed to strengthen the sector's resilience and governance. Digital transformation has been a key focus area for Indian banks, driven by factors such as increasing internet penetration, smartphone adoption, and government initiatives like Digital India. Banks are investing in technology to enhance the customer experience, streamline operations, and offer innovative products and services (Jaiswal & Chaurasia, 2021). Financial inclusion continues to be a priority for the Indian government and regulators. Initiatives like Jan Dhan Yojana, Pradhan Mantri Mudra Yojana, and Payments Banks aim to extend banking services to the unbanked and underbanked population, especially in rural areas (Sengupta & Chakraborty, 2020). The Indian banking sector faces several challenges, including governance issues, NPA (non-performing asset) management, and competition from non-banking entities.

However, it also presents vast opportunities, such as the untapped potential of retail banking, wealth management, and cross-border expansion (Gupta & Chauhan, 2021). In today's rapidly evolving banking landscape, the pursuit of competitive advantage is paramount for financial institutions seeking to thrive amidst fierce market competition. One key avenue through which banks strive to gain an edge is by embracing process innovation – the strategic redesign and optimization of operational processes to enhance efficiency, effectiveness, and customer satisfaction. Process innovation holds promise for banks not only in streamlining internal operations but also in delivering superior services and experiences to customers. However, the precise relationship between process innovation and competitive advantage within the banking sector remains a subject of empirical inquiry. This empirical study sets out to explore the dynamics of process innovation and its impact on competitive advantage in the banking industry. By delving into the extent and nature of process innovation initiatives adopted by banks, this research aims to shed light on the strategies and practices that financial institutions employ to stay ahead in an increasingly digital and customer-centric environment. Moreover, by examining how process innovation influences key dimensions of competitive advantage – such as cost efficiency and employee training – this study seeks to uncover the mechanisms through which innovation translates into tangible benefits for banks. Drawing on theoretical frameworks from innovation management, organizational theory, and strategic management, this study employs a mixed-methods approach to gather and analyze empirical data. Through surveys, interviews, and statistical analysis, we seek to uncover patterns, relationships, and insights that elucidate the complex interplay between process innovation and competitive advantage in banking. The results of this investigation are likely to provide significant insights for banking executives, policymakers, and researcher's alike, providing guidance on how to effectively leverage process innovation to cultivate and sustain competitive advantage in the dynamic and challenging banking landscape.

REVIEW OF LITERATURE

The conceptual foundation has been developed to specify the topics covered by the literature review such as "employee empowerment", "employee training", "impact of employee empowerment on firm performance" and the "process innovation".

Employee Empowerment

Within the banking sector, employee empowerment has become a key tactic for improving organizational performance and competitiveness. In an organizational environment that is becoming more intricate and dynamic, empowered people are essential for fostering innovation, enhancing customer satisfaction, and accomplishing strategic goals. Recent research has emphasized the significance of employee empowerment within the banking industry, emphasizing its influence on a range of organizational results. For instance, a study conducted by Khan and Ali (2020) discovered that, among banking professionals, employee empowerment has a beneficial impact on work satisfaction, organizational dedication, and performance. Employees that feel valued and invested in their work report increased job satisfaction, which boosts motivation and dedication to company objectives. Furthermore, in the banking industry, enhanced customer happiness and service have been associated with staff empowerment. Empowered bank employees are more likely to provide consumers with individualized and prompt service, which raises customer satisfaction and loyalty, according to a study by Wang and Lo (2021). By giving frontline staff members the freedom to decide for themselves and take initiative, banks may develop a customer-focused culture that encourages customer loyalty and trust. Additionally, it has been demonstrated that employee empowerment improves organizational agility and creativity in the banking industry. According to research by Al-Abdallah and Obeidat (2019), empowered employees are more open to embracing change and adjusting to new procedures and technology, which promotes organizational creativity and agility. Giving staff members the freedom to find and apply creative fixes and process enhancements will give banks a competitive advantage in the quickly changing financial services sector. Notwithstanding the possible advantages of employee empowerment, organizational culture, leadership styles, and support systems must all be carefully considered for it to be implemented successfully in the banking industry. Research has demonstrated how transformational leadership can foster employee empowerment and foster a positive work atmosphere (Rizwan et al., 2021). Transformational leaders cultivate an environment of trust, cooperation, and empowerment inside their organizations by inspiring and motivating staff members to reach their full potential. Employee empowerment is a key driver of organizational success and competitiveness within the banking sector. By empowering employees to make decisions, take initiative, and innovate, banks can enhance job satisfaction, customer service, and organizational performance. However, achieving employee empowerment requires strong leadership, an effective organisational environment, as well as a dedication to innovation and continuous growth.

Employee Training

Employee training is an essential part of human resource development for the banking business. Its goal is to provide employees the competencies, know-how, and abilities they require to perform their jobs effectively and adjust to shifting market conditions. In the banking industry, staff happiness, customer service, and organizational performance are all improved by employee training, as evidenced by recent studies. Several studies have emphasized the importance of ongoing training and development programs in addressing the evolving needs and challenges faced by banking professionals. For instance, research by Ahmad and Ahmad (2021) evaluated the effect of training affecting employee performance within the banking sector; their findings suggest a positive relationship between training effectiveness and employee productivity. Effective training programs not only enhance employees' technical skills and job-related knowledge rather also encourages an environment of ongoing learning and development inside the organisation. Moreover, employee training has been identified as a key driver of customer satisfaction and loyalty in the banking sector. A study by Kumar and Mohanty (2020) revealed that The bank employees with proper training are better able to recognise and meet the demands of their customers, increasing the degree of customer retention and satisfaction. Making investments into development and training of staff members allows banks to

80022

Afsar Ali *et al.,*

increase service quality, build customer trust, and gain a competitive advantage in the marketplace. Most recent studies has emphasised the significance of technology-enabled training methods in enhancing learning outcomes and employee engagement in the banking sector. With the advent of digital technologies, banks have increasingly adopted virtual learning facilities, virtual classrooms, and mobile-based training tools to offer training programmes to employees (Al-Kalbani et al., 2021). These technology-enabled training methods offer flexibility, accessibility, and interactivity, enabling employees to acquire new skills and knowledge at their own pace and convenience. However, despite the benefits of employee training, challenges persist in the effective implementation and evaluation of training programs within the banking sector. Research by Al-Habsi et al. (2021) identified various factors that influence the success of training initiatives in banks, including leadership support, organizational culture, and alignment with business objectives. Moreover, measuring the impact of training on organizational performance remains a complex and multifaceted issue, requiring the use of appropriate metrics and evaluation methods. Employee training performs a vital part in enhancing organizational performance, customer service, and employee satisfaction within the banking sector. By making training and development programme investments, banks can empower employees, improve service quality, and gain a competitive edge in the marketplace. However, addressing challenges related to training effectiveness, technology adoption, and performance evaluation is essential for maximizing the benefits of employee training in banking.

Process Innovation

Process innovation has become increasingly important in the banking sector as financial institutions seek to improve efficiency, maintain competitiveness in a market that is changing quickly and improve the customer experience. Recent literature highlights various aspects of process innovation and its implications for banking operations, customer service, and organizational performance. Empirical studies have shown that process innovation can significantly impact various dimensions of competitive advantage in the banking sector. For example, Damanpour (1991) found that banks that invest in process innovation tend to achieve greater cost efficiency, as streamlined processes and automation lead to reduced operational costs and improved resource allocation. Similarly, research has highlighted the role of process innovation in enhancing service quality and customer satisfaction in banks (Dodgson et al., 2005). By leveraging innovative technologies and process improvements, banks can deliver faster, more convenient and personalized services to their customers, thereby strengthening customer relationships and loyalty. Studies have emphasized the role of process innovation in driving efficiency gains and cost reductions within banks. For example, research by Al-Tarawneh and Maqableh (2021) examined the impact of process innovation on operational efficiency in Jordanian banks, finding that innovative process redesign and automation initiatives led to significant improvements in productivity and cost efficiency. By streamlining workflows, reducing manual tasks, and leveraging technology solutions such as "Robotic process automation (RPA)" and "Artificial intelligence (AI)", banks can achieve operational excellence and resource optimization. Process innovation has been shown to have a positive impact on customer experience and satisfaction in the banking sector.

A study by Chang et al. (2020) investigated the relationship between process innovation and customer satisfaction in Taiwanese banks, revealing that innovative service delivery platforms, like "mobile banking apps" and "online account opening platforms", contributed to higher levels of customer satisfaction and loyalty. By simplifying processes, reducing wait times, and offering convenient and personalized services, banks can strengthen their bonds with their valued customers and improve their overall experience with them. The literature has explored the implications of process innovation for regulatory compliance and risk management in banking. With the increasing regulatory scrutiny and complexity facing financial institutions, banks are under pressure to ensure compliance with regulatory requirements while maintaining operational efficiency. Research by Cheng and Xu (2021) examined the impact of process innovation on risk management practices in Chinese banks, highlighting the role of innovative technologies such as block chain and data analytics in enhancing transparency, security, and compliance with regulatory standards. The potential benefits of process innovation, challenges remain in the effective implementation and adoption of innovative processes within banks. Studies have identified organizational barriers, legacy systems, and cultural resistance as key obstacles to successful process innovation initiatives (Loonam et al., 2020). Overcoming these challenges requires strong leadership, a culture of innovation, and investment in employee training and change

management efforts. Process innovation is a critical driver of performance and competitiveness in the banking sector. By embracing innovative processes, leveraging technology solutions, and promoting an environment that values constant growth, banks can increase effectiveness, customer satisfaction, and risk management capabilities. However, addressing organizational barriers and cultural resistance is essential for realizing the full potential of process innovation in banking operations.

Firm Performance

Understanding firm performance in the banking sector is essential for stakeholders ranging from investors to policymakers, as it reflects the financial health, competitiveness, and overall effectiveness of financial institutions. Recent literature has examined various factors influencing firm performance within the banking sector, including financial metrics, strategic management practices, and external market conditions. Financial metrics such as profitability, efficiency, and asset quality are commonly used indicators of firm performance in the banking sector. Research by Khan et al. (2021) investigated the determinants of bank profitability in emerging markets, finding that factors such as capital adequacy, liquidity, and loan quality significantly impact bank profitability. Effective risk management practices, prudent lending policies, and sound capital allocation strategies are crucial for maintaining profitability and sustainability in the banking industry. Strategic management practices play a key role in shaping firm performance and competitiveness in the banking sector. Studies have highlighted the importance of strategic planning, innovation, and market positioning in driving long-term success for banks (Zaidi et al., 2020). Research by Li et al. (2021) investigated the association involving strategic orientation and firm performance in Chinese banks, revealing that banks with a customer-focused strategy and a commitment to innovation tend to outperform their competitors. External market conditions and regulatory environment significantly influence firm performance in the banking sector. For example, research by Gao et al. (2021) examined the impact of regulatory changes on bank performance in the European Union, finding that regulatory reforms such as Basel III and MiFID II have both positive and negative effects on bank profitability and risk-taking behavior. Adapting to regulatory changes, complying with reporting requirements, and managing regulatory risks are essential for banks to maintain performance and meet stakeholders' expectations. Challenges remain in assessing and improving firm performance within the banking sector. Research by Zhang et al. (2021) highlighted the role of corporate governance practices in enhancing firm performance and mitigating agency conflicts in Chinese banks. Effective governance mechanisms, including board independence, executive compensation, and risk oversight, are crucial for aligning managerial incentives with shareholder interests and promoting sustainable performance. The firm performance in the banking sector requires a holistic approach that considers financial metrics, strategic management practices, and external market conditions. By focusing on factors such as profitability, efficiency, strategic orientation, and regulatory compliance, banks can enhance their performance, strengthen their competitive position, and achieve long-term success in a dynamic and challenging industry environment.

Objectives

- To investigate the extent and nature of process innovation initiatives adopted by banks.
- To examine the impact of process innovation on various dimensions of competitive advantage, including employee empowerment and Employee training
- To study the role of Process innovation in mediating the relationship between Employee Empowerment, Employee Training and Firm performance

Hypotheses

H1: There is a significant relationship between Employee Empowerment and Process innovation of the bank
H2: There is a significant relationship between Employee Training and Process innovation of the bank
H3: Process innovation mediates among Employee Empowerment, Employee training and Firm performance

RESEARCH METHODOLOGY

This research work is descriptive. This research aims to collect detailed information on employee empowerment, employee training, process innovation and firm performance of banking sector. For the purposes of this investigation, a descriptive research design was adopted. Primary data was collected using the field survey method and a structured questionnaire that was developed after evaluating pertinent literature. The primary data collection includes questionnaires to determine employee empowerment and training and the firm performance of the firm in the banking sector. The variables of the research study were identified by means of a literature review, which plays a critical role in influencing empowerment, training and process innovation which leads to firm performance. Various statistical tools were employed according to the requirement and suitability. The questionnaire included items related to employee empowerment, employee training, process innovation and firm performance. All the questionnaire items were measured with a Likert scale (ranging from 1= strongly disagree to 5= strongly agree). The data was analysed using appropriate statistical techniques like SPSS and M.S. Excel software. The Structural Equation Modelling (S.E.M.) was used to test the proposed model and hypotheses using PLS-SEM 4.1.0 software for mediation analysis.

Sampling Design

The study has adopted the convenience sampling method. The convenience sampling methodology was adopted since it serves as a highly feasible approach to seek the appropriate source of the target population available to participate in providing the required data for the research. The sample population for this research comprises banking employees' who are working in the selected banks. According to Neuman (2000), for populations larger than 10,000, researchers should collect samples at least 10% of the overall population, and for populations larger than 100,000, researchers should collect samples at least 1%. Accordingly, in this research, it was decided to collect a sample of a total 218 bank employees. Data were collected from the branches of Jammu and Kashmir Bank Ltd. and State Bank of India, Srinagar (J&K).

RESULTS

Data Analysis - Structural Model

The assessment of the structural model involves examining the estimates and conducting hypothesis tests to assess the causal association among endogenous and exogenous variables as depicted in the path diagram. In this process, the model's estimates are compared to the observed data to determine how well the model fits the actual relationships. Hypothesis tests are then used to assess the significance of these relationships, helping to determine if they are statistically meaningful. The goal is to determine whether the proposed causal relationships in the model are supported by the data. Goodness of fit in a global matric that evaluates the complete measurement model efficiency in terms of average communality (Tenenhaus et al, 2005). The models' overall goodness of fit should be the starting point for model evaluation. When the SRMR is below 0.08, the model fits well (Hu & Bentler, 1998). The NFI (Normed Fit Index) can range between 0 & 1. Bentler, (1992) the value close to 0.9 is consider for model fit. For composite model the thresholds for the NFI is still to be determined. Overall, the NFI is still not widely used (Byrne, 2008).

Convergent validity

For assessing convergent validity, three main tests are commonly used: "Cronbach's alpha, reliability, and average variance extracted". In this study, internal reliability was evaluated using Cronbach's alpha, with a value greater than 0.7 indicating strong internal consistency and thus adequate reliability. Table 2 demonstrates that the internal consistency and reliability of this study exceed 0.7, making them suitable for further analysis. Convergent validity requires an average variance extracted greater than 0.5 and standardized factor loadings of all items not less than 0.5. If factor loadings are less than 0.5, it suggests that items contribute more to measurement error than to the variance in the constructs. Every variable in this investigation had an average extracted variance higher than 0.5.

The structural model's overall analysis focuses on the strength of explanatory power, assessed through two criteria: the "coefficient of determination (R-square) and effect size (F-square)". A higher R-square value indicates a stronger explanatory capacity of the construct (Hair et al., 2016). R-square ranges from 0 to 1, with higher values indicating a greater level of explanatory power. Table 6 displays the data, showing strong explanatory power through bootstrapping.

Hypothesis Analysis

Figure 2 illustrates the positive association among Employee Empowerment and Process Innovation (T-value= 9.309 > 1.96, Path coefficient= 0.673, Standard deviation= 0.072, P-value= 0.000 < 0.01) thus supported H1.

As result reveals there is a positive relationship between Employee training and Process Innovation (T-value= 4.353 > 1.96, Path coefficient= 0.315, Standard deviation= 0.072, P-value= 0.000 < 0.01) thus supported H2.

In addition, there is a positive relationship between the quality of Process Innovation and Firm Performance (T-value= 7.397 > 1.96, Path coefficient= 0.945, Standard deviation= 0.012, P-value= 0.000 < 0.01) leading to supported H3.

DISCUSSION

Determinants of Process Innovation: Conducting empirical research to identify and analyze the key determinants that drive process innovation within the banking sector. This could involve exploring variables including technological advancements, market competition, regulatory changes and organizational culture. Impact of Process Innovation on Performance: Investigating the impact of process innovation on various performance metrics within banks, such as efficiency, productivity, customer satisfaction, and profitability. Understanding how different types of process innovations contribute to these outcomes could provide valuable insights for banks aiming to enhance their competitive position. Strategic Responses to Competitive Pressures: Examining how banks strategically respond to competitive pressures through process innovation. This could involve analyzing the strategies adopted by different types of banks (e.g., traditional banks vs. fintech startups) and how these strategies evolve over time in response to changes in the competitive landscape. Role of Data Analytics and Technology: Exploring the role of data analytics, artificial intelligence, and other emerging technologies in driving process innovation within the banking sector. This could involve investigating how banks leverage data-driven insights to identify opportunities for innovation and improve operational efficiency. Cross-Industry Comparisons: Conducting comparative studies to understand how process innovation in the banking sector differs from other industries and how lessons learned from one industry can be applied to another. This could help identify transferable best practices and inform strategic decision-making across different sectors. Overall, the findings provides a foundation for further research on process innovation in the banking sector, offering valuable insights that can be expanded upon and refined through additional empirical analysis and theoretical development.

CONCLUSION

Finally, by applying a data-driven methodology to examine the competitive landscape, our study clarifies the dynamics of process innovation in the banking industry. Our study has revealed important trends and drivers of process innovation, emphasizing the part played by elements including market competition, regulatory changes, and technological improvements. Our results highlight the significance of adopting a strategic approach to counteract competitive pressures and the potential of data analytics and emerging technologies to spur innovation. Furthermore, our research contributes to the broader literature on innovation management and competitive strategy by providing empirical insights into the specific context of the banking industry. By understanding the determinants and outcomes of process innovation in this sector, policymakers and practitioners can make informed decisions to enhance organizational performance and navigate the evolving competitive landscape. However, it is imperative to recognise the limitations of this study, including the dependency on primary data and the potential for measurement

errors. Future research could address these limitations by conducting more extensive both primary and secondary data collection and employing advanced analytical techniques. Additionally, further investigation is warranted to explore the long-term sustainability and effectiveness of process innovations in the banking sector. Overall, our research offers insightful implications for theory and practice and advances our understanding of process innovation in banking. In the pursuit of competitive advantage, we hope that our findings will contribute to strategic decision-making and inspire more study in this field.

ABSTRACT

The increasing prevalence of NICU admissions prompts a critical examination of the antecedent factors originating during the maternal phase of the perinatal period. While advancements in neonatal care have significantly improved survival rates. To comprehensively investigate and identify maternal risk factors associated with the admission of newborns to the Neonatal Intensive Care Unit (NICU). Information of NICU admitted infants was gathered from multiple paediatric hospitals located in different Surat zones, especially those that had Neonatal Intensive Care Units (NICUs).After selection, the following maternal risk factors were evaluated for the infants in accordance with the evaluation form, which also contains the patient's demographic information and maternal risk factors Descriptive analysis of the current study identified that male Neonates (57%) are more than female neonates (43%) with advanced maternal age more than 35 (5.3%), twin pregnancy (9.5%), preeclampsia (11.3%), and peripartum infections (3.5%), history of miscarriage (7%), IVF Pregnancy (8.5%) and oligohydramnios (9.2%) were the predominant maternal risk factors for NICU admission. Additionally gestational diabetes (2.8%), anaemic mother (3.9%), consanguineous marriage (2.5%) are also playing a role for admission in NICU Factors related to being in intensive care found in this study should be understood and interpreted in all of the steps of health services, and interventions should be executed when necessary

Keywords: Prenatal or maternal risk factors, NICU admission

INTRODUCTION

The increasing prevalence of NICU admissions prompts a critical examination of the antecedent factors originating during the maternal phase of the perinatal period. While advancements in neonatal care have significantly improved survival rates. Admission to the neonatal intensive care unit (NICU) is an important parameter for neonatal outcomes, because newborns admitted to NICU are at risk for increased mortality and morbidity[1].There are various indications and risk factors for NICU admission. About 5% to 18% of term neonates are admitted to the NICU every year[2]. However, the risk factors for NICU admission in neonates have not been extensively reviewed. Previously reported risks include gestational age, intrauterine growth restriction, methods of delivery, maternal diabetes, preeclampsia, meconium aspiration syndrome (MAS), and respiratory distress syndrome (RDS)[3-5]. Maternal factors play a pivotal role in shaping the health and well-being of newborns, impacting their susceptibility to adverse outcomes. This cross-sectional study aims to investigate and identify key maternal risk factors that contribute to the increased likelihood of neonatal intensive care unit admissions. By improving prenatal care practices, this research project to improve prenatal care strategies and reduce the incidence of NICU admissions associated with maternal risk factors.

AIM AND OBJECTIVE
To comprehensively investigate and identify maternal risk factors associated with the admission of newborns to the Neonatal Intensive Care Unit (NICU).

METHODOLOGY

We retrospectively reviewed the medical records of patients with 284 mothers and evaluated, maternal factors to analyse the risk for NICU admission. This study was part of a larger neonatal cohort study that enrolled neonates born at Surat, Gujarat.

Study design: cross sectional study
Study Population: Male and Female high risk NICU Infant, from different hospital of different zones of Surat
Sampling: Purposive
Sample size: 284
Source of data: Different Paediatric hospitals with NICU centres from different zones of Surat, visited frequently, from different zones of Surat, India

Inclusion Criteria
1. Infants who admitted In NICU within one month after birth,
2. Both Male and Female NICU Infants

Exclusion Criteria
1. Infant who had a major congenital abnormality such as eg, Hydrocephalus, Spinabifida, Arnold Chiari malformation etc.

Procedure
Following the acquisition of institutional ethical permission, a review of the literature was conducted to identify maternal risk factors. During the data collecting phase, information was gathered from multiple paediatric hospitals located in different Surat zones, especially those that had Neonatal Intensive Care Units (NICUs). Parents were contacted and personally met; they were informed of the study's goal and asked for their written, informed permission. After selection, the following maternal risk factors were evaluated for the infants in accordance with the evaluation form, which also contains the patient's demographic information and maternal risk factors which are in

details as follows: Demographic data includes Name, gender, Date of Birth, Mothers age, fathers age, mother education and occupation, father age and occupation

Maternal Risk Factors
Maternal and Paternal age (<18 or >35 maternal, >50 Paternal), Any infection during Pregnancy, Seizure, Diabetes, Hypertension/Pre-eclampsia, Anemia, Multiple gestation, IUGR (Intra Uterine Growth Retardation), Radiation exposure, TORCH infection, History ofmiscarriages, Consanguineous marriage, Smoking, Abnormal fetal growth, IVF Pregnancy, Abnormal uterine blood flows, Maternal medications, Oligohydramnios

DATA ANALYSIS
The subsequent step involved performing descriptive analysis of 284 infants' data, by using SPSS 20.0

RESULT
Table-1 Shows that From NICU admitted Neonates male Neonates(57%) are more than female neonates(43%). Table 2 shows Mean of mother's age 28 years and father's age 31 year during pregnancy with minimum age of 17 of mother and 21 of father and maximum age of mother is 46 and fathers age 49. Table 3 and graph 1 shows percentage of maternal risk factors in mothers whose neonates admitted in NICU

DISCUSSIONS

The current study identified that advanced maternal age, twin pregnancy, preeclampsia, and peripartum infections, history of miscarriage, IVF Pregnancy and oligohydramnios were the predominant maternal risk factors for NICU admission. Additionally gestational diabetes, anaemicmother, consanguineous marriage are also playing a role for admission in NICU. In our cross-sectional study on maternal risk factors for NICU admission, a noteworthy observation emerged from the age distribution analysis. Among the participants, three mothers under the age of 18, a recognized high-risk age group, had infants requiring intensive care in the neonatal intensive care unit (NICU). Additionally, the study revealed that 15 mothers aged 35 yearsolder and also mother who had infants admitted to the NICU with maximum age at 46 years Some evidence indicates that advanced maternal age is connected with placental malfunction, which may raise the risk of newborn deaths and stillbirths or exacerbate pre-existing maternal medical conditions. It is also said that age > 35 years and first birth were associated with preterm birth in a previous study in Jordan[6]. Preeclampsia, a condition characterized by hypertension and organ dysfunction during pregnancy, emerged as a substantial risk factor for NICU admission. This emphasizes the critical need for proactive monitoring and management of preeclampsia to mitigate its potential impact on neonatal outcomes.

In our study There are various indications and maternal causes of NICU admission among neonates, the most common of these include hypertension/Preeclampsia, (11.3%) IVFPregnancy, (8.5%) multiplegestation, (9.5%) history of miscarriages (7%) The possibility of staying in intensive care unit is higher for the babies whose mothers have such risky conditions in their pregnancies. These relationships were shown in several studies [7,8] In our study multiple gestation (9.5%) shows high risk factor which matches with other study in which Multiple pregnancies are the most important factor found to be related to intensive care in the USA constitute 14% of neonatal deaths and increase perinatal mortality 10 times[7,9]. we also observed that In Vitro Fertilization (IVF) pregnancies (8.5%) pose a significant risk among maternal factors. This finding is supported by a relevant study, indicating that the increasing prevalence of infertility treatments contributes to higher rates of multiple pregnancies. Consequently, multiple pregnancies are associated with elevated risks such as low birth weight and other complications, leading to an increased need for intensive care. In one of the studies Examining the maternal factors, they found that mothers with a history of five or more previous births are at a higher risk of stillbirth or neonatal death, as well as spontaneous second-trimester abortion or preterm labour. Notably, these risks are further amplified in cases where babies require admission to the Neonatal Intensive Care Unit (NICU). A history of miscarriage has also emerged as a noteworthy factor linked to NICU admissions. This finding prompts further exploration into the potential physiological and

psychological implications of previous pregnancy losses on subsequent neonatal outcomes.The presence of a history of spontaneous second-trimester abortion or preterm labour remains a significant contributing factor to these outcomes.[10] Conditions such as urinary infection and preeclampsia are also the factors resulting in prematurity.[11,12]

We found case of mother with Oligohydramnios (9.2%), itis characterized by a lower-than-normal level of amniotic fluid, has been identified as a significant risk factor for NICU admission. This finding emphasizes the importance of vigilant monitoring and timely interventions for pregnancies with this particular complication. In our study mother with gestational diabetes is (2.8%) Furthermore, it is mentioned in one study that mothers with pregestational diabetes mellitus have a higher risk for complications such as FGR, asphyxia, and hypoglycemia.[13,14] The comprehensive identification of these maternal risk factors holds significant implications for antenatal care practices and public health interventions. Strategies aimed at mitigating the impact of these risk factors may include targeted surveillance, early detection, and specialized care pathways for at-risk pregnancies. By addressing these maternal risk factors, healthcare providers can contribute to a reduction in NICU admissions, ultimately improving both maternal and neonatal health outcomes.

CONCLUSION

This study is a first step in improving our understanding of the risk factors for NICU admission among mothers. The information gathered from this study could influence prenatal care procedures, direct healthcare policy, and eventually enhance the course of newborn health outcomes. Factors related to being in intensive care found in this study should be understood and interpreted in all of the steps of health services, and interventions should be executed when necessary

ABSTRACT

Twelve genotypes of Black gram (*Vigna mungo* L.) from the Tamilnadu region were examined for morphological characterization utilizing 21 Distinctiveness, Uniqueness and Stability descriptors (DUS) provided by Protection of Plant Varieties and Farmer's Rights, 2007 (PPV and FR). Based on the data and analysis, 16 characters showed genetic variance among genotypes, helpful in choosing genotypes for the Crop Improvement Program. Mahalanobis D² statistics was employed to analyze the observed data and associated scores in order to cluster genotypes with similarity. Each of the twelve genotypes was divided into four clusters. Cluster I had the highest number of genotypes with seven, followed by Clusters II and III with two each, and Cluster IV with one genotype. There was significant genetic diversity evident since the inter-cluster distance between two clusters was greater than the intra-cluster distance. Clusters II and III, with the greatest inter-cluster distance, could be employed in the hybridization program to create superior and agronomically competent varieties.

Keywords: Black gram, Morphological markers, DUS, D² analysis, Cluster analysis.

INTRODUCTION

Pulse crops are valued for their rich protein, vitamins, mineral, and fiber content making them essential for millions worldwide [*Apurva Verma et. al., 2022*][1]. Black gram [*Vigna mungo* L. Hepper] is suitable for both irrigated and rainfed condition [*Singh et. al., 2020*][2] and occupies the bulk of 10.16% of India's total pulse production (27.30 M.T.)[3]. It is the fourth most important pulse crop in India after Chickpea, Pigeon pea and Green gram in terms of area and production[3]. Despite a 3% increase in net area sown of black gram in Tamilnadu, it is yet to achieve its full potential of productivity. Enhancing crop yield relies significantly on genetic variability within the base population, necessitating a thorough evaluation of variation and diversity. Distinctiveness, Uniqueness and Stability (DUS) assessment is a mandate to differentiate genotypes on the basis of their morphology. Morphological markers are cost-effective and easy to score that facilitates grouping of genotypes with specific traits efficiently [*Kumawat et. al.*, 2020][4]. In this context, the current study was undertaken to evaluate 12 popular genotypes from Tamilnadu by scoring 21 characters in line with Protection of Plant Varieties and Farmer's Rights (PPV and FR) guidelines.

MATERIALS AND METHODS

The field trial was conducted during *Kharif – 2024*, at the experimental farm of the Department of Genetics and Plant Breeding in the Faculty of Agriculture, Annamalai University, Cuddalore, India., following Randomized Block Design. The trial involved planting of twelve genotypes (Table 1) in rows with 16 plants per row in three replication, each sized 740 x 440 cm^2. The plant spacing was maintained as 45 x 15 cm^2, at the rate of 16 hills per row and three seeds per hill, that later thinned out. Recommended agricultural practices and crop protection measures were implemented. In each replication, 10 plants were randomly tagged, totaling 30 samples per genotype across three replications. Totally 21 DUS characters were observed. The anthocyanin colouration in hypocotyl was scored when the cotyledons unfolded i.e. 5-6 Days After Sowing (DAS). Time of flowering was recorded when 50% of the plants have had at least one fully opened flower. Plant growth habit, habit of the plant, stem colour, pubescence on the stem, terminal leaflet shape, foliage colour, colour of the leaf veins and pubescence on the leaves were recorded during 50% flowering stage. Colour of the petiole, colour of the premature pods and pubescence on the pod were scored when the green pods were fully developed. Peduncle length, pod length, colour of the matured pod and plant height were observed during harvest maturity. Seed characters such as seed colour, seed lusture, seed shape and the test weight were recorded after the harvest maturity. All the data recorded were analyzed for Clustering through d2m program available in TNAUSTAT platform [*Manivannan, 2014*][5].

RESULTS AND DISCUSSION

DUS characterization
All the 21 characters were either observed or measured as per PPV and FR guidelines. Scores from three replication were compared to arrive at the results shown in the Table 2 and 3. The results are discussed individually as follows.

Seedling character
Hypocotyl: Anthocyanin colouration
No variation was observed in any of the genotypes, as all the genotypes had purple colour hypocotyl. This uniformity was due to the accumulation of water-soluble pigments with anti-oxidant properties aiding plant defense mechanisms [*Satveer Kaur et. al., 2023*][6]. This uniformity may be indicated as common genetic background or conserved trait within the species or specific genotypes evaluated, that could serve as a baseline characteristic for the seedling stage and useful in identifying potential off-types or mutants in future breeding or genetic studies.

Flower character
Time of Flowering
Out of 12 genotypes observed, three genotypes (ADT 5, T 9 and VBN 10) exhibited early flowering (<40 DAS) and all other nine genotypes were of medium (40-50 DAS) duration. None of the genotypes was in late (>50 DAS) category, suggesting limited genetic diversity for this trait. Early-flowering genotypes could be advantageous in regions with shorter growing season, while medium-duration genotypes could be preferred in regions with longer growing seasons or a balance between vegetative and reproductive development.

Plant characters
Plant Growth Habit
Out of 12 genotypes, only T 9 genotype had erect growth habit; nine genotypes (NUL 7, VBN 3, MDU 1, ADT 5, VBN 4, VBN 10, VBN 8, ADT 3 and VBN 5) exhibited semi-erect growth habit and two of them (VBN 11 and KBG 28) were of spreading type. Erect growth habits are preferred in certain cropping systems [Apurva Verma et. al., 2022][1], while semi-erect habit balances plant density and air circulation. Spreading growth habits are advantageous in low-input or organic farming systems, but may require more spacing between plants. Genetic differences in factors like internode length, branching patterns, and stem strength could be exploited in breeding programs to develop cultivars with desired growth habits.

Plant Habit
Out of twelve genotypes, only NUL 7 displayed indeterminate growth and all other eleven genotypes were observed with determinate growth. This has significant implications for crop management and yield potential. Indeterminate genotypes may have a longer growing period and higher yields, but may require more intensive management practices. Determinate genotypes have more predictable growth and better suited for mechanized harvesting. Therefore, selecting genotypes with determinate habit could be appreciated in plant breeding.

Plant Height
Plants were categorized into Short (<45 cm), Medium (45 - 60 cm) and Long (>60 cm). Out of twelve genotypes observed, four of them (VBN 3, MDU 1, VBN 11 and VBN 4) had medium-height and all other eight genotypes were short-height plants. No long-statured genotypes were recorded. Genetic differences in factors like internode length, stem strength, and plant architecture contribute to this variation. Short-statured genotypes are preferred in cropping systems or environments with lodging, while medium-height plants may balance yield potential and lodging resistance. The absence of long-statured genotypes suggested either limited genetic diversity or their exclusion from evaluation. This could guide breeding efforts and crop management strategies to develop cultivars better adapted to specific environmental conditions and production systems.

Stem characters
Stem colour
Out of the twelve genotypes, NUL 7 had green with purple splashes on the stem. Nine genotypes (MDU 1, VBN11, ADT 5, VBN 4, T 9, VBN 10, KBG 28, ADT 3 and VBN 5) exhibited purple with green splashes and two genotypes (VBN 3 and VBN 8) had purple stem and no genotypes displayed green stem. The difference is from pigment biosynthesis and accumulation influenced by genetic factors, environmental conditions, and interactions. Purple pigmentation may offer protection against stress and influence light absorption. Stem may take part in non-foliar photosynthesis contributing up to four percent of total photosynthetic activity [Andrew J Simkin et. al., 2020][2]. This trait can well be used as a marker for varietal identification and registration.

Stem Pubescence
The presence of minute hairs on the stem was observed across all twelve genotypes suggesting a conserved characteristic within the blackgram genotypes. While this lack of variation limits its usefulness for varietal identification or characterization, it could be associated with agronomic traits or stress tolerance mechanisms, which

could be of interest in breeding programs or understanding genotype adaptation. Stem pubescence in diverse germplasm resources can provide insights for future breeding aimed at enhancing stress resilience and productivity.

Leaf characters

Terminal Leaflet Shape

Out of twelve genotypes, five (VBN 3, MDU 1, VBN 11, KBG 28 and VBN 5) had ovate leaflet shape while six of them (NUL 7, ADT 5, VBN 4, T 9, VBN 8 and ADT 3) had cuneate type of leaflet. Only VBN 10 genotype exhibited lanceolate type. Leaf morphology is influenced by both phylogeny and developmental processes like heteroblastic progression and organ stage of a plant *[Daniel H Chitwood et. al., 2012]*[8]. As reported by *Vridi et. al.*[9], Leaflet shape affects crop canopy coverage and lanceolate type often showing drought tolerance *[Jayamani et. al., 2014]*[10]. Genotypes with narrow terminal leaflet should be selected for pest resistance breeding as it shows negative correlation with insect pest attack *[Taggar and Gill, 2012]*[11]. So, while breeding for crop architecture, one may choose VBN 10 to improve solar radiation harnessing efficiency and the production of more biomass potentially boosting yield.

Foliage colour

Out of twelve genotypes, four (NUL 7, T 9, KBG 28 and ADT 3) had green foliage and all other eight genotypes had dark green foliage. This variation results from both the genetic and environmental condition. Higher chlorophyll content produces dark green leaves, enabling sun-light capture even at low radiation level, as in stress-tolerant genotypes *[R. M. Nair et. al., 2024]*[12]. Chlorophyll content and seed yield is negatively correlated *[Mohanlal et. al., 2018]*[13]. Breeder may choose dark green foliage for tolerance and green foliage for yield optimizing.

Leaf Vein Colour

All the twelve genotypes were possessing green colour leaf vein. Although polymorphism was observed in T 9, it was not widespread among the samples considered. While leaf vein colour is not a primary target trait in blackgram breeding programs, it offers insights into plant health, photosynthetic efficiency, stress tolerance, and genetic marker identification; making it necessary to consider this trait alongside key agronomic characteristics for varietal improvement.

Leaf Pubescence

Minute hairs on the leaf surface were visually observed for all twelve genotypes and all exhibited this trait. Trichomes are the first line of plants' defense against biotic and abiotic stress *[Dan Gong et. al., 2024]*[14]. This uniformity shows the evolutionary path of genetics for tolerance against biotic and abiotic stress. While no variation was observed, breeders may still opt for genotypes with densely pubescence to enhance plants to tolerate stress compared with sparsely pubescence.

Petiole Colour

Out of twelve genotypes, eight (NUL 7, VBN 3, MDU 1, VBN 11, ADT 5, VBN 4, T 9 and ADT 3) had green with purple splashes petiole; three (VBN 10, VBN 8 and VBN 5) had entirely purple petiole and only KBG 28 had green petiole. This trait offers insight on genetic diversity, accumulation of pigments, potential stress tolerance mechanisms, and serve as a morphological marker for crop characterization. Further research could unravel the potential applications of petiole colour variation in black gram improvement and cultivation.

Pod characters

Intensity of green colour of pre-mature pods

Out of twelve genotypes, eight (NUL 7, MDU 1, VBN 11, T 9, VBN 10, KBG 28, ADT 3 and VBN 5) had green pre-mature pods; four (VBN 3, ADT 5, VBN 4 and VBN 8) had dark green pre-mature pods and none of them was with yellowish green pre-mature pods. Dark green colour of pre-mature pods contribute to the total crop yield through participation in non-foliar photosynthesis activity *[Andrew J Simkin et. al., 2020]*[7], and it can regulate seed growth and its timely maturation *[Young B Cho et. al., 2023]*[15], This makes dark green pods to be preferred over other in yield maximization program.

Pod Pubescence

Among the twelve genotypes, only NUL 7 and T 9 did not exhibit any pubescence on their pods while all other ten genotypes had pod pubescence. This trait is controlled by a single dominant gene *[Ramakrishna M. Nair et. al., 2024]*[12] and hairy pods are dominant over non-hairy pods. The presence of minute hairs on the pod provides resistance against attack of Pod borers. Pod pubescence is negatively correlated with pod shattering effect *[Gawhane et. al., 2022]*[16]. So, genotypes with dense pubescence on their pods may be preferred due to their increased level of biotic and abiotic stress tolerance as compared to sparsely or non-hairy genotypes.

Peduncle length

Plants were categorized into Short (<5 cm), Medium (5-10 cm) and long peduncle (>10 cm) based on their peduncle length. Out of twelve genotypes, four (VBN 11, ADT 5, VBN 4 and ADT3) had long peduncle and all other eight genotypes had medium peduncle. No genotypes exhibited short peduncle. Peduncle length shows a highly significant positive correlation with seed yield *[Gita Kumari et. al., 2022]*[17] indicating that longer peduncle is favourable for yield maximization program.

Pod length

Plants were categorized into Short (<5 cm), Medium (5 - 7 cm) and long peduncle (>7 cm) based on their pod length. Out of twelve genotypes, five (NUL 7, VBN 11, VBN 4, T 9 and KBG28) had small pods; five (MDU 1, ADT 5, VBN 10, VBN 8 and VBN 5) had medium sized pods and only VBN 3 and ADT 3 had long sized pods. Pod length shows high significant positive correlation with seed yield *[Gita Kumari et al., 2022]*[17] and negatively correlated with pod shattering *[Gawhane et al., 2022]*[16]. Hence, variation in this character may rightly be utilized to select genotypes for various breeding objectives.

Colour of the mature Pod

Among twelve genotypes, three (VBN 3, MDU 1 and VBN 10) had brown mature pods and all other nine genotypes had back mature pods. No genotypes displayed off-white/ buff pods. Consumer preferences or traditional beliefs may influence the choice of mature pod colour. Specific pod colors may be preferred for culinary purposes or cultural traditions. Understanding these preferences can guide variety selection and marketing strategies. Pod colour can provide insights into seed quality characteristics, such as size, vigor, and nutrient content; though the direct relationship requires further investigation. Some plant species link pod colour with enhanced resistance to pathogens, pests, or abiotic stress through specific pigments and compounds, such a direct relationship also warrants exploration.

Seed characters
Seed colour

Out of twelve genotypes, only T 9 had greenish brown seeds and MDU 1 had brown seeds while all other ten genotypes had black seeds. No genotypes displayed green colour seeds. Seed coat colour is a significant genetic marker in genotype identification. Seed coat colour results from the accumulation of anthocyanin on the outer seed coat. Research suggests that only black and dark brown-coloured seeds are having three variant of anthocyanin pigment while two of them are lacking in T 9 genotype and all are absent in genotypes with light brown, green or mottled seed coat, as cited from *Pandey et al., 1981*[18]. The absence of anthocyanin pigments may indicate an imbalance between biosynthesis and degradation. Thus, breeder may opt for black seeded genotypes capable of accumulating ample anthocyanin, showcasing the plant's ability to combat biotic and abiotic stress through antioxidant properties of anthocyanin.

Seed lusture

All the twelve genotypes were dull in nature and no shiny outer coat was reported. Seed lusture is linked to variation in seed coat morphology. Seeds with smooth and shiny surfaces are categorized as shiny and seeds with rough, pitted, adhered depression with surface deposits as dull *[C. Partheeban et. al., 2022]*[19]. Shiny seed surface is a resultant of monogenic dominant gene action over dull seed lusture *[(Nair et. al., 2023)*[12] *and (Gupta et. al., 2023)*[20]]. Sometime,

the deposit present on the seed surface may not be desirable, as creating 'seed dust' that affects allergic people. Correlation between seed lusture and seed quality is yet to be explored.

Seed shape

Among twelve genotypes, seven (VBN 3, MDU 1, ADT 5, VBN 4, KBG 28, VBN 8 and VBN 5) had globose seeds; only T 9 and VBN 10 had oval shaped seeds; three others (NUL 7, VBN 11 and ADT 3) had drum shaped seeds. It is a critical trait in identifying genotypes based on their width-to-length ratio, significantly influencing yield, quality and market preference. It is a criterion in selecting genotypes with desirable seed protein content and seed size. As like the works on the relationship of the seed shape and seed protein content in Chickpea and Soybean *[Karthick Babu et. al., 2023]*[21], further work is needed in blackgram to correlate the same. Notably, three genotypes including VBN 3, MDU 1 and VBN 5 which had large class of seed size are of globose seeds with other globose shaped seeds are also falling near the mean of large class (4.48 centimeter to 4.97 centimeter).

Seed Size (Weight of 100 seeds)

Based on the weight, the seeds were categorized as small (<3 grams), medium (3-5 grams) and large (>5 grams). Out of twelve genotypes, three (VBN 3, MDU 1 and VBN 5) were large in size; all other nine genotypes were medium. No genotype was recorded with small seeds. Seed size shows positive correlation with total seed yield i.e. as the size increases, the weight of the seed increases, boosting total seed yield *[Gita Kumari., 2022]*[17]. So, large-sized seeds may be preferred for yield maximization program. Out of 21 DUS characters observed, 16 characters had shown significance variation among the twelve genotypes studied, as shown in the Table 4.1 and 4.2.

D² analysis
Clustering Pattern

Based on the D² value (Table 5), the twelve genotypes of black gram were grouped into four clusters. Among these clusters, cluster I consisted maximum seven genotypes followed by two genotypes each in cluster II and cluster III and one genotype in cluster IV. The grouping pattern constellation proved the presence of significant amount of variability. The genotype clustering pattern revealed that the clustering did not follow any specific patterned clustering, in relation to the origin.

Intra and inter cluster distance

The average cluster distance (intra and inter) was measured for each cluster and each pair of clusters, in all possible combinations respectively (Table 6). The results revealed that the highest intra cluster distance was observed on cluster III (41215.9062) followed by cluster I (34668.6342), while the lowest intra cluster distance was recorded on cluster IV (each 0.00). The highest inter cluster distance of 1152780.6421, was observed between cluster II and cluster III followed by cluster I and II (511894.7425) while the lowest was observed between cluster I and cluster IV (107741.6485). Genotypes in the same cluster indicated that they were closely related as compared to genotypes in another cluster. Therefore, it may be expected that genotypes in one cluster is less divergent among themselves than those genotypes present in different cluster. The hybridization between the most diverse genotypes (higher inter cluster distance) may result desirable segregates with the accumulation of favourable genes in the segregating generation, which help in hybridization *[Elangaimannan et. al., 2008]*[22].

Cluster Mean

A considerable difference in cluster mean values were apparent for all the traits (Table 7). The preference ranking for the genotypes was allotted, not solely based on the cluster with the highest mean value, rather the ranking considered the scores allotted in the PPV FR manual, to the preferred class of character. As in flowering, early flowering is preferred to mitigate pest and pathogen attacks during the maturity stage. Therefore, the cluster with minimum value for time of flowering would be given the first rank, as the score allotted for earliness is the lowest compared to the other classes.

Dhanraj *et al.,*

Flower Character
Early flowering plants are beneficial in plant breeding. So, genotypes from Cluster III, which had taken less time to flower, may be preferred.

Plant Characters
Erect statured plants are preferred for their enhanced sunlight utilisation and their accommodation in a cropping system within less area. So, genotypes from cluster IV may be preferred here. While Plants with determinate growth are preferred over indeterminate to facilitate synchronization of maturity and mechanical harvest. So, genotypes from cluster I, II and IV may be preferred for plant habit. Plants with medium-height are preferred over short and long-height as it mediates the lodging resistance and yield maximizing. To remind, plant height is non-significant negatively correlated with seed yield *[Shanthi et. al., 2019][23]*. So, genotypes from cluster I may be preferred for plant height.

Stem Characters
Purple coloured stem is preferred as it provides stress tolerance with its high anthocyanin content. So, genotypes from cluster IV can be preferred. While, plants with stem pubescence are preferred due to their resistance for insect pest attack. So, for stem pubescence, genotypes from clusters II and IV can be preferred.

Leaf Characters
Plants with lanceolate leaf type are preferred. So, genotypes from cluster III can be preferred. While genotypes for foliage colour can be selected based on requirements as it is negatively correlated with seed yield *[Mohanlal et. al., 2018][13]*. Greenish petiole is preferred over purplish, for which, genotypes from cluster III can be preferred.

Pod Characters
Dark green pre-mature pods are preferred for efficient seed growth. So, genotypes from cluster IV can be preferred. As that, pod length and peduncle length have high significant positive correlation with seed yield *[Gita Kumari et. al., 2022][17]*, for which genotypes from cluster II are preferred for both the traits. Colour of the mature pod is preferred based on the consumer' preference and market status. Mostly, Blackish brown is preferred followed by deep brown. So, for colour of the mature pods, genotypes from cluster II and IV can be preferred.

Seed Characters
Seeds with other than black and brown seed coat are devoid of anthocyanin pigment as reported by *Pandey, 1989[18]*. Black seed coat is preferred for which genotypes from cluster I can be preferred. Seeds of large size and oval with slight curvature shape is preferred. So, for these two characters, genotypes from cluster II can be preferred. Out of 21 DUS characters, significant variation was exhibited for 16 characters (including time to flowering, plant habit, stem and leaf characteristics, pod traits, and seed properties like color, shape, and size). All those variabilities could well be tapped for Crop Improvement Program by comparing the results of D^2 analysis. Based on D^2 analysis, the genotypes were grouped into four separate clusters, with cluster II (ADT 3 and VBN 5) and cluster III showing the highest levels of divergence. Cluster II exhibited favorable characteristics for yield metrics, such as determinate habit, longer peduncles and pods, and large oval seeds, according to cluster means, while genotypes for early blooming were present in cluster III. The study suggests, to employ genotypes from the highly divergent clusters II and III in hybridization programs to combine advantageous features and create improved black gram varieties with increased productivity and adaptability based on the preference ranking of trait values.

ABSTRACT

Kala Sharir is an essential concept in *Ayurved*, referring to the layers within the body that serve as interfaces between different *Dhatus* (tissues) and organs. *Shleshmdhara Kala*, one of these layers, is associated with the lubrication and proper function of joints. Osteoarthritis (OA), a degenerative joint disease, can be correlated with the dysfunction of *Shleshmdhara Kala* due to the vitiation of *Vata Dosha*. To explore the role of *Shleshmdhara Kala* in the pathogenesis of osteoarthritis and evaluate the effectiveness of *Ayurvedic* treatments aimed at restoring the balance of this *Kala*. A single case study was conducted on a 60-year-old male patient diagnosed with osteoarthritis of the knees. The patient underwent a comprehensive *Ayurvedic* treatment plan, including oral medications, *Panchakarma* therapies, and lifestyle modifications, over a period of 3 months. Clinical assessments and diagnostic evaluations were performed to monitor the patient's progress. The patient exhibited significant improvement in symptoms, including reduced pain, stiffness, and swelling in the knee joints. The range of motion in the affected joints improved, and the patient reported enhanced ability to perform daily activities. These outcomes suggest that the *Ayurvedic* treatment effectively addressed the vitiation of *Shleshmdhara Kala*, thereby alleviating the symptoms of osteoarthritis. This case study highlights the potential of *Ayurvedic* principles in managing osteoarthritis through the targeted treatment of *Shleshmdhara Kala*. The holistic approach, encompassing internal medications, *Panchakarma* therapies, and lifestyle modifications, proved beneficial in improving joint health and overall quality of life for the patient. Further research with larger sample sizes is recommended to validate these findings.

Keywords: *Kala Sharir*, *Shleshmdhara Kala*, Osteoarthritis, *Ayurved*,

INTRODUCTION

Kala Sharir is a fundamental concept in *Ayurved*, referring to the layers or membranes within the body that serve as interfaces between different *Dhatus* (tissues) and organs. [1,2] These layers are critical in maintaining the physiological functions and integrity of the body's structures. The term "*Kala*" signifies a protective sheath or a thin layer, and in the context of *Sharir* (body), it denotes specific layers that support and nourish the *Dhatus*. [3,4]

Classification and Description of *Kala*[5]
According to *Ayurvedic* texts, there are seven *Kalas* in the human body, each associated with a particular tissue or physiological function. These *Kalas* are:
1. *Mamsadhara Kala*
2. *Raktadhara Kala*
3. *Medodhara Kala*
4. *Shleshmdhara Kala*
5. *PurishdharaKala*
6. *Pittadhara Kala*
7. *ShukradharaKala*

Each *Kala* has a specific role and location within the body, which is essential for the proper functioning of the respective *Dhatus* and overall health.

Detailed Description of Each *Kala*
***MamsadharaKala* (Layer Associated with Muscle Tissue):[6]**
- **Location:** It is located between the skin (*Twak*) and muscles (*Mamsa*).
- **Function:** This *Kala* supports the muscle tissue by providing strength and nourishment. It plays a crucial role in the movement and structural integrity of the body.

***RaktadharaKala* (Layer Associated with Blood Tissue):[7]**
- **Location:** Found within the blood vessels (*Dhamanis*) and heart (*Hridaya*).
- **Function:** It is responsible for the formation, storage, and circulation of *Rakta* (blood). It ensures the nourishment and oxygenation of all body tissues.

***MedodharaKala* (Layer Associated with Fat Tissue):[8]**
- **Location:** Present around the muscles and organs, particularly in the abdominal region.
- **Function:** This *Kala* is involved in the metabolism and storage of fat. It provides lubrication and protection to the organs and acts as a reserve of energy.

***Shleshmdhara Kala* (Layer Associated with Lubrication and Joint Function):[9]**
- **Location:** Found in the joints (*Sandhis*) and synovial membranes.
- **Function:** It is responsible for producing and maintaining Sleshaka Kapha, which lubricates the joints, facilitating smooth movement and preventing friction. This *Kala* is crucial in maintaining joint health and preventing conditions like osteoarthritis.

***PurishdharaKala* (Layer Associated with the Formation of Faeces):[10]**
- **Location:** Located in the intestines (*Koshtha*), particularly the large intestine.
- **Function:** It helps in the formation and excretion of faeces. This *Kala* ensures the proper elimination of waste products from the body, maintaining digestive health.

***PittadharaKala* (Layer Associated with Bile and Digestive Enzymes):[11]**
- **Location:** Found in the stomach and small intestine.

▪ **Function:** It is responsible for the production and regulation of *Pitta* (bile and digestive enzymes), which are essential for digestion and metabolism. This *Kala* plays a key role in the digestive process and nutrient assimilation.

ShukradharaKala (Layer Associated with Reproductive Tissue):[12]
▪ **Location:** Present in the reproductive organs.
▪ **Function:** This *Kala* supports the formation, storage, and function of Shukra (reproductive tissue). It is crucial for reproductive health and the continuation of the species.

Significance of *Kala* Sharir in Health and Disease
The concept of *KalaSharir* underscores the importance of these protective layers in maintaining the integrity and function of body tissues.[13] Each *Kala* has a specific role in supporting the *Dhatus* and ensuring their proper function. Any imbalance or dysfunction in these *Kala*s can lead to various health issues, highlighting the need for maintaining their balance through appropriate *Ayurvedic* practices.[14]

Role of *Shleshmdhara Kala* in Osteoarthritis
Shleshmdhara Kala, associated with joint lubrication, is particularly significant in the context of osteoarthritis.[15] The vitiation of *Vata Dosha* leads to the depletion of *Shleshaka Kapha*, causing dryness and degeneration of joint cartilage.[16] This results in pain, stiffness, and restricted movement, characteristic of osteoarthritis.[17]*Ayurvedic* treatment aims to restore the balance of *Shleshmdhara Kala* through internal medications, external therapies, and lifestyle modifications to alleviate symptoms and improve joint health.[18]

CASE STUDY
Kala Sharir, as described in *Ayurvedic* literature, represents the distinct layers within the body responsible for various Anatomical Structure and functions. Among these, *ShleshmdharaKala* is specifically associated with the lubrication and nourishment of the joints, facilitating smooth movement and preventing friction. This case study delves into the correlation between *Shleshmdhara Kala* and osteoarthritis, elucidating how Ayurvedic principles can be effectively applied to manage this condition.

Patient Profile
• **Age:** 60 years
• **Gender:** Male
• **Occupation:** Retired School Teacher
• **Residence:** Urban Area
• **Medical History:** Diagnosed with osteoarthritis 7 years ago, history of hypertension and mild obesity.

Chief Complaints
• Chronic pain in the knee joints for the past 7 years
• Morning stiffness lasting for about 30 minutes
• Swelling and tenderness in the knee joints
• Difficulty in performing activities such as walking, climbing stairs, and standing for extended periods

History of Present Illness
Patient reported the gradual onset of knee pain, which initially started as a mild discomfort and progressively worsened over time. He noticed increased pain during cold weather and after prolonged periods of inactivity. Over-the-counter pain relievers provided temporary relief but did not address the underlying problem. Lastly, he came to PAH (Parul *Ayurved* Hospital), Limda, Vadodara for Ayurvedic Treatment.

Yesha A. Kacha *et al.*,

Personal History
- **Diet:** Mixed diet with a preference for spicy and oily foods
- **Appetite:** Normal
- **Bowel Movements:** Regular
- **Sleep:** Disturbed due to pain
- **Exercise:** Sedentary lifestyle with minimal physical activity

Examination:
- **General Condition:** Fair, moderately obese (BMI: 29)
- **Vital Signs:Blood pressure**: 140/80 mmHg, **Pulse**: 80 bpm, **Respiratory rate**: 18/min
- **Local Examination:**
  - Visible swelling and tenderness in both knees
  - Reduced range of motion in the knee joints
  - Audible crepitus on knee movement
  - Mild deformity of the knees

Investigations
- **X-Ray of Knees:** Revealed joint space narrowing, osteophyte formation, and subchondral sclerosis, indicative of osteoarthritis.
- **Blood Tests:** Elevated ESR and CRP levels, normal rheumatoid factor, and uric acid levels.

Diagnosis
Based on the clinical presentation and diagnostic findings, Patient was diagnosed with osteoarthritis, primarily affecting the knee joints. From an *Ayurvedic* perspective, this condition correlates with *SandhigataVata*, where the vitiated *Vata Dosha* affects the joints and impairs the function of *Shleshmdhara Kala*.

Ayurvedic Understanding
In *Ayurved*, the *Shleshmdhara Kala* is essential for maintaining the lubrication (*ShleshakaKapha*) in the joints, which prevents friction and wear and tear. The aggravation of *Vata Dosha* leads to the depletion of *Shleshaka Kapha*, causing dryness, pain, and restricted movement in the joints, characteristic of osteoarthritis.

Treatment Plan
Objectives:
- Pacification of aggravated *Vata Dosha*
- Nourishment and strengthening of *Shleshmdhara Kala*
- Reduction of pain and inflammation
- Improvement of joint function and mobility

Outcome
After 3 months of consistent *Ayurvedic* treatment and lifestyle modifications, Patient reported significant improvement in his symptoms. The pain and stiffness in his knees reduced considerably, allowing him to resume his daily activities with ease. The swelling around his joints diminished, and he experienced improved joint mobility.

Follow-up
Regular follow-up visits were scheduled to monitor his progress and adjust the treatment plan as necessary. Continued adherence to dietary and lifestyle recommendations was emphasized to maintain the benefits achieved.

DISCUSSIONS

Osteoarthritis (OA) is a degenerative joint disease characterized by the breakdown of cartilage, leading to pain, stiffness, and impaired joint function. In *Ayurved*, the condition can be correlated with *Sandhigata Vata*, where the vitiated *Vata Dosha* primarily affects the joints.[19] The concept of *KalaSharir*, particularly *Shleshmdhara Kala*, is crucial in understanding the pathogenesis and treatment of osteoarthritis from an *Ayurvedic* perspective.[20]

Understanding *KalaSharir* and *Shleshmdhara Kala*
KalaSharir refers to the protective layers within the body that support and separate the different *Dhatus* (tissues). *Shleshmdhara Kala* is one such layer associated with the production and maintenance of *ShleshakaKapha*, the synovial fluid that lubricates the joints.[21] The integrity of *Shleshmdhara Kala* ensures smooth joint movements and prevents friction and wear of the articular surfaces.[22] Vitiation of Vata Dosha disrupts this balance, leading to a reduction in Sleshaka Kapha, resulting in the clinical manifestations of osteoarthritis.[23]

Case Presentation and Ayurvedic Approach
The case study presented a 60-year-old male diagnosed with osteoarthritis of the knees. The patient exhibited typical symptoms such as chronic knee pain, morning stiffness, swelling, and limited range of motion. From an Ayurvedic perspective, these symptoms were indicative of aggravated Vata Dosha affecting the *Shleshmdhara Kala*.
The treatment plan was designed to pacify Vata Dosha, nourish the affected *Kala*, and restore joint function. This involved a combination of oral medications, local applications, Panchakarma therapies, and lifestyle modifications.

Treatment Efficacy and Outcomes
The treatment protocol included:
- **Oral medications** like *Rasnasaptaka Kashaya, Yograj Guggulu, and Ashwagandha Churna*, which have anti-inflammatory and *Vata*-pacifying properties.[24]
- **Local applications** of *PanchatiktaGhrita*and *MahaNarayanTaila* for reducing inflammation and nourishing the joints.[25]
- **Panchakarma therapies** such as Snehana, Swedana, Virechana, and Basti, aimed at expelling vitiated Vata and rejuvenating the *Shleshmdhara Kala*.[26] After three months of treatment, the patient reported significant improvements. Pain and stiffness were notably reduced, swelling diminished, and joint mobility improved. These outcomes suggest that the Ayurvedic treatment effectively addressed the imbalance in *Shleshmdhara Kala*, facilitating joint lubrication and function.

Comparative Analysis with Conventional Treatments
Conventional treatments for osteoarthritis often focus on pain management and symptom relief through NSAIDs, corticosteroid injections, and physical therapy. While these treatments provide temporary relief, they do not address the underlying pathology and may have side effects.
the Ayurvedic approach aims at Traditional healing by targeting the root cause, i.e., the vitiation of Vata Dosha and the impairment of *Shleshmdhara Kala*. This comprehensive strategy not only alleviates symptoms but also promotes long-term joint health and prevents disease progression.[27]

Implications for Future Research
This case study underscores the potential of Ayurvedic treatments in managing osteoarthritis. However, further research with larger sample sizes and controlled clinical trials is needed to validate these findings. Integrating Ayurvedic principles with modern medical practices could offer a more holistic and effective approach to managing osteoarthritis and other degenerative joint diseases.

CONCLUSION

The case study highlights the significance of *Shleshmdhara Kala* in the pathogenesis and treatment of osteoarthritis. The Ayurvedic approach, focusing on restoring the balance of this *Kala* through targeted therapies and lifestyle modifications, proved effective in alleviating symptoms and improving joint function. This reinforces the value of *Kala* Sharir in understanding and managing musculoskeletal disorders in *Ayurved*.(S3, 2022)

Table 1:Treatment Plan

Treatment Protocol	Dose	Dosage	Duration	Purpose
Oral Medications				
Rasnasaptaka Kashaya	20 ml	Twice daily before meals	3 months	Pacify Vata Dosha, reduce inflammation
Yograj Guggulu	2 tablets	Twice daily after meals	3 months	Strengthen joints, reduce pain
Ashwagandha Churna	1 tsp	With warm milk at bedtime	3 months	Nourish Dhatus, reduce stress

Local Applications				
Panchatikta Ghrita	-	External application on affected joints	Daily	Reduce inflammation, nourish joints
Mahanarayan Taila	-	Local Abhyanga followed by hot fomentation	Daily	Lubricate joints, improve mobility
Panchakarma Therapies				
Snehana (Oleation)	-	*Abhyanga with Mahanarayan Taila*	Daily	Lubricate joints, prepare for *Swedana*
Swedana (Sudation)	-	Post-*Abhyanga*	Daily	Reduce stiffness, improve circulation
Virechana (Purgation)	-	-	Once during the treatment period	Expel aggravated Vata
Basti (Medicated Enema)	-	*Matra Basti* with *Sahacharadi Taila* and *Anuvasana Basti* with *Dashmooladi Taila*	Weekly	Pacify *Vata*, nourish *Shleshmdhara Kala*
Diet and Lifestyle Modifications	-	-	Ongoing	Maintain overall health, prevent Vata aggravation
Anti-inflammatory diet	-	Include fresh fruits, vegetables, whole grains, lean proteins	Ongoing	Reduce inflammation, support healing
Avoid *Vata*-aggravating foods	-	Exclude cold, dry, and processed foods	Ongoing	Prevent Vata imbalance
Gentle exercises	-	*Yoga*, walking	Daily	Improve joint mobility, maintain fitness
Adequate rest and sleep	-	-	Daily	Promote healing, reduce stress

ABSTRACT

This research article deals with the study of quality of pond water. They are the habitats of many aquatic animals and plants. The analysis of physico-chemical parameters of pond water from July 2021- June 2022, Periyakulam, Meenakshipuram, Kattakamanpatty, Sengulathupatty and Katroad ponds at Theni and Dindigul District, Tamil Nadu (India). The water samples were collected by 1 litre water bottle and analysed for 13 physico-chemical parameter. pH range is normal in all (Meenakshipuram, Periyakulam, Sengulathupatty, Katroad and Kattakamanpatty) pond water .Temperature, Total Dissolved Solids, Salinity Electrical Conductivity, Free CO_2 were maximum in summer season and minimum in winter season. Dissolved Oxygen were maximum in winter season and minimum in summer season. The result of these study revealed that the pond water is suitable for various purposes like domestic, outdoor bathing, agriculture, fish culture and aquatic life propagation by direct.

Keywords: Selected pond, Physico-chemical parameters, water quality

INTRODUCTION

Ponds are described as a small area filled with water, natural or man-made. They are smaller than a lake and are the habitat of various aquatic plants and animals (Swarnakar, A. K., & Choubey, S. 2016)[6]. Water is the most necessary component for the living being. Life on the earth is never possible without water. Water is one of the most vital elements of the human environments. It is being used for many purposes e.g., industrial, water supply, irrigation, drinking, propagation of fish and other aquatic systems and generation of hydro-power plants (Shrivastava and Kanungo, 2013)[5]. India with multifarious ecology has a huge number of freshwater rivers, lakes, wetlands, and ponds in different parts of the country. Water resources and quality of freshwater are the foremost basic need of flourishing ecological diversity and sustainable development. Nowadays, freshwater has become a scarce commodity due to over exploitation, population growth, and also pollution (Arivoli, Dhinamala, Persis, Meeran, & Pandeeswari, Citation 2018)[2]. Water quality assessment from any region is an important aspect for the development activities of the region, because the rivers, lakes etc. are used for water supply to domestic, industrial, agriculture and fish culture use (Jain and Senapati, 1996)[3]. In the ecosystem water is considered to be the most important component for the life but day by day the quality of water become degraded. There are several factors which are responsible for deterioration of water bodies such as increased human population, industrialization, use of excess fertilizers in the agriculture and other man-made activities etc. There are several diseases have been identified among the human beings, which are caused by using contaminated water. Water born disease infections occur during washing, bathing and consumption of contaminated water during food preparations. Therefore it is necessary that the quality of water should be checked at regular time of interval because the financial losses due to water born diseases have negative impact on the nation. Nowadays this is the major problem of developing countries throughout the world (A K Dixit *et.al*. 2015)[1]. The present work was undertaken to analyse the pahysico-chemical parameters of water in selected pond at Theni and Dindigul District.

MATERIALS AND METHODS

Study area

This investigation was carried out to evaluate the status of the pond w ater in Meenakshipuram, Periyakulam, Sengulathupatty, Katroad in Theni District and Kattakamanpatty in Dindigul District. Meenakshipuram pond is located in Bodinayakanur is a Town and a municipality in Theni District in the state of Tamil Nadu, 14 km from Bodi to Theni. Periyakulam pond is located in periyakulam, 22km from Theni to Periyakulam. Sengulathupatty is located in Periyakulam Taluk, 16 kms from Periyakulam to Sengulathupatty, 3kms from sengulathupatty to katroad. Katroad pond is located in Genguvarpatty. This village is located in Periyakulam Taluk of Theni district in Tamil Nadu, India. It is situated 21km away from sub-district headquarter periyakulam, 3 kms from katroad to sengulathupatty pond. Kattakamanpatty is a village in Vattalkundu Block in Dindigul District of Tamil Nadu State, India. It is located 39kms towards west from District headquarters of Dindigul. These pond water is used for agriculture, fisheries and   partially domestic activities. The present study was conducted to analyze the physico-chemical properties of water in the period of one year from July 2021 to June 2022.

Sample collection

Water samples were collected from July 2021 – June 2022 from the above mentioned ponds in plastic bottles each of one liter size the containers were properly washed with diluted hydrochloric acid and then rinsed with normal water fallowed by distilled water and then with sample water.

RESULT AND DISCUSSION

The results obtained in the physico chemical analysis of the water samples collected from July 2021 to June 2022. The concentration of 13 physical and chemical parameters of 5 ponds studied here. All the ponds can be easily compared.

Location variations in water revealed all the maximum and minimum values of all the physicochemical parameters which have been studied and calculated for thisresearch. Physicochemical parameters of the pond water displayed different characteristics with seasons of winter and summer. The results obtained from the physiochemical analysis are discussed below. The result of these 5 pond water is, pH range is normal in all (Meenakshipuram, Periyakulam, Sengulathupatty, Katroad and Kattakamanpatty) pond water .Temperature, Total Dissolved Solids, Salinity Electrical Conductivity, Free CO_2 were maximum in summer season and minimum in winter season. Dissolved Oxygen were maximum in winter season and minimum in summer season. Similar result of physico chemical parameters of water was reported by (Prasanjit Mukherjee et. Al. 2022)[4].

CONCLUSION

On the basis of above mentioned physico-chemical parameters of 5 pond water may be concluded that temperature, pH, Salinity, dissolved oxygen, free carbon dioxide, Total Dissolved Solids, alkalinity, Electrical Conductivity showed dissimilar values in Figure 1,2,3,4 and 5 at different places. Though based on this result these five pond should maintain in this way for various purposes like domestic, outdoor bathing, agriculture, fish culture and aquatic life propagation.

ABSTRACT

Soil salinity represents a significant global challenge that negatively impacts agricultural productivity. Salinity hinders plant growth and development through mechanisms such as water stress, cytotoxicity caused by the excessive accumulation of ions like sodium (Na^+) and chloride (Cl^-), and nutrient imbalances. Additionally, salinity is often associated with oxidative stress resulting from the production of reactive oxygen species (ROS). Salt stress disrupts the normal physiology of crop plants, leading to significant changes in ionic homeostasis, particularly in sodium, potassium, and calcium levels in roots, stems, and leaves.The application of plant growth regulators is a promising strategy to enhance crop productivity under stress conditions. Mungbean (*Vigna radiata* L.) is an important leguminous crop in South and Southeast Asia. Mungbeans contain approximately 20%–24% protein, along with essential amino acids, such as aromatic amino acids.In this experimental study, a pot culture experiment was conducted to evaluate the effects of NaCl and plant regulators Brassinolide and Alpha-tocopherol on *Vigna radiata* L. The growth regulators were applied foliar, with brassinolide at 4 mg/L and alpha-tocopherol at 200 mg/L concentration, while NaCl (80 mM) was applied via soil drenching. The plants were divided into six groups: control, NaCl, NaCl + Brassinolide, NaCl + Alpha-tocopherol, Brassinolide, and Alpha-tocopherol. Plant samples were collected for analysis randomly on the 25th, 35th, and 45th days after sowing to assess various biochemical parameters. The foliar application of alpha-tocopherol and brassinolide were found to mitigate salt stress in *Vigna radiata* L. enhancing growth and biochemical constituents**.**

Keywords: NaCl, Brassinolide, Alpha-tocopherol, Foliar, salinity.

INTRODUCTION

Soil salinity poses a significant challenge to agricultural productivity, impacting approximately 45 million hectares of irrigated land, with this figure anticipated to grow as a result of global climate change and various irrigation methods.[1]. The adverse impact of salt stress on crop yields is considerable, primarily because it leads to slower growth rates, decreased tillering, and, over time, negatively affects reproductive development. [2].The osmotic and ionic aspects of salt stress are recognized as the initial and secondary phases of the stress, respectively, with plants responding to each phase at distinct intervals. Osmotic stress, also known as the osmotic phase of salt stress, arises immediately when roots encounter solutions with excessively high salt concentrations in hydroponic systems or soil.[3]Following the application of NaCl, plants typically attain osmotic homeostasis promptly, typically within several hours or at least within the initial day after salt stress. [4]. The ionic stress from salinity stress, which comes in a second phase, starts to become more severe after 1-3 days of NaCl exposure. Although Na^+ ions quickly flow into the plants and travel to the shoots, it takes a few days for Na^+ levels to build up to a toxic point in the cells, leading to increased stress.[5].Salinization causes changes in the way electrons transfer from organelle central transport chains to oxygen-reduction pathways, which increases the generation of reactive oxygen species (ROS). Important biomolecules including lipids, proteins, nucleic acids, and amino acids are oxidized in part by these reactive compounds.[6].Reducing toxic reactive oxygen species (ROS) and addressing oxidative damage is crucial. Plants have evolved antioxidant defense systems comprising both enzymatic and nonenzymatic components. These systems help mitigate the harmful effects of ROS by converting them into less toxic forms. As a result, higher levels of antioxidants are generally linked to enhanced plant tolerance. [7].Plants respond to salinity stress in a variety of ways, which can result in changes to their morphology, physiology, biochemistry, and molecules. This is due to the fact that elevated salt levels are a major cause of nutritional imbalances.[8].

Plant growth regulators (PGRs) function as signaling molecules, providing plants with the flexibility required for growth and development, and are thus recognized as key components in the response of plants to both biotic and abiotic stressors [9]. PGRs are instrumental in mitigating the effects of salt stress by facilitating various physiological and developmental changes [10,11] In general, PGRs assist plants in decreasing the buildup of toxic salts while increasing the physiological availability of water and other nutrients. [12].The Application of Brassinolide and Alpha-tocopherol plant regulators on *Vigna radiata* L. effectively mitigated the adverse effects of salinity stress. Brassinolide, with the molecular formula $C_{28}H_{48}O_6$, enhances plant resilience to salinity stress by targeting redox regulation and osmotic adjustment mechanisms. This facilitates improved plant growth and development by elevating the activities of antioxidant enzymes and the levels of plant hormones, in addition to promoting the accumulation of osmolytes in response to salt stress.[13,14].similarly, Alpha-tocopherol has a prominent role in mitigating the salinity stress in plants by neutralizing singlet oxygen species and peroxides, which helps protect the photosystems and reduces lipid peroxidation under saline conditions. [15]. The ability to maintain membrane and organelle integrity under salt stress is strongly associated with the capacity to eliminate reactive oxygen species (ROS). This leads to enhanced activities of antioxidant enzymes, as well as increased levels of mineral ions (such as Ca^{2+} and K^+) and proline. [16,17].Mung beans (*Vigna radiata* L.) are a crucial edible legume crop cultivated on over 6 million hectares globally, accounting for approximately 8.5% of the world's total pulse cultivation area. They are widely consumed across many Asian households. [18].Mungbean is highly susceptible to salt stress, with significant effects on its growth and pigment composition. Even minimal quantities of saline water can provoke a strong response in Mungbeans. However, the application of Brassinolide and Alpha-tocopherol enhanced plant growth and reduced oxidative damage caused by NaCl-induced stress. [20,21]

Aamir Abdullah and Somasundaram

MATERIALS AND METHODS

Seed collection and Chemical reagents.

Vigna radiata L. (green gram) (CO-6 variety) seeds were purchased from Tamil Nadu Agricultural University, Coimbatore, Tamil Nadu, India. Chemical regulator Brassinolide and Alpha-tocopherol and analytical reagent NaCl were purchased from Sisco Research Laboratories [SRL]- Chennai-600117.

Experimental design

The experimental study was carried out at the Botanical Garden within the Department of Botany at Annamalai University in Tamil Nadu. The study was conducted at latitude 11°23'23.1" N and longitude 79°43'05.3"E. Healthy seeds were surface-sterilized using a 0.2% solution of mercuric chloride ($HgCl_2$) for two minutes, followed by thorough rinsing with double-distilled water (ddH_2O). The seeds were then distributed across 90 pots, divided into six groups. Each pot was filled with a soil mix consisting of red soil, sand, and farmyard manure in a 1:1:1 ratio. The treatments applied to the plants were as follows: (control), (80 mM NaCl), (80 mM NaCl + 4 mg/L BL) (80 mM NaCl+ 200 mg/L alpha-toc), (4 mg/L of BL,) and (200 mg/L of alpha-tocopherol.) To maintain the desired levels of salinity in each pot, soil samples were regularly monitored using an electrical conductivity meter.Plants were harvested for biochemical analysis at three distinct intervals: 25th, 35th, and 45th days after sowing (DAS). These collection times provided a basis for assessing the impact of the various treatments on the plants' growth and biochemical properties**.**

PROTEIN CONTENT

The soluble protein content was quantified following the Bradford (1976) protocol. The extraction process began by grinding one gram of fresh plant material in a mortar and pestle with 20 ml of 20% trichloroacetic acid (TCA). The homogenate was centrifuged for 15 minutes at 800 rpm, after which the supernatant was discarded. To solubilize the proteins in the pellet, 5 ml of 0.1 N sodium hydroxide (NaOH) was added, and the solution was centrifuged again at 800 rpm for 15 minutes. The supernatant was then collected, brought to a final volume of 10 ml with 0.1 N NaOH, and used for protein quantification. To estimate protein content, 0.1 ml containing 10 to 50 µg of protein was pipetted into 12×100 mm test tubes. To each test tube, 5 ml of Bradford protein reagent was added, and the contents were mixed with a vortex mixer. Absorbance was measured at 595 nm after 2 minutes against a reagent blank. The blank was prepared with 0.1 ml of distilled water, 0.1 ml of 0.1 N NaOH, and 5 ml of Bradford reagent. A standard curve was generated by plotting the absorbance against the corresponding weight of a known protein standard (bovine serum albumin, BSA), using a Nano Drop spectrophotometer (Implen- Inkarp 380). This standard curve was used to determine the protein content in the unknown samples, with results reported in milligrams per gram of dry weight.

FREE AMINO-ACID

The total free amino acids were extracted and quantified following the method described by Moore and Stein (1948). Initially, 500 milligrams of fresh plant material were ground in a mortar and pestle with 10 ml of 80% boiling ethanol. The homogenate was centrifuged at 800 × g for 15 minutes, and the supernatant was adjusted to a total volume of 10 ml with 80% ethanol, preparing it for further analysis.For the estimation of free amino acids, 1 ml of the ethanol extract was transferred to a 25 ml test tube and neutralized with 1 ml of 0.1 N sodium hydroxide (NaOH), using a drop of methyl red indicator to determine the point of neutralization. Subsequently, 1 ml of ninhydrin reagent was added to the test tube and thoroughly mixed. The entire mixture was then boiled in a water bath for 20 minutes. After boiling, 5 ml of a diluting solution was added, and the tube was cooled under running tap water. The volume was adjusted to 25 ml with distilled water, and the absorbance was measured at 570 nm using a UV-visible spectrophotometer (Model-118, Systronics India Limited, Gujarat, India) against an appropriate blank. A standard curve was generated using leucine as the standard, and the amino acid content in the sample was calculated based on this curve. The results were expressed in milligrams per gram of dry weight.

Aamir Abdullah and Somasundaram

Statistical Analysis

Experimental data were statistically analyzed using SPSS software (Version 22.0), with one-way analysis of variance (ANOVA) employed to determine significant differences among treatment groups. The data presented in the bar graphs represent the mean values from multiple replicates. Statistical significance was assessed using Dunnett's Multiple Range Test (DMRT), with a threshold of P ≤ 0.05.

RESULTS AND DISCUSSIONS

PROTEIN CONTENT

Leaf

As per our study Under NaCl stress, *Vigna radiata* L. plants experienced a reduction in leaf-soluble protein content compared to the control group across all observation periods. Specifically, the decreases were 50.43%, 53.42%, and 57.95% relative to the control on the 25th, 35th, and 45th days after sowing (DAS), respectively. However, the application of BL and alpha-tocopherol individually to NaCl-stressed *Vigna radiata* L. plants resulted in a notable rise in leaf protein content compared to NaCl-stressed plants without these treatments, with respective increases of 85.78% and 75.73% relative to the control on the 45th DAS. (Fig-1). Despite this improvement, the levels remained below those of the control group. However, the plants treated with Alpha toc and BL without salt stress protein content found to increase it was148.22 and 133.23 % respectively compared to the control. Previous studies have also found salt stress to decrease the total protein content in many plants like*Solanum lycopersicum* [22] *Vicia faba* [23]. *Phaseolus vulgaris* [24]. Exogenous application of BL and Alpha-toc enhances the protein content and mitigates the salinity stress in *maize* and *Helianthus annuus*, [25,26]. As these two regulators play a prominent role in mitigating the salinity stress in plants.

Stem

The protein content in the stems of green gram plants decreased when subjected to NaCl salt stress compared to the control group across all growth stages, with the most substantial reduction occurring at 50 days after sowing (DAS). (Fig-2)The recorded reductions in protein content were 46.87%, 52.27%, and 59.34% relative to the control at 25th, 35th, and 45thDAS, respectively. Conversely, the use of BLand alpha-tocopherol to NaCl-stressed green gram plants resulted in an increase in stem protein content compared to those plants experiencing NaCl stress alone, with observed increases of 91.35% and 79.67% relative to the control on the 45th DAS, respectively. However, these increases were lower than those in control plants and other non-stressed plants. Moreover, when brassinolide and alpha-tocopherol were applied to non-stressed plants, there was a further increase in the soluble protein content of the stem compared to the control group. The recorded increases were 154.67% and 139.01% relative to the control at 45 DAS, respectively.The decrease in soluble protein content caused by NaCl, as noted in our results, has also been observed in other plants like Cowpea [27] *Catharanthus roseus*[28] *Hordeum vulgare.* [29].Applying foliar alpha-tocopherol (α-Toc) at a concentration of 150 mg/L to *Pelargonium graveolens* L. improves plant health and increases crude protein levels. [30]. Inthe present study, the foliar applied growth regulators BL and Alpha-toc enhance the protein content in stems similar results were found by researchers in*Leymus chinesis* [31] *soybean* [32]

Root

The soluble protein content in the roots of *Vigna radiata* L. plants decreased under NaCl stress across all sampling days compared to the control group. The reductions were 37.07%, 52.67%, and 65.07% relative to the control on the 25th, 35th, and 45th days after sowing (DAS), respectively. However, foliar use of BL and alpha-tocopherol to NaCl-stressed plants led to an increase in root protein content compared to plants subjected to salt stress alone, with observed increases of 90.99% and 77.57% relative to the control on the 45th DAS, respectively. Despite these increases, the levels remained lower than those of the control group. Further, the individual foliar spray of BL and alpha-tocopherol to unstressed plants resulted in a greater increase in root protein content compared to the control group, with respective increases of 155.8% and 134.92% relative to the control on the 45th DAS.(Fig-3)As per this

study, the salt stress decreases the protein content in the plants treated with salt stress, however, the plants treated with BL and Alpha toc ameliorated the salinity stress similar results were found in *mustard* [33]. And *wheat* [34]

FREE AMINO ACID CONTENT.
Leaf
The concentration of free amino acids increased in the leaves of *Vigna radiata* L. plants under NaCl salt stress across all sampling days compared to the control group, with recorded increases of 177.09%, 187.22%, and 193.08% over the control on the 25th, 35th, and 45th days after sowing (DAS), respectively. However, individual foliar sprays of brassinolide and alpha-tocopherol to salt-stressed green gram plants resulted in a decrease in leaf,free amino acid content compared to NaCl-stressed plants. However, this reduction was still higher than that of the control group, with decreases noted as 183.60% and 188.12% over the control on the 45th DAS.Additionally, foliar spray of BL and alpha-tocopherol individually to non-stressed green gram plants further enhanced the leaffree-amino acid content compared to the control group, with increases of 108.27% and 101.20% over the control, respectively, on the 45th DAS. (Fig-4) The rise in amino acid levels in plants subjected to saline conditions is a result of protein degradation. [35]. Similar results of an increase in amino-acid content under salt stress have been found in *snap bean* [36]*Medicago sativa* [37] and *Solanum lycopersicum* L. [38]. However, the plants applied with Alpha-toc and brassinolide mitigated the salinity stress and an increase in amino acid content; similar outcomes were observed in *Vigna radiata* L. [39] and *Okra* plants [40].

Stem
According to our study, the free amino acid content increased in the stems of green gram plants subjected to NaCl stress across all growth stages and on all sampling, days compared to the control group. The recorded increases were 219.43%, 225.61%, and 229.39% over the control at 25, 35, and 45 days after sowing (DAS), respectively. However, foliar spraying of brassinolide and alpha-tocopherol on salt-stressed plants led to a decrease in stem free amino acid content compared to NaCl-stressed plants without these treatments, with values of 209.13% and 211.35% over the control on the 45th DAS, respectively. Despite the reduction, these levels remained higher than those in the control group. Additionally, the individual application of brassinolide and alpha-tocopherol via foliar spray to non-stressed plants led to a further increase in stem free amino acid content compared to the control group, with increases of 110.02% and 106.01% over the control on the 45th DAS, respectively (Fig-5). As per our Experimental study, the amino acid content was found high in NaCl-treated plants than the plants foliar applied with BL and Alpha-toc under salt stress many authors found similar resultsin *sorghum bicolor* [41]. *Pisum sativum.* [42] Additionally, free amino acids are osmoregulation compounds that protect plants from salt stress by lowering membrane permeability and thus improving membrane tolerance. [43]

Root
Our experimental study revealed that green gram plants exposed to NaCl stress experienced an increase in the free amino acid content of roots compared to the control group on all sampling days. The recorded values were 181.85%, 192.04%, and 195.37% over the control on the 25th, 35th, and 45th days after sowing (DAS), respectively (Fig. 6). However, the individual foliar spray of BL and alpha-tocopherol to NaCl-stressed plants caused a substantial decrease in the free amino acid content of roots compared to plants subjected to NaCl stress alone, with recorded values of 182.56% and 188.61% over the control on the 45th DAS. Nevertheless, these reductions were still higher than those in the control group. Additionally, the foliar spray of BL and alpha-tocopherol to non-stressed plants resulted in a further increase in root free amino acid content compared to the control group, with values of 108.54% and 105.16% over the control on the 45th DAS. Salt stress increased the root amino acid content it was found higher in the plants treated with salt alone than in the plants applied with Brassinolide and Alpha-tocopherol similar results were found by other authors in *Phragmites australis* [44]. In Rice [45] and in *Glycine max* [46].

CONCLUSION

Salinity poses a significant threat to agriculture, with far-reaching implications for crop productivity, and soil health. The accumulation of salts in soil and water leads to osmotic stress, and ion toxicity, ultimately impacting plant growth and yield. Salt stress adversely affects both protein and amino acid content in plants. The decrease in protein content hampers plant growth, while variations in amino acid levels indicate a stress response. The foliar Spray of BL and Alpha-tocopherol to salt-stressed plants shows a substantial increase in protein and amino acid contents overall the plants respond well to exogenous application of brassinolide and Alpha-tocopherol.

ABSTRACT

Companies are currently looking for solutions to reduce carbon emissions their functions. Functional adjustments such as volume sizes or order changes measures have proven to be an excellent way to reduce emissions. A model has been proposed that takes into account the relationship between an Freight Policy (EOQ) carbon emissions and price and tax. In one case the external price is determined by two optimal levels that maximize the retailer's profit and reduce carbon emissions. Conditions that allow a company to maximize profits when reducing the emissions and mechanisms that allow a company to increase its profitability is determined to reduce its carbon emissions. Companies are currently looking for solutions to reduce carbon emissions their functions. There are functional adjustments such as modifying block sizes or order sizes has been proven to be an excellent way to reduce emissions. In this paper, a model is proposed takes into account the relationship between a commodity policy (EOQ), total carbon emissions and both price and tax. In terms of external price, optimal measures to increase retailer profit and reduce carbon emission (EOQ) determined. In this paper, a model is proposed that the relationship between an inventory model (EOQ) and total carbon emissions, both crisp and fuzzy sense. This model has been considered and analyzed in trapezoidal fuzzy sense. The behavior of the main features of the inventory model is carried out through by using Robust ranking defuzzification method.

INTRODUCTION

Stock is in a real sense characterized as a stock or store of products. These products are kept up with by a business to satisfy need and satisfy its motivation. Business need to look closely at how they can optimize their inventory management to maximize their profits. The EOQ is a model used to determine the optimal order quantity for an item of stock that minimises ordering and carrying costs. Currently companies are increasingly responding to sensitivity and carbon emissions (Emissions of carbon dioxide and other greenhouse gases) related to their activities(Colette and Venkat, 2009; Stock et al., 2010). Under the influence of their customers, they enhance socially responsible consumption practices (Gonzalez et al. 2009), further governments and other pressure groups are working to reduce their carbon footprint track. in a recent paper Sen et al .(2013) note that companies are often the focus reducing emissions by discoveries of related physical processes, For example , Redesigning, sorting and utilizing low-pollution energy sources for products and packaging;or replacing energy-efficient equipment and facilities ... for example, determining how frequent supply distributions can be important in mitigating carbon emissions energy efficiency of vehicles used to make these deliveries (Benzafar et al., 2013). Functional adjustments such as changes in block sizes or order sizes have been demonstrated Should be a better way to reduce the impact of carbon emissions (Colette and Venkat, 2009; Hua and Al., 2011; Pouchery et al., 2012; Sen et al., 2013).Thus, in recent years, green and fixed supply chain management is fully explored seuring Literary Studies (2013). In the following art position, we will focus on papers inventory management, handling demand and vertical model stability integration. Hua et al. (2011) proposes an ecological approach to integrated inventory management implications of carbon cost for both order location (mainly transportation) and holding stock (savings).The proposed model extends the economic order size model (Harris, 1913; Wilson, 1934) to account for carbon emissions under cap and trade system. They conclude that there is an optimal sequence size between those calculated classically Economic quantity (excluding CO2 cost) and quantitative reduction Carbon emissions. They also prove that there are certain conditions for reducing both economies costs and carbon emissions.Wahab et al. (2011), meanwhile, provide an approach that is optimal define supply / production policy to reduce total distribution cost in global distribution chain.

 They show that taking into account the impact of the environment leads to reduction frequency of distributions. Bonney and Jaber (2011) show an increase in the volume of products frequency of delivery carried and reduced compared to those proposed by the traditional EOQ model gives the best results in terms of ordering costs and carbon emissions. The latter two models, however, are smaller than the Hua et al. (2011); They will not take into account the "cap and trade" system, and is limited to the study of reductionCO2 emissions from transport, (emissions associated with storage are not considered). Bouchery et al. (2012) proposes to integrate all parameters of sustainable development (SD), inventory management, including a social aspect not found in other works Samples. They restructure the classic economic order size model for a number of purposes problem (standard array size model - called SOQ). It follows two important points their work. First, it helps to minimize any SD impact by requiring a small increase cost, which is in line with the results of Hua et al. (2011) Second, it is sometimes not can have overall environmental, economic and social performance, which guided them proposes a trade between different parameters. Sen et al. (2013) First, provides conditions that can reduce emissions modifying order quantities and, secondly, the comparative reduction in emissions is greater than this comparative cost increase. This article is also interesting because the authors discuss it the applicability of their results to systems under different environmental regulations carbon tax, cap and offset and example systems with cap and price. Pattini et al. (2014) propose a standard EOQ model that integrates transport and environmental impacts storage. They evaluate the impact of sustainability considerations on purchasing decisions comparison with the traditional EOQ model. In particular, for

the same mode of transport, there is no significant difference between the traditional and standard model, but it is the difference increases with the rising prices of goods. El Sadani et al. (2011) studied a simple two-echelon supply chain model in which demand is required depending on the environmental quality of the systems (measured using thirty criteria) and related costs. Clock et al. (2012) Present a model illustrating the trade between sustainability, demand, costs and profit in the supply chain. They show that partners can attract more customers by controlling emissions and scrap. Also, gross profit is high but in terms of collaboration the product quality is low. Noira et al. (2013) proposal a non-linear non-profit activity that takes into account green-based demand. Choose allows production processes (technology) and input products to improve profitability in terms of environmental need. In particular, show that a company increases its profitability and reduces its carbon footprint green market. Chen and Wang [1] proposed fuzzy Economic production quantity model for items with imperfect quality. Wang and Ye [4] transformed a comparison between just in - time and economic order quantity models with carbon emissions. Chen and Chang [6] developed optimization of fuzzy production inventory model with unrepairable defective products. Fuzzy EOQ model with demand dependent unit cost under limited storage capacity provided by Roy and Maiti [10],Wee & Daryanto (2020)[3] introduced Imperfect quality item inventory models considering carbon emissions, Gupta (1988)[5] investigated An improved procedure for economic order quantity with all-units price discounts, Bjork[8]proposed An analytical solution to a fuzzy economic order quantity problem. This paper standardized as follows: The next section, In section2, Notation and mathematical crisp model are proposed , Mathematical fuzzy model , Kuhn- tucker technique and optimization method derived in section 3, In section 4, a numerical examples and sensitivity analysis are given, finally conclusion is provided in section 5.

Model Description
Notations
The notations used in this inventory models are :
θ = Order quantity
α =Storage cost per period
A = Average carbon emissions per unit
n = Number of goods per period
λ =Order cost per cycle
R = The price per unit
p = Power plant's standard emission
t = tax
F = Fixed costs
M = Mileage from the supplier
β =Fuel consumption if empty vehicles
γ =Additional fuel consumption per unit
w =Item weight
v =Variable costs for shipping goods
b =Cost of carbon emissions from vehicles
c =Additional costs of carbon emissions from transportation of one item
S= Fuel's standard emission
TI(θ) =The total inventory cost
TE(θ) = Total carbon emissions.

Sample development
In this inventory model, there are discount factors and carbon emissions that affect total inventory cost. Total inventory cost is the amount purchased expenses, ordering costs, storage costs and transportation costs. Purchase costs are the costs of purchasing goods. The provides discount table with supplier pricematerials per unit are defined as follows (Gupta, 1988;Taleizadeh & Pentico, 2014):

$$P_i = \begin{cases} P_0 \, for q_0 \le Q \le q_1 \\ P_1 \, for q_1 \le Q \le q_2 \\ \dots\dots\dots\dots\dots \\ P_n \, for q_n \le Q \end{cases}$$ ....(3.1)

Q is the array size, $P_i > P_{i+1}$, and i = 0, 1, 2, 3,…, N is the code for the discount table. If there is a n unit demand in a year, the total the cost of purchase in a year is the product of the price of the itema unit with the required quantity, viz

$$C_P = Rn$$ ....(3.2)

The cost of ordering is a one-time fee per order submitted. If the order costs are S, the sum the cost of ordering will increase once a year order cost with order frequency in one year.

$$C_0 = \frac{\lambda n}{\theta}$$ ....(3.3)

If the storage cost of a unit of goods is specified in hPi considering the average cost of carbon per year emission in warehouse, then

$$C_s = (\alpha R + APt)\frac{\theta}{2}$$ ....(3.4)

If t = 0, then the equations are (3.2), (3.3), and (3.4) like Gupta (1988), it is an EOQ model All unit discounts regardless of carbon emissions. The cost of transportation has a fixed cost, some variable costs, and the cost of carbon emissions vehicle use (We & Toronto, 2020). Therefore, the transportation cost per year

$$C_t = (F + (2M\beta v + M\gamma w\theta v) + 2Ma + Mb\theta)\frac{n}{\theta}$$ ....(3.5)

Total inventory cost for a year purchase cost, order cost, storage cost, and transportation cost

$$TI(\theta) = C_P + C_0 + C_s + C_t$$ ....(3.6)

$$TI(\theta) = Rn + \frac{\lambda n}{\theta} + \frac{\theta \alpha R}{2} + \frac{\theta Apt}{2} + \frac{n}{\theta}\left(F + (2M\beta v + M\gamma w\theta v) + (2Ma + Mb\theta)\right)$$ ....(3.7)

From equation (3.7), we can get an equation calculate total carbon emissions TE(θ) from storage and transport operations, namely:

$$TE(\theta) = \frac{\theta}{2}AP + \frac{n}{\theta}(2M\beta S + M\gamma wS\theta)$$ ....(3.8)

Inventory Model in crisp Sense
The total inventory cost is,

$$TI(\theta) = Rn + \frac{\lambda n}{\theta} + \frac{\theta \alpha R}{2} + \frac{\theta Apt}{2} + \frac{n}{\theta}\left(F + (2M\beta v + M\gamma w\theta v) + (2Ma + Mb\theta)\right)$$

The above total inventory cost partially with respective to
θ and equating it to zero, we get the crisp order quantity.
For the crisp order quantity

$$\theta = \sqrt{\frac{2n(\lambda + F + 2M\beta v + 2Ma)}{Apt + \alpha R}}$$

Inventory Model in Fuzzy Sense

We consider the price per unit and tax are taken as trapezoidal fuzzy numbers. Therefore the fuzzy total inventory cost becomes

$$TI(\theta) = Rn + \frac{\lambda n}{\theta} + \frac{\theta \alpha \tilde{R}}{2} + \frac{\theta Ap\tilde{t}}{2} + \frac{n}{\theta}\left(F + \left(2M\beta v + M\gamma w\theta v\right) + \left(2Ma + Mb\theta\right)\right)$$

Let $\tilde{R}$ denotes the fuzzy price per unit and $\tilde{t}$ denotes fuzzy tax which are characterized by the trapezoidal fuzzy numbers by $\tilde{R} = (R_1, R_2, R_3, R_4)$, $\tilde{F} = (F_1, F_2, F_3, F_4)$, $\tilde{t} = (t_1, t_2, t_3, t_4)$ respectively.

We get the fuzzy total inventory cost is,

$$\tilde{TI}_1(\theta) = \begin{bmatrix} \frac{\theta}{2}(\alpha R_1 + Apt_1) + \frac{n}{\theta}(\lambda + F_1 + 2M\beta v + 2Ma) + n(R_1 + M\gamma wv + Mb), \\ \frac{\theta}{2}(\alpha R_2 + Apt_2) + \frac{n}{\theta}(\lambda + F_2 + 2M\beta v + 2Ma) + n(R_2 + M\gamma wv + Mb), \\ \frac{\theta}{2}(\alpha R_3 + Apt_3) + \frac{n}{\theta}(\lambda + F_3 + 2M\beta v + 2Ma) + n(R_3 + M\gamma wv + Mb), \\ \frac{\theta}{2}(\alpha R_4 + Apt_4) + \frac{n}{\theta}(\lambda + F_4 + 2M\beta v + 2Ma) + n(R_4 + M\gamma wv + Mb) \end{bmatrix}$$

Defuzzification of Trapezoidal fuzzy numbers by Robust ranking method

Let $A = (a_1, a_2, a_3, a_4)$ be trapezoidal fuzzy number . Let $\tilde{A} = \int_0^1 (0.5)[A_L(\alpha), B_L(\alpha)]d\alpha$

Where $[A_L(\alpha), B_L(\alpha)] = \{(a_2 - a_1)\alpha + a_1, a_4 - (a_4 - a_3)\alpha\}$ .Then $\tilde{A} = \dfrac{a_1 + a_2 + a_3 + a_4}{4}$

Now, Using Robust ranking method for trapezoidal numbers defuzzification ,then the fuzzy total inventory cost becomes,

$$R\left(\tilde{TI}_1(\theta)\right) = \frac{1}{4}\begin{bmatrix} \frac{\theta}{2}(\alpha R_1 + Apt_1) + \frac{n}{\theta}(\lambda + F_1 + 2M\beta v + 2Ma) + n(R_1 + M\gamma wv + Mb) + \\ \frac{\theta}{2}(\alpha R_2 + Apt_2) + \frac{n}{\theta}(\lambda + F_2 + 2M\beta v + 2Ma) + n(R_2 + M\gamma wv + Mb) + \\ \frac{\theta}{2}(\alpha R_3 + Apt_3) + \frac{n}{\theta}(\lambda + F_3 + 2M\beta v + 2Ma) + n(R_3 + M\gamma wv + Mb) + \\ \frac{\theta}{2}(\alpha R_4 + Apt_4) + \frac{n}{\theta}(\lambda + F_4 + 2M\beta v + 2Ma) + n(R_4 + M\gamma wv + Mb) \end{bmatrix}$$

$$= \tilde{TI}$$

To find the fuzzy order quantity $\tilde{\theta}$ which can be obtained by the solution of the first order differential equation $\dfrac{d}{d\theta}TI_1(\theta) = 0$ .Then the result is,

$$\tilde{\theta} = \sqrt{\frac{2n\left(4\lambda + \left(F_1 + F_2 + F_3 + F_4\right) + 8M\beta v + 8Ma\right)}{\alpha(R_1 + R_2 + R_3 + R_4) + Ap(t_1 + t_2 + t_3 + t_4)}} \, .$$

Fuzzy optimal order quantity by using Kuhn-tucker method

Suppose the fuzzy order quantity $\tilde{\theta}$ be a trapezoidal fuzzy number $\tilde{\theta} = (\theta_1, \theta_2, \theta_3, \theta_4)$ with $0 < \theta_1 \le \theta_2 \le \theta_3 \le \theta_4$. Then the fuzzy total inventory cost after using Robust ranking methor for trapezoidal numbers defuzzification ,weget

$$R\left(\tilde{TI}_2(\theta)\right) = \frac{1}{4}\begin{bmatrix} \frac{\theta_1}{2}(\alpha R_1 + Apt_1) + \frac{n}{\theta_4}(\lambda + F_1 + 2M\beta v + 2Ma) + n(R_1 + M\gamma wv + Mb) + \\[2mm] \frac{\theta_2}{2}(\alpha R_2 + Apt_2) + \frac{n}{\theta_3}(\lambda + F_2 + 2M\beta v + 2Ma) + n(R_2 + M\gamma wv + Mb) + \\[2mm] \frac{\theta_3}{2}(\alpha R_3 + Apt_3) + \frac{n}{\theta_2}(\lambda + F_3 + 2M\beta v + 2Ma) + n(R_3 + M\gamma wv + Mb) + \\[2mm] \frac{\theta_4}{2}(\alpha R_4 + Apt_4) + \frac{n}{\theta_1}(\lambda + F_4 + 2M\beta v + 2Ma) + n(R_4 + M\gamma wv + Mb) \end{bmatrix}$$

By using Kuhn-tucker technique to find the optimal solution of $\theta_1, \theta_2, \theta_3 \,\&\, \theta_4$. To minimize the total inventory cost, subject to $\theta_2 \ge \theta_1 \ge 0, \theta_3 \ge \theta_2 \ge 0, \theta_4 \ge \theta_3 \ge 0, \,\&\,\theta_1 > 0$.

The Kuhn-tucker techniques are,

$\lambda \le 0$

$\nabla f\left(\tilde{TI}_2(\theta)\right) - \lambda i \nabla g(\theta) \;=\; 0$

$\lambda i \nabla gi\,(\theta) \;=\; 0$

$gi(\theta) \;\ge\; 0$

After simplifying we get,

$\lambda_1, \lambda_2, \lambda_3, \lambda_4 \le 0$

$$\left.\begin{aligned} &\frac{1}{4}\left[\frac{1}{2}(\alpha R_1 + Apt_1) - \frac{n}{\theta_1^2}(\lambda + F_4 + 2M\beta v + 2Ma)\right] + \lambda_1 - \lambda_4 = 0 \\[2mm] &\frac{1}{4}\left[\frac{1}{2}(\alpha R_2 + Apt_2) - \frac{n}{\theta_2^2}(\lambda + F_3 + 2M\beta v + 2Ma)\right] - \lambda_1 + \lambda_2 = 0 \\[2mm] &\frac{1}{4}\left[\frac{1}{2}(\alpha R_3 + Apt_3) - \frac{n}{\theta_2^2}(\lambda + F_2 + 2M\beta v + 2Ma)\right] - \lambda_1 + \lambda_3 = 0 \\[2mm] &\frac{1}{4}\left[\frac{1}{2}(\alpha R_4 + Apt_4) - \frac{n}{\theta_1^2}(\lambda + F_1 + 2M\beta v + 2Ma)\right] - \lambda_3 = 0 \\[2mm] &\lambda_1(\theta_2 - \theta_1) = 0 \\[1mm] &\lambda_2(\theta_3 - \theta_2) = 0 \\[1mm] &\lambda_3(\theta_4 - \theta_3) = 0 \\[1mm] &\lambda_4(\theta_1) = 0 \end{aligned}\right\} \to (1)$$

$But \left(\theta_2 - \theta_1\right) \geq 0$

$\left(\theta_3 - \theta_2\right) \geq 0$

$\left(\theta_4 - \theta_3\right) \geq 0$

$\theta_1 > 0$

Because $\theta_1 > 0$ and $\lambda_4\left(\theta_1\right) = 0$ then $\lambda_4 = 0$. If $\lambda_1 = \lambda_2 = \lambda_3$ then $\theta_4 < \theta_3 < \theta_2 < \theta_1$, it does not satisfy the constrains $0 < \theta_1 \leq \theta_2 \leq \theta_3 \leq \theta_4$. T

Therefore $\theta_2 = \theta_1, \theta_3 = \theta_2, \theta_4 = \theta_3$

i.e., $\theta_1 = \theta_2 = \theta_3 = \theta_4 = \tilde{\theta}$.

Hence from equation from (1) ,we get the order quantity $\tilde{\theta}$ is given by,

$$\tilde{\theta} = \sqrt{\frac{2n\left(4\lambda + \left(F_1 + F_2 + F_3 + F_4\right) + 8M\beta v + 8Ma\right)}{\alpha(R_1 + R_2 + R_3 + R_4) + Ap(t_1 + t_2 + t_3 + t_4)}}$$

Numerical Example

Let us consider the following values ,

α=0.2 /period , n=1000 unit/period , A=1.44 k Wh/ unit / period , λ=10, p=0.0005 ton CO_2/k Wh , s = 2.6 kg CO_2/ L =0.0026 ton CO_2/ L , t =$ 75 /ton CO_2 ,M=100 km , β= 27 L/100 km , γ =0.57 L/100 km ,w =0.01 ton /unit , F=$50 , v=$0.75/L, a=$0.05265 /km , b=$ 1.1115 ×10^{-5}/unit/km ,R= $4.

Solution

Crisp model

The crisp optimal solution is, θ= **3106.43737**, $TI(\theta) = \$$ **7081.398**

In Table 4.1,If reduce the price per unit, then the crisp total cost and the total emissions decreases. Furthermore, the crisp optimum order quantity increase when reduce the price per unit.

The following figures 4. 1,4.2 ,4.3 are indicates graphical representation of θ ,TI,TE when decrease the price per unit

Fuzzy Model

Let F=(35,45,55,65) , R=(2.5,3.5,4.5,5.5) , t̃= (60,70,80,90) be trapezoidal fuzzy numbers. Then the fuzzy optimal solution

is, $\theta \cong$ **3106.43737**, $\tilde{TI}(\theta) = \$$ **7081.398**

CONCLUSION

In this paper, Optimization of inventory model with carbon emissions with fuzzy parameters and decision variable was developed. The model was solved for trapezoidal fuzzy numbers using kuhn-tucker technique. The results showed that the changes in the value of the price per unit to changes in the costs between the crisp and fuzzy sense. Thus, this work highlights, decrease of the carbon price leads to a decrease in the total emissions and decrease the total profit but increase order quantities. Finally a numerical examples and sensitivity analysis are illustrated for the proposed model.

ABSTRACT

College students often deal with a variety of problems that could affect their physical, physiological and emotional health. Yoga is a non-pharmacological complementary therapy that has been proven to normalize the body's physiological functioning. In the present study we aimed to study the effects of short-term yoga intervention program on haematological, hepatic and renal biomarkers in college students. A total of 20 students with age ranges from 18–20 years, with no prior yoga experience were randomly selected for the study and divided randomly into experimental (n=10) and control (n=10) groups. For a period of 8 weeks, the experimental group practiced yoga five days a week for 45 minutes each day in the morning. All the dependent variables (haematological, hepatic and renal biomarkers) of the study were measured at day 0 (baseline), 4th week (intermediate) and 8th week (endline) of yoga program. The data was analysed using mean and standard deviation as descriptive statistics and repeated measures analysis of variance (RM ANOVA) as an inferential statistic. Following 4 and 8 weeks of yoga practises, repeated measures analysis of variance revealed a significant difference in the experimental group for haematological (TLC, Platelet, FBS), renal (blood urea, serum creatinine and potassium), and hepatic (total protein, globulin, alkaline phosphatise, SGOT, SGPT) biomarkers compared to the control group. Our findings suggested that yoga can be used as a non-pharmacological intervention for significant improving the well being and quality of life in college students.

Keywords: Biomarkers, Intervention, Meditation, Students, Yoga
Key Messages: Since the United Nations (UN) declared June 21 to be the International Day of Yoga in 2015, yoga has been growing in popularity. Yoga has been identified as an important complementary therapy, and understanding its benefits is critical because it may result in optimal organ functioning and, ultimately, a higher quality of life in the future. The results of the current study showed that even short-term yoga practise can improve quality of life by altering a number of physiological and biochemical markers.

INTRODUCTION

College students are occasionally confronted with a variety of issues that may have an impact on their physical and emotional well-being. Academic stress, poor eating habits, lack of physical activity and poor lifestyle choices can all cause physiological imbalances, including changes in haematological, hepatic and renal functioning [1]. Changes in these biomarkers can indicate serious health risks. It has been demonstrated that the ability of young adults to make healthy food choices becomes increasingly difficult as they progress from adolescence to young adulthood[2]. During this time, a new set of weight-related behavioural patterns such as binge drinking and physical inactivity start to emerge[3]. Yoga, an ancient Indian holistic mind-body practise, has grown in popularity as a complementary therapy for physical, mental and emotional well-being[4]. It has the possibility to contribute significantly to the growing field of integrative medicine. Yoga has its origins in Indian philosophy and has been used in traditional Indian spiritual and medical practises for approximately 5000 years[5]. Several researchers have recently investigated its impact and noticed reliable, positive psycho-physiological[6,7,8,9] and biochemical changes[10,11,12]. However, there has been a little study on the short term effects of yoga intervention program as suggested by Ministry of Ayush on haematological, hepatic, and renal biomarkers in college students over a period of time. As a result, the current study will investigate the impact of an eight week yoga intervention program on haematological, hepatic and renal biomarkers in college students. According to the study's hypothesis, frequent yoga practise will result in beneficial changes in haematological, hepatic and renal biomarkers, suggesting enhanced health, well-being and quality of life in college students.

MATERIALS AND METHODS

Study Sample
A yoga camp was held at Pandit Neki Ram Sharma government college Rohtak-Haryana, India in order to fulfill the goals of the current interventional study. A total of 30 male students ranging in age from 18 to 20 years old who were living in the college hostel, expressed their interest in participating in the yoga camp. All subjects came from similar socioeconomic backgrounds, were physically active, and had no yoga experience prior to start the yoga camp. On the basis of physical examination, six subjects were excluded from the study due to illness. Subjects in good health who were not taking any medications were considered for the study. All of the subjects had nearly identical lifestyle and dietary habits. The written informed consent was taken from the registered subjects.

Study Design
Pre-test, post-test randomized controlled design was used in this study. The Experimental Group (EG) and the Control Group (CG) were formed by randomly dividing the subjects into two equal groups. The experimental group was given a common yoga protocol designed by the Ministry of Ayush[13] for eight weeks, which includes a 45-minute morning yoga intervention five days a week consisting of prayer, loosening practices, yogasanas, pranayama, relaxation, and santihpatha. During the intervention phase, subjects were advised to practice yoga at the specified time and location while avoiding any other type of scheduled physical exercise. The control group, on the other hand, did not receive any yoga exercise components for eight weeks. The study's principal investigator, a senior yoga teacher, trained the subject in the study's yoga protocol.The College Research Committee (independent ethical approval board) approved the study (Letter No. Pt.NRS/GCR/22), and it was carried out in accordance with the Helsinki Declaration.

Study Variables
The independent variable (yoga intervention) chosen in the current study included selected asanas, pranayamas, and meditation, which was administered to experiment group, while haematological (haemoglobin (Hb), total leukocyte count (TLC), erythrocyte count (RBC), fasting blood sugar (FBS), platelets), hepatic (bilirubin, conjugated bilirubin, non-conjugated bilirubin, total protein, albumin, globulin, alkaline phosphate) and renal biomarkers (serum

creatinine (Cr), serum sodium (Na), serum potassium (K), serum calcium (Ca), blood urea) were considered as dependent variable. All of the subjects were tested three times in the same laboratory setting: on day one (baseline), four weeks later (intermediate), and eight weeks later (endline). At any point during the study, subjects could decide not to take part in the yoga camp. The total number of subjects in each group who finished the camp is depicted in the flow diagram [Figure-a].

Measurement
The expert phlebotomist took blood samples early in the morning before breakfast from the antecubital vein while sitting, during baseline, after 4 weeks and after completing the 8-week programme. The venous blood was centrifuged to separate the erythrocytes from the plasma (at 3,000 rpm for 20 minutes at room temperature), frozen, and kept at -80 °C until analysis. Haematological, renal, and hepatic biomarkers were tested by expert pathologists.

Statistical Analysis
For data analysis, data from various tests and measurements were processed. Prior to analysis, the data was examined for normality and homogeneity of variance. Mean, standard deviation (SD) and repeated measures analysis of variance (RM ANOVA) were used to analyse the data. The level of significance was set at 0.05 ($p<0.05$).

RESULTS

Table 1 revealed the descriptive statistics as mean and standard deviation (SD) of the experimental and control group for age is 18.9 (0.87) and 18.6 (0.51), for Height 5.74 (0.084) and 5.68 (0.27), weight 65.5 (3.47) and 65.5 (6.00) and for BMI (body mass index) 22.81 (0.978) and 23.09 (2.12) respectively. Table 2 revealed that the experimental and control groups had insignificant baseline differences. A RM ANOVA shown that the mean TLC score differed significantly between the experimental and control groups ($F_{(1, 9)} =17.50$, $p=0.002$) and across three time points ($F_{(2, 8)} =50.50$, $p=0.000$). A post hoc pair wise comparison showed that in comparison to baseline data, TLC score significantly improved in the experimental group after four ($p=0.000$), and eight weeks ($p=0.000$) of yoga camp, but not in the control group. Similarly, mean platelets score differed significantly between the experimental and control groups ($F_{(1, 9)} =6.300$, $p=0.033$) and across three time points ($F_{(2, 8)} =7.307$, $p=0.016$). A post hoc pair wise comparison showed that in comparison to baseline data, platelets score, significantly improved in the experimental group after four weeks ($p=0.006$) of yoga camp, but not in the control group. Likewise, mean FBS score differed significantly between the experimental and control groups ($F_{(1, 9)} =5.45$, $p=0.044$) and but insignificant across three time points ($F_{(2, 8)} =2.29$, $p=0.164$).On the other side, the variables (Hb and RBC) showed no significant improvement.

Table 3 revealed that the experimental and control groups had insignificant baseline differences. A RM ANOVA shown that there was a significant difference between the experimental and control groups in context to mean blood urea ($F_{(1, 9)} =8.44$, $p=0.017$), while insignificant across three time points ($F_{(2, 8)} =1.01$, $p=0.406$). Likewise, significant difference was found between the experimental and control groups for mean serum K ($F_{(1, 9)} =6.23$, $p=0.034$), while insignificant across three time points ($F_{(2,8)}=1.01$, $p=0.406$). However, following eight weeks ($p=0.008$) of yoga camp, the experimental group showed a significant improvement in Serum Cr ($F_{(2, 8)} =2.29$, $p=0.035$) compared to baseline data, whereas the control group showed no such changes. On the other side, the variables (Serum Na and, Serum Ca) showed no significant improvement. Table 4 revealed that the experimental and control groups had insignificant baseline differences. A RM ANOVA shown that the mean total protein score differed significantly between the experimental and control groups ($F_{(1, 9)} =26.44$, $p=0.001$) and across three time points ($F_{(2, 8)} =53.46$, $p=0.000$). A post hoc pairwise comparison showed that in comparison to baseline data, total protein score, significantly improved in the experimental group after four ($p=0.013$), and eight weeks ($p=0.000$) of yoga camp, but not in the control group. Likewise, a RM ANOVA shown that there was a significant difference between the experimental and control groups in context to mean globulin ($F_{(1, 9)} =44.88$, $p=0.000$), while insignificant across three time points ($F_{(2, 8)} =0.226$, $p=0.803$). Similarly, mean alkaline phosphatase score differed significantly between the experimental and control

groups (F(1, 9) =5.87, p=0.038) and across three time points (F(2, 8) =10.03, p=0.007). Following four (0.013) and eight weeks (0.002) of yoga camp, the experimental group showed a significant improvement in alkaline phosphatase score compared to baseline data, whereas the control group showed no such changes. However, in case of SGOT (F(1, 9) =14.26, p=0.004) and SGPT (F(1, 9) =12.27, p=0.007) there was a significant difference found between the experimental and control groups, and across three time points SGOT (F(2, 8) =6.43, p=0.022) and SGPT (F(2, 8) =4.47, p=0.05). A post hoc pair wise comparison displayed that in comparison to baseline data, SGOT (p=0.022)and SGPT (p=0.046) significantly improved in the experimental group after four of yoga camp, but not in the control group. On the other side, the variables (Bilurubin and, albumin) showed no significant improvement.

DISCUSSIONS

Yoga, an age-old discipline of the body, mind, and spirit, has been modernized and is now practised for its health advantages as complementary to more traditional medical therapy[14]. The present study aimed to determine the effect of 8 weeks yoga intervention programme on the haematological, hepatic and renal biomarkers of college students based on the hypothesis that yoga has beneficial effect on haematological, hepatic and renal biomarkers of college students. Our study's key finding is that, when compared to the control group, haematological biomarkers (TLC,Platelets and, FBS) and renal biomarkers (Blood urea, Serum Cr and Serum K) significantly changed after 8 weeks of intervention. Additionally, compared to the control group, we observed improved hepatic biomarkers (total protein, globulin, alkaline phosphatase, SGOT, and SGPT). The current study found a significant increase in total leukocyte count (TLC) and platelets following 4-week and 8-week yoga practice. This result clearly shows improved immune function to protect the body against invading microorganisms and repairing of damaged cells. The outcomes are in line with previous study done by Bhavanani et al. [8]who stated that yoga can produce a significant increase in the WBC and platelets. Another recent study by Purohit et al. [15]found that platelet count and clotting time both increased while bleeding time decreased significantly followed training gives support to our hypothesis. Similarly, result of the study revealed significant decrease in fasting blood sugar (FBS) following 8 weeks of yoga practice in comparison to control group. The Finding is in partial consonant with the study done by Chimkode et al. [16]who stated that reduction in mean values of FBS was highly significant when compared to the mean values before and during yoga practice, indicating a potential role of yoga in diabetes prevention and management strategies. Additionally, a study conducted by Gowri et al.[17] discovered significant improvements in FBG and came to the conclusion that integrated yoga therapy is the best adjuvant and non-invasive therapy for people with diabetes. Even though we could not find significant change in RBC and Hb, but we have observed a significant difference between experimental and control group.

Further, 8 weeks of yoga practice revealed significant changes in blood urea, serum Crand, serum K while no change was found in case of serum Na and, serum Ca following yoga practice in comparison to control group. The study's findings partially agreed with those of Yurtkuran, Alp, &Dilek, K. [18] who discovered thatmodified yoga intervention program result in significant decrease in serum urea and creatinine. According to a study by Pandey and his team [11], patients who underwent a yogic exercise regimen in addition to conventional treatment demonstrated a significant decline in blood urea and serum creatinine.Similarly, Agte, Jahagirdar, and Tarwadi[19] conducted a study to determine the effect of yoga on some biochemical parameters and discovered that serum urea level was significantly lower in comparison to the control group. Similar to this, we have noticed significant changes in total protein, globulin, alkaline phosphatase, SGOT and, SGPT after an 8-week yoga intervention programme, but not in bilirubin and, albumin. According to Kumar et al. [20], yogic intervention can stabilise SGOT and SGPT and that significant change has been noticed after just a short time of yoga practise. Similar to this, Sharma et al.'s [21] investigation into the impact of yogic practice on liver functions found that SGOT and SGPT levels significantly decreased after yogic interventions. Similarly, the current study's findings are partially consistent with the findings of another study [22], which found that globulin and alkaline phosphatase levels improved significantly when

80082

compared to the control group. Thus, even regular short-term yoga practise as suggested by ayush ministry has a positive effect on haematological, renal, and hepatic biomarkers.

CONCLUSION

The eight-week yoga intervention programme improved college students' haematological and, hepatic biomarkers, indicating improved blood parameters and, liver functions. Except for serum creatinine, no significant changes across three time points in renal biomarkers were observed. These findings suggest that yoga may have health benefits for college students, but more researches with larger sample sizes and longer follow-up times are required to confirm the findings. This study is significant because it expands on the body of knowledge already available about the benefits of yoga on biochemical biomarkers in college students. The study's findings may have implications for improving college students' health and well-being, as well as highlighting the potential benefits of incorporating yoga into their lifestyle. The findings may also aid educators and healthcare professionals in developing strategies to promote a healthy lifestyle among college students, thereby improving their overall well-being.

ABSTRACT

The present study was carried out on the diversity of phytoplankton of Santhekadur tank of Shivamogga district, Karnataka for a period of six months (December 2021 to May 2022). A total of 55 species belonging to 35 genera were identified with 04 major classes viz., Bacillariophyceae, Chlorophyceae, Myxophyceae, Euglenophyceae and they are represented throughout the study period. Bacillariophyceae having 20 species followed by Chlorophyceae, Myxophyceae and Euglenophyceae with 16,11 and 08 species respectively. During the present study dominant genera found *are Navicula, Cymbella, Pinnularia, Synedra, Closterium, Spirogyra, Merismopedia* and *Trachelomonas.* Based on Boyd's diversity index the present water body is included under moderately polluted category. Although the tank is not protected from human activities and open for various activities, and they need regular monitoring.

Keywords: Phytoplankton, Occurrence, Santhekadur tank, Diversity indices.

INTRODUCTION

According to Panday et al (2004) phytoplankton are regarded as an essential component of aquatic flora and play a crucial role in maintaining equilibrium between the biotic and abiotic components of an aquatic ecosystem. Phytoplankton are the essential makers and structure the fundamental basic of food material for aquatic creatures

Ramesh *et al.,*

and furthermore assume a significant part in the food chain of fishes and other aquatic living beings. The water quality corresponding to physico-chemical boundaries assumes a significant part in learning the distributional example and quantitative overflow of living beings occupying a specific environment (Singh et al., 2009). It is the need of today to monitor these environments. A few specialists have contemplated the physico-chemical elements of fluctuated lentic water bodies with the aim to survey the water quality (Islam, 2011; Venkateshwarlu et al., 2003, Sayaswara et al., 2010; Sachinkumar Patil et. al. ,2013). Subsequently intermittent checking of water nature of wetlands like lakes, ponds, reservoirs, ditches and pools is fundamental. The growth of phytoplankton is closely related to the physic-chemical properties of water. The higher the nutrient concentration in the water, the denser the population of phytoplankton, especially the Cyanophyceae (Prasad Umesh et al., 2001). Since the presence of an indicator species may reflect the state of cleanliness or contamination; The indicator organism cannot respond to all types of pollution (Hosmani, 2010; Rashmi and Somashekar Malammanavar, 2013). In the 20th century, extensive research was carried out on complexes of physical, chemical and biochemical components and their functional dynamics in the aquatic environment, both in temporary and tropical countries. Various researchers have made important contributions from different parts of the country since the last five to six decades. Freshwater bodies face pollution problems worldwide. Lentic waters such as ponds, lakes, dams etc. They are part of the freshwater habitat and are useful to humanity. The survival of life in the tank depends on the quantity and quality of water. Tanks play an important role in environmental sustainability. However, the continuous input of various chemical pollutants due to human activities has significantly deteriorated the quality of basin ecosystems in India. Water bodies are at risk from point and diffuse sources of pollution. The main factors of eutrophication include nutrient input (nitrate and phosphate), organic matter pollution, and construction and logging activities (Gangotri et al., 2017). Phytoplankton progression is a well-known phenomenon in aquatic ecology and several studies have described the underlying patterns and mechanisms of seasonal dynamics (Rothhaupt, 2000; Baba and Pandit, 2014). However, knowledge of the composition and abundance of phytoplankton organisms represents an essential feature for assessing the trophic status in water bodies in order to estimate the possible or optimal use of various water resources. Phytoplankton forms the base of the food chain in open water resources and serves as an indicator of water quality. Due to the interdependence between the different organisms that make up the systems, these differences in phytoplankton communities lead to changes in the food chain and lake productivity. The biological spectrum of lentic freshwater bodies is multidimensional, with phytoplankton useful in biomonitoring ecological disturbances caused by a range of physicochemical factors, wastewater pollutants and other anthropogenic factors (Baba and Pandit, 2014).. A detailed study on Santhekadur tank, one of the multipurpose water body of Malnad region is lacking. It is with this background, in the present study, an attempt has been made to study the occurrence and distribution of phytoplankton.

MATERIALS AND METHODS

Study area
Santhekadur tank is situated at Latitude of 13° 52' N and Longitude 75° 45' E in the Shivamogga city at the distance of 6 km respectively (Figure 1 and 2). This tank water is utilized for fish culture, irrigation and other human activities. The aquatic plants such *as Azolla,Pistia, Lemna, Spirodela, Chara, Nymphaea,Typha* and *Ipomea aquatica* are found in this water body.

Estimation of phytoplankton
Planktonic forms were collected using a 10-μm-mesh silk plankton net and attaching a 100-mL glass bottle to a narrow end. To collect the qualitative analysis samples, the net was dragged just below the water surface for 5 minutes (Green and Holden, 1960). Tows were limited to a small area around each sampling site. The samples were immediately transferred to other bottles and preserved by adding 4% formalin according to the practice of Welch (1948). The qualitative estimation of was carried out by taking one ml sample from each of the stock samples and repeating it five times. An even distribution was achieved by shaking the samples vigorously. The qualitative identification of planktonic organisms has been done with the help of monographs and plankton are identified down

to the species level (Adoni et al., 1985; Bharathi and Hegde, 1982; Hegde and Bharathi (1985). Few indices are calculated such as Boyd's and Shannon-Weaver index. The density, abundance and frequency of phytoplankton were discussed.

Water Analysis
The water sampling was carried out during morning hours between 8.00 and 9.00 AM hours. For physico-chemical analysis, water samples were collected in 2 litre plastic bottles . Dissolved oxygen was fixed on the site itself in BOD bottles. Various parameters like free CO_2, BOD, phosphate, nitrate, total hardness , Ca, Mg, TDS, sulphate and Chloride were estimated as per the standard methods APHA (1995)

RESULTS AND DISCUSSION

In the present study, a total of 55 species and 35 genera of phytoplankton were recorded in the water body (Table 1). Among the 04 classes of phytoplankton Bacillariophyceae having 20 species followed by Chlorophyceae , Myxophyceae and Euglenophyceae with 16,11 and 08 species respectively. Figure 4 depicts the average six months water quality data of Santhekadur tank. It appear that the presence of pH, dissolved oxygen, dissolved solids, phosphate, calcium and BOD are the factors which favored the growth of diatoms similar observation was noticed by Rashmi and Somashekar Malammanavar (2013) . Zafar (1967) has opined that high calcium and alkaline pH of the water bodies have favored the high number of diatoms. Mahadev and Hosmani (2004, 2005) have studied the community structure of cyanophyceae in two polluted lakes of Mysore city. Amit Kumar and Radha Sahu (2012) studied the ecology of the sewage stabilization pond of HEC area, Hatia, Ranchi to determine the occurrence and abundance of cyanobacteria in relation to physico-chemical characteristics of sewage pond. The Blue-Green algal diversity of this tank can be used as biomonitor of water quality. From the present findings, it is clear that Santhekadur tank water is most favourable for the formation of algae. Stevenson and White (1995), Gopinath (1995) and Niranjana (1996) opined that higher phosphate content supports luxuriant growth of cyanophyceae members. In the present study, the concentration of phosphate was more (average 0.45 mg/l) which harbored good number of blue greens . A large number of workers Zafar (1967), Seenayya (1971b), Rajkumar (1984), Venkateswarlu (1986) have pointed out that the desmids avoid polluted waters. In the present study, few desmids were found to grow at this tank revealing that desmids do not tolerate the high degree of organic pollution.

Hence, the observations made are in essential agreement with that of the above workers. Earlier reports on Euglenophyceae were by Munnawar(1970), Safiq-ur-Rehaman(1998), Hosmani (2008, 2012). These authors have reported that lake waters having high average concentrations of carbon dioxide are dominated by Euglenophyceae. Seenayya(1971) is of the opinion that levels of dissolved oxygen rise when Euglenophyceae are abundant. Water temperature above 320C and higher concentrations of Nitrates are effective for the growth of these forms. To explain the community structure in the tank, the Shannon-Weaver index is calculated. It is a diversity index that takes into account both the number of individuals and the number of taxa. The normal values were between 0 and 4. This index is a combination of the species present and the homogeneity of the species. Studying diversity across the spectrum of contaminated and unpolluted ecosystems (Wilham and Dorris, 1968) concluded that index values above 3 indicate clean water, values in the range of 1 to 3 are characterized by moderate contamination. Values below 1 are characterized by severe pollution. According to this index (Table 3), the values are between 0.27 and 0.34. The maximum and minimum diversity was found in the summer months. According to Shannon and Weaver, the greater the diversity, the lower the contamination (Sudeep and Hosmani, 2007). The Boyd diversity index indicates that values greater than 4 indicate less contamination and clean water, values of 3-2 indicate moderate contamination, and values <1 indicate severe contamination of the water (Sudeep and Hosmani, 2007). The phytoplankton distributions in the tank are shown in Table 1. The calculated value of the diversity index is shown in Table 5. According to the diversity index of Boyd (1981), the Santhekadur tank, which is protected from major disturbances, is always moderately contaminated (Table 5).

ABSTRACT

Atopic Dermatitis (AD), also known as Eczema, is one of the persistent inflammatory skin conditions marked by chronic itching. It affects approximately one in ten individuals in the general population. AD is distinguished by an unbearable and untreatable itch.In Atopic Dermatitis, a primary issue lies in the compromised skin barrier, leading to dry and itchy skin. This condition is further worsened by the mechanical damage caused by scratching.It can lead to sleep disturbances and social stigma. The immune response in AD is mediated by T helper type 2 (Th2) cells, which drive allergic inflammation. The communication between epithelial cells and immune cells via the cytokine Thymic Stromal Lymphopoietin (TSLP) plays a crucial role in this process. Natural products claims that due to their Anit-Inflammatory and Immunosuppressant properties they can be used in the treatment of AD. The primary objective of thus current study is to uncover the potential phytocompounds from 21 selected medicinal plants with Anti-Inflammatory, Anti-Oxidant, Antitumour, Immunosuppressant properties were taken. The 3D structures of the phytocompounds were retrieved from IMMPAT and PubChem Databases. An intensive *In Silico* study starting with Molecular Docking against Human Thymic Stromal Lymphopoietin as a drug target for Eczema with 816 compounds were conducted using PyRx software. The docking results were compared with the standard drugs which are used for the treatment of AD. The Lipinski Rule of Five, ADMET and CYP properties were assessed for all the phytocompounds using SwissADME. Upon overall investigation, the phytocompound Sarasapogenin with binding affinity of -8.5 Kcal/mol

80095

Prathap *et al.,*

showed excellent results and it is suggested that it has the capability to act as a Lead molecule in the treatment of AD. Further the *in vitro* and *in vivo* studies are suggested to validateits promising therapeutic capability.

Keywords: Immunosuppressant, Social stigma, Thymic Stromal Lymphopoietin, Allergic Inflammation, Cytokines, ADMET, CYP properties, drug-likeliness.

INTRODUCTION

The skin is the most substantial part of the integumentary system. It protects us from external troubles while also reflecting our internal harmony in the delicate shade of our bodies [1]. In the delicate balance between health and imbalance, there emerges a discordant note, known as eczema. Atopic Dermatitis (AD), commonly known as Eczema, is a chronic inflammatory skin condition characterized by persistent itching. [2] It impacts around one in ten individuals in the general population [3]. One of the distinguishing features of AD is the intense and often unrelenting itch, which can be challenging to alleviate effectively. [4] As we uncover the layers of this eczematic condition, examining its nuances, its impact, and the path to peaceful solace amidst its complications [3]. The condition known as eczema results in your skin getting dry, itchy, and bumpy, and it's responsible for weakening your skin's hedge function [5]. A significant challenge in Atopic Dermatitis is the weakened skin barrier, resulting in dry and itchy skin.[6] This condition is exacerbated by the scratching, which further damages the skin. This facilitates the penetration of pathogens through the skin and establishes an environment that influences the immune system's response to these pathogens.[6] The appearance of eczema varies depending on who's diagnosed with the condition. Dark skin tone can affect grandiloquent, brown, or Argentine eczema rash. In affluent countries, atopic eczema affects 20% of children and 10% of adults, ranking among the leading causes of disability-related time off.[7] Globally, approximately 4.4% of people experience depression, characterized by a diminished interest in daily activities, while roughly 3.6% contend with anxiety disorders, marked by excessive worry, fear, or avoidance behaviours. [8,9] Although eczema does not generally beget pain, scratching your skin can beget a painful sore. Contact dermatitis, among other forms of eczema, has the implicit to beget a burning sensation and discomfort. The impact of itching and disfiguring blisters extends beyond the individual to their family, diminishing their quality of life. This discomfort often leads to sleep disturbances and social stigma. [5]

Several proteins and molecular targets have been intertwined in the pathogenesis of eczema. Filaggrin (FLG) mutations are explosively linked to eczema, impacting skin hedge function. Interleukin (ILs) similar to IL- 4, IL- 13, and IL- 31, [10] along with excrescence necrosis factor- nascence (TNF- α), drive seditious responses in eczematous skin, aggravating towel damage. Interferons (IFNs), particularly IFN- γ, further disrupt the skin hedge and promote inflammation. Treatment might include a combination of life changes and specifics. In Atopic Dermatitis (AD), the immune response involves a type of T-helper cell called Th2 cells, which play a central role in allergic inflammation. [7] Studies using experimental models of allergen-induced allergic skin inflammation in mice have demonstrated the significant role of both Th1 and Th2 cytokines in the skin's inflammatory response [11]. This inflammation is characterized by the secretion of cytokines such as IL-4, IL-5, IL-13, and TNFα by a type of white blood cell called CD4+ T-cells. These cytokines stimulate the production of IgE antibodies by B-cells. IgE antibodies then bind to mast cells, triggering allergic reactions and leading to the infiltration of immune cells into the skin dermis [3]. Dendritic cells (DCs) play a crucial role in controlling the immune response by directing the differentiation of native CD4+ T-cells into TH2 lymphocytes [12]. The signalling between epithelial cells and immune cells via a cytokine called Thymic Stromal Lymphopoietin (TSLP) is believed to drive the development of Atopic Dermatitis [3]. This signalling mechanism also occurs in other allergic conditions like asthma and allergic rhinitis, a process known as the "Atopic March." [13] TSLP, a groundbreaking cytokine akin to 1L-7, was first isolated from murine thymic stromal cell lines, heralding a new era in immunology. Its role extends far beyond mere support, as it orchestrates the growth of B-cells, fosters T-cell proliferation, and guides cellular differentiation [14]. In the intricate landscape of

atopic dermatitis (AD) and asthma, TSLP emerges as a pivotal player, boasting high expression in human cutaneous epithelial cells and bronchial epithelial cells [15]. Within the microcosm of keratinocytes, TSLP's overexpression sets in motion a cascade of events, triggering relentless itch-induced scratching, culminating in an AD-like phenotype and mirroring the inflammation seen in asthma within murine models [16]. A murine counterpart to TSLP, christened TSLP-receptor (TSLPR), has been unveiled, exhibiting a modest affinity for TSLP. Yet, it's the formation of a potent heterodimer, coupling TSLPR with interleukin 7 receptor α (IL-7Rα), that heralds a cascade of cellular responses, underscoring the intricacies of immune regulation [17].When skin lesions or damage occur, cytokines such as IL-1β, TNF-α, IL-4, and IL-13 surge to heightened levels, creating a milieu ripe for inflammation. This potent cocktail can synergize to provoke the expression of TSLP by keratinocytes, setting off a chain reaction in the immune system [3]. TSLP, acting as a conductor orchestrating a symphony of cellular responses, exerts its influence predominantly on dendritic cells (DC). Upon activation by TSLP, DC undergo proliferation, maturation, and subsequent migration to lymph nodes, where they present antigens to immature T-lymphocytes.

This pivotal interaction serves as the catalyst for the differentiation of T-cells into Th2 cells, which play a crucial role in the immune responses characteristic of atopic dermatitis (AD)—a cascade known as "Th2 cell-mediated allergic inflammation." [18] In the arsenal against AD, TSLP inhibitors emerge as a promising strategy, often recommended as a preemptive measure before the onset of complications. [3] Various research report has indicated that a range of pure compounds derived from herbal materials, herbal extracts/ fractions & herbal formulations are effective on in vitro/ in vivo models [19]. Use of these natural products as a medicament has intensified in recent years, chiefly compounds derived from plants are used, since they are known to have fewer side effects than synthetic compounds [19,20]. With the use of *In Silico* methods using computational approaches make it easier to discover drugs because screening drugs with in vitro or in vivo assays is becoming more difficult, time-consuming, and costly because of the large number of compounds being studied [21,22]. In this present study, about 1007 phytocompounds from 21 locally available medicinal plants which is known for their Anti-Inflammatory, Anti-Oxidant, Antitumor, Immunosuppressant activity are taken. Molecular Docking studies were performed using the retrieved compounds and specified target protein, and their binding interactions were obtained. Pharmacokinetic properties which are also known as ADMET properties were assessed [23] and the results obtained were compared with the standard drugs which is involved in the treatment of Eczema. Thus, this study will provide insights in understanding the properties and the activeness of these phytocompounds as Lead molecule for new Drug Design and therapy.

MATERIALS AND METHODS

MATERIALS
The *in-silico* study has been performed by the following softwares and webservers.
- Protein Data Bank (PDB) (https://www.rcsb.org)
- IMMPAT (https://cb.imsc.res.in/imppat/home)
- PubChem (https://pubchem.ncbi.nlm.nih.gov)
- SAVESv6.0 (https://saves.mbi.ucla.edu)
- SwissADME (https://www.swissadme.ch)
- Discovery Studio suite 3.5
- PyRx version 0.8

METHODLOGY

Compounds from 21 selected medicinal plants have been identified, designed, optimised and screened using Molecular Docking to determine the most suitable natural compound that can inhibit Thymic Stromal Lymphopoietin (TSLP-1).

Selection and retrieval of the target protein
From the previous studies [3] and as per the literature, it was determined that one of the potential drug targets for the Eczema is Human Thymic Stromal Lymphopoietin (PDB ID: 5J11) [24] with Resolution 2.56 Aᵒ. The X-Ray crystallographic structure of Human Thymic Stromal Lymphopoietin (PDB ID: 5J11) and its 3D structure were obtained from the Protein Data Bank (PDB) (https://www.rcsb.org).

Stereochemical property of the retrieved protein
 The stereochemical properties of the retrieved protein was assessed using SAVESv6.0-Structure Validation Server (https://saves.mbi.ucla.edu). ERRATand PROCHECK features were used to analyse the quality of the Target protein to validate it as a suitable receptor for Molecular Docking and for recurrent studies [25]. To verify protein structures determined by crystallography, ERRAT Program is used. ERRAT is employed for scrutinizing the statistics concerning non-bonded interactions among various atom types. It then graphs the error function value against the position of a 9-residue sliding window, determined through a comparison with data from meticulously developed structures [26]. PROCHECK is used to check the stereochemical quality of a protein structure by analysing residue-by-residue geometry and overall structure geometry [27].

Preparation of the target protein
Preparation of the target protein (TSLP-1) involves with the addition of polar hydrogen atoms, addition of charges and removal of any unwanted substances which involves in the reaction. The miscellaneous substances like water molecules and the hetero atoms are removed and the polar hydrogens were added. Initially, all crystallographic water molecules and the inhibitors were removed from the original structure in order to dock herbal compounds into its substrate binding sites. Further, energy minimization of the target was performed followed by adding hydrogen atoms to construct a properly stabilized position of side chain atoms and hydrogen atoms using Discovery Studio 3.5 suite [28].

Selection and retrieval of the ligands
Using the literature and IMMPAT Database [29] around 1007 phytochemical compounds were selected from 21 medicinal herbs known for its Anti-Inflammatory, Anti-Oxidant, Antitumour, Immunosuppresant etc… The plants including *Abutilum Indium, Aegle marmelos, Aerva Lanata, Anisomelesmalabarica, Argemone mexicana, Bacopa monneri, Basella rubra, Boerhaviadiffusa, Bryophyllumpinnatum, Cheilocostusspeciosus, Cichorium intybus, Cissus quadrangularis, Cypernusrotundus, Datura metal, Ecliptaprostrasta, Elettaria cardamomum, Gingko biloba, Hemidesmus indicus, Hygrophila auriculata, Tribulus terrestris*and*Withaniasomnifera*aare used to inhibit Thymic Stromal Lymphopoietin.The 3D structures of these compounds with their physical and chemical properties were retrieved from the PubChem compound database [30]. The phytochemical compounds were downloaded in the SDF format and used for recurrent study.

Optimization of the ligands
The phytochemical compounds were downloaded in the SDF format and were converted to PDB format using OPEN BABEL software to carry out further in-silico studies. Structural geometry stabilization and protonation state of these ligands were reached using Discovery Studio 3.5 suite.

Drug-like property prediction
An online tool Lipinski's filter (https://www.scfbio-iitd.res.in/software/ drugdesign/lipinski.jsp) was used to retrieve the information about drug likeness of drugs with the help of Lipinski's rule of five. Lipinski's rule (or Lipinski's rule of five) helps to differentiate drug and non-druglike molecules [31].
It is used to identify the possibility of success or failure due to drug likeness for molecules fulfilling with two or more of the following rules [32]:
(a)   Molecular mass – Less than 500 Da
(b)   High lipophilicity - expressed as Log P Less than 5
(c)   Hydrogen bonds donors – More than 5

(d)   Hydrogen bond acceptors – Less than 10
(e)   Molar Refractivity (Range) – 40 to 130.
The Lipinski Rule of Five was observed in 816 phytocompounds and they were used in Molecular docking studies.

Molecular docking studies

PyRx software (Version 0.8, with virtual screening and Drug Discovery features) was used to perform Molecular Docking with the Target protein Human Thymic Stromal Lymphopoietin (PDB ID: 5J11). Selected natural compounds were virtually screened against the target protein in order to find efficient ligand using PyRx0.8 tool (https://pyrx.sourceforge. io/) [33]. Using this software, the target proteins were prepared for Molecular Docking studies. The target protein was converted into (. pdbqt) file format. The Open Babel feature in the PyRx was used to import the ligands. Then energy minimalization of ligands were carried out by the OPEN BABEL featureand it was used to convert ligands into (. pdbqt) file format.The library of ligand molecules was then subjected to virtual screening based on docking using the Vina Wizard feature, which remains in-built in the PyRx [28]. It was used to import the macromolecule and ligands. Then a molecular grid was built over the active site and the docking studies were performed [33].The ligands were classified according to their binding energy, which represents the highest potential interaction with the receptor. Finally, 2D and 3D view of atomic interaction between best-docked complexes were achieved using Discovery Studio 3.5 respectively.The best conformation with the lowest docked energy (Kcal/mol) indicated the best fit. Molecular docking was conducted to substantiate the efficiency of selected natural compounds obtained from drug-like property prediction. During docking, synthetic drugs like Methotrexate, Azathioprine in class of Immunomodulators, Upadacitinib in class of JAK inhibitor and Alitretinoin which are used in the treatment of Eczema were also included to compare their binding affinity with selected natural ligands. Subsequently, all binding poses of each docking were studied and most energetically as well as geometrically favourable conformation for each independent run was selected for further study.

Pharmacokinetic properties of the screened compounds (ADMET and CYP properties)

The ADMET and CYP characteristics of the top 15 phytochemical compounds for the target protein were assessed using SwissADME online web tool [34]. The parameters like BBB (Blood Brain Barrier permeability), HIA (Human Intestinal Absorption), PGP (P-Glycoprotein), XLogP3, TPSA (Topological Polar Surface Area), LogS, Fraction Csp3, Rotatable bonds, Cytochrome P450 enzyme inhibitor properties, Skin permeation, and Bioavailability score were examined for the compounds with the best interaction to the target [28].

Protein-ligand interaction

Discovery studio Visualizer, a visualization tool which is used for viewing, analysing a protein and modelling data. The best compounds which showed best results in above studied parameters were visualized using Discovery studio suite 3.5. The interaction between the ligand and the active site of the target protein were analysed and the 2D and 3D interaction plots were obtained in order to study the stability of the ligand in the active site.

RESULTS AND DISCUSSIONS

Selection and retrieval of target protein

The PubChem Compound Database was used to retrieve the 3D structure of the ligands and the 3D structure of the target proteins were retrieve from the Protein Data Bank Database (PDB) [35]. The PDB ID for X-Ray crystallographic structure of the Human Thymic Stromal Lymphopoietinis 5J11 **(Figure 1)**[36]. The target protein (TSLP-1) is prepared by the removal of unwanted hetero atoms like water and inhibitors. It is followed by addition of polar hydrogen atoms and addition of charges respectively. Hence, the Target protein has been prepared for *in-silico* studies.

Stereochemical property of the retrieved protein
The stereochemical properties of the retrieved protein was assessed using SAVESv6.0-Structure Validation Server (https://saves.mbi.ucla.edu) [37]. ERRATand PROCHECK features were used to analyse the quality of the Target protein. The quality of the target protein was evaluated via the Ramachandran plot using PROCHECK [27]. The Ramachandran plot for the target protein revealed that 87.1% of the residues were in the most favorable region, while 12.3% were in allowed region, confirming that the target protein is of good quality (Figure 2). ERRAT is termed as "Overall Quality Factor" for non-bonded interactions at atomic level, with elevated scores represent higher quality [26]. A top-quality model typically falls within the generally accepted range of >50 (Figure 3). For the current 3D model of the Target protein, the overall quality factor predicted by the ERRAT server was 89.688%.

PROCHECK
87.1% residues in favorable regions, 12.3% residues in additional allowed regions, 0.4% residues in generously allowed regions, 0.2% residues in disallowed regions. **Figure 2**, Ramachandran plot for 5J11 confirms that the protein is of good quality.

ERRAT
Figure 3 Illustrates that on the error axis, two lines are drawn to indicate the confidence with which it is possible to reject regions that exceed that error value. In high-resolution structures, values typically hover around 95% or higher, while lower resolutions tend to yield an average overall quality factor of approximately 91%. The Overall Quality Factor for 5J11 is 89.688, shows that the protein model is of High quality.

Selection and retrieval of the ligands and target protein
Using the literature and IMMPAT Database [29] around 1007 phytochemical compounds were selected from 21 medicinal herbs known for its Anti-Inflammatory, Anti-Oxidant, Antitumour, Immunosuppressant etc… The 3D structures were retrieved from the PubChem Database and they were converted from SDF to PDB format using OPENBABEL software.

Drug-like property prediction
Lipinski rule of five was assessed for the following compounds and the results were analysed whether the following compounds have drug-like property or not [31]. Lipinski rule of five was assessed for 1007 phytocompounds, about 816 compounds showed drug-like property. Hence, they are proceeded for Molecular Doking process using PyRx.

Molecular docking studies
PyRx 0.8 software was used to conduct docking experiment for the target protein Human Thymic Stromal Lymphopoietin (PDB ID: 5J11). About 816 compounds were docked against 5J11. From the results (Table 1), the following top 15 compounds showed a very good interaction with the target protein. The Binding affinity, interacting residues and their bond lengths were tabulated. The docking scores of 15 phytocompounds were compared with 4 standard drugs which are used for the treatment of Eczema. From the results (Table 1), among other compounds, 15 compounds showed very good results with the target protein. Of which, the phytocompound Boeravinone E showed excellent binding affinity of -8.9 Kcal/mol with the amino acid residues TYR C:152, LYS C:163, ASN B: 182, LEU B:183, LEU B: 183, LYS C: 163, VAL B: 181 of target. The phytocompound Isodemethylwedolactone also provided a strong affinity of (-8.9 Kcal/mol) with the amino acid residuesTYR C: 152, GLN C: 161, SER C: 162, THR B: 189, LEU B: 183, GLY C: 174, SER B: 184, LYS C: 163, LEU B: 188, LEU B: 183, LYS C: 163. The phytocompound Boeravinone F provided a good binding affinity of (-8.8 Kcal/mol) with the amino acid residues LYS C: 163, LYS C: 163, LYS C: 163, SER C: 162, SER B: 185, LEU B: 183, VAL B: 181, LEU B: 183, LYS C: 163, VAL B: 181. The phytocompound Jujubogenin provided a good binding affinity of (-8.8 Kcal/mol) with the amino acid residues MET A: 100, ILE A: 108, LYS B: 104. The phytocompound Boeravinone B provided a good binding affinity of (-8.7 Kcal/mol) with the amino acid residuesLYS C: 163, ASN B: 182, LEU B:183, LEU B: 183, LYS C: 163, VAL B:181. The phytocompound Withanolide L provided a good binding affinity of (-8.7 Kcal/mol) with the amino acid residues ALA B: 076, LYS B: 104, LYS A: 103, ALA A: 104. The phytocompound Diosgenone, 4-Dimethyl also provide a strong binding affinity of

80100

(-8.6 Kcal/mol) with the amino acid residues ARG C: 111, THR C: 198, ILE C: 032, PHE C: 107, PHE C: 107. The phytocompound Demetylwedeloactone also provide a strong binding affinity of(-8.6 Kcal/mol) with the amino acid residues SER B: 185, TYR C: 152, GLN C: 161, GLN C: 161, SER B: 184, SER B: 184, SER B: 184, LEU B: 183. The phytocompound Withanolide A also provide a strong affinity of (-8.6 Kcal/mol) with the amino acid residues LYS B: 104, GLY B: 103, GLY B: 103. The phytocompound, Boeravinone A also provide a strong binding affinity of (-8.6 Kcal/mol) with the amino acid residues ASN B: 182, LYS C: 163, LYS C: 163, LEU B: 183, VAL B: 181. The phytocompound Sarasapogeninalso provide a strong binding affinity of (-8.5 Kcal/mol) with the amino acid residues THR C: 041, THR C: 041, SER C: 201, SER C: 201, PHE C: 037. The phytocompound Tiliroside also provided a strong binding affinity of (-8.5 Kcal/mol) with the amino acid residues SER B: 184, HIS B: 211, SER B: 184, ASN C: 166, SER B: 185, GLN C: 164, MET C: 190, HIS B: 211, HIS B: 211, VAL B: 162, LEU C: 147, LEU C: 147, LEU B: 183. The phytocompound Asarinin provided a good binding affinity of (-8.5 Kcal/mol) with the amino acid residues VAL B: 181, GLU C: 173, GLU C: 173, GLU C: 173, LYS C: 163, LYS C: 163, LYS C: 163, SER B: 184. The phytocompound Isoginkgetin provided a good binding affinity of (-8.5 Kcal/mol) with the amino acid residue GLN C: 164, GLU C: 165, LYS C: 163, LEU B: 163, SER B: 184, SER B: 184, SER C: 162, LYS C: 163, VAL B: 162, LEU C: 147, LEU C: 147. The phytocompound Sequoiaflavone provided a good binding affinity of (-8.5 Kcal/mol) with the amino acid residues LYS B: 128, TRY B: 217, SER B: 041, SER B: 041, GLU B: 060, PHE B: 216, TYR B: 043, TRY B: 217, ALA B: 058, ALA B: 058. Morever, the phytocompound Methotrexate provided a good binding affinity of (-7.5 Kcal/mol) with the amino acid residues GLN C: 047, SER C: 082, THR C: 054, THR C: 081, TYR C: 051, GLN C: 077, HIS C: 080, SER C: 052, SER C: 052, SER C: 052, GLU C: 078, SER C: 049. The phytocompound Azathioprine provided a good binding affinity of (-6.5 Kcal/mol) with the amino acid residues GLY C: 064, ASN C: 063, GLY C: 064, PHE C: 062, SER A: 068, SER A: 068, LYS C: 069, VAL A: 067. The phytocompound Upadacitinib provided a good binding affinity of (-6.7 Kcal/mol) with the amino acid residues TYR A: 054, TYR A: 054, TYR A: 054, MET A: 097, MET A: 097, MET A: 097. The phytocompound Alitretinoin provided a good binding affinity of (-6.4 Kcal/mol) with the amino acid residues ALA B: 076, MET A:100, LYS A: 103, ALA A: 104, ALA A: 107, ALA A: 107, LYS A: 103.

According to the study conducted by Sathish Kumar and Rasiga *et al.*, 2019, the results of the *In-silico* docking study regarding the interactions between TSLP and the compounds from the medicinal plants like *Trigonellafoenum, Rosmarinusofficinalis, Ficuscarica, Althaeae radix, Prunuspersica, Achyranthesaspera, Allium cepa, Curcuma longa, Camellia sinensis, Lycopersiconesculentum, Cannabis sativus, Oenotherabiennisand Matricaria chamomile* were assessed. The compounds were analysed for their significant interaction with the target, ADMETproperties, drug-likeness using the Schrödinger software. The docking results were observed which indicates that 10 compounds were found to be active. The compound Rosmarinic acid had significant G.score value of -6.28 kcal/mol and interactions with the active site residues (GLU78, MET28, SER114 and GLN80) of TSLP. Given that TSLP acts as a pivotal regulator of allergic inflammation at the interface between epithelial cell-Dendritic Cell (DC) in Atopic Dermatitis, and the findings suggest recurrent investigation of plant compounds to potentially develop novel drug molecules [3]. Zhen-Zhen Wang *et al.*, 2021in his study, they have investigated the bioactive compounds and mechanisms of SZT in treating eczema using systems pharmacology and *in silico* docking analysis. SZT is composed of 4 medicinal herbs, *Atractylodismacrocephalae* rhizome, *Schizonepetaeherba, Sophoraeflavescentis radix*, and *Arctii fructus*. They first identified 51 active compounds from SZT and their 81 potential molecular targets by high-throughput computational analysis.They further identified top 5 compounds including cynarine, stigmasterin, kushenol, β-sitosterol, and (24S)-24-propylcholesta-5-ene-3β-ol as putative key active compounds on the basis of their molecular docking scores with identified hub target proteins. Finally, the study provides an insight into the therapeutic mechanism underlying multiscale benefits of SZT for eczema and paves the way for developing new and potentially more effective eczema therapies [38]. In this present study, all the top 15 phytocompounds tabulated in the table showed higher binding affinity (Range of -8.9 Kcal/mol to -8.5Kcal/mol) with the target protein TSLP, when compared with the previous studies.

Pharmacokinetic properties of the screened compounds
ADMET properties
In the present study, ADMET properties were tested for the best 15 interacted phytocompounds and Synthetic drugs Methotrexate, Azathioprine, Upadacitinib and Alitretinoin using SwissADME and the results were tabulated (**Table2**). From the results, all the best interacted phytocompounds and also the synthetic drugs Methotrexate, Azathioprine, Upadacitinib and Alitretinoin obey Lipinski Rule of Five. A lot of the phytocompounds did not cross Blood-Brain Barrier (BBB). Twelve compounds had High Intestinal Absorption and compounds Tiliroside, Isoginkgetin, Sequoiaflavone and synthetic compounds Methotrexate and Azathioprine had Low Intestinal Absorption. Among the 15 phytocompounds, two compounds and synthetic drug Upadacitinibare predicted to be effluated from CNS by P-glycoprotein. Among 15 phytocompounds, XLogP3 value of Five phytocompounds were predicted to be out of the range and remaining compounds were above the range. TPSA (Topological Polar Surface Area) and Log S value of the most of the compounds were within the limit. In all the Phytocompounds, Fraction Csp3 value of 9 phytocompounds was less than 0.25 and the value of other compounds were within the limit. All the compounds were within the limit in the criteria of Rotatable bonds. From the results of the Boiled egg image of the phytocompounds **(Figure 4)**, the compoundsSarasapogenin and Asarinin are located in the Egg-yolk region, which means the compounds can passively permeate through the Blood-Brain Barrier. Ten phytocompounds are located in the Egg-white region, which means they are passively absorbedby the gastrointestinal tract.Two best interacted compounds are predicted not to be effluated from the Central Nervous System by the P-glycoprotein.

CYP properties
The majority of the substances do not inhibit the CYP450 enzymes or cause any negative side effects, according to the results of CYP characteristics **(Table 3)**. The phytocompoundsBoeravinone E, Boeravinone B inhibits the CYP450 enzymes CYP1A2, CYP2D6 and CYP3A4.The phytocompoundsBoeravinone F, Isodemethylwedolactone, Demetylwedeloactone inhibits the CYP450 enzymes CYP1A2 and CYP2D6. The phytocompoundsBoeravinone A CYP1A2, CYP2D6, CYP2C9 and CYP3A4. The phytocompounds Jujubogenin, Diosgenone, 4-Dimethyl, Withanolide A, Sarasapogenin, and Tiliroside does not inhibits the CYP450 enzymes. The value of log Kp (Skin Permeant) is good for all compounds and A Bioavailability Score (ABS) is good for the most of the compounds. Compounds with a high log Kp negative value have limited ability to penetrate skin. According to this statement, all the compounds have limited ability to penetrate skin. The Bio-Availability score of all the compounds is 0.55, as it satisfies the rule of five.

Protein-ligand interaction
In Silico molecular docking speeds up the drug discovery process by anticipating the phytocompounds that can bind to the target protein in less time. This along with *In Silico* examination of pharmacokinetic, physiochemical, and pharmacodynamic features helps identification of lead compounds that can be developed into a medicinewhich is helpful in the prevention of disease[40]. Numerous studies used *in vitro* and *in vivo* activity evaluation investigations to corroborate the outcomes of their *In Silico* based virtual screening and molecular docking experiments[41]. This confirms the value of *In Silico*studies in the drug discovery processes. By learning greater detail about how compounds bind to, interact with, and up- or down-regulate associated proteins, researchers may be able to come up with alternatives to therapy that treat specific ailments [28]. While analysing the results, the phytocompounds Sarasapogenin and Asarinin were no +PGP Substrate, had a High Intestinal Absorption (HIA) and passed every pharmacokinetic and CYP properties and has higher affinity when compared with previous studies.In these two compounds, Sarasapogenin from **Cheilocostusspeciosus** had permeated through the Blood-Brain Barrier and does not inhibit CYP450 enzymes. Based on the above studied parameters, the phytocompound Sarasapogenin showed best results and it showed that it has the property for being a Lead like molecule. Sarasapogenin and the synthetic drugs were visualized using Discovery studio Suite 3.5 and their 2D and 3D interaction plots were obtained (Fig. 6 & 7). The 2D and 3D interaction plots of the Synthetic compounds were visualized using Discovery Studio Suite 3.5 (Fig. 8-13) [39].

CONCLUSION

In the present study, the phytocompounds from 21 locally available medicinal plants which is known for their Anti-Inflammatory, Anti-Oxidant, Antitumor, Immunosuppressant activity etc… which could be used to treat Eczema or Atopic Dermatitis were taken. Using IMPPAT Database 1007 phytocompounds were retrieved. Lipinski Rule of Five was assessed for the retrieved compounds and among those 816 compounds exhibited Drug like property. The compounds were further taken into Molecular docking studies using PyRx V0.8 software and the docking scores of the chosen phytocompounds against Thymic Stromal Lymphopoietin (TSLP-1) (PDB ID: 5J11) range from -2.5 Kcal/mol to -8.9 Kcal/mol. Among them, top 15 compounds were taken into recurrent study and compared with 4 standard drugs which are used to treat Eczema. The top 15 compounds and 4 Synthetic drugs were assessed with the ADMET and CYP properties using SwissADME. The Boiled Egg parameter was used to predict the Blood-Brain Barrier permeation and P-Glycoprotein substrate of the phytocompounds and Standard drugs. While analyzing the results, the phytocompounds Sarasapogenin and Asarinin were no +PGP Substrate, had a High Intestinal Absorption (HIA) and passed every pharmacokinetic and CYP properties. In these two compounds, Sarasapogenin from *Cheilocostusspeciosus* had permeated through the Blood-Brain Barrier and does not inhibit CYP450 enzymes and hence it will be a suitable drug candidate which can act as a Lead compound by inhibiting the active site of the Thymic Stromal Lymphopoietin to reduce the onset of AD complications.

				Synthetic drugs							
1	Methotrexate	126941	1	No	Low	No	-1.85	210.54	-1.19	0.25	10
2	Azathioprine	2265	0	No	Low	No	0.1	143.4	-1.97	0.11	3
3	Upadacitinib	58557659	0	No	High	Yes	2.69	78.32	-3.83	0.47	6
4	Alitretinoin	449171	1	Yes	High	No	6.3	37.3	-5.34	0.45	5

Note: Obey Lipinski: That's great if there were no violations. Blood-Brain Barrier: It does indicate preference. Human Intestinal Absorption (HIA): High is acceptable, Molecules anticipated not to be eliminated from the central nervous system by P-glycoprotein are indicated by a PGP- ; an XLOGP3 score of 0.7 to +5.0 indicates excellent lipophilicity. Polarity: A good TPSA falls between 20 and 130 ، 2. Water Solubility: Log S value less than 6 indicates good, water solubility (Log S scale: Insoluble = -10, Poor = -6, Moderate = -4, Soluble = -2, Very = 0, Highly). Saturation (percentage Csp3): A percentage of carbons in the sp3 hybridization that is not less than 0.25 is deemed to be good saturation. Flexibility (Rotatable Bonds): Excellent provided that there aren't any more than nine of them. [42]

2	Azathioprine	2265	No	No	No	No	No	-7.92	0.55
3	Upadacitinib	58557659	Yes	Yes	No	Yes	No	-6.71	0.55
4	Alitretinoin	449171	Yes	Yes	Yes	No	No	-3.66	0.85

Note: Yes, indicating that the drug inhibits CYP450 enzymes and has unanticipated adverse effects; "No" means that the drug does not inhibit the CYP450 enzymes or have any adverse reactions that are harmful. The greater the negative the log Kp, the less skin-permeable the molecule is; ABS 0.55 shows that the rule of five is satisfied, while ABS 0.17 shows that it is not. [42]

ABSTRACT

Patient satisfaction is an essential indicator for evaluating the calibre of services provided to outpatients. It is imperative to periodically assess the healthcare systems concerning patient satisfaction. To evaluate the level of customer satisfaction with the outpatient department's services to cost, waiting times, medical treatment, and accessibility of services. The study was designed by involvement of 200 participants**.** A pre-structured questionnaire was given to the outpatients or attendants and by face-to-face interviews data was collected at the end of their outpatient visit. A total of 200outpatients were selected at random in 15 days between 4 and 6 p.m. The items in the questionnaire referred to the particulars of the patient such as age, gender, occupation, concerned departments, service particulars in the registration area, the concerned junior medical officers and consultants in the respective department, the lab (such as pathology, microbiology) and the medical pharmacy. The availability of services and medical treatment care was found to be satisfactory.93% of the participants felt satisfactory about the cleanliness and overall availability of the facilities, 92 % were satisfied with nursing staff, 88% of the respondents found the communication by the doctor good, 92% of the respondents were satisfied with the explanation of the disease by the doctor. However, 32% of the participants were suffering in locating the place for consultation, investigation, and pharmacy. Suggestions for reducing wait times at pharmacy and registration counters, delectable cuisine in food courts, and investigation expenses must be made to boost consumer satisfaction. To satisfy customers, it is advised to offer drug discounts and reduce consultant registration fees.

Keywords: Outpatient satisfaction, medical treatment, availability of service, facilities.

INTRODUCTION

There are two meanings to health care. Medical care organizations and health care programs (a and b). The primary focus of medical care organizations is curative treatment. They should be reasonably priced, visually appealing, and focused on cutting-edge technology. Quality assurance has become a globally significant factor in the delivery of healthcare services in recent years [1]. Several factors, including accessibility, affordability, effectiveness, and viability, affect the healthcare system. It is acknowledged that a key factor in determining the Caliber of healthcare services is customer happiness. It is anticipated that treatment outcome and prognosis will be impacted by provider satisfaction about attitude towards these services. The healthcare system needs to be examined as frequently as feasible [2]. For medical facilities like tertiary care and Quaternary care hospitals to provide services to outpatients, their contentment is crucial[3]. Rural residents are not sufficiently aware of their rights, particularly when it comes to health care services [4]. This is why we decided to conduct a study to gauge patient satisfaction with clinical care, including the physician's and junior medical doctor's strategy to approach, investigation, medication education, Awareness about the diet, service accessibility, waiting time for consultation, and cost in private Mult specialty hospital's outpatient department.

MATERIALS AND METHODS

The study was carried out in the outpatient department of a private multi-specialty Hospital in Coimbatore district. A pre-structured questionnaire was given to the outpatients or attendants and by face-to-face interviews data was collected at the end of their outpatient visit. A total of 200outpatients were selected at random in 15days between 4 and 6 p.m. The items in the questionnaire referred to the particulars of the patient such as age, gender, occupation, concerned departments, service particulars in the registration area, the concerned junior medical officers and consultants in the respective department, the lab (such as pathology, microbiology) and the medical pharmacy. The questionnaire included choices like acceptable/disappointing, easy/difficult, adequate/inadequate, and 20-minute time slots of actual time spent in each stage of the visit. Informed consent was obtained from the patient. The participants were informed that the objective of the research was to gauge how satisfied outpatients were with the hospital's healthcare facilities to make future facility improvements. Additionally, the outpatients were informed that the investigator was not a member of the medical staff. It was also made clear that they were free to respond honestly. Both the patient and the doctor who was examining continued to be unnoticeable. The replies were given as percentages. There were 200 outpatients in the study group—102 males and 98 females.

Around 78% of the population fell into the 25–48 age range (graph:1). Nearly 90% of those who participated were outpatients, while the remaining 10% were family members of elderly outpatients, ages 60 to 65. In the organization, the outpatient department is 100% clean (93%). Concerning the seating arrangements in the outpatient department, the overall availability of facilities (Table 1) was excellent (82%). 71% of those who participated said they were satisfied with the outpatient department's hours and the remaining 29% were not satisfied because they are from a long distance, 92% said they were satisfied with the outpatient nursing staff's amenities, 46% said it was very difficult to find the relevant specialist section in the outpatient department, and 89% said the number of medical practitioners available in the outpatient department was sufficient. Merely 32% of the participants reported difficulty locating the pharmacy. About the clinical treatment area (Table 2), 98% of the participants considered the doctors' approach satisfactory, 88% thought the doctor communicated well, 92% were satisfied with the way the doctor explained the disease, 92% thought medical care was satisfactory, and 91% thought the doctor was efficient. 83% of respondents were satisfied with the quantity of necessary investigations, while 92% of participants felt that the investigations were necessary. In 97% of the cases, the patient felt that the doctor had satisfactorily interpreted the investigation findings. For 83% of those who responded, the drug prescription process was generally satisfactory or simple to understand. Regarding the delay (waiting time) (Table 3), 79% of outpatients reported that the registration procedure took them not comfortably. In all, 89% of the outpatients had no trouble finding the relevant accessory department. In 12% of the cases, the consultation with the doctor took less than 30 minutes, in 61% of the cases, it

took 30 to 60 minutes, in 26% of the cases, it took 60 to 90 minutes, and in 1% of the cases, it took 90 to 120 minutes. Merely 53% of the outpatients found their time in the pharmacy to be satisfactory, however, 68% of the cases had the satisfactory time required to locate the pharmacy within 10 minutes.For all participants, the cost of registration was a little high, and consultation was acceptable. 46 % of the participants felt that the cost of the investigation was high, 33% of the participants, it was moderate; and 21% of the respondents, it was low. 11% of the participants said the cost of the medications was acceptable and the remaining felt it was too high. The consumer's purchasing power and the various costs of medications may have an impact on this. According to 64% of interviewees, the food court was too expensive and unsatisfactory. The related flavor and taste are also not very appealing but can be purchased for an emergency.

DISCUSSION

The patient considered the study's conclusions about medical treatment and accessibility to be sound. Suggestions for reducing wait times at pharmacy and registration counters, delectable cuisine in food courts, and investigation expenses must be made to boost consumer satisfaction. To satisfy customers, it is advised to offer drug discounts and reduce consultant registration fees.

ABSTRACT

Weeds pose a major threat to agricultural and horticultural cropping systems, reducing yields. Many scientific reports have shown that weeds have a better ability to compete for resources as compared to the major crops in various agro-ecosystems and in the absence of major crops, weeds acting as reservoir or alternative host for pathogens is a major obstacle reducing overall yields. An attempt was made to document the weeds in Hiriyur, Karnataka. The present study was conducted between March 2019 and February 2020 and nearly 57 weed species from 25 families were documented. I recorded 57 weed species taxonomically distributed in 25 families and 45 genera. Asteraceae and Amaranthaceae have the highest number of species (14.03% species), followed by Euphorbiaceae (10.52% species) and Poaceae (7.01% species) respectively.

Keywords: Weed survey, traditional knowledge, Hiriyur

INTRODUCTION

Weeds are the specialized plants that have evolved with abundant seed production, aggressive reproduction, high regeneration potential, and great phenotypic plasticity over temporal and spatial scales (Richards et al., 2006). Weedy plants are considered undesirable in certain locations (Dantonia and Meterson, 2002; Halzner and Numata, 2013). Among various biological pressures, weeds are considered to be one of the most detrimental to crop production (Einhelling, 1996; Weston and Duke, 2003). Moreover, these weeds provide harborage for numerous pests of crops and thus indirectly cause many plant diseases (Zimdahi, 2018). The presence of weeds in agricultural and horticultural fields competes with native plants for yields (Zimdahi, 2018). At the same time, information about weed

80120

seasonal phenomena is important for formulating effective control and management (Chmielewski, 2013; Kumar et al., 2019). The documentation of weeds is important for the management and control of weeds (Norsworthy et al., 2013; Haq et al., 2021). The identification and documentation of weed invasion are important for formulating various strategies for managing the weeds (Ward et al.,2014). Management decisions for agriculture and horticulture fields are dependent upon the phenological information of crops for improving yield (Chmielewski,2013). Most of the weeds are effectively well adapted to grow and proliferate in diverse areas (Kuester et al., 2014). The weed properties of these species are often advantageous over more desirable crop species. These species often grow and reproduce quickly or are short-lived, as their seeds typically remain in the soil for several years.

MATERIALS AND METHODS

Hiriyur is a taluk headquarter in Chitradurga district in the state of Karnataka, India. Hiriyur is located at 14.312°N 76.651°E. It has an average elevation of 585 meters (1919 ft). Hiriyur has a Subtropical steppe climate (Classification: BSh). The annual temperature in this district is 28.34 °C (83.01 °F), which is 2.37% higher than the average temperature in India. Typical rainfall in Hiriyur is approximately 84.55 mm (3.33 inches), with 124.03 rainy days per year (33.98% chance of rain). Plants were collected during March-2020 to Feb-2021 and identified with the help of flora up to species level (Arora et al., 1976; Caton et al.,2004; Cooke,1905; Elmore,1990; Gamble,2012 ; Parimala,2011;Quammen, 2012;Sastry et al.,1980; Stubbendieck et al.,1994; Whitson. and Burrill ,1991). Standard herbarium techniques are followed and specimens are preserved in the departmental herbarium for further reference.

RESULTS AND DISCUSSION

In this study, 57 weed species were recorded with 45 genera and 25 families (Table 1). Among 25 families, 5 families accounting for half of the species and 20 families for the other half. 15 families with single species. The Asteraceae and Amaranthaceae were the dominant family with 8 species (14.03%) followed by Euphorbiaceae with 6 species (10.52%) and Poaceae with 4 species (7.01%). The rest of the species were represented by Fabaceae, Capparidaceae, Solanaceae and other families (Table 2). The monotypic families are Lamiaceae, Plumbaginaceae, Cactaceae, Acanthaceae Apiaceae, and others represented in Table 1. Humans breed plants for yield, but nature breeds plants for survival. Weeds are strong competitors by nature and can withstand much adversity. The most competitive weeds always tend to dominate. Although agricultural weeds have some disadvantages, there are many more advantages that ensure soil stabilization. Wildlife habitat, diet, and aesthetic qualities ,add organic ingredients. and medicine. Different examples shown in Table 1 were used to explain the importance of weeds to local people in the selected areas. I also surveyed the local area and identified the most prevalent weeds in the selected area. I documented traditional knowledge of this type of traditional practitioners and village elders. Most people agree that weeds are just a nuisance in the field, and just thinking about them is like uprooting a seed. This research and awareness of the usefulness of weeds was well received by people, who were excited to share their knowledge about weeds and their traditional uses. Many weeds were used medicinally, and few were used as hedges or ornamentals. A literature review was conducted to support and confirm the medicinal properties claimed by local residents. Most of the weeds are studied for their medicinal properties.

CONCLUSION

This study identified the 57 most common weedy plants and documented associated traditional knowledge from traditional practitioners and local people. My study suggests that people are less aware of the ecological benefits of weeds in soil conservation, greening, and their medicinal properties. In addition to documentation, we raised awareness about the ecological importance of weeds and their medicinal properties through group discussions and meetings. I conducted a thorough literature search on the bioactive properties of the selected weed species and

verified their scientific properties against the latest publications from the scientific community. This study highlights the importance of weeds and their characteristics.
