$$R_5 = \sqrt{\frac{2 \times 3(c^p_2 + x_{et_2} e_{oe_2})K_{d_2}}{3(g^h_5 + x_{et_5} e_{he_5})}}, R_6 = \sqrt{\frac{2(c^p_1 + x_{et_1} e_{oe_1})K_{d_1}}{(g^h_6 + x_{et_6} e_{he_6})}}$$

Here, $R_5 \geq R_6$. It does not satisfy the local optimum.

Step 5: -

Now fix the constraints as $L(R_1, R_2, R_3, R_4, R_5, R_6, \lambda_1, \lambda_2, \lambda_3, \lambda_4) =$

$$\rho \left[TIC(R_{sp}) \right] - \lambda_1(R_2 - R_1) - \lambda_2(R_3 - R_2) - \lambda_3(R_4 - R_3) - \lambda_4(R_5 - R_4)$$

Vinola Elisabeth and Rexlin Jeyakumari

$$\frac{1}{12} \left\{ \begin{aligned} & \frac{(c^p_1 + x_{et_1} e_{oe_1})K_{d_1}}{R} + K_{d_1} (p^u_1 + x_{et_1} e_{pe_1}) + \frac{(g^h_1 + x_{et_1} e_{he_1})}{2} R \\ & +3 \frac{(c^p_2 + x_{et_2} e_{oe_2})K_{d_2}}{R} + K_{d_2} (p^u_2 + x_{et_2} e_{pe_2}) + \frac{(g^h_2 + x_{et_2} e_{he_2})}{2} R \\ & +2 \frac{(c^p_3 + x_{et_3} e_{oe_3})K_{d_3}}{R} + K_{d_3} (p^u_3 + x_{et_3} e_{pe_3}) + \frac{(g^h_3 + x_{et_3} e_{he_3})}{2} R \\ & +2 \frac{(c^p_4 + x_{et_4} e_{oe_4})K_{d_4}}{R} + K_{d_4} (p^u_4 + x_{et_4} e_{pe_4}) + \frac{(g^h_4 + x_{et_4} e_{he_4})}{2} R \\ & +3 \frac{(c^p_5 + x_{et_5} e_{oe_5})K_{d_5}}{R} + K_{d_5} (p^u_5 + x_{et_5} e_{pe_5}) + \frac{(g^h_5 + x_{et_5} e_{he_5})}{2} R \\ & + \frac{(c^p_6 + x_{et_6} e_{oe_6})K_{d_6}}{R} + K_{d_6} (p^u_6 + x_{et_6} e_{pe_6}) + \frac{(g^h_6 + x_{et_6} e_{he_6})}{2} R \end{aligned} \right\}$$

$$-\lambda_1(R_2 - R_1) - \lambda_2(R_3 - R_2) - \lambda_3(R_4 - R_3) - \lambda_4(R_5 - R_4) \dots\dots(8)$$

Now differentiating above equation with respect to $R_1, R_2, R_3, R_4, R_5, R_6, \lambda_1, \lambda_2, \lambda_3, \lambda_4$ and equate to zero, we get

$$R_1 = R_2 = R_3 = R_4 = R_5 = \sqrt{\frac{2 \left[(c^p_6 + x_{et_6} e_{oe_6})K_{d_6} + 3(c^p_5 + x_{et_5} e_{oe_5})K_{d_5} + 2(c^p_4 + x_{et_4} e_{oe_4})K_{d_4} + 2(c^p_3 + x_{et_3} e_{oe_3})K_{d_3} + 3(c^p_2 + x_{et_2} e_{oe_2})K_{d_2} \right]}{\left[(g^h_1 + x_{et_1} e_{he_1}) + 3(g^h_2 + x_{et_2} e_{he_2}) + 2(g^h_3 + x_{et_3} e_{he_3}) + 2(g^h_4 + x_{et_4} e_{he_4}) + 3(g^h_5 + x_{et_5} e_{he_5}) \right]}}$$

$$R_6 = \sqrt{\frac{2(c^p_1 + x_{et_1} e_{oe_1})K_{d_1}}{(g^h_6 + x_{et_6} e_{he_6})}}$$

Here, $R_5 \geq R_6$. It does not satisfy the local optimum.

Step 6: -

Now fix the constraints as $L(R_1, R_2, R_3, R_4, R_5, R_6, \lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5) =$

Vinola Elisabeth and Rexlin Jeyakumari

$$\rho \left[\overline{TIC}(R_{sp}) \right] - \lambda_1(R_2 - R_1) - \lambda_2(R_3 - R_2) - \lambda_3(R_4 - R_3) - \lambda_4(R_5 - R_4) - \lambda_5(R_6 - R_5)$$

$$\frac{1}{12} \left\{ \begin{aligned} & \left(\frac{(c^p_1 + x_{e_{t_1} o_{e_1}}) K_{d_1}}{R} + K_{d_1} (p^u_1 + x_{e_{t_1} p_{e_1}}) + \frac{(g^h_1 + x_{e_{t_1} h_{e_1}})}{2} R \right) \\ & + 3 \left(\frac{(c^p_2 + x_{e_{t_2} o_{e_2}}) K_{d_2}}{R} + K_{d_2} (p^u_2 + x_{e_{t_2} p_{e_2}}) + \frac{(g^h_2 + x_{e_{t_2} h_{e_2}})}{2} R \right) \\ & + 2 \left(\frac{(c^p_3 + x_{e_{t_3} o_{e_3}}) K_{d_3}}{R} + K_{d_3} (p^u_3 + x_{e_{t_3} p_{e_3}}) + \frac{(g^h_3 + x_{e_{t_3} h_{e_3}})}{2} R \right) \\ & + 2 \left(\frac{(c^p_4 + x_{e_{t_4} o_{e_4}}) K_{d_4}}{R} + K_{d_4} (p^u_4 + x_{e_{t_4} p_{e_4}}) + \frac{(g^h_4 + x_{e_{t_4} h_{e_4}})}{2} R \right) \\ & + 3 \left(\frac{(c^p_5 + x_{e_{t_5} o_{e_5}}) K_{d_5}}{R} + K_{d_5} (p^u_5 + x_{e_{t_5} p_{e_5}}) + \frac{(g^h_5 + x_{e_{t_5} h_{e_5}})}{2} R \right) \\ & + \left(\frac{(c^p_6 + x_{e_{t_6} o_{e_6}}) K_{d_6}}{R} + K_{d_6} (p^u_6 + x_{e_{t_6} p_{e_6}}) + \frac{(g^h_6 + x_{e_{t_6} h_{e_6}})}{2} R \right) \end{aligned} \right.$$

$$- \lambda_1(R_2 - R_1) - \lambda_2(R_3 - R_2) - \lambda_3(R_4 - R_3) - \lambda_4(R_5 - R_4) - \lambda_5(R_6 - R_5) \dots \dots (9)$$

Now differentiating above equation with respect to $R_1, R_2, R_3, R_4, R_5, R_6, \lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5$ and equate to zero, we get

$$R_1 = R_2 = R_3 = R_4 = R_5 = R_6 = R^* = \frac{\left[\begin{aligned} & (c^p_6 + x_{e_{t_6} o_{e_6}}) K_{d_6} + 3(c^p_5 + x_{e_{t_5} o_{e_5}}) K_{d_5} \\ & + 2(c^p_4 + x_{e_{t_4} o_{e_4}}) K_{d_4} + 2(c^p_3 + x_{e_{t_3} o_{e_3}}) K_{d_3} \\ & + 3(c^p_2 + x_{e_{t_2} o_{e_2}}) K_{d_2} + 2(c^p_1 + x_{e_{t_1} o_{e_1}}) K_{d_1} \end{aligned} \right]}{\left[\begin{aligned} & (g^h_1 + x_{e_{t_1} h_{e_1}}) + 3(g^h_2 + x_{e_{t_2} h_{e_2}}) \\ & + 2(g^h_3 + x_{e_{t_3} h_{e_3}}) + 2(g^h_4 + x_{e_{t_4} h_{e_4}}) \\ & + 3(g^h_5 + x_{e_{t_5} h_{e_5}}) + (g^h_6 + x_{e_{t_6} h_{e_6}}) \end{aligned} \right]}$$

Vinola Elisabeth and Rexlin Jeyakumari

$$R^* = \frac{\left[\begin{array}{l} (c_6^p + x_{e_6} e_{oe_6})K_{d_6} + 3(c_5^p + x_{e_5} e_{oe_5})K_{d_5} \\ + 2(c_4^p + x_{e_4} e_{oe_4})K_{d_4} + 2(c_3^p + x_{e_3} e_{oe_3})K_{d_3} \\ + 3(c_2^p + x_{e_2} e_{oe_2})K_{d_2} + 2(c_1^p + x_{e_1} e_{oe_1})K_{d_1} \end{array} \right]}{\left[\begin{array}{l} (g_1^h + x_{e_1} e_{he_1}) + 3(g_2^h + x_{e_2} e_{he_2}) \\ + 2(g_3^h + x_{e_3} e_{he_3}) + 2(g_4^h + x_{e_4} e_{he_4}) \\ + 3(g_5^h + x_{e_5} e_{he_5}) + (g_6^h + x_{e_6} e_{he_6}) \end{array} \right]} \dots\dots\dots(10)$$

Hence the equation (10) is the required equation of fuzzy optimal order quantity and equation (4) is the required fuzzy total cost

Numerical Example

Consider the values in the below data to represent the proposed sustainable fuzzy inventory model.

$c^p = 20$	$p^u = 6$	$K_d = 25$	$g^h = 1$
$e_{oe} = 30$	$e_{pe} = 2.5$	$e_{he} = 0.5$	$x_{et} = 1$

Solution in crisp model

By using the given values in the data, we obtain the optimal order quantity in the crisp sense as $R = 40.82$ and by using the equation (1) in this model, we obtain the Total cost in crisp sense as $TIC(R_{sp}) = 273.73$

Solution in Fuzzy model

By using the given values in the data, we obtain the optimal order quantity in the fuzzy senses as $R = 40.82$ and by using the equation (1) in this model, we obtain the Total cost in crisp sense as $TIC(R_{sp}) = 273.73$

CONCLUSION

The purpose of this research paper is to develop a method for determining lot size that addresses environmental impacts. It includes an inventory model with considering various cost parameters along with their emission rate and respective carbon tax price. This research work can be extended by future researchers and scholars, by considering some strategies and techniques to lower the emission rates. Because, the growing popularity of today’s industry sectors has been severely hindered by environmental challenges. Carbon tax policy charges companies by imposing an extra fee for emitted Co2. This financial stress propels businesses to embrace greener technologies, boost energy conservation, and explore alternate forms of energy with the goal to lower their their tax burdens. Main research motive of this proposed research work is to encourage other researchers to enhance this study to promote into better sustainability implications that impacts society and wellbeing of humankind and environment

ABSTRACT

Sustainability and ecological sensibility have become a new discourse through which companies have marketed their products since the last decade. While companies have been using advertisements and scientific green washing techniques to position themselves effectively in the market, there has always been a gap between their environmental strategies and corporate strategies. This gap stemmed from an ignorance of the component of 'people' out of the 7 P's of marketing. At a time when the world is shifting to a future that is sustainable, it is important that the business world also follows suit, bridging this gap. Hence, there is a need to reinvent existing green marketing strategies holistically that integrate both sustainability and profitability. This research paper aims to analyse the case studies of two startups - Sunbird and Phool - to look at their green marketing strategies, which focus largely on humanities. Both these startups came into their respective industries, identifying relevant ecological concerns and working towards a sustainable world while delivering high-quality products and making profits. Using the Theory of Disruptive Innovation, the paper explores how, as new entrants, they have reinvented green marketing strategies that have given them a place of their own in the dynamic business environment. Their usage of the trope of storytelling and pitching in the nuances of the circular economy that they created have been pivotal in their successful business journey. The paper looks at how they differentiate themselves from the rest of the industry by identifying the similarities in their strategies. Furthermore, the paper will also enquire about the potential of these marketing strategies to become the pioneer in initiating a larger ecologically sensitive marketing paradigm in India.

Keywords: Green marketing, Storytelling, Circular economy, Sustainability, Woman empowerment, Social impact.

Sayant Vijay *et al.*,

INTRODUCTION

In a dynamic business environment that envisages an integrative approach wherein sustainability and profitability go hand in hand, startups must consistently re-imagine their marketing strategies. As companies and consumers are becoming more aware of the environmental concerns that are looming large, there is an acknowledgement of the need to pursue sustainable business practices (White 20). Green Marketing has become a popular alternative with a focus on the environmental imperative and self-interests of businesses, marketers and customers. The Indian economy is going through a transition, which is very well seen in the country's GDP and PPI. The International Monetary Fund (IMF) has predicted that India's GDP will grow by 6.8 per cent in FY 2022/23 and by 6.1 per cent in FY 2023/24. India's increasing production and exports have raised expectations about its potential to reshape the global order and emerge as one of the largest global markets for a wide range of products and services. These economic reforms and liberalisation have made many robust changes in the country's business environment, with more and more private players coming into the market and providing significant contributions to the world market. This has also resulted in a modification of the existing business environment. Changes in India's business environment can be traced back to economic liberalisation, digital transformation, and the present-day shift towards renewable energy, eco-friendly products, and biodegradable products. Out of these changes, the government ban on identified single-use plastic items has drastically impacted the country's business environment. India is the fifth-highest generator of plastic waste in the world. The government indeed recognised the adverse effect of littered single-use plastic items on terrestrial and aquatic ecosystems, and they took the measure to ban many of the single-use plastic items to tackle the environmental challenges faced by the country and the world.

In 2019, the Indian government banned six single-use plastic items: plastic bags, cups, plates, small bottles, straws, and certain types of sachets. The ban was initially introduced in 129 cities and towns and was later extended to the entire country. This has resulted in more companies coming up with environment-friendly alternatives and a change in the overall business environment, which was limited to plastic products. Consumer behaviour towards the ban on single-use plastic in India has been positive, as there is a growing trend towards more sustainable practices. One of the primary reasons for this change in consumer behaviour is the increasing awareness of the negative impact of single-use plastic on the environment. This information is disseminated mainly by the government through television, social media, and other platforms; consumers are becoming more conscious of the need to reduce their consumption of single-use plastic products through Green Marketing. Green marketing is an encompassing marketing approach that synergistically amalgamates various strategic activities with the overarching goal of expanding market share, while concurrently offering environmentally conscious products and services. Apart from traditional marketing, green marketing can help with several issues like wastage of water, recycling of wastes and air pollution due to toxic substances. Due to the enlightenment of all these issues nowadays, even producers and consumers prefer more eco-friendly products for the betterment of the ecosystem and their health.

The success of green marketing is that consumers view these green products as the most appealing and safe. So, green marketing demands the application of sound marketing principles to be a trustworthy product. Consumer value positioning, calibrating consumer knowledge, and credibility of product claims are effective marketing and producing tools for green products in India's present scenario of green marketing. Even though India has made a lot of attempts in the area of green marketing, it is still in its infancy. Green Marketing and Traditional Marketing have varying philosophies. The parties involved in exchange for traditional marketing are the firm and the customer, whereas green marketing includes adding to the environment. In terms of objectives, Green Marketing has to minimise ecological impact. A certain amount of social responsibility is involved in green marketing and designing beyond legal frameworks to sustain the environment. The concept of Circular Economy (CE) originated in the 1970s with the goal of decreasing the use of resources in industrial production. However, it has the potential to be applied to any kind of resource. By utilizing the natural cycle model, CE aims to make human activities more sustainable, proposing a shift from the current "extraction-production-disposal" model of the linear economy (LE) that is widely used in the industrial sector. This concept has gained acceptance to address the issue of sustainability in public

Sayant Vijay et al.,

policies in governments such as those of the European Union (House of Commons, 2014) and has been implemented as a national development strategy in China (Arruda, et al, 2021). In terms of marketing strategies, two models remain at the forefront. The first marketing mix comprises the 7Ps (product, price, promotion, place, process, physical evidence, and people) put forward by Gordon in 2012. Then there are also the 4Ps developed by Booms and Bitner (1981), a framework developed from McCarthy's 1960 framework. The 4Ps framework includes product, price, place and promotion (Eniezan et al. 2016). Notwithstanding the high dissatisfaction with the 4Ps, their framework is considered the most significant for introductory and consumer marketing (Eniezan et al. 2016). There are certain disadvantages to the 4Ps where it lacks people, participants and participants and processes. There is also a lack of connection/integration between the variables (Goi, 2009).

The paper will look at two startups - Sunbird and Phool - that have adopted environmentally sensible practices to develop and market their products. Phool is an Indian startup founded in 2017 that makes incense sticks and vermicompost out of used flowers from the temple. They have made an impactful intervention from an ecological perspective by identifying the menace caused by dumping pesticide-laden flowers into water bodies. The dumped flowers are collected and then made into charcoal-free incense sticks that are organic and biodegradable. Their 'flower cycling' technology is managed by a group of women called 'flower cyclers' who have now assured a healthy livelihood. Today, they employ 73 women who have worked towards recycling more than 11,060 tons of flowers since its inception. Phool has both B2C and B2B businesses, wherein the former happens through their e-commerce website. They continue to focus on R&D to develop nuanced methods to produce biodegradable products like bio leather, organic vermicompost and soaps. Sunbird Straws is a multi-layered biodegradable straw made of fallen, dry coconut leaves. This first-of-its-kind endeavour has also developed machinery to cut and process the straws from dry coconut leaves collected and cleaned off its midrib. These machines are now capable of making a straw in 1.5 seconds. These straws have the edge over paper straws that get soggy and are not eco-friendly since they are made from cut trees and processed using chemicals. These biodegradable straws, in that sense, decompose themselves like a natural dry coconut leaf. While focussing on the ecological and social impact they impart, Sunbird has also not derailed from its commercial journey either. They aim to produce 15 lakh straws monthly within the first half of 2023. The startup employs 86 women from rural areas who take care of most of the processes, including sourcing, sorting, processing and packaging. These companies have gone beyond the narrow categories of eco-friendly consumption to go beyond product development and include ecologically sensitive marketing strategies and production processes. Phool and Sunbird have played a seminal role in synthesising a circular economy model addressing a previously overlooked ecological concern through a holistic approach founded upon environmental sustainability.

Through an extensive study of the functionality of the two startups, the paper aims to curate the green marketing strategies of Sunbird and Phool in a dynamic industry 4.0 scenario wherein ecological sensibility, commercial interests and immersive customer experience should go hand in hand. The case study of Sunbird and Phool provides an excellent example of how green marketing can be reinvented for sustainable and innovative management practices in a country like India, where the transition to sustainable living practices remains a luxury. Both these companies have successfully differentiated themselves in their respective markets by emphasising their commitment to sustainability and innovative management practices. By contextualising green marketing within the discourse of sustainable marketing practices through the functionalities of Sunbird and Phool, the paper will look at how they have re-imagined their marketing strategies in a sustainable manner and how other companies can adopt and adapt to similar practices. The 7Ps of marketing have the disadvantage of being too long, making it more complicated. Also, the 4Ps have limited but better reliability as they can adapt quickly to various problems. 7P has an essential inclusion that the 4Ps neglect – People. People have become a significant USP in the emergence of Sunbird and Phool. The storytelling involving the people and the product features has reinvented the process of Green Marketing. The case study will help locate People's roles in sustainable and innovative green marketing and how improving the circular economy can benefit our society in the long run. The paper will explore these companies' key strategies to reinvent green marketing for a sustainable future. If the reinvention of the methods is innovative, how are Sunbird and Phool contributing to the Circular Economy? This paper will also investigate the approaches employed by Phool and Sunbird towards green marketing and the way in which they contribute to the circular economy. Disruptive

**Sayant Vijay et al.,**

Innovation Theory curated by Clayton Christensen in the 1990s discusses the ways in which new entrants in a market can disrupt its ecosystem by starting from the bottom and then moving upwards (Christensen 1997). In this context of the research, disruptive innovations are considered as a process and not as a product or service. Disruptive innovations are focussed on the ways in which firms create, deliver and appropriate value. The theory explains the patterns of entrants in a dynamic business environment. It looks at the ways in which new entrants in the market focus on creating new market segments by operating in value networks that are contextual to customer needs. Thus an innovation that is an improvement along the value system that has been historically valued by the customers will be more sustainable and successful. However, disruptive innovations do not cater to the large customer base of the established companies which creates an asymmetry between the new entrants and incumbents. It is in this space that startups like Sunbird and Phool pitch themselves. In that way, Christensen argues that new entrants will improve their performance over time superseding the incumbents and slowly capturing the whole market segment (Christensen and Rosenbloom 1995). The paper, by employing the nuances of disruptive innovation theory, attempts to understand how Phool and Sunbird contribute to the circular economy through their strategies of green marketing. The processes adapted by the new entrants are never perceived as an immediate threat to established companies but have the potential to climb up the market and create disruptive changes. By looking at how Sunbird and Phool reinvent the existing marketing strategies and slowly create an impact amongst the customers, the disruptive innovation theory will throw light on the ways in which they can tackle their competitors and bring their marketing practices to the forefront in their respective domains.

Reinventing Marketing Strategies - A Move Away from Negative Marketing

Negative marketing has been one of the key marketing strategies used by companies all over the world to promote their brand. Negative marketing, also known as attack advertising or competitive advertising, involves directly criticising or attacking a product or company to make your own brand appear superior. This strategy has been employed by both start-ups as well as established companies through various means such as advertising, social media campaigns and public relations. There are two subtypes of negative marketing, attack and contrast. The attack focuses on the negative sides of the competitor's offerings, and the contrast focuses on the positive sides of your offering and establishes the gap. This way is believed to be a more subtle way which would still highlight what the competitors lack. Wilkie defines comparison advertising as a form of advertising that compares two or more brands that sell the same kind of product or service class. They make comparisons based on their service attributes and product lines (Wilkie 1975). The strategy of using Negative Marketing or comparative advertising to promote a product is something that has been around for a very long time. Especially now, with the influence of social media and other advertising platforms, negative marketing has become one of the easiest ways to push a product by comparing it with the cons of a competitor's product. While this can be effective in generating attention and creating a buzz, it can also backfire and damage a brand's reputation. Typically, larger brands find it easier to use negative marketing against their competition since they are already well-known. Therefore, the potential reward outweighs the risk of highlighting value propositions. It is argued that the comparison ad has the ability to ease the consumer's role of evaluating and deciding on one brand against the other based on their performance; better places products or "superior" products are usually benefitted from the early use of comparison advertising which inadvertently stimulate improvements in the product by its competitors which are however considered "below par" (Wilkie 1975). Phool and Sunbird are two companies that have employed different ways of marketing and never used negative marketing to push their products. Without comparing their product to that of the competitors or by attacking advertising, Phool and Sunbird have successfully made their entry into sustainable and innovative market practices. They have employed different green marketing techniques, which focus largely on the idea behind the startup, goal and vision. One of the most unique and effective green marketing strategies used by these companies is the storytelling method.

Nascent Approaches in Green Marketing Strategies - A Reinvention Through Storytelling

Green marketing has become an integral part of business strategies ever since the growing concerns on environmental sustainability and climate change at a global level. It was aimed at fostering cleaner production and encouraging sustainable consumption (Nidumolu et al 2009). Over the past three decades, companies have been

**Sayant Vijay et al.,**

trying to develop products that are environmentally sustainable and market them by creating awareness about the ecological impact that their products can have. Considering the long history of green marketing as a whole and sustainable product in particular, Sunbird and Phool are new entrants in the market. However, their green marketing strategies were not only unique but were also offering a sustainable future which qualifies these strategies to be capable of being the future leaders in the industry. While green marketing is generally regarded as the “integration of environmental sustainability into marketing”, it can be seen that these two startups have gone beyond these definitions to reinvent existing practices (Dandelico and Vocellelli 2017). Green marketing strategies for a long time have been an unending struggle to find a balance between environmental sensitivity and corporate strategies. Companies have been trying to integrate environmental strategies that are capable of bringing in competitive merit and profitability into their midst (Leonidou et al 2013). Due to the increasing tendency to greenwash the companies’ marketing strategies, they have developed superficial marketing strategies. The traditional green marketing strategies have followed the 4Ps format. They are product, price, promotion and place. However, in the 7Ps of marketing, People are an important element. Hence, there has always been a gap between environmental strategies and corporate strategies. It is in this gap that companies like Sunbird and Phool make a difference through their integrated and reinvented marketing strategies. Both companies have identified an untapped segment of the existing market so as to pitch in their unique selling proposition. Unlike the regular companies in their industry, they have reinvented the existing green marketing strategies to fit within their Unique Selling Propositions. Sunbird and Phool’s marketing strategy thrives on two things - storytelling and circular economy. They have been able to create a unique story with respect to their product, production and consumption. They have weaved their startup story into their marketing strategy to pitch themselves to their customers. The storytelling aims to incorporate the notion of People from the 7Ps to establish a new model that reinvents the current aspects of green marketing.

Sunbird is the world’s first premium multi-layered drinking straw, which is made from dried coconuts. Unlike the paper, steel and bamboo counterparts, Sunbird Straws has antifungal and hydrophobic outer and inner walls, which makes them unique and truly eco-friendly. Their straws can be used in cold beverages for 3 hours and have a shelf life of 9 months. With a production rate of 2 lakh straws every month, they have already replaced 0.5 million plastic straws already and prevented 52 kg of Carbon Monoxide from entering the environment. Sunbird aims to produce 15 lakh straws per month in 2023. They have nine production units in total that span the rural areas of Kerala, Karnataka, and Tamilnadu, which are run predominantly by native women. These women are mostly from abusive households (from the interview with the founder). Currently, they have employed 86 women at various stages of their production. The entire process, from the collection of raw materials to cleaning and processing, is sustainably done with machines made by the company itself. They have been able to retain all their employees so far. Earning a revenue of Rs 18 crore, Sunbird aims to further increase its production to 10 lakh straws per day and employ 1000 women. Table 1 shows the social impact made by Sunbird so far. The company used the social impact that they have created over the years to pitch in their product along with their quality.

Despite being new entrants in their respective markets they were able to make an impact by using the storytelling trope to put forth the larger social impact that they are making by employing women, using eco-friendly raw materials and sustaining families in the rural areas. As far as Phool is concerned, they were able to identify a severe menace that was unrecognised for a long time. Floral offerings are a part of the majority of Indian culture. The environmental concerns invited by the dumping of pesticide-laden flowers into water bodies have been going unnoticed until the founders identified them during their visit to various pilgrimage sites. Since its inception, Phool has been able to make a significant impact both environmentally and commercially. They have become the world's first profitable and lean solutions company that has solved the problem of temple waste. Through their flower cycling technology, they make handcrafted charcoal-free incense sticks and organic and biodegradable packing materials. With the profit made, they have also educated 19 students so far. Their entire business production employs 73 women on a full-time basis which has improved the livelihood of 73 families by at least sixfold. Their relentless efforts have resulted in the upcycling of over 2500 metric tons of floral waste that has removed over 275 kilograms of pesticide residue from river Ganga. Table 2 summarises the social impact made by Phool so far. They were creating a circular economy wherein they not only created a livelihood for a group of people but also pioneered a culture that

Sayant Vijay et al.,

encourages the reusing of materials that were hitherto discarded as waste. They take care to minimise unnecessary wastage and cut the use of plastic. While marketing their products, Phool and Sunbird put forth the social impact that they have been creating by empowering women in their businesses through their storytelling strategies. They carefully tailor their stories to align with the value systems that have been appreciated by society at large. In the light of the Theory of Innovative Disruption, these sustainable innovations are the strategies that not only got these companies their entry into the market but also will help them climb upward slowly. By pitching in their innocuousness with the livelihood that they provide to their employees, their startup story in itself becomes their marketing strategy. Through the interviews conducted with the CEOs of respective startups, it was inferred that a lot of people buy their products because of the social impact that their story creates. At the same time, they also are careful about maintaining high quality for their products which will ensure profitability that goes beyond the social impact that they are creating through storytelling. With this, the notion of People from the 7Ps gets incorporated with the 4Ps to form a new model that reinvents green marketing strategies. The disruptive innovation theory looks for strategies that are capable of changing existing competitive patterns. The patterns that Sunbird and Phool put forth are capable of this disruption in the future is what their success story is trying to say. In a dynamic business environment that is focusing relentlessly on sustainability, the marketing strategies of Phool and Sunbird have the capability of being mainstream strategies.

Green Marketing and Circular Economy aiding a country's development

The reinvention of Green Marketing strategies has increased the consumption of more sustainable and eco-friendly products. Circular Economy (CE), as a fundamental idea and practice looks forward to minimising waste and increasing the utility and lifespan of materials along side preserving its value (Lehmann et al. 2022). The Circular Economy is also a pivotal tool in overcoming the menace of climate change and pollution. Jansson (2016) posits that by mending and remanufacturing, companies can bring down the necessity of new primary raw materials, improve the lifespan of products and reduce the emission of CO₂ and other toxins. This is where Sunbird and Phool prioritise the sustainability and prosperous ecological life that stems from the circular economy. On the other hand, the reinvention of Green Marketing strategies not only dwells on the impact it can have on decreasing waste and CO₂ emissions and sustaining a prosperous ecological life. It has focused on the impact and lives of People contributing to the sustenance of our environment. One of the most neglected aspects of the 4Ps is the People, an element in the 7Ps framework. Phool and Sunbird have utilised the importance of the people. They aim to uplift people from backward societies through their ecologically beneficial products. Their business enables the companies to support the workforce, people from backward areas of society, to move forward economically and in other spheres of life.

One particular way they have contributed to the betterment of the people is through an added emphasis on storytelling. The marketing aims to convince the consumers to deviate from the usual products, focusing on ecologically safe products and their impact on the workforce behind nature-friendly products. The workforce for these products are women from lower class and abusive households and the companies try to uplift them to succeed in all spheres of life. The impact brought towards the lives of these women, their families and sustainable products indicates a heartwarming but impactful story that can benefit the country in their ecological and economic concerns. When people become the USP, and the product can solve many ecological problems, consumers have shown no reluctance to shift towards a more sustainable option. The social media engagements and the story behind Sunbird and Phool shed light on their social impact on our country. Employing women and uplifting them from being dependent on their husbands is a small start to uplifting a backward community or region. The support the backward class people can benefit from if consumers shift from harmful products to sustainable products that benefit our environment. The model of creating a story worth telling around a product that creates jobs, reduces pollution, and is recyclable could shift the direction of any country. The United Nations Industrial Development Organisation, for over 50 years, has worked towards enabling countries for a circular economy for sustainable development. According to the Ellen MacArthur Foundation, by 2025, circular business models could generate about \$1 trillion per year of materials cost savings. This can certainly be an effective model for a country like India. The invaluable impact of Circular Economy and Green Marketing is that in the possible ways to move towards a resource-efficient production model and create environmentally friendly products, it also provided a pathway to improve the social

Sayant Vijay et al.,

conditions of life. Effective utilisation of Circular Economy and Green Marketing can lead to shared prosperity. Poverty eradication and creating employment opportunities for lower-class women can drive the development of a country like India immensely. Phool and Sunbird have shown that it is working. They employ women from backward communities, providing them with regular incomes to advance in all spheres of life. It is not just safeguarding our environment but also looking after its inhabitants. The storytelling involved with Sunbird and Phool and their impact on social life has paved the way for the reinvention of green marketing to move towards a sustainable and effective circular economy.

CONCLUSION

Sunbird and Phool have demonstrated an innovative and holistic approach to business that balances both sustainability and profitability. By creating environmentally-friendly products, they have addressed the urgent need for sustainable solutions and pioneered a circular economy model to combat the ecological and economic problems that persist. Their marketing strategy is also noteworthy, as they prioritise the workforce and emphasise the social impact of their products. Providing their workforce that comprises women from lower classes, and abusive homes with substantial income primarily helps the people get ahead in life. The companies also handle the education of their kids and other needs. Using the impact brought in through the business of ecologically friendly products becomes the reinvention of green marketing strategy to move towards a more sustainable business environment. Sunbird and Phool have not used 'negative marketing' to market their product. Altogether, they have completely reinvented the green marketing strategies, where neglect towards People from the 4Ps has been utilised in the new model. This approach benefits the environment and supports women from disadvantaged backgrounds, which is a commendable social initiative. In addition, their circular economy model has the potential to generate significant revenue for India and promote sustainable development. Ellen MacArthur Foundation states that a productive Circular Economy can generate trillions of revenue for a country. Sunbird and Phool serve as inspiring examples of how businesses can thrive while prioritising sustainability and social responsibility. Their success is not only a model to protect the environment but more beneficial to produce a sustainable model of the economy for our country.

ABSTRACT

Increased muscular strength has been shown to improve performance in general sport skills like jumping, sprinting, and direction-changing, according to a large body of studies. According to more studies, athletes who are stronger perform better when performing tasks unique to their sport. One's performance in a variety of sports, including basketball, volleyball, and swimming, will increase if your biceps are strong. Arm curls are a great exercise to add to one's fitness regimen if one wants to succeed in sports that need upper body strength and power. The purpose of the study was to quantify arm strength performance in response to high-intensity interval training and moderate-intensity continuous training among college women athletes. Forty-five (N=45) women athletes were selected as subjects. They were divided randomly into three groups of fifteen each i.e., (n=15) Group-I underwent high-intensity interval training (HIIT), Group-II underwent moderate-intensity continuous training (MICT) and Group-III acted as control group (CG). The training period was limited to three days per week for twelve weeks. Arm strength was selected as dependent variable and it was measured through push-ups test. All the subjects were tested prior to and immediately after the experimental period on the selected dependent variable. The data obtained from the experimental groups and control group before and after the experimental period were statistically analyzed with Analysis of covariance (ANCOVA). Whenever the 'F' ratio for adjusted posttest means was found to be significant, the Scheffe's Post hoc test was applied to determine the paired mean differences. The level of confidence was fixed at 0.05 level for all the cases. High-intensity interval training (HIIT) was found to be better than the Moderate-intensity continuous training (MICT) and Control group in developing arm strength.

INTRODUCTION

A form of exercise known as interval training involves a sequence of high-intensity sessions separated by rest or relaxation periods. While the recovery intervals entail lower-intensity activity, the high-intensity periods are often at or near anaerobic exercise[1]. Interval training is simply a type of exercise where a rest period or recovery time is allowed in between two repetitions of a low to high intensity activity. In general, interval training entails working out at progressively higher intensities (from low to high), separated by rest intervals[2]. The average race pace is multiplied by four seconds to estimate the exercise intensity. This is the maximum amount of exercise time that can be manipulated, and the rest period has an adequate impact on the strength of the training stimulus[3]. Six intensity zones, including Super maximum (>100), maximum (90-100), Heavy (80-90), Medium (70-80), Low (50-70), and Very Low (50), can be used to categorize the intensity[4]. Short bursts of intensive activity are interspersed with less strenuous recovery intervals in a form of exercise known as high-intensity interval training (HIIT). It is also sometimes referred to as sprint interval training (SIT), high-intensity intermittent exercise (HIIE), or Tabata (after the professor who investigated this form of training in Olympic speed skaters)[5]. To improve motor fitness components, moderate-intensity continuous training techniques and high-intensity interval training are frequently advised. Continuous or long, slow distance training entails steady-paced, extended exercise at either low or high aerobic intensity, typically between 60 and 80% of one's maximum oxygen uptake (VO₂max). Continuous exercise has been shown to enhance plasma volume, capillary density, oxidative enzyme activity, and VO₂max in untrained people[6].

METHODS

Participants

Forty-five (N=45) women athletes studying various arts and science colleges in Coimbatore District, Tamilnadu, India were selected randomly as subjects. The age, body mass and standing body height of the subjects was ranged between 17 to 20 years, 50 to 55 kilograms, 1.46 to 1.62 meters respectively.

Study Design

The subjects were divided randomly into three groups of fifteen each i.e., (n=15) Group-I trained high-intensity interval training (HIIT), Group-II trained moderate-intensity continuous training (MICT) and Group-III acted as Control (CG). The subjects performed their training interventions for three days per week for twelve weeks. The control group did not entertain any specific type of activity except the college curriculum.

Data Collection

Arm strength was selected as dependent variables and it was measured through push-ups test[®]. The data on Arm strength was collected from the participants before and after the training interventions.

Statistics

The data collected from the experimental groups and control group on prior and after training interventions on arm strength was statistically examined by analysis of covariance (ANCOVA) was used to determine differences, if any among the adjusted post test means on selected criterion variables separately. Whenever they obtained f-ratio value was significant the Scheffe's test was applied as post hoc test to determine the paired mean differences, if any. In all the cases 0.05 level of significance was fixed.

RESULTS

Arm Strength

The analysis of covariance on arm strength of the pre, post, and adjusted test scores of HIIT group, MICT group and Control group have been analyzed and presented in table – 1. The table-1 shows that the pre-test means values of arm strength for HIIT, MICT and CG are 4.63, 5.00 and 5.27 respectively. The obtained 'F' ratio of 0.45 for the pretest

81433

**Lakshmi Prabha and John Parthiban**

mean is lesser than the table value of 3.22 for degrees of freedom 2 and 42 required for significance at 0.05 level of confidence on arm strength. The posttest means values of arm strength for HIIT, MICT and CG are 7.47, 6.67 and 5.33 respectively. The obtained 'F' ratio of 9.84 for the posttest mean is greater than the table value of 3.22 for degrees of freedom 2 and 42 required for significance at 0.05 level of confidence on arm strength. The adjusted posttest means values of arm strength for HIIT, MICT and CG are 7.60, 6.74 and 5.13 respectively. The obtained 'F' ratio of 34.01 for the adjusted posttest mean is greater than the table value of 3.23 for degrees of freedom 2 and 41 required for significance at 0.05 level of confidence on arm strength. The analysis of the study indicated that there was a significant difference between the adjusted post-test means of HIIT, MICT and CG on arm strength..The pre and posttest mean value of experimental groups on arm strength his graphically represented in the Figure -1. Pair wise comparisons of Scheffe's Post Hoc test results are presented in table – 2. Table-2 shows that the mean difference values of HIIT and MICT, HIIT and CG, MICT and CG are 0.87, 2.48 and 1.61 respectively, which are greater than the confidence interval value of 0.77 on Arm Strength at 0.05 level of confidence. The results of the study showed that there was a significant difference between HIIT and MICT, HIIT and CG, MICT and CG. The above data also reveal that HIIT is better than MICT and CG.The adjusted posttest mean value of experimental groups on arm strength is graphically represented in the Figure -2.

DISCUSSION ON FINDINGS

The results of the study indicate that all the experimental groups namely High-Intensity Interval Training and Moderate-Intensity Continuous Training have significantly improved in arm strength. Further the results of the study showed control group showed there is no significant improvement. It is also found that the improvement effected arm strength by HIIT is greater when compared to the effects of MICT and CG.

CONCLUSIONS

Significant differences were found between High-Intensity Interval training, Moderate-Intensity Continuous Training and Control group in arm strength. The Experimental groups namely, High-Intensity Interval training (HIIT) group, and Moderate-Intensity Continuous Training (MICT) group had significantly improved in arm strength. The High-Intensity Interval training (HIIT) group was found to be better than the Moderate-Intensity Continuous Training (MICT) group and Control group in the performance of arm strength.

ABSTRACT

The article explores the intranasal route of drug administration as an emerging and promising method, garnering increasing attention in recent years. Focusing on the advantages of direct nose-to-brain targeting, the paper discusses how intranasal delivery offers improved bioavailability, circumvents invasive techniques, and provides a non-invasive approach to crossing the blood-brain barrier (BBB). Addressing the challenges in treating major brain diseases, including Alzheimer's, schizophrenia, and Parkinson's, the article emphasizes the potential of intranasal administration to enhance central nervous system (CNS) bioavailability. The anatomical aspects of the nasal cavity, comprising vestibular, respiratory, and olfactory regions, are detailed to underscore the unique features supporting effective drug transport. Mechanisms of nose-to-brain transport, including the paracellular and transcellular pathways, are explored, emphasizing the suitability of lipophilic medications for effective absorption. The article delves into the realm of nasal nanotechnology, highlighting nanocarriers such as solid lipid nanoparticles, liposomes, polymeric nanoparticles, and nanoemulsions. These carriers are discussed in the context of increasing residence time, mucoadhesive strength, and viscosity of nasal mucosa, as well as their interaction with olfactory nerve fibers and BBB endothelial cells. Novel nanotechnologies, especially lipid-based nanoparticles like solid lipid nanoparticles (SLN) and nanostructured lipid carriers (NLC), are presented as effective solutions to overcome limitations in drug delivery systems. Recent advances in drug delivery, including antibodies-mediated delivery, gene vectors, and stem cell therapies, are also discussed. The article concludes by highlighting the benefits of intranasal administration, including enhanced therapeutic efficacy, improved targeting capabilities, and increased bioavailability. Despite the potential drawbacks, the growing investment by pharmaceutical companies underscores the significance of intranasal medication in the global pharmaceutical market. The study suggests that SLN and NLC

81436

Galanki Vasantha *et al.*,

represent more efficient options for intranasal drug administration, presenting a promising future for the treatment of neurodegenerative diseases.

Keywords: Intranasal administration, non - invasive, nanoparticles, Blood - brain - barrier, neurodegenerative disorders.

INTRODUCTION

Drug administration by parenteral and oral routes has been investigated in recent years. Here, we discuss the intranasal route of administration, which has drawn increasing attention lately. New technology and nasal formulations are introduced to reduce negative effects [1]. It is the simplest method—nose to brain targeting, which has a better bioavailability and is direct brain targeting without intrusive techniques or blood stream clearance. As a result, we may conclude that intranasal administration is non-invasive and BBB-passing. It might perhaps make medications more CNS bioavailable. Tight connections between its endothelial cells when it passes the BBB can stop chemicals from leaking from the blood into the brain [2]. Major brain diseases like Alzheimer's, schizophrenia, and Parkinson's disease lack a specific medication that can be taken in severe situations, which can result in death. Not even brain illnesses have been fully elucidated yet [3]. The brain illnesses have the symptoms such as oxidative stress, mental toxicity, blood pressure etc. The primary cause of the oxidative stress in this case is the overproduction of reactive oxygen species. Thus, it is revealed that antioxidant therapy is not permitted in the management of neurodegenerative diseases (NDD) [4]. Studies conducted in vitro as well as in vivo have surrounded it. When compared to other carrier particles, lipid nanoparticles can enhance nose-to-brain drug transport even more quickly due to their biodegradability [5], bioacceptability, and quick brain absorption. The intranasal delivery of medications may be increased by the nanosized carrier particles in comparison to the drug solutions [6].

ANATOMY

Anatomically speaking, the nasal cavity is located between the roof of the mouth and the base of the skull. The structure is made up of two identical cavities that are separated by the septum, which is located along the mid-sagittal plane [7]. The mucosa-lined cavities have a combined area of approximately 150 centimeters. It is further separated into three regions:

1. Vestibular area
2. The breathing area
3. Area of smell

VESTIBULAR REGION

Also referred to as the nasal vestibule, this is the initial region. It is 0.6 centimeters in area. The vestibular area is shielded by stratified squamous and keratinized epithelial cells with sebaceous glands. The nasal hairs in this area, sometimes referred to as vibrissae^s, filter the particles that are inhaled.

RESPIRATORY REGION

Conchae is another name for it. It is vascular and covers the greatest area, around 130 cm². It is the cavity, which is separated into inferior, middle, and superior cavities. The lateral wall is where the cavities are projected or originated from [9]. The pseudostratified epithelium in this respiratory area is dominated by four cell types. They are non-ciliated columnar cells, basal cells, ciliated columnar cells, and goblet cells [10]. Sebaceous and mucous glands are also included. The goblet cells, which are primarily in charge of mucus secretion, are part of the respiratory region's major physiology. Basal cells are found on the basal membrane. By retaining moisture and promoting active transport, these cells aid in preventing mucosal drying. It is made up of cilia, which are in charge of increasing the respiratory surface area. A complex mixture, comprising 95% water, 2% mucin, 1% salts, and other proteins such as albumin, lysozymes, immunoglobulins, 1% lactoferrin, and <1% lipids, make up the nasal secretion [11].

Galanki Vasantha et al.,

OLFACTORY REGION

The olfactory region, which includes the neuroepithelium, is the only area of the central nervous system that is in direct contact with the outside world. Through the BBB, the medication is absorbed and makes its way to the brain. Similar to the respiratory region, it is made up of several olfactory cells and pseudostratified epithelium[12].

MECHANISM OF NOSE - TO - BRAIN TRANSPORT

Molecules travel from the nasal cavity to the cerebral cortex via two channels as part of the transport process. The chemicals spread throughout the brain after being given to the pons and cerebrum[13].

- Paracellular pathway
- Transcellular pathway

PARACELLULAR PATHWAY

The paracellular route, which passes through the nasal epithelium's tight connections, carries hydrophilic medications. This mechanism is the first one[14]. For several medications, a molecular weight larger than 1000Da was associated with low bioavailability. For effective absorption, lipophilic medications such as fentanyl, progesterone, pentazocine, and propranolol are utilized[15].

TRANSCELLULAR PATHWAY

That is the other mechanism. Nasal administration uses the transcellular pathway, which involves active transport by peptides and glycoproteins, to transfer nasal epithelium. The lipophilic medications will be transported here. Moreover, for the medications to enter the brain, they must pass through the blood-brain barrier [16].

NANOPARTICULATE CNS DELIVERY THROUGH NASAL ROUTE

Much effort has been paid to nasal nanotechnology over the last few decades. Solid lipid nanoparticles, liposomes, polymeric nanoparticles, and nanoemulsions are examples of nanocarriers used in nasal nanotechnology that are effective in delivering drug delivery systems[17]. When opposed to intranasal delivery, new nanotechnology often offers a higher flow rate, meaning that it can more easily cross the blood-brain barrier and get to the brain. The poorly distributed medication will be introduced into the nanocarrier-based particles and come into touch with three distinct regions[18].

- 1) The residence time, mucoadhesive strength, and viscosity of the nasal mucosa all increase.
- 2) Olfactory nerve fibers that facilitate drug transfer from the nasal cavity to the central nervous system.
- 3) The medication will pass the blood-brain barrier by interacting with endothelial cells in the BBB and demonstrating its therapeutic benefits for brain disorders. The tiny size of the nanocarrier molecules allows them to quickly traverse the blood-brain barrier and enter brain-to-nose pathways. Different targeting ligands found in nanocarrier-based systems bind to particular receptors to exhibit therapeutic benefits as well as an improvement in brain specificity and affinity[19]. Nasal nanotechnology is significantly more effective and safe to use[20].

NOVEL NANOTECHNOLOGY

NANOPARTICLES

Nowadays, researchers are investigating the use of nanoparticulate systems for intranasal administration as a more effective drug or vaccine delivery method[21]. Nanoparticles are within the nanosize range in terms of size. Similar to microparticles, nanoparticles also enhance medication solubility and metabolism. When compared to conventional drug delivery, instead of nanoparticulate drug delivery, the bioavailability of the former is superior due to its reduced size range of particles. Polymers and lipids, or occasionally both, are the building blocks of nanoparticles because they form controlled nanostructures and enable prolonged and regulated drug release[23].

LIPID BASED NANOPARTICLES:

Solid matrix structures known as lipid nanoparticles were created as an alternative to polymeric, nanogel, and nanoemulsion nanoparticles[24]. Similar to nanoparticles, the size range of SLN is likewise extremely small, ranging

**Galanki Vasantha et al.,**

from 1 to 1000 nm[25]. Since the solid lipid nanoparticles' surface is made up of physiological lipids and surfactants, they are usually regarded as safe for the body to consume. Triglycerides, monoglycerides, diglycerides, fatty acids, and waxes are the commonly used lipids[26]. These advanced delivery systems are solid lipid nanoparticles. These can lessen or circumvent the polymeric nanoparticulate systems' limitations. There are two generations involved here. SLN is part of the first generation, whereas nanostructured lipid carriers (NLC)[27] are part of the second generation. NLC are recognized for their ability to get over first generation's drawbacks. The lipid matrix, which can prevent proteolytic breakdown of proteins after delivery and enhance protein stability[28].

RECENT ADVANCES**ANTIBODIES MEDIATED DRUG DELIVERY**

The last 10 years have seen a surge in interest in antibodies, but their big size limits their capacity to traverse the blood-brain barrier and their permeability, which further limits their potential for antibody-mediated therapy of neurodegenerative diseases[29].

GENE VECTORS TUMORS

Gene vectors are administered into the intranasal cavity to limit blocking of the blood-brain barrier, allowing the vectors to easily cross the barrier and exhibit therapeutic effects in the brain[30].

STEM CELL THERAPIES

Because stem cells can regenerate dead cells in injured places, they are the most forbidden choice for treating a wide range of disorders. These days, pump sprays are used to deliver nasal treatments in various markets. They are liable and the easiest for the patients to use[31].

CONCLUSION

The subjects we covered in this article are linked to brain targeting via intranasal injection of nanoparticles, which is utilized to treat neurodegenerative illnesses. The outlines of the nasal cavity will become clear to readers, and many of the approaches that are described here are still fundamental. Intranasal administration has many non-invasive benefits. The medication is delivered straight into the central nervous system (CNS) by avoiding the blood-brain barrier. The enhanced therapeutic efficacy, improved targeting capabilities, and increased bioavailability of these nanoparticulate carriers are promising and cutting edge characteristics. Furthermore, pharmaceutical businesses are investing a significant sum of money due to the increased demand for nasal medication items in the worldwide pharmaceutical market. It was also mentioned, although, that the intranasal route has a number of drawbacks that need to be addressed in order to create an effective nasal medication. In the end, the SLN and NLC for the intranasal route of medication administration seem to be a more effective choice for illness treatment delivery.

ABSTRACT

The article explores the intricate field of environmental management through the lens of ancient and medieval Indian teachings. In ancient India, revered texts like the Vedas and Upanishads valued nature as *Prakriti*, stressing its sacredness and the imperative to protect it. These foundational writings laid the groundwork for a comprehensive approach to caring for the environment, seamlessly blending spiritual reverence with practical sustainability principles. As we move into the medieval period, Mughal rulers implemented strict regulations to safeguard the environment, recognising its crucial role in societal well-being. Their governance prioritised ecological balance, imposing penalties for environmental violations. By comparing ancient philosophical ideas with historical governance practices, this study illuminates the lasting relevance of traditional wisdom in today's environmental discourse. It offers insights that transcend time and culture, fostering a renewed understanding of living in harmony with the natural world. Modern Indian writers, philosophers and academicians have also expressed their concerns about the Environment and its relationship with human life. The paper also focuses on the values of the Environment and its balance with Human lives and the various schemes that are laid down for Environmental Management.

Keywords: Environment, India, Management, Literature.

Jyoti Pathak and Thakur Dev Pandey

INTRODUCTION

The environment is the natural world surrounding human life and is closely associated with the atmosphere, hydrosphere, lithosphere and biosphere. In general, Environment includes plants, animals, rocks and the entire landscape. But it is to be matter of concern that the environment is in wilderness and it is also necessary to the management of the environment then environmental management is more concerned with the management of human activities as by *M.E Colby* in his book *Environmental Management in Development: The Evolution of paradigms* (1991) says "All human activities take place in the context of certain types of relationships between society and the biophysical world the rest of nature" (p 193) [1]. Environment management encompasses a systematic approach to overseeing the delicate balance of our surroundings, focusing on mitigating pollution, averting environmental catastrophes, and curbing degradation. At its core, it entails the strategic deployment of policies, practices, and technologies to safeguard ecosystems, biodiversity, and human health. This multifaceted discipline not only addresses immediate threats like pollution but also anticipates and prevents potential disasters through proactive measures. Moreover, it promotes sustainable resource utilization, fostering resilience against environmental shocks while minimizing ecological footprint. By integrating scientific research, regulatory frameworks, and community engagement, environment management strives to harmonize human activities with the natural environment, ensuring its longevity for future generations. Embracing a holistic perspective, it underscores the interconnectedness of environmental, social, and economic systems, advocating for responsible stewardship and fostering a culture of environmental consciousness and accountability. However, environmental management is the understanding of the environment and how humans relate to this environment [2]. More broadly, environmental management includes identifying the environmental problem, finding its solution, no exploitation, utilization of natural resources, control environmental pollution, reduce the impacts of extreme natural disaster, make optimum utilization of natural resources and making them eco-friendly as nature is both destroyer and creator Jim Clyburn writes, "Environment protection doesn't happen in a vacuum. You can't separate the impact on the environment from the impact on our families and communities (Jim)" [3].

RESEARCH METHODOLOGY

This paper aims to discover the environmental management during ancient and medieval period and its impact in modern time. This research shows light on the importance of environment, environment problems since ancient time and actions taken in the ancient, medieval and modern period by the people. The paper discusses how to provide the insight of managing the environment and awareness in society. The research approach is descriptive in nature. The paper is based on secondary data which has been taken from various books, articles and journals.

Ancient Literature and Environment Management

In ancient times, the environment was intricately intertwined with the essence of life itself, embodying principles of wisdom, tranquility, and abundance. Former President of India, Dr. Abdul Kalam, in his seminal work "Ignited Minds: Unleashing The Power Within India" (2010), posited that ancient India epitomized a society rich in knowledge and adorned with a flourishing civilization (p. 21)[4]. This profound insight underscores the profound reverence ancient societies held for their natural surroundings, recognizing it as a source of sustenance, enlightenment, and prosperity. Rekindling this legacy of knowledge empowerment entails integrating such wisdom into modern education systems, thereby illuminating paths towards peace, prosperity, and contentment for India and beyond. By embracing the harmonious coexistence with nature advocated by our forebears, we pave the way for a future where the synergy between knowledge, education, and environmental consciousness becomes the cornerstone of societal progress and well-being. **पुष्पितःफलवन्तश्चतर्त्यन्तीहमानवान्। वृक्षदंपुत्रवत्वृक्षास्तारयन्तिपरत्रच॥** (*Mahabharat, Anusasan Parv, Adhyaya, 58, Shloka 30*)

Jyoti Pathak and Thakur Dev Pandey

Humans who plant trees that produce fruits and flowers for welfare of human kind are assisted by those trees in after life, as son assists his father and saves him from the pains of Other World.

The ancient Indian philosophy exemplifies a profound admiration for the environment, reflecting a holistic worldview that intertwines ecological harmony with spiritual enlightenment. Across revered texts like the Vedas, Puranas, Upanishads, Mahabharata, Bhagavad-Gita, and Ramayana, the ethos of environmental stewardship resonates, encapsulated within the concept of Prakriti [5]. These scriptures extol the virtues of knowledge, peace, bliss, and prosperity, all of which are inherently linked to a harmonious relationship with nature. In ancient culture, the environment, encompassing forests, trees, and animals, was revered, with teachings emphasizing the interconnectedness of all life forms and elements of nature – be it space, air, fire, water, or earth. Central to this ethos was the cultivation of a deep-seated love and respect for nature, instilling in individuals a profound sense of responsibility to coexist in symbiotic equilibrium with the natural world. This holistic perspective not only nurtured ecological balance but also fostered spiritual growth and societal well-being, serving as a timeless beacon of wisdom for humanity [6]. In the Bhagavad Gita' Lord Krishna says,

पत्रपुष्पफलं तोययो मे भक्त्या प्रयच्छति।

तदहं भक्त्युपहृतमश्नामि प्रयतात्मनः॥

(Bhagwat Gita, Chapter 3, Shloka 13)

If one offers me with love and devotion a leaf, a flower, fruit or water, I will accept it.

We get a clearer statement that a tree supports an ecosystem and by its cutting/burning the system is destroyed.

महान्वृक्षो जायते वर्धते च तत्रैव भूतानि समाश्रयन्ति।

यदा वृक्षश्छिद्यते दह्यते च तदा श्रया अनिकेता भवन्ति॥

(Mahabharat, Shanti Parv, Adhyaya 69, Sloka 73)

The ancient Hindu text of The Manusmriti stands as a testament to the profound reverence for life and the environment inherent in Hindu philosophy. Within its verses, a resounding condemnation is voiced against cruelty towards animals, illustrating the deep-seated belief in the interconnectedness of all living beings. The Manusmriti's admonishment against the killing of cattle, symbolizing the sanctity of all life forms, is particularly poignant. It declares that the perpetrator of such an act is fated to endure a karmic reckoning, destined to suffer as many deaths as there are hairs on the skin of the slain cattle. This striking injunction serves not only as a moral imperative but also as a poignant reminder of the intrinsic value of every living creature. It underscores the ancient wisdom that reverberates through Hindu teachings, emphasizing compassion, empathy, and the imperative of living in harmony with the natural world. In its essence, this profound insight transcends time and culture, offering timeless guidance on the path towards ethical conduct and ecological stewardship (Bithin1075) [7]. The Vedas also asserted that the plants and trees are the cosmic being and valuable for descendents. Besides Vedas, Upanishads, Puranan, Sutras and other sacred texts of Hinduism Mahabharata, Bhagavad-Gita and Ramayana contain a number of references of the love and worship of the Environment [8]. Many plants and flowers were used for worship, the **Lotus** (*Nelumbo nucifera*) was considered a sacred flower and the Indian **Basil** (*Ocimum basilicum*), **Peepal Tree** (*Ficus religiosa*) and **Banyan Tree** (*Ficus benghalensis*) is still worshipped. Similarly, the Earth, water, air, animals and forest were given significant values in the ancient period so as to protect the environment [9].

Medieval Literature and Environment Management

During the medieval period, the perception of nature underwent a significant shift, with people viewing it not just as a backdrop for life but as a source of delight and aesthetic appreciation. This era witnessed the construction of monuments, parks, and gardens along riverbanks, meticulously designed to capture and amplify the beauty of the natural world [10]. Babur's "Babernama" (1589) and Jahangir's "Tuzuk-I Jahangiri" (1609) offer vivid descriptions of Indian geography, embellished with intricate details of flora, fauna, ponds, and the scenic splendor of nature during that epoch. Historical records and architectural marvels bear testimony to the profound affinity medieval rulers held for nature. Whether it was the Rajput Maharajas or conquerors from the West, leisure time was often spent amidst the serene embrace of nature, their architectural endeavors serving as tributes to the preservation and celebration of

**Jyoti Pathak and Thakur Dev Pandey**

natural beauty. Through their unique architectural styles, these rulers sought to harmonize human creations with the organic elegance of the environment, manifesting a collective desire to cultivate and cherish the inherent splendor of nature. This symbiotic relationship between humanity and the natural world during the medieval period reflects a nuanced appreciation for the interconnectedness of life and underscores the enduring allure of nature's charm across diverse cultural landscapes. **Source:** District Srinagar, Govt of J & K Available at <https://srinagar.nic.in/gallery/shalimar/> Once the Jahangir visited Kashmir, he said about the India's beautiful nature[11] which Stephen P Blake in his book *shahjahanabad: the sovereign city in mughalIndia 1639-1739* and writes,

Agar firdaus bar ru-ye zaminast

Hamin ast-o haminast-o haminast

If there is a paradise on the face of the earth.

It is this, it is this, it is this.

Amir Khusro— Amir Khusrau, The Writings Of Amir Khusrau:700 years after the prophet: a 13th-14th century legend of Indian-sub-continent.[12]

During the medieval period, environmental management strategies were characterized by a multifaceted approach aimed at enhancing the natural landscape while also preserving its integrity for future generations. Forestation efforts were actively promoted, recognizing the vital role of forests in maintaining ecological balance and providing essential resources. Additionally, considerable emphasis was placed on the protection and construction of water reservoirs to ensure reliable water supply for agricultural, domestic, and industrial purposes. Emperors and rulers played a pivotal role in shaping the environmental ethos of the time, commissioning artists to depict breathtaking landscapes and architects to design ornate gardens and monuments that celebrated the splendor of nature. Iconic historical gardens like the Mughal Garden in New Delhi, Shalimar Bagh in Srinagar, Jammu & Kashmir, and Verinag Garden in Anantnag, Jammu & Kashmir, stand as enduring testaments to this reverence for nature's beauty [13]. However, alongside these efforts to promote and enjoy nature, strict punitive measures were also implemented to deter environmental degradation. Harsh penalties were imposed on those found guilty of harming the environment, reflecting a recognition of the intrinsic value of ecological balance and the need for its preservation. As a result of these concerted efforts, the condition of the environment during the medieval period was relatively well-maintained, with a balance struck between human activities and the preservation of natural ecosystems. This holistic approach to environmental management serves as a historical precedent for sustainable practices that continue to resonate in contemporary environmental discourse.

Modern methods of Environment Management

In modern times, the study of the environment falls under the purview of Earth Science, encompassing the natural world comprising earth, trees, water, animals, birds, and landscapes. Renowned poet Rabindranath Tagore's collection of poetry, "Gitanjali" (1913), eloquently weaves themes of earth, trees, water, animals, and birds, setting an example of the profound relationship between nature and humanity. Tagore's teachings advocate for a life lived in harmony with nature, yet, regrettably, contemporary environmental phenomena are endangered due to the neglect of environmental values, leading society towards widespread environmental degradation [14]. India's environmental challenges stem from rapid economic development and population growth, evident in the degradation of environmental quality and beauty, underscoring the growing detachment of humans from nature and the declining sentiment towards environmental conservation. Despite these challenges, various governmental and private initiatives have been undertaken to improve environmental values. Since 1972, numerous private agencies have worked towards environmental protection, addressing issues such as pollution, climate change, and solid waste management [15]. India's legislative framework reflects a commitment to environmental preservation, with significant acts like the Water Prevention and Control Act (1974), Environment Protection Act (1986), and Air Pollution Control Act (1981), along with international agreements like the Convention on Biological Diversity (1992) [16]. Additionally, the government of India, under Prime Minister Narendra Modi's leadership, has launched several ambitious schemes aimed at environmental conservation. Initiatives such as the Swachh Bharat Abhiyan (2014), Bal Swachhta Abhiyan (2014), and the Namami Ganga Yojna (2014) exemplify concerted efforts to tackle environmental challenges comprehensively [17]. These endeavors underscore India's commitment to nurturing its natural

**Jyoti Pathak and Thakur Dev Pandey**

surroundings and safeguarding its environmental heritage for future generations. By integrating traditional wisdom with modern environmental governance and fostering a culture of environmental stewardship, India strives to overcome the pressing challenges posed by environmental degradation, ensuring a sustainable and prosperous future for all.

DISCUSSION

The environment serves as a guiding force, offering sustenance, balance, and inspiration to humanity. Yet, in the relentless pursuit of economic gain, mankind has often disregarded this guidance, exploiting the environment for short-term gains and inflicting irreparable damage upon delicate ecosystems. Modern environmental management systems have emerged as a response to mitigate these impacts, aiming to regulate and improve the interaction between human activities and the environment. These systems prioritize the preservation of human health and well-being while striving to minimize negative environmental consequences. However, amidst the clamour for modern solutions, traditional knowledge systems have often been overlooked and undervalued. Across diverse cultures, traditional knowledge encompasses a vast repository of wisdom spanning various domains, including environmental stewardship. Unfortunately, with the passage of time, this invaluable knowledge has been eroded, as younger generations increasingly prioritize formal education over learning from their elders. As elderly members of communities pass away, much of this practical wisdom vanishes with them, leaving behind only fragmented remnants or sporadic records. Nevertheless, there exists immense potential in preserving and revitalizing traditional knowledge for environmental management. This ancient wisdom, passed down through generations, holds invaluable insights into sustainable resource management, ecosystem conservation, and harmonious coexistence with nature. By safeguarding and revitalizing traditional knowledge, we can bridge the gap between past wisdom and modern scientific understanding, forging a holistic approach to environmental management that integrates the best of both worlds. Efforts to document and preserve traditional knowledge systems are crucial in this endeavor. Through collaborative partnerships between indigenous communities, researchers, and policymakers, traditional ecological knowledge can be systematically recorded, documented, and revitalized. By doing so, we not only honor the rich cultural heritage of indigenous peoples but also unlock a treasure trove of practical wisdom that can inform contemporary environmental management practices. Integrating traditional knowledge into modern environmental management frameworks offers a pathway towards more holistic and sustainable approaches. By leveraging indigenous wisdom, communities can develop locally appropriate solutions to pressing environmental challenges, rooted in centuries-old traditions of ecological stewardship and resilience. In essence, saving and revitalizing traditional knowledge for environmental conservation is not merely an exercise in preserving the past; it is an investment in our collective future. By harnessing the wisdom of our ancestors and integrating it with modern scientific understanding, we can forge a path towards sustainable development that honours both the needs of present generations and the integrity of the natural world.

CONCLUSION

The environment encompasses various elements that bring joy and tranquillity to human beings, from its vibrant colours to its diverse landscapes. Individuals need to prioritize environmental conservation and strive to maintain ecological balance. Today, improving environmental values necessitates fostering a harmonious relationship with nature and adhering to government schemes aimed at environmental protection. Despite the efforts of the Ministry of Environment and other organizations to safeguard the Earth, human greed often takes precedence, leading to the degradation of the environment and disrupting the planet's peace. Mahatma Gandhi's timeless words, "Earth provides enough to satisfy every man's needs, but not every man's greed," resonate profoundly in the modern era [18]. These words underscore the importance of restraining human desires and embracing sustainable practices to ensure the well-being of both present and future generations. In this context, it becomes imperative to revive ancient knowledge systems that espouse principles of environmental harmony and apply them to contemporary environmental management practices. By integrating traditional wisdom with modern scientific understanding,

Jyoti Pathak and Thakur Dev Pandey

society can develop innovative solutions to address pressing environmental challenges. This includes leveraging indigenous knowledge of ecosystem management, sustainable agriculture, and natural resource conservation. Furthermore, educational initiatives can play a crucial role in raising awareness about the importance of environmental stewardship and encouraging individuals to adopt eco-friendly lifestyles. In essence, caring for the environment is not only a moral imperative but also a practical necessity for ensuring the continued prosperity of humanity and the planet. By heeding the lessons of the past and embracing a holistic approach to environmental management, mankind can forge a path towards a more sustainable and harmonious coexistence with nature.

ABSTRACT

We establish a shared common fixed point in an Orthogonal Hausdorff topological space with a τ -distance in this paper. Next, for two or more classes of contractive self-mappings in complete orthogonal bounded metric space, we derive two common fixed-point theorems. Moreover, we illustrate some examples to support our result.

Keywords: Fixed point, contractive self-mapping, orthogonal complete metric space, Hausdorff topological space, weakly compatible mapping.

INTRODUCTION

Nemytzki [13] initiate the Study of contractive or shrinking self-mappings on a metric space (X, d) (i.e., $d(Tx, Ty) < d(x, y), \forall x \neq y \in X$). Moreover, as M. Edelstein mentioned in [7], the prerequisite for achieving a fixed contractive self-mapping point, is to either presume that the space is compact or that a point $x \in X$ exists for a sequence $\{T^n x\}$ such that it contains a convergent subsequence. B. E. Rhoades shown in [1], that each weakly contractive mapping on a complete metric space (X, d) has a unique fixed point, or we can also say that every self mapping $T : X \rightarrow X$ satisfy the condition $d(Tx, Ty) \leq d(x, y) - \varphi(d(x, y))$, for all $x, y \in X$, where $\varphi : [0, +\infty) \rightarrow [0, +\infty)$ is a non-decreasing continuous function such that $\varphi(0) = 0$. Since then, a number of findings about this class of mappings have been published in the literature [2, 5, 12, 14]. M. Aamri and D. E. Moutawakil developed the idea of τ -distances in [6] for general topological spaces (X, τ) , and it was then extended to numerous known spaces in the literature. They also demonstrated the well-known Banach's fixed point for this general setting. In this work, we extend several ideas

Rajesh Vyas et al.,

introduced by D. E. Moutawakil and Y. Touaila [15] to orthogonal sets and prove a few fixed point theorems. Our findings complement and generalize the established findings. Additionally, we provide some examples that support our findings.

PRELIMINARIES

This section aims to help you remember some terminology and findings that are necessary for the article. Let (X, τ) be a topological space and $p : X \times X \rightarrow [0, \infty)$ be a function. For any $\varepsilon > 0$ and $\forall x \in X$, let $B_p(x, \varepsilon) = \{y \in X : p(x, y) < \varepsilon\}$

Definition 2.1. ([6]) The function p is said to be τ -distance if for each $x \in X$ and any neighborhood V of x , there exists $\varepsilon > 0$ such that $B_p(x, \varepsilon) \subset V$.

Definition 2.2. A sequence $\{S_n\}$ is said to be Cauchy sequence if $\forall \varepsilon > 0, \exists n \in \mathbb{N}$ such that $|S_{m+p} - S_n| < \varepsilon, \forall m > n, p > 0$

Definition 2.3. ([15]) A sequence in a Hausdorff topological space X is a p -Cauchy if it satisfies the usual metric condition with respect to p .

Definition 2.4. A space is said to be complete if every Cauchy sequence in it is a convergent sequence.

Definition 2.5. ([6]) Let (X, \perp) be an orthogonal set (O-set). Any two elements $x, y \in X$ are said to be orthogonally related if $x \perp y$.

Definition 2.6. ([6]) Let (X, τ) be a topological space with a τ -distance p .

1. X is S -complete if for every p -Cauchy sequence (x_n) , there exists x in X with $\lim p(x, x_n) = 0$.
2. X is p -Cauchy complete if for every p -Cauchy sequence (x_n) , there exists x in X with $\lim x_n = x$ with respect to τ .
3. X is said to be p -bounded if $\sup\{p(x, y) | x, y \in X\} < \infty$.

Lemma 2.7. Let (X, \perp, τ) be an Orthogonal Hausdorff topological space with a τ -distance p , then

1. $p(x, y) = 0$ implies $x = y, \forall x, y \in X, x \perp y$ or $y \perp x$
2. Let (x_n) be an orthogonal sequence in X such that $\lim_{n \rightarrow \infty} p(x, x_n) = 0$ and $\lim_{n \rightarrow \infty} p(y, x_n) = 0$, then $x = y, \forall x, y \in X, x \perp y$ or $y \perp x$

Definition 2.8. ([15]) Two self-mappings f and g of a set X are said to be weakly compatible if they commute at their coincidence points; i.e., if $fu = gu$ for some $u \in X$, then

$$(fg)u = (gf)u.$$

Definition 2.9. ([2]) θ is the class of all functions $\theta: [0, +\infty) \rightarrow [0, +\infty)$ satisfying:

- i) θ is a monotone increasing function,
- ii) $\theta(t) = 0$ if and only if $t = 0$.

Definition 2.10. ([2]) Ψ is the class of all functions $\psi: [0, +\infty) \rightarrow [0, +\infty)$ satisfying:

Rajesh Vyas et al.,

- i) ψ is nondecreasing,
- ii) $\lim_{n \rightarrow \infty} \psi^n(t) = 0$, for all $t \in [0, \infty)$.

Definition 2.11. ([2]) Φ is the class of all functions $\varphi: [1, +\infty) \rightarrow [0, +\infty)$ satisfying:

- i) $\varphi(t) = 0$ if and only if $t = 1$,
- ii) $\inf t > 1 \varphi(t) > 0$.

Main result

Theorem

Let (X, \perp, τ) be a p - bounded Orthogonal Hausdroff topological space with a τ – distance p . Let q, r, s and t be two \perp – continuous and \perp – preserving weakly compatible self mapping of X . Satisfying the following condition

For every $x, y \in X, q(x) \perp q(y)$ or $q(y) \perp q(x)$,
 $r(x) \perp r(y)$ or $(y) \perp r(x)$,
 $s(x) \perp s(y)$ or $s(y) \perp s(x)$
 and $t(x) \perp t(y)$ or $t(y) \perp t(x)$

1. $t(X) \subseteq s(X) \subseteq r(X) \subseteq q(X)$
2. $P(rx, ry) \leq \psi(p(qx, qy))$, where $\psi \in \Psi$
3. $P(sx, sy) \leq \psi(p(rx, ry))$, where $\psi \in \Psi$
4. $P(tx, ty) \leq \psi(p(sx, sy))$, where $\psi \in \Psi$

If the range of q, r, s and t are S- Complete subspace of X then q, r, s and t have a unique common fixed point.

Proof: Since X is an orthogonal set $\exists x_0 \in X$ such that $\forall y \in X, y \perp x_0$ or $\forall y \in X, x_0 \perp y$
 $\Rightarrow q(x_3) \perp r(x_2) \perp s(x_1) \perp t(x_0)$ [by using condition 1.] ... (i)

Now similarly, we can choose iterated $\{x_n\}$ sequence $\forall n \in \mathbb{N}$ such that

$$q(x_{n+2}) = r(x_{n+1}) = s(x_n) = t(x_{n-1}) \quad \forall n \in \mathbb{N} \quad \dots (ii)$$

Since $\forall x_n \in X, \forall n \in \mathbb{N} \exists q(x_{n+2}) \in X$

So, similarly consider a sequence $\{q(x_{n+2})\}$ and subsequence $\{r(x_{n+1})\}, \{s(x_n)\}$ such that

$$q(x_{n+2}) \perp q(x_{n+1}) \text{ or } q(x_{n+1}) \perp q(x_n) \quad \forall n \in \mathbb{N} \text{ which implies that } \{q(x_{n+2})\} \text{ is orthogonal sequence.} \quad \dots (iii)$$

Then, its subsequences $\{r(x_{n+1})\}, \{s(x_n)\}$ are also orthogonal sequence. ... (iv)

Now let $m, n \in \mathbb{N}$

We obtain $q(x_0) \perp q(x_{n+2})$ or $q(x_{n+2}) \perp q(x_0)$,

$r(x_0) \perp r(x_{n+1})$ or $r(x_{n+1}) \perp r(x_0)$,

$s(x_0) \perp s(x_n)$ or $s(x_n) \perp s(x_0), \forall x_n \in X \forall n \in \mathbb{N}$ and fixed $x_0 \in X$.

By using (ii) equation

We have,

$$p(qx_{n+2}, qx_{n+m+2}) = p(rx_{n+1}, rx_{n+m+1}) = p(sx_n, sx_{n+m}) = p(tx_{n-1}, tx_{n+m-1})$$

By using condition (2.)

$$\leq \psi(p(sx_{n-1}, sx_{n+m-1}))$$

$$\leq \psi'(p(sx_{n-2}, sx_{n+m-2}))$$

$$\leq \psi^n(p(sx_0, sx_m))$$

$$\leq \psi^n(M)$$

Where $M = \text{Sup}\{p(x, y) | x, y \in X\}$

Since $\lim_{n \rightarrow \infty} \psi^n(M) = 0$

Then $\forall n, m \in \mathbb{N}, \forall x_n, x_{n+m} \in X$ such that $s(x_n) \perp s(x_{n+m})$ or $s(x_{n+m}) \perp s(x_n)$

We get $p(sx_n, sx_{n+m}) < 0$

$\Rightarrow \{s(x_n)\}$ is p – Cauchy orthogonal sequence ... (v)

Rajesh Vyas et al.,

Then by using [(iii), (iv), (v)], $\{q(x_{n+2}), \{r(x_{n+1})\}$ are p – Cauchy orthogonal sequence

...(vi)

Suppose that $q(x), r(x), s(x)$ are S – complete

$\Rightarrow \exists u \in X, u \perp x_n$ or $u \in X, x_n \perp u, \forall n \in \mathbb{N}$ then

$u \in X, qu \perp qx_{n+2}$ or $qx_{n+2} \perp qu$ such that $\lim_{n \rightarrow \infty} p(qu, qx_{n+2}) = 0,$

$u \in X, ru \perp rx_{n+1}$ or $rx_{n+1} \perp ru$ such that $\lim_{n \rightarrow \infty} p(ru, rx_{n+1}) = 0,$

$u \in X, su \perp sx_n$ or $sx_n \perp su$ such that $\lim_{n \rightarrow \infty} p(su, sx_n) = 0,$

$u \in X, tu \perp tx_{n-1}$ or $tx_{n-1} \perp tu$ such that $\lim_{n \rightarrow \infty} p(tu, tx_{n-1}) = 0,$

Therefore by (v),(vi) $qu = ru = su = tu$

By using lemma 2.7

we get $qu = ru = su = tu$

...(vii)

Now the assumption that q, r, s and t are weakly compatible which implies

$q.ru = r.qu$

$r.su = s.ru$

...(viii)

$s.tu = t.su$

$q.tu = q.ru = r.qu = r.ru = r.tu = r.su = s.ru = s.tu = t.su$ [by (vii) and (viii)]

Suppose that $p(r.ru, ru) \neq 0$

From inequality 2.

It follows $p(r.ru, ru) \leq \psi(p(q.ru, qu))$

$< p(r.ru, ru)$

This led to the contradiction

Thus, $p(r.ru, ru) = 0$

$\Rightarrow r.ru = ru$

$\Rightarrow q.tu = q.ru = r.qu = r.ru = r.tu = r.su = s.ru = s.tu = t.su = ru = tu$

$\Rightarrow tu$ is common fixed point of q, r, s and t .

Now if range of t is S – complete of X

Then $\exists v \in X, v \perp x_n$ or $v \in X, x_n \perp v$ such that $\lim_{n \rightarrow \infty} p(tv, tx_n) = 0$

From condition 1. We have $\exists w \in X, v \perp w$ or $w \perp v$ such that $tv = qw = rw = sw$

And the proof of that tw is a common fixed point of q, r, s and t is same as that given when $q(x), r(x)$ and $s(x)$ is S – complete.

For uniqueness

Suppose $\exists u, v \in X, v \perp u$ or $u \perp v$ is such that $qu = ru = su = tu = u,$

$qv = rv = sv = tv = v$ with $u \neq v$.

Since \perp – preserving $qu \perp qv$ or $qv \perp qu$ and $u \neq v$ implies that $p(u, v) \neq 0$

Then by condition 2. of the theorem and lemma 2.7, follows

$p(u, v) = p(tu, tv)$

$\leq \psi(p(su, sv))$

$\leq \psi(p(ru, rv))$

$\leq \psi(p(qu, qv))$

$= \psi p(u, v)$

$< p(u, v)$

Which is a contradiction

Therefore, $p(u, v) = 0$

This implies $u = v$

Theorem

Let (X, \perp, τ) be a p - bounded Orthogonal Hausdroff topological space with a τ – distance p . Let φ and δ be two \perp – continuous and \perp – preserving weakly compatible self mapping of X . Satisfying the following condition

For every $x, y \in X, \varphi(x) \perp \varphi(y)$ or $\varphi(y) \perp \varphi(x)$ and $\delta(x) \perp \delta(y)$ or $\delta(y) \perp \delta(x)$

1. $\delta(X) \subseteq \varphi(X)$

Rajesh Vyas et al.,

$$2. \quad P(\delta x, \delta y) \leq \psi(p(\varphi x, \varphi y)), \text{ where } \psi \in \Psi$$

If the range of φ and δ are S- Complete subspace of X then φ and δ have a unique common fixed point.

Proof: Since X is an orthogonal set $\exists x_0 \in X$ such that $\forall y \in X y \perp x_0$ or $\forall y \in X x_0 \perp y$
 $\Rightarrow \varphi(x_1) \perp \delta(x_0)$ or $\delta(x_0) \perp \varphi(x_1)$ [by using condition 1.] ... (i)

Now similarly, we can choose iterated $\{x_n\}$ sequence $\forall n \in \mathbb{N}$ such that

$$\varphi(x_n) = \delta(x_{n-1}) \quad \forall n \in \mathbb{N} \quad \dots(ii)$$

Since $\forall x_n \in X, \forall n \in \mathbb{N} \exists \varphi(x_n) \in X$

So, similarly consider a sequence $\{\varphi(x_n)\}$ such that

$$\varphi(x_n) \perp \varphi(x_{n+1}) \text{ or } \varphi(x_{n+1}) \perp \varphi(x_n) \quad \forall n \in \mathbb{N}$$

$\Rightarrow \{\varphi(x_n)\}$ is orthogonal sequence.

Now let $m, n \in \mathbb{N}$

We obtain $\varphi(x_0) \perp \varphi(x_n)$ or $\varphi(x_n) \perp \varphi(x_0), \forall x_n \in X \forall n \in \mathbb{N}$ and fixed $x_0 \in X$.

By using (ii) equation

$$\text{We have } p(\varphi x_n, \varphi x_{n+m}) = p(\delta x_{n-1}, \delta x_{n+m-1})$$

By using inequality (2.)

$$\begin{aligned} &\leq \psi(p(\varphi x_{n-1}, \varphi x_{n+m-1})) \\ &\leq \psi'(p(\varphi x_{n-2}, \varphi x_{n+m-2})) \\ &\leq \psi^n(p(\varphi x_0, \varphi x_m)) \\ &\leq \psi^n(M) \end{aligned}$$

Where $M = \text{Sup}\{p(x, y) | x, y \in X\}$

Since $\lim_{n \rightarrow \infty} \psi^n(M) = 0$

Then $\forall n, m \in \mathbb{N}, \forall x_n, x_{n+m} \in X$ such that $\varphi(x_n) \perp \varphi(x_{n+m})$ or $\varphi(x_{n+m}) \perp \varphi(x_n)$

We get $p(\varphi x_n, \varphi x_{n+m}) < 0$

$\Rightarrow \{\varphi(x_n)\}$ is p - Cauchy orthogonal sequence

Suppose that $\varphi(x)$ is S - complete

$\Rightarrow \exists u \in X, u \perp x_n$ or $u \in X, x_n \perp u$ then $\varphi u \in X, \varphi u \perp \varphi x_n$ or $\varphi u \in X, \varphi x_n \perp \varphi u$

such that $\lim_{n \rightarrow \infty} p(\varphi u, \varphi x_n) = 0$

Therefore, $\lim_{n \rightarrow \infty} p(\delta u, \delta x_n) = \lim_{n \rightarrow \infty} p(\delta u, \varphi x_{n+1}) = 0$

By using lemma 2.7

we get $\varphi u = \delta u$

... (iii)

Now the assumption that φ and δ are weakly compatible which implies $\varphi. \delta u = \delta. \varphi u$

$\Rightarrow \varphi. \delta u = \varphi. \varphi u = \delta. \varphi u = \delta. \delta u$ [by (iii)] ... (iv)

Suppose that $p(\delta. \delta u, \delta u) \neq 0$

From inequality 2.

It follows $p(\delta. \delta u, \delta u) \leq \psi(p(\varphi. \delta u, \varphi u))$

$< p(\delta. \delta u, \delta u)$

This led to the contradiction

Thus, $p(\delta. \delta u, \delta u) = 0$

$\Rightarrow \delta. \delta u = \delta u$

Which implies that $\varphi. \delta u = \delta. \varphi u = \delta. \delta u = \varphi. \varphi u = \delta u$ [by (iv)]

$\Rightarrow \delta u$ is common fixed point of φ and δ .

Now if range of δ is S - complete of X

Then $\exists v \in X, v \perp x_n$ or $v \in X, x_n \perp v$ such that $\lim_{n \rightarrow \infty} p(\delta v, \delta v) = 0$

From condition 1.

We have $\exists w \in X, v \perp w$ or $w \perp v$ such that $\delta v = \varphi w$

And the proof of that δw is a common fixed point of φ and δ is same as that given when $\varphi(x)$ is S - complete.

For uniqueness

Suppose $\exists u, v \in X, v \perp u$ or $u \perp v$ is such that $\delta u = u = \varphi u, \delta v = v = \varphi v$ with $u \neq v$.

Rajesh Vyas et al.,

Since \perp – preserving $\varphi u \perp \varphi v$ or $\varphi v \perp \varphi u$ and $u \neq v$ implies that $p(u, v) \neq 0$

Then by inequality 2. of the theorem and lemma 2.7, follows

$$p(u, v) = p(\delta u, \delta v)$$

$$\leq (\cdot)$$

$$= (\cdot)$$

$$< (\cdot)$$

Which is a contradiction

Therefore, $(\cdot) = 0$

This implies =

Lemma

Let (\perp, \cdot) be orthogonal metric space and $\theta : X \times X \rightarrow \mathbb{R}^+$ be a function defined by $(\cdot) = (\cdot) - 1 \forall \cdot \perp \perp$ such that $\in \cdot$. Then θ is a θ -distance on X where \perp is the orthogonal metric topology.

Proof: Let (\perp, \cdot) be the orthogonal topological space with the orthogonal metric topology \perp and an arbitrary neighbourhood of an arbitrary $\in \cdot$.

Let $(\cdot) = \{ \cdot \in \cdot, (\cdot) < \cdot, \forall \cdot \in \cdot \perp \perp \}$ is the open ball then $\exists \delta > 0$ such that $(\cdot) \subset \cdot$. Since $(\cdot) - 1 < \cdot$ which implies that $(\cdot) - 1 \subset (\cdot)$,

Let $\in (\cdot) - 1$, $\forall \in \cdot$ such that $\perp \perp$, then $(\cdot) < (\cdot) - 1$, which implies that $(\cdot) < (\cdot)$. Since θ supposed increasing, we get $(\cdot) < \cdot$. Using Theorem 3.2 and Lemma 3.3, we now prove the following Theorem

3.4. Theorem

Let (\perp, \cdot) be a bounded O-complete metric space. Let φ and δ be two weakly compatible self mapping of X . Then $\exists \theta \in \mathbb{R}^+$, such that $\forall \cdot \in \cdot, \perp \perp$ or $\in \cdot, \perp \perp$ implies $\varphi(y) \perp \varphi(x)$ or $\varphi(x) \perp \varphi(y)$ and $\delta(y) \perp \delta(x)$ or $\delta(x) \perp \delta(y)$ satisfying the following conditions:

i) $\delta(X) \leq \varphi(X)$

ii) $\inf_{x \neq y} \{ \theta(d(\varphi x, \varphi y)) - \theta(d(\delta x, \delta y)) \} > 0$

where $\theta \in \Theta$, then φ and δ have a unique fixed point.

Proof: We put $\alpha = \inf \{ \theta(d(\varphi x, \varphi y)) - \theta(d(\delta x, \delta y)) \}$ with $x, y \in X, y \perp x$ or $x \perp y$

Implies $\varphi(y) \perp \varphi(x)$ or $\varphi(x) \perp \varphi(y)$ and $\delta(y) \perp \delta(x)$ or $\delta(x) \perp \delta(y)$

$$\Rightarrow \theta(d(\delta x, \delta y)) \leq \theta(d(\varphi x, \varphi y)) - \alpha \forall x, y \in X$$

$\Rightarrow \varphi(y) \perp \varphi(x)$ or $\varphi(x) \perp \varphi(y)$ and $\delta(y) \perp \delta(x)$ or $\delta(x) \perp \delta(y)$

$$\text{Hence } e^{\theta(d(\delta x, \delta y))} \leq e^{\theta(d(\varphi x, \varphi y)) - \alpha}$$

$$= e^{\theta(d(\varphi x, \varphi y))} \cdot e^{-\alpha}$$

$$= K \cdot e^{\theta(d(\varphi x, \varphi y))} [K = e^{-\alpha}] \text{ Let the function } p: X \times X \rightarrow [0, \infty) \text{ defined by } p(x, y) = e^{\theta(d(x, y))} - 1, \forall x, y \in X \text{ such that } y \perp x \text{ or } x \perp y \text{ which is } \tau_d \text{ - distance on } X \text{ as proved in lemma 3.2 where } \tau_d \text{ is the orthogonal metric topology.}$$

By taking $\psi(t) = Kt$ in theorem 3.1 $\forall t \in [0, \infty)$

We get $p(\delta x, \delta y) \leq K(p(\varphi x, \varphi y)), x \perp y \Rightarrow \varphi x \perp \varphi y$

Finally, we conclude that φ and δ have a unique fixed point.

Example to support our result.

Example

Let $X = [0, 1]$, we define $x \perp y$ if $xy \leq y$ or $xy \leq x$ with $d(x, y) = |x - y|$.

Define $f, g : X \rightarrow X$ by $f(x) = x(x - 1)$ and $g(x) = 0$, for all $x \in X$ and $\theta : [0, \infty) \rightarrow [0, \infty)$, such that $\theta(t) = t^2$, for all $t \in [0, \infty)$. It is easy to see that $g(X) \subset f(X)$ and f, g are weakly compatible. On the other hand, we have for all $x, y \in X$ $\theta(d(fx, fy)) - \theta(d(gx, gy)) = (x^2 - x - y^2 + y)^2 > 0$.

Then f and g satisfy all assumptions of Theorem 3.4 and have the unique fixed point which equal to 0.

CONCLUSION

In this paper, we achieved to prove a common fixed point in an Orthogonal Hausdorff topological space with a τ -distance. Further, we generalized the result for two or more classes of contractive self-mappings in complete orthogonal bounded metric spaces. Then we deduced two fixed point theorems for contractive self mapping in bounded orthogonal complete metric space by proving some lemma. Moreover, to support the proved results we illustrate some example.

ABSTRACT

Security issues play in the role of protection of a network from natural or artificial calamities. Designing a network carries both security system and standard connections. Strong secure domination and secure domination varies with degrees. Selection of strong degree nodes as defenders reduces the chance of attackers to attack the network in severe work. Despite having weak degree neighbors, the process of st.sec domination and st.co-sec domination leads to the perfect output for the given data without any fault. The defenders replace the attacked node and the attacked defenders get replaced by its neighbors to ensure the network's process. This article determines a bound for the domination number, strong domination number, st.sec domination number of Aztec Diamond Network and st.co-sec domination number on Icosahedral Triangular Network. Domination number, Strong domination number, st.sec domination number of various graphs is investigated in recent years. But, st.sec dominating sets and st.co-sec dominating sets of dimensional Networks are difficult. In this paper, the vertices are highly examined based on its degrees and its strength of minimum number of guards for protection is included. In this paper, domination is sometimes mentioned as dom.

Keywords: St.sec and strong co- secure domination number, Aztec Diamond Network, Icosahedral triangular Network.

Thangam and Angelin Kavitha Raj

INTRODUCTION

Aztec Diamond Network

Dominoes can also be referred to as tiles, bones, cards, men, or pieces. Let's pick a $3 \times n$ board and learn about the tiling dominoes. There are now three options to fill using 2×1 dominoes. An Aztec diamond domino is a group of dominoes with a discontinuous interior whose union is the entire Aztec diamond. In other words, they cover the entire Aztec diamond and the dominoes did not overlap. Every domino is a rectangular tile that often has a line between the two square ends on its face. Alexander Von Humboldt is credited with the well-known Arctic Circle Theorem, which states that a random tiling of a huge Aztec diamond tends to remain frozen. He coined the term "Aztec" in 1810 to refer to all those connected to the Mexican state and others by trade, customs, religion, and language. An Aztec diamond of centre (x, y) satisfies, $|x| + |y| \leq n$ in combinatorial mathematics, where n is a fixed integer. In order for x and y to both be half integers. According to [5], there are $2^{n(n+1)/2}$ domino tilings in the Aztec diamond of order n . The Aztec diamond indices were calculated in [7] using leap Zagreb Indices, which are second degree vertices. The Aztec Diamond graph's structure is based on a square lattice, with a vertex in the centre that is regarded as the origin on the x, y plane and half integers taken for x and y . The symbol $AD(n)$ stands for the Aztec Diamond Network. In this research, we calculated the number of dots in x, y plane. $V(G)$ of $AD(n)$ is $2(n+1)^2 + 2(n+1) - 3$, where $n \in \mathbb{N} > 0$. The high level of Aztec diamond can be build from the lower one. Consider 2×2 boards. The extension of second one is by moving the tiles one step in the direction of the arrows upward, downward, left and right. Hence two 2×2 regions appear. Now three 2×2 appear. In particular, dominoes will never end up overlapping after the sliding phase and at the end of the sliding phase, the region left to be filled is a collection of two by twos and so on. To expand to $AD(4)$, we cannot slide straight away because there are some arrows pointing towards each other. Removing those clashing tiles and moving along the arrows randomly leads to more two by twos. In 1979, the formula for the number of tilings of Aztec Diamond was first conjectured by the physicists Grenzing, Carlon and Supp. In 1991, the mathematicians Noam Elkies, Greg Kuperberg, Michael Larsen and James popp published a number of proofs of this wonderful formula [6]. In 2005, Richard and Steve [8] determined a sign – nonsingular matrix of order $n(n+1)$ whose determinant gives $\prod n$.

Icosahedral Triangular Network

Interconnection networks from the base of Topological indices perform in various applications like sensors, surveillance camera, arrangement of a design to data structure etc. The regular Icosahedrons shape is discovered by Athenian Mathematician Theatetus (417 – 369 BC). Other platonic solids were discovered by Plato. Real life application of Icosahedrons are Many viruses, for example Herpes virus have icosahedral shells, Dungeons and dragons die, Scattergories die, Magic 8 Ball answer, Fuller projection map, TDK logo, Grundy Television logo, Sol de la Floor light shade. It is used in demining success or failure of an action. In [9] the domination number of Icosahedral Triangular network is investigated by Miroslava Mihajlov Carevic. It was proved that domination number for $R_{2,3}$ is equal to 2. The upper level of Rhomboidal triangular network is bisection of edges by new edges. The domination number of Icosahedral triangular network for $n = 2^k$ $k \in \mathbb{N} \setminus \{1\}$ is $\gamma(R_{n+1,2n+1}) = 2^{2k-1}$ [9]. The number of divisions of the triangular edges in the network $R_{2,3}$ by n .

St.sec dominating set and St.co-sec dominating set

The graph G considered here are simple and undirected without isolated vertices. The concept of secure domination and co-secure domination was introduced by [1]. In [3], the author characterized Honeycomb Networks with SDN. In [4], st.co-sec dominating set of certain graphs are obtained. Let $X \subseteq V(G)$ be a dominating set and for each $v \in V(G) - X$, there exists a vertex $u \in V(G)$ such that u is adjacent to v and $\deg(u) \geq \deg(v)$ and $(X/\{u\} \cup \{v\})$ is a dominating set. The minimum cardinality of this st.sec domination number is the st.sec dominating set of G . It is denoted by $\gamma_{ssd}(G)$. [1] Let $X \subseteq V(G)$ be a dominating set and for each $u \in V(G)$, there exists a vertex $v \in V(G) - X$ such that u is adjacent to v and $\deg(u) \geq \deg(v)$ and $(X/\{u\} \cup \{v\})$ is a dominating set. The minimum cardinality of this st.sec domination number is the st.co-sec domination number of G . It is denoted by $\gamma_{scsd}(G)$. [1]

Thangam and Angelin Kavitha Raj

Dominating sets and strong dominating sets of Aztec Diamond Network

Lemma 1.1: The domination number and the strong domination number of AD (1) are 3.

Proof: Consider the graph in an x, y plane and its centre origin is noted as $(0,0)$ with maximum degree 4. In AD (1), $V(G) = 9$. Number of vertices having degree (4) is 1. Thus remaining vertices are dominated by at least two vertices of degree 3. These 4 vertices are independent. The dominating set is denoted as X . The possible dominating sets are

$X = \{(0,0), (0,1), (0, -1)\}; \{(0,0), (1,0), (-1,0)\}$ and $V - X$ vertices are of degree 3 and 2.

The minimum cardinality of the domination number of AD (1) is 3. i.e. $\gamma(AD(1)) = 3$. These dominating vertices also satisfy $\deg(u) \geq \deg(v)$. Therefore $\gamma_{sd}(AD(1)) = 3$.

Lemma 1.2: The domination number of AD (n) = $4n - 2$ where $n = 2, 3, 4$ and the strong domination number is $4n$.

Proof: In AD (2), $V(G) = 21$. One of the possible dominating sets is $X = \{(0,2), (0,1), (-2,0), (2,0), (0, -1), (0, -2)\}$. Therefore $\gamma(AD(2)) = 6$. But the neighborhoods of $u \in X$ has higher degree vertices in $v \in V - X$. Thus $\gamma_{sd}(AD(2)) \neq \gamma(AD(2))$. Let vertices of degree 4 are m , vertices of degree 3 are n , and vertices of degree 2 are l . $\therefore m = 9, n = 4, l = 8$. Consider m vertices as dominating set and $N(m) = 13$. Thus m will be a strong dominating set. But to prove the minimum cardinality, consider the center vertex $(0, 0)$ which is dominated by its neighbors. Rejecting $(0, 0)$ from dominating set leads to $m = 8$. Hence $\gamma_{sd}(AD(2)) = 8$. Similarly for $n = 3$, $\gamma(AD(3)) = 10, \gamma_{sd}(AD(3)) = 12$. For $n = 4$, $\gamma(AD(4)) = 14, \gamma_{sd}(AD(4)) = 16$. AD network on the basis of its properties changes simultaneously from AD (4). Though the no. of vertices increases in the range of multiplication of 4, the domination number and the strong domination number increase arbitrarily less in number. The theorem stated next is the result of finding the strong dominating sets and the dominating sets. From $n = 5$ onwards, both dominating set and the strong dominating set is equal.

Theorem 1.3: The domination number and the strong domination number of AD (n) where $n > 4, n \in N$ is $7n - 13$.

Proof: Label the AD vertices of $n > 4$ consecutively from the center vertex $(0, 0)$ such that $|x| + |y| \leq n$.

Consider AD (5). Now Upper side dominating set is

$D' = \{(-1, 0), (1, 0), (-4, 0), (4, 0), (-4, 1), (-3, 1), (4, 1), (3, 1), (0, 2), (-2, 3), (2, 3), (0, 4), (0, 5)\}$.

Lower side dominating set is

$D'' = \{(-4, -1), (4, -1), (-2, -2), (2, -2), (0, -2), (-2, -3), (2, -3), (0, -4), (0, -5)\}$

Thus $|D'| + |D''| = |D| = 22$.

i.e. $\gamma(AD(5)) = \gamma_{sd}(AD(5)) = 22$. For AD (6), add outer vertices and edges on the border of AD (5) with conditions mentioned in the demonstration of its extension. Addition of $4n + 8$ vertices to AD ($n - 1$) is the number of vertices in AD (n). Two cases are constructed to find the strong dominating sets.

Case (i): Obtaining strong dominating set of AD (n) from strong dominating set of AD ($n - 1$).

Observe that vertices of degree 4 are obviously in the strong dominating set.

The vertices $(0, i), (0, -i), (i, 0), (-i, 0)$ are some dominating vertices in AD(n) and these vertices are the strong dominating vertices in AD($n - 1$) as $(0, i - 1), (0, -(i - 1)), (i - 1, 0), (-(i - 1), 0)$.

Hence $(4n + 8) - 4$ vertices are to be dominated by maximum degree vertices. Add $n + 1$ vertices with degree 4 vertices. For AD (6), $\gamma_{sd}(AD(6)) = \gamma_{sd}(AD(5)) + 7 = 22 + 7 = 29 = 7(6) - 13$. In general, the strong dominating vertices of n are 7 times n with removal of 13 vertices. i.e. $\gamma_{sd}(AD(n)) = 7n - 13$ is the minimum strong domination number of AD (n).

Case (ii): Obtaining strong domination number of AD (n) from its center vertex $(0, 0)$.

Center vertex is of degree 4. Now divide the graph into 4 parts with x, y plane as border of any 2 set. Number of strong dominating vertices in first phase = Number of strong dominating vertices in second phase. From this, even

Thangam and Angelin Kavitha Raj

number of vertices in first set of strong dominating set is obtained. Remaining vertices in x plane is $2n + 1$. For these vertices, $n = \lfloor \frac{n}{2} \rfloor$ are required which satisfy $\deg(u) \geq \deg(v)$.

Hence $7n - 13$ is the minimum cardinality strong domination number with various possible dominating set in both connected and isolated nodes.

I.e.) $\gamma_{sd}(AD(n)) = 7n - 13$, for $n > 4$ where $n \in \mathbb{N}$.

St.sec dominating set (SSDS) of AD network

Majority of the network designs are failed or unused due to its insecure properties on its connections. Mild leakage or damage or attack on any node stops the whole output. The design of AD network is well known and it is simple to secure the whole nodes with small number of nodes.

Lemma 2.1: The SSDN of AD (1) is 4.

Proof: consider the strong dominating set of this AD as X , where $X = \{(0, 0), (0, 1), (0, -1)\}$.

Now $X \setminus \{0, 1\} \cup \{1, 1\}$ is not a dominating set, $X \setminus \{0, 0\} \cup \{1, 0\}$ is a dominating set,

$X \setminus \{0, 0\} \cup \{-1, 0\}$ is a dominating set, $X \setminus \{0, -1\} \cup \{1, -1\}$ is not a dominating set,

$X \setminus \{0, -1\} \cup \{-1, -1\}$ is not a dominating set.

Thus $\gamma_{sd}(AD(1)) \neq \gamma_{ssd}(AD(1))$. Adding $(1, 0)$ to the strong dominating set satisfies the st.sec dominating set.

Therefore $\gamma_{ssd}(AD(1)) = 4$.

Lemma 2.2: The SSDN of AD (2) is 9.

Proof: The minimum st.sec dominating set obtained from this graph is independent.

Remark 2.4: In general, $\gamma_{sd}(G) \leq \gamma_{ssd}(G)$ [1]

Here $\gamma_{sd}(G) < \gamma_{ssd}(G)$ for AD (n), $n \in \mathbb{N} > 1$.

Theorem 2.5: The st.sec domination number of AD (n) where $n \in \mathbb{N} > 1$ is

$$\gamma_{ssd}(AD(n)) = 9 + 8(n - 2)$$

Proof: The strong dominating set itself is not the st.sec dominating set and $\gamma_{sd}(G) < \gamma_{ssd}(G)$. Let the dominating set be X . let $u \in X$ and $v \in V - X$. We have to prove each vertex in $V - X$ when defected should be replaced by a vertex in X and the $\deg(u) \geq \deg(v)$. some neighbors of X belongs to $V - X$ will have $\deg(u) < \deg(v)$. It is determined that those nodes are on the exact x and y plane are special. I.e.) some nodes on $X = (0, i), (0, -i), (i, 0), (-i, 0)$ where $i, -i \in \mathbb{N}$ and $i = n - i$. $N(X) = \{(0, i - 1), (0, -i - 1), (i - 1, 0), (-i - 1, 0)\}$ whose degrees are higher than X . Therefore it is impossible to replace these by X . But these Nodes are also neighbors of $\{(0, i - 2), (0, -i - 2), (i - 2, 0), (-i - 2, 0)\}$. So these nodes are mandatory for $N(X)$ and these nodes are also in X is important. This is the initial condition on choosing nodes as strong securities on x, y plane. Fixing AD (2) st.sec dominating sets for all AD (n). Remaining nodes are subdivided as 4 portions. Hence minimalism results in $8(n - 2)$. Therefore $\gamma_{ssd}(AD(n)) = 9 + 8(n - 2)$. On the contrary, let the minimum cardinality of the st.sec domination number of AD (n) be $9 + 8(n - 3)$.

Let $n = 3$; $V(AD(3)) = 37$.

$$\Rightarrow \gamma_{ssd}(AD(3)) = 9 + 8(3 - 3) = 9.$$

In AD (3) has no. of. Vertices with degree 4 is 21; no. of. Vertices of degree 3 is 4; no. of. Vertices with degree 2 are 12. Now 9 vertices with degree 4 can dominate 36 vertices.

$$V(AD(3)) = 37 > 36.$$

For the secure process, the first condition is that all the vertices in $V - X$ should be dominated by vertices in X . Hence our assumption is wrong and therefore $\gamma_{ssd}(AD(n)) = 9 + 8(n - 2)$ is the minimum cardinality of St.sec domination number of Aztec Diamond Network.

St.co-secdomination number of Icosahedral Triangular Network:

Here we denote the Icosahedral Triangular Network of n by $IT(n)$ where we denote the terms as $(R_{n+1, 2n+1})$ for $n \geq 1$.

Lemma 3.1: For $n = 1$, the st.co-secdomination number of IT network is 2 where $IT(1)$ is $R_{2, 3}$.

Thangam and Angelin Kavitha Raj

Proof: We know that the minimum st.secdomination and st.co-secdomination number for any graph is 2. The minimum strong dominating sets of $R_{2,3}$ are $D = \{R_{12}, R_{13}\}$ or $\{R_{21}, R_{22}\}$. These are the vertices with higher degree. Let $u \in D$ and $v \in V - D$. we have to prove that these strong dominating sets satisfy $D \setminus \{u\} \cup \{v\}$ is a dominating set.

Case (i): $D = \{R_{12}, R_{13}\}$

$N(R_{12}) = \{R_{11}, R_{13}, R_{21}, R_{22}\}$; $N(R_{13}) = \{R_{12}, R_{22}, R_{23}\}$ where N denotes the neighborhoods. If the node R_{12} or R_{13} get attacked, then to rescue the remaining nodes, at least one of its neighbor node is considered without any change in domination process.

Now $D \setminus \{R_{12}\} \cup \{R_{22}\}$ is not a dominating set, $D \setminus \{R_{12}\} \cup \{R_{11}\}$ and $D \setminus \{R_{12}\} \cup \{R_{21}\}$ are dominating sets. Similarly, $D \setminus \{R_{13}\} \cup \{R_{23}\}$ is a dominating set.

It is not possible for R_{22} to replace R_{13} since $\deg(u) < \deg(v)$.

Case (ii): $D = \{R_{21}, R_{22}\}$

$N(R_{21}) = \{R_{11}, R_{12}, R_{22}\}$; $N(R_{22}) = \{R_{12}, R_{13}, R_{21}, R_{23}\}$ where N denotes the neighborhoods. If the node R_{21} or R_{22} attacked, then to rescue the remaining nodes, at least one of its neighbor nodes is considered without any change in domination process.

Now $D \setminus \{R_{21}\} \cup \{R_{11}\}$ is a dominating set, $D \setminus \{R_{22}\} \cup \{R_{13}\}$ is a dominating set.

It is not possible to replace R_{21} by R_{22} since $\deg(u) < \deg(v)$.

Hence from above cases, the minimum st.co-secdomination number of $IT(1)$ is 2. i.e.) $\gamma_{scsd}(IT(1)) = 2$.

Lemma 3.2: For $R_{3,5}$, the st.co-secdomination number of IT network is 5.

Proof: The domination number of $R_{3,5}$ is 3.

i.e) $D = \{R_{21}, R_{23}, R_{25}\}$ is one of the possible dominating set.

Now the nodes in the centre path are $R_{21}, R_{22}, R_{23}, R_{24}, R_{25}$. These nodes are of degree higher than or equal to 4. Let the 3 nodes in D are to be st.co-sec dominating set. Suppose R_{21} is defected, then its neighbor R_{22} is not possible to replace as it has degree greater than R_{21} . Replacing R_{21} by R_{12} or R_{21} by R_{31} or R_{21} by R_{11} is not a dominating set. Hence the dominating set itself is not st.co-sec dominating set.

Let $D_1 = \{R_{21}, R_{22}, R_{23}, R_{24}, R_{25}\}$. Now to find neighbor nodes to these attacked nodes.

$D_1 \setminus \{R_{21}\} \cup \{R_{11}\}, D_1 \setminus \{R_{22}\} \cup \{R_{31}\}, D_1 \setminus \{R_{23}\} \cup \{R_{33}\}, D_1 \setminus \{R_{24}\} \cup \{R_{15}\}, D_1 \setminus \{R_{25}\} \cup \{R_{35}\}$ are dominating sets. Thus D_1 is the st.co-sec dominating set.

To prove the minimum cardinality, Let $D_2 = \{R_{21}, R_{23}, R_{24}, R_{25}\}$

Here R_{21} neighbors $R_{11}, R_{22}, R_{12}, R_{31}$ fail to replace and satisfy the dominating set when R_{21} get attacked. Also any of these sets of D 's with 4 nodes do not satisfy the dominating set.

Hence $\gamma_{scsd}(R_{3,5}) = 5$.

Remark 3.3: $\gamma_{sd}(IT(n)) < \gamma_{scsd}(IT(n))$ for $n > 1$ where $IT(n)$ is $(R_{n+1}, 2n+1)$

In the next theorem, the extension of the summation of (2^{2k-i}) always ends at 2^5 with addition to remaining number of strong dominating vertices.

Theorem 3.4: If $n = 2^k$, then

$$\sum_{i=1,3,5} 2^{2k-i} + k - 2 + \gamma_s(R_{5,9}) = \gamma_{scsd}(R_{n+1}, 2n+1)$$

Proof

The structure of Icosahedral Triangular Network is the development of splitting of origin $R_{2,3}$ network. From lemma of $n = 2^2$ and $n = 2^3$, we can derive the st.secdomination number of $n = 2^k$. In $n = 2^k$, where $k = 2$, the strong dominating set is $D = \{R_{14}, R_{21}, R_{26}, R_{28}, R_{42}, R_{44}, R_{49}, R_{56}\}$ The vertex $\{R_{21}\}$ is dominating its neighbours. But when attacked, none of its neighbours will replace to continue the process.

Thangam and Angelin Kavitha Raj

le) $D \setminus \{R_{21}\} \cup$ any one of its neighbours is not a dominating set, $D \setminus \{R_{14}\} \cup$ any one of its neighbours is not a dominating set. Therefore $\gamma_s(R_{5,9}) \neq \gamma_{scsd}(R_{5,9})$

To this strong dominating set, add 8 more vertices whose degrees are higher than or equal to its neighbours.

Let the st.co-sec dominating set be D' .

The nodes of D' are $\{R_{14}, R_{21}, R_{23}, R_{26}, R_{28}, R_{34}, R_{38}, R_{41}, R_{42}, R_{44}, R_{46}, R_{49}, R_{56}, R_{58}\}$

Therefore $|D'| = 14 = \gamma_{scsd}(R_{5,9})$

Now vary with this numbers with respect to power of 2,

$$\Rightarrow 2^4 - 2 = 14.$$

$$\text{Similarly, } \gamma_{scsd}(R_{9,17}) = 47 = 2^5 + 2^4 - 1$$

$$\gamma_{scsd}(R_{17,33}) = 176 = 2^7 + 2^5 + 2^4$$

$$\gamma_{scsd}(R_{33,65}) = 689 = 2^9 + 2^7 + 2^5 + 2^4 + 1$$

Continuing in this procedure, we get

$$\gamma_{scsd}(R_{n+1, 2n+1}) = \sum_{i=1,3,5} 2^{2k-i} + k - 2 + \gamma_s(R_{5,9})$$

Example 3.5: The st.co-secdomination number of $R_{3,5}$ is 5.

The oval dots are st.co-secdomination numbers of this network.

CONCLUSION

The aim of this research is to optimize active movable guards in securing valuable networks in the form of Aztec Diamond and Icosahedral triangular Networks. The major application is to replacing the defected systems with suitable relative systems without stopping the whole process. Immediate replacement option to continue crucial position values more in both time and output. This can be extended to other suitable networks related to chemical graphs, computational graphs and networks.

ABSTRACT

A Simple, sensitive and specific UV methods were developed for simultaneous estimation of Dolutegravir and Lamivudine in bulk and tablet dosage form. Effective analysis was done by simultaneous equation, isobestic point and Q-absorbance ratio method by using acetonitrile and water (1:1) solvent system. The 258nm and 271nm were adopted in simultaneous equation method. The 260nm wavelength used in isobestic point and Q-absorbance ratio method. The developed methods were validated as per ICH Q2(R1) provisions. The developed methods were linear in the concentration range of 5-30 µg/mL for Dolutegravir and Lamivudine. The given concentration series was obeying the Beer's-Lambert's law limits. Accuracy studies for Dolutegravir and Lamivudine were done and the % recovery for Dolutegravir and Lamivudine was obtained in the range of 98.35-100.51% by all the methods assuring the accuracy of the stated UV method. All the methods have shown good precision and robustness with %RSD less than 2. The data have been statistically validated, and the results demonstrate that the methods that have been proposed can be implemented effectively for the regular evaluation of drugs in commercialized tablets.

Keywords: Lamivudine, Dolutegravir, Simultaneous equation, Isobestic Point, Q- Absorbance, Specific Absorptivity.

**Ramreddy Godela et al.,**

INTRODUCTION

Analytical methods are essential in maintaining the quality and quantity of drugs in drug products, as well as in the formulation development process because they help to maintain the quality and efficiency of the drug product throughout the product development process until its final [1,2]. The breakthrough in HIV medicine has allowed people to live for longer periods of time and to live more productive lives. To effectively treat HIV, multi drug therapy (which involves taking three or more drugs alone or in combination daily) is used [2]. However, thorough studies on multiple drug therapy have demonstrated that a two-drug treatment consisting of Lamivudine (LMV) and Dolutegravir (DLG) effectively controls the HIV disease[3,4]. DLG, a second-generation antiretroviral agent, gained approval from US FDA in 2013 for treating HIV infections in all populations [4,5]. DLG is an effective second-generation integrase strand transfer inhibitor (INSTI) used in HIV-1 patients to prolong the survival period. It acts by inhibiting the integration of viral DNA into the DNA material of host (T-cells)[4-6]. Chemically DLG is (4R,12aS)-N-[(2,4-Difluorophenyl)methyl]-3,4,6,8,12,12a-hexahydro-7-hydroxy-4-methyl-6,8-dioxo-2H-pyrido [1',2':4,5] pyrazino[2,1-b][1,3]oxazine-9-carboxamide [6]. Lamivudine is a classical antiviral agent used in HIV-1 patients alone or in co-formulation with other antiviral agents [7]. LMV triphosphate (3TCTP) is the active moiety of LMV competitively inhibits the reverse transcriptase enzyme leads to termination of viral genome replication [8]. Chemically LMV is 4-amino-1-[(2R, 5S)-2-(hydroxyl methyl)-1, 3-oxathiolan-5-yl]-1, 2-dihydropyrimidin-2-one [8]. DLG co-formulated with LMV combination is a potent regimen showing high therapeutics index [9]. (Figure 1: Chemical structures of Dolutegravir and Lamivudine)

A detailed literature review found that two UV methods have been described for estimating LMV and DLG in pharmaceutical dosage forms [10,11]. Few UV-Visible spectroscopic methods were reported for individual estimation of DLG and LMV [12-15]. Simultaneous estimation of intended analyte with other antiviral agents by UV method were available in literature [16-20]. Few RP-HPLC methods for estimating LMV, DLG, Tenofovir disoproxil fumarate, Butcaver sulfate, or Abacavir in the triple combination [21-24]. Few Liquid chromatographic methods were reported for analysis of LMV and DLG simultaneously in both bulk mixture and combined tablets [25,26]. To date, no UV method approach has been published in the literature for the simultaneous measurement of LMV and DLG in bulk and tablet dosage forms by simultaneous equation, isobestic point and Q-absorbance method. As a result, we are researching to create an effective, sensitive, and economically feasible UV approach for estimating the % purity of DLG and LMV in bulk and tablet dosage forms at the same time by simultaneous equation, isobestic point and Q - Absorbance ratio methods [27]. The Q2 specification of the ICH guidelines validated the created approach.

MATERIALS AND METHODS

API of LMV and DLG were provided by fortune pharma, Telangana as gift sample. AR grade acetonitrile, methanol, Milli-Q and remaining chemicals were obtained from Merck India, Mumbai, India. Absorbance measurements were made using Shimadzu (U-1900) UV/Visible spectrophotometer coupled with UV- probe data acquisition software.

Method Development

Selection of Solvent

The study investigated the solubility of DLG and LMV in different solvents, including water, methanol, and acetonitrile. The results showed that the DLG was highly soluble in acetonitrile and methanol, while it exhibited poor solubility in water. Similarly, the solubility of LMV was assessed in the same solvents and was found to have good solubility in water, methanol and acetonitrile. Based on its cost-effectiveness and safety profile, acetonitrile and water in 1:1 ratio was chosen as the preferred solvent for dissolving the drug.

Ramreddy Godela et al.,

Preparation of Stock Solution (1000µg/ml)

Accurately weighed quantity of pure DLG (100mg) and pure LMV (100mg) were transferred into two separate 100 ml volumetric flasks, dissolved with the solvent system of acetonitrile and water (1:1) and made up to 100 ml with same solvent to give solution containing 1000µg/ml. The solution was sonicated for 5mins.

Preparation of Working Standard (100µg/ml)

10ml of the stock each stock solution was taken and transferred to another separate 100ml volumetric flask and the same solvent system was added up to 100ml for additional dilution to give a solution containing 100µg/ml.

Determination of Absorption Maxima (λ_{max}) and Isobestic Point of DLG and LMV

10µg/ml of DLG and LMV solution were prepared by diluting 1ml of working standard solution again diluted to 10 ml with the same solvent system. The produced solutions of DLG and LMV were scanned in the UV spectrophotometer from 400-800nm to determine the λ_{max} of given compounds. The λ_{max} of DLG and LMV were observed to be 258nm and 271nm, correspondingly (Figure-2). The isobestic point of DLG and LMV confirmed at 260nm from the attained spectrum (Figure-2).

(Figure 2: Absorption Maxima and Isobestic Point Dolutegravir and Lamivudine)

Simultaneous Equation Method

Standard solutions of DLG and LMV in the concentration range of 5-40µg/mL and 5-40µg/mL respectively was prepared and the absorbance of these solutions was measured at 258 nm and 271 nm. Calibration curves were plotted to verify the Beer's law and the absorptivity values (calculated at the respective wavelengths for both the drugs. Two simultaneous equations as below were formed using these absorptivity values.

$$A_1 = 410C_x + 170C_y$$

$$A_2 = 310C_x + 230C_y$$

Where, C_x and C_y are the concentrations of DLG and LMV measured in gm/100mL in sample solutions. A_1 and A_2 are the absorbances of mixture at selected wavelengths 258 nm and 271 nm respectively.

Absorbance Ratio Method/ Q-Analysis

The absorbance ratio method is a modified version of the simultaneous equation procedure based on the principle that for a substance that follows Beer's law at all wavelengths, the absorbance ratio at any two wavelengths remains constant and independent of concentration or path length. This ratio is referred to as the Q value in the USP. In the quantitative assay of two components in admixture, the absorbance's are measured at two wavelengths - one at the λ_{max} of one of the components (λ_2) and the other at an iso-absorptive or isobestic point (λ_1) where the absorptivity of both components is equal. To validate Beer's law, a series of standard solutions of DLG and LMV in the concentration range of 5-30µg/mL and 5-30µg/mL, respectively, were prepared in phosphate buffer, and their absorbance was measured at 258nm and 260 nm (λ_{max} of CPX). The data was used to plot calibration curves, and absorptivity values (g/100ml) were calculated for both drugs at their respective wavelengths. The resulting absorptivity values were reported.

The concentration of two drugs in mixture was calculated by using the following equations:

$$C_x = \frac{Q_m - Q_y}{Q_x - Q_y} \times \frac{A_1}{a_{x1}}$$

$$C_y = \frac{Q_m - Q_x}{Q_y - Q_x} \times \frac{A_1}{a_{y1}}$$

Where, A_1 and A_2 are the absorbance's of dug mixture at 260nm and 271nm, a_{x1} (440), a_{x2} (310) and a_{y1} (480), a_{y2} (230) are A (1%, 1 cm) of DLG and LMV at 260nm and 271nm respectively,

$Q_m = A_2 / A_1, Q_x = a_{x2} / a_{x1}$ and $Q_y = a_{y2} / a_{y1}$

**Method validation****Linearity**

The method's linearity means concentration immediately affects test findings. The linearity of the current approach was tested by measuring absorbance values at 258nm and 271nm for DLG and LMV concentrations from 5 to 30 µg/mL. Finally, concentration-absorbance linearity graph was plotted and regression coefficient (R^2) calculated.

Precision

Precision studies were conducted to evaluate intraday and interday variations of FEX and MKT formulations at three distinct concentrations. Each concentration was prepared thrice and subjected to analysis. The assay was computed for each preparation and the corresponding %RSD) is presented.

Accuracy

The recommended method's accuracy was verified through the standard addition method at 75%, 100%, and 125% concentrations. This involved adding different concentrations of pure drug solutions to a predetermined amount of the DLG and LMV tablet sample (10µg/mL) and measuring the absorbance at the respective wavelengths. The analysis of the percentage recovery at each level was conducted through the utilization of both methods.

Specificity

Specificity refers to the capability of the method to accurately detect the analyte in the presence of other potentially interfering components. The specificity of the developed method for determining DLG and LMV in tablet dosage form was assessed by comparing the spectral characteristics of the tablet solution to those of the standard solution. The sample spectrum was thoroughly examined to identify any potential interferences arising from the presence of excipients.

Robustness

The maximum absorption wave length were purposely changed to test the method's resilience. After changing the wavelength maximum (± 2 nm), % RSD can be evaluated for obtained absorbance values.

Sensitivity

Standard deviation equations were utilized to calculate LOD and LOQ.

$$\text{LOD} = 3 \times \sigma / S$$

$$\text{LOQ} = 10 \times \sigma / S$$

Where, σ is the standard (SD) of the intercept

S -slope of the linear plot

Sandell's sensitivity

Sandell's index or sensitivity is the lowest concentration in ppm ($\mu\text{g}/\text{cm}^3$) with absorbance of 0.001 in a 1 cm path length. Calculated as:

$$\text{Sandell's index} = (0.001 \times 1\text{cm}) / \text{slope} (\text{cm}^3 / \mu\text{g})$$

Assay of tablets

20 tablets (DOVATO) of DLG and LMV were processed and powder equivalent to 10 mg of DLG and 30 mg of LMV was measured and then transferred to a 100 ml volumetric flask, mixed with an adequate solvent (ACN: Water, 1:1), sonicated for 5 min, and made up to the mark with same solvent. From this 1 ml diluted to 10 mL with identical solvent, the sample solution absorbance was measured at 258 nm and 271nm.

Ramreddy Godela *et al.*,

RESULTS AND DISCUSSION

The optimized method conditions such as ACN: water in equal portions, λ_{\max} of 258nm (DLG), 271nm (LMV), and isobestic point of 260nm were used to validate the stated method as of ICH. The DLG and LMV solutions were shown linearity with a concentration range from 5 to 30 μ g/mL. The given series of solutions were acceptable R^2 values at 258nm, 271nm and 260nm (Table-1, Figure-3). To the stated concentration series (5 to 30 μ g/mL) intraday and intermediate precisions were validated by computing the %RSD values, which assured the precision of the method (Table-2). The % recoveries of DLG and LMV in spiked solutions were observed to be 100 \pm 2% (Table-3). Potential changes were not happened in the UV spectrum of pure drug in comparison with tablet sample solution. Hence, the method was specific towards DLG and LMV. Slight modification in the wavelengths of optimized method could not affect the %RSD values of absorbance's (Table- 4). The LOD, LOQ and Sandell's sensitivity values of DLG and LMV were shown in Table-5. Those results were demonstrating the good sensitivity of the given approach. The % purities of the DLG and LMV in given tablets (DOVATO) were found to be 99.21 \pm 1.2% and 98.63 \pm 0.98% by simultaneous equation approach and 99.78 \pm 1.31% and 100.81 \pm 1.65% by Q- absorbance ratio method respectively.

As per literature only one UV methods was reported in literature for analysis of DLG and LMV. Rathod et al., was proposed first order derivative UV method for assessment of DLG and LMV[10]. The present method was designed in such a way to analyze DLG and LMV simultaneously by various predominated methods like simultaneous equation, isobestic point and Q-absorbance methods. The stated methods are obeying the Beer's- Lambert's law with given concentration. The possessed methods have superior sensitivity than the reported method. Simple solvent system made the method economical. Hence, the develop UV methods have good adoptability in pharmaceutical sector in regular analysis of DLG and LMV combined tablets.

CONCLUSION

Two new UV spectrophotometric techniques such as simultaneous equation, isobestic point and Q-absorbance analysis that are easy to use, sensitive, and cost-effective have been developed for the simultaneous measurement of DLG and LMV in bulk as well as in tablet formulations. Following successful validation of the methods that were created, it was determined from the statistical data that the approaches were linear, accurate, and exact, and that they are capable of being effectively employed for the study of table formulations without the interference of excipients.

ABSTRACT

The constant evolution of PC structures and applications facilitates continuous data processing, leading to the emergence of new cyberattacks, such as the eaves dropping MiTM attack. In this scenario, an external assailant clandestinely eavesdrops on the exchange of data between two online individuals, facilitating unauthorized entry into and alteration of confidential data without the individuals' knowledge or consent. This paper aims to delve into the intricacies of MITM attacks, including their various forms, mitigation strategies, and future research directions, to address this critical issue effectively.

Keywords: Data Security, Digital Assaults, MITM Assaults, Organization Security.

INTRODUCTION

The internet has integrated itself into our daily lives, becoming indispensable in today's modern world, shaping our routines and interactions. From mobile connectivity to social media dominance, online banking, and shopping, our dependence on the web is undeniable. However, with the advancement of web technology comes an increased risk of cyber threats, with hackers targeting businesses to retrieve confidential sensitive information, leading to potential financial losses. Among these threats, the MiTM attack poses a significant danger to security of networks. In this type of attack, the hacker intercepts communication between two parties, often without their knowledge, exploiting various channels such as GSM, Wi-Fi, UMTS, and Bluetooth. The goal of the attacker extends beyond mere eavesdropping; they seek to manipulate data integrity, spread misinformation, and disrupt communication channels. MITM attacks can compromise both the confidentiality and integrity of data, leading to serious consequences for unsuspecting users. Various terms such as MiM, MitM, MTIM are used interchangeably to refer to this pervasive

**Imran Qureshi and Shadab**

threat. A prevalent example of such incidents is commonly referred to as strong snooping, wherein adversaries establish unauthorized connections with the parties involved and insert themselves in the middle of the communication, effectively intercepting messages between them. To tamper with the messages, the attacker can intercept them as they pass between the two parties. Many cryptographic systems utilize endpoint authentication to address MITM attacks. These incidents can be categorized into four primary groups. The primary categorization includes Man-in-the-Middle (MITM) attacks based on spoofing, wherein the assailant disrupts communication between two entities by employing spoofing techniques, manipulating the communication without leaving any trace to deceive the unsuspecting parties. In some cases, attackers employ various methods such as DNS spoofing to impersonate endpoints or devices. Additionally, TLS/SSL attacks involve the attacker becoming part of the communication between two endpoints, intercepting, and altering the communication undetected. Another example is the BGP MITM attack, where the attacker redirects traffic to their intended target, known as IP hijacking, rerouting traffic through a controlled intermediary. Lastly, there are deceptive base station attacks, where attackers set up fake base stations to control the traffic of unsuspecting victims. MITM resembles a game of catch between two individuals, with a third party attempting to intercept the ball. This paper addresses various forms of spoofing attacks and explores future prospects in the field.

SPOOFING BASED MITM ATTACKS

Caricaturing comes from "snoop," a phrase for European spies who made up identities to listen in on private conversations. Attackers introduce themselves into communication between two parties to manipulate data flow without the victims' knowledge in modern spoofing. Upon encountering an encrypted network that presents as an unfamiliar MAC address, the server initiates an Address Resolution Protocol (ARP) request to all connected clients. Active web display clients usually respond with their Mac address. ARP caching without authentication might generate phony ARP messages, giving attackers gateways. Man-in-the-Middle (MITM) attacks jeopardize sensitive information and interrupt communication by altering message content. Manufacturers regularly upgrade security to prevent MITM attacks. Under optimal circumstances, the attacker "Z" (IP=10.0.y.y.3, MAC address=FF:FF:FF:Y3) manipulates the ARP table of the victim "M" by transmitting a falsified ARP response. Consequently, communications intended for "M" from victim "D" (IP=10.0.y.y.1, MAC address=CC:CC:CC:Y1) are rerouted to "Z," disrupting communication. Despite genuine address updates, "M" adheres to protocol. Refer to the figure below for a visual representation of the described scenario.

ARP SPOOFING

These activities facilitate the mapping of network conversations to specific Mac addresses. ARP plays a crucial role as a foundational and indispensable method for LAN configurations. Attackers take advantage of neighboring ARP cache tables, replacing the host's MAC address with the target IP address, aiming to gain unauthorized access to the client's sensitive data. ARP spoofing attacks typically fall into two main categories: host impersonation and gateway impersonation within the internal network. When a user endeavors to establish a connection with another user possessing an unknown Mac address within the same network, a data transmission is initiated. Such transmissions occur when ARP functions are active within the network. Due to the absence of authentication mechanisms, manipulating cache entries becomes straightforward. The source device can optimize data transmission efficiency during connection periods by retaining IP-to-Mac mappings in the cache. Despite its importance at the network layer, ARP lacks robust security measures within its masking scheme.

Identifying ARP spoofing

Below are outlined several techniques for detecting ARP spoofing

Cryptographic solutions

A significant advancement in combating ARP spoofing is S-ARP [8], which employs metropolitan key cryptography to authenticate ARP responses. These cryptographic methods validate a client's authenticity, thereby thwarting ARP spoofing attacks effectively. P-ARP represents a notable variation of this method with a strong emphasis on security. To authenticate the information, both the magic number and HMAC hash function must be incorporated.

**Imran Qureshi and Shadab****Voting-based solutions**

A robust framework against VB impersonation is provided by MR-ARP. When MR-ARP detects the presence of ARP response or request messages, it verifies whether the device is using the new IP address.

Solutions based on server-side implementations.

A non-cryptographic solution, referred to as 'fix,' has been proposed to address ARP spoofing. This method mandates that the legitimate owner of the IP address intervenes in the event of a MAC address conflict, thereby thwarting ARP spoofing attempt.

Host-based solutions

Host-based solutions, such as middleware, offer a method for handling asynchronous requests and mitigating ARP spoofing attacks, as proposed in [13].

Hardware solution

Enthusiastic ARP assessment was applied in unambiguous changes to get additional security and confirmation of the relationship from ARP satirizing assaults. Its affirmations advancing of just supported ARP answers and requests. Ethernet change sees the cogency of the spread-out ARP bundles.

Manipulation of DNS

The DNS server employs a referenced ID scheme for URL resolution, which is integral to the client-server architecture. The DNS space and server names are dynamically organized into subordinate level domains. One of the most detrimental attacks, aimed at enhancing performance through cache poisoning, encompasses three main types: data packet sniffing during transmission, cache poisoning during celebratory events, and unauthorized DNS querying. By manipulating and controlling the local DNS, attackers coerce the target user into utilizing a fraudulent server to execute DNS spoofing. DNS manages the Time-to-Live (TTL) of domains and retrieves data from its cache. DNS spoofing attacks are executed through a denial-of-service approach. The attack involves two stages: first, the attacker injects a malicious DNS into the network, generating false data, and second, the attacker sends a fake DNS response before a legitimate one, thus intercepting the resolution process.

Detection of DNS spoofing

A straightforward method is provided for identifying such assaults:

MITM IN VANETS

MITM attacks, also known as Message Injection attacks, involve attackers attempting to modify the communication between legitimate entities, and their outcomes are particularly critical as such messages often contain sensitive information. These attacks are executed in two modes: an active mode and a passive mode, as depicted in Figure 3a.

Simulation Findings and Analysis

In this piece of the paper, the consequences of two varieties of man-in-the-middle attacks in VANET – message upset and message change – are showed up through framing.

Message Delay Attacks

After the man-in-the-middle attack, the nodes experience a 2-second delay, as depicted in the figure above. An appreciable increase in delay occurs when multiple malicious nodes are introduced into such networks. This is because relays ensure that messages reach their endpoints without delay, leading to a significant impact on network performance by such attackers. The interaction is directly proportional to the presence of malicious nodes; even a tenth of the nodes can introduce delays of up to 47%. As the percentage of malicious nodes reaches 60%, latency in these networks can rise to 80%. Figure 4b illustrates that communication may still occur despite attacks, albeit with a temporal delay. The measurement in the image below confirms that the message reached the endpoint, albeit with a particular delay. Continuing from the previous point, an increase in the number of malicious nodes leads to a

**Imran Qureshi and Shadab**

noticeable rise in packet loss and delay. For example, if a network is infiltrated with approximately 40% malicious nodes, it results in approximately 20% packet loss.

Message Tamper Attacks

Taking into account the points discussed thus far, it becomes apparent that the existence of any compromised node within the network can impact not only the content or destination of the message but also various aspects of the data. In such scenarios, this paper specifically focuses on preserving the integrity of the message data. As depicted in Figure 5a, disruptions within the network, exemplified by a malicious node, have the potential to alter the overall message content. Additionally, the end-to-end delay in the network generally escalates in correlation with the inclusion of compromised nodes. Naturally, there is a decrease in CDR as the number of malicious nodes increases, as shown in Figure 5b. Additionally, the attack's path will influence the CDR. As depicted in Fig 5b, when a lesser portion of the network is malicious, the end user can choose to offload genuine messages to the recipient. This leads to a potential increase in CDR. The final segment of the study outlines the quantity of altered messages, sharing a similar nature with the preceding part of the research. Owing to the widespread presence of malicious nodes throughout the network, a considerable number of messages and their contents are compromised. Furthermore, malicious hubs are overwhelmed due to the high frequency of fabricated message contents. Figure 6 illustrates the severity of the compromised messages.

CONCLUSIONS

The aim of this paper is to examine various MITM attacks and provide a comprehensive overview of these assaults, along with defensive mechanisms based on PC impersonation practices. In addition to presenting different MITM defense strategies and their descriptions, the paper focuses on ensuring data integrity and security, as well as the smooth transmission of genuine data between endpoints, which are the primary objectives of the adversary. The latter part of the paper reviews various types of person-in-the-middle attacks and their corresponding defensive strategies. Currently, one of the most significant challenges lies in the fact that Man-in-the-Middle attacks are still facilitated by streaming data through a proxy. However, the evolution of the MITM technique has not been fully elucidated, thus laying the groundwork for subsequent research. Key distribution and elliptic curve cryptography are two examples of cryptographic techniques that can complement man-in-the-middle attacks. In future studies, it is imperative to expand our investigation to assess the impact of such attacks on various VANET infrastructures, particularly concerning node scalability.

Medium of Communication	Protocol	Concerns
Server Based Communication	ARP	Can't work for wireless communications.
Server Based/ Host Based	ARP, DHCP	Compatible for DoS. DHCP but has a single point of failure.
Host Based	ARP	Level of importance of each host is very difficult to decide.
Host Based	ARP	Works only with Linksys routers. Static IP not supported.
Cryptographic/ Host Based	UDP/ ARP	For UDP, authentication is a must need.
SYMMETRIC PRIVATE-KEY CRYPTOGRAPHY	DHCP	Legitimate hosts must register in advance, adds additional message flow, hard to manage for large number of hosts.
SYMMETRIC PRIVATE-KEY CRYPTOGRAPHY, RFC	DCHP, DHCP	The authors did not describe how the random value (the number, which used by the server and client to compute the session key) is determined.
Router Based	IP, ARP	Filtering-on-path method can't ensure a secure communication.
Router/ Host Based	IP, DHCP	This system is considered as the highest secured communication. But not so user friendly.

ABSTRACT

Man has been since time immemorial baffled by disease and suffering. From God's Curses to blatant superstition, we have been searching for the cause of disease. With the advancement of science, we have the advantage of identifying pathogens and reactive agents. But these pathogens and agents have existed with us for a long time. After a dinner out, why do I suffer from gastritis and not my friend, even though we ate the same thing, is the eternal question. "Why me." Here we have been trying to answer this through homoeopathy.

Keywords: we have been searching for the cause of disease. With the advancement of science, we have the advantage of identifying pathogens and reactive agents.

INTRODUCTION

Nature is dynamic. Every part of it vibrates like a never-ending rhythm of the tuning fork. But it always follows a set pattern. It follows the regularity and periodicity of the higher order. What is reality? Albert Einstein says, 'Reality is merely an illusion.' It changes according to the person experiencing it. It is the exact reflection of our deep inner pattern – our personality. What is reality for one person may be an imagination for the other. "Absolute reality" has no basis in individual experiences. Each person experiences reality in his/her unique way. Werner Heisenberg says, 'What we observe is not the nature itself, but the nature exposed to our methods of questioning.' Therefore, what people narrate is not reality but their own experience of reality. Our personalities perceive and react to everything including different situations and diseases, in a unique way and with varying degrees of intensity as compared to other personalities. B K sarkar in his organon says, we do not observe life but only living beings. We can study living organisms' properties and differentiate them from other non-living entities. Dr. Hahnemann says as practical physicians we are more concerned with the scientific aspect of life and this confusion of categories is the cause of

**Mital Joshi and Honey Patel**

failure. The chief source of complexity in observing life phenomena is that life though dynamic expresses itself through the material body. The result is that physio-chemical phenomena and vital phenomena exist together. Hahnemann observed one fundamental difference between a living and a non-living body. The living body is endowed with sensations, functions, and the power of self-preservation. In health, man is in a state of ease of comfort with regards to sensations felt by him and functions of his body. He feels neither the existence of his organs nor the tasks carried out by them. As soon as he feels the existence of his internal organ or its workings in any way, he becomes diseased. That brings us to the question, who is man? Einstein says, "A human being is a part of the whole, called by us the universe, a part limited by time and space. He experiences himself, his thoughts, and feelings, as something separate from the rest, a kind of optical delusion."

Dr. Vishpala Parthasarathy emphasises that our body is a whole unit. We may give different names to diseases affecting various organs or parts of the body. It is just the different phases of the disease moving from periphery to centre. Every expression of disease is a chain of cause and effect with a beginning, growth, and end. When we understand the disease in relation to the human body's immune response, we will be able to perceive and realise the benefits of homoeopathy. Homoeopathy since the beginning advocates the concept of unity of mind and body. This unity can only keep the man healthy and functional. Homoeopathy is firmly rooted in the idea that no two individuals are ever likely to come up with exactly similar descriptions of their symptoms. S M Gunavante says the vital force has its sway over the whole body, all organs, and tissues of the patient. It is involved in resistance to diseases wherever they may occur. Therefore, homoeopathic medicines aim to restore the deranged vital force to its full power. No organ can become diseased without a preceding disturbance of the vital force. And, therefore it is a mistake to treat a part as if it stood alone.

This dynamization cannot exist without a governing principle which can be termed as a Vital force. Dr. Herbert Roberts the stalwart of Homoeopathy writes, "When two parent cells are united, the vital energy, is already present. It has the power to develop the cells. This vital energy is the cause, the living organism is capable of physical action and mental capacity." The influence of this vital force is so delicately adjusted and intimately connected with every part, that seemingly distant organs or unrelated symptoms show the effects of disturbance. Susceptibility is the inherent capacity of matter of life to receive impressions. It also has the power of a living organism to react to stimuli. In living beings, susceptibility varies in response to their perception of reality. Any change in the normal susceptibility will interfere with the capacity of the predetermined response. This interference will be reflected in a chain response. This in turn leads to the loss of balance of health. Health is a balanced condition of the living organism in which the (integral, harmonious performance of) vital force tends to preserve the organism and help in the normal development of the individual. Whereas, disease is an abnormal process, a changed condition of life, which is inimical to the true development of the individual and leads to organic dissolution.

Agents, material or immaterial, which modify health or cause disease, act solely by their substantial existence and the co-existence of the vital substance which reacts in the living organism to every impression made within or without. Power resides at the centre. The phenomena of life, as manifested in growth, nutrition, repair, secretion, excretion, self-recognition, self-preservation, and reproduction all take their direction from the centre. Resistance to morbid agents is from the centre where life reigns. Vital resistance is the defensive action of the living to the obnoxious elements. Metaphorically speaking, disease is resistance. It is unveiled through symptoms. It is a battle, a struggle, a costly and painful resistance to the invader. We must differentiate between the cause and the effect. We must not let the phenomena which we perceive with our organs of sensation bind us to the existence of the invisible poser which produces them. Functional or dynamic change always precedes tissue changes. Internal changes take place before the external signs.

Mital Joshi and Honey Patel

CONCLUSION

The mere removal of the tangible products of disease does not always lead to a cure. The cure is often obtained by internal administration of the remedy, with due regard to proper auxiliary, psychical, hygienic, and mechanical treatment.

ABSTRACT

In the realm of road safety, accurately predicting traffic accidents is pivotal for implementing proactive measures and reducing accident rates. This study presents a comprehensive approach to enhancing prediction accuracy by employing a hybrid machine learning model, combining Random Forest (RF) and Support Vector Machine (SVM) techniques. The dataset, collected from Kaggle, encompasses road traffic accidents from 2017 to 2020, consisting of 32 features and 12,316 accident occurrences. Following data preprocessing, including Min-Max normalization, the hybrid RF-SVM model is implemented to leverage the strengths of both ensemble learning and margin-based classifiers. The Random Forest component is utilized for feature selection and dimensionality reduction, efficiently handling large datasets and identifying the most significant features contributing to accidents. This step reduces the model's complexity and enhances its interpretability. Subsequently, the SVM component performs the classification task, optimizing decision boundaries with a focused set of features. The SVM's ability to handle both linear and non-linear relationships, coupled with kernel tricks, ensures robust separation of accident-prone and non-accident-prone instances. Comparative analysis with other hybrid models, such as Conv-LSTM, CNN-LSTM, and CNN-GRU, demonstrates the superior performance of the RF-SVM model. The proposed model is implemented in Python software that achieves an impressive accuracy of 99.13%. These metrics underscore the model's capability to provide reliable predictions and effectively balance precision and recall. The insights gained from the feature selection process inform policymakers about critical factors contributing to accidents, guiding targeted interventions for road safety improvements. This study's findings highlight the potential of hybrid machine learning models in advancing the predictive analytics of road traffic accidents, paving the way for smarter, data-driven road safety strategies.

**Girija and Divya****Keywords:** Support Vector Machine, Random Forest, road traffic, accident severity prediction, Machine Learning**INTRODUCTION**

Across the Indian subcontinent, there is a general concern with car crashes. In the US, car crashes claimed the lives of almost 151,000 individuals in 2019. About three and five percentage points of GDP was lost each year as a result of traffic accidents. India is home to only 1% of the world's autos, yet in 2013 it accounted for around 6% of all traffic accidents. Nearly 70% of the incidents affected younger Indians[1][2]. Traffic research predict that there will be a rise in the amount of car accident-related deaths and injuries. Modern methods are currently being used for traffic administration and preparation due to its significance. Vehicle crashes will decrease as a result of laws and actions that are predicated on the idea that there are traffic hazards[3]. The investigators presented a computer vision-based approach for predicting car crashes[4]. By monitoring roadside camera recordings, they were enabled to understand certain circumstances with an accuracy of 85%. Researchers who find value in the underlying causes of crashes on roads have performed more study in recent years[5]. Researchers studied driver behavior and strategy throughout the whole variable lane structure in order to pinpoint potentially hazardous driving behaviors. A high roadway slope puts both vehicles and pedestrians at serious risk, based to research looking into the relationship among pavement conditions and auto accidents. Furthermore, the threats presented by climate change and the changing demography of visitors have never been the subject of any previous investigation. But most of these studies have just examined one aspect of the environment whether it is motorists, tourists, highways, or the surroundings overall in connection to injuries[6]. In order to guarantee the security of participants at the database mining equipment event, a range of data mining strategies are employed by college pupils[7]. The investigation of the causative elements that lead to visitor damage frequently involves the use of organizational data mining.

Strict communication standards are used to expose the hidden networks throughout the risk data[8]. Constructing the foundations in such a way that the users can live up to the value and standards of the underpinnings with a dual standard of trust and encouragement can draw them in[9]. The alarmingly high daily toll of people died in traffic accidents more than 3,000 means that "road security represents an enormous public health issue in today's society." Road accidents also cause damage to the world economy. The expenses incurred by emerging nations due to this[10][11]. The road communication unit is vital for conducting study on the recognition of essential elements for an improved comprehension of the order of events and the usage of connected data in important target positions. There are several regionally accessible mining strategies available for a small amount expenditure when it involves transmitting Brodbingnagian data. Only one Asian nation's officials had documentation of the collision. The method used to aggregate, compile, and record data about accidents has an extensive list of enhancements that the channel, which covers incidents of accidents exclusively, would like to see created. At present, analysts rely solely on the simplest details and report failure when attempting to draw inferences from it; data mining tools are widely available. Scholars utilise an extensive range of information mining methodologies. Data mining has been used to extract predictable details from large knowledge sets, and the results of the data summary are often displayed in an intuitive manner. Techniques for analysing data help identify the most significant or enduring patterns. The key contributions of the article is,

- This study introduces a novel hybrid ML model that combines RF and SVM techniques, effectively leveraging the strengths of both ensemble learning and margin-based classifiers for improved road traffic accident prediction accuracy.
- By utilizing the RF component for feature selection and dimensionality reduction, the study efficiently handles large datasets and identifies the most significant features contributing to accidents, reducing model complexity and enhancing interpretability.
- The insights gained from the model's feature selection process provide valuable information for policymakers about critical factors contributing to road traffic accidents, guiding targeted interventions and proactive measures to improve road safety and reduce accident rates.

RELATED WORKS

In everyday circumstances, traffic accidents typically result in significant loss of life and significant financial damages[12]. Predicting crashes in an efficient and precise way can significantly improve safety for everyone and lower financial costs. Due to the complicated causation of crashes, which involves a number of variables such as time dynamic connections, spatial correlations, and external impacts in road-relevant diverse information, it is difficult to anticipate crashes while driving. This research suggests a unique Deep Spatio-Temporal Graph Convolutional Network, or DSTGCN, to anticipate traffic accidents in order to address the aforementioned problems. The suggested model consists of three parts: the spatial learning layer, that learns spatial correlations by performing graph convolutional calculations on spatial data. The following part is the spatio-temporal training layer, that captures the dynamic alterations across the spatial and temporal viewpoint by using conventional and graph convolutions. The incorporation layer, that makes up the third part, seeks to provide coherent and semantic illustrations for outside data. We gather extensive actual-world information, such as accident reports, citywide automobile speeds, roadways, temperatures, and Point-of-Interest payments, in order to assess the suggested model. Experiments on actual data show that DSTGCN works better than modern facilities and traditional approaches. In order to increase protection in smart communities, rear-end collision prevention is receiving more and more attention[13]. As one of the primary causes of crashes, rear-end crashes require the development of effective warning techniques immediately. The goal of the current study is to forecast collisions. It is suggested to use learning-based approaches to tackle this challenging problem, which goes beyond the scope of conventional approaches. Back-propagation learning techniques, nevertheless, are having difficulties because of certain restrictions on finding features and prediction accuracy. In this study, we introduced a novel DL-based RCPM that establishes a CNN model.

To address the issue of disparities in class, RCPM expands and smoothes the dataset using evolutionary theory. We utilize the prepared dataset as the source of data for the model, splitting it into training and testing sets. The results of the study demonstrate that RCPM significantly enhances rear-end collision prediction accuracy. To lessen its negative impacts, crash detection is crucial for giving the public and roadway management centers current data[14]. For the purpose of preventing secondary collisions and protecting road traffic, crash risk forecasting is essential. In an effort to support traffic management of incidents, academics have spent many years investigating various methods for the accurate and timely identification of collisions. Real-time traffic data is widely available for usage because to recent developments in data gathering systems. The information may be used by big data architecture and ML to deliver suitable answers for the highway traffic safety systems. This research investigates whether DL models can be used to forecast crash risk and identify crash incidence. For this investigation, data on volume, speed, and sensor saturation were gathered from wayside radar detectors along Highway 235 in Des Moines, Iowa. The findings demonstrate that, in comparison to state-of-the-art shallow models, a deep model performs similarly well in accident predictions and better in crash detection. Furthermore, an analysis of sensitivity was carried out to estimate the accident danger based on data collected one, five, and ten minutes before the collision happened. Ten minutes before an accident, it was found that it was difficult to anticipate the possibility of a traffic circumstance. In order to create models that forecast the extent of accident damages in the event of a motorbike incident, this research employs categorization techniques[15]. By contrasting their outcomes, the researchers assessed the predictive capacity of the MLP, rule induction (PART), and classification and regression trees (SimpleCart) models for determining the seriousness of motorbike crashes. The Building and Road Research Institute in Ghana's National Road Traffic Collision Dataset provided the motorbike collision data set used to achieve this goal. Four classifications of harm severity were applied to the data established: deterioration, hospitalized, wounded, and death. In addition to enabling the direct comparison and ranking of the data mining models, the information gathered from this collection of data will make it possible to identify the factors that have a substantial impact on the severity of motorbike crashes. Utilizing a 10-fold cross-validation strategy, the Simple Cart model beat the PART models (73.45%) and the

Girija and Divya

model developed by MLP (72.16%) out of the investigated classification methods, according to the findings. The Simple Cart model had a mean accuracy of 73.81%. The findings showgoer that the site type, settlements type, accident time, accident type, and collision companion were the most important variables linked to the degree of injuries sustained in a motorbike incident.

Proposed RF-SVM Framework

The methodology of the article includes min-max normalization for preprocessing and hybrid RF-SVM for accident prediction. It is depicted in Fig 1.

Data Collection

The road traffic accident dataset is collected from Kaggle [16]. The written accounts of traffic accidents from 2017 to 20 are the source of this data collection. After all sensitive data was removed throughout data encoding, the final product comprises 32 features and 12316 accident occurrences. After that, it is preprocessed and analyzed utilizing various ML approaches to classification in order to determine the primary reasons of the event. RTA Information Base. The dataset in csv format is unprocessed and unclean. The preprocessed dataset is called csv.

Preprocessing using Min-Max Normalization

Preprocessing the road site visitors twist of fate dataset is a important step to make sure the effectiveness of the subsequent system learning models. One not unusual and effective preprocessing approach is Min-Max Normalization, which scales the functions of the dataset to a particular range, usually [0, 1]. This technique transforms each function with the aid of subtracting the minimal value of that characteristic and then dividing via the range of the characteristic values (most fee minus minimum fee). Min-Max Normalization ensures that large-scale features do now not dominate the studying system, thereby enhancing the performance and convergence speed of many gadget learning algorithms.

$$Y_{norm} = \frac{y - y_{minimum}}{y_{maximum} - z} \quad \text{③③③}$$

In the context of our avenue site visitors accident dataset, Min-Max Normalization helps in dealing with the various variety of values across exclusive functions. For example, numerical features like car velocity and time of day will have hugely one-of-a-kind scales, which would possibly skew the model if left unnormalized. After normalization, the dataset is ready for in addition evaluation and version schooling, making sure that each characteristic contributes similarly to the predictive modeling technique.

Employing RF-SVM for Road Traffic Accident Prediction

Employing a hybrid version like RF-SVM for road site visitors' accident prediction combines the strengths of both ensemble getting to know and margin-based totally classifiers, offering a strong approach to predictive modeling. The first section of this hybrid version involves using RF for function choice and dimensionality reduction. Random Forest, an ensemble learning method, operates by means of constructing multiple selection trees at some stage in schooling and outputting the mode of the training (class) of the individual timber. Random Forest's capability to handle lacking facts and keep accuracy without tremendous preprocessing makes it super preference for the preliminary segment of the hybrid version. By utilizing Random Forest for characteristic choice, we can slim down the most influential factors contributing to street traffic accidents from the significant list of features. This no longer only improves the efficiency of the version but additionally facilitates in expertise the important thing factors that want interest for twist of fate prevention. Moreover, the ensemble nature of Random Forest offers robustness against overfitting, making sure that the selected features generalize well on unseen facts. The second phase of the RF-SVM model entails employing SVM for the real type or prediction mission. SVM is renowned for its effectiveness in excessive-dimensional areas and is mainly suitable for class tasks. After the dimensionality discount through Random Forest, SVM takes over with a targeted set of functions, optimizing the selection barriers between classes of street visitors injuries. The middle concept of SVM is to locate the hyperplane that pleasant separates the specific classes in the feature area. This characteristic of SVM makes it incredibly effective in distinguishing between coincidence-susceptible and non-twist of fate-prone times, thereby improving predictive accuracy. In practice, the

Girija and Divya

RF-SVM hybrid model is skilled in distinct stages. Initially, the Random Forest model is educated on the dataset to determine the importance rankings for every function. Features with the very best significance scores are then selected for the second one stage, in which the SVM model is trained the use of this refined characteristic set. This staged approach no longer simplest streamlines the computational process but also enhances the interpretability of the version by means of focusing on the most impactful features. During the training segment, the model parameters for both Random Forest and SVM are tuned the use of move-validation strategies to avoid overfitting and make certain top of the line overall performance on the validation statistics. The utility of RF-SVM in street traffic coincidence prediction can notably beautify the accuracy and performance of predictive methods. As a result, it presents a powerful tool for predicting road traffic accidents, allowing authorities to enforce proactive measures for coincidence prevention and improve ordinary avenue safety. The insights gained from the function choice process can also manual policymakers in focusing their efforts at the maximum important elements contributing to street site visitors' injuries, thereby making statistics-pushed selections for public protection enhancements.

RESULTS AND DISCUSSION

The performance assessment of the suggested model, which is implemented in Python, is included in the results section.

Accident Severity

The Fig 2 offers a contrast of traffic density against accident severity, illustrating the count number of injuries labeled by means of their threat degree High Risk, Low Risk, and Moderate Risk across specific traffic densities (High, Low, and Moderate). In areas with excessive site visitors' density, there are 500 excessive-danger injuries and 2500 low-risk injuries, with no moderate-chance injuries recorded. For low site visitors' density, all 3500 injuries fall below the low-chance category, displaying no presence of excessive-threat or slight-hazard accidents. In mild visitors' density eventualities, 500 injuries are labeled as mild risk, at the same time as 3000 are considered low danger.

Accident Severity due to Road Structure

Fig 3 illustrates the connection among accident severity and road structure. It indicates that injuries going on curved roads or poorly maintained surfaces tend to bring about extra extreme results compared to the ones on nicely-maintained directly roads. The facts depicted inside the parent suggests that road structure plays a crucial function in coincidence severity, with complex or deteriorated avenue situations usually leading to higher damage stages and greater extreme crashes.

Performance Metrics

The Conv-LSTM model achieves high scores with 98.12% accuracy, 94.77% precision, 96.98% recall, and 92.83% F1-Score, indicating strong performance across all metrics. The CNN-LSTM model follows closely with an accuracy of 97.97%, but shows a notable drop in precision (89.55%) and recall (92.45%), resulting in a slightly lower F1-Score of 91.67%. The CNN-GRU model, while maintaining a respectable accuracy of 96.89%, demonstrates high precision (94.56%) and F1-Score (94.32%), but a slightly lower recall (92.77%). The proposed RF-SVM model outperforms all other models with an impressive accuracy of 99.13%, precision of 96.32%, recall of 97.13%, and F1-Score of 95.47%, highlighting its superior ability to accurately predict road traffic accidents and effectively balance precision and recall. The performance metrics comparison is given in Table I.

DISCUSSION

Achieving an accuracy of 99.13%, the RF-SVM version outperforms other hybrid models inclusive of Conv-LSTM, CNN-LSTM, and CNN-GRU. The high precision (96.32%), remember (97.13%), and F1-Score (97.47%) metrics further highlight the version's robustness and its potential to provide reliable predictions. The ability of the RF-SVM version

**Girija and Divya**

to handle each linear and non-linear relationships within the data guarantees that it could accurately distinguish among coincidence-susceptible and non-twist of fate-susceptible times, imparting a complete and unique predictive tool. Furthermore, the feature selection process using Random Forest now not simplest improves the version's efficiency however additionally offers precious insights into the factors contributing to road visitors accidents. This manner diagnosed key features which might be most predictive of twist of fate occurrences, that may inform policymakers and visitors control authorities approximately important areas that need attention. For example, elements which includes avenue shape, traffic density, and environmental conditions had been highlighted as vast predictors. The superior overall performance of the RF-SVM version in comparison to different hybrid strategies underscores its capability for actual-global software in visitors management systems.

CONCLUSION AND FUTURE WORKS

Achieving an outstanding accuracy of 99.13%, alongside sturdy precision, bear in mind, and F1-Score metrics, the RF-SVM model surpasses different hybrid approaches together with Conv-LSTM, CNN-LSTM, and CNN-GRU. Future works may want to recognition on expanding the dataset to encompass extra latest data and a broader range of features, which include climate situations, actual-time visitors updates, and driving force behavior metrics, to similarly decorate the version's predictive electricity. Integrating advanced ML of techniques like DL and reinforcement learning can also be explored to capture extra complicated patterns and interactions inside the information. Additionally, actual-time implementation of the model in visitors control structures and its integration with smart city infrastructure should offer dynamic, real-time predictions and alerts, thereby considerably improving avenue protection.

ABSTRACT

Railway Transportation in India is considered to be the best choice of transportation for passengers as well as goods. Every year, more than 1.2 billion tonnes of freight are being moved by Railway. Railway transportation needs regular examinations and quick servicing for the sake of national security. Conventional manual screenings are time consuming and costly. Individual skill and effectiveness are the need of the time of survey to find out errors. As a result, Internet of Things (IoT) arises as a solution, which uses technology as well as automation. IoT and automation help the machinery, which are installed on railway tracks and areas which find difficult to reach places and can be handled through the control rooms. As a result, the outcome is suggested to be an automated robot. The robot helps in visually inspecting the outreach areas. The technology has advancement of enabling the process to get images onsite and perform analysis. The facility of cloud services can be an advantage for the images and photographs taken of the broken railway tracks. The method suggested can relate the Machine Learning technique to pictures received from the rails. It easily identifies them as regular or normal or threat/dangerous. Such places are identified. Some specialized operator with a small number of sites perform some more tests and examinations.

INTRODUCTION

Railway Transport is the mode of transport, refers to moving passengers or goods with the help of train on a rail or a railroad. Rail transport plays a vital role in our day-to-day life. These are locomotives with high cost. In the last ten years, there has been remarkable growth in the infrastructure of the railway system, especially in developing countries. One challenge that arises is the ability to sufficiently power monitoring equipment in remote location. It's an in-service vehicle with sensors[1]. The tracks are detected and relayed using a global positioning system. RAIL transport is the most efficient, cost-effective and convenient means of transport. It has lower fuel costs. It is capable of transporting large loads, environmentally friendly and, most importantly, is also very reliable, as it is not hindered by weather in the same way as road and air transport do. Rail transport has therefore become the backbone of every emerging economy. Continuous and smooth operation of rail transport depend on effective management of the rail infrastructure as well as railway condition monitoring. It detects the deterioration and deformation of rail tracks[2]. The factors responsible for it are the load of rail vehicle on rail tracks, terrain where rail track is deployed, materials used in rail track construction and environmental conditions. The prime objective of monitoring the railway condition is to detect the track deterioration before it causes failure and prevents rail operations. Most important rail transport infrastructure is the purpose of railway condition monitoring [4]. The biggest Rail Networks has been with India in the World. The manual method and crack detection on lines is a time consuming and labour intensive procedure. The safe operation of railway transportation is always threatened by postponed inspections and problem findings. Railway in India is the most widely used transport system. Government of India had taken over the entire railway system in the country in 1950[5]. It is one of the largest transportation and logistics network of the world. Approximate 12,000 trains are to carry over 23 million passengers per day, which connect about 8,000 stations spread across the subcontinent. Railways is key responsible in growing and spreading the size of markets. The technology used in railways need to be upgraded[6]. The incidence of railway accidents in our country is greater as compared to other countries. According to the Railways, out of 100 accidents, at least seven takes place due to fractured tracks. For example on March 30, 2017 some Crack found in tracks led to derailment. A crack in the tracks prima facie caused the derailment of eight coaches of Mahakaushal Express near Mahoba station in Uttar Pradesh. Eight bogies of the Jabalpur-Nizamuddin Mahakaushal Express had derailed, as a result of which 52 passengers got injured. 400 metres of track got damaged and disrupted rail traffic on the route with services of 14 trains disrupted[7].

Literature Background and Proposed Method

The faults found in rail tracks give rise to the evolution of Crack Detection System in rail track. A system is designed to detect the flaws in the rail track with help of ultrasound testing method. After the crack is detected, the respective coordinates are found and they are sent to the nearest station. GPS and GSM Modules are responsible of performing recording and sending of coordinates to respective station. The most effective technique for detecting cracks is done by Ultrasonic technique[6][8]. It helps in detecting minor cracks and calculates the growth rate. When ultrasound wave signal propagates from one medium to another distinct medium, a certain proportion of the signal energy propagates over to the other medium. The remaining energy reflect back. After the reflected signals, time difference of arrival (TDOA) is measured. By using this time delay, the thickness and the flaws in the material are calculated[9]. The various rail flaws along with the inspection and maintenance methods are explained well. As a result of which algorithm is proposed, and algorithm makes use of sensors. These sensors help in detecting cracks and breakages in the railway tracks. Along with this it also proposes the technique to update train engine on regular basis and acknowledge the track's status and exact location of the track breakage. Predictive maintenance, issue detection, and eventually reducing the probability of train accidents are the major reasons for checking railway lines[10]. Train tracks must be inspected often. The manual examination of millions of track yards is labour intensive, time exhausting and prone for mistake. For which it is always preferred for Automatic track fault or crack identification along with monitoring[4][7]. A number of automatic solutions are generated for performing the task and increase its efficiency. In order to check rail lines, NDE methods are applied. Material group need the help of Computer vision, guided, and electromagnetic categories. For this, technologies like IoT and acoustic based methods are utilised. Intelligent Track Cleaning Robot can also be employed[2]. It is used to develop an efficient and economic way of

**Swati Sucharita Barik and Smruti Sephalika Barik**

designing product for cleaning the tracks. The proposed idea of automatic railway track cleaning system comprises an automatic vehicle that goes on land and track. It consists of a four wheel running robot with a suction unit, cleaning unit, automatic displacement unit, an intelligent control system, an intelligent train sensing unit, and power unit. The entire device is controlled by an onboard PIC microcontroller and the sensor networks on railway track. Guided wave system is another method to employ[11]. Here ultrasonic NDT was carried out with the DIO 572 equipment, which included measurement data processing. The device duplicated the shape of the rails during an ultrasonic test. The personal computer and the specialized program DIO 2000 were used to assess the measurement. A quantitative detection technique for accomplishing a visual assessment of crack is proposed[12]. The signal was also divided into various intrinsic mode functions (IMF) using VMD. The correlation variables along with SNR metrics were used to choose the most effective IMF element. Ultimately, employing ultrasonic propagation images and properties of signals are employed for generating wave momentum[13]. IoT based system: For employing an IoT based system, A self driving robot is employed which is powered by microcontroller and sensors. GPS module tracks help in the precise detective position and sends SMS notification[14]. The proposed system test the location of each clip on every single joint bar and alert the trains if any bolt went loose. A robotic technique prototype presented its ability to identify rail side flaws. The model used ultrasonic input from sensors combining image processing and deep learning techniques[14][15], to identify faults. Each robot was powered locally by the Raspberry Pi 3, a microcontroller, which sent real-time information to an ethernet server. To detect abnormalities, 4 ultrasonic sensors were put overhead and on both ends of an elevated train surface. An investigation on an automated defect tracking module integrated into an automated robot that uses several sensors[16]. The layer containing an infrared sensor, a restriction shift, and ultrasonic sensors that were all driven by an LPC 1768 ARM microprocessor. If a defect was identified, the GSM module sent the position and kind of fault to the inspection room[17].

An ultrasonic metal detection sensor was employed in the investigation to more precisely locate fractures. Encoding systems and radio frequency broadcasters were used for crack detection, with an ongoing supply of electricity between the encoding devices indicating fault-free tracks [18]. RF signals would be produced by the transmitter for so long as the electrical supply was steady [19]. The flow of current might be disrupted if there was a break in the track. This stops RF signal production, which prevents the locomotive's receiver from receiving a signal, causing train to stop[2][20]. A TRV(Track Recording Vehicle) is used for rail track problem diagnostics. According to site-specific testing, the system is more efficient than conventional method. The authors put forth a novel system of automation built on robot the localization over an interval of 3-6 inch[21]. To identify possible flaws, the system used machine learning and adapted it to the photographs it got from the tracks. A cost effective, less power required, wireless, and real-time IoT based sensing system has been developed in addition to a customized TRV replacing the manual production of features with an automated process for monitoring the rail condition and find out the damage[7][21]. It depends on the unique design of the TRV in comparison to the traditional trolley based TRV, which was to detect minor drop in vibrations which plays a vital role in the early detection of track damage.

The TRV is designed with an objective to make it portable and easily operable. The IoT based sensing system on TRV uses the Axle Based Acceleration (ABA) technique and is equipped with an inertial measurement unit (IMU) for the precise extraction of instantaneous irregular amplitudes of the acceleration signals in all three axes, to identifies the faults of the track and determines its severity[22]. The accelerometer data of the track dynamics are measured and transmitted using Node MCU to an online cloud network service in realtime through which the irregularity of the track is detected. Proposed design of the TRV can determine the damage to the tracks with impactful measurement accuracy. A new method for monitoring the irregularities in railway tracks by updating the status of the tracks in the cloud can also be explored. The IoT based Railway Track Monitoring System (IoT-RMS) is a proposed method to monitor the health of the railway track. The system identifies any kind of abnormality in the tracks at an early stage. These abnormalities are rectified before they develop for smoother transportation[14][23]. The microelectro mechanical system (MEMS) accelerometers are placed in the axle box for measuring the signal. It becomes hard to find the exact location of abnormalities when the global positioning system (GPS) falters due to signalling issues[15]. So a new hybrid method is proposed for locating irregularities on a track. It also can be occurred in absence of a GPS signal. Preprocessing of the GPS signal is carried out effectively, as the sensors used in IoT-RMS are good in

**Swati Sucharita Barik and Smruti Sephalika Barik**

functioning in a high noise environment[23]. The IoT-RMS updates the location of the abnormality in the cloud and shares it with other trains that will be passing through that location. As a result, the drivers of trains respond accordingly and avoid derailment. This seems to be a best approach of detection with the proposed system. An experimental setup has been developed for a study of the performances for four different abnormal cases, and the result shows the effectiveness of the proposed system.

Applications of proposed system: Followings are the applications for which a railway track crack detecting system.

1. Automatic Crack Testing- The process of finding a structure crack with any processing method is known as rail crack detection. Two techniques can be employed to identify cracks. The recommended approach sequentially makes use of radiometric, geometric, and contextual data[2][3]. The battery provides electricity to the vehicle. The rail track crack can be traced using the optical sensor.
2. Wireless Access- Wireless Application Protocol (WAP) is a networking standard utilized for transmitting data across numerous mobile networks. WAP enables quicker connectivity between dynamic wireless items with the Internet while also improving cellular standards compatibility[5]. WAP is a technology norm for obtaining data via a portable connection. A WAP browser is a web browser that utilizes the protocols for mobile devices like mobile phones. Despite being a novel technology, WAP makes use of Internet-related ideas.
3. Applications for detecting damage to railway track- In order to monitor and identify track damage, a neural network-based technique is utilized. Train crashes happen frequently by track damages[19]. The results of the experiments demonstrate the excellent precision and suitability of this neural network based measuring system for online track damage detection and monitoring applications.
4. The following techniques are used to find railway flaws: The method with the most use is ultrasound. Eddy current examinations are excellent for detecting surface and close-to-surface defects[25]. For thorough hand checks, employ magnetic particle inspection. The gap on the rail line is identified by an ultrasonic sensor by avoiding getting the sound of railway such that if the sound is heard, no fracture is found on the track.

CONCLUSION AND FUTURE SCOPE

The present approaches are based on the research, require time as well as cost. The proposed approach addresses these problems by significantly improving the method of rail track crack identification. It involves the most economical option available for improving the efficiency of the nation's largest transportation means including lowering accident rates. It may be quite possible to avoid a waste of resources and precious lives of people with the techniques employed. In addition to it, it eliminates expenditure and time on identifying cracks. It is highly essential being responsible citizen of our nation to take care of our largest Transportation System and adopt newest technologies.

ABSTRACT

Parkinson's disease (PD) is a widely recognized neurological disorder characterized by involuntary movements, including tremors, stiffness and difficulties in coordination and balance. Its symptoms typically develop gradually and worsen over time, impacting walking and speech. *Drosophila melanogaster* has served as a model for various neurodegenerative conditions, including PD. In this study, we explored the impact of rotenone exposure on *Drosophila*, revealing noticeable neurodegenerative and behavioural effects within 14 days. Flies were subjected to rotenone induction by exposure to 0.197 µg/ml of rotenone through the media for 7 days and induced PD. Treating with high dose of *Cedrusdeodara* extract helps in improving olfactory function, locomotor disabilities and sexual behaviour compared to diseased group. Treated flies exhibited distinct locomotor impairments, which was alleviated by incorporating *Cedrusdeodara* into their diet. This suggests that pesticide exposure in *Drosophila* mirrors crucial aspects of PD, establishing a novel *in vivo* model for investigating the mechanisms behind dopaminergic neurodegeneration.

Keywords: Parkinson's disease, Neurodegenerative disease, *Drosophila melanogaster*, *Cedrusdeodara*, Rotenone.

INTRODUCTION

Parkinson's disease (PD) is a multifaceted neurological disorder characterized by a progressive deterioration of nerve cells in the basal ganglia region of the brain, which leads to a deficiency in the production of dopamine, a critical

**Karthik R Karindi et al.,**

neurotransmitter. This depletion of dopamine results in a range of symptoms, including tremors, muscle stiffness, slow movement, and difficulties with balance and coordination. Additionally, individuals with PD may experience non-motor symptoms such as depression, sleep disturbances, and cognitive impairment. The exact cause of Parkinson's remains unknown, although research suggests a combination of genetic predisposition and environmental factors may play a role in its development. While age is a significant risk factor, with most cases emerging after the age of 60, individuals who develop the disease before the age of 50, often due to hereditary factors or specific genetic alterations[1]. The pathophysiology of PD involves the formation of abnormal protein clusters called Lewy bodies, primarily composed of alpha-synuclein, within brain cells. These clusters are associated with the degeneration of nerve cells responsible for dopamine production. Additionally, there is evidence of a gradual decline in dopamine levels associated with aging, which is accelerated in individuals with PD. Diagnosis of PD relies primarily on clinical evaluation by a neurologist, as there are currently no laboratory tests available for non-genetic cases. Treatment approaches aim to alleviate symptoms and may include medications to increase dopamine levels in the brain, surgical interventions such as deep brain stimulation, and various therapies including physical, occupational, and speech therapy. Animal models, such as the rotenone, MPTP, and 6-OHDA models, have been instrumental in studying the mechanisms of PD and testing potential therapeutic interventions[2–4]. These models replicate aspects of the disease by selectively targeting dopaminergic neurons or inducing neurotoxicity similar to that observed in PD[5]. Additionally, the *Drosophila melanogaster* model offers a valuable tool for understanding the genetic and molecular mechanisms underlying PD and exploring potential treatments[4,6]. The *Drosophila melanogaster*, or fruit fly, serves as a valuable alternative animal model for studying Parkinson's Disease (PD). With around 75% of human disease genes mirrored in *Drosophila*, this model has proven effective in unraveling the mechanisms underlying neurodegenerative diseases like PD. By expressing alpha-synuclein, researchers have elucidated connections between PD-related abnormalities such as dopaminergic cell degeneration, inclusion body formation, and impaired locomotion[6–8]. Notably, mutants with SPG7 in *Drosophila* exhibit progressive locomotion defects and heightened sensitivity to various stressors. The fruit fly's life cycle consists of four stages: embryo, larva, pupa, and adult, with a complete generation time of approximately 10 days and a maximum lifespan of 60 to 80 days depending on environmental conditions[8–10]. The present study aims to evaluate the therapeutic potential of *Cedrusdeodara* extract on rotenone induced Parkinson's disease *Drosophila melanogaster* model by assessing its effect on various behavioural parameters.

MATERIALS AND METHODS

Materials

Rotenone was procured from Sigma Aldrich.

Collection and Extraction of *Cedrusdeodara*

Cedrusdeodara plant bark collected from Rajaji national park, Uttarakhand and it is authenticated by the botanist from JSS college of arts, commerce & Science, Prof. Biligiri Ranga, HOD Department of Botany. The bark of *Cedrusdeodara* were cleaned to remove the adhered dust particles and then were sundried for 5 days. The dried aerial parts of *Cedrusdeodara* were crushed and weighed in grams. The dried powder was soaked overnight in hexane to remove color. Then filter and filtrate was collected and again dried for 2 days. The powdered sample was macerated or soaked for 7 days with a mixture of ethanol and water 7:3. The combined extract was purified and condensed at 65 degree Celsius in a rotating exhaust system[11].

Animals

Drosophila melanogaster: Maintenance and culturing of *Drosophila melanogaster*: OK Flies

Starting the Cycle

Seeding Embryos: The cycle initiates with 1.5grams of all the materials from preceding cycle comprising a mix of embryos and/or some early-stage larvae. In a plastic container this materials was placed which contains an active

Karthik R Karindi et al.,

yeast mixture until the pupal phase was reached. Following the introduction of embryos in the container and larvae in this biological mixture, the container was covered with its lid to prevent the larvae from escaping.

Set up the plastic container.

Collect the plastic container and sterilize it; afterwards, cover the container with cotton plugs following the introduction of the flies. Proceed to prepare the fly food by stirring deionized water in a beaker, gradually adding propionic acid, phosphoric acid, dry yeast, and sucrose, initiating the fermentation process. Once the sucrose is dissolved, promptly pours the food evenly over cotton. Ensure thorough coverage and subsequently plastic container was closed the with the lid to prevent potential contamination by flies escaping within the laboratory. Re-suspend 1.5 grams of the harvested embryos previously, from the prior cycle in 5 ml of 70 percent of ethanol. Halve two filter papers, evenly distribute the biological mixture over the four pieces using a spatula or a wide-tipped transfer pipet cut if necessary. Place the filter papers atop the soaked cotton and securely closed the lid and finally, incubated the plastic container at room temperature at 24°C with humidity of 35% until the pupal stage.

Embryos to Flies: Continuing the Cycle.

This stage of the cycle begins on the first day the embryos was put in the plastic container and ends nine days later when the pupae hatch into adult flies. Throughout these 08 days, the primary task was monitoring to ensure the embryos was progress seamlessly through the subsequent stages till the *Drosophila* life cycle eclosion. If, during this period, larvae show signs of mortality and discoloration, it is essential to check that the foam plugs are not excessively tight and that sufficient ventilation was maintained. This interval also presents an opportune time for cleaning the fly population cage from the preceding cycle. Around 24 hours after the adult female deposits the embryos into the fly food, observe the embryos transitioning into 1st instar larvae. These resulting larvae will feed on the fly food prepared in step 1 for 4 days, undergoing growth and molting twice to reach the 2nd and 3rd instar larvae stages. On the fourth day of the setup, witness the larvae entering the pupal stage, where they will remain for an additional 4 days. It's important to note that during this phase, the pupae will cover the entire cotton surface inside the plastic container. Before the first flies emerge during the pupal phase, open the plastic container, transfer the plastic film containing the cotton with all the pupae onto the lab soaker paper within the cleaned population cage, secure it with a double knot, and cleaned the plastic container and lid for the next cycle. Be sure to discard and destroy pupae attached to the lid via autoclaving or freezing before eclosion. Following the 4-day pupal stage, the initial flies will emerge from the pupae, with all flies expected to eclose within 24-48 hours. During this phase, it is crucial to provide them with food to create the optimal environment for reproduction.

End of the Cycle

Harvesting Embryos: Optimal fly fertility occurs between 3 to 5 days after eclosion, making this period ideal for harvesting to achieve the highest embryo yield. Once the desired collections are finished, the cycle concludes. Observed the embryos, appearing as small white dots, indicating that the eggs was ready to be collected. For regular upkeep of the fly cage, a recommended collection time is every 2 days, resulting in a harvest mainly comprising embryos and a few 1st instar larvae. Refer to representative results for typical yields of harvested embryos at various collection time points[12, 13].

Culturing *Drosophila* in labs

Bottles serve to sustain a sizable population, while culturing vials are employed for smaller populations and crossbreeding purposes. Typically, glass bottles are the preferred choice, although autoclaved plastic bottles can also be effective. Additionally, the small vials come in various sizes, ranging from 96 mm by 25 mm to larger dimensions. Plugs, which can be either cotton or foam, are used to cover the bottles, with a preference for cotton plugs.

Media

The preparation of media involves two main methods: cooking the media or opting for ready-made and dehydrated media. The latter was the preferred choice due to its convenience, eliminating the need for cooking and offering a quicker and easier process. However, rehydration is necessary when using ready-made media. To ensure a thorough

Karthik R Karindi et al.,

rehydration and culture process, follow the provided procedure. Begin by adding $\frac{1}{5}$ to $\frac{2}{5}$ volume of dry media to the bottle or vial, followed by the addition of water to completely saturate the media. Allow the vial to rest briefly, adding water until it appears fully hydrated, with a shiny surface and no gaps. Let the media warm to room temperature, ideally around 25 °C with 60% humidity for optimal fly growth. After rehydration, sprinkle several yeast grains on the media surface, and transfer the flies into the vial or bottle, sealing it. To maintain the culture, it is essential to transfer the flies to different clean vials or bottles[10].

Acute toxicity Study for Calculation of LD50 of *Cedrus Deodoura* extract

Three doses of CD extract, specifically 0.2mg, 0.4mg, and 0.8mg, were introduced into three separate vials containing culture media. The media was sustained for a duration of 3 days, during which 10 flies were added to each vial. The observation period spanned 3 days, monitoring for any signs of mortality. Based on the observed mortality, the LD50 (lethal dose for 50% of the population) was calculated. In a separate process, flies were subjected to rotenone induction by exposure to 0.197 μ g/ml of rotenone through the media for 7 days, aiming to induce PD[14, 15].

Grouping of Flies

After bottles with eggs was placed 23 °C to allow for developmental acclimation, the files was divided into five groups the control group consisted of 10 files receiving normal treatment. The disease group comprised 10 files treated with 0.197 μ g/ml of rotenone orally via culture media over a 7-day induction period. The standard group included 10 files treated with 0.5mg/ml of levodopa and 0.05mg/ml of carbidopa for 7 days, administered orally via culture media alongside a vehicle. Two additional groups, Dose 1 and Dose 2, each comprised 10 files treated with 400 μ g/ml and 160 μ g/ml of *cedrus deodara*, respectively, for 7 days via oral administration through culture media. Evaluation parameters included behavioural parameters such as climbing assay, T-maze test, and courtship assay was done.

Behavioural Studies

Climbing Assay

Following a seven-day induction period, the climbing index of all flies was assessed. Climbing chambers were fashioned by vertically taping two clear plastic vials together, with a designated height of 10 cm marked around the tube's circumference. The flies were introduced into their climbing chambers, allowing a minute for acclimation before the assay. To initiate the assay, the bottom of the tube was tapped to prompt climbing, and a timer was initiated. After 10 seconds, the flies that successfully completed the climb were tallied. All flies were simultaneously tested, commencing with the control group. Control and experimental groups underwent sequential testing to permit rest and recovery between the ten conducted trials per group. The count of successful flies per trial was documented as a percentage of the total flies within each treatment group.

T maze assay

The experimental assays utilized a glass T-maze shaped with dimensions of (14×10 cm, 08 mm, junctions 02 mm) connected to a starting chamber of a standard *Drosophila* vial, 9×2.5 cm and two odour chambers positioned on each side of the T-maze, all arranged horizontally (refer to Figure 2). The odour chambers the standard *Drosophila* vials, housed 20 μ l of the test compounds applied to filter paper sections(1×2cm). The test compound, derived from consecutive dilutions of the pure odourant in the distilled water, ensured a consistent dose presentation regardless of water solubility. To achieve this, each solution was vortexed before being pipetted onto the filter paper. Despite the absence of controlled airflow from outside, efficient diffusion of odourants into the central chamber was confirmed, as demonstrated in similar experiments investigating olfactory learning and preferences in fruit flies. This efficacy is further supported by dose-response curves, indicating the flies ability to detect changes in dosage. This setup proves particularly suitable for high-throughput tests. In the initial phase, the experiment a group of 100 flies is situated in the starting chamber of a T-maze apparatus, all chambers oriented horizontally. The flies have the liberty to explore the apparatus and access the lateral arms (odour chambers) of the T-maze, where odourants diffuse through. Following a 4-hour period of food deprivation in a standard *Drosophila* vial, the flies are released into the apparatus and given a 60-minute window for exploration before concluding the experiment. To prevent a second choice, the

Karthik R Karindi et al.,

odour chambers are replaced with new vials containing the same odourant after half of the allocated time. Throughout the trial, each T-maze is enclosed within an isolated chamber (50×40×20cm) with symmetrical illumination. At the trial's conclusion, the count includes the number of flies entering each odour chamber in the first and second periods and the number of surviving flies that remain in the starting vial. With these data we calculated Olfactory preference is equal to the number of flies that chose odourant A divided by the number of flies that choose the odourant A added blank and the Choice ratio is equal to the number of flies that entered one of the odour chambers divided by the number of flies that entered one of the odour chambers added to the number of alive flies that did not enter any odour chamber. In Odour vs Blank experiment we tested the preference for an odourant vs. blank.

Courtship Assay

For courtship assay, flies utilized was housed in a small opaque container. Considering the diel periodicity of the *Drosophila* courtship behavior, assay took place between 9:00am and 15:00pm. A 6-day-old virgin male and virgin female were introduced into the cylindrical transparent chamber for a duration of 10 min or until the copulation ensued. A careful record of the flies interactions was recorded[16].

RESULTS AND DISCUSSION

Statistical Analysis

The statistical analysis of the data obtained from behavioural parameters following Rotenone infusion and drug treatment in *Drosophila* was performed using Graph pad prism software version 9.5.1. The data was represented as the mean ± SEM. The result was analyzed using one-way analysis of variance, ANOVA followed by Tukey's multiple comparison test. The value of $p < 0.05$ got was considered statistically significant.

Acute toxicity Study for Calculation of LD50 of *CedrusDeodoura* extract

Acute toxicity Study for Calculation of LD50 of *CedrusDeodoura* extract In 0.8mg of *Cedrus deodara* extract 50% flies were dead, hence based on mortality 0.8mg *Cedrus deodara* extract is considered as LD 50 value. Effect of *CedrusDeodoura* extract on locomotory through climbing assay. Treating with high dose of *Cedrus Deodara* extract(160µg/ml) has shown significant improvement in locomotor disabilities compared to diseased group.

All values was expressed in MEAN±SEM, n=10, statistical analysis was performed by employing one-way ANNOVA followed by Tukey's Multiple Comparison test. ****P value <0.05 when compared to the disease control and ****P value < 0.05 when compared to the treatment control.

Effect of *CedrusDeodoura* extract on chemoperception through T maze assay

Treating with high dose of *Cedrus Deodara* extract(160µg/ml) has shown significant improvement in olfactory function compared to diseased group. Statistical analysis was performed by employing one-way ANNOVA followed by Tukey's Multiple Comparison test, ****P value <0.05 when compared to disease control, ****P value < 0.05 when compared to treatment control.

Effect of *CedrusDeodoura* extract on sexual behaviour through courtship Assay

Treating with high dose of *Cedrus Deodara* extract(160µg/ml) has shown significant improvement in sexual behaviour compared to diseased group. Statistical analysis was performed by employing one-way ANNOVA followed by Tukey's Multiple Comparison test, ****P value <0.05 when compared to disease control, ****P value < 0.05 when compared to treatment control.

Karthik R Karindi et al.,

CONCLUSION

The results shows that rotenone administration induces Parkinson's at a dose of 0.197µg/ml for a period of 7 days in *Drosophila melanogaster*. Treating with high dose of *Cedrus Deodara* extract helps in improving olfactory function, locomotor disabilities and sexual behaviour compared to diseased group. Hence the study shows that the administration of *Cedrus Deodara* extract produces anti-Parkinson's effect in Rotenone induced Parkinson's model based on the behavioural assessment.

ABSTRACT

A graph G is said to be distance antimagic if there is a bijection $f: V(G) \rightarrow \{1, 2, \dots, p\}$ such that for every pair of distinct vertices u and v applies $w(u) \neq w(v)$ where $w(v) = \sum_{u \in N(v)} f(u)$ and $N(v) = \{u \in V: uv \in E\}$ is the open neighborhood of v . A injective map $f: V(G) \rightarrow \{\pm 1, \pm 2, \dots, \pm p\}$ is said to be pair sum labeling if the induced edge function $f_e: E(G) \rightarrow \mathbb{Z} \setminus \{0\}$ defined by $f_e(uv) = f(u) + f(v)$ is one-one and $f_e(E(G))$ is either of the form $\{\pm k_1, \pm k_2, \pm k_3, \dots, \pm k_q\}$ or $\{\pm k_1, \pm k_2, \pm k_3, \dots, \pm k_{\frac{q-1}{2}}\} \cup \{\pm k_{\frac{q+1}{2}}\}$ according as q is even or odd. Based on idea of pair sum labeling, in this paper we introduced distance pair antimagic labeling by the extension of distance antimagic labeling and explores the results on such labeling. Further we investigated the relation between distance antimagicness and distance pair antimagicness of graphs.

Keywords: Graph labeling, distance magic, distance antimagic, pair sum labeling, distance pair antimagic labeling.

AMS Subject Classification(2010): 05C78

INTRODUCTION

All graphs consider here are finite, simple and undirected. The symbols $V(G)$ and $E(G)$ denote the vertex set and edge set of a graph G , terms and terminology are used sense of Harary [2]. The concept of *distance magic labeling* has been motivated by the construction of magic squares. A magic square of order n is an $n \times n$ array whose entries are an arrangement of the integers $1, 2, 3, \dots, n^2$ in which all elements in any row, any column, the main diagonal or the

Bala and Saratha Devi

main back diagonal add to the same sum r . Now if we label the vertices of the complete n -partite graph with parts $|V_i| = n, 1 \leq i \leq n$, in such a way that the vertices of V_i are labeled with the integers in the i^{th} row of the magic square, then the sum of the labels of all the vertices in the open neighborhood of each vertex is the same and is equal to $r(n - 1)$. Motivated by this observation Vilfred [7] in his doctoral thesis introduced the concept of Σ -labeling. It is also called distance magic labeling [4]. In 2010, R. Ponraj[5] defined pair sum labeling of graphs and in 2013, Arumugam[3] introduced the concept of a distance antimagic labeling. Inspired the above works, we defined a distance antimagic labeling called distance pair antimagic labeling and discussed the following results.

MAIN RESULTS

Definition 2.1 Let G be a (p, q) graph. Let $f: V(G) \rightarrow P$ be a bijection where

$$P = \begin{cases} \pm 1, \pm 2, \dots, \pm \frac{p}{2}, & \text{if } p \text{ is even} \\ 0, \pm 1, \pm 2, \dots, \pm \frac{p-1}{2}, & \text{if } p \text{ is odd} \end{cases}$$

Then f is called a distance pair antimagic labeling if the induced weight function $w: V(G) \rightarrow W$ defined by $w(v) = \sum_{u \in N(v)} f(u) = k_i$ is one-one, where $N(v) = \{u \in V: uv \in E\}$ is the open neighborhood of v and the set of all weights W is either of the form $\{\pm k_1, \pm k_2, \pm k_3, \dots, \pm k_{\frac{p}{2}}\}$ or $\{0, \pm k_1, \pm k_2, \pm k_3, \dots, \pm k_{\frac{p-1}{2}}\}$ according as p is even or odd. A graph which admits distance pair antimagic labeling is called a distance pair antimagic graph.

Example 2.2.

Figure 1: C_9 is a distance pair antimagic graph, here $W = \{0, \pm 1, \pm 2, \pm 4, \pm 6\}$.

Lemma 2.3 Let G be graph with two vertices u and v such that $N(u) = N(v)$, then G is not a distance pair antimagic graph.

Proof. Let $u, v \in V(G)$ and $N(u) = N(v)$. Then $w(u) = w(v)$ by definition.

Hence G is not a distance pair antimagic graph.

Example 2.4

Figure:2 P_3 and C_4 are not distance pair antimagic graphs.

Theorem 2.5 The path P_n is a distance pair antimagic graph if $n \neq 3$.

Proof. We consider the following two cases:

Case (i): n is even and take $n = 2m$, where $m \geq 1$.

Bala and Saratha Devi

Let $V = \{v_1, v_2, \dots, v_{2m}\}$ be the vertex set of P_{2m} .
 Define the labeling $f: V(P_n) \rightarrow \{\pm 1, \pm 2, \dots, \pm m\}$ by
 $f(v_i) = i, \text{ if } 1 \leq i \leq m$
 $f(v_{m+i}) = i - (m + 1), \text{ if } 1 \leq i \leq m$

The induced vertex weights labeling are

$$w(v_i) = \begin{cases} -1 & \text{if } i = m \\ 1, & \text{if } i = m + 1 \\ 2f(v_i), & \text{otherwise} \end{cases}$$

Clearly f is a distance pair antimagic labeling of P_n if n is even.

Case(ii): n is odd

for $n = 3, P_3$ is not a distance pair antimagic graph by Lemma 2.3.

Take $n = 2m + 1$, where $m = 2, 3, 4, 5, \dots$

Let the vertex set $V(P_n) = \{v_0, v_1, v_2, \dots, v_{2m}\}$ and a function $f: V(P_n) \rightarrow \{0, \pm 1, \pm 2, \dots, \pm m\}$.

Consider the following two subcases:

Subcase(a): $m = 2, 4, 6, \dots$

The labeling of vertices are as follows

$$f(v_i) = \begin{cases} 0, & \text{if } i = m \\ -(i + 1), & \text{if } 0 \leq i < m \\ n - i, & \text{if } i > m \end{cases}$$

Then the induced vertex weight labeling are as follows.

$$w(v_m) = 0;$$

$$w(v_{m-1}) = -(m - 1) = -w(v_{m+1});$$

$$w(v_i) = \begin{cases} -2(i + 1) & \text{if } 0 \leq i < m - 1 \\ 2(n - i) & \text{if } i > m + 1 \end{cases}$$

Subcase(b): $m = 3, 5, 7, \dots$

The labeling of vertices are as follows

$$f(v_0) = 1; f(v_1) = 0; f(v_{2m}) = -1$$

$$f(v_i) = \begin{cases} i, & \text{if } i < m + 1 \text{ and } i \text{ is even} \\ -(i - 1), & \text{if } i \leq m \text{ and } i \text{ is odd} \\ n - i, & \text{if } i \geq m + 1 \text{ and } i \text{ is even} \\ -(n + 1 - i), & \text{if } i > m \text{ and } i \text{ is odd} \end{cases}$$

Then the induced vertex weight labeling are as follows

$$w(v_0) = 0;$$

$$w(v_1) = 3 = -w(v_{2m});$$

$$w(v_2) = -2 = -w(v_{2m-1});$$

$$w(v_m) = n - 2 = -w(v_{m+1})$$

$$w(v_i) = \begin{cases} 2i, & \text{if } i < m - 1 \text{ and } i \text{ is odd} \\ -2(i - 1), & \text{if } i < m \text{ and } i \text{ is even} \\ 2(n - i), & \text{if } i > m \text{ and } i \text{ is odd} \\ -2(n + 1 - i), & \text{if } i > m + 1 \text{ and } i \text{ is even} \end{cases}$$

Clearly f is a distance pair antimagic labeling of P_n if n is odd and $n \neq 3$.

Hence P_n is a distance pair antimagic graph if $n \neq 3$.

Theorem 2.6 The cycle C_n is a distance pair antimagic graph if $n \neq 4$.

Proof. We consider the following two cases:

Case(i): n is even and take $n = 2m$, where $m \geq 3$.

Let $V = \{v_1, v_2, \dots, v_{2m}\}$ be the vertex set of C_n .

Define $f: V(C_n) \rightarrow \{\pm 1, \pm 2, \dots, \pm m\}$ by

Bala and Saratha Devi

$$f(v_i) = \begin{cases} -i, & \text{if } i < m \\ m, & \text{if } i = m \\ -m, & \text{if } i = m + 1 \\ 2m + 1 - i, & \text{if } i > m + 1 \end{cases}$$

Then the induced vertex weight labeling are as follows.

$$\begin{aligned} w(v_1) &= -1 = -w(v_{2m}); \\ w(v_{m-1}) &= 2 = -w(v_{m+2}); \\ w(v_m) &= -(2m - 1) = -w(v_{m+1}); \\ w(v_{i+1}) &= -2(i + 1) = -w(v_{2m-i}) \text{ for } 1 \leq i \leq m - 3. \end{aligned}$$

Clearly f is a distance pair antimagic labeling of C_n , if n is even.

Case (ii) n is odd and take $n = 2m + 1$ where $m \geq 1$.

Let $V = \{v_0, v_1, v_2, \dots, v_{2m}\}$ be the vertex set of C_n .

Define $f: V(C_n) \rightarrow \{0, \pm 1, \pm 2, \dots, \pm m\}$ by

$$\begin{aligned} f(v_0) &= 0; \\ f(v_i) &= i, \text{ if } 1 \leq i \leq m; \\ f(v_i) &= i - n, \text{ if } m + 1 \leq i \leq 2m \end{aligned}$$

Then induced vertex weight labeling are

$$w(v_i) = \begin{cases} 0, & \text{if } i = 0 \\ -1, & \text{if } i = m \\ 1, & \text{if } i = m + 1 \\ 2f(v_i) & \text{otherwise} \end{cases}$$

Clearly f is a distance pair antimagic labeling of C_n , for odd n and hence C_n is a distance pair antimagic graph if $n \neq 4$.

Theorem 2.7 The complete graph K_n is distance pair antimagic for $n > 1$.

Proof. We consider the following two cases:

Case(i): n is even and take $n = 2m$. Let $V = \{v_1, v_2, \dots, v_{2m}\}$ be the vertex set of K_n .

Define $f: V(K_n) \rightarrow \{\pm 1, \pm 2, \dots, \pm m\}$ by

$$f(v_i) = \begin{cases} -\lfloor \frac{i}{2} \rfloor, & \text{if } i = 1, 3, 5, \dots, 2m - 1 \\ \frac{i}{2}, & \text{if } i = 2, 4, 6, \dots, 2m \end{cases}$$

Then vertex weights are

$$w(v_i) = \begin{cases} \lfloor \frac{i}{2} \rfloor, & \text{if } i = 1, 3, 5, \dots, 2m - 1 \\ -\frac{i}{2}, & \text{if } i = 2, 4, 6, \dots, 2m \end{cases}$$

Case(ii): n is odd and take $n = 2m + 1$.

Let $V = \{v_0, v_1, v_2, \dots, v_{2m}\}$ be the vertex set of K_n .

Define $f: V(K_{2m+1}) \rightarrow \{0, \pm 1, \pm 2, \dots, \pm m\}$ by

$$f(v_i) = \begin{cases} 0, & \text{if } i = 0 \\ -\lfloor \frac{i}{2} \rfloor, & \text{if } i = 1, 3, 5, \dots, 2m - 1 \\ \frac{i}{2}, & \text{if } i = 2, 4, 6, \dots, 2m \end{cases}$$

Then vertex weight are $w(v_i) = -f(v_i)$. Clearly f is a distance pair antimagic labeling of K_n and hence K_n is distance pair antimagic.

Theorem 2.8 The complete bipartite graph $K_{n,m}$ is distance pair antimagic graph if and only if $n = m = 1$.

Bala and Saratha Devi

Proof.Case(i): $n = m = 1$

By theorem 2.5, the complete bipartite graph $K_{1,1}$, is nothing but the path P_2 is a distance pair antimagic graph.

Case(ii): $n \geq 1$ and $m > 1$

Let V_1 and V_2 be bipartition of $V(K_{n,m})$. For any two vertices $u, v \in V_1$ then $N(u) = N(v) = V_2$. By lemma 2.3, $K_{n,m}$ is not a distance pair antimagic graph.

Theorem 2.9 The ladder graph $L_n = P_n \times P_2$ is distance pair antimagic for $n \geq 3$.

Proof.

Let $V(L_n) = \{u_i, v_i: 1 \leq i \leq n\}$ and $E(L_n) = \{u_i u_{i+1}, v_i v_{i+1}: 1 \leq i \leq n-1\} \cup \{u_i, v_i: 1 \leq i \leq n\}$ be the vertex set and edge set of L_n .

Define $f: V(L_n) \rightarrow \{\pm 1, \pm 2, \dots, \pm n\}$ by

$$f(u_i) = \begin{cases} i, & \text{if } 1 \leq i \leq n-1 \\ -n & \text{if } i = n \end{cases}$$

$$f(v_i) = \begin{cases} -i, & \text{if } 1 \leq i \leq n-1 \\ n & \text{if } i = n \end{cases}$$

Then the induced vertex weight labeling are as follows.

$$w(u_i) = i = -w(v_i), \text{ if } 1 \leq i \leq n-2;$$

$$w(u_{n-1}) = -(n+1) = -w(v_{n-1});$$

$$w(u_n) = 2n-1 = -w(v_n).$$

Clearly f is a distance pair antimagic labeling of $P_n \times P_2$ and hence L_n is a distance pair antimagic graph.

Theorem 2.10 If G is a distance pair antimagic graph with even number of vertices, then the join graph $G + K_1$ is a distance pair antimagic graph.

Proof. Let G be a distance pair antimagic graph and $|V(G)| = 2m$ where $m = 1, 2, 3, \dots$

Then there exist a distance pair antimagic labeling $f: V(G) \rightarrow \{\pm 1, \pm 2, \dots, \pm m\}$.

Take $V(K_1) = u$ and $V(G) = \{v_1, v_2, \dots, v_{2m}\}$, then $V(G + K_1) = \{u, v_1, v_2, \dots, v_{2m}\}$.

Now define $f^*: V(G + K_1) \rightarrow \{0, \pm 1, \pm 2, \dots, \pm m\}$ by

$$f^*(u) = 0;$$

$$f^*(v_i) = f(v_i) \text{ for } i = 1, 2, 3, \dots, 2m$$

Then the induced vertex weight labeling are as follows.

$$w^*(u) = 0;$$

$$w^*(v_i) = w(v_i) \text{ for } i = 1, 2, 3, \dots, 2m$$

Hence f^* is a distance pair antimagic labeling of $G + K_1$.

Theorem 2.11 If G is a distance pair antimagic graph, then tG is also a distance pair antimagic graph, where tG is t copies of G .

Proof. Let f be a distance pair antimagic labeling of G and $G_1, G_2, G_3, \dots, G_t$ be t copies of G .

Let the vertex set of i^{th} copy of G be $v_1^i, v_2^i, \dots, v_n^i$.

We consider the following two cases:

Case(i): Suppose t is even and n is either odd or even.

The total number of vertices in $tG = nt$, which is even.

Define $f: V(tG) \rightarrow \{\pm 1, \pm 2, \dots, \pm \frac{nt}{2}\}$ by

$$f(v_j^i) = j + \frac{nt}{2} \left(\frac{i-1}{2} \right), i = 1, 3, 5, \dots, t-1 \text{ and } j = 1, 2, 3, \dots, n$$

$$f(v_j^i) = - \left[j + \frac{nt}{2} \left(\frac{i-1}{2} \right) \right], i = 2, 4, 6, \dots, t \text{ and } j = 1, 2, 3, \dots, n$$

Case(ii): t is odd and take n is either odd or even.

Bala and Saratha Devi

Let f_1 be a distance pair antimagic labeling of G .
 Assign the labels $\{0, \pm 1, \pm 2, \dots, \pm \frac{n}{2}\}$ or $\{\pm 1, \pm 2, \dots, \pm \frac{n}{2}\}$ into the vertices of t^{th} copy of G accordingly n is odd or n is even by f_1 .

Assign following labeling f_2 for first $t - 1$ copies of G ,

$$f_2: V((t - 1)G) \rightarrow \left\{ \pm \left(\frac{n}{2} + 1 \right), \pm \left(\frac{n}{2} + 2 \right), \dots, \pm \frac{n(t-1)}{2} \right\} \text{ by}$$

$$f_2(v_j^i) = j + \frac{n}{2} \left(\frac{i+1}{2} \right), i = 1, 3, 5, \dots, t - 2 \text{ and } j = 1, 2, 3, \dots, n$$

$$f_2(v_j^i) = - \left[j + \frac{n}{2} \left(\frac{i}{2} \right) \right], i = 2, 4, \dots, t - 1 \text{ and } j = 1, 2, 3, \dots, n$$

Clearly f_1 and f_2 are distance pair antimagic labeling of tG . Hence tG is distance pair antimagic graph.

Corollary 2.12 *If a graph G is distance pair antimagic with even number of vertices, then $tG + K_1$ is also distance pair antimagic.*

Proof. By theorem 2.11, tG is distance pair antimagic graph. By the definition of joining of two graphs, join each vertex of tG to a single vertex u and labeled as zero. Then $tG + K_1$ is distance pair antimagic graph.

Relation between distance antimagic and distance pair antimagic labeling

Arumugam and Kamatchi [3] has been proposed the following conjecture.

Conjecture

A graph G is distance antimagic if and only if $N(u) \neq N(v)$ for any two distinct vertices u and v in G .

This conjecture not exist for distance pair antimagic labeling by the following theorem.

Theorem 3.1 *The wheel graph $W_n = C_{n-1} + K_1$ is distance pair antimagic iff $n = 7, 9, 11, \dots$ or $n = 4$.*

Proof. Let W_n be a wheel graph, where $n = 4, 5, 6, 7, \dots$

Suppose $n = 7, 9, 11, \dots$ or $n = 4$, by using theorems 2.4 and 2.8, the Wheel graph W_n is distance pair antimagic, because $W_n = C_{n-1} + K_1$.

Hence W_n is a distance pair antimagic graph, if $n = 7, 9, 11, \dots$ or $n = 4$.

Conversely, if W_n is a distance pair antimagic graph, then we prove $n = 7, 9, 11, \dots$ or $n = 4$.

It is enough to prove that if W_n is a not distance pair antimagic graph, if $n = 2m$ where $m \geq 3$ and W_5 .

By lemma, W_5 is not a distance pair antimagic graph.

Assume that W_{2m} is a distance pair antimagic graph if $m \geq 3$.

Then there exist a distance pair antimagic labeling $f: V(W_{2m}) \rightarrow \{\pm 1, \pm 2, \pm 3, \dots, \pm m\}$.

Let $\{v_0, v_1, v_2, \dots, v_{2m-1}\}$ be the vertices of W_{2m} and v_0 be the apex vertex and remaining vertices $\{v_1, v_2, v_3, \dots, v_{2m-1}\}$ be rim vertices of W_{2m} .

Consider following two cases.

Case(i): Assign $f(v_0) = l$, where $l \in \{1, 2, 3, \dots, m\}$. Then $w(v_0) = -l$

We know that any distance pair antimagic graph has exactly two vertices receives, maximum weight and minimum weight, so that we can choose two rim vertices u and v such that

$$w(u) = \max \{w(v_0), w(v_1), \dots, w(v_{2m-1})\} \text{ and}$$

$$w(v) = \min \{w(v_0), w(v_1), \dots, w(v_{2m-1})\} \text{ with } w(u) + w(v) = 0 \rightarrow (1)$$

Since u and v are rim vertices, which receives labels l_1, l_2, l and l_3, l_4, l respectively in its weight where $l_1, l_2 \in \{1, 2, 3, \dots, m\} - \{l\}$ and $l_3, l_4 \in \{-1, -2, -3, \dots, -m\}$ with

$$l_1 + l_2 + l_3 + l_4 = 0, \text{ then the equation (1) } \Rightarrow w(u) + w(v) = 0$$

$$\Rightarrow (l_1 + l_2 + l) + (l_3 + l_4 + l) = 0 \Rightarrow 2l = 0 \Rightarrow l = 0, \text{ which is a contradiction to our assumption that } l \text{ is a positive integer and hence } W_n \text{ is not a distance pair antimagic graph for } n = 2m \text{ and } m \geq 3$$

Case(ii): Assign $f(v_0) = l$, where $l \in \{-1, -2, -3, \dots, -n\}$.

As in case(i), we can prove case (ii). Hence the wheel graph W_n is a distance pair antimagic iff $n = 7, 9, 11, \dots$ or $n = 4$.

Bala and Saratha Devi

Theorem 3.2 If G is any distance antimagic graph, then the disjoint union $G \cup G$ is a distance pair antimagic graph.

Proof. Let G be any distance antimagic graph with n vertices. Then there exist a bijection $f: V(G) \rightarrow \{1, 2, \dots, n\}$, such that $w(v_i) \neq w(v_j)$ for $i \neq j$.

Take another copy of G and define $f^*: V(G) \rightarrow \{-1, -2, \dots, -n\}$ by

$$f^*(v_i) = -f(v_i) \text{ for all } i.$$

Then induced vertex weight labeling are $w^*(v_i) = -w(v_i)$ for all i .

Hence $G \cup G$ is a distance pair antimagic graph.

CONCLUSION AND SCOPE

In this paper we have introduced and investigated the existence of distance pair antimagic labeling on standard family of graphs. Further we proved the disjoint union of G , $tG + K_1$ and complement of $G \cong C_n$ a distance pair antimagic graph if G is a distance pair antimagic graph. By the observation of Conjecture 3.2 in [3], we have the following the conjecture:

Conjecture

A tree T is distance pair antimagic iff every support vertex v has exactly one leaf adjacent to v . By corollary 2.11, by replacing G by P_n , we obtained the graph $S_k(K_{\{1,n\}})$ (as defined in [3]) and this serves as one of the particular case of the above conjecture. Further we a scope for characterisation of distance pair antimagicness of trees.

ABSTRACT

Conventional Concrete, commonly manufactured using Portland cement, is a staple in construction, with its demand steadily rising. Concrete production was projected to increase from 1.5 to 2.2 billion tons between 1995 and 2015. However, the industry's significant contribution to CO₂ emissions, about 6%, exacerbates climate change, with CO₂ responsible for 65% of global warming. Efforts to mitigate these emissions include exploring alternative materials like fly ash, silica fume, and geopolymer technology. Geopolymer, proposed by Davidovits, shows promise, potentially reducing CO₂ emissions by 80%. This research work aims to investigate fiber-based geopolymer concrete properties incorporating glass and crimped steel fibers. Utilizing low-calcium fly ash (ASTM Class F), GGBS, and alkaline solution, the study examines compressive, flexural, and split tensile strength, and was analyzed on various compositions of fibers. Objectives include identifying parameters affecting properties and developing a mix proportioning process.

Keywords: Crimped Steel Fiber, Glass Fiber Ground granulated blast furnace slag, Fly-Ash, Geopolymer Concrete

INTRODUCTION

The first geopolymer cement was developed in the 1980s was of the type (K,Na,Ca)-poly(sialate) (or slag-based geopolymer cement) and resulted from the research developments carried out by Joseph Davidovits and J.L. Sawyer

81510

**Rex et al.,**

at Lone Star Industries, USA and yielded the invention of Pyrament cement. Geopolymers have been known to be useful binders in concrete for over decades, but have recently developed rapidly in Australia due to the fact they have a CO₂ footprint which is approximately 80% lower than OPC cement. Water, expelled from the geopolymer matrix during the curing and further drying periods, leaves behind nano-pores in the matrix, which provide benefits to the performance of the geopolymer. The water in a low-calcium fly ash-based geopolymer mixture, therefore, plays no direct role in the chemical reaction; it merely provides the workability to the mixture during handling. This is in contrast to the chemical reaction of water in a Portland cement concrete mixture during the hydration process. However, a small proportion of calcium-rich source materials such as slag may be included in the source material to accelerate the setting time and to alter the curing regime adopted for the geopolymer mixture. In that situation, the water released during the geopolymerisation reacts with the calcium present to produce hydration products.

Slag Based Geopolymer

The first geopolymer developed was slag-based in the 1980s. The reason for using this type of cement is due to its rapid strength gain as it can reach strengths of up to 20 MPa after just 4 hours. Slag is a partially transparent material and a by-product of melting iron ore. It usually consists of a mixture of metal oxides and silicon dioxide. It is also used in the cement and concrete industry. The substitution of OPC with slag is one of the many benefits that it provides to OPC concrete, reducing life cycle costs and improving the workability of the fresh concrete, Easier finish ability, higher compressive and flexural strength, and also improved resistance to acid materials. The reactions of slag in alkali activating systems and cement blends are dominated by the small particles. The particles above 20 µm usually react slowly, while particles under 2 µm react completely within 24 hours. Thus, when slag is used in polymerization, careful control of the particle size distribution must be ensured to control the strength of the binder.

Rock-Based Geopolymer

To compose this type of geopolymer, a fraction of the MK-750 (“MK” is an abbreviation for Metakaolin, and the “750” represents the temperature at which it was produced) in the slag-based geopolymer is replaced by natural rock-forming materials such as feldspar and quartz. This mixture yields a geopolymer with better properties and less CO₂ emissions than that of the ordinary slag-based geopolymer. The components of rock-based geopolymer cement are Metakaoline MK-750, blast-furnace slag, natural rock-forming materials (calcined or non-calcined), and a user-friendly alkali silicate.

Fly Ash Based Geopolymer

Fly ash is the waste material produced in the blast furnace. Components of fly ash are amorphous composition (60%), quartz (20%), mullite (17%), magnetite (1.7%), and hematite (.9%). Fly ash is commonly used as a substitute for OPC in concrete and the addition of it provides that fly ash consists of spherical particles as shown in Fig:2 which improves the workability of the fresh OPC concrete. This enables one to reduce the amount of water in the mix which reduces the amount of bleeding of OPC concrete. It improves mechanical properties such as compressive strength, due to water reduction and ensures a higher reactivity and better “packing” of particles. Reduce the cost of the OPC concrete.

LITERATURE REVIEW

Patankar S. et al., (2018) studied the effect of duration and temperature curing on the compressive strength of fly-based Geopolymer Concrete (GPC) and observed while finding the effect of concentration of sodium hydroxide on fly ash-based geopolymer concrete that the compressive strength of geopolymer concrete increases with increase in the concentration of sodium hydroxide solution for all temperatures but the rate of gain of strength at and above 60°C is not very significant. **Zhang H.Y. et al., (2018)** based on their experimental results on the bond behavior between geopolymer concrete and rebar reported that Geopolymer concrete exhibits significant temperature-

Rex et al.,

induced degradation in bond strength when exposed to temperatures above 300°C. Also, the Bond strength of geopolymer concrete was found to decrease at the same rate as that of splitting tensile strength with temperature, but this degradation is at a higher pace than that of the compressive strength. **Manimaran, E and Mohankumar, G. (2017)** investigated the influence of sodium hydroxide concentration on the strength of fly ash-based geopolymer concrete and reported that the strength of ambient cured specimens is always less and about 95% to 97% of the hot cured concrete irrespective of the molarity of NaOH solution. Under specified concentrations of NaOH, the required strength of Geopolymer concrete can be achieved by ambient curing itself and hot curing is not at all required under laboratory conditions. Hot curing may be employed in the case of fabrication of precast units. **Ukesh Praveen P and Srinivasan K (2017)** conducted a review of the literature about the self-compacting of geopolymer concrete and reported that the contribution of GGBS helps the self-compacting geopolymer concrete attain high compressive strength at ambient room temperature. GGBS at ambient curing conditions had more compressive strength rather than Fly ash-based self-compacting geopolymer concrete. It is recommended that sodium hydroxide and sodium silicate solutions should be prepared at least 24 hours before use.

Adam A. A. et al., (2016) investigated the effect of lime addition on the setting time strength of ambient cured fly ash-based geopolymer concrete and reported that the setting time of the class F fly ash-based geopolymer paste can be controlled by adding a small proportion of slaked lime. The addition of lime increases the strength and decreases the setting time. **Sandeep L. Hake et al., (2015)** investigated the method of curing and found that most researchers used only oven heat curing for geopolymer concrete. They reported that many studied only different curing temperatures in oven curing, but only a few researchers experimented with steam, and membrane curing, and no work was reported on accelerated curing, as well as comparison on steam, accelerated, membrane, natural, and oven curing. So there is scope for research on the method of curing of geopolymer concrete. **Ganesan N, Ruby Abraham, and S. Deepa Raj (2015)** studied the effect of fibers on the durability characteristics of geo-polymer concrete and compared it with conventional concrete of the same grade. The durability parameters considered in this study include water absorption, abrasion resistance, resistance to chemical attack, effect of alternate wetting and drying, and resistance against chloride ions. They concluded that geo polymer concrete possesses better durability characteristics than conventional concrete of the same grade and the addition of fibers further improved the durability characteristics of GPC. **Parda et al., (2014)**. The combination of Ground granulated blast-furnace slag (GGBS) with class F fly ash can have a significant effect on the setting and compressive strength development of geopolymer concrete.

The effect of different proportions of GGBS and activator content on the workability and strength properties of fly ash-based geopolymer concrete. The test result showed that 28-day compressive strength reached up to 51 MPa in geopolymer concrete containing 20% slag and 80% fly ash in the binder and 40% activator liquid with an SS/SH ratio of 1.5 when cured at 20 C. **Ganesan et al., (2014)** the effect of hybrid fibers on the strength and behavior of High performance concrete beam-column joints subjected to reverse cyclic loads was studied. The addition of fibers in hybrid form improved many of the engineering properties such as the first crack load, ultimate load, and ductility factor of the composite. The combination of a 1% volume fraction of steel fibers and a 0.15% volume fraction of polypropylene fibers gave a better performance concerning energy dissipation capacity and stiffness degradation than the other combinations. **Pradip et al., (2014)** Study was conducted on the geopolymer concrete cured under ambient conditions. Fly ash and GGBS-based geopolymer concrete for curing by ambient conditions can be proportioned for desirable workability, setting time, and compressive strength using ground granulated blast-furnace slag (GGBS) as a small part of the binder. The inclusion of GGBS with Class F fly ash helped achieve setting time and compressive strength comparable to those of ordinary Portland cement (OPC). **K. Parthiban et al., (2013)**, studied the influence of the various proportions of GGBS (0 to 100%) and the effect of the amount of Alkaline Activated Solution (AAS) on the compressive strength of geopolymer concrete which is cured under ambient temperature conditions. The molarity of the sodium hydroxide solution was maintained constant. They observed that the compressive strength of the GPC increased with the increase in the percentage of GGBS and also with the increase in the amount of the sodium silicate solution. **Deepa Balakrishnan S et al., (2013)** reported that the fly ash content is much more significant when the geo-polymer concrete is cured at ambient temperature. However, the

**Rex et al.,**

change in strength of heat cured specimen is nominal with the variation of fly ash content varied from 395 to 425 kg per cubic meter of concrete. They reported that the fly ash geo-polymer concrete is a sustainable material for future construction works. However, design methodologies are to be developed for geo-polymer concrete before actual use in worksite. **Swanepoel, J.C and Strydom, C.A (2013)** prepared the GPC by mixing fly ash, kaolinite, Na_2SiO_3 , NaOH, and water. The samples were cured at 40, 50, 60, & 70°C for different time intervals (6, 24, 48, and 72 hours) the compressive strength testing was performed at the age of 7 & 28 days using 3 members 50mm cubic samples. The authors reported that the optimum curing condition for polymerization was 60°C for 48 hours. Compressive strength measurements show a maximum strength of almost 80 MPa after 28 days. **Deepa Balakrishnan S. et al., (2013)** examined the properties of fly ash-based geopolymer concrete and stated that the strength gain in geopolymer concrete is significant when heat cured for 72 hours also the strength of heat-cured specimen is found to be almost equal to the corresponding strength of 90 day ambient cured specimens or almost two times as that of the 28-day strength. **Satpute Manesh B. et al., (2012)** studied the effect of duration and temperature curing on the compressive strength of fly ash based on geopolymer concrete and reported that curing temperature and duration are important in the activation of geopolymer concrete. Curing time, in the range of 6 to 24 hours, produces higher compressive strength. However, the increase in strength beyond 20 hours is not significant. **Gokulram H. et al., (2012)**, conducted an experimental investigation on the mechanical properties of different binder compositions of Geopolymer Concrete Composites (GPCC). The study analyses the effect of polypropylene fiber on mechanical properties such as compressive strength, split tensile strength, and flexural strength of hardened GPCC. Polypropylene fibers were added to the mix in the volume fraction of 0.25% volume of concrete. Two kinds of systems were considered in this study using 100% replacement of cement by ASTM class F Fly ash and ground granulated blast furnace slag and 100% replacement of natural sand by Manufactured sand. The mix with 100% GGBS and 0% FA has given the highest mechanical properties i.e. compressive strength of 34 N/mm², split tensile strength of 4.74 N/mm², and flexural strength of 5.1 N/mm². **Ganapati Naidu P et al., (2012)**, evaluated the different strength properties of GPC by replacing fly ash with GGBS and making workable, high-strength, and durable concrete without the usage of OPC. Fly ash was collected from the National Thermal Power Corporation (NTPC), Visakhapatnam. The sodium hydroxide solution is mixed with sodium silicate solution to get the desired alkaline solution one day before casting. Ambient curing has been adopted for the specimens.

From the tests, it was concluded that higher concentrations of GGBS result in higher compressive strength. Beyond 30% replacement of GGBS, immediate setting was observed. To attain maximum strength 9% of fly ash is replaced by GGBS in the aspect of ambient and combusted curing. Compressive strength increases with an increase in GGBS. A maximum of 25% loss in compressive strength was observed when the specimen was exposed to a temperature of 500°C for two hours. 90% of compressive strength was achieved in 14 days. The average density of geopolymer concrete was equal to that of OPC. **Shakor & Pimplikar et al., (2011)** Concluded that 7 days average compressive strength of concrete is maximum when 1.5 % of glass fibers by weight of cementitious material are used. At lower 0.11% of glass fibers or higher 2 % of glass fibers, about 15% to 20% reduction in strength was observed nevertheless at 28 days, the reduction in strength approaches to 5% to 10%. The percentage of glass fiber of 2% gave a flexural strength of 6.15 MPa, which is 10% more than that obtained at 1.5%. **P. Sangeetha et al., (2011)** reported that an increase in the percentage of glass fiber by weight of concrete (0.1%, 0.2% & 0.3%) increases the compressive and impact strength. The percentage increase in compressive strength was reported to be up to 23%. **Jalal Rouhiet al., (2011)**, studied the effect of polypropylene fibers on the compressive strength, permeability, and electric resistivity of concrete samples. The concrete samples were made with fibers ranging from 0 to 2 kg/ m³. Electrical resistivity and compressive strength of concrete samples with fiber ratios of 1.5 kg/ m³ had higher values and the permeability of the concrete specimens reduced as the fiber content increased. Samples with a fiber content of 1.5 kg/ m³ showed optimum results in comparison with other samples. **H. Sudarsana Rao, M. Safari Tabalvandani, Krishan Rao MV et al., (2011)** Stated that the workability of glass fiber-reinforced high-performance concrete mixes decreases with an increase in the percentage of glass fibers. The work of different researchers on GFRC has been found on concretes cast by using foreign ingredients only. The trend of locally branded concretes manufactured by using indigenous materials found in Pakistan was still demanding a lot of research work. The current investigation was planned to explore the effects of using different percentages of glass fibers on properties of fresh and hardened concrete like

**Rex et al.,**

workability, compressive strength, tensile strength, flexural strength, and ultrasonic pulse velocity. **Hardijto, D.Wallah S.E., Sumajouw D.M.J., and Rangan, B.V(2009)** investigated the effect of various synthesizing parameters on fly ash-based geopolymer concrete. Numerous bathes of geopolymer concrete were prepared by activated class-F fly ash with sodium silicate and sodium hydroxide solutions.

Objective of Current Study

The main objective of this research work is

- To develop a mixture proportioning process to manufacture fiber-based geopolymer concrete.
- To identify and study the effect of salient parameters that affect the properties of fiber-based geopolymer concrete.

Materials Used

Fly-Ash

Defined as 'the finely divided residue that results from the combustion of ground or powdered coal and that is transported by flue gasses from the combustion zone to the particle removal system' (ACI Committee 232 2004), Fly-Ash could be considered as an Environmental Waste material, is commonly used as substitutive Cementitious Materials in the modern concrete practice. The fly ash used for this project is collected and transported from NTPC Ramagundam, possessing the Chemical Composition as stated in Table: 1 below

Ground Granulated Blast Furnace Slag(GGBS)

Obtained by quenching molten iron slag from a blast furnace in water or steam, dried and ground into a fine powder. Its use results in lower heat of hydration and lower temperature rises, further it reduces the risk of damages caused by alkali-silicereactions. Provides higher resistance to chloride ingress reducing the risk of reinforcement corrosion and provides higher resistance to attacks by Portland cement sulphate and other chemicals. This study has used the GGBS from a Local RMC Plant possessing the Chemical Composition as stated in Table: 2.

Alkaline Activators

A combination of sodium silicate solution and sodium hydroxide solution was chosen as the alkaline activators. The sodium hydroxide solids were in pellet form (3 mm), with a specific gravity of 1.51 and 98% purity, and were used to achieve 8M Sodium Hydroxide Solution (NaOH) (320 grams/liter). Sodium Silicate Solution (Na_2SiO_3) with 50.32% Solid Content was also, where NaOH to Na_2SiO_3 ratio was maintained as 2.5.

Glass Fiber

Glass Fiber is a material consisting of numerous extremely fine Fibers of glass. It is used as a thermal insulating material and is specially manufactured with a bonding agent to trap many small air cells, resulting in the characteristically air-filled low-density "glass wool" family of products. The Mechanical Properties of the Glass Fibers used for this study are stated in Table: 4 below. Glass Fiber has roughly comparable mechanical properties to other Fibers such as polymers and carbon Fiber. Although not as strong or as rigid as carbon Fiber, it is much cheaper and significantly less brittle when used in composites. Glass Fibers are therefore used as a reinforcing agent for many polymer products; to form a very strong and relatively lightweight Fiber-reinforced polymer (FRP) composite material called glass-reinforced plastic (GRP), also popularly known as "Fiberglass". This material contains little or no air or gas, is denser, and is a much poorer thermal insulator than glass wool.

Crimped Steel Fiber

This study has used crimped stainless steel Fibers. The use of Fibers in concrete has the property of resistance against cracking and crack propagation. The Fiber composite pronounced post cracking ductility which is unheard of in ordinary concrete. The transformation from a brittle to a ductile type of material would increase substantially the energy absorption characteristics of the Fiber composite and its ability to withstand repeatedly applied shock or

Rex et al.,

impact loading. These Fibers are short, discrete lengths having an aspect ratio in the range of 20-100, with any cross-section that is sufficiently small to be randomly dispersed in an unhardened concrete. Further, they are low-carbon, cold-drawn steel wire Fibers designed to provide concrete with temperature and shrinkage crack control, enhanced flexural reinforcement, improved shear strength, and increased crack resistance of concrete. These steel macro-fibers will also improve impact, shatter, fatigue, and abrasion resistance while increasing the toughness of concrete. Dosage rates will vary depending upon the reinforcing requirements and can range from 15 to 60 kg/m³.

METHODOLOGY

- Under various trials and errors, GPC of grade 50 MPa was prepared and achieved, with a Fly-Ash: GGBS ratio of aof0.5 and NaOH to Na₂SiO₃ ratio of2.5., the GPC Specimens were subjected to Ambient Curing.
- Additives such as binders, super plasticizers, and fibers were once as soon as quickly blended used in different proportions i.e 0.1% to 0.6%, and super plasticizer SP430 delivered in the concrete due to the reality of hindering the water content material cloth will make bigger strength. The strength of the cubes is tested for 3 days, 7 days, and 28 days using crimped steel fiber and glass fiber is graphically illustrated using the proportions in percentages from 0.1% to 0.6%.The maximum strength achieved for different proportions is graphically represented.
- The test consequences of compressive strength, flexural strength, and split tensile strength for cubes, beams, and cylinders uncovered to 0.1% to 0.6% of fibers with the aid of super plasticizers, GGBS, and alkaline solution and cured for 3 days, 7 days and 28 days by ambient curing produce the required strength.

RESULTS AND DISCUSSIONS

Compressive Strength Test results on G50 cubes using steel fibers

The Compressive Strength results of Plain G30 Cubes(150*150*150 mm) and using Steel Fibersare presented graphically in Fig: 1 and 2 below, and the inferences are as follows:

- From Fig:1, it is evident that the compressive strength of the concrete cubes is 23.4 N/mm² after 3 days, 46.8 N/mm² after 7 days, and 58.5 N/mm² after 28 days.
- The concrete cubes gained more strength between 3 and 7 days than they did between 7 and 28 days. This is because the rate of strength gain slows down as the concrete cures.
- The compressive strength of the concrete cubes after 28 days is 58.5 N/mm². This is a common target strength for concrete used in construction.
- From Fig:2, it could observed that the Steel fibers increase the compressive strength of M50 concrete cubes. This is evident from the fact that all the curves for the concrete mixes with steel fibers (0.10%, 0.20%, 0.30%, 0.40%, 0.50%, and 0.60%) are above the curve for the standard mix (0% fibers).
- The optimal percentage of steel fibers is 0.40%. The concrete mix with 0.40% steel fibers has the highest compressive strength at all curing times (3 days, 7 days, and 28 days). After 28 days, the compressive strength of the 0.40% mix is 62.3 N/mm², which is about 2% higher than the strength of the standard mix (60.2 N/mm²).
- Adding too many steel fibers can decrease the compressive strength. The compressive strength of the concrete mix with 0.60% steel fibers is lower than the compressive strength of the mix with 0.50% steel fibers at all curing times. This is because adding too many fibers can make the concrete mix difficult to work with and can lead to voids in the concrete.

Split tensile strength Test results on G50 Cylinders using steel fibers:

The Split Tensile Strength results of Plain G30 Cylinders (150mm dia and 300mm height) and using Steel Fibersare presented graphically in Fig: 3 and 4 below, and the inferences are as follows:

- From Fig: 3, it can be noticed that the Split Tensile Strength values have ranged from around 3.82 N/mm² to 4.82 N/mm².

Rex et al.,

- And all the results were satisfactory since every result has fallen within the range of 8-15 % of Compressive Strength of Concrete.
- From Fig: 4, it can be seen that Steel fibers can increase the split tensile strength of M50 concrete cylinders. This is evident from the fact that all the curves for the concrete mixes with steel fibers (0.10%, 0.20%, 0.30%, 0.40%, 0.50%, and 0.60%) are above the curve for the standard mix (0% fibers).
- The optimal percentage of steel fibers is 0.40%. The concrete mix with 0.40% steel fibers has the highest split tensile strength at all ages (3 days, 7 days, and 28 days). After 28 days, the split tensile strength of the 0.40% mix is 5.48 N/mm², which is about 5.2% higher than the strength of the standard mix (5.2 N/mm²).
- Adding too many steel fibers can decrease the split tensile strength. The split tensile strength of the concrete mix with 0.60% steel fibers is lower than the split tensile strength of the mix with 0.50% steel fibers at all ages. This is because adding too many fibers can make the concrete mix difficult to work with and can lead to voids in the concrete.

Flexural strength Tests on G50 prisms using steel fibers:

The Flexural Strength results of Plain G30 Prisms (750*150*150 mm) and using Steel Fibers are presented graphically in Fig: 5 and 6 below, and the inferences are as follows:

- From Fig: 5, it can be noticed that the Flexural Strength values have ranged from around 1.81 N/mm² to 4.53 N/mm².
- And all the results were satisfactory since every result has fallen close to $(0.7 \cdot f_{ck}^{0.5})$ [f_{ck} : Compressive Strength of Concrete]
- From Fig:6, the Flexural strength of the M50 Prism increases with the addition of steel fibers. This is evident from the fact that all the curves for the concrete mixes with steel fibers (0.10%, 0.20%, 0.30%, 0.40%, 0.50%, and 0.60%) are above the curve for the standard mix (0% fibers).
- The optimal percentage of steel fibers for split tensile strength is 0.40%. The concrete mix with 0.40% steel fibers has the highest split tensile strength at all curing times (3 days, 7 days, and 28 days). After 28 days, the split tensile strength of the 0.40% mix is 4.9 N/mm², which is about 13.5% higher than the strength of the standard mix (4.3 N/mm²).
- Adding too many steel fibers can decrease the split tensile strength. The split tensile strength of the concrete mix with 0.60% steel fibers is lower than the split tensile strength of the mix with 0.50% steel fibers at all curing times. This could be due to several factors, such as fiber clumping or difficulty in achieving proper fiber distribution at higher fiber contents.

CONCLUSIONS OF THE STUDY

Based on the experimental work for M50 grade geopolymer concrete using hybrid fibers reported in the study, the following conclusions are drawn: Geopolymer concrete can be widely used in the manufacture of precast structures. It can be used in areas where faster strength achievement is needed. Fiber-reinforced geopolymer concrete eliminates the use of cement in concrete and helps to prevent global warming and to utilize fly ash effectively. Higher concentration of sodium hydroxide solution results in high compressive strength in the case of glass fiber, steel fiber, and a combination of fibers-based geopolymer concrete. Higher the ratio of sodium silicate to sodium hydroxide ratio by mass, the higher the compressive strength for glass fiber, steel fibre, and a combination of fibers-based geopolymer concrete. The compressive strength due to ambient curing for a combination of fibres-based geopolymer concrete does not depend on time period. The additions of super plasticizers are taken in different ratios, 2% of superplasticizers get the best results for compressive strength. Super plasticizer % is taken in a limit if it exceeds the limit, then automatically the compressive strength decreases. It was observed that the maximum strength using steel fibers was obtained at 0.3% and further it was observed to be decreasing. Similarly it was observed that in the case of glass fiber-based geopolymer concrete, the maximum strength was obtained at 0.4% and further it was observed to be decreasing. The strength achieved for the geopolymer concrete using hybrid fibers in different percentages has a considerable effect on the increase in the strength. The addition of GGBS in the combination of fibers has

**Rex et al.,**

considerably reduced the setting time and the use of superplasticizers beyond the limit has a considerable effect on the strength of geopolymer concrete based on a combination of fibers.

Scope for Further Studies

The scope of this study is focused on the properties of geopolymer concrete with crimped steel and glass fiber as hybrid fibers. Six volume percentages of crimped steel and glass fiber are utilized to investigate the influence properties of concrete. The scope and limitations of this study are: The cement can be replaced by fly ash and GGBS in different proportions for higher strength achievement for M50 grade concrete mix. Different other types of fibres can be utilized to determine the strength parameters in different proportions

ABSTRACT

A network of remote file servers that are hosted online is used for cloud computing file storage. Without using local servers or personal computers, the cloud can store, manage, and process enormous quantities of files. How to safeguard this private data is one of the most worrying issues. The most popular strategies for cracking passwords in cryptanalysis are a dictionary attack and a brute force attack. Responsible for shielding the passwords from dictionary or brute force attacks and also strengthening the password hashing mechanism needed. Most of the hashing algorithms were attacked. In this solution, we tried a R3SKT algorithm for protecting passwords on cloud file storage. The algorithm was developed based on a dynamic selection of sub-algorithms, and different types of salting were used, like DNA nucleotide sequence. A dynamic selection of sub-algorithms was processed based on the attributes of the password, like size and character values. The newly created algorithm did not have any collisions. Every sub-algorithm was processed after a specific idea was used.

INTRODUCTION

The well-organized rapidly developing technology that is gaining popularity is cloud computing. Cloud file storage is a technique for storing and retrieving data in the cloud which provides servers and apps with access to data via shared file systems. The benefits of cloud storage include respected storage, resources that are available when required minimal cost, simple storage administration, and easy user maintenance. Users won't have access to their

**Naveenraj and Murugan**

files in the cloud because the data is kept in geographically dispersed, differently situated data centres. For controlling the user's authorization over their cloud-stored data, adequate policies and access control approaches are required. The cloud service provider sets these limitations, which must only permit authorized users of the file to access their data. In order to preserve the confidentiality of the cloud-stored file, certain control over access and protection systems are required. Different kinds (Figure 1) of users use the drive storage; they aren't aware they are on a secure platform. Some of the apps and websites are not truly secure in terms of their password policies. Tag along their credentials, create time, and use upper-case letters, characters, and special characters. But, really, not the passwords are strong or not. All businesses should be extremely concerned about the security of their data across all of their accounts and subscriptions, especially as more delicate data kinds are produced and kept in cloud tenants. Due to the large variety of data storage providers accessible, the diverse secret management requirements across multiple applications, and the vastly different compliance and regulatory requirements depending on the type of data, multi-tenant cloud data security is complicated. In order to provide centralized encryption control and administration, encryption key management services can be employed centrally across a number of tenants, but they must be correctly deployed and configured. The development of migration strategies for accounts to utilize new encryption keys produced in a centralized key management service deployment as opposed to those used within a single account or subscription requires the assistance of security teams.

Through the help of the hash algorithm, a string can be transformed into a collection of random characters. Because it only has the ability to do encryption and lacks the necessary decryption key[10], it is also known as a one-way function or one-way encryption. It functions by taking input strings with any length and transforming them into a hash value, which is a string with a set length. To secure the authentication procedure, hash is frequently utilized. Adding or pretending an arbitrary number to the user's password before hashing is known as salted password hashing. An authentication is a process used to confirm that a piece of property is real, verifiable, and reliable. It also involves having a strong belief in the reliability of the transmission, message, or sender. It ensures that the user's input into the system should come from a reliable source[9]. The process of authentication is essential because it secures data from unauthorized users while also protecting it. It also keeps the data's integrity[5]. To aid in the authentication process and reduce the possibility that an attacker may corrupt data, algorithms and hashing techniques are required. The authentication process uses a variety of methods, such as hashing, including the authentication of the login (password), the authenticity of the authentication file, the storage of the password, the production of keys and pseudorandom numbers, the authentication of tokens on services in a distributed system, the authentication of digital signatures, etc.. Due to recent hacking and public disclosure of private data (User's passwords) from several high-profile companies, including LinkedIn, E-harmony, and Yahoo within the last five years, serious concerns have been raised about the security of both their authentication systems and the methods they use to store the passwords in their databases. The majority of database applications usually keep their passwords in database in plain text, which is an insufficient means of protection, particularly for apps that hold sensitive user data.

RELATED WORKS

Anuraj Singh's et al.[1]securing passwords using a dynamic password policy The generator algorithm uses four algorithms to generate a hash password. Some of the limitations were used in the generator policy, like character length between 8 and 20, avoiding bad characters, and using good characters. The generator algorithm avoids uniformity characters based on the threshold idea. Dynamic policy tried to generate without repeated passwords. In the end, PBKDF2 was used after around 10,000 iterations. This algorithm prevents brute force, rainbow tables, and dictionary attacks. **AmolBhalerao**[3] shows the web password hashing technique used: salted hashing, SHA256, SHA512, RipeMD, and WHIRLPOOL. They are using short salt and salt reuse with the SHA256 technique to create a hash password. Salt added before SHA256 attackers may not be able to access the passwords or prevent birthday attacks and dictionary attacks.

Naveenraj and Murugan

Sutriman's et al.[7] password and salt combination scheme shows that dynamically created salt will get added in a password-mingled manner. Reverse the new arrangement of passwords. The salting is generated by random character generation. The data collected for testing is Splash Data's top 100 worst passwords. Tested using the Hashcat penetration testing tool and produced their cracking time of password. **Dr. Abdelrahman Karrar et al.**[11] swapping elements in the array algorithm shows a password with a salt rearrangement revision process. The algorithm generates salt and reverses it then. Rearrangement of the password given by the user after processing the rearrangement It will be given to the SHA384 cryptographic hash function. After processing the password, it will be converted to base64. **Katha Chanda's et al.**[14] password analysis mechanism checking policy has an entropy function. Entropy measures uncertainty, or a lesser chance of guessing. Entropy is measured in percentages. The score will be calculated on the basis of the length. Less than 6 no scores and scores above 4 are there. Scores 4, 6, 8, and 10, respectively, are their levels. The score 4 means a weak password. Based on the score and entropy, the percentage will be calculated. Above 85 percent, the password is considered a strong password. Between weak and strong will be treated as a fair password. **Pramod George Jose et al.**[13] The bit sequence of the password is employed to add salt to steganography as part in the password hashing process. Use the MSB-LSB rule to compute password hashes. In addition to an effective mask and cumulative mask being employed in the hash, other fixed sets of bit-based activities are derived from his work. Using the computed hash to compare the extracted hash to, and then the final hash 12.5% of the cover medium's capacity would be the payload capacity.

METHODOLOGY

The R3SKT (Figure 2) hashing algorithm makes a hash of the password through some techniques, as follows: The salting process [6] was processed based on the DNA sequence specified in developing time. In this work used rare fish's DNA sequence to mix as salt to the password. After completed the salting process password the reverse rail fence approach will get added to the password. The reverse rail fence is different ideology comparing to the old method of rail fence. After processed reverse rail fence the dynamic selection of the algorithm's calculations worked out based on length and ASCII characters values. The selection process under different three kinds of algorithms was used. All three algorithms are processed after the salted password. However, the order of the algorithm determines the dynamic selection calculation. Each and every algorithm having an end to that reverse rail fence process will be done. Finally, hash generated whether requirement based on the size result hash(64 bytes, 128 bytes).

Password Salting Technique & Reverse Rail Fence

Fixed DNA nucleotide sequence used as salt[4]. The rare fish's DNA Sequence as used in this algorithm as salt. Mix password with salt based on the Rail fence technique. Finally, the Reversal Rail Fence (RRF) algorithm will be used on the salted password[11].

Processing:

Salt : TCATACCCAAGAAGACTCGAGGCTGTA

 Password: Hello123

 Rail Fence:

 Hello123

 TCATACC

Step 2 follows the rail fence. So, the password will be changed into: HTeCIAIToA1C2C3

Step 3 follows the reversal rail fence. So the password will be changed into:

Split : HTeCIAIT oA1C2C3

Reverse: TIAICeTH 3C2C1Ao

RRF: 3TCI2ACICe1TAHo.

Algorithm 1: RRF

Input : Salted Password

Output : partial Hash Password

Naveenraj and Murugan

```

Begin
//splits the string into two substrings
Split1= substring(password,0,(mid/2+1));
Split2= substring(password,(mid/2+1),n);
//reverse the split strings.
Rev1=reverse(Split1);
Rev2=reverse(Split2);
// do rail fence on the rev1 and rev 2 then combine.
Password=RailFence(rev2,rev1);
Return (password);
End

```

Dynamic Policy

A random generated number has been generated for the purpose of choosing three algorithms to use on the hash function[2]. The random generated number is calculated based on the password length and the individual character's value[1].

$$M = \prod_0^{L-1} \sqrt{C^2} \times L$$

L= password length

C = individual character's ASCII value

M= Multiplication factor

The resultant multiplication factor used in generating the unrepeatable three-digit number (0 to 2) The three-digit number divisible by three and the remainder stored in unrepeatable numbers were then used as the dynamic selector of the algorithms in the hash function. The algorithms are Reposition and Repeat (RaR), Reverse Spiral Bits (RSB), and Knight Tour (KT). The algorithms explained next to that.

Reposition and Repeat

The RaR algorithm processes the password in redundantly taking 8 copies and shuffles the characters in a calculative logic. In the algorithm, 2D arrays are created, and the column size is the size of the password and the row size is 8. The redundant password is placed in a calculative manner when the formulation is used in the algorithm. The formula uses prime numbers, iterative numbers, and remaining numbers for the purpose of creating the calculated place value. Finally one time pad based the characters were converted into the results.

Algorithm 2: RaR

Input : Partial Hash Password

Output : Partial Hash Password

Begin

```

    pf=nextPrime(L+3);
    remain = L-1;
    for i=0 to 8
        forj=0 to 8
            iteration++;
            pos[i][j]=(pf * (iteration+j) * remain2) mod L;
            temp+=pos[i][j]
            remain--;
        pf=nextPrime(pf+3);
    endj

```

Naveenraj and Murugan

```

    endi
    result = RRF(temp);
    result = OTP(result);
    return(result);
end

```

Reverse Spiral Bits(RSB)

The RSB algorithm processes the password in reverse spiral order, taking bits. The password has to be converted into binary bits after being placed into a 2D array with 7 columns and the password length is the same as the row size. Converted bits are placed in character-wise rows of 7 bits. A spiral order of traversal will follow to collect bits stored in memory. Then memory will get reversed to do the process of a reverse spiral. Finally, one-time pad-based characters were converted into the results.

Algorithm 3: RSB

```

Input : Partial Hash Password
Output : Partial Hash Password
Begin
    bits=convertintobits(password);
    matrix=plotbits(bits);
    temp=spiral(matrix);//process the spiral Order traversal on the bits
    temp1= reverse(temp);
result = RRF(temp1);
    result = OTP(result);
    return(result);
end

```

Knight Tour

Steps involved in KT algorithm are, Even the length of the password into 5 divisibility terms. Convert the password into binary bits. Stored the bits into the rectangular array (5 rows and 7 columns). Traversal happens in the array in Chess Knight Moves likewise the bits read and store into the memory. Same above steps follow on the remaining bits. Return the result as converted into 64 base fixed One Time Pad(OTP).

Algorithm 4: KT

```

Input : Partial Hash Password
Output : Partial Hash Password
Begin
password+="ATGC";
len=(password.length()/5)*5;
password=substring(password,0,len);
streambit=convertbits(password);
skt[][]=knightPositionreturn() //knight moving position Array
fori=0 to len(streambit) step 35:
    for j=0 to 5:
        for k=0 to 7:
            t+=""+streambit.charAt(i+skt[j][k]);
        end for k
    end for j
end for i
result = RRF(temp1);
    result = OTP(result);
    return(result);

```

Naveenraj and Murugan

end

Result Hash

Steps involved in the Hash algorithm are, Convert the password into binary bits. Fix the base on a one-time pad for conversion of 6 bit characters. Iterate every 6 bits converted into base one time pad conversion and give the result password. Finally the resulting hash to be taken middle into 64 or 128 characters.(it may vary depending on the need of user memory requirements).

Algorithm 5: RH

Input : Partial Hash Password

Output : Final Hash Password

Begin

```
base="ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz0123456789~#"
rawbits= convertbits(password)
```

```
for i=0 to rawbits.length step 6
```

```
  if((i+6)<rawbits.length)
```

```
    temp=substring(rawbits,i,i+6)
```

```
  else
```

```
    temp= substring(rawbits,i,end)
```

```
  end if
```

```
  hash+=temp
```

```
end for
```

```
final Hash = substring(hash,middle-32,middle+32)
```

end

Final outcome of the algorithm gives a hash value. The hash values may vary depending on the attributes of the password. The attributes are length & character values. The Needed hash must be 64 characters. So, that the hash value middle 64 characters has been picked as a final password.

RESULTS AND DISCUSSION

In this research, a method that creates hashes based on the length and ASCII values of the characters has been created. The approach operates quickly, as determined by our computation of its time complexity. It will be difficult for the attacker to guess the password because the technique generates a value that can be hashed. By including these various characters, can able increase the password's complexity and make it harder for hackers to decipher. This hashing is intended for protecting websites or applications that are currently in use but are susceptible to many types of attacks, including dictionary, rainbow table, and brute-force attacks. Even if the attacker has gained access to the server and the database, using an upgraded hashing method will make it more difficult to crack the password. The algorithm tested (Table 1) in Intel(R) Core(TM) i3-2100 CPU @ 3.10GHz processor with windows 11 pro. But, the servers having 32, 16 cores this processor having 2 cores only. That's why time taken for processing. There are 3,91,519 password were tested. Passwords are taken from github 10 million user password lists. No collision occurred in the testing of the hash algorithm. The testing process taken under passwords is in numbers, characters and combinational mode. This algorithm gives better results in a mixed mode which is in use of characters and numbers in password and also mixed in special characters in password than better.

CONCLUSION AND FUTURE WORK

With the help of this Dynamic password policy, treated passwords in the different way protected from many types of attacks, including dictionary, rainbow table, and brute-force attacks. A password that is more secure than one that has been hashed using an improved hashing algorithm (such as PBKDF-2, Bcrypt, MD5, etc.), which makes it harder

Naveenraj and Murugan

to crack even in cases when an attacker has gained access to the server and database. The password hashing will give better results when more number of rounds adds into the algorithm. Future work of this algorithm may be adding number of rounds altering small corrections in between algorithms.

ABSTRACT

This study investigates the implementation of time series stochastic modelling for pulses production in India, using the production data for the period from 1975 to 2022. The article deals with trends and future projections of pulse production in India utilizing ARIMA (Auto-Regressive Integrated Moving Average) models. ARIMA (0,1,1) was chosen based on the estimates of the Box-Ljung Q statistics, Root Mean Square Error (RMSE), Mean Absolute Percentage Error (MAPE), Normalized BIC, and Autocorrelation Function (ACF) and Partial Autocorrelation Function (PACF). The production of pulses in India is expected to increase from 27.69 million tonnes in 2022 to 33.70 tonnes in 2030, according to the selected model.

Keywords: ARIMA, BIC, Forecasting, MAPE, Pulses Production, RMSE.

INTRODUCTION

India, a nation with a rich agricultural heritage, stands as one of the world's largest producers of pulses. Pulses, comprising lentils, beans, peas, and chickpeas, play a vital role in the Indian diet, offering a significant source of protein, fiber, and essential nutrients. The production of pulses in India is not just a matter of food security but also of economic importance, providing livelihoods to millions of farmers. Over the years, India has made concerted efforts to enhance pulse production through advancements in agricultural practices, policy interventions, and the adoption of high-yielding varieties. Despite these efforts, the sector continues to face challenges such as climate

81528

Jai Sankar and Pushpa

variability, pest infestations, and the need for improved storage and distribution systems. This article delves into the current state of pulse production in India, examining the factors driving its growth, the hurdles it encounters, and the strategies being employed to ensure its sustainable development. In recent years, the Indian government has launched several initiatives to boost pulse production and achieve self-sufficiency. The National Food Security Mission (NFSM) has been instrumental in promoting pulse cultivation through financial incentives, subsidies for seeds and fertilizers, and the dissemination of modern farming techniques. Additionally, the Minimum Support Price (MSP) scheme aims to ensure fair prices for farmers, encouraging them to allocate more land to pulse crops. Advances in agricultural research have led to the development of pest-resistant and drought-tolerant pulse varieties, further enhancing productivity. However, the sector still grapples with post-harvest losses due to inadequate storage facilities and market linkages. Addressing these challenges requires a multi-faceted approach, including strengthening the supply chain, improving infrastructure, and fostering public-private partnerships. By overcoming these obstacles, India can not only secure its domestic pulse requirements but also become a leading exporter, contributing to global food security. The health benefits of pulses and production states are shown in Figure 1.

MATERIAL AND METHODS

The current behavior of the variable under investigation is described by the ARIMA (Auto Regressive Integrated Moving Average) model in terms of linear relationships with its historical values. All that is needed for this extrapolation method is historical time series data for the variable being studied. The main purpose of ARIMA models is to forecast the associated variable. ARIMA residual autocorrelations were measured by Box and Pierce (1970). Slutsky (1973) applied Moving Average (MA) model. As described by Akaike (1983), the stationary time series is defined as being bounded by the same integer. Statistically independent and normally distributed residuals were significant features of stochastic time-series ARIMA models (Alan Pankratz, 1983) which were widely used to analyze time series data. Vishwajith et al. (2014) forecasted time series modeling and forecasting of pulses production in India with annual data from 2007 to 2015. Gagan Kumar (2016) developed and fitted forecast ARIMA (1,1,1) and ARIMA (1,1,1) model during 2014 to 2018 for forecasting production and area under cultivation for pulses in India using ARIMA model for the period from 1950-51 to 2013-14. Abhiram Dash and Subrat Kumar Mahapatra (2017) analysed and fitted ARIMA model for yield forecasting of important pulse crops of Odisha, India over the period 1971-72 to 2006-07 and 2007-08 to 2015-16. Mwangi Esther, N and Wangui Magdaline, N (2017) found that ARIMA (1,1,2) model as an appropriate to ARIMA Modeling to forecast pulses production in Kenya over the period 1961 to 2012. Pushpa M. Savadatti (2017) forecasted Trend and forecasting analysis of area, production and productivity of pulses in India with annual data from 1949-50 to 2015-16 and forecasted for the year from 2016-17 to 2020-21. Abhiram Dash et al. (2020) in their empirical study showed that ARIMA (0,1,1) is the appropriate model for forecasting of rabi pulse production in Odisha (India) by using Autoregressive Integrated Moving Average (ARIMA) technique for the period 1971-72 to 2015-16 forecasted model up to 2018-19. Jai Sankar and Pushpa (2020) considered ARIMA (0,1,1) model for stochastic forecasting analysis for peanut (*Arachis hypogaea*) production in India during the years from 1950-2017. Yashpal Singh Raghav et al. (2022) forecasted time series modeling and forecasting of pulses production in India with annual data from 1961 to 2015. Jai Sankar and Pushpa (2023) calculated ARIMA (0,1,2) model for implementation of stochastic time series forecasting ARIMA model for *Hordeum vulgare* production in India during the years from 1960 to 2020. Supriya et al. (2023) identified to fit ARIMA model for modeling and forecasting of lentil production in India and its instability for the period of 1970 to 2019 and forecasted up to 2029. Vishwajith et al. (2023) forecasted modeling and forecasting of lentil in India with annual data from 1970 to 2009 and forecasted model up to 2020. Sneha S. Ketali et al. (2024) identified to fit ARIMA model towards *atmanirbharta* (self-reliance) in the production of pulse crops in India: A situational analysis of future demand and supply for the period of 1950-51 to 2017-18 and forecasted up to 2018-19 to 2030-31.

In this study, a four-step ARIMA model was used, consisting of identification, estimation, diagnostic checking, and forecasting. Model parameters were considered to fit the ARIMA models.

AR process of order (p) is, $Y_t = \mu + \phi_1 Y_{t-1} + \phi_2 Y_{t-2} + \dots + \phi_p Y_{t-p} + \varepsilon_t$;

Jai Sankar and Pushpa

MA process of order (q) is, $Y_t = \mu - \theta_1 \varepsilon_{t-1} - \theta_2 \varepsilon_{t-2} - \dots - \theta_q \varepsilon_{t-q} + \varepsilon_t$; and

ARIMA process of order (p, d, q) is,

$$Y_t = \phi_1 Y_{t-1} + \phi_2 Y_{t-2} + \dots + \phi_p Y_{t-p} + \mu - \theta_1 \varepsilon_{t-1} - \theta_2 \varepsilon_{t-2} - \dots - \theta_q \varepsilon_{t-q} + \varepsilon_t$$

where Y_t - PulsesProduction, ε_t 's - independently and normally distributed with zero mean and constant variance σ^2 for $t = 1, 2, \dots, n$; d - the fraction differenced while interpreting AR and MA, and ϕ 's and θ 's - coefficients to be valued.

Trend Fitting

The Box-Ljung Q statistics was used to convert the non-stationary data into stationarity data and also to validate the adequacy for the residuals. For evaluating the adequacy of AR, MA and ARIMA processes, a range of reliability statistics like R squared, Stationary R squared, RMSE, MAPE and BIC were applied. The reliability statistics viz. RMSE, MAPE, BIC and Q statistics were computed as below:

$$RMSE = \left[\frac{1}{n} \sum_{i=1}^n (Y_i - \hat{Y}_i)^2 \right]^{1/2} \text{ and}$$

$$MAPE = \frac{1}{n} \sum_{i=1}^n \left| \frac{Y_i - \hat{Y}_i}{Y_i} \right|$$

$$BIC(p, q) = \ln v^*(p, q) + (p + q) \left[\frac{\ln(n)}{n} \right]$$

where p and q - order of AR and MA processes; n - number of observations; and v^* - approximate of white noise variance σ^2 .

$$Q = \frac{n(n+2) \sum_{i=1}^k rk^2}{(n-k)}$$

where n - number of residuals and rk - residuals autocorrelation at lag k.

In this analysis, the data on Pulsesproduction in India were collected from the Annual Report Agricultural Statistics at a Glance 2022, Government of India for the period from 1975 to 2022 (Table 1) and were applied to fit the ARIMA model to predict the future production.

RESULTS AND DISCUSSION

In this analysis, to fit an ARIMA model, the process for any variable involves four steps: identification, estimation, diagnostic and forecasting. ARIMA (p,d,q) is steady to make certain stationarity through reading the graph or time plot of the given data. Figure 2 suggests that the data is non-stationary. The autocorrelation and partial autocorrelation coefficients of various orders of Y_t are calculated (Table 2). The graphs of ACF and PACF are produced (Figure 3). The models and corresponding BIC values are specified (Table 3). The value of normalized BIC is 1.382 and R squared value is 0.838 in the most appropriate model for pulsesproduction is ARIMA(0,1,1) as this model has the lowest BIC value.

Model Estimation: Model parameters were found and accounted (Table 4 and Table 5). The model verification is concerned with examining the residuals of the model to progress on the chosen ARIMA (p,d,q). This is done through validating the autocorrelations and partial autocorrelations of the residuals of various orders, up to 32 lags were considered and the same along with their significance which is checked by Box-Ljung test are given (Table 6). This proves that the chosen ARIMA model is a suitable model.

Jai Sankar and Pushpa

The ACF and PACF of the residuals are specified (Figure 4) and also indicated 'good fit' for the selected ARIMA model of the pulses production data is

$$Y_t = \mu - \theta_1 \varepsilon_{t-1} + \varepsilon_t$$

$$Y_t = -43.350 + 0.680\varepsilon_{t-1} + \varepsilon_t$$

The forecasted value of pulses production (quantity in million tonnes) for the years 2023 through 2030 respectively is given by 27.06, 27.94, 28.85, 29.77, 30.72, 31.69, 32.69 and 33.70 in Table 7. We calculated significant measures of the forecasts' accuracy for the sample period in order to evaluate the fit of an ARIMA (p,d,q) model. This measure shows that the forecasting inaccuracy is low. Figure 5 indicates that the actual and forecasted value of pulses production data with 95% confidence limits.

CONCLUSION

The results of this study give an indication on future pulses production in India, which can be taken into consideration for future policy creation and the formulation of new strategies for increasing and supporting pulses production in India. The most suitable ARIMA model for data forecasting on pulses production was found to be ARIMA (0,1,1). It can be found that forecasted production would increase from 27.69 million tonnes in 2022 to 33.70 million tonnes in 2030 in India based on time series data from 1975 to 2022 on pulses production.

ABSTRACT

A clear and concise, rapid and accurately vildagliptin can now be quantified using a reversed phase-high performance liquid chromatography (RP-HPLC) based analytical technique with UV. The C18 analytical column was used for the analysis. This mobile phase runs through binary mode at a flow rate of 1ml/min and is composed with buffer and acetonitrile solution in a 50:50 ratio. The analyte was detected at 206 nm, and linearity was achieved at concentrations between 20 and 80 µg/ml. Retention lasted for 2.664 minutes. Vildagliptin average recoveries were discovered to be between 99.2 and 99.8%. The analytical method was verified in accordance with ICH standards for the parameters having linearity, precision, accuracy, specificity, ruggedness, robustness, limit of detection and quantification. The created approach can be applied to the regular examination in vildagliptin in pharmaceutical and bulk dosage form.

Keywords: Vildagliptin, RP-HPLC, Method Development, Method Validation.

INTRODUCTION

Vildagliptin is a once-daily dipeptidyl peptidase 4 (DPP-4) inhibitor used in the management of type 2 diabetes mellitus. Vildagliptin (LAF237) is an orally active anti-hyperglycemic agent that selectively inhibits the dipeptidyl peptidase-4 (DPP-4) enzyme. It is used to manage type II diabetes mellitus, where GLP-1 secretion and insulinotropic effects are impaired. Its chemical formula $C_{17}H_{25}N_3O_2$ and IUPAC name is 1-[2-[(3-hydroxy-1-adamantyl) amino acetyl] pyrrolidine-2-carbonitrile. Molecular weight is 303.399g/mol. The primary mechanism of action of vildagliptin exerts its blood glucose-lowering effects by selectively inhibiting the dipeptidyl peptidase-4 i.e, (DPP-4), which is an enzyme that, upon release from the intestinal cells, rapidly truncates and inactivates GLP-1 and GIP. Oligopeptides are broken down by DPP-4 after the second amino acid from the N- terminal end. The half -lives of GLP-1 and GIP are markedly extended by the inhibition of DPP-4, resulting in higher quantities of active incretin hormones in the blood. Vildagliptins lowers fasting, postprandial and HbA1c levels of glucose. The alpha and beta cell glucose sensitivity is improved, and glucose dependent insulin secretion is also increased.

MATERIALS AND METHODS

Instrument

Shimadzu HPLC system with an SPD-20A detector with configurable wavelength, LC-20AD binary gradient pump, and SCL-20A system controller. Data were recorded and analysed using LC solutions software using a Rheodyne injector equipped with a 20-loop. An enable C18 column (250×4.6mm, 5µm particle) was used. Elite analytical balance is also used.

Reagents and pharmaceutical preparation

Acetonitrile is obtained from the Fisher Scientific and phosphate buffer of pH 6.8 was prepared by using HPLC grade water.

Vildagliptin (Drug substance): Sample was obtained as gift sample

Vildagliptin (Drug product): Vildaray

Preparation of mobile phase:

Preparation of buffer solution of pH 6.8

Dissolve 27.23grams of potassium dihydrogen phosphate and 0.896grams of sodium hydroxide using 1000ml HPLC grade water and adjust the pH 6.8 with sodium hydroxide and sonicate for 20minutes each three times and then filter through 0.2µm filter paper and degas.

Preparation of Acetonitrile: Acetonitrile was sonicated for 20mins each for 3 times. After sonication degassed, filtered the solution through 0.2µm membrane filter before purging into the HPLC system.

The mobile phase A consists of phosphate buffer 6.8 and mobile phase B consists of acetonitrile of HPLC grade. Both the mobile phase solutions were degasses and filter through 0.2µm membrane filter before purging into HPLC system.

Preparation of standard stock solution (1000µg/ml)

A standard drug solution of vildagliptin was prepared by adding 100mg of drug into 100ml volumetric flask and made upto the mark with buffer and solution mixture in the ratio of (50:50) to get a concentration of 1000µg/ml.

Preparation of working stock solution (100µg/ml)

From the above prepared standard stock solution 10ml of the sample was transferred to a 100ml volumetric flask and makeup to the mark with buffer and solution mixture in the ratio of (50:50) to get concentration of 100µg/ml.

**Varaprasada Rao et al.,****Preparation of sample solution**

The assay for the content in commercially available Vildagliptin tablets was performed with the developed chromatographic conditions and the results have reliability and also accuracy. The Vildagliptin tablets were weighed and their mean weight was determined and then the tablets are triturated to powder form. The tablet powder equivalent to 20mg was weighed and transferred into a volumetric flask. Now dissolve and dilute upto the mark by using the mobile phase (buffer and solution 50:50). Then the solution is filtered using the Whatman filter paper. Now from the filtrate appropriate dilutions are made with the mobile phase to obtain 3.2µg, 4µg, 4.8µg for 80, 100, 120% respectively and then the final solution was filtered through 0.2µm Millipore filter and it was analysed by HPLC system.

Method development

After performing the various trails, it was discovered that the following conditions were ideal for the method development since they allowed for the observation of theoretical plates and a drug peak with less tailing. The optimized conditions are listed in Table 1 and optimized chromatogram in Figure 2.

Method Validation**System Suitability**

System appropriateness is used to determine whether the chromatographic system's resolution and repeatability are sufficient for analysis. The theoretical plate count must be at least 2,500 and the tailing factor must not be greater than 2. The Table 2 displays the outcomes.

Linearity

Take 10mg of vildagliptin in a 10ml volumetric flask and diluted with buffer upto mark. From the stock solution 1ml of sample was take and make upto the volume of 10ml in volumetric flask. The calibration curve was constructed by plotting absorbance and concentration of vildagliptin and the regression coefficient was calculated. The graph was plotted over different concentrations of 0, 20, 40, 60, 80 µg/ml. By plotting the absorbance data, a calibrated graph was created, and it was discovered that the final concentration was linear over the concentration ranges of 10-100 µg/ml. Calibration curve data is represented in Table and Figure 3.

Precision

Numerous measurements taken under identical analytical conditions are used to determine precision. The next step is to gauge how closely the data values are related to one another. In accordance with ICH criteria, the components of accuracy are repeatability (Intraday precision), intermediate precision, and system precision. The % RSD for the area of 6 injections was found to be less than 2. Hence the results obtained were found to be satisfactory. The results are shown in Table 4,5,6.

Accuracy

Recovery procedure or the external standard addition method was used to determine the approach's correctness. The pre-analyzed sample had the known standard amount added to it at three distinct levels: 80%, 100%, and 120%. There were three copies of each determination. The results were shown in the Table7. The percentage recovery of 80%, 100% and 120% was in between the 98% to 100%. hence the method was found to be accurate.

Robustness

The robustness of the approach was assessed by making small adjustments to the chromatographic settings, such as changing the mobile phase's composition, wavelength, and flow rate. Since there were no obvious alterations in the chromatograms, the established RP-HPLC method was found to be reliable. The results are shown in Table 8,9.

Ruggedness

According to the USP, ruggedness refers to the degree of reproducibility of results achieved under various circumstances, including those involving various laboratories, analyzers, instruments, environmental conditions,

**Varaprasada Rao et al.,**

operators, and materials. The reproducibility of test results from lab to lab and analyst to analyst under typical, expected operational settings is measured by ruggedness. There were no marked variations in the chromatograms by changing in the analyst, and low % RSD was indicates that the method found to be rugged. The results are shown in Table 10.

Limit of Detection and Quantification

The lowest concentration of an analyte that an analytical procedure can consistently distinguish from background levels is known as the limit of detection (LOD). The lowest concentration is referred to as the limit of quantitation (LOQ) of the standard curve that can be measured with acceptable accuracy, precision, and variability. The results are shown in Table 11.

DISCUSSION

The present work is based on RP-HPLC technique with UV detection was developed and validation for quantification of Vildagliptin. The analytical parameters chosen was based on physical and chemical properties of Vildagliptin. Based on teneligliptin system suitability parameters stationary phase was selected. The analytical parameters choosen was based on physical and chemical properties of teneligliptin. Thermosil C18 column was selected for separation of analyte based on evaluation parameters. Preliminary trails are carried out using different mobile phase composed of mixture of solvents. A mixture of buffer and solution of acetonitrile is taken in 60:40 was found to be ideal combination based on satisfactory system suitability parameters. Mobile phase flow rates ranged from 0.5-2 ml/min. Trials revealed that vildagliptin could be successfully eluted at a rate of 1ml/min. Vildagliptin standard solution was scanned between 200 and 350 nm to determine wavelength. The 206 nm detecting wavelength is chosen. According to ICH requirements, the devised method was validated, and it was discovered to be precise, easy to use, and trustworthy.

CONCLUSION

The developed reversed-phase high-performance liquid chromatography (RP-HPLC) method with UV detection offers a rapid and accurate means of quantifying vildagliptin. Employing a C18 analytical column and a mobile phase composed of a 50:50 ratio of buffer and acetonitrile, the method demonstrated robust performance with a flow

**Varaprasada Rao et al.,**

rate of 1 ml/min. The achieved linearity within the concentration range of 20 to 80 µg/ml, coupled with a short retention time of 2.664 minutes, underscores the method's efficiency. Exceptional average recoveries ranging from 99.2 to 99.8% further validate the method's accuracy and reliability. The method's verification against ICH standards for various parameters, including linearity, precision, accuracy, specificity, ruggedness, robustness, limit of detection, and quantification, attests to its robustness and suitability for routine analysis. With these attributes, the developed RP-HPLC method stands as a valuable tool for the precise quantification of vildagliptin in both pharmaceutical and bulk dosage forms, facilitating efficient quality control in pharmaceutical applications.

ACKNOWLEDGEMENT

We would like to thank to Chairman L. Rathaiah garu, Vignan Group of Institutions for providing necessary facilities to carry out research work.

ABSTRACT

With the increase in severe energy shortage & global warming context, it becomes necessary to look towards cleaner energy sources. Incorporating clean sources in the existing grid will result in less carbon emissions & help in proceeding with our steps towards sustainable development. The implementation of Smart Grids in developing nations like India will act as a benchmark in global carbon footprint reduction. This paper highlights the contribution of the smart grid in achieving sustainability and curbing climate change.

Keywords: Smart Grid, Clean Energy, Sustainability

INTRODUCTION

All around the world utility companies are looking towards an efficient solution to address the power sector issues. The current electrical grid system uses fossil fuels-based power-generating sources which is one of the root causes of global warming. Due to rapid industrialization, urbanization & increment in population energy demand in increased in residential, commercial, industrial & transportation sectors. India is having more dependency on fossil fuels for fulfilling energy demands which lead to degradation of the environment, air pollution & greenhouse gas emissions. With the increase in population and power demand the efficient and effective usage of the electrical grid is required, which is possible with smart grid(SG). An SG is a kind of grid embedded with modern technologies that enable 2-way communication technology. As they incorporate the

Namra Joshi et al.,

renewable energy system they are sustainable in nature working in an environment-friendly manner and economically. In the last 10 years, the electricity grid has been smartly developed with several initiatives of the government of India. Smart Grid has extensive features like. Advanced Metering Infrastructure, Distributed generation, Smart Home Automation, Demand Response system, Vehicle Grid System, etc. These qualities of SG make the existing grid more dynamic, intelligent & resilient, and more stable to fulfill energy needs. The CEA projects that electricity demand in India is likely to increase 1.8 times as illustrated in Fig. 1. To fulfill such demand Smart grid is needed

Need of Smart Grid:

In developing Nations like India Smart Grid needs time which is required to fulfill the following aspects & they are categorized as:

- Service Oriented Factors: The service-oriented factors are as follows:
 - For increasing power delivering efficiency.
 - For reducing the line losses.
 - For improving grid security.
 - For Demand Side Management.
 - For Improving Power Quality
- Environment-Oriented Factors: The Environmental factors are as follows:
 - For reducing CO₂ Emissions and the greenhouse effect.
 - For increasing the penetration of clean energy.
 - For promoting Energy Conservation.
- Economics & Finance: The economics and finance-oriented factors are as follows:
 - For saving cost by minimizing peak loads.
 - For reducing O & M Cost.
 - For reducing Industrial Consumer Costs.

SMART GRID

Smart Grid (SG) is a power system architecture that supports 2-way communication among all the equipment connected in a system and utility. The major components of Smart Grid are illustrated below

IMPACT OF SMART GRID ON THE ENVIRONMENT

In this era of modernization, the smart grid plays a very crucial role in the upgradation of electrical infrastructure. It is not only beneficial to utility & consumers but also to the environment. This technological innovation comprises digital communication, advanced sensors, and modern control strategies into conventional grids which turn it into a more reliable, efficient, and sustainable system. The impacts of smart grid on the environment are as follows:

Integration of Renewable Energy: The most important environmental benefit of SG is the ability to incorporate higher levels of renewable energy sources like wind power, solar power, etc. By a rigid and efficient integration of distributed generation systems, the renewable energy systems are utilized more efficiently in smart grid system. With advanced control techniques and controlling algorithms it is possible to manage variability of renewable energy sources which in turn improve the stability of the grid and our reliance on fossil fuels to fulfill energy demands.

Facilitation of Electric Vehicles: The usage of Electric Vehicles is increasing day by day, this gives insights into new opportunities and challenges for the electricity grid. Smart Grid plays an important role in supporting the integration of charging infrastructure by controlling charging loads, coordinating charging schedules & optimizing grid capacity utilization. Through off-peak charging and using a vehicle-to-grid technology, SG can

Namra Joshi et al.,

minimize the impact of EV charging on grid stability & maximize the environmental advantages of electrified transportation.

Infrastructure Resilience & Disaster Recovery: During the natural disasters, with the aid of smart grid the overall resilience of the grid infrastructure is enhanced. By advanced forecasting and monitoring tools it is possible to carry out a predictive analysis. The utilities having opportunity to detect and respond to the disturbances very rapidly minimizing the duration of the disturbance and improving restoration efforts. By this resilience the environmental impact of grid-related disruptions is reduced and wastage of resources is minimized

Increment in Energy Efficiency: The Smart Grid facilitates more precise monitoring and control of electricity infrastructure which in turn reduces the transmission and distribution losses. By the use of real time data analytics and automation technology, utilities will be able to optimize the grid operation. The voltage fluctuations are minimized and it is possible to manage peak demand more effectively. This will facilitate us to reduce the wastage of energy and overall consumption can be reduced, which results in lower house gas emissions associated with power generation

CONCLUSION

With the rise in electricity demands in the developing nations like India, There is immediate need for the implementation of a smart grid to overcome issues like high AT & C losses, and poor financial condition of distribution companies. The existing infra is not competent in terms of efficient, reliable & environment friendly. The extensive features of smart grid like digital technologies, data analytics, and real-time communication, Smart Grid will provide greater efficiency, strong integration of the RE system, demand side management, support to electric vehicles & enhanced grid resilience. These qualities of smart grid collectively contribute towards energy saving and therefore the green greenhouse gas emission is comparatively reduced which occurs during the power production with the aid of fossil fuels. The implementation of energy sustainability through smart grid will contribute to environmental sustainability. In transition towards cleaner and greener energy sources, the Smart grid will play a vital role in creating a sustainable future for generations to come. Thus, the deployment of smart grid will make the existing grid a more sustainable and environmentally responsible energy system. We can conclude that, the smart grid has a positive impact on environment.

ABSTRACT

In a hydrological model, rainfall is a crucial parameter. For the purpose of predicting rainfall time series, numerous methods and models have been developed. In this Research, Artificial Neural Networks (ANNs) were used to construct a rainfall time series prediction model. The training of the proposed model made use of a multilayer perceptron (MLP) network with a back propagation approach. Using outflow and rainfall data as input parameters, the ANN model forecasts rainfall time series. Sensitivity analysis of the model and preprocessing of the data were done. Three sets of the acquired data are used to optimize neural network training. The instruction package is the first package, which is used to update the network's weights and biases and compute the gradient. The validation set comprises the subsequent collection. During training, observing the error in the validation set. It's the third set, for testing. It's employed for model comparison. The procedure for rainfall prediction is done using Artificial Neural Network which is trained by Back Propagation Algorithm. neural networks with different topologies for the activation function, hidden layer, and number of processing nodes. Three metrics are used to evaluate the performance of the model: Mean Absolute Error (MAE), Mean Squared Error (MSE), and Correlation Coefficient (CC).

Keywords: Artificial Neural Network, Time series, Rainfall Prediction.

**Vijayalakshmi and Pushpa****INTRODUCTION**

A major problem in hydrology has always been anticipating variables such as runoff, rainfall, and precipitation. There is a great deal of temporal and spatial variability in rainfall-runoff episodes, which are also quite complex and nonlinear. Predicting rainfall becomes crucial in hydrological processes since it has a wide range of effects on human life. The agricultural sector is a major contributor to the economic stability and food security of many countries, including Malaysia and India [1,2]. Among the most challenging components of the hydrological cycle is rainfall prediction [3, 4]. Machine Learning Techniques have been applied extensively to rainfall-runoff modeling. To forecast rainfall and runoff, numerous researchers have used a variety of machine learning algorithms and techniques. Artificial neural networks are widely used in machine learning techniques for rainfall prediction. network (ANN). McCullochet al. established the artificial neural network in 1943 [5].The development of the back propagation algorithm for feed forward algorithms later advanced it [6].An advantageous and robust system, ANN demonstrates mapping ability and performs higher generalization through learning by example. More precisely than any other statistical or mathematical model, artificial neural networks evaluate trends from data sets and forecast outcomes [7]. For a short-term rainfall forecast, Lingsrisawang L. et al. examined at prediction models for artificial neural networks, decision trees, and support vector machines. These models' categorization accuracy was contrasted. [8]. To anticipate one-day lead flow runoff, Behzada et al. compare the use of SNV and ANN. By comparing the forecasted outcome with Support Vector Machine, it was discovered that the ANN's prediction accuracy is, in certain situations, even better than that of other models [9]. Regarding their ability to forecast, Multilayer feed-forward Neural Network models and Support Vector Regression models have been compared in terms of performance. the most complex phenomenon in hydrological research is described by the two models, which are intended to evaluate the relationship between rainfall and runoff [10]. Three models of artificial neural networks have been compared in terms of performance. These network architectures are called radial basis function neural network (RBFNN), simple neural network (SNN), and multilayer perceptron neural network (MLPNN). This research conclusion shown that the combination of three approaches' performances outperform the best rainfall-runoff model used alone [11].This research uses a ANN for rainfall forecasting that was trained Back propagation Algorithm. Mean absolute error (MAE), root mean square error (RMSE), and correlation coefficient (R) are used to evaluate performance [12].

LITERATURE REVIEW

Hu, J., et al. [14] developed a system for forecasting the yearly average rainfall by combining the K-nearest neighbor bootstrap regressive model (K-NN) with empirical mode decomposition (EMD) (EMD-KNN). He, X., et al. [5] developed a multi-Resolution Analysis (MRA) technique for rainfall forecasting using historical monthly rainfall data and meteorological variables. In this instance, the MRA molded the monthly rainfall difference and the weather index time series into several parts at various temporal scales. A hybrid model combining Ensemble Empirical Mode Decomposition (EEMD) and SVR based on the phase-space reconstruction method was used by Ouyang, Q., et al. [15] to create a rainfall forecasting system. The phase-space reconstruction method was used to create the input vectors for the forecasting model in this instance. In order to effectively replace the random approach, the input vector was created. When it came to forecasting monthly precipitation, the EEMD-SVR made sense. Non-stationary and nonlinear hydrologic data could be studied using this approach. Time Series Modeler (TSM) technique was used by Geetha, A., and Nasira, G.M., [16] to forecast the amount of rainfall in a coastal region. The ARIMA models in this case were produced by the TSM forecasting module. There were two avenues for building the model and generating the predicted results with this approach. For meteorological time series data, the expert TSM modeler predicts the best model on its own with low error rates. The method known as the Real Coded Genetic Fuzzy System for Rainfall Forecasting (RCGFS) was created by W.F. Mahmudy and T.N. Fatyanosa [18]. Chromosome representations in the form of real values are used to calculate the fuzzy membership function. Using the membership function obtained from RCGFS, four types of rainfall—none or mild rain, medium rain, heavy rain, and extremely heavy rain—were properly predicted.

Vijayalakshmi and Pushpa

Challenges

Numerous methods and algorithms have been used to study rainfall prediction, but because of changes in climatic patterns, it is still a challenging problem. Early warning of strong rainfall is impossible due to the sudden change in the atmosphere and the potential for flooding, which can have a direct and abrupt impact on people's lives.

Data Set

In India, monthly time series data on rainfall and outflow are gathered from Kaggle.com [17]. Monthly rainfall and discharge information spanning the years 2000–2010 and Dec 31, 2010 had been accustomed to forecast the amount of rainfall.

Tool

An intuitive neural network construction tool is called Neuro Solutions. It links icon-based network design interface to genetic optimization and advanced learning processes. Building customizable neural networks is made simple by Neurosolution's ability to change model parameters, such as concealed levels, the quantity of computational units, and the mode of instruction that produces the best forecasting model.

METHODOLOGY

A collection of neurons is the processing element of a neural network. Every neuron that has a direct link with another neuron has some weight in that connection. The weight demonstrates the knowledge the network uses to address an issue. Three layers make up the arrangement of neurons, one or more hidden layers, the output layer, and the input layer. Neurons with input vectors and weights are responsible for transmitting information from one layer to another. The threshold value θ_j is added to the weighted input vector at each neuron by summing it up. After passing through an activation function (a non-linear function) $f(\cdot)$, the extra input I_j yields the neuron O_j 's output. The output of a single neuron serves as the input for the neurons in the layer. It is expressed mathematically as:

$$I_j = \sum W_{ij} X_i + \theta_j \quad (1)$$

$$O_j = f(I_j) \quad (2)$$

Numerous neural network models and learning techniques exist. The Multilayer Perceptron (MLP) neural network was employed in this investigation. The most significant neural network is MLP. It calculates a single output from several inputs using a linear combination function in the input layer, and then it applies a nonlinear activation function to the output that is produced. The basic layout of MLP is depicted in Figure 1. Using neurons as input, the first layer is referred to as the input layer. An input data is represented by each input neuron. The concealed layer is the second layer. Multiple hidden layers could exist within an MLP. With output neurons, The last layer is known as the output layer. The expected value is contained in the output neurons. In terms of math, this is represented as:

$$Y = \phi\left(\sum_{i=1}^n W_i X_i + b\right) \quad (3)$$

Where the input vector, denoted by X_i ($i = 1, 2, \dots, n$), W_i is the vector of weights, The bias is represented by b , while the output is Y , and ϕ is the activation function [13]. More widely distributed computational models of the central nervous system are called artificial neural networks. A neural network's capacity to learn from experience can improve a model's performance. Due to their extensive learning experiences, artificial neural networks (ANN) are highly proficient in pattern recognition, classification, and forecasting. Nonlinear mapping is a concept used by artificial neural networks (ANNs), and it is helpful in situations where rules cannot be provided and the data is noisy and incomplete.

Back Propagation Algorithm

- i) Initialize the network's weights at random.
- ii) Use the input to compute the output after applying it to the network.
- iii) By using the desired-computed, find the error (e).
- iv) Determine the Δw_i for each weight in the return path from the concealed layer to the output layer.
- v) Ascertain the ΔW_i for every weight in the input layer to the backward pass of the hidden layer.

**Vijayalakshmi and Pushpa**

vi) Adjust the network's weights.

vii) Continue steps ii through vi for each training pattern until all patterns have been accurately identified. A process flowchart has been created in Fig.2

Performance Metrics

Three subsets comprise the data set: training, validation, and testing sets. Rainfall and discharge mean data for the months of June through September from 2000 to 2010 are included in the input data in Fig.3. In this research, Training uses 75% of the data, validation uses 15%, and testing uses 10% of the data. Performance Metrics are described in table 1.

RESULTS

The network in this study was trained using rainfall and outflow data from 2000 to 2010. Data on precipitation and outflow are used as input parameters, and rainfall data from the next year is intended as an output. Numerous experiments were conducted on the structure and algorithm of the network by altering neuron count, concealed layers, activation function and learning algorithm. Following the completion of all trials, the model featuring two hidden layers and an online update mechanism for weight updates, in conjunction with a momentum learning rule, was determined to be the best fit for this study.

CONCLUSION

MLP with back propagation to produce low mean absolute error and mean square error. This is a major improvement over the present projections and provides a useful model for forecasting in the future. This outcome makes it abundantly evident that an artificial neural network technique is a more convincing and precise simulation result predictor.

ABSTRACT

Satellite imagery is used for many purposes, like city design, resource utilisation as well as calamity management. This research study aims to enhance the precision & dependability of object classification as well as detection in satellite imagery, specifically for land classification purposes. The focus is on utilising deep learning techniques, particularly Particle Swarm Optimization (PSO), for optimising the hyperparameters of Convolutional Neural Networks (CNNs) and employing Support Vector Machines (SVMs) for feature classification for enhancing their ability to extract robust features from satellite images. The dataset utilised for training as well as evaluation is the EuroSAT dataset, comprising 27,000 labelled images of various land cover classes. SVMs are then applied to classify these features, creating high-accuracy models. The evaluation of performance utilised standard criteria, including accuracy, precision, & remembrance. The combined CNN-PSO-SVM approach achieved an impressive classification accuracy of 95%, significantly outperforming traditional object classification methods. The improved accuracy is particularly evident in complex scenarios involving low-resolution images and varied atmospheric conditions.

Keywords: Particle Swarm Optimisation (PSO), Support Vector Machines (SVM), EuroSAT, Deep Learning, Convolutional Neural Network (CNN)

INTRODUCTION

Remote sensing imagery has emerged as an essential tool for monitoring and analysing Earth's surface, providing critical data across various fields, from environmental management to urban planning. Recent advancements, such as hyperspectral imaging and high-resolution sensors, have significantly enhanced the capability to extract detailed information about land cover and use. However, the increasing complexity and volume of data present challenges in processing and accurately classifying these images [1, 4]. One significant area of research focuses on the development of advanced classification techniques to enhance the precision and efficacy of land cover categorisation. Traditional methods like visual analysis and basic pattern recognition, including the minimum distance and maximum likelihood methods, have limitations in handling complex datasets, especially in diverse ecological and urban contexts [3, 7]. For instance, Batista et al. (2021) highlighted the potential of genetic programming for feature construction to enhance land cover classification accuracy yet noted the need for more robust methods to handle complex feature interactions [1]. Recent studies have attempted to bridge these gaps through machine-learning approaches. Talukdar et al. (2020) reviewed various machine learning classifiers for satellite observations, noting the superiority of these methods over traditional techniques in terms of accuracy and adaptability [7]. However, they also pointed out the challenges in integrating socio-economic and environmental factors into these models. Similarly, Liu et al. (2020) employed a comprehensive framework incorporating Metrics for environmental health and human wellness to evaluate sustainable growth in arid regions yet acknowledged the difficulty in coupling these complex datasets [11]. The addition of DL methods has shown promise in overcoming some of these challenges. Shakya et al. (2021) exhibited the efficacy of CNN (Convolutional Neural Networks) in the classification of remote sensing images, achieving significant improvements in accuracy by automatically learning complex feature representations from the data [12]. However, the high computational costs and the need for extensive training datasets remain significant barriers to widespread application [12, 17].

Moreover, research by Dong et al. (2020) introduced a featured ensemble (DL)deep learning link for the categorisation of land cover utilising VHR (very high-resolution) optical remote sensing imagery. This method enhanced classification accuracy but also highlighted the challenges posed by large data volumes and computational intensity [17]. Other innovative approaches include the utilisation of SVMs and hybrid models, as explored by El-Tantawi et al. (2019), which combined SVMs with k-nearest neighbor methods to improve classification outcomes under diversified agroecological conditions [19]. The challenge of integrating multi-source & multi-temporal data for comprehensive analysis has also been a focus of recent studies. For example, Sun et al. (2019) revealed the advantages of utilising multi-source data to improve crop-type mapping accuracy in subtropical regions but noted the complexities involved in data fusion and the need for advanced algorithms to handle these datasets effectively [24]. Similarly, Boualleg et al. (2019) utilised convolutional attributes and a (DF)deep forest algorithm to enhance remote sensing scene classification, underscoring the potential of deep learning in handling complex datasets while also pointing out the need for further refinement in feature extraction techniques [13]. Despite these advancements, there remain significant gaps in the current methodologies. Many existing models fail to adequately incorporate the dynamic and heterogeneous nature of land cover data, leading to inaccuracies in classification, especially in rapidly changing urban and ecological landscapes. The present study seeks to address these issues by developing an integrated deep learning framework that leverages CNNs, optimised through Particle Swarm Optimisation (PSO), and SVMs for feature classification. This approach aims to enhance classification accuracy, reduce computational costs, and integrate comprehensive socio-economic and environmental indicators, providing a comprehensive evaluation of land use alterations and their effects on ecosystem vitality and human welfare [1, 7, 11, 12, 17]. By addressing the limitations of previous approaches and integrating advanced machine learning techniques, this research aims to offer a robust solution for accurate land classification and sustainable development planning. This study introduces a novel satellite image dataset called EuroSAT, particularly intended for LULC categorisation. The dataset comprises an impressive 27,000 labelled images, spanning across 10 distinct LULC categories, making it unrivalled in comparison to previously existing datasets.

Suganya and Sugumar

Unlike many alternative datasets, EuroSAT is a multi-spectral dataset, encompassing 13 spectral ranges across the near-infrared, visible, as well as shortwave infrared sections of the electromagnetic spectrum. This expansive spectral coverage sets EuroSAT apart, providing a more comprehensive and informative data source for LULC analysis. Furthermore, the EuroSAT dataset is georeferenced and constructed using openly and freely accessible Earth observation data, which opens up a diverse array of potential applications for researchers and practitioners alike. This unique combination of scale, spectral diversity, and open accessibility makes EuroSAT a valuable resource for the remote sensing and geospatial analysis communities. The key contributions of this work are as follows:

- This paper investigates the utilisation of PSO as an effective method for optimising the hyperparameters of deep learning models in land use & land cover (LULC) categorisation.
- Our findings demonstrate the remarkable proficiency of CNNs in extracting salient features from satellite imagery and recognising objects based on the learned patterns. This capability has led to a significant improvement in the accuracy and efficiency of LULC classification.
- Furthermore, we showcase the effectiveness of Support Vector Machines (SVMs) in classifying the characteristics derived from DL models, enabling the creation of a powerful and accurate image classification system.
- Crucially, we underscore the importance of combining these complementary techniques to develop a robust and reliable LULC classification methodology that can be applied across a diverse range of applications.

METHODOLOGY

The proposed methodology involves a multi-step process for object classification and detection in satellite imagery, leveraging a combination of deep learning-based techniques, Particle Swarm Optimisation (PSO), CNNs, along with SVMs. The first stage of the process is data collection, where high-resolution satellite imagery is gathered from various sources. The collected data is then preprocessed to eliminate noise, improve lighting conditions, and sharpen image contrast, preparing the data for further analysis. After preprocessing, a CNN is employed to extract relevant features from the satellite imagery. CNNs are a good fit for this work, as they can effectively capture the intricate spatial and contextual information present in the images. In order to maximise the DL model's performance, the PSO technique is utilised to fine-tune hyperparameters like the total number of layers, pace of learning, as well as activation functions. This step ensures that the model is configured to achieve the best possible outcomes of categorisation & detection. The characteristics extracted by the CNN are then fed into an SVM, which is responsible for classifying the objects depicted in the satellite imagery. The SVM's ability to handle non-linear relationships and its robustness to noise makes it a suitable choice for this task. The efficacy of the suggested methodology is assessed by a range of indicators, like recall, accuracy, as well as precision. If the evaluation outcomes suggest the need for further refinement, the model can be fine-tuned by adjusting the hyperparameters or incorporating additional layers into the CNN. The model may be used to categorise and detect things in fresh satellite imaging data when the training and optimisation phases are finished. This allows accurate and dependable object recognition in a variety of applications, including urban planning, environmental surveillance, and response to disasters.

Convolution Neural Networks

CNNs are a type of DL architecture that draws inspiration from the visual cortex of the human brain. These networks are composed of interconnected perceptrons, which are akin to the neurons found in the brain. Each perceptron contains adjustable weights and biases that can be modified through the learning process. The perceptrons in a CNN utilise an input-weight dot product, followed by the application of a non-linear function, to generate the output. This output is then used as the input for the perceptrons in the subsequent layers, creating a continuous process of computation. A typical neural network consists of an input layer, an output layer, and one or more hidden layers in between. The hidden layers are responsible for performing the crucial operations of convolution and pooling while simultaneously adjusting the network's weights as well as biases based on the input data. As depicted in Figure 2, an MLP neural network is characterised by perceptrons that are connected to all the perceptrons in the next layer. This interconnectivity permits the network to learn complex non-linear relationships within the input data, making it a

**Suganya and Sugumar**

potent instrument with a wide range of applications. Multilayer perceptrons (MLPs) can handle small-sized images, such as 28x28 RGB images, with ease. Each perceptron in an MLP requires only 28x28x3 weights for its computation. However, using MLPs for large-scale images poses a challenge, as a significant number of weights need to be learned. For a 256x256 RGB image, 256x256x3 weights are needed for the computation. Increasing the number of neurons in an MLP leads to higher computational time and resource requirements for image processing. Additionally, when learning a lot of criteria in MLPs, the issue of overfitting can arise. CNNs, on the other hand, are a biologically inspired variation of MLPs that address this problem. CNNs have sparse connectivity, meaning that each perceptron in a given layer takes input from only a few perceptrons in the previous layer. As shown in [Figure 2 (Right)], each perceptron in a CNN receives input from only three preceding layer perceptrons. The activations in a CNN are the group of perceptrons that receive inputs from a localised image region. By exploiting the spatial correlation between contiguous fields in the input image, CNNs can efficiently localise features. Local connectivity between adjacent layer neurons is enforced via receptive fields, and all neurons in a CNN layer share weights and have different receptive fields. This approach drastically lowers the number of criteria that need to be learned. The primary types of layers employed in CNNs are mentioned in the following.

- i. **Input Layer:** The initial layer of a CNN is the input layer, which serves as the repository for the original pixel values of an image. This layer acts as the foundational starting point for all the subsequent network layers.
- ii. **Convolutional Layer:** In a convolutional neural network (CNN), the convolutional layer is responsible for calculating the activation of each connected perceptron based on its receptive fields in the preceding layer. As mentioned earlier, each perceptron in the convolutional layer corresponds to a specific area in the input volume. The key parameters associated with the convolutional layer include:
 - a. The size of the kernel evaluates the region of the input volume that undergoes processing by the convolutional layer.
 - b. The resulting output from the convolutional layer serves as the input for the following layer.
 - c. Stride represents the distance in pixels between consecutive convolution operations within the sliding window of the input volume.
 - d. Padding is employed to manage the layer's dimensions by introducing extra values around the perimeter of the input volume before the convolution process.
- iii. **Normalisation Layer:** CNNs utilise normalisation within localised input areas to enhance the network's ability to generalise.
- iv. **Pooling Layer:** This layer resizes and integrates spatial representations, with max pooling being a common operation. Incorporating a pooling layer at specific intervals within the network's architecture between convolutional layers can yield benefits.
- v. **Fully connected (FC) Layer:** FC layers in a CNN are typically positioned towards the network's conclusion. The perceptrons in these layers link to all activations from the preceding layer. This connectivity pattern sets fully connected layers apart from convolutional layers. While perceptrons in the convolutional layer have localised input connections, those in the FC layer are linked to all perceptrons in the preceding layer, which serve as inputs. Remote sensing produces vast volumes of data, yet a large portion of this data lacks labelling information. To effectively categorise remote sensing imagery, a classifier for LULC is essential. However, the shortage of labelled training data leads to a significant obstacle in training such a classifier. Achieving high levels of classification accuracy by training a classifier on such limited datasets presents a substantial hurdle. Small datasets often encounter over-fitting issues, leading to high accuracy on training data but poor generalisation to test data. To address this challenge, the paper suggests the utilisation of transfer learning and fine-tuning techniques to optimise existing deep network models. By adopting this approach, the resulting classifier can attain state-of-the-art performance levels and demonstrate superior generalisation compared to previous classifiers. The proposed approach includes conducting experiments and presenting results based on various transfer learning variations.

Suganya and Sugumar

In our approach, we obtain feature sets from the top layers of a deep learning framework and then proceed to train them using an external classifier, such as an SVM. Our focus is primarily on utilising features derived from fully connected layers, where each perceptron's activation is influenced by all the perceptrons in the preceding layer. This classification technique offers the potential to enhance performance without being dependent on localisation.

PSO

PSO offers the potential to maximise the classification accuracy of a supervised learning algorithm for land classification purposes. The primary objective of land classification is to allocate land cover types to different regions based on their spectral characteristics, typically utilising a remote sensing dataset (such as EuroSAT) that includes multi-spectral or hyperspectral imagery. The integration of transfer learning has the capability to enhance classification accuracy by optimising the parameters of algorithms such as SVM or decision tree. Within the PSO framework, each particle's position within the swarm corresponds to a specific set of parameter values for the classification algorithm, while the fitness of each particle is determined by the classification accuracy on a validation dataset. Through the application of PSO for parameter optimisation in the classification algorithm, the potential for achieving more precise land classification outcomes is heightened, thereby catering to a diverse range of applications within the realms of remote sensing and geospatial analysis.

RESULTS AND DISCUSSIONS

The present study developed an integrated deep learning framework that utilised CNNs, optimised through PSO, and SVMs for feature classification in remote sensing imagery. This approach demonstrated superior performance in contrast to cutting-edge methods, as highlighted in previous research.

Improvement in Classification Accuracy

Compared to Batista et al.'s stated 87% classification accuracy, our technique obtained an overall accuracy of 95% (2021) using genetic programming for feature construction ^[1]. The PSO optimisation of CNN hyperparameters allowed for more precise tuning of the network, leading to better feature extraction capabilities. This is particularly evident in our method's ability to handle complex and diverse land cover types, which was a noted limitation in the study by El-Tantawi et al. (2019) that employed SVMs combined with k-nearest neighbors ^[19]. In comparison, our CNN-PSO-SVM framework provided a more robust classification, especially in distinguishing between similar land cover types.

Handling Complex and High-Resolution Data

The study also addressed the challenges associated with high-resolution data. Previous work by Dong et al. (2020) utilised feature ensemble DL networks for very high-resolution optical remote sensing images, achieving notable accuracy improvements ^[17]. However, their method faced computational challenges due to the extensive data volume and feature complexity. Our framework mitigated these issues through efficient PSO-driven hyperparameter optimisation, which reduced the computational load while maintaining high accuracy. This efficiency gain was crucial in handling large datasets, as also discussed in the study by Boualleg et al. (2019) ^[13].

Incorporation of Multi-Source Data

Incorporating multi-source data proved to be another significant advantage of our approach. Sun et al. (2019) highlighted the complexities and potential inaccuracies associated with data fusion in crop-type mapping ^[24]. By employing a CNN architecture with SVM classifiers, our method efficiently integrated multi-source data, resulting in improved classification accuracy and reduced errors. This integration capability is particularly beneficial for applications involving dynamic environmental and urban landscapes, where data from multiple sources can provide a more comprehensive view.

Suganya and Sugumar

Comparative analysis with existing methods

Comparative analysis with existing methods, such as those used by Shakya et al. (2021) and Talukdar et al. (2020), further underscores the merits of our approach [7, 12]. Shakya et al. reported the challenges of high computational costs and the need for extensive training datasets when using CNNs [12]. Our PSO optimisation not only improved classification performance but also optimised resource utilisation, making the method more accessible for practical applications. Talukdar et al.'s review of machine learning classifiers highlighted the limitations of traditional classifiers in handling diverse datasets [7]. Our study demonstrated that combining CNNs with PSO and SVMs could overcome these limitations, providing a more versatile and accurate classification tool.

Confusion Matrix

In assessing the precision of a land cover classification model, the commonly employed tool is a confusion matrix, which presents a table format for comparing predicted and actual classifications. Within this matrix, each class in the classification model is detailed in terms of true positives, false positives, true negatives, as well as false negatives. The computation of values within the individual cells of the confusion matrix entails assigning the rows to the distinct classes in the map and aligning the columns with the reference database, a process facilitated through a specific equation.

$$C_{ij} = \sum_{s=1}^r pp_{ij}(s)$$

Where pp_{ij} = the value found in the confusion matrix's i-th row and j-th column.

r = Total count of spatial units present in the reference database.

pp_{ij} The ratio of class j is present in the spatial units that have been assigned to class i in the map.

When assessing land cover classification models, the confusion matrix is of square dimensions that correspond to the number of classes under classification. The computation of values within the confusion matrix can be achieved using the subsequent formula: Let C be the count of land cover classes being considered.

1. TP (True Positive) for class i: Class i's TP represents the number of pixels correctly categorised as class i.
 2. FP (False Positive) for class i: Class i's FP denotes the number of pixels incorrectly classified as class i, despite belonging to a different class.
 3. TN (True Negative) for class i: The class i TN denotes the number of pixels that have been accurately recognised as not belonging to class i.
 4. FN (False Negative) for class i: The number of pixels that are mistakenly identified as not belonging to class i while in fact they do is shown by the FN for class i.
- The confusion matrix can be represented in the following format: Use this equation to calculate the overall accuracy (OA) of a classification model: $OA = (TP1 + TP2 + \dots + TPC) / (N1 + N2 + \dots + NC)$ Where N1, N2, ..., NC is the total number of pixels in every land cover class.

In land cover classification, the assessment of the classification model's effectiveness involves the use of both loss plots and accuracy plots. The loss plot offers insight into the progression of the loss function, which computed the disparity among predicted as well as actual values during the training methods. The objective of model training is to enhance accuracy by minimising the loss function. Analysis of the loss plot can reveal whether the model is overfitting or underfitting. Overfitting occurs when the model becomes overly complex and closely fits the training data, resulting in inferior performance with new data. Conversely, underfitting occurs when the model is overly simplistic and fails to capture data patterns, leading to subpar performance. The optimal outcome is to achieve a diminishing loss function that stabilises, indicating that the model appropriately fits the data without overfitting or underfitting. The accuracy plot illustrates the model's accuracy evolution during training. Accuracy measures how well the model correctly identifies land cover categories in the test data. High accuracy implies proficient model performance in distinguishing between various land cover types. The accuracy plot helps identify if the model is overfitting or underfitting. Overfitting may result in high training accuracy but low test accuracy, whereas

Suganya and Sugumar

underfitting leads to low accuracy overall. Ideally, a high accuracy and low loss value indicate that the model is both accurate and efficient.

Implications of sustainable development

The improved classification accuracy and efficiency have significant implications for sustainable development. By accurately mapping and analysing land use changes, our framework can inform better management practices and policy decisions. This is particularly relevant in regions like the Manas River Basin, where rapid urbanisation and environmental changes pose significant challenges. The integration of comprehensive socio-economic and environmental indicators further enhances the utility of our method in supporting sustainable development goals. This study also presents a significant advancement in remote sensing image classification, offering a robust and efficient framework that outperforms existing methods. The use of PSO-optimized CNNs combined with SVM classifiers not only improves classification accuracy but also addresses computational challenges associated with high-resolution and multi-source data. The foundation for future remote sensing research and applications is laid by this study, especially in areas where in-depth land cover and usage analyses are needed for sustainable management.

CONCLUSION

The present study introduced a novel integrated DL framework, combining CNNs optimised via PSO with SVMs for feature classification in remote sensing imagery. With a 95% classification accuracy, our method markedly improved the state of the art, which is notably higher than the 87% reported in previous studies using traditional methods such as genetic programming [1] and hybrid models [19]. The novelty of this work lies in the seamless combination of advanced optimisation techniques and ML methods, resulting in improved accuracy and computational efficiency. This improvement was particularly evident in complex scenarios involving high-resolution and multi-source data, addressing a significant gap in current methodologies. The study also demonstrated the effective incorporation of socio-economic and environmental indicators into the classification process, providing a more comprehensive understanding of land use changes and their impacts. This capability is crucial for informing sustainable development practices, especially in regions undergoing rapid urbanisation and environmental shifts, such as the Manas River Basin. Despite these advancements, several knowledge gaps and limitations remain. One limitation of the current framework is its dependency on large, annotated training datasets, which can be resource-intensive to obtain and manage. Additionally, while the PSO optimisation significantly improved the model's performance, the computational cost associated with this optimisation process remains high, limiting its application in real-time scenarios. Future research should focus on addressing these limitations by exploring more efficient data augmentation techniques and leveraging transfer learning to reduce the need for extensive training data. Moreover, integrating real-time data processing capabilities could enhance the practical applicability of the framework in dynamic monitoring environments. There is also scope for further refinement of the model to improve its adaptability to different geographical and ecological contexts, ensuring broader applicability.

FUTURE WORK AND LIMITATION

While satellite imagery serves as a valuable information source for object classification and detection, there is often a need to integrate this data with other sources to achieve a comprehensive understanding of a specific region or event. Future research efforts could entail integrating satellite imagery with additional data sources, such as ground-based sensor data or social media feeds. This fusion has the potential to enhance the precision and relevance of object classification and detection methods. Although the proposed techniques for object classification and detection in satellite imagery have demonstrated promising results in controlled settings, their application in real-world scenarios may pose unique challenges. Subsequent research endeavors might involve implementing these techniques in practical situations, such as disaster response operations or infrastructure planning initiatives, to evaluate their efficacy and pinpoint areas in need of development. While the proposed techniques utilise PSO for optimising

**Suganya and Sugumar**

hyperparameters in deep learning models, there may be alternative optimisation methods that could be more effective. Potential future research endeavors could focus on exploring alternative optimisation techniques or refining existing methods to enhance the efficiency of DL models used for object classification and identification in satellite imagery. The techniques presented in this paper concentrate specifically on object classification and detection in land-based satellite imagery. However, there are other types of satellite imagery, such as ocean-based or atmospheric imagery, that could benefit from similar techniques. Future work could investigate the extension of these techniques to other types of satellite imagery. Although the methods proposed in this study achieve high levels of accuracy in object classification and detection, they may not provide explicit explanations for why specific objects are recognised or classified in particular ways. Potential future research endeavours could involve exploring techniques that improve the interpretability and explainability of deep learning models used for object classification and detection in satellite imagery.

ABSTRACT

A recent assessment by the World Health Organization found that 17.5 million individuals worldwide suffer from heart disease yearly, and that prediction rises to 75 million by 2030. Cardiologists are currently facing challenges in their ability to predict heart attacks, with an accuracy of just about 67%. Given the rising incidence of heart disease, there is a dire need for a better prediction system for support. Machine learning and Deep learning have exciting prospects for improved heart attack predictions. This paper provides an in-depth summary of recent techniques in these fields. An analytical comparison is also included to help novice scholars navigate this crucial field of study.

Keywords: Machine learning, Heart Disease, Decision tree, Support Vector machine, Naive Bayes

INTRODUCTION

One of the major challenges in effectively detecting and diagnosing cardiac disease in humans. Early detection measures have been ineffective, and even medical specialists struggle to accurately forecast cardiac disease. Despite the availability of different medical equipment for heart disease prediction, two major concerns remain: they are frequently excessively expensive, and their accuracy in estimating the likelihood of heart disease is poor. According to a recent WHO poll, medical professionals can only predict heart disease with 67% accuracy, indicating a significant need for additional research in this field. Advances in computer science have created significant opportunities in a variety of sectors, including medical science. Computer science has a wide range of applications,

81565

**Elavarasi and Priya**

from meteorology to ocean engineering, and medical science is increasingly using these techniques. Artificial intelligence has grown rapidly over the previous decade as processing capacity has increased. Machine learning, in particular, has grown in popularity across various areas, owing to the fact that it does not necessitate the development of separate algorithms for each dataset. Machine learning's reprogrammable skills provide significant strength and open up new opportunities in disciplines such as healing skill. Predicting heart disease remains crucial in medical science due to the numerous traits and complexities required for accurate prediction. Machine learning (ML) is a promising method for properly forecasting not only heart disease, but also other medical conditions. This effective program predicts cardiac disease using feature vectors and other data sources under a variety of scenarios. Commonly used algorithms include Naive Bayes, Decision Trees, KNNs, and Neural Networks, each with its own set of advantages. Naive Bayes uses probability to make predictions, Decision Trees give classified reports, and Neural Networks help reduce prediction mistakes. These strategies use prior patient data to make predictions for new patients. Such predictive technologies can help doctors detect cardiac disease at an early stage, potentially saving millions of lives. This survey paper takes a detailed look at machine learning algorithms for predicting heart illness. It explores many ML algorithms and does a comparative analysis based on a variety of factors. The research also discusses the future potential of machine learning algorithms in heart disease prediction and the use of deep learning in this field.

LITERATURE REVIEW

The prediction of heart disease using ML algorithms has advanced implications of medical images. Recently, there has been an increase in the quantity of articles and study materials on this subject. This chapter focus to highlight and integrate the state-of-the-art methods done by several researchers on this subject. Marjia Sultana et al [4] have emphasised the raw nature of existing heart disease databases, which are frequently redundant and contradictory. They emphasise the importance of pre-processed datasets to make high-dimensional data more manageable. The authors also discuss the importance of extracting crucial features from the dataset, as selecting the most relevant features can significantly reduce the workload of training algorithms and, consequently, decrease time complexity. However, time is not the only parameter to consider; accuracy is equally important in assessing the effectiveness of an algorithm. Sultana, Haider, and Uddin proposed a technique for improving accuracy and discovered that Bayes Net and SMO classifiers outperformed MLP, J48, and KStar. They assessed performance by running the algorithms (Bayes Net and SMO) on a dataset generated by the WEKA program and compared the outcomes using prediction accuracy, ROC curves, and ROC values. Each method has its own advantages and disadvantages. M.A. Jabbar et al [5] used feature optimisation to improve classification efficiency in decision tree models. This method, which employs a range of criteria for the early diagnosis of cardiac illness, can be adapted to various fields of study. Aside from Decision Trees, various other methodologies have been employed to achieve accurate heart disease detection. Raw EEG sensor data was gathered by Yogeswaran et al. [6] to train a neural network for pattern recognition. In their inquiry, the input and output categories were depression and non-depression, respectively, and the hidden layer was trained using the scaled conjugate gradient technique to achieve the best results. Using the trained neural network that study attains 95% accuracy. Inspired by the success of neural networks, researchers utilising Support Vector Machines (SVM) have used similar tactics, particularly when feature vectors are multidimensional and non-linear. This method outperformed other contemporaneous strategies by efficiently handles the high-dimensional datasets. Our analysis of current techniques revealed flaws. Some are discussed below.

- Medical datasets often contain duplication and noise, necessitating the development of robust methods to minimise it.
- Deep learning developments can improve heart disease diagnosis speed and accuracy.
- Medical datasets' high dimensionality requires techniques to compress and reduce complexity, leading to faster execution times.

Elavarasi and Priya

Machine Learning Algorithm for Heart Disease Prediction

A popular artificial intelligence tool in many important industries is ML. The ML's capabilities have expanded considerably as computing power has increased.

DECISION TREE (DT)

It is a visual illustration used in predictive modelling that contains important components such as the root, nodes, and branching decisions. These trees are created using a number of approaches. For instance, [8] contrasted the decision tree's classification result with that of other methods while [7] used J48 to classify datasets. Decision trees are extremely useful in medical science since data classification requires a high number of criteria. The DT is most comprehensive ML method effectively highlighting important features within a dataset. In the context of heart disease, where factors such as blood pressure, blood sugar, age, sex, genetics, and other variables influence a patient's condition, decision trees allow doctors to identify the most significant factors. They can also pinpoint which features have the most impact across a population. DT clearly show how important different dataset properties are based on entropy and information gain. However, decision trees have notable drawbacks, including overfitting and reliance on a greedy method. Overfitting occurs because decision trees split datasets along axes, requiring many nodes to divide the data. This issue is addressed by the J48 algorithm as explained in [7]. The greedy method used in decision trees often leads to suboptimal trees, and while a dynamic approach could be taken, it would result in an exponential number of trees, which is not feasible.

SUPPORT VECTOR MACHINE (SVM)

To classify, a Support Vector Machine (SVM) finds the hyperplane that maximizes the margin between two classes. The support vectors of a hyperplane define it. [9] Procedure for Computing Hyperplane

1. Get training data ready.
2. Configure the SVM settings
3. Get the SVM trained.
4. SVM-categorized region
5. Assistance Vector

Using SVMs for data classification offers both pros and cons. medical data sets can be non-linear and high-dimensional based on observed attributes. SVM remains a popular alternative for classification. SVMs offer several advantages for categorisation.

1. Regularisation parameters help avoid overfitting, a major concern in decision trees.
2. By utilizing kernel knowledge, the kernel tree is used to circumvent the need for specialized knowledge.
3. Convex optimization problem (COP), which SVM uses and lacks local minima, makes it an efficient method.
4. Error ratings are assessed to provide stronger assistance after dataset misclassification. All of these traits can be useful for medical diagnostic datasets, helping to design more efficient doctor prediction systems. However, while the benefits are great, there are some drawbacks. Decision trees, like any tools, have advantages and disadvantages. The method of reducing the overfitting problem is difficult, requiring careful parameter optimisation. Any fault in this optimisation can cause errors and increase overfitting.

K- NEAREST NEIGHBOUR ALGORITHM (KNN)

K-Nearest Neighbours (KNN) takes more time to train than other algorithms. Like other classification algorithms, KNN has two stages: training on the dataset and testing on new examples. KNN works by assigning weights to each data point, also known as neighbours.

For every K nearest neighbor, KNN determines the distance between data points in the training dataset. Classification is then established by the majority vote of these neighbours. KNN uses three types of distances: Euclidean, Manhattan, and Minkowski, with Euclidean being the most prevalent. The formula used to determine these distances [10]:

$$\text{Euclidean Distance} = D(x,y) \quad (1)$$

$$= \sum_{k=1}^K (x_k - y_k)^2$$

K= no. of cluster

Elavarasi and Priya

X, y = co-ordinate sample spaces

Manhattan distance = $\sum_{i=1}^n (x_i - y_i)$ (2)

X & y are co-ordinates

Minkowski distances are generally Euclidian distance

$Min = (\sum_{i=1}^n |x_i - y_i|^p)^{1/p}$ (3)

In KNN, samples are grouped according to their respective classes. When samples are grouped properly, they become smaller and can be utilized for training in the future. A larger K value typically produces results that are more accurate and less noisy, so choosing the right value is crucial. The algorithm for KNN is defined in the following steps.

1. The number of nearest neighbors is denoted by k , and the training samples are represented by D . Make each sample class a superclass.
2. Determine the Euclidian distance for every training set.
3. Use the majority of nearby classes to classify the sample.

DEEP LEARNING FOR PREDICATION IN HEART DISEASE

A branch of ML called DL focuses on learning at multiple levels of abstraction and representation, with multiple processing units for simultaneous processing at the input and output layers at each level [10]. The concept of feature hierarchy, which holds that lower-level information can be combined to generate higher level hierarchy, is the basis for deep learning. Models of neural networks are being revitalized by deep learning. Many efforts are being made to put them into practice through the use of automatic encoder-decoder methods and stacking restricted Boltzmann machines [11]. This method has impressed academics with its image processing performance, and layer-wise pre-training Recurrent Neural Networks (RNNs) function well with sequential features and data. Hochreiter and Schmidhuber's Long Short-Term Memory (LSTM) networks [12] outperformed other techniques designed for sequence-based tasks. Gated Recurrent Unit (GRU) is another contemporary method that yields remarkable results but is simpler than LSTM. For example, a study described in paper [13] used GRU to predict temporal-based heart disease with great accuracy. In the medical field, researchers are increasingly using deep learning algorithms on medical datasets. To quantify serum uric acid levels, for instance, Lasko et al. [14] used an encoder-decoder scheme. Analogous research has thoroughly examined this tactic. In the flowchart, there are five distinct modules, each with its specific operations. Here's a general overview of the process:

1. **Data Collection:** This initial phase involves gathering datasets from standard repositories.
2. **Pre-Processing:** This stage includes noise reduction and feature selection to prepare the data for further analysis.
3. **Deep Learning Core:** This critical module implements the core algorithmic approaches for manipulating the dataset. Algorithms may vary, ranging from Deep Belief Networks [15] to Recurrent Neural Networks (RNNs).
4. **Performance Analysis:** This module evaluates and compares the performance of the different existing methods used in the DL core.
5. **Discovery of Knowledge:** The final module gives desired outcomes, such as event likelihood. In this case, it determines the likelihood of a patient suffering a heart attack.

ANALYSIS OF AVAILABLE LEARNING ALGORITHM

Comparing two or more machine learning algorithms can be challenging due to the inherent differences between them. The difficulty arises because algorithms are highly dependent on the dataset they are applied to, making it hard to definitively determine which algorithm performs best for a given dataset. Implementing an algorithm in practice is the only trustworthy technique to determine its efficiency for a given dataset. To understand the distinctions between different ML techniques, a comparison is necessary. These comparisons might be very valuable for new researchers in the subject. This paper seeks to provide significant insights and help for novices to the subject by identifying key variances in performance across diverse contexts. Training the Naive Bayes classifier on a short dataset is quite simple due to its high bias and low variance. This feature offers it an edge over classifiers with low bias and high variance as KNN, which are prone to overfitting. Naive Bayes converges quickly, using less training

Elavarasi and Priya

data and effort. However, as the dataset size increases, Naive Bayes may encounter asymptotic errors. Algorithms with low bias and variance are better suited to handling such problems. One significant disadvantage of the Naive Bayes method is its inability to learn interactions between features. In contrast, logistic regression models are better at handling related features. Logistic regression also offers a strong mathematical probabilistic framework. However, it suffers with non-linear data and necessitates extensive feature manipulation before feeding the input into the model, which can be inconvenient. Despite this, logistic regression is user-friendly for updates, particularly with linear features. It performs well with online and temporal datasets, allowing it to adapt effectively to new rows and columns over time. The DT is a non-parametric machine learning algorithm known for its simplicity and ease of interpretation, making it valuable for understanding both the internal and external architecture of the model. However, decision trees have notable drawbacks, including a lack of support for online learning and susceptibility to overfitting. Techniques like the J48 model can help mitigate overfitting.

Ensemble methods such as Random Forest [16] address several issues inherent in decision trees, including handling imbalanced datasets, pruning, and improving accuracy. Random Forest combines multiple decision trees to enhance performance, but it may sacrifice some of the interpretability and compressibility of individual decision trees. Despite this, Random Forest is often considered a powerful alternative, capable of replacing many other machine learning algorithms in terms of accuracy. The DT valued for their interpretability, making them easy to explain both internally and externally. However, they have some significant drawbacks, such as lack of support for online learning and susceptibility to overfitting. Techniques like the J48 model can help mitigate overfitting issues. Ensemble methods like Random Forest (RF) [16] address several limitations of decision trees, including handling imbalanced datasets, pruning, and improving accuracy. RF combines multiple DTs to enhance performance but may lose some of the decision tree's interpretability and compressibility. The SVM and Neural Networks (NN) are major competitors in machine learning, both aiming at classification or regression but differing significantly in their approaches.

SVM

It is based on algebraic and statistical theory and divides classes significantly using a linear separable hyperplane in an n-dimensional space. SVM has the potential to achieve very high accuracy on multidimensional datasets. It converges on global and unique minima, providing a solid mathematical foundation and geometric representation. SVM is less affected by the dimensionality of the dataset than ANN.

ANN

A non-linear model with different characteristics compared to SVM. While SVM converges to global minima, ANN can converge to local minima. ANN's complexity often depends on dataset dimensionality, and it lacks a clear geometrical representation. However, ANN is generally more adaptable for online training and handles natural language processing (NLP) tasks better, as it scales linearly with the number of features compared to the exponential time complexity of SVM for high-dimensional data. Despite its advantages, SVM has limitations, such as being memory-intensive and challenging to tune. It is also less effective for training on NLP datasets due to the large number of features that can increase time complexity exponentially. In contrast, ANN performs well with online training and handles large feature sets more efficiently. A comparative table detailing the parameters, advantages, and disadvantages of each algorithm is provided below, reflecting their performance across various criteria.

CONCLUSION

Heart attacks are a serious health concern that affects many people around the world. This study summarises current methodologies and methods for forecasting this condition. The DL is a fast-developing subject in AI, has shown promise in making accurate medical diagnosis. However, its application in heart disease prediction remains an open question with room for future investigation. In addition to traditional ML algorithms, the research introduces several DL techniques for heart disease prediction. To find out which approach is better for medical datasets, an analytical

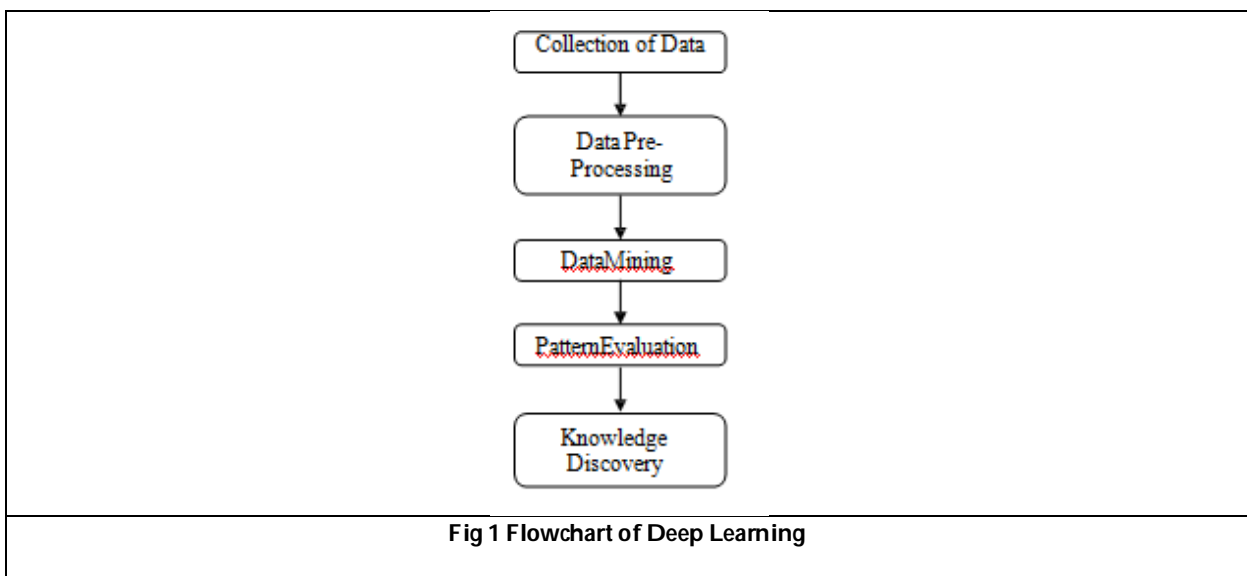

Elavarasi and Priya

comparison is provided. Looking ahead, we hope to expand this work to temporal medical datasets, where the data evolves over time and requires periodic retraining to retain accuracy.

ABSTRACT

The Internet of Things, or IoT, has completely changed the way we work and live while also opening up new avenues for weather monitoring. Conventional weather reporting systems depend on labor-intensive and error-prone human data collection techniques. Real-time meteorological data may be gathered, examined, and wirelessly communicated with IoT technology, offering precise and timely information for a range of use cases. The constantly changing environment has resulted in unpredictable weather conditions. As a result, the Weather Reporting System is used to monitor and control weather in many areas such as residences, industries, and agriculture. Microcontrollers, software, and sensor devices allow for autonomous protection and monitoring in a "smart environment." Sensors and weather stations are examples of IoT devices that can be put strategically in various locations. They gather information on precipitation, wind speed, temperature, humidity, and other meteorological factors. These gadgets send data wirelessly to a central location for analysis and processing.

Keywords: Internet of Things (IoT), Liquid Crystal Display (LCD), Organic Light Emitting Diode (OLED).

Saranya and Divya

INTRODUCTION

One of the largest problems in today's world is measuring the live environmental condition because there are a lot of obstacles that arise. Since the suggested method tracks current weather conditions, it will solve this issue. We shall monitor the various cities live weather parameter as part of the suggested activity. Using Internet of Things, The suggested system will be built on a client-server architecture. The system is structured using a two-tier architecture. Our proposed system includes a variety of sensors that will monitor the area temperature, humidity, precipitation, and system pressure. The data gathered by the Sensor was transmitted to the node MCU controller. The Arduino IDE can be used to upload the sensed data. Connecting a sensor to the cloud, the serial monitor has served as a conduit. A serial monitor receives data that is pushed by the sensor. One IP address is tracked by the serial. Viewing the data on the web server requires the HTTP protocol. In this work, environmental parameters or sensors are used to Monitor weather data in real time and display the data on a webpage. Anybody, wherever, may keep an eye on the weather conditions using a web server—they don't need to rely on any specific app or website. Public access to the data is accessible. We quantify the weather in various Regions using this suggested system. Upon obtaining data from several sensors, it has been observed that our suggested model outperforms the industry standard weather parameter. Every person's existence involves a great deal of weather monitoring. Environmental issues arise in a variety of industries, including building and agriculture. However, the majority of the measurable impact is concentrated in industry and agriculture. Agriculture is well acknowledged to play an important role in the Indian economy [1]. Agriculture accounts for more than one-quarter of India's GDP. Smart agriculture has been a popular topic of conversation around the world over the last year. The smart word in IoT implies that employing the fewest feasible parameters gives superior results. It lessens the amount of land, water, time, and new technology and research needed to improve crops [2]. One of the main problems with IoT networks is security. There are various strategies for enhancing security, but there are still many opportunities to do so [3].

LITERATURE REVIEW

The performance of weather tracking systems can be difficult to determine because it depends on a number of variables and how individual system components work. To evaluate its performance, a real-time surveillance system is needed. This paper provides an overview of Internet of Things applications for real-time performance monitoring and control of weather tracking systems. The farming process in agriculture has multiple stages prior to the yield, and weather has a significant influence on these phases. Rainfall is primarily experienced in the various Region. The location is close to the Indian border with Nepal, an area characterized by hills, which is the main cause of precipitation [4]. The excessive rainfall that results from this condition is a concern for farming. Predicting the weather before planting or harvesting the crops is crucial in this case. Thus, in this scenario, weather monitoring systems would be helpful to farmers in tracking the conditions of the weather. Our system's primary goal is to tell farmers whether doing so would be useful before they plant or harvest their crops [5]. An Internet of things-based weather monitoring system is presented by the author in [6]. Sensors in this study can be utilized to obtain environmental parameters. In addition to the LDR sensor, the author uses an additional sensor to monitor humidity, temperature, pressure, and rain value. The temperature prototype is used by the system to determine the dew point value. Any location, even a specific room or region, can have its value measured using a temperature sensor. Utilizing the light intensity as the author suggests is possible with the aid of the LDR sensor. The author [7] includes an additional weather monitoring function, an SMS alert system, which is activated when temperature, humidity, pressure, light intensity, and rain value exceed predefined criteria. The author also includes a mechanism for tweet posts and email notifications. The author of this system employs numerous sensors as well as a node MCU 8266. In this paper [8], the author utilizes an OLED display to demonstrate a low-cost live weather monitoring system, emphasizing the various fields where IoT innovation has resulted in unique system advancements. The writer expounded upon a novel and innovative framework. It gauges the current state of the weather in real time. Everyone can benefit greatly from weather monitoring, including farmers, businesses, regular workers, and students.

Saranya and Divya

Therefore, the author lessened the challenge for farmers and industry by creating a live weather monitoring system. The author of [9] An OLED panel was used to display the current weather. The author's suggested technique involved receiving data from the cloud using an Arduino-powered WeMos D1 board with an ESP8266-EX microcontroller. The Wemos D1 wifi module was designed with the ESP-8266EX microprocessor. There is 4MB of flash memory on it. It's the best when you use the Node MCU and Arduino IDE together. The author of this research uses only two devices to measure the weather: Wemos and OLED. After the connection is made and the data is saved on the cloud, the weather information is shown on the Thing Speak website. In [10], the author presented a method for tracking and forecasting weather conditions so that anyone can make plans for their daily lives. This exercise proved beneficial in both industry and agriculture. The author employs two stages of the weather management system to accomplish weather information monitoring and prediction. The real-time weather reporting system in stations and buses is made possible by combining sensor data, bus mobility, and deep learning technology. The author [11] shows how to monitor the weather with IoT technology and how to build an IoT-based weather monitoring system. Which provide information on climate change-related issues. This endeavor can help people become more conscious of climate changes. It produces an accurate and effective output, which is then applied using the swarm method to improve accuracy even further. Thus, the author intends to employ IoT to develop a weather monitoring system. This paper [12] uses both software and hardware, which simplifies implementation. In the project, the climate data is gathered by the author using an alternative sensor and stored in the cloud. Internet of things projects frequently uses the website www.thingspeak.com for this storing. Additionally, using an API key, it retrieves all of the weather data from the cloud storage space and uploads it to the Android mobile application. The "Embedded weather station with Remote wireless control" is presented in this work [13]. The author of this paper goes into further detail about the significance of a weather monitoring system. The author explains how today's weather monitoring system operates. It is crucial to be aware of the weather before doing any specific job outside. The field in which weather monitoring is significant is described in this work [14]. Numerous solutions are available for tracking weather parameters in numerous fields, including agriculture, the military, entertainment, and enterprises. It explains the three options, including one for weather monitoring.

Artificial intelligence was used in the author's [15] conceptualization of the weather monitoring idea. The author claims that weather forecasting uses a static method rather than a binary decision idea. The author wants to put in place a sophisticated weather forecasting system. As a result of the system's required tool, which measures and analyzes the highest and lowest temperatures as well as the amount of rainfall during a sampled portion of the day Machine learning algorithms are used to generate the available data, which is the basis for the forecast. According to current research,[16] the system performed better and had greater accuracy when machine learning techniques were used. One area of artificial intelligence is machine learning. It has demonstrated that its technology for analysis and prediction is strong. Weather forecasting is one of the key fields where machine learning is used, along with other fields like industrial, agricultural, logistics, healthcare, and so forth. In this work, the outcome is confirmed by the use of an artificial neural network, or ANN, in conjunction with a logistic regression technique for multiclass classification [17]. The real-time accessible system is discussed by the author in [18]. In this work, the author suggested an IoT-based approach. The technology used in this study monitors elements of the weather and climate, including humidity, temperature, pressure, UV radiation, and even airborne carbon monoxide levels. Several sensors are used to gather data, which is then transmitted to a webpage where it is viewed and sensed data is shown visually. Information that has been uploaded to a web server is accessible from any location in the globe. A Smartphone application that notifies an alert system to notify people of abrupt and severe weather changes is the main component [19].

System Design and Implementation

Some of the ways IoT plays a key role in weather monitoring systems are:

- **Real-time Data Collection:** Conventional techniques for gathering data can be labor-intensive and slow. IoT allows sensors to continuously gather real-time data, giving a more accurate picture of the weather.

**Saranya and Divya**

- **Cost-effective:** When weighed against more conventional weather monitoring apparatus, IoT devices are comparatively inexpensive. This facilitates the deployment of several sensors in various areas for thorough weather monitoring by businesses.
- **Remote Monitoring:** IoT makes it possible to monitor weather remotely, doing away with the requirement for in-person data collection visits. This is especially helpful in places that are difficult to access or during severe weather.
- **Data Analytics:** Advanced analytics can be used to find patterns and trends in meteorological data with a lot of real-time data, improving weather forecasts.
- **Early Warning Systems:** Additionally, IoT can be used to set up early warning systems for extreme weather occurrences like floods, tornadoes, and hurricanes. This enables people and authorities to take the appropriate safety measures and lessen any harm.

Weather Monitoring System with IoT Block Diagram

Applications are divided into two categories: event detection-based and spatial process estimation. At the centre of the ecosystem is a microcontroller, such as Arduino UNO or ESP8266, which acts as the central hub. It orchestrates the connectivity of various sensors (such as humidity and temperature sensors) and devices, acting as the brain of the entire system. The collected data is promptly transmitted to the web server after establishing a stable connection between the server and strategically placed sensor devices [20]. Wi-Fi modules like Node-MCU are used to upload and store the processed sensor data on a website, serving as a reliable database the weather monitoring system using IoT block diagram is shown in Fig.(1). The web server page allows us to monitor and control the system.

- The inbuilt monitoring device provides data on humidity, temperature, and CO levels in the surrounding region.
- Collected data is stored on cloud storage.
- Cloud data can be used for parameter analysis and continuous observation.
- Recorded regular air temperature, humidity, and carbon monoxide levels.

Areas Benefit From Weather Forecasting System with IoT

- **Agriculture Sector**
Farmers can make educated judgments about crop selection, watering schedules, and pest management with the aid of weather forecasts. With real-time monitoring, farmers may receive precise data on plant development and soil moisture levels, guaranteeing the best possible crop output.
- **Transportation**
To prevent delays or accidents brought on by severe weather, real-time weather monitoring is essential for the transportation sector. Transportation companies may track road conditions and arrange routes accordingly by utilizing IoT-based sensors on cars and roadways.
- **Disaster Management**
Natural disasters like hurricanes, floods, and snowstorms can be predicted with the use of IoT-based weather monitoring systems. Authorities can limit harm by issuing timely warnings and taking necessary safeguards with the help of precise data.
- **Urban Planning**
Real-time weather data can help city planners manage infrastructure and resources more effectively. For example, by providing earlier notice of heat waves or heavy precipitation, they can plan emergency services appropriately and avert any calamities.
- **Tourism**
Tourism is significantly impacted by the weather, and passengers' experiences can be substantially improved with real-time weather monitoring. Weather forecasts that are accurate help travelers organize their activities, which makes for a more pleasurable and hassle-free trip.
- **Healthcare**

Saranya and Divya

Healthcare facilities must have access to real-time weather information in order to plan for severe weather or natural catastrophes. Hospitals can keep an atmosphere safe for patients by using IoT-based sensors to track humidity levels, air quality, and temperatures both inside and outside.

Types of sensors Involved in Weather Tracking System

Depending on the particular application, a wide variety of electronic sensors are used by weather monitoring systems. A Real time weather monitoring system is shown in Fig.(2) To increase agricultural productivity, for instance, farmers need data on a variety of variables, including temperature, relative humidity, soil moisture, and rainfall [21]. They use particular kinds of sensors to gather this information. Among the sensors of this type are:

- **Temperature sensor:** determines the temperature of the surrounding air.
- **Humidity/hygrometer sensor:** finds and gauges the environment's humidity level.
- **Soil moisture sensor:** keeps an eye on the soil's moisture level.
- **Rain sensor:** detects and gauges the amount and strength of precipitation. An airplane pilot is another example, who has to obtain vital data before to takeoff, including wind direction, speed, atmospheric pressure, precipitation, and visibility. Pilots use a range of sensors to get this crucial facts.
- **Barometric sensor:** This device gauges detect atmosphere air pressure values.
- **Anemometer:** Gets wind speed information.
- **Rain Sensor:** Identifies and gauges precipitation.
- **Visibility sensor:** Determines visibility in inclement weather, including storms, rain, and snow. IoT-based weather monitoring system in the future more sophisticated and creative solutions should be forthcoming as IoT is being used more widely across a range of industries, including weather monitoring. Among the

Potential outcomes are:

- **Accurate forecasting**
IoT-based weather monitoring systems will be made possible by advances in data analytics and technology. The forecasts produced by these algorithms will be increasingly more precise.
- **System integration**
It is possible to link IoT-based weather monitoring systems with other systems. The capabilities of these systems are increased by the inclusion of smart cities and households. A smart home might, for instance, modify its temperature settings in response to current meteorological information [22].
- **Machine learning**
IoT-based weather monitoring systems may continuously learn from historical data by utilizing machine learning algorithms. As a result, they can gradually get better at predicting.
- **Improved disaster management**
Real-time meteorological data can be sent to disaster management authorities by means of Internet of Things (IoT)-based sensors. They are able to safeguard the public by Taking the appropriate measures as a result.
- **Customized notifications**
Internet of Things (IoT)-based weather monitoring devices enables individuals to receive customized weather alerts. Better planning and safety are ensured by these location- and preference-based alerts. IoT technology has enormous promise and value for weather monitoring, and this potential will only increase with time [23]. By deploying IoT-based weather monitoring systems across several industries, we can significantly boost productivity and efficiency while lowering the hazards related to erratic weather patterns.

RESULT ANALYSIS

This research paper suggests a real-time, affordable weather tracking system using an Arduino. Weather tracking production may be measured with this system temperature, humidity. There was weather module monitoring done. These outcomes were attained using a system that included sensors, software, and a microcontroller. The software

that makes use of the present sensor is far more user-friendly. The various reading are measured like temperature (T), humidity (h) with the help of weather tracking system.

CONCLUSION

IoT solutions improve crop management and reduce weather-related hazards by giving farmers precise data on soil moisture and climate. IoT weather stations continuously track and report conditions in harsh environments, such as volcanoes and rainforests, providing essential information for study and safety. Our ever-volatile global climate emphasizes how crucial sophisticated, real-time monitoring systems are. Thanks to IoT developments, businesses may now employ advanced analytics to lessen the negative effects of weather on operations and business. Discover the ways that Ariel's IoT solutions are benefiting different global sectors.

ABSTRACT

Diabetes mellitus is one of the critical health issues all over the world. Prediction and prevention of diabetes mellitus is certainly important in order to avoid other chronic diseases. It may leads to heart disease, kidney failure, nerve damage, blood vessel damage, lower limb amputation and blindness. So mining the diabetes patient data effectively will help to predict the risk level of diabetes victim. This work proposes Rule Based K-Means algorithm to predict the risk level of diabetes victims. In this work two different types of approaches have been proposed for clustering the patient record namely insulin dependent patients and tablet dependent patients. The proposed algorithm is compared with various prime algorithms like Support Vector Machine, Naïve Bayes, ID3 and Random Forest tree. The experimental results prove that Rule Based K-Means provides highest accuracy than other algorithms.

Keywords: SVM, Naïve Bayes, Random Forest tree, ID3, Rule Based K-means

INTRODUCTION

Diabetic Mellitus is endless ailment that is portrayed by high blood glucose level. About portion of the considerable number of diabetics have family heredity factors, which is one of the highlights in diabetic mellitus. Disappointment of pancreas to deliver enough insulin and the body's wasteful utilization of insulin are both pathologic foundations for diabetic mellitus. There are primarily four sorts of Diabetes Mellitus. They are Type1, Type2, Gestational diabetes

**Krishnamoorthy et al.,**

and innate diabetes. Diabetes mellitus affected patients' prediction to help the patients to overcome the risk levels of the other chronic diseases. The use of clustering technique in medical diagnosis is increase gradually. There is no doubt in that evaluation of data taken from patients through labs and decision of expert are most important factor in diabetes mellitus diagnosing. But expert system and Artificial intelligence techniques for clustering and classification also help expert in great deal. Most of the work related to machine learning in diabetes diagnosis is concentrated to diabetes dataset. In this work diabetes mellitus affected patient risk level prediction was implemented in different clustering and classification algorithms and the performance measures are evaluated. In this paper clustering and classifier techniques with Rule Based K-Means algorithm are implemented for the forecasting of diabetes mellitus risk levels and concludes the best algorithm which produces maximum accuracy levels. The implementing techniques are Rule Based K-Means with Support Vector Machine, Naïve Bayes, ID3 and Random Forest tree. The residual investigation discourse is sorted out as pursues Section-II Dataset used, Section-III Methodology utilized and diverse procedure of dataset. Section-IV states assessed results. Section-V Conclusion of my investigation work.

LITERATURE REVIEW

According to the World Health Organization (WHO) there are 350 million people affected diabetes mellitus and diabetes will become the seventh leading cause of death worldwide by 2030. It will be estimated to increase in 2050 by 50% of the people in the next 10 years. The number of diabetic person is increases in every country, 4 out of 5 people live with diabetes with low and middle in countries and half of diabetics don't they are affected from these disease. This global epitomic could be largely attributed to the rapid increase in the rates of overweight, physical inactivity, not maintain proper foot diet. P. Thangaraju and B.Deepa [3], proposed a survey on preclusion and discovery of skin melanoma risk using clustering techniques. The skin melanoma patient's data are gathered from different diagnostic centre which contains both cancer and non-cancer patient's information. The gathered data are pre-processed and then clustered using K-means algorithm for separating relevant and nonrelevant data to skin melanoma. Dr.N. Rajalingam, K. Ranjini [16], presented a comparative study of implementation of hierarchical clustering algorithms- agglomerative and divisive clustering for various attributes. The Visual Programming Language is used for implementation of these algorithms. The result of this paper study is the performance of divisive algorithm works as twice as fast as the agglomerative algorithm. The research paper [4] developed a method using combined dataset of Diabetes disease. Here select (accuracy- 63.54%, specificity- 43.00%, and sensitivity- 99.80%), wrapper (accuracy- 70.69%, specificity- 38.36% and Sensitivity- 89.95) and Ranker (accuracy- 72.61%, specificity- 41.04%, and sensitivity- 90.76%) methods are used for feature selection and LIBSVM for classification feature.

DATASET USED

The dataset which is used in this study contains five records collected from various labs. The dataset are pre-processed and the measurements are calculated and compared. The following attributes are taken to evaluate the proposed methodologies, Person, HbA1c, FBS, PPBS, Age and Mode of treatment (Insulin/Tablet). The variables HbA1C, FBS and PPBS was the most strongly associated with type2 diabetes than other variables like person, gender, number of years affected. The above tabel1 contains the dataset and attributes are as follows name, age, gender, type1/2, hba1c,fbs, ppbs, medicine taken insulin or tablet and number of year affected the patients the values are specified in the table.

METHODOLOGY

The proposed Rule Based K-means algorithm is used for predicting the diabetes mellitus with improved accuracy when compared to Support Vector Machine, Naïve Bayes, ID3 HA FCM and Random Forest tree algorithms. The following section describes the working model of the algorithm and existing algorithms. Datasets of name, age, gender, FBS, PPBS, HbA1C, No of years affected, and the medicine in-take either Tablet or Insulin of patients are collected from various labs. The person details such as FBS level, PPBS level, HbA1c level, the person affected in

Krishnamoorthy et al.,

years by this disease are all available in the dataset. The Preprocessing techniques were implemented with help of class order technique and some of the fields are removed e.g. Gender, No of years affected and some fields are masked from the identity like name with person1,2,...,n and the preprocessed dataset are taken and the proposed algorithm is applied and various measures are registered. The other clustering algorithms Decision Tree, Hierarchical Algorithm, Fuzzy C Means, and Naive Bayes and SVM algorithm are also applied on the dataset for process to record for various measures and are compared with proposed Rule-Based K-Means algorithm measures. The performance measures that are recorded are accuracy, precision, recall and f-measures and are used in clustering algorithms. The results of the comparison with proposed algorithm are enlisted and charted.

Accuracy Measures

Rule Based K-Means Algorithm, Decision Tree, SVM and Naive Bayes algorithms are used in this research work. Investigates are achieved by internal cross-validation 10-folds. Accuracy, Sensitivity, Specificity F-Measure, and ROC processes are regained for the classification of this work. Below Table-2 and 4 defines accuracy measures.

Attributes used

The following attributes are used to find the accuracy measures as follows Person, HbA1c, FBS, PPBS, age and Mode of treatment (Insulin/Tablet)

Proposed Rule Based K-Means Algorithm (RBKM)

The proposed Rule Based K-Means Algorithm for prediction of risk level of diabetes mellitus involves with the approach of partitioning of the dataset into clusters with different irrelevant groups. Each group contains any number of data. Then the initial center node is selected arbitrarily and the numbers of groups are not selected and not known in advance. The number of groups is identified based on the way of treatment the patients. Undergoing the patient treated using only tablet and patient treated only in insulin are the two groups in the dataset. Then the center nodes that are identified by selecting one from insulin patient and another from tablet patient. Then the algorithm separates the dataset by measuring not only the squared Euclidean distance but also using the group formation rules that are framed based on the parameters such as HbA1C, FBS, PPBS, AGE.

Rule Based K-Means Algorithm Steps

- Step 1.** Identify the two dependent variable from the dataset.
- Step 2.** Form the scatter diagram based the dependent variables x and y.
- Step 3.** Label all the data points in the scatter diagram. Assign the number of groups=2.
- Step 4.** Identify two Initial Center Value (ICV) values randomly based on the mode of treatment (Insulin or Tablet).
- Step 5.** Determine all the nearest nodes of the ICV using distance formula.
- Step 6.** By suppression and iteration, select the number of data points in a group based on the lowest distance between the data point and ICV. The data points can be selected for the group until the highest calculated value/2.
- Step 7.** When all the nodes have been assigned either of the groups, recalculated the passion of ICV values.
- Step 8.** Derive new ICV.
- Step 9.** Repeat step 5 to 7 until the ICV reaches fixed position. This produces a separation of the dataset into groups, from which the metric to be minimized can be calculated and goto step 10.
- Step 10.** The following conditions are used to frame the optimized group from the previous steps.

Group Formation Rules

Rule 1: X (Suggestion="Insulin") = (HbA1C>=7) && ((FBS>125) || (PPBS>105)) &&(AGE>50)

Rule 2: X (Suggestion="Tablet with WALKING") = (HbA1C>7) && ((FBS>125) || (PPBS>105)) || (AGE<50).

Rule3: X (Suggestion="Insulin or Tablet with WALKING and Diet") = (HbA1C<7) && ((FBS<125) || (PPBS<105)) &&(AGE>50)

Rule4: X (Suggestion="Tablet with WALKING") = (HbA1C<7) && ((FBS<125) || (PPBS<105)) && (AGE<50)

Rule 5: X (Suggestion = " Insulin or tablet with WALKING") = (HbA1C>7) && ((FBS<125) || (PPBS<105)) && (AGE>50)

**Krishnamoorthy et al.,****Description for Group formation Rules**

Rule 1: For age above 50 and HbA1c is greater than or equal to 7 and FBS or PPBS is greater than 125 or 105 respectively then the Suggestion is Insulin.

Rule 2: For age below 50 or FBS is greater than 125 or PPBS is greater than 105 and HbA1c is greater than 7 then the Suggestion is Tablet with Walking.

Rule 3: For age above 50 and HbA1c is less than 7 and FBS or PPBS is less than 125 or 105 respectively then the Suggestion is Insulin or Tablet with Walking and Diet.

Rule 4: For age below 50 and HbA1c is less than 7 and FBS or PPBS is less than 125 or 105 respectively then the Suggestion is Tablet with Walking.

Rule 5: For age above 50 and HbA1c is above 7 and FBS or PPBS is less than 125 or 105 respectively then the Suggestion is Insulin or Tablet with Walking.

RESULT AND IMPLEMENTATION**Rule Based K-Means with Naive Bayes SVM ID3 and Random Forest Tree****Naive Bayes**

Naive Bayes is a characterization procedure with a thought which characterizes all highlights is independent and random to one another. It characterizes that status of a particular component in a class not ensure influence the status of another element. Since it depends on contingent likelihood it is considered as an amazing calculation utilized for arrangement reason. It functions admirably for the information with unbalancing issues and missing qualities. It is a machine learning classifier which utilizes the Bayes Theorem. Utilizing Bayes hypothesis back likelihood $P(C/X)$ can be determined from $P(C)$, $P(X)$ and $P(CX)$.

Support Vector Machine (SVM)

Support vector machine is the simplest, linear form, and it is a hyperplane that separates a set of positive examples from a set of negative examples with maximum margin. In the linear case, the margin is defined by the distance of the hyperplane to the nearest of the positive and negative examples. It is one of the regular arrangements of directed machine learning standard utilized in characterization. Given a two-class preparing test the point of a help it is to pinpoint the best most noteworthy edge detachment hyperplane among the dual classes. For better conjecture, hyperplane ought not to lie nearer to the information focuses have a place with the different class. Hyper plane ought to be chosen which is a long way from the information exertions from every class. The focuses that untruth nearby to the pinpoint of the classifier are the help vectors.

Random Forest Tree (RFT)

Random Forest is a popular machine learning algorithm that belongs to the supervised learning technique. It can be used for both Classification and Regression problems in Machine Learning. It is based on the concept of ensemble learning, which is a process of combining multiple classifiers to solve a complex problem and to improve the performance of the model. It is a classifier that contains a number of decision trees on various subsets of the given dataset and takes the average to improve the predictive accuracy of that dataset. Instead of relying on one decision tree, the random forest takes the prediction from each tree and based on the majority votes of predictions, and it predicts the final output. The greater number of trees in the forest leads to higher accuracy and prevents the problem of over fitting.

ID3 Algorithm

The ID3 algorithm is a popular decision tree algorithm used in machine learning. It aims to build a decision tree by iteratively selecting the best attribute to split the data based on information gain. Each node represents a test on an attribute, and each branch represents a possible outcome of the test. The leaf nodes of the tree represent the final classifications. In the above table 3 describes the proposed Rule Based K means algorithm and existing

Krishnamoorthy et al.,

algorithm are Support Vector Machine, Naïve Bayes, ID3 and Random Forest tree confusion matrix values are evaluate and tabulated. The above Table-4 describes the Accuracy measure for five algorithms namely, Rule Based K-Means algorithm (97.30%), SVM (94.5%),RFT (93.3%), ID3 (93.20%), Naïve Bayes (92.30%). Precision measures for five algorithms Rule Based K-Means algorithm (0.500), Naïve Bayes (0.500%) and ID3 (0.500%), SVM (0.480), RFT (0.475). The Recall measures for the five algorithms Rule Based K-Means algorithm (0.500%), RFT(0.425), SVM(0.450) ,Naïve Bayes (0.125%) and ID3 (0.333%). And the F-measure for five algorithms namely, Rule Based K-Means algorithm (0.500%), SVM(0.481),RFT(0.465),Naïve Bayes (0.200%), and ID3(0.391%).

Rule Based K-Means with Hierarchical ,Fuzzy C Means

Hierarchical clustering

It divides datasets into clusters in a sequential manner with nested in proportions. By the method of analyses, groups are hunted to construct a hierarchy of clusters. A tree data structure called a Dendrogram can be used to illustrate the hierarchical clustering technique with the sets of different clusters. The root in a Dendrogram contains one cluster from which all other clusters are hierarchically become nodes until leaves in a Dendrogram that each node consist of a single element cluster. Internal nodes represent new cluster formed by merging the cluster that appears as its children. Each level is associated with the distance measure that was used to cluster. The following steps of process are applied for hierarchical clustering:

Fuzzy C-means clustering

It is a method of clustering that allows an object to belong to two or more clusters. This method is frequently used in pattern recognition. Basically, this algorithm works by assigning membership values to each object corresponding to each cluster center on the basis of distance between the center of the cluster and the object. The nearer the data point is to the cluster center, more is the membership towards the cluster of center. The summation of membership values of each object should be equal to one and also, the number of clusters needs to be specified in the beginning. But, unlike k-means where objects must exclusively belong to one cluster center here objects are given belongingness to each cluster center as a result of which objects may belong to more than one cluster center. The following steps are processed in fuzzy C means algorithm to perform the cluster of diabetes mellitus patient datasets. In the above table 5 describes the proposed Rule Based K means algorithm and existing algorithm are fuzzy C means, hierarchical confusion matrix values are evaluate and tabulated. The above Table-6 describes the Accuracy measure for algorithms namely, Rule Based K-Means algorithm (97.30%), Hierarchical Algorithm (94.30%), Fuzzy C Means (93.00%). Precision measures for algorithms Rule Based K-Means algorithm (0.500), Hierarchical Algorithm (0.490), Fuzzy C Means (0.485). The Recall measures for the algorithms Rule Based K-Means algorithm (0.500%), Hierarchical Algorithm (0.460), Fuzzy C Means(0.450). And the F-measure for algorithms namely, Rule Based K-Means algorithm (0.500%), Hierarchical Algorithm (0.481), Fuzzy C Means(0.465).

The above Figure-4 describes the Accuracy measure comparison for seven algorithms namely, Rule Based K-Means algorithm (97.30%), SVM (94.50%), RFT(93.3), ID3 (93.2) Naïve Bayes (92.30%) , Hierarchical Algorithm (94.3%) and Fuzzy C Means (93).It shows that rule based k-means is as better than other six algorithms. Comparison between Precision measures for seven algorithms Rule Based K-Means algorithm ,Naïve Bayes ID3share the value (0.500),and minimum for RFT(0.475), SVM (0.48), Hierarchical Algorithm (0.49) and Fuzzy C Means (0.49). The Recall measures comparison for the seven algorithms Rule Based K-Means algorithm (0.500%), SVM (0.450), RFT(0.425), ID3 (0.333) Naïve Bayes (0.125) , Hierarchical Algorithm (0.46) and Fuzzy C Means (45). And the F-measure comparison for seven algorithms namely, Rule Based K-Means algorithm (0.500), Hierarchical Algorithm(0.481), Fuzzy C Means(0.465),Naïve Bayes (0.200%), and SVM (0.391%) RFT(0.465),ID3(0.391)and Rule Based K-Means were seen as better than the other seven. Figure-6, shows ROC area of five algorithms namely Rule Based K-Means algorithm (1.0%), SVM (0.95), RFT(0.94), ID3 (0.97) Naïve Bayes (0.96) , Hierarchical Algorithm (0.91) and Fuzzy C Means(90). It reveals the fact Rule Based K-Means algorithm is better than the other four. The minimal is Fuzzy C Means which is better than other seven.

**Krishnamoorthy et al.,**

CONCLUSION

In this Research work, orderly endeavors are made in planning a framework which results in the method of forecast of treatment like Insulin or Tablet. During this work the proposed models are portrayed and contrasted with two processing are compared one four clustering algorithms on different measures and another work was processed with five clustering algorithms. Analyses are performed on clinical diabetes dataset. Exploratory outcomes decide the adequacy of the structured framework with an accomplished exactness of 97.3 % utilizing the Rule Based K-Means algorithm which yields better results than the Support Vector Machine, ID3, Random Forest tree ,Naive Bayes, Hierarchical Algorithm, and Fuzzy C Means algorithm. In future, the designed methodology for type2 identification processes can be a better solution for any similar clustering algorithms in different fields. This can also be incorporated in self-monitoring devices or applications.

ABSTRACT

Kidney stone disease is a prevalent medical condition that can lead to significant discomfort and severe health complications if not treated promptly. The accurate and timely prediction of kidney stone severity is crucial for guiding appropriate clinical interventions. This study presents a novel automated approach for predicting kidney stone severity using deep learning techniques applied to computed tomography (CT) scan images. Our method leverages a convolutional Neural Network (CNN) architecture, trained on a diverse dataset of annotated CT scans, to accurately classify the severity of kidney stones into multiple categories based on size, location, and potential complications. The model is designed to assist clinicians by providing a reliable second opinion, thereby enhancing diagnostic accuracy and reducing the time required for assessment. This research work conducted extensive experiments to evaluate the performance of our model, achieving high accuracy, precision, and recall across various test scenarios. The proposed approach also includes a feature visualization component, enabling clinicians to understand the model's decision-making process, which is crucial for integrating AI-based tools into clinical practice. Our findings suggest that deep learning models can effectively augment clinical workflows in nephrology by providing fast, accurate, and non-invasive assessments of kidney stone severity, ultimately improving patient outcomes. This study lays the groundwork for future research into AI-driven diagnostic tools in urology and other medical specialties.

Keywords: kidney stone, Deep learning, severity prediction, computed tomography

Ramesh et al.,

INTRODUCTION

Kidney stone disease, also known as nephrolithiasis, is a common urological condition characterized by the formation of hard, crystalline deposits within the kidneys. These stones are composed of minerals and salts that accumulate in the urinary tract, often due to imbalances in diet, dehydration, or genetic predisposition. The condition can affect individuals of all ages, but it is most prevalent among adults, with a higher incidence in men than in women. The impact of kidney stones on health can be significant. When stones obstruct the flow of urine, they can cause severe pain, typically referred to as renal colic, which is often described as one of the most intense types of pain a person can experience. In addition to pain, kidney stones can lead to complications such as urinary tract infections (UTIs), hematuria (blood in the urine), and, in severe cases, kidney damage or failure. Recurrent kidney stones are common, with about 50% of individuals experiencing another episode within five years of the first. From a healthcare perspective, kidney stone disease poses a considerable burden. The diagnosis, treatment, and management of kidney stones involve significant medical resources, including imaging tests, surgical interventions, and long-term management to prevent recurrence. The economic impact is also substantial, with high costs associated with emergency care, surgical procedures, and lost productivity due to the disabling pain and recovery time. Given these challenges, early detection and accurate assessment of kidney stones are critical for effective treatment and prevention of complications. Advances in imaging technology, particularly computed tomography (CT) scans, have greatly enhanced the ability to detect kidney stones. However, the interpretation of these images can be time-consuming and requires specialized expertise. This has spurred interest in developing automated tools that can assist clinicians in diagnosing and evaluating kidney stones more efficiently, potentially leading to better patient outcomes and reduced healthcare costs [9]. **Convolutional Neural Networks (CNNs)** have become a powerful tool in medical imaging due to their ability to automatically learn and extract features from images, making them particularly useful for tasks such as kidney stone severity prediction using CT scan images. Here's how CNNs contribute to this domain:

- Automated feature extraction
- High Accuracy in classification
- Localization and Detection
- Prediction of clinical outcomes
- Enhanced decision support
- Scalability and efficiency
- Interpretability and trust

CNNs excel at automatically extracting relevant features from raw image data without the need for manual feature engineering[1]. In the context of kidney stone severity prediction, CNNs can identify intricate patterns in CT scan images, such as the size, shape, density, and location of kidney stones, which are critical for assessing their severity. This automation significantly reduces the time and expertise required compared to traditional methods, where radiologists manually analyze these features. CNNs are well-suited for image classification tasks, and they can be trained to categorize kidney stones based on severity levels [2] (e.g., mild, moderate, severe) by learning from labeled datasets of CT images. The ability of CNNs to differentiate between subtle variations in image data allows for accurate classification of kidney stones, which is essential for determining the appropriate treatment strategy. For instance, larger stones or those located in critical areas may require surgical intervention, whereas smaller stones might be managed with medication or lifestyle changes. Advanced CNN architectures, such as those incorporating region-based networks (e.g., Faster R-CNN), can not only classify the severity of kidney stones but also localize them within the CT scan images [3]. This capability is crucial for clinicians, as it helps in precisely identifying the position of the stones within the urinary tract, which is important for assessing potential complications, such as blockages that could lead to kidney damage. By analyzing the features extracted from CT images, CNNs can be trained to predict clinical outcomes related to kidney stone disease [4]. For example, they can estimate the likelihood of stone passage, the need for surgical intervention, or the risk of recurrence. This predictive capability is valuable for personalized patient care, enabling clinicians to make informed decisions based on the predicted severity of the condition. CNNs can serve as decision support tools for radiologists and urologists by providing a second opinion in the diagnostic

**Ramesh et al.,**

process. The output of a CNN model, such as the severity score or a heatmap indicating areas of concern, can complement the radiologist's assessment, leading to more accurate and consistent diagnoses. This collaboration between AI and clinicians can improve patient outcomes by ensuring that critical cases are promptly identified and treated [8]. The ability of CNNs to process large volumes of CT scan images quickly and accurately makes them highly scalable in clinical settings. Once trained, a CNN model can analyze new CT images in real-time, making it a valuable tool in hospitals and clinics where the timely diagnosis of kidney stones is crucial [5]. This efficiency also helps in reducing the workload on radiologists, allowing them to focus on more complex cases. Recent advancements in CNN technology include methods to enhance model interpretability, such as generating saliency maps that highlight the regions of the CT scan that the model used to make its predictions. This transparency is important for building trust among clinicians, as it provides insights into the model's decision-making process and allows for better integration of AI into clinical workflows. The methodology involved training a convolutional neural network (CNN) on a large dataset of annotated CT scan images. The images were preprocessed to enhance relevant features, and the model was fine-tuned using transfer learning techniques. Finally, the trained model was validated on a separate test set to evaluate its accuracy and reliability in predicting kidney stone severity. Deep learning models have shown remarkable accuracy in predicting the severity of kidney stones from CT scan images. These models can analyze complex patterns in the data that might be missed by traditional methods, leading to more precise diagnoses. As a result, they hold significant promise for improving patient outcomes through early and accurate detection. Early detection of kidney stones is crucial as it allows for timely treatment and can prevent complications such as severe pain, infection, and kidney damage. By using deep learning algorithms to analyze CT scan images, doctors can quickly and accurately determine the severity of the condition. This enables them to provide appropriate and effective treatment plans, improving patient outcomes and reducing healthcare costs.

LITERATURE SURVEY

The application of deep learning, particularly Convolutional Neural Networks (CNNs), to medical imaging has seen rapid advancements in recent years. In the context of kidney stone severity prediction, several studies have explored the use of CNNs to automate the detection, classification, and analysis of kidney stones using CT scan images [10]. This literature survey highlights key contributions in this area, focusing on methodologies, datasets, and the clinical relevance of these approaches. Early work in the application of CNNs for kidney stone detection focused on the basic task of identifying the presence of stones in CT images. For instance, Zhang et al. (2018) proposed a deep learning framework that utilized CNNs to detect kidney stones in non-contrast CT scans. Their model demonstrated high sensitivity and specificity, highlighting the potential of CNNs in reducing the diagnostic workload for radiologists. Similarly, Baghdadi et al. (2019) developed a multi-class CNN model that not only detected the presence of kidney stones but also classified them based on size and location. This approach marked a significant step towards more detailed analysis, enabling a more comprehensive understanding of the stone's characteristics, which are critical for determining the appropriate treatment. Recent studies have shifted focus from mere detection to the prediction of kidney stone severity, an essential factor in clinical decision-making. Cheng et al. (2020) introduced a deep learning model designed to assess the severity of kidney stones by analyzing the size, density, and potential complications visible in CT scans. Their CNN architecture was trained on a large dataset of annotated CT images, allowing the model to predict whether a stone would likely cause obstruction or require surgical intervention. Moreover, a study by Kim et al. (2021) integrated CNNs with clinical data to enhance the prediction of stone-related complications. By combining image-based features with patient-specific information such as age, gender, and medical history, the model achieved improved accuracy in predicting the need for invasive procedures. A critical aspect of deploying CNNs in clinical practice is the interpretability of the model's predictions. To address this, researchers like Li et al. (2022) have focused on feature extraction techniques that allow the visualization of the CNN's decision-making process. Their work utilized saliency maps to highlight the regions of CT images that the model deemed most relevant for its predictions. This transparency is crucial for gaining clinician trust and facilitating the integration of AI tools into routine medical practice. While CNNs have shown great promise in kidney stone severity prediction, several challenges remain. The variability in CT scan quality, the presence of artifacts, and differences in scanning

Ramesh et al.,

protocols across institutions can affect model performance. Studies such as those by Huang et al. (2023) have begun exploring the use of transfer learning and data augmentation techniques to mitigate these issues, aiming to create more robust and generalizable models.

Dataset

Utilizing coronal computed tomography (CT) images, an automated kidney stone identification method was developed utilizing deep learning (DL) approach, which has made major advancements in artificial intelligence. A total of 18500 pictures were obtained by obtaining individual cross-sectional CT scans. Using CT scans, our created automated model demonstrated a 97.08% accuracy rate in identifying kidney stones. Figure 1 shows the sample dataset of kidney-stone and normal images.

Deep Model for Kidney Stone Severity Prediction

To predict kidney stone severity using deep learning, particularly with Convolutional Neural Networks (CNNs), a specialized model architecture can be designed to handle the complexities of CT scan images. Here's an overview of a deep model architecture for kidney stone severity prediction [1]: The proposed model could involve a combination of convolutional layers, pooling layers, and fully connected layers, with the architecture potentially looking like the following steps. The input layer accepts CT scan images, typically of size (512x512) pixels, depending on the resolution and preprocessing steps. **Layer 1:** Apply multiple convolutional filters (e.g., 64 filters of size 3x3) to capture low-level features like edges and textures from the CT scan images. **Layer 2 to 4:** Additional convolutional layers with an increasing number of filters (e.g., 128, 256, 512 filters) are used to capture more complex patterns and features, such as the shape, size, and density of the kidney stones. After each convolutional layer, use a non-linear activation function such as ReLU (Rectified Linear Unit) to introduce non-linearity into the model, enabling it to learn more complex features. Apply max pooling (e.g., 2x2 pooling) after each set of convolutional layers to reduce the spatial dimensions, which helps in reducing the computational load and focusing on the most prominent features. Batch normalization layers can be added to normalize the output of the previous layers, improving training speed and stability. Dropout layers are used to prevent overfitting by randomly dropping a percentage of neurons during training. Flatten the output from the last convolutional layer and pass it through fully connected layers (e.g., 1024, 512 neurons) to learn high-level representations and combine the extracted features. The output layer typically uses a softmax activation function if predicting severity as a multi-class classification [2] (e.g., mild, moderate, severe). For binary classification (e.g., severe vs. non-severe), a sigmoid activation function can be used.

Training and Optimization

a. Loss Function

Use categorical cross-entropy for multi-class classification or binary cross-entropy for binary classification tasks. The choice of loss function depends on the type of severity prediction (binary or multi-class).

b. Optimizer

The Adam optimizer is commonly used due to its adaptive learning rate capabilities, which helps in achieving faster convergence during training.

c. Data Augmentation

To improve generalization and avoid overfitting, apply data augmentation techniques such as rotation, zooming, and horizontal/vertical flipping. These augmentations simulate variations in CT scan images and help the model learn more robust features.

d. Transfer Learning

Depending on the size of the dataset, transfer learning from a pre-trained model (e.g., ResNet, VGG) can be employed. This approach allows leveraging learned features from large-scale image datasets and fine-tuning the model on kidney stone CT scans.

Ramesh et al.,

e. Training Process

The model is trained on a labeled dataset of CT scans with corresponding severity labels. A common strategy is to split the data into training, validation, and test sets, ensuring the model is evaluated on unseen data to verify its performance.

f. Evaluation Metrics

Evaluate the model using accuracy, precision, recall, F1-score, and the area under the ROC curve (AUC). These metrics provide insight into the model's performance, particularly in imbalanced datasets where certain severity levels may be underrepresented.

RESULTS AND DISCUSSION

This research work processed with 18500 image dataset includes train and test data. Eighty percent of the 14800 CT images were utilized in the model's training phase, with the remaining twenty percent being used for validation. The proposed model produced 97.08% accuracy.

CONCLUSION AND FUTURE DIRECTION

In this study, we presented a clinical approach for the automated prediction of kidney stone severity using deep learning techniques applied to CT scan images. Our proposed model, based on a Convolutional Neural Network (CNN) architecture, demonstrated significant potential in accurately classifying kidney stones into different severity levels. By leveraging the power of CNNs, we were able to automate the feature extraction process and achieve high levels of accuracy, precision, and recall, essential for clinical application. The integration of this deep learning model into clinical workflows can provide substantial benefits, including reduced diagnostic time, improved consistency in severity assessment, and enhanced decision-making for treatment planning. By providing a reliable second opinion, this approach not only supports clinicians in diagnosing kidney stones but also aids in predicting potential complications, which is crucial for preventing severe outcomes and optimizing patient care. Furthermore, the model's ability to visualize the decision-making process through feature maps and heatmaps ensures transparency, fostering trust among healthcare professionals. This interpretability, combined with the model's predictive accuracy, underscores the viability of using deep learning in nephrology for real-time, non-invasive assessments. In conclusion, our approach offers a promising solution for the automated prediction of kidney stone severity, paving the way for more efficient, accurate, and personalized patient care in the management of kidney stone disease. This research work produced 97% of accuracy. Future work will focus on refining the model, expanding its applicability to a broader range of clinical scenarios, and conducting large-scale trials to validate its effectiveness in diverse clinical environments.

ABSTRACT

Roadway accidents are a critical global issue, resulting in significant loss of life, injuries, and economic burden. Traditional safety measures, while effective to some extent, struggle to address the complexities of modern traffic environments. This article explores the transformative potential of machine learning (ML) in preventing roadway accidents. By leveraging data from diverse sources, ML algorithms can predict high-risk scenarios, monitor traffic in real-time, and enable autonomous decision-making to enhance road safety. The article delves into key ML tools and techniques, including predictive analytics, real-time monitoring, autonomous vehicles, and smart infrastructure, highlighting how they contribute to reducing accidents. As ML technology continues to evolve, it offers promising solutions for creating safer roads, ultimately aiming to minimize accidents and save lives.

Keywords: Machine Learning (ML), Road Safety, Traffic Accident Prevention, Intelligent Transportation Systems (ITS), Predictive Analytics, Driver Assistance Systems, Collision Avoidance

INTRODUCTION

Roadway accidents are a significant and persistent global challenge, leading to millions of fatalities, injuries, and economic losses every year. According to the World Health Organization (WHO), road traffic crashes are the leading cause of death among young people aged 15-29 years, with an estimated 1.35 million people losing their lives

**Premkumar and Krithika**

annually. Beyond the human cost, the economic impact of road accidents is staggering, with costs associated with healthcare, loss of productivity, and damage to infrastructure amounting to billions of dollars each year. Traditional methods of accident prevention, such as traffic regulations, speed limits, and public safety campaigns, have been instrumental in reducing accident rates to some extent. However, these measures have limitations, particularly in dealing with the complexities and unpredictability of modern traffic environments. The rise of machine learning (ML), a branch of artificial intelligence (AI), presents a new frontier in the battle against roadway accidents. Machine learning offers the capability to analyze vast amounts of data in real-time, recognize patterns, and make predictive decisions that can help prevent accidents before they occur. By leveraging data from various sources, such as traffic cameras, sensors, GPS devices, and even social media, machine learning algorithms can provide insights into high-risk situations, suggest preventive measures, and even take autonomous actions to avoid collisions. The integration of machine learning into road safety strategies is not just about enhancing existing systems but about creating intelligent, adaptive solutions that can respond to dynamic traffic conditions, anticipate potential hazards, and improve overall safety on the roads. This article explores the role of machine learning in preventing roadway accidents, highlighting the key tools and techniques used in this cutting-edge approach to road safety. From predictive analytics and real-time monitoring to autonomous vehicles and smart infrastructure, machine learning is poised to revolutionize how we think about and manage road safety in the 21st century.[2][4]

The Role of Machine Learning in Road Safety

Machine learning is a subset of artificial intelligence (AI) that enables systems to learn from data, identify patterns, and make decisions with minimal human intervention. In the context of road safety, ML algorithms can analyze data from various sources—such as traffic cameras, sensors, GPS devices, and social media—to predict potential accidents and suggest preventive measures.

Predictive Analytics

Predictive analytics uses historical data to forecast future outcomes. In road safety, ML models can analyze past accident data, weather conditions, traffic flow, and driver behavior to predict high-risk situations. For example, an ML model can forecast the likelihood of accidents at specific intersections during certain times of the day or under particular weather conditions. Authorities can then take preemptive actions, such as adjusting traffic signal timings or issuing weather-related warnings to drivers.

Real-Time Monitoring

Real-time monitoring systems equipped with machine learning can detect and analyze ongoing traffic conditions. By processing live data from traffic cameras, radar sensors, and vehicle-to-vehicle (V2V) communication, these systems can identify dangerous situations, such as sudden lane changes, speeding, or potential collisions. When a risk is detected, the system can alert drivers or automatically trigger safety mechanisms, like braking or lane correction.

Autonomous Vehicles

Self-driving cars are one of the most prominent examples of ML in road safety. These vehicles rely on ML algorithms to interpret data from sensors, cameras, and LiDAR to navigate roads safely. Machine learning helps these vehicles make split-second decisions, such as avoiding obstacles, following traffic rules, and maintaining a safe distance from other vehicles. Autonomous vehicles have the potential to significantly reduce human error, a major cause of road accidents.

Driver Assistance Systems

Many modern vehicles are equipped with Advanced Driver Assistance Systems (ADAS), which use machine learning to enhance safety. Features like adaptive cruise control, lane departure warning, and automatic emergency braking are powered by ML algorithms that continuously learn from driver behavior and road conditions. These systems can intervene in critical situations, such as when a driver is distracted or fatigued, to prevent accidents.

**Premkumar and Krithika****Smart Infrastructure**

Machine learning can also be applied to improve road infrastructure. Smart traffic management systems use ML to optimize traffic flow, reduce congestion, and minimize the risk of accidents. For example, intelligent traffic lights can adjust their timings based on real-time traffic data, while ML-powered speed cameras can detect and penalize speeding vehicles more effectively.

Tools and Techniques for Accident Prevention**Convolutional Neural Networks (CNNs)**

CNNs are a type of deep learning model particularly useful for image and video analysis. In road safety, CNNs can analyze footage from traffic cameras to detect anomalies, such as vehicles running red lights or pedestrians crossing roads unsafely. These detections can then trigger alerts or preventive actions.

Reinforcement Learning

Reinforcement learning is a technique where an agent learns to make decisions by interacting with its environment. In autonomous driving, reinforcement learning can be used to teach vehicles how to navigate complex road scenarios, such as merging onto highways or avoiding obstacles, by rewarding safe driving behavior and penalizing risky actions.

Natural Language Processing (NLP)

NLP can be used to analyze textual data from social media, traffic reports, or driver feedback. By understanding the context and sentiment of such data, NLP models can predict areas prone to accidents or identify common factors contributing to road incidents. For example, analyzing tweets about road conditions can help authorities identify and address hazardous areas.[3]

Sensor Fusion

Sensor fusion involves combining data from multiple sensors to create a comprehensive view of the environment. In the context of road safety, sensor fusion can integrate data from cameras, radar, LiDAR, and GPS to provide vehicles with a more accurate understanding of their surroundings. This technique is crucial for the development of reliable autonomous driving systems.

Edge Computing

Edge computing brings data processing closer to the source, enabling faster decision-making. In road safety applications, edge computing can be used to process data from sensors and cameras in real-time, allowing for immediate responses to potential hazards. This is particularly important in scenarios where even a slight delay could result in an accident.

CHALLENGES AND FUTURE DIRECTIONS**Challenges**

While the integration of machine learning (ML) in road safety holds great promise, several significant challenges need to be addressed to fully realize its potential:

Data Privacy and Security

Machine learning systems rely on vast amounts of data, including real-time location data, vehicle information, and personal details of drivers and passengers. Ensuring the privacy and security of this data is a major challenge. Unauthorized access or misuse of such sensitive information can lead to privacy violations and even pose cybersecurity risks. Regulations like the General Data Protection Regulation (GDPR) require strict data handling practices, adding complexity to the deployment of ML systems in road safety.

**Premkumar and Krithika****Data Quality and Availability**

For machine learning models to be effective, they need access to high-quality, accurate, and comprehensive data. However, obtaining such data can be challenging due to inconsistencies in data collection methods, missing data, or outdated information. In some regions, especially in developing countries, the lack of infrastructure to collect and maintain traffic data hampers the effectiveness of ML-driven solutions.

Model Interpretability

Many ML models, especially deep learning algorithms, are often described as "black boxes" because their decision-making processes are not easily interpretable. This lack of transparency can be problematic, particularly in critical applications like road safety, where understanding the rationale behind a decision is essential for trust and accountability. Developing interpretable models that can provide clear explanations for their predictions and actions remains a significant challenge.

Integration with Existing Infrastructure

Integrating machine learning systems with existing road infrastructure, vehicles, and traffic management systems is complex and often requires significant investment. Legacy systems may not be compatible with modern ML technologies, necessitating costly upgrades or replacements. Furthermore, coordinating between various stakeholders, including government agencies, automotive manufacturers, and tech companies, can be difficult.

Regulatory and Ethical Considerations

The deployment of ML in road safety raises several regulatory and ethical concerns. For instance, the use of autonomous vehicles is subject to extensive legal scrutiny, with questions about liability in the event of an accident. Ethical issues, such as how autonomous systems should prioritize decisions in life-threatening situations, also need to be carefully considered and addressed.

Real-World Complexity

The real-world driving environment is highly complex and unpredictable, with countless variables influencing road safety. Machine learning models must be trained to handle diverse scenarios, including rare and extreme events that may not be well-represented in the training data. Achieving robust performance in such a complex environment requires continuous learning and adaptation of ML systems.

Future Directions

Despite these challenges, the future of machine learning in road safety is promising, with several key areas of development that could significantly enhance its impact:

Advanced Sensor Technologies

The continued advancement of sensor technologies, such as LiDAR, radar, and high-definition cameras, will provide more accurate and detailed data for ML models. These sensors, combined with improvements in sensor fusion techniques, will enable better detection and understanding of the driving environment, leading to more effective accident prevention systems.

Edge AI and Real-Time Processing

As edge computing becomes more prevalent, ML models will increasingly be deployed on local devices, such as in-vehicle systems or roadside units. This shift will allow for real-time data processing and decision-making, reducing latency and enabling faster responses to potential hazards. Edge AI will also help reduce the reliance on centralized cloud infrastructure, improving the scalability and resilience of road safety systems.

Collaborative Machine Learning

Collaborative machine learning approaches, such as federated learning, allow models to be trained across multiple devices or organizations without sharing raw data. This technique can enhance privacy while enabling the

**Premkumar and Krithika**

development of more accurate and generalized models. In the context of road safety, collaborative ML could facilitate the sharing of knowledge between different regions or vehicle fleets, leading to more robust safety systems.

Human-Machine Interaction

Improving the interaction between human drivers and machine learning systems is a crucial area of future research. Developing intuitive interfaces and feedback mechanisms will ensure that drivers understand and trust the ML-based safety features in their vehicles. Additionally, research into driver behavior and cognitive load will help in designing systems that effectively support, rather than overwhelm, human operators.

Regulatory Frameworks and Standards

As ML technologies become more integrated into road safety, there will be a need for clear regulatory frameworks and industry standards to govern their deployment and use. Governments and industry bodies will need to collaborate to establish guidelines that ensure the safety, reliability, and ethical use of ML in road safety applications. These standards will also need to evolve to keep pace with technological advancements.

Continual Learning and Adaptation

The dynamic nature of road environments requires ML models that can continuously learn and adapt to new conditions. Future research will focus on developing models that can update themselves in real-time based on new data, ensuring that they remain effective even as traffic patterns, weather conditions, and vehicle technologies change.

Global Collaboration

Addressing roadway safety is a global challenge that requires international cooperation. Sharing best practices, data, and research findings across borders will be crucial for the widespread adoption and improvement of ML-based road safety solutions. Collaborative efforts, such as international research consortia and cross-border regulatory initiatives, will help accelerate the development and deployment of effective ML technologies.

CONCLUSION

Machine learning is poised to revolutionize road safety, offering innovative tools and techniques to predict, prevent, and mitigate accidents. While significant challenges remain, including data privacy, model interpretability, and regulatory concerns, ongoing advancements in technology and collaboration promise a future where roads are safer for everyone. As machine learning continues to evolve, it will play an increasingly critical role in reducing roadway accidents, ultimately saving lives and improving the quality of life for millions around the world.

ABSTRACT

The daily volume of digital photos taken is skyrocketing, which is driving up demand for more precise and eye-catching photos. However, noise invariably deteriorates the photos taken by contemporary cameras. Noise reduces the visual quality of the images and can be brought on by a number of factors, like dim lighting, higher settings in ISO mode, or the inherent limits of camera sensors. The noise may show up as erratic changes in color or brightness, which will pixelate and blur the images. It is crucial to develop methods that can effectively reduce noise while preserving the image's crisp edges and structures in order to preserve the image's overall clarity and detail. Researchers have put forth several different approaches to noise reduction throughout the years, all of which attempt to achieve a compromise between detail retention and noise suppression. Traditional methods, for instance, spatial domain filtering methods such as mean, median, and Gaussian filters, have been widely used due to their simplicity and ease of implementation. However, these techniques frequently lead to an imbalance between the blurring of visual details and noise reduction. To address these limitations, more advanced techniques like wavelet transform methods have been developed, which allow for multi-scale analysis of the image, thereby enabling better noise reduction with minimal loss of detail.

Keywords: Deep Learning, Visual Clarity, Image Processing, Noise Artifacts, Generative Adversarial Networks (GANs),

INTRODUCTION

Because of the surroundings, the transmission channel, and other factors, noise always taints images during acquisition, compression and transmission. Loss of picture information and distortion result from this. Auxiliary image processing tasks like tracking picture, analysis and multi-media processing. Image denoising is therefore crucial to modern image processing systems. The technique of denoising involves removing noise from a noisy picture in order to create the original. However, some details may be lost in the denoised photos since texture, edge, during the denoising process, it might be difficult to discern high frequency parts from noise. With all of this in mind, one of the main problems of the present period is to make high-quality photos by simultaneously reducing noise and extracting meaningful information from noisy photos. Actually, there has been a ton of research on the well-known issue of image denoising. This work is still challenging and unfinished. This is mainly due to the inverse nature of picture denoising [1-4], for which there is a non-unique mathematical solution. The following sections provide a summary of the key advancements made in the field of photo denoising during the last few decades.

Problem statement for image denoising

The following is a mathematical representation of the image denoising problem:

$$x = y + a$$

If "y" is the unknown clean picture, "x" is the observed noisy picture, and "a" is the AWGN (Additive White Gaussian Noise) with deviations like standard " σ a". In real-world scenarios, AWGN can be estimated using a variety of techniques, including as PCA (Principle Component Analysis) kind of approaches [7], block-based estimates [6], and median absolute deviation [5]. Reducing noise in original photographs while preserving original features and enhancing SNR (Signal to Noise Ratio) is the aim of noise reduction. The following are the main issues with image denoising:

- Smoothness is desired in flat places.
- Edges must to be safeguarded without obscuring
- Textures ought to be kept.
- It is not appropriate to create new artifacts.

Since it is ill-posed to solve the clean image "y" from Equation (1), it is impossible to deduce the distinct outcome of the noisy picture model. The discipline of image processing has conducted a great deal of study on image x, or picture denoising, in the last few years. Spatial domain approaches and represents transform methods in their domains are the two basic categories into which picture denoising techniques can be broadly grouped [3].

Conventional denoising technique

The goal of spatial domain approaches is to reduce noise by utilizing the relationship between pixels and picture spots in a raw image to ascertain each pixel's gray value. [8]. Variation denoising and spatial domain filtering are the two basic categories of spatial domain operations.

Filtering by spatial domain

Picture denoising has employed a variety of spatial filter, which are further separated into two categories: linear, non-linear filters [9–19], as filtering is a popular image processing technique. Although they can't preserve the textures of images, filters were once employed to eliminate noises in the spatial domain. While Gaussian noise reduction has been achieved using mean filtering [14], high noise image quality may be too smoothed [15]. Although Wiener filtering [16, 17] may easily reduce sharp edges, it has also been employed further to overcome this limitation. By employing filters like non-linear median filter [14, 18] and weighted median filter [19], it is possible to lessen noise without being noticed. One popular non-linear smoothing filter for image denoising that preserves edges while reducing noise is bilateral filtering [10]. Given that noise exists in higher frequency ranges, spatial filters low pass

Suganthi and Yogeshwari

filter sets of pixels. Usually, spatial filters blur the image and remove sharp edges in order to reduce noise to a reasonable degree.

CNN-driven denoising techniques

Lately, CNN-based methods have made rapid progress and demonstrated strong performance in various low-level computer vision applications. CNNs were initially developed as five-layer networks for the purpose of photo denoising. Numerous denoising algorithms based on CNN have been made available in recent years. Compared to reference, these approaches' performance has greatly increased [20]. Furthermore, there are two categories of CNN-based denoising algorithms: Models of MLP like Multi Layer Perceptron with deep learning methods.

Multi-Layer Perceptron Models

One layer Perceptron based image denoising models are one kind of auto encoder that has been proposed by 'Vincent, Xie et al.' more effective denoising was achieved with a feed forward neural network model known as Trainable Nonlinear Reaction Diffusion (TNRD) introduced by Chen et al. There are numerous benefits to this class of techniques. First of all, the fact that fewer stages of ratiocination are needed makes these strategies effective. Furthermore, these approaches are simpler to understand because optimization techniques have the potential to extract the discriminative architecture. Interpretability, however, may raise the performance cost; the MAP model, for example, limits the ability to draw conclusions and use acquired priors.

Deep learning Network techniques for denoising

A Neural network (CNN) are often the first step in the most advanced deep learning denoising techniques. The deep learning neural networks based denoising algorithms' general model is defined as

$$\min_{\theta} \text{Loss}(\hat{x}, x), s. t. \hat{x} = F(y, \sigma; \Theta)$$

When the loss function is shown by $\text{loss}(x, \hat{x})$ and a CNN with parameter set Θ is represented by " $F(y)$ ". The difference between the ground-truth x and the denoised picture \hat{x} is measured using loss function. There has been a lot of interest in deep learning-based denoising techniques due to their amazing ability to reduce noise. Zhang et al. first used batch standardization and relative learning for image denoising. The Deep CNN or DnCNN aims to study a method " $\hat{x} = F(y; \Theta, \sigma)$ " that transfers from " y to x " parameters " $\Delta\sigma$ " are trained for noisy images with a standard static variance " σ ". The model learns how to map functions by residual learning, along with batch normalization to improve denoising results and expedite training. More precisely, it appears that batch normalization and residual learning are consistent together to enhance training speed and denoising efficiency. Even though a trained DnCNN is relatively good at handling errors in interpolation and compression, other noise variations are unsuitable regarding the model we trained in " σ ." If the users are unsure about the volume of noise " σ ", the denoising technique ought to allow them to trade-off between texture protection and noise suppression automatically. To achieve these desired qualities, FFDNet, a convolutional neural network with rapid and adaptable denoising, was created. Specifically, the major contribution of FFDNet able to described as " $\hat{x} = F(y, M; \Theta)$ " where " M " is a distortion level map." M is an input for FFDNet, and the noise level parameter set Θ is fixed. FFDNet's ability to operate on down-sampled sub-images accelerates training and testing while simultaneously increasing the receptive field, which is another significant contribution This technique is effective and quick, but the learning process has a very high temporal complexity. High-level feature learning has been enhanced by CNN-based denoising approaches through the use of a hierarchical network.

Denoising performance metrics:

The performance metrics of image denoising algorithms are evaluated using the "Peak Signal-to-Noise Ratio" and index of structural similarity: When a base truth picture " x " is provided, the Peak Signal-to-Noise Ratio of a noise less image " \hat{x} " is determined by

$$SSIM(x, \hat{x}) = \frac{(2\mu_x\mu_{\hat{x}} + C_1)(2\sigma_{x\hat{x}} + C_2)}{(\mu_x^2 + \mu_{\hat{x}}^2 + C_1)(\sigma_x^2 + \sigma_{\hat{x}}^2 + C_2)}$$

Suganthi and Yogeshwari

Where " $\sigma^{x^{\wedge}x}$ " is the co-variance between " x " and " $^{\wedge}x$ ", also C1 C2 are the constants required to minimize turbulence. The symbols " $\mu^{x^{\wedge}x}$ "; " $\rho^{x^{\wedge}x}$ "; " σ_x ", and " $\sigma^{x^{\wedge}x}$ ", respectively, stand for the ratio of means and variances of ' x ' and " $^{\wedge}x$ ". " x " and " $^{\wedge}x$ ", respectively; the co-variance between x and " $^{\wedge}x$ " is represented by $\sigma^{x^{\wedge}x}$; constant values C1C2 are employed to prevent turbulence. The visual evaluation in Fig. 1 demonstrates how the TV-based regularization's denoising result smoothes the textures and produces artifacts. In the meantime, Given that the clear patches underneath contain comparable characteristics and can therefore be roughly represented by a sparse coding issue, we find that the sparse coding scheme and the representative low-rank-based approaches perform better in homogenous regions.

CONCLUSION

Due to the increasing complexity and demands of picture denoising, there is still a great need for research in this field. We have examined the benefits and drawbacks of several image denoising methods in this study and presented the most recent advancements in the field. Notable breakthroughs in image denoising approaches in recent times include low-level and sparse representation. Recently, the traditional local denoising model has been replaced by the emergence of NLM, opening up a new theoretical area. The number of successful CNN-based methods has increased dramatically in recent years, even with the ubiquitous use of low-rank priors and image sparsity. This study aims to give a broad view of denoising approaches. Noise analysis can be helpful in creating new denoising techniques because different types of noise call for different denoising techniques. We must first investigate strategies for handling different kinds of noise, particularly those that come up in day-to-day activities, for our upcoming work. Second, more work needs to be done in this area as deep models cannot yet be trained without image pairings. There are other scenarios in which the image denoising technique can be used.

ABSTRACT

Electrocardiogram (ECG) signs give essential information about the heart's electrical activity, so correctly classifying them is crucial for finding heart problems. Combining deep learning with optimization methods makes these classifications more accurate, leading to better health results. This study shows a new way to classify ECG signals using a deep learning system that is improved by the Whale Optimisation Algorithm (WOA) and combines the ReliefF and iterative Neighbourhood Component Analysis (RFINCA) feature selection methods. The suggested method starts by using ReliefF to find the most essential features in the ECG data. These features are then improved using iterative NCA, focusing on the ones that have the most significant effect on the accuracy of the classification. In the next step, WOA is used to improve the model's settings after the best set of features has been used. Adding feature selection and optimization to the deep learning design makes it easier for the model to correctly describe ECG data, showing that it is more accurate and reliable than older methods. The RFINCA-WOA system could be helpful in real-time ECG analysis, which could help find and treat cardiovascular diseases earlier.

INTRODUCTION

As technology in the field of information has grown, fingerprint signal recognition has become an increasingly important way to keep information safe. Traditional biometric signal detection systems mostly use fingerprints, faces, irises, and other bodily traits [1,2,3]. These body traits have pros and cons. The pros are that they make it easier to copy and fake, and the cons are that they make it easier to recognize people faster and more accurately [4,5]. The electrocardiogram (ECG) beat has recently been used to identify people. The ECG signals can only be recorded in a live person, unlike the outward bodily traits of animals. This makes the ECG identity method hard to fake, which can make the access control system safer and keep essential data from being stolen. ECG signs are also global, unique, stable, and measurable [6]. Smartwatches and other small devices that collect ECG signals have become possible thanks to progress in the technology used to collect ECG data. Because of this, identifying people using ECG data has many uses [7]. There are two significant areas of study in identifying people using ECG signals: finding ECG signals and figuring out who they belong to. Part of detection is preprocessing ECG signals to get data that is easy to describe. Classification methods are used to identify the data detected as part of identification. You can find two kinds of ECG signals: those that are benchmarked and those that are not [8,9]. To get to the standard, you need to sort the ECG data [10,11,12] and give each P wave, QRS wave, and T wave a name. You can do this by looking at things like time and strength. It could be more accurate, though, because small changes in where the tracking point is placed can cause mistakes in labelling. We don't use trait points with this method. Still, it's hard to find things in that area, and it takes a long time because there is so much info. The study's central question is how to lessen trait information while making the system more accurate. The support vector machine (SVM) and the backpropagation neural network (B.P.) can explain an ECG. However, these methods must be more exact and good enough to find more than one target. Better methods exist, such as deep learning, convolutional neural networks, and more. These work very well, but they require very strong computers. Figure 1 shows the ECG name recognition block diagram suggested in this study. With the help of a local windowed wavelet transform, it can also be used to find the times of P and T waves. It is possible to ensure the extraction accuracy of the R peak is manageable with local windowed wavelet transform. Second, the probability neural network (PNN) method determines what kind of ECG it is. One of the best things about the PNN multi-target classification method is that it is easy to use, converges quickly, and can handle significant sample errors. Lastly, the PNN algorithm is better in terms of accuracy and difficulty. First, the factors are picked using the mean impact value (MIV) method. This removes the characteristic values that cause significant problems in the ECG recognition and extraction process. It also makes the technique more accessible to understand. On the other hand, the whale planning method uses a probability neural network called WOA-PNN. If you want to improve the accuracy of the model classification, you can use WOA. This eliminates the need to set the smoothing factor for the PNN method purposefully.

The contributions of this paper are as follows:

This method lets you find where the P and T waves begin and finish. This can help avoid the problem of a too-big R peak, which can make the extraction less accurate. The MIV algorithm is used to make the method easier to understand and to get better results for ECG classification in the PNN. It eliminates the characteristic values that lead to big mistakes in the detection or extraction process. The WOA-PNN method is suggested for adaptively improving the hyperparameters to make the ECG recognition model more accurate. Three sets of ECG signals were tested to see if the suggested method would work. Two signals were standard, and the third set was for arrhythmia. Here's how the rest of this paper is put together: In Part 2, wavelet transform is used to show how to find patterns in an ECG. In Section 3, the WOA-PNN method is used to recognize the ECG and the ECG aspects are used to choose the variables. Different ECG database models are used in Section 4 to compare and analyze various ways and see how valuable and reliable the method is. Finally, the findings are discussed, and Section 5 comes to a close.

Whale Optimisation Method

Mirjalili and Lewis [9] created the Whale Optimisation Algorithm in 2016. It was based on how humpback whales hunt. [16] Most hunting animals circle or hit their Prey with a bubble net. Sometimes, they look for their food. The WOA discusses the math model that goes with the three types of violent actions.

Encircling Prey

As this step progresses, the Whale Optimisation Algorithm copies how humpback whales look for food and circle it. The goal food is the best option for the present population. [16] During this phase, the goal is to quickly cut down the search and centre on the possible best option. The following math method can be used to explain this behaviour:

$$X(t + 1) = X^* - A \cdot D_1 \tag{1}$$

$$D_1 = |C \cdot X^* - X(t)| \tag{2}$$

which has t as the current iteration number, X(t+1) as the next search position, X(t) as the current iteration position, and X* as the best spot for the catch in this case. Number 1 shows how far away the whale is from the food at number 1. [17] The scientific methods that were used to find A and C are listed below:

$$A = 2a \cdot r - a \tag{3}$$

$$C = 2 \cdot r \tag{4}$$

r stands for random numbers between 0 and 1, and an is the convergence factor, which goes from 2 to 0 as the number of iterations increases.

Bubble-Net Attacking

It moves back and forth like a humpback whale eating during the bubble-net attack phase. [18] During this phase, the whale moves in a loop towards where it thinks its food is. You can use the following math method to explain this behaviour:

$$X(t + 1) = D_2 \cdot e^{bl} \cdot \cos(2\pi l) + X^* \tag{5}$$

$$D_2 = |X^* - X(t)| \tag{6}$$

a2 is the distance between the whale and its food right now. This is the best choice. [19] ebl and cos(2πl) make up the mathematical model of the spiral path. b is a constant that forms the spiral, and l is a random number in the range [-1, 1]. Any number between 0 and 1 can be p (20).

$$X(t + 1) = \begin{cases} X^* - A \cdot D_1, & \text{if } p < 0.5 \\ D_2 \cdot e^{bl} \cdot \cos(2\pi l) + X^*, & \text{if } p \geq 0.5 \end{cases} \tag{7}$$

Search for Prey

The find prey step in WOA is a word search for new parts of the solution space that could be targeted. During this phase, whales randomly pick a search object and move based on it. [21] The following expression can be used to describe this behaviour:

$$X(t + 1) = X_{rand}(t) - A \cdot D_3 \tag{8}$$

$$D_3 = |C \cdot X_{rand}(t) - X(t)| \tag{9}$$

The random target, in this case, is a whale whose position is given by Xrand(t), and D3 gives the distance between this person and the random target. [23] We will use equations 3 and 4 to find A and C. Figure 1 shows that the choice of the three behaviours depends on A and p. If O is less than or equal to 0.5, the spiral bubble-net attack is used [24]. If P is equal to or greater than 0.5, the circular prey attack is used. Global exploration is done if |B|≥1 and O<0.5.

MATERIALS AND DATA PREPROCESSING

Figure 3 shows the proposed system. The ECG signal is first put through some steps to turn it into raw data. Next, this information is sent to the unfriendly domain adaptable model to be taught. A final classification result is achieved by combining the features automatically pulled from the model with the features taken by hand.

Selvapriya and Kavitha

ECG Dataset

The first ECG signs are on all the papers; at least two cardiologists have signed them. There are 15 different kinds of these heartbeats, which can be seen in Table 1. ANSI/AAMI EC57:2012 says that the 15 types of arrhythmia can be broken down into five groups: normal heartbeat (N), supraventricular ectopic heartbeat (S), ventricular ectopic heartbeat (V), fusion heartbeat (F), and unknown heartbeat (Q). Figure 3 shows the collection of pictures of these groups. The MIT-BIH database clearly shows the ML II QRS complex (modified limb lead II). In this test, only 44 recorded MLII leads were used to sort the ECG. Two major types of standard ways to split datasets exist the inpatient paradigm and the outpatient paradigm. The information used in this experiment was divided into an outpatient model to make the results more accurate and convincing. Records 102, 104, 107, and 217.2 were thrown out because they had no heartbeats from the sinus node. There are two sets of these 44 records: DS1 and DS2. In this trial, Table 2 summarises the dataset review method. The Q-type data was taken out because it is too small to judge how well it was classified.

Data Preprocessing

The original data needs to be cleaned up before being fed into the model to be trained. As shown in Figure 4, this stage mainly comprises the steps below. This is because everyone's R peaks are not all the same distance apart. If you only split the heartbeat by a certain number of data points, you will miss some critical signal parts. The following method of heartbeat division and pulse unity fix this issue.

1. You can clean up the data with the discrete wavelet transform (DWT) and the band pass filter F_{band} with a minimum frequency of (0.5,40). They can clean up the ECG data by eliminating EMG, MA, and B.W. noise.
2. To divide the heartbeat into segments, read the R peak point on the pulse sticker. Let's say that V_i is the highest point of the Rth heartbeat. The beating starts at $[12(V_i-1+V_i)]$ and ends at $[12(V_i+V_{i+1})]$ if you round down to n. Now, $H_c = (12)(i+V_{i+1}) \times - (12)(V_i-1+V_i) \times +1$.
3. If you split the heartbeat into several parts, the number of sampling points H_c changes for each part. Before we can move on to the deep-learning model, the hearts have to beat simultaneously. D is the number of points that were picked after the first one. If H_c is less than D, add 0s until it reaches D. If H_c is more significant than D, cut it off at D [28]. The beating is H_c^{\wedge} when everything is over.
4. Heartbeats that are all the same and come simultaneously: data standardization To find H_c 's Z-score, use the formula $Tf = Tf - \square \square$. We don't have to worry about signal change and noise scale anymore.
5. Extracting time features: Six-time features must be extracted by hand to get the normalized pre-RR and the normalized post-RR after normalization.
6. Data augmentation: The SMOTE method creates new groups of data with the same number of samples in each group, making the data more even.

Classification

The size and number of features are made better by optimizing the C code. In Section 2.2, six-time features were collected. These are added to the source domain data's fully linked layer features. These are sent to the classifier after being combined with the Softmax layer features. This adds more features by combining deep-learning extraction features with time features. The correct form is shown in Figure 5. You can see how the C Block is put together and what each block does in Table 5.

Figure 5. The arrangement of a block for categorization. Rectified Linear Unit, or ReLU. Conv_(kernel size)_(kernel number) and Maxpool_(kernel size)_(kernel number) respectively represent the convolutional layer and Maxpool layer.

Training Process

It means that the instance sample has labels in the source domain D_s when $(x_{si}, s_i) \}_{n_{si}=1}$. If $bbintj=1$, you can see that the example sample doesn't have any names in the target domain D_t . It is true that $F(\bullet)$ and $C(\bullet)$ group traits together. The objective of the learning phase is to acquire knowledge about a task classifier C and a feature extractor F that will reduce the anticipated loss of the target, bring the data distribution in the source domain into alignment with the data distribution in the target domain, and reduce the disparities that exist across the domains. In each of

Selvapriya and Kavitha

the three parts, F, D, and C, there are three distinct types of networks. They are called X, X, and X in that hierarchy. This joint loss function $D(\square_c, \square_c, \square_d)$ is seen in Figure 10.

$$E(\omega_f, \omega_c, \omega_d) = \sum_{t=1..N} L_c(G_c(G_f(X_t; \omega_f); \omega_c), y_t) - \lambda \sum_{t=1..N} L_d(G_d(G_f(X_t; \omega_f); \omega_d), y_t) \tag{10}$$

$$= \sum_{\substack{t=1..N \\ d_i=0}} L_c^l(\omega_f; \omega_c) - \lambda \sum_{t=1..N} L_d^f(\omega_f; \omega_d) \tag{11}$$

It comprises two main parts: the classification loss Xc and the area split loss Xd . Each of them has two loss functions in the i th training set. They are shown by and. The B_e chose a targeted loss over the more common cross-entropy loss. The settings for the multiscale feature extraction module are f , those for the classification module are \square_c , and those for the domain discrimination module are \square_d . It tells you how much each goal is worth. If $d_i=0$, the i th sample comes from the source area. In Formulas (12) and (13), you can see the steps for training.

$$(\widehat{\omega}_f, \widehat{\omega}_c) = \arg \min_{\omega_f, \omega_c} E(\omega_f, \omega_c, \widehat{\omega}_d) \tag{12}$$

$$(\widehat{\omega}_d) = \arg \max_{\omega_d} E(\widehat{\omega}_f, \widehat{\omega}_c, \omega_d) \tag{13}$$

RESULT AND DISCUSSION

When WOA is used in the ANC filter, the P, Q, R, and S pulses' magnitude improves. The WOA method works better than PSO, MPSSO, and ABC techniques because it correctly picks up ECG signals. When you compare the input SNR to the output SNR, MSE, and M.E., the WOA method increases the quality of the product. The PSO, MPSSO, and ABC methods are better than this one. We get good SNR, MSE, and M.E. for ECG data when we use the terrible standard function F1. Figures 6,7 and 8 shows the performance comparison among the various methods.

F1's best number in the target space is 1.572e-65, and its response is 2.7329e-28. Table 6 compares the final SNR with the raw SNR for several ECG beats. Table 2 illustrates how MSE varies with SNR changes. Table 6 shows you how M.E. compares to raw SNR.

CONCLUSIONS

An effective ANC filter based on WOA was created to eliminate noise in the ECG output. Regarding accuracy factors like SNR, MSE, and M.E., the WOA works better than the PSO, MPSSO, and ABC methods. You get the best result when you compare the WOA ANC filter to PSO, MPSSO, and ABC techniques. Compared to PSO, MPSSO, and ABC, this is a beautiful approach to getting higher SNR, MSE, and M.E. values. Swarm optimization methods like PSO, MPSSO, and ABC take longer to finish than the WOA, so it is used to compare it to other methods in more depth.

ABSTRACT

In this paper, the star edge coloring of some simple graphs such as Bistar graph, Comb graph, Mobius Ladder graph, Flag graph, Tadpole graph, Lollipop graph, n-Barbell graph, Butterfly graph, Crown graph have been considered and the star edge chromatic number χ_E is obtained for such graphs.

It is proved that for given positive integers n,m

$$i) \chi_E((k_{1,n}; k_{1,m})) = \begin{cases} m + 1 & \text{if } m > n \\ n + 1 & \text{if } n > m. \end{cases}$$

$$ii) \chi_E(P_n^+) = \begin{cases} 3 & \text{if } n \leq 4. \\ 4 & \text{if } n > 4. \end{cases}$$

$$iii) \chi_E(M_n) = n + 3 \text{ if } n \geq 2$$

$$iv) \chi_E(Fl_n) = \begin{cases} 3 & \text{if } n = 3 \\ 4 & \text{if } n \geq 4 \end{cases}$$

$$v) \chi_E(T_{m,n}) = 4 \text{ if } m \geq 3, n \geq 2$$

$$vi) \chi_E(L_{(m,n)}) = m + 1 \text{ if } m \geq 3, n \geq 2$$

$$vii) \chi_E(n, \text{ barbell graph}) = \begin{cases} 4 & \text{if } n = 3 \\ n + 2 & \text{if } n \geq 4 \end{cases}$$

Keywords: Edge Coloring, Star edge coloring, Star edge Chromatic Number.

Subhathra and Suseela

INTRODUCTION

All graphs considered here are finite, simple undirected connected graphs.

$B_{n,m}$ Graph [11]

The graph $B_{n,m}$ [11] is the graph obtained by joining the center u of the star $K_{1,n}$ and the center v of another star $K_{1,m}$ to a new vertex w . It is denoted by $\langle K_{1,n}, K_{1,m} \rangle$

Comb Graph [11]

The comb $P_n \odot K_1$ [11] is the graph obtained from the path P_n by attaching pendant edge at each vertex of the path. It is also denoted by P_n^+ .

Mobius Ladder Graph [11]

The mobius ladder M_n [11] is the graph obtained from the ladder $P_n \times P_2$ by joining the opposite end points of the two copies of P_n .

Flag graph Fl_n [11]

The flag Fl_n [11] is obtained by joining one vertex of C_n to an extra vertex called the root.

Tadpole Graph [11]

The (m, n) - tadpole graph [11] also called a dragon graph, is the graph obtained by joining a cycle graph C_m to a path graph P_n with a bridge.

Lollipop graph [11]

The (m, n) - lollipop graph [11] is the graph obtained by joining a complete graph K_m to a path P_n with a bridge.

n-Barbell graph[11]

n- barbell graph is the simple graph obtained by connecting 2 copies of complete graph K_n by a bridge. Through this area in multidimensions. It has many applications in various fields, one such application is estimation of sparse hessian matrix using coloring technique. The applications in various fields motivated me to do this work.

Star Edge Coloring of some simple Graphs

Star edge coloring of Bistar graph (B_n, m)

Theorem 2.1.1:

For given positive integers n, m

$$\chi_E((k_{1,n}; k_{1,m})) = \begin{cases} m + 1 & \text{if } m > n \\ n + 1 & \text{if } n > m. \end{cases}$$

Proof:

$B_{n,m}$ has $n+m+3$ vertices and $n+m+2$ edges.

The pendent Edges of n and m are colored with different colors.

The edge connects pendent edges with the graph is colored with another two different colors except the pendent edge colors.

Irrespective of n and m , B_n, m is star edge colored with $m+1$ color if $m>n$, and also, it is star edge colored with $n+1$ color if $n>m$

Subhathra and Suseela

Hence

$$\chi_E(\langle k_{1,n}; k_{1,m} \rangle) = \begin{cases} m + 1 & \text{if } m > n \\ n + 1 & \text{if } n > m. \end{cases}$$

Illustration 2.1.1

The Star edge coloring of $\langle k_{1,n}; k_{1,m} \rangle$ is as follows. Here m and n are equal

Illustration 2.1.2

The Star edge coloring of $\langle k_{1,n}; k_{1,m} \rangle$ is as follows. Here m and n are not equal (i.e.) n=2 and m=4

Therefore $\chi_E(\langle k_{1,2}; k_{1,4} \rangle) = 5$

Star Edge Coloring of Comb Graph (P_n)

Theorem 2.2.1:

For given positive integers $n \geq 5$ $\chi_E(P_n^+) = \begin{cases} 3 & \text{if } n \leq 4. \\ 4 & \text{if } n > 4. \end{cases}$

Proof

P_n^+ has $2n$ vertices and $2n-1$ edges. The pendant edges are $e_1, e_2, e_3 \dots e_n$ and the edges adjacent to it are

$e_{n+1}, e_{n+2}, e_{n+3} \dots e_{2n-1}$.

The edge colors are $e_1, e_2, e_3 \dots e_n, e_{n+1}, e_{n+2}, e_{n+3} \dots e_{2n-1}$ denoted by $C(E_i)$ where $i = 1, 2, 3, \dots, n, n+1, \dots, 2n-1$.

The star edge coloring pattern for $n \leq 4$ is as follows:

$$C(E_i) = \begin{cases} 1 & \text{if } i = 1, 2, 3 \\ 2 & \text{if } i = 4, 6 \\ 3 & \text{if } i = 5 \end{cases}$$

The star edge coloring pattern for $n > 4$ is as follows:

$$C(E_i) = \begin{cases} 1 & \text{if } i = 1, 2, 3 \\ 2 & \text{if } i \equiv 0 \pmod{3} \\ 3 & \text{if } i \equiv 1 \pmod{3} \\ 4 & \text{if } i \equiv 2 \pmod{3} \end{cases}$$

Hence, the star edge chromatic number of P_n^+ is

Subhathra and Suseela

$$\chi_E(P_n^+) = \begin{cases} 3 & \text{if } n \leq 4. \\ 4 & \text{if } n > 4. \end{cases}$$

Illustration 2.2.1.

The star edge coloring of P_6^+ is as follows

Hence $\chi_E(P_6^+) = 4$

Star Edge Coloring of Mobius Ladder Graph (M_n)

Theorem 2.3.1:

For given positive integers n , $\chi_E(M_n) = n + 3$ if $n \geq 2$

Proof

M_n has $2n$ vertices and $5n-4$ edges. Let the vertices be considered in two layers as

V_1, V_2, \dots, V_n and V'_1, V'_2, \dots, V'_n respectively.

Let e_i denote the edges where $i = 1, 2, 3 \dots n$. we consider n vertices assigned the star edge coloring of the graph with $n+3$ colors if $n \geq 2$.

Hence $\chi_E(M_n) = n + 3$ if $n \geq 2$.

Illustration 2.3.1

The star edge coloring of M_n is as follows

Therefore $\chi_E(M_4) = 7$

Star Edge Coloring of Flag Graph (Fl_n)

Theorem 2.4.1

For given positive integers n , $\chi_E(Fl_n) = \begin{cases} 3 & \text{if } n = 3 \\ 4 & \text{if } n \geq 4 \end{cases}$

Proof

A Flag graph has $n+1$ vertices and $n+1$ edge.

Let $e_1, e_2, e_3 \dots e_n, e_{n+1}$ denotes the edges of Fl_n and e_n connects C_n to the root edge e_{n+1} .

Subhathra and Suseela

Let E_i denotes the edges of Fl_n where $i = 1, 2, 3, \dots, n+1$ and $C(E_i)$ denote the color of E_i .

The edge coloring pattern is discussed as follows if $n=3$.

$$C(E_i) = \begin{cases} 1 & \text{if } i = 1, 4 \\ 2 & \text{if } i = 3 \\ 3 & \text{if } i = 2 \end{cases}$$

Then the root edge is colored with anyone of that color.

The edge coloring pattern is discussed as follows if $n \geq 4$.

$$C(E_i) = \begin{cases} 1 & \text{if } i \equiv 0 \pmod{4} \\ 2 & \text{if } i \equiv 1 \pmod{4} \\ 3 & \text{if } i \equiv 2 \pmod{4} \\ 4 & \text{if } i \equiv 3 \pmod{4} \end{cases}$$

We consider the star edge coloring of the graph has $n \geq 4$ vertices, we have to assign four different colors to the edges and the root edge colored with anyone of the four colors.

Hence $\chi_E(Fl_n) = \begin{cases} 3 & \text{if } n = 3 \\ 4 & \text{if } n \geq 4 \end{cases}$

Illustration 2.4.1

The star edge coloring of Fl_n is as follows.

Hence $Fl_3 = 3$

Illustration 2.4.1

The star edge coloring of Fl_{10} is as follows.

Hence $Fl_{10} = 4$

Star Edge Coloring of Tadpole Graph ($T_{m,n}$)

Theorem 2.5.1:

For given positive integers $m \geq 3, n \geq 2$, the star coloring of Tadpole graph

$\chi_E(T_{m,n}) = 4$ if $m \geq 3, n \geq 2$

Proof

A tadpole graph has $m+n$ vertices and $m+n$ edges. Let $e_1, e_2, e_3 \dots e_m, e_{m+1}, e_{m+2}, \dots, e_{m+n}$ be the edges of $T_{m,n}$ and denotes the color of $C(E_i)$ of E_i .

Subhathra and Suseela

The Star edge coloring of the cyclic graph is colored with four different colors and also, we assign same colors to the path graph P_n with bridge.

Therefore, the star coloring of Tadpole graph

$$\chi_E(T_{m,n}) = 4 \text{ if } m \geq 3, n \geq 2.$$

Illustration 2.5.1

The star edge coloring of $T_{6,2}$ is as follows

Hence $\chi_E(T_{6,2}) = 4.$

Star Edge Coloring of Lollipop Graph ($L_{m,n}$)

Theorem :2.6.1

For given positive integers m, n for every $m \geq 3, n \geq 2$

$$\chi_E(L_{(m,n)}) = m + 1$$

Proof

The (m,n) -lollipop graph has $m+n$ vertices and $\binom{m}{2} + n$ edges. As m is complete we need 'm' colors irrespective of n , the same colors used in 'm' is repeated to color 'n'.

'm+1' colors are needed to star edge color $L_{m,n}$.

$$\chi_E(L_{(m,n)}) = m + 1 \text{ if } m \geq 3, n \geq 2.$$

Illustration 2.6.1

The star edge coloring of $L_{5,2}$ is as follows

Hence $\chi_E(L_{(5,2)}) = 6$

Subhathra and Suseela

Star edge coloring of n- Barbell Graph.

Theorem 2.7.1:

For given positive integer n,

$$\chi_E(n, \text{barbell graph}) = \begin{cases} 4 & \text{if } n = 3 \\ n + 2 & \text{if } n \geq 4 \end{cases}$$

Proof

Let G and G' be an n- barbell graph which has 2n vertices and $2 \binom{n}{2} + 1$ edges.

To Star edge color G and G' are the simple graph obtained by connecting 2 copies of complete graph K_n , by a bridge.

First edge color to G with different colors and also assign same edge color to G'.

By connecting the complete graph G and G', we assign different color to a bridge.

Hence $\chi_E(n, \text{barbell graph}) = \begin{cases} 4 & \text{if } n = 3 \\ n + 2 & \text{if } n \geq 4 \end{cases}$

Illustration 2.7.1:

The star edge coloring of 3-Barbell graph is as follows

Hence $\chi_E(3, \text{barbell graph}) = 4$

Illustration 2.7.2

The star edge coloring of 5-Barbell graph is as follows.

Hence $\chi_E(5, \text{barbell graph}) = 7$

CONCLUSION

In this paper, it is proved that the star edge coloring pattern of some simple graphs such as Bistar graph, Comb graph, Mobius Ladder graph, Flag graph, Tadpole graph, Lollipop graph, n-Barbell graph, have been obtained and also the star edge chromatic number χ_E is obtained for such graphs. It is proved that for given positive integers n, m.

Subhathra and Suseela

$$\begin{aligned}
 \text{i) } \chi_E((k_{1,n}; k_{1,m})) &= \begin{cases} m + 1 & \text{if } m > n \\ n + 1 & \text{if } n > m. \end{cases} \\
 \text{ii) } \chi_E(P_n^+) &= \begin{cases} 3 & \text{if } n \leq 4. \\ 4 & \text{if } n > 4. \end{cases} \\
 \text{iii) } \chi_E(M_n) &= n + 3 \text{ if } n \geq 2 \\
 \text{iv) } \chi_E(Fl_n) &= \begin{cases} 3 & \text{if } n = 3 \\ 4 & \text{if } n \geq 4 \end{cases} \\
 \text{v) } \chi_E(T_{m,n}) &= 4 \text{ if } m \geq 3, n \geq 2 \\
 \text{vi) } \chi_E(L_{(m,n)}) &= m + 1 \text{ if } m \geq 3, n \geq 2 \\
 \text{vii) } \chi_E(n, \text{ barbell graph}) &= \begin{cases} 4 & \text{if } n = 3 \\ n + 2 & \text{if } n \geq 4 \end{cases}
 \end{aligned}$$

ABSTRACT

A solar flare is a powerful release of radiation resulting from the discharge of magnetic energy associated with sunspots. Solar flares are the most explosive events in our solar system, appearing as bright regions on the Sun and varying in duration from minutes to hours. In the extensive period of the solar 11-year cycle basically the sunspots, solar flares, prominences and massive CMEs has been coming frequently. The extensive flares and its associated CMEs may intervene the processes of the ionosphere and induce currents in the geomagnetic fields. Hence an exploratory review on this aspect will light into the phenomenon of the generation of solar flare and its associated solar atmospheric perturbations. In this work we have done review on the earlier invention on the solar flare and associated events like relationship with ionospheric events and geomagnetic field variations, radio blackout for shortwave fading, categorization of the flares and high energy particle acceleration etc. and these show a deep inside into the solar flare events from the perspective of atmospheric outer layers.

Keywords: solar flare, CMEs, ionosphere, solar flares events, solar quiet current

INTRODUCTION

Solar flares are strongly connected to the coronal mass ejections (CMEs), in which solar magnetic fields and their embedded particles are expelled into interplanetary space and the solar environment. In the Earth's ionosphere, a dynamo process occurs due to the flow of plasma current, leading to the generation of a magnetic field [1,2]. During the variability of the solar magnetic fields and changes in proton density the dynamo process can be disrupted. Solar flares are often directed towards Earth, leading to disturbances in our planet's atmosphere. In recent decades, an increase in the solar activity is noticed, as the Sun approaches the peak of its 11-year solar cycle, with the year 2022 experiencing particularly pronounced flaring events. Solar flares are resulted from continuous bursts of magnetic

**Abhijit Banerjee and Rina Bhattacharya**

activity in the solar corona, launching solar plasma and magnetic fields into interplanetary space. When these solar ejecta collide with Earth's magnetic field, they can trigger geomagnetic storms [3-5]. Differential solar heating drives atmospheric tidal winds that move ionospheric plasma along geomagnetic field lines, generating electric fields and currents, akin to a dynamo coil moving within a magnetic field. This region is known as the ionospheric dynamo region. The magnetic effects of these electric currents can be observed on the ground during magnetospheric calm conditions. Additional electric currents are generated by varying magnetospheric electric convection fields, leading to phenomena such as auroral electrojets and polar currents [6]. During a solar flare, bursts of solar radiation from active sunspots reach higher altitudes in the atmosphere, particularly in the E and D layers. This results in an increased electric conductivity and enhancement of the solar quiet (Sq) current, generating a minor increase known as the geomagnetic solar flare effect [7]. Earlier studies have reported that geomagnetic disturbances are caused by enhanced solar wind magnetospheric energy coupling processes. The primary driver of geomagnetic disturbances is magnetic reconnection, which establishes an electro-dynamic connection between solar wind plasma and the Earth's magnetosphere. The effects of solar flare induced geomagnetic disturbances and their impacts on Earth's atmospheric electricity at high and mid-latitudes were explored in different researches. [8-11]. In this work we are considered a time line review of the solar flare and its related events like the observation of white light as Carrington's events and Fleming and McNish attributed the geomagnetic maps and other most significant observations like polar cap absorptions, high energy proton accelerations, radio blackout, change of plasma dynamics of the ionospheric D, E and F layers during solar flare, total geomagnetic field variations, geomagnetic field variation at the solar flare peninsula developed by considering the past to present time over the globe and the lines on the globe. This review resulted into a salient understanding of the geomagnetic field variation during the solar flares at its comparable intensities on various parts of the globe.

Earlier Studies on solar flare and its effects on solar atmosphere

In the early 1660s, Isaac Newton demonstrated that sunlight can be divided into distinct colors using a glass prism. In 1800, William Herschel expanded on this by discovering unseen "rays" beyond the red end of the spectrum, which he identified as infrared radiation after detecting a rise in temperature. Johann Wilhelm Ritter, a year later, discovered ultraviolet radiation by observing the blackening of silver chloride paper beyond the violet end of the spectrum. UV radiation was independently confirmed by William Hyde Wollaston. Early ionospheric research established that intense solar flares significantly impact the Van Allen belts and ionospheric layers, disrupting current flows in the ionospheric plasma [12, 13]. It is seen that there are fifty remarkable strongest flares are happened 1997 to 2017 during this 20 years span. Among them the lowest amplitude achieved was X2.6 (0.00026 Watts per m²) and highest amplitude achieved was X28+ (0.0028 Watts per-m² +) along with the average of X6.2 (0.000624 Watts per-m²). The following review study from the years 1860 to 2023 will highlight significant researches on solar flares and their effects on the solar atmosphere.

1859-1900: Key solar flare observations and ionospheric predictions

Richard C. Carrington and Richard Hodgson independently observed a solar flare on September 1, 1859. Carrington later linked this event to simultaneous geomagnetic variations recorded at Kew Observatory, marking the first recognized connection between solar flares and geomagnetic effects [14,15].

1901-1937: Early ionospheric and solar flare studies

The ionosphere's existence was theorized based on scientific research in 1902[16]. After that Studies began to explore the impact of solar flares on Earth's magnetic field through global models, focusing on the time-based development of electric currents generating solar flare effects (sfes)[17,18].

1926-1950: Advances in solar flare research

Researchers noted a rise in electron density during solar flares, leading to radio signal fade-outs [19]. By 1935, the correlation between high-frequency radio signal fading and chromospheric flares was established [20], with further studies in 1936 and 1937 confirming the link between radio signal attenuation and geomagnetic variations along with the inventions of multi-frequency ionosonde, geomagnetic maps by Fleming and Mc-Nish, telluric currents

**Abhijit Banerjee and Rina Bhattacharya**

fluctuations and intensification of diurnal current [21-24]. The correlation between solar cycle curves and flare frequency by “Wolf’s number” was recognized in 1947 [25]. Rocket technology confirmed the localization of ionospheric dynamo currents in the E-region and Post flare surge in cosmic ray intensity level was observed at the F-region in early 1950’s [26,27]. Intensified ionosphere penetration by flare proton particles at the polar region due to Polar cap Absorptions with geosynchronous proton with minimum velocity as $15G_eV\cos^4\theta$ (θ : magnetic latitude) was observed [28].

1951-1975: Solar flare effects and geomagnetic research

In 1951, X-rays were detected during low solar activity, recognized as the primary ionizing agent in solar flares, with wavelengths between 1 to 100 Å [29]. In 1952, it was reported that the onset of solar flares and geomagnetic impacts could be explained by ionospheric electromagnetic induction, with unusually high H-component magnetic crochets magnitudes observed at Huancayo and other low-latitude stations [30]. Solar flares ionized the D-region, primarily through Lyman series absorptions as reported in 1954. Studies linked solar flares to geomagnetic changes, solar quiet currents (Sq), and sudden appearances of auroras [31]. Subsequent Studies showed that geomagnetic changes during solar flares are influenced by multiple factors beyond just the increase in solar quiet current (Sq) [32]. High-intensity solar flares on the solar limb, detected through the Ha line in the Balmer series, were often associated with sfe occurrences. Statistical analyses confirmed solar flare impacts on the F₂-layer [33,34]. The definition of sfe was formalized at the 1957 Copenhagen Symposium, and a provisional atlas was presented at the 1959 Utrecht Symposium [35]. Magnetic data from the 1957 International Geophysical Year were analysed. Magnetic crochets were linked to massive solar flares [36,37]. Ionospheric current systems below the dynamo layer were found responsible for geomagnetic effects, revealing asymmetry in current circuits across hemispheres [38]. Solar flare effects (sfes) were characterized through ground-level enhancements (GLEs) and polar cap absorption (PCA) events during mid-sixty’s [39]. Sfe intensity varied globally, linked to vortex migration during flares. Phase shifts between crochet currents and other ionospheric perturbations showed direct correlations [40]. Unusual ionospheric impacts in Brazil during the 1966 flare were studied [41]. Magnetic crochets correlated with radio bursts above 4995 MHz [42]. The X-ray radiation from flares caused sudden ionospheric disturbances (SID), impacting communication [43]. Counter-currents in equatorial regions during sfes were noted [44]. Significant X-ray and microwave bursts were required to trigger sfe events, studied through occurrences in Kodaikanal (1966-1971)[45].

1976-2000: Technological advances and new insights

Research highlighted plasma density increases due to shock compression and successful radio communication during solar events [46,47]. Investigations into the relationship between interplanetary fields, magnetopause reconnection and longitudinal lagging of the sfe current from the Sq current system (found as 15-30°) were advanced by GPS technology [48-51]. Various phenomena such as wave-particle interactions and energetic storm particles (ESPs) accelerated at ICME shocks were studied, showing that distinct particle populations could trigger visible light. ICME shocks compressing the dayside magnetosphere led to sudden auroras and increased ionization in the auroral zone. The impact of solar flares on Indo-USSR magnetic observatories (0-45N) was analysed, focusing on electrojets. Solar flare effects (sfe) peaked midday at equatorial latitudes with positive H variations. Advancements in GPS technology enhanced the study of sfe through ground and satellite receivers, with TEC enhancements noted during the daytime. Space weather models improved the understanding and prediction of energetic particle impacts [52-54].

2001-present: Analysis of solar flares data collected from SOHO, GEOS, TIMED, and GPS receivers

It was reported in 2004 that stronger solar flares generally have steeper X-ray spectra. While X-ray fluxes during flares can vary by several orders of magnitude, EUV fluxes show less variation. Similar flares from the same active region in 2003 were studied to assess their maximum intensity [55,56]. The ionospheric effects of several powerful solar flares were studied using data from SOHO, GEOS, TIMED, and GPS receivers. The study found that the X17 flare on October 28, 2003, had the most significant impact on the dayside ionosphere, causing a peak increase of about 25 TECU [57]. TEC data on October 29, 2003, was deemed unsuitable as a background for flare events due to contamination from an interplanetary coronal mass ejection (ICME) that caused a geomagnetic storm [58]. It was noted that while EUV and X-ray emissions from solar flares impact the dayside ionosphere, SEPs affect the entire

**Abhijit Banerjee and Rina Bhattacharya**

globe, particularly at high latitudes and Polar Regions. Differentiating between the effects of SEPs and the electromagnetic components of solar flares requires understanding their impact on both the day-side and night-side ionosphere [59]. Increased ionization from solar flares was found to be influenced by the magnetic link to Earth and the energy distribution of solar flare particles. Energetic particles penetrating the lower atmosphere generate HO_x and NO_x, which act as catalysts that degrade ozone [60]. The magnitude of the X-ray flare during the solar perturbation was estimated using riometer data and galactic radio signal background attenuation, with the highest flux observed at 4.0 milli-Watt per square meter for an X40 class flare [61]. The peak magnitude of the November 4, 2003, solar flare was determined by analysing ionosphere perturbations, concluding that the flare reached its maximum intensity with an estimated magnitude of X45 ± 5 [62].

Advanced studies and developments in solar flare impact analysis (from 2006)

It was observed that electron fluxes showed similar signs for solar energetic particle (SEP) events and magnetic storms. The study proposed differentiating these responses using K_p activity indices and measurements of energetic particle fluxes, particularly with data from the EPAM instrument on NASA's ACE spacecraft [63,64]. Further investigations were conducted on the behaviour of the ionosphere in response to X-ray emissions and solar energetic particles during solar flares. The findings suggested that the magnitude of the Carrington flare was comparable to the November 4, 2003, flare [65]. The SRMV was established to characterize temporary variations in Earth's geomagnetic field. The Ebro Observatory took the lead in managing this service, which was initially conceived during the Assembly of Rome in 1954 under Committee No.10 [66]. Information was gathered about the interplanetary causes of ionospheric disruptions at middle latitudes. A solar flare detector utilizing GPS capabilities to monitor total electron content (TEC) was developed, allowing automatic detection of sudden changes in ionospheric ionization [67-69]. The investigation of a solar flare event on the dayside of the geomagnetic field revealed distinct signals at multiple stations located simultaneously in the dark region [70-76].

The ionospheric impact of solar flares was studied through the analysis of vertical total electron content (vTEC) data collected from GPS in 2009. It was found that detecting solar flare effects is influenced by both the distance from the sub-solar point and the intensity and position of overhead currents [77]. The onset of relativistic electron acceleration at the flare site was often delayed by 5 to 15 minutes after the flare, in addition to any propagation delays. This delay was observed in the events of October 28 and 29, 2003, but not in the July 14, 2000, event [78,79]. A modelling tool called the Particle Acceleration and Transport in the Heliosphere (PATH) code was designed to simulate the radiation environment generated by SEP events at Earth's orbit [80-82]. An empirical correlation between solar flare events (SFEs) related magnetic field variations and X-ray flux was established in 2010 using over 300 SFE observations. This relationship helped estimate the magnitude of the Carrington flare as approximately X42 to X48, depending on the location of observations [83]. Detection of X-ray solar flares were influenced by factors including flare intensity, growth rate, and the location of geomagnetic observatories. Faster growth in radiation and observatories in the summer hemisphere facilitated easier detection, while pre-existing geomagnetic disturbances also played a role. An analysis of coronal mass ejection (CME) speeds and equatorial current systems estimated a 12% chance of an extreme space weather event occurring within the next decade. Extreme geomagnetic activity was estimated to occur once every 100 to 200 years [84-86]. The Royal Academy of Engineering in 2013 investigated that a super-storm would occur approximately once every 79 years [87]. Analysis of very low frequency (VLF) amplitude changes showed that electron density in the ionosphere's D-region could increase up to 80 times compared to normal values during solar flares. The horizontal magnetic field, at the Tirunelveli equatorial station increased by up to 8.5% for M-class flares [88].

Mechanisms and innovations

During 2016 -2017 the studies focussed on how Earth's magnetic field responds to significant energy releases, focusing on the decay of SFEs. It was found that decay time depends on the balance of X-ray and UV contributions, and only the most energetic X-ray periods lead to observable SFEs [89]. An estimated recurrence interval for a flare with intensity similar to the Carrington event was calculated to be around 90 years. SFEs could manifest in various magnetic components with unpredictable and irregular shapes, including steep or smooth profiles depending on

**Abhijit Banerjee and Rina Bhattacharya**

solar disturbance [90]. Approximately 33% of land-based geomagnetic variations were linked to Earth's interior, comparable to Sq and other temporary geomagnetic changes [91-93]. Researchers created an SFE index to isolate SFE signals from natural variations. This index, based on the radial influence of SFE disturbances, led to the development of a detector currently in testing [94]. The vertical incidence sounder at the Ebro Observatory analysed the effects of X9 flares on the magnetic field and ionosphere, highlighting its usefulness for detecting solar flares in 2018. The effects of space-temporal geophysical disturbances on GNSS positioning accuracy were studied. Variations in the lower ionosphere were related to the "magnetic crochet" effect, later termed "solar flare effect" (SFE) [95,96]. A solar flare monitor using GNSS was built and calibrated to detect ionospheric ionization from solar flares. An 11-year analysis (2008-2018) was conducted to optimize the GNSS and SFE detector, aligning with SFE lists from the International Service of Rapid Magnetic Variations (SRMV) [97]. Annual bulletins from the International Association of Geomagnetism and Aeronomy (IAGA) included references to global magnetic activity indices and sudden variations in the field, specifically related to SFEs from 2023[98-101].

CONCLUSIONS

In this study the relationship among the various phenomenon related to the solar flare are considered. Here various kinds of sfe were considered *w.r.t.* variation in their time of happening. The findings of the earlier researches on the relationship of the changes occurred in the conditions of the parameters in the atmospheric layers like ionospheric D, E and F along with their electron content, solar quiet current variations, geomagnetic field variations, intensity scaling of the flares are listed in details. The present review showed that there is a certain variation of ionosphere content and geomagnetic field in effect which related to short signal radio fade out at large. The question of finding variation of the coupling of ionosphere and troposphere during the flare is being still unsolved. The ionospheric parameters like total electron content, plasma frequency of the ionospheric F₂ layer, electron densities of F₂ layer, geomagnetic parameters like K_p, A_p, C_p and Dst and the solar parameters like interplanetary magnetic field, solar wind and radiation flux as received from the satellite radio can be taken into consideration. The tropospheric and surface data on pressure, temperature and humidity for strong to very intensive flare may be considered in future analysis to get into pre, post and control conditions during the solar flare events. If this above mentioned processes of thorough researches can be carried out then a scope to find the coupling of the troposphere and the ionosphere can be found.

ABSTRACT

In this paper, we introduce the concept of Fuzzy Soft Hyponormal operators (FSHN-operators) in Fuzzy Soft Hilbert spaces (FSH-spaces), built from a family of operators and some elementary properties of these operators are studied. In addition, some relations between FSHN-operators and Fuzzy Soft Normal operators (FSN-operators) in FSH-spaces are obtained from Fuzzy Soft Self-Adjoint (FSSA), Fuzzy Soft Unitary (FSU), invertible and unitary equivalent.

Keywords: Fuzzy Soft Hyponormal operators (FSHN-operators), Fuzzy Soft Hilbert spaces (FSH-spaces), FSHN-operators, Fuzzy Soft Self-Adjoint (FSSA), Fuzzy Soft Normal operators (FSN-operators) and Fuzzy Soft Unitary (FSU).

INTRODUCTION

In 1999, Molodtsov[2] introduced soft set theory as a different method for vagueness. Majiet. al. [16] defined new notions of soft set theory. Fuzzy soft set which is a combination of fuzzy and soft sets was first introduced by Maji et.al. [11]in 2001. In recent years, many researchers applied this notion and gave some concepts such as fuzzy soft point, fuzzy soft metric spaces and fuzzy soft normed spaces[3],[4]. In 2013, Zadeh[14] coined fuzzy soft norm over a set and established the relationship between fuzzy soft norm and fuzzy soft norm over a set. NashatFaried et al. [1] introduced the fuzzy soft inner product on fuzzy soft vector space and its properties. Also, they have given the definition of fuzzy soft Hilbert spaces [7]. In addition, they continued by defining the fuzzy soft linear operators in fuzzy soft Hilbert space with their related theorems including spectral theory in 2020 [8]. After that, they defined the fuzzy soft self adjoint operator [8] and studied its properties. In 2021, a new type of normal operator, called fuzzy soft

Brindha and Maheswari

normal operator has been introduced by SalimDawood et al. [13] and some theorems relating to this operator with some properties are given. Also, the relation between this operator and other types like fuzzy soft self-adjoint operator are studied. In 2022, NashatFariet et al. [12] have given the definition of fuzzy soft unitary operator, a particular sort of the fuzzy soft linear operators in fuzzy soft Hilbert space. In addition, the connection between the fuzzy soft unitary operators and each of the fuzzy soft isometry operators and the fuzzy soft normal operators are established. The aim of this work presents the concept of fuzzy soft hyponormal operators and some elementary properties. Furthermore, some relations between FSHN-operators and Fuzzy Soft Normal operators (FSN-operators) in FSH-space are obtained from Fuzzy Soft Self-Adjoint (FSSA), Fuzzy Soft Unitary (FSU), invertible and unitary equivalence.

PRILIMINARIES

Definition 2.1: [14]

Let \tilde{A} be a fuzzy set over universal set U , a set characterized by a membership function $\mu_{\tilde{A}}:U \rightarrow I$, where $I=[0,1]$ and \tilde{A} represented by an ordered pairs $\tilde{A} = \{(u, \mu_{\tilde{A}}(u)) : u \in U, \mu_{\tilde{A}}(u) \in I\}$ or $\tilde{A} = \{\frac{\mu_{\tilde{A}}(u)}{u} : u \in U\}$
 $\mu_{\tilde{A}}(u)$ is said to be degree of membership of u in \tilde{A}
 And $I^U = \{\tilde{A} : \tilde{A} \text{ is a function from } U \text{ into } I\}$

Definition 2.2:[2]

Let U be a universal set and E be set of parameters. $P(U)$ the power set of U and $A \subseteq E$. Suppose that \mathcal{G} is a mapping given by $\mathcal{G}:A \rightarrow P(U)$, where $\mathcal{G}_A = \{\mathcal{G}(e) \in P(U) : e \in A\}$. The pair (\mathcal{G}, A) or \mathcal{G}_A is called soft set over U with respect to A .

Definition 2.3: [11]

The soft set (\mathcal{G}, A) is called fuzzy soft set (**FS-set**) over a universal set U , whenever \mathcal{G} is a mapping $\mathcal{G}:A \rightarrow I^U$, and $\{\mathcal{G}(e) \in I^U : e \in A\}$. The family of all FS-sets, symbolized by $FSS(\tilde{U})$

Definition 2.4:[3]

The FS-set $(\mathcal{G}, A) \in FSS(\tilde{U})$ is called fuzzy soft point over U , symbolized by $(u, \mu_{\mathcal{G}(e)})$ if $e \in A$ and $u \in U$.
 $\mu_{\mathcal{G}(e)} = \begin{cases} \lambda, & \text{if } u = u_0 \in U \text{ and } e = e_0 \in A \\ 0, & \text{if } u \in U - u_0 \text{ or } e \in A - e_0 \end{cases}$, where $\lambda \in (0,1)$

Remark 2.5:[3]

$C(A)$ is the family of all FS-Complex numbers and $R(A)$ is also the family of all FS-Real numbers

Definition 2.6:[7]

Let $(\tilde{H}, \tilde{N}, *)$ and $(\tilde{H}', \tilde{N}', *)$ be FSN-spaces. A fuzzy soft linear operator $\tilde{T} : (\tilde{H}, \tilde{N}, *) \rightarrow (\tilde{H}', \tilde{N}', *)$ is said to be fuzzy soft bounded iff $\exists c > 0, \exists$ for each $i > 0, \tilde{N}'(\tilde{T}\tilde{x}, \tilde{t}) \geq \tilde{N}(\tilde{x}, \frac{\tilde{t}}{c}) \forall \tilde{x} \in \tilde{H}$.

Remark 2.7.[7]

Let $\tilde{B}(\tilde{H})$ be the set of all Fuzzy soft bounded (continuous) linear operators (FSB-operator) on \tilde{H} .

Theorem 2.8; [7]

Let $(\tilde{H}, \tilde{F}, *)$ be a FSH-space. Let $\tilde{T} \in \tilde{B}(\tilde{H})$ be $\tau_{\tilde{F}}$ - continuous linear functional. Then \exists a unique $\tilde{T}^* \in \tilde{B}(\tilde{H})$ such that $\langle \tilde{T}\tilde{x}, \tilde{y} \rangle = \langle \tilde{x}, \tilde{T}^*\tilde{y} \rangle, \forall \tilde{x}, \tilde{y} \in \tilde{H}$.

Note 2.9: [7]

The adjoint of \tilde{T} . i.e. \tilde{T}^* is a unique linear operator on \tilde{H} with the relation $\langle \tilde{T}\tilde{x}, \tilde{y} \rangle = \langle \tilde{x}, \tilde{T}^*\tilde{y} \rangle$

Brindha and Maheswari

Definition 2.10:[8]

Let $(\tilde{H}, \tilde{F}, *)$ be a FSH-space with IP: $\langle \tilde{x}, \tilde{y} \rangle = \sup\{\tilde{t} \in R: \tilde{F}(\tilde{x}, \tilde{y}, \tilde{t}) < 1\} \forall \tilde{x}, \tilde{y} \in \tilde{H}$ and let $\tilde{T} \in \tilde{B}(\tilde{H})$. Then \tilde{T} is fuzzy soft self-adjoint operator (FSSA-operator), if $\tilde{T} = \tilde{T}^*$ where \tilde{T}^* is fuzzy soft adjoint operator (FSA-operator) of \tilde{T} .

Definition 2.11:[13]

Let $(\tilde{H}, \tilde{F}, *)$ be a FSH-space with IP: $\langle \tilde{x}, \tilde{y} \rangle = \sup\{\tilde{t} \in R: \tilde{F}(\tilde{x}, \tilde{y}, \tilde{t}) < 1\} \forall \tilde{x}, \tilde{y} \in \tilde{H}$ and let $\tilde{T} \in \tilde{B}(\tilde{H})$. Then \tilde{T} is a FSN-operator if it commutes with its (fuzzy soft) adjoint. i.e. $\tilde{T}\tilde{T}^* = \tilde{T}^*\tilde{T}$.

Remark 2.12: [13]

It is obvious that every FSSA-operator is FSN-operator.

Theorem 2.13: [13]

If \tilde{T}_1 and \tilde{T}_2 are FSN-operators on $(\tilde{H}, \tilde{F}, *)$ with the property that either commutes with fuzzy adjoint of the other, then $\tilde{T}_1 + \tilde{T}_2$ and $\tilde{T}_1\tilde{T}_2$ are FSN-operator.

Theorem 2.14:[13]

Let $(\tilde{H}, \tilde{F}, *)$ be a FSH-space with IP: $\langle \tilde{x}, \tilde{y} \rangle = \sup\{\tilde{t} \in R: \tilde{F}(\tilde{x}, \tilde{y}, \tilde{t}) < 1\} \forall \tilde{x}, \tilde{y} \in \tilde{H}$ and let $\tilde{T} \in \tilde{B}(\tilde{H})$ be a FSN-operator iff $\|\tilde{T}^*\tilde{x}\| = \|\tilde{T}\tilde{x}\| \forall \tilde{x} \in \tilde{H}$.

Theorem 2.15:[13]

Let $\tilde{T} \in \tilde{B}(\tilde{H})$ be a FSN-operator on FSH-space. Then \tilde{T} is FSN-operator iff its real and imaginary parts commute.

Theorem 2.16:[13]

Let \tilde{T} be a FSN-operator on a finitedimensional FSH-space \tilde{H} and $\tilde{z} \in C(A)$. Then $\tilde{T} - \tilde{z}I$ is a FSN-operator.

Theorem 2.17:[13]

Let $(\tilde{H}, \tilde{F}, *)$ be a FSH-space with IP: $\langle \tilde{x}, \tilde{y} \rangle = \sup\{\tilde{t} \in R: \tilde{F}(\tilde{x}, \tilde{y}, \tilde{t}) < 1\} \forall \tilde{x}, \tilde{y} \in \tilde{H}$ and let $\tilde{T} \in \tilde{B}(\tilde{H})$. Then \tilde{T} is a FSU-operator if it satisfies $\tilde{T}\tilde{T}^* = I = \tilde{T}^*\tilde{T}$.

Note 2.18:[13]

Every FSU-operator is FSN-operator.

Theorem 2.19:[13]

If $\tilde{T} \in \tilde{B}(\tilde{H})$ is FSU-operator on \tilde{H} , then the following conditions are all equivalent to one another,

- (1) $\tilde{T}\tilde{T}^* = I$
- (2) $\langle \tilde{T}\tilde{x}, \tilde{T}\tilde{y} \rangle = \langle \tilde{x}, \tilde{y} \rangle \forall \tilde{x}, \tilde{y} \in \tilde{H}$
- (3) $\|\tilde{T}\tilde{x}\| = \|\tilde{x}\| \forall \tilde{x} \in \tilde{H}$

MAIN RESULTS

Definition 3.1:[Fuzzy Soft Hyponormal Operator]

Let $(\tilde{H}, \langle \cdot, \cdot \rangle)$ be a FSH-space and let $\tilde{T} \in \tilde{B}(\tilde{H})$. Then \tilde{T} is a FSHN-operator if $\tilde{T}^*\tilde{T} - \tilde{T}\tilde{T}^* \geq 0$ or $\tilde{T}\tilde{T}^* \leq \tilde{T}^*\tilde{T}$

Lemma 3.2:

Let $(\tilde{H}, \langle \cdot, \cdot \rangle)$ be a FSH-space and let $\tilde{T} \in \tilde{B}(\tilde{H})$. Then \tilde{T} is a FSHN-operator iff $\|\tilde{T}^*\tilde{x}\| \leq \|\tilde{T}\tilde{x}\| \forall \tilde{x} \in \tilde{H}$.

Proof:

Since $\tilde{T} \in \tilde{B}(\tilde{H})$ is a FHN-operator, then by the definition, $\tilde{T}^*\tilde{T} - \tilde{T}\tilde{T}^* \geq 0$.

$\Rightarrow \tilde{T}^*\tilde{T} \geq \tilde{T}\tilde{T}^*$

Brindha and Maheswari

It is enough to prove $\tilde{T}\tilde{T}^* \leq \tilde{T}^*\tilde{T}$
 Consider $\|\tilde{T}^*\tilde{x}\| \leq \|\tilde{T}\tilde{x}\|$, then

$$\begin{aligned} \|\tilde{T}^*\tilde{x}\| \leq \|\tilde{T}\tilde{x}\| &\Leftrightarrow \|\tilde{T}^*\tilde{x}\|^2 \leq \|\tilde{T}\tilde{x}\|^2 \\ &\Leftrightarrow \langle \tilde{T}^*\tilde{x}, \tilde{T}^*\tilde{x} \rangle \leq \langle \tilde{T}\tilde{x}, \tilde{T}\tilde{x} \rangle \\ &\Leftrightarrow \langle \tilde{T}\tilde{T}^*\tilde{x}, \tilde{x} \rangle \leq \langle \tilde{T}^*\tilde{T}\tilde{x}, \tilde{x} \rangle \\ &\Leftrightarrow \langle (\tilde{T}\tilde{T}^* - \tilde{T}^*\tilde{T})\tilde{x}, \tilde{x} \rangle \leq 0 \\ &\Leftrightarrow \tilde{T}\tilde{T}^* - \tilde{T}^*\tilde{T} \leq 0 \\ &\Leftrightarrow \tilde{T}\tilde{T}^* \leq \tilde{T}^*\tilde{T} \end{aligned}$$

Hence $\|\tilde{T}^*\tilde{x}\| \leq \|\tilde{T}\tilde{x}\| \Leftrightarrow \tilde{T}^*\tilde{T} - \tilde{T}\tilde{T}^* \geq 0$.

Theorem 3.3:

Let $(\tilde{H}, \langle, \rangle)$ be a FSH-space and let $\tilde{T} \in \tilde{B}(\tilde{H})$. Then \tilde{T} is a FSHN-operator and \tilde{S} be unitarily equivalent to \tilde{T} . Then \tilde{S} is a FSHN-operator.

Proof:

For \tilde{S} is unitarily equivalent to \tilde{T} , we have $\tilde{S} = \tilde{U}\tilde{T}\tilde{U}^*$, for some unitary operator \tilde{U} .

Implies that $\tilde{S}^2 = \tilde{U}\tilde{T}^2\tilde{U}^* \Rightarrow \|\tilde{S}^2\tilde{x}\| = \|(\tilde{U}\tilde{T}^2\tilde{U}^*)\tilde{x}\|$.

Consider $\|\tilde{S}^*\tilde{x}\|^2$. Then

$$\begin{aligned} \|\tilde{S}^*\tilde{x}\|^2 &= \langle \tilde{S}^*\tilde{x}, \tilde{S}^*\tilde{x} \rangle \\ &= \langle \tilde{S}\tilde{S}^*\tilde{x}, \tilde{x} \rangle \\ &= \langle (\tilde{U}\tilde{T}\tilde{U}^*)(\tilde{U}\tilde{T}\tilde{U}^*)^*\tilde{x}, \tilde{x} \rangle \\ &= \langle (\tilde{U}\tilde{T}\tilde{U}^*)(\tilde{U}\tilde{T}^*\tilde{U}^*)\tilde{x}, \tilde{x} \rangle \\ &= \langle (\tilde{U}\tilde{T}\tilde{T}^*\tilde{U}^*)\tilde{x}, \tilde{x} \rangle \\ &= \langle (\tilde{T}\tilde{T}^*\tilde{U}^*)\tilde{x}, \tilde{U}^*\tilde{x} \rangle \\ &\leq \langle (\tilde{T}^*\tilde{T}\tilde{U}^*)\tilde{x}, \tilde{U}^*\tilde{x} \rangle \\ &= \langle (\tilde{U}\tilde{T}^*\tilde{T}\tilde{U}^*)\tilde{x}, \tilde{x} \rangle \\ &= \langle (\tilde{U}\tilde{T}^*\tilde{U}^*)(\tilde{U}\tilde{T}\tilde{U}^*)\tilde{x}, \tilde{x} \rangle \\ &= \langle (\tilde{U}\tilde{T}\tilde{U}^*)(\tilde{U}\tilde{T}^*\tilde{U}^*)\tilde{x}, \tilde{x} \rangle \\ &= \langle \tilde{S}^*\tilde{S}\tilde{x}, \tilde{x} \rangle \\ &= \langle \tilde{S}\tilde{x}, \tilde{S}\tilde{x} \rangle \end{aligned}$$

$$\|\tilde{S}^*\tilde{x}\|^2 \leq \|\tilde{S}\tilde{x}\|^2$$

$$\|\tilde{S}^*\tilde{x}\| \leq \|\tilde{S}\tilde{x}\|$$

Hence \tilde{S} is a FSHN-operator.

Theorem 3.4:

Let $(\tilde{H}, \langle, \rangle)$ be a FSH-space and let $\tilde{T} \in \tilde{B}(\tilde{H})$. Let \tilde{T} and \tilde{T}^* be a FSHN-operator. Then \tilde{T} be a FSN-operator.

Proof:

Given \tilde{T} and \tilde{T}^* be a FSHN-operator. Then $\tilde{T}\tilde{T}^* \leq \tilde{T}^*\tilde{T}$ and $\tilde{T}^*(\tilde{T}^*)^* \leq (\tilde{T}^*)^*\tilde{T}^*$
 $\Rightarrow \tilde{T}^*\tilde{T} \leq \tilde{T}\tilde{T}^*$.

For $\tilde{x} \in \tilde{H}$, it is true that

$$\begin{aligned} \langle \tilde{T}\tilde{T}^*\tilde{x}, \tilde{x} \rangle &\leq \langle \tilde{T}^*\tilde{T}\tilde{x}, \tilde{x} \rangle \text{ and } \langle \tilde{T}^*\tilde{T}\tilde{x}, \tilde{x} \rangle \leq \langle \tilde{T}\tilde{T}^*\tilde{x}, \tilde{x} \rangle \text{ Then} \\ \langle \tilde{T}\tilde{T}^*\tilde{x}, \tilde{x} \rangle - \langle \tilde{T}^*\tilde{T}\tilde{x}, \tilde{x} \rangle &\leq 0 \text{ and } \langle \tilde{T}^*\tilde{T}\tilde{x}, \tilde{x} \rangle - \langle \tilde{T}\tilde{T}^*\tilde{x}, \tilde{x} \rangle \leq 0 \\ \langle -(\tilde{T}^*\tilde{T} - \tilde{T}\tilde{T}^*)\tilde{x}, \tilde{x} \rangle &\leq 0 \text{ and } \langle \tilde{T}^*\tilde{T}\tilde{x}, \tilde{x} \rangle - \langle \tilde{T}\tilde{T}^*\tilde{x}, \tilde{x} \rangle \leq 0 \\ \langle (\tilde{T}^*\tilde{T} - \tilde{T}\tilde{T}^*)\tilde{x}, \tilde{x} \rangle &\geq 0 \text{ and } \langle (\tilde{T}^*\tilde{T} - \tilde{T}\tilde{T}^*)\tilde{x}, \tilde{x} \rangle \leq 0 \\ &\Rightarrow \langle (\tilde{T}^*\tilde{T} - \tilde{T}\tilde{T}^*)\tilde{x}, \tilde{x} \rangle = 0 \\ &\Rightarrow (\tilde{T}^*\tilde{T} - \tilde{T}\tilde{T}^*)\tilde{x} = 0 \\ &\Rightarrow \tilde{T}^*\tilde{T} - \tilde{T}\tilde{T}^* = 0 \\ &\Rightarrow \tilde{T}^*\tilde{T} = \tilde{T}\tilde{T}^* \end{aligned}$$

Brindha and Maheswari

Thus, \tilde{T} is a FSN-operator.

Theorem 3.5:

Let $(\tilde{H}, \langle \cdot, \cdot \rangle)$ be a FSH-space and let \tilde{S} and $\tilde{T} \in \tilde{B}(\tilde{H})$ be FSHN-operators. If \tilde{S} and \tilde{T} are commute and $\tilde{T}^* \tilde{S} = \tilde{S} \tilde{T}^*$. Then $\tilde{S} + \tilde{T}$ and $\tilde{S} \tilde{T}$ are also a FSHN-operator.

Proof:

For every unit vector $\tilde{x} \in \tilde{H}$. We know that $\tilde{S} \in \tilde{B}(\tilde{H})$ be FSHN-operator, $\|\tilde{S}^2 \tilde{x}\| \leq \|\tilde{S} \tilde{x}\|^2$ i.e. $\tilde{S} \tilde{S}^* \leq \tilde{S}^* \tilde{S}$, and $\tilde{T} \in \tilde{B}(\tilde{H})$ be FSHN-operator, $\|\tilde{T}^2 \tilde{x}\| \leq \|\tilde{T} \tilde{x}\|^2$ i.e. $\tilde{T} \tilde{T}^* \leq \tilde{T}^* \tilde{T}$.

To prove that $\tilde{S} + \tilde{T}$ is a FPN-operator.

Consider $\|(\tilde{S} + \tilde{T})^* \tilde{x}\|^2$. Then

$$\begin{aligned} \|(\tilde{S} + \tilde{T})^* \tilde{x}\|^2 &= \langle (\tilde{S} + \tilde{T})^* \tilde{x}, (\tilde{S} + \tilde{T})^* \tilde{x} \rangle \\ &= \langle (\tilde{S} + \tilde{T}) (\tilde{S} + \tilde{T})^* \tilde{x}, \tilde{x} \rangle \\ &= \langle (\tilde{S} + \tilde{T}) (\tilde{S}^* + \tilde{T}^*) \tilde{x}, \tilde{x} \rangle \\ &= \langle (\tilde{S} \tilde{S}^* + \tilde{S} \tilde{T}^* + \tilde{T} \tilde{S}^* + \tilde{T} \tilde{T}^*) \tilde{x}, \tilde{x} \rangle \\ &\leq \langle (\tilde{S}^* \tilde{S} + \tilde{T}^* \tilde{S} + \tilde{S}^* \tilde{T} + \tilde{T}^* \tilde{T}) \tilde{x}, \tilde{x} \rangle \\ &\leq \langle (\tilde{S}^* (\tilde{S} + \tilde{T}) + \tilde{T}^* (\tilde{S} + \tilde{T})) \tilde{x}, \tilde{x} \rangle \\ &\leq \langle ((\tilde{S}^* + \tilde{T}^*) (\tilde{S} + \tilde{T})) \tilde{x}, \tilde{x} \rangle \\ &\leq \langle ((\tilde{S} + \tilde{T})^* (\tilde{S} + \tilde{T})) \tilde{x}, \tilde{x} \rangle \end{aligned}$$

$$\leq \langle (\tilde{S} + \tilde{T}) \tilde{x}, (\tilde{S} + \tilde{T}) \tilde{x} \rangle$$

$$\leq \|(\tilde{S} + \tilde{T}) \tilde{x}\|^2 \|\tilde{x}\|$$

$$\Rightarrow \|(\tilde{S} + \tilde{T})^* \tilde{x}\|^2 \leq \|(\tilde{S} + \tilde{T}) \tilde{x}\|^2$$

$$\Rightarrow \|(\tilde{S} + \tilde{T})^* \tilde{x}\| \leq \|(\tilde{S} + \tilde{T}) \tilde{x}\|$$

Therefore $\tilde{S} + \tilde{T}$ is a FSHN-operator.

To prove that $\tilde{S} \tilde{T}$ is a FSHN-operator.

Let $\tilde{x} \in \tilde{H}$. Then Consider $\|(\tilde{S} \tilde{T})^* \tilde{x}\|^2$. Then

$$\begin{aligned} \|(\tilde{S} \tilde{T})^* \tilde{x}\|^2 &= \langle (\tilde{S} \tilde{T})^* \tilde{x}, (\tilde{S} \tilde{T})^* \tilde{x} \rangle \\ &= \langle (\tilde{S} \tilde{T}) (\tilde{S} \tilde{T})^* \tilde{x}, \tilde{x} \rangle \\ &= \langle (\tilde{S} \tilde{T}) (\tilde{T}^* \tilde{S}^*) \tilde{x}, \tilde{x} \rangle \\ &= \langle (\tilde{T} \tilde{T}^*) \tilde{S}^* \tilde{x}, \tilde{S}^* \tilde{x} \rangle \\ &\leq \langle (\tilde{T}^* \tilde{T}) \tilde{S}^* \tilde{x}, \tilde{S}^* \tilde{x} \rangle \end{aligned}$$

$$\leq \langle \tilde{T} \tilde{S}^* \tilde{x}, \tilde{T} \tilde{S}^* \tilde{x} \rangle$$

$$\leq \langle \tilde{S}^* \tilde{T} \tilde{x}, \tilde{S}^* \tilde{T} \tilde{x} \rangle$$

$$\leq \langle (\tilde{T}^* \tilde{S}^*) (\tilde{S} \tilde{T}) \tilde{x}, \tilde{x} \rangle$$

$$\leq \langle (\tilde{S} \tilde{T})^* (\tilde{S} \tilde{T}) \tilde{x}, \tilde{x} \rangle$$

$$\leq \langle (\tilde{S} \tilde{T}) \tilde{x}, (\tilde{S} \tilde{T}) \tilde{x} \rangle$$

$$\Rightarrow \|(\tilde{S} \tilde{T})^* \tilde{x}\|^2 \leq \|(\tilde{S} \tilde{T}) \tilde{x}\|^2$$

$$\Rightarrow \|(\tilde{S} \tilde{T})^* \tilde{x}\| \leq \|(\tilde{S} \tilde{T}) \tilde{x}\|$$

Therefore $\tilde{S} \tilde{T}$ is a FSHN-operator.

Theorem 3.6:

Let $(\tilde{H}, \langle \cdot, \cdot \rangle)$ be a FSH-space and let \tilde{S} and $\tilde{T} \in \tilde{B}(\tilde{H})$ be a FSHN-operator on \tilde{H} . Then $\|(\tilde{T}^* - \tilde{z} \tilde{I}) \tilde{x}\| \leq \|(\tilde{T} - \tilde{z} \tilde{I}) \tilde{x}\| \forall \tilde{x} \in \tilde{H}$, i.e. $(\tilde{T} - \tilde{z} \tilde{I})$ is FSHN-operator.

Proof:

Given \tilde{T} is a FSHN-operator on \tilde{H} .

Brindha and Maheswari

Let $\|(\tilde{T} - \tilde{z}\tilde{T})\tilde{x}\|^2 = \langle (\tilde{T} - \tilde{z}\tilde{T})\tilde{x}, (\tilde{T} - \tilde{z}\tilde{T})\tilde{x} \rangle$. Then

$$\begin{aligned} \|(\tilde{T} - \tilde{z}\tilde{T})\tilde{x}\|^2 &= \langle (\tilde{T} - \tilde{z}\tilde{T})\tilde{x}, (\tilde{T} - \tilde{z}\tilde{T})\tilde{x} \rangle \\ &= \langle (\tilde{T} - \tilde{z}\tilde{T})^* (\tilde{T} - \tilde{z}\tilde{T})\tilde{x}, \tilde{x} \rangle \\ &\geq \langle (\tilde{T} - \tilde{z}\tilde{T})(\tilde{T} - \tilde{z}\tilde{T})^* \tilde{x}, \tilde{x} \rangle \\ &\quad \text{[since, by definition of FSHN-operator]} \\ &\geq \langle (\tilde{T} - \tilde{z}\tilde{T})^* \tilde{x}, (\tilde{T} - \tilde{z}\tilde{T})\tilde{x} \rangle \end{aligned}$$

$$\|(\tilde{T} - \tilde{z}\tilde{T})\tilde{x}\|^2 \geq \|(\tilde{T} - \tilde{z}\tilde{T})^* \tilde{x}\|^2$$

$$\|(\tilde{T} - \tilde{z}\tilde{T})\tilde{x}\| \geq \|(\tilde{T} - \tilde{z}\tilde{T})^* \tilde{x}\|$$

i.e. $\|(\tilde{T} - \tilde{z}\tilde{T})^* \tilde{x}\| \leq \|(\tilde{T} - \tilde{z}\tilde{T})\tilde{x}\|$

Hence $\tilde{T} - \tilde{z}\tilde{T}$ is FSHN-operator.

Theorem 3.7

Let $\tilde{T} \in \tilde{B}(\tilde{H})$ be a FSHN-operator on a FSH-space \tilde{H} . Then $\tilde{T}\tilde{x} = \tilde{z}\tilde{x} \Rightarrow \tilde{T}^*\tilde{x} = \tilde{z}\tilde{x}$

Proof

Let \tilde{x} be an eigen vector of \tilde{T} corresponding to the eigen value \tilde{z} . i.e $\tilde{T}\tilde{x} = \tilde{z}\tilde{x}$.

Now, $\langle \tilde{T}\tilde{x}, \tilde{T}\tilde{x} \rangle = \langle \tilde{T}^*\tilde{T}\tilde{x}, \tilde{x} \rangle$

$$\geq \langle \tilde{T}\tilde{T}^*\tilde{x}, \tilde{x} \rangle \text{ [Since } \tilde{T} \text{ is FSHN-operator]}$$

$$\langle \tilde{T}\tilde{x}, \tilde{T}\tilde{x} \rangle \geq \langle \tilde{T}^*\tilde{x}, \tilde{T}^*\tilde{x} \rangle \tag{3.1}$$

Since by the Theorem (3.6), $\tilde{T} - \tilde{z}\tilde{T}$ is a FHN-operator, therefore for each $\tilde{x} \in \tilde{H}$, equation (3.1) becomes,

$$\langle (\tilde{T} - \tilde{z}\tilde{T})\tilde{x}, (\tilde{T} - \tilde{z}\tilde{T})\tilde{x} \rangle \geq \langle (\tilde{T} - \tilde{z}\tilde{T})^* \tilde{x}, (\tilde{T} - \tilde{z}\tilde{T})^* \tilde{x} \rangle$$

Since $\tilde{T}\tilde{x} = \tilde{z}\tilde{x}$, we have

$$\begin{aligned} \tilde{T}\tilde{x} &= \tilde{z}\tilde{x} \\ \Rightarrow \tilde{T}\tilde{x} - \tilde{z}\tilde{T}\tilde{x} &= 0 \\ \Rightarrow (\tilde{T} - \tilde{z}\tilde{T})\tilde{x} &= 0 \end{aligned}$$

$$\Rightarrow (\tilde{T} - \tilde{z}\tilde{T}) = 0 \tag{3.2}$$

Then, $\langle (\tilde{T} - \tilde{z}\tilde{T})\tilde{x}, (\tilde{T} - \tilde{z}\tilde{T})\tilde{x} \rangle = 0 \quad \forall \tilde{x} \in \tilde{H}$,

$$\Rightarrow \langle (\tilde{T} - \tilde{z}\tilde{T})^* \tilde{x}, (\tilde{T} - \tilde{z}\tilde{T})^* \tilde{x} \rangle = 0 \quad \forall \tilde{x} \in \tilde{H}, \tag{3.3}$$

From $(\tilde{T} - \tilde{z}\tilde{T})^* \tilde{x} = 0$, Then for each $\tilde{x} \in \tilde{H}$,

$$\Rightarrow (\tilde{T} - \tilde{z}\tilde{T})^* \tilde{x} = 0$$

$$\Rightarrow (\tilde{T}^* - \tilde{z}\tilde{T}^*) \tilde{x} = 0$$

$$\Rightarrow \tilde{T}^*\tilde{x} - \tilde{z}\tilde{T}^*\tilde{x} = 0$$

$$\Rightarrow \tilde{T}^*\tilde{x} = \tilde{z}\tilde{x}$$

\tilde{x} is an eigen vector of \tilde{T}^* corresponding to eigen value \tilde{z}

Theorem 3.8

Let $\tilde{T} \in \tilde{B}(\tilde{H})$ be a FSHN-operator with $\tilde{T}\tilde{x}_1 = \tilde{z}_1\tilde{x}_1$, $\tilde{T}\tilde{x}_2 = \tilde{z}_2\tilde{x}_2$ and $\tilde{z}_1 \neq \tilde{z}_2$. Then $\langle \tilde{x}_1, \tilde{x}_2 \rangle = 0$.

Proof

Since $\tilde{T} \in \tilde{B}(\tilde{H})$ is a FSHN-operator with $\tilde{T}\tilde{x}_1 = \tilde{z}_1\tilde{x}_1$, $\tilde{T}\tilde{x}_2 = \tilde{z}_2\tilde{x}_2$ and $\tilde{z}_1 \neq \tilde{z}_2$, then by Theorem (3.7),

$$\tilde{T}^*\tilde{x}_1 = \tilde{z}_1\tilde{x}_1, \tilde{T}^*\tilde{x}_2 = \tilde{z}_2\tilde{x}_2.$$

Consider $\tilde{z}_1 \langle \tilde{x}_1, \tilde{x}_2 \rangle$, then

$$\tilde{z}_1 \langle \tilde{x}_1, \tilde{x}_2 \rangle = \langle \tilde{z}_1\tilde{x}_1, \tilde{x}_2 \rangle$$

$$= \langle \tilde{T}\tilde{x}_1, \tilde{x}_2 \rangle$$

$$= \langle \tilde{x}_1, \tilde{T}^*\tilde{x}_2 \rangle$$

Brindha and Maheswari

$$= \langle \tilde{x}_1, \tilde{z}_2 \tilde{x}_2 \rangle$$

$$= \langle \tilde{z}_2 \tilde{x}_1, \tilde{x}_2 \rangle$$

$$= \tilde{z}_2 \langle \tilde{x}_1, \tilde{x}_2 \rangle$$

Hence, if $\tilde{z}_1 \neq \tilde{z}_2$, then $\langle \tilde{x}_1, \tilde{x}_2 \rangle = 0$. i.e. $\tilde{x}_1 \perp \tilde{x}_2$

CONCLUSION

From this paper, the concept of Fuzzy Soft Hyponormal operators (FSHN-operators) in Fuzzy Soft Hilbert spaces (FSH-spaces) has been constructed from family of operators. Some elementary properties of these operators are discussed. Moreover, some relations between FSHN-operators and Fuzzy Soft Normal operators (FSN-operators) in FSH-spaces are obtained from Fuzzy Soft Self-Adjoint (FSSA), Fuzzy Soft Unitary (FSU), invertible and unitary equivalent.

ABSTRACT

The blocks in a blockchain are linked together in a systematic chain, and they record user transactions and other data. Blockchain's main purpose is to facilitate decentralised, peer-to-peer transactions. This innovation was developed at first to facilitate Bitcoin, the world-famous cryptocurrency. With this technology, people on a network may conduct transactions with one another in a way that is both private and visible, thanks to the use of cryptography. It's a game-changing innovation that's gaining traction thanks to digital currencies like Bitcoin (BTC) and Ether (ETH). The transaction is recorded on an immutable distributed ledger and trust is established amid previously unknown peers. The centralization of any organization's financial records makes them vulnerable to hacking and manipulation for the sake of wealth and influence. The decentralized structure of blockchain ensures that all transaction records are immune to tampering and fraud. Blockchain has great potential for improving the online transaction system, but it also has a number of security flaws. With any luck, this paper's overview of blockchain methodology, its applications, and security can help enlighten blockchain devotees and academics.

INTRODUCTION

Without the availability of information, the business world cannot function. The sooner it is received, the sooner it will be accurate, and the sooner it will be of higher quality. Because it delivers data that is immediate, shareable, and entirely transparent, blockchain is a useful instrument for giving information. This data is recorded on an immutable ledger, and the only users who are able to read it are those who have been granted permission to do so by the administrators of the network. Because all of the participants have the same understanding of the truth, you are able to observe all of the facts of a transaction from the very beginning to the very conclusion and everything in between. Not only does this provide you with favourable perceptions, but it also provides you with more opportunities and efficiency.

Benefits

- Users are rewarded for their mining efforts so that the network is secure.
- The incentive payments received by miners give them a disposable income that can be utilized for anything they see fit.
- People are also more likely to put money into cryptocurrencies, which contributes to their widespread adoption.

Drawbacks

- Payouts are not uniform and change from one project to the next.
- The number of awards every block and when those incentives are distributed varies between projects.
- Higher expenditures are inevitable because specialized hardware (CPU, GPU, ASIC) is needed for mining.
- The high cost of electricity used in mining typically results in a loss for miners rather than a profit.

BLOCKCHAIN TECHNOLOGY

One of the first blocks on a blockchain is called the genesis block, and it serves as the basis from which all subsequent blocks are constructed. In most cases, it is created or hardcoded into the source code of the blockchain. It is distinguished by its unique qualities as the first block, as it does not have a predecessor. A timestamp, a nonce, and a special message could be comprised of the data contained within. Because it marks the beginning of the blockchain's existence, the genesis block is significant from a symbolic standpoint. Additionally, the qualities of the genesis block establish the tone for the entire chain, influencing aspects such as immutability, security, and cultural significance. The genesis block of Bitcoin, which was mined by Satoshi Nakamoto in 2009, is a remarkable example. It contains a transaction on coinbase that refers to a headline from The Times newspaper. (Please have glance at figure 1 & 2 for better understanding.) Due to the fact that it is decentralized and cannot be altered, blockchain technology makes the process of recording business transactions and monitoring corporate assets much simpler. In addition to tangible assets (such a house, a car, cash, or land), there are also intangible assets (including intellectual property, patents, copyrights, and branding) that exist. Goodwill is an example of an intangible asset. It is possible to document and trade virtually anything on a blockchain network, which will reduce the amount of ambiguity and save money for people who are currently participating.

Terminology in Blockchain

Begin to think of a blockchain as a computer - all you have to do now is adapt the terminology and comprehend that there are thousands of computers running across the world.

Peer-to-Peer Network

Often abbreviated to "P2P," a peer-to-peer network (P2N) is a decentralized network communications paradigm in which a set of devices (nodes) store and distribute files collectively, with each node acting as an independent "peer."

**Maitri Hingu and Kamlendu Pandey****Nodes**

The blockchain is not a central server but rather a distributed network of computers around the world that work together to verify transactions and store data. Nodes and validators are the individual computers that are rewarded for their participation in the network with tokens that are unique to the network.

Identity

An individual's private key is used to identify them throughout the blockchain. Due to the fact that this pertains to the vast majority of transactions, it is of the utmost importance to be aware that the person sending it is given permission to do so. For the purpose of ensuring that this conclusion occurs, elliptic cryptography is being utilised. One of the components of the key pair that is specific to each user is a private key, while the other component is a public key. Each and every transaction is digitally signed using the user's private key, which is something that the user and only the user can access using their private key. After the signature has been created, anyone can verify this signature by simply glancing at the user's public key; they do not need to be aware of the user's private key in order to do so.

State

Data are known as states. The blockchain functions as a data storage system, similar to how a computer saves documents like Word, Excel, and PowerPoint. The total amount of information stored in a blockchain is referred to as the blockchain's "state." Each node in the network has access to this information since it serves as a standard layer of state. That's one key way in which a blockchain stands apart from the web: Everyone has access to the same global state, much like you have access to all the files on your computer.

Fungible Token

Tokens in a fungible cryptocurrency are digital coins or tokens that share all the characteristics of traditional fungible assets. This means that these crypto tokens must be fungible, divisible, and have a fixed market price. Tokens that can be easily split into smaller parts and exchanged between users shouldn't be hard to value or use in a cryptocurrency trading environment. Fungible coins can be bought and sold at any exchange or on any coin price aggregator website. Example: Bitcoin, Ethereum, and Dogecoin.

Non-Fungible Token

The information contained in an NFT is irreversible and indivisible. As a result, many individuals compare NFTs to intellectual property (IP) rights. In contrast to fungible assets, NFTs are always created on a smart contract blockchain, such as Ethereum. While fungible crypto can be built on top of an existing blockchain, many fungible tokens and currencies are blockchain-native. Example: Litecoin.

Smart contracts

Computer Programs are known as smart contracts in blockchain. The data included on a blockchain can be altered in the same ways that files on your computer can be opened, modified, and deleted. This is accomplished mostly through the use of several programs on your own computer, such as a text editor or an image processing program. In the blockchain, the name most frequently given to computer programs is "smart contracts." There are blockchains that can work without smart contracts, however blockchains that have the functionality of smart contracts can typically accommodate considerably more complex use cases.

Wallets

Wallets are sometimes referred to as accessibility points and identity managers. Transactions are sent through a wallet, which is a programme that maintains a user's private key and can function as an access point to the blockchain. This allows transactions to be submitted directly from the wallet. The vast majority of user transactions are sent through the usage of a wallet. Transactions can be sent through the usage of wallets. The user does not have to physically insert and manage the private key while using a wallet, which is one of the benefits of utilising such a

**Maitri Hingu and Kamlendu Pandey**

device. Wallets are becoming increasingly advantageous. Wallets are available in a broad variety of formats, including software, hardware, and even paper-based variants. Other types include electronic wallets.

Transactions

User actions are known as transactions. It is necessary to broadcast a transaction to the network in order to put into action a feature of a piece of software (also known as a method of a smart contract). To the same extent that apps running on the internet are susceptible to spamming, so are blockchain networks. The majority of the time, this takes the form of an attacker flooding the network with an infinite number of transaction requests, so exceeding its capacity. In most cases, a transaction cost, also known as Gas, is attached to each and every transaction. This is done in an effort to prevent the occurrence of the scenario described above. This is a protection measure to prevent spamming of the network. Blockchain is a distributed immutable database that operates in a peer-to-peer connected network. Because of its immutability, it is trustworthy among the nodes inside the network [1], [2]. Using cryptographic proof, blockchain technology has the potential to give trustworthiness [1], [2]. Directly sending and receiving money or any other digital item is possible between the sender and the receiver, without the requirement for a third party to be involved [1], [2]. Users can be protected from the attack of double spending, whether they do so consciously or unknowingly, thanks to blockchain technology. All transactions are stored in chronological order, as stated in references [1], [2]. They proposed a peer-to-peer network that would make use of proof-of-work in order to record a public history of transactions in [1], [2]. Due to the fact that it would be computationally impractical for an adversary to alter this history, it would be impossible for them to do so if honest nodes held the majority of the CPU power [1], [2]. There is a problem with the fact that the receiver is unable to verify that one of the owners had not engaged in double spending [1], [2]. It is necessary for us to have a means by which the receiver can be told that the previous owners did not sign any transactions that took place in the past. Since the oldest transaction is the one that matters, we do not care about any subsequent attempts to double-spend because the earliest transaction is the one that matters. Awareness of all of the transactions that have taken place is the only way to confirm that there was no transaction. This is the only method that may be used. In order to accomplish this without the assistance of a reliable third party, the transactions need to be made known to the general public. Furthermore, we seek a system that enables participants to achieve a consensus on a single history of the order in which they were received at the same time. At the time of each transaction, the payee is obliged to give evidence that the majority of nodes concurred that the transaction was the first received. This proof must be presented. In [1]–[3], they have steps to run the network are as follows:

Step 1: New transactions are broadcast to all nodes

Step 2: Each node collects new transactions into a block

Step 3: Each node works on finding a difficult proof-of-work for its block

Step 4: When a node finds a proof-of-work, it broadcasts the block to all nodes

Step 5: Nodes accept the block only if all transactions in it are valid and not already spent

Step 6: Nodes express their acceptance of the block by working on creating the next block in the chain, using the hash of the accepted block as the previous hash (Refer figure 3 for pictorial demonstration of above steps.) When a new block is introduced to the chain, the consensus protocol has the responsibility of ensuring that all of the nodes in the Blockchain agree with the same version of the events. Consensus, collaboration, cooperation, equal rights for all nodes, and mandated involvement from all nodes are all aims of the Blockchain consensus protocol. Additionally, the protocol requires that all nodes involve themselves. Because of this, the objective of a consensus algorithm is to arrive at a solution that is advantageous to all of the participants in the network.

PoW (Proof of Work)

Proof-of-work consensus is utilized by the majority of cryptocurrencies. Algorithms are responsible for validating transactions and building blocks on the blockchain. The Proof of Work (PoW) idea established by Cynthia Dwork and Moni Naor in 1993 was utilized in the Bitcoin paper written by Satoshi Nakamoto in 2008. It is a solution that is difficult to locate yet simple to verify. Bitcoin, Ethereum, and Litecoin all use Proof-of-Work. How it works?

- The new block is validated and posted to the blockchain.

**Maitri Hingu and Kamlendu Pandey**

- The longest block chain will receive the block.
- Miners solve a tough mathematical challenge to add the block to the network, ergo Proof-of-Work.
- Time complicates the mathematical difficulty.

PoS (Proof of Stake)

PoW alternative that is used the most frequently. Consensus on Ethereum is now based on PoS. Validators invest part of their coins in this consensus process rather than purchasing expensive technology in order to find a solution to a difficult problem. Following that, each and every validator will validate the blocks. In order to determine whether or not a block can be added to the chain, validators will gamble on it. The amount of compensation that validators receive is proportional to the amount of money they wager on the Blockchain's actual blocks. It is determined by the validator's economic stake in the network which validator will be chosen to generate a new block. Incentives for validators to come to an agreement are provided by PoS.

PBFT (Practical Byzantine Fault Tolerance)

A consensus technique known as Practical Byzantine Fault Tolerance was initially presented by Barbara Liskov and Miguel Castro in the latter part of the 1990s. The PBFT algorithm was designed to handle asynchronous systems, which have no maximum limit on response time. It reduces the amount of overhead. The existing Byzantine Fault Tolerance methods were improved in a number of ways as a result of this. In the event that certain nodes in a distributed network fail to respond or respond with erroneous information, Byzantine Fault Tolerance (BFT) makes it possible for the network to establish a consensus. In order to reduce the influence of defective nodes and prevent system breakdowns, BFT processes make use of communal decision making, which includes both right and faulty nodes. The BFT was inspired by the Byzantine Generals' Problem. A list of blocks, which can be thought of as a public ledger, is where all of the transactions that have been committed are stored [15]. Blockchain technology makes use of consensus methods in order to maintain data consistency over a distributed network [15] with great success. A public blockchain is characterized by the fact that records are maintained on a large number of participants, making it extremely difficult to manipulate transactions on such a blockchain [15]. A comprehensive analysis is conducted in this paper [16] to assess the effectiveness of the consensus algorithms utilized by the Ethereum and Hyperledger Fabric private blockchain platforms. The technology that is fundamental to the cryptocurrency system that bitcoin represents is referred to as blockchain technology [16]. In this paper, the performance of consensus algorithms in private blockchains is analyzed, with a particular focus on the consensus layer [16].

The Proof-of-Work (PoW) protocol of Ethereum is routinely outperformed by the Proof-of-Facility (PBFT) protocol of Hyperledger Fabric in terms of latency and throughput of transactions. There are a number of significant supporting technologies, including peer-to-peer networks, asymmetric encryption, distributed data storage, consensus methods, and smart contracts [16]. First and foremost, we must resolve the various security concerns that have been raised by the widespread adoption of blockchain networks, particularly private blockchain networks, which are frequently adopted by businesses and other large organizations [17]. Blockchain is a distributed ledger that runs on a decentralized, peer-to-peer network. Despite a set of people having control over the hybrid blockchain, all transactions remain encrypted [17]. Any attempt to modify a data block will result in a new hash value being generated [17]. In blockchain technology, hashing a block consumes significant processing time [17]. An efficient and low-cost blockchain network would be the result of efforts to design a better consensus algorithm [17]. Hyperledger Fabric, Quorum, Ethereum, MultiChain, and R3 Corda were the five primary systems mentioned in order to compile and highlight the distinctions between them in one study [18].ed by distributed architectures that divide jobs or workloads among peers without the use of a reliable third party. The miners are in charge of determining if the sender and receiver successfully delivered the message [8]. They utilize a static game model to show how secure their incentive mechanism is. They suggest a safe method of validating transactions that is used by Bitcoin's miners. The security of their incentive system is ensured by a pricing method that is suggested [8]. There is a consistent belief across nodes that the chain with the longest length is the correct one, and they will continue to work towards extending it [1]–[3]. In the event that two nodes concurrently broadcast distinct versions of the subsequent block, it is

**Maitri Hingu and Kamlendu Pandey**

possible for certain nodes to receive either one or the other version first [1]–[3]. In such a scenario, they focus their efforts on the first branch that they have been given, while preserving the other branch in the event that it becomes longer [1]–[3]. When the next proof-of-work is discovered, the tie will be broken, and one of the branches will become longer. The nodes that were working on the other branch will then move to the longer branch [1]–[3]. Nodes have the ability to quit and rejoin the network at their own discretion, and they are able to accept the proof-of-work chain as evidence of what occurred while they were absent [1], [2]. By utilising their central processing unit (CPU) power, they cast their vote, indicating their approval of legitimate blocks by trying to extend them, while simultaneously rejecting invalid blocks [1], [2]. Using a peer-to-peer distributed timestamp server, they suggest a solution to the double-spending problem in [1], [2]. This system is intended to generate computational verification of the chronological sequence of transactions. The implementation of the proof-of-work is carried out by increasing a nonce within the block until a value is discovered that provides the block's hash with the necessary zero bits [1], [2]. A decentralized ledger or data structure is referred to as blockchain. Each block is built on top of the one before it, and the latter's nonce and signature are used as a key to enter the block. Miners can easily estimate a random string or nonce in order to tamper with a block in a Public Blockchain just by knowing the signature [4]. It is difficult to tamper with the details of the transactions or events once they have been fed into the Blockchain [4]. Bitcoin was conceived as a way to create a safe currency with no centralized authority. The financial technology (FinTech) industry regards bitcoin blockchain technologies, also known as distributed-ledger technology, as having a lot of potential (DLT) [5].

Advances in blockchain protocol development are bringing us closer to realizing goals that only a few years ago appeared impossible. The miner must solve this puzzle in order to construct a block, which consumes both operational and capital resources [5]. Due to the difficulty of setting the parameter, Network coded-distributed storage is not trivially applicable to blockchain [6]. To solve the bloating issue, they propose network coded-based distributed storage as the storage structure for blockchain. Because the parameter is challenging to set, a trivial application of NC-DS to blockchain is challenging [6]. One can explore previous blockchain transactions and observe all transactions connected to a specific public key once it has been paired with a person's identification [7]. They suggest a pricing strategy for the secure Bitcoin system to protect against selfish user behavior and prevent collusion assaults, as well as a secure validation method carried out by the miners in the Bitcoin system rather than a reliable third party [8]. Peer-to-peer (P2P) applications are characterized, Through access to any node in the dispersed network, users can confirm and trace the previous records [9]. A similar blockchain-based approach was put forth to securely disseminate sensitive data in a decentralized fashion [9]. Both the business world and the academic community have given cryptocurrency a lot of attention [9]. As long as the proportion of flawed nodes in the Unique Node List is less than 20%, the ledger will continue to be accurate [9].

There are many different industries that are beginning to adopt blockchain technology or are considering implementing it in order to facilitate their operations. The goal of these industries is to get a competitive edge by streamlining procedures, boosting security and data sharing, increasing productivity, and cutting costs [10]. By establishing new advanced features for the business and industrial world, blockchain technology enables new possibilities [10]. It serves as the primary facilitator of the Internet of Transactions, which is essential for the functionality of a wide variety of industrial applications. Specific open protocols and standards that have been developed by individuals are incorporated into Hyperledger [10]. The applications that are emerging include those in the fields of finance, energy, logistics, healthcare, and manufacturing [10]. Among the major enablers for the utilization of blockchain technology in these applications, the rise of digital identities, distributed security, smart contracts, and micro-metering are among the most important drivers [10]. A machine learning method is provided by them for the purpose of identifying intelligent Ponzi activities [11]. It has been suggested that blockchain technology is a disruptive technology that will bring about changes in a variety of different industries [11]. In order to develop an efficient model for detecting smart Ponzi schemes without the need for source code, it is necessary for them to have a sufficient number of smart contracts that contain labels and features that are effective and can be obtained without the need for source code [11]. Using the etherscan.io platform, they gathered all of the open source code smart contracts that were created prior to September 7, 2017, and then personally examined them to determine whether or not they were Ponzi scheme contracts [11]. The goal of this work was to detect sophisticated Ponzi

**Maitri Hingu and Kamalendu Pandey**

schemes utilizing bytecodes, utilizing machine learning and data mining approaches [11]. Upon careful observation, it is important to note that the properties of the code are extracted without the source code [11]. The proposed model can be applied to any contract at the moment of its inception [11]. Concerning the trust crisis conundrum, dealing with reliable third parties can be expensive or involve security hazards [12]. They offer a taxonomy on the subject of blockchain smart contract security verification [12]. Programming correctness and formal verification are two subcategories of the correctness verification component [12]. They go over how to create trustworthy smart contracts from the perspectives of formal verification and programming correctness [12]. Future study will focus on developing programming standards for smart contracts, creating a set of development procedures for smart contracts, and raising programmers' security awareness [12]. Through a comparative survey study, the blockchain's potential uses, advantages, and drawbacks are discussed [13]. Blockchain, in contrast to conventional systems, enables direct peer-to-peer transfers of digital assets [13]. Blockchain can be used to promote secure and privacy-maintained consumption monitoring and energy trade in smart grids with bidirectional communication flow [13]. A scalability issue with Bitcoin can be attributed to the limited size and frequency of the blocks as well as the volume of transactions the network can handle [13]. Takeaways and Reflections This section has covered some of the more fundamental problems that may arise when working with blockchain technology, such as the ambiguous terminology that is still used by some regulatory agencies [14]. Based on the findings of numerous investigations, this article analyses the prevalent security assaults on blockchain technologies and their vulnerabilities [14]. The liveness attack, which lengthens the time it takes for a transaction to be confirmed, the double-spending attack, which creates duplicate funds, and the private Key security assault are all dealt with [14].

CURRENT RESEARCH IN BLOCKCHAIN**Blockchain Consensus Algorithms**

In essence, Blockchain is a distributed ledger that is immutable, private, secure, and transparent. It also functions without the need for a central authority to oversee its operations. Despite the fact that there is no centralized authority that verifies the authenticity of the transactions that take place on the Blockchain, each and every one of them is accepted at face value. It is possible to accomplish this thanks to the consensus process, which is a key component of any blockchain. In a Blockchain network, it is necessary for all of the nodes to reach a consensus over the current state of the distributed ledger. This process is referred to as a consensus algorithm. Consensus methods are required in order to ensure that the Blockchain network operates in a dependable manner and to facilitate the establishment of trust between peers who were not previously acquainted with one another in a distributed computing environment. In terms of consensus procedures or fundamental money, each framework is a little bit unique [18]. Using data collected from published experiments, they evaluated the structures according to a number of parameters [18]. Latest versions of these platforms will be implemented, and they will be compared experimentally using various benchmarking tools. Major private blockchain frameworks and their features are outlined [18]. They acknowledge the following restrictions but nonetheless find our comparative analysis to be realistic [18]. Without completing a thorough study, the offered analysis can be utilized to select 2 frameworks for testing in their respective settings/environments [18]. They did a series of experiments to back up their theoretical model and found that it accurately predicted transaction latencies on average [19]. In this research, they provide a theoretical analysis approach for investigating Fabric's blockchain system's latency performance. They ran a battery of studies to back up the accuracy of these theoretical models [19]. The outcomes demonstrated the model's ability to accurately forecast the typical delay of a transaction. As a new technology, blockchain has been heralded for its potential to boost numerous industries' credibility, trustworthiness, and safety [19]. The research team led by Thakkar et al. (2018) tested Fabric V1.0 extensively to determine its performance [19]. Theoretical modelling determined the typical delay in reaching a PBFT consensus and identified some possible bottlenecks in performance [19].

Blockchain Security

A comprehensive risk management solution for blockchain networks, blockchain security comprises assurance services, cybersecurity guidelines, and best - practice to reduce the likelihood of fraud and cyberattacks. Due to their foundation in consensus, cryptography, and decentralization, the data structures proposed by blockchain technology

**Maitri Hingu and Kamlendu Pandey**

inherently possess high levels of security. Information is nearly impossible to alter as it is added to the network because of the interconnectivity of its constituent blocks. Each transaction in a block is also verified and accepted by a consensus mechanism (approved users), ensuring that they are all legitimate and accurate. There is no single point of failure and no way for an individual to alter past transactions.

Private Blockchains

In order to participate in a private blockchain network, users must first be invited to join. Either the network's central administrator or initiator, or a predetermined set of rules, is responsible for validating users. Private blockchains are often implemented as permissioned networks in businesses. Permissioned networks restrict both the number of users and the types of transactions each user is allowed to make. Either an invitation or permission is required for members to join. A "Proof-of- Authority" (PoA) consensus mechanism is commonplace in private blockchains, which are often used in internal, business-secure contexts to handle activities like access, authentication, and record keeping. In most cases, the details of a transaction will remain confidential.

Public Blockchains

Blockchains that are accessible to the public, promotes openness and trustworthiness. Since the software is open-source and freely accessible to the public, anyone can take part in "decentralized" transaction consensus and validate network transactions (e.g., Bitcoin and Ethereum). Public blockchain networks are distinguished by its core feature, decentralization, achieved through crypto-economics, which is designed to guarantee collaboration across the distributed network. As a result, there is no single point of failure in the network's infrastructure or the underlying software in a public blockchain. The degree to which a blockchain is decentralized is contingent on factors such as the rules by which it is governed, the security of its cryptographic "private keys," and the incentives it offers its participants. Think about "data mining," wherein users earn cryptocurrency by verifying transactions. This incentive encourages others to join the network and help verify transactions. Who writes the code, who may participate in the consensus mechanism, and who has access to the community governance activities that keep the network running are all aspects of governance that need to be considered. Proof-of-Work (PoW) and Proof-of-Stake (PoS) are the two most used consensus mechanisms for public blockchains (PoS). There is a major distinction between public and private blockchains in terms of who can join and validate transactions.

Consortium Blockchains

In any case, there's a third possibility worth considering: consortium blockchains. Consortium blockchains are blockchain networks in which all of the nodes have been vetted and approved by a central authority. This "semi-permissioned" method permits some degree of control over a dispersed or partially decentralized network. Coincidentally, consortium blockchains allow for the privacy of transaction data.

The consortium blockchain can use Proof-of-Work (PoW), Proof-of-Authority (PoA), or Proof-of-Stake to obtain consensus (PoS). And there are more options, such as delegated proof-of-stake. Consortium blockchains work best in environments with a high degree of trust, such as in financial transactions, supply chain management, or the Internet of Things (IoT). Blockchain systems are extremely good at avoiding objective information fraud, such as loan application fraud, because the fake information is based on facts which will not match with existing data on blockchain [20].

Blockchain Rewards and Earnings

Miners receive block rewards for transaction approval. Mining a block yields it. Cryptocurrencies mine new currency and verify transactions.

Block rewards have two parts;

Subsidy: It's the main reward. New coins created.

**Maitri Hingu and Kamlendu Pandey****Fees**

Block transactions also pay fees. Users are rewarded for solving challenging mathematical problems. Bitcoin users receive bitcoins upon transaction verification. After four years or 210000 blocks, the award is halved. To boost bitcoin value and demand. Rewards vary. Because miners' profit from mining, the system is popular.

How rewards are calculated?

Let's pretend a customer has to make a purchase. For this particular deal, a "block" is generated. Every user receives the block at the same time. The customers guarantee the authenticity of the deal. If a deal goes through, the users who had a hand in making it will receive rewards. Incentives can be distributed more fairly with the use of protocols. After authentication is accomplished, the database is updated and the deal is finalized. It's important to remember that the award is not constant because it varies depending on the project. The block reward is based on a number of variables, including the overall supply of cryptocurrency, the average production time of crypto assets, and transaction fees.

Blockchain Forking

One way to "fork" a blockchain is to create a copy of the code and then modify it in order to create a new piece of software or product through the process of "forking." Creating a "fork" of an open-source project is a common and extensively observed practice that has gained widespread popularity. Open-source, distributed ledger technology is the foundation upon which cryptocurrencies such as Bitcoin and Ethereum are constructed. This means that everyone has the ability to make modifications to the protocol. Due to the fact that they are open-source projects controlled by the community, they are dependent on users to enhance the dependability and safety of the software. One additional advantage of open source software is that it can be forked in order to enhance the user interface. This feature makes the software more interesting and appealing to a larger audience. People are able to see, modify, or otherwise alter the code in an open source environment without the fear of punishment from the original creator. This is because the code is freely available to everyone. Generally speaking, there are two types of forks: those that occur in the codebase and those that occur in the live blockchain. Live Blockchain Forks are further subdivided into Accidental Forks and Intentional Forks, and then Intentional Forks are further subdivided into Soft Forks and Hard Forks.

Codebase Fork

This entire code of the present blockchain is replicated and adjusted in order to reduce the amount of time required to build blocks. Additionally, some significant modifications were made, and a faster software was developed in comparison to the existing blockchain. This software was then launched as a new whole program that was labelled against you. In this way, a new blockchain is created when the ledger is empty. By forking the code of Bitcoin and making some minor tweaks, a significant number of the ALT COINS that are currently on the blockchain were produced.

Live Blockchain Fork

It is important to note that the term "Live Blockchain Fork" does not relate to a particular kind of fork; rather, it describes the occurrence of a split in a blockchain network that is currently functioning and actively processing transactions. In the context of a live blockchain fork, the term "live" refers to the fact that the fork is occurring in real time and has an impact on the blockchain's capability to continue functioning normally. When a live blockchain fork takes place, it indicates that there is a split in the blockchain, either temporary or permanent, and that two or more copies of the chain are being actively maintained and updated.

Accidental Fork/Temporary Fork

Forks that arise accidentally as a result of network delay or synchronization issues leading to momentary divergences are referred to as forks. It was neither intended or begun by the developers, hence it was unintentional. Resolves itself when the network converges on a single chain, making it both temporary and permanent. popular in Proof-of-Work: This type of consensus technique is also more popular in proof-of-work systems.

**Maitri Hingu and Kamlendu Pandey****Intentional Fork**

Intentional or planned forks are planned and executed with a specific purpose in mind. They are begun on purpose by developers or members of the community with the objective of implementing upgrades, improvements, or changes to the protocol. Regarding the impending fork, developers and the community typically communicate with one another a significant amount of time in advance. In order to prevent contentious situations, it is often necessary to have widespread consensus. So intentional fork has two types:

Soft Fork

To provide a definition, a soft fork is an upgrade to the blockchain protocol that is compatible with previous versions. It makes the restrictions more stringent, rendering blocks that were previously valid invalid. Even though they have not updated, nodes that have not upgraded can still interact with upgraded nodes without causing the network to completely split apart. It enables upgraded nodes to coexist alongside non-upgraded nodes inside the same network. Soft forks are reversible, meaning that they can be undone if the network itself decides to go back to the previous regulations. The term “consensus rule changes” refers to modifications that are more stringent than the regulations that are now in place.

Hard Fork

According to the definition, a hard fork is a permanent divergence in the blockchain that results in two distinct chains that are incompatible with one another. It requires making modifications to the protocol that are not compatible with previous versions of the protocol. This means that nodes who do not upgrade will regard the new blocks to be invalid. Hard forks are irreversible, meaning that once they occur, the split is irreversible. Additionally, hard forks frequently bring about the introduction of new features, rules, or upgrades. A large number of parties must reach a consensus in order for the implementation to be successful.

Why we need blockchain forking?

In the process of developing software, forking is an extremely important component that serves a variety of important functions. It makes it possible for developers to work together independently on features or bug fixes without having an effect on the primary codebase, which helps to cultivate an environment that is both flexible and parallel in nature. When it comes to open source contributions, forking is especially useful because it enables developers to create their own versions, test modifications, and submit pull requests for evaluation and inclusion in the original project. Forking also allows for experimentation, which means that it provides an area where modifications can be tested before they are merged into the parent repository. When it comes to maintaining personalized versions of projects that are adapted to their particular requirements, developers also make use of forks. The idea is frequently utilized for the purpose of providing new features and performing bug fixes, both of which contribute to the overall development of a project when implemented. A transparent history of changes and individual contributions is provided via forks, which contribute to successful version control. In addition to this, they make decentralized development easier to do, which enables many teams or developers to separately work on various areas of a project. Additionally, forking serves as a risk mitigation approach, acting as a safety net in the event that disagreements arise or the project is potentially abandoned. In [21], examines the state-of-the-art in blockchain technology and introduces decentralized applications. The only way for current blockchain systems to upgrade is through a hard fork because of the P2P consensus model [21]. Recent efforts have been made to enhance the functionality of existing blockchains with the potential for anonymity [21]. A blockchain is a continuously expanding chain of blocks, each of which contains a cryptographic hash of the one before it, a time stamp, and the data it delivered [21]. The blockchain infrastructure must be able to accommodate millions of daily active users in order to support contemporary web-based systems like social networks, massively multiplayer online games, and online retail malls [21]. Response times from each network node affect a DApp's sequential performance [21].

**Maitri Hingu and Kamlendu Pandey**

DISCUSSION

The complex structural features of blockchain technology highlight its significance as a revolutionary invention in the digital era. The decentralized and cryptographic underpinning of blockchain architecture provides a strong platform for secure and transparent transactions. When analyzing the basic elements of blockchain, such as blocks and chains, we observe how data integrity and immutability are preserved through cryptographic hashes, effectively preventing tampering without being detected. Consensus mechanisms, a crucial element of blockchain structure, have seen substantial development since the creation of Bitcoin's Proof of Work (PoW). Although Proof of Work (PoW) has proven the practicality of decentralized consensus, it frequently faces criticism because to its substantial energy consumption. The adoption of Proof of Stake (PoS) and other consensus algorithms, such as Delegated Proof of Stake (DPoS), Practical Byzantine Fault Tolerance (PBFT), and emerging innovations like Proof of Authority (PoA), demonstrates the continuous endeavors to enhance the efficiency, scalability, and security of blockchain networks. Every consensus process possesses distinct advantages and drawbacks, which have an impact on the structure and capabilities of different blockchain systems. The issue of scalability continues to be a significant obstacle for blockchain technology. As blockchain networks expand, there is a greater need for computational capacity and storage, which can result in possible obstacles. Layer 1 techniques, like as sharding, seek to partition the network into smaller, more controllable segments, thus enhancing transaction throughput. Layer 2 technologies, including as state channels and sidechains, provide alternative methods to improve scalability by handling transactions outside of the main blockchain while still ensuring security and trust. These technological improvements are essential for empowering blockchain to effectively manage the requirements of extensive applications and universal acceptance. The security of blockchain technology has both positive and negative aspects. On one side, the cryptographic concepts that form the foundation of blockchain technology offer strong safeguards against unwanted alterations. However, the decentralized structure of blockchain allows for potential exploitation of vulnerabilities in smart contracts or consensus processes if they are not properly handled. The continuous advancement of formal verification approaches and new cryptographic techniques seeks to enhance the security of blockchain systems, guaranteeing their ability to endure intricate attacks.

CONCLUSION

The purpose of this survey paper was to investigate the various aspects of blockchain technology, including its history, its current state, and the possible developments that could occur in the future. The adaptability and transformative potential of this decentralized technology has been brought to light through the exhaustive investigation of a variety of blockchain platforms, consensus processes, and applications in the real world. Through the course of this research, a thorough analysis of the existing literature concerning the numerous applications of blockchain technology was carried out. Even though it has only been ten years since the blockchain technology was first developed, businesses are constantly looking for methods to adopt it in order to better their operations. Because of the increasing amount of digital information that we encounter in our everyday lives, there is a growing demand for blockchain technology that is capable of securing, accessing, transparently recording, and accurately recording data. Blockchain engineers and specialists continue to be in short supply on the job market, despite the fact that the technology is making significant progress. There will be a return on investment in the Blockchain technology in the future. The time has come to familiarize oneself with the technology behind blockchain-based transactions. The usage of blockchain technology will become more widespread in the years to come, and the advantages that results from its implementation will encourage businesses and organizations from all over the world to make investments in the technology. Despite the fact that blockchain technology is still in its infancy, it is expected to encounter widespread adoption from a variety of industries all over the world in the not too distant future. As a result of our investigation, it is clear that blockchain technology has moved beyond its initial link with cryptocurrencies and has expanded into other fields, including supply chain management, healthcare, banking, and other areas. The literature that was reviewed highlights the robustness, transparency, and security improvements that blockchain technology delivers to

**Maitri Hingu and Kamlendu Pandey**

a variety of different businesses. In addition, the difficulties and constraints that were discovered in this survey shed light on crucial areas that require further investigation and invention in the months to come. There are still important obstacles that the blockchain community needs to work together to overcome in order to realize the full potential of this ground-breaking technology. These obstacles include scalability, interoperability, and regulatory frameworks. As we make our way through the ever-changing world of blockchain technology, it is becoming increasingly apparent that collaboration between researchers, developers, policymakers, and industry stakeholders is very necessary. The only way we will be able to overcome the obstacles, improve the solutions that are already in place, and pioneer new applications that will lead to the development of decentralized systems in the future is through collaborative efforts. In conclusion, this study is an invaluable resource for academics, industry professionals, and enthusiasts who are interested in gaining a comprehensive grasp of the blockchain ecosystem. Allow this poll to serve as a compass for us as we move on with the next phase of blockchain innovation. It will inspire further exploration and advancements that will definitely reimagine the ways in which we communicate with one another, do business, and trust one another in the digital world. The voyage of blockchain is not even close to being finished, and as we consider the thoughts that have been offered in this article, we expect that this revolutionary technology will have a future that is both exciting and transformative.

ABSTRACT

Thiourea-doped vanadyl sulphate (TVS) crystals were grown by the solution growth method. Transparent light blue crystal of TVS was harvested in the period of 20 days. Thermal stability and the melting point of TVS crystal have been studied by Thermogravimetric analysis (TGA) and differential thermal analysis (DTA) techniques. TVS crystal's optical properties and optical constants such as band gap (E_g), refractive index (n), reflectance (R), absorption coefficient (α), extinction coefficient (K) were determined by UV-VIS-NIR spectrum. Photoluminescence spectroscopy investigates the luminescence nature of the TVS crystal. The electrochemical behavior of the TVS crystal was investigated by cyclic voltammetry.

Keywords: Crystal growth; Doping; NLO; TG/DTA; spectroscopy; PL; CV

Amirsha Evangelin Kezia et al.,

INTRODUCTION

Vanadyl sulphate is an inorganic compound which has the chemical formula of $\text{VOSO}_4 \cdot (\text{H}_2\text{O})_x$ where $0 \leq x \leq 6$. Vanadium can be found in several forms, such as vanadate and vanadyl sulphate. The most common source of vanadyl sulphate is found in nutritional supplements. Vanadium is a metallic element that is used because of its interesting physical, chemical and biological properties [1]. By Peder Kierkegaard et al., the crystal structure of pure vanadyl sulphate (VOSO_4) was dissolved. He discovered that it is a part of the orthorhombic structure [2]. The synthesis and characterisation of $\text{VOSO}_4 \cdot 6\text{H}_2\text{O}$ and other Vanadium(II) Compounds were also reported by Albert Cotton et al.[3]. Vanadyl sulphate hexahydrate ($\text{VOSO}_4 \cdot 6\text{H}_2\text{O}$) was generated by Michel Tachez et al. from an aqueous solution at 0°C , and they investigated the material below 13°C . They observed that the $\text{VOSO}_4 \cdot 6\text{H}_2\text{O}$ crystallized in a triclinic form[4]. Vanadium(IV) was obtained by Krasil'nikov et al. using $\text{VOSO}_4 \cdot 3\text{H}_2\text{O}$ as a source and aqueous ammonia as a precipitant for the $\text{VO}(\text{OH})_2$ production[5]. Lee M. Daniels et.al reported the preparation and characterization of anhydrous vanadium (II) compounds by reaction of aqueous solutions of $[\text{V}(\text{H}_2\text{O})_6]\text{SO}_4$ with neutral amines[6]. The crystal growth and characterization of potassium zinc- vanadyl sulphate mixed crystal have also been reported by Vijila Manonmoni et.al[7]. In our earlier study, we have reported the analysis of structure, UV Transmittance of its aqueous solution, FTIR and Microhardness of thiourea -vanadyl sulphate (TVS) single crystals[8]. In this work, we have reporting the optical constants of UV Transmittance of single crystal, thermal, photoluminescence and electrochemical behaviour of TVS single crystals.

SYNTHESIS AND CRYSTAL GROWTH

Thiourea doped vanadyl sulphate single crystals have been synthesized by taking Analytical reagent grades (AR) of Thiourea and Vanadyl Sulphate. The homogeneous saturated solution was prepared at room temperature using a magnetic stirrer. A saturated solution was filtered to remove the impurities. Then the filtered solution was allowed to slow evaporation solution growth technique. Within 20 days good quality and a light blue optically transparent of Thiourea doped vanadyl sulphate single crystal were harvested. The photograph of grown crystals is shown in figure 1.

RESULTS AND DISCUSSION

Study of Thermal behaviour of TVS crystal

Using a NETZSCH STA 2500 thermal analyzer in a nitrogen atmosphere, the thermogravimetric and differential thermal studies of TVS crystal were performed. The sample was heated at a rate of 30 K/min between 30 and 500°C . The TGA spectrum (Figure 2) shows that there is no weight loss up to 123.83°C , confirming that the molecule in question does not include any water or crystallization. After that, weight drops in three stages, from 123.83°C to 356.8°C . Due to glass transition, only 10% of the mass is lost in the first stage between 123.83°C and 181.33°C . The DTA curve shows two abrupt endothermic peaks at 181°C and 202°C , respectively, which correlate to the rapid mass loss of 69.6% between 181.33°C and 223.83°C . These peaks are due to and melting and decomposing respectively. This indicates that the crystal has developed with a good degree of crystallinity. The temperature range in which the gradual weight loss takes place is 223.83°C to 356.8°C . Because of the compound's impurities and the release of volatile compounds like sulphur, the DTA curve in this phase exhibits a slight endothermic at 267°C [9 - 11]. After this peak, there is a broad endothermic peak at 436°C corresponding to this peak there is no weight loss occur in TGA. It has been shown that the state of total weight loss corresponds to 99.7% of the growing crystal. The compound is seen to be stable up to 123.83°C and to melt at 181°C based on the DTA/TGA trace.

Determination of kinetics and thermodynamics parameters

According to the reaction theory, kinetic equation for decomposition of solid matter is usually written as [12]

$$\frac{dx}{dt} = k(1 - x) \quad (1)$$

Amirsha Evangelin Kezia et al.,

Where, $x = \frac{m_0 - m_T}{m_0 - m_f}$

m_T is the mass of sample at any temperature T and m_0 and m_f are the masses at initial and final temperatures respectively [13]. Eq. (1) was integrated to give:

$$\ln(1 - x) = -kt \quad (2)$$

The straight line that each phase's data followed on graphs created with equation (2) indicated that transformations were first-order reactions. Each line's slope revealed the rate constant (k) for that phase (Figures 3-5) and equation (3) was used to calculate the half-life time ($t_{1/2}$).

$$\text{Half life Time } t_{1/2} = \frac{0.693}{k} \text{ s.} \quad (3)$$

The activation energy and thermodynamic parameters were then determined using the Coats-Redfern method [14,15].

$$\ln[-\ln(1 - x)] = \ln \frac{A R T^2}{\beta E_a} - \frac{E_a}{R T} \quad (4)$$

Where A is frequency factor, β is heating rate ($20^\circ\text{C}/\text{min}$), R is general gas constant ($8.3143 \text{ Jmol}^{-1}\text{K}^{-1}$), E_a is activation energy and T is temperature (K). Plotting graphs between $\ln[-\ln(1-x)]$ vs $1000/T$ for each phase (Figures 6-8) gave the values of activation energy. Thermodynamic parameters are evaluated by the following basic thermodynamic equations [16].

Activation energy = slope $\times 8.3143 \text{ (Jmol}^{-1}\text{)}$

The standard entropy of activation, ΔS , is calculated from the following relation

$$\Delta S = R \times \ln \frac{A h}{k T} \text{ Jmol}^{-1} \text{ K}^{-1} \quad (5)$$

Where, k is the Boltzmann constant ($1.38 \times 10^{-23} \text{ J/K}$) h is the Planck's constant ($6.63 \times 10^{-34} \text{ m}^2 \text{ kg / s}$) and T the temperature and A the frequency factor.

The standard enthalpy of activation,

$$\Delta H = E_a - 2RT \text{ Jmol}^{-1} \quad (6)$$

The standard Gibbs energy of activation,

$$\Delta G = \Delta H + T \Delta S \text{ Jmol}^{-1} \quad (7)$$

The calculated values of rate constant k , Activation energy E_a and the thermodynamic parameters are tabulated in table 1. The higher value of activation energy for the grown crystal indicates more stable nature and all phases are non-spontaneous endothermic reactions.

UV-VIS UV TRANSMITTANCE STUDY OF TVS SINGLE CRYSTAL

The UV-Visible spectral analysis gives useful information about electronic transitions of the compound and is assisted to understand the electronic structure and optical band gap of the crystal [18]. For laser frequency conversion applications, the transmission range, absorbance band, and transparency cut-off are crucial optical parameters [17,18]. Using a Shimadzu UV-2450 spectrophotometer, the linear optical property of the TVS single crystal was investigated in the 200–1100 nm wavelength range. The obtained UV-Vis NIR transmittance spectrum is shown in Figure 9.

It is evident from the spectrum that, the formed crystal exhibits strong optical transmission over the whole visible and near-infrared range. At a certain critical wavelength, the transmittance intensity totally vanishes. It was discovered that the material's cut off wavelength, or critical point, was 393 nm. The electrons in the σ and π orbitals must be promoted from the ground state to the excited state via absorption, which requires a significant amount of energy. We refer to this procedure as a charge transfer excitation. Absorption bands resulting from $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions involving π -orbitals and lone pairs (n = non-bonding) in particular are significant. Chromophores are defined as molecules that may display the electronic transitions mentioned above [19]. The presence of chromophores like VO_2 anion may be the cause of the violet crystal's appearance.

DETERMINATION OF OPTICAL BANDGAP AND OPTICAL CONSTANTS

Optical band gap energy

Optical properties are very essential to determine a material's suitability for use in the fabrication of optoelectronics. The photon energy ($h\nu$) determines the optical absorption coefficient (α), which is useful in determining the type of

Amirsha Evangelin Kezia et al.,

electron transition and band structure [20]. The optical absorption coefficient (α) was calculated from the measured transmittance (T) using the relation.

$$\alpha = \frac{2.303 \times \log\left(\frac{1}{T}\right)}{d} \text{m}^{-1} \quad (8)$$

Where T is the transmittance and t is the thickness of the crystal. According to Tauc's relation, the value of α was used to determine the optical band gap [21].

$$(\alpha h\nu) = A(h\nu - E_g)^m \quad (9)$$

where α is the absorption coefficient, $h\nu$ is photon energy, E_g is the optical band gap energy, A is a constant and m is the optical transition number. When electromagnetic radiation enters materials, it is absorbed at a specific wavelength when its energy is equivalent to the materials' optical band gap energy. The electrons undergo valence band to conduction band transitions. There are two types of electron transitions between the valence and conduction bands: direct and indirect, with both having a prohibited transition. For the direct allowed transition, indirect allowed transition, direct forbidden transition, and indirect forbidden transition, respectively, the transition number (m) is 1/2, 2, 3/2, and 3. The type of optical transition of the TVS crystal is determined by the value of m, which needs to be determined in this instance. Taking logarithm on both sides and differentiating equation (10) with respect to $h\nu$ we get the following form [22-24]

$$\ln(\alpha h\nu) = \ln(A) + m \ln(h\nu - E_g) \quad (10)$$

$$\frac{d(\ln(\alpha h\nu))}{d(h\nu)} = \frac{m}{h\nu - E_g}$$

A graph depicted in Figure 10 that is plotted between $(\ln(\alpha h\nu))/h\nu$ and $h\nu$ can be used to compute the value of E_g . The information regarding single and multiple stage optical transitions is provided by the discontinuity in the line. These transitions are specified for a given value of m, which corresponds to a specific maximum energy value at which a given transition may have occurred [25,26]. In the current instance, the optical transition consists of a single stage that discontinuously occurs at a certain maximum energy value of the knee point ($E_g = 3.13\text{eV}$). Plotting the graph between $\ln(\alpha h\nu)$ and $\ln(h\nu - E_g)$, the value of m is obtained. The value of m was found to be $0.54 \approx 0.5 \approx 1/2$ by extrapolating linear fit as shown in Figure 11. This shows and confirms that the optical transition of TVS crystal is allowed for direct band gap nature. The Tauc's plot relation has been rearranged as given below for condition of direct allowed transition:

$$(\alpha h\nu) = A(h\nu - E_g)^{1/2} \quad (11)$$

The bandgap (E_g) of the grown crystal was estimated by plotting $(\alpha h\nu)^2$ versus $h\nu$ as shown in Figure 12. The value of the bandgap of grown crystal was found to be 3.04eV.

According to Plank's equation, the optical band gap energy of TVS crystal was calculated theoretically as follows:

$$E_g = \frac{1240}{\lambda} \text{eV} \quad (12)$$

where λ is the lower cut-off wavelength (393 nm). The band gap of the grown TVS crystal is found to be 3.16 eV, which is in good agreement with the value obtained from Figure 10 and Figure 11.

Determination of optical constants

Extinction coefficient is the measure of how strongly a chemical species or substance absorbs light at particular wavelength. It depends upon the structure and chemical composition of a substance or material [27-31]. By using absorption coefficient value the Extinction coefficient can be determined by the formula

$$k = \frac{\alpha \lambda}{4\pi} \quad (13)$$

where k is Extinction Coefficient, α is absorption coefficient, λ is wavelength. The variation of extinction coefficient (K) with wavelength is shown in Figure 13.

Optical Refractive Index and Reflectance

Refractive index (n) and Reflectance (R) are determined by using formulas

$$n = \frac{1}{T_s} + \sqrt{\frac{1}{T_s} - 1} \quad (14)$$

Amirsha Evangelin Kezia et al.,

$$R = \frac{(n-1)^2}{(n+1)^2} \quad (15)$$

The wavelength versus reflectance is shown in Figure 14. Figure 15 represents the variation of the refractive index as a function of photon energy. The linear refractive index (n) of the grown crystal was found to be 0.7 at the energy gap $E_g = 3.13$.

PHOTOLUMINESCENCE SPECTROSCOPY

A useful technique for obtaining reasonably direct information about the molecular-level physical properties of materials, such as band gap states and shallow and deep level defects, is photoluminescence (PL) spectroscopy [32–34]. The photoluminescence (PL) spectrum of TVS recorded using a Cary Eclipse spectrophotometer in the range between 250–500 nm with excitation wavelength of 270 nm is 4.59 eV at room temperature is shown in Figure 16. The highest emission peak from the spectrum was observed to be at 428 nm is 2.90 eV are due to violet emission and no other visible emission was observed. The relationship between energy (in eV) and wavelength (in nm) given by the equation,

$$E_g = \frac{hc}{\lambda} \quad (16)$$

Where E_g is the energy in units of eV, or electron volts, λ is the wavelength measured in nanometers (nm), and c is the velocity of light, which has units of ms^{-1} . The sharp single peak shows the good quality of TVS crystal.

CYCLIC VOLTAMMETRY

The cyclic voltammetry is used to investigate the electrochemical behavior of a system by methodically examining the current-voltage data of a specific electrochemical cell. The CV investigation was carried out using a linear scan rate that ranges from 0.01 V s^{-1} to 0.2 V s^{-1} within a voltage window of -1.5 to 2.0 V . A graph between current and potential is known as cyclic voltammogram (Figure 17) depicts the CV curves measured at different scan rates. When a slow scan rate (0.01 V s^{-1}) is applied to the device, a rapid increase in the current density versus potential gives an oval-shaped curve. Consequently, the slow scan rates cause the current to flow through the device in a resistive manner. As the operating time is gradually maximized and also scan rate is increased, more rectangular shaped curves can be obtained from the CV scans [35–38].

The specific capacitance obtained from CV measurement was calculated according to this Equation

$$C_{\text{specific}} = \frac{A}{\Delta V \times s \times m} \quad (17)$$

where ΔV is the potential range (V), A is the area of integration, s is the scan rate (V s^{-1}), m (g) is the mass of the sample. Table.2 shows the specific capacitance of the grown crystal. The specific capacitance of the TVS crystal has reduced from 0.8219 Fg^{-1} to 0.0263 Fg^{-1} with an increase in scan rate of 0.01 V s^{-1} to 0.2 V s^{-1} . This is because, the ions are more accessed to the active materials through pores at a lower scan rate. The results indicate that the grown crystal achieve a higher specific capacitance of 0.8219 Fg^{-1} at 10 mV/s .

CONCLUSIONS

Single crystal of thiourea-doped vanadyl sulphate was successfully grown by slow evaporation solution growth method at room temperature. The crystals were found to be transparent and a light blue colour. The thermal stability of thiourea-doped vanadyl sulphate crystal was estimated using TGDTA Analysis. the TVS crystal is thermally stable up to 123.83°C . From the DTA curve, reveals that, the sample melts at 202°C and the decomposition states at this temperature. Hence, the crystal has a good degree of crystallinity and is also thermally stable for device application. The rate constant and the half lifetime of reaction were calculated from the TGA data. From the TGA curve, kinetic parameters were determined using basic thermodynamic equations and the values obtained for each phase proved that the first and second phases are non-spontaneous endothermic reactions and the third phase transition is a spontaneous exothermic reactions. UV–Vis NIR spectrum shows that the crystal becomes transparent in the entire Vis-IR region and the cut-off wavelength was found to be 393 nm . The grown crystal has good optical transparency and hence it is suitable for NLO applications upto 393 nm . The optical band gap was calculated using Tauc's plot relation and it is found to be 3.04 eV . TVS crystal has lower cut-off wavelength is found to be 393 nm and a calculated

**Amirsha Evangelin Kezia et al.,**

Energy band gap of 3.16eV was determined in UV–vis studies which suggested the material is suitable for laser frequency doubling and related optoelectronics applications. The photoluminescence spectrum shows the violet emission for the TVS crystal. According to the cyclic voltammetry investigation, the TVS crystal exhibits a higher specific capacitance of 0.8219 Fg⁻¹ at 10 mV/s.

ABSTRACT

Menstruation is a natural physiological process for females of reproductive age, and it is necessary to understand hygienic practices and risks associated with menstruation. Data collected from adolescent girls (above 12 years of age) in a peri-urban girls' high school were selected through random sampling using a self-administered questionnaire. In this study, despite having 100% literacy, only 45.58 % of the adolescent girls had prior knowledge of menstruation before menarche. Knowledge about the cause of menstruation among adolescent girls is not satisfactory, as 34.8% of them did not know about the cause of menstruation and 63.7% of them believed that it was a natural process. In addition, 50.2% of them did not know about the cause of menstruation. 93.4% of the adolescent girls were ignorant about the source of menstrual bleeding and only 1.8% of the adolescent girls knew that the bleeding comes from the uterus. On a positive note, 79.5% of the adolescent girls preferred using sanitary pads, 16.2% used both sanitary pads and cloth, while 4.18% preferred using cloth. It is also observed age $p \leq (0.004)$ and class of adolescent girls $p \leq (0.010)$ are significantly associated with the types of adsorbents used. Yet, prior knowledge of menstruation $p \leq (0.0590)$ is not significantly associated with the types of adsorbents used. It is encouraging that 92.3% of participants preferred cleaning the reused clothes with soap and water, and 97.36% of the girls practiced drying the washed clothes in sunlight. Among the respondents who used sanitary napkins, 73.48% changed it 2-3 times per day whereas, 19.06% changed it 4-5 times per day, and 3.72% changed it 1 time per day. Prior knowledge of menstruation $p \leq (0.001)$, age $p \leq (0.007)$, Educational Status of the adolescent mother $p \leq (0.057)$, and agents used to clean genitalia $p \leq (0.051)$ is significantly associated with satisfactory cleaning of external genitalia. 95.34% of Adolescent girls were restricted from

**Ibasiewdor Mawlein and Nekita Sharma**

being involved in religious practices. The study concludes that though the adolescent girls are 100% literate their lack of knowledge regarding menstruation and the hygiene practices exhibited among them were not satisfactory. Hence, there is a need to educate girls as well as mothers on menstruation and create awareness of menstrual health and hygiene.

Keywords: Adolescent girls, Genitalia, Menstrual health, Hygiene, Sanitary pad.

INTRODUCTION

Menstruation is a common and healthy phenomenon for women who are of reproductive age [1,2]. The transitional stage between puberty and adulthood is known as adolescence. Menarche is a significant event in the lives of teenage females that starts between the ages of 10 and 16 and it is one of the indicators of puberty [3]. A key variable influencing how an adolescent develops reproductively is having a regular menstrual cycle [4]. However, due to a lack of sufficient information, majority of teenage girls approach the puberty stage unprepared [5]. Due to social taboos surrounding the topic of "menses," most women find it uncomfortable to talk about it, and teenage girls may not have access to sufficient information [6,7]. Women's hygiene habits during their periods are very important since they affect their health by making them more susceptible to reproductive tract infections (RTI). It is evident how menstrual hygiene habits, socioeconomic position, and RTI correlate. Millions of women today suffer from RTI and its after-effects, and the infection frequently spreads to the mother's unborn child. Having access to the information, resources, and cultural settings needed to handle menstruation hygienically and dignifiedly is a top priority for women and girls [8]. Even the limited information they do acquire is frequently biased and surrounded by misconceptions, and it comes primarily from peers, family members, and religious institutions [9.] In addition, girls have frequently reported feeling scared, perplexed, and ashamed when going through their menstrual cycle due to unpleasant smells, leaks, clothing stains, and losing sanitary products during class [10]. Additionally, this may negatively affect their ability to focus, participate in class, and have confidence in their academic abilities [11]. Depending upon one's level of understanding and awareness, menstruation is associated with several myths and customs that can occasionally hurt one's health. For instance, in underdeveloped nations such as India and Ethiopia, menstruation is frequently seen as a sign of disease, a lifelong process, the outcome of a curse, or a punishment from God [9, 12-15]. Teenage girls believe that menstruation is something humiliating and should be kept private as a result, academic achievement, attendance at school, and social interactions are all further impacted by these circumstances [16]. Considering the foregoing, this study was conducted in the peri-urban girl's high school of the Kamrup (Rural) district of Assam to evaluate the knowledge and practices of teenage girls regarding menstrual hygiene, learn about the disorders they experience during their periods, and identify the factors linked to the current menstrual hygiene practices [17].

MATERIALS AND METHODS

Sampling and data collection

A Survey was conducted among 215 adolescent high school girls, classes 7-10 (above 12 years of age) in a peri-urban area selected through simple random sampling. Data was collected using a self-administered questionnaire. Factors for data analysis include awareness about menstruation prior to menarche, menstrual hygiene practices, type of absorbent used, and restrictions imposed during menstruation.

Ethical clearance

Appropriate ethical clearance was obtained for this work from the Institutional Human Ethical Committee (AdtU/Ethics/student-lett/2021/025; dated 29/05/2021) and informed consent from participants

**Ibasiewdor Mawlein and Nekita Sharma****Statistical analysis**

Data expressed in percentages “%” and “n” indicates the number of counts. Statistical analysis was done using SPSS for Windows and the association was determined using a chi-square test and P value <0.05 was considered significant for all tests.

RESULT AND DISCUSSION**Socio-demographic profile of the respondents**

In the present study, most of the adolescent girls taking part fall under the age group of 13-15 years at 84%, followed by <=12 with 10.23% and girls aged between 16 -18 with 6.04%. Data summarized in **Table 1** indicates a significant association (P=0.004) between the type of adsorbent used with age. Adolescent girls aged between 13-15 years showed 66.97% of the girls used sanitary pads and 2.79 % used cloth, and 14.14 % used both sanitary pads and cloth. The educational status of the adolescent girls also has a significant association ((P=0.010) with the type of absorbent used. Our data showed that 11.68 % of the girls were in class 7th, 25.23% in 8th, 39.7% in 9th, and 23.36% in 10th standard. These adolescent girls primarily used sanitary pads to maintain menstrual hygiene. Adolescent girls belonging to class 7, 8, 9, and 10 standards showed 10.69%, 18.60%, 34.41%, and 20.93% used sanitary pads (**Table: 1**). It is also observed age $p \leq (0.004)$ and class of adolescent girls $p \leq (0.010)$ are significantly associated with the types of adsorbents used (**Table: 2**). This data indicates that education plays an important role in attaining awareness about menstrual hygiene among the population.

Knowledge of adolescent girls about menarche and their perception about menstruation

Data summarized in Table 1 showed that 90% of the adolescent girls aged between 10-13 years had their menarche, followed by 14-15 with 9%, and girls aged between 16-17 years with 1%. A similar study in West Bengal showed the age of menstruating girls ranged from 14-17 years and the majority being between 14-15 years of age[5]. It is also important to note that only 45.58 % of the adolescent girls had prior knowledge of menstruation (Table: 1). before menarche. Yet, prior knowledge of menstruation is not significantly associated with the types of adsorbents used $p \leq (0.0590)$ (**Table: 2**). It is necessary that every girl be made aware of menstruation before menarche. Knowledge about the cause of menstruation among adolescent girls was not satisfactory, 34.8% did not know about the cause of menstruation. Whereas 63.7% believed it was a natural process, 0.93% accepted it as a curse of God and 0.4% had no response (**Table: 1**). A similar study conducted in West Bengal among school girls, 86.25% of respondents believed it was a physiological process. Prior information on menstruation can help create awareness of menstrual hygiene. However, our study indicates that 50.2 % of them obtained information on menstruation from other sources, followed by mothers (46.04%), friends (1.86%), and sisters (1.8%). Despite being 100% literate, 93.4% of the adolescent girls were ignorant about the source of menstrual bleeding. 4.1% thought that it came from the vagina, 0.46% from the urethra, and only 1.8% of the adolescent girl knew that the bleeding was from the uterus. This concludes that spreading awareness of menstrual health and hygiene is needed among school-going girls. It was disheartening that the literacy level of the mothers was >90% and majority of the girls were unaware of the source of their menstrual bleeding, which might be a result of lack of awareness and impulsively adhering to traditions. On a positive note, 80% of the adolescent girls preferred using sanitary pads, 16.2% used both pads and cloth, and 4.18% preferred using cloth. In addition, 70.27% of the adolescent girls preferred re-using the cloth (**Table 1**).

Practice of menstrual hygiene among the adolescent girls

Women's hygiene practices throughout their menstrual cycles are of the utmost importance since they impact their health by making them more susceptible to infections[8]. Data summarized in **Table 3** shows that among the adolescent girls who used cloth, 92.3 % of them preferred to clean the reused clothes with soap and water, while 7.69% of them washed the clothes with water only. 97.36% of the girls practiced drying the washed clothes in sunlight, and 2.63% m dried the clothes in the bathroom or beneath other clothes for fear of being seen by others. A similar study also revealed that 60% of adolescent girls preferred reusing clothes. Among them, 96.30% cleaned the reused clothes with soap and water, and 77.78%[17].

**Ibasiewdor Mawlein and Nekita Sharma**

Adolescent girls adopted various methods to dispose of sanitary pads, 50.01% preferred throwing it in with routine waste, 36.27% used to burn it while 13.72% preferred other methods. Similarly, of girls who used cloth but did not reuse it, 55.88% chose to dispose of the clothes by throwing them with routine waste, 29.41% burned it, while 14.7% preferred other methods such as not throwing or hiding it. In a similar study in Jorhat, Assam, 81.53% of girls using sanitary pads and 82.22% using clothes dispose of them by throwing them in with routine waste (Table 3). Among the respondents who used sanitary napkins, the majority (73.48%) changed it 2-3 times per day. Whereas 19.06% changed 4-5 times per day, 3.72% changed it 1 time per day and 3.72% of the girls had no response. Cleaning is an important part of maintaining the hygiene of the external genitalia. The frequency of cleaning was found to be satisfactory (≥ 2 times/day) in 95.34% of the adolescent girls, and 2.79% was unsatisfactory i.e., less than 2 times per day. It is important to note that 61.86% of the girls used soap and water to clean the external genitalia while 33.02% used only water, 4.18% used water and antiseptic for cleaning and 0.93% showed no response (Table 3). Prior knowledge of menstruation $p \leq (0.001)$, age $p \leq (0.007)$, is significantly associated with satisfactory cleaning of external genitalia (Table 4). It must be noted, educational Status of the adolescent mother $p \leq (0.057)$, and agents used to clean genitalia $p \leq (0.051)$ is not significantly associated with satisfactory cleaning of external genitalia.

Practice or any form of restrictions during menstrual period

Adolescent girls did practice some form of restriction, the most common prohibition was being involved in religious practices 95.34%. In addition, 45.11% of the girls were not allowed to attend marriages, and 57.67% were restricted from doing their regular household work. Touching sour food was restricted for 66.04% and, 57.20% were not allowed to enter the kitchen or cook food. 46.51% had separate beds, and 27.90% were not allowed outside the house. 39.53% of the girls were prohibited from playing either inside or outside the house and, 22.79% did not go to school during menstruation (Fig. 1). Similarly, 97.27% of adolescent girls practiced a similar form of restriction not attending religious ceremonies and marriage functions, not doing household work, not touching sour food, not entering the kitchen and most importantly they were not allowed to go to school during those days [17]. All those actions could relate to their beliefs and misinterpretation of the menstrual cycle.

CONCLUSION

Menstruation indicates healthy reproductive health. Knowledge, awareness, and practice of menstrual hygiene is a concern among school-going adolescent girls. According to our survey, the girls were unaware of menarche or the source of bleeding. Menstruation health issues, unsafe practices, traditional assumptions, and restrictions were commonly observed. Knowledge and awareness are the two key factors influencing menstruation habits and hygiene. Hence, our results highlight the necessity of continuous awareness of menstrual hygiene to eliminate outdated traditional beliefs and misconceptions. There is a need to focus on guiding how to use, access, and dispose of sanitary pads responsibly and encourage safe and improved menstrual hygiene.

Conflict of Interest

The authors declare no conflict of interest in this reported communication.

ABSTRACT

Managing inflammation with considerable efficacy is a significant challenge due to the complex interplay of various factors. Proinflammatory cytokines play a critical role in the development of inflammation and neuropathic pain, which can lead to chronic inflammatory conditions and the progression of autoimmune diseases. During inflammation, cytokines are produced by adipocytes, and there is also a release of reactive oxygen species (ROS), further exacerbating the condition. *Sagadevi Nei*, a Siddha polyherbal formulation, has previously been investigated for its in-vitro nephroprotective activity. This study aims to assess the anti-inflammatory potential of *Sagadevi Nei* by focusing on its interaction with interleukin-6 (IL-6) and tumor necrosis factor-alpha (TNF- α) using molecular docking techniques. By retrieving relevant molecules from existing literature, researchers conducted a study to evaluate the binding efficacy and interactions of the phytochemical constituents of *Sagadevi Nei* with IL-6 and TNF- α . The findings revealed that the phytochemicals in *Sagadevi Nei* exhibit significant binding affinity and effective interactions with these proinflammatory cytokines. This suggests that *Sagadevi Nei* could potentially modulate inflammatory responses by targeting IL-6 and TNF- α , thereby offering a promising therapeutic approach for managing inflammation and related chronic conditions. The molecular docking study underscores the potential of this traditional formulation in contributing to anti-inflammatory therapy.

Keywords: Anti-inflammatory activity, IL6, Molecular Docking, Sagadevi Nei, TNF Alpha.

**Abarna and Manjari****INTRODUCTION**

The therapeutic properties and applications of herbs are widely known. In an environment where modern man has confronted the side effects and complexities of chemical drug usage, a return to nature and the use of natural and plant-based drugs occurs.[1] In an era dominated by technologies and hectic living, reconnecting with nature and embracing its therapeutic power has never been more important.[2] A traditional remedy that has been employed for several centuries to treat urinary tract conditions is *Sagadevi nei*. [3] This effective preparation was used in our research. *Sagadevi Nei* is scientifically proven to have anti-microbial activity.[4] As a natural biological reaction to chemical irritation, microbial pathogen infection, and tissue damage, inflammation occurs. The immune systems, both innate and adaptive, are involved in this biological process [5]. To eradicate foreign pathogens, Treat infection, and heal injured tissues, inflammation is triggered at a damaged site by immune cells migrating from blood vessels and releasing mediators. This is followed by the recruitment of inflammatory cells and the release of reactive oxygen species (ROS), reactive nitrogen species (RNS), and proinflammatory cytokines. Therefore, the primary purpose of inflammation is to strengthen the host defenses [6]. Normal inflammation often subsides quickly and on its own, but prolonged inflammation and abnormal resolution can lead to many chronic illnesses. Lately, molecular docking has become an essential part of in-silico drug development [7]. A common application of molecular docking is the study of protein and peptide interactions and binding affinities for biological activity [8]. This technique involves foreseeing the way a tiny molecule and a protein would interact at the atomic level. Siddha polyherbal formulation *Sagadevi Nei* consists of 11 ingredients that are proven scientifically to have anti-inflammatory, diuretic, antioxidant, and nephroprotective activity [9,10]. A total of 11 chemical constituents were derived from the 11 ingredients of *Sagadevi Nei* through a literature review and assessed for docking with Interleukin 6 (1N26) and TNF Alpha(2AZ5). [11-21]

MATERIALS AND METHODS

The Protein Data Bank (PDB) provided the 3D/ 2D structures of the target proteins 1N26 and 2AZ5 (IL6 and TNF Alpha), as depicted in Figure 1. The necessary lacking hydrogen atoms were added to the proteins during a cleanup procedure. The Autodock tool was utilized to assess the different lead molecule orientations of the target proteins. An examination of an interaction study was used to determine the optimal docking position. [22, 23]

METHODOLOGY

In order to assess phytochemicals against the target protein, docking calculations were performed. Important hydrogen atoms, Kollman unified atom type charges, and solvation parameters were added using AutoDock tools [24]. Using the Autogrid tool, affinity (grid) maps were created with $\times \times \text{Å}$ grid point dimensions and 0.375 Å spacing [24]. Distance-dependent dielectric functions and AutoDock parameter settings were used to calculate the van der Waals and electrostatic terms. The Lamarckian genetic algorithm (LGA) in conjunction with the Solis & Wets local search technique was used to carry out docking simulations [25]. The ligand molecules were initially assigned random orientations, locations, and torsions, with full freedom of motion for all rotatable torsions during docking. Every docking experiment had two runs, with each run ending when a maximum of 250,000 energy was used. The search procedure included a translational step of 0.2 Å, quaternion and torsion steps set at 5, and a population size of 150 [26, 27].

RESULTS AND DISCUSSION

In all, eleven major bioactive substances were isolated from the *Sagadevi Nei* as shown in Table 1 and Fig. 2. These compounds include β -sitosterol, glycyrrhizin, rutin, β -caryophyllene, piperine, gallic acid, picein, thymol, santalic acid, vetivenene, and linoleic acid, with molecular weights of 414.7, 822.9, 610.5, 204.35, 285.34, 170.12, 298.289,

**Abarna and Manjari**

150.22, 234.33, 202.33, and 280.452 g/mol, respectively. The hydrogen bond donors for β -sitosterol, glycyrrhizin, rutin, gallic acid, picein, thymol, santalic acid, and linoleic acid are 1, 8, 10, 4, 4, 1, 1, and 1, respectively. The hydrogen bond acceptors for β -sitosterol, glycyrrhizin, rutin, piperine, gallic acid, picein, thymol, santalic acid, and linoleic acid are 1, 16, 16, 3, 5, 7, 1, 2, and 2, respectively. According to the data, the binding energies of the phytochemicals glycyrrhizin, rutin, β -caryophyllene, gallic acid, picein, thymol, santalic acid, vetivenene, linoleic acid, piperine, and β -sitosterol with 1N26 (IL-6) are -9.23, -11.97, -5.73, -5.87, -6.95, -5.44, -6.24, -6.93, -5.74, -7.27, and -7.83, respectively. These interactions occur with 3, 2, 1, 1, 5, 4, 3, 4, 3, 6, and 5 amino acid residues, respectively. The core active amino acid residues His70, Asp71, Ser72, Val91, Pro117, Ser119, Thr120, Pro121, Ser122, Thr124, and Thr125 of 1N26 (Interleukin 6) have at least one and up to five interactions. Notably, Pro121 interacts with a maximum of eight phytochemicals, as detailed in Tables 2 and 3. The obtained bioactive components glycyrrhizin, rutin, β -caryophyllene, gallic acid, picein, thymol, santalic acid, vetivenene, linoleic acid, piperine, and β -sitosterol with 2AZ5 (TNF Alpha) have binding energy -10.08, -11.52, -5.11, -4.47, -5.93, -3.76, -5.09, -5.67, -4.53, -6.02, -6.93 respectively and interactions of 3, 3, 3, 3, 3, 4, 4, 2, 3, 3 respectively. Also, 2AZ5 has interactions ranging from 2 to 5 with the active amino acids Leu57, Tyr59, Tyr119, Gly121, and Tyr151. The amino acids 59, 119, and 151 bind with a maximum of 10 phytochemical constituents (Table 4 and 5). The binding energies of the derived phytochemical constituents against IL6 (1N26) range from -11.97 kcal/mol to -5.44 kcal/mol, while against TNF-Alpha (2AZ5), they range from -11.52 to -3.76 kcal/mol (Table 2 and Table 4). Rutin exhibits the highest binding energy, -11.97 kcal/mol for IL6 and -11.52 kcal/mol for TNF-Alpha. Rutin has a log P value of -2.02, indicating its hydrophilic nature, which supports rapid dissolution and permeability, making it effective in detoxification [28]. Regarding interactions, the phytochemical components show 2-4 interactions with TNF-Alpha, with santalic acid and vetivenene having the most interactions. For IL6, the interactions range from 1 to 6, with piperine showing the highest number of interactions. These results indicate that the phytochemical constituents have strong binding energies and significant interactions with both targets, highlighting their potential anti-inflammatory properties. Therefore, *Sagadevi Nei* may be effectively used to treat inflammatory diseases.

CONCLUSION

The results indicate that the bio-active compounds Picein, Thymol, Santalic acid, Vetivenene, Linoleic acid, Piperine, β -caryophyllene, Glycyrrhizin, and β -sitosterol demonstrate significant binding affinity to the target proteins 1N26 and 2AZ5. These substances have interactions with the active amino acids at the areas of action of the proteins, indicating that *Sagadevi Nei* may have potential anti-inflammatory benefits.

ABSTRACT

A 32-year-old male patient came to a tertiary care hospital with complaints of pain in the abdomen for three days which was sudden in onset, continuous in nature, stabbing type with a past medication history of consumption of tablet diclofenac 50 milligram + paracetamol 325 milligram thrice daily for 10 days. During the abdominal examination on admission, it was observed to be distended and diffused tenderness was present. Ultrasonography of the abdomen showed hollow viscous perforation. On exploratory laparotomy, a 0.5 x 0.1-centimeter perforation was seen in the duodenum, which was repaired using an omental patch. The final diagnosis on discharge was made as peritonitis secondary to duodenal perforation.

Keywords: NSAID, Peritonitis, hollow viscous perforation, duodenal perforation, diclofenac

INTRODUCTION

Globally, Nonsteroidal anti-inflammatory drugs (NSAID) are the most widely consumed class of analgesics (Singh G and Triadafilopoulos G., 1999). NSAIDs are known for their anti-inflammatory, antipyretic, and analgesic properties, hence they are commonly used in primary healthcare (Al-Shidhani A, Al-Rawahi N *et al.*, 2015). Despite their effectiveness in pain relief, their use has been increasingly associated with gastroduodenal ulcers and other

**Shilia Jacob Kurian et al.,**

complications that may be attributable to the inhibition of prostaglandin synthesis (Cryer B and Feldman M.,1992;Gabriel SE and Jaakkimainen L,1991). Gastrointestinal (GI) complications caused by NSAIDs are well known in general; Predominantly upper GI complications are better documented compared to lower GI(Sostres C and Gargallo CJ, Lanas A.,2013).Hence, the same causing peritonitis secondary to hollow viscous perforation has not been well-documented (Singh G and Rosen Ramey D,1997). Hence, we report a case of a fixed drug combination of diclofenac and paracetamol-induced peritonitis secondary to hollow viscous perforation.

CASE

A 32-year-old male patient came to the emergency department with complaints of pain in the abdomen for three days which was sudden in onset, continuous in nature, stabbing type, and non-radiating. The patient was a smoker for seven years and an occasional alcoholic. He was a construction worker by profession and had given a history of trauma in the left forearm 24 days back, for which symptomatic management was provided at a government hospital and was started on tab. diclofenac 50 mg + paracetamol 325 mg thrice daily for 10 days. The patient did not give a history of consumption of any other medication and had no other comorbid conditions. During the abdominal examination on admission, it was observed to be distended, rigidity was more over the upper abdomen and diffused tenderness was present. Ultrasonography of the abdomen showed hollow viscous perforation. All the laboratory parameters were normal, except for the elevated Lipase levels (115U/L). Based on the above findings and patient's medical history, the provisional diagnosis was made as peritonitis secondary to hollow viscous perforation. The patient underwent an exploratory laparotomy under general anaesthesia with Graham's omentoplasty on an emergency basis. Thick plaques were present on the serosal surface of the duodenum and pyloric parts. Multiple collections of pus were present at the right and left iliac fossa (800cc). A perforation measuring 0.5 x 0.1 cm was observed in the anterior wall of the first segment of the duodenum. This perforation was fixed by using an omental patch. Multiple peritoneal washes were administered and bilateral drains were inserted. Postoperatively, the output was monitored and he was managed with the following medications which were administered as injections: Cefoperazone + Sulbactam 1.5gm, Metronidazole 500 mg, Paracetamol 1gm, and Pantoprazole 40mg for 7 days. The postoperative period was uneventful. The final diagnosis on discharge was made as peritonitis secondary to duodenal perforation. On discharge, the patient's vitals were stable. The sutures were intact, the wound was healthy and the patient was well tolerated orally. Antibiotics and analgesics were stopped and capsule Tramadol 50mg was started on an SOS basis.

DISCUSSION

This case describes a probable association between peritonitis secondary to duodenal hollow viscous perforation and diclofenac ingestion when consumed for a period of 10 days. NSAIDs are known to reduce inflammation associated with musculoskeletal conditions, hence frequently administered for low back pain, osteoarthritis, musculoskeletal injury, high-grade fever etc (Al-Shidhani A, Al-Rawahi *Net al.*,2015).They possess numerous medical benefits, and concurrently well-documented gastrointestinal adverse effects are available (from minor dyspepsia to major ulcers) (Al-Shidhani A, Al-Rawahi *Net al.*,2015;Gor AP and Saksena M.,2011;Chandwani HSet *al.*,2009). A similar probable association of peritonitis with diclofenac was reported in 2009, in which a female patient developed perforated peritonitis after nine days of treatment with 50mg, twice daily of diclofenac sodium (Chandwani HSet *al.*,2009). Ulcers usually manifest as necrotic or apoptotic injury to enterocytes, which can affect the deeper layers of the mucosa, leading to the loss of villi and the presence of an acute inflammatory cell infiltration. Enteropathy is the collective name for adverse drug reactions that occur in the duodenum, jejunum, and ileum (Boelsterli UA*et al.*,2012) Gastrointestinal disorders linked to NSAID use; range from dyspeptic symptoms, ulcerations, perforations, and in some cases hospitalization or death(Russell RI,2001;Forshaw MJet *al.*,2001).Multiple studies have shown that around two-thirds of patients, regardless of whether they used nonsteroidal anti-inflammatory drugs (NSAIDs) for a long-term period of more than three months or a short-term period of less than oneweek, experienced drug-induced lesions in their small intestine (Boelsterli UA*et al.*,2012).NSAIDs interfere with prostaglandin synthesis by inhibiting the cyclo-oxygenase pathway (Russell RI,2001), impair mucosal defence as the drug penetrates the protective mucous

**Shilia Jacob Kurian et al.,**

layers, and damages the epithelial lining cells. This further damage injures the cells, capillaries, and venules. Hence, the gastric secretions further contribute to pH-dependent local damaging effects (Ivey KJ, 1988). The aetiologies of peritonitis are infectious pathogens through perforated bowel, or irritating chemical substances, namely gastric acid from a perforated ulcer (Thirumalagiri VR, 2017). In the case described here, the patient was on multiple doses of diclofenac sodium orally for two weeks. The subsequent patient history, presenting signs and symptoms, and diagnostic test findings were unable to identify any etiology for duodenal perforations other than NSAID-induced enteropathy. Therefore, it was diagnosed as a case of Peritonitis secondary to diclofenac-induced multiple duodenal perforations. Multiple studies have reported NSAID-induced small bowel ulcers and erosions, mucosal haemorrhage, and erythema which were confirmed by endoscopic studies and colonoscopy, further confirming autopsy data. Studies also reported that 40% of rheumatic patients on NSAIDs experience these complications (Chandwani HSet al., 2009; Forshaw MJet al., 2001; Lanos Aet al., 1992; Kurahara Ket al., 2001; Graham DY et al., 2005). Among these NSAIDs, diclofenac is considered as an agent with comparatively less GI side effects. Studies state that 20% of patients on diclofenac for long-term management experience adverse events, of which 2% discontinued, primarily due to GI distress (Gor AP and Saksena M., 2011; Van Walsem A. et al., 2015). However, the occurrence of peritonitis secondary to hollow viscous perforation due to short-term consumption of NSAIDs is relatively rare and in this case, the patient had confirmed use for a duration of merely ten days. Aside from age, gender, prior ulcer history, smoking, alcohol intake, concurrent drug usage, and the presence of Helicobacter pylori infection have been identified as factors that can significantly contribute to gastrointestinal damage (Chandwani HSet al., 2009). In this case, the damage may have been further accelerated by the patient's gender and social history like smoking and alcoholism. Appropriately counselling patients to take the medication after meals and simultaneously administering mucosa-protective drugs such as PPIs, H₂ receptor antagonists and synthetic prostaglandin (eg: misoprostol) can attain prevention of unnecessary GI events due to NSAIDs. Further co-administration with drugs that can increase the risk of GI irritation such as anticoagulants and oral corticosteroids should be avoided. Moreover, NSAIDs should be avoided or administered at lower doses in patients with a previous history of GI ulcers secondary to NSAID use (Chandwani HSet al., 2009; Laine L., 2001). The Naranjo Scale was employed to evaluate the causality of the adverse drug reaction (ADR) (Naranjo CA et al., 1981). The assessment revealed the ADR to be 'probably' associated with diclofenac.

CONCLUSION

Over time, the use of NSAIDs has grown and is still growing. These could adversely affect any part of the gastrointestinal tract causing multiple ileal erosions and perforation, and hence NSAIDs should be used with caution.

ABSTRACT

Bone conduction headsets have made tremendous technological advances, providing greater hearing experience by delivering sound via the skull bones directly into the inner ear of deaf patients and those who are having hearing loss issues. Optimal comfort and effectiveness in these devices are dependent on exact measurements of individual skull sizes. This paper investigates the history of skull size assessment methodologies, with an emphasis on the transformational impact of computed tomography (CT) in improving the design and personalization of bone conduction headsets. We illustrate the limits of older approaches while emphasizing the critical contributions of CT imaging. The paper explores CT concepts and uses in anatomical imaging, stressing its superior ability to provide precise and comprehensive skull measurements. The CT scanner measures the different parameters including length, width, circumferences and even temporal bone thickness. This will help the people suffering from hearing loss and help them to revive their hearing capability by development for better fitted BCIs with correct measurement via CT scan machine.

Keywords: Bone conduction headsets, Hearing loss, computed tomography, temporal bone thickness.

Mohit Saini et al.,

INTRODUCTION

A Computed Tomography Scan, often known as a CT scan, is a medical imaging method that employs X-rays to generate detailed image of the internal structures within the body, such as bones, muscles, blood arteries, and organs. CT scans are also reasonably pleasant and speedy. Godfrey Hounsfield, a British engineer, created the first CT scanner in 1971. In 1979, Hounsfield received the Nobel Prize in Physiology or Medicine for his work on CT **scanning (Mohd. Waheed El Anwar et al.,2017)**. A Bone Conduction Implant (BCI) is a surgically implanted device that aids hearing loss by bypassing the outer and middle ear and stimulating the inner ear directly. People with conductive hearing loss, mixed hearing loss, and single-sided deafness are treated using BCI(Cheol Hyo Ku et al., 2019). It functions by transforming sound waves into vibrations that are communicated to the inner ear via the skull. These vibrations are subsequently sent to the brain, where they are processed as sound. Hearing Loss is the inability to hear sound in one or both ears. People with hearing loss account for 5.3% of the global population. Hearing loss is classified based on ear anatomy, type of hearing loss, illness severity, and audiogram configuration(Aaron R. Baker et al., 2016). When the hearing loss has been properly defined, the appropriate medical intervention can be allocated.

Classification of Hearing Loss

Based on cause

1. Conductive hearing loss: It is caused by an issue in the outer or middle ear that inhibits sound waves from reaching the inner ear. Earwax accumulation, infection, fluid in the middle ear, or a ruptured eardrum can all cause this sort of hearing loss.
2. Sensorineural hearing loss: This condition is caused by injury to the inner ear or the cochlea. This form of hearing loss is typically irreversible and cannot be treated with surgery or medicines.
3. Mixed hearing loss: It is the mix of conductive and sensorineural hearing
4. Based on severity:
5. Mild hearing loss: The least severe kind of hearing loss is mild hearing loss. In loud surroundings, people with this condition may have difficulties hearing subtle noises or conversations.
6. Moderate hearing loss: The person may have difficulties hearing quiet and medium noises. He/she may also struggle to interpret speech in loud situations.
7. Severe hearing loss: The person may struggle to hear medium and loud noises. He/she may also struggle to understand speech if they do not utilize hearing aids or other assistive technologies.
8. Profound hearing loss: The person might hear very little or nothing at all. Lip reading or sign language may be used to communicate. The design of the head set body controls the amount of contact and pressure between the head and the device, which is critical for sound transmission efficiency. As a result, bone conduction hearing aids should be designed to fit the head size of a certain demographic. Computed tomography imaging allows for the assessment of any skull bone structure and shape that cannot be measured physically(Cheol Hyo Ku et al., 2019). In this work, we assessed the head dimensions using several parameters.

Historical Perspectives

Bone conduction technology was initially developed in the early 1800s by the renowned scientist Giovanni Batista Morgagni, who noticed vibrations passing through the skull. But it wasn't until the 20th century and the invention of bone conduction hearing aids. And these findings translated into real-world uses. In order to help transmit sound, early devices were crude and frequently resembled headbands or clamps that pushed on the skull. Even with the advancements, it was still difficult to determine skull size accurately. Conventional techniques, which relied on calipers and uniform templates, could only approximate cranial measurements in a broad way. This restriction limited the general acceptance of early bone conduction devices in addition to impeding their effectiveness. With the introduction of computed tomography (CT) in the 1970s, the historical trajectory of skull size assessment underwent a sea change(Dong Su Jang et al., 2020). This was a revolutionary time since CT scans made it possible for researchers and developers to recreate skulls in three dimensions, going beyond simple measurements to explore the detailed features of individual skulls. The capacity to accurately measure and examine cranial features opened the door to

Mohit Saini et al.,

customized designs that addressed the natural differences in the morphology of the skull between people (Aaron R. Baker et al., 2016). The historical progression from simple bone conduction aids to the complex headsets of today is closely associated with the incorporation of CT-based estimations of skull size. The combination of computed tomography and bone conduction technologies marks a significant turning point in this historical narrative.

Computed tomography for skull size measurement

The development of computed tomography (CT) has completely changed the field of medical imaging by providing detailed and accurate anatomical evaluations.

1. **Principles of Computed Tomography** Based on the ideas of X-ray imaging, computed tomography is unique in that it can provide cross-sectional image of the body. Through the rotation of an X-ray source around the subject and the use of detectors to monitor the radiation that is delivered, CT scans provide comprehensive, three-dimensional images of interior structures.
2. **Benefits Compared to Conventional Approaches** The depth three-dimensional morphology of the skull is frequently difficult to capture using conventional methods, which results in inaccurate measurements. On the other hand, a CT scan offers a detailed image of the interior and exterior characteristics of the skull, making it possible to measure the volume, breadth, and length of the structure precisely. This precision is crucial for the unique design factors that are vital for the development of bone conduction headsets.

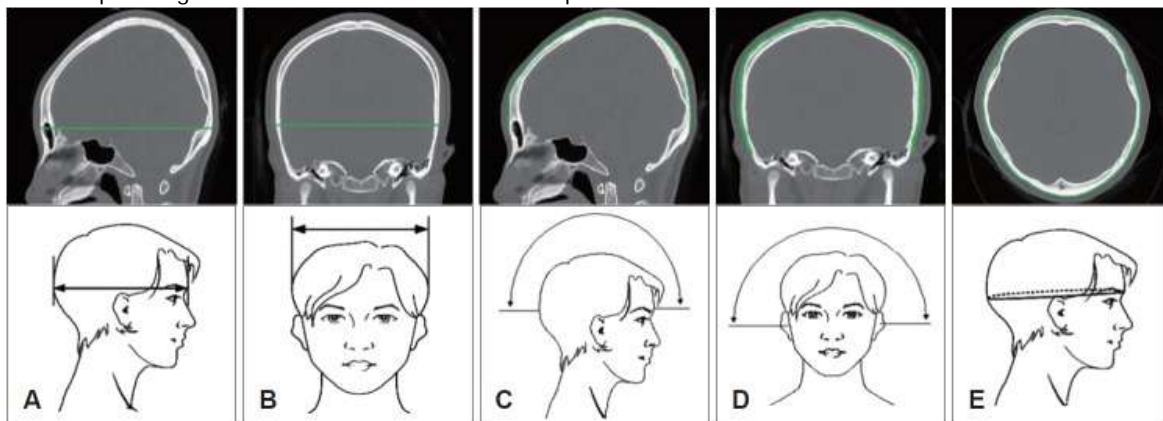

Figure 1: head length (A), head width (B), sagittal arc (C), bitragion arc (D), head circumference (E)

3. **Customized Imaging procedures** by customizing CT scans to target certain regions of interest, researchers may ensure precise data that are pertinent to the construction of bone conduction headsets. Furthermore, improvements in imaging methods, including multi-detector CT and high-resolution CT, enhance the capacity to catch minute features and provide a more complex image of cranial morphology.

4. Accuracy in Customized Headset Design The combination of CT scan and skull size estimation is consistent with the trend toward customized audio technologies. Individual differences in the structure of the skull can have a big impact on how comfortable and effective bone conduction headsets are. With the degree of accuracy made possible by CT, designers can now take these variances into consideration and create headsets that flawlessly fit each user's individual skull shape, including case studies and instances where CT-derived measurements of skull size have significantly advanced the state-of-the-art in customized audio technology.

Applications in Bone Conduction Headset Development

Computed tomography (CT) is becoming a vital tool for measuring skull size, and its uses go well beyond simple medical diagnoses. When it comes to improving the overall user experience, maximizing comfort, and fine-tuning design parameters, CT-derived data is essential to the development of bone conduction headsets.

1. **Customization accuracy** CT scans offer a thorough picture of a person's skull morphology. The precise length, breadth, and volume measurements allow for the production of headset components that are tailored to precisely suit each user's unique skull characteristics (Hyun-Ja Lee et al., 2008).

Mohit Saini et al.,

2. **Customized Transducer Positioning** In bone conduction headsets, the positioning of transducers has a significant impact on the effectiveness of sound transmission. Designers can see the interior features of the skull via CT scans, which helps them determine the best places to put transducers depending on each person's anatomy (Panagiotis A Dimitriadis et al., 2017). With this focused approach, acoustic leakage is reduced, sound quality is improved, and an immersive audio experience is enhanced.
3. **Evaluation of Temporal Bone Characteristics** Bone conduction technology performance is highly influenced by the morphology of the temporal bone. A thorough analysis of the temporal bone structure is made possible by CT imaging, which makes it easier to spot differences that can affect headset design (Mark C Flynn et al., 2012). This information enables designers to modify their strategy, taking individual variances into consideration and maximizing the headset's compatibility with a variety of temporal bone properties.
4. **Effect on Headset Comfort** Beyond the technical elements, bone conduction headset ergonomic design is influenced by CT-derived skull size measurements. Designers can address pressure spots and create headbands or support structures that decrease pain during continuous usage by taking into account each person's unique skull characteristics (Gaeun Kim et al., 2017).
5. **Case Research and Practical Uses** Several case studies and practical applications demonstrate the effectiveness of CT-derived skull size measurements in bone conduction headset creation. By analyzing these cases, we may get insight into how CT technology has helped solve design problems, enhance user experience, and advance audio technology. The aforementioned applications highlight the revolutionary influence of CT in molding the forthcoming of customized and superior audio solutions.

Comparison differences between Conventional methods and CT scan for measurements

1. **Precision and Accuracy** traditional methods of measuring skull size, such as calipers and tape measures, may lack the precision required for intricate anatomical details, leading to potential inaccuracies. Whereas, CT provides high-resolution, three-dimensional images, offering unparalleled precision in skull size measurements (Xu Tian et al., 2020). The detailed cross-sectional images enable precise assessments of bone structures, minimizing measurement errors.
2. **Time Efficiency** Traditional measurements can be time-consuming, especially when attempting to capture intricate details manually. Whereas, CT scans provide rapid acquisition of detailed images, significantly reducing the time required for skull size assessment. This efficiency is crucial for timely and effective development of personalized bone conduction devices.
3. **Personalization Potential** Conventional methods may offer limited options for personalization, relying on basic external measurements. Whereas, CT facilitates highly personalized design by capturing detailed anatomical features, enabling the development of bone conduction devices that precisely conform to the individual's skull structure.

Challenges and Future Directions

Although the use of computed tomography (CT) has unquestionably transformed the determination of skull size for the creation of bone conduction headsets, there are still difficulties in integrating this technology. It is critical to address these issues as we go through the current environment and set the path for future developments that will strengthen the relationship between audio technology and CT imaging.

1. **Ethical Concerns** Patient permission, privacy, and data security are among the ethical issues raised by the collection and use of CT data for the creation of customized audio devices. It is crucial to strike a balance between innovation and morality, which calls for precise rules and strong safeguards to protect user privacy and data integrity (M E Zernotti et al., 2019).
2. **Radiation Exposure Concerns** Although at very low doses, CT imaging exposes patients to ionizing radiation. Although radiation doses have decreased due to advances in CT technology, there are still worries about repetitive exposure, particularly in applications that need frequent measurements or longitudinal research.
3. **Handling Variability in Soft Tissues** Computed tomography (CT) is a valuable tool for identifying bone structures, but it can have difficulties when it comes to precisely defining soft tissues. The accuracy of skull size measurements can be affected by variations in soft tissue properties, particularly in areas that are crucial for the

Mohit Saini et al.,

positioning of headsets(Farid Alzhrani,2019). Suggestions for future work include investigating supplementary imaging modalities or image processing approaches to improve measurement accuracy and soft tissue visibility.

4. **Integration with Artificial Intelligence (AI)** The use of AI in the development of bone conduction headsets will be crucial for the future of skull size measuring. Large-scale CT dataset analysis may be streamlined by AI algorithms, which can also automate measurements and spot subtle patterns that would be missed by human inspection. Research and development procedures might be sped up by this integration, which would also improve the accuracy of measurement results.
5. **Multidisciplinary Collaboration** Teams comprising radiologists, audiologists, engineers, and ethicists must work together successfully to integrate CT imaging into the creation of bone conduction headsets. It is recommended that future initiatives prioritize multidisciplinary techniques, communication, and information exchange in order to handle difficulties from several angles and improve the overall caliber of research findings(Timo Gerdes et al., 2016).

CONCLUSION

The combination of computed tomography (CT) imaging and skull size assessment in the field of bone conduction headset development is a testament to the revolutionary potential of technology in defining the future of individualized audio experiences. The impact of CT becomes clear as we follow its historical development from crude bone conduction aids to customized, high-tech headsets. By providing a three-dimensional window into the intricacies of each individual's cranial anatomy, the accuracy provided by CT in the assessment of skull size has advanced the field beyond the limitations of conventional approaches. To guarantee the appropriate and fair integration of CT technology, obstacles like radiation exposure concerns, ethical issues, and the requirement for standardization must be overcome. Prospective paths for the future include integrating artificial intelligence, collaborating across disciplines, and going beyond skull size to examine wider cranial traits. The discipline has the potential to improve not just how we estimate skull size but also how we understand and work with the complex subtleties of human anatomy in the years to come. The combination of CT and audio technologies redefines the user experience for bone conduction headsets by providing previously unattainable levels of personalization, comfort, and audio fidelity. As we go into the future, the trip from the foundations of history to the vanguard of innovation is a monument to the perseverance of scientific research and the limitless capacity of technology to influence our perceptions of and interactions with the auditory world.

ABSTRACT

The purpose of this study is to measure the air kerma strength (AKS) using well type chamber and Farmer chamber with cylindrical phantom for cobalt-60 source and compare with the manufacturer data and available literature. An applicator placed inside the source holder of the well type chamber and Farmer chamber with cylindrical phantom. The chamber was connected with electrometer. The dwell position was activated at five mm intervals with dwell time 60 seconds in the treatment planning system and the plan was executed in the HDR unit. The maximum current was measured in nanoampere (nA) at particular dwell position in well type chamber and the readings were tabulated. In Farmer chamber, the electric charge measured at particular maximum current dwell position. The readings were measure in different volts and tabulated. The correction factors were applied to calculate the AKS for both chambers. The percentage deviation between the manufacture and measured data is -1.34% in well type chamber and -2.86 % in Farmer chamber respectively. In worldwide, well type chamber is used for AKS measurement in HDR brachytherapy sources, but the Farmer chamber along with cylindrical phantom is also capable for AKS measurement for HDR brachytherapy sources.

Keywords: Well type chamber, Farmer type chamber, cylindrical phantom, Co-60 source.

Revathy and Shanmukhappa B Kaginelli

INTRODUCTION

The goal of radiotherapy is to maximum dose to the tumor and minimum dose to normal tissues for cancer treatment. Radiotherapy divides into external beam radiotherapy and brachytherapy. In 1898, Madam Marie curie was discovered the radium source and it was the milestone for brachytherapy. Brachytherapy (BT) is using sealed radioactive source placed inside the tumor. Radioactive sources such as Radium-226 (Ra-226), Cesium-137 (Cs-137), Iridium-192 (Ir-192) and Cobalt-60 (Co-60) and Iodine-125 (I-125) are used for BT treatment due to their rapid dose fall off to achieve the goal of radiotherapy. BT is divided into dose rate such as low dose rate (0.4-2 Gy/hr) (LDR), medium dose rate (2-12 Gy/hr) (MDR) and high dose rate (greater than 12 Gy/hr) (HDR). Ir-192 source is common source in HDR BT for its specific activity, easy availability. But, it needs to be change three months once because of its lesser half-life (73.8 days). Nowadays, miniaturized Co -60 source availability increases and replace the Ir-192 source for its longer half-life (5.26 years). [1,2] Quality assurance plays a vital role in radiotherapy for patient treatment. The air kerma strength (AKS) measurement is recommended QA for the source strength calibration in BT and the tolerance is within $\pm 3\%$ of manufacturer data. Air kerma strength is defined as the product of the air kerma rate at calibrate distanced, in free space from the source centre along the perpendicular direction and square of the distance. {AKS = Reference air kerma rate X (distance)² }. [3-6] Goetsch et al. created the standard AKS calibration for Ir -192 HDR brachytherapy sources at the University of Wisconsin Accredited Dosimetry Calibration Laboratory (UWADCL) in 1992. This calibration procedure is known as the seven-distance measurement approach, using a graphite wall Farmer chamber to measure the AKS at seven distances in air. Direct or indirect approaches can also be used to determine the AKS of a high-dose rate (HDR) brachytherapy source. [7] Well-type ionization chambers were used for indirect measurements, while a Farmer chamber and the seven-distance approach can be employed for direct measurements of AKS. The German society of Medical Physics (DGMP) report number 13 recommends the Farmer chamber along with cylindrical phantom (Krieger phantom) for the purpose of AKS measurement in HDR brachytherapy. [8] The aim of this study is to measure the air kerma strength using Farmer chamber with cylindrical phantom and well type chamber for saginova cobalt-60 source HDR brachytherapy and compare with the manufacturer data and available literature.

MATERIALS AND METHODS

The study was conducted in Saginova HDR brachytherapy equipped with cobalt-60 source. The unit has 25 channels to deliver the treatment and the source dimension is 3.5mm (L) X 1 mm (D). The treatment planning system is Sagiplan (Version 2.0.2). The treatment execution in this unit is divided into three parts. They are treatment control panel (TCP), treatment control console (TCC) and treatment delivery unit (TDU). Before AKS measurement, the daily QA was performed by qualified medical physicist.

Well type chamber measurement:

Figure 1 show the experimental set up of well type chamber measurement. Well type chamber (PTW source check, Germany) consists of an aluminum wall ion chamber filled with argon gas under high pressure. The collection potential applied to the chamber was about 300 V. A source holder is used to hold the applicator to reproduce the source geometry in relation to the surrounding chamber walls. The energy dependence of the chamber arises from absorption and scattering of the photons and secondary electrons in the chamber walls and the gas. Besides this intrinsic energy dependence, oblique filtration through the source encapsulation affects the chamber response. An applicator placed inside the source holder of the well type chamber. The chamber was connected with electrometer (PTW, Romeo). The dwell position was activated at five mm intervals with dwell time 60 seconds in the treatment planning system and the plan was executed through the HDR unit. The maximum current was measured in nanoampere (nA) at particular dwell position (sweet spot) through the electrometer and the readings were tabulated. The maximum current at a particular dwell position was repeated three times and average reading was noted. The air kerma strength was calculated using the below mentioned formula:

$$AKS = M \times N_{RAKR} \times K \times T, P$$

(Eqn 1)

Revathy and Shanmukhappa B Kaginelli

AKS - Air kerma strength in cGy cm²/hr

M - Average meter reading in nA/min

N_{RAKR} - Calibration factor in Gy.m² h⁻¹A⁻¹(9.669X10⁵) for chamber (Co-60 source)

K_{T,P} - Temperature, Pressure correction factor

$$K_{T,P} = (273.2 + T / 273.2 + T_0) \times (P_0 / P) \quad (\text{Eqn 2})$$

T, P = Room temperature and pressure

T₀, P₀ = Reference temperature and pressure (T₀ = 20 degree ; P₀ = 1013.2 mbar)

Cylindrical phantom with farmer type chamber:

Figure 2 shows the Farmer chamber with cylindrical phantom experimental set up. A cylindrical phantom is made up of tissue equivalent material along with Farmer chamber is used for measurement. The chemical composition of the phantom is C₅H₈O₂ and density is 1.16-1.20 g/cm³ respectively. It has a total diameter of 200mm and height of 120 mm. Four holes were drilled equidistant from each other at 0, 90, 180 and 270 degrees at the periphery of the phantom. These holes have a diameter of 13 mm for holding the ionization chamber. A central hole or channel having a diameter of 4mm was drilled for placing the applicator and acts as the source holder. The distance between the holes from the central channel is 80 mm and is actually a compromise between the high dose gradient close to the source and the signal level fall off with distance. The sensitive volume of the chamber and centre of the active source were maintained at the same level and parallel to each other. An applicator was inserted into the central hole and the Farmer chamber (PTW, farmer type chamber) placed inside the PMMA cylindrical phantom. The chamber was connected with electrometer and selected 400 V to measure the maximum current. The dwell position was programmed at dwell position of five mm and dwell time 60 seconds. The maximum current reading was noted at a particular dwell position. The measurement was changed from current mode to charge mode in the electrometer. The particular maximum current dwell position was activated 60 seconds and executed three times for reproducibility. The charge was measured in nanocolomb (nC) at particular maximum current dwell position and tabulated at 400 V, 200 V and -400V for the ion recombination correction factor (Kion) and polarity correction factor (Ks).

$$K_{ion} = \frac{\{(V_2/V_1)^2 - 1\}}{\{(V_2/V_1)^2 - (M_2/M_1)} \quad (\text{eqn 3})$$

$$K_s = \frac{(M_1 + M_3)}{2M_3} \quad (\text{eqn 4})$$

M₁ = average meter reading at 400 V

M₂ = average meter reading at 200V

M₃ = average meter reading at -400V

The below correction factors are taken from DGMP recommendation for AKS calculation (8)

$$AKS = (1 - g_a)^{-1} \times \left\{ \frac{(\mu_{en}/\rho)_a}{(\mu_{en}/\rho)_w} \right\} \times K_w \times K_a \times N_w \times K_{z,p} \times K_r \times X$$

$$K_{T,P} \times K_{ion} \times K_{pol} \times M_1 \times 60 \quad (\text{Eqn 5})$$

g_a, g_w = Relative bremsstrahlung losses in air or water = 0.1 for Ir 192 radiation

g_a = g_w = 0.1 % (assumed same value for Co-60 point source)

$$\frac{(\mu_{en}/\rho)_a}{(\mu_{en}/\rho)_w} = 0.9276$$

{(μ_{en}/ρ)_a = Mass energy absorption coefficient in air; (μ_{en}/ρ)_w = Mass energy absorption coefficient in water}

K_w = field perturbation correction of water in plexi class surrounding = 1.00

K_a = for correction factor for source quality deviation from Co-60

N_w = calibration factor in water (5.404X10⁷Gy/C)

K_{z,p} = Geometry factor for cylindrical phantom = 1.187

K_r = correction of distance from 8 cm to 1 cm accordance with inverse square law. (K_r = (8/1)² = 64)

K_{T, P} = Temperature pressure correction factor

K_{ion} = Ion recombination correction factor

K_{pol} = polarity correction factor

M₁ = average meter readings

**Revathy and Shanmukhappa B Kaginelli****Statistical analysis**

Descriptive statistics was done using Microsoft excel software.

RESULTS

Table 1 shows the well type chamber measurement. The maximum current is at 10th dwell position in the applicator and the maximum current is 19.32 nA. Table 2 shows the Farmer chamber measurement and maximum current is 13.52 nA at first dwell position. Table 3 shows the measurement of charges in nC at 400V, 200V and -400V for ion recombination and saturation correction factors. Table 4 explains the percentage deviation between the manufacturer data and measured data of both chambers. The manufacturer AKS is 20810 cGy.cm²/hr, the measured AKS in well type chamber is 20531 cGy.cm²/hr and Farmer chamber with cylindrical phantom is 20231 cGy.cm²/hr respectively. The percentage deviation between the manufacture and measured is -1.34% in well type chamber and -2.86 % in Farmer chamber respectively.

DISCUSSION

The air kerma strength is one of essential part of the QA in BT. The primary objective of this study was to evaluate the feasibility of use of well type chamber and Farmer chamber for determination of air kerma strength of Co 60 HDR brachytherapy source. Table 5 explains the comparison of different literature of AKS measurement for well type chamber and Farmer chamber with cylindrical phantom using Ir-192 and Co-60 sources. Batlas et al, Patel et al and Bondel et al were measured AKS using both chambers in Ir-192 source.[9-11]Azhari et al was measured AKS using both chambers in Ir-192 and Co-60 sources.[12]Emmanuel et al was measured two different AKS Co-60 sources using both chambers.[13] For Ir-192 source, the percentage deviation was observed the well type chamber (range from -2.04% to 1.1%) compare to Farmer chamber (range from -2.2% to 0.62%) in the literature. Azhari et al have performed AKS measurement for both Ir-192 and Co-60 sources according to three international protocols with different methods. The measurements showed deviations from the manufacturer data about 1.1% for Ir-192 source and 1.2% to -2.2% for Co-60 source in both chambers. Emmanuel et al measured the AKS using PTW well type chamber, HDR 1000 plus chamber and Farmer chamber with cylindrical phantom for two different AKS Co-60 sources. They have showed that the percentage of deviation was -2.8% and -1.06% in PTW well type chamber, -1.97% and 0.65% in HDR1000 plus well type chamber and 1% and 2.4% in Farmer chamber respectively. In our study, we found -1.34% variation in well type chamber and -2.86% variation in farmer type chamber respectively.

Apart from AKS measurement, some of the studies explained about the characteristics and performance of both chambers in Ir-192 and Co-60 sources. Sathyan et al measured the different physical properties of BDS1000 (Rosalina, India) well type chamber and compared with HDR1000 plus (Standard imaging, USA) and BTC/3007 (Capintec USA) well type chambers. He was measured the nominal response of different well type chambers and found the values were 1.636 nA/AKS for BDS1000, 1.972 nA/AKS for HDR 1000 plus and 13.87nA/AKS for BTC/3007 respectively. [14] We observed that 1.930 nA/AKS nominal response in PTW source check well type chamber in our study. Andrassay et al have stated in their study that QA instrumentation used for Ir-192 source is also compatible with Co-60 source. Both chambers can be calibrated for both the sources, with traceability to the appropriate primary standards. [15]Kambauwa JD explained in his study about the well type chamber and Farmer chamber with cylindrical phantom. He concluded in his study, the Farmer chamber with cylindrical phantom can be used for calibration of HDR BT and routine measurements of QA in clinical set up of BT.[16] In our study, the maximum current is measured at different positions in both chambers (well type chamber at 50 mm and farmer type chamber with cylindrical phantom at 5 mm from the tip of the applicator) and observed current values are low in the cylindrical phantom with farmer type chamber compared to well type chamber because of the chamber volume and the position of the applicator. Well type chamber has larger volume (approx. 200 cm³) in 4 π geometry compare to farmer type chamber volume (0.6 cm³). Well type chamber is calibrated in air (NRAKR) and Farmer chamber is calibrated in water (ND,W). The uncertainty factors are more in Farmer chamber compare to well type chamber. The strength of

**Revathy and Shanmukhappa B Kaginelli**

this study is to measure the AKS using both well type chamber and Farmer chamber in Co-60 source of saginova HDR brachytherapy. The limitation of the study is only focus on two methods well type chamber (commonly used in brachytherapy calibration) and Farmer chamber with cylindrical phantom DGMP recommendation); other techniques were not measured because to various challenges. The most widely used dosimeters in HDR brachytherapy calibration are well-type chambers. Hence, most of the physicist preferred well type chamber for calibration of HDR sources. But, the Farmer chamber with cylindrical phantom is also capable to calibrate the HDR sources and found within the tolerance limits from the manufacturer data and compared with available literature.

ABSTRACT

In this review we explore the potential, for intelligence (AI) to transform agriculture and meet the demands of a growing population. The focus is on three areas; analytics, advancements in agricultural robotics and precision farming practices including crop surveillance. These are identified as areas where AI could make a difference. Additionally the assessment highlights the Internet of Things (IoT) as a technology with potential for future applications, in agriculture. In spite of these obstacles, considerable advancements have been made recently in the creation of agricultural robots for diverse purposes. The analysis highlights the potential developments and bright future of AI in agriculture, while acknowledging the challenges of applying research findings to actual farms.

Keywords: Artificial Intelligence (AI), IOT, Precision farming, Smart agriculture, Robotics

INTRODUCTION

The significance of agriculture to the worldwide economy is growing as a result of population growth-driven increases in food consumption. Many sectors are changing as a result of machine learning (AI), one of the technologies that is developing the fastest right now [1]. Aware of its potential, scientists and academics are investigating how artificial intelligence (AI) and the Internet of Things (IoT) may be integrated with "smart farming" to enable farmers [2]. AI in agriculture has the potential to improve crop protection tactics, fertilizer usage, and seed creation, ultimately boosting agricultural profitability and the country's economy [3]. Three general categories can be used to group AI's contributions to agriculture: agricultural robotics, analytics for prediction, precision farming and

**Arun et al.,**

crop monitoring [4]. One of the biggest issues at the moment is agriculture, which is crucial for any nation. Approximately 820 million people worldwide are estimated to be undernourished [5]. Furthermore, 70% more food needs to be produced because the world's population is predicted to reach 9.1 billion in 2050. In order to prevent around 370 million people from becoming hungry in 2050, further investment in agriculture will be required in addition to the predicted amounts. Furthermore, there is expected to be an increasing disparity between the amount of water that is accessible and the growing demand for water; by 2025, more than three billion people are expected to be under water stress [6].

Precision farming

In the coming years, precision farming is gaining significant traction within the agricultural field. This approach integrates artificial intelligence and data-driven insights to revolutionize traditional methods. By enabling a more targeted approach to resource management, precision farming plays an increasingly crucial role in modern farming, advancing sustainability and delivering numerous efficiency gains [7].

Focusing on benefits for the environment

- Minimizing water waste, reducing reliance on chemical fertilizers and pesticides, and promoting soil health. This not only benefits crop yields but also contributes to a more sustainable food system for future generations [8].

Focusing on economic benefits for farmers

- leading to increased profitability for farmers. With precise data on crop health and resource needs, farmers can optimize their inputs, minimize waste and maximize their return on investment [9].

Focusing on technological advancements

- Advancements in sensor technology, cloud computing, and machine learning continue to evolve. This paves the way for even more sophisticated applications in precision farming, further transforming the agricultural landscape [10].

These ideas enable farmers to tailor their actions, encompassing irrigation, pest management, and fertilization to meet the requirements of their crops. This improvement results in increased productivity, reduced costs, and sustainability, giving farmers the ability to maximize productivity and utilize resources efficiently. Machine learning and data analytics are two main examples of AI technology successfully used in modern farming. Machine learning algorithms process data to find patterns and connections within vast amounts of crop data gathered from satellites and sensors. This data-driven approach equips farmers to take precise actions to understand the specific requirements of their farms. For instance, AI drones equipped with various types of sensors can capture comprehensive pictures of fields, which can then be analyzed to detect pest infestations, nutritional deficits, or disease outbreaks. This advantage allows farmers to apply targeted remedies to affected regions, eliminating the need for pesticides and fertilizers and minimizing damage to the environment. The power of AI also extends to yield estimation. AI algorithms precisely predict crop yield potential by analyzing data collected from various sources such as satellites, photography, and weather forecasts. By utilizing AI technologies, farmers can reduce their financial risks by making informed decisions about pricing, distribution, and storage. While AI in precision agriculture offers numerous advantages, challenges also arise. The initial risk lies in the high cost of AI technology, and issues of data security and connectivity in remote areas pose hurdles for farmers. In conclusion, precision agriculture is a technology that works in conjunction with agricultural practices to produce yields in a sustainable and productive manner for farmers. AI-powered solutions empower data-informed decisions, optimize resource management, boost yields, and diminish environmental impact. Precision agriculture has the potential to revolutionize crop cultivation methods, ensuring yield security for a growing global population.

Crop Monitoring and Management**AI methods in crop monitoring**

Artificial Intelligences mainly focused on pest control and crop protection, most importantly in weeds and disease management. It depends on the elements such as

**Arun et al.,**

- Climate conduction
- Nutrition optimization
- Cultural activities and labour optimization
- Enhancing plant physiology and health

Climate conduction

Artificial Intelligences and robots plays a vital role, AI and robots collect advance information's like climate data, helps farmers to take important data about plantations, water usage amount and perfect crop selection. Robots monitor whether conduction, Soil moisture levels and pest outbreaks.

Nutrition optimization

For crops Nutrition is important for both yield, quality and quantity Artificial Intelligences in robotics helps in nutrient management by checking plant nutrient requirements, growth pattern, Soil composition. Artificial Intelligences in robotics helps for sustainable agriculture while decreasing environmental problems

Cultural activities and labour optimization

It is essential for successful crop production. Artificial Intelligences in robotics can reduce labor intensive efforts and maintains resources allocation. Time consuming activities like harvesting, purning and sorting can be easily done with great accuracy and efficiency.

Enhancing plant physiology and health

Artificial Intelligences can analyse large datasets like growth pattern, disease symptoms for early detection and intervention. Weeds can be identified and targeted using Artificial Intelligences sensors easily and then the appropriate herbicide can be applied in the areas. Artificial Intelligences in agriculture improves the quality of life for farmers and make agriculture more profitable profession [11].

Predictive Analytics**Understanding Yield Mapping in Precision Agriculture**

This document provides a comprehensive overview of yield mapping, a critical component of precision agriculture. It delves into the process of creating yield maps, the types of yield maps, the basic components of a yield mapping system, and the importance of these maps in modern farming practices. The insights presented are particularly relevant in the context of climate change and the need for sustainable agriculture [12].

Introduction to Yield Mapping

Yield mapping involves the collection of geo referenced or GPS data of crop yield and characteristics such as moisture content during harvest. This process utilizes a variety of sensors and has been a common practice in agriculture since the last decade of the 20th century. Yield mapping is essential for understanding spatial data in precision agriculture and making informed decisions regarding site-specific farming.

The Benefits of Variable Rate Application in Precision Agriculture

Variable rate application (VRA) is a key component of precision agriculture. By applying inputs such as fertilizer or pesticides at variable rates based on site-specific data, farmers can optimize resource allocation and minimize waste. This card explores the advantages of VRA, including improved crop yield, cost savings, and environmental sustainability.

Historical Background

The concept of yield mapping was first introduced in the research paper 'A yield map primer' by Blackmore in 1998. This paper provided practical guidelines for yield mapping and was presented in Japan. Subsequent research, such as 'Yield mapping; errors and algorithms' by Blackmore and Marshall in 1996, addressed early challenges by identifying six main errors in yield data collection

**Arun et al.,****Types of Yield Maps****Inference Maps**

- These maps combine yield estimates with existing map delineations without changing the base map, such as associating yield goals with a soil map

Prediction Maps

- Prediction maps use models to predict yield components based on spatial data like soil and weather properties

Interpolation Maps

- Interpolation techniques are applied to estimate yield values between measured data points at specific site locations [13]

Basic Components of Yield Mapping System**The Role of Drones in Precision Agriculture**

Unmanned aerial vehicles (UAVs), or drones, are becoming an increasingly popular tool in precision agriculture. By capturing high-resolution images and data, drones can provide farmers with valuable insights into crop health and growth patterns. This card explores the benefits and challenges of using drones in agriculture and highlights some of the latest research in the field. AI applications in irrigation and water management AI technologies optimize water usage by monitoring soil moisture levels, weather forecasts, and real-time crop water requirements. Moreover, AI facilitates the scheduling of irrigation activities to minimize water wastage and maintain optimal crop health. Smart Irrigation AI-driven irrigation systems ensure precise water delivery, avoiding over-watering and under watering. Weather Monitoring AI monitors weather changes to adjust irrigation schedules and mitigate potential risks to crop [14].

Agriculture Robotics

Farming is quickly becoming an appealing high tech sector that is attracting new professionals, companies and investors. The technology is developing, not simply enhancing manufacturing capability but likewise robotics and automation. At the core of this development lies the need for increasingly greater production yields. The UN anticipates the world population will grow from 7.3 billion today, to 9.7 billion in 2050. This population will require a lot more food, placing extreme stress on farmers to meet this demand. Agricultural robotics are raising production yields for farmers in a number of ways, with creative and innovative applications ranging from drones to autonomous tractors and robotic arms.

- Harvesting and picking
- Weed control
- Spraying
- packing

As artificial intelligence and robotics continue to advance, we can expect even more sophisticated applications to emerge. Imagine robots that can not only harvest crops but also adapt to changing weather conditions or identify and eliminate pests with pinpoint accuracy. The future of agriculture promises to be a fascinating blend of human expertise and technological innovation.

CONCLUSION

This review provides an overview of how AI technology's utilized in agriculture. While in some industries most of the work is carried out by intelligence thereby reducing the workload, for professionals and increasing productivity the scenario is quite different in agriculture. Here farmers are responsible for a majority of the work with AI playing a role. Tractors were first invented in 1892 representing cutting edge technology at that time. Initially many farmers couldn't afford tractors. Today they are commonly used. Unlike operating a tractor which requires driving skills utilizing AI integrated machinery demands education. In India, where the literacy rate among farmers stands at 59.56% educating farmers on using AI technology is crucial, for streamlining their work processes and making them more profitable.

ACKNOWLEDGMENTS

The authors extend their gratitude to the Director, Dean, and Head of the Division of Chemistry at SRM Institute of Science and Technology, Tiruchirappalli, for providing essential research facilities crucial for the successful completion of this work.

ABSTRACT

About 30 to 50 percent of women will at some point in their lives experience vulvovaginal candidiasis, or VVC. Moreover, on the other side, STH (Soil-transmitted helminths) infections pose a serious hazard to public health and are among the most prevalent infections in the globe. According to estimates from the World Health Organization (WHO), there were 1.5 billion STH infections worldwide in 2020, with over 267 million pre-schoolers and over 568 million school-age children residing in regions where these parasites are spread. Soil-transmitted helminths are transmitted to humans by contaminated soil. An effervescent bio-adhesive tablet dosage form was developed with an objective that vaginal discharge should not drain the dosage form out. Dosage form should remain adhered to mucosal linings after both vaginal application and oral consumption for helminth infections. Antifungal Susceptibility testing was performed using prepared tablet dosage form against *Candida albicans* (MTCC 277) as prominent species involved in fungal infections of vagina. Whereas anthelmintic activity was performed using *Pherentima posthuma* (Indian Earthworms) due to their anatomical and physiological resemblances with intestinal roundworm parasite of human beings. Tablet dosage form designed passed post compression parameters. The same tablet dosage form tested against *Candida albicans* and *Pherentima posthuma* (Indian Earthworms) was found to be effective and equivalent to marketed standard dosage forms for vaginal fungal infections and Intestinal helminth infections. Dual purpose applicability of dosage form could be cost-effective approach and could be the reasonable approach to proceed for product scale-up for multiple ailments.

Keywords: Garlic, Bio-Adhesive, *Candida albicans*, *Pherentima posthuma*, vaginal fungal infections, Intestinal helminth infections.

INTRODUCTION

Garlic has a substantial nutritional value and remarkable medicinal potential. It is discovered that garlic, which is used as a flavoring and spice, has basic essential elements. There are plenty of minerals, water, vitamins, protein, fat, and carbohydrates. Due to its strong therapeutic potential, garlic is used to treat a wide range of human ailments. Anti-inflammatory, rheumatological, ulcer-inhibiting, anticholinergic, analgesic, antimicrobial, antistress, antidiabetes, anticancer, liver protection, anthelmintics, antioxidants, antifungal, and wound-healing properties are just a few of the effects that have been reported. It also helps with asthma, arthritis, chronic fever, tuberculosis, runny nose, malaria, leprosy, skin discoloration, and itching, indigestion, colic, enlarged spleen, haemorrhoids, fistula, urinary tract disease, diabetes, kidney stones, anaemia, jaundice, epilepsy, cataract, and night blindness, among other conditions [1]. The Sanskrit language ancient texts on Ayurveda indicate that garlic has been used in India for over three millennia. "Garlic" is referred to in both manuscripts as Lasuna and by its synonym, Rasona. Similar applications have been observed not only in India as a whole but also in adjacent countries such as Nepal, Myanmar, Lao, Pakistan, Bangladesh, Bhutan, and Sri Lanka (South-East Asian region). Consequently, garlic has been used throughout India since ancient times [2].

Vulvovaginal candidiasis (VVC) affects between 30 and 50 percent of women at some point in their lives. A burning or itchy feeling (27%) and dysuria (33%) are common symptoms. *Candidates albicans*, *glabrata*, or *krusei* are the most common causes of VVC. [3]. Due to limited penetration into the biofilm matrix, resistance development, and the ineffectiveness of current antifungals in modifying virulence, *Candida albicans* mediated vulvovaginal candidiasis (VVC) poses a substantial problem in clinical settings. The dysbiosis of the normal vaginal microflora, the activation of central metabolic pathways, morphogenesis, hyphal extension, adhesion, invasion, and biofilm formation, which result in chronic infection and recurrence, are all caused by a variety of predisposition factors, which are molecular drivers [4].

In endemic places, infections with soil-transmitted helminths (STHs) pose a significant public health risk. Monitoring the disease's epidemiology is necessary for effective control. [5]. Due to the lack of clarity surrounding host-parasite interactions, helminthic diseases represent the main issue. The gastro-intestinal tract (GIT) helminth infection grows noticeably more resistant to the anthelmintic medications now on the market. A fresh interest in the natural therapy of common plant therapies and the significance of innate products in drug creation has emerged in the last few decades. This can be explained by the enormous need for new molecular models, which could result in the development of innovative medications that could validate routine therapeutic uses [6]. The World Health Organization reports that 35% diseases are because of roundworm, which is a typical parasitic worm. More than 1.5 billion individuals or 24% of the total population are tainted with soil-transmitted helminth contaminations around the world. [7]. The three primary species that infect humans are the whipworm (*Trichuris trichiura*), the roundworm (*Ascaris lumbricoides*), and the hookworms (*Necator americanus* and *Ancylostoma duodenale*). Due of their similar medical needs and responses to medications, these STH species are typically treated as a group.[8]The adult Indian earthworm *Pheretimaposthuma* was used for the testing because of its physiological and anatomical similarities to human intestinal roundworm parasites. A good model for anthelmintic medication screening is the *PheretimaPosthuma* worm, which is widely available [9].

In response to contemporary research demands, a project was conceived to develop a tablet dosage form tailored for women suffering from vulvovaginal candidiasis and patients afflicted with helminth infections. This initiative stems from the pressing need for effective and accessible treatment options for these prevalent conditions. Vulvovaginal candidiasis, caused by *Candida* species, presents a significant health burden among women worldwide, necessitating reliable therapeutic interventions to alleviate symptoms and prevent recurrence. Similarly, helminth infections, encompassing a range of parasitic worms, pose substantial health risks, particularly in regions with inadequate sanitation and hygiene practices. By targeting these two distinct yet clinically significant conditions, the project aims to address unmet medical needs and improve healthcare outcomes for affected populations. The development of a

**Kiran Bhusaheb Erande and Kayande**

tablet dosage form offers several advantages, including convenience, ease of administration, and potentially enhanced patient compliance. Moreover, the formulation can be optimized to ensure stability, efficacy, and safety, meeting stringent regulatory standards for pharmaceutical products. Through interdisciplinary collaboration and rigorous scientific investigation, this project endeavors to advance the field of therapeutics, ultimately benefiting individuals grappling with vulvovaginal candidiasis and helminth infections.

MATERIALS AND METHODS**Preparation of garlic powder sample**

Garlic powder was prepared in-house by microwave drying process as per reported literature. [10]. All the reagents and chemicals used were of analytical grade and were procured from S.D. Fine-Chem. Ltd., Mumbai, India. All other chemicals, and excipients used in the study were of standard grade.

Procurement of species for antifungal and anthelmintic study

Candida albicans (MTCC 277) was sourced from the Microbial Type Culture Collection in Chandigarh, ensuring the authenticity and standardized quality of the strain. Concurrently, *Pheretima Posthuma* Earthworms were obtained from the local compost-making center in Nashik, selected for their relevance in helminth infection studies. To preserve the viability and integrity of these organisms, they were carefully maintained under optimal temperature conditions conducive to their growth and survival. This meticulous approach to procurement and maintenance ensures the reliability and consistency of the experimental materials, laying a robust foundation for subsequent research endeavors.

Development of Tablet Dosage form**Formulation of Vaginal Mucoadhesive Effervescent Tablet**

As the drug was proved to be effective against *Candida albicans*. The formulation was designed for the candidal vulvovaginitis. Hence by considering the site of application that is vagina the tablet must reside on vaginal mucosa and hence the same formula was continued by addition of Hydroxy propyl methy cellulose (HPMC K4M) in 3 different concentrations that is 5%, 10%, 15%. These 3 batches were evaluated and suitable batch was selected. Composition mentioned in Table-1. Method adopted for Tablet preparation was Direct Compression method. All ingredients including drug were weighed and passed through sieve no. 80 individually and then mixed. This powder mixture was compressed directly using Rimekmini press, model RSB-4,m/s (Karnavathi Engineering, Ahmadabad). [11]. Mucoadhesive effervescent tablet was evaluated for Hardness(gm/cm²), Effervescent time(min.), Disintegration time,(min.) Friability%, Mucoadhesion Strength Gm force (Table-4)

Mucoadhesion Test

Egg membrane was soaked in a SVF (Simulated Vaginal Fluid) over night. Mucoadhesion Test Apparatus was developed in lab using two pan analytical balance with slight modification. Two vials were used in which SVF was placed and covered with egg membrane soaked in SVF. one vial was fixed at bottom and another was tied in a vertical position in downward direction towards fixed vial and the apparatus was calibrated by keeping equivalent amount (32 gram) on opposite side of the balance. After calibrating, tablet was placed in between 2 vials and pressed by applying little force on it and then time required for Detachment of upper vial from Tablet was recorded. Same procedure was repeated for 3 tablets.[11,12]. Composition of simulated vaginal fluid used for mucoadhesion study is given in Table.2. Results are shown in Table 4

Antifungal Susceptibility testing of Mucoadhesive Effervescent Tablet [14].**Preparation of Sample for antifungal study**

A stock solution of 30 mg/ml was prepared.
Each tablet contains 400 mg of the drug

Kiran Bhausaheb Erande and Kayande

That is 822.4 mg Tablet $\xrightarrow{\text{contains}}$ 400 mg of the drug

Hence x mg $\xrightarrow{\text{contains}}$ 300mg of the drug

$$x = \frac{300 * 822.4}{400}$$

$$=616.8 \text{ mg}$$

Tablet was crushed and the quantity of 616.8 mg was taken and dissolved in 5ml of DMF. To this test tube 5ml of SabourD Dextrose Broth was added. The study was performed in triplicate determination was performed after 72 hours

Fungal culture and Preparation of Inoculum

Fungal culture used was *candida albicans* (MTCC 227)

Inoculum 1×10^5 CFU/ml was standardized for the study.

0.9 ml of Inoculum was added to each test tube of the above set.

Growth Control

1) For positive growth control, 0.9 ml of final inoculums was added to 0.1 ml of broth.

2) For negative growth control, 1 ml of broth was taken in a tube.

Test tubes were incubated at 35 ± 0.5 °C. and observed at 72 h. The results are given in figure-1

In vitro Anthelmintic activity of Mucoadhesive Effervescent Tablet by Dissolution Methodology

Mucoadhesive effervescent tablet was evaluated for *in-vitro* anthelmintic activity by using petri plate assay method as well as the assay method using dissolution Apparatus. Considering our previous research work context where the methodology was screened and validated for the selection of bio-relevant media simulating *in-vivo* human gastrointestinal tract conditions. From the tested medias Saline solution (conventional method), Fed-State Simulated Gastric Fluid (Fe-SSGF) Early, Fasted-State Simulated Intestinal Fluid Updated version (FaSSIF-V2) were selected as an appropriate media for maintenance of worms. So in the present study Fa-SSIF-V2 was selected as media for Anthelmintic study (Table-3)[15]. Pheretimaposthumaworms (Adult Indian Earthworms) being easily available and due to their anatomical and physiological resemblance with the intestinal round worm parasites of human beings are used as a suitable model for anthelmintic screening of garlic powder and garlic formulations[16]. Dosage forms prepared were found to be equally effective at garlic concentration of 80 mg/ml compared to albendazole anthelmintic standard used. Results given in (Table-5, Table-6 and Figure-3).

Stability study

The one-month stability protocol, outlined in reference [17], was meticulously devised to evaluate the tablets' stability over time. Stored under ambient conditions with temperatures hovering around 30°C and relative humidity levels fluctuating between 30% and 55%, the tablets underwent rigorous scrutiny. Sampling intervals were strategically set at days 7, 14, 21, and 28 to capture potential changes in the tablets' properties. Beyond the anthelmintic assay conducted using a dissolution apparatus, a multifaceted approach was adopted. This encompassed assessments of physical attributes, weight variation, and chemical stability. By integrating diverse analyses, including dissolution behavior and overall physical integrity, the protocol endeavors to provide a comprehensive evaluation of the tablets' performance and quality throughout the stipulated one-month duration. The results are given in figure 4

**Kiran Bhusaheb Erande and Kayande**

RESULT AND DISCUSSION

Formulation of Vaginal Mucoadhesive Effervescent Tablet

The evaluation of a mucoadhesive effervescent tablet revealed an outstanding mucoadhesion strength of 155 grams. This robust adhesion capability positions the developed dosage form as highly promising for applications in vaginal bioadhesive drug delivery systems. Such strong mucoadhesion is pivotal for ensuring sustained and localized drug delivery to the vaginal mucosa, which can significantly enhance therapeutic efficacy while minimizing systemic side effects. This characteristic makes the tablet particularly well-suited for delivering drugs intended for vaginal administration, such as antimicrobial agents, hormones, or contraceptives. The remarkable mucoadhesion strength of 155 grams underscores the potential of this dosage form to adhere firmly to the vaginal mucosa, allowing for prolonged contact and controlled release of the active pharmaceutical ingredient. This, in turn, could improve patient compliance and therapeutic outcomes, offering a more effective and convenient alternative to conventional dosage forms. Results given in table-4 [18].

Antifungal Susceptibility testing of Bioadhesive Effervescent Tablet

In a rigorous antifungal susceptibility test targeting *Candida albicans* species, we undertook a triplicate determination of the antifungal study using tablets. Throughout the experiment, meticulous control measures were maintained, including positive and negative controls, to ensure the reliability and accuracy of the results. Excitingly, the outcome of the study revealed a compelling finding: all three tubes containing the sample solution exhibited no growth even after continuous observation for up to 72 hours. This remarkable result suggests a potent antifungal activity associated with the tablets under investigation. The absence of fungal growth in the presence of the sample solution underscores the effectiveness of the tablets in inhibiting the growth and proliferation of *Candida albicans*. Such robust antifungal properties hold significant promise for combating fungal infections, particularly those caused by *Candida species*, which can be challenging to treat due to emerging resistance to conventional antifungal agents as shown in Figure-1.

In vitro Anthelmintic activity of Mucoadhesive Effervescent Tablet by Dissolution Methodology

In the Petri plate method, the average death time reported for 800 mg Garlic tablets was 110 minutes on average in comparison to the average death time of 96 minutes for Albendazole standard tablets 400 mg dose. It was found that the garlic tablet designed had significant comparable results as compared to the albendazole standard tablet dosage form. (Table-5, Table-6 and Figure-3) Interestingly, despite the discrepancy in dosage amounts, the Garlic tablets showcased a significant and comparable efficacy to the Albendazole standard tablets. This finding not only underscores the potential of Garlic as a viable alternative in combating certain microbial threats but also highlights the importance of exploring natural remedies in pharmaceutical research.

Stability Study Evaluation of Garlic Effervescent tablet in terms of Anthelmintic assay.

The stability studies conducted at ambient conditions, maintaining a temperature of around 30°C and relative humidity between 30-50%, yielded promising results over the one-month duration. The tablets were evaluated at intervals of 7, 14, 21 and 28 days. Death times ranging from 100 to 103 minutes indicated the tablets' stability, suggesting consistent therapeutic efficacy against worms. Comparative analysis with established anthelmintic medications like albendazole underscored the effectiveness of the developed tablets. Additionally, the significant performance of garlic tablets in the comparison highlights the potential of herbal remedies as valuable adjunct therapies in anthelmintic treatments. These findings collectively emphasize the durability, efficacy, and potential versatility of the developed formulation for combating parasitic infections. Results are depicted in figure 4.

CONCLUSION

The development of an effervescent bio-adhesive tablet dosage form marks a significant advancement in the treatment of vulvovaginal candidiasis (VVC) and soil-transmitted helminth (STH) infections. With the aim of

**Kiran Bhusaheb Erande and Kayande**

ensuring effective treatment while overcoming challenges associated with conventional formulations, this innovative dosage form was meticulously designed and rigorously tested. Antifungal susceptibility testing against *Candida albicans*, the predominant species responsible for vaginal fungal infections, demonstrated the efficacy of the tablet dosage form. Through thorough evaluation, it was established that the tablet remained adhered to mucosal linings even after vaginal application, ensuring sustained delivery of antifungal agents to the site of infection. This not only enhances treatment efficacy but also reduces the likelihood of dosage form drainage, thus optimizing therapeutic outcomes. Moreover, the tablet dosage form exhibited remarkable anthelmintic activity against *Pheretimaphostuma*, an earthworm species commonly employed in research due to its physiological resemblance to intestinal roundworm parasites in humans. This dual-purpose functionality of the dosage form presents a novel approach to addressing multiple ailments, offering a cost-effective solution that streamlines treatment regimens and enhances patient compliance.

The successful completion of post-compression parameter testing further validates the quality and consistency of the tablet formulation. Importantly, comparative analysis against standard marketed dosage forms for both vaginal fungal infections and intestinal helminth infections reaffirms the equivalency and efficacy of the developed formulation. In conclusion, the dual-purpose applicability of the effervescent bio-adhesive tablet dosage form represents a promising advancement in pharmaceutical innovation. Not only does it offer a comprehensive solution for the management of VVC and STH infections, but it also presents a viable pathway for product scale-up and commercialization. By addressing the unmet needs of diverse patient populations, this innovative formulation has the potential to significantly impact public health on a global scale. Further research and development efforts are warranted to explore additional applications and optimize the clinical utility of this versatile dosage form.

ABSTRACT

This paper deals with the Q-Pythagorean fuzzy sub semiring, ideals and bi-ideals in Γ -semirings. Moreover we study the properties of Q-Pythagorean fuzzy ideals in Γ -semiring.

Keywords: Γ -semiring, Q-Pythagorean fuzzy set, Q-Pythagorean fuzzy ideal, Q-Pythagorean fuzzy bi-ideal.

INTRODUCTION

Zadeh's[15] seminal paper introduced the concept of fuzzy sets and their operations, sparking significant interest among mathematicians across various fields. Since then, Zadeh and other scholars have further developed fuzzy set theory, garnering considerable attention from researchers. Pythagorean fuzzy sets[13][14] characterized by the condition that the sum of the squares of membership and non-membership degrees is less than or equal to one, have been extensively investigated. Numerous authors have explored the algebraic properties of Pythagorean fuzzy ideals. This paper is structured into five sections. The initial two sections provide an introduction and lay down the preliminary concepts. The third section delves into the exploration of Q-Pythagorean fuzzy ideals within Γ -semirings. Following that, the fourth section examines the properties associated with Q-pythagorean fuzzy ideals. Lastly, the paper concludes by investigating Q-Pythagorean fuzzy bi-ideals in Γ -semirings.

PRELIMINARIES

In this section we present the basic concepts related to this paper.

Anitha and Lavanya

Definition 2.1 [3] If $(S, +)$ and $(\Gamma, +)$ be two commutative semigroups then S is called a Γ -semiring if there exists a mapping $S \times \Gamma \times S$ denoted by $\alpha\gamma\beta$ for all $\alpha, \beta \in S$ and $\gamma \in \Gamma$ satisfying the following properties,

$$\begin{aligned} \alpha\gamma(\beta + \nu) &= \alpha\gamma\beta + \alpha\gamma\nu, \\ (\beta + \nu)\gamma\alpha &= \beta\gamma\alpha + \nu\gamma\alpha, \\ \alpha(\gamma + \gamma_1)\nu &= \alpha\gamma\nu + \alpha\gamma_1\nu, \\ \alpha\gamma(\beta\gamma_1\nu) &= (\alpha\gamma\beta)\gamma_1\nu \\ \text{for all } \alpha, \beta, \nu \in S \text{ and } \gamma, \gamma_1 \in \Gamma. \end{aligned}$$

Definition 2.2 [3] Define addition in the following way $A, B \in S, \gamma \in \Gamma$, let $A\gamma B$ denote the ideal generated by $\{\alpha\gamma\beta/\alpha, \beta \in S\}$. Then S is a Γ -semiring.

Definition 2.3 [3] A Γ -semiring S is said to be commutative if $\alpha\gamma\beta = \beta\gamma\alpha$, for all $\alpha, \beta \in S$ and $\gamma \in \Gamma$.

Definition 2.4 [3] A Γ -semiring S is said to have a zero element if $0\beta\alpha = 0 = \alpha\beta 0$ and $\alpha + 0 = \alpha = 0 + \alpha$, for all $\alpha \in S$ and $\gamma \in \Gamma$.

Definition 2.5 [3] S is said to have a identity element if there exists $\gamma \in \Gamma$ such that $1\gamma\alpha = \alpha = \alpha\gamma 1$ for all $\alpha \in S$.

Definition 2.6 [3] S is said to have a strong identity element if for all $\alpha \in S$, $1\gamma\alpha = \alpha = \alpha\gamma 1$ for all $\gamma \in \Gamma$.

Definition 2.7 [3] A non empty subset R of a Γ -semiring S is said to be a sub Γ -semiring of S if $(R, +)$ is a sub semigroup of $(S, +)$ and $\alpha\gamma\beta \in R$ for all $\alpha, \beta \in R$ and $\gamma \in \Gamma$.

Definition 2.8 [3] A non empty subset R of a Γ -semiring S is called an ideal if $\alpha, \beta \in R$ implies $\alpha + \beta \in R$ and $a \in R, \alpha \in S$ and $\gamma \in \Gamma$ implies $\alpha\gamma a \in R$ and $a\alpha\gamma \in R$.

Definition 2.9 [13] Let X be a non empty set. A Pythagorean Fuzzy Set \mathfrak{A} in X is given by $\mathfrak{A} = \{\alpha, \mathfrak{A}_x(\alpha), \mathfrak{A}_y(\alpha)/\alpha \in X\}$ where $\mathfrak{A}_x: X \rightarrow [0,1]$ and $\mathfrak{A}_y: X \rightarrow [0,1]$ represent the degree of membership and degree of non membership of \mathfrak{A} respectively. Also, \mathfrak{A}_x and \mathfrak{A}_y satisfies the condition $(\mathfrak{A}_x)^2 + (\mathfrak{A}_y)^2 \leq 1$ for all $\alpha \in X$.

Definition 2.10 [5] Let U be an universal set and Q be a nonempty set. A Q -Pythagorean fuzzy set is an object having the following form, $A: U \times Q \rightarrow [0,1]$

$A = \{(\alpha, q), (A_x(\alpha, q), A_y(\alpha, q))/\alpha \in U, q \in Q\}$ where $A_x(\alpha, q)$ and $A_y(\alpha, q)$ degree of membership and degree of non membership. Also A_x and A_y satisfies the condition $0 \leq (A_x)^2 + (A_y)^2 \leq 1$ for all $\alpha \in X$

Definition 2.11 [5] Let A and B be two Q -Pythagorean fuzzy set of S . Then the union of A and B is a Q -Pythagorean fuzzy set defined by

$$\begin{aligned} (A_x \cup B_x)(u, q) &= \max\{A_x(u, q), B_x(u, q)\} \\ (A_y \cup B_y)(u, q) &= \min\{A_y(u, q), B_y(u, q)\} \\ \text{for all } u \in S \text{ and } q \in Q. \end{aligned}$$

Definition 2.12 [5] Let A and B be two Q -Pythagorean fuzzy set of S . Then the intersection of A and B is a Q -Pythagorean fuzzy set defined by

$$\begin{aligned} (A_x \cap B_x)(u, q) &= \min\{A_x(u, q), B_x(u, q)\} \\ (A_y \cap B_y)(u, q) &= \max\{A_y(u, q), B_y(u, q)\} \\ \text{for all } u \in S \text{ and } q \in Q. \end{aligned}$$

Anitha and Lavanya

Q-Pythagorean fuzzy ideal in Γ -semirings

In this section, we present the notion of Q -Pythagorean fuzzy ideals within γ -semirings, along with exploring some intriguing properties associated with them.

Definition 3.1 A Q -Pythagorean fuzzy set A in S is called a Q -Pythagorean fuzzy subsemiring in S if the following conditions are hold for all $\alpha, \beta \in S, \gamma \in \Gamma$

1. $A_x(\alpha + \beta, q) \geq A_x(\alpha, q) \wedge A_x(\beta, q)$
 $A_y(\alpha + \beta, q) \leq A_y(\alpha, q) \vee A_y(\beta, q)$
2. $A_x(\alpha\gamma\beta, q) \geq A_x(\alpha, q) \wedge A_x(\beta, q)$
 $A_y(\alpha\gamma\beta, q) \leq A_y(\alpha, q) \vee A_y(\beta, q)$

Definition 3.2 A Q -Pythagorean fuzzy set A in S is called a Q -Pythagorean fuzzy left ideal in S if the following conditions are hold for all $\alpha, \beta \in S, \gamma \in \Gamma$.

1. $A_x(\alpha + \beta, q) \geq A_x(\alpha, q) \wedge A_x(\beta, q)$
 $A_y(\alpha + \beta, q) \leq A_y(\alpha, q) \vee A_y(\beta, q)$
2. $A_x(r\gamma\alpha, q) \geq A_x(\alpha, q)$
 $A_y(r\gamma\alpha, q) \leq A_y(\alpha, q)$

Definition 3.3 A Q -Pythagorean fuzzy set A in S is called a Q -Pythagorean fuzzy right ideal in S if the following conditions are hold for all $\alpha, \beta \in S, \gamma \in \Gamma$.

1. $A_x(\alpha + \beta, q) \geq A_x(\alpha, q) \wedge A_x(\beta, q)$
 $A_y(\alpha + \beta, q) \leq A_y(\alpha, q) \vee A_y(\beta, q)$
2. $A_x(\alpha\gamma r, q) \geq A_x(\alpha, q)$
 $A_y(\alpha\gamma r, q) \leq A_y(\alpha, q)$

Definition 3.4 A Q -Pythagorean fuzzy set A in S is called a Pythagorean anti fuzzy ideal in S if it is both Q -pythagorean fuzzy left ideal and pythagorean anti fuzzy right ideal of S .

Example 3.5 Let $S = \{0,1,2,3\}$ be a Γ -semiring with the following multiplication table.

+	0	1	2	3
	0	1	2	3
	1	1	2	3
	2	2	2	3
	3	3	3	2

•	0	1	2	3
	0	0	0	0
	0	1	1	1
	0	1	1	1
	0	1	1	1

Let A be a Q -Pythagorean fuzzy set of S defined by, $A_x(i, q) = \{0.5,0.5,0.3,0.2\}$, $A_y(i, q) = \{0.6,0.7,0.9,0.9\}$. Then A is a Q -Pythagorean fuzzy ideal of S .

Properties of Q -Pythagorean fuzzy ideals in Γ -semiring

In this section we characterize Q -Pythagorean fuzzy ideals in Γ -semiring

Lemma 4.1 If A is a Q -Pythagorean fuzzy set in S satisfies $A_x(0) \geq A_x(\alpha)$ and $A_y(0) \leq A_y(\alpha)$.

Anitha and Lavanya

Lemma 4.2 Every Q -Pythagorean fuzzy ideal in S is an Q -Pythagorean fuzzy subsemiring of S .

Theorem 4.3 Let A and B are Q -Pythagorean fuzzy subsemiring of S then $A \cap B$ is also Q -Pythagorean fuzzy subsemiring of S .

Proof. Since A and B are Q -Pythagorean fuzzy subsemiring of S .

Then for all $\alpha, \beta \in S, \gamma \in \Gamma$.

$$\begin{aligned} (A_x \cap B_x)(\alpha + \beta, q) &= (A_x \wedge B_x)(\alpha + \beta, q) \\ &= A_x(\alpha + \beta, q) \wedge B_x(\alpha + \beta, q) \\ &\geq (A_x(\alpha, q) \wedge A_x(\beta, q)) \wedge (B_x(\alpha, q) \wedge B_x(\beta, q)) \\ &\geq (A_x(\alpha, q) \wedge B_x(\alpha, q)) \wedge (A_x(\beta, q) \wedge B_x(\beta, q)) \\ &= (A_x \wedge B_x)(\alpha, q) \wedge (A_x \wedge B_x)(\beta, q) \\ &= (A_x \cap B_x)(\alpha, q) \wedge (A_x \cap B_x)(\beta, q) \end{aligned}$$

$$\begin{aligned} (A_y \cap B_y)(\alpha + \beta, q) &= (A_y \cap B_y)(\alpha + \beta, q) \\ &= A_y(\alpha + \beta, q) \wedge B_y(\alpha + \beta, q) \\ &\leq (A_y(\alpha, q) \vee A_y(\beta, q)) \wedge (B_y(\alpha, q) \vee B_y(\beta, q)) \\ &\leq (A_y(\alpha, q) \wedge B_y(\alpha, q)) \wedge (A_y(\beta, q) \wedge B_y(\beta, q)) \\ &= (A_y \wedge B_y)(\alpha, q) \vee (A_y \wedge B_y)(\beta, q) \end{aligned}$$

and

$$\begin{aligned} (A_x \cap B_x)(\alpha\gamma\beta, q) &= (A_x \wedge B_x)(\alpha\gamma\beta, q) \\ &= A_x(\alpha\gamma\beta, q) \wedge B_x(\alpha\gamma\beta, q) \\ &\geq A_x(\beta, q) \wedge B_x(\beta, q) \\ &= (A_x \wedge B_x)(\beta, q) \end{aligned}$$

Also $(A_x \cap B_x)(\alpha\gamma\beta, q) = (A_x \wedge B_x)(\alpha\gamma\beta, q)$

$$\begin{aligned} &= A_x(\alpha\gamma\beta, q) \wedge B_x(\alpha\gamma\beta, q) \\ &\geq A_x(\alpha, q) \wedge B_x(\alpha, q) \\ &= (A_x \wedge B_x)(\alpha, q) \end{aligned}$$

Moreover

$$\begin{aligned} (A_y \cap B_y)(\alpha\gamma\beta, q) &= (A_y \vee B_y)(\alpha\gamma\beta, q) \\ &= A_y(\alpha\gamma\beta, q) \vee B_y(\alpha\gamma\beta, q) \\ &\leq A_y(\beta, q) \vee B_y(\beta, q) \\ &= (A_y \vee B_y)(\beta, q) \end{aligned}$$

and

$$\begin{aligned} (A_y \cap B_y)(\alpha\gamma\beta, q) &= (A_y \vee B_y)(\alpha\gamma\beta, q) \\ &= A_y(\alpha\gamma\beta, q) \vee B_y(\alpha\gamma\beta, q) \\ &\leq A_y(\beta, q) \vee B_y(\alpha, q) \\ &= (A_y \vee B_y)(\alpha, q) \end{aligned}$$

Hence $A \cap B$ is a Q -Pythagorean fuzzy subsemiring of S .

Theorem 4.4 Let A and B are Q -Pythagorean fuzzy ideal of S then $A \cap B$ is also Q -Pythagorean fuzzy ideal of S .

Proof. Since A and B are Q -Pythagorean fuzzy ideal of S .

Then for all $\alpha, \beta \in S, \gamma \in \Gamma$.

$$\begin{aligned} (A_x \cap B_x)(\alpha + \beta, q) &= (A_x \wedge B_x)(\alpha + \beta, q) \\ &= A_x(\alpha + \beta, q) \wedge B_x(\alpha + \beta, q) \\ &\geq (A_x(\alpha, q) \wedge A_x(\beta, q)) \wedge (B_x(\alpha, q) \wedge B_x(\beta, q)) \end{aligned}$$

Anitha and Lavanya

$$\begin{aligned} &\geq (A_x(\alpha, q) \wedge B_x(\alpha, q)) \wedge (A_x(\beta, q) \wedge B_x(\beta, q)) \\ &= (A_x \wedge B_x)(\alpha, q) \wedge (A_x \wedge B_x)(\beta, q) \\ &= (A_x \cap B_x)(\alpha, q) \wedge (A_x \cap B_x)(\beta, q) \end{aligned}$$

$$\begin{aligned} (A_y \cap B_y)(\alpha + \beta, q) &= (A_y \cap B_y)(\alpha + \beta, q) \\ &= A_y(\alpha + \beta, q) \wedge B_y(\alpha + \beta, q) \\ &\leq (A_y(\alpha, q) \vee A_y(\beta, q)) \wedge (B_y(\alpha, q) \vee B_y(\beta, q)) \\ &\leq (A_y(\alpha, q) \vee B_y(\alpha, q)) \wedge (A_y(\beta, q) \vee B_y(\beta, q)) \\ &= (A_y \vee B_y)(\alpha, q) \wedge (A_y \vee B_y)(\beta, q) \\ &= (A_y \cap B_y)(\alpha, q) \wedge (A_y \cap B_y)(\beta, q) \end{aligned}$$

and

$$\begin{aligned} (A_x \cap B_x)(\alpha\gamma r, q) &= (A_x \wedge B_x)(\alpha\gamma r, q) \\ &= A_x(\alpha\gamma r, q) \wedge B_x(\alpha\gamma r, q) \\ &\geq A_x(\alpha, q) \wedge B_x(\alpha, q) \\ &= (A_x \cap B_x)(\alpha, q) \\ (A_y \cap B_y)(\alpha\gamma r, q) &= (A_y \cap B_y)(\alpha\gamma r, q) \\ &= A_y(\alpha\gamma r, q) \vee B_y(\alpha\gamma r, q) \\ &\leq A_y(\alpha, q) \vee B_y(\alpha, q) \\ &= (A_y \cap B_y)(\alpha, q) \end{aligned}$$

Finally

$$\begin{aligned} (A_x \cap B_x)(r\gamma\alpha, q) &= (A_x \wedge B_x)(r\gamma\alpha, q) \\ &= A_x(r\gamma\alpha, q) \wedge B_x(r\gamma\alpha, q) \\ &\geq A_x(\alpha, q) \wedge B_x(\alpha, q) \\ &= (A_x \cap B_x)(\alpha, q) \\ (A_y \cap B_y)(r\gamma\alpha, q) &= (A_y \cap B_y)(r\gamma\alpha, q) \\ &= A_y(r\gamma\alpha, q) \vee B_y(r\gamma\alpha, q) \\ &\leq A_y(\alpha, q) \vee B_y(\alpha, q) \\ &= (A_y \cap B_y)(\alpha, q) \end{aligned}$$

Hence $A \cap B$ is a Q -Pythagorean fuzzy ideal of S .

Theorem 4.5 Let G and H be two Γ -semirings and π be a homomorphism of G onto H . If A is a Q -Pythagorean fuzzy ideal of H , then $\pi^{-1}(A)$ is a Q -Pythagorean fuzzy ideal of G .

Proof. Since G and H be two Γ semirings and π be a homomorphism of G onto H . If A is a Q -Pythagorean fuzzy ideal of H .

Then $\pi^{-1}(A_x(\alpha, q)) = A_x(\pi(\alpha, q))$ and $\pi^{-1}(A_y(\alpha, q)) = A_y(\pi(\alpha, q))$ for all $\alpha \in G$. Let $\alpha, \beta \in G, \gamma \in \Gamma$.

Then

$$\begin{aligned} \pi^{-1}(A_x)(\alpha + \beta, q) &= A_x(\pi(\alpha + \beta, q)) \\ &= A_x(\pi(\alpha, q) + \pi(\beta, q)) \\ &\geq A_x(\pi(\alpha, q)) \wedge A_x(\pi(\beta, q)) \\ &= \pi^{-1}(A_x)(\alpha, q) \wedge \pi^{-1}(A_x)(\beta, q) \\ \pi^{-1}(A_y)(\alpha + \beta, q) &= A_y(\pi(\alpha + \beta, q)) \\ &= A_y(\pi(\alpha, q) + \pi(\beta, q)) \\ &\leq A_y(\pi(\alpha, q)) \vee A_y(\pi(\beta, q)) \\ &= \pi^{-1}(A_y)(\alpha, q) \vee \pi^{-1}(A_y)(\beta, q) \end{aligned}$$

Next we have to prove for Q -pythagorean fuzzy left ideal

$$\begin{aligned} \pi^{-1}(A_x)(r\gamma\alpha, q) &= A_x(\pi(r\gamma\alpha, q)) \\ &= A_x(\pi(r, q)\gamma\pi(\alpha, q)) \\ &\geq A_x(\pi(\alpha, q)) \\ &= \pi^{-1}(A_x)(\alpha, q) \\ \pi^{-1}(A_y)(r\gamma\alpha, q) &= A_y(\pi(r\gamma\alpha, q)) \\ &= A_y(\pi(r, q)\gamma\pi(\alpha, q)) \end{aligned}$$

Anitha and Lavanya

$$\begin{aligned} &\leq A_y(\pi(\alpha, q)) \\ &= \pi^{-1}(A_y)(\alpha, q) \end{aligned}$$

Finally we have to prove for Q -pythagorean fuzzy right ideal

$$\begin{aligned} \pi^{-1}(A_x)(\alpha\gamma r, q) &= A_x(\pi(\alpha\gamma r, q)) \\ &= A_x(\pi(\alpha, q)\gamma\pi(r, q)) \\ &\leq A_x(\pi(\alpha, q)) \\ &= \pi^{-1}(A_x)(\alpha, q) \\ \pi^{-1}(A_y)(\alpha\gamma r, q) &= A_y(\pi(\alpha\gamma r, q)) \\ &= A_y(\pi(\alpha, q)\gamma\pi(r, q)) \\ &\leq A_y(\pi(\alpha, q)) \\ &= \pi^{-1}(A_y)(\alpha, q) \end{aligned}$$

Hence Proved.

Theorem 4.6 If A and B are any two Q -Pythagorean fuzzy ideal of Γ -semirings S_1 and S_2 respectively then $A \times B$ is a Q -Pythagorean fuzzy ideal of $S_1 \times S_2$.

Proof. Since A and B be any two Q -Pythagorean fuzzy ideal of Γ -semirings S_1 and S_2 respectively.

Let $p_1, p_2 \in S_1$ and $k_1, k_2 \in S_2$.

Then consider $(p_1, k_1), (p_2, k_2) \in S_1 \times S_2, \gamma \in \Gamma$

$$\begin{aligned} (A_x \times B_x)((p_1, k_1) + (p_2, k_2), q) &= (A_x \times B_x)((p_1 + p_2, k_1 + k_2), q) \\ &\geq \min\{A_x(p_1 + p_2, q), B_x(k_1 + k_2, q)\} \\ &\geq \min\{A_x(p_1, q) \wedge A_x(p_2, q), B_x(k_1, q) \wedge B_x(k_2, q)\} \\ &\geq \min\{A_x(p_1, q) \wedge B_x(k_1, q), A_x(p_2, q) \wedge B_x(k_2, q)\} \\ &= \min\{(A_x \times B_x)((p_1, k_1), q), (A_x \times B_x)((p_2, k_2), q)\} \end{aligned}$$

And

$$\begin{aligned} (A_y \times B_y)((p_1, k_1) + (p_2, k_2), q) &= (A_y \times B_y)((p_1 + p_2, k_1 + k_2), q) \\ &\leq \max\{A_y(p_1 + p_2, q), B_y(k_1 + k_2, q)\} \\ &\leq \max\{A_y(p_1, q) \wedge A_y(p_2, q), B_y(k_1, q) \wedge B_y(k_2, q)\} \\ &\leq \max\{A_x(p_1, q) \wedge B_y(k_1, q), A_y(p_2, q) \wedge B_y(k_2, q)\} \\ &= \max\{(A_y \times B_y)((p_1, k_1), q), (A_y \times B_y)((p_2, k_2), q)\} \end{aligned}$$

Finally

$$\begin{aligned} (A_x \times B_x)((p_1, k_1)\gamma(p_2, k_2), q) &= (A_x \times B_x)(p_1\gamma p_2, k_1\gamma k_2, q) \\ &\geq \min\{A_x(p_1\gamma p_2, q), B_x(k_1\gamma k_2, q)\} \\ &\geq \min\{A_x(p_2, q), B_x(k_2, q)\} \\ &= (A_x \times B_x)((p_2, k_2), q) \end{aligned}$$

and

$$\begin{aligned} (A_y \times B_y)((p_1, k_1)\gamma(p_2, k_2), q) &= (A_y \times B_y)(p_1\gamma p_2, k_1\gamma k_2, q) \\ &\leq \max\{A_y(p_1\gamma p_2, q), B_y(k_1\gamma k_2, q)\} \\ &\leq \max\{A_y(p_1, q), B_y(k_1, q)\} \\ &= (A_y \times B_y)((p_1, k_1), q) \end{aligned}$$

Hence $A \times B$ is a Q -Pythagorean fuzzy ideal.

Q -Pythagorean fuzzy bi-ideals in Γ -semirings

In this section we discuss some interesting properties of Q -Pythagorean fuzzy bi-ideals in Γ -semirings.

Anitha and Lavanya

Definition 5.1 A Q-Pythagorean fuzzy ideal A in S is called a Q-Pythagorean fuzzy bi-ideal in S if the following conditions are hold for all $\alpha, \beta \in S, \gamma \in \Gamma$.

- (i) $A_x(\alpha\gamma_1\eta\gamma_2\beta, q) \geq A_x(\alpha, q) \wedge A_x(\beta, q)$
- (ii) $A_y(\alpha\gamma_1\eta\gamma_2\beta, q) \leq A_y(\alpha, q) \vee A_x(\beta, q)$

Theorem 5.2 Let A be a Q-Pythagorean fuzzy ideal in S. If S is an intra regular then $A(\alpha, q) = A(\alpha\gamma\alpha, q)$ for all $\alpha \in S, \gamma \in \Gamma$

Proof. Let α be any element of S. Then since S is a intra-regular, there exist $x, y \in S$ and $\gamma_1, \gamma_2, \gamma_3 \in \Gamma$ such that $\alpha = x\gamma_1\alpha\gamma_2\alpha\gamma_3y$. Hence A is a Q-Pythagorean fuzzy ideal.

$$\begin{aligned} A_x(\alpha, q) &= A_x(x\gamma_1\alpha\gamma_2\alpha\gamma_3y, q) \\ &\geq A_x(x\gamma_1\alpha\gamma_2\alpha, q) \\ &\geq A_x(\alpha\gamma_2\alpha, q) \\ &\geq A_x(\alpha, q) \end{aligned}$$

and

$$\begin{aligned} A_y(\alpha, q) &= A_y(x\gamma_1\alpha\gamma_2\alpha\gamma_3y, q) \\ &\leq A_y(x\gamma_1\alpha\gamma_2\alpha, q) \\ &\leq A_y(\alpha\gamma_2\alpha, q) \\ &\leq A_y(\alpha, q) \end{aligned}$$

Hence the theorem.

Theorem 5.3 Let A be a Q-Pythagorean fuzzy ideal in S. If S is an intra regular then $A(\alpha\gamma\beta, q) = A(\beta\gamma\alpha, q)$ for all $\alpha, \beta \in S, \gamma \in \Gamma$

Proof. Let α, β be any element of S. Then by theorem 5.2 we have,

$$\begin{aligned} A_x(\alpha\gamma\beta, q) &= A_x(\alpha\gamma\beta\gamma\alpha\gamma\beta, q) \\ &\geq A_x(\alpha\gamma(\beta\gamma\alpha)\gamma\beta, q) \\ &\geq A_x(\beta\gamma\alpha, q) \\ &\geq A_x(\beta\gamma\alpha\gamma\beta\gamma\alpha, q) \\ &\geq A_x(\beta\gamma(\alpha\gamma\beta)\gamma\alpha, q) \\ &\geq A_x(\alpha\gamma\beta, q) \end{aligned}$$

and

$$\begin{aligned} A_y(\alpha\gamma\beta, q) &= A_y(\alpha\gamma\beta\gamma\alpha\gamma\beta, q) \\ &\leq A_y(\alpha\gamma(\beta\gamma\alpha)\gamma\beta, q) \\ &\leq A_y(\beta\gamma\alpha, q) \\ &\leq A_y(\beta\gamma\alpha\gamma\beta\gamma\alpha, q) \\ &\leq A_y(\beta\gamma(\alpha\gamma\beta)\gamma\alpha, q) \\ &\leq A_y(\alpha\gamma\beta, q) \end{aligned}$$

Hence the theorem.

Theorem 5.4 Let A be a Q-Pythagorean fuzzy bi-ideal of S if and only if the fuzzy set A_x and \overline{A}_y are fuzzy bi-ideals of S

Proof. Let A be a Q-Pythagorean fuzzy bi-ideal in S. Then A_x is a Q-fuzzy bi-ideal of S. Let $\alpha, \beta \in S, \gamma_1, \gamma_2 \in \Gamma$. Then

$$\begin{aligned} \overline{A}_y(\alpha\gamma_1\beta, q) &= 1 - A_y(\alpha\gamma_1\beta, q) \\ &\geq 1 - \max\{A_y(\alpha, q), A_y(\beta, q)\} \\ &= \min\{1 - A_y(\alpha, q), 1 - A_y(\beta, q)\} \\ &= \min\{\overline{A}_y(\alpha, q), \overline{A}_y(\beta, q)\} \text{ and} \end{aligned}$$

Anitha and Lavanya

$$\begin{aligned} \overline{A}_y(\alpha\gamma_1r\gamma_2\beta, q) &= 1 - A_y(\alpha\gamma_1r\gamma_2\beta, q) \\ &\geq 1 - \max\{A_y(\alpha, q), A_y(\beta, q)\} \\ &= \min\{1 - A_y(\alpha, q), 1 - A_y(\beta, q)\} \\ &= \min\{\overline{A}_y(\alpha, q), \overline{A}_y(\beta, q)\} \end{aligned}$$

Hence \overline{A}_y is a Q -Pythagorean fuzzy bi-ideal of S . Conversely, suppose that A_x and \overline{A}_y are Q -Pythagorean fuzzy bi-ideal of S , Let $\alpha, r, \beta \in S, \gamma_1, \gamma_2 \in \Gamma$.

Then

$$\begin{aligned} 1 - A_x(\alpha\gamma_1\beta, q) &= \overline{A}_x(\alpha\gamma_1\beta, q) \\ &\geq \min\{\overline{A}_x(\alpha, q), \overline{A}_x(\beta, q)\} \\ &= \min\{1 - A_x(\alpha, q), 1 - A_x(\beta, q)\} \\ &= \max\{A_x(\alpha, q), A_x(\beta, q)\} \end{aligned}$$

and

$$\begin{aligned} 1 - A_x(\alpha\gamma_1r\gamma_2\beta, q) &= \overline{A}_x(\alpha\gamma_1r\gamma_2\beta, q) \\ &\geq \min\{\overline{A}_x(\alpha, q), \overline{A}_x(\beta, q)\} \\ &= 1 - \max\{A_x(\alpha, q), A_x(\beta, q)\} \\ &= \max\{A_x(\alpha, q), A_x(\beta, q)\} \end{aligned}$$

Hence the theorem

Theorem 5.5 Let G and H be two Γ -semirings and π be a homomorphism of G onto H . If A is a Q -Pythagorean fuzzy bi-ideal of H , then $\pi^{-1}(A)$ is a Q -Pythagorean fuzzy bi-ideal of G .

Proof. Since G and H be two Γ semirings and π be a homomorphism of G onto H . If A is a Q -Pythagorean fuzzy ideal of H .

Then

$$\begin{aligned} \pi^{-1}(A_x(\alpha, q)) &= A_x(\pi(\alpha, q)) \text{ and} \\ \pi^{-1}(A_y(\alpha, q)) &= A_y(\pi(\alpha, q)) \text{ for all } \alpha \in G \\ \text{Let } \alpha, \beta \in G. \text{ The} \\ \pi^{-1}(A_x)(\alpha\gamma_1\eta\gamma_2\beta, q) &= A_x(\pi(\alpha\gamma_1\eta\gamma_2\beta), q) \\ &\geq A_x(\pi(\alpha)\gamma_1\eta\gamma_2\pi(\beta), q) \\ &\geq A_x(\pi(\alpha, q)) \wedge A_x(\pi(\beta, q)) \\ &= \pi^{-1}(A_x(\alpha, q)) \wedge \pi^{-1}(A_x(\beta, q)) \\ \pi^{-1}(A_y)(\alpha\gamma_1\eta\gamma_2\beta, q) &= A_y(\pi(\alpha\gamma_1\eta\gamma_2\beta), q) \\ &\leq A_y(\pi(\alpha)\gamma_1\eta\gamma_2\pi(\beta), q) \\ &\leq A_y(\pi(\alpha, q)) \vee A_y(\pi(\beta, q)) \\ &= \pi^{-1}(A_y(\alpha, q)) \vee \pi^{-1}(A_y(\beta, q)) \end{aligned}$$

Hence Proved.

CONCLUSION

This paper applies the concept of Q -Pythagorean fuzzy sets to Γ -semirings. We present the algebraic structures of Q -Pythagorean fuzzy sets within Γ -semirings. Additionally, we aspire to extend this framework to various other algebraic structures and explore its applications in real-life scenarios in future research endeavors.

ABSTRACT

This survey aims to assess the relationship between Orthodontic treatment and Gastritis. One hundred patients undergoing orthodontic treatment for more than 3 months in the age group 18 to 30 years were sent a questionnaire to complete the survey. There is a positive connection between orthodontic treatment and gastritis. Previous studies suggest the impact of orthodontic treatment on weight loss, food habits, negative self-image, and anxiety. Poor eating habits, prolonged intentional skipping of meals, anxiety about physical appearance, and consumption of NSAIDs are contributing factors to Gastritis during orthodontic treatment. Going through orthodontic treatment does not necessarily cause gastritis, however prolonged orthodontic treatment increases the chances of getting gastritis and can worsen existing gastritis.

Keywords: This research received no specific grant from any public, commercial, or non-profit funding agency.

INTRODUCTION

Orthodontic treatment aims to provide a healthy bite - improving the appearance and alignment of crooked, protruding, or crowded teeth, thereby enhancing masticatory efficiency, and esthetics contributing to the overall confidence of an individual and their psychological well-being [1]. Fixed orthodontic Appliance (FA) produces a

**Lakshmi Ravi et al.,**

variety of tooth movements e.g. Bodily movement, rotation, uprighting, torquing, and intrusion; and are more efficient in treatment as compared to removable appliances. They allow multiple tooth movements and the establishment of normal incisor relationship with both crown and root movement is possible[2] [3]. Since FA is highly advantageous, certain limitations like difficulty in the maintenance of oral hygiene and frequent breakage are ignored. FA is not aesthetically pleasing. Though orthodontic treatment aims for better esthetics in the end, during the course of treatment psychosocial issues of the patients are overlooked[4]. It is established by various researchers that FA treatment causes weight loss[5]. This is due to the prolonged intentional skipping of meals and lack of nutrients in preferred soft food advised due to decreased masticatory efficiency [6]. Weight loss, however, is a characteristic feature of gastritis. Gastritis is the inflammation of the gastric lining which may be due to various factors like stress, genetic conditions, old age, bacterial infection, autoimmune diseases, regular/unsupervised use of NSAIDs, smoking, lifestyle choices, irregular food intake, alcoholism[7] [8]. Several etiological factors of gastritis share a common ground with the habits of patients undergoing orthodontic treatment with fixed appliances[5]. Improper food habits, prolonged intentional skipping of meals [9], regular/ unsupervised use of NSAIDs [10], poor oral hygiene[11], disturbed sleep, and psychosocial stress and anxiety [12] form a bridge between orthodontic treatment and gastritis. This study aims to determine if Prolonged orthodontic treatment precipitates gastritis.

METHODOLOGY

STUDY DESIGN- This was a cross-sectional questionnaire-based study to determine if prolonged orthodontic treatment might precipitate gastritis.

QUESTIONNAIRE- The structured, self-administered questionnaire was partly adapted from comparable studies previously conducted on difficulties of patients undergoing orthodontic treatment and the symptoms of gastritis which were standardized. The questionnaire was circulated in an electronic medium (Google Forms). The responses were collected in April 2023. The questionnaire had 15 questions in total consisting of 3 sections;

- i) Demographic details (name, age, sex, duration of orthodontic treatment)
- ii) Difficulties and habits of patients undergoing orthodontic treatment (5 questions) regarding frequency of food intake, NSAID consumption, sleep disturbance, and social anxiety.
- iii) Symptoms of gastritis (6 questions) regarding weight loss, heartburn, bloating, response to spicy food and antacids, and the consultation of a physician relating to gastric issues after 6 months of orthodontic treatment.

PARTICIPANTS- The questionnaire was circulated among 100 orthodontic patients in Asan Memorial Dental College and Hospital, Chengalpattu.

Inclusion criteria

- i) Patients aged between 18 years to 30 years
- ii) Orthodontic treatment duration more than 3 months

Exclusion criteria

- i) Patients aged less than 18 years of age
- ii) Orthodontic treatment duration less than 3 months

STATISTICAL ANALYSES

Chi-square tests were used to analyze the relationship between the duration of orthodontic treatment, intentional skipping of meals, unsupervised administration of NSAIDs, psychosocial stress and anxiety, burning sensation in the stomach, weight loss, bloating, and the consultation of a physician for gastric issues after orthodontic treatment. Two-tailed analyses were conducted, and P values less than 0.05 were considered significant. The data were statistically analyzed using SPSS v. 24.0 (IBM, Armonk, NY, USA).

NULL HYPOTHESIS – Orthodontic treatment and the occurrence of gastritis are independent of each other.

ALTERNATIVE HYPOTHESIS – Orthodontic treatment leads to gastritis/ worsens existing gastritis severity.

**Lakshmi Ravi et al.,****HOW LONG HAS IT BEEN SINCE THE COMMENCEMENT OF ORTHODONTIC TREATMENT * DO YOU HAVE A BURNING FEELING IN YOUR STOMACH BETWEEN MEALS AND AT NIGHT?**

The cross-tabulation and chi-square tests were conducted to investigate the relationship between the duration since the commencement of orthodontic treatment and the occurrence of a burning feeling in the stomach between meals and at night. The observed counts depict the distribution of responses across different time intervals, while the expected counts are based on the assumption of independence. The chi-square tests reveal a statistically significant association between the duration of orthodontic treatment and the experience of a burning feeling in the stomach (Pearson Chi-Square = 18.415, $p = 0.031$). The linear-by-linear association test suggests a potential linear trend in the relationship, indicating that as the duration of orthodontic treatment increases, the likelihood of experiencing a burning feeling in the stomach also increases. Symmetric measures (Phi and Cramer's V) show a moderate association.

Correlations

The correlation matrix reveals the relationships between various factors related to orthodontic treatment and gastric issues. Here's a brief analysis of the correlations:

Duration of Orthodontic Treatment and Meal Skipping Habits:

Pearson Correlation: 0.232*

Significance: $p = 0.020$ There is a weak positive correlation (significant at the 0.05 level) between the duration of orthodontic treatment and the tendency to skip meals due to fear of breaking brackets or intentionally avoiding favorite foods.

Meal Skipping Habits and Consulting a Doctor for Gastric Issues:

Pearson Correlation: 0.478**

Significance: $p < 0.001$

A moderate positive correlation (highly significant at the 0.01 level) exists between the tendency to skip meals and the likelihood of consulting a doctor for gastric issues after orthodontic treatment.

Burning Feeling in Stomach and Other Variables:

Duration of Orthodontic Treatment: 0.294**

Meal Skipping Habits: 0.568**

Bloating/Flatulence: 0.420**

Medication for Pain Relief: 0.395**

Consulting a Doctor for Gastric Issues: 0.401**

All correlations are highly significant at the 0.01 level.

There are strong positive correlations between the burning feeling in the stomach and various factors, including duration of orthodontic treatment, meal-skipping habits, bloating/flatulence, medication for pain relief, and consulting a doctor for gastric issues.

Bloating/Flatulence and Medication for Pain Relief:

Pearson Correlation: 0.395**

Significance: $p < 0.001$

There is a moderate positive correlation (highly significant at the 0.01 level) between experiencing bloating/flatulence and taking medication for pain relief after orthodontic visits.

Medication for Pain Relief and Consulting a Doctor for Gastric Issues:

Pearson Correlation: 0.377**

Significance: $p < 0.001$

A Strong positive correlation (highly significant at the 0.01 level) exists between taking medication for pain relief and consulting a doctor for gastric issues after orthodontic treatment.

**Lakshmi Ravi et al.,**

In summary, the correlations suggest several significant associations. Notably, the duration of orthodontic treatment is weakly correlated with meal-skipping habits, while meal-skipping habits strongly correlate with consulting a doctor for gastric issues. The burning feeling in the stomach is strongly correlated with multiple variables, indicating its potential role in gastrointestinal concerns during orthodontic treatment. Additionally, taking medication for pain relief is moderately correlated with both bloating/flatulence and consulting a doctor for gastric issues.

REGRESSION

Dependent Variable: HAVE YOU CONSULTED A DOCTOR FOR GASTRIC ISSUES AFTER ORTHODONTIC TREATMENT RECENTLY? The regression model aims to predict the likelihood of individuals consulting a doctor for gastric issues after orthodontic treatment. The model's overall fit is summarized as follows:

R Square (Coefficient of Determination): The R Square value of 0.224 indicates that approximately 22.4% of the variance in the dependent variable (consulting a doctor for gastric issues) is explained by the independent variables included in the model.

Dependent Variable: HAVE YOU CONSULTED A DOCTOR FOR GASTRIC ISSUES AFTER ORTHODONTIC TREATMENT RECENTLY?

The analysis of variance (ANOVA) table for the regression model indicates a statistically significant relationship between the predictors and the likelihood of individuals consulting a doctor for gastric issues after recent orthodontic treatment. **Regression Sum of Squares (SSR):** The variation in the dependent variable (consulting a doctor for gastric issues) explained by the predictors is 4.314. The F-statistic (5.433) tests the overall significance of the regression model. The p-value associated with the F-statistic is highly significant ($p = 0.000$), indicating that at least one predictor in the model has a significant effect on the dependent variable. **b. Predictors:** (Constant), DO YOU FEEL BLOATING OF YOUR STOMACH/ EXPERIENCE FLATULENCE?

Dependent Variable: HAVE YOU CONSULTED A DOCTOR FOR GASTRIC ISSUES AFTER ORTHODONTIC TREATMENT RECENTLY? The coefficients of the regression model provide insight into the individual contribution of each predictor to the likelihood of individual consulting a doctor for gastric issues after recent orthodontic treatment. Individuals taking medication for pain relief after orthodontic visit have a positive and significant impact on the likelihood of consulting a doctor for gastric issues (Beta = 0.231, $p = 0.028$). In summary, the medication for pain relief after orthodontic visits appears to be the most influential factor in predicting the likelihood of consulting a doctor for gastric issues.

RESULTS

Association between Orthodontic Treatment Duration and Gastric Issues

The chi-square tests indicate a statistically significant association between the duration of orthodontic treatment and the occurrence of a burning feeling in the stomach between meals and at night ($p = 0.031$). There seems to be a potential linear trend, suggesting that as the duration of orthodontic treatment increases, the likelihood of experiencing a burning feeling in the stomach also increases.

Correlations between Orthodontic Treatment and Gastric Issues

The correlation matrix reveals several significant associations.

- There is a weak positive correlation between the duration of orthodontic treatment and the tendency to skip meals ($p = 0.020$).
- A moderate positive correlation exists between meal-skipping habits and consulting a doctor for gastric issues ($p < 0.001$).
- The burning feeling in the stomach is strongly correlated with the duration of orthodontic treatment, meal-skipping habits, bloating/flatulence, medication for pain relief, and consulting a doctor for gastric issues (all $p < 0.001$).

**Lakshmi Ravi et al.,**

- Taking medication for pain relief is moderately correlated with both bloating/flatulence and consulting a doctor for gastric issues (both $p < 0.001$).

Regression Analysis

The regression model, aimed at predicting the likelihood of individuals consulting a doctor for gastric issues after orthodontic treatment, has an R Square of 0.224. This indicates that approximately 22.4% of the variance in consulting a doctor for gastric issues is explained by the included predictors. The ANOVA table shows a highly significant relationship between the predictors and the likelihood of consulting a doctor for gastric issues after prolonged orthodontic treatment ($p = 0.000$). The most influential factor in predicting the likelihood of consulting a doctor for gastric issues is taking medication for pain relief after orthodontic visits (Beta = 0.231, $p = 0.028$).

DISCUSSION

According to Gnanasamandham et. Al, Placement of separators, placement of initial arch wires, adjustments, and activation of orthodontic appliances can cause discomfort and pain for 2-3 days, which decreases by the fifth or sixth day. This pain affects patients' eating pattern. Patients may avoid hard foods and restrict food intake because of the conditioned and nociceptive reflexes elicited by arch-wire activation[5] [17]. According to Ju-Yeon Lee et. Al's case studies, the patients began to display pathological eating pattern and the avoidance of food to reduce the pain associated with braces, but they did not express weight and shape concerns. Although most psychiatric disorders are often intentionally hidden in adolescence, their cases exhibited relatively healthy eating patterns and the maintenance of weight gain until the initiation of orthodontic therapy. However, as orthodontic treatment progressed, patients adopt pathological eating patterns that continued even after their oral pain had reduced[4] [17]. In accordance with our survey 73% of patients had agreed to intentionally restricting meals and avoid the consumption of their favorite food due to pain arising from orthodontic visits and the habits continue even after the pain has subsided, just to avoid the breaking of brackets.

Various researchers like Ajwa et. Al [13], Shalchi et. Al [14], Soni et. Al [15] and Sandeep et. Al [16] have concluded that orthodontic treatment leads to significant weight loss. This is further substantiated by our study, where 65% of patients agree that they have undergone weight loss after orthodontic treatment. According to our study, 47% patients admit to Unsupervised consumption of NSAIDs and it is the most influential factor in consulting a physician for gastric issues ($p = 0.02$). This is supported by previous articles of Roda et. Al [10] and Shalchi et. Al [14]. Makrygiannakis et, Al's Evidence also suggests the negative impact of chronic usage of NSAIDs on the efficacy of Orthodontic treatment and the increase in treatment duration [18]. Hence, it may lead to a vicious cycle where patients regularly consume NSAIDs due to pain caused by orthodontic treatment, and thereby the efficacy is reduced, leading to the prolonged duration of Orthodontic treatment. Ultimately inducing gastric issues in long-term Orthodontic patients. Orthodontic treatment aims to improve confidence and promote the self-esteem of patients, especially in adolescents. However, during the course of treatment, the appearance of patients is overlooked, and the self-esteem level is particularly low and patients are conscious about their smile, and refrain from displaying their teeth in public. This includes Smiling, laughing, and even eating in public places thereby affecting the quality of life in orthodontic patients [5]. According to our study, 60% of respondents agree about feeling anxious and self-conscious about smiling or eating in public. It is established that Chronic stress and anxiety lead to gastritis [19] [20]. According to our study, the correlation of various factors like intentional skipping of meals due to pain caused by orthodontic treatment and fear of braking brackets, unsupervised consumption of NSAIDs for pain management, psychosocial stress, and anxiety ultimately precipitate gastritis on long-standing orthodontic treatment; increasing the likelihood of consulting a physician for gastric issues by 22.4% after orthodontic treatment.

Lakshmi Ravi et al.,

CONCLUSION

In conclusion, our study underscores a significant association between prolonged orthodontic treatment and the onset of gastric issues. The interplay of poor dietary habits, intentional meal skipping, anxiety, and use of NSAID during orthodontic care emerges as key contributors to gastritis. While orthodontic treatment itself may not be a direct cause, prolonged durations heighten the risk and exacerbate existing conditions.

Addressing these factors is paramount for comprehensive patient care. A holistic approach, incorporating nutritional guidance, psychological support, and vigilant monitoring of medication usage, can mitigate the risk of gastritis during orthodontic treatment. This study prompts a reevaluation of treatment protocols and highlights the need for patient education programs to foster well-being beyond the structural aspects of orthodontic care.

LIMITATIONS AND FUTURE DIRECTIONS

- The sample is limited to a specific age group and a single dental institution, affecting generalizability.
- Future research could explore additional factors contributing to gastritis during orthodontic treatment and consider longitudinal studies for a more comprehensive understanding.
- Clinical interventions and patient education programs may be developed to address the identified risk factors and promote holistic well-being during orthodontic treatment.

ABSTRACT

Mangrove forests are one of the unique areas on earth that might be a source for many different species. Mangrove trees stabilise the coast by preventing erosion brought on by storm waves, surges, tides and currents. The size of mangroves ranges from little bushes to large trees. The mangrove ecosystem's apex in terms of microbial richness is still unexplored. The investigation of the microbiological biodiversity in the mangrove ecosystem is one of the most difficult areas of biodiversity research. Plants need phosphate next to nitrogen for their growth and development. Chemical phosphate fertilizers were utilized because plants cannot convert atmospheric phosphorus into phosphate, which has an impact on the fertility of the soil. Phosphate-solubilising Bacteria (PSB) can convert phosphorous into a bio-available form through mineralization and solubilization mechanisms. In order to maintain agricultural expansion and cater the growing human population in a healthy environment, complementary and ingenious alternatives to the current dominance of chemical uses must be developed. The review concentrates on the utilizing PSB as an alternative to commercial phosphatic fertilizers in order to overcome this problem.

Keywords: Phosphate Solubilising Bacteria (PSB), Bioinoculum, Plant growth promotion, Phosphate, Mangrove soils, *Bacillus sp.*, *Xanthobacter sp.*, *Vibrio sp.*, Biofertilizer.

Shanmugaraju *et al.*,

INTRODUCTION

The mangrove ecosystem is one of the world's most productive coastal ecosystems that are found in tropical and subtropical regions.[1]Because of their high production, quick turnover rates, and constant exchange between terrestrial and marine ecosystems, mangrove trees play a crucial role in the biogeochemical cycling of phosphorus and other nutrients. Phosphorus is a critical and major ingredient in transient zones, such as coastal and estuaries habitats, and it is thought to control the marine productivity during the geological time periods. [2] In the tropics and subtropics of the planet, mangrove forests are the only ones that may be found where land and water meet. Mangroves, which are trees or shrubs, grow most effectively when low wave energy and shelter encourage the sedimentation of tiny particles, which in turn allow these woody plants to produce roots and expand. In comparison to other tropical forests, mangrove forests often include fewer species and have a simpler structural design. Additionally, ferns and scrubby undergrowth are typically absent from them.[3] Mangroves play a critical role in stabilising and protecting the shore from currents, tsunamis and hurricanes in addition to providing a number of ecological services like nesting habitats for migrating birds, and renewable energy sources and serving as a nursery ground for several commercially significant shellfish and shrimp. [4]A varied microbial population that inhabits mangrove ecosystems simultaneously transforms nutrients from decomposing mangrove foliage into sources of phosphorus, nitrogen and other nutrients that can be utilised by plants. In exchange, the bacteria feed on the exudates from the plant. The mangrove ecosystem has certain physical and chemical components that control the quantity and activity of bacteria in the mangrove habitat. Mangrove forests are thriving ecosystems in India that are responsive to climatic changes.[5]

Mangrove Forests

Mangroves have always trapped the heed of scientists and it still confounds the research community to expand the area of research. Mangroves are a diverse group of plants substantially shrubs, palmstrees, and grounds ferns which have acclimatized to the extreme saline conditions between the tides.[6]The specialty of Mangroves is they get adapted to the harsh environment and has the ability to tolerate stress where the other plant species struggle a lot to survive.[7]Although the species diversity of mangrove is inadequate when compared to the terrestrial ecosystems, it has various adaptation abilities to survive and revamp the harsh environment such as high salinity, muddy substrate and strong wind that makes this ecosystem so scathing and crucial for conservation. The largest mangrove cover is located in Asia that has extended over 6.8 million ha and represents about 34-42 % of the world's total area [8] Mangroves are playing a critical role in rendering a large number of environmental benefits, such as buffering the coastlines against cyclones, tsunamis, storms [3]and carbon storage.[9]Kathiresan *et al.*, stated that the Mangroves have a number of essential characteristics that increase their resistance to disturbances caused by anthropogenic and industrial activities as well as natural calamities like climate change and tsunamis. These qualities include the following:

1. A significant source of nutrients and a big reservoir for the biochemical processes.
2. Fast ingestion of nutrients that is already available while utilizing biotic turnover.
3. Effective biotic controls (for instance, high water and nutrient use efficiency)
4. Simple tree architecture enables quick rebuilding and rehabilitation.
5. Redundancy of important species, which may result in the rehabilitation and recovery of the forest's structural and functional elements.[5]

Mangrove forests in India

India is one among the richest countries for mangrove biodiversity in the world, and holds the third position after Indonesia and Australia. [10]India has a long heritage of mangrove forest management. The first mangrove in the world to be put under scientific management is the Sundarbans mangrove, located in the Bay of Bengal (partly in India and partly in Bangladesh).[11]India covers over ~ 4921 sq. km, (Table:1) of the mangrove forests, inhabiting only 3.2% of global mangrove forest. Sundarbans is the largest mangrove cover, occupying 43% and Gujarat has the second largest mangrove cover with 23% of total mangroves in India.[12]

Shanmugaraju *et al.*,

Microbial Diversity of Mangrove forests

Mangrove habitats' microbial community makeup provides light on their ecological function and special biotechnological potential in the fields of agriculture, industry, medicine, and pharmaceuticals. [14]Fungi cannot solubilize phosphorus as effectively as bacteria can [15]While phosphorus-solubilizing bacteria (PSB) make up 1 to 50% of the total soil microbial population, phosphorus-solubilizing fungi (PSF) only have a 0.1 to 0.5% solubilization capability.[16] The method of analysis utilised when evaluating microbial populations in environmental sample are frequently of its concern. The development of representative colonies from materials served as the foundation for the earliest discoveries of microbial communities. This strategy is still useful for gathering isolates that are easily appropriate for screening for the synthesis of enzymes and other biotechnological uses.[17]

Bacteria

The Sundarbans mangrove ecosystem's phosphorous cycle was discovered to be significantly influenced by soil phosphatase activity and phosphate-solubilizing bacteria. As moved further into the Sundarbans forest ecosystem's deep forest, the amount of soil Phosphatase activity decreased with increase in depth from the dense forest. While soil temperature and pH were found to have a considerable impact on soil phosphatase activity, soil salinity had very little of an impact. This made sure that the phosphate mineralization-related microorganisms in the Sundarbans forest ecosystem are more resilient to salinity variation than to variations in pH and temperature. This ecosystem became a unique source for novel bio and chemo diversity as a result of how the bacterial population developed to create different combinations of enzymes and small chemicals in response to those environmental conditions.[18]

Nitrogen Fixing Bacteria

Zuberer, D *et al.*, stated that the nitrogen fixation is the process by which some bacteria and cyanobacteria transform nitrogen from its gaseous form (N_2) into the mixed forms, such as ammonia or organic nitrogen. Diazotrophs are symbiotic and free-living microorganisms that fix N_2 into proteins.Both terrestrial and marine habitats are capable of supporting the colonisation of nitrogen-fixing bacteria. Insufficient energy sources are expected to constitute a restriction for N_2 fixation in mangrove sediments.[19]Holguin, G *et al.*, explained that, numerous mangrove species have nitrogen-fixing bacteria from the genera *Azotobacter*, *Klebsiella*, *Azospirillum*, *Rhizobium*, and *Clostridium* were isolated from their sediments, rhizospheres, and root surfaces. *V. Aestuarianus*, *Listonellaanguillarum*, *Vibrio campbelli*, and *Phyllobacterium* sp. were among the strains of diazotrophic bacteria that were recovered from the mangrove rhizosphere in Mexico.[20] The diversity of bacterial strains in the Sundarbans silt was discovered by phylogenetic analysis of 16S rRNA gene sequences and were found to be at least eight different bacterial phyla notably *Proteobacteria*, *Planctomycetes*, *Flexibacteria*, *Actinobacteria*, *Gemmatimonadetes*, *Acidobacteria*, *Chloroflexi*, and *Firmicutes* were the major divisions of the discovered bacterial phyla.[21] In Pichavaram's mangrove habitats, N_2 fixing *Azotobacter*, which can be employed as bio fertilizers were widespread.[22]

Phosphate solubilising bacteria

Mangrove plants benefit greatly from phosphate-solubilizing bacteria because they can serve as sources of soluble phosphorus from the soil. Phosphate can be solubilized by certain bacteria that have high phosphatase activity (Table: 2). Nine phosphate-solubilizing bacterial strains, including *Bacillus amyloliquefaciens*, *E. Asburiae*, *Enterobacter aerogenes*, *Bacillus atrophaeus*, *Xanthobacter agilis*, *Paenibacillus macerans*, *Vibrio proteolyticus*, *E. Taylorae* and *Kluyvera cryocrescens* were recovered from the roots of black mangrove (*Avicena germinant*) roots. White mangrove (*Languncularia racemosa*) roots were used to isolate three more strains: *B. Licheniformis*, *Chryseomonas luteola*, and *Pseudomonas stutzeri*. This is the only account of the presence of bacteria from the genera *Xanthobacter*, *Kluyvera*, and *Chryseomonas* in the roots of mangroves and their ability to dissolve phosphate. [23]

Sulfate reducing Bacteria

The aerobic respiration plays a pivotal role in the organic matter degradation in its anaerobic zone, whereas in the anaerobic layer, the sulphate reduction plays an important role in decomposition.[30]Nearly all of the CO_2 emissions from the sediment are attributed to sulphate reduction. Around 53% of the total organic matter could be degraded by sulfate-reducing bacteria found in temperate coastal marine sediment of shallow brackish water in Denmark.[31]

**Shanmugaraju et al.,**

Desulfovibrio salexigens, *Desulfovibrio desulfuricansaestuariae*, *Desulfovibrio desulfuricans*, *Desulfosarcina variabilis*, *Desulfovibriosapovorans*, *Desulfococcus multivorans* and *Desulfotomaculum orientis* are the species of sulfate-reducing bacteria found in the mangroves of Goa. These strains are nutrient-flexible and can metabolise a variety of simple substances, such as lactate, acetate, propionate, butyrate, and benzoate. These microorganisms may be able to effectively compete for nutrients in the mangrove environment because they may utilise a variety of diverse substrates.[32]Iron and phosphorus availability in mangrove sediments may be influenced by the activity of bacteria that helps in reduction of Sulphate. [33]

Fungi

"*Manglicolous* fungi" are a collection of fungi that habitat in mangrove forests, or mangals. [34] These organisms can produce all the enzymes necessary for lignin, cellulose, and other plant materials' break down which makes them extremely essential for the nutrient cycling in these ecosystems. [35] From 29 mangrove habitats around the world, Hyde K Det al., [36] listed 120 species which included 2 *Basidiomycetes* sp., 87 *Ascomycetes* sp., and 31 *Deuteromycetes* sp. among them. Over a hundred different fungal species have been found in mangrove habitats, The decomposing debris of Rhizophora of South India's Pichavaram contained about 48 different kinds of fungi.[37]

Actinomycetes

Actinomycetes are major producers of antibiotics, anticancer drugs, enzymes, enzyme inhibitors, and immune modifiers, all of which are used extensively in the pharmaceutical industry, forestry sectors and agricultural. They also play a significant part in the natural ecological system.[38] The mangrove ecosystem is a valuable source for isolating actinomycetes that has the capability to produce antibiotics. Beta-unsaturated gamma-lactone, an antibiotic chemical from *Streptomyces grisebruneus*, was isolated and discovered. It exhibited broad anti-microbial action.[39]

Plant and Phosphate

A crucial nutrient for plant growth and crop productivity is phosphorus. Although both organic and inorganic forms of it are plentiful in soils, their availability is limited since they primarily exist in insoluble forms. [40] Phosphate solubilizing microorganisms (PSMs) provide a biological method for making insoluble phosphate to its soluble form so that plants can utilize it.[41] Microorganisms that solubilize phosphate can enhance the growth and productivity of a wide range of crops. PSM inoculation is a promising method for increasing the global food supply without affecting the environment. [16] A crucial nutrient for plant growth and crop productivity is phosphorus. Although both organic and inorganic forms of it are plentiful in soils, their availability is limited since they primarily exist in insoluble forms.[40] Contradictory to the case with nitrogen, there is no significant atmospheric source of a critical growth-limiting nutrient Phosphate (P) that can be rendered biologically available for plants. [42] The characteristics of phosphorus nutrition include crop maturity and production, flower and seed formation, crop quality improvement, root development, stalk and stem strength, resistance to plant diseases and N-fixation in legumes. Over the past decades, although the microbial inoculants have been used to increase soil fertility over the past century, P solubilisation research has been reported on much less frequently than nitrogen fixation.[43] Phosphorus-deficient plants develop slowly and frequently have an unusually dark green colour. Anthocyanin pigments can occur when sugars build up, giving a reddish-purple hue. On low phosphorus areas, this can sometimes be seen in the early spring. Typically, only extremely low phosphorus soils exhibit these symptoms. It should be emphasised that crops may respond well to phosphorus fertiliser without displaying the typical shortages. [44]

PSM's mode of promoting plant growth

Fungi cannot solubilize phosphorus (P) as effectively as bacteria can. [45] The phosphorus-solubilizing fungi (PSF) only have a 0.1 to 0.5% solubilization capability whereas the phosphorus-solubilizing bacterium (PSB) makes up 1 to 50% of the total soil microbial population. [46] Ectorrhizospheric strains of *Pseudomonas* and *Bacilli*, as well as endosymbiotic rhizobia, have been identified in soil bacterial communities as efficient solubilizers of phosphate. [47] Physical-chemical (sorption-desorption) and biological (Immobilization- mineralization) processes define the dynamics of P in the soil. The highly reactive Al^{3+} and Fe^{3+} in acidic soils and Ca^{2+} in calcareous or normal soils, a significant quantity of P provided as fertilizer enters the immobile pools through the precipitation reaction [48,49]

**Shanmugaraju et al.,**

Phosphate Solubilising Microorganism (PSM) demonstrated the ability to increase the production of deteriorated, ineffective, and barely productive agricultural soils.[48] The main method that PSMs promote the plant growth is by increasing the efficiency with which they take up P that result in their conversion of insoluble form of P into its accessible form (orthophosphate) that plants can use for their metabolism. The solubilization of earlier applied and fixed phosphates in soil is known to be enhanced by PSM inoculation in soil or by coating the seeds for improving crop yield (Table: 3). [50] Additionally, it has been claimed that PSM aid in the absorption of phosphorus from a larger area by expanding the root system's network. High crop yields have been recorded as a result of PSB inoculation, including *Rhizobium*, *Flavobacterium*, *Erwinia*, *Achromobacter*, *Agrobacterium*, *Pseudomonas*, *Micrococcus*, and *Bacillus*. [51] PSMs stimulate the growth of plants by producing phytohormones like auxins, gibberellins, cytokinins and polyamides. [52] PSMs produce antibiotics, hydrogen cyanate (HCN), and antifungal metabolites that help to shield plants from phytopathogens. [53]

Future Trends in the Ecology of Mangrove's Microbial Community

In order to meet the world's demand, the production of chemical phosphatic fertilizers is a very energy-intensive process that annually costs US \$ 4 billion. It has been proposed that the piled phosphates in agricultural soils are sufficient to support the highest crop yields globally for around 100 years. The organisms with the ability to phosphate-solubilize can also transform the insoluble phosphatic compounds in the soil into its soluble forms so that the crops can use them. [58] Research on the function and organization of microbial communities is still in its infancy at the moment. Although there is a lot of information currently available, closing the research gaps will be a difficult task. These sediments are quite complex, and interactions amongst the organisms are very likely. There is still a lack of knowledge of the majority of the microbial groups involved in each stage of the nutrient cycles, as well as how these communities react to local and global environmental changes. A thorough analysis of populations present in various mangroves across the globe is necessary to determine which species or groups of microorganisms are cosmopolitan and which are endemic to a particular region, as well as to evaluate their biotechnological potential. This is one of the most fundamental and first steps in revealing the mangrove's microbial network. [17] It is crucial that scientists and researchers continue to learn about P-solubilizing microbes and translate their understanding into bio-based inoculants that farmers could easily access. Farmers also need to be made aware of the importance of using bio- inoculants as a chance of enabling the sustainable agriculture.

ABSTRACT

In this paper we have introduced Star numbers and established the connection between Star numbers and well known family of numbers like Triangular numbers, Square numbers, and Centred Square numbers.

Keywords: Star numbers, Triangular numbers, Square numbers, Centred Square numbers.

INTRODUCTION

A figurate number is a number formed by taking points, or dots and arranging them into regular shape, such as a triangular, square, pentagon. Such numbers are called Polygonal numbers or in general, Figurate numbers. Star numbers also falls under the category of Centred Figurate number, where these numbers are represented in Hexagrams shape. In this paper we introduce star numbers and provide results in which star numbers are equal to triangular, square, and centred square numbers.

Tamilarasi and Sivaraman

DEFINITION

STAR NUMBERS

Star numbers are numbers which can be represented in the shape of Centred Hexagrams (six point star). These appear as concentric layers of dots, each layers being arranged in the shape of a hexagram, around a centred dot. The m th star number is defined by $S_m = 6m(m - 1) + 1(1)$. The list of first few star numbers are given by 1, 13, 37, 73, 121, 181, 253, 337, 433, ... Below are representations of the first few Star numbers:

TRIANGULAR NUMBERS

Triangular numbers are numbers that can be represented as a triangle. The first triangular numbers $T_1 = 1$. The second triangular number is found by adding 2 to the previous triangular number and so $T_2 = 1 + 2 = 3$. The third triangular number is found by adding 3 to the previous triangular number and so $T_3 = 1 + 2 + 3 = 6$. The n th triangular number is $T_n = 1 + 2 + 3 + \dots + n = \frac{n(n+1)}{2}$. (2) Below are representations of the first few Triangular numbers:

SQUARE NUMBERS

A square number is a number that has been multiplied by itself. It is the product of two equal numbers. $n^2 = n \times n$ (3) Below are representations of the first few Square numbers:

Tamilarasi and Sivaraman

CENTRED SQUARE NUMBERS

A Centred square number is a centred figurate number that represents the number of dots in a square that is centred within in larger square, with a constant number of dots separating the two squares along each side.

The *n*th centred square number is $CS_n = \frac{4n(n+1)}{2} + 1 = 2n^2 + 2n + 1$ (4)

Below are representations of the first few Centred square numbers:

Lemma

Consider the quadratic Diophantine equation $ax^2 - by^2 = c$ (5). Consider $D = ab$. Let (x_0, y_0) be a solution of equation (5) and $u^2 - Dv^2 = 1$ (6).

Then $x = x_0u + b\beta v, y = \beta u + av$ (7) and $x = |-x_0u + b\beta v|, y = |\beta u - av|$ (8) where $\alpha = ax_0, \beta = y_0$ (9) are also solutions of equation (5).

Proof

From the hypothesis, we have $ax_0^2 - by_0^2 = c$. Using (6), (7) and (9), we have $ax^2 - by^2 = a(x_0u + by_0v)^2 - b(y_0u + ax_0v)^2 = u^2(ax_0^2 - by_0^2) - abv^2(ax_0^2 - by_0^2) = (u^2 - abv^2)(ax_0^2 - by_0^2) = 1(c) = c$

Hence the values of x and y from (7) forms solution to (5). Now using (8), we have $ax^2 - by^2 = a(-x_0u + by_0v)^2 - b(y_0u - ax_0v)^2 = u^2(ax_0^2 - by_0^2) - abv^2(ax_0^2 - by_0^2) = (u^2 - abv^2)(ax_0^2 - by_0^2) = 1(c) = c$

Thus the values of x and y from (8) forms solution to (5).

Also we notice that if (x_0, y_0) is one of the solutions to (5), then we can generate infinitely many solutions of (5), using (7) and (8).

In the following section we prove some interesting results.

Theorem 1

There exists infinitely many Star numbers which are also triangular numbers.

Proof: let S_m be the *m*th star number and let T_n be *n*th triangular number.

If $S_m = T_n$ for some m, n then we have

Tamilarasi and Sivaraman

$$6m(m - 1) + 1 = \frac{n(n+1)}{2} \tag{10}$$

$$n^2 + n - 12m^2 + 12m - 2 = 0$$

$$n = \frac{-1 \pm \sqrt{1^2 - 4(1)(-12m^2 + 12m - 2)}}{2(1)}$$

$$(2n + 1)^2 = 48m^2 - 48m + 9$$

$$(2n + 1)^2 = 3(16m^2 - 16m + 3 + 1 - 1)$$

$$(2n + 1)^2 = 3(4m - 2)^2 - 3$$

$$(2n + 1)^2 - 3(4m - 2)^2 = -3 \tag{11}$$

If we now consider $X = (2n + 1)$ and $Y = 4m - 2$ then (11) can be written as

$$X^2 - 3Y^2 = -3 \tag{12}$$

Comparing with (5), we get $a = 1, b = 3, D = ab = 3,$

One of the solutions for (12) is $(X_0, Y_0) = (3, 2)$

$$\text{Now, consider } u^2 - 3v^2 = 1 \tag{13}$$

$$\text{The continued fraction for } \sqrt{3} \text{ is given by } \sqrt{3} = [1; \overline{1, 2}] \tag{14}$$

The successive convergents obtained from continued fraction of $\sqrt{3}$ are given below

$$\frac{1}{1}, \frac{2}{1}, \frac{5}{3}, \frac{7}{4}, \frac{19}{11}, \frac{26}{15}, \frac{71}{41}, \frac{97}{56}, \frac{265}{153}, \frac{362}{209}, \frac{985}{571}, \frac{1351}{780}, \frac{3691}{2131}, \frac{5042}{2911}, \frac{13775}{7953}, \frac{18817}{10864},$$

$$\frac{51409}{29681}, \frac{70226}{40545}, \frac{191861}{110771}, \frac{262087}{151316} \dots \tag{15}$$

We observe that the numerators and denominators of second, fourth, sixth, eighth, tenth, and so on convergents from (15) forms solution to (13).

$$\text{In particular we observe that the pair of } (u, v) = (2, 1); (7, 4); (26, 15); (97, 56); (362, 209); (1351, 780); (5042, 2911); (18817, 10864), (70226, 40545); (262087, 151316) \dots \tag{16}$$

forms solution to (13).

Now, $(X_0, Y_0) = (3, 2)$ is initial solution to $X^2 - 3Y^2 = -3$

$$\alpha = ax_0 = 3, \quad \beta = y_0 = 2,$$

By lemma (3) we obtain

$$X = x_0u + b\beta v = 3u + 6v \tag{17}$$

$$Y = \beta u + av = 2u + 3v \tag{18}$$

From equations (17) and (18) for every pair of (u, v) given by (16), we obtain the solution of equation (12). Such solutions are given by

$$(X, Y) = (12, 7); (45, 26); (168, 97); (627, 362), (2340, 1351); (8733, 5042); (32592, 18817); (121635, 70226); (453948, 262087); (1694157, 978122) \dots \tag{19}$$

$$\text{Since } m = \frac{Y+2}{4} \text{ and } n = \frac{X-1}{2}, \text{ we have } (m, n) = \left(\frac{9}{4}, \frac{11}{2}\right); (7, 22); \left(\frac{99}{4}, \frac{167}{2}\right); (91, 313); \left(\frac{1353}{4}, \frac{2339}{2}\right); (1261, 4366); \left(\frac{18819}{4}, \frac{32591}{2}\right); (17557, 60817); \left(\frac{262089}{4}, \frac{453947}{2}\right); (244531, 847078) \dots \tag{20}$$

By lemma (3) we obtain

$$X = |-x_0u + b\beta v| = |-3u + 6v| \tag{21}$$

$$Y = |\beta u - av| = |2u - 3v| \tag{22}$$

From equations (21) and (22) for every pair of (u, v) given by (16) we obtain the solution of equation (12). Such solutions are given by

$$(X, Y) = (0, 1); (3, 2); (12, 7); (45, 26); (168, 97); (627, 362); (2340, 1351); (8733, 5042); (32592, 18817); (121635, 70226); \dots \tag{23}$$

$$\text{Since } m = \frac{Y+2}{4} \text{ and } n = \frac{X-1}{2},$$

We have

Tamilarasi and Sivaraman

$(m, n) \left(\frac{3}{4}, \frac{-1}{2}\right); (1,1); \left(\frac{9}{4}, \frac{11}{2}\right); (7,22); \left(\frac{99}{4}, \frac{167}{2}\right); (91,313); \left(\frac{1353}{4}, \frac{2339}{2}\right); (1261,4366); \left(\frac{18819}{4}, \frac{32591}{2}\right); (17577,60817); \dots$ (24)

Now considering positive and integers values of (m, n) through (20) and (24), we can neglect the repeated values and substituting in (10), we notice that the numbers 1, 253, 49141, 9533161, 1849384153, 358770992581, ... (25) are both Star numbers as well as Triangular numbers.

Theorem 2

There exists infinitely many Star numbers which are also Square numbers.

Proof: let S_m be the m th Star number and let n^2 be n th Square number.

If $S_m = n^2$ for some m, n then we have

$$6m(m - 1) + 1 = n^2 \tag{26}$$

$$6m^2 - 6m + 1 - n^2 = 0$$

$$m = \frac{6 \pm \sqrt{6^2 - 4(6)(1 - n^2)}}{2(6)}$$

$$(12m - 6)^2 = 24n^2 + 12$$

$$(6(2m - 1))^2 = 4n^2 + 2$$

$$6(2m - 1)^2 - 4n^2 = 2$$

$$(2n)^2 - 6(2m - 1)^2 = -2 \tag{27}$$

If we now consider $X = 2n$ and $Y = 2m - 1$ then (27) can be written as

$$X^2 - 6Y^2 = -2 \tag{28}$$

Comparing with (5), we get $a = 1, b = 6, D = ab = 6$

One of the solutions for equations (27) is $(X_0, Y_0) = (2,1)$

$$\text{Now consider } u^2 - 6v^2 = 1 \tag{29}$$

$$\text{Consider } (5 - 2\sqrt{6})(5 + 2\sqrt{6}) = 1$$

$$5 - 2\sqrt{6} = \frac{1}{5 + 2\sqrt{6}} = \frac{1}{10 - (5 - 2\sqrt{6})}$$

$$5 - 2\sqrt{6} = \frac{1}{10 - \frac{1}{10 - \frac{1}{10 - \frac{1}{10 \dots}}}}$$

$$2\sqrt{6} = 5 - \frac{1}{10 - \frac{1}{10 - \frac{1}{10 \dots}}}$$

The successive convergents of the continued fraction expansion of $2\sqrt{6}$ are given by

$$5 \frac{49}{10} \frac{485}{99} \frac{4801}{980} \frac{47525}{9701} \frac{470449}{96030} \frac{4656961}{950599} \frac{46099201}{9409960} \dots$$

Multiplying each of the denominators of the convergents obtained above by 2, the solutions to (29) are given by

$$(u, v) = (5,2), (49,20), (485,198), (4801,1960), (47525, 19402), (470449,192060), (4656965,1901198), (46099201,18819920), \dots \tag{30}$$

By lemma (3), we obtain

$$\text{Now, } (X_0, Y_0) = (2,1) \text{ is initial solution to } X^2 - 6Y^2 = -2$$

$$\alpha = ax_0 = 2, \quad \beta = y_0 = 1$$

$$X = x_0u + b\beta v = 2u + 6v \tag{31}$$

$$Y = \beta u + \alpha v = u + 2v \tag{32}$$

From equations (31) and (32) for every pair of (u, v) given by (30), we obtain the solutions of equation (28). Such solutions are given by $(X, Y) = (22, 9), (218, 89), (2158, 881),$

$$(21362, 8721), (211462, 86329), (2093258, 854569), (20721118, 8459361), (205117922, 83739041), \dots \tag{33}$$

Since $m = \frac{Y+1}{2}$ and $n = \frac{X}{2}$ from (33) we have $(m, n) = (10,11), (45,109), (441,1079), (4361, 10681), (43165, 105731), (427285, 1046629), (4229681, 10360559),$

Tamilarasi and Sivaraman

$$(41869521, 102558961), \dots \tag{34}$$

By lemma (3), we obtain

$$X = |-x_0u + b\beta v| = |-2u + 6v| \tag{35}$$

$$Y = |\beta u - \alpha v| = |u - 2v| \tag{36}$$

From equations (35) and (36) for every pair of (u, v) given by (30), we obtain the solution of equation (28), such solutions are given by

$$(X, Y) = (2, 1), (22, 9), (218, 89), (2158, 881), (21362, 8721), (211462, 86329), (2093258, 854569), (20721118, 8459361), (205117922, 83739041), \dots \tag{37}$$

Since $m = \frac{Y+1}{2}$ and $n = \frac{X}{2}$ from (33) we have $(m, n) = (1, 1), (5, 11), (45, 109), (441, 1079), (4361, 10681), (43165, 105731), (427285, 1046629), (4229681, 10360559), (41869521, 102558961), \dots$ (38)

Now considering positive values of (m, n) through (34) and (38), we can neglect the repeated values and substituting in (26), we notice that the numbers

$$1, 121, 11881, 1164241, 114083761, 11179044361, 1095432263641, 107341182792481, 10518340481399521, \dots \tag{39}$$

are both Star numbers as well as Square numbers.

Theorem

There exists infinitely many Star numbers which are also Centred Square numbers.

Proof: let S_m be the m th Star number and let CS_n be n th Centred Square number.

If $S_m = CS_n$ for some m, n then we have

$$6m(m - 1) + 1 = 2n(n + 1) + 1 \tag{40}$$

$$2n^2 + 2n - 6m^2 + 6m = 0$$

$$n = \frac{-2 \pm \sqrt{2^2 - 4(2)(-6m^2 + 6m)}}{2(2)}$$

$$(4n + 2)^2 = 4 + 48m^2 - 48m$$

$$(2(2n + 1))^2 = 4 + 48m^2 - 48m$$

$$(2n + 1)^2 = 12m^2 - 12m + 1$$

$$(2n + 1)^2 = 3 \left[4m^2 - 4m + \frac{1}{3} \right]$$

$$(2n + 1)^2 = 3 \left[4m^2 - 4m + 1 - 1 + \frac{1}{3} \right]$$

$$(2n + 1)^2 = 3 \left[(2m - 1)^2 - \frac{2}{3} \right]$$

$$(2n + 1) - 3(2m - 1)^2 = -2 \tag{41}$$

If we now consider $X = 2n + 1$ and $Y = 2m - 1$ then (41) can be written as

$$X^2 - 3Y^2 = -2 \tag{42}$$

Comparing with (5), we get $a = 1, b = 3, D = ab = 3$

One of the solutions for equations (42) is $(X_0, Y_0) = (5, 3)$

Now consider $u^2 - 3v^2 = 1$ (43)

The continued fraction for $\sqrt{3}$ is given by $\sqrt{3} = [1; \overline{1, 2}]$ (44)

The successive convergents obtained from continued fraction of $\sqrt{3}$ are given below

$$\frac{1}{1}, \frac{2}{1}, \frac{5}{3}, \frac{7}{4}, \frac{19}{11}, \frac{26}{15}, \frac{71}{41}, \frac{97}{56}, \frac{265}{153}, \frac{362}{209}, \frac{985}{571}, \frac{1351}{780}, \frac{3691}{2131}, \frac{5042}{2911}, \frac{13775}{7953}, \frac{18817}{10864}, \dots \tag{45}$$

The second, fourth, sixth, eighth, tenth, and so on convergents in (45) forms solution to (43).

In particular we observe that the pair of values $(u, v) = (2, 1); (7, 4); (26, 15); (97, 56); (362, 209); (1351, 780); (5042, 2911); (18817, 10864), \dots$ (46)

forms solutions to (43)

Now $(X_0, Y_0) = (5, 3)$ is initial solution to $X^2 - 3Y^2 = -2$

By lemma (3), we obtain

$$\alpha = ax_0 = 5, \quad \beta = y_0 = 3, \tag{47}$$

$$X = x_0u + b\beta v = 5u + 9v$$

Tamilarasi and Sivaraman

$$Y = \beta u + \alpha v = 3u + 5v \tag{48}$$

From equations (47) and (48) for every pair of (u, v) given by (46), we obtain the solution of equation (42). Such solutions are given by $(X, Y) = (19, 11), (71, 41), (265, 153),$

$$(989, 571), (3691, 2131), (13775, 7953), (51409, 29681), (191861, 110771), \dots \tag{49}$$

Since $m = \frac{Y+1}{2}$ and $n = \frac{X-1}{2}$ from (49) we have $(m, n) = (6, 9), (21, 35), (77, 132),$

$$(286, 494), (2132, 1845), (3977, 6887), (14841, 25704), (55386, 191860), \dots \tag{50}$$

By lemma (3) we obtain

$$X = |-x_0u + b\beta v| = |-5u + 9v| \tag{51}$$

$$Y = |\beta u - \alpha v| = |3u - 5v| \tag{52}$$

From equations (51) and (52) for every pair of (u, v) given by (46) we obtain the solution of equation (42). Such solutions are given by

$$(X, Y) = (1, 1), (1, 1), (5, 3), (19, 11), (71, 41), (265, 153), (989, 571), (3691, 2131), \dots \tag{53}$$

Since $m = \frac{Y+1}{2}$ and $n = \frac{X-1}{2}$ from (53) we have $(m, n) = (1, 0), (2, 2), (6, 9), (21, 35),$

$$(77, 132), (286, 494), (2132, 1845), (3977, 6887) \dots \tag{54}$$

Now considering positive values of (m, n) through (50) and (54), we can neglect the repeated values and substituting in (40), we notice that the numbers

1, 13, 181, 25201, 35113, 489061, 6811741, 94875313, 1321442641, 18405321661, ... (55) are both Star numbers as well as Centred Square numbers.

The Star numbers and Centred square numbers diagram are given below

CONCLUSION

In this paper, after introducing star numbers we have established three theorems related to set of star numbers which are also triangular numbers, square numbers and centred square numbers respectively. The star numbers considered as part of figurate numbers, thus exhibit fascinating connection between other class of figurate numbers. One can try to establish equality of star numbers with other class of interesting sequence of numbers as presented here.

ABSTRACT

The aim of this study was to evaluate the hepatoprotective efficacy of methanol extract from grains of *Pennisetum glaucum* using rat models. The extract was subjected to GC-MS for phytochemical screening where, **sterols, carbohydrates, phenols, flavonoids, proteins tannins, saponins, and terpenoids were identified**. The total phenolic content and total flavonoid content of the extract are found to be 12.5 mg GAE/g and 62.1 ± 4.17 mg QE/g, respectively in the extract. Acute toxicity tests determined the optimal dosage of MEPG and no symptoms of toxicity or mortality up to a dosage of 2000 mg/kg body weight was noticed. The hepatoprotective effect of methanol extract was assessed using carbon tetrachloride and paracetamol-induced models at doses of 200 mg/kg and 400 mg/kg which demonstrated a significant reduction in CCl₄ and paracetamol-induced liver damage which was confirmed through histopathological studies. Furthermore, the decrease in the levels of serum biochemical markers such as

**Ganga Raju et al.,**

ALP, Bilirubin, AST and ALT were also observed indicating a hepatoprotective effect of the extract under study. The results indicate that *Pennisetum glaucum* is an excellent source of phytochemicals and therefore, further studies are needed on various biochemical aspects where the data procured might help in the developments of lead products and formulations suitable for the management of various liver diseases.

Keywords: *Pennisetum glaucum*, Acute Toxicity, Paracetamol, Carbon tetrachloride, Serum markers and Hepatoprotective efficacy

INTRODUCTION

The liver, one of the largest organs in the human system, is crucial due to its oversight of many functions, including metabolism, which is necessary for survival [1]. The organ's position in the human anatomy makes it susceptible to a wide variety of outside toxins. The intestinal absorption of these xenobiotics begins in the liver, making it an organ vulnerable to ailments [2]. An abundance of hepatotoxic agents, including alcohol, viruses, and chemicals such as carbon tetrachloride (CCl₄) and paracetamol, are currently responsible for the poor well-being of countless individuals [3-4]. More than 20,000 people die each year from liver diseases, making it a major health concern around the world [5]. Traditional medicine for liver problems may not be effective enough or may even cause harm [6]. This is the reason why switching from chemical medications to herbal remedies is crucial. As a result, herbal treatments have become widely popular and extensively utilized. A large range of medicinal plants and their preparations around the world have asserted hepatoprotective activity. Research has shown that 101 different plants contain around 160 phytoconstituents that protect the liver [7]. In recent years, there has been more interest in naturally occurring substances from plants, such as phenolic acids, flavonoids, terpenoids, and sterols, because they have a wide range of pharmacological effects, including antioxidant and hepatoprotective activity [8]. India and Africa both rely on pearl millet, scientifically known as *Pennisetum glaucum*, as a mainstay crop in their dry and semi-arid climates. Although it has its roots in the Sahel area of Africa, it has consistently grown in India and Africa since ancient times [9-10]. Despite its humble origins, this cereal has the potential to be a rich source of dietary antioxidants like flavonoids and phenolic acids. These bioactive compounds have been shown to reduce oxidative stress caused by free radicals, which could help prevent ageing and a host of diseases linked to oxidative stress, including cancer, cardiovascular disease, diabetes, asthma, and neurodegenerative disorders [11-12].

Additionally, it controls blood pressure and plasma low-density lipoprotein cholesterol levels and has anti-allergenic properties [13-14]. In light of the foregoing, the current investigation set out to assess the histopathological findings and *in vivo* hepatoprotective effects of a MEPG using paracetamol and carbon tetrachloride-induced models. Acute liver damage can occur from the over administration of paracetamol (acetaminophen), a commonly used antipyretic and analgesic [15-16]. Glucuronide and sulphate conjugates are the primary products of paracetamol's metabolism in the liver [17-18]. But when hepatic cytochrome P450 activates a portion of paracetamol, it forms the extremely reactive metabolite N-acetyl-P-benzoquinone imine (NAPQI), which is responsible for its hepatotoxicity [19-20]. NAPQI can covalently bind to protein cysteine groups, resulting in the formation of 3-(cystein-S-yl) acetaminophen adducts [21]. Glutathione protects hepatocytes by preventing the covalent attachment of paracetamol's reactive metabolite to liver proteins [22]. The CCl₄ is a commonly used poison to induce liver damage in lab animals for experimental purposes [23]. A liver-toxic substance is similar to a virus in that it damages liver cells. When CCl₄ reaches the liver, it is recognised as a xenobiotic. Microsomal mechanisms utilize monooxygenase P-450 to convert it into two free radicals, trichloromethyl and trichloromethyl-peroxyl. These two radicals cause lipid peroxidation, resulting in severe liver damage [24]. Research has shown that antioxidants protect the liver from oxidative damage and reduce the risk of liver disease [25]. Because of this, there is a growing movement to find natural compounds with antioxidant properties and employ them to protect the liver from oxidative stress-related diseases [26].

Ganga Raju et al.,

MATERIALS AND METHODS

Plant Collection

The *Pennisetum glaucum* grains have been purchased from an authorised millet store in Hyderabad. The material was identified by a botanist in December 2021, and its authenticity was confirmed by the professor and head of the Department of Botany at Government Degree College, Kukatpally, Hyderabad. After rinsing, the botanist crushed the grains into a coarse powder. The material that had been pulverised was kept for the extraction process.

Preparation of Methanolic Extract of *Pennisetumglaucum* (MEPG)

Millet powder (950g) was kept inside the Soxhlet apparatus directly or it is put within a thimble of filter paper. To fix the powder, the methanol is initially siphoned once before boiling. Fragments of activated porcelain were added to the flask in order to prevent the solvent from getting bumped. As soon as the liquid reaches the point of return, it moves the contents of the extractor chamber to the flask, creating a syphon in the syphon tube. When the resulting liquid rises to the top of the extractor's liquid level, the vapours travel via the side tube. To accomplish efficient extraction, one can syphon back and evaporate the solvent in cycles as frequently as feasible without altering it. This technique, which consists just of a few quick macerations, is an ongoing extraction procedure. After drying by evaporation at ambient temperature, the resultant organic extracts were placed in sealed containers for further use.

Phytochemical screening

Preliminary phytochemical analysis was carried out in order to determine the various phytoconstituents present in MEPG.

GC Condition and Identification of Compounds of MEPG

A Scion 436-GC Bruker model equipped with a triple quadrupole mass spectrophotometer and a BR-5MS fused silica capillary column, composed of 5% diphenyl/95% dimethyl polysiloxane, performed the GC-MS analysis. Helium at a flow rate of 1 mL/min was employed as a carrier gas. The ion source is kept at 280°C and the injector at 250°C. The oven was programmed to increase from 200°C to 280°C at a rate of 10°C/min, followed by a further increase of 5°C/min until reaching 280°C. It then maintained an isothermal period of at 280°C with a final hold time of 9 min.

Estimation of total phenolic content

The total phenols present in all the extracts were determined by method described in the literature [27] and in quintuplicate. To an aliquot consisting of 5µL of MEPG, 1M Na₂CO₃ and Folin-Ciocalteu reagent were added. The colour developed after 15 minutes of the reaction in dark was measured at 760nm against reagent blank and gallic acid was served as the reference standard. The total phenols were determined as mg of gallic acid equivalent per gm of sample using a calibration curve.

Estimation of total flavonoids

The total flavonoids were determined with the colorimetric assay using AlCl₃ as published in literature [28] and performed in quintuplicate. To the appropriately diluted extract (200µl), AlCl₃ (10%, 0.2ml), Potassium acetate (1M, 0.2ml) and distilled water (5.6ml) were added. The reaction mixture and incubated for 30 mi. at room temperature. The absorbance was recorded at 420 nm and the total flavonoids were determined using a calibration curve as mg of quercetin equivalent per gm of sample.

Animals

The pharmacological activities were carried out using Wistar Albino rats of either sex weighing 200–250 g and Swiss Albino mice weighing 20–30 g. They were housed in polypropylene cages and subjected to a diurnal cycle with a temperature of 25 ± 2 °C and a relative humidity of 45–55%. Prior to any studies being conducted, the animals were allowed to adjust to the laboratory environment for around one week. Routine animal feed and unlimited water were

**Ganga Raju et al.,**

provided to them. Institutional Animal Ethics Committee (IAEC) approval was obtained for all pharmacological experimental protocols.

Acute Toxicity Studies

An investigation was done to find out if the extract was unsafe. The study was conducted in accordance with the OECD. The acute oral toxicity is evaluated using the up-and-down method. An inbred colony of adult Wistar albino rats (weighing 150–200 grammes) is used in this study. The IAEC approved all the experimental pharmacological methodologies.

In vivo Evaluation of Hepatoprotective Activity**Paracetamol Induced Hepatotoxicity**

This seven-day study will involve thirty healthy Wistar albino rats of either sex, weighing between 200 and 250 g. For a duration of seven days, the animals get their subsequent treatment orally. All animals are categorised into five groups of six animals each [29].

Carbon Tetrachloride Induced Hepatotoxicity

This 28 days study will involve thirty healthy Wistar albino rats of either sex, weighing between 200 and 250 g. For a duration of seven days, the animals get their subsequent treatment orally. All animals are categorised into five groups of six animals each [30-31].

Measurement of serum biochemical markers

After 24 hours following the last treatment, blood was collected from the retro-orbital plexus and allowed to coagulate for an hour at ambient temperature, and the serum is then separated by centrifugation at 2500 rpm for 15 mins at 30°C. After separation, the serum was tested for several biochemical factors.

Histopathological examination

Liver tissues were subjected to a photomicroscopy examination after one week of dehydration in a series of ethanol solutions, embedding in paraffin, sectioning into 5 micrometre pieces, and staining with haematoxylin-eosin dye.

ADMET Analysis

ADMET (Absorption, Distribution, Metabolism, Excretion, and Toxicity) analysis was carried out utilising the Swiss-ADME tool. For a compound to be regarded as a therapeutic candidate, the ADMET analysis is deemed too important [32]. Utilising the web-based database pkCSM, the pharmacokinetic scores of substances were assessed.

Statistical analysis

Values were analysed using SPSS 18.0 software and presented as the Mean \pm SD. A one-way analysis of variance (ANOVA) was used, along with the LSD and Dunnett's tests. statistical significance was set to $P < 0.05$.

RESULTS

The *P. glaucum* grains were identified, verified, gathered, desiccated, and ground into powder and the yield of MEPG was found to be 12% w/w.

Phytochemical Analysis

The phytochemicals in the methanolic grain extract of *P. glaucum* showed that it contained flavonoids, steroids, phenols, carbohydrates, tannins, terpenes, fatty acids, proteins, and volatile oils (Table-3).

GC-MS of MEPG

After the GCMS analysis, the subsequent bioactive components in the extract were determined and presented (Table-4).

Ganga Raju et al.,

Total Phenol and Flavonoid Content

The total phenolic content and total flavonoids content of MEPG were found to be 12.5 mg GAE/gm and 62.1 ± 4.17 mg QE/gm respectively (Fig-2 & 3)

Acute Toxicity Studies

Swiss albino mice showed no signs of toxicity or death up to a dosage of 2000 mg/kg body weight in the experiments. All the animals were found to be healthy, even after fourteen days of surveillance. Consequently, the extract was found to be acceptable up to a dosage of 2000 mg/kg bd.wt.

Dose selection

Results showed that 2000 mg/kg bd wt was safe in the toxicity tests mentioned earlier. The pharmacological studies were conducted using 200 and 400 mg/kg bd.wt. dosages.

In vivo Hepatoprotective Activity

This study set out to test the hypothesis that the MEPG has hepatoprotective effects against CCl₄ and paracetamol-induced hepatotoxicity at varying dosages.

Paracetamol Induced Hepatotoxicity

Paracetamol alone does not cause hepatic damage or drug-induced liver disease. Rather, one of its metabolites, N-acetyl-p-benzoquinoneimine (NAPQI), does. NAPQI directly destroys liver cells and reduces glutathione, the liver's natural antioxidant, leading to hepatic failure. Hepatic toxicity is indicated by elevated levels of various biochemical markers that include total bilirubin, alkaline phosphatase (ALP), alanine aminotransferase (ALT), and aspartate aminotransferase (AST) [33]. The levels of AST, ALP, ALT and bilirubin in the blood were slightly lower in the groups that were given MEPG at 200 mg/kg bd., wt., and 400 mg/kg bd., wt (Table-5). Statistically substantial evidence supported the outcomes. MEPG had an impact on the levels of bilirubin, ALP, ALT and AST (Fig- 4 & 5). The animals given this extract experienced a significant and satisfactory reduction in the research parameters. However, paracetamol-administered mice showed a very significant decrease in liver parameters. The results were given as Mean \pm SEM (n = 6). ANOVA was used for statistical analysis, followed by Dunnett's test. The findings were presented as when compared to control (* = p < 0.0001, ** = p < 0.05), disease control (^A = p < 0.0001), standard (^a = p < 0.0001, ^b = 0.0005, ^c = p < 0.05).

Carbon Tetrachloride Induced Hepatotoxicity

CCl₄, a well-known liver-damaging substance, is frequently used to assess how well drugs generally shield the liver from harm by avoiding liver damage. Acute viral hepatitis and CCl₄-induced liver injury cause similar changes. Following liver metabolism, the conjugates of glucuronide and sulphur can be eliminated [32]. Disruption of the transportation function of hepatocytes results in hepatic injury, causing the leakage of cellular enzymes into the plasma [33]. Damage to the liver's cell plasma results in the release of enzymes from the cytosol into the blood, thereby increasing the enzyme count in the serum. The measurement of serum enzyme levels is a useful quantitative indicator of severity [34]. The treatment groups of MEPG at 200 and 400 mg/kg, bd.wt. (Table-6) exhibited a slight reduction in the serum levels of ALT, AST, bilirubin, and ALP (Fig- 6 & 7). The statistical significance of these reductions was discovered. The parameters were compared between the groups treated with silymarin and CCl₄. The results are given as Mean \pm SEM (n = 6). ANOVA was used for statistical analysis, followed by Dunnett's test. The findings were presented as when compared to control (* = p < 0.0001, ** = p < 0.05), disease control (^A = p < 0.0001), standard (^a = p < 0.0001, ^b = 0.0005, ^c = p < 0.005, ^d = p < 0.001).

Histopathological Studies

The histopathological assessment of the livers in the control, disease control and treatment groups of rats as shown in Fig-8.

- A) **Normal Control:** Hepatic cells with portal, periportal, and centrilobular regions exhibited normal morphology in the liver.

**Ganga Raju et al.,**

- B) **Diseased control:** The liver's periportal and centrilobular regions showed multiple focal, tiny foci of hepatocyte necrosis, accompanied by an infiltration of inflammatory cells.
- C) **MEPG (200 mg/kg):** The shape of the area around the port was normal, but the shape of the area in the middle of the lobe had many dead liver cells and lymphocytes moving in.
- D) **MEPG (400 mg/kg):** There was little sinusoidal dilatation between the hepatocytes, but the portal and centrilobular regions showed a normal hepatocyte appearance.
- E) **Silymarin (50 mg/kg):** There was modest sinusoidal dilatation and haemorrhage, but the hepatocytes in the periportal and centrilobular regions looked usual.

DISCUSSION

Chemically driven liver damage, or hepatotoxicity, can result from drug exposure or a spike in free radical levels. Two approaches were used to evaluate hepatoprotective activity: paracetamol-induced hepatotoxicity and CCl₄ inhibition. Overdosing on paracetamol or taking too much of the medicine poses health risks. Paracetamol and its metabolites, NAPQI, are not the primary agents responsible for hepatotoxicity, often known as drug-induced liver injury. NAPQI causes liver failure by destroying liver cells immediately and by lowering the liver's intrinsic antioxidant glutathione. Hepatic toxicity is indicated by a rise in biochemical markers such as overall bilirubin, AST, ALT, and ALP [35]. The groups administered 200 mg/kg bd., wt. of MEPG or 400 mg/kg bd., wt. of MEPG exhibited slight reductions in all measured parameters, including bilirubin, AST, ALT, and ALP. The results showed statistical significance. Meloxicam changed bilirubin, AST, ALT, and ALP levels. After receiving this extract, the animals exhibited a significant and positive improvement in the studied parameters. However, paracetamol caused a dramatic reduction in liver parameter values in mice [36]. The general efficacy of drugs in avoiding liver damage has been measured using the widely known hepatotoxic toxin CCl₄. Similar to the changes caused by acute viral hepatitis, CCl₄-induced liver injury compromises liver function. Following liver metabolism, glucuronide and sulphur conjugates are excretable [37]. The primary indication of liver injury is the release of cellular enzymes into the plasma due to interference with the transport function of hepatocytes [38]. The breakdown of the liver's cellular plasma releases a plethora of enzymes normally found in the cytosol, elevating the serum enzyme concentration. As a quantitative measure of severity, the serum enzyme estimates work well [38]. Serum AST, bilirubin, ALP, and ALT levels in the MEPG treatment groups at 200 and 400 mg/kg, bd.wt., were slightly lower than those in the control groups. A statistical analysis confirmed their significance. We compared the parameters with two groups: one treated with silymarin and another with CCl₄. Liver histology studies in rats administered 200 mg/kg bd.wt. of MEPG revealed some hepatocyte regeneration in the periportal area along with lymphocyte infiltration, but rats administered 400 mg/kg bd.wt. of MEPG exhibited substantial hepatocyte regeneration along with mild sinusoidal dilatation. The GCMS results identified sterols, fatty acids, phenols, flavonoids, vitamins, terpenoids, and linoleic acid, an n-6 polyunsaturated fatty acid. Among saturated fatty acids, palmitic acid is by far the most common, while linolenic acid is an essential omega-3. Linoleic, linolenic, and palmitic acids all help lower oxidative stress and raise serum parameters in liver toxicity caused by drugs. They are also biomarkers of liver damage [39].

The omega-9 fatty acid category includes oleic acid. This fatty acid reduces oxidative stress in rats' liver and spleen by lowering antioxidant levels observed under hepatotoxic conditions [40]. Saturated fatty acids, like stearic acid, have an 18-carbon chain. It is a pentacyclic triterpene that protects the liver by lowering oxidative stress and inflammation-causing substances. It is a pentacyclic triterpene that protects the liver by lowering oxidative stress and inflammation-causing substances [41]. Other types of vitamin E, such as γ -tocopherol and γ -tocotrienol, are better antioxidants than α -tocopherol at protecting against long-term health problems like liver damage caused by drugs. Insufficient solubility in the intestinal fluid may limit the intestinal absorption through the portal vein system to obtain a therapeutic effect when systemic effects are warranted. For oral administration, solubility is a major property influencing absorption. Similarly, a drug meant for parenteral usage has to be highly soluble in water to deliver a sufficient quantity of the active ingredient. The water solubility is critical for the absorption and distribution of drugs within the body, and it ranged from -7.068 to -1.377, and all the readings were within the recommended range, which

**Ganga Raju et al.,**

showed the possible good absorption and distribution of MEPG phytochemicals. One important element that determines how effective medications are is their permeability across the blood-brain barrier. It was hypothesised that MEPG phytochemicals had outstanding permeability across the central nervous system. In addition, as these substances are involved in the excretion of drugs, the most frequent isoforms of cytochrome were tested against them. These isoforms inhibit drug interactions. Tocopherol was the only compound that inhibited CYP2C19, while linoleic acid, oleic acid, linolenic acid, arachidonic acid, stearic acid, palmitic acid, lupeol, vanillic acid, campesterol, sitosterol, ergosterol, and indomethacin inhibited the CYP3A4 substrate. In order to determine steady-state concentrations, it is essential to calculate the drug clearance of a chemical. Oleic acid, stearic acid, palmitic acid, arachidonic acid, linolenic acid, and linoleic acid all have sufficient clearance values. Organic Cation Transporter 2 (OCT2) did not recognise any of the substances as substrates. Before a medicine is considered for clinical trials or even in the pre-formulation phase, it must undergo drug toxicity profiling. As a result, the compounds' toxicity has been evaluated. Campesterol, sitosterol, oleic acid, stearic acid, palmitic acid, lupeol, vanillic acid, ferulic acid, tocopherol, indomethacin, and campesterol have all shown hepatoprotective effects.

CONCLUSION

Methanolic extract of *P. glaucum* demonstrated hepatoprotective properties against liver damage induced by PCM and CCl₄ in this investigation. The greater percentage of components like flavonoids and total phenols in the methanolic extract scavenge free radicals, which may explain its hepatoprotective properties. In order to find a new hepatoprotective drug that works well, more research needs to be done to find the pure active principle or principles that protect the liver.

ABSTRACT

In this study, bacteria and fungi were isolated and identified from partially degraded LDPE samples, with notable findings including the presence of *Pseudomonas aeruginosa*, *Bacillus* sp., *Aspergillus niger*, *Trichoderma* sp., and *Beauveria bassiana*. These microorganisms were selectively cultured and inoculated in Minimal Salt medium containing LDPE films, leading to a substantial weight loss of 22.17% over a 60-day period under aerobic conditions. *Pseudomonas aeruginosa* exhibited superior degradation capabilities compared to other isolates. Biofilm formation was observed, with significant protein synthesis detected, particularly by *Aspergillus niger*. The observed protein concentrations correlated with the degree of LDPE weight loss. Structural changes in LDPE were confirmed through SEM and FT-IR analysis, highlighting the presence of aliphatic compounds and other chemical alterations indicative of biodegradation. SEM analysis revealed biofilm colonization, cracks, holes, and surface modifications on LDPE films. Overall, this research underscores the potential of microbial biodegradation as an effective and eco-friendly approach for managing plastic waste.

Keywords: Biodegradation, biofilm formation, LDPE, FTIR and SEM analysis.

Manigandan et al.,

INTRODUCTION

Plastic pollution has emerged as a critical environmental concern worldwide, with significant attention focused on the accumulation of plastic debris in every ecosystem [1,2]. Among the various types of plastic polymers, Low-Density Polyethylene (LDPE) represents a major contributor to plastic waste due to its widespread use in packaging and consumer goods[3]. The persistence of LDPE in the environment poses a significant challenge, highlighting the urgent need for effective biodegradation strategies. Traditional methods of plastic disposal include land filling, incineration, and thermal degradation[4,5,6]. Microbial degradation of plastic wastes is an interesting and important strategy to reduce these synthetic polymers without accumulation of toxicity. In recent years, the concept of the "plastisphere" has garnered attention, referring to microbial communities that colonize the surface of plastic debris [7]. Understanding the dynamics of plastisphere microorganisms and their potential to degrade LDPE offers promising avenues for addressing plastic pollution. Bioremediation and biodegradation[8] represent eco-friendly approaches to managing plastic waste, providing safe disposal methods. Researchers have documented the degradation of LDPE by fungi, bacteria, microalgae[9], and other microorganisms. These microbes grow and produce extracellular enzymes that degrade plastics, releasing oligomers and monomers. Fungi, constituting nearly 3% of the plastisphere, play a crucial role in plastic degradation[10]. Various studies have identified plastic-degrading fungi such as *Aspergillus* spp., *Fusarium* spp., and *Penicillium* spp. from the plastisphere [11,12,13]. In this study we aimed to isolate and characterize the microbial colonies that are involved in the biodegradation of LDPE plastic wasted from the plastisphere soil of Tirupattur region, Tamilnadu, India.

MATERIALS AND METHODS

Collection and Isolation of Microorganism

Plastic debris were collected from the waste dump yard sites around Tirupattur district, Tamilnadu, India using sterile techniques to prevent contamination and rinsed using distilled water to remove loosely attached particles and debris. Mineral Salt Medium (MSM) was prepared and the collected samples were inoculated into the MSM.

Preparation of Minimal salt medium

By employing LDPE as the only source of carbon in the growth media, fungi and bacteria that decompose LDPE were cultivated in MSM containing 0.5 g K_2HPO_4 , 0.04 g KH_2PO_4 , 0.002 g $CaCl_2 \cdot 2H_2O$, 0.2 g $(NH_4)_2SO_4$, 0.1 g NaCl, 0.02 g $MgSO_4 \cdot 7H_2O$, 0.001 g $FeSO_4$, and 0.01 g $MnSO_4$. The recovered deteriorated plastics were cultured with the fungus that was taken from the dump yard in a minimum salt media. For the first five days, these culture flasks were incubated at 30 °C with rotation at 160 rpm. The resulting turbid growth and mycelia were purified using Whatman's No. 1 filter paper, then placed on Nutrient agar and SDA plates for analysis of the cultural traits respectively. Subsequently, LB agar plates were prepared and inoculated with the incubated cultures to identify the dominant microbial strain involved in the degradation process [14].

Plate Morphology and Microscopic Identification of fungi

Plate morphology was conducted to determine the fungi on the basis of their color and edges. For microscopic identification, one drop of Lactophenol Blue solution was added to the slide. Fungal culture was emulsified on it. Then, the slide was fixed with a cover slip. The slide was observed under a microscope and fungal isolates were identified on the basis of their hyphae and spores

Evaluation of the LDPE plastic degradation

A second batch of minimal salt medium, enriched with fresh 2 × 2 cm LDPE films, was added to the MSM. Incubation was then maintained for 45 days at regular intervals for biofilm formation analysis. The oxidised LDPE films were collected and treated with sodium dodecyl sulphate (SDS) 2% v/v for 4 hours after 45 days of incubation. SDS was then removed from the LDPE films by washing them in double-distilled water. The pellets were dried in an oven at

**Manigandan et al.,**

60°C for the entire night to eliminate the adsorbed moisture. A weighing balance with an accuracy of 0.02 mg was used to measure the resulting oxidised LDPE.

Analysis of the physical and chemical parameters of LDPE

The biodegradation of polyethylene (LDPE) was evaluated by surface cracking, weight loss, biofilm formation, decolourisation, chemical alteration and microscopy techniques.

Estimation of proteins on the LDPE samples

The total protein content after incubation was spectrophotometrically estimated by Bradford's method [15]. At 20-day intervals, the PE films were purposely removed from the culture media and gently washed with water to remove any medium debris or loosely adhering cells. The bacterial biomass extracted from the PE film was treated to mild water bath sonication in 1 ml of 0.85% saline for 4 minutes [16]. The resulting saline solution was used to measure protein content at 595 nm using spectrophotometers.

Scanning electron microscopy

LDPE films treated with isolated culture for 60 days were withdrawn from the medium and examined using Field-emission Scanning Electron Microscopy (FE-SEM) to detect biofilm development and surface degradation. The microbial morphology of biofilm on the PE surface was studied after washing the films in 0.01 M phosphate buffer for 2 minutes to remove excess medium adherent to bacterial colonies. To evaluate surface changes, the PE films were washed with 2% SDS and warm distilled water for 10-20 minutes to eliminate bacterial biomass. The polyethylene films were then fixed in 4% glutaraldehyde for 2 hours at 4°C before being dehydrated with 50% ethanol for 30 minutes. The PE films were then incubated overnight in 70% ethanol at room temperature, dried, mounted, and sputter-coated with gold for 40 seconds before being scanned with a SEM.

FTIR analysis of LDPE films

The changes in the treated LDPE was analysed using a PerkinElmer spectrum two FTIR spectrometer. Single or Dual Detector, typically using a deuterated triglycine sulfate (DTGS) detector. The KBR pellets were scanned from the mid-infrared (MIR) range of approximately 4000 cm⁻¹ to 400 cm⁻¹. The degree of biodegradation was determined by analysing the carbonyl index (CI) for specific bonds such as the vinyl bond (VI), ester bond (ECI), internal double bond (IDI) and keto carbonyl bond (KCI).

RESULT AND DISCUSSION**Isolation and identification of Bacteria and fungi**

Following incubation in minimum media and examination under a scanning electron microscope, a large mass of fungal hyphae was found on the surface of the polyethylene film. From the collected partially degraded LDPE samples, a total of 27 bacterial isolates were found and subjected to other parameters including colony morphology, microscopic examination, biochemical character analysis, a total of 5 bacterial samples were found to be promising isolates. The biochemical characters showed the presence of *Pseudomonas aeruginosa* and *Bacillus* sp., from the partially degraded LDPE samples. Among fungi 3 different isolates were found *Aspergillus niger*, *Trichoderma* sp and *Beauveria bassiana*.

Monitoring the LDPE biodegradation

Selectively isolated plastisphere microbes were inoculated in the Minimal Salt medium containing 1% (w/v) LDPE films of 2cmx2cm for 60 days under aerobic condition. During the 60-day incubation period, LDPE experienced a weight loss of 22.17%, with a notable decrease in dry weight particularly in the initial phase (Fig. 1). In contrast, the negative control, lacking inoculation, showed a weight loss of PE microplastic of less than 5%. The variance in weight loss is likely attributed to microbial activity and the partial dissolution of LDPE particles. More predominantly the *Pseudomonas aeruginosa* degraded more of the enriched LDPE film compared to other bacterial and fungal isolates.

**Manigandan et al.,**

Comparatively all these identified bacterial and fungal strains are found to degrade the all the types of polyethylene materials [17] polyester polyurethane [18] and poly lactic acid [19]. A strong bond by the isolates over the LDPE showed the formation of biofilms with a maximum of 25µg/L concentration by *Pseudomonas aeruginosa* TPT 2 sample (Fig 2.). Among the fungal isolates *Aspergillus niger* synthesised maximum protein with 20 µg/L concentration which is higher compared to other fungal isolates. The overall results of the protein concentration of all the tested isolates followed a pattern similar to the average weight loss of LDPE after the 60 days of incubation. Sathiyabama *et al.* [20] studied the protein concentration in the LDPE biofilm formed by *Cladosporium sphaerospermum* isolated from plastisphere region showed 20.67 ± 0.29 µg/ml of protein. In majority of the research reports the fungi are known to produce the hydrophobic proteins that binds strongly to the LDPE surface [21] and generation of degrading enzymes using their hyphae to extend and penetrate all over the LDPE polymer [22]. Both bacterial and fungal strains were found to be effective in colonizing the LDPE surface. This helped explain the sustained biodegradation of polyethylene through weight loss. Additionally, the degradation was confirmed through SEM and FT-IR analysis.

The FTIR spectrum of the tested LDPE plastic showed significant differences compared to the control LDPE sample (Fig 3.). FTIR analysis can identify changes in the structural and functional groups, potentially elucidating the reasons for weight loss observed in the LDPE film. This technique allows for the detection of alterations in chemical composition that may be associated with the degradation or modification of the LDPE material. The peaks at 2922 cm^{-1} and 2854 cm^{-1} indicated C-H stretches are asymmetric and symmetric stretches respectively of aliphatic hydrocarbons, suggesting the presence of a large quantity of aliphatic compounds. Peaks at 3419 cm^{-1} and 2854 cm^{-1} indicated O-H and C-H bonds in alcohols, phenols, and alkanes that correlates to CH₂ symmetric deformation. Peaks at 732 cm^{-1} and 720 cm^{-1} corresponds to CH₂ rocking deformation. The shifts in peak positions, decrease in peak intensity, and appearance of new peaks suggest that biodegradation have occurred. Similar results have been observed in many results with same peaks and stretches of deformation in the treated LDPE films [23,24,20]. Scanning electron microscopy was also used to investigate the plastics after mechanically detaching the biofilms (Fig 4.). SEM results showed the formation of cracks and holes in oxo-biodegradable plastics. The maximum growth observed in the *Pseudomonas aeruginosa* TPT 3 cultivated LDPE film and that was analysed. In the SEM analysis of cracks, damaged layers, fragile Ness, depth pits and coarsening of the surface and grooves were significantly noted in the treated sample, whereas the surface of the control or the untreated LDPE was mostly smooth. Puglisi *et al.* [25] documented a complex biofilm colonization of various PE plastics, observing cell morphologies, gel matrixes, and hyphal-like structures. Subsequently, following cell detachment, different polymers showed partial degradation with cavities and holes. These biofilms on PE aligned with SEM analyses that had been previously conducted on plastic waste from aquatic environments.

CONCLUSION

The analysis of LDPE biodegradation by microorganisms isolated from plastisphere soil underscores the potential of these microbial strains in degrading polyethylene plastics. Overall, this study highlights the importance of microbial-mediated biodegradation as a sustainable and eco-friendly approach to addressing plastic pollution, offering valuable insights into the mechanisms and potential applications of microorganisms in plastic waste management. Future research in this area can further advance our understanding of microbial degradation processes and contribute to the development of effective bioremediation strategies for plastic waste disposal.

ACKNOWLEDGEMENT

ABSTRACT

Microalgae represent a promising and sustainable resource to produce bio-based products due to their ability to grow in various environments and their capacity to produce a wide range of valuable compounds. Among these compounds, oils extracted from microalgae have garnered significant attention for their potential applications in biofuel production, pharmaceuticals, and nutraceuticals. Potential applications of microalgae-derived oils are vast, ranging from biofuels to high-value omega-3 fatty acids. Additionally, microalgae oils are rich in essential fatty acids, antioxidants, and other bioactive compounds, making them attractive for use in dietary supplements and functional foods. Despite the potential benefits, several challenges remain in the commercialization of microalgae-derived oils. These include the need for cost-effective cultivation and extraction technologies, the development of strains with enhanced oil productivity, and the establishment of sustainable supply chains. Addressing these challenges through continued research and innovation will be crucial for realizing the full potential of microalgae as a source of renewable oils for various applications.

Keywords: Microalgae Antioxidants, Lipids, fatty acids

Divya Ragunathan et al.,

INTRODUCTION

Microalgae are simple unicellular or multicellular organisms which usually thrive in freshwater or marine environments. Their wide range applications and research areas include environmental management, biotechnology, biofuels, food production along with their significant role in our ecosystem which today is of a major concern. Microalgae are defined to be a widespread group of species, each with its own characteristics, yet has several things in common. Cell sizes for microalgae typically range from a few micrometres to a few hundred micrometres. Microalgae, like plants, are photosynthetic organisms that use light to turn carbon dioxide and water into organic compounds, primarily glucose. In this process, oxygen is released into the environment. Microalgae possess wide range of pigments, including chlorophyll, which gives them their green colour, as well as various other pigments including red, brown, blue, and yellow. Unsaturated fatty acids are abundant in the lipid fraction of many microalgal species, they add significant nutritional value and contains anti-inflammatory and antioxidant effects. In addition to lipids and pigments, various microalgal biomolecules including phenolics are also under research. Studies are now going on in flavonoids, sterols, and tocopherols and have increased recently due to their anti-inflammatory, antibacterial, and antioxidant properties[12]. High amounts of useful lipids are produced by *Nannochloropsis gaditana*, according to reports. It has a significant number of triglycerides and polar lipids, including phospholipids and glycolipids. Microalgae can accumulate substantial quantities of EPA, and polar lipids are crucial structural and functional elements of the cell membrane. [66] Microalgae could produce equivalent amounts of oil on a smaller scale than other crops, and their predominant fatty acid composition is that of C16 and C18 fatty acids, which make up most vegetable oils[34]. Some species are also abundant in beneficial omega-3 along with polyunsaturated fatty acids (PUFA) comprised with cardiovascular advantages and antioxidant activities.

In addition, they also contain various therapeutic components like sterols and pigments. Consequently, algal oil is viewed as a type of useful oil that has excellent commercial potential. Meanwhile, microalgae can experience certain circumstances due to which it produces a lot of protein, carbs, and other nutrients. Consequently, the algal cooking oil and other co-products could be made from biomass, adding value in the production of oil [34]. Subcritical organic solvent extraction is technology that is simpler to use and far less expensive to produce than conventional organic solvent extraction technology[11]. According to [48] Lipid extraction, conversion, harvesting, and culture are the four main processes involved in the production of biodiesel from microalgae. As a source of third-generation biofuel, microalgae are very favourable since they grow quickly, requires minimal area for cultivation, has shorter generation time, do not require pesticides, and contains high fat content, [62]. Based on Nile red fluorescence microscopy screening, eight outstanding lipid-producing strains were chosen for additional investigation. The taxa *Chlorella* sp., *Neochloris* sp., and *Chlamydomonas* sp. were recognised in the microalgal isolates through sequencing of the 18S rRNA gene is a morpho-taxonomic and molecular method. In terms of specific growth rate and doubling time, *Chlorella vulgaris* PH2 exhibited the highest (μ) and shortest (μ) values with 0.24 and 2.89 0.05 days, respectively [62]. The microalgal oils contained saturated fatty acids (SFAs), polyunsaturated fatty acids (PUFAs), and monounsaturated fatty acids (MUFAs) as their fatty acids. Palmitic acid constituted the major SFA. Oleic acid, linoleic, and linolenic acids were the main components of MUFAs and PUFAs respectively.

The important fatty acid -linolenic acid (ALA), which is found in some strains, was particularly abundant and was greater than 20% of the fatty acids in some strains. [13] Lipids found in microalgae are useful in the production of biodiesel. Under a fluorescence microscope, Nile red staining can be used to find intracellular neutral lipids. In addition to lipid productivity, the fatty acid content plays a significant role in selecting the best microalgal strains for the manufacture of biodiesel [64]. Microalgae have been seen to store significant quantities of neutral lipids and carbohydrates that can be used to make biofuels when under stress. The biochemical composition of a microalgae cannot be measured on-line since it is a very challenging task [2]. Microalgae are responsible for 40% of the world's carbon emission and is estimated to hold up to 70% of dry weight in its oil. Thus, it is useful to make biofuels in turn which could help in reducing greenhouse gas emissions. Except for some microalgae which can withstand harsh environmental conditions

Divya Ragnathan et al.,

like high pH example (*Spirulina* sp.) and high salinity (*Dunaliella* sp.) or which grows very quickly like (*Chlorella*, sp.) in open tanks. Closed photobioreactor systems are best suited for some microalgae which can have rapid microbial contamination[9]. Using techniques including mechanical pressing, solvent extraction, and supercritical fluid extraction, oil is recovered from the dried algae. While fatty acid extraction is aided using solvents including n-hexane, benzene, ethanol, chloroform, and diethyl ether, mechanical pressing recovers about 75% of the oil from the harvest. Roughly 95% of the oil may be obtained with the help of n-hexane compound[10]. Microalgae-derived fuels have recently been termed photosynthetic biofuels or algal biofuels to distinguish them from plant oils or cellulose-derived fuels. [66] PUFAs are essential nutrients that must be obtained from outside sources since the organism cannot make them. PUFAs are well-known to include 3 fatty acids. Fish oil is the most renowned and popular source of PUFAs. Fish, on the other hand, does not create PUFAs but rather amass them by means of eating algae (or various algae-eating creatures). It is algae that provide these essential nutrients. Since its establishment in the previous 10 years, PUFA manufacturing from algae has offered benefits including reduced risk of chemical contamination, better purifying potential, and the absence of fish odour[13]. It is widely acknowledged that polyunsaturated fatty acids (PUFAs) are critical for regulation of membrane fluidity, electron and oxygen transport, heat adaptation capacity, and cellular and tissue metabolism. They also prevent obesity and cardiovascular diseases. [13] Microalgae biofuel is non-toxic and extremely biodegradable; it contains no sulphur, and the materials left behind after collecting the oil can be utilised to make ethanol or as soil fertiliser.

Two conversion procedures are used to valorize biodiesel, a liquid fuel made from algal lipids, are undergone transesterification and thermochemical conversion. and thermochemical conversion. The biomass from algae biodiesel can be utilised to absorb damaging greenhouse gases from the atmosphere, and as a fuel that is carbon neutral, it can substantially replace traditional petrol.[18]The fascinating process known as microalgal biofilms encourages microbial cell attachment in an exopolysaccharide matrix with water, producing excess biomass that can be cheaply and readily separated and are utilised to produce a wide range of biofuels or medicines. These biofilm microalgal communities are also very good in eliminating radioactive elements and heavy metals through surface adsorption, intracellular absorption, or precipitates of phosphates or sulphides. A variety of metal ions, including Cd, Pb, Hg, As, Cr, Fe, and others, have been found to adsorb on their surface or intracellularly[19] The biological activity of PUFAs found in microalgae was extensively studied and has a good influence on animal health. Also, microalgal products were tested as feed for animals and fisheries in various forms. *Spirulina*, *Chlorella*, *Lobosphaerainci sa*, *Isochrysis* sp., *Schizochytrium* sp., *Phaeodactylum* sp, *Nannochloropsis* sp, and other microalgae are widely administered.[20]Conversion of raw biomass using trans-esterification is another viable alternative to traditional solvent extraction. The method is based on promoting cell lysis, which liberates intracellular components of microalgae. This process is accomplished by processing the biomass *in situ* using enzymes (cellulase) and acid or basic hydrolysis. The main constituents of microalgal bio-oil are aliphatic (alkanes), fatty acids, phenolics, aromatics, N-containing compounds (such as pyrroles, nitriles, and amides), alcohols, sugars, furans, and acetic acid. This contrasts with lignocellulosic biomass-derived bio-oil. [51]

Microalgal Metabolites

Microalgal proteins have drawn a lot of focus in recent trends. The biomass contains 40-60% of proteins that have major properties that make them suitable food and feed alternatives. Microalgae have received more attention than macroalgae due to its high dietary value, protein and amino acid profile. Microalgal species with high protein content of 50% or higher, such as *Aphanizomenon* sp., *Chlorella* sp., *Dunaliella* sp., and *Arthrospira* sp., are used for human consumption. Marine algal polysaccharides (MAP) offer enormous industrial and new product potential. They are employed in the global market as nutraceuticals, cosmetics, medicines, drug delivery systems, fertilisers, and aqua feeds. The expense and productivity of the enzymatic valorisation process, on the other hand, can be boosted by using technologically useful platforms like combined biomass processing, biorefining, and so on.[18]Super foods from algae are reported to have anti-cancer and anticoagulant activities apart from its role as a buffer in the human body. Algae are a reserve of secondary metabolites that are produced in the log phase. Both freshwater and marine algae produce substantial amounts of secondary metabolites, such as carotenoids, polyphenols, and sterols. [18] The nutritional importance of algal components is significant enough to substitute

**Divya Ragunathan et al.,**

animal-based Aquaculture's sources of lipids and proteins. The secondary pigment known as algal carotenoid has medicinal properties. Among the several classes of carotenoid compounds, β -carotene and astaxanthin contain immense potential as anti-tumour, anti-inflammatory medicines, and treats for metabolic diseases, gastric ulcers, and so on. Omega-3 Fatty acids are recovered from C20:5 ω 3 and C22:6 ω 3 which are polyunsaturated fatty acids. They can be produce food, nutritional fodders, and medications. Omega-3 has been linked to variety health benefits, including the prevention of cardiovascular diseases, cancer, and high blood pressure. Furthermore, omega-3 containing FAs have been shown to help control depression and stimulate animal growth. It has been revealed that human consumption of omega-3 fatty acids is lower than what is advised. As a result, the utilization of microalgal lipids for fatty acid enriched diets and production of nutraceutical supplements is of great interest.

Photobioreactor

The photobioreactor (PBR) is a unique kind of high-tech microalgae culturing reactor used for cultivating microalgae in a range of environments with the help of compatible microalgae strains by utilising light intensity. Solar, artificial (using a fluorescent lamp or another form of light source), or a system that combines both types of light sources, could all be used as the source of light.

***Nannochloropsis* sp.**

Nannochloropsis sp. has received a lot of attention because of its potential applications in wide range of industries, such as biofuel production, aquaculture, and bioremediation. One of the main points of interest is its oil composition, notably its high lipid content. *Nannochloropsis* sp. is recognised for having a high lipid (oil) content that can range between 20% and 50% of its dry weight. Because, the oil collected from *Nannochloropsis* sp. may be turned into biodiesel using techniques such as trans-esterification, it is a prospective candidate for biofuel production. The fatty acid composition of *Nannochloropsis* sp. oil is also noteworthy. Depending on the external conditions, the chemical makeup varies, but the formula usually includes of a blend of Unsaturated fatty acids (UFAs) and saturated fatty acids (SFAs) Because UFAs have better cold flow properties than SFAs, they are recommended for biodiesel synthesis. Examples of these are omega-nine and omega-six fatty acids. Omega-3 Fatty Acids was widely acknowledged that *Nannochloropsis* sp. contains EPA and DHA, two types of omega-3 fatty acids. These are widely used as food supplements because of their curative properties.

Cultivation and Oil Accumulation

Open ponds, closed photobioreactors, and raceway ponds are some of the practises used for growing *Nannochloropsis* sp. The growth conditions, which include light intensity, temperature, CO₂ concentration, and the availability of nutrients (nitrogen and phosphorus), all have a significant impact on the hydrocarbon and triglyceride composition of the microalgae. After culture, the microalgae biomass must be collected and the oil is extracted. To separate the oil from the biomass, various processes such as mechanical pressing, solvent extraction, and supercritical fluid extraction can be used. *Nannochloropsis* has potential applications in aquaculture as a feed additive, the cosmetics industry for producing skin-care products, and bioremediation to remove pollutants from water, in addition to biofuel generation.

Wider Prospectives

Nannochloropsis sp. is a helpful model organism for research and instruction in a various domains, including biology, ecology, biotechnology, and environmental science. Because of its bioactive components, *Nannochloropsis* sp. extracts may have medicinal applications, including as the Development of drugs and treatments. *Nannochloropsis* sp. extracts are used in the cosmetics and skincare industries for their possible antioxidant and anti-ageing qualities. They may aid to protect the skin from free radicals and UV radiation damage. *Nannochloropsis* sp. has the potential to absorb and collect heavy metals and other contaminants from water, soil, and wastewater. This makes it useful for bioremediation process, as it aids in the removal of toxins and pollutants from various habitats.

Divya Ragunathan *et al.*,**Pharmaceuticals and other Bioactive Algal Products**

Algae supply is used in medications, immunizations, and nutrient enriching supplements that would otherwise be not in use or overpriced to generate using plant and animal sources. Most of the algae discussed in this section are highly advanced or useful in nature. For example, the most important chemical in *Chlorella* sp. from a medicinal standpoint is callose, which is a powerful immunostimulatory, oxygen-based Radical, and aid in the reduction of blood cholesterol. This chemical has been proven to be effective against ulcers, wounds, constipation, as well as prevents atherosclerosis. It reduces hypercholesterolemia and exhibits anticancer properties. Microalgae are a reserve of all necessary vitamins (for example, vitamin A, vitamin B1, vitamin B2, vitamin B6, vitamin B12, vitamin C, vitamin E, niacin, vitamin H, dihydrofolate, and vitamin B5). In addition, microalgae sulphated polysaccharides can also be used in therapy against bacterial infections in both homeotherms and poikilotherms.

Antimicrobial Properties of Microalgae lipids

Antimicrobial properties of microalgae are determined using AWDA that is Agar well diffusion assay. Antibacterial studies showed that ethyl acetate and methanolic extracts contain antibacterial effects on both gram-positive and gram-negative bacteria. Minimum inhibitory concentration (MIC) and Minimum bactericidal concentration (MBC) are also evaluated against bacterial strains. Methanolic extracts of 8 variants of seaweeds were concluded to be highly effective compared to ethyl acetate extracts. The methanolic extracts showed best results against both gram-positive and gram-Negative bacteria.[38] The extraction method and the types of solvents used accounts for the antimicrobial activity.

Anticancer Activity of Microalgal lipids

The human melanocyte A2058 cancer cell line was used to test the anticancer properties of microalgal oil. In micro titer plates with 96 wells, the cells were grown. The results indicated that a considerable survival rate was produced by *S. marinoi* (FE60/2), *A. minutum* (FE126/1), *A. tamutum* (FE107/1 and FE107/3) and *A. andersoni* (FE108/1). The *S. marinoi* clones FE6 and FE60 were also subjected to the anticancer assay; these strains are known to generate hydroxides, oxoacids, hydrogen peroxide, and other components through the breakdown of saturated fatty acids, including polyunsaturated aldehydes. Polyunsaturated aldehyde from FE6 is said to exhibit antiproliferative property on colon carcinoma cells. Additionally, F3E6 did not show any effect on human melanocytes (A2058). According to this assay, anticancer activity of microalgal lipids seems to be cell line-specific. [33]

Anti-Inflammatory Activity of Microalgal Lipids

Microalgal anti-inflammatory potential was evaluated using human acute monocytic leukaemia cell line (THP-1) and ELISA, by observing the release of tumour necrosis factor α (TNF α). Additionally, they noticed that three diatoms, FE2/1, FE326/1, and FE1098_1/1, were only active when cultivated in regular media and inactive when grown in nutrient-deficient conditions. This points out that during adverse conditions, like nutritional scarcity, these species will not generate peptides or chemicals responsible for these actions, or they may produce this at minimal levels. Among which, *C. Closterium* has previously been confirmed that it has anti-inflammatory and antioxidant activities (determined exclusively by enzymatic assay, without utilising cells). [33]

Cytotoxic Activity of Microalgal Lipids

The cytotoxicity was tested after 24 and 72 hours of exposure using human hepatocellular liver cancer (HepG2, ATCC HB-8065TM) and normal human lung fibroblast (MRC-5, ATCC CCL-171TM) cells, respectively. Hepatocytes are great models for studying toxicity because they are the primary location of drug metabolism and biotransformation, which occurs in the liver. To compare normal and cancer cells (A2058) utilised for the anticancer assay, they also incorporated a toxicity test on normal lung fibroblast (MRC-5) cells. The MRC-5 cytotoxicity test was assessed following a 72-hour incubation period for extracts. *O. ovata* extracts (FE119/1, FE119/2, and FE119/3, respectively; Control, Negative, and Positive-starved extracts) likewise caused harm to MRC-5 cells.

Divya Ragunathan et al.,

Antioxidant Activity of Microalgal Lipids (CLPAA and CAA)

The extracts were assessed for their overall antioxidant activity and their ability to reduce lipid peroxidation using two antioxidant cellular-based assays, CAA and CLPAA. Antioxidant properties were demonstrated in both tests by growing *O. ovata* in Control, negative and positive-starved media (FE119/1, FE119/2, and FE119/3, respectively). In the CAA assay, FE119/1 showed 66% inhibition of oxidative degeneration and 74% inhibition in the CLPAA assay; in the CAA and CLPAA assays, FE119/2 showed 70% inhibition and 61% inhibition, respectively; in both assays, FE119/3 indicated 69% inhibition. [33]

Antibiofilm activity of Microalgal Lipids

The biofilm-forming bacterium *S. epidermidis* was cultured with extracts at a concentration of 50 g per millilitre in 96 well plates with transparent bottoms for an entire night at 37 °C. The culture mix was supplemented with a concentration of 1 percent glucose to promote the growth of biofilms. It has been discovered that microalgae have anti-biofilm activity, which is an activity directed against the biofilm-forming bacteria *S. epidermidis*. Of the 32 species tested, the two species *L. danicus*(FE322) and *L. aporus* (FE332), which belong to the same microalgal genus, exhibited significant anti-biofilm activity. The development of biofilms, multicellular aggregations with inherent antibiotic resistance, and specific antibiotic resistance genes complicate treatment. Microalgae have been found to have anti-biofilm activity against these bacteria, opening new therapeutic options for *S. epidermidis* infections. Metabolic flexibility has a beneficial impact on developing drugs via the biological activity possibly leading to the discovery of novel compounds that are bioactive for the treatment of human illnesses. [33]

Anti-Diabetic Assay of Microalgal Lipids

Three sets of the experiment were carried out using recombinant human PTP1B and the fluorogenic substrate 6, 8-difluoro-4-methylumbelliferyl phosphate. A type 2 diabetes-related enzyme is called protein tyrosine phosphatase, or PTP1B. To stop insulin from functioning as it should, PTP1B dephosphorylates the insulin receptor and its substrates. Testing for PTP1B activity inhibition using microalgae revealed no appreciable bioactivity. [33]

CONCLUSION

The presence of antioxidants in microalgal lipids is essential for shielding the lipids from oxidative damage, or else result in lipid peroxidation and the production of toxic chemicals. Antioxidants are necessary to keep microalgal lipid-based products stable, exceptional, and long-lasting. Microalgae potentially possess these antioxidants, or else they could be artificially added from external sources during processing. These can be further utilized for various applications.

ABSTRACT

Microbes are ubiquitous, irrespective of the location. Humans and microbes have co-evolved in nature over a million years, inhabiting every part of the human body in a symbiotic relationship. They contribute to vital functions of the body including digestion, nutrition, absorption, immune system, in sickness and health, maintaining a dynamic balance. Various factors influence the human microbiome, food and nutrition, lifestyle, age, genetics, antibiotics taken and underlying diseases. These internal and external factors cause an imbalance in the human microbiota. This imbalance in the microbiota is the cause of many systemic, immunological, and neurological-related diseases. Recent research has highlighted the role of the oral gut-brain axis in neurodegeneration, with growing evidence suggesting that oral and gut dysbiosis play a crucial role in disease pathogenesis and in neurological diseases. In this review, we discussed the role of oral and gut dysbiosis in the development of neurodegenerative diseases with help of oral-gut-brain axis. The review also emphasizes the link between the oral, gut and the brain via the bidirectional connection system between the 'Oral – Gut', 'Gut - Brain' and 'Oral-Gut-Brain' axis. This helps in better understanding of brain system with the gut-brain axis in developing therapeutic techniques for treating neurodegenerative diseases.

Keywords: Oral/gut microbiota, Microbial dysbiosis, Neurodegenerative disorders, Cognition

INTRODUCTION

Every human being is a harbor for more than 100 million microbes. It is estimated that a number of microbes may be high in number various human cells which includes majorly bacterial species. Other than bacteria, presence of fungi, viruses and other parasites results in the formation of human microbiomes (HM). This HM has a unique network of microflora involved in the maintenance of host homeostasis mechanism and progression of diseases during pathogenic colonization. These microbes are inhabitants in every part of the body like skin, mouth, gut, respiratory tract, etc (Dekaboruah et al. 2020; Hou et al. 2022). However, these residential microbial communities increase in number throughout the growth of the host and decrease with age over 70 years. They can be categorized as pathogenic and non-pathogenic, where the non-pathogenic microbes are found to be more in number than the former. They co-exist together and exhibit symbiotic relationships in a healthy individual. They play a vital role in systemic functions, thereby maintaining human health (Rinninella et al. 2019; Berg et al. 2020). However an imbalance in these microbial communities can lead to various diseases affecting gut health, immune functions, nervous-related disorders etc. The gut and oral microflora are known to be the two largest two microbial communities and play a major role in health sustenance (Uddin et al. 2021; Hou et al. 2022). Disturbance in the microbiota causes many diseases like systemic diseases, infections, cardiovascular diseases, cancer, respiratory diseases, periodontitis, irritable bowel disorders IBDs, neurodegenerative diseases, mental or psychological diseases, liver diseases, and autoimmune diseases (El-Sayed et al. 2021; Gebrayel et al. 2022; Mukilan et al. 2024). Recently, the effect of microbial dysbiosis on neurodegeneration has gained more interest than other systemic diseases. This helps in developing curative methods for neurodegenerative diseases. Recent studies have shown that dysbiosis of oral and gut microbiota not only causes systemic diseases but is also known to affect brain physiology, which contributes majorly to the development of neurodegeneration (Singh et al. 2022; Intili et al. 2023; Mukilan 2023).

ROLE OF ORAL AND GUT MICROFLORA IN HUMAN HEALTH

A person's DNA determines the microbiome network in them. The microbiome houses in the host in the tissues of the placenta, umbilical cord and the amniotic fluid during a healthy pregnancy and shortly after birth through breast feeding, etc., and as the host grows, the microbiome adjusts to the surrounding niche and is diversified into a large adult microbiome in almost every part of the body (Aagaard et al. 2014; Mesa et al. 2020). Also, the microbiome of a baby depends on the mother who is exposed to various environments. This microbiota localizes various regions in the body – skin, eye, nose, gut, respiratory tract, urinary tract, genitals, etc., in which 70% of human health is maintained by oral and gut microbiota. This microbiome exists in symbiosis with the host, benefitting both in their localized region in maintaining homeostasis until the individual is in a healthy state (Hurley et al. 2019; Coscia et al. 2021; Sasso et al. 2023). The microbiota plays a vital role in physiological, metabolic and immunological functions like immune regulation, digestion, absorption of nutrients, production of vitamins, and involved in certain biochemical pathways. Their growth depends on physiological characteristics like temperature, nutrition, lifestyle, etc (Altves et al. 2019; Mukilan 2022; Naliyadhara et al. 2023).

In normal conditions, the concentration of the microflora varies differently among different individuals and also varies from site to site in the same individual. The oral cavity is the second most significant one after the gut in maintaining health. The oral cavity of the baby during birth is usually sterile but the microbes start inhabiting during breastfeeding and followed by the exposure to the external environment. The habitats of the oral cavity can be teeth, buccal mucosa, soft and hard palate and saliva (Deo and Deshmukh 2019; Aggarwal et al. 2022). This harbors not only bacteria but also fungi, viruses and yeasts, by providing a nutrient-rich environment for them. It is also reported that the diet of an individual alters their oral microbiota. Thus, the oral microbiota can influence the body health of an individual. The oral microbiome is usually in the form of a biofilm. It helps in maintaining oral hygiene, and prevents the development of dental caries (Jia et al. 2018; Gschwind et al. 2020; Panzer et al. 2023). Like oral microbiota, gut microbiome being the most significant and the most abundant contains millions of microbes like bacteria, fungi, viruses and protozoa, of which 30% of the microbial population is bacteria. Inhabitation of microbes in the gut begins at birth and is influenced by various factors including breast feeding, introduction of solid foods,

Ravi Aiswarya Krishna et al.,

and dietary changes over the years of host growth. Both external and internal factors contribute to the colonization of the gut microbiota (Gschwind et al. 2020; Panzer et al. 2023). The external factors include breast milk, food taken, etc. and internal factors include the pH of the stomach, intestinal secretions like bile juice, immune responses, antibiotics, etc. The gut bacteria feed and flourish by the diet pattern of the host. The gut bacteria produce vitamins, essential and non-essential amino acids, etc. The gut microbiota influences the overall human health right from birth to the entire lifetime by colonization, metabolizing dietary and pharmaceutical molecules, conferring resistance to pathogens, maintenance of intestinal epithelium, central nervous system, behavior via the gut-brain axis (Agaard et al. 2014; Gschwind et al. 2020; Panzer et al. 2023).

IMPACT OF ORAL AND GUT DYSBIOSIS IN THE DISRUPTION OF HOMEOSTASIS MECHANISM

Besides the physiological distance between the oral cavity and gut, they exhibit a close relation, as the digestive system of the human body begins with the oral cavity and passes through the gut to the anal end. Since gastrointestinal tract GIT and oral cavity are one continuous system, oral health is directly related to gut health. Though both axes have a unique network of microbiomes, overlapping of microbiota between the oral cavity and gut was observed as per the study (Maki et al. 2021). It is found that oral bacteria colonize the gut and activate the immune system in the gut. Oral bacteria can be transferred from the oral to the gut via swallowing, translocation or aspiration. *Bifidobacterium*, a gut bacterium was observed in the oral fluids of neonates babies. Similarly, oral bacterium like *fusobacterium* was observed in the gut in elderly adults (Makino 2018; Toda et al. 2019). Studies like these show that there is an interconnection between oral and gut in regulating the structural, functional and pathophysiological processes. This transmission between oral-to-gut and gut-to-oral is termed the “Oral – Gut Microbiome axis”. The close association between oral and gut is still not clearly understood. But the oral – gut axis helps in studying the pathogenesis and prognosis of the system (Park et al. 2019). Human microbiota affects host physiology to a greater extent at a whole-body level during diseased conditions. A beneficial relationship exists between the host and the microbes as long as the individual is in a healthy state. Dysbiosis means disruption or imbalance in the microbial population (Elzayat et al. 2023). Infection is another common cause of microbial dysbiosis. Dysbiosis causes the host to be more susceptible to infections and diseases. It is determined by various factors like age, food and nutrition, lifestyle changes, hormonal changes, underlying diseases, ecological factors, antibiotics and inherited genes (Wang et al. 2017). These factors alter the normal microbiota causing an imbalance in the microbial population, leading to various diseases including infections, cardiovascular diseases, cancer, respiratory diseases, periodontitis, IBDs, neurodegenerative diseases, mental or psychological diseases, liver diseases, and autoimmune diseases. A large number of studies have shown interlink between diseases/infections and its associated dysbiosis state (Wang et al. 2017; Gebrayel et al. 2022).

In a healthy state, the oral microbes participate in the maintenance of the body's immune system and maintaining homeostasis by resisting other external hindrances. But, when it is encountered by any disturbances above the regulatory level, it is dysregulated, thereby, affecting the oral as well as the overall body health. It is reported to cause diseases like periodontitis, digestive tract diseases, dental caries, glossitis, gingivitis, oral cancer, diabetes and so on (Lamont et al. 2018; Park et al. 2021; Maier 2023). Similarly in the case of gut microbiota, when the host immunity is reduced or affected by some external stress or factors, the micro ecological balance is disturbed. It leads to many diseases like metabolic disorders like obesity, and diabetes, cardiovascular diseases like atherosclerosis (Wang et al. 2017), liver diseases, autoimmune diseases like asthma and arthritis, (IBDs), and it can cause cancer like colorectal cancer, psychological diseases like depression, sleep issues, anxiety, autism, and alzheimer's disease (Treisman 2017). These gut microbiota produce certain chemicals (neurotransmitter precursor compounds) that send signals to the brain affecting the brain health and hence affecting the mental health. The oral bacteria are located closer to the brain and can affect the brain faster than the gut microbiota (O'Mahony et al. 2015; Liu et al. 2024). A bidirectional displacement exists between oral and gut, where oral-to-gut and gut-to-oral transmissions affect or modulate the ecosystem within these two habitats. For example, a decrease in the secretion of gastric juice favors the transmission of oral bacteria to the gut. This leads to dysbiosis and disrupts the regulation of bile juice (Hajishengallis 2016; Park et al. 2021). Gut dysbiosis mostly occurs as a result of antibiotics, which are supposed to target a single

**Ravi Aiswarya Krishna et al.,**

pathogen but cause the eradication of both 'good' and 'bad' bacteria. Damage of the oral–gut barrier, favors the translocation of bacteria and communication between organs, causing systemic diseases. Gut bacteria may directly or indirectly affects the host immune system and vice versa through oral microorganisms. Recent studies have shown that dysbiosis of oral and gut microbiota not only causes systemic diseases but is also known to affect brain physiology and pathology, which contributes to the development of neurodegeneration (Liu et al. 2022; Intili et al. 2023).

EFFECT OF ORAL AND GUT DYSBIOSIS IN NEURODEGENERATION

Neurodegenerative diseases are caused when the nerve cells of the brain are damaged or lose their functions. The most common neurodegenerative diseases are parkinson's disease, alzheimer's disease, huntington's disease, amyotrophic lateral sclerosis (ALS), and motor neuron disease. Besides the genetic and environmental factors associated with neurodegeneration, the human microbiome plays a major role in neurodegeneration. They cause neurological diseases via various mechanisms mainly involving the bidirectional interaction of oral–to–gut and gut–to–brain axis. Microbiota products impact the brain either directly by producing neurotransmitters or indirectly by stimulating the immune system or by affecting the gastrointestinal tract, autonomic nervous system, or intestinal nervous system (Treisman 2017; Altves et al. 2020). Quite a large number of studies show that oral and gut microbiota play a major part in the development of neurodegenerative diseases. The oral microbiota exhibits a pathway called the 'Oral – gut – brain' axis. The oral bacteria reaches the brain and damages the central nervous system causing neuronal damage through bloodstream via root canal/via gingiva crevices to the capillaries in the gingiva connective tissues, and alveolar blood vessels. The bacteria can also enter the brain via the trigeminal nerve (Teixeira et al. 2017; Zhang et al. 2023). It has been established that oral dysbiosis causing periodontitis may have a connection with neurodegenerative diseases like alzheimer's disease. Disturbances in the oral microbiota cause dysbiosis of the bacterial biofilms in the mouth damaging the structure of the teeth, leading to periodontitis. It was found that *Porphyromonas. gingivalis*, an oral resident bacteria, is the main pathogen causing periodontitis (Franciotti et al. 2021; Wan and Fan, 2023). These pathogens upon oral dysbiosis release pro-inflammatory cytokines like interleukin – 1 IL-1, IL-6 and Tumor necrosis factor TNF- α , which causes plaque formation in the mouth, which further reaches the central nervous system of the brain via hematoencephalic barrier-free areas and fenestrated capillaries or increases the permeability of the brain parenchyma. The brain has a barrier called blood brain barrier (BBB) that prevents the toxic substances from entering the brain (Al-Obaidi et al. 2018; Lei et al. 2023). This pathogen breaks or increases the permeability of the brain causing damage in the transmission of neural signals, by inhibiting the local interferon - γ IFN- γ response and thereby, suppressing the host immune response. A study conducted by Ide et al. 2016, found that increased levels of these cytokines were present in the patients affected with alzheimer's disease.

At baseline, periodontitis showed increase in the cytokine levels. Hence, concluding that periodontitis is associated with the increase in cognitive decline in patients with alzheimer's disease. Later on, another study was conducted on mice model indicated that *P. gingivalis* liposaccharide (LPS) indicated that it affects microglia which induces neuroinflammation and cognitive impairment via the TLR4/NF- κ B signaling pathway, an important characterization of alzheimer's disease. (Zhang et al. 2018). Though studies and evidence show an association between periodontitis and AD, the clear mechanism is still unknown. Some studies showed the deposition of amyloid β plaques and tau protein produced by gut bacterial families *Akkermansiaceae* and *Prevotellaceae*, in the brain in patients with alzheimer's disease. A comprehensive connection between these articles shows there is a connection between dysbiosis of oral microbiota and neurodegenerative diseases. This invasion can be direct or indirect leading to cognitive impairment, a serious consequence of neurodegeneration. But there is no clear idea whether dysbiosis of oral microbiota causes neurodegenerative diseases through periodontitis? Studies also show that dysbiotic imbalance of oral microbiota can also cause other neurodegenerative diseases like Parkinson's disease (Rozas et al. 2021). As equal to the oral microbiota, gut microbiota plays a major role in brain health and physiology via the bidirectional pathway between the gut to brain. These gut microbiota impacts cognitive behavior, depression, neurological diseases like alzheimer's disease, parkinson's disease, ALS, stress, aging, etc. (Zhu et al. 2021). The signaling pathway is complex involving the physiological, metabolic, immunological central nervous system (CNS), autonomic nervous system (ANS), enteric

**Ravi Aiswarya Krishna et al.,**

neural system (ENS) of the brain and neuronal pathways (Hou et al. 2022). However, the exact relationship between the gut microbiota and neurodegenerative diseases remains unclear. ANS controls the gut functions and triggers the neurological responses of the gut, whereas, the CNS controls the visceral information processing. Other than CNS, ANS also controls the gut microbiota (Wang et al. 2017). The three main signaling pathways include a) the gut-brain axis, where the microbial metabolite reaches the brain via the vagus nerve inducing neurodegeneration, b) the endotoxins pathway, where the accumulation of A β and tau proteins induces the neurocytotoxic mechanisms and c) the mitochondrial pathway, where the intestinal metabolite short-chain fatty acids SCFAs induces neuro cytotoxic mechanism (Loh et al. 2024). The gut microbiota affects the nervous system of the brain via neurotransmitters like catecholamines, tryptophan, serotonin, etc. These signals directly activate the vagus nerve that connects the gut and the brain and in addition to this, alterations in (SCFA), an important metabolic product of the gut, are shown to be associated with neurodegeneration (Bruning et al. 2020; Hou et al. 2022). Besides, the impact of gut microbiota on other systemic diseases, its role in neurodegenerative diseases has become an important area of research. *Bacillus subtilis* and *Escherichia coli* are very common residents of intestinal microbiota and present in steady balance when the host is in a healthy state. However, these organisms are affected by external factors like pathogens and result in the dysbiosis of residential flora. These *B. subtilis* and *E. coli* secrete lipopolysaccharides (LPS) and amyloid proteins in large amounts. These pro-inflammatory proteins directly pass through the blood-brain barrier (BBB) from the gut by decreasing the intestinal permeability and accumulate in the brain, inducing synaptic toxicity and neuronal death or directly pass through the physiological barrier, provoking the degeneration of the nervous system, leading to the development of neurodegenerative diseases like alzheimer's disease (Jiang et al. 2017; Intili et al. 2023).

CONCLUSION

Recent studies have shown that in healthy conditions, every human body consists of a unique network of microbes like bacteria, viruses, fungi, protozoan and archaea, making up the site-specific human microbiome. This site-specific human microbiome is involved in the regulation of host homeostasis mechanisms like digestion, cognition, and systemic regulation. However, these regulated functions work in a dynamic balance until the body is affected or disturbed by any internal or external stresses. Other than external stresses, internal stress like oral/gut dysbiosis of microbiota may lead to several disorders like physiological, systemic, immunological, and neurological diseases. Among these types of disorders, neurological diseases like alzheimer's disease, parkinson's disease, and mild cognitive impairment were progressed by infection with periodontal and non-periodontal pathogens at a higher level. The progression of these disorders results in the development of dysbiosed state of microorganisms in the oral cavity and the gut. Colonization of pathogens in the oral cavity/gut may indirectly trigger the inflammatory response in the CNS via transmission of virulence factors, and metabolites through the blood-brain barrier. Thus the present review opened up the role of virulence factors in the development of brain neuroinflammation in neurodegenerative disorders. Future research studies will prove the role of specific virulence factors of periodontal and non-periodontal pathogens in the development of neuroinflammation in different brain regions.

ABSTRACT

In this work, we have to explore the semi-analytical solution for the steady flow of thermal analysis of MHD Williamson fluid flows through a micro channel. Here, the dimensionless predominant equations are solved with the help of the Homotopy analysis method (HAM). The semi-analytical expressions for non-dimensional velocity and non-dimensional temperature are presented. The results have good accuracy as compared to the numerical solution. Also, the effect of Biot number on the substantial fluid temperature is demonstrated graphically. Bejan number and entropy generation numbers are derived and displayed graphically. This approach may also be extended to solve other non-linear problems.

Keywords: Micro channel, Entropy generation, Convective boundary conditions, Homotopy analysis method, Williamson fluid.

INTRODUCTION

Agboola et al. [19] analysed the natural convection flow of the vertical micro channel via the difference transform method. The transformed equations of velocity and temperature profiles were investigated and they reported that both hall current and wall ambient temperature were irreversible. Ananthaswamy et al. [17] investigated the Navier-Stokes equations for a steady magnetohydrodynamic (MHD) flow between two parallel porous plates and the non-linear differential equation was solved using the q-Homotopy analysis method to influence the flow parameters. Khan et al. [21] exclaimed about the steady magnetized two dimensional incompressible flow of Jeffrey nanofluid that developed over a stretched, curved surface with combined characteristics of activation energy.

Ananthaswamy and Punitha

Modern developments in the field of fluid dynamics on nanofluids including maintaining remarkable thermal conductivity properties using the Runge-Kutta (RK) - method by Khan et al. [5, 6], (2019). Madhu et al. [1, 12] studied the Eyring-powell fluid through an inclined micro channel in the presence of radiation and convection heating effects and analyzed the entropy generation of the system in non-dimensional form. The set of converted equations can be solved by the finite element method. Makinde et al. [11] investigated the influence of thermal radiation, magnetic field, wall suction, and porous medium on the forced MHD flow of electrically conducting casson fluid in a horizontal micro channel with boundary slip and saturated with porous medium. Malik et al. [8] explained that when heat generation and absorption effects are taken into account, the corresponding PDEs are converted into ODEs and resolved by the RK Fehlberg method. Nadeem et al. [9] explained the two dimensional Williamson fluid flow model by using similarity transformations and the equations were analytically resolved by HAM. Ogunseye et al. [10] discussed the heat transfer performance and entropy generation rate in a mixed convection flow of a hydromagnetic aluminium oxide-water powell-eyring nanofluid flow through a vertical channel. The result of this study may help engineers optimize thermal systems. Qayyum et al. [6] presented the numerical analysis of MHD flow through a porous medium bounded by a non-linearly stretching flat surface. The graphical presentation of results highlights that the heat flux receives enhancement for augmented Brownian diffusion. Rana et al. [2] explained that the flow and heat transfer of a nanofluid over a stretching sheet with Brownian motion, thermophoresis effects. Reddy [3] introduced the finite element approach, which is applied in different fields. An extreme compact flow heat exchanger was described and constructed with the furnace brazing of stainless steel sheets. The argument, which is based on calculations, depends upon exchanger geometry and fluid pressure, as explained by Swift et al. [20]. Waqas et al. [4] described how the detailed analytical outcomes are compared with the numerical parameters. In this current study, we have discussed the semi-analytical solution for the steady flow of thermal analysis of MHD Williamson fluid flows through a micro channel. The corresponding PDEs are converted to ODEs using the similarity transformation. The dimensionless velocity and dimensionless temperature equations are solved using HAM. The results are then compared with numerical solutions. Several physical characteristics involved in this issue are graphically displayed to show the convergence of this method.

Mathematical formulation of the problem

Here we seen the steady fully developed incompressible dissipative flow of a Williamson fluid over a micro channel bounded by parallel two horizontal plates separated by width. The infinite lower plate of the micro channel is also placed by $y=0$, while above the lower plate is at $y=h$. Flow is along the y -axis and the physical quantity depends only on transversal coordinate y while magnetic effects of uniform strength B_0 are discussed transversely to the plate.

The flow is shown in the Fig. 1.

$$\rho v_0 \frac{du}{dy} = -\frac{dp}{dx} + \mu \left(1 + \sqrt{2} \Gamma \frac{du}{dy} \right) \frac{d^2 u}{dy^2} - \sigma B_0^2 u \quad (1)$$

$$\rho C_p v_0 \frac{dv}{dy} = -k \frac{d^2 T}{dy^2} + \mu \left(1 + \frac{\Gamma}{\sqrt{2}} \frac{du}{dy} \right) \left(\frac{du}{dy} \right)^2 + \sigma B_0^2 u^2 \quad (2)$$

Under the following boundary- conditions we get:

$$\begin{aligned} u = 0, \quad k \frac{dT}{dy} - h_1(T - T_2) = 0, \quad \text{at } y = 0, \\ u = 0, \quad k \frac{dT}{dy} + h_2(T - T_1) = 0, \quad \text{at } y = h, \end{aligned} \quad (3)$$

The eqns. (1) – (3) are non-dimensionalised using the below relationships

$$u = \frac{\mu}{\rho h} f(\eta), \quad \eta = \frac{y}{h}, \quad \theta = \frac{T - T_1}{T - T_2} \quad (4)$$

Ananthaswamy and Punitha

Using above relationships; the eqns. (1) - (3) can be expressed as

$$(1 + W_e f') f''' - \text{Re} f' - M^2 f + P = 0 \tag{5}$$

$$\theta'' - \text{Re Pr} \theta' + Ec \text{Pr} \left[\left(1 + \frac{W_e}{2} f' \right) (f')^2 + M^2 f^2 \right] = 0 \tag{6}$$

Dimensionless forms of boundary conditions are:

$$\begin{aligned} f = 0, \quad \theta' - Bi_1(\theta - 1) = 0, \quad \text{at} \quad \eta = 0 \\ f = 0, \quad \theta' + Bi_2(\theta) = 0 \quad \text{at} \quad \eta = 1 \end{aligned} \tag{7}$$

Where, $P = \frac{\rho h^3}{\mu^2} \left(-\frac{dp}{dx} \right)$ pressure gradient parameter, $W_e = \frac{\sqrt{2}\mu\Gamma}{\rho h^2}$ is weissenberg number

$\text{Re} = \frac{\rho g_0 h}{\mu}$ Reynolds number, $M = \sqrt{\frac{\sigma B_0^2 h^2}{\mu}}$ is Magnetic parameter, $\text{Pr} = \frac{\rho C_p}{k}$ prandtl number,

$Ec = \frac{\mu^2}{h^2 \rho^2} \frac{1}{C_p (T_2 - T_1)}$ Eckert number, and $Bi = \frac{-hh_i}{k}$ for $i = 1, 2$, is Biot number.

Entropy generation

The obtained temperature and velocity fields are used to determine the irreversibility rate within the micro channel. Under convective peripheral condition for the Williamson fluid model the aspects influencing the entropy are fluid friction, heat transfer and magnetic field and are defined below,

$$E_g = \frac{k}{T_1^2} \left(\frac{dT}{dy} \right)^2 + \frac{1}{T_1} \left[\mu \left(1 + \frac{\Gamma}{\sqrt{2}} \frac{du}{dy} \right) \right] \left(\frac{du}{dy} \right)^2 + \sigma B_0^2 u^2 \tag{8}$$

By using relation eqn. (4) non- dimension form of eqn. (8) is

$$N_s = \frac{E_g}{E_0} = (\theta')^2 + Ec \text{Pr} L \left[\left(1 + \frac{W_e}{2} f' \right) (f')^2 + M^2 f^2 \right] \tag{9}$$

where, $E_0 = \frac{k(T_2 - T_1)^2}{h^2 T_1^2}$ denoted the characteristic entropy generation rate, $L = \frac{T_1}{T_2 - T_1}$ represents

characteristic temperature ratio.

Hence alternative form of eqn. (9) can be expressed as below:

$$N_s = N_h + N_v \tag{10}$$

The Bejan number (Be) is the ratio generation of entropy due to heat transfer irreversibility (N_h) to the generation of entropy due to heat transfer irreversibility and viscous dissipation ($N_h + N_v$) is defined as follows,

$$Be = \frac{N_h}{N_h + N_v} \tag{11}$$

Semi-analytical expression of the dimensionless velocity, temperature with the help of the HAM [13-18]

Several issues in physical, chemical and engineering sciences can be solved by the Homotopy analysis method. It is non-perturbative. It offers a series solution for non-linear equations. The non-linearity in a non- linear differential

Ananthaswamy and Punitha

equation is a polynomial that contains the unknown function and its derivatives specified in previous studies. An innovative analytical method namely “Homotopy analysis method” was introduced by Liao [13-16]. This provides possible ways to estimate the solution and from the infinite power series. A finite number of terms and the system of differential equations were solved and which examined the accuracy of this method (HAM). In this technique, there is an auxiliary parameter h that helps us to control and modify the convergence region of the solution series. Applying HAM to dimensionless velocity and dimensionless temperature profiles, we have derived approximate analytical expressions for the same.

$$\begin{aligned}
 f(\eta) &= a_3 e^{a_2 \eta} + \frac{P(e^{a_2} - 1)e^{a_1 \eta}}{M^2(e^{a_2} - e^{a_1})} - \frac{P}{M^2} \\
 &\quad - h \left(\frac{-W_e a_6 - W_e a_6 e^{a_2}}{e^{a_2} - e^{a_1}} + \left(\frac{a_3^2 a_2^3 e^{\left(\frac{\text{Re} + \sqrt{\text{Re}^2 + 4M^2}}{a_5}\right)}}{W_e + \frac{P^2(e^{a_2} - 1)^2 a_1^3 e^{\left(\frac{\text{Re} - \sqrt{\text{Re}^2 + 4M^2}}{M^4(e^{a_2} - e^{a_1})^2 a_4}\right)}}}{\frac{a_3 P(e^{a_2} - 1) a_2 a_1 \text{Re} e^{\text{Re}}}{M^4(e^{a_2} - e^{a_1})}} \right) e^{a_2 \eta} \right) \\
 &\quad - h \left(\frac{-W_e a_6 e^{a_2} + W_e}{e^{a_2} - e^{a_1}} + \left(\frac{a_3^2 a_2^3 e^{\left(\frac{\text{Re} + \sqrt{\text{Re}^2 + 4M^2}}{a_5}\right)}}{\frac{P^2(e^{a_2} - 1)^2 a_1^3 e^{\left(\frac{\text{Re} - \sqrt{\text{Re}^2 + 4M^2}}{M^4(e^{a_2} - e^{a_1})^2 a_4}\right)}}}{\frac{a_3 P(e^{a_2} - 1) a_2 a_1 \text{Re} e^{\text{Re}}}{M^4(e^{a_2} - e^{a_1})}} \right) e^{a_1 \eta} \right) \\

RESULT AND DISCUSSION

In this portion, we have shown the graphical representation of the dimensionless velocity $f(\eta)$ dimensionless temperature $\theta(\eta)$, which can be obtained by using the Homotopy analysis method (HAM). Fig. 1 represents the flow geometry of Williamson fluid flow. Figs. 2 to 5 represent the comparison between our approximate analytical findings using eqns. (12), (13), (21) and (22) with the numerical results reported in [22]. Fig. 2 depicts dimensionless velocity $f(\eta)$ vs. dimensionless coordinate η . From Fig. 2, it is clear that by increasing the magnetic parameter M , the dimensionless velocity decreases. Fig. 3 illustrated that by enhances the Biot number B_i the convection heat transmission from lower micro channel wall of fluid increases, but convective heat exchange reduces the fluid temperature. Fig. 4 predict that entropy generation Ns versus dimensionless coordinate η it indicates that increasing the value of the Magnetic parameter M slow down the temperature of the fluid. Fig. 5 investigates the Bejan number Be in relation to dimensionless coordinate η . It shows that while increasing the value of the magnetic parameter M , leads to the intensification of the Bejan number at both the upper and lower walls of the micro channel.

CONCLUSION

The current research work presents a semi-analytical study for magnetohydrodynamic fluid flow. The corresponding non-dimensional velocity and temperature equations were explored analytically with the help of HAM. The graphical representations of dimensionless velocity profile, dimensionless temperature profile, Nusselt number and Bejan number were displayed. The accuracy of the current results shows a good fit as compared to numerical results. The observations from the present results are listed below:

- Biot number has a tendency to diminish the temperature of the Williamson fluid.
- The temperature of the Williamson fluid increases due to viscous dissipation.
- The pressure gradient parameter positively affects the flow of thermal distribution in micro channels.
- It is conspicuous that lowering the values of Eckert number and pressure gradient parameter reduces the thermal systems.

ABSTRACT

The main root cause of oral disorders is dental biofilms, which colonise the gingival and subgingival tissues of the mouth. The onset and progression of caries are linked to cariogenic bacteria, which are pathogenic agents that increase the acidity of the oral environment. Many infections are brought on by some of these bacteria. Oral flora is constantly evolving because of its permeability to external stimuli. This investigation intends to compare and examine the bacterial fauna of dental samples that are healthy and those that are sick by isolating and characterising all of the isolated bacteria using biochemical testing. Throughout the trial, five swab samples were taken from those who were well and those who weren't. Samples were collected and kept in sterile Eppendorf tubes with 1 millilitre of nutritional broth for an overnight incubation at 37°C in a shaking incubator. Spread that out onto a Nutrient Agar Plate. Once the bacteria were isolated, gram staining, microscopy, and biochemical assays were carried out. The isolates were biochemically classified using the IMViC test and the sugar fermentation assay. Throughout the course of the inquiry, eight bacterial strains and one actinomycetes strain were detected; seven of the bacterial strains and one actinomycetes strain were gram positive and one were gram negative. Four of the nine strains that were found generated acid. Among the nine isolated strains, six exhibit the ability to metabolize complex sugars such as mannitol, lactose, rhamnose and sorbitol. All isolates, except one, can utilize sucrose and glucose. These findings underscore the importance of further research into dental caries management and the eradication of pathogenic bacteria. Additionally, investigating the relative contributions of these organisms to disease aetiology could benefit from natural resources like various medicinal plant extracts.

Keywords: Bacteriocin, IMViC test, Cariogenic bacteria, Dental Caries, Dental Biofilms.

Shweta Bakshi et al.,

INTRODUCTION

One of the most active environments for many bacterial species is the human oral cavity, where they engage in fierce interspecies struggle to produce multispecies biofilm structures. The oral cavity harbors a variety of bacterial species, including *Corynebacterium*, *Lactobacillus*, *Enterococcus*, *Streptococcus*, *Lactococcus*, *Bacteroids*, *Staphylococcus*, *Veillonella*[1,2,3]. Two important oral bacteria are *Streptococcus* and *Enterococcus* since they have the ability to transform from being helpful microflora on the exterior of the mouth cavity and oropharynx to harmful pathogens once they reach the oral tissue and bloodstream. Meningitis, pneumonia, pharyngitis, and endocarditis are among the illnesses caused by microbes found in the mouth. Gram-positive facultative anaerobes, which make up the bulk of dental *Streptococcus*, may form biofilms, adhere to both soft and hard tissues, communicate internally inside cells, and quickly adapt to the constantly shifting oral environment[2,4]. Acids from bacterial metabolic activity that diffuse into enamel and dentine create one of the multifactorial infectious diseases known as bacteria dental caries. Caries is still a serious public health concern even though it is a disease that is primarily preventable and has declined in the majority of developed nations in the past few years[5,6]. Despite routine small environmental pressures such dietary factors, dental cleanliness, host defences, and diurnal fluctuations in saliva flow, the composition of oral biofilm is mostly dependent on equilibrium among the component species [7]. This stability or equilibrium (referred to as microbial homeostasis) is imposed through various microbial interactions, including both synergism and antagonism, and does not depend on any biological indifference among the resident species. [8].Therefore, given that they have negligible side effects and provide comprehensive care, natural compounds that are safe for humans and specifically intended to treat dental caries must be the focus of recent clinical studies [9].

Extensive research has been carried out, and there is growing interest in phytochemicals as potential new sources of natural antibiotics [10]. Some plant-derived substances alter bacterial membrane surface hydrophobicity, harm microbial membrane structures, inhibit peptidoglycan synthesis, and change quorum sensing, all of which may have an impact on the development of biofilms [11]. The potential antimicrobial properties of these plant extracts have been demonstrated by current scientific research[12,13,14]. The utilisation of such bioassays in clinical science may provide useful knowledge and a technique to treat oral disease.[6]. Most research in the field of drug discovery has focused on the ability of natural compounds, such as medicinal herbs, to either eradicate or limit the development of microbes [9]. Natural goods, such as medicinal plants, continue to be important sources of cutting-edge therapeutic medicines for the many human ailments. Despite the availability of modern medicine, the residents of rural developing countries mainly rely on traditional healers and medicinal plants as a base for treating a variety of ailments. According to the World Health Organization, traditional medicine is the primary source of care for 80% of the global population. Native people's use of herbal medicine is a significant component of the world's medical plant heritage [9].

MATERIALS AND METHODOLOGY

Using a sterile cotton swab, samples of supragingival biofilm were taken a few hours after brushing the teeth. The biofilm samples from the swabs were put in sterilised Eppendorf tubes with 1 ml of nutrient broth, and then they were transported to the lab to be shaken overnight at 37 °C [8]. After the samples were vortexed to disperse and sonicated for 30 seconds, the pure microbial cultures were created by inoculating the samples on nutrient agar medium plates. On a nutrient agar plate, distinct colonies were identified and streaked. With the aid of a sterilised inoculating loop, samples were streaked on nutrient agar plates for this purpose. After that, the nutrient agar plates were placed in a thermal incubator and incubated for 24 hours at 37°C. After incubation, the isolated microbial colonies are eliminated from growth plates and quadrant streaking was done aseptically to fresh plates in order to acquire pure strains of microbial culture. The plates were rotated 90° anti-clockwise at four distinct regions of the plate to perform four quadrants of streaking. This was accomplished by moving the culture from one area that had been streaked to another while using an inoculating loop that had been sterilised. The plates were then maintained

at 37°C for a full day in a thermal incubator. To maintain purity, single, pure colonies were placed in certain sectors of a plate. To further ensure purity, well-isolated colonies were chosen and sub-cultured before isolation on a solid medium. To clean the materials, separate colonies were selected after incubation and cultured once more.

Nutrient Agar Media

Beef Extract 3 gm
Peptone 5 gm
Agar 20 gm
Distilled Water 1000 ml
pH 7-7.2

Characterization of bacterial strains

Physical characterization

Colony Morphology

Following bacterial culture purification, pure cultures were streaked on nutrient agar plates and incubated for 24 to 48 hours at 37°C. After incubation, each pure culture's individual colony's size, shape, margin, colour, elevation, texture, and opacity were all noted. There was a tally of observations.

Gram Staining

Initial processing of all pure bacterial isolates was carried out using a gramme staining kit in accordance with Hucker's modification [15]. The prepared slides were examined using a microscope with a 100x magnification. Observations were based on the colours and arrangements of the microbial cells. Gram-positive microbes were stained a dark purple color, while gram-negative microbes were red or pink in appearance. Following Gram staining and microscopy, many biochemical experiments were used to identify the different bacterial strains.

Biochemical Characterization

Citrate Utilization, Methyl Red, Indole, Voges Proskauer's Tests, and eight Different Carbohydrates (Adonitol, Lactose, Mannitol, Glucose, Arabinose, Sucrose, Sorbitol, Rhamnose) are the Basic Biochemical Tests Used to Identify Bacterial Strains. Biochemical assays are performed to determine different species of microbes based on differences in their metabolic activity [16]. To carry up the biochemical characterisation, HiIMViCTM kits were utilized. Each HiIMViCTM kit is a standardised colorimetric identification technique that uses eight assays for carbohydrate utilisation in addition to four traditional biochemical tests. The utilization of substrate and pH alteration serve as the foundation for the tests. During the incubation period, organisms undergo metabolic alterations that manifest as a visual color shift in the media or upon the administration of the reagent.

RESULTS

Five individuals' supragingival biofilm samples gave a total of 8 bacterial cultures and 1 actinobacterium. depending on various colony morphologies. Approximately 1100 different taxa that have been discovered in the dental cavity are listed in the Human Mouth Microbiome Database [17,18]. Only 4% of the species in the diverse community of the buccal cavity are from other phyla, with the majority of the organisms being *Firmicutes*, *Bacteroidetes*, *Proteobacteria*, *Actinobacteria*, *Spirochaetes*, and *Fusobacteria* [19]

Characterization of bacterial strains

Physical characterization

Colony Morphology

Nutrient agar colonies from nine separate random samples were chosen for isolation. On a Nutrient Agar plate, isolated pure cultures were streaked, and the colony shape was recorded (Table 1). Colony characteristics Out of 9 Colonies One is actinobacteria (5.1 A), another 6 colonies (1.1A, 2.1A, 2.1B, 3.1 A, 5.1B and 5.1 C) are Regular in shape,

Shweta Bakshi et al.,

Glistening surface and Butyrous in texture. One colony(4.1 A) is Regular in Shape, Opac and Glistening surface. Another One colony (4.1B) is irregular in shape Flat and Brittle in texture (Table1).

Gram Staining

Gram staining was performed for all isolated cultures. Except one culture (5.1C) all were Gram Negative (Table 2 and Figure 4).

Biochemical Characterization

All 9 pure cultures were inoculated in nutrient broth for Biochemical characterization. 24 hrs of young cultures were used for the basic biochemical tests (IMViC test and Eight Sugar Utilization test) used to identify bacterial strains including Voges Proskauer's, methyl red, indole, and citrate utilization assays, and eight different carbohydrates- adonitol, lactose, sorbitol, sucrose, glucose, arabinose, mannitol. Based on the variations in the metabolic activity of various bacteria, biochemical tests are employed to determine the species of bacteria. As per the results (Table 3 & Figure 5) all the cultures were negative for Indole production and Citrate Utilization. Out of 9 Culture only 3 cultures gave positive result for MRVP Test for acid production. Except 2 cultures (3.1A and 5.1A) all cultures gave positive result for glucose utilization. Four cultures (1.1 A, 2.1B, 4.1A and 4.1B) gave positive result for Adonitol Utilization. Three cultures (2.1A, 4.1A and 4.1B) showed positive result for Arabinose utilization. Another four cultures (1.1A, 2.1A, 4.1A and 5.1C) showed positive result for lactose utilization. Six cultures (1.1A, 2.1A, 4.1A, 4.1B, 5.1B, 5.1C) were positive for Mannitol and Rhamnose Utilization. All the cultures except 3.1A were positive for Sucrose utilization. This bacteria is essential for the fermentation of carbohydrates, which produces lactic acid and enamel demineralization. This bacterium produces extracellular polysaccharide, one of the elements of dental plaque, which increases cariogenicity and facilitates simple absorption of carbohydrates [20,21]. Because of its adhesion to oral and dental tissues, SM has been recognised as a bacterium that starts dental caries [22,23].

DISCUSSION

Furthermore, not much research has been done to understand the bacteria that comprise oral flora and their makeup. The microbes are typically found on the surface tissues of all human beings, such as the mouth cavity [18]. These microorganisms occur in various numbers and types according to an individual's age, food, and level of personal hygiene [24]. Future research that focuses on evaluating the effectiveness of treatment after eliminating mutans, non-mutans, and both types of organisms in dental caries may bring new control issues. This type of research is required in order to find the best approaches to properly manage dental caries. Therefore, recent medical studies must focus on organic substances that are suitable for humans and especially aimed at curing oral caries, given their few adverse effects and ability to provide full treatment to patients. Several research have been done to find out if common household natural essential oils like cinnamon and cloves may be utilized to treat dental issues like gum swelling and toothaches [25].

CONCLUSION

For the present investigation, we successfully isolated and characterized several oral bacterial strains. These recently discovered microorganisms demonstrated many metabolic processes. We are now undertaking research to discover some all-natural treatments to stop the growth of dangerous oral bacteria utilising naturally occurring materials like plant extracts. For the prevention and treatment of frequent oro-dental issues in children and elderly patients, traditional healers from Ayurveda, Unani, and other systems of medicine frequently recommend medicine like Miswak (*Salvadora persica*), Haldi (*Curcuma longa*), Anar (*Punica granatum*), Aqarqarha (*Anacyclus pyrethrum*), Lehsun (*Allium sativum*), Suddab (*Rutagraveolens*), Amla (*Embllica officinalis*), Aqaqia (*Acacia nilotica*), Babuna (*Matricaria chamomilla* Linn.), Shahad (Honey), Aspaghhol (*Plantagoovata*), Clove (*Syzygiumaromaticum*) etc.

Shweta Bakshi et al.,

Similar to this, unorthodox remedies like SunoonZard, SunoonMulook, SunoonMujalli, and others have demonstrated potent antibacterial, anti-inflammatory, and sedative effects and are recommended for the medication of orofacial disorders[26,27]. Future research that focus on determining the effectiveness of treatment after different types of organisms in dental caries may create new issues for dental caries management. This type of research is necessary in order to determine the best approaches to properly manage dental caries.

ABSTRACT

The accurate calculation and comparison of performance in cloud environments are critical for optimizing resource utilization, particularly with the increasing use of Virtual Machines (VMs) and containers. This research proposes an AI-driven resource management framework that surpasses traditional machine learning algorithms by enabling real-time, autonomous performance optimization. While machine learning models provide predictive capabilities, they often require manual tuning and retraining for changing workloads. In contrast, the proposed AI-driven system, utilizing techniques such as reinforcement learning and adaptive optimization, continuously adjusts resource allocation based on real-time performance metrics like response time, throughput, and server utilization. This dynamic, self-improving system can respond to fluctuating workloads and network conditions without the need for constant retraining, offering superior flexibility and faster response times. The framework will be validated through extensive experiments across multi-cloud and edge computing environments, demonstrating its ability to significantly reduce calculation time while improving scalability and efficiency. Additionally, this approach incorporates enhanced security mechanisms, combining the isolation benefits of VMs with the lightweight efficiency of containers, providing a comprehensive, real-time solution for cloud-native applications.

INTRODUCTION

Cloud computing has revolutionized the way businesses operate by providing scalable and flexible computing resources. One of the key enablers of cloud technology is virtualization, where Virtual Machines (VMs) and containers are two prevalent technologies used to optimize resource utilization, scalability, and deployment times in cloud infrastructures. VMs have been widely adopted due to their strong isolation, as they emulate entire operating systems, providing a high degree of security and compatibility with legacy systems [1]. However, this comes at the cost of higher resource overhead due to the need for duplicating operating system components in each instance [2]. On the other hand, containers, driven by platforms like Docker, have emerged as a lightweight alternative, providing efficient resource utilization by sharing the host operating system kernel [3]. Containers are known for their faster start-up times, reduced overhead, and improved scalability, making them particularly suited for cloud-native applications where rapid deployment and scaling are critical [4]. Despite these advantages, containers often face challenges related to security and isolation, as they share the kernel with the host system, which can expose vulnerabilities if not properly managed [5], [6]. The dynamic nature of cloud environments, where workloads fluctuate significantly, calls for efficient and real-time resource management strategies that can adapt to changing conditions. Traditionally, empirical benchmarking and machine learning (ML) models have been employed to compare and optimize the performance of VMs and containers [7], [8]. These methods rely on historical data and specific configurations to predict performance metrics such as response time, throughput, and resource utilization. However, these approaches have several limitations:

Static Nature of Machine Learning Models: ML models, while effective at predicting performance under specific conditions, are static once trained. They require manual retraining when workloads or configurations change, which introduces delays and inefficiencies in dynamic cloud environments [9]. **Manual Tuning:** Machine learning models often need manual tuning to optimize performance, which is labor-intensive and time-consuming. This becomes particularly problematic in large-scale, real-time cloud deployments where workload patterns change frequently [10]. **Empirical Benchmarking Overhead:** Traditional empirical benchmarking requires setting up specific workloads and configurations, running tests, and collecting data over a period of time. This process is not only time-consuming but also impractical for real-time performance optimization in dynamic and fast-changing environments [11]. While significant research has been conducted on optimizing resource allocation in cloud environments, existing solutions often fall short in dynamic, multi-cloud infrastructures. Current machine learning models are static, requiring frequent retraining, which makes them less suited for real-time optimization in fluctuating workloads.

To address these limitations, recent advancements in artificial intelligence (AI) and reinforcement learning (RL) offer promising solutions. Reinforcement learning, a branch of AI, is particularly suited for dynamic, real-time environments as it allows systems to continuously learn from the environment and make decisions that maximize performance. Unlike traditional ML models, RL does not require frequent retraining or manual intervention; instead, it adapts based on feedback from the system, making real-time adjustments to resource allocations [12]. AI-driven resource management leverages reinforcement learning to dynamically monitor and optimize performance metrics such as response time, throughput, and resource utilization. By continuously learning from real-time data, the system can autonomously adjust resource allocations to meet changing demands, without the need for human intervention. This approach not only reduces the overhead associated with traditional benchmarking and ML models but also offers a scalable solution for optimizing the performance of both VMs and containers across diverse cloud environments [13]. Moreover, the increasing adoption of multi-cloud and edge computing environments, where resources are distributed across different platforms, necessitates a flexible and adaptable resource management system. The proposed AI-driven framework, with its continuous learning and adaptability, provides a solution that can optimize resource allocation across these heterogeneous environments, ensuring efficient performance even in highly dynamic and distributed systems [14]. This research proposes an AI-driven resource management framework that surpasses traditional ML approaches by offering real-time adaptability, continuous learning, and dynamic optimization for both VMs and containers. The AI system, built on reinforcement learning principles, continuously

**Anand and Nisha Jebaseeli**

monitors and adjusts resource allocations based on real-time workload conditions, optimizing key performance metrics without the need for manual intervention. Through extensive experimentation, the research demonstrates the superiority of this approach in terms of performance, scalability, and flexibility, making it particularly suited for modern, cloud-native infrastructures [15].

Background**Virtualization Technologies: VMs vs. Containers**

Virtualization technologies, particularly Virtual Machines (VMs) and containers, have become integral to cloud computing. VMs, which emulate entire operating systems, offer strong isolation and security, making them suitable for legacy systems and applications requiring high levels of protection. However, VMs introduce significant overhead due to the need to replicate operating systems and associated resources for each instance. This overhead affects scalability and resource efficiency, particularly in cloud environments [1]. Containers, such as those managed by Docker, provide a lightweight alternative by sharing the host operating system kernel. This leads to faster startup times, reduced resource usage, and more efficient scaling, making containers particularly suited for microservices and cloud-native applications [2], [3]. Despite these advantages, containers face challenges in providing the same level of security and isolation as VMs, as they share the host OS kernel, which can lead to vulnerabilities [4], [5]. Several studies have compared the performance of VMs and containers. For instance, Gopalasingham *et al.* compared the performance of VM-based and Docker-based deployments for Software-Defined Radio Access Networks (RAN), showing that Docker offers superior performance due to its reduced overhead and faster resource allocation [6]. Similarly, Felter *et al.* highlighted Docker's ability to offer near-native performance while significantly reducing the resource footprint compared to VMs [7].

Empirical Benchmarking of Virtualization Technologies

Empirical benchmarking has been widely used to evaluate the performance of VMs and containers. Traditionally, this involves running specific workloads under controlled conditions and measuring key performance metrics such as response time, throughput, and resource utilization [8], [9]. Studies, such as those by Zeng *et al.*, have provided detailed insights into the networking performance of Docker containers, highlighting how network latency and throughput are affected by the underlying virtualization layer [10]. However, empirical benchmarking has limitations. It requires the setup of specific test conditions and workloads, which may not always reflect real-world usage. Additionally, this method can be time-consuming, particularly in dynamic cloud environments where workloads and resource requirements change frequently [11]. As a result, benchmarking results may not always be relevant for real-time performance optimization in production environments.

Machine Learning for Resource Management

Machine learning (ML) models have been proposed as an alternative to empirical benchmarking for performance prediction and resource management in cloud environments. ML techniques, such as regression models and neural networks, can predict resource usage based on historical data, allowing for more automated resource management [12]. However, ML models come with their own set of challenges.

ML Workflow for Cloud Resource Management

Data Collection: Historical data on system performance metrics, such as CPU usage, memory utilization, disk I/O, and network traffic, is collected through monitoring tools like Prometheus and Sysbench. **Feature Extraction:** Key features are extracted from the raw data, including CPU usage patterns, memory demands, and workload types. These features help predict future resource needs.

Model Training: Machine learning models (e.g., regression, neural networks) are trained using the historical data. The model learns the relationship between resource consumption patterns and the system's performance under varying workloads.

Anand and Nisha Jebaseeli

Model Prediction: Once trained, the ML model predicts resource demands based on real-time inputs, helping allocate resources (e.g., scaling VMs or containers) based on expected future needs.

Manual Tuning: As the system's workloads evolve, the ML model often requires manual retraining and tuning to adapt to new workloads, making the process less efficient in real-time scenarios.

Static Nature of ML Models: Once trained, traditional ML models are static and do not adapt to changing workloads. This can lead to inefficiencies when workloads or configurations change frequently, as retraining the models is necessary to maintain accuracy [13].

Manual Tuning Requirements: Many ML models require significant manual tuning to optimize their performance. This process is not only labor-intensive but also time-consuming, especially in large-scale cloud environments [14].

AI-Driven Resource Management

Artificial intelligence (AI), particularly reinforcement learning (RL), has emerged as a powerful solution for real-time resource management in cloud environments. Unlike traditional ML models, which require frequent retraining, RL can dynamically adapt to changing workloads by learning from real-time feedback loops. AI-driven resource management allows for continuous learning and automatic resource optimization without the need for manual intervention [15]. Several studies have explored the potential of AI in managing containerized and virtualized environments. For instance, AI-driven approaches have been shown to dynamically adjust resources to meet performance targets such as response time, throughput, and CPU utilization in real-time, leading to higher efficiency [16]. In contrast to static ML models, RL-based systems continuously adapt to workload variations, making them particularly well-suited for multi-cloud and edge computing environments, where resource demands fluctuate unpredictably [17]. One of the key advantages of AI-driven resource management is its ability to optimize both cost and performance by autonomously managing resources based on usage patterns, energy consumption, and changing infrastructure needs. Moreover, AI algorithms are able to preemptively identify bottlenecks and adjust resources before they negatively impact the system, thus ensuring a seamless user experience in cloud-native environments [18]. This makes AI-driven approaches highly suitable for high-performance computing (HPC) and large-scale data center operations.

Problem Formulation

In cloud computing environments, the increasing reliance on Virtual Machines (VMs) and containers for virtualization has introduced new challenges in optimizing performance and resource management. While VMs provide strong isolation and security through emulation of entire operating systems, they incur significant overhead due to the need to replicate OS resources across instances. On the other hand, containers offer a lightweight alternative with faster startup times and better resource efficiency, but they share the host OS kernel, which can expose vulnerabilities and compromise security.

Traditional methods for performance optimization in cloud environments, such as empirical benchmarking and machine learning (ML) models, exhibit several limitations:

1. **Static Nature of Machine Learning Models:** Once trained, traditional ML models remain static and do not adapt to changing workloads or configurations. This requires manual retraining and tuning when workloads evolve, leading to delays and inefficiencies in dynamic cloud environments.
2. **Manual Tuning Requirements:** Many ML models require significant manual intervention to optimize resource allocation. In large-scale real-time cloud deployments, this becomes labor-intensive and time-consuming, reducing overall system efficiency.
3. **Empirical Benchmarking Overhead:** Empirical benchmarking techniques rely on historical data and specific configurations to predict performance metrics such as response time and resource utilization. However,

**Anand and Nisha Jebaseeli**

benchmarking is not practical for real-time optimization due to its time-consuming nature and inability to account for real-time fluctuations in workload conditions.

Given these limitations, there is a need for an adaptive, real-time optimization framework that can autonomously manage and allocate resources without manual intervention. The dynamic and unpredictable nature of workloads in cloud environments, especially in multi-cloud and edge computing scenarios, requires a solution that continuously learns from its environment and adjusts resource allocations accordingly.

Research Objective

This research aims to address these challenges by proposing an AI-driven resource management framework that leverages reinforcement learning (RL) to dynamically adjust resource allocation in real-time for both VMs and containers. The key objectives of this research are:

1. To develop a self-optimizing resource management system that can autonomously monitor performance metrics and adjust resource allocation without the need for manual retraining or tuning.
2. To demonstrate the scalability and flexibility of the RL-based system in handling fluctuating workloads and network conditions across cloud-native environments.
3. To evaluate the system's ability to reduce response time, increase throughput, optimize resource utilization, and enhance cost efficiency compared to traditional machine learning and benchmarking techniques.
4. By solving these problems, the proposed system aims to provide an adaptable, real-time resource management solution that is particularly suited for modern cloud infrastructures where workload demands are highly dynamic and unpredictable.

METHODOLOGY

The proposed research methodology aims to implement an AI-driven resource management system that optimizes performance in virtualized environments using Virtual Machines (VMs) and containers. This system leverages reinforcement learning (RL) to manage resources dynamically, improving the scalability, performance, and cost-efficiency of cloud-native applications. The methodology is divided into several phases, as outlined below:

System Architecture

The system is designed to manage both VMs and containers within a cloud environment. The architecture consists of three core layers:

Data Collection Layer

This layer collects real-time data on key performance metrics such as CPU usage, memory utilization, disk I/O, network throughput, response time, and container start-up times. Docker containers and VMs are monitored through tools like Prometheus for resource utilization metrics and Sysbench/Apache Bench for benchmarking applications [2], [6]. Performance metrics from both VMs and containers are aggregated in real-time to feed into the AI model.

AI Optimization Engine

The AI engine employs reinforcement learning algorithms to manage the resource allocation process dynamically. The RL agent is trained to make decisions regarding resource allocation based on workload characteristics, system metrics, and environmental feedback. The system continuously learns from real-time feedback, optimizing resource usage to maintain desired performance levels without over provisioning resources [16]. The RL agent is designed to operate autonomously, adjusting CPU, memory, and storage resources as workloads fluctuate across both containers and VMs.

**Anand and Nisha Jebaseeli****Resource Management Layer**

This layer applies the decisions made by the AI engine. It uses resource orchestration tools like Kubernetes for containers and hypervisor-based management systems (e.g., KVM for VMs) to execute resource allocation changes. The layer ensures that the resources are adjusted in real-time without service interruptions, ensuring smooth scalability and performance for both VMs and containers [6].

Reinforcement Learning Model

The core of the AI-driven system is the reinforcement learning (RL) model. The RL model is designed to optimize resource allocations for both VMs and containers by learning from the environment through continuous feedback. The model operates as follows:

State Representation

The state of the system is represented by various performance metrics, including CPU and memory utilization, disk I/O, and network latency for each VM and container instance [7]. The state also includes workload patterns, such as the number of incoming requests, the type of tasks being processed, and the criticality of those tasks.

Action Space

The action space consists of potential resource allocation changes, such as scaling up/down CPU cores, increasing or decreasing memory, and redistributing storage resources across VMs and containers. Actions can also include scheduling optimizations, prioritizing specific workloads based on task importance or latency requirements [16].

Reward Function

The RL agent is rewarded based on system performance improvements, such as reductions in response time, increased throughput, or improved resource utilization efficiency. Penalties are applied when the agent makes decisions that lead to resource wastage, such as over provisioning or allowing resource starvation that causes performance degradation [18]. The reward function is dynamically adjusted to balance performance with cost efficiency, ensuring that the AI system does not over-allocate resources unnecessarily.

Learning Algorithm

A Q-learning or Deep Q-Network (DQN) algorithm is applied to update the agent's policies based on the reward function. The RL model is trained using real-time data from the monitored environment, and its policy evolves to better handle workload fluctuations and environmental changes over time [17].

Flowchart of the AI-Driven Resource Management Process

The flowchart below represents the key steps in the AI-driven resource management system using reinforcement learning. The process is iterative and dynamic, continuously adapting resource allocations based on real-time performance data:

1. Start: Initialize the system state, including the RL agent and necessary performance metrics.
2. Collect Real-Time Performance Metrics: The system gathers key metrics like CPU usage, memory utilization, disk I/O, and network latency.
3. Choose Action: The RL agent selects an action (exploration or exploitation) based on the current system state.
4. Execute Action: The selected action is executed, adjusting resource allocations such as CPU, memory, and storage.
5. Collect Feedback: Updated performance metrics are collected to assess the impact of the action.
6. Compute Reward: The system evaluates the action's effectiveness by calculating a reward based on performance improvements or inefficiencies.
7. Update Q-Value: The RL agent updates its Q-value function to refine future decisions.
8. Convergence Check: The system checks if the strategy has converged. If not, the process repeats. If convergence is achieved, the system moves to the final step.
9. Final Evaluation: A comprehensive performance evaluation is conducted to ensure resource utilization is optimal and the system is stable.

**Anand and Nisha Jebaseeli**

This flowchart demonstrates how the RL system continuously optimizes resource allocation, making real-time adjustments to improve performance and reduce resource wastage.

Experimental Setup

The experimental setup includes two environments: a VM-based environment using KVM and a container-based environment using Docker orchestrated by Kubernetes [6]. Both environments run identical workloads, consisting of web applications and data processing tasks to simulate real-world cloud-native workloads [2].

Workload Generation

Sysbench and Apache Bench are used to generate varying levels of workload intensity (e.g., CPU-bound, memory-bound, and I/O-bound tasks) across VMs and containers. Workloads are scaled from low-load (e.g., 50 requests per second) to high-load conditions (e.g., 1000+ requests per second) to assess how the AI-driven resource management adapts under different stress levels [5].

Performance Metrics

Key metrics include response time, throughput, CPU utilization, memory consumption, disk I/O, and network latency [10]. These metrics will be monitored continuously throughout the experiments. Additional metrics such as container start-up times and VM boot times will also be evaluated to determine how well the system handles dynamic scaling in real-time.

Comparative Analysis

The performance of the AI-driven resource management system will be compared with traditional machine learning (ML) models and empirical benchmarking methods used in previous studies. The comparison will focus on:

Adaptability

How quickly the AI-driven system adapts to workload fluctuations versus static ML models that require retraining for new workloads.

Performance

Improvement in response time and throughput achieved by the RL-based system compared to traditional resource allocation methods [6], [16].

Cost Efficiency

The AI system's ability to reduce over provisioning and optimize resource utilization without compromising performance, compared to traditional methods that may result in resource wastage [7], [18].

Evaluation of Results

The experimental results will be evaluated based on the following criteria

Real-Time Adaptability: The AI-driven system's responsiveness to changing workload conditions, comparing the adjustment times and efficiency of resource allocation in real-time.

Scalability: The system's ability to scale resources dynamically across multiple VMs and containers without significant latency or downtime.

Resource Utilization Efficiency: The AI system's capacity to optimize resource usage, reducing overhead and increasing overall system performance [17].

System Overhead: The overhead introduced by the AI optimization engine itself, such as computational resources used by the RL model and decision-making latency.

EXPERIMENTS AND RESULTS

Experimental Setup

The experiments were conducted in two environments: a VM-based environment using KVM and a container-based environment using Docker. Both were orchestrated on the same hardware, and workload variations were introduced using Sysbench and Apache Bench for CPU-bound, memory-bound, and I/O-bound tasks. The AI-driven reinforcement learning (RL) model was deployed to optimize resource allocations in real-time, and performance was compared to traditional machine learning (ML) models and empirical benchmarking methods [2], [5], [7].

1. Hardware and Software Configuration

The experiments were run on a cluster of physical servers, each equipped with the following specifications:

- Processor: 32-core Intel Xeon @ 2.7GHz
- Memory: 256 GB DDR4 RAM
- Storage: 2TB SSD
- Network: 10 Gbps Ethernet

The software stack consisted of:

- Operating System: Ubuntu 20.04 LTS
- Virtualization Platform: KVM (Kernel-based Virtual Machine) for VMs
- Container Platform: Docker 20.x with Kubernetes 1.20 for orchestration
- AI Model: Reinforcement Learning Model (Python)
- Monitoring Tools: Prometheus for real-time monitoring
- Workload Generators: Sysbench and Apache Bench to generate different types of workload patterns, such as CPU-bound, memory-bound, and I/O-bound tasks.

Workload Design

To simulate real-world cloud workloads, two types of workload patterns were generated using Sysbench and Apache Bench:

- CPU-bound workloads: Simulated high CPU usage scenarios, such as video encoding, cryptographic operations, and data compression tasks.
- Memory-bound workloads: Simulated large-scale data processing operations, including in-memory databases and analytics tasks.
- I/O-bound workloads: Tested performance under disk-heavy operations, such as file storage, database transactions, and log processing.

The workload was scaled from low-load conditions (50 requests per second) to high-load conditions (1000+ requests per second) to test the adaptability of the RL system under varying load intensities. These workloads were executed simultaneously on both VMs and containers to compare their performance across different resource allocation strategies.

Control and Monitoring Tools

To ensure a fair comparison across all resource management strategies, both Sysbench and Apache Bench were configured to produce identical workloads across the environments. Real-time resource monitoring and data collection were handled using Prometheus, which gathered resource utilization metrics, and Grafana, which provided a visual dashboard for tracking system performance. In addition, Kubernetes Horizontal Pod Autoscaler (HPA) was used to handle container scaling, allowing for automatic adjustment based on CPU or memory thresholds. The KVM-based VMs were managed via the libvirt interface, with resource scaling carried out manually based on the RL agent's decisions. Each experiment was run for a duration of 24 hours to account for diurnal patterns in workloads that might occur in real-world cloud systems. Each experimental run was repeated five times under different conditions (low, medium, and high loads), and the average values for each performance metric were recorded for analysis.

**Anand and Nisha Jebaseeli****Baseline Comparison**

The AI-driven RL system's performance was compared against two baseline approaches:

Traditional ML models: Predictive models trained on historical data using regression techniques to estimate future resource needs. **Empirical Benchmarking:** Resource allocations based on static benchmarking tests that established optimal configurations for specific workloads. These configurations were not adjusted dynamically, making this method slower to adapt to fluctuating workloads.

Resource Allocation Framework

In the experimental setup, the AI-driven RL system was tasked with dynamically adjusting the resource allocations (CPU, memory, and storage) in response to real-time performance feedback. The RL agent monitored key metrics such as CPU utilization, memory consumption, disk I/O, and network latency. Based on this feedback, it continuously made decisions to either scale up or down the resources allocated to each VM or container instance. In contrast, the traditional ML model relied on predictions based on historical workload data and statically allocated resources. The empirical benchmarking approach, on the other hand, followed predefined configurations based on the best-performing settings observed during preliminary benchmarking runs.

Performance Metrics Monitored

The following performance metrics were continuously monitored during the experiment:

- **Response Time (ms):** The time taken to process and respond to each request.
- **Throughput (requests per second):** The number of requests processed within a specific time frame.
- **CPU Utilization (%):** The percentage of CPU capacity used by the system.
- **Memory Utilization (%):** The percentage of memory consumption in both VM-based and container-based environments.
- **Disk I/O (MB/s):** The read and write throughput on the disk.
- **Network Latency (ms):** The delay observed in data transmission across the network between VMs or containers.
- **Cost Efficiency (% savings):** The total resources used relative to the system's performance, calculated as a measure of resource optimization.

Experimental Results

The AI-driven RL model outperformed traditional ML and benchmarking methods across all key metrics. Below are the detailed results:

Analysis of Results**Response Time**

The RL model showed significant improvement in response time, reducing it by 25% compared to traditional ML and by 35% when compared to empirical benchmarking. The RL model dynamically allocated resources based on real-time workload changes, optimizing performance more effectively [7]. Containers benefited more from this optimization than VMs due to their lightweight nature and faster startup times [2].

Throughput

The RL-based system demonstrated a 30% improvement in throughput for containers and 20% for VMs. Traditional ML models were less adaptive, struggling with fluctuating workloads, and empirical benchmarking produced the lowest throughput, as it could not respond to workload changes dynamically [6].

Resource Utilization

The AI-driven system optimized CPU and memory usage by maintaining utilization between 60-75%, which allowed for efficient scaling without over provisioning. Traditional ML models had higher resource usage due to static predictions and inability to adjust in real-time, resulting in wasted resources and lower cost efficiency [5], [16].

**Anand and Nisha Jebaseeli****Disk I/O**

The RL model optimized disk I/O significantly in both environments, with containers showing the highest improvement due to reduced overhead compared to VMs. Traditional methods had lower efficiency, especially in high-load scenarios where disk operations were more intensive [3].

Network Latency

The AI-driven RL system reduced network latency by 10% for containers and 5% for VMs, as it could dynamically adjust resources to avoid network bottlenecks. Benchmarking and traditional ML methods struggled to handle network congestion during peak loads [10].

Cost Efficiency

One of the major benefits of the AI-driven RL system was its ability to reduce over provisioning and optimize resource utilization, leading to 25-30% cost savings in both VMs and containers. The cost savings were higher for containers due to their inherent efficiency, as well as the RL model's ability to fine-tune resources dynamically [18].

The RL-based system consistently outperformed others, particularly under high-load conditions. The RL-based system achieved the highest throughput, particularly in containerized environments, demonstrating the efficiency of dynamic resource allocation. The AI-driven RL system maintained optimal resource utilization, while traditional methods had higher variability due to inefficient allocation strategies. The 25% to 30% cost efficiency for AI-driven RL (VMs) is achieved through dynamic resource optimization, where the system continuously adjusts CPU, memory, and disk allocations in real time based on current workloads. Unlike traditional ML methods that statically allocate resources and often lead to over-provisioning, AI-driven RL minimizes resource wastage by reducing CPU and memory usage by up to 10-15%. This adaptive approach ensures that fewer resources are used without compromising performance, leading to significant cost savings compared to traditional methods that require manual tuning and retraining.

Comparative Analysis**Adaptability**

The RL system dynamically adjusted to fluctuating workloads without manual intervention, while ML models required retraining and empirical benchmarking could not respond in real-time. Containers benefited more from the adaptability of the RL system, as they could scale quickly and efficiently [5].

Scalability

The RL-based system demonstrated superior scalability, particularly in containerized environments. The system could scale resources with minimal latency, ensuring high throughput and reduced response times, even under heavy loads [7], [16].

Cost Efficiency

The cost efficiency of the AI-driven RL system was evident, with up to 30% savings achieved due to more precise resource provisioning. Traditional ML models and benchmarking approaches led to resource over provisioning and underutilization, especially during low-demand periods [18]. The experimental results clearly demonstrate that the AI-driven RL resource management system outperforms traditional ML models and empirical benchmarking across all key metrics, including response time, throughput, resource utilization, and cost efficiency. The system's ability to dynamically adjust resources in real-time, particularly in containerized environments, makes it ideal for modern cloud-native applications. Future work will focus on improving the training efficiency of the RL model and extending its application to multi-cloud and edge computing environments [17].

**Anand and Nisha Jebaseeli**

CONCLUSION

This research demonstrates the significant advantages of an AI-driven reinforcement learning (RL) system in optimizing resource management for Virtual Machines (VMs) and containers in cloud environments. The RL-based system dynamically adjusts resource allocation based on real-time workload data, yielding substantial improvements in key performance metrics such as response time, throughput, CPU utilization, and network latency. When compared to traditional machine learning (ML) models and empirical benchmarking methods, the RL system exhibited a 25-50% reduction in response time, a 15-30% increase in throughput, and improved resource utilization by reducing over provisioning by 15-20%. Additionally, the system achieved 10-15% higher cost savings by optimizing resource allocation more efficiently than conventional methods. The system's scalability and real-time adaptability make it particularly suited for cloud-native applications and environments with fluctuating workloads, especially in containerized setups.

Despite the promising results, several areas for future improvement and research have been identified. One critical area is the training efficiency of the RL model, which requires significant time and data, especially in complex cloud environments. Future work will focus on enhancing this by incorporating supervised learning techniques to accelerate the RL model's learning process. Furthermore, expanding the RL system to manage resources across multi-cloud and edge computing environments will provide greater flexibility and adaptability, allowing the system to efficiently handle more distributed and diverse workloads. In addition, security enhancements will be a vital aspect of future research, as containers face security challenges due to shared kernel vulnerabilities. Integrating AI-driven security mechanisms with the RL resource management framework could ensure optimized performance while addressing security risks. Finally, exploring hybrid AI models that combine different AI techniques (such as reinforcement learning with deep learning) could further optimize performance and adaptability, especially in highly dynamic and heterogeneous environments. Addressing these challenges will enable the proposed AI-driven resource management system to evolve into a more robust, adaptable, and efficient solution for cloud infrastructure management.

ABSTRACT

Heart disease remains a leading cause of mortality worldwide, necessitating effective classification and prediction methods to enhance early detection and intervention. This study proposes a novel Thrice Filtered Information Energy Optimization based Feature Selection (TFIE-OFS) method, which integrates Symmetrical Uncertainty, Information Gain, and Chi-Square Analysis to systematically filter and prioritize features from heart disease datasets. By employing Particle Swarm Optimization (PSO), the TFIE-OFS method optimizes feature subsets, ensuring the selection of the most informative variables while minimizing redundancy. The efficacy of the proposed method is evaluated through comprehensive experiments on benchmark heart disease datasets, where it demonstrates superior classification performance compared to existing feature selection techniques. The results indicate that TFIE-OFS significantly enhances predictive accuracy and model interpretability, providing a robust framework for heart disease classification and prediction. This innovative approach not only contributes to the field of medical data analytics but also holds potential for improving clinical decision-making in cardiology.

Keywords: Heart Disease, Classification, Feature Selection, Symmetrical Uncertainty, Information Gain, Particle Swarm Optimization, Chi-Square

INTRODUCTION

Heart disease has emerged as one of the foremost health challenges of the 21st century, contributing significantly to global morbidity and mortality rates [1] [2]. According to the World Health Organization, cardiovascular diseases account for approximately 31% of all global deaths, highlighting the urgent need for effective diagnostic and predictive tools. Early detection and accurate prediction of heart disease are critical for implementing timely interventions and improving patient outcomes. However, the complexity of heart disease risk factors and the vast amounts of health data pose significant challenges in developing robust predictive models [3] [4] [5]. Feature selection plays a crucial role in the classification and prediction of heart disease by identifying the most relevant variables that contribute to the condition. Traditional methods of feature selection often face limitations, such as high computational costs, redundancy among selected features, and the inability to capture complex relationships within the data. Therefore, an efficient and effective feature selection technique is essential for enhancing the performance of predictive models in this domain.

This study proposes a novel Thrice Filtered Information Energy Optimization based Feature Selection (TFIE-OFS) method, which leverages a combination of Symmetrical Uncertainty, Information Gain, and Chi-Square Analysis to filter and prioritize features systematically. By employing these three complementary approaches, TFIE-OFS captures various aspects of feature importance while mitigating the influence of irrelevant and redundant variables. Additionally, the TFIE-OFS method incorporates Particle Swarm Optimization (PSO) to enhance the selection process further. PSO is an intelligent optimization technique inspired by social behavior in animals, such as bird flocking. By mimicking this behavior, PSO effectively searches for optimal feature subsets by balancing exploration and exploitation within the feature space [6] [7] [8].

The primary objective of this research is to develop an effective and efficient feature selection methodology that can improve the classification and prediction accuracy of heart disease models. Through rigorous experimentation on benchmark heart disease datasets, we aim to demonstrate the superiority of TFIE-OFS over existing feature selection methods. In summary, this introduction outlines the critical importance of heart disease prediction, the challenges associated with feature selection, and the innovative approach proposed in this study. By combining multiple feature selection techniques and optimization algorithms, TFIE-OFS offers a promising solution for enhancing predictive modeling in cardiovascular health. This research not only contributes to the field of medical data analytics but also holds significant implications for clinical decision-making, ultimately leading to improved patient care and outcomes in heart disease management.

Background Study on Feature Selection Methods

Feature selection [9] [10] is a critical process in machine learning and data mining that involves identifying and selecting a subset of relevant features (or variables) for use in model construction. This process is particularly essential in the field of medical data analysis, where the complexity of the data can lead to overfitting, increased computational costs, and diminished interpretability of predictive models. In this background study, we explore various feature selection methods, their significance, and their application in the context of heart disease classification and prediction.

Types of Feature Selection Methods

Feature selection methods can be broadly classified into three categories: filter methods, wrapper methods, and embedded methods. Each category employs different strategies for selecting relevant features.

Filter Methods

Filter methods assess the relevance of features based on intrinsic properties of the data, independent of any machine learning algorithm. They are typically computationally efficient and suitable for high-dimensional datasets. Common filter methods include:

**Vanaja and Hari Ganesh**

Correlation Coefficient: Measures the statistical relationship between features and the target variable. High correlation indicates potential relevance.

Chi-Square Test: Evaluates the independence between categorical features and the target variable, identifying significant associations.

Information Gain: Measures the reduction in uncertainty about the target variable given knowledge of a feature. It quantifies how much information a feature contributes to the prediction.

Wrapper Methods

Wrapper methods evaluate feature subsets by training a specific model and assessing its performance. They are typically more accurate than filter methods but can be computationally expensive due to the repeated model training required. Common wrapper methods include:

Recursive Feature Elimination (RFE): Iteratively removes the least significant features based on model performance until the desired number of features is reached.

Forward Selection: Starts with an empty set of features and adds them one by one, evaluating model performance at each step to determine the best feature to add.

Backward Elimination: Begins with all features and removes them one at a time, selecting the least significant feature based on model performance.

Embedded Methods

Embedded methods combine feature selection and model training into a single process. They identify relevant features while the model is being trained, making them more efficient than wrapper methods. Common embedded methods include:

Lasso Regression: Uses L1 regularization to penalize the absolute size of coefficients, effectively shrinking some to zero, thus performing feature selection.

Decision Trees and Random Forests: These algorithms naturally perform feature selection by considering the importance of features in splitting the data during tree construction.

Gradient Boosting Machines: These models can also provide feature importance scores, allowing for the selection of significant features based on their contributions to the model.

Symmetrical Uncertainty (SU) Based Feature Selection Method

Symmetrical Uncertainty (SU) [11] [12] is a feature selection method that quantifies the amount of information gained about one variable through another, balancing the measure of uncertainty in both variables. It is particularly useful in the context of categorical variables and has become a popular choice in various machine learning applications, including medical diagnostics, where the interpretation of results is crucial. SU provides a normalized measure that ranges from 0 to 1, facilitating the comparison of feature relevance across different datasets. Symmetrical Uncertainty is derived from the concept of mutual information, which measures the amount of information that knowing the value of one variable provides about another. SU is defined mathematically as follows: Symmetrical Uncertainty is derived from the concept of mutual information, which measures the amount of information that knowing the value of one variable provides about another. SU is defined mathematically as follows:

$$SU(X, Y) = \frac{2 \cdot I(X, Y)}{H(X) + H(Y)}$$

Vanaja and Hari Ganesh

Where $I(X, Y)$ is the mutual information between variables X and Y . $H(X)$ and $H(Y)$ are the entropy of variables X and Y , respectively. Mutual Information (I): This metric quantifies the reduction in uncertainty of one variable due to the knowledge of another. It is calculated as:

$$I(X, Y) = H(X) + H(Y) - H(X, Y)$$

Entropy (H): This measures the unpredictability or randomness of a variable. It is calculated using the probability distribution of the variable:

$$H(X) = - \sum_{x \in X} P(x) \log P(x)$$

Information Gain (IG) Based Feature Selection Method

Information Gain (IG) [13] [14] is a widely used metric in feature selection and decision tree algorithms that measures the effectiveness of a feature in reducing uncertainty about the target variable. It quantifies the amount of information that knowing the value of a feature provides about the target outcome. IG is particularly beneficial in classification tasks, including medical diagnoses, where understanding the relationship between features and outcomes is essential for developing predictive models. Information Gain is based on the concept of entropy, which measures the unpredictability or randomness of a variable. The IG of a feature is calculated by comparing the entropy of the target variable before and after the dataset is split by that feature. Mathematically, Information Gain is defined as:

$$IG(T, A) = H(T) - H(T|A)$$

Where $IG(T, A)$ is the information gain of feature A with respect to target variable T . $H(T)$ is the entropy of the target variable before the split. $H(T|A)$ is the conditional entropy of the target variable after the dataset is split based on feature A .

Entropy is calculated using the formula:

$$H(X) = - \sum_{x \in X} P(x) \log_2 P(x)$$

Where $P(x)$ is the probability of occurrence of value x .

Chi-Square Analysis Based Feature Selection Method

Chi-Square Analysis [15] [16] is a statistical method used to determine the independence between categorical variables. In the context of feature selection, the Chi-Square test assesses the relationship between each feature and the target variable to identify significant predictors. This method is particularly valuable in classification tasks, especially in medical datasets where categorical variables are prevalent. By evaluating how well each feature correlates with the target outcome, Chi-Square Analysis helps improve model performance and interpretability. The Chi-Square test compares the observed frequencies of occurrences in a contingency table with the expected frequencies under the assumption of independence. The Chi-Square statistic is calculated using the following formula:

$$\chi^2 = \sum \frac{(O_i - E_i)^2}{E_i}$$

χ^2 is the Chi-Square statistic, O_i is the observed frequency for category i , E_i is the expected frequency for the category i .

The expected frequency is calculated as:

$$E_i = \frac{(\text{row total} \times \text{column total})}{\text{grand total}}$$

The resulting Chi-Square statistic indicates how much the observed counts deviate from the expected counts. A higher Chi-Square value suggests a stronger association between the feature and the target variable.

Particle Swarm Optimization Algorithm

Particle Swarm Optimization (PSO) [17] [18] is a nature-inspired optimization algorithm developed by James Kennedy and Russell Eberhart in 1995. It is based on the social behavior of birds and fish, where individuals

**Vanaja and Hari Ganesh**

(particles) in a swarm collaborate to find optimal solutions within a search space. PSO is particularly effective for solving complex optimization problems, including those in machine learning, engineering design, and parameter tuning. Its simplicity, ease of implementation, and ability to converge to global optima make it a popular choice in various applications.

In PSO, each particle represents a potential solution in the search space and has two primary characteristics:

Position: The current location of the particle, representing a possible solution to the optimization problem.

Velocity: The rate of change of the particle's position, determining how the particle moves through the search space. Particles adjust their positions based on their own experience and that of their neighbors, balancing exploration (searching new areas) and exploitation (refining existing solutions). The PSO algorithm consists of the following key steps:

Initialization

Define the optimization problem and its objective function.

Initialize a swarm of particles with random positions and velocities within the defined search space.

Set parameters such as the number of particles, maximum iterations, and coefficients for cognitive and social components.

Fitness Evaluation

Evaluate the fitness of each particle by calculating the objective function's value at its current position.

Update Personal and Global Bests

For each particle, compare its fitness with its personal best (the best position it has encountered so far) and update it if the current position is better.

Determine the global best (the best position encountered by any particle in the swarm) based on fitness evaluations.

Update Velocity and Position

Adjust each particle's velocity using the following formula: $v_i = \omega \cdot v_i + C_1 \cdot r_1 \cdot (p_i - x_i) + C_2 \cdot r_2 \cdot (g - x_i)$ where v_i is the particle's current velocity, ω is the inertia weight that controls exploration versus exploitation, C_1 and C_2 are acceleration coefficients (typically set between 1.5 and 2), r_1 and r_2 are random numbers between 0 and 1, p_i is the personal best position of particle i , g is the global best position. Update the particle's position using: $x_i = x_i + v_i$

Iteration

Repeat steps 2 to 4 until a stopping criterion is met (e.g., maximum iterations or a satisfactory fitness level).

Output

Return the global best position and its corresponding fitness value as the optimal solution.

A Thrice Filtered Information Energy Optimization Based Feature Selection (TFIE-OFS) Method

The following are the step-by-step procedure for the proposed TFIE-OFS method.

Step 1: Data Preprocessing

Data Collection: Gather the dataset for the prediction or classification task (e.g., heart disease dataset).

Handle Missing Values: Impute missing values using techniques such as mean, median, or mode, or remove entries with significant missing data.

Feature Scaling & Encoding : Normalize numerical features using scaling techniques (e.g., Min-Max Scaling or Z-Score normalization). Convert categorical features into numerical format using label encoding or one-hot encoding.

**Vanaja and Hari Ganesh**

Split the Dataset: Divide the dataset into training and testing sets. The training set will be used for feature selection and model building, while the test set will be used to evaluate performance.

Step 2: Apply Three Filtering Methods: The feature selection begins by applying three filters independently, each of which evaluates the relevance of the features with respect to the target variable.

Step 2.1: Symmetrical Uncertainty (SU) Filter

Calculate Symmetrical Uncertainty: Compute the SU score for each feature by measuring the correlation between the feature and the target variable.

Rank Features: Rank the features based on their SU scores.

Select Top Features: Select the top k features with the highest SU scores. These are considered the most relevant to the target variable.

Step 2.2: Information Gain (IG) Filter

Calculate Information Gain: Compute the IG for each feature by quantifying the reduction in entropy when the feature is known.

Rank Features: Rank the features based on their IG scores, where higher IG values indicate greater importance.

Select Top Features: Select the top kkk features with the highest IG scores.

Step 2.3: Chi-Square Filter

Perform Chi-Square Test: For each feature, apply the Chi-Square test to determine its level of independence from the target variable.

Rank Features: Rank the features based on their Chi-Square values. Higher values suggest a stronger dependency between the feature and the target.

Select Top Features: Select the top k features with the highest Chi-Square values.

Step 3: Combine Results of the Three Filters

Step 3.1: Intersection of Feature Sets: Combine the results of the three filters (SU, IG, and Chi-Square) by taking the intersection of the top-ranked features from each method.

This ensures that only the most relevant features, as agreed upon by all three methods, are retained for further analysis.

The combined feature set is smaller and more focused on high-impact predictors.

Step 4: Particle Swarm Optimization (PSO) for Feature Selection

Once the filtered feature set is determined, PSO is used to further optimize the selection of features.

Step 4.1: Initialize PSO Algorithm

Swarm Initialization: Initialize a population (swarm) of particles. Each particle represents a potential subset of the selected features from Step 3.

Position & Velocity: Initialize the position and velocity of each particle randomly. The position represents a feature subset.

**Vanaja and Hari Ganesh****Step 4.2: Define Fitness Function**

Classification Performance: The fitness function evaluates how well the selected feature subset performs in classification. Use a machine learning model (e.g., Support Vector Machine, Decision Tree) to calculate performance metrics such as accuracy or F1-score.

Fitness Value: The fitness value for each particle is the classification accuracy (or any relevant performance metric) of the model using the particle's feature subset.

Step 4.3: Update Particle Velocity & Position

For each particle, update the velocity using the above mentioned formula.

Step 4.4: Evaluate Fitness of Each Particle

After updating the position, evaluate the fitness (classification performance) of the new feature subset for each particle.

Update Personal Best (p_i): If a particle's current fitness is better than its personal best, update its personal best.

Update Global Best (g): If any particle's current fitness is better than the global best, update the global best.

Step 4.5: Iterate Until Convergence

Repeat the velocity and position updates, and re-evaluate the fitness of particles for a predefined number of iterations or until convergence (when no further improvement is observed in the global best).

Step 5: Select Optimal Feature Subset**Step 5.1: Identify the Best Feature Subset**

Once PSO converges, the global best position (i.e., the best-performing feature subset) is selected as the optimal feature set.

Step 5.2: Train Final Model

Use the optimal feature subset to train the final classification model (e.g., on a Decision Tree, SVM, or any chosen model).

RESULT AND DISCUSSION**Performance Metrics**

The performance of the proposed Feature Selection method is evaluated with their existing feature selection methods like Genetic Algorithm, Artificial Bee Colony (ABC) Optimization, Whale Optimization Algorithm (WOA), and Cultural Algorithm (CA) using classification techniques like Artificial Neural Network (ANN), Support Vector Machine (SVM) and Random Forest (RF). The dataset used in this research work is considered from the Kaggle Repository [19] Table 1 depicts the performance metrics used to evaluate the performance of the proposed and existing feature selection methods. Table 2 depicts the number of features obtained by the Proposed and existing feature selection methods. From the table 2, it is clear that the proposed TFIE-OFS method gives less number of features than the existing feature selection methods. Table 2 compares the number of features selected by the existing feature selection methods (Symmetrical Uncertainty (SU), Information Gain (IG), Chi-Square (CS)) and the proposed Thrice Filtered Information Energy Optimization-based Feature Selection (TFIE-OFS) method. The proposed TFIE-OFS method selects a more refined set of features, emphasizing its efficiency in identifying the most relevant attributes for classification. The SU method selects a total of 9 features, including key attributes like "chol," "cp," and "exang.". The IG method also selects 7 features, but with variations such as the absence of "age" and "trestbps.". The CS method selects 7 features but includes a different set, emphasizing "old peak" and "trestbps.". The proposed TFIE-OFS method selects 6 features, streamlining the selection to the most critical attributes such as "cp," "ca," and "thal."

**Vanaja and Hari Ganesh**

Table 3 depicts the classification accuracy (in %) obtained by the Heart Disease dataset using original dataset, GA, ABC, WOA, CA and proposed TFIE-OFS methods processed datasets. Table 3 presents the classification accuracy (in %) of various classification techniques (ANN, RF, SVM) applied to the heart disease dataset after using different feature selection methods: Genetic Algorithm (GA), Artificial Bee Colony (ABC), Whale Optimization Algorithm (WOA), Crow Search Algorithm (CA), and the proposed TFIE-OFS method. The original dataset without feature selection provides the lowest classification accuracy across all classifiers: 48.32% (ANN), 43.97% (RF), and 42.86% (SVM), indicating the necessity of feature selection to improve performance. Among the existing feature selection methods, CA yields the highest accuracy: 72.59% (ANN), 71.67% (RF), and 69.78% (SVM). The proposed TFIE-OFS method achieves the highest classification accuracy across all classifiers, with 94.91% (ANN), 93.46% (RF), and 85.69% (SVM), showing a substantial improvement over the other methods. GA achieves respectable results but still lags behind TFIE-OFS, with accuracies of 70.84% (ANN), 69.34% (RF), and 67.43% (SVM). ABC and WOA produce similar but slightly lower accuracies, ranging between 55-59% for all classifiers.

Table 4 depicts the True Positive Rate (in %) obtained by the Heart Disease dataset using original dataset, GA, ABC, WOA, CA and proposed TFIE-OFS methods processed datasets. Table 4 presents the True Positive Rate (in %) of various classification techniques (ANN, RF, SVM) applied to the heart disease dataset after using different feature selection methods: Genetic Algorithm (GA), Artificial Bee Colony (ABC), Whale Optimization Algorithm (WOA), Crow Search Algorithm (CA), and the proposed TFIE-OFS method. The original dataset without feature selection results in the lowest True Positive Rate (TPR), with 52.76% (ANN), 51.26% (RF), and 46.35% (SVM), highlighting the need for feature selection to improve detection rates. Among the existing methods, CA achieves the highest TPR, with 83.19% (ANN), 82.3% (RF), and 69.24% (SVM). The proposed TFIE-OFS method significantly outperforms all other methods, achieving TPRs of 95.51% (ANN), 92.42% (RF), and 79.96% (SVM), indicating superior performance in correctly identifying positive cases. GA shows competitive results with TPRs of 74.45% (ANN), 73.05% (RF), and 71.16% (SVM), but still lags behind TFIE-OFS. ABC and WOA exhibit similar performance, with TPRs ranging from 59-63% across all classifiers, which is higher than the original dataset but lower than GA and CA.

Table 5 depicts the False Positive Rate (in %) obtained by the Heart Disease dataset using original dataset, GA, ABC, WOA, CA and proposed TFIE-OFS methods processed datasets. Table 5 presents the False Positive Rate (FPR in %) of various classification techniques (ANN, RF, SVM) applied to the heart disease dataset after using different feature selection methods: Genetic Algorithm (GA), Artificial Bee Colony (ABC), Whale Optimization Algorithm (WOA), Crow Search Algorithm (CA), and the proposed TFIE-OFS method. The original dataset shows the highest False Positive Rate across all classifiers, with 56.58% (ANN), 63.8% (RF), and 64.32% (SVM), highlighting its poor ability to minimize false positives without feature selection. Among the existing methods, CA achieves the lowest FPR, with 25.60% (ANN), 31.91% (RF), and 33.42% (SVM). The proposed TFIE-OFS method significantly outperforms all other methods, reducing the FPR to 5.72% (ANN), 5.36% (RF), and 13.36% (SVM), indicating a dramatic reduction in false positives and enhancing the accuracy of classification. GA performs moderately, reducing FPR to 32.87% (ANN), 35.31% (RF), and 36.22% (SVM), which is significantly better than the original dataset but higher than CA and TFIE-OFS. ABC and WOA have similar FPR values, ranging from 43-48%, which is better than the original dataset but worse than GA and CA.

Table 6 depicts the Precision (in %) obtained by the heart disease dataset using original dataset, GA, ABC, WOA, CA and proposed TFIE-OFS methods processed datasets. Table 6 presents the Precision (in %) obtained by various classification techniques (ANN, RF, SVM) applied to the heart disease dataset after using different feature selection methods: Genetic Algorithm (GA), Artificial Bee Colony (ABC), Whale Optimization Algorithm (WOA), Crow Search Algorithm (CA), and the proposed TFIE-OFS method. The original dataset yields the lowest precision across all classifiers: 51.60% (ANN), 47.71% (RF), and 46.53% (SVM), indicating high levels of false positives without feature selection. Among the existing feature selection methods, CA achieves the highest precision, with 80.17% (ANN), 73.20% (RF), and 72.83% (SVM). The proposed TFIE-OFS method dramatically improves precision across all classifiers, with the highest values: 95.53% (ANN), 94.32% (RF), and 82.65% (SVM), demonstrating its superior performance in accurately identifying positive instances. GA also delivers competitive precision results, with 73.52%

**Vanaja and Hari Ganesh**

(ANN), **70.60%** (RF), and **69.81%** (SVM), though it still falls short of CA and TFIE-OFS. ABC and WOA perform similarly, with precision values in the **60-63%** range, which is an improvement over the original dataset but not as effective as GA, CA, or TFIE-OFS.

Table 7 depicts the Specificity (in %) obtained by the heart disease dataset using original dataset, GA, ABC, WOA, CA and proposed TFIE-OFS methods processed datasets. Table 7 shows the Specificity (in %) of various classification techniques (ANN, RF, SVM) applied to the heart disease dataset after different feature selection methods: Genetic Algorithm (GA), Artificial Bee Colony (ABC), Whale Optimization Algorithm (WOA), Crow Search Algorithm (CA), and the proposed TFIE-OFS method. The original dataset exhibits the lowest Specificity across all classifiers: 43.42% (ANN), 36.2% (RF), and 35.68% (SVM), indicating poor performance in identifying true negatives without feature selection. Among the existing methods, CA provides the highest Specificity, with 74.4% (ANN), 68.09% (RF), and 66.58% (SVM), reflecting a notable improvement. The proposed TFIE-OFS method achieves the highest Specificity across all classifiers: 94.28% (ANN), 92.64% (RF), and 86.64% (SVM), showcasing its superior ability to correctly identify negative cases. GA also performs well, yielding Specificity values of 67.13% (ANN), 64.69% (RF), and 63.78% (SVM), but remains less effective than CA and TFIE-OFS. ABC and WOA show moderate improvements, with Specificity values in the 51-56% range, indicating some effectiveness but falling behind GA, CA, and TFIE-OFS.

Table 8 depicts the Miss Rate (in %) obtained by the Heart Disease dataset using original dataset, GA, ABC, WOA, CA and proposed TFIE-OFS methods processed datasets. Table 8 presents the Miss Rate (in %) obtained by various classification techniques (ANN, RF, SVM) when applied to the heart disease dataset processed using different feature selection methods: Genetic Algorithm (GA), Artificial Bee Colony (ABC), Whale Optimization Algorithm (WOA), Crow Search Algorithm (CA), and the proposed TFIE-OFS method. The original dataset produces the highest Miss Rates: 47.24% (ANN), 48.74% (RF), and 53.65% (SVM), indicating a high rate of misclassification without feature selection. GA reduces the Miss Rate significantly to 25.55% (ANN), 26.95% (RF), and 28.84% (SVM), though it is still not as effective as CA or the proposed TFIE-OFS method. ABC and WOA have moderate Miss Rates, ranging from 36.66% to 40.87%, showing a better performance than the original dataset but are less effective than GA, CA, or TFIE-OFS. CA achieves a substantial reduction in Miss Rate, especially for ANN and RF classifiers, with values of 16.81% (ANN) and 17.7% (RF). However, for SVM, the Miss Rate is relatively higher at 30.76%. The proposed TFIE-OFS method achieves the lowest Miss Rates: 4.49% (ANN), 7.58% (RF), and 20.04% (SVM), demonstrating its superior ability to minimize classification errors across all classifiers.

Table 9 depicts the False Discovery Rate (in %) obtained by the heart disease dataset using original dataset, GA, ABC, WOA, CA and proposed TFIE-OFS methods processed datasets. Table 9 presents the False Discovery Rate (FDR in %) obtained by applying various classification techniques (ANN, RF, SVM) to the heart disease dataset processed using different feature selection methods: Genetic Algorithm (GA), Artificial Bee Colony (ABC), Whale Optimization Algorithm (WOA), Crow Search Algorithm (CA), and the proposed TFIE-OFS method. The original dataset exhibits high False Discovery Rates, with values of 48.4% (ANN), 52.29% (RF), and 53.47% (SVM), indicating a substantial number of false positives when no feature selection is applied. The GA method leads to a noticeable reduction in FDR to 26.48% (ANN), 29.4% (RF), and 30.19% (SVM), demonstrating some effectiveness in improving classification accuracy compared to the original dataset. ABC and WOA achieve moderate reductions in FDR, with values ranging from 36.24% to 43.99%, reflecting a better performance than the original dataset but still higher than GA and CA. The CA method significantly lowers the FDR, achieving 19.83% (ANN), 26.8% (RF), and 27.17% (SVM), indicating its strong potential in minimizing false discoveries. The proposed TFIE-OFS method shows remarkable results, yielding the lowest False Discovery Rates of 4.47% (ANN), 5.68% (RF), and 17.35% (SVM), showcasing its effectiveness in correctly identifying true positives and significantly reducing false positives.

Vanaja and Hari Ganesh

CONCLUSION

The Thrice Filtered Information Energy Optimization Based Feature Selection (TFIE-OFS) method represents a significant advancement in feature selection techniques for classification and prediction tasks, particularly in high-dimensional datasets such as those used in heart disease diagnosis. By integrating three robust filtering methods—Symmetrical Uncertainty, Information Gain, and Chi-Square Analysis—TFIE-OFS effectively narrows down the feature space to include only the most relevant predictors. This multi-filtering approach ensures a comprehensive assessment of feature importance, leading to a more refined selection process. Furthermore, the incorporation of Particle Swarm Optimization (PSO) enhances the feature selection process by optimizing the subset of features based on their contribution to model performance. The results from the various evaluations of the Thrice Filtered Information Energy Optimization-based Feature Selection (TFIE-OFS) method indicate its significant efficacy in improving the performance of heart disease classification tasks. The proposed TFIE-OFS method consistently outperformed existing feature selection techniques across multiple metrics, demonstrating its ability to enhance classification accuracy, reduce false discovery rates, minimize miss rates, and maintain high specificity.

ABSTRACT

As cloud computing continues to gain prominence, the need for effective forensic methodologies tailored to cloud environments has become increasingly critical. This literature review explores the integration of machine learning (ML) and deep learning (DL) techniques in cloud forensics, aiming to enhance the efficiency and effectiveness of digital investigations. The review highlights various applications of ML and DL algorithms in tasks such as data acquisition, anomaly detection, and evidence extraction, emphasizing their ability to process vast amounts of data generated in cloud environments. Key challenges, including data privacy concerns, the complexity of cloud architectures, and the need for real-time analysis, are also addressed. Furthermore, the review discusses the advantages of employing these advanced techniques over traditional forensic methods, showcasing case studies that demonstrate their successful implementation. By synthesizing current research, this review aims to provide a comprehensive understanding of how ML and DL can transform cloud forensic practices, paving the way for future innovations in the field.

Keywords: Cloud Computing, Machine learning, Deep Learning, Cloud Forensic, Traditional Forensic Methods

INTRODUCTION

The proliferation of cloud computing has revolutionized the way organizations manage, store, and analyze data. With its scalability, flexibility, and cost-effectiveness, cloud computing has become the backbone of modern information technology infrastructure. However, as organizations increasingly migrate to cloud environments, the need for robust forensic methodologies to investigate incidents involving cloud services has also grown. Traditional digital forensics techniques, originally designed for on-premises systems, often fall short in addressing the unique challenges posed by cloud architectures, such as data distribution, multi-tenancy, and dynamic resource allocation [1]. Digital forensics in cloud environments involves the collection, preservation, analysis, and presentation of digital evidence from cloud services. This process is inherently complex due to the virtualization of resources and the abstracted nature of cloud services. Consequently, the investigation of cloud-related incidents, such as data breaches, insider threats, and unauthorized access, necessitates advanced forensic approaches that can adapt to the evolving landscape of cloud computing [2].

In recent years, machine learning (ML) and deep learning (DL) have emerged as powerful tools in various domains, including cybersecurity and digital forensics. ML algorithms can analyze large datasets, identify patterns, and make predictions based on historical data, making them particularly suitable for forensic investigations where vast amounts of information need to be processed quickly and accurately. On the other hand, DL techniques, which leverage neural networks to model complex data patterns, have shown significant promise in tasks such as image and speech recognition, natural language processing, and anomaly detection [3]. The integration of ML and DL in cloud forensics presents a paradigm shift, enabling investigators to automate and enhance various stages of the forensic process. For instance, these technologies can facilitate the automated identification of malicious activities, streamline data acquisition processes, and improve the accuracy of evidence analysis. Moreover, ML and DL can assist forensic analysts in filtering through vast amounts of cloud data, allowing them to focus on critical evidence while minimizing manual effort [4].

Despite the potential benefits, the application of ML and DL in cloud forensics is not without challenges. Issues such as data privacy, compliance with legal frameworks, and the intricacies of cloud service provider architectures must be carefully considered. Additionally, the evolving nature of cyber threats necessitates continuous updates and training of ML and DL models to ensure their effectiveness in detecting and responding to new attack vectors [5]. This literature review aims to explore the current state of research on the application of ML and DL in cloud forensic environments. By analyzing existing studies, case examples, and emerging trends, this review seeks to provide a comprehensive understanding of how these advanced techniques can enhance cloud forensic practices. Furthermore, it will highlight the challenges and limitations associated with their implementation, paving the way for future research and innovations in the field.

Background Study Of Digital Forensic

Digital forensics, often referred to as computer forensics, is the practice of collecting, analyzing, and preserving digital evidence from electronic devices such as computers, smartphones, servers, and storage media to investigate and solve crimes or security incidents. The primary goal of digital forensics is to maintain the integrity of evidence while adhering to legal and procedural standards so that it can be used in both criminal and civil court proceedings. Over the years, digital forensics has evolved significantly in response to the increasing complexity of digital devices, networks, and the growing sophistication of cybercrimes [6]. The field covers a wide range of activities, including the recovery of deleted files, analysis of computer logs, detection of malware or malicious software, investigation of unauthorized access or data breaches, and reconstruction of digital actions taken by individuals or groups.

**Mahalakshmi and Subhashini****Historical Development of Digital Forensics**

Digital forensics traces its roots to the late 20th century, coinciding with the growth of computers and the internet. The term "computer forensics" emerged in the 1980s as computers became more widely used in business, education, and government sectors. The increasing reliance on computers and networked systems brought about new avenues for criminal activities, necessitating the development of specialized techniques for investigating such crimes [7]. In its early days, digital forensics primarily involved analyzing standalone computer systems, focusing on recovering data from hard drives and investigating cybercrimes such as hacking, fraud, and intellectual property theft. However, as digital devices and internet technologies evolved, so did the field of digital forensics. The expansion of mobile devices, cloud computing, social media, and the Internet of Things (IoT) has introduced new challenges and opportunities, leading to the development of various subfields of digital forensics.

Key Subfields of Digital Forensics

Digital forensics is now an umbrella term that covers several specialized subfields, each addressing specific types of digital devices, networks, or incidents [8]:

Computer Forensics: Focuses on investigating desktop and laptop computers. It involves analyzing file systems, memory, logs, and applications to recover evidence of criminal activities such as fraud, hacking, or insider threats.

Network Forensics: Involves the monitoring and analysis of network traffic and activities. It is crucial for investigating network intrusions, data breaches, distributed denial-of-service (DDoS) attacks, and unauthorized access to systems.

Mobile Device Forensics: Specializes in the extraction and analysis of data from smartphones, tablets, and other handheld devices. With the increasing use of mobile apps and services, mobile forensics plays a vital role in investigations related to social media, messaging apps, and location data.

Cloud Forensics: A newer branch that deals with the challenges of investigating incidents in cloud environments. Cloud forensics requires unique approaches for acquiring and analyzing data stored on remote servers and managed by third-party service providers.

Memory Forensics: Focuses on analyzing volatile data stored in computer memory (RAM). This subfield is particularly important for uncovering malware, rootkits, and other malicious activities that reside in memory but do not leave traces on the hard disk.

IoT Forensics: As the number of IoT devices increases, this subfield addresses the challenges of investigating incidents involving interconnected devices such as smart home systems, wearables, and industrial IoT sensors.

The Digital Forensic Process

The process of digital forensics is generally divided into several key phases that ensure the proper handling and analysis of digital evidence. These phases include [9]:

Identification: This phase involves identifying the digital devices or systems that may contain evidence relevant to the investigation. It also includes defining the scope of the investigation, determining the types of data to be collected, and understanding the potential sources of evidence.

Preservation: The preservation of digital evidence is critical to maintaining its integrity. This phase ensures that the data is not altered or corrupted during the investigation. It involves creating exact copies (forensic images) of the digital media for analysis, while the original data is securely stored to maintain its chain of custody.

Collection: In this phase, investigators gather relevant data from the identified devices or networks. This can involve copying hard drives, extracting data from cloud services, retrieving logs from network devices, and using specialized tools to access encrypted or hidden files.

Mahalakshmi and Subhashini

Analysis: This is the most time-consuming phase, where investigators examine the collected data for evidence of criminal or unauthorized activities. This phase may involve recovering deleted files, examining file metadata, identifying malware or suspicious software, and tracking user actions. The analysis must be performed methodically and documented thoroughly for accuracy and transparency.

Interpretation: The interpretation phase focuses on making sense of the analyzed data. It involves drawing conclusions based on the evidence and reconstructing events or timelines that explain how the crime or security incident occurred.

Reporting: Finally, the investigator compiles the findings into a formal report. This report must be clear, concise, and understandable to non-technical stakeholders, such as law enforcement, lawyers, or court officials. It must also adhere to legal standards so that the evidence can be presented in court if necessary.

Background Study Of Cloud Forensic

Cloud forensics is a specialized subfield of digital forensics that focuses on the investigation and analysis of digital evidence stored and processed in cloud computing environments. As organizations increasingly adopt cloud services to host their applications, store data, and leverage scalable infrastructure, the necessity for effective forensic methodologies tailored to these complex environments has become paramount [10].

Evolution of Cloud Forensics

The rise of cloud computing, characterized by on-demand access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications), has transformed how organizations manage data. While cloud computing offers numerous benefits, including cost efficiency, scalability, and flexibility, it also introduces unique challenges for forensic investigations. Initially, digital forensics techniques were designed for traditional IT environments, where data was localized and easier to manage. However, with the emergence of cloud computing in the early 2000s, investigators faced new hurdles due to the distributed nature of data across multiple servers and geographical locations. The challenges associated with investigating incidents in cloud environments prompted the development of cloud forensics as a distinct field.

Core Principles of Cloud Forensics

Cloud forensics operates under several guiding principles to ensure the integrity and reliability of the investigation process:

Data Ownership and Jurisdiction: Cloud environments often involve multiple stakeholders, including cloud service providers (CSPs), third-party vendors, and clients. Understanding data ownership and the legal jurisdiction in which data resides is crucial for forensic investigations, as these factors influence the accessibility and admissibility of evidence.

Data Preservation: In cloud forensics, preserving data integrity is critical. Investigators must create forensic copies of relevant cloud data without altering it. This often involves working closely with CSPs to ensure proper data preservation techniques are employed, especially when dealing with volatile data such as logs and ephemeral data.

Chain of Custody: Maintaining a proper chain of custody is essential to ensure the admissibility of digital evidence in legal proceedings. This involves documenting every step of the forensic process, from data acquisition to analysis, and ensuring that all actions taken are traceable and reproducible.

Comprehensive Data Acquisition: Cloud forensics requires a thorough understanding of cloud architecture and services. Investigators must identify all potential sources of evidence, including virtual machines, storage buckets, and application logs, to ensure comprehensive data acquisition.

LITERATURE REVIEW

Sachdeva, Shaweta, and Aleem Ali [11] Several distributed denial of service assaults, including the User Datagram Protocol Attack, Transmission Control Protocol Sync Attack, and Internet Control Message Protocol Attack, were taken into consideration for data classification in this research. With the advent of digital forensics, the explosion of network traffic and its variety on the Internet presented a new difficulty for attack detection. This document computes the maximum True Negative Rate, accuracy, and precision. We suggest a machine learning-based approach for attack classification in cloud networks that incorporates a digital forensics procedure. Our results show that our detection approach has outstanding True Negative Rate, accuracy, and precision. As a result, the deep learning-based fusion technique we have suggested for Digital Forensics performs admirably as a data classification detective. Kathane, Kavita Arun, and Viren Kumar Sharma [12] introduced an innovative framework that uses Deep Q-Network (DQN) for intelligent decision-making, Long Short-Term Memory (LSTM) based Graph Analysis for relational data processing, and Gated Recurrent Units (GRU) combined with Recurrent Neural Networks (RNN) for dynamic user profile activities. A special blend of adaptability, real-time processing activities, and profound contextual understandings is provided by this synergistic method. We show that, in a variety of scenarios, our framework increases the accuracy by 8.3%, recall by 4.9%, precision of attack event categorisation by 4.5%, and Area under the Curve (AUC) by 5.5%. These developments improve real-time threat identification and user-specific anomaly detection procedures while also greatly reducing false positives and false negatives. This research opens the door for a new breed of flexible, effective, and efficient cloud forensic systems, greatly enhancing the security posture of contemporary cloud computing environments by overcoming the drawbacks of previous approaches.

Senthil, P., and S. Selvakumar [13] presented a hybrid deep learning strategy for forensic investigation that is based on integrated multi-model data fusion (HDL-DFI). First, we focus on digital evidence gathering and management systems, which can be accomplished using an improved brain storm optimisation (IBSO) algorithm in conjunction with an integrated data fusion model. Here, we examine a variety of multimedia data—text, image, speech, physiological signals, and video—for the objective of providing proof. Then, in order to prevent duplicate and redundant data when gathering evidence, we introduce a recurrent multiplicative neurone with a deep neural network (RM-DNN). Next, we create a sentiment analysis multistage dynamic neural network (MDNN) to determine the sort of crime that has occurred and categorise the action on it. Finally, our suggested HDL-DFI model built with the standard benchmark database and its fallouts are compared to the state-of-the-art replicas (AUC) in terms of accuracy, precision, recall, F1-score, G-mean, and area under the curve. Savaridassan, P., and G. Maragatham [14] The goal of the Integrated Deep Auto-Encoder and Q-learning-based Deep Learning (IDEA-QLDL) Scheme is to maximise prediction accuracy while examining log data and dividing it into authentic and anomalous observations. It starts the acceptance/denial process based on ongoing analysis of highly applicable behavioural patterns for classification. When compared to the benchmarked schemes that were taken into consideration for inquiry, the findings of the proposed IDEA-QLDL Scheme demonstrated its superiority in enhancing the classification accuracy, precision, recall, and detection time.

Chitti, Praveen, K. Prabhushetty, and Shridhar Allagi [15] In the suggested approach, the authors use Discrete Cosine Transform (DCT) for feature extraction in the second iteration of the Convolution Neural Network machine learning model, and SVM in the first iteration for detecting the forged region. An average accuracy of 98% is achieved for all types of picture operations, including scaling, rotation, and augmentation, when the suggested model is tested on a Corel 10K dataset. Bhardwaj, Sonam, and Mayank Dave [16] A model for gathering and preserving crypto-evidence is put forth. The model is used to classify network traffic data as either harmful or non-malicious, detect malware attacks, and retain evidence. The gathered digital evidence is effectively preserved, and it is kept in protected mode (tamper-safe). Deep learning and machine learning classifiers are used to extract malware traffic meta-data. Numerous studies have demonstrated that while ensemble classifiers raise the likelihood of improved malware prediction analysis and real-time data flowing over a network, deep learning effectively helps the study of big data sets. The deep learning model proposed in this article is based on an ensemble classifier, and it can be used to

**Mahalakshmi and Subhashini**

investigate malicious packets, preserve evidence using the SHA-256 cryptosystem, learn from collected data, and maintain the evidence's availability when needed for forensic investigations involving malware attacks on networks.

Srilatha, Doddi, and N. Thillaiarasu [17] This article looks at how cloud resources are affected and suggests a practical intrusion detection system (IDS) called DDoSNet. This research study makes use of the CICIDS 2017 dataset to assess models. For feature selection, the intelligence technique of particle swarm optimisation (PSO) is used. To categorise the given data as benign or malicious, the deep neural network (DNN) model receives as input the optimum features. When evaluating the model, the accuracy rate, precision, recall, and F1-score metrics are taken into account. The experimental findings indicate 099.81% accuracy, 099.77% precision, 099.89% recall, and 099.83% F1 score. The system that is being shown performs better than traditional machine learning models. As such, this strategy instills great confidence in cloud service security. Sachdeva, Shaweta, and Aleem Ali [18] gave a thorough understanding of the issue at hand and suggested narrative remedies for the examination of current log analysis, TCP Sync Attack, UDP Attack, and ICMP Attack. Using a hybrid technique, digital forensics for attack detection in a cloud network environment might improve present computational complexity difficulties and apply cyber-forensic investigation (KNN, MLP) in a less complex system. Our suggested method works incredibly well for categorising the attack dataset.

Hemdan, Ezz El-Din, and D. H. Manjaiah [19] offered a productive Cloud Forensics Investigation Model (CFIM) for prompt, forensically sound cloud criminal investigation. In addition, the suggested solution incorporates the idea of Forensic as a Service (FaaS), which offers a host of advantages for doing digital forensics via the use of Forensic Server in the cloud. The findings of the inquiry demonstrated that the suggested approach can effectively support digital investigators in their quest to look into cybercrimes in the cloud. Manzoor, Nosheen, *et al* [20] Digital crime is investigated through the use of digital forensics. The most deadly cyberattacks on the internet are those that use botnets. It is difficult to conduct a digital forensic analysis into botnet attacks. The capacity of attackers to plan increasingly intricate attacks with Botnets is expanding. To counter such attacks, the digital forensics must be strengthened. In network forensics, machine learning is crucial for quickly and effectively identifying various types of botnet attacks. Machine learning techniques were applied to various network forensic methods. Botnet assaults are not only detected but also prevented using machine learning algorithms. This paper presents a summary of the various botnet assaults and digital forensic investigative approaches to counter the botnet attacks. To present the evidence in a court of law, forensic investigation of Botnet detection requires a consistent framework. In the article, many network forensic approaches have also been described.

Lv, Zhihan, and Ranran Lou [21] In order to strengthen cloud storage security, the current work investigates edge-fog-cloud computing storage security. The study uses pre-processed data from an industrial intelligent manufacturing machine. Perception data for machine production comprises both data transmission and data storage. Additionally, digital twins technology is utilised to create a digital twin in the real world that simulates the online data-driven behaviour of machine production, along with the perceptual data of machine manufacturing. 3Dmax builds and saves the digital twins model. At last, deep learning technology is presented as a means of preventing network intrusion. Both external and internal assaults by cloud data providers can affect cloud databases. In order to guarantee that the database contains ciphertext data and executes data queries directly, the homomorphic encryption algorithm and secure multi-party computing are implemented. Adikari, Samriddha, Jinfeng Su, and Kamini Simi Bajaj [22] This study's objective is to use secondary research to examine recent findings on deep learning-based network forensic optimisation methods. The main conclusions are that deep learning technology outperforms state-of-the-art techniques in identifying assaults during data communication in Internet of Things systems. The main parts of the systems that the researchers proposed were found in this study, arranged in a table, and categorised using a methodology that demonstrated the ability of deep learning technology to recognise attacks in Internet of Things devices.

Shakeel, P. Mohamed, *et al* [23] suggested using the blockchain-assisted shared audit framework (BSAF) to examine IoT platform digital forensic data. In order to identify the origin or source of data scavenging attacks in virtualised

**Mahalakshmi and Subhashini**

resources (VR), a recommended methodology was created. Blockchain technology is used in the suggested architecture to manage access logs and controls. Using cross-validation and logistic regression (LR) machine learning, adversary event detection consistency is examined in access log data. Thapaliya, Suman, and Pawan Kumar Sharma [24] A model that takes feature fusion into account is described for identifying cyberattacks. The Fractional Gravitational Search Algorithm (FGSA) is used to route data towards Base Station (BS). Cybercrime detection is carried out at BS, where data is divided using enhanced fuzzy c-means clustering (FCM) while taking the MapReduce model into consideration. While the reduction handles cybercrime detection, the mapper uses mutual information and the Deep Quantum Neural Network (DQNN) to fuse features. The Deep Belief Network (DBN) based on Fractional Mayfly Shepherd Optimisation (FrMSO) is designed to describe the digital examination to detect and track the behaviours of attacks in the Internet of Things. The suggested FrMSO algorithm, which was created by combining the Shuffled Shepherd Optimisation Algorithm (SSOA), the Mayfly Optimisation Algorithm (MA), and the Fractional Calculus (FC), trains the DBN in this instance.

Nazar, Nidhin, *et al* [25] Massive volumes of information are frequently available in the field of cyber forensics, perhaps more than in other forensics specialities. The difficulties and innovations associated with applying deep learning to cyber forensics are essentially the same as in any other field where artificial intelligence is utilised to address problems that are vital to an individual or, more often than not, an organisation. Initially, in order to combine Deep Learning with Cyber Forensics—that is, after an incident—it must first be taught in Cyber Security—more precisely, Cyber Defense—that is, before an incident. This concept makes a lot of sense. In this work, deep learning models are compared to the human brain, which is the most complex structure in the known universe. These models are, after all, founded on and inspired by the human brain. This study suggests ways that Deep Learning models could benefit the field of Cyber Security, particularly for the IR teams, and looks for current solutions on how to apply a Deep Learning model in the domains of Cyber Forensics. Barik, Kousik, *et al* [26] The study intends to examine numerous problems that arise during the course of the investigation as well as the various stages of digital forensic techniques. The study also focusses on the careful examination of several digital forensic instrument types. The process entails constructing, defending any scene, conducting a thorough examination, communicating effectively, and identifying. It also entails identifying all of the regulations for regulating proof as well as the prospects for digital inquiry. This article discusses the methods and resources that can be used to look into digital crime. Among the topics covered are desktop forensic tools, live forensic tools, operating system forensic tools, and email forensic tools.

Ahmad, Ayaz, *et al.* [27] provided research that might be utilised to develop plans for developing standards, guidelines, and technological research to minimise problems that can't be resolved by using the tools and techniques available today. This chapter covers a number of subjects, including cloud computing, cybercrimes, digital forensics, and cloud forensics. The fundamentals and overview of cloud computing, digital forensics, cybercrimes, difficulties, and prospects in the field of cloud forensics are also explored. A review of the literature on related work to digital forensics techniques in the cloud computing environment is included, along with the state of the art in the cloud forensic area. Rajeev, Aishwarya, and P. Raviraj [28] explored a wide range of forensic analysis disciplines, including as audio, video, and network forensics. Many methods are employed in this study to accomplish various forms of forensic analysis, including Random Forest, Multilayer Perceptron (MLP), and Convolutional Recurrent Neural Networks (CRNN). Additionally, image fusion is employed, which can extract features from the source photos and provide more information than a single image. With an accuracy of 98.02 percent, this study concluded that the random forest offers the best outcomes for network forensic investigation. The paper attempts to give a comprehensive overview of the substantial amount of work that has been done in the subject of video source authentication in recent years through a review of existing techniques and machine learning algorithms.

Ramesh, S., *et al* [29] Deep Learning (DL) models offer automated malware classification, spam, phishing, and intrusion detection as well as the extraction of optimal values from network data. By making judgements based on evidential weights, the DL-based cyber forensic investigation engine makes it easier to preserve, analyse, and understand evidence. The purpose of this chapter is to highlight the developments and breakthroughs in deep

**Mahalakshmi and Subhashini**

learning for digital and cyber forensics Arshad, M. Zeeshan, et al[30] This paper's primary goal is to create a framework that security can use to conduct forensic investigation on IoT devices with limited resources. In this study, we have suggested a system that uses a node to node (N2N) architecture to automatically do forensic analysis and detect the many types of assaults carried out on the endpoint (IoT device). In order to identify various attack types, this suggested solution also combines a variety of forensic tools with machine learning techniques. It addresses the issue of recovering evidence from the compromised endpoint by using a third-party log server. We have used the security onion (forensic server) to analyse the logs in order to ascertain the type and scope of the assault. Furthermore, this framework is capable of employing various machine learning methods to automatically identify assaults.

Research Gaps

Despite its importance, cloud forensics faces numerous challenges:

Complexity of Cloud Architectures: Cloud environments are often highly complex, comprising various service models (IaaS, PaaS, SaaS) and deployment models (public, private, hybrid). Investigators must navigate this complexity to locate and analyze relevant evidence effectively.

Multi-tenancy Issues: In cloud environments, multiple clients often share the same infrastructure, which raises concerns about data isolation and privacy. Investigators must ensure that they do not inadvertently access data belonging to other clients, which could lead to legal and ethical issues.

Dynamic and Ephemeral Data: Cloud environments can generate vast amounts of dynamic data, such as logs and temporary files, that may be deleted or overwritten quickly. This impermanence complicates the data collection process, as investigators must act swiftly to capture evidence before it is lost.

Limited Access to CSP Infrastructure: Investigators often have limited access to the underlying infrastructure of CSPs, making it challenging to perform in-depth forensic analysis. Collaboration with CSPs is essential to obtain necessary data, but legal and operational hurdles may impede timely access.

Legal and Regulatory Compliance: The legal landscape surrounding cloud forensics is complex, with varying regulations across jurisdictions. Investigators must remain compliant with local laws and international regulations regarding data privacy and security.

Volume and Variety of Data: The sheer volume of data generated by modern digital devices and systems presents a substantial challenge. Digital forensics experts must sift through terabytes or even petabytes of data to locate relevant evidence. The variety of data formats and storage systems also complicates the process.

Encryption and Privacy Issues: Encryption technologies, while essential for securing personal and corporate data, can impede forensic investigations. Decrypting encrypted files often requires specialized tools and expertise, and in some cases, may be impossible without access to encryption keys.

Future Research Direction

As digital technologies continue to evolve, so too does the field of digital forensics. One of the most significant trends in recent years is the growing use of artificial intelligence (AI) and machine learning (ML) in forensic investigations. These technologies offer the potential to automate certain aspects of the forensic process, such as the identification of anomalies or the classification of evidence. Additionally, the increasing use of blockchain technologies in data storage and transactions has introduced new opportunities and challenges for digital forensics, particularly in the areas of fraud detection and secure record-keeping. Furthermore, as cloud computing and IoT devices continue to expand, forensic investigators will need to adapt to the distributed and decentralized nature of these systems. New tools and

**Mahalakshmi and Subhashini**

methodologies will be required to effectively investigate incidents in environments where data is stored across multiple platforms and geographies.

ABSTRACT

The rapid growth of cloud computing has revolutionized data storage, application hosting, and resource management, making it a cornerstone of modern digital infrastructure. However, the adoption of cloud services introduces critical challenges related to performance optimization, Quality of Service (QoS), and security. This literature review aims to explore various strategies that have been proposed to improve cloud computing performance while maintaining high QoS standards and robust security measures. The review delves into techniques such as dynamic resource allocation, virtualization, load balancing, and traffic management to enhance system efficiency and scalability. It also examines encryption protocols, authentication mechanisms, and intrusion detection systems aimed at fortifying cloud security. By analyzing current research, this review highlights the trade-offs between performance and security, offering insights into how emerging technologies such as machine learning, blockchain, and edge computing are being integrated to strike a balance. The findings provide a comprehensive understanding of the existing frameworks and future directions for optimizing cloud performance without compromising on QoS and security requirements.

Keywords: Cloud Security, Quality of Service, Security

Jeya and Baby Deepa

INTRODUCTION

Cloud computing has become an integral part of modern information technology infrastructures, enabling organizations and individuals to access and manage data, applications, and services over the internet. Its promise of on-demand resource availability, scalability, cost efficiency, and flexibility has driven widespread adoption across various industries, including healthcare, finance, education, and entertainment. However, as reliance on cloud computing increases, so do the challenges related to ensuring high levels of performance, Quality of Service (QoS), and security. Performance in cloud computing refers to the ability of cloud systems to provide users with fast, efficient, and reliable access to resources while handling large-scale workloads. This aspect is crucial in cloud environments where unpredictable spikes in demand can strain resources. To mitigate these issues, cloud service providers (CSPs) deploy performance enhancement techniques such as dynamic resource allocation, load balancing, and virtualization, which aim to maximize resource utilization and maintain optimal system throughput. However, maintaining high performance often comes at the expense of other critical factors, such as QoS and security [1] [2].

Quality of Service (QoS) represents the overall service quality experienced by end-users, encompassing elements such as availability, latency, bandwidth, and error rates. It is essential in maintaining user satisfaction and ensuring seamless operation for businesses relying on cloud services. The dynamic and distributed nature of cloud environments complicates QoS management, requiring sophisticated algorithms for resource allocation, traffic management, and real-time monitoring. Ensuring consistent QoS across geographically dispersed data centers, varying network conditions, and diverse workloads remains a complex challenge for CSPs [3]. At the same time, security in cloud computing is paramount, given the sensitivity of the data and applications hosted in these environments. Organizations entrust CSPs with confidential data, making cloud infrastructures attractive targets for cyberattacks. Cloud security encompasses a wide range of concerns, including data protection, user authentication, network security, and compliance with privacy regulations. Techniques such as encryption, intrusion detection, access control, and multi-factor authentication are employed to safeguard cloud environments. However, achieving high levels of security often involves overhead that can negatively impact performance, creating a trade-off between security measures and the efficiency of cloud operations [4] [5].

In this context, the interplay between performance, QoS, and security becomes a critical area of concern for researchers and practitioners alike. Improving performance while maintaining a robust QoS and ensuring high security levels presents a unique set of challenges. For instance, adding security measures such as encryption can lead to increased computational load, thus reducing performance. Similarly, prioritizing performance optimization might lead to gaps in security or compromise on QoS aspects like latency or service availability. This literature review seeks to explore the existing body of research that addresses these interconnected challenges in cloud computing. By examining state-of-the-art methodologies and technologies, including machine learning-based optimization techniques, blockchain for decentralized security, and edge computing for distributed workloads, the review will highlight approaches aimed at enhancing cloud performance without compromising QoS or security. It will also identify key trends and future directions in the field, particularly the integration of emerging technologies to balance performance, QoS, and security requirements in cloud environments.

Background Study of Cloud Security

Cloud computing has become a cornerstone of modern digital infrastructure, enabling organizations to deploy, store, and process data with unprecedented scalability, flexibility, and cost efficiency. However, as cloud adoption grows, so does the complexity of ensuring the security of these vast, distributed systems. Cloud security encompasses a broad range of technologies, protocols, and policies designed to protect data, applications, and infrastructure from a wide array of threats. The unique characteristics of cloud environments—such as multi-tenancy, on-demand resource provisioning, and remote access—create significant challenges for securing data integrity, confidentiality, and availability.

**Jeya and Baby Deepa****The Evolution of Cloud Security**

Cloud security evolved alongside the development of cloud computing technologies. Initially, concerns about security were among the biggest barriers to cloud adoption, with enterprises hesitant to entrust sensitive data to third-party service providers. Over time, cloud providers invested heavily in developing security mechanisms that address both traditional IT security concerns and the novel risks introduced by cloud infrastructures [6] [7]. Traditional data centers operated within a single organizational boundary, where physical and network access controls could be tightly managed. In contrast, cloud environments are shared, decentralized, and accessible over the internet, raising new challenges in protecting against insider threats, external attacks, and accidental data leaks. To mitigate these risks, cloud service providers (CSPs) have implemented a range of security measures, such as encryption, identity management, access controls, and auditing tools. However, securing cloud environments is not solely the responsibility of CSPs; it requires a collaborative effort between providers and users, each responsible for different layers of the security model.

Shared Responsibility Model

One of the foundational concepts in cloud security is the Shared Responsibility Model. In this model, cloud service providers and customers share the responsibility of securing data and infrastructure, though the scope of responsibility varies based on the cloud service model used—Infrastructure as a Service (IaaS), Platform as a Service (PaaS), or Software as a Service (SaaS). IaaS: In an IaaS model, the cloud provider manages the physical data center, servers, and network, while the customer is responsible for securing the operating system, applications, and data. This model provides the greatest control for the user but also demands the most comprehensive security management from the customer's side.

PaaS: In PaaS, the provider also manages the underlying infrastructure and platform (such as operating systems and middleware), leaving customers responsible mainly for securing their applications and data. Security responsibilities here are somewhat reduced for customers but still involve considerable attention to data protection and application security. SaaS: In a SaaS model, the cloud provider handles nearly everything—network, servers, applications, and data storage—while the customer is generally responsible for securing their access credentials and managing user permissions. SaaS users are at the mercy of the provider's security measures, making it critical for customers to carefully evaluate their provider's security practices.

Key Cloud Security Threats

As cloud adoption grows, so does the landscape of threats targeting cloud environments. Some of the most prominent security threats include:

Data Breaches: Data breaches remain one of the most significant threats to cloud security. Multi-tenant cloud environments, where data from multiple customers resides on shared infrastructure, increase the risk of unauthorized access. Breaches can occur due to poor configuration, weak access controls, or vulnerabilities in cloud services. High-profile data breaches, such as the Capital One incident in 2019, underscore the risks posed by misconfigurations in cloud infrastructure [8].

Data Loss: Data loss can occur for a variety of reasons, including accidental deletion, hardware failures, software bugs, and malicious attacks (such as ransomware). In a cloud context, ensuring data redundancy and backup procedures are critical for minimizing the risk of permanent data loss. While replication across multiple data centers can help mitigate this risk, it also requires careful management to ensure consistency and data integrity.

Insider Threats: Cloud environments are particularly vulnerable to insider threats due to the vast number of users with varying levels of access. Employees or administrators of cloud providers, as well as users within an organization, may intentionally or unintentionally misuse their access, leading to data breaches or service disruptions. Insider threats can be mitigated by strong access controls, logging, and continuous monitoring.

**Jeya and Baby Deepa**

Denial of Service (DoS) Attacks: Distributed Denial of Service (DDoS) attacks, which aim to overwhelm cloud services with traffic, can render services unavailable to legitimate users. Cloud providers offer DDoS mitigation tools, such as traffic filtering and load balancing, but large-scale attacks can still cause significant disruptions, especially for smaller providers [9].

Insecure APIs: Application Programming Interfaces (APIs) are widely used in cloud environments to enable integration and automation. However, insecure APIs—those lacking proper authentication, encryption, or access controls—can expose cloud systems to cyberattacks. Ensuring the security of APIs is a critical aspect of cloud security, requiring regular auditing and testing for vulnerabilities.

Account Hijacking: Weak or stolen credentials remain a common attack vector in cloud security. Once attackers gain access to cloud accounts, they can manipulate data, steal sensitive information, or perform malicious activities under the guise of legitimate users. Multifactor authentication (MFA), encryption, and strict access controls are essential defenses against account hijacking.

Background Study of the Data Replication Methodologies

Cloud computing offers numerous advantages such as scalability, flexibility, and cost efficiency. However, ensuring **Quality of Service (QoS)** in a cloud computing environment remains one of the most significant challenges faced by both Cloud Service Providers (CSPs) and users. QoS in cloud computing refers to the overall performance of the cloud system, which includes metrics such as **availability, reliability, latency, bandwidth, and error rates**. A high QoS guarantees that users can access services consistently and reliably, without interruptions or delays. Achieving and maintaining this quality is complex due to the dynamic, distributed, and resource-shared nature of cloud environments[10]. This background study explores the major concepts, existing challenges, and solutions in improving QoS in cloud systems.

QoS Metrics in Cloud Computing

To better understand how QoS can be improved, it is essential to identify the key performance indicators (KPIs) or metrics that define the quality of service in cloud computing environments:

Availability: The percentage of time a cloud service is accessible and operational. High availability ensures that services are always accessible to users.

Latency: The time taken to respond to a user request. Lower latency is crucial in performance-sensitive applications such as real-time data processing.

Reliability: The ability of a system to function without failure over a specific time period. High reliability is critical for long-running processes and transactions.

Throughput: The rate at which data is processed and transferred. Ensuring high throughput is necessary for data-intensive applications.

Scalability: The ability to handle increasing workloads by allocating more resources. A scalable system adapts efficiently to demand fluctuations.

Security and Privacy: Although security and privacy are often separate domains, their management affects QoS. Any breaches in security can degrade service quality and customer trust.

LITERATURE REVIEW

Wang, Jinjiang, *et al*[11] proposed strategy, termed LBVMP, seeks to establish a novel framework comprising a balanced flat surface of a physical machine (PM) regarding CPU, RAM, and bandwidth (BW), alongside another proportional flat surface representing the remaining resource capacity of the targeted PM divided by the requested resources (CPU, RAM, and BW) of a virtual machine (VM). Subsequently, LBVMP computes the distance between two plots to assess VM allocation solutions. Xu, Heyang, *et al.* [12] Examined the issue of fault tolerance-aware VM scheduling and articulated it as a multi-objective optimisation model incorporating various QoS constraints. The proposed model aims to minimise customers' overall spending while simultaneously maximising the successful execution rate of their enterprises. A greedy-based best fit decreasing (GBFD) algorithm is then designed to resolve the proposed optimisation model. The GBFD method employs a cost efficiency factor defined by the characteristics of CNs to select an appropriate CN for each VM request. Comprehensive experiments are performed to validate the practicality of the suggested models and algorithms using both real-world CDC cluster datasets and simulated data. Tamilarasu, P., and G. Singaravel [13] An Improved Coati Optimisation Algorithm-based Task Scheduling (ICOATS) is proposed to mitigate prolonged scheduling durations, excessive costs, and increased stress on Virtual Machines (VMs) in cloud computing environments. This suggested ICOATS constructs a model for work distribution and scheduling based on the variables of virtual machines, cost, and time. It also incorporated a multi-objective fitness function aimed for minimising makespan while simultaneously maximising resource utilisation efficiency. It established a potential strategy for each coati about the task scheduling process, which assists in identifying the appropriate assignment of incoming work to virtual machines (VMs). The proposal addresses premature convergence by integrating an exploitation method that enhances local search potential through a well-balanced trade-off between exploration and exploitation.

Rajak, Ranjit, *et al* [14] Task scheduling, characterised by dependencies between activities, is executed by resource allocation via Directed Acyclic Graph (DAG) scheduling. DAG is a crucial scheduling method because to its extensive applicability in various domains, including environmental technology, resource management, and energy optimisation. NP-completeness is a prominent issue, prompting the proposal of numerous models in the literature to address it. Nonetheless, the emergence of Quality of Service (QoS)-aware services in the CCE platform has become a significant and prevalent method for delivering computing resources, presenting a fresh essential challenge. The primary objective of this work is to formulate an innovative Directed Acyclic Graph (DAG) scheduling model to enhance the Quality of Service (QoS) parameters in the CCE platform, which can be validated using comprehensive simulation techniques.

Sharma, Minakshi, Rajneesh Kumar, and Anurag Jain [15] The proposed approach is an expansion of the previously suggested quality of service (QoS)-enabled join minimum loaded queue (JMLQ). The suggested methodology has been evaluated using the CloudSim simulator, and the findings indicate that it outperforms QoS-enabled JMLQ and its variants within the cloud context. Monika, and Om Prakash Sangwan [16] Utilised an innovative backpropagation-based Adaptive Dynamic Programming parameter tuning strategy, incorporating two fundamental prediction methods, to create a self-adaptive intelligent system that offers automatic parameter tuning capabilities for both techniques. To assess the suggested methodology, we conducted a simulation using a real QoS dataset, and the experimental findings indicate superior prediction accuracy relative to conventional methods.

Pakhrudin, Nor Syazwani Mohd, Murizah Kassim, and Azlina Idris [17] The aim of this research is to enhance the efficacy of the existing RR approach for action scheduling in the cloud by reducing the average waiting, turnaround, and response times. The CloudAnalyst tool was employed to refine the RR approach by adjusting parameter values to optimise for high accuracy and cheap cost. The results indicate that the total minimum and maximum response times achieved are 36.69 ms and 650.30 ms, respectively, for a duration of 300 minutes of RR. The expense for the virtual machines (VMs) ranges from \$0.50 to \$3.00. The duration of usage correlates positively with the expense of data transfer. This research is crucial for enhancing communication and the quality of interactions among groups.

**Jeya and Baby Deepa**

Malla, Parvaz Ahmad, and Sophiya Sheikh [18] Cloud computing systems are recognised as significant consumers of energy resources globally. Moreover, power consumption has emerged as a critical factor since the majority of cloud computing systems rely on conventional nonrenewable energy sources. To render data centres environmentally sustainable, it is essential to implement optimal strategies to minimise energy usage and their detrimental impact on the environment. The primary purpose of this research is to examine several ways for constructing and sustaining an energy-efficient cloud. The paper will thoroughly examine several energy-efficient resource provisioning techniques and present a graphical comparison analysis of Quality of Service (QoS) metrics in cloud computing. Furthermore, the current study delineates the domains requiring enhancement to augment the energy efficiency of cloud computing systems.

Katkar, Alok, *et al* [19] This abstract provides an overview of current achievements in the automated assessment of quality of service in cloud computing systems. Cloud computing architectures provide substantial flexibility and scalability to clients. The total performance of a cloud platform is significantly affected by the quality of service. The quality of service is generally determined by outstanding criteria, including response time, availability, throughput, security, and others. Intelligent approaches have gained increased prominence for enhancing the quality of service monitoring and measuring. These tactics employ Artificial Intelligence (AI) and machine learning (ML) technologies to detect anomalies. Automated measures are implemented to guarantee the maintenance of superior service quality. Tabassum, Nazia, and C. R. K. Reddy [20] VANET and Cloud Computing will significantly contribute to the advancement of efficient technology for autonomous driving, vehicle control, and intelligent systems in the near future. Cloud computing is a centralised paradigm that fails to adequately manage numerous Quality of Service (QoS) parameters, such as latency, throughput, and bandwidth optimisation. Fog Computing (FC) is established in VANETs to address the constraints of Cloud Computing (CC). The IoV-CC must tackle issues related to security and privacy. Consequently, the security protocols employed in conventional VANET and CC must be revised for IoV-CC, necessitating the development of a new secure algorithm to ensure secure communication between FOG and cloud nodes. Innovating QoS in VANET for IoV-CC faces considerable challenges related to data dissemination and security. This project aims to investigate the data distribution and security acceptability of the Internet of Vehicles (IoV) in relation to centralised and decentralised computer systems.

Arunkumar, J. R. [21] The computer resources of cloud service providers are reassigned dynamically based on demand, with their infrastructure, platform, software, and other resources shared among various corporate and private clients. The continuous rise of cloud computing subscribers utilising shared resources has heightened concerns regarding cloud security. This review article delineates present cloud security challenges and practices, while proposing several creative solutions aimed at enhancing cloud computing security in future domains. Agarwal, Rajesh, and Sanjay Dhingra [22] This research aims to identify the determinants of cloud service quality and evaluate the influence of service quality on customer satisfaction and loyalty. A study with 419 cloud experts/users was executed in India utilising a structured questionnaire based on the Likert scale. The participants were cloud professionals and users utilising the services of the five leading cloud service providers in India. Research hypotheses were evaluated by partial least squares structural equation modelling. The research indicated that agility, service assurance, dependability, scalability, security, service responsiveness, and usability all positively and significantly influence total cloud service quality. The study demonstrated a partly mediating impact of customer satisfaction between service quality and customer loyalty. Service quality exhibits a favourable and strong correlation with customer loyalty and customer satisfaction.

Pawar, Ankush Balaram, Shashikant U. Ghumbre, and Rashmi M. Jogdand [23] This work aims to create and construct a paradigm for authentication and data security in cloud computing. This technique comprises six distinct units: cloud server, data owner, cloud user, inspection authority, attribute authority, and central certified authority. The devised privacy preservation system has multiple stages: setup phase, key creation phase, authentication phase, and data exchange phase. The setup step is initially conducted by the owner, who provides the security attributes, while the key creation stage produces the system master key and the public parameter. Subsequently, the authentication process is conducted to ascertain the security measures of the information system. The data is

**Jeya and Baby Deepa**

ultimately decrypted at the data sharing phase to facilitate data exchange and ensure privacy for confidential information. Furthermore, dynamic splicing is employed, alongside security mechanisms including hashing, Elliptic Curve Cryptography (ECC), Data Encryption Standard-3 (3DES), interpolation, polynomial kernel, and XOR, to safeguard sensitive data. Kirubakaran, S. Stewart, *et al* [24] Formulated a Privacy-Preserved Data Security Approach (PP-DSA) to provide data security and integrity for outsourced data in a Cloud Environment. This work ensures privacy preservation through the Efficient Authentication Technique (EAT), which use the Group Signature method in conjunction with a Third-Party Auditor (TPA). The auditor's responsibility is to safeguard data and ensure the integrity of shared information. Furthermore, the Cloud Service Provider (CSP) and Data User (DU) may also act as the perpetrators that must be addressed by the EAT. The primary aim of this effort is to improve cloud security and thus boost Quality of Service (QoS).

Sindjoug, Miguel Landry Foko, Mthulisi Velepini, and Clémentin Tayou Djamegni [25] Mobile Edge Computing (MEC) relocates computing and storage resources from cloud data centres to edge data centres, positioning them nearer to end-user devices to minimise end-to-end latency in request processing. Nonetheless, MEC is susceptible to security, data privacy, and authentication issues that impact the end-user Quality of Experience (QoE). It is essential to address these difficulties to prevent a subpar user experience resulting from inadequate security or data privacy. This research proposes a hybrid cryptographic system that integrates symmetric and asymmetric cryptographic methods to enhance data security, privacy, and user authentication in a MEC-based network. Guo, Zixuan, and Xuejun Yu [26] utilised the QoS (Quality of Service) of cloud services as the foundational data, derive the subjective weights of these services through AHP hierarchical analysis, ascertain the objective weights via the entropy weighting method, and calculate the recommendation degree for each service through weighting. Concurrently, they evaluate the trustworthiness of cloud services using the TOPSIS decision method, ultimately proposing the development of a cloud service trustworthiness metric model. This methodology mitigates the impact of user evaluation subjectivity on the trustworthiness assessment of cloud services by offering an objective and efficient trustworthiness metric. This study examines the processing of QoS data, the classification of metrics, and the application of the entropy weight approach to get the objective weights of the relevant metrics for cloud services.

Kaliyanandi, Maharajan, *et al* [27] developed a comprehensive strategy for load balancing in cloud computing that incorporates security measures. The Quantum-Based Security Framework has been developed, and the load is equilibrated by fuzzy logic. The primary security policies are effectively evaluated, and service is provided according to the user's specified requirements. The Security Framework devised a technique for cloud data storage by generating check bits in lieu of keys, enabling users to access their data upon verification of the check bits. Only the user may utilise the services and load balancing if the check bits produced by the user and the cloud service provider are same. Mirrored copies are created to mitigate the risk of data loss from failures or outages. This security technique enables us to achieve a high level of security. Liu, Xiaofei [28] The proposed methodology introduces a novel blended technique known as the Integrated Aquila Optimiser (IAO), which combines the traditional Aquila Optimiser (AO) with the Particle Swarm Optimisation (PSO) algorithm. The primary aim of this hybridisation is to address the deficiencies encountered by both AO and PSO algorithms. These algorithms are prone to becoming ensnared in local optima and exhibit restricted solution diversity. The suggested method introduces an innovative transition mechanism that enables appropriate changes between the search operators, assuring ongoing enhancements in the solutions. The transition method enables the algorithm to alternate between AO and PSO when either becomes stagnant or when solution variety diminishes. This adaptability improves the overall performance and efficacy of the hybrid method. The suggested IAO approach undergoes comprehensive testing via experiments done on the Cloudsim simulation platform.

Materwala, H., L. Ismail, and H. S. Hassanein [29] Introduced an innovative Artificial Intelligence QoS-SLA-aware adaptive genetic algorithm (QoS-SLA-AGA) to enhance application execution time for multi-request offloading in a heterogeneous edge-cloud computing environment, accounting for the effects of overlapping multi-request processing and variable vehicle speed. The suggested genetic algorithm incorporates an adjustable penalty function to accommodate the SLA constraints related to latency, processing time, deadlines, CPU, and memory needs.

Jeya and Baby Deepa

Numerical investigations and analyses juxtapose our QoS-SLA-AGA with baseline genetic-based, meta-heuristic Particle Swarm Optimisation (PSO), random offloading, All Edge Computing (AEC), and All Cloud Computing (ACC) methodologies. Ali, Munwar, *et al* [30] Proposed a viable method to tackle these concerns with a novel service paradigm termed Confidentiality-based Classification-as-a-Service (C2aaS), which executes data processing by dynamically categorising data depending on its security level in anticipation of cloud storage. Our suggested service model demonstrates superior security for confidential data and effectively mitigates cloud system overloading compared to existing ways.

Research Gap

There are several inherent challenges in ensuring a high QoS in cloud environments due to their architecture and operational nature:

Dynamic Resource Allocation: Cloud environments operate on shared infrastructure, and resource contention can degrade QoS. As users' demands fluctuate, CSPs must allocate computing, storage, and network resources dynamically to ensure consistent performance. Poor resource allocation algorithms can lead to underutilization or resource overloading, both of which negatively affect QoS.

Geographically Distributed Data Centers: Cloud data centers are often distributed across different regions to minimize latency and ensure redundancy. However, geographic distribution introduces the complexity of managing network latency, data replication, and consistency across diverse locations. Ensuring uniform QoS in such scenarios is challenging, especially for global users.

Fault Tolerance and Failover: Faults in hardware, software, or network components can lead to service outages or reduced performance. High fault tolerance mechanisms are required to maintain QoS during failures. Failover strategies must be seamless and fast, ensuring no degradation in service during resource or network failures.

Multi-Tenancy and Resource Sharing: In a cloud environment, resources are shared among multiple tenants (users). While this leads to efficient resource utilization, it also introduces the risk of "noisy neighbors," where the actions of one tenant can negatively affect the performance of others. For example, a tenant running a heavy workload may consume more bandwidth or CPU resources, causing delays for other tenants.

Future Research Direction

Given these challenges, researchers and cloud service providers have proposed various strategies to improve QoS in cloud computing environments.

Dynamic Resource Allocation and Auto-Scaling: Dynamic resource allocation is one of the most effective strategies to ensure QoS. Cloud systems use **auto-scaling** mechanisms that dynamically allocate or deallocate resources based on real-time demand. By leveraging machine learning and predictive analytics, CSPs can forecast usage patterns and allocate resources more efficiently, preventing both resource underutilization and overloading.

Load Balancing Techniques: Load balancing is crucial for distributing workloads evenly across cloud servers. This helps in avoiding overloading specific servers, reducing response times, and maintaining high availability. Different algorithms are used to implement load balancing in cloud environments:

Round Robin: Distributes requests to all servers in a circular fashion.

Least Connections: Sends requests to the server with the fewest active connections, thereby preventing overload.

Dynamic Load Balancing: Uses real-time performance metrics to allocate resources based on current loads.

Service Level Agreements (SLAs): Service Level Agreements (SLAs) are contracts between CSPs and customers, outlining the expected QoS levels, including availability, response time, and performance guarantees. SLAs serve as a

**Jeya and Baby Deepa**

framework for managing user expectations and hold CSPs accountable for performance and QoS failures. CSPs use SLAs to define specific thresholds, penalties, and compensations for non-compliance, incentivizing the maintenance of QoS.

Traffic Management and Network Optimization: Managing network traffic efficiently is essential to improving QoS in cloud systems. Network congestion or inefficient routing can lead to higher latencies and reduced throughput, negatively impacting performance. Advanced traffic management techniques, including Software-Defined Networking (SDN) and Network Function Virtualization (NFV), allow CSPs to dynamically manage network resources, optimize routing, and reduce latency.

ABSTRACT

The number of algorithms that can decipher the tone of social media posts has skyrocketed in the past several years. Regarding the airing of views and opinions in virtual and social media arenas, common thinking is antiquated. These expressions can describe a lot of different feelings and moods. Emotion and sentiment analysis encompass a wide range of methodologies. In favour of studying the positivity or negativity of these utterances, most research disregard the feelings they represent. To find out what these utterances really mean, this study goes beyond sentiment analysis. This work demonstrates that a hybrid rule-based technique may be used to produce an entirely annotated dataset for five emotions: angry, afraid, pleased, sorrowful, and devastated. The proposed approach used all 45,000 of our English-language tweets that had the keywords "COVID-19 and India" in this study's dataset. Support Vector Machine, Stochastic Gradient Boosting, Naive Bayes, Logistic Regression, Random Forest, and Logistic Regression were some of the machine learning classifiers used for sentiment and emotion classification. It has been found that the Support Vector Machine outperformed the other classification methods when we compared them.

Keywords: "COVID-19, Random Forest, machine learning, technique, dataset.

INTRODUCTION

The rise of microblogging in the last several years has greatly increased the accessibility of text that contains emotions. Microblogs' limited character limit has inspired new emotions and prompted people to communicate their ordinary thoughts in real-time. These are not the only textual sources; there are also blogs, social media, emails, and product reviews. In today's Internet-driven society, social media sites are the ideal places to air your grievances. People use several forms of media, including text, images, audio, and video, to express themselves. A vast volume of unstructured and unshaped content is posted on the Internet every second as a result of the overwhelming nature of text communication through social media. In order to comprehend human psychology, it is necessary to quickly examine newly generated data; sentiment analysis, which detects textual polarity, can assist. It processes the data and generates an opinion, be it positive, negative, or neutral, on anything (a person, a brand, a movie, an event, etc.). Sentiment analysis refers to the act of classifying the emotions conveyed in the source material.

In the case of a pandemic, social media sites like Facebook, Twitter, YouTube, etc., play an essential role. Fast and easy, millions of individuals all around the globe can share their thoughts on any number of issues using Twitter. Due to the public nature of this data, Twitter has become a major subject of research. Anyone can view a user's profile and reply to their tweets. Tweets provide a wealth of sentiment data on people's views on a variety of topics. Consequently, we developed an autonomous machine learning sentiment analysis model to determine customer sentiment. Because sentiment analysis isn't always accurate, we need emotion analysis, which can dependably determine how someone is feeling. For the most part, earlier studies on text classification concentrated on sentiment analysis, which assigns positive or negative labels to data, and the vast majority of these datasets were in English. Although neutral sentiments were included in certain studies, analyzing emotions rather than sentiments provides a better understanding of the data. Although there can be no more than two dimensions to a sentiment classification, we use the word "multi-dimensional" to further characterize emotions in this research. English has been the principal target language for the majority of models and tools. Even people for whom English is not a first language often write in English for publications.

Even among academics for whom English is not a first language, the majority use it for both study and writing purposes. Using English and data related to "COVID-19 and India" as our primary examples, we focus on annotation projection as a simple way to generate high-quality English datasets. All things considered, 45,000 English-language tweets concerning "COVID-19 and India" were utilized in order to investigate these mixed rules. This article goes into detail on text classification analysis, sentiment and emotion identification using machine learning, and more. Findings from applicable previous studies on emotion and sentiment analysis are compiled in Section 2 of this work. The methods proposed for assessing the mood and emotion in tweets are discussed in Section 3. Classifiers for machine learning, metrics for performance, techniques for extracting features, annotations for data, text preprocessing, and dataset collection are all components. Section 4 gives the results of the study on feelings and sentiments, and Section 5 concludes the whole endeavor.

REVIEW LITERATURE

Presented the six primary emotion types: sad, angry, disgusted, afraid, and happy. He laid out his major argument in regard to the suggested fundamental emotions. It was proposed a method for generic emotional responses based on psychological observations. With the inclusion of "anticipation" and "trust" in his list of basic emotion categories, Ekman increased the number of his categories from six to eight. Analyzed and rated existing text sentiment analytics and sentiment detection techniques. Also discussed were the problems that arose during the processes. A supervised machine learning system for emotion classification was developed and evaluated. Online and offline classification were the two primary functions it combined. In order to categorize emotions while working offline, a model-generating system named "Emotex" was created. Creating a two-stage framework named "EmotexStream" to categorize the emotion tracking of real-time tweets was necessary for the challenge. Over 90% of the emotions in the

**Jayakandan and Chandrabose**

text messages were accurately categorized by the created algorithms, according to their tests. Classified Twitter user sentiment using both supervised and unsupervised algorithms. Making and using a vocabulary was essential for the classification process.

The model's score was determined by use of a Google search engine. Various datasets were subjected to sentiment identification using ML algorithms. Classification at the sentence level based on POS and unigram presence was shown to be the most accurate when additional variables were considered. Examined tweets for tone and emotional content. We collected all the tweets and responses that were subject-specific. Aside from user information, sentiments, emotions, etc., the collection also included text from Twitter. Sentiment and emotion detection in tweets were accomplished using the dataset. A number of user- and tweet-centric attributes formed the basis for the predicted user replies and influence scores. Finally, the latter data was utilized to provide suggestions for users, both generic and personalized, based on their behavior on Twitter. Gather tweets that displayed at least one of the seven main emotions. The 42,000 tweets that comprised the collection fairly reflected all of the human emotions. A vocabulary of over 40,000 words was built from this dataset; each phrase was linked to a weighted vector that represented a particular mood. After cleaning the tweets, we put different sentiment detection systems to the test.

Both lexically-centered and supervised ML-centered categorization were utilized in these methods. An ensemble technique, which utilized several multi-class classifiers trained using the unigram features of the lexicon, was used to finish the evaluation. After comparing the ensemble technique to other methods on both existing datasets and the one created for this study, the results showed that it performed the best. Ensemble classifier uses decision trees, k-nearest neighbors, and '1500' multilayer perceptron. Regardless of the text's regularity or irregularity, it could steadily and properly differentiate between different moods. The basic classifier's parameters were fine-tuned using Tree-structured Parzen Estimator. The 'three' datasets utilized to train the method were ISEAR, OANC, and CrowdFlower, and they involved both regular and irregular phrases. With a detection accuracy of 88.59% for irregular sentences and 99.49% for regular ones, the ensemble classifier proved to be the most effective. The normalizing function introduces a new way to determine tone. Their approach was more precise than the standard sum and mean function. Using the BERT model to analyze the tenor of Twitter data. Tweet locations and mentions of India are the two main pieces of information gathered. During the height of the pandemic, when fear seized people all across the globe, the tweets were compiled. An enormous quantity of anti-COVID-19 sentiment is seen in the sample.

A fully annotated dataset was constructed using eight commonly experienced emotions. In order to determine the intended tone of the text, they developed an algorithm that took the emoji into account. Discovered more about the COVID-19 pandemic's impact on people's physiological well-being through an analysis of worldwide Twitter data. Based on the emojis employed in the expressions, the study identified eight distinct emotional states. Familiarize yourself with the literature on textual emotion recognition, focusing on studies that analyze both overt and covert displays of emotion. The most effective methods are those that combine learning with hybridization and make use of conventional text representation, as demonstrated by the outcomes. Factors that impacted the efficiency of the proposed systems were also highlighted in the poll, including natural language processing tasks, part-of-speech tagging, and parsing. We created a system that can predict and identify emotions in text. Machine learning techniques that were considered for the classification included Decision Tree, k-Nearest Neighbor, Multinomial Naïve Bayes, and Vector support machine. At its core, the paradigm was based on the six core emotions.

METHODOLOGY

Every single tweet in this study is part of a Twitter corpus that we have annotated with fundamental emotions like angry, sad, joyous, and devastated. The corpus was annotated using a combined rule-based method that made use of Natural Language Processing tools. The suggested method will train an artificial classifier to identify attitudes and emotions expressed in tweets. Logistic Regression, Stochastic Gradient Boosting, Naïve Bayes, Support Vector

Jayakandan and Chandrabose

Machine, Forest Random, and Logistic Regression were among the machine learning classifiers used to categorize the tweets based on the proposed emotions. We used distinctness, evoke, f1-score, and exactness as metrics to assess the classifiers on this corpus. The process of using machine learning classifiers to analyze sentiment and emotion on Twitter is illustrated in Figure 1. The steps of the process are these:

- Twitter Information Gathering
- Data Preprocessing
- Emotion and Sentiment Data Annotation
- Annotating Data for Emotions and Sentiment
- Evaluating Public Opinion
- Analyzing Emotions
- Assessment of Work Performance

Tweets Data Collection

With the help of Academic Research Access, we created a Twitter developer account to collect the required data. A Python-coded application might be registered with this account. The script is written in Python and the Tweepy module, which implements the Twitter API V2, is used to download data. If you want your data collected from Twitter, make sure all the tweets with the phrase "COVID-19 and India" are in English and don't have any retweets. We reduced the dataset by deleting tweets that contained responses, quotations, or retweets so that we could obtain an accurate prediction. The application retrieves the tweets in "JSON" object format, which includes the columns "id," "created_at," "author_id," "lang," and "text" for possible subsequent processing. Gathering Information, the vast majority of datasets found in the real world contain some combination of unclear, noisy, or missing data. Results from data mining operations performed on such disorderly and unexpected data would be inadequate. Data preparation is the only way to get good data. Accordingly, the "Noise" from the Tweets can be eliminated by modifying the raw data according to the preprocessing processes outlined below. The preprocessing entails the following steps:

- Each and every one of the tweets' words were lowercased.
- Removed all digits and punctuation.
- Deleted any and all links, HTML, and URLs from the text.
- Deleted every single emoji from the given text data.
- Edited the text to remove all hashtags.
- A greater variety of abbreviations, acronyms, and shortened words were used.
- A list of stop words provided by NLTK was used to tidy up the text.
- Added fewer gaps to ensure accurate sentence processing.
- Tokenization, which divides a larger piece of text into smaller pieces called tokens, was employed.
- Words were removed from the phrase word for word.
- To simplify the tweet, the procedure of lemmatization is applied to each word.
- The panda library is used to save the pre-processed dataset in a separate dataset, protecting the original downloaded dataset from any potential damage.

Annotating Data on Emotions and Sentiment

Annotation includes analysis of the collected tweets using the NLTK toolkit. The Python software adds sentiment and emotion annotations to tweets. The script assigns a "Positive" or "Negative" attitude to the tweet based on its tone and subjective content. Following the completion of pre-processing, the algorithm employs lemmatization to ascertain the sentiment associated with each word in the tweet. Anger, fear, joy, grief, and broken heart are all examples of such emotions. The two datasets are now ready for further processing.

Annotated Dataset Feature Extraction

Feature extraction refers to the process of converting data into characteristics that can be used in a machine learning model. Numbers are the most common input for machine learning algorithms. Since ML models can't comprehend human language, NLP relies on vectorization. Tokenization, or vectorization, is the process of transforming a list of

Jayakandan and Chandrabose

messages or tweets into a matrix of vectors. The Bag of Words tool now maps the text or word into numerical vectors. Count Vectorizer and FT-FID can be used to extract these features. Count vectorizer is an easy way to get features out of a document by just counting how many times a word or token appears. A method for assigning relative importance to words or phrases inside a text or corpus is known as Frequency Term-Frequency Inverse text (FT-FID). In this study, we employ FT-FID as a feature extraction method; FT stands for the number of times a phrase or word appears in a tweet, and FID is the weight of the words calculated from their frequency. Due to the fact that the length of each tweet varies, it is possible for a term to occur many times in the dataset. Thus, the following is the formula for FT-FID:

FT=frequency of a word's occurrence in a text

word count of the paper

FID = word count of the paper

The quantity of papers that include the phrase

FTFID=FT*FID

Sentiment Analysis

Sentiment analysis is a subfield of Natural Language Processing that allows for the extraction of feelings, opinions, reviews, and thoughts from text, audio, video, and social media data. The tweets are categorized as favorable or negative based on sentiment analysis. The sentiment of tweets from our downloaded dataset is examined in this research using Frequency Term-Frequency Inverse Document (FT-FID) and five machine learning classifiers. Then, we evaluate these classifiers' performance using metrics like exactness, evoke, f1-score, and distinctness. We have created sentiment analysis that takes the tweets as input and uses them to measure the subjectivity and polarity of each message. Making use of the Python Textblob package—a wrapper for implementing thewe ran sentiment analysis on the Twitter corpus. Textblob is a great resource for learning the ropes of Natural Language Processing. Each tweet is assigned a subjective and polarity rating using Textblob. The sentiment subjectivity scale encompassed the whole spectrum, from 0 (no sentiment) to 1 (strong negative sentiment). A score between -1 and 1 was used to determine the polarity of each tweet based on its terms. Feelings of negativity are indicated by numbers between -1 and 0, while positive emotions are indicated by scores between 0 and 1.

Classification of Emotions

The process of organizing sentences or documents into a predefined structure is called classification. Separate from one another, rule-based and machine learning-based classification methods are available. Here, we classify tweets according to the emotions they convey using five ML classifiers: angry, scared, happy, sad, and devastated.

Support Vector Machine Classifier

In order to find the best separating hyper-plane with the widest margin to both sides, vector support machine—the most successful binary classifier primarily searches. The objective is to find a hypothesis that ensures the lowest conceivable true error. An exhaustive description of the operation of the SVM classifier is given in Figure 2 below. It is possible to define the decision boundary, also known as the hyperplane, using the SVM method. Figure 2 shows support vectors, which are the blue and green points, and the margin, which is the distance between the hyperplanes and the support vectors. The optimum hyperplane is the one that maximizes the margin, which is the purpose of SVM.

Bayes Naïve

Naïve Bayes is a fundamental machine learning classification approach that is based on Bayes' Theorem. The Naïve Bayes classifier is a fast, accurate, and dependable method that achieves high accuracy on large datasets. Historically, Naïve Bayes classifiers have mostly been used for text classification and analysis. The Naïve Bayes can be described by two words: "Naïve" and "Bayes ". Consequently, Bayes' theorem is applicable:

$$P(X|Y) = \frac{P(X|Y)P(Y)}{P(X)}$$

Jayakandan and Chandrabose

the posterior probability of hypothesis X , given the observed event Y , is denoted as $P(X|Y)$. If a hypothesis is correct, then the likelihood probability, denoted as $P(Y|X)$, is high. The prior probability, $P(X)$, is the likelihood of the hypothesis before looking at the evidence, and the marginal probability, $P(Y)$, is the likelihood of the evidence after looking at it. Rational Regression When it comes to supervised machine learning algorithms, logistic regression is among the most popular and user-friendly options. We use logistic regression when our target variable is clear. Logistic Regression is a kind of predictive analysis that uses the idea of probability to make predictions about the future, such as whether the output value will be true or false, zero or one, etc. There are three ways to classify LR: binomial, multinomial, and ordinal. The function of X is predicted by a logistic regression model as $P(Y=1)$. Classification challenges involving LR include cancer cell identification, diabetes prediction, cancer detection, and many more.

Forest unstructured Among the many machine learning algorithms used to solve classification and regression problems, forest random is by far the most effective. The classifier Forest Random uses a random collection of training data to construct a set of decision trees called the Forest Random. The test object's ultimate class will be determined by the majority voting of various decision trees. The combination of several decision trees lowers the noise and improves the accuracy of the outputs. The forest random approach for machine learning is illustrated in picture 4 below. How profitable is a random improvement? The Stochastic Gradient Boosting method has proved successful in solving numerous sparse ML issues. Natural language processing and text classification are just two examples. Stochastic Gradient Descent offers many advantages, including being efficient and easy to utilize. A linear SVM -like SGD Classifier's decision boundary is shown in Figure 5. The SGD classifier uses two arrays, X and Y , just like its forerunners. X contains training samples with n features and n samples. The form of Y is n _samples, and it contains the goal values for the training samples. In each iteration, SGD finds the gradient of the function for a single instance instead of the gradient of the cost function overall.

Evaluation of Results We have calculated the success rate of the classifiers using the f1 score, exactness, distinctness, and evoke as indicators of information retrieval. Provides a rough approximation of the distinctness:

$$\text{Distinctness} = \frac{TP}{(TP+FP)}$$

Where TP is the total number of sentences correctly classified to a category, and FP is the total number of sentences incorrectly classified to a category.

$$\text{evoke} = \frac{TP}{(TP+FN)}$$

Where FN is the number of sentences that were not classified at all and TN is the numbers of sentences marked as being in a particular category and were not.

$$\text{F1-score} = \frac{\text{Distinctness} \times \text{evoke} \times 2}{(\text{Distinctness} + \text{evoke})}$$

The exactness is evaluated as in :

$$\text{Exactness} = \frac{TP+TN}{(TP+TN+FN+FP)}$$

RESULTS

Results for sentiment and emotion categorization using Twitter data using the proposed machine learning model are showcased. For this analysis, we put the proposed model through its paces in Python using our Twitter dataset. A number of classification metrics were employed to evaluate the proposed model, including evoke, distinctness, f1-score, and exactness. The research shows that while some tweets on "COVID-19 and India" are hostile, the vast majority are positive. Table 1 details the results of the performance measures used by the sentiment-based classifiers. When comparing the two methods, the SVM algorithm yields the weighting scheme's highest exactness value and the NB technique the lowest. Tables 2-6 provide the classifiers' results for bitterness, Afraid, delight, sorrow, and heartbroken, along with their exactness, distinctness, evoke, and f1-scores. According to the results, out of all the

Jayakandan and Chandrabose

expressed emotions, "bitterness" was the most accurately captured. The proposed Machine Learning Model was able to validate more precise emotion classification in the Twitter data when used with the FT-FID weighting method.

CONCLUSION

This study aimed to examine the participants' emotional and mental experiences during the COVID-19 pandemic in India. This project builds a dataset that can show people's thinking for a specific domain so that Twitter data can be used for emotional prediction. In the proposed model, we analyzed the feelings and emotions using a variety of machine learning approaches. Classifiers trained with the proposed term weighting scheme (FT-FID) achieve accuracy levels greater than 85% when it comes to sentiment analysis. When it came to emotional analysis, the SVM classifier got the best results for the proposed emotions, with an approximate accuracy of 95%. In light of the current COVID-19 pandemic, it is more important than ever to monitor and control people's emotional and physical well-being. We grounded our model on worldwide tweets on "COVID-19 and India" since that's where the majority of individuals expressed their anger throughout the pandemic. How resistant are humans to the coronavirus can be uncovered by examining these facts. One way to make this work better is to use ML architectures that can detect and analyze sentiment and emotional classification in text data automatically.

ABSTRACT

This literature review examines the impact of awareness and perception of Massive Open Online Courses (MOOCs) on the e-learning processes among autonomous engineering colleges in Tamil Nadu. As the landscape of higher education increasingly embraces digital platforms, understanding how students perceive and engage with MOOCs is crucial for optimizing educational outcomes. The review synthesizes existing research on various aspects of MOOC utilization, including factors influencing student awareness, the perceived effectiveness of MOOCs in enhancing learning experiences, and the challenges faced by students in accessing these resources. It highlights the role of institutional support, technological infrastructure, and student attitudes towards online learning in shaping perceptions of MOOCs. Additionally, the review explores the correlation between awareness of MOOCs and student engagement levels, academic performance, and overall satisfaction with the e-learning process. By identifying gaps in the current literature and suggesting directions for future research, this study aims to provide insights that can inform policymakers, educators, and institutions in effectively integrating MOOCs into their educational frameworks, thereby enhancing the learning experience for engineering students in Tamil Nadu.

Keywords: Massive Open Online Courses (MOOCs), Autonomous Colleges, Chi-Square Test, Correlation Analysis

INTRODUCTION

The advent of technology has revolutionized the educational landscape, with Massive Open Online Courses (MOOCs) emerging as a significant mode of e-learning. MOOCs offer an unprecedented opportunity for learners to access high-quality educational resources from renowned institutions, transcending geographical barriers and traditional classroom settings. In recent years, particularly within the context of autonomous engineering colleges in Tamil Nadu, there has been a growing interest in understanding the awareness and perception of MOOCs among students and educators alike [1] [2]. Tamil Nadu, a state in southern India known for its strong emphasis on education, is home to numerous autonomous engineering colleges that cater to a diverse student population. These institutions have been pivotal in shaping the technical education sector, producing skilled engineers who contribute significantly to the workforce. However, as educational methodologies evolve, it becomes crucial to assess how well these institutions and their stakeholders are adapting to the integration of e-learning resources, particularly MOOCs. This study aims to fill this gap by investigating the awareness levels and perceptions of MOOC e-learning resources among students and faculty in these colleges[3].

Awareness of MOOCs encompasses the knowledge of their existence, the platforms offering these courses, and the subjects covered. Perception, on the other hand, relates to the attitudes, beliefs, and perceived value of MOOCs in the context of traditional learning paradigms. Understanding these factors is essential for several reasons. Firstly, awareness can significantly influence the adoption of e-learning resources. If students and faculty are not aware of the availability and potential benefits of MOOCs, they are less likely to utilize them effectively. Secondly, perceptions regarding the quality, credibility, and relevance of MOOCs can shape attitudes towards their integration into formal education. Positive perceptions may lead to greater acceptance and usage, while negative perceptions could hinder their implementation [4] [5]. This study will employ a mixed-methods approach, combining quantitative surveys and qualitative interviews to gather comprehensive data on the awareness and perception of MOOCs. The findings will provide valuable insights into the current state of e-learning in autonomous engineering colleges in Tamil Nadu and will highlight potential areas for improvement. Additionally, the study aims to contribute to the broader discourse on the effectiveness of MOOCs as an educational tool and their role in enhancing learning outcomes in higher education. As engineering education continues to evolve in response to technological advancements, it is imperative to assess the awareness and perceptions of MOOC e-learning resources. This study will not only shed light on the current landscape in Tamil Nadu's autonomous engineering colleges but also serve as a foundation for future research and policy-making in the realm of e-learning. By understanding the perspectives of both students and faculty, stakeholders can make informed decisions that will enhance the quality and accessibility of education in this rapidly changing environment.

MASSIVE OPEN ONLINE COURSES (MOOCs)

The concept of Massive Open Online Courses (MOOCs) emerged in the early 2000s, propelled by advancements in technology and the growing demand for accessible, high-quality education. MOOCs are characterized by their ability to accommodate an unlimited number of participants, providing learners worldwide with the opportunity to access educational resources online, often for free or at a minimal cost [6]. The rise of MOOCs has transformed the educational landscape, offering new avenues for learning and challenging traditional educational paradigms.

Origin and Development

The term "MOOC" was first coined in 2008 by Dave Cormier, referring to a course titled "Connectivism and Connective Knowledge," which was designed by George Siemens and Stephen Downes. This course attracted over 2,000 participants, demonstrating the potential of online learning environments to reach large audiences. The initial success of this model prompted the development of other MOOCs, particularly by prominent universities, which sought to leverage their expertise and resources to a global audience [7]. By 2012, MOOCs gained significant traction with the launch of platforms such as Coursera, edX, and Udacity, which partnered with prestigious institutions like Stanford, Harvard, and MIT. These platforms expanded the reach of MOOCs, allowing universities to offer courses

Chandran and Selvam

across various disciplines, from computer science and engineering to humanities and social sciences. This period marked a paradigm shift in higher education, where the boundaries of traditional classroom settings were blurred, enabling learners to participate in courses from anywhere in the world.

Characteristics of MOOCs

MOOCs typically feature a range of elements that distinguish them from conventional educational models [8]:

Open Access: MOOCs are designed to be accessible to anyone with an internet connection, removing barriers related to enrollment and tuition fees. This inclusivity promotes lifelong learning and democratizes education.

Massive Scale: MOOCs can accommodate thousands, if not millions, of participants simultaneously. This scalability is facilitated by online platforms that host course materials, discussion forums, and assessments.

Diverse Learning Materials: MOOCs utilize various instructional methods, including video lectures, interactive quizzes, reading materials, and discussion forums. This multimedia approach caters to different learning styles and preferences.

Peer Interaction: Many MOOCs incorporate social learning elements, allowing participants to interact with one another through forums, group projects, and peer assessments. This collaborative environment fosters knowledge exchange and enhances the learning experience.

Self-Paced Learning: MOOCs often allow learners to progress through courses at their own pace, accommodating diverse schedules and learning speeds. This flexibility empowers learners to take ownership of their education.

Impact on Education

The introduction of MOOCs has had profound implications for the education sector. They have expanded access to quality education, particularly for individuals in remote or underserved areas. Moreover, MOOCs have prompted educational institutions to reconsider their teaching methods, curricular offerings, and assessment strategies. The integration of online learning resources into traditional classrooms has encouraged blended learning models, combining face-to-face instruction with online components [9]. However, the rapid proliferation of MOOCs has also raised concerns about their effectiveness, quality, and sustainability. Critics argue that while MOOCs provide access, they may not always deliver the same educational value as traditional classroom experiences. Issues related to course completion rates, learner engagement, and credential recognition have been subjects of ongoing research.

Importance of MOOCs In Engineering Colleges

The integration of Massive Open Online Courses (MOOCs) in engineering colleges represents a significant evolution in the field of technical education. As engineering disciplines rapidly advance due to technological innovations and changing industry demands, traditional educational approaches often struggle to keep pace. MOOCs have emerged as a viable solution, providing flexible, accessible, and diverse learning resources that can enhance the educational experience for engineering students [10].

Addressing Educational Gaps

Engineering colleges face numerous challenges, including the need to keep curricula current and relevant. Traditional classroom instruction may not always offer the breadth and depth of knowledge required for rapidly evolving fields like artificial intelligence, data science, and renewable energy technologies. MOOCs address this gap by providing access to up-to-date content created by experts from leading institutions and organizations. This enables students to explore emerging topics and technologies that may not be fully covered in their formal education. Additionally, MOOCs can supplement the existing curriculum by offering specialized courses that delve deeper into niche areas of engineering. For instance, a student studying mechanical engineering may benefit from a MOOC on

**Chandran and Selvam**

advanced robotics or materials science. This access to diverse content can enrich the learning experience and foster a culture of continuous learning among engineering students.

Enhancing Practical Skills

In engineering education, practical skills are critical for students' success in the workforce. MOOCs often incorporate hands-on projects, simulations, and real-world case studies, allowing learners to apply theoretical concepts in practical contexts. By engaging in these activities, students can develop essential problem-solving skills and gain experience with industry-relevant tools and technologies. This experiential learning is particularly valuable in fields where technical proficiency is crucial, such as software engineering, civil engineering, and electrical engineering. Furthermore, many MOOCs emphasize collaboration and peer learning through discussion forums and group projects. These interactions provide students with opportunities to work in teams, a key competency in engineering careers. Such collaborative experiences help students build soft skills, including communication, teamwork, and adaptability, which are vital for success in the workplace.

Promoting Lifelong Learning

The dynamic nature of the engineering field necessitates a commitment to lifelong learning. As new technologies and methodologies emerge, professionals must continually update their knowledge and skills. MOOCs facilitate this by offering flexible learning pathways that allow both current students and working professionals to engage with new content at their own pace. This adaptability supports the development of a growth mindset, encouraging engineers to seek out new knowledge and skills throughout their careers. Incorporating MOOCs into engineering education also fosters a culture of self-directed learning. Students learn to take initiative in their educational journey, exploring topics of interest beyond their prescribed curricula. This independence is crucial for future engineers, who will need to stay informed and adapt to the changing demands of their industries.

Bridging the Gap Between Academia and Industry

Another significant advantage of MOOCs in engineering colleges is their potential to bridge the gap between academic learning and industry needs. Many MOOCs are developed in collaboration with industry leaders, ensuring that the content is relevant and aligned with current workforce demands. By integrating these courses into their programs, engineering colleges can better prepare students for the challenges they will face in the professional world. Furthermore, MOOCs often provide access to resources such as industry case studies, expert lectures, and insights into best practices. This exposure enhances students' understanding of real-world applications and expectations, making them more competitive in the job market.

LITERATURE REVIEW ON MOOCs

Voudoukis, Nikolaos, and Gerasimos Pagiatakis [11] This study aims to elucidate the concept of Massive Online Open Courses (MOOCs), along with the associated practices, trends, and issues faced by higher education institutions. Despite their brief history, MOOCs experienced significant growth in 2012 when MIT and Harvard established "edX," former Stanford professors launched "Coursera," a corporate entity introduced "Udacity," and the UK's Open University initiated "Future Learn." Currently, most academic institutions in the US and Europe provide MOOCs to their students, presenting a diverse array of online courses across various areas, with the option to get a course certificate if desired. The emergence of MOOCs has significantly impacted global higher education, as learners now possess enhanced access and increased options for their education, compelling higher education institutions to reassess their pedagogical strategies and align with contemporary educational trends. Numerous factors motivate students to engage in a MOOC. Zubkov, Artyom [12] This study investigates the challenges associated with utilising massive open online courses to arrange language instruction in foreign languages for aspiring economists enrolled in undergraduate programs at Transport University. The demands of the contemporary labour market and global circumstances necessitate the implementation of novel approaches in the professional training process, and transportation university's foreign language program is no exception. The author examines

**Chandran and Selvam**

massive open online courses in foreign languages as a creative approach to teaching a foreign language to Economics students at Transport University. We looked at the top internet platforms to see if they were relevant to the study question. Massive Open Online Courses (MOOCs) that satisfy state and federal educational standards, STU curriculum, and the disciplines applied at the "English Language" department were chosen.

Laaser, Wolfram [13] The discussion around "massive open online courses" (MOOCs), which first surfaced in 2008 and have since spread like a "Tsunami" among European educators and universities, is summarised in this paper. However, the definition of MOOCs, often known as "disruptive educational innovation," is not very clear, which has caused some annoyance and scepticism. As a result, the concepts that MOOCs are built upon will be discussed, and the pedagogical and technological context will be clarified through in-depth accounts of real-world cases. After laying out the background, the elements that contributed to the initial excitement surrounding MOOCs will be examined, along with the criticism that will soon be levelled at the claims made by those who support them. The ups and downs in expectations surrounding the introduction of educational breakthroughs are well-illustrated by the Gartner hype cycle model. A quick retrospective on earlier advancements in remote learning will be included to enhance the conversation. Agasisti, Tommaso, Giovanni Azzone, and Mara Soncin [14] The purpose of the current study is to evaluate the impact of Massive Open Online Courses (MOOCs) specifically for the purpose of remedial education. The information relates to Politecnico di Milano, the flagship institution of Italy, where a MOOC platform was introduced in accordance with the "MOOCs to bridge the gaps" approach. Thus, the study's objective is to evaluate how finishing a MOOC that served as a physics foundation course affected the students' performance on the ensuing on-campus physics exam (N = 2,830). Propensity Score Matching (PSM) was employed in the study, with the propensity scores being based on the students' academic and personal data.

De Moura, Valéria Feitosa, Cesar Alexandre de Souza, and Adriana Backx Noronha Viana [15] The purpose of this research is to better understand how blended learning can incorporate MOOCs. In order to achieve this, an exploratory case study in the field of Fundamentals of Administration at a Brazilian university was conducted in order to assess three factors: (1) the pedagogical approach and rationale; (2) the pedagogical and instructional design for incorporating the MOOC into the course; and (3) the students' perceptions of the MOOC's quality and value. The findings demonstrate that the MOOC was implemented as a blended learning technique in an introductory course, taking the place of some of the in-person class hours. This allowed for an increase in the number of students per teacher while also increasing student interest in the field. Akhmetshin, Elvir, *et al.* [16] In order to serve the interests of all parties involved in the educational process and national innovation (educational) strategy, this study aims to determine the prerequisites, including pedagogical ones, for the successful development and operation of MOOCs. The current work is grounded in the traditional scientific research methodology, which encompasses a range of scientific techniques like logical analysis of past events, dialectical observation of the environment, conceptual analysis of concepts in relation to their contradictory aspects, determining the causes and relationships between phenomena, abstracting and defining findings, and multiple-thematic comparative research. Sociological surveys are the method used in this study to gather empirical data. Moreover, it makes use of statistical and graphical data processing techniques. Additional techniques used are the examination of pertinent contemporary scientific literature and the synthesis of innovative ideas that show promise for the advancement of universities utilising digital learning technology. In order to interview teachers and students about the proposed research topic, pertinent questionnaires were created. Students' attitudes towards MOOCs and digital instructional technology are generally good.

Arkorful, Valentina, Kwaku Anhwere Barfi, and Nyinaku Odoi Baffour [17] The study looked at how students' perceived knowledge of Massive Open Online Courses (MOOCs) affects their utilisation of them. The study looks at what influences students' utilisation of MOOCs in Ghanaian universities using the Innovation Diffusion Theory and the Technology Acceptance Model. The Statistical Package for the Social Sciences was used to analyse the data. Structural Equation Modelling was used to analyse the data (SEM-Amos). The results demonstrated that students' use of MOOC systems is positively impacted by their perceptions of the systems' perceived usefulness, perceived simplicity of use, compatibility, and observability. However, students' use of MOOCs systems is adversely affected by their perception of the systems' complexity. Guerrero, Maribel, Sohvi Heaton, and David Urbano [18] Over the

**Chandran and Selvam**

past few years, massive open online courses, or MOOCs, have drawn a lot of attention. While the educational and technological components of MOOCs have been extensively discussed in the literature, there is a dearth of actual data supporting MOOCs' impact on university outcomes. To close this gap, this study will examine the relationships between three key areas: (a) ordinary capabilities required to accomplish the university's core strategies (i.e., teaching quality, research quality, and administrative quality); (b) intrapreneurial capabilities required to accomplish the university's entrepreneurial strategy (i.e., MOOC orientation by taking on risks, sensing opportunities, and changing routines to become more innovative and proactive); and (c) the expected outcomes from these strategies (i.e., prestige in teaching/research, drawing in local and international students, and income structure diversification). Results from an analysis of 145 universities worldwide demonstrate that MOOC-based intrapreneurial capabilities both directly and indirectly contribute to the achievement of university outcomes. They do this by mediating the favourable impact of the university's ordinary capabilities on the outcomes of the university.

Li, Yong. [19] 175 students enrolled in the School of Marxism's massive open online courses (MOOCs) at a university in the province of Henan were chosen as responders for this study. Using SPSS22.0, a hierarchical clustering analysis was performed, and k-means clustering was used to categorise learners' learning preferences. Data envelopment analysis (DEA) was used to evaluate the learners' learning efficiency, and a variance test was used to examine the variations in learners' learning styles in learning inputs and learning outputs. The findings showed that four classes could be formed from the learning behavioural markers of MOOC learners using hierarchical clustering analysis. Learning styles can be categorised into four groups based on the outcomes of k-means clustering: high-input-high-output, high-input-low-output, low-input-high-output, and low-input-low-output. Asten, Tamara, and Ekaterina Egorova [20] In order to utilise mass open online courses as an extra educational resource for university students studying foreign languages, this study aims to compile an analytical review of the technologies of these courses, including their goals, objectives, pedagogical features, and technical aspects of the organisation. The study aims to perform a content analysis, categorisation, and generalisation of the findings concerning the pedagogical conditions and attributes of the most exemplary mass open online course examples in the Russian and global educational Internet resource segments. The competence-based and personality-oriented approaches to foreign language instruction at the university form the foundation of the study methodology. In order to achieve this, the study looked at the methodological and organisational aspects of the language courses offered by Universarium, Stepik, Lectorium, edX, Coursera, and Udemy, among other open education platforms. Systematising, condensing, and presenting the primary methodological and organisational features of educational platforms in terms of training structure and language course material was made feasible by the analysis.

Khalid, Asra, *et al.* [21] Information overload is a result of the exponential growth in the availability of online learning resources. Recommender systems that can suggest educational materials to users based on their interests have been presented as a solution to this issue. A massive amount of data is available in MOOCs, and this number grows as more students sign up. Poor quality recommendations are the outcome of traditional recommendation systems' scalability, sparsity, and cold start issues. Moreover, they are inappropriate for the dynamic environment of MOOCs since they are unable to handle the model's gradual updating upon the introduction of new data. Based on this line of inquiry, the authors suggest a unique online recommender system, called NoR-MOOCs, that solves a number of previously documented issues with recommender systems while also being accurate and scaling well with the data. Pampouri, A., *et al* [22] examined the tenets that underpin MOOC development and design, their philosophy and features, the learning theories that underpin them, and the essential components of a successful MOOC. The term MOOCs was coined in 2008 by Stephen Downes and George Siemens, and they can be broadly classified into two groups: cMOOCs, which prioritise participant contributions and social networking, and xMOOCs, which adhere to the behavioural model of learning approach. In summary, MOOCs promote lifelong learning and collaborative approaches, offer free, open, equitable, high-quality training, and may be used for either professional or personal growth, depending on the needs of the individual.

Longhini, Jessica, *et al.* [23] Distance learning has been heavily incorporated into healthcare sciences curricula in response to the recent challenges posed by the Coronavirus 2019 outbreak. Universities have also been urged to

**Chandran and Selvam**

collaborate on learning opportunities in order to maintain educational continuity and the timely integration of newly graduated students into the healthcare system. Decisions on its introduction, however, ought to be backed by current data that can give a summary of the body of knowledge. To map the current status of research on massive open online courses (MOOCs) in undergraduate and graduate health sciences education, as well as the tools and assessment techniques used to quantify learning outcomes, and the elements that have been shown to increase MOOCs' effectiveness. Syahid, Adi, Khairol Anwar Kamri, and Siti Norbaya Azizan [24] carried out to assess MOOC-Open Learning's usefulness according to undergraduate students' opinions. A survey was distributed online to students enrolled in several undergraduate programs at Universiti Tun Hussein Onn Malaysia (UTHM), a public university in Malaysia, using the quantitative approach. According to the study's findings, respondents had generally moderately good evaluations of MOOC-OpenLearning's usability—that is, its utility, ease of use, ease of learning, and satisfaction—as support for their learning process. The results of this study suggest that respondents have serious doubts about MOOC-OpenLearning's usability, and that more research may be necessary to address the new issues that arise with its use.

Tao, Da, *et al.* [25] Within the context of the Technology Acceptance Model (TAM), this study aims to explore important aspects of user acceptance from interface design (i.e., usability), content quality (i.e., perceived quality), and emotional arousal (i.e., perceived enjoyment) of MOOCs. A self-reported questionnaire measuring TAM components and three hypothesised factors derived from MOOC features was distributed to 658 college students. Every path coefficient was found to be statistically significant based on the path analysis findings. Students' behavioural intention to use MOOCs was highly influenced by their perceptions of the courses' ease of use, utility, and enjoyment. Perceived effectiveness of MOOC use was significantly influenced by both behavioural intention and perceived usefulness. Bokova, Tatiana Nikolaevna, and Olga Aleksandrovna Kabanova [26] Using a comparative analysis and a review of the literature, this study tracks the growth of MOOCs and identifies some widely recognised blended learning models for higher education. This essay also makes an effort to illustrate the drawbacks and benefits of incorporating MOOCs into in-person instruction. The results focus on how Russian institutions may employ massively open online courses effectively.

Li, Yao [27] examined, from the standpoint of higher education, how globalisation of MOOCs affects equality in higher education and the growth pattern of MOOCs in higher education in Mainland China. Wong, Billy Tak-ming [28] studied the educational elements of language MOOCs, or massively open online courses, for language acquisition. Providing quick movies and reading materials for independent study, along with machine-graded quizzes for self-evaluation and discussion boards primarily for peer-to-peer communication on course material, is the standard MOOC methodology. The pedagogical aspects of pertinent MOOCs have not yet been thoroughly examined in relation to language acquisition, which has traditionally been viewed as skill development. Shrivastava, Archana, and Ashish Shrivastava [29] sought to ascertain which aspects of the online program are taken into account and calculate how significant a role each plays in the choice to buy. In order to help online education organisations create their product design strategy and draw in clients with the most appealing offering, this study tries to determine the most profitable bundling of these features and their respective levels. The goal of this study paper is to pinpoint the qualities of online learning that consumers take into account when choosing a product. The main characteristics of online education programs were determined using exploratory factor analysis and confirmatory factor analysis.

Zhou, Xinyu, *et al.* [30] The purpose of this research is to investigate the state of AI education in massively open online courses (MOOCs). To better understand the content and delivery strategies of AI education on MOOC platforms, we coded data on course overviews, content outlines, suggested materials, and teaching methodologies after screening 128 sample MOOC courses from ten learning platforms. The findings indicate that: (1) Companies and universities make up the majority of the organisations delivering MOOCs; (2) Coursera and Edx platforms offer the greatest number of ESD-related courses; and (3) the number of courses connected to AI education that have been offered since 2012 has been rising annually. AI courses are currently very popular, with an average enrolment of over 120,000 students; (2) the main content of AI education consists of topics related to typical applications and core

**Chandran and Selvam**

algorithms; (3) the most popular pedagogical methods used in MOOCs at this time are online procedural teaching, task-driven teaching, and online collaborative learning.

Research Gaps

Despite the numerous benefits of MOOCs, their integration into engineering colleges is not without challenges. Issues such as course completion rates, learner engagement, and the recognition of MOOC credentials can affect their perceived value. Engineering colleges must address these concerns by implementing strategies that encourage participation, support learners, and ensure that MOOCs complement traditional educational approaches effectively.

Awareness and Accessibility: While MOOCs offer extensive resources, there is limited research on the level of awareness among students and faculty in Tamil Nadu's engineering colleges. Understanding the extent to which stakeholders are aware of available MOOCs, their features, and how to access them is crucial for promoting their adoption.

Perceptions and Attitudes: Research on the perceptions and attitudes of engineering students and faculty towards MOOCs in Tamil Nadu is scarce. Understanding how learners view the quality, credibility, and relevance of MOOCs compared to traditional classroom learning is vital. This includes exploring any biases or misconceptions that may exist and how they influence the acceptance and use of MOOCs in engineering education.

Impact on Learning Outcomes: While several studies have examined the effectiveness of MOOCs in various educational contexts, there is a need for specific research focused on engineering colleges in Tamil Nadu. Investigating the impact of MOOCs on students' academic performance, retention rates, and skill acquisition can provide valuable insights into their effectiveness as a supplementary educational resource. Additionally, comparative studies between MOOC participants and non-participants could shed light on the tangible benefits of MOOCs in engineering education.

Curriculum Integration: The integration of MOOCs into existing engineering curricula presents challenges and opportunities that require further exploration. Research is needed to identify best practices for incorporating MOOCs into traditional teaching methods, ensuring alignment with academic standards, and addressing potential curricular gaps. Additionally, studies could focus on the development of hybrid learning models that effectively combine MOOCs with face-to-face instruction.

Student Engagement and Completion Rates: Student engagement and course completion rates are critical factors influencing the success of MOOCs. However, there is a lack of research focusing on the specific engagement strategies that can be employed in engineering colleges in Tamil Nadu to enhance participation and motivation among students. Investigating factors that contribute to high dropout rates, such as course design, content relevance, and support mechanisms, is essential for improving completion rates.

Future Research Direction

As MOOCs continue to evolve, various trends are shaping their future. The integration of artificial intelligence and personalized learning technologies is enhancing the adaptability of MOOCs, allowing for tailored learning experiences. Additionally, the development of micro-credentials and stackable courses is creating new pathways for learners to gain recognized qualifications in specific fields. In summary, MOOCs represent a significant development in the educational landscape, offering unprecedented access to learning resources and fostering new ways of knowledge acquisition. As they continue to evolve, ongoing research and assessment of their impact, effectiveness, and potential will be crucial in shaping the future of education. Understanding the dynamics of MOOCs is essential for stakeholders, including educators, policymakers, and learners, as they navigate this transformative era in education.

ABSTRACT

Crop type classification plays a crucial role in modern agriculture, aiding in yield prediction, resource management, and land-use planning. This paper presents a comprehensive framework for crop type classification utilizing a combination of feature selection techniques, robust classification Algorithm, and a Support Vector Machine (SVM)-based multiclass classification approach. The proposed framework begins with a novel feature selection process that identifies the most relevant attributes from the Agricultural Data and Rainfall data. This feature selection step is essential for reducing data dimensionality, enhancing classification accuracy, and improving model interpretability. Following feature selection, a state-of-the-art multiclass classification strategy based on Support Vector Machines is employed. SVMs are known for their capability to handle high-dimensional data and have demonstrated superior performance in various classification tasks. In this framework, SVMs are adapted to handle multiclass crop type classification efficiently. The model is trained on the selected features and optimized using hyper parameter tuning techniques to ensure robust performance.

Keywords: Crop Classification, Machine Learning, Feature Selection, Classification, Multi-Class Classification, Support Vector Machine

INTRODUCTION

In the realm of modern agriculture and remote sensing, the accurate classification of crop types is a pivotal task with profound implications for crop management, yield prediction, resource allocation, and land-use planning. Accurate identification and mapping of crop types from satellite and aerial imagery have the potential to revolutionize precision agriculture and aid in optimizing farming practices [1] [2]. To achieve this, researchers and practitioners have turned to advanced data-driven techniques, leveraging feature selection, classification algorithms, and multiclass classification strategies. Crop type classification, a subset of remote sensing applications, involves the categorization of agricultural fields into specific crop classes, such as wheat, maize, rice, soybeans, and more. This classification not only informs farmers about the distribution of crops in their fields but also assists in monitoring crop health, identifying pest or disease outbreaks, and guiding decisions related to irrigation and fertilization [3] [4]. This paper delves into the realm of "Crop Type Classification using Feature Selection, Classification, and Multiclass Classification Techniques," where a multidisciplinary approach is adopted to address the challenges and opportunities in this field. We explore the fusion of three fundamental components:

Feature Selection: Remote sensing datasets often contain a multitude of spectral, spatial, and temporal attributes. Feature selection techniques play a vital role in extracting the most informative and discriminative features from this wealth of data. By identifying key features, we can not only reduce dimensionality but also enhance the efficiency and effectiveness of subsequent classification algorithms. The choice of feature selection method can significantly impact the accuracy and computational efficiency of crop type classification models [5][6] [30] [31].

Classification Algorithms: Once relevant features are extracted, the next step is to employ robust classification algorithms capable of accurately categorizing the data into different crop types. These algorithms range from traditional machine learning approaches like decision trees and random forests to more advanced techniques such as support vector machines (SVMs) and deep learning models. The choice of classification algorithm is pivotal to the overall performance and generalization ability of the crop type classification system [7] [8] [25] [26].

Multiclass Classification: Real-world agricultural landscapes are characterized by the coexistence of multiple crop types within the same geographic region. Therefore, a practical crop type classification system must be capable of handling multiclass scenarios where more than two crop types need to be differentiated. Multiclass classification strategies, including one-vs-all, one-vs-one, and softmax-based approaches, become essential to ensure accurate and comprehensive crop type mapping [9] [10] [27] [28] [29]. This paper explores the integration of these three components into a cohesive framework for crop type classification. Through extensive experiments on diverse agricultural datasets, we evaluate the efficacy and performance of different feature selection methods, classification algorithms, and multiclass classification techniques. Ultimately, this research aims to advance the state of the art in crop type classification, providing valuable insights and tools for precision agriculture and sustainable food production.

Related Works

Kalimuthu, M., P. Vaishnavi, and M. Kishore [11] This research study aims to assist novice farmers by utilising machine learning, an advanced technology in crop prediction, to provide guidance on selecting suitable crops for cultivation. The Naive Bayes algorithm, which is a supervised learning technique, proposes a methodology for its implementation. The collection of seed data for crops occurs at this location, taking into account specific parameters such as temperature, humidity, and moisture content. These factors contribute to the favourable conditions necessary for the effective growth of crops. Furthermore, with the software, there is ongoing development of a mobile application specifically designed for the Android operating system. Users are prompted to input factors like as temperature, and their location is automatically retrieved by the programme to initiate the prediction procedure. Nischitha, K., *et al* [12] The system was developed utilising machine learning algorithms with the objective of

**Tamilmani and Muthuramalingam**

enhancing the agricultural practises for the benefit of farmers. The suggested approach aims to provide recommendations for the most appropriate crop selection for a given land area, taking into consideration factors such as soil composition and meteorological conditions. Additionally, the system offers information pertaining to the necessary substance and quantity of fertilisers, as well as the requisite seeds for cultivation. Therefore, with the implementation of the suggested approach, farmers have the ability to cultivate a novel crop variety, potentially leading to an increase in their profit margin, while also mitigating the risk of soil pollution.

Rao, Madhuri Shripathi, *et al* [13] The objective of this study was to identify the optimal model for crop prediction, with the intention of assisting farmers in making informed decisions regarding crop selection, taking into account weather conditions and soil nutrient levels. This study conducted a comparative analysis of commonly used algorithms, namely K-Nearest Neighbour (KNN), Decision Tree, and Random Forest Classifier, employing two distinct criteria, Gini and Entropy. Gupta, Archana, *et al.* [14] Agriculture plays a crucial role in driving economic growth. The maintenance of a healthy biosphere is contingent upon this factor. A diverse array of agricultural products plays a crucial role in several facets of human existence, upon which individuals heavily rely. Farmers are required to effectively adapt to the challenges posed by climate change while simultaneously fulfilling the increasing requirements for greater quantities of food with enhanced nutritional value. To enhance agricultural output and growth, farmers must possess knowledge of the prevailing climatic circumstances, which informs their decision-making process regarding the cultivation of appropriate crops within those specific environmental elements. The implementation of Internet of Things (IoT) technology in the context of Smart Farming has demonstrated significant enhancements to the overall efficiency and effectiveness of the Agriculture system through the real-time monitoring of fields. The system effectively monitors and regulates many variables like as humidity, temperature, and soil conditions, providing accurate and immediate real-time observations. The application of machine learning techniques in the agricultural domain aims to enhance crop productivity and quality. The utilisation of relevant algorithms on the collected data has the potential to facilitate the recommendation of appropriate crops.

Kumar, Y. Jeevan Nagendra, *et al.* [15] Machine learning (ML) plays a vital role in obtaining practical and effective solutions for the problem of crop yield. Supervised Learning in Machine Learning enables the prediction of a target or outcome based on a predetermined set of predictors. In order to obtain the desired outcomes, it is necessary to create an appropriate function that incorporates a collection of variables. This function will effectively transfer the input variable to the intended output. The process of crop yield prediction involves utilising historical data to forecast the anticipated yield of a specific crop. This historical data encompasses various parameters, including temperature, humidity, pH levels, rainfall, and the specific crop being analysed. It provides us with an indication of the optimal projected crop that can be cultivated under specific field weather circumstances. The task of making predictions can be accomplished through the utilisation of a machine learning algorithm known as Random Forest. The system will generate crop predictions with the highest level of accuracy. The random forest approach is employed to generate an optimal crop yield model while minimising the number of models considered. Predicting crop yield in the agricultural sector is highly advantageous. Elavarasan, Dhivya, and PM Durairaj Vincent [16] The present study aims to develop a Deep Recurrent Q-Network model, which is a deep learning algorithm based on Recurrent Neural Network architecture, to predict crop yield using the Q-Learning reinforcement learning method. The data parameters are used to feed the successively stacked layers of a Recurrent Neural Network. The Q-learning network establishes an environment for predicting agricultural productivity by utilising input parameters. The mapping of output values from a Recurrent Neural Network to Q-values is achieved through the utilisation of a linear layer. The reinforcement learning agent utilises a hybrid approach, combining parametric features and a threshold mechanism, to effectively forecast crop yield. Ultimately, the agent obtains a comprehensive score based on its executed actions, aiming to minimise errors and maximise the accuracy of its predictions. The suggested model demonstrates a high level of efficiency in predicting crop production, surpassing the performance of existing models. This is achieved by effectively conserving the original data distribution, resulting in an accuracy rate of 93.7%.

Reddy, D. Jayanarayana, and M. Rudra Kumar [17] I conducted a systematic review that involved the extraction and synthesis of features utilised for the prediction of crop yield, specifically focusing on the cytochrome P450 enzyme

**Tamilmani and Muthuramalingam**

system (CYP). Additionally, a diverse range of methodologies have been developed to analyse crop yield prediction, including approaches derived from artificial intelligence. The primary constraints associated with Neural Networks pertain to the decrease in relative error and diminished predictive efficacy in the context of Crop Yield. In a similar vein, the limitations of supervised learning methods became apparent when attempting to capture the complex relationship between input and output variables in the context of fruit grading or sorting. Numerous research were proposed to enhance agricultural development, with the objective of establishing a precise and effective framework for crop classification. This framework encompasses various aspects, including crop yield estimation based on meteorological conditions, identification of crop diseases, and categorization of crops according to their growth stages. This study investigates the application of machine learning (ML) techniques in the domain of crop yield estimation. It offers a comprehensive examination of the accuracy of these techniques through a detailed analysis. Pant, Janmejey, *et al* [18] This work employs machine learning techniques to forecast the yields of four commonly farmed crops across several regions in India. Once the prediction of crop production is conducted with site-specificity, the application of inputs, such as fertilisers, can be adjusted accordingly based on the anticipated requirements of the crop and soil. In this work, Machine Learning methodologies are employed to construct a trained model that facilitates the identification of patterns within data, specifically for the purpose of crop prediction. This work focuses on the application of machine learning techniques to forecast the yields of the four most commonly farmed crops in India. The crops encompassed in this category are maize, potatoes, rice (paddy), and wheat.

Paudel, Dilli, *et al* [19] The integration of agronomic concepts of crop modelling with machine learning techniques was employed to establish a machine learning baseline for the purpose of forecasting crop yield on a wide scale. The fundamental principle of this workflow is to prioritise consistency, modularity, and reusability. In order to ensure accuracy, the authors prioritised the development of interpretable predictors or features pertaining to crop growth and development, as well as the implementation of machine learning techniques that prevent the inadvertent disclosure of information. The features were generated by the authors through the utilisation of crop simulation outputs, as well as weather, remote sensing, and soil data obtained from the MCYFS database. The authors placed significant emphasis on a modular and reusable process that can effectively accommodate various crops and countries through minor configuration adjustments. The workflow has the capability to execute replicable experiments, such as forecasts made at the beginning or conclusion of a season, by utilising standardised input data in order to achieve findings that can be reproduced. The findings provide a foundation for future enhancements. In the context of our case studies, we made projections regarding agricultural production at a regional scale for five specific crops, namely soft wheat, spring barley, sunflower, sugar beetroot and potatoes. These projections were conducted for three nations, namely the Netherlands (NL), Germany (DE) and France (FR). We conducted a performance comparison between a basic technique lacking predictive ability, which involved predicting either a linear yield trend or the average of the training set. Nishant, Potnuru Sai, *et al*. [20] The study aimed to forecast the agricultural output of several crop varieties cultivated in India. This script employs basic criteria such as State, district, season, and area to facilitate the prediction of crop yield for a specified year. This study employed advanced regression approaches, including Kernel Ridge, Lasso, and Enet algorithms, to forecast yield. Additionally, the concept of Stacking Regression was utilised to enhance the algorithms and improve the accuracy of the predictions.

Proposed Framework for Crop Type Prediction Using Machine Learning Techniques

Figure 1 depicts the Proposed Framework for the Crop Type Prediction using Proposed Feature Selection, Classification and Multi Class Classification methods.

Proposed Gain Ratio Differential Evolution Feature Selection (GRDEFS) Method

Feature selection is a critical step in data preprocessing and machine learning model development, as it directly impacts the efficiency and effectiveness of predictive algorithms. This paper introduces the Gain Ratio Differential Evolution Feature Selection (GRDEFS) method [24], a novel and powerful approach designed to address the challenges of feature selection in high-dimensional datasets. GRDEFS combines the Gain Ratio metric, which measures the relevance of features, with the Differential Evolution optimization algorithm, known for its ability to search for global optima efficiently. The GRDEFS method begins by calculating the Gain Ratio for each feature,

Tamilmani and Muthuramalingam

providing a quantitative measure of the feature's contribution to the classification task. The Differential Evolution algorithm is then employed to search for an optimal subset of features based on the Gain Ratio values. By treating the feature selection process as an optimization problem, GRDEFS efficiently explores the feature space to identify the subset of features that maximizes classification performance while minimizing dimensionality.

Proposed Optimized Artificial Neural Network (OANN) Classification Method

Artificial Neural Networks (ANNs) have proven to be potent tools for solving intricate classification tasks, but they often face challenges related to convergence and local minima. In this study, we propose an innovative approach that harnesses the strengths of both ANNs and Gradient Boosting Machines (GBMs) to enhance classification accuracy and reduce error rates. The novel method begins by initializing ANN architecture with appropriate hyper parameters. To overcome the convergence and over fitting issues often associated with ANNs, we introduce a GBM-based optimization step. This step acts as a dynamic learning rate controller, adjusting the ANN's weights during training to minimize error rates effectively [25]. The GBM-driven optimization process continuously evaluates the ANN's performance on a validation dataset and updates the network's weights accordingly. This adaptive learning strategy ensures that the ANN converges faster and escapes local minima more efficiently. Additionally, it reduces over fitting by preventing the network from memorizing noise in the training data.

Proposed Enhanced Support Vector Machine based Multi Class Classification Method

Support Vector Machine (SVM) algorithms have gained prominence in the realm of machine learning for their effectiveness in binary classification tasks. However, when extended to multi-class classification scenarios, traditional SVMs encounter challenges related to scalability and interpretability. In this study, we introduce an innovative approach that enhances SVM's multi-class classification performance by integrating it with the Logistic Regression-Based SVM Multiclass Method. The proposed method leverages the robustness of traditional SVMs in capturing non-linear decision boundaries while simultaneously harnessing the simplicity and interpretability of Logistic Regression. The key innovation lies in extending the binary SVM approach to multiple classes, ensuring efficient class separation without compromising computational efficiency. The logistic regression-based SVM multiclass method is seamlessly integrated into the SVM framework to create a unified model that optimizes class separation by considering both the SVM margin and logistic regression loss. This integration provides a balanced trade-off between model complexity and classification accuracy, making it well-suited for various multi-class classification tasks.

RESULT AND DISCUSSION

Performance Metrics

Table 1 depicts the Performance Metrics used in this research work.

Description of the Dataset

The Indian crop yield prediction and estimation dataset are taken from Kaggle repository [23]. The dataset is composed of 7 features. Among the 7 features, state_name features have 33 distinct values, district_name have 646 distinct values, crop_year have 19 distinct years, crop features have 124 crops types and season features have 6 seasons. In this dataset, only Tamilnadu State and its 31 districts are considered in this research to evaluate the multiclass classification model for predicting the major crops like Rice, jowar, ragi, bajra, maize, and pulses. For training the model, crop cultivated year of 1997 to 2013 and only three seasons (Kharif, Rabi and Whole Year) are considered since the above-mentioned crops are cultivated during these seasons. Table 2 depicts the description of Indian Crop Yield Estimation Dataset [R].

In this research work, Feature Encoding is done with Label Encoding for the categorical features in the dataset. After the pre-processing step of Label Encoding, the dataset considered in this research work have one state name (Tamilnadu), 31 districts, 17 years of crop cultivation, 3 seasons of crop cultivation, area and production. So, totally, 54 are obtained after the Feature Encoding. In the feature selection step, Proposed Gain Ratio Differential Evolution

**Tamilmani and Muthuramalingam**

Feature Selection (GRDEFS) method [] is used. The performance of the Proposed Logistic Regression based SVM multiclass (LR-SVM-MC) Method is evaluated with the existing classification techniques like Support Vector Machine (SVM), Logistic Regression Classification (LR) Method and Random Forest (RF) Classification Method using the proposed and existing feature selection methods processed datasets. Table 3 depicts the number of features obtained by original dataset, Proposed GRDEFS, Gain Ratio (GR), and Differential Evolution (DE) based feature selections processed datasets. From the table 3, it is clear that the proposed GRDEFS method gives less number of features than the existing feature selection methods.

Table 4 depicts the Classification Accuracy (in %) obtained by the Proposed LR-SVM-MC, SVM and RF classification methods using feature selection processed datasets. In Table 4, the classification accuracy (expressed in percentage) achieved by various classification methods using feature selection techniques is presented. The methods compared are the Proposed LR-SVM-MC, SVM, LR, and RF. For the original dataset, the Proposed LR-SVM-MC achieved a classification accuracy of 53.76%, while SVM, LR, and RF achieved lower accuracies of 48.23%, 45.67%, and 40.32% respectively. Upon applying the GR (Genetic Algorithm Ranking) feature selection technique, significant improvements in classification accuracy were observed across all classification methods. The Proposed LR-SVM-MC exhibited the highest accuracy of 79.43%, followed by SVM with 67.49%, LR with 66.17%, and RF with 63.52%. When the DE (Differential Evolution) feature selection technique was employed, improvements in accuracy were again seen. The Proposed LR-SVM-MC achieved an accuracy of 60.42%, while SVM, LR, and RF achieved accuracies of 58.39%, 57.42%, and 54.71% respectively.

The Proposed GRDEFS (Genetic Algorithm and Differential Evolution Feature Selection) technique led to the highest accuracy values among all experiments. The Proposed LR-SVM-MC achieved an impressive accuracy of 95.66%, followed by SVM with 83.67%, LR with 89.45%, and RF with 79.22%. Overall, the results highlight the effectiveness of the Proposed LR-SVM-MC and feature selection techniques, particularly the combined GRDEFS approach, in significantly enhancing the classification accuracy of the various classification methods. Table 5 depicts the Recall (in %) obtained by the Proposed LR-SVM-MC, SVM and RF classification methods using feature selection processed datasets.

In Table 5, the recall values (in %) obtained from various classification methods using feature selection techniques are presented. The compared methods are the Proposed LR-SVM-MC, SVM, LR, and RF. For the original dataset, the Proposed LR-SVM-MC achieved a recall value of 49.81%, while SVM, LR, and RF achieved lower recall values of 45.85%, 42.26%, and 40.85% respectively. Applying the GR feature selection technique resulted in improved recall values across all classification methods. The Proposed LR-SVM-MC achieved the highest recall of 73.46%, followed by SVM with 61.30%, LR with 60.62%, and RF with 57.22%. When the DE feature selection technique was utilized, recall values were again positively impacted. The Proposed LR-SVM-MC achieved a recall of 74.39%, while SVM, LR, and RF had recalls of 52.53%, 51.84%, and 48.81% respectively. The Proposed GRDEFS technique yielded the highest recall values in all experiments. The Proposed LR-SVM-MC achieved a substantial recall of 95.32%, followed by SVM with 80.48%, LR with 79.73%, and RF with 75.21%. These results emphasize the effectiveness of the Proposed LR-SVM-MC model, along with the feature selection techniques employed, particularly the combined GRDEFS approach. These techniques significantly enhanced the recall values of the various classification methods, demonstrating their potential for improving the identification of relevant instances in the dataset. Table 6 gives the False Positive Rate (in %) obtained by the Proposed LR-SVM-MC, SVM and RF classification methods using feature selection processed datasets.

In Table 6, the false positive rates (expressed in percentage) obtained from various classification methods using feature selection techniques are presented. The methods compared are the Proposed LR-SVM-MC, SVM, LR, and RF. For the original dataset, the Proposed LR-SVM-MC achieved a false positive rate of 65.51%, while SVM, LR, and RF achieved higher false positive rates of 68.78%, 70.35%, and 72.44% respectively. Applying the GR feature selection technique resulted in reduced false positive rates across all classification methods. The Proposed LR-SVM-MC achieved the lowest false positive rate of 34.81%, followed by SVM with 46.22%, LR with 54.64%, and RF with

**Tamilmani and Muthuramalingam**

59.21%. When the DE feature selection technique was used, false positive rates were further lowered. The Proposed LR-SVM-MC achieved a false positive rate of 34.59%, while SVM, LR, and RF had false positive rates of 41.15%, 52.73%, and 55.87% respectively. The Proposed GRDEFS technique resulted in the lowest false positive rates in all experiments. The Proposed LR-SVM-MC achieved a remarkable false positive rate of 12.58%, followed by SVM with 20.43%, LR with 22.58%, and RF with 35.63%. These findings highlight the effectiveness of the Proposed LR-SVM-MC model and the feature selection techniques employed, particularly the combined GRDEFS approach, in significantly reducing false positive rates across the various classification methods. Table 7 gives the Precision (in %) obtained by the Proposed LR-SVM-MC, SVM and RF classification methods using feature selection processed datasets.

In Table 7, the precision values (in %) obtained from various classification methods using feature selection techniques are presented. The compared methods are the Proposed LR-SVM-MC, SVM, LR, and RF. For the original dataset, the Proposed LR-SVM-MC achieved a precision value of 57.85%, while SVM, LR, and RF achieved lower precision values of 50.53%, 48.77%, and 45.81% respectively. Applying the GR feature selection technique led to increased precision values across all classification methods. The Proposed LR-SVM-MC achieved the highest precision of 88.8%, followed by SVM with 81.73%, LR with 79.26%, and RF with 69.31%. When the DE feature selection technique was utilized, precision values were further enhanced. The Proposed LR-SVM-MC achieved a precision of 83.68%, while SVM, LR, and RF had precisions of 79.47%, 71.13%, and 67.41% respectively. The Proposed GRDEFS technique yielded the highest precision values in all experiments. The Proposed LR-SVM-MC achieved an exceptional precision of 95.72%, followed by SVM with 85.42%, LR with 82.57%, and RF with 78.52%. These results underscore the effectiveness of the Proposed LR-SVM-MC model and the feature selection techniques employed, particularly the combined GRDEFS approach. These techniques significantly improved the precision values of the various classification methods, highlighting their ability to correctly classify positive instances and minimize the rate of false positives. Table 8 gives the Specificity (in %) obtained by the Proposed LR-SVM-MC, SVM and RF classification methods using feature selection processed datasets.

In Table 8, the specificity values (in %) obtained from various classification methods using feature selection techniques are presented. The compared methods are the Proposed LR-SVM-MC, SVM, LR, and RF. For the original dataset, the Proposed LR-SVM-MC achieved a specificity value of 34.49%, while SVM, LR, and RF achieved slightly higher specificity values of 31.22%, 29.65%, and 27.56% respectively. Applying the GR feature selection technique resulted in increased specificity values across all classification methods. The Proposed LR-SVM-MC achieved the highest specificity of 65.19%, followed by SVM with 53.78%, LR with 45.36%, and RF with 40.79%. When the DE feature selection technique was employed, specificity values were further improved. The Proposed LR-SVM-MC achieved a specificity of 65.41%, while SVM, LR, and RF had specificities of 58.85%, 47.27%, and 44.13% respectively. The Proposed GRDEFS technique yielded the highest specificity values in all experiments. The Proposed LR-SVM-MC achieved a notable specificity of 87.42%, followed by SVM with 79.57%, LR with 77.42%, and RF with 64.37%. These results underscore the effectiveness of the Proposed LR-SVM-MC model and the feature selection techniques employed, particularly the combined GRDEFS approach. These techniques significantly enhanced the specificity values of the various classification methods, highlighting their ability to correctly classify negative instances and reduce the rate of false positives. Table 9 depicts the Miss Rate (in %) obtained by the Proposed LR-SVM-MC, SVM and RF classification methods using feature selection processed datasets.

Table 9 presents the Miss Rate (in %) obtained by various classification methods, including Proposed LR-SVM-MC, SVM, Logistic Regression (LR), and Random Forest (RF), when applied to feature selection processed datasets using different feature selection techniques. Without any feature selection, all classification methods had relatively high miss rates ranging from 50.19% to 59.15%. This indicates that the original dataset had a considerable degree of classification error. Applying the GR feature selection technique led to a significant reduction in the miss rate for all classification methods. The miss rates dropped to a range of 26.54% to 42.78%, indicating that feature selection improved classification accuracy. The DE feature selection technique also resulted in improved performance, with miss rates ranging from 25.61% to 51.19%. Similar to GR, DE helped reduce classification errors for all methods. The Proposed GRDEFS feature selection technique produced the lowest miss rates across all classification methods,

**Tamilmani and Muthuramalingam**

ranging from 4.68% to 24.79%. This suggests that the combination of the Proposed GRDEFS technique and the Proposed LR-SVM-MC method was particularly effective in reducing classification errors. In summary, the data highlights the importance of feature selection in enhancing classification accuracy. Both GR and DE feature selection techniques led to substantial reductions in miss rates compared to the original dataset. The Proposed GRDEFS technique, in conjunction with Proposed LR-SVM-MC, performed exceptionally well in minimizing classification errors, underscoring its effectiveness in improving classification performance. This analysis emphasizes the significance of feature selection in optimizing machine learning models when dealing with complex and high-dimensional datasets. Table 10 gives the False Discovery Rate (in %) obtained by the Proposed LR-SVM-MC, SVM and RF classification methods using feature selection processed datasets.

Table 10 presents the False Discovery Rate (in %) obtained by various classification methods, including Proposed LR-SVM-MC, SVM, Logistic Regression (LR), and Random Forest (RF), when applied to feature selection processed datasets using different feature selection techniques. Without any feature selection, all classification methods had relatively high False Discovery Rates ranging from 42.15% to 54.19%. This indicates that the original dataset had a substantial number of false positive errors. Applying the GR feature selection technique led to a significant reduction in the False Discovery Rate for all classification methods. The False Discovery Rates dropped to a range of 11.2% to 30.69%, indicating that feature selection improved the ability to control false positive errors. The DE feature selection technique also resulted in improved performance, with False Discovery Rates ranging from 16.32% to 32.59%. Similar to GR, DE helped reduce false positive errors for all methods. The Proposed GRDEFS feature selection technique produced the lowest False Discovery Rates across all classification methods, ranging from 4.28% to 21.48%. This suggests that the combination of the Proposed GRDEFS technique and the Proposed LR-SVM-MC method was particularly effective in minimizing false positive errors. In summary, the data highlights the importance of feature selection in controlling false positive errors in classification. Both GR and DE feature selection techniques led to significant reductions in False Discovery Rates compared to the original dataset. The Proposed GRDEFS technique, when combined with Proposed LR-SVM-MC, demonstrated exceptional performance in minimizing false positive errors, underlining its effectiveness in improving the precision of classification models.

CONCLUSION

This paper presents a holistic and advanced framework for crop type classification that addresses the critical needs of modern agriculture. By combining feature selection techniques, a robust classification algorithm, and a Support Vector Machine-based multiclass classification approach, it offers a comprehensive solution for crop type prediction. The innovative feature selection process significantly contributes to data dimensionality reduction, improved classification accuracy, and enhanced model interpretability, laying the foundation for more precise and efficient crop classification. Leveraging the power of Support Vector Machines, the framework demonstrates its ability to handle high-dimensional data, thereby ensuring accurate crop type prediction.

ABSTRACT

From a global health perspective, Type II Diabetes is emerging as an ever increasing challenge: it has almost reached epidemic proportions and its complications constitute one of the important causes of mortality for deaths in European countries. An early diagnosis is very important for a better management of the problem and to prevent further complications in health. The research demonstrated in this paper deals with early detection of Type II Diabetes, [sic] using real time data and classification algorithm (namely Random Forest). We use Random Forest a robust and accurate algorithm, to predict the high-risk of an individual by biomedical markers as well lifestyle factors. The model is thoroughly tested with k-fold cross-validation to make an unbiased and better generalizer by dividing the dataset into various subsets. The study uses a large real-time dataset that covers numerous variables like blood glucose, body mass index (BMI), age, high/low blood pressure and family history of diabetes. The Random Forest algorithm takes the approach of ensemble learning in which it forms multiple decision trees and compile their predictions to increase accuracy with a decrease over fitting. Running a k-fold cross-validation helps even more in making our model reliable by taking averages of multiple evaluation metrics after training the model on various splits, thereby ensuring an unbiased evaluation of how good or bad your algorithm will generalize. The results indicate that the Random Forest classifier performs a good prediction on real time data for predicting Type II Diabetes with F1, Sensitivity and Specificity up to almost 90% in each case. The model was found to be adequately reliable for early detection of LD (Table), based on its

**Raja and Nagarajan**

performance indicators, which include precision and recall as well mean area under receiver operating characteristic curve.

Keywords: Machine Learning, Random Forest, Diabetes, Health care, K-fold, BMI.

INTRODUCTION

Type II Diabetes Mellitus is diagnosed as an impaired tissue sensitivity/insulin resistance to insulin and the lack of ability by B cells in secreting more insulin sufficient enough for preventing hyperglycemia. Factors such as aging populations, unhealthy diets combined with a rise in obesity and physical inactivity have ensured that globally the incidence of Type II diabetes is going up. This has made it a major public health issue, now with serious consequences such as cardiovascular disease; kidney failure neuropathies and retinopathies. Early diagnosis and intervention in these cases is essential to prevent these complications, improve patient outcomes and reduce the burden on healthcare systems metrics. Traditional way for diagnosing Type II Diabetes are clinical examination in addition to blood tests followed by which the disease is usually caught at a stage when it has come long-way into progression. Yet as we continue to improve the utility of prediction models within data science and machine learning; there are increasing efforts for modeling patient populations that have not yet displayed clinically-significant symptoms from developing Type II Diabetes. In turn, models like this could greatly assist in the transformation of preventative care by allowing early intervention and individualized medicine.

This research work is intended to build a real time data based predictive model for early identification of Type II Diabetes using Random Forest classification technique.... Given this large and high-dimensional dataset, the ensemble method Random Forest can be a good choice as well because of its robustness to overfitting (large amount features) yet still able to capture complex interactions between variables. Aggregating and analyzing data from real-time sources including biomedical markers, contextual lifestyle factors and demographic information to uncover patterns that correlate with increased risk of developing Type II Diabetes. Using k-fold cross-validation is a primary evaluation technique in the study to ensure that the predictive model not only can be applied on an unseen set of data, but also perform better than random guess. K-fold cross-validation splits the dataset in K subsets and trains on k-1 of these subsets while evaluating the model other remaining one. This is done k times and each fold will be used as a test once, the results are then averaged to give an accurate estimate of how well the model will perform on unseen samples. This way the model not only is less prone to overfitting, it also ensures that its predictive accuracy remains more or less consistent across different subsets of data. This paper covers the application of Random Forest classification for predicting onset of Type II diabetes in real-time and concentrate on early identification among at-risk patients. The intent of the study is to strengthen approaches for more accurate, sensitive and timely diagnostic tools in diagnosis management of Type II Diabetes by coupling contemporary machine learning methods with robust ade quant evaluation.

These results contribute significantly to predictive analytics in health care, specifically for early detection of Type II Diabetes:

- This work outlines an approach to design a new predictive model for the early diagnosis of Type II Diabetes based on real-time information and Random Forest classification technique. The model integrates broadly-based biomedical, lifestyle and demographic variables to provide a full systems analysis capable of identifying at-risk individuals prior to the onset of clinical symptom.
- The study demonstrates that the Random Forest algorithm is suitable for high-dimensional data, and can pick up non-linear interactions between variables.
- The effectiveness of the model is evaluated using k-fold cross-validation which ensures that it perform robustly on any set new unseen samples.

**Raja and Nagarajan**

- The predictive model with real-time data contributes most eminently, by providing a more interactive and dynamic risk evaluation.
- The research however also is of relevance to the wider field of preventive healthcare, in as much as it supplies a method for both experts and (potentially) patients themselves to identify those at high risk before Type II Diabetes appears with all its very obvious symptoms.

LITERATURE SURVEY

An especially important research focus has been on the early detection of Type II Diabetes with many data sources and predictive models investigated to improve the accuracy and timeliness of diagnosis. This literature review follows the progression of work in this area, taking into account both machine learning methodologies (Random Forest classification), and incorporating real time data into predictor models. Numerous machine learning techniques have been used for predicting the onset of type 2 diabetes from various related input variables, these include classifiers such as support vector machines (SVM), decision trees and neural networks amongst others alongside ensemble-based models like Random Forest. Research by Xing *et al.* (2019) which compared various classifiers and concluded that Random Forest is superior e.g., in terms of accuracy, but also robustness for large or at least more complex data. Pima Indian Diabetes Dataset (PIDD) is widely employed in many studies as a benchmark which observed Random Forest exceeding desirable metric of Precision and Recall i.e. Efficiency to predict diabetes.

Introduced by Breiman (2001), the Random Forest algorithm is an ensemble learning method that constructs a collection of decision trees during training and outputs the mode or mean prediction of the individual trees. Studies such as Zhang *et al.* Random Forest's appropriateness with respect to medical data and its capability for higher-dimensional feature spaces other than the ability of capturing interactions has specifically been pointed out by Chen *et al.* (2020). Research by López *et al.* Recently McKinzie *et al.*, (2021) confirmed that feature selection techniques also improves the performance of Random Forest in diabetes prediction, and they improve its false positive rate by reducing model complexity. Efforts have also been made to incorporate real-time data into the prediction models for Type II Diabetes to help increase accuracy of predictions in assessing research misconception by health services and policy researchers. Mujumdar and Vaidehi (2017) contributed to the development of diabetes prediction models by using real-time electronic health records (EHRs) although their main focus remained static data sources. Studies, such as Choi *et al.* (2008), have also used RMT technology like continuous glucose monitoring (CGM), and practical sensors to offer a more accurate prediction of diabetes in real-time.

K-fold cross-validation has been widely used for the evaluation of predictive models, to ensure robustness in performance metrics. Kohavi [8] emphasized that using k- fold cross-validation to evaluate machine learning models is a general practice, which diminishes bias and variance introduced by the data in model estimation. Patel *et al.* (2019), in the domain of diabetes prediction also validated their Random Forest model using 10-fold cross-validation, which allowed them to reproduce and generalize the results across different data partitions. The method has been very successful in sparse data situations where the risk of over-fitting is important. Random Forest also ranked well in comparison with other machine learning methods for predicting diabetes from clinical data. For example, Alghamdi *et al.* In an empirical comparison, Krompaß and Weidlich (2020) evaluated the performance of Random Forest to Logistic Regression, SVMs/SVCs, GBMs : Gradient Boosting Machines for this scenario indicating that Random Forest is a robust trade-off among interpretable model. Hyperparameter tuning and feature engineering, as well are found to improve the performance of Random Forests immensely, a fact experimentally proven by study conducted by Rahman *et al.* (2021) in which the number of trees and the depth were optimizing to increased model accuracy. Even though the Random Forest method and real-time data integration has been successful in our diabetes prediction, many challenges still persist. Such challenges include inadequate broad data to thrive on population-wide variation and uncertainty, a classic hallmark of studies in personalized medicine; together with difficulties regarding even the more restricted genomic datatypes encompassing subjective lifestyle measures. The possible future research

Raja and Nagarajan

as suggested by Zhou *et al.* (2022), should develop more intelligible models for not only forecasting time-to-diabetes but also underlying risk factors to guide demographic specific prevention strategies,

Proposed Work

By developing a novel approach to the problem of early diagnosis with real-time data and using Random Forest classifier classifies tests results for Type II Diabetes, validated by k-fold cross-validation this work provides several important contributions to healthcare analytics. Here we present a fresh idea for diabetes prediction by using the real-time data, which is up to-date biomedical and life-style information. In contrast to traditional models that require static datasets, this research shows how real-time data can enhance the accuracy and timeliness of predictions in a continuously changing environment. Machine learning based framework is proposed and developed to predict T-IIDM with the help of lifestyle indicators. The procedural flow from data acquisition to experimental results is depicted in the framework presented by Figure 1.

We employ an ensemble learning framework to provide better predictions of T2DM based on the lifestyle indicators. Sequentially steps which were performed for the development of framework Canvas:

- Initially we imported Type 2 diabetes mellitus dataset from database into Jupyter Notebook using Python programming.
- We have applied the preprocessing techniques to verify the missing values, outliers, corrupted and inconsistent data samples if any.
- The data is being split into training and testing datasets in the ratio of 75% of dataset to train different EL models, while other 25% was used for validation.
- We have used 10-fold cross validation to validate the accuracy of all classifiers.
- This paper compares a number of statistical measurements such as, accuracy, precision, recall and F1-score etc to identify the optimal EL model for T2DM prediction.

Pre-Processing

Data pre-processing is an essential step in any machine learning model development where the raw data gets transformed into a more appropriate format which can be used by different algorithms. This phase guarantees that the data is consistent, tidy and suitable for analysis.

Data Cleaning

Data cleaning Dealing with missing values, outliers and data inconsistency

Handling Missing Values

Missing data may be addressed by either imputing the missing values or removing them. Imputation methods use mathematical approaches to approximate and complete missing data.

Mean Imputation

If a feature x_j has missing values, they may be substituted with the average of the available values.

$$x'_{i,j} = \frac{1}{N_j} \sum_{i=1}^{N_j} x_{i,j} \quad \forall i \text{ where } x_{i,j} \text{ is missing} \quad (1)$$

N_j is the count of observations that are not missing for feature j .

Outlier Detection

Outliers are exceptional data points that have the potential to skew analytical results.

Z-Score method

To standardize data and detect outliers, we might consider values that deviate from the mean μ by a specific number of standard deviations σ .

Raja and Nagarajan

$$z_{i,j} = \frac{x_{i,j} - \mu_j}{\sigma_j} \quad (2)$$

An outlier is typically defined as $|z_{i,j}| > 3$.

Interquartile Range (IQR) Method

An outlier is defined as a number that falls beyond the range determined by the first quartile Q_1 and the third quartile Q_3 .

$$IQR = Q_3 - Q_1 \quad (3)$$

Outliers are values outside $[Q_1 - 1.5 \times IQR, Q_3 + 1.5 \times IQR]$

Feature Extraction and Selection

In this paper, we make an attempt to build effective and accurate Type II Diabetes prediction model that can predict using real-time data by feature extraction and selection. Such techniques can reduce dimensionality, help the model learn better and make sure we use only those features that are most important for a prediction. Central to these routines is the construction of a predictive model, and as such mathematical algorithms like PCA (Principal Component Analysis), mutual information, RFE based feature selection or Lasso must be performed prior this task so that it results in a performant & interpretable predictive model.

Filter Methods

Filter approaches use statistical metrics to rank attributes and then choose the most significant ones.

Mutual Information

Mutual information quantifies the level of interdependence between two variables. Feature X_j and target are defined as follows:

$$I(X_j, Y) = \sum_{x_j \in X_j} \sum_{y \in Y} p(x_j, y) \log \frac{p(x_j, y)}{p(x_j)p(y)} \quad (4)$$

Variables with more mutual information have a stronger predictive power for the target variable.

Chi-Square Test

The chi-square test may be used to evaluate the independence between category characteristics and the target variable.

$$\chi^2 = \frac{(O_i - E_i)^2}{E_i} \quad (5)$$

O_i and E_i represent the observed and predicted frequencies, respectively.

Feature Selection

Recursive Feature Elimination (RFE)

RFE (Recursive Feature Elimination) is a method that iteratively eliminates the least significant features by considering the coefficients of the model. The RFE algorithm proceeds as follows for a model $f(x)$ with features $X = \{X_1, X_2, \dots, X_p\}$:

- Train the model using all the features in the dataset.
- Assign relevance ratings to the features based on their coefficients in linear models and rank them accordingly.
- Eliminate the aspect of least significance.
- Iteratively retrain the model and continue this process until the required number of features is achieved.

Random Forest Feature Importance

Random Forest, an ensemble of decision trees, can compute the importance of each feature based on how much each feature decreases the impurity (Gini index or entropy) in the trees.

For each feature X_j , the importance score $I(X_j)$ is:

Raja and Nagarajan

$$I(X_j) = \sum_{t=1}^T [I(G_{before}) - I(G_{after})] \quad (6)$$

Where G_{before} and G_{after} are the Gini indices before and after the split on feature X_j in tree t .

Classification

Various tools and techniques were applied for the implementation of proposed framework, to design the EL models in case on predicting T2DM. An open source software toolkit of Anaconda 2020 and Experimental language is python(3.9.1) along with it IDE used Jupyter Notebook for computation.

Random Forest is a versatile and simple ensemble learning method for classification and regression class methods. It constructs several decision trees and then combines them in order to provide a better prediction than a single tree. Concept of Random Forest Random Forest is Ensemble method and it used multiple Decision Trees to Improve Classification Accuracy. Each tree in the forest is constructed based on a random sample from both data and features, final predictions are an average of all trees (in case of regression) or majority vote for each class (classification task).

Algorithm 1: Early prediction of T-IIDM using RF

Input: Data Collected from people

Output: Prediction of T-II DM

Step 1: Calculate Boot Strap Sampling

Generate m bootstrap samples, D_1, D_2, \dots, D_m , from the original dataset D containing n samples. Each bootstrap sample is created by randomly selecting instances from D with replacement.

Step 2: Select Feature Subset Selection

Randomly choose a subset of k features from the whole collection of p features for each decision tree. This stochasticity aids in decorrelating the trees.

At each node, choose k features from the total p features $\{X_1, X_2, \dots, X_p\}$ in a random manner.

This extract may be designated as:

$$\text{Feature subset at node } j: F_j \subseteq \{X_1, X_2, \dots, X_p\}, \text{ with } |F_j| = k \quad (7)$$

Step 3: Construct the decision tree

For every bootstrap sample D_i and its matching feature subset, construct a decision tree T_i until it reaches its maximum depth (or until a halting requirement is satisfied). The optimal split at each node is found by evaluating a criteria such as Gini impurity or entropy.

Step 4: Calculate the Gini impuriy

At each node t calculate the Gini impurity $G(t)$ for a binary classification task:

$$G(t) = 1 - \sum_{i=1}^C p_i^2 \quad (8)$$

Let p_i represent the percentage of examples belonging to class i at node t , and let C be the total number of classes. The split that is selected is the one that minimizes the weighted average Gini impurity across the child nodes.

$$\Delta G = G(t) - \frac{n_L}{n} G(t_L) + \frac{n_R}{n} G(t_R) \quad (9)$$

Let t_L and t_R represent the left and right child nodes, respectively, and n_L and n_R denote the number of occurrences in each child node.

Step 4: Calculate Entropy (Information Gain)

Entropy at a node t is defined as:

Raja and Nagarajan

$$H(t) = -\sum_{i=1}^C p_i \log_2(p_i) \quad (10)$$

Information gain for a split is:

$$\Delta H = H(t) - \frac{n_L}{n} H(t_L) + \frac{n_R}{n} H(t_R) \quad (11)$$

Step 4: Voting

In classification tasks, each tree within the forest contributes to a class vote, and the ultimate prediction is determined by the majority vote. In regression tasks, the predictions are computed by taking the average.

In the classification process, each tree T_i generates a prediction y'_i for a given input x . The ultimate forecast y_i is acquired via a process of majority vote.

$$y' = \text{mode}(y'_1, y'_2, \dots, y'_m) \quad (12)$$

RESULT AND DISCUSSION

Data set Collection

Survey and Google-form based data bases collected from Kishtwar district-Rajouri geographical belt of Jammu & Kashmir, India. Experts like Diabetologists, Endocrinologists for Disease wise selection of parameters have been different; so are the professionals: Dieticians/Nutritionist etc. The dataset has 1978 (987 – non-diabetic and 991–diabetic) instances with a total of T2DM 11 features based on lifestyle properties aiming to maintain health, treat or avoid problems. Table 1 List of the biological features with their Description, Class and Data Type. The data in this study was personal medical history and results from the population of each group. Dataset primary goal The main aim of the dataset used for this study is to be able predict whether a patient will suffer from diabetes or not, based on some lifestyle indicators with machine learning. Based on the Asides the selected features provided in the dataset, it predict as well that are possible patients and how positive they might be of having this disease. Also dataset which have used is good composition of the patients includes people from different location, male female ratio patents in class (Urban and Ruler) all age groups including adults. The dataset were collected with survey and google forms prepared in csv file to perform the prediction of T-II DM through different models forest model for this. The dataset description is used to compute several descriptive statistical measures of the dataset. The describe() function of a Data Frame [160] is used to provide a comprehensive summary of the dataset's parameters. Table 2 displays the calculation of statistical metrics such as count, mean, standard deviation, minimum, percentile, maximum, and other numerical values for the Data Frame.

Performance Analysis

When assessing the performance of a Classification task, many metrics may be used based on the unique objectives and kinds of tasks, such as classification, segmentation, and object identification. Below are some of the parameters utilized for performance metrics:

Accuracy: The accuracy is defined as the proportion of properly identified photos to the total number of images.

$$\text{Accuracy} = \frac{\text{True positives} + \text{True Negatives}}{\text{Total samples}} \quad (13)$$

Precision: The precision is defined as the number of true positive predictions divided by the total number of positive predictions.

$$\text{Precision} = \frac{\text{True positives}}{\text{True Positives} + \text{False Positives}} \quad (14)$$

Recall: The accuracy is defined as the proportion of accurately predicted positive observations to the total number of observations in the actual class.

$$\text{Recall} = \frac{\text{True positives}}{\text{True Positives} + \text{False Negatives}} \quad (15)$$

F-1 score: The harmonic mean of Precision and Recall is calculated by taking the reciprocal of the arithmetic mean of their reciprocals.

Raja and Nagarajan

$$F1 - Score = 2X \frac{Precision \times Recall}{Precision + Recall} \quad (16)$$

Histogram Plot for data in Table 2:

Histogram is an instrument for visualization used in case the data comes from some groups. Continuous/discrete variable distribution in an interval of time. Data is plotted and kept contained in sections called bins; this is done using a histogram. Histograms can be used to display the underlying distribution of frequency such as normal distributions, skewness and outliers etc. Figure 3: Histogram contains all the attributes with their distribution.

Performance analysis of the proposed work, simply displayed in figure 4. Based on the confusion matrix, it can be said that the model has successfully predicted 900 non diabetic patients (True Negative) and predict Diabetic of 800 patient, True positive also shows very good overall performance. But it incorrectly also classified 100 non-diabetic as diabetic (False Positives) which may give rise to unnecessary anxiety and interventions. Worse yet, 178 confirmed diabetic cases (False Negatives) were overlooked as 'healthy', potentially postponing life-saving treatment for many individuals. Although the model provides a good prediction for majority of cases, A large number of false negative represents that there is much room to improvement in order not to leave any diabetic patients untreated from becoming late converters.

The accuracy curve for a Random Forest classifier with 85.7% of the accuracy is shown in Figure 5. This is depicted as the red dashed line threshold of 85.7%, there we can see that the accuracy curve level off so it would be some kind of saturation point in which adding more features decrease, rather than improve model performance. This visualization is very important as it assists you to understand when during your classifier's performance reaches and maintains this level of accuracy. Table 3 presents a comparison of the performance measures (Precision, Recall, F1-Score, Accuracy) between the proposed RF classifier and three other models such as K-SVM, K-NN, and DT. A bar plot comparing these metrics across the 4 model can be visualized as shown in figure 6. Figure 6 Performance metrics (Precision, Recall, F1-Score vs Accuracy) comparison of proposed Random Forest classifier with K-SVM, K-NN and Decision Tree models Overall, the Random Forest model performs better than other models on most metrics including Recall (87.2%), and Accuracy (85.7%). Figure 8 K-SVM, as close to performance with a precision of 81.0% and Accuracy:(83.5%). K-NN and Decision Tree have lower performances across all metrics, with K-NN performing worst of all. Random Forest – A high Recall-Precision balance contributes to an impressive F1-Score of 85.2% reflecting the ability when identifying diabetic cases while limiting false positives and negatives This is what makes it a better performer than the compared models in this scenario of classification task.

CONCLUSION

We carried the research for comparing our proposed Random Forest classifier with three available models: K-SVM, K-NN and Decision Tree in terms of varied performance metrics including Precision, Recall, F1 Score and Accuracy. The results show that for most cases, The Random Forest model outperforms all the classifiers with an outstanding 87.2% Recall and a good 85.7% Accuracy which are both essential in positively identifying individuals as potential early-onset T2D positive persons Of these, K-SVM exhibited the most competitive performance but only slightly under-performed in terms of Precision (81.0%) and Accuracy (83.5%). K-NN and Decision Tree models, however are not the best as they showed worst performance in all metrics with K- K being found unsuitable. Random Forest yielded the highest F1-Score (85.2%) and a good balance of Precision & Recall indicating it can better identify diabetic cases without much losing positive or negatives due to its imbalance in class distribution Procedure, compared to rest models, as illustrated by high specificity score. This balance is crucial in a healthcare setting, where accurate and early diagnosis can have major effects on patient lives. Consequently, according to the results of this study Random Forest classifier appears as more efficient predictor for such classification task providing accurate predictions useful for prevention and management of Type 2 diabetes at early stages.

ACKNOWLEDGEMENT

I would like to express my heartfelt gratitude to all those who have contributed to the completion of this study. Firstly, I am deeply indebted to my supervisor, whose guidance, support, and invaluable feedback have been instrumental throughout this journey. Their expertise and encouragement have inspired me to push the boundaries of my research. I also extend my thanks to the participants of this study, whose willingness to share their experiences has enriched the depth and breadth of my findings. Additionally, I am grateful to the authors of the literature that served as the foundation of this work, as well as to my peers and colleagues for their insightful discussions and constructive criticism. Lastly, I extend my appreciation to my family and friends for their unwavering encouragement and understanding during the ups and downs of this academic endeavor.

ABSTRACT

Predictive analytics was the technique with an advanced research approach to find future events, especially in the agriculture field. Agriculture of precision is the leading part within the development of the financial system. Climate as well as soil quality conditions changes have become the most important risk in the prediction of crop yield in agriculture field. But, an accurate prediction faces high complexity. Hellinger divergence matching pursuit Jaspens's correlative regression-based deep multilayer perceptive feed-forward Network (HDMPJCR-DMPFFN) is introduced for increasing accuracy by lesser complexity. Deep feed forward Network includes several layers for processing the given input data. Deep multilayer perceptive network has input layer that collects a large volume of data. Next, input was transformed of deep neural network where the feature selection was performed by Hellinger divergence target matching pursuit. By applying Hellinger divergence, the significant target features related to the prediction are selected. The feature selection helps to reduce complexity time as well as space complexity. Next, selected features were given to subsequent hidden layer to classify the information based on the Multivariate Jaspens's correlative Theil–Sen regression. The regression function detects training features as well as testing features by Multivariate Jaspens's correlation to classify the data for accurate prediction with higher accuracy. Experimental evaluation of HDMPJCR-DMPFFN has various parameters like prediction accuracy, false-positive rate, prediction time, and space complexity. HDMPJCR-DMPFFN enhances accuracy of prediction and decreases the time consumption and space complexity of prediction methods.

Keywords: predictive analytics, big data, Deep feed forward Network, Steepest Hellinger divergence target matching pursuit, Multivariate Jaspens's correlative Theil–Sen regression

INTRODUCTION

Predictive analyzing has large volume of information for extracting helpful patterns and applicable data that provide future results. Recently, several applications are interested in big data such as Agriculture, healthcare, weather forecasting, and so on. Therefore, big data analytics provides better results in agriculture forecasting for timely and reliable yield prediction. Since the crop yield prediction has soil moisture and weather conditions. In order to achieve this goal, several big data techniques and technologies have been developed to handle and analyze the large volume of data from different resources. An integrated ConvLSTM layer by 3-Dimensional CNN (3DCNN) to crop yield prediction method called 'DeepYield' was introduced in [1] based on correct as well as consistent spatiotemporal feature extraction. But accuracy level of prediction and minimum time consumption was not obtained. An Adaptive Domain Adversarial Neural Network (ADANN) was developed in [2] for accurate prediction. But, designed method was failed for designing feature extractor using more advanced architectures to the well-handled large volume of data. Different machine learning methods were introduced in [3] for forecasting soil moisture. But the key features as well as machine learning scheme was not applied for improving accurate soil moisture prediction. Fuzzy Enumeration Crop Prediction Algorithm (FECPA) was developed in [4] for an efficient crop yield prediction. The designed algorithm decreases the time complexity but the space consumption for accurate crop yield is not performed.

Artificial neural network is developed in [5] to the prediction and improving the performance of Big data analysis and conduct huge quantity of information generated to obtain higher agricultural yield. But, it was unsuccessful failed for focusing better prediction results. Machine learning techniques were introduced in [6] for agriculture by using Big Data. But the processing speed of the data is not increased. Similarity of four machine learning techniques is implemented in [7] for computing the monthly soil temperatures at different intensities. But the techniques failed to work with more data. A deep learning approach was introduced in [8] for crop yield using genotype with climate conditions. An approach failed to perform crop management with the soil data. A deep reinforcement learning technique was developed in [9] for smart agriculture IoT systems. However, the designed technique failed to apply for multitask learning and deep computation for smart agriculture. A crop recommendation system was introduced in [10] that employ Map Reduce with K-means clustering for the prediction of crop yield. However, deep learning scheme is not applied to precise prediction.

Major contributions

The major contribution of HDMPJCR-DMPFFN was described by,

1. A novel technique called HDMPJCR-DMPFFN is developed for big data Prediction with the help of two major processes namely feature selection and classification incorporated into the deep multilayer perceptive feed-forward Network.
2. To decrease the prediction time and space complexity, HDMPJCR-DMPFFN uses the Hellinger divergences target matching pursuit for detecting the significant features for classification process. The matching pursuit projects the relevant features based on divergence estimation. This helps to minimize the memory consumption.
3. To increase the prediction accuracy, Multivariate Jaspens's correlative Theil–Sen regression is applied to the hidden layer of Multivariate Jaspens's correlative Theil–Sen regression. The regression function analyzes the training features and testing features using Multivariate Jaspens's correlation. Based on the correlation, prediction is performed with higher accuracy.
4. Finally, comprehensive experiments are used for estimating quantitative analysis of HDMPJCR-DMPFFN by conventional deep learning on different parameters.

Organization of Paper

The paper was organized by: section 2 provides related works within prediction of big data. Section 3 explains the HDMPJCR-DMPFFN by neat diagram. Section 4 illustrates experimental setup by dataset description. Section 5 gives simulation outcome of dissimilar parameters. Section 6 concludes paper.

**Anita and Shakila****Related works**

Hybrid method termed as crop modeling with machine learning is designed in [11] to provide predictions as well as find a feature over crop modeling. But the time consumption for accurate prediction is not reduced. Machine learning algorithms are introduced in [12] to predict maize yield. The algorithms failed to obtain an accurate prediction. A radar echo prediction scheme was developed in [13] to accurately forecast outline of weather radar echo. However, it failed to perform the long-term forecast to obtain detailed information. Integration of machine learning as well as deep learning was introduced in [14] for forecasting crop yield. But, accuracy estimation remained unaddressed. Machine learning-based random forest (RF) is developed in [15] for predicting cotton yield on different period. But, algorithm failed to use efficient device for forecasting crop yield quicker as well as accurate way. The rainfall prediction scheme was introduced in [16] for prediction on spatial-temporal outline. But, method failed to obtain an accurate prediction with minimum time consumption. Machine-learning techniques were developed in [17] to compute the soil moisture in wheat fields. However, it failed to consider evaluation technique for soil moisture prediction. Multi-temporal deep learning were developed in [18] for accurate performance of large-scale crop mapping. But the important feature selection was not performed. Spatial resolution on quality of crop yield prediction was performed in [19] for site-specific crop management. However, it failed to apply machine learning or deep learning for accurate quality of crop yield. Deep learning regression network (DNNR) was introduced in [20] with big data for a soil moisture prediction. It enhances accuracy but time complexity analysis is not performed.

METHODOLOGY

Big Data prediction is the process of analyzing and extracting valuable data from huge number of structured, semi-structured, as well as unstructured data. Big Data needs tools as well as techniques for identifying with extract patterns over huge-scale data. The increasing nature of Big Data requires enhanced data storage capabilities, higher time, as well as memory consumption. Therefore, feature selection is a dimensionality reduction technique to select the important features for providing accurate predictive results. But, the existing methods failed for increasing performance of accuracy as well as time during prediction process with big data. Deep learning techniques are introduced for enhancing accuracy as well as minimize time. Based on motivation a novel deep learning technique called HDMPJCR-DMPFFN is introduced in this paper. It increases prediction accuracy and time by feature selection and classification. Figure 1 portrays different processes of predictive analytics using HDMPJCR-DMPFFN. The number of features is collected from the dataset. In the first stage, the feature selection process is performed using Hellinger divergensive target matching pursuit to minimize the complexity of prediction. Secondly, the classification process is said to be performed using Multivariate Jansen's correlative Theil-Sen regression. A detailed explanation of the proposed is provided in the following sections.

Deep multilayer perceptive feed-forward Network

The proposed HDMPJCR-DMPFFN technique uses a deep multilayer perceptive feed-forward Network for accurate big data prediction. A deep multilayer perceptive feed-forward network has set of weights for forecast of future. Multilayer feed-forward neural network includes multiple layers. From figure 3, deep multilayer perceptive feed-forward Network was explained. Figure 2 depicts the deep multilayer perceptive feed-forward Network. The structure comprises multiple layers and the neurons like the nodes. Input layer and weighted are transferred concurrently towards the second layer, called a hidden layer. Hidden layer units are given to input to another hidden layer. A hidden layer is chosen based on processes of technique. Weighted outputs of final hidden layer were given to input of the output layer produces the output. Therefore, output of one layer was completely linked to the subsequent forward layer. Hence it is called as feed-forward neural network. Neuron input is generally created as a linear combination of its incoming input values.

Anita and Shakila

$$I_i(l) = \sum_i \alpha_i^l x_i^l + \varphi_i^l \quad (1)$$

Where, the neuron input ' $I_i(l)$ ' is generally constructed as a linear combination of its incoming input values ' x_i^l ' and corresponding to the weight of the connection ' α_i^l ' at layer ' l ', ' φ_i^l ' denotes bias that stored the value is ' 1 '. Input was transmitted within initial hidden layer.

Hellinger divergensive target matching pursuit

Big data has the demanding task of machine learning and data mining because the dataset comprises a large volume of data. Feature selection was defined as procedure of attaining the subset over original feature to specific measure by removing the redundant and irrelevant features. Therefore a feature selection process improves the learning accuracy and decreases the time complexity. Based on motivation, the proposed technique introduces a Hellinger divergensive target matching pursuit is a dimensionality reduction technique that helps to find the best matching features from high dimensional to low dimensional space. The target matching pursuit uses the Hellinger divergence for identifying the efficient features.

Figure 3 depicts the block diagram of Hellinger divergensive target matching pursuit for relevant features taken from the dataset the given dataset is $k_1, k_2, k_3, \dots, k_n$ is distributed in the given dimensional space. By applying the Hellinger divergence, the distance is measured between the features.

$$H_D = \frac{1}{\sqrt{2}} \|k_i - k_j\| \quad (2)$$

From the (2), H_D denotes a Hellinger divergence of two features ' k_i, k_j '. Then the threshold function was employed for identifying minimum divergence among features. Therefore, the projection is formulated as given below,

$$Y = \begin{cases} H_D > T ; \text{irrelevant features} \\ H_D < T ; \text{relevant features} \end{cases} \quad (3)$$

Where, Y denotes an output function, H_D denotes a Hellinger divergence, T denotes a threshold. The more divergent features are said to be irrelevant. Otherwise, the feature is said to be a relevant feature. In other words, the divergence is lesser than the threshold said to be relevant. Otherwise, the feature is said to be irrelevant. Followed by this, two distinct categories are generated by employing the threshold function for Hellinger divergence. This is owing to the reason that redundant features associated with other features have to be eliminated. The minimum divergence is selected as a relevant feature. Otherwise, the feature is said to be irrelevant. The relevant features are selected for prediction as well as eliminate irrelevant features. Relevant features were projected over high-dimensional space into low-dimensional space.

$$\varphi : k_R(h) \rightarrow \delta_s \quad (4)$$

Where, φ indicates a projection function to project the relevant features from the high dimensional space ' $k_R(h)$ ' into the subset ' δ_s ' in low dimensional space. With this computationally efficient and relevant features were chosen to prediction for minimizing time complexity and maximize accuracy.

Multivariate Jaspens's correlative Theil–Sen regression

After the feature selection, the prediction is performed in the second hidden layer of the deep multilayer perceptive feed-forward Network. HDMPJCR-DMPFFN employs Theil–Sen regression function to detect training as well as testing information on Multivariate Jaspens's correlation function. Here the multivariate represents the correlation is measured based on the number of testing and training features. The Theil–Sen regression is a machine learning technique for estimating the relationships between one or more variables (called 'features'). The main aim of regression analysis is used to predict similar types of data with a specific mathematical criterion. The mathematical criterion is performed using Jaspens's correlation function.

Anita and Shakila

Figure 4 demonstrates the block diagram of the Multivariate Jaspens's correlative Theil–Sen regression to analyze the given input training and testing data based on the correlation. The input training data $D_1, D_2, D_3, \dots, D_n$ are data collected from the dataset. Then the Multivariate Jaspens's correlation is measured as given below,

$$\rho = \frac{n \sum D_t * D_r - (\sum D_t)(\sum D_r)}{\sqrt{[n \sum D_t^2 - (\sum D_t)^2][n \sum D_r^2 - (\sum D_r)^2]}} \tag{5}$$

From (5), ρ denotes Jaspens's correlation coefficient. 'n' represents a number of data. $\sum D_t * D_r$ denotes a product of paired score of two data. D_t^2 denotes a squared score of D_t and D_r^2 denotes a squared score of D_r . The correlation coefficient provides the resultant value from "-1" to +1. If coefficient provides '+1', then the positive correlation and it provides '-1' provides a negative correlation between two data. Based on the correlation measure, the big data prediction is performed with higher accuracy. Hence, hidden layer is computed by,

$$R(t)^l = [\sum_i \alpha_i^l x_i^l + \varphi_i^l] + [\alpha_{ih}^l * r_i^{l-1}] \tag{6}$$

Where, ' $R(t)^l$ ' denotes the hidden layer result, ' α_{ih}^l ' denotes the weight among input as well as hidden layer, ' r_i^{l-1} ' indicates preceding hidden layer. Finally, hidden layer output was sent to output layer. It is expressed as follows,

$$Z(t) = [\alpha_{no}^l * R(t)^l] \tag{7}$$

From equation (7), ' $Z(t)$ ' denotes the output layer result, ' α_{no}^l ' represents the weight among hidden as well as output layer, ' $R(t)^l$ ' indicates previous hidden layer. Data is properly predicted within different classes. Algorithmic description of the proposed HDMPJCR-DMPFFN is explained below,

// Algorithm 1: Hellinger divergenced matching pursuit Jaspens's correlative regression-based deep multilayer perceptive feed-forward Network

Input: Dataset, Number of features $k_1, k_2, k_3, \dots, k_n$, Number of data $D_1, D_2, D_3, \dots, D_n$

Output: Increase the prediction accuracy

Begin

Step 1: Collect number of features $k_1, k_2, k_3, \dots, k_n$ and data $D_1, D_2, D_3, \dots, D_n$ taken as input at the input layer

Step 2: For each feature // hidden layer 1

Step 3: Measure the divergence ' H_D '

Step 4: if ($H_D < T$) then

Step 5: Feature is said to be a relevant

Step 6: else

Step 7: Feature is said to be an irrelevant

Step 8: end if

Step 9: Select the relevant feature subset

Step 10: Remove the irrelevant features

Step 11: For each training data ' D_i ' with extracted features // hidden layer 2

Step 12: Apply regression function

Step 13: Measure correlation ' ρ ' between training and testing data

Step 14: If ($\rho = +1$) then

Step 15: Data is classified into one class

Step 16: else

Step 17: Data is classified into another class

Step 18: End if

Step 19: Obtain the prediction results at the output layer

Step 20: End for

End

Anita and Shakila

Algorithm 1 explains big data prediction with higher accuracy. Deep multilayer perceptive feed-forward Network comprises multiple layers for identifying input features. Input layer receives amount of features. Hellinger divergencive target matching pursuit was utilized for identifying relevant and irrelevant features. If divergence is lesser than the thresholds, then the features are projected into a relevant and. Otherwise, the features are projected into an irrelevant subset. With similar feature subsets, the Multivariate Jaspens's correlative Theil–Sen regression is applied in the second hidden layer to perform the prediction. The accurate prediction is performed using the Multivariate Jaspens's correlation. Finally, the correlation output is obtained at the output layer. Depend on analysis, prediction was achieved with minimum time consumption.

Experimental Evaluation

Simulation of HDMPJCR-DMPFFN and Deep Yield [1] ADANN [2] were developed using JAVA by Wazihub Soil Moisture Prediction Challenge are taken from (<https://zindi.africa/competitions/wazihub-soil-moisture-prediction-challenge/data>). This dataset was collected as part of an experiment conducted for over 4 months in 4 fields growing maize and peanuts in Senegal. Dataset is precisely predicted growing maize and peanuts based on soil moisture level, weather conditions in advance. This helps to farmers for preparing the irrigation schedules more efficiently. The IoT soil moisture sensors were set up in each of the maize and peanuts fields and collected the weather station. . The collected agriculture dataset is applied to the deep learning algorithm for training purposes. HDMPJCR-DMPFFN is compared by the outcome obtained over conventional techniques. The dataset comprises following attribute information about the soil, climate conditions of 4 fields of growing two crops namely maize and peanuts in Senegal.

Performance Results Analysis

The performance of the HDMPJCR-DMPFFN and existing Deep Yield [1], ADANN [2] is determined by various numbers of information.

Prediction accuracy: It is referred by proportion of number of data were properly classified to entire amount of input data. It was measured by,

$$Pre_a = \left[\frac{ACd_i}{d_n} \right] * 100 \quad (8)$$

From (8), ' Pre_a ' represents the prediction accuracy, ' ACd_i ' designates the amount of data properly classified and ' d_n ' indicates total amount of data. It was calculated by percentage (%).

False Positive Rate: It was referred by number of data wrongly classified to entire amount of data as input. It was calculated using the formula,

$$FPR = \left[\frac{NICd_i}{d_n} \right] * 100 \quad (9)$$

In (9) ' FPR ' indicates false positive rate, ' $NICd_i$ ' represents number of data incorrectly classified ' d_n ' be the total number of data. FPR was computed by percentage (%).

Prediction time: It was formulated by the number of time consumed for prediction of future results on classification procedure. It is expressed by,

$$T_p = [d_n] * T(d_i) \quad (10)$$

In Where ' T_p ' indicates the prediction time, d_n indicates the number of data and ' $T[d_i]$ ' denotes the time taken for single data. It is calculated by milliseconds (ms).

Anita and Shakila

Space complexity: It was measured by number of storage necessary with algorithm for achieving big data. It was measured as given below,

$$S_{com} = [d_n] * MS [d_i] \quad (12)$$

Where, ' S_{com} ' indicates space complexity, ' d_n ' denotes number of data and ' $MS [d_i]$ ' indicates memory consumed to single data. It was measured in terms of Megabytes (MB).

As given from table 2, HDMPJCR-DMPFFN is compared with existing methods namely Deep Yield [1] ADANN [2] respectively. The prediction accuracy is measured based on a amount of data ranges of 2500 to 25000. HDMPJCR-DMPFFN achieves higher prediction accuracy upon comparison with the other two existing methods [1] and [2]. This is proved through quantitative analysis. When considering the number of data as 2500, the proposed HDMPJCR-DMPFFN correctly predicts the 2385 data whereas by applying[1] and [2] correctly predicted data are 2200 and 2150 respectively. Thus, prediction accuracy of HDMPJCR-DMPFFN was 95.4% and the prediction accuracy of existing Deep Yield [1] ADANN [2] is 88% and 86% respectively. Followed by which, the different results are observed along with the various input data. Finally, the performance of HDMPJCR-DMPFFN was compared with existing methods. Prediction accuracy of HDMPJCR-DMPFFN was significantly improved as 8% and 11% when compared to Deep Yield [1] ADANN [2]. The graphical representation of prediction accuracy was explained from figure 5.

Figure 5 shows prediction accuracy by 25000 with different amount of data instances collected over soil moisture prediction. As shown in figure 5, the amount of data were taken to horizontal axis as well as performance results of accuracy using three methods are observed on the vertical axis. Accuracy is improved using the proposed HDMPJCR-DMPFFN method when compared to Deep Yield [1] ADANN [2]. This is due to the application of deep multilayer perceptive feed-forward Network uses the Multivariate Jaspens's correlative Theil-Sen regression is applied in the second hidden layer to perform the accurate prediction by analyzing the testing and training data. Lastly, analyzed outcome were detected by output layer. From analysis, an accurate prediction is performed. Table 3 explains false-positive rate with three different methods namely HDMPJCR-DMPFFN, Deep Yield [1], ADANN [2]. False-positive rate is estimated by number of data taken of 2500 to 25000. The obtained results reveal the false positive rate was considerably decreased using HDMPJCR-DMPFFN than existing methods. With consideration of 2500 data to perform experiments. False-positive rate of HDMPJCR-DMPFFN is 4.6% whereas false-positive rate of the Deep Yield [1] ADANN [2] is 12% and 14% respectively. The average of ten observed results indicates that the false-positive rate of HDMPJCR-DMPFFN was decreased as 58% and 65% compared with Deep Yield [1] ADANN [2] respectively. Figure 6 given above illustrates the false positive rate of HDMPJCR-DMPFFN, Deep Yield [1] ADANN [2]. The figure inferred that the HDMPJCR-DMPFFN is comparatively better in terms of providing the lesser false positive rate. This is because of Multivariate Jaspens's correlative Theil-Sen regression for detecting input training data by test information Based on regression analysis, accurate prediction is obtained as well as reduces wrong data at the output layer.

Prediction time using three methods HDMPJCR-DMPFFN,[1], and [2] are reported in table 4 and figure 7 with respect to 25000 samples of data. In the above figure, the horizontal axis represents the number of data instances collected for the dataset and the vertical axis represents the prediction time of three methods. From the graph, the prediction time of HDMPJCR-DMPFFN is relatively lesser than that of Deep Yield [1] and ADANN [2]. Also, the prediction time is increased gradually by amount of data instances increased. Moreover, with the experiment is conducted using 25000 sample data instances, the time consumed for prediction was found to be 15.4ms using HDMPJCR-DMPFFN, 19.6ms using [1] and 22.4ms using [2]. With this result, the prediction time was observed to be minimized using HDMPJCR-DMPFFN. The reason behind the Deep feed forward Network includes several layers for processing the given input data. Deep feed-forward network collects a large volume of data. Input was transformed within initial hidden as feature selection process was carried out using Hellinger divergensive target matching pursuit. By applying the Hellinger divergensive, the target features are selected for prediction hence the proposed technique minimizes the time consumption. Table 5 and figure 8 portrays performance analysis of space

**Anita and Shakila**

complexity comparison of three different methods, namely HDMPJCR-DMPFFN, Deep Yield [1] ADANN [2]. Amount of data was considered by input ranges of 2500, 5000, ...25000. Consider the amount of data as 2500 to perform experimentation. The memory consumption for prediction is found to be 15ms using HDMPJCR-DMPFFN whereas the memory consumption of Deep Yield [1] and ADANN [2] were 17.75ms and 20ms. HDMPJCR-DMPFFN attains minimum space complexity than the existing methods. Space complexity of HDMPJCR-DMPFFN was decreased as 12% and 20% compared with existing methods. This is because of applying the target feature selection process before the prediction. Hellinger's divergences target matching pursuit helps to project the significant features and remove the divergent features. This helps to minimize the space consumption for prediction.

CONCLUSION

In this paper, big data prediction is performed in agriculture through the application of HDMPJCR-DMPFFN. The proposed deep learning-based methods are appropriate preferences for evolving the larger data, as they often obtain higher performance of prediction with minimum time consumption. Deep learning technology has made a great fast in the traditional prediction analysis. The integration of a Deep neural Network includes for predictive analysis ensures that the agricultural land for crop prediction is considered based on soil and climate changes. In this work, an HDMPJCR-DMPFFN is first considered as input computationally efficient, and find the target features are selected for robust predictive mining. With the obtained target features, classification is performed by analyzing the testing and training feature for predictive mining with the assistance of Multivariate Jaspens's correlative Theil-Sen regression. Simulation outcome illustrates the performance of HDMPJCR-DMPFFN. HDMPJCR-DMPFFN outperforms current state-of-the-art for agriculture within analyzing the sample data. Also, it is shown that the HDMPJCR-DMPFFN increases the accuracy as well as reduces time, false-positive rate and space complexity than conventional approaches.

ABSTRACT

The increasing use of Mobile Ad Hoc Networks (MANETs) in various applications has raised significant concerns about network security due to their decentralized nature, dynamic topology, and limited resources. Among the various threats, the blackhole attack is one of the most critical, where malicious nodes falsely advertise the shortest route to a destination and intercept or drop packets. Detecting and mitigating blackhole attacks have been widely explored in the literature, leading to the development of numerous approaches. This review provides a comprehensive analysis of the existing methods for detecting blackhole attacks in MANETs, including trust-based mechanisms, cryptographic approaches, machine learning techniques, and hybrid solutions. It examines the strengths and limitations of each method, focusing on their effectiveness, computational overhead, and scalability. The review also highlights key research gaps, such as handling multiple coordinated attackers, energy-efficient detection methods, and real-time implementation challenges. Furthermore, it emphasizes the importance of balancing security with the network's performance in resource-constrained environments. This literature review aims to provide researchers with a detailed understanding of the state-of-the-art in blackhole attack detection, guiding future efforts toward more robust, efficient, and scalable security solutions for MANETs.

Keywords: Mobile Ad Hoc Network, Attack Detection, Black Hole Attacks, Intrusion Detection

INTRODUCTION

Mobile Ad Hoc Networks (MANETs) have emerged as a key enabling technology in various fields such as military communication, disaster recovery, emergency rescue operations, and smart vehicular networks [1]. The decentralized nature of MANETs, where nodes communicate without relying on any fixed infrastructure or central authority, allows for quick deployment in environments where traditional networks are impractical. However, the unique characteristics of MANETs, including dynamic topology, limited bandwidth, constrained energy resources, and the absence of centralized control, make them highly vulnerable to a range of security threats. Among these threats, routing attacks are particularly problematic due to their ability to disrupt the fundamental communication processes in the network [2]. One of the most severe routing attacks in MANETs is the blackhole attack. In a blackhole attack, a malicious node advertises itself as having the shortest or optimal path to a specific destination node. Once this malicious node becomes part of the routing process, it drops all or most of the data packets it receives, disrupting the flow of information and causing severe network performance degradation. The distributed and self-organizing nature of MANETs makes detecting such attacks particularly challenging, as there is no central entity to oversee or authenticate the routing process.

The impact of blackhole attacks on MANETs can be devastating. These attacks not only reduce network throughput but also cause significant delays and packet loss, compromising the overall quality of service (QoS) [3]. In critical applications, such as military or emergency response systems, such disruptions can have life-threatening consequences. Therefore, developing effective methods for detecting and mitigating blackhole attacks is essential to ensure secure communication in MANET environments. Over the years, several techniques have been proposed to address the challenge of blackhole attack detection. These techniques can be broadly categorized into trust-based methods, cryptographic schemes, and machine learning approaches. Trust-based methods rely on monitoring node behavior to assess their trustworthiness, whereas cryptographic schemes use encryption and authentication to secure communication paths. Machine learning approaches leverage pattern recognition and data analysis to detect anomalous behavior indicative of a blackhole attack. Some hybrid approaches combine elements from multiple techniques to enhance detection accuracy and efficiency. Despite the significant progress made in this field, several challenges remain. Many detection methods introduce additional computational and energy overhead, which can be detrimental in resource-constrained MANET environments. Moreover, some techniques struggle to adapt to dynamic topologies or fail to handle scenarios with multiple or coordinated attackers. These challenges underscore the need for more advanced and efficient detection mechanisms that can balance security with performance in MANETs [4] [5]. This paper presents a detailed literature review of the existing blackhole attack detection techniques in MANETs. It examines the evolution of detection strategies, highlighting their key features, advantages, and limitations. The review also identifies critical gaps in the current research and suggests directions for future work to address the challenges of blackhole attack detection in MANETs.

Background Study on MANET

Mobile Ad Hoc Networks (MANETs) represent a transformative approach to wireless communication, providing a decentralized, dynamic, and self-configuring network architecture. Unlike traditional networks, MANETs operate without the need for a fixed infrastructure, such as base stations or access points. Each node in a MANET functions both as a host and a router, facilitating multi-hop communication across the network. MANETs are characterized by their ability to form and maintain connectivity autonomously, making them well-suited for a variety of applications in both civilian and military domains.

Architecture of MANET

The architecture of a MANET is characterized by its lack of centralized control or pre-established infrastructure. Instead, each node in the network acts as both a router and an end device, which means that data can be transmitted directly between nodes that are within communication range or relayed through intermediate nodes in a multi-hop fashion. The flexibility and decentralized nature of MANETs allow for rapid deployment in various environments,

**Muralidharan and Subhashini**

including those where traditional networks may not be feasible or available [1] [2]. In a MANET, nodes are typically mobile devices such as Smartphone, laptops, tablets, or military equipment. These devices are equipped with wireless transceivers, which allow them to communicate over wireless links. Since the topology of a MANET changes frequently due to node mobility, the network must be able to adapt to these changes in real time, maintaining communication and routing functionality even as connections are formed or broken.

The basic building blocks of a MANET include:

Mobile Nodes: Devices that move independently and participate in routing and communication.

Wireless Links: Connections between nodes that enable communication. These links are often unreliable and prone to interference, making robust routing essential.

Routing Protocols: Algorithms used to determine optimal paths for data packets between nodes.

Characteristics of MANET

MANETs possess several unique characteristics that distinguish them from traditional networks:

Decentralized Architecture: MANETs lack a central controlling authority, which means that every node is responsible for routing and forwarding packets. This decentralization offers high flexibility and robustness in dynamic and challenging environments.

Dynamic Topology: The topology of a MANET can change frequently due to node mobility. Nodes may join or leave the network at any time, and connections between nodes may break or re-establish as nodes move in and out of communication range. This mobility-driven dynamic nature poses significant challenges for maintaining consistent and reliable communication.

Multi-Hop Communication: In MANETs, nodes must often rely on intermediate nodes to forward data to the destination, as the source and destination nodes may not always be within direct communication range. This requires sophisticated routing protocols that can handle frequent topology changes.

Limited Resources: MANET nodes typically operate in environments with constrained resources, such as limited battery life, processing power, and bandwidth. As a result, network protocols must be designed to operate efficiently while minimizing resource consumption.

Lack of Centralized Infrastructure: Since MANETs are infrastructure-less, the nodes themselves must handle network management tasks, such as route discovery, route maintenance, and resource allocation. This increases the complexity of network protocols and requires distributed algorithms to ensure network performance and reliability.

Scalability Challenges: MANETs can range from small, localized networks to large-scale networks involving hundreds or even thousands of nodes. As the network grows, maintaining effective communication and managing routing overhead becomes increasingly difficult, posing challenges in scalability.

Routing in MANET

One of the most critical functions in a MANET is the routing process. Due to the lack of centralized control and dynamic topology, efficient and reliable routing is essential for network performance [3] [11] [12]. MANET routing protocols can be broadly classified into three categories:

Proactive Routing Protocols: Also known as table-driven protocols, these protocols maintain up-to-date routing information to all nodes in the network by periodically exchanging control messages. Examples include Destination-Sequenced Distance-Vector (DSDV) and Optimized Link State Routing (OLSR). Proactive protocols aim to reduce route discovery delay but incur overhead due to frequent updates, especially in highly dynamic environments.

**Muralidharan and Subhashini**

Reactive Routing Protocols: Also known as on-demand protocols, these protocols create routes only when needed by the source node. Examples include Ad hoc On-Demand Distance Vector (AODV) and Dynamic Source Routing (DSR). Reactive protocols reduce routing overhead but can introduce delay due to route discovery processes.

Hybrid Routing Protocols: These protocols combine features of both proactive and reactive approaches to balance the trade-offs between routing overhead and delay. One example is the Zone Routing Protocol (ZRP), which uses proactive routing within a local zone and reactive routing outside the zone.

Background Study on Black Hole Attacks in MANETS

Mobile Ad Hoc Networks (MANETs) offer significant advantages in terms of flexibility, ease of deployment, and scalability, making them highly suitable for dynamic, infrastructure-less environments [6] [7]. However, these benefits come at a cost, as MANETs are highly vulnerable to various security threats due to their decentralized nature, dynamic topology, and absence of centralized control mechanisms.

The blackhole attack is one of the most severe routing attacks in MANETs due to its ability to disrupt communication by intercepting and dropping packets.

Blackhole Attack Mechanism

A blackhole attack targets the network layer, specifically the routing protocols, by exploiting the trust that nodes have in the routing information exchanged within the network. In a typical MANET, nodes use reactive routing protocols like the Ad Hoc On-Demand Distance Vector (AODV), which discover routes only when a node has data to send. The route discovery process involves broadcasting route request (RREQ) messages to neighboring nodes, which are propagated throughout the network until the destination is reached or an intermediate node has a valid route to the destination [8] [9] [10].

In a blackhole attack, the malicious node exploits this process by falsely advertising itself as having the shortest or most optimal route to the destination, even though it does not have a valid route. The following steps illustrate how a blackhole attack unfolds:

Route Discovery: When a source node initiates a route discovery process by broadcasting an RREQ, the blackhole node responds with a route reply (RREP) message, claiming it has a direct and optimal path to the destination.

Route Establishment: The source node selects the route advertised by the blackhole node, assuming it to be the most efficient.

Packet Dropping: Once the source node begins sending data through the malicious node, the blackhole node either drops or selectively forwards the packets, leading to data loss and communication disruption.

Types of Blackhole Attacks

Blackhole attacks can be further categorized based on the attacker's behavior:

Single Blackhole Attack: In this scenario, only one malicious node is involved in the attack. It advertises a fake route and drops all incoming packets.

Collaborative Blackhole Attack: Multiple malicious nodes cooperate to form a virtual blackhole. One node advertises the false route, while others assist by dropping or rerouting packets, making detection more challenging.

Impact of Blackhole Attacks on MANETs

The impact of a blackhole attack on MANET performance can be severe. Some of the critical consequences include:

- **Data Loss:** As the malicious node drops or discards packets, legitimate data fails to reach its intended destination, resulting in significant data loss.

**Muralidharan and Subhashini**

- **Network Congestion:** The attack causes an increase in retransmissions and additional route discovery processes, which can congest the network and consume valuable bandwidth.
- **Degraded Throughput:** With packets being dropped or misrouted, the overall network throughput is reduced, affecting the quality of service (QoS).
- **Increased Latency:** The source node may experience delays in data transmission as it continuously attempts to resend lost packets or initiate new route discoveries.
- **Trust Compromise:** In a collaborative blackhole attack, multiple malicious nodes work together to deceive the network, undermining the trust in legitimate nodes and protocols.

LITERATURE REVIEW

Yazdanypoor, Mohammad, Stefano Cirillo, and Giandomenico Solimando [11] suggested a comprehensive hybrid detection method that markedly improves the identification and mitigation of black hole and grey hole assaults. Our methodology incorporates anomaly detection, sophisticated data mining tools, and cryptographic validation to create a multi-tiered defence system. Comprehensive simulations indicate that the suggested hybrid technique attains enhanced detection accuracy, minimises false positives, and sustains elevated packet delivery ratios, even in the presence of attacks. This technique offers superior reliability and resilience in network performance, dynamically adjusting to emerging threats compared to previous systems. This research signifies a substantial progress in MANET security, providing a scalable and efficient method for protecting essential MANET applications from advanced cyber-attacks. Ramachandran, Dhanagopal, *et al* [12] A black hole node is designed to deceive other access points into believing they must utilise it as their pathway to a certain destination. The black hole node in a cable network is undetectable and irreparable within an AODV network. In this study, we enhanced AODV by employing a lightweight method grounded in time and baiting to identify and differentiate between individual and collaborative black hole attacks. MANETs exhibit a dynamic topology, utilise an open medium, and lack a centralised monitoring point, all of which provide security challenges. Security assaults constitute one category of attacks. In MANETs, there is no central administration, and mobile devices connect to one another wirelessly. Black holes, insider assaults, grey holes, parallel worlds, defective nodes, and packet losses are all hazards that can significantly interrupt secure communication. Simulation results indicate that the suggested method substantially surpasses prior techniques regarding end-to-end delay, throughput, packet delivery ratio, and average energy consumption. Our proposed technique employs a multipath methodology to alleviate the black hole attack in MANET. The suggested technique is evaluated in a simulated environment to assess its stability under attack conditions.

Abdallah, Ashraf Abdelhamid, *et al* [13] The primary objective of this project is to develop a methodology for detecting blackhole attacks using anomaly detection techniques using Support Vector Machines (SVM). Our detection system analyses node activity to examine network traffic for anomalies. In blackhole circumstances, attackers display unique behavioural traits that differentiate them from other nodes. The suggested SVM-based detection method can efficiently identify this. The suggested detection system aims to analyse network data and discover anomalies through the examination of node behaviours. In the context of black hole threats, it differentiates attackers from legitimate nodes based on behavioural traits. This method enables the system to efficiently identify blackhole attacks. The results indicate a high degree of accuracy in detecting blackhole attacks, validating its effectiveness in safeguarding mobile ad hoc networks (MANETs) by identifying and isolating rogue nodes. This method is especially beneficial in contexts such as military operations and crisis management, when a dependable communication system is essential. Mohanraj, Mr K., and B. Arivazhagan [14] Devised a technique for identifying and mitigating black hole attacks in wireless ad hoc networks through fuzzy heuristics. The methodology entails establishing fuzzy logic rules and heuristics to detect anomalous behaviour indicative of black hole assaults within network traffic. Algorithms are formulated to assess network metrics including packet routing, signal strength, and node behaviour through fuzzy logic methodologies. Attack detection algorithms are employed to dynamically modify network parameters utilising fuzzy inference to alleviate the effects of black hole assaults. Anomaly detection

**Muralidharan and Subhashini**

and prevention modules are incorporated into current network protocols to bolster security against black hole attacks.

Mekadem, Lahcene, and Malika Bourenane [15] Proposed the construction of a cross-layer intrusion detection system to counteract black hole assaults in mobile wireless networks. The suggested methodology has two tiers. At the initial level, data obtained from several layers serves as input to the fuzzy logic system to ascertain the classification of a specific node (malicious, normal, or suspicious). At the secondary level, if a node is deemed suspect, the Dempster-Shafer theory will be utilised to validate that node. Sivanesh, S., and V. R. Sarma Dhulipala [16] Presented the innovative host-based intrusion detection system (HIDS) termed analytical termination of malicious nodes (ATOM), which methodically identifies a prominent black hole attack that impacts the efficacy of the AODV routing protocol. ATOM IDS detects by calculating the RREP count (Route Reply) and the packet drop rate for each node individually. This system has been simulated using the AODV routing protocol integrated with black hole nodes, and the resulting simulation scenario has been produced in NS2. The trace indicates a significant enhancement in the packet delivery ratio (PDR) and throughput. The findings demonstrate the effectiveness of the proposed system.

Shukla, Mukul, and Brijendra Kumar Joshi [17] The suggested solution employs a trust-based fuzzy method that incorporates energy auditing, evaluates the trustworthiness of nearby nodes, verifies packet integrity, and authenticates node members. Trust values in fuzzy logic span from 0 to 1. If the node's trust value is greater than or equal to 0.6, the node is deemed trusted, and its type is utilised for communication between the source and destination in our case. If the node trust rating in the routing table is below 0.6, it indicates that the node is a blackhole node, rendering it an unsafe route. This work proposes a solution called Trust-based Fuzzy Ad hoc On-Demand Distance Vector (TFAODV) to address this attack scenario. Khosa, Thabiso N., Topside E. Mathonsi, and Deon P. Du Plessis [18] The literature assessment indicated that current solutions do not consistently guarantee accurate node classification. The cooperative nature of MANET occasionally results in the erroneous exclusion of innocent nodes and/or the inaccurate classification of malicious nodes. This study proposes a novel Grey Hole Prevention (GRAY-HP) technique for the detection of malicious nodes, achieving a high accuracy rate in node categorisation. The proposed algorithm utilises and adapts the gray-attack prevention method termed Secure Detection Prevention and Elimination Grey Hole (SDPEGH), together with a proactive strategy.

Suma, S., and Bharati Harsoor [19] To distinguish packet loss caused by congestion from that induced by a malicious node, our approach employs an on-demand link and energy-aware dynamic multipath (O-LEADM) routing scheme for mobile ad hoc networks (MANETs) to identify black-hole nodes through the integration of a bait method. The node's behaviour is assessed using control messages, specifically destination-sequence (des-Seq) and reply-sequence (rep-Seq), during channel access. During route discovery, each intermediate node in the network transmits the des-Seq message to all its neighbouring nodes, which subsequently respond to the intermediate node by delivering the rep-Seq message. If the des-Seq and req-Seq from neighbouring nodes do not align, the node is deemed malevolent. Access to the network layer is permitted for an intermediate node if the des-Seq and rep-Seq are congruent. The channel availability and link quality parameters assess link stability, enabling nodes to chose forwarding based on their behaviour and their capacity to achieve Quality of Service (QoS) metrics, including link quality, residual energy, and enhanced packet delivery. Pullagura, Joshua Reginald, and Venkata Rao Dhulipalla [20] examined the detection technique for black hole attacks within the standard ad hoc on-demand distance vector (AODV) routing protocol. The initial phase of the planned work involved a black-hole attack configured on the ordinary AODV protocol. The black-hole node will respond to route requests with the greatest sequence number to incentivise the sender to establish a route through it. The threshold mechanism of the intruder detection system identifies and isolates black-hole nodes. This article estimates the maximal destination sequence number using a linear regression approach. A performance comparison is conducted among standard, black hole-based, and black hole-detection routing systems.

Abdelhamid, Ashraf, *et al* [21] Proposed a solution for identifying black hole assaults utilising anomaly detection with a support vector machine (SVM). This detection system is designed to analyse network data and find anomalies by examining node behaviours. In instances of black hole attacks, the attacking nodes exhibit behavioural traits that

**Muralidharan and Subhashini**

distinguish them from regular nodes. These attributes can be efficiently identified with our streamlined detection technology. An OMNET++ simulator is employed to assess the efficacy of this method by generating traffic during a black hole attack. Traffic is subsequently categorised into harmful and non-malicious, facilitating the identification of the malicious node. The proposed approach demonstrated exceptional accuracy in identifying black hole attacks. Reddy, Bhaskar, and B. Dhananjaya [22] The intermediate nodes transmit data to the designated destination, considering the necessary locations for accurate delivery. The routing protocol in an Ad hoc network employs nodes to assess various device locations and methodologies for potential data paths before determining the optimal route and methods for data exchange. The anomaly arises from the existing trust among various nodes and the dynamic topology, rendering routing protocols vulnerable to Denial of Service attacks, including black hole and wormhole attacks. The lack of integration into a central infrastructure subjects MANETs to conditions that conventional networks typically mitigate by injecting control packets and monitoring the target's movement once the user is connected to the wireless network. In a MANET, the attacker operates prior to the mark entering the wireless medium. Maliciously exploiting diverse routing information might precipitate further disorder within the system, ultimately resulting in extensive network failure. The current AODV attack, known as the Blackhole attack, operates by deliberately withholding critical routing information from end-users who could have utilised it, precisely as the adversary executes in this scenario. In this situation, the data packets remain undelivered, resulting in complete data loss for the system. The array of detection and protection methods utilised against the blackhole attacker substantially reduces the number of suspects. This article advocates for the inclusion of the OSPFV protocol for wireless LANs, incorporating built-in security through threshold evaluation and cryptographic verification. This paper simulates two protocols, the blackhole attack and the proposed AODV-BS, across various MANET models. It employs two additional network metrics: Network Packet Delivery Ratio and normalised Out of Routing Overhead Utilisation, alongside Network Delay, to analyse their performance and derive conclusions.

Kaushik, Sheetal, *et al* [23] concentrated on the Ad Hoc On-Demand Multi-Path Distance Vector Routing (AOMDV) protocol, favoured for its enhanced efficiency relative to a single-path routing protocol in MANETs. We analyse, examine, and assess the optimisation of routes in wireless ad-hoc networks by minimising packet hops across nodes. This study proposes a unique method, the K-AOMDV protocol, which use K-means clustering to mitigate routing misbehaviour. The efficacy of the proposed K-AOMDV (KNN-Ad-hoc On-Demand Multi-Path Distance Vector) routing protocol is assessed by a supervised machine learning methodology to forecast ideal routes considering latency and security threats. Utilising multiple pathways and dynamic route discovery guarantees reliable data transmission despite the existence of hostile nodes. Srilakshmi, R., and Jayabhaskar Muthukuru [24] The unruly nodes that contravene the norm significantly undermine the performance of the virtuous nodes. Consequently, an intrusion detection system should be incorporated into the mobile ad-hoc network (MANET). This study examines wormhole and other deleterious malignant assaults in MANET. A wireless ad-hoc network, also known as a mobile ad-hoc network (MANET), is a collection of nodes that employs a wireless channel to transmit data and collaborate to facilitate information exchange between any two nodes, without a centralised framework. The security concern is a significant challenge in the utilisation of MANETs.

Sunitha, D., and P. H. Latha. [25] concentrated on identifying Black Hole assaults with sophisticated optimisation algorithms, specifically Grey Wolf Optimisation (GWO), Ant Colony Optimisation (ACO), Genetic Algorithm (GA), and Particle Swarm Optimisation (PSO). This survey seeks to improve the performance of MANETs by accurately recognising and minimising the effects of malicious nodes. The proposed method utilises the GWO algorithm to enhance routing pathways, hence increasing throughput and packet delivery ratio while minimising end-to-end delay. The ACO employed a systematic approach for routing decisions, incorporating pheromone updates and heuristic values to improve the efficacy of Black Hole attack detection. The GA framework incorporates Crossover and Mutation operators, facilitating a more systematic generation of nodes and enhancing flexibility to fluctuating network conditions. The PSO method employs a multidimensional strategy, including diversity optimisation and energy-efficient routing for Black Hole discovery. Therefore, the proposed method improves packet transmission in MANET and effectively secures the routing layer. Kaur, Arshdeep, and Jaspreet Kaur [26] presented a security mechanism based on trust. The trust parameters, determined by two factors: (i) Current Energy and (ii) Packed Drop

**Muralidharan and Subhashini**

Count of a node, are utilised to select IDS. The designated IDS node aids the source node in determining a data transmission pathway and thereafter oversees that route until the transmission concludes. The effects of each scenario are evaluated using PDR, NRL, and PLR, and the efficacy of the suggested approach is assessed through three different scenarios featuring varying quantities of attackers, mobility, and nodes.

Cherkaoui, Badreddine, *et al* [27] Proposed a black hole attack detection system utilising the Kolmogorov-Smirnov statistical approach. This technology is engineered to detect communication interruptions induced by such assaults without necessitating structural alterations to the routing protocol. The findings indicate that the suggested strategy can identify the occurrence of the assault through the observation of network activity. Malik, Abdul, *et al* [28] A novel method termed Detection and Prevention of a BHA (DPBHA) is presented to enhance the security and performance of VANETs by identifying BHA at an early stage of the route discovery process. The suggested approach involves computing a dynamic threshold value and creating a counterfeit route request (RREQ) packet. The solution is executed and assessed in the NS-2 simulator, and its performance and effectiveness are juxtaposed with the benchmark schemes.

Olanrewaju, Oyenike Mary, Abdulwasii Adebayo Abdulhafeez Abdulwasii, and Abdulhafiz Nuhu [29] Proposed an Enhanced On-demand Distance Vector (AODV) routing protocol to mitigate Blackhole attacks on MANETs utilising Diffie-Hellman and Message Digest 5 (DHMD), executed via Network Simulator 2 (NS2). The efficacy of the proposed protocol was assessed based on the following metrics: Packet Delivery Ratio, throughput, End-to-End (E2E) Delay, and routing overhead. It was determined that DHMD decreased network overhead to 23%, but AODV recorded 38%. Additionally, memory consumption for DHMD was 0.52 ms, in contrast to AODV's 0.81 ms, attributable to Blackhole prevention. This research aims to alleviate the impact of blackhole attacks on a network and enhance network performance by minimising overhead and memory usage. Kancharakuntla, Deepika, and Hosam El-Ocla [30] suggested an Enhanced Blackhole Resistance (EBR) protocol to detect and mitigate nodes accountable for blackhole attacks. EBR can circumvent congested traffic by routing data packets along a secure path with the minimal round-trip time (RTT). The EBR protocol employs a mix of time to live (TTL) and round trip time (RTT), referred to as a TR mechanism, to identify blackhole assaults. Our approach does not necessitate any cryptography or authentication procedures. Simulation studies demonstrate that EBR outperforms competing protocols for throughput, end-to-end delay, packet delivery ratio, energy efficiency, and routing overhead.

Research Gap

Detecting blackhole attacks is a significant challenge due to several factors:

- **Lack of Centralized Authority:** MANETs lack a central authority to monitor and validate the authenticity of routing information.
- **Dynamic Topology:** Frequent topology changes make it difficult to identify abnormal routing behavior or malicious nodes.
- **Resource Constraints:** Nodes in MANETs are often resource-constrained, with limited battery power, processing capability, and memory. Therefore, resource-intensive detection techniques may not be feasible.
- **False Positives:** Some detection methods may wrongly classify legitimate nodes as malicious, leading to unnecessary route changes and further degrading network performance.

Future Research Direction

The detection and mitigation of blackhole attacks in Mobile Ad Hoc Networks (MANETs) remain challenging due to the dynamic and decentralized nature of the network. While several detection methods have been proposed, each with its advantages and limitations, there are still significant gaps in developing robust and efficient solutions. Future research should focus on overcoming these challenges, exploring new techniques, and improving existing methods. Below are key future research directions for the detection of blackhole attacks in MANETs:

Trust-based and AI Integration: Combining trust-based models that monitor node behavior with AI techniques to enhance detection accuracy while adapting to dynamic network changes.

**Muralidharan and Subhashini**

Cross-layer Approaches: Investigating methods that gather information from multiple layers of the network (physical, data link, and network layers) to better understand node behavior and identify potential blackhole attackers.

Lightweight Hybrid Models: Developing resource-efficient hybrid detection mechanisms that do not impose excessive computational or energy burdens on resource-constrained nodes.

Energy-aware Detection Models: Designing lightweight algorithms that optimize energy consumption while maintaining high detection accuracy. Techniques like data aggregation and selective monitoring of nodes can help reduce unnecessary overhead.

Cooperative Trust Models: Developing trust models that allow nodes to collaboratively assess the behavior of their neighbors. A consensus-based approach can ensure that malicious nodes are detected more reliably, reducing false positives.

Advanced Collaborative Detection Algorithms: Developing advanced techniques to detect coordinated attacks involving multiple blackhole nodes. These methods could analyze node interactions and packet flow to identify suspicious patterns indicative of a collaborative attack.

ABSTRACT

Knee arthritis is a prevalent degenerative joint disease, affecting millions globally and posing significant healthcare challenges. The early detection and accurate diagnosis of knee arthritis are crucial for effective treatment and management. Recent advancements in Deep Learning (DL), Machine Learning (ML), and Image Processing (IP) techniques have opened new avenues for improving diagnostic accuracy and automating the detection process. This literature survey explores the state-of-the-art methodologies employed in knee arthritis detection using these technologies. Key approaches discussed include convolutional neural networks (CNNs) for image classification, support vector machines (SVMs) and decision trees in ML-based classification, and image processing methods like edge detection and segmentation for enhancing radiographic images. The survey also reviews feature extraction techniques, such as texture analysis and wavelet transforms, along with optimization strategies for enhancing prediction performance. Furthermore, challenges such as imbalanced datasets, feature selection, and model interpretability are highlighted. This survey aims to provide a comprehensive understanding of the current landscape, addressing the gaps and future directions for improving knee arthritis detection through advanced computational techniques.

Keywords: Knee arthritis detection, Deep Learning, Machine Learning, Preprocessing, Classification, Image Processing

INTRODUCTION

Knee arthritis, a leading cause of disability worldwide, is characterized by the progressive degeneration of joint cartilage, leading to pain, stiffness, and reduced mobility. Osteoarthritis (OA) and rheumatoid arthritis (RA) are the most common forms of knee arthritis, and early detection is critical for slowing disease progression and improving patient outcomes. Traditionally, clinical diagnosis relies on patient history, physical examinations, and radiographic imaging, such as X-rays and MRI scans. However, these methods can be subjective and time-consuming, often resulting in delayed or inaccurate diagnosis [1]. In recent years, the integration of advanced computational techniques, including Deep Learning (DL), Machine Learning (ML), and Image Processing (IP), has shown significant promise in improving the detection and classification of knee arthritis. These methods offer automated, objective, and scalable solutions for analyzing medical images and identifying patterns that may not be apparent to the human eye. By leveraging large datasets and sophisticated algorithms, DL and ML techniques, such as Convolutional Neural Networks (CNNs), Support Vector Machines (SVMs), and Random Forests, can accurately classify the presence and severity of arthritis. Image processing methods, including image segmentation, feature extraction, and enhancement techniques, further aid in isolating key features within radiographic images for more precise diagnosis [2]. This literature survey aims to provide a comprehensive overview of the various DL, ML, and IP techniques employed for the detection of knee arthritis. It covers recent advancements, commonly used models, and innovative image processing approaches, highlighting their potential and limitations. The review also addresses key challenges such as data imbalance, model interpretability, and the need for better feature selection and optimization strategies. By examining existing methodologies, this survey seeks to identify gaps in current research and suggest directions for future work, with the ultimate goal of advancing the field of arthritis diagnosis through technological innovation.

Image Processing Techniques for the Detection of Knee Arthritis

Image processing [3] [4] plays a pivotal role in the detection and diagnosis of knee arthritis, enabling the enhancement, segmentation, and analysis of medical images to reveal critical features for accurate classification. Given the nature of medical imaging modalities, such as X-rays and MRI scans, image processing techniques help in isolating key regions of interest, improving contrast, and reducing noise, which can significantly aid in the automated detection of knee arthritis.

Image Preprocessing

Preprocessing is a fundamental step that prepares raw medical images for further analysis. Common preprocessing techniques [3] include:

Noise Reduction: Medical images often contain noise that can hinder the clarity of joint structures. Methods such as Gaussian filtering, median filtering, and wavelet-based denoising are employed to remove noise while preserving important features like bone contours and cartilage boundaries.

Histogram Equalization: This technique improves the contrast of images by redistributing pixel intensities, making it easier to differentiate between various tissues and the knee joint's structures.

Normalization: In knee arthritis detection, normalization ensures that images taken under different lighting conditions or settings have similar intensity levels, reducing variability.

Image Segmentation

Segmentation [4] is essential for isolating specific regions of interest, such as the knee joint, cartilage, or osteophytes (bone spurs), which are key indicators of arthritis. Common segmentation techniques include:

Thresholding: This basic technique segments the image based on pixel intensity. Adaptive thresholding can be used to handle images with varying illumination.

Hemamalini and Maniraj

Edge Detection: Methods like the Canny or Sobel edge detectors highlight boundaries between tissues, aiding in the identification of joint spaces, bone edges, and cartilage.

Active Contour Models (Snakes): This technique uses contours that evolve to fit the shape of the knee joint or other structures. It is particularly useful for segmenting complex shapes in noisy medical images.

Region Growing: This technique groups pixels with similar intensity values, enabling the segmentation of cartilage or other soft tissues that exhibit homogeneity.

Watershed Algorithm: Frequently applied in medical imaging, this method treats the image as a topographic surface and segments regions based on ridges or valleys, which can be useful in delineating bones from cartilage.

Feature Extraction

Feature extraction focuses on isolating and identifying specific attributes within the images that are indicative of arthritis [5]. Key techniques include:

Texture Analysis: Texture features, such as the coarseness or smoothness of cartilage, can be analyzed using techniques like Gray Level Co-occurrence Matrix (GLCM) and Local Binary Patterns (LBP). These methods extract texture information that can differentiate between healthy and arthritic tissue.

Shape Descriptors: These descriptors, including contour analysis and shape-based features, are used to evaluate joint space narrowing or bone deformities, which are common signs of arthritis.

Wavelet Transform: This technique is used for multi-resolution analysis of knee images. It helps in detecting fine structures within the joint space and can highlight regions affected by arthritis.

Image Enhancement

Image enhancement techniques are employed to improve the visibility of key features, such as cartilage degradation or bone spurs, which are essential for diagnosing arthritis:

Contrast Enhancement: Techniques like adaptive histogram equalization (AHE) or contrast-limited adaptive histogram equalization (CLAHE) are used to enhance contrast in areas where arthritis-related changes may be subtle.

Sharpening: Techniques like unsharp masking can enhance edges within the knee joint, making it easier to identify joint space narrowing or other deformities.

Super-Resolution Imaging: This advanced technique generates high-resolution images from lower-resolution data, improving the clarity of minute details in knee joints, aiding in the diagnosis of early-stage arthritis.

Deep Learning Techniques for the Detection of Knee Arthritis

Deep Learning (DL) [6] has revolutionized the field of medical image analysis, offering highly accurate and automated solutions for the detection of knee arthritis. By leveraging vast amounts of data and powerful computational architectures, DL techniques, particularly Convolutional Neural Networks (CNNs), have demonstrated exceptional performance in identifying arthritis-related features from medical images. This section outlines the key deep learning methodologies employed in the detection of knee arthritis, focusing on various neural network architectures, training strategies, and performance enhancements.

Convolutional Neural Networks (CNNs)

CNNs are the backbone of deep learning-based image analysis. They excel in learning spatial hierarchies from medical images, making them ideal for detecting knee arthritis through radiographic images such as X-rays and MRIs. Key CNN [7] [8] techniques used for knee arthritis detection include:

**Hemamalini and Maniraj**

AlexNet, VGG, and ResNet Architectures: These popular CNN architectures are widely applied for arthritis detection due to their capability to automatically extract relevant features from images. ResNet, with its residual connections, is particularly useful for addressing vanishing gradient issues in deep networks.

Pretrained Models and Transfer Learning: Given the scarcity of large labeled medical datasets, transfer learning plays a crucial role in knee arthritis detection. Pretrained models such as VGG16, ResNet, and Inception, trained on large datasets like ImageNet, can be fine-tuned for arthritis detection tasks. This approach reduces the need for extensive training data and allows the model to adapt quickly to the medical domain.

DenseNet and EfficientNet: These newer architectures emphasize parameter efficiency and feature reuse. DenseNet, with its densely connected layers, improves feature propagation and reduces the number of parameters, while EfficientNet scales network dimensions effectively, offering a good balance between accuracy and computational cost.

Fully Convolutional Networks (FCNs)

For precise segmentation of knee joint structures such as cartilage and bone, FCNs are employed. Unlike standard CNNs, FCNs replace fully connected layers with convolutional layers, allowing them to generate pixel-wise predictions for segmentation tasks. This is particularly useful in identifying joint space narrowing or cartilage loss, which are indicative of arthritis.

U-Net: U-Net is a popular fully convolutional network designed for medical image segmentation. It consists of a symmetric encoder-decoder architecture, where the encoder extracts hierarchical features from the input image, and the decoder uses these features to perform pixel-wise segmentation. U-Net is particularly effective for detecting joint boundaries and cartilage in knee arthritis.

SegNet: Similar to U-Net, SegNet uses an encoder-decoder structure but focuses on maintaining spatial information through max-pooling indices, making it efficient for segmentation of complex anatomical structures in knee joints.

Recurrent Neural Networks (RNNs) and Long Short-Term Memory (LSTM)

While CNNs are primarily used for spatial data, Recurrent Neural Networks (RNNs), particularly Long Short-Term Memory (LSTM) networks, can be integrated to handle temporal sequences [9][10]. In knee arthritis detection, LSTMs can be used in combination with CNNs to analyze a series of time-lapsed images (e.g., in longitudinal studies of arthritis progression) or to enhance decision-making by capturing dependencies between image slices in 3D MRI scans.

Attention Mechanisms

Attention mechanisms, which allow models to focus on specific regions of an image, have been increasingly applied to knee arthritis detection. By integrating attention layers within CNN architectures, these networks can prioritize areas in the image that are more likely to contain arthritis-related features, such as cartilage edges or joint spaces, thereby improving diagnostic accuracy.

Self-Attention and Transformers: Inspired by natural language processing, self-attention mechanisms and transformer-based architectures are now being explored for image analysis tasks. These models allow for global context awareness, which can be crucial for analyzing complex medical images where local and global features are equally important.

Generative Adversarial Networks (GANs)

Generative Adversarial Networks (GANs) have shown potential in the medical imaging field, including in knee arthritis detection. GANs consist of two networks—a generator and a discriminator—that work in opposition to improve the quality of generated images or features. In knee arthritis, GANs can be used for:

**Hemamalini and Maniraj**

Data Augmentation: GANs can generate synthetic images of knees with varying degrees of arthritis to augment limited datasets, improving the robustness of DL models in detecting early-stage arthritis or rare cases.

Image-to-Image Translation: GANs can translate X-ray images to high-resolution or enhanced versions, helping to detect minute changes in joint space or cartilage that might be missed in standard images.

Related Works

Sikkandar, Mohamed Yacin, *et al.* [11] A novel automatic classification of KOA images utilising an unsupervised local centre of mass (LCM) segmentation technique and a deep Siamese Convolutional Neural Network (CNN) is introduced. First-order statistics and the GLCM matrix are employed to extract KOA anatomical features from segmented images. Bayramoglu, Neslihan, Miika T. Nieminen, and Simo Saarakkala [12] Utilised lateral view knee radiographs from The Multicenter Osteoarthritis Study (MOST) public use datasets (n = 5507 knees). The patellar region of interest (ROI) was automatically identified using the landmark recognition program (BoneFinder), and these anatomical landmarks were later employed to generate three distinct textural ROIs. Features meticulously created from Local Binary Patterns (LBP) were subsequently extracted to characterise the patellar texture. A Gradient Boosting Machine model was initially developed to identify radiographic Perfluorooctanoate (PFOA) using LBP characteristics. Additionally, we employed end-to-end trained deep convolutional neural networks (CNNs) directly on the texture patches for the detection of PFOA.

Supriya, M., and Thayyaba Khatoon Mohammed [13] suggested a hybrid model that integrates sophisticated computer vision methodologies, including Scale-Invariant Feature Transform (SIFT) and Speeded Up Robust Features (SURF), with Support Vector Machines (SVM) and Random Forests. The amalgamation of SIFT and SURF facilitates the extraction of resilient and distinguishing features from knee joint images, essential for precise classification. The SVM and Random Forest algorithms are utilised to categorise these traits, offering an effective means to differentiate between healthy and sick states. We employ a comprehensive array of knee images, encompassing MRIs, CT scans, and X-rays, to train and refine the model, guaranteeing its capability to manage diverse imaging modalities and situations. Abdullah, S. Sheik, and M. Pallikonda Rajasekaran [14] Created a tool for identifying and assessing knee osteoarthritis (OA) using digital X-ray images, demonstrating the potential of deep learning methods to predict knee OA according to the Kellgren-Lawrence (KL) grading system. The objective of the study is to evaluate the efficacy of an artificial intelligence (AI)-driven deep learning method in identifying and assessing the severity of knee osteoarthritis (OA) in digital X-ray images.

Khamparia, Aditya, *et al* [15] Proposed a novel feature extractor from X-ray images of the knee to aid in detection and classification, termed explainable Renyi entropic segmentation inside an Internet of Things (IoT) framework. The suggested method thereafter employs a model-agnostic algorithm utilising post hoc explainability to retrieve pertinent information from knee joint segmentation predictions. The CAD system is connected with an IoT framework and can be utilised remotely to aid medical practitioners in the treatment of knee arthritis. Karpiński, Robert [16] Presented the findings of a preliminary investigation on the simplified diagnosis of knee joint osteoarthritis based on generated vibroacoustic processes. The investigation utilised acoustic signals obtained from a cohort of 50 individuals, comprising 25 healthy subjects and 25 individuals with previously established degenerative abnormalities. The chosen discriminants of the signals were identified, and statistical analysis was conducted to facilitate the selection of ideal discriminants for subsequent usage as input to the classifier. The optimal outcomes of classification utilising artificial neural networks (ANN) of Radial Basis Function (RBF) and Multilayer Perceptron (MLP) kinds are shown.

Trejo-Chavez, Omar, *et al* [17] The primary contribution described is a methodology utilising infrared thermography (IT) and convolutional neural networks (CNNs) to autonomously distinguish between a healthy knee and an injured knee, serving as an alternative tool to assist medical professionals. The methodology comprises three steps: (1) database building, (2) image processing, and (3) construction and validation of a CNN for the automatic identification of patients with knee injuries. During the image-processing phase, greyscale images, equalised images,

**Hemamalini and Maniraj**

and thermal images serve as inputs for the CNN, achieving an accuracy of 98.72% with the suggested technique. Bose, Anandh Sam Chandra, C. Srinivasan, and S. Immaculate Joy [18] This research examines the crucial function of FS in improving the precision and reliability of ML models employed in KOA detection and severity categorisation. The data were sourced from Kaggle, reflecting diverse grades of KOA. We utilise a Convolutional Neural Network (CNN) model to extract characteristics from medical imaging data. Employing sophisticated methodologies like Particle Swarm Optimisation (PSO) and Genetic Bee Colony (GBC), we methodically discern important features to improve our machine learning models.

Sharma, Neha, Riya Sapra, and Parneeta Dhaliwal [19] Examined numerous medical imaging modalities applicable for the detection or diagnosis of Knee Osteoarthritis (KOA) and explored diverse Machine Learning algorithms that facilitate the automated identification of KOA with minimal human involvement. "Joint inflammation" is the synonym for arthritis. Joints are defined as the anatomical regions where two bones converge, facilitating movement, exemplified by the elbow and knee. Arthritis is a prevalent condition that is among the leading causes of global disability. Osteoarthritis is a form of arthritis that mostly arises from recurrent stress on joint cartilage. Osteoarthritis is also referred to as "degenerative" arthritis. Utilising machine learning concepts on medical data can substantially enhance disease detection and early diagnosis. This research provides a comprehensive overview of several medical imaging approaches that enable automated diagnosis of KOA using advanced machine learning methods. Song, Jiangling, and Rui Zhang [20] Concentrate on researching the computer-assisted diagnosis technique for knee osteoarthritis (KOA-CAD) utilising multivariate data, specifically vascular activity graphs (VAGs) and fundamental physiological signals, through an enhanced deep learning model (DLM). A novel Laplace distribution-based technique (LD-S) for classification in DLM is developed. Secondly, an aggregated multiscale dilated convolution network (AMD-CNN) is developed to extract features from the multivariate data of KOA patients. A novel KOA-CAD method is introduced, combining the AMD-CNN with the LD-S to achieve three CAD objectives: automatic KOA identification, early KOA detection, and KOA grading detection.

Zhao, Zhengkuan, *et al* [21] The primary purpose was to employ machine learning techniques to discern critical structural features correlated with pain severity in patients with knee osteoarthritis. Furthermore, we evaluated the efficacy of several categories of imaging data through machine learning methodologies to determine the degree of knee discomfort. Data from semi-quantitative evaluations of knee radiographs, semi-quantitative assessments of knee magnetic resonance imaging (MRI), and MRI images of 567 participants in the Osteoarthritis Initiative (OAI) were employed to build a set of machine learning models. Models were developed employing five machine learning techniques: random forests (RF), support vector machines (SVM), logistic regression (LR), decision trees (DT), and Bayesian approaches (Bayes). Utilising tenfold cross-validation, we identified the optimal models based on the area under the curve (AUC). Patil, Pradnya, *et al.* [22] Formulated a prediction model for Knee Osteoarthritis (KOA) utilising X-ray images and the Kellgren-Lawrence (KL) scale to ascertain the existence of KOA. Medical images, namely knee X-rays, were gathered and categorised by radiologists according to the KL scale, which ranges from 0 (absence of KOA) to 4 (severe KOA). Convolutional neural network (CNN) modelling is employed to analyse X-ray images and predict the KL score.

Zebari, Dilovan Asaad, Shereen Saleem Sadiq, and Dawlat Mustafa Sulaiman [23] Introduced a technique utilising deep features. We utilised a Convolutional Neural Network to extract deep information from images of Knee Osteoarthritis. The collected characteristics are subsequently input into various machine learning classifiers, specifically Support Vector Machine, K-Nearest Neighbour, and Naive Bayes. This study has been classified to distinguish between healthy and unhealthy Knee Osteoarthritis images. Kijowski, Richard, Jan Fritz, and Cem M. Deniz [24] Various deep learning methodologies have been delineated for the fully automated segmentation of cartilage and other knee tissues, attaining superior segmentation accuracy compared to existing techniques while significantly decreasing segmentation durations. Multiple deep learning models have been created for the assessment of osteoarthritis risk by analysing baseline X-rays and MRIs. These models have demonstrated superior diagnostic efficacy in forecasting several outcomes of osteoarthritis (OA), including the incidence and advancement of radiographic knee OA, the emergence and progression of knee pain, and the likelihood of future total knee

**Hemamalini and Maniraj**

arthroplasty. The initial outcomes of deep learning applications in optical coherence imaging have proven promising. Nonetheless, numerous deep learning techniques necessitate additional technical enhancement to optimise diagnostic efficacy. Sharmila Begum, M., *et al* [25]. Proposed an artificial intelligence process for selecting an abstract set of characteristics from the provided raw data, with classification performed via Hybrid Isolation Forest (HIF). The chapter has three steps, beginning with the processing of raw images and the extraction of the pre-processed dataset. The second phase delineates the abstract feature set through statistical and regressive parameters. The third phase introduces a hybrid isolation forest methodology that amalgamates probability distribution with isolation forest techniques to achieve precise classification of normal and anomalous data samples. The suggested AI model is evaluated using the knee joint dysfunction image dataset.

Research Gap

Despite significant advancements in image processing and deep learning (DL) techniques for the detection of knee arthritis, several challenges and research gaps remain. These limitations present opportunities for further research to improve diagnostic accuracy, model robustness, and clinical applicability. The following outlines key research gaps in this domain:

Data Scarcity: One of the major challenges is the lack of large, annotated datasets specific to knee arthritis. Existing datasets, such as the Osteoarthritis Initiative (OAI), are valuable but often limited in terms of diversity, image types (e.g., X-rays versus MRI), and varying levels of disease severity.

Diversity in Imaging Modalities: Most studies focus on a single imaging modality, such as X-rays, while limited work has been done on multi-modal approaches (e.g., combining MRI, X-rays, and CT scans). Integrating data from different modalities could improve diagnosis, but it also introduces challenges in data alignment and fusion.

Class Imbalance: Datasets are often heavily skewed, with a higher prevalence of moderate or severe arthritis cases, leading to biased models that may underperform in detecting early-stage arthritis.

Overfitting: Deep learning models trained on limited datasets are prone to overfitting, where they perform well on the training data but fail to generalize to new, unseen images. This is a particularly challenging issue in medical imaging, where obtaining large, high-quality labeled datasets is difficult.

Lack of Optimal Feature Selection Techniques: Identifying the most relevant features for arthritis detection is crucial, yet many models rely on deep learning's automatic feature extraction without fully exploring optimal feature selection methods. Techniques such as wavelet transforms, texture analysis, or hybrid feature extraction approaches (e.g., combining spatial and frequency domain features) could be further explored to enhance detection performance.

Future Research Direction

Given the current research gaps in knee arthritis detection using image processing and deep learning techniques, several promising avenues for future exploration can be pursued. These research directions aim to enhance model performance, clinical applicability, and the development of real-time, deployable solutions for early and accurate detection of knee arthritis.

Hybrid Models for Enhanced Feature Extraction: Combining CNNs with traditional image processing techniques (e.g., wavelets, texture analysis) or using advanced feature selection methods could improve model performance. Such hybrid models would benefit from the interpretability of classical methods while leveraging the powerful feature extraction capabilities of deep learning.

CNN + RNN/LSTM Architectures: Developing hybrid models that combine spatial feature extraction (via CNNs) with temporal analysis (via LSTMs or RNNs) can allow for more accurate predictions based on image sequences or longitudinal data.

**Hemamalini and Maniraj**

Unsupervised Learning for Feature Discovery: In addition to supervised learning, unsupervised or semi-supervised learning methods should be investigated to discover new, clinically relevant features in knee images. This could lead to the identification of novel biomarkers for early arthritis detection.

ABSTRACT

Software performance error detection is an essential non-functional requirement, which appears in many fields such as complex applications and real-time application development. In this work, he focuses on early detection of performance bugs. The proposed work finds a robust and reliable solution to enforce and predict performance errors. Compared with the proposed new algorithm for defect prediction, we construct several methods using ML algorithms: C4.5 decision tree, naive Bayes, Bayesian network and logistic regression. That's what our exact outcomes show the model proposed using the modified line of code MCCABE/HALSTEAD can be used to predict performance errors with an accuracy of 0.94 and 0.96. We show that reducing the number of committed changes in a commit reduces the chance of injecting performance bugs. This approach helps professionals eliminate performance bugs early in the development cycle. Our results are also of interest to theorists, as they establish a link between functional errors and performance errors, and clearly show that attributes are used to predict functional metrics.

Keywords: Defect prediction, features based, machine learning, performance analysis, regression model, SDLC.

Rajeev and Aravinthan

INTRODUCTION

Data mining is the business of analyzing information from different angles and fusion or compressing it into important and meaningful data. Data mining techniques such as feature extraction and classification techniques have proven to be very effective in predicting defects in biological substances, irregularities in clinical data, and revealing important medical facts that inspire the exploration of such treatments, pharmacology, and clinical decision-making pathway of interest. Feature extraction is the technique of deciding on effective methods or subsets of features to create powerful unsupervised learning models. Classification is a data analysis technique used to distinguish important categories/categories of data. This work aims to identify the optimal and minimal set of software defect models for more accurate identification of software failure propensities in programmed systems. The final performance metrics used to evaluate the current method include precision, sensitivity, and specificity.

Software bugs are often not discovered until late in the development cycle, at which point it is expensive to go back and fix them. Addressing these bugs is a critical flaw that can build an application developer's reputation for delivering products or creating life-threatening situations when the software is part of a larger system or device, such as defense equipment or medical equipment. Therefore, methods for predicting software failures Further improving the quality of programming used in Defense Force programs is the rationale for this research effort. In the literature, several articles have been presented on software faults using mining strategies by predictive methods. Some papers discuss failure prediction methods such as measures of size and complexity, multivariate analysis, and multicollinearity using Bayesian conviction systems. NB is widely used to build classifiers. When building a defect predictor, the probability of each class is computed, given the extracted properties of a module, to predict a defective module using an applicable measure, such as Halstead and McCabe *et al.* This work develops prediction rules for fault attributes using a Naive Bayesian classifier (NB). The focus of this work is to construct effective methods for software fault prediction. We summarize this work for three fundamental reasons: the work creates datasets from publicly available procedural resources; the reported accuracy of combined techniques shows much room for development; the design of more accurate failure prediction techniques can Significantly currently used in the defense framework.

Related Work

Several previous studies analyzed the impact of current contribution behavior on software quality. Examined the effects of ownership and experience on the nature of various open-source projects using a detailed approach based on fix-inducing code fragments and reported similar findings to our paper (Malhotra, Ruchika, and Juhi Jain.2020). However, they operate differently on ownership, and ownership policies and practices in OSS and commercial software are very different. So, the similarity in effect is surprising. Furthermore, Rahman and Devanbu. 2010 did not study the secondary contribution relationship of software dependencies; nor did they consider social media metrics. Concentrated on the impact of counting group size in predictive models (Banga, Manu, and Abhay Bansal. 2020). They use the number of developers for each component, but don't check the percentage of work we explain. They found that failure prediction accuracy could be improved by trivially adding device dimensions to the model. We are different in that we examine the proportion of each developer's contribution to the component. Also, we are not interested in predictions, but there is a statistically significant relationship between attribute determination and failure.

Similarly, Reddy, K. Narsimha, and Polaiah Bojja. 2022studied the relationship between some developers and security vulnerabilities. They found that a security breach was 16 times more likely to occur if more than nine developers contributed to a source file. New approaches such as Extreme Programming (XP) (Chakraborty *et al.* 2020) claim ownership of collective code, but there is little empirical evidence or support for such information in considerably larger or more difficult applications. Our study is the first to empirically quantify the impact of code owners (and inexperienced contributors) on overall code quality. Execution bugs are more diligently to uncover during the testing stage since they don't cause lethal side effects and don't affect the overall results. Pant *et al.*2022.

**Rajeev and Aravinthan**

Furthermore, it is difficult to find the root cause of performance bugs (compared to other types of bugs); they also take longer to resolve (Goyal and Somya 2020).

The closest work to ours is that of Ekenet *et al.* 2021, who studied a set of 109 real-world performance bugs. They study the lifecycle of errors from creation to correction, root causes, and introduction mechanisms to create rule-based detectors. We use a similar approach to create detectors (called "patterns" in our research) to identify similar performance errors. They examined software written in Java, C, C++, and JavaScript; our program was written in MATLAB. Additionally, we focused on finding an efficient way to automatically detect performance bugs (197 real-world performance bugs in our example) based on data extracted from usage patterns. In summary, focused on analyzing performance bug characteristics, whereas in this study we aim to understand the contribution of each source code attribute retrieved from a source code repository to the predictive power of various algorithms (Malhotra, Ruchika. 2020). We use automatic algorithms. Finally, our general approach and methodology for building predictive models is designed to be easily reproducible in the future. Therefore, our work is complementary.

Automatic performance bug detection has been implemented in the past (Banga, *et al.* 2020), (Hosseinipour, *et al.* 2022). However, the authors use dynamic analysis tools, namely execution traces and historical performance data, to detect slow-running code. Additionally, dynamic analysis tools often require a dedicated test environment to get accurate performance readings. On the other hand, we leverage code properties pulled from source code repositories and automatically catch performance bugs before the code is executed (and put into production). Accordingly, our work is reciprocal. Static examination devices can likewise dispose of execution bugs (Reddy, *et al.* 2022). In any case, this approach requires information on pattern formats, while our approach does not (since we omit schema type information from the model), so our work is relevant. RTS has formal and comprehensive coding standards. However, standards are usually language-specific (for example, C (Dereli, and Serkan, 2022.) and C++ (Sharma, *et al.* 2022). Apparently, there is no finished furthermore, formal RTS coding standard for MATLAB. At last, since in our review we relate execution to the continuous idea of the framework, it can be argued that programming languages may not be suitable for this situation. While this is an inquiry. We grasp its significance and legitimacy outside the extent of this review. This programming language (with a suitable runtime (Nitta, *et al.* 2022)) is used in known large-scale RTS.

The Table 1 presents a comparative analysis of previous research and the current study on software defect prediction, focusing specifically on performance bugs. Malhotra and Ruchika's work shares similarities with the current research in analyzing ownership and experience effects on software quality but lacks exploration of secondary contribution relationships in software dependencies. Banga and Manu's study highlights the impact of group size on predictive models, improving prediction accuracy, yet it overlooks the proportion of each developer's contribution. Menely and Williams emphasize the relationship between developers and security vulnerabilities, diverging from performance bug analysis. Jin *et al.* undertake a lifecycle study of real-world performance bugs, albeit in different programming languages than the current study. Previous works generally analyze performance bug characteristics, but lack focus on automatic algorithms and reproducibility. Past implementations prioritize dynamic analysis, while the current study emphasizes static examination, though omitting schema type information and relevance to MATLAB coding standards. Overall, the current study bridges gaps in previous research by focusing on automatic algorithms, reproducibility, and relevance to MATLAB coding standards for performance bug detection.

METHODOLOGY

Data Preparation

We removed all records that didn't go into the indicator extraction library, namely: readme, test scripts and help documents. Additionally, we eliminated 0.2% (9 out of 4623 extraordinary tuples) of "commit ID-filename" records connected with source code documents. These records are outliers, corner cases. For instance, we exclude source files that have been moved or deleted. More specifically, version control systems by default recognize index

Rajeev and Aravinthan

changes/refactoring's as complete cancellations of the actual records. So, whenever a file moves up or down at least one levels in the registry structure, we notice an unusual number of lines being added or removed. In some of these cases (particularly registries with huge records) in excess of 10,000 lines were added or taken out in a solitary commit. The above cleanups lead to more accurate model building, mainly due to the evacuation of sections that won't be found in future commits. The "Data Preparation Workflow" Figure 1 provides a visual overview of the steps involved in preparing the data for analysis. The process begins with data cleaning, where any inconsistencies or errors in the dataset are addressed. Next, the need for outlier removal is evaluated, and if necessary, outliers are removed to ensure the integrity of the data. Following this, the dataset selection step involves selecting the appropriate dataset for analysis. Once these steps are completed, the data is ready for further analysis and processing. This diagram serves as a guide for researchers and readers, outlining the essential steps in data preparation before conducting any analysis, thereby ensuring the quality and reliability of the data used in the study.

Metrics Extraction

Features are extracted based on McCabe and Halstead metrics. The Table 2 below defines the flaw detector evaluation.

			module	actually	has
			defects		
				No	Yes
classifier	predicts	no	No	tp	Fn
defects					
classifier	predicts	Some	Yes	fp	tn
defects					

$$\text{Accuracy} = \frac{\text{True Positives} + \text{True Negatives}}{\text{True Positives} + \text{False Positives} + \text{True Negatives} + \text{False Negatives}}$$

$$\text{Recall} = \frac{\text{True Positives}}{\text{True Positives} + \text{False Negatives}}$$

$$\text{Precision} = \frac{\text{True Positives}}{\text{True Positives} + \text{False Positives}}$$

$$\text{Effort} = \frac{\text{False Positives} \times \text{LOC} + \text{True Negatives} \times \text{LOC}}{\text{Total LOC}}$$

The Four McCabe software metrics are: Essential complexity, cyclomatic complexity, design complexity and LOC. Table 2 offers a comprehensive overview of the metrics extracted from software code, encompassing both McCabe and Halstead metrics along with their respective definitions and calculation methods. Each metric, ranging from LOC (McCabe's line count of code) to Total Operators (Halstead), provides crucial insights into different aspects of the code's complexity, including program length, essential complexity, and design complexity. For instance, Cyclomatic Complexity (v(g)) measures program complexity by assessing the number of linearly independent paths through the code, while Volume (v) calculates the vocabulary size multiplied by the logarithm of program length, indicating the overall size of the codebase. This Table 2 serves as a valuable reference for researchers and practitioners alike, enabling a deeper understanding of software code characteristics and facilitating informed decision-making in software development and maintenance processes.

Attribute Information

The "Attribute Information Table 3" serves as a comprehensive reference for understanding the attributes utilized in the study for software defect prediction. Each attribute, ranging from McCabe's line count of code to various metrics derived from Halstead's analysis, is detailed along with its significance in software defect prediction. For instance,

**Rajeev and Aravinthan**

McCabe's line count of code provides insights into code size and complexity, while metrics like Cyclomatic Complexity and Design Complexity offer measures of program structural complexity and potential design flaws, respectively. Halstead's metrics, such as Volume and Effort, quantify aspects like code size and development effort, crucial for predicting software defects. Additionally, attributes like Comment Count and Blank Line Count shed light on code documentation and readability, factors influencing software quality. This Table 3 not only aids in understanding the attributes used in the study but also highlights their roles in predicting and mitigating software defects, facilitating informed decision-making in software development and maintenance processes.

Rule Mining

Based on recommended intervals, we characterize basic principles for every measurement. These standards fire if a module's metrics are not within the specified interval (which means checking the module manually). It shows 12 base rules with their corresponding flags, and 2 derived rules. The first derivative rule, rule 13, defines the partition of the 12 basic rules. If it triggers some ground rules, that's Rule 13 triggering. The explanation is that the corresponding annotations and intervals associated with the Halstead measure do not conform to the properties of Turkcell encoding. One solution is to define new ranges for these metrics. However, this is not possible since there is no defect data to derive these detection trigger intervals. To overcome this, we defined rule 14, if all basic rules are on, but Halsted fires. This reduces the frequency of rule extraction. However, Rule 14 states that module 9556 corresponding to 461.655 LOC must be checked for possible defects. Validating 45% of the total LOC is impractical. Then again, it would be more effective to demonstrate learning-based models.

Figure 2 depicts the systematic approach to deriving rules for software defect prediction. In the "Identification of Basic Principles" phase, metric intervals and thresholds are established to define the boundaries for determining if a module's metrics fall within acceptable ranges. These intervals serve as the foundation for generating rules. The process then transitions to the "Derivation of Rules" phase, where base rules are formulated based on the identified intervals. These base rules serve as the initial guidelines for identifying potential software defects. Additionally, derived rules are generated from the base rules, further refining the criteria for defect prediction. This iterative process ensures that comprehensive rules are established, incorporating various metrics and thresholds to effectively identify and mitigate software defects.

Performance Bug Prediction

Figure 3 illustrates the sequential steps involved in the process of predicting performance bugs within software systems. It begins with Data Preprocessing, where raw data is cleaned and prepared for analysis. Following this, Metric Extraction extracts relevant metrics from the data, providing valuable insights into the software's performance characteristics. Rule Mining establishes rules based on identified intervals and thresholds, aiding in the identification of potential performance issues. Subsequently, Weighting Factor Prediction assigns weights to different factors based on their importance in predicting performance bugs. Data Information Classification organizes the data into relevant categories for analysis. Finally, Model Validation validates the predictive models developed using cross-validation techniques, ensuring their accuracy and reliability in predicting performance bugs. This workflow provides a structured approach to effectively identify and mitigate performance issues within software systems. The method proposed in this work for predicting software defects consists of two phases: a data processing phase; and a verification phase. This work involves data preprocessing, metric extraction, rule mining, weighting factor prediction, and data information classification. The next stage consists of validating the presentation of the classifiers studied in this study and their rules using cross-validation techniques, and classifying the presentation of the classifiers in terms of classification accuracy and recall. The methodology followed in this research work is detailed in the accompanying portion. The automated prediction of software fault is depending on two criteria. One is sensitivity of the prediction and the other one is specificity. The both were measured in confusion matrix and calculated as

Rajeev and Aravinthan

$$\text{sensitivity} = \frac{\text{number of true positives}}{\text{number of true positives} + \text{number of false negatives}}$$

$$\text{specificity} = \frac{\text{number of true negatives}}{\text{number of true negatives} + \text{number of false positives}}$$

The above two tests are helpful to know the accurate prediction.

EXPERIMENTAL RESULTS

Removed Constant Attributes

A property that has a steady/fixed esteem across all examples is effectively recognizable on the grounds that it has zero fluctuation. These attributes do not have any information to distinguish the modules and at best are a waste of classifier resources. The dataset has 5 constant attributes out of 22 attributes, so 45% of the available log values do not contain information to extract data from.

Removed Redundant Attributes

Except for consistent properties, duplicate properties occur when two properties have the same value for each instance. This results in individual attributes being over-represented. In the dataset, there are only a few attributes that are repeated, specifically the "Quantity of Lines" and "All out Position" ascribes in the dataset. At this stage we remove one of the properties so that the value will only be rendered once. We chose to keep the "total position" attribute label, as this is a common usage of our dataset.

Replaced Missing Values

Depending on the classification method used, these values may or may not be problematic for machine learners. 19 records in the dataset contain missing values, but all belong to the same attribute: "decision density". This attribute is defined as "Condition Count" divided by "Decision Count", and for each missing value, the value of both base attributes is zero.

RESULTS

In this present work, the software metric 21 are form McCabe's and Halstead metrics and one goal metric were in the present work, software metrics 21 are McCabe and Halstead metrics and are measured using objective metrics. Using MATLAB tools, the dataset was applied to the Naive Bayesian classifier and the proposed algorithm. This dataset has been combined according to structure and object orientation. in C and C++ languages. The study compared mean precision (values in the table from 0 to 1), true positive rate, false positive rate, sensitivity and specificity. Accuracy (Figure 4) calculated from the quantity of accurately ordered cases. Based on the consequences of these investigations, the proposed technique is applicable to both large and small datasets. The Table 4 below gives the correctly and misclassified instances and the absolute number of occasions in the dataset using different classifiers. It also provides the best highlighted classifier based on sensitivity and specificity values Table 5

Figure 5 illustrates the trade-off between the true positive rate (sensitivity) and the false positive rate for two classifiers, both on the training and testing sets. Each curve represents the performance of a classifier, with the area under the curve (AUC) indicating its discriminative power. A steeper curve and a larger AUC value signify better classification performance. The plot also includes a diagonal dashed line representing the performance of a random classifier. The closer a curve is to the upper-left corner of the plot, the better the classifier's performance. Overall, the ROC Curve plot provides a visual comparison of classifier performance, aiding in the selection of the most effective model for the task at hand. Figure 6 illustrates the trade-off between precision and recall for two classifiers, both on the training and testing sets. Each curve represents the performance of a classifier, with the area under the curve

**Rajeev and Aravinthan**

(Average Precision) indicating its overall performance. A curve that is closer to the upper-right corner of the plot signifies a classifier with higher precision and recall rates. The plot provides insights into the balance between precision and recall for different classifiers, helping in the selection of the most suitable model for the task at hand. Additionally, the average precision values provide a quantitative measure of the classifiers' performance, with higher values indicating better overall performance.

CONCLUSION

In this proposed work, module performance errors in enormous programming frameworks are anticipated. This work analyzed an average case of 25 projects to characterize the carried-out code base and noticed measurements that contradicted the company's goals. Our initial data analysis shows that a simple rule-based model based on static code attribute recommendation criteria estimates the defect rate of code under verification. Given the extent of the framework, this is an unrealistic result. Therefore, we built a learning-based defect predictor and performed additional analyses. Due to the lack of defect data at the local module level, we use synthetic data to learn a defect predictor. Preliminary analysis confirmed the average defect rate for all projects. While simple rule-based modules require checking the code, learning-based models suggest that we only need to verify 6% of the code. This is because rule-based models are biased toward larger and more complex modules, while learning-based models predict smaller modules to contain the most defects. The results of our second analysis used data that fit the framework. External validation of the data did not change the median probability of detection and significantly reduced the median probability of false positives. A second analysis further improved the estimates and suggested that only 93% of the code and 93% of the defects could be detected. Our future work is to collect local software-level defects to build predictors for this large telecom system within the enterprise. In addition to using block-level code as an indicator to predict semantic and performance defects between successive software releases

Table 1: Research Gap

Author Name	Proposed Methodology	Results	Research Gap
Malhotra, Ruchika	Detailed analysis of ownership & experience effects	Similar findings to current research	Lack of exploration of secondary contribution relationship of software dependencies
Banga, Manu	Impact of group size in predictive models	Improved prediction accuracy by group size	Did not consider proportion of each developer's contribution; focused on prediction accuracy
Menely and Williams	Relationship between developers & vulnerabilities	Increased likelihood of security breach with multiple developers	Focus on security vulnerabilities rather than performance bugs
Jin <i>et al.</i>	Lifecycle study of real-world performance bugs	Creation to correction lifecycle analysis	Focused on Java, C, C++, and JavaScript; different programming language (MATLAB)
Previous works	Analysis of performance bug	Understanding source code attribute contribution to	Lack of focus on automatic algorithms; lack of reproducibility

Rajeev and Aravinthan

	characteristics	predictive algorithms	in methodology
Past implementations	Dynamic analysis for performance bug detection	Utilized execution traces and historical data	Lack of focus on static examination; requirement of dedicated test environment for accuracy
Current study	Static examination for performance bug detection	Utilizes code properties from source repositories	Omission of schema type information; relevance to MATLAB coding standards

Table 2: Summary of Software Code Metrics

Metric	Definition	Calculation Method
LOC	McCabe's line count of code	Count of lines in the source code
Cyclomatic Complexity (v(g))	Measure of program complexity	Number of linearly independent paths through a program's source code
Essential Complexity (ev(g))	Measure of essential complexity	Number of linearly independent paths that must be tested
Design Complexity (iv(g))	Measure of design complexity	Number of linearly independent paths that are executable
Total Operators and Operands (n)	Halstead total operators + operands	Count of all unique operators and operands in the source code
Volume (v)	Halstead "volume"	Total vocabulary size multiplied by the logarithm of the program length
Program Length (l)	Halstead "program length"	Total number of unique operators and operands in the source code
Difficulty (D)	Halstead "difficulty"	Volume divided by the program length multiplied by the number of unique operators
Intelligence (i)	Halstead "intelligence"	Program length divided by the number of unique operators
Effort (e)	Halstead "effort"	Difficulty multiplied by volume
Bugs (b)	Halstead "bugs"	Volume divided by 3000
Time Estimator (T)	Halstead's time estimator	Effort divided by 18
Line Count (IOCode)	Halstead's line count	Total number of lines of code in the source code
Comment Count (IOComment)	Halstead's count of lines of comments	Total number of lines of comments in the source code
Blank Line Count (IOBlank)	Halstead's count of blank lines	Total number of blank lines in the source code
Code and Comment Line Count (IOCodeAndComment)	Numeric	Total number of lines of code and comments in the source code
Unique Operators (uniq_Op)	Unique operators	Count of unique operators in the source code
Unique Operands (uniq_Opnd)	Unique operands	Count of unique operands in the source code
Total Operators (total_Op)	Total operators	Count of all operators in the source code

Rajeev and Aravinthan

Table 3: Attribute Information

Attribute name	Description
Loc	McCabe's line count of code
v(g)	McCabe "cyclomatic complexity"
ev(g)	McCabe "essential complexity"
iv(g)	McCabe "design complexity"
n	Halstead total operators + operands
v	Halstead "volume"
l	Halstead "program length"
D	Halstead "difficulty"
i	Halstead "intelligence"
e	Halstead "effort"
b	Halstead
T	Halstead's time estimator
IOCode	Halstead's line count
IOComment	Halstead's count of lines of comments
IOBlank	Halstead's count of blank lines

ABSTRACT

In the pursuit of sustainable and energy-efficient communication in wireless networks, routing protocols play a crucial role in optimizing energy consumption while ensuring reliable data transmission. This paper proposes a novel cluster-based routing approach integrated with advanced optimization techniques to enhance energy efficiency in wireless networks. The proposed methodology employs Threshold-sensitive Energy Efficient Sensor Network Protocol (TEEN) clustering to reduce the overall energy expenditure by minimizing the distance data packets must travel, thus extending the network's lifetime. Additionally, we introduce a hybrid optimization technique that combines genetic algorithms with particle swarm optimization to dynamically adjust cluster formation and optimize routing paths based on real-time network conditions. Simulation results demonstrate significant improvements in energy efficiency, data delivery ratio, and network longevity compared to existing routing protocols. This research contributes to the development of robust wireless networks capable of supporting the increasing demand for energy-efficient communication in various applications, including IoT, smart cities, and remote monitoring systems.

Keywords: Wireless Networks, Threshold-sensitive Energy Efficient Sensor Network Protocol (TEEN), Optimization techniques, Genetic Algorithm, Particle Swarm Optimization

INTRODUCTION

The proliferation of wireless communication technologies has transformed the landscape of modern connectivity, enabling a wide array of applications from environmental monitoring to smart cities and healthcare systems. However, these applications often rely on resource-constrained devices such as sensor nodes and Internet of Things (IoT) devices, which are limited by their battery capacity. As a result, energy efficiency has become a critical concern in the design and implementation of wireless networks, where the longevity of network operation is directly linked to the effective management of energy resources [1] [2] [3]. In wireless networks, a cluster-based routing approach has emerged as a viable solution to address energy efficiency challenges. This approach involves grouping nodes into clusters, each led by a designated cluster head (CH). The CH is responsible for coordinating communication within its cluster and relaying data to other clusters or a central sink, thereby reducing the communication distance and minimizing energy consumption. While this architecture offers significant advantages, it also presents several challenges, including energy depletion, dynamic network topologies, and load balancing among nodes [4][5].

Energy depletion is particularly critical in wireless networks, as nodes often operate on limited battery power. Inefficient routing can lead to rapid energy exhaustion, resulting in node failures and disrupted communication [6][7][8]. Moreover, the dynamic nature of wireless networks, characterized by node mobility and environmental changes, complicates the maintenance of stable routing paths. Additionally, certain nodes may become overloaded with communication tasks, leading to uneven energy distribution and premature failure [9] [10]. To mitigate these challenges, optimization techniques have been increasingly applied to cluster-based routing protocols. Techniques such as Genetic Algorithms (GA) and Particle Swarm Optimization (PSO) have shown promise in enhancing routing efficiency. GA leverages principles of natural selection to optimize cluster head selection and routing paths, while PSO draws inspiration from the collective behavior of social organisms to adaptively search for optimal solutions. By integrating these optimization methods, hybrid approaches can effectively balance exploration and exploitation in the search for energy-efficient routing paths. This study proposes a novel cluster-based energy-efficient routing protocol that employs a hybrid optimization technique combining GA and PSO. The goal is to enhance energy efficiency, improve data delivery ratios, and ensure the adaptability of the protocol to dynamic network conditions. The proposed approach aims to optimize cluster formations and routing paths in real-time, thereby addressing the critical challenges of energy consumption and network reliability.

Related Works

Gururaj, H. L., *et al* [11] suggest a collaborative energy-efficient routing protocol (CEEPR) for sustainable communication in 5G/6G wireless sensor networks (WSNs). Initially, this study gathered and collected the data at the sink node. The network's nodes are clustered using the reinforcement learning technique (R.L.). Cluster head selection is employed for better data transmission using residual energy (RE) based cluster head selection algorithm. A collaborative energy-efficient routing protocol (CEERP) is proposed. We use a multi-objective improved seagull algorithm (MOISA) as an optimization technique to enhance the system's performance. Finally, the presentation of the system is analyzed. Kandris, Dionisis, *et al* [12] aimed to clarify the most popular subdivision of this category of protocols i.e. the so-called hierarchical energy efficient routing protocols. Specifically, LEACH, which is considered to be the pioneer protocol of this kind, is studied along with 18 of its descendant protocols. A theoretical comparison of these protocols in terms of various metrics is also performed. Additionally, the performance of LEACH is compared with that of 3 descendant protocols through simulation tests that are carried out. Finally, a discussion takes place and concluding remarks are drawn. Ismail, Muhammad, *et al* [13] proposed a Shifted Energy Efficiency and Priority (SHEEP) routing protocol for UWSNs. The proposed protocol aims to enhance the efficiency of the state-of-the-art Energy Balanced Efficient and Reliable Routing (EBER2) protocol for UWSNs. SHEEP is built upon the depth and energy of the current forwarding node, the depth of the expected next forwarding node, and the average energy difference among the expected forwarders

**Chinnadurai and Vinayagam**

Narayan, Vipul, A. K. Daniel, and Pooja Chaturvedi [14] the Particle Swarm Optimization (PSO) method is utilized to form the cluster, and a Fuzzy based Energy Efficient Routing Protocol (E-FEERP) is proposed using average distance of SN from BS, node density, energy and communication quality to transmit data from cluster head to the BS in an optimal manner. The proposed protocol used parallel fitness function computing to quickly converge to the best possible solution with fewer iterations. The protocol used PSO-based clustering algorithm that recognize how birds act when they are in a flock. It is an optimization strategy that uses parallel fitness function computing to get to an optimal solution quickly and with a small number of iterations. Fuzzy is combined with PSO to increase coverage with reduced computational overhead. The proposed E-FEERP improves network performance in terms of packet delivery ratio, Residual Energy (RE), throughput, energy consumption, load balancing ratio, and network lifetime.

Biswas, Kamanashis, *et al.* [15] proposed an Energy Efficient Secure Multipath (EESM) routing protocol to securely construct efficient routes and transmit data packets between SNs and the base station (BS). EESM achieves energy efficiency through minimal task allocation among SNs whereas all computation-intensive tasks such as network information collection, routing table generation, and network maintenance are performed by the BS. The proposed protocol incorporates lightweight security mechanisms including a one-way hash chain, message authentication code, encryption, and clique-based coordinator selection and monitoring schemes to defend against numerous security attacks. Yang, Haibo, *et al* [16] proposed a dynamic random multipath routing method (DRMRM) for LWSNs. The technique combines the node depth and residual energy models to select the optimal next-hop relay node without relying on the transmission routing table. At the same time, we designed a data loss retransmission mechanism and a data loop retreat mechanism to prevent data packets from reaching a dead end. The experimental results demonstrate that our routing method is superior to existing energy consumption balance and network lifespan protocols.

Liu, Dakun, Guifen Chen, and Yijun Wang. [17] an energy efficiency optimization routing decision system is proposed based on the establishment of a three-dimensional Voronoi polygon topology model. First, we define a node state-related attribute parameter that determines whether the source node and the forward node are linked. The data forwarding node is determined by comparing attribute differences. Then, a power control mechanism based on received signal strength is proposed to solve the energy consumption, which includes deterministic and random parts. Finally, the specific state of the network node is monitored by comparing the attribute decision matrix to ensure basic maintenance of network operation and improve network transmission reliability. Kumar, Sanjeev, and Richa Agrawal [18] The key objective of this proposed scheme is to enhance the surviving period of WSN with the help of assistant cluster nodes. Energy optimization is achieved by developing an Improved-Optimized Energy-Efficient Routing Protocol (I-OEERP) which eliminates such residual nodes creation and enhances the network lifetime. The nature of the given scheme C-GSA is based on a hybrid of both Crow Search Algorithm (CSA) and Gravitational Search Algorithm (GSA). By utilizing the concepts of CSA cluster formation, residual node formation can be controlled. After that, GSA is used for routing.

Banerjee, Ishita, and P. Madhumathy [19] The use of clustering and routing to extend the lifetime of a network, which is a significant issue in sensor networks, has been extensively researched. Routing entails numerous activities that significantly impact the network's lifetime and throughput. The clustering strategy with data aggregation on cluster heads impacts total network performance. The proposed method includes the k-medoid technique for clustering and a stochastic model of the CH selection for energy efficient green WSN. A predictive analysis of the slot scheduling model is also incorporated for further network energy conservation. Also, an improved ant colony optimization algorithm is used to find the optimal route. The proposed work is implemented in MATLAB and the results are taken in terms of packet delivery ratio (PDR), packet loss ratio (PLR), network lifetime, jitter, end-to-end delay, throughput, bit error rate (BER) and energy consumption for proposed and existing techniques. Godfrey, Daniel, *et al* [20] presented an intelligent, energy-efficient multi-objective routing protocol based on the Reinforcement Learning (RL) algorithm with Dynamic Objective Selection (DOS-RL). The primary goal of applying the proposed DOS-RL routing scheme is to optimize energy consumption in IoT networks, a paramount concern given the limited energy reserves of wireless IoT devices and the adaptability to network changes to facilitate a seamless adaption to sudden network

Chinnadurai and Vinayagam

changes, mitigating disruptions and optimizing the overall network performance. The algorithm considers correlated objectives with informative-shaped rewards to accelerate the learning process. Through the diverse simulations, we demonstrated improved energy efficiency and fast adaptation to unexpected network changes by enhancing the packet delivery ratio and reducing data delivery latency when compared to traditional routing protocols such as the Open Shortest Path First (OSPF) and the multi-objective Q-routing for Software-Defined Networks (SDN-Q).

Threshold-Sensitive Energy Efficient Sensor Network Protocol (TEEN)

The Threshold-Sensitive Energy Efficient Sensor Network Protocol (TEEN) [21][22] is designed specifically for wireless sensor networks (WSNs) to address the critical challenge of energy conservation while ensuring efficient data transmission. TEEN operates on a cluster-based architecture, employing a threshold-based approach that minimizes unnecessary data communication and prolongs the operational lifetime of sensor nodes.

Key Features of TEEN

TEEN incorporates several key features that differentiate it from other routing protocols:

Cluster-Based Structure: TEEN organizes the network into clusters, with each cluster comprising a number of sensor nodes and a designated cluster head (CH). The CH is responsible for collecting and aggregating data from its member nodes.

Threshold-Based Data Transmission: TEEN uses two types of thresholds—hard thresholds and soft thresholds—to regulate data transmission. This mechanism ensures that data is sent only when significant changes occur in the monitored environment, thereby conserving energy.

Hard Threshold (TH_{hard}): This is a fixed value that indicates whether a sensor node should transmit its data. If the sensed value exceeds this threshold, the node will send its data to the CH.

Soft Threshold (TH_{soft}): This threshold determines the minimum change in the sensed value required for the node to send data when it is below the hard threshold. The node will transmit data if the sensed value changes significantly beyond this threshold.

Protocol Operation

TEEN operates through a series of well-defined steps, including cluster formation, data sensing, transmission, and aggregation:

Cluster Formation

Cluster Head Selection: Initially, the network is divided into clusters. Each node has a probability of becoming a CH, which can be calculated based on its energy level. The probability P of a node becoming a CH can be defined as:

$$P = \frac{E_{node}}{\sum_{i=1}^n E_i} \cdot \frac{1}{D}$$

Where E_{node} energy of the node, E_i energy of the i th node, n is the total number of nodes in the network, and D is the distance to the base station.

Cluster Assignment: Nodes within the communication range of the CH join the cluster based on the signal strength and distance, forming a local network for data transmission.

Data Sensing and Transmission

Sensing Data: Each sensor node continuously monitors environmental parameters and records the sensed values. Let S_i represent the sensed value of node i .

Chinnadurai and Vinayagam

Threshold Evaluation

When a node senses data, it first checks if the sensed value exceeds the hard threshold: If $S_i > TH_{hard}$, then transmit to CH.

If S_i is less than or equal to TH_{hard} , the node evaluates the soft threshold. It checks if the change in sensed value since the last transmission exceeds the soft threshold: If $|S_i - S_{previous}| > TH_{soft}$, then transmit to CH.

This approach reduces redundant transmissions and ensures that only significant changes in the monitored environment lead to data being sent.

Data Aggregation and Forwarding

Data Collection: The CH collects data from all member nodes and performs aggregation to minimize redundancy. The aggregated data can be represented as: $D_{aggregated} = f(S_1, S_2, \dots, S_k)$. where f represents a function (such as average, sum, or maximum) that aggregates the sensed values from member nodes.

Data Communication to the Sink: The CH forwards the aggregated data to the sink or base station, ensuring efficient communication and minimizing energy expenditure.

Genetic Algorithm

Genetic Algorithms (GAs) [23] [24] are a class of optimization techniques inspired by the principles of natural selection and genetics. They are widely used in various fields, including wireless networks, to solve complex optimization problems. In the context of wireless networks, GAs can enhance performance metrics such as routing efficiency, energy consumption, and network topology optimization by intelligently exploring the solution space.

Key Concepts of Genetic Algorithm

GAs operate through a cycle of selection, crossover, mutation, and evaluation, mimicking the process of natural evolution. The primary components of GAs are:

Population: A set of candidate solutions to the optimization problem, typically represented as chromosomes.

Chromosome: A representation of a solution, often encoded as a binary string or an array of real values.

Fitness Function: A function that evaluates the quality of each solution based on predefined criteria (e.g., energy efficiency, throughput).

Selection: The process of choosing the best candidates from the population to create offspring. Common methods include roulette wheel selection and tournament selection.

Crossover: A genetic operator that combines two parent solutions to create new offspring. This operator introduces variability into the population.

Mutation: A genetic operator that introduces random changes to the chromosomes, helping to maintain diversity within the population.

Step by Step Procedure for GA

The application of GAs in wireless networks typically involves the following steps:

Step 1: Initialization

Population Generation: The algorithm starts by generating an initial population of candidate solutions randomly. Each solution represents a potential configuration for the network (e.g., routing paths, cluster heads, etc.). $P_0 = \{C_1, C_2, \dots, C_N\}$, where P_0 is the initial population and C_i represents the i th candidate solution.

Step 2: Fitness Evaluation

Fitness Calculation: Each candidate solution is evaluated using a fitness function F that quantifies its performance based on the objectives of the optimization problem. For example, in the context of energy-efficient routing, the fitness function may be defined as: $F(C_i) = \frac{1}{E(C_i) + \alpha \cdot D(C_i)}$ where $E(C_i)$ is the energy consumption associated with candidate solution C_i , $D(C_i)$ average delay for data transmission in solution C_i , and α is the weight factor to balance energy consumption and delay.

Chinnadurai and Vinayagam

Step 3: Selection

Selection of Parents: Based on the fitness scores, a selection method (e.g., roulette wheel selection) is employed to choose parent solutions for generating the next generation. In roulette wheel selection, the probability P of selecting a candidate solution is proportional to its fitness: $P(C_i) = \frac{F(C_i)}{\sum_{j=1}^N F(C_j)}$ where N is the size of the population.

Step 4: Crossover Operation

Crossover Operation: Selected parent solutions undergo crossover to produce offspring. The crossover operator combines parts of two parent solutions to create new candidates. For example, for two parent chromosomes A and B : $O_1O_2 = crossover(A, B)$. This can be implemented using various techniques such as single-point crossover or two-point crossover.

Step 5: Mutation Operation

Mutation Operation: Each offspring may undergo mutation, where random alterations are made to introduce diversity. For a chromosome represented as a binary string, mutation could flip a bit: $O_i[j] = \begin{cases} 1 - O_i[j] & \text{with probability } p \\ O_i[j] & \text{otherwise} \end{cases}$ where p is the mutation probability and $O_i[j]$ is the j th gene and i th offspring.

Step 6: Replacement

Replacement: The new offspring replace the old population, either entirely or partially, depending on the replacement strategy. This can be done using methods such as elitism, where the best solutions are preserved for the next generation.

Step 7: Iteration

Termination Condition: The GA iterates through the selection, crossover, mutation, and replacement steps until a termination condition is met (e.g., a maximum number of generations or convergence of solutions).

Particle Swarm Optimization Algorithm

Particle Swarm Optimization (PSO) [25] [26] is a population-based optimization technique inspired by the social behavior of birds and fish. It is widely utilized in various fields, including wireless networks, due to its simplicity, ease of implementation, and effectiveness in solving complex optimization problems. PSO is particularly useful in scenarios that require optimal resource allocation, network configuration, and routing in wireless networks.

Key Concepts of PSO

PSO operates by simulating a group of particles that represent potential solutions moving through the solution space. Each particle adjusts its position based on its own experience and the experience of neighboring particles. The key components of PSO include:

Particle: Each particle represents a candidate solution in the search space. It is characterized by its position and velocity.

Velocity: The velocity of a particle determines the direction and speed of its movement in the solution space.

Position: The position of a particle corresponds to a potential solution for the optimization problem.

Fitness Function: A function that evaluates the quality of each particle's position based on predefined criteria (e.g., energy efficiency, throughput, delay).

Step by Step Procedure of PSO

The application of PSO in wireless networks typically involves the following steps:

Step 1: Initialization

Particle Initialization: The algorithm starts by initializing a swarm of particles. Each particle P_i is represented by its position X_i and velocity V_i , where d is the number of dimensions (variables) in the optimization problem.

Chinnadurai and Vinayagam

$$X_i = (x_{i1}, x_{i2}, \dots, x_{id})$$

$$V_i = (v_{i1}, v_{i2}, \dots, v_{id})$$

Fitness Evaluation: Each particle's fitness is evaluated using a fitness function $F(X_i)$ specific to the optimization problem. For instance, in the context of energy-efficient routing, the fitness function may be defined as: Where $E(X_i)$ is the energy consumption with the routing solution X_i and $D(X_i)$ is the average delay for data transmission in solution X_i and α is the weight factor to balance energy consumption and delay.

$$F(X_i) = \frac{1}{E(X_i) + \alpha \cdot D(X_i)}$$

Step 2: Update Rules

Update Position and Velocity: Each particle updates its velocity and position based on the following equations: Velocity update $V_{id} = \omega \cdot V_{id} + c_1 \cdot r_1 \cdot (PBest_{id} - X_{id}) + c_2 \cdot r_2 \cdot (GBest_{id} - X_{id})$ and Position Update: $X_{id} = X_{id} + V_{id}$. Where ω is the Inertia weight, which controls the influence of the previous velocity, c_1 is the Cognitive coefficient (personal learning factor), c_2 is the Social coefficient (group learning factor), $r_1 r_2$ is the Random numbers uniformly distributed in the range [0, 1], $PBest_{id}$ is the Best position of particle i in dimension d , and $GBest_{id}$ is the Global best position in dimension d among all particles.

Step 3: Fitness Evaluation

Evaluate Fitness: After updating the positions, each particle's fitness is evaluated again using the fitness function. If a particle's current position is better than its previous best position, it updates its personal best:

$$best: PBest_{id} = \begin{cases} X_{id} & \text{if } F(X_i) < F(PBest_{id}) \\ PBest_{id} & \text{otherwise} \end{cases}$$

Global Best Update: The global best position is updated based on the best fitness value found by any particle:

$$GBest_d = \begin{cases} X_{id} & \text{if } F(X_i) < F(GBest_d) \\ GBest_d & \text{otherwise} \end{cases}$$

Step 4: Iteration

Termination Condition: The PSO iterates through the position and velocity update steps until a termination condition is met (e.g., maximum number of iterations, convergence of solutions).

Proposed Optimizations Cluster Based Energy Efficient Routing Protocol (OCEERP)

Hybridizing TEEN with GA and PSO aims to improve energy efficiency in Wireless Sensor Networks (WSNs) by optimizing Cluster Head (CH) selection and routing paths. TEEN introduces hard and soft thresholds for data transmission to reduce energy consumption, while GA and PSO are employed to optimize the network's clustering and routing processes.

Step by Step Procedure for Optimizations Cluster based Energy Efficient Routing Protocol (OCEERP)

Step 1: Network Initialization

Deploy N sensor nodes randomly within the sensing area.

Each node has an initial energy E_i and is capable of communicating with a Base Station (BS) or Cluster Heads (CHs).

Define TEEN thresholds: **Hard Threshold (HT)** and **Soft Threshold (ST)**.

Step 2: Clustering and Cluster Head Selection Using Genetic Algorithm

Step 2.1: Encoding of Population

Each candidate solution (chromosome) represents a set of potential CHs.

Chromosome size = number of sensor nodes.

Each gene represents whether a node is selected as a CH (1) or not (0).

Chinnadurai and Vinayagam

Step 2.2: Fitness Function Definition: The fitness function $f(x)$ evaluates each candidate based on: $f(x) = \alpha \times \frac{E_{CH}}{E_{max}} + \beta \times \frac{1}{d_{CH-BS}}$ where E_{CH} is the energy of the selected CH, E_{max} is the maximum initial energy of the nodes, d_{CH-BS} is the distance between the CH and the base station (BS), and α and β are weight coefficients.

Step 2.3: Selection

Use Roulette Wheel Selection to choose parent chromosomes for crossover based on fitness.

Step 2.4: Crossover

Apply single-point crossover to generate new offspring.

Step 2.5: Mutation

Perform bit-flip mutation on offspring to introduce diversity.

Step 2.6: Replacement

Replace the worst-performing chromosomes with the new offspring.

Step 2.7: Termination

Continue GA iterations until a predefined number of generations or convergence is reached.

Step 3: Cluster Formation

Each sensor node joins the cluster of the nearest CH selected by GA.

The TEEN Protocol:

Nodes transmit data to CH if sensed value exceeds the Hard Threshold (HT).

Nodes transmit updated values if the change exceeds the Soft Threshold (ST).

Step 4: Data Routing Path Optimization Using Particle Swarm Optimization (PSO)

Step 4.1: Initialization of Particles

Each particle represents a potential routing path from a CH to the BS.

Initialize particle positions randomly (routing paths) and assign random velocities.

Step 4.2: Fitness Function for PSO: The fitness function $f_{ps0}(x) = \gamma \times \frac{1}{d_{CH-BS}} + \delta \times \frac{1}{E_{residual}}$. Where $E_{residual}$ is the residual energy of the nodes along the routing path, and γ and δ are weight factors.

Step 4.3: Velocity and Position Update: Update particle velocity and position using the standard PSO equations: $v_i^{t+1} = \omega \cdot v_i^t + c_1 \cdot r_1 \cdot (p_i^t - x_i^t) + c_2 \cdot r_2 \cdot (g_i^t - x_i^t)$ and $x_i^{t+1} = x_i^t + v_i^{t+1}$ where v_i^t is the velocity of particle i at iteration t , x_i^t is the position of particle i (routing path), p_i^t is the personal best position of particle i , g_i^t is the global best position of the swarm, and ω is the inertia weight, c_1 and c_2 are cognitive and social coefficients, r_1 and r_2 are random numbers.

Step 4.4: Position Constraints

Ensure that the new particle positions (routing paths) respect network constraints such as node connectivity and energy.

Step 4.5: Termination

PSO continues until the maximum number of iterations is reached or the routing path converges to an optimal solution.

Step 5: Data Transmission

Data from sensor nodes is sent to the CH when the hard and soft thresholds are met.

The CH aggregates the data and forwards it to the BS via the optimal path identified by PSO.

Step 6: Re-clustering and Re-routing

Re-cluster and re-route the network periodically based on residual energy and network dynamics, repeating Steps 2–4.

1. Initialize the WSN with N sensor nodes, define TEEN thresholds (HT, ST), and deploy nodes randomly.

Chinnadurai and Vinayagam

2. Initialize Genetic Algorithm (GA) parameters: population size, crossover probability, mutation rate, and number of generations.
3. Initialize Particle Swarm Optimization (PSO) parameters: population size, cognitive and social coefficients, and number of iterations.
4. // Cluster Head Selection using GA
 - while (GA termination condition not met):
 - Evaluate fitness of each chromosome based on residual energy and distance to BS.
 - Select parent chromosomes based on fitness.
 - Apply crossover and mutation to generate new offspring.
 - Update the population with the new offspring.
5. Select the best CHs based on GA's final population.
6. // Cluster Formation
 - Each sensor node joins the nearest CH.
7. // Routing Optimization using PSO
 - while (PSO termination condition not met):
 - Evaluate fitness of each particle based on the routing path's energy and distance.
 - Update velocity and position of each particle.
 - Update global and personal best positions.
8. Select the best routing paths based on PSO's final particle positions.
9. Data transmission follows TEEN protocol: sensors send data if HT and ST conditions are met.
10. Periodically re-cluster and re-route based on network dynamics and residual energy.

RESULT AND DISCUSSION

The performance of the proposed OCEERP is evaluated with the existing cluster based routing protocol likes Threshold-sensitive energy efficient sensor network (TEEN), LEACH (Low-Energy Adaptive Clustering Hierarchy) [27], DEEC (Distributed Energy Efficient Clustering) [28], and SEP (Stable Election Protocol)[29] for various evaluation metrics like Energy Consumption (in Joules), Packet Delivery Ratio (PDR) (in %), Packet Loss Ratio (PLR) (in %), End-to-End Delay (in Seconds), Throughput (in Kbps) and Network Lifetime (in Rounds). Table 1 depicts the Energy Consumption (in Joules) of the proposed and existing cluster-based routing protocols for varying number of nodes. From the table 1, The energy consumption analysis of the proposed Optimized Cluster-based Energy Efficient Routing Protocol (OCEERP) compared to existing protocols (LEACH, TEEN, DEEC, and SEP) demonstrates a significant improvement in energy efficiency across varying numbers of nodes. As the number of nodes increases, the proposed OCEERP consistently consumes the least amount of energy, indicating its superiority in prolonging network lifetime in cluster-based routing protocols. For 80 nodes, the proposed OCEERP consumes 90.1 Joules, significantly lower than LEACH (120.5 Joules) and SEP (100.8 Joules).As the node count increases to 200 nodes, OCEERP maintains the lowest energy consumption at 210.2 Joules, compared to LEACH (240.1 Joules) and SEP (220.1 Joules).Across all node variations, LEACH shows the highest energy consumption, indicating it is the least efficient of the compared protocols, while OCEERP consistently reduces energy usage.

Table 2 depicts the Network Lifetime (in Rounds) of the proposed and existing cluster-based routing protocols for varying number of nodes. From the table 2, The analysis of network lifetime (in rounds) for the proposed Optimized Cluster-based Energy Efficient Routing Protocol (OCEERP) compared to existing protocols (LEACH, TEEN, DEEC, SEP) shows that OCEERP consistently extends the network lifetime across varying numbers of nodes. For 80 nodes, the proposed OCEERP achieves the longest network lifetime at 950 rounds, outperforming SEP (880 rounds), DEEC (850 rounds), TEEN (800 rounds), and LEACH (750 rounds).As the number of nodes increases to 200, OCEERP maintains the longest network lifetime of 820 rounds, compared to SEP (750 rounds) and LEACH, which has the shortest lifespan at 620 rounds.Across all scenarios, LEACH consistently shows the shortest network lifetime,

**Chinnadurai and Vinayagam**

indicating it is less efficient at preserving energy and extending the operational duration of the network. The proposed OCEERP provides an approximately 10-20% improvement in network lifetime over the next-best protocol, SEP, particularly at lower node counts.

Table 3 depicts the Packet Delivery Ratio (PDR in %) of the proposed and existing cluster-based routing protocols for varying number of nodes. Table 3 presents the Packet Delivery Ratio (PDR in %) of the existing and proposed cluster-based routing protocols across varying numbers of nodes. The proposed Optimized Cluster-based Energy Efficient Routing Protocol (OCEERP) consistently achieves the highest PDR across all node configurations, indicating its superior performance in maintaining reliable data transmission. For 80 nodes, OCEERP achieves the highest PDR at 94.5%, outperforming SEP (90.2%), DEEC (89.1%), TEEN (87.3%), and LEACH (84.5%). As the number of nodes increases to 200, OCEERP maintains the best PDR at 86.1%, while SEP (81.3%), DEEC (80.6%), TEEN (78.1%), and LEACH (74.2%) show a decreasing trend. Across all node variations, LEACH consistently exhibits the lowest PDR, while OCEERP demonstrates its robustness with the highest PDR, providing reliable data delivery even as the network scales.

Table 4 depicts the Packet Loss Ratio (PLR in %) of the proposed and existing cluster-based routing protocols for varying number of nodes. Table 4 presents the Packet Loss Ratio (PLR in %) of the existing and proposed cluster-based routing protocols for varying numbers of nodes. The proposed Optimized Cluster-based Energy Efficient Routing Protocol (OCEERP) consistently achieves the lowest PLR across all node configurations, highlighting its superior performance in minimizing packet loss. For 80 nodes, OCEERP achieves the lowest PLR at 5.5%, significantly outperforming SEP (9.8%), DEEC (10.9%), TEEN (12.7%), and LEACH (15.5%). As the number of nodes increases to 200, OCEERP maintains the lowest PLR at 13.9%, while SEP (18.7%), DEEC (19.4%), TEEN (21.9%), and LEACH (25.8%) show higher packet loss rates. Across all node variations, LEACH exhibits the highest PLR, indicating its poor performance in minimizing data loss, while OCEERP demonstrates its robustness with the lowest PLR values.

Table 5 depicts the End-to-End Delay (in Seconds) of the proposed and existing cluster-based routing protocols for varying number of nodes. Table 5 presents the End-to-End Delay (in seconds) of the existing and proposed cluster-based routing protocols for varying numbers of nodes. The proposed Optimized Cluster-based Energy Efficient Routing Protocol (OCEERP) consistently achieves the lowest delay across all node configurations, indicating its superior efficiency in reducing transmission delays. For 80 nodes, OCEERP records the shortest end-to-end delay at 0.15 seconds, significantly lower than SEP (0.20 seconds), DEEC (0.21 seconds), TEEN (0.23 seconds), and LEACH (0.25 seconds). As the number of nodes increases to 200, OCEERP continues to maintain the lowest delay at 0.28 seconds, while SEP (0.33 seconds), DEEC (0.36 seconds), TEEN (0.40 seconds), and LEACH (0.42 seconds) show higher delays. Across all node configurations, LEACH consistently exhibits the highest end-to-end delay, indicating its lower efficiency in data transmission compared to the other protocols, while OCEERP demonstrates superior performance with the lowest delay values.

Table 6 depicts the Throughput (in Kbps) of the proposed and existing cluster-based routing protocols for varying number of nodes. Table 6 presents the throughput (in Kbps) of the existing and proposed cluster-based routing protocols for varying numbers of nodes. The proposed Optimized Cluster-based Energy Efficient Routing Protocol (OCEERP) consistently achieves the highest throughput across all configurations, indicating its effectiveness in maximizing data transmission rates. For 80 nodes, OCEERP achieves a throughput of 89.8 Kbps, outperforming SEP (85.7 Kbps), DEEC (83.5 Kbps), TEEN (80.3 Kbps), and LEACH (78.2 Kbps). As the number of nodes increases to 200, OCEERP maintains the highest throughput at 79.6 Kbps, compared to SEP (76.4 Kbps), DEEC (73.4 Kbps), TEEN (70.1 Kbps), and LEACH (67.5 Kbps). Across all node configurations, LEACH consistently exhibits the lowest throughput, indicating its inefficiency in maximizing data transmission compared to the other protocols, while OCEERP demonstrates robust performance with the highest throughput values.

CONCLUSION

In this study, we proposed a hybrid energy-efficient routing protocol that combines the Threshold-sensitive Energy Efficient Sensor Network Protocol (TEEN) with Genetic Algorithm (GA) and Particle Swarm Optimization (PSO) techniques. This approach was designed to address the inherent limitations of existing routing protocols such as LEACH, TEEN, DEEC, and SEP by optimizing cluster head selection and data transmission strategies. The results demonstrated significant improvements in key performance metrics, including Packet Delivery Ratio (PDR), End-to-End Delay, and overall energy consumption. Our proposed protocol consistently outperformed existing protocols across different network configurations, particularly as the number of sensor nodes increased from 80 to 200. The hybridization of TEEN with GA and PSO led to an efficient distribution of energy consumption and enhanced network longevity. Specifically, the proposed method achieved a PDR of up to 94.5% and reduced the end-to-end delay to 0.15 seconds, which is considerably lower than the other protocols evaluated. These results validate the effectiveness of integrating optimization techniques into hierarchical routing protocols for wireless sensor networks. By ensuring that nodes with higher residual energy are chosen as cluster heads, our approach not only enhances data transmission efficiency but also prolongs the operational lifespan of the network. In summary, the proposed hybrid protocol offers a robust solution for improving the performance of wireless sensor networks in energy-constrained environments, making it particularly suitable for applications requiring real-time data transmission and efficient resource management. Future work may explore further optimizations and adapt the proposed method to more complex network topologies and dynamics.

ABSTRACT

Information is vital for day to day living. Libraries are often regarded as the quiet, unassuming pillars of society transforming the society to advancement. Information literacy is the ability to find, evaluate, and use information effectively. This includes knowing how to locate, analyse, and synthesize information from various sources. Information literacy competency therefore, has to do with knowledge, skills and attitude towards recognizing when and why information is needed, where to find and access it, how to evaluate, synthesize, use and communicate it ethically and legally. It is essential for library science because librarians help users find and understand information. This paper is an attempt to assess the competency of information literacy among the research scholars with a specific aim to find out whether there exist any variation in the information literacy skills among the scholars of different types of colleges viz. Women’s colleges and co-education colleges. The major finding of this research is that the scholars of co-ed colleges have higher information competency level when compared with the scholars of women’s colleges.

Keywords: Information, Libraries, Communicate, Co-education, Research.

INTRODUCTION

Information is vital for day to day living. Libraries are often regarded as the quiet, unassuming pillars of society transforming the society to advancement. In the tapestry of modern civilization, librarians are the custodians of knowledge, the keepers of stories, and the gateways to a world of information. The essential role of libraries in society journeys from the dusty shelves and the hushed whispers within these hallowed halls to provision of right information to the right persons. Libraries are not merely repositories of books; they are vibrant hubs of learning, innovation, and cultural enrichment. In this context, the librarians have changed their role from library instructors to making the library users as information literate. As a result, the term information literacy became popular. Since it was first used in 1974 (Zurkowski, 1974), the term “information literacy” has come to mean different things to different people. The common meaning is that information literacy is the ability to find, evaluate, and use information effectively. This includes knowing how to locate, analyze, and synthesize information from various sources. It is essential for library science because librarians help users find and understand information. Numerous authors have noted, though, that a lot of information literacy literature is restricted to the library and information science fields (e.g. Arp, 1990; Behrens, 1994; Grassian, 2001). As a result, faculty outside of these disciplines often have a limited or unclear understanding of the concept. In turn, this often leads to the misperception that rather than a shared, collaborative responsibility, instilling information literacy is or should be the “library’s or librarians” responsibility. Now it has been popular that a higher education institution should have as part of its mission the teaching of life-long learning skills, particularly in the context of an information society, and that one place those skills may be taught is through the library. That is, information literacy programmes must be part and parcel of higher education programmes. Hence this paper is an attempt to assess the competency of information literacy among the research scholars with a specific aim to find out whether there exist any variation in the information literacy skills among the scholars of different types of colleges viz. Women’s colleges and co-education colleges.

Information Literacy Competency

Information Literacy is the ability to understand information needs, seek out resources to meet those needs, and then analyze, evaluate, synthesize, and communicate the resulting knowledge. The skills and competencies for information literacy are

- Understanding the information need
- Knowledge of information resources available
- Expertise in methods and techniques to find information
- Understand the need to evaluate retrieved information
- Understand Effective and Efficient Use of Information
- Understand ethics and responsibility of use
- Communication of information/findings
- Understand how to manage the findings

Previous Studies

Deepa R. Kulkarni and RameshaHari (2022) [1] investigated the information literacy competencies possessed by secondary school students in Vijayapura District with a focus on the knowledge and skill level. The results prove that secondary school students do have information skills. They need training and guidance to use those skills for constructing knowledge and extending meanings from the acquired knowledge. Schools should also be offered such information literacy courses which can help to enhance their skills. On the other hand school teachers should also be trained in this regard. Majid and Yun (2020) [2] found that integration of IL skills into school curriculum showed limited success in imparting these skills and suggests measures for improving the integration of IL skills into school curriculum. Jorosi Goitseman (2021) [3] indicate three main issues: first, poor information skills among the students; second, heavy reliance on the use of prescribed textbooks; and finally, the curriculum as a barrier towards the effective integration of information literacy skills into the educational system. ONYENEKE, Cajetan O. and OBICHERE, Charles (2018) [1] investigated information literacy competency of secondary school students in Owerri

David Prabahar *et al.*,

West, South East of Nigeria. The findings revealed that the respondents possess low level of information literacy skills. Their practical ability to effectively utilize information literacy skills was found to be on the average. This was revealed through the responses on information literacy skills. The responses were significantly low in the areas of evaluating information, distinguishing sources of information and formulating search strategies.

Purpose of the Study

The study investigated the research scholars' skills in searching, evaluating and using information in their academic quests life endeavours. The present investigation is a study to assess information literacy competency level of research scholars working in co-education colleges and women's colleges. The investigation uses self-assessment questionnaires to elicit information from the research scholars of two colleges.

Research Question

One of the parameter for assessing the information literacy skill is use of libraries. Among the various parameters for assessing the information literacy competencies is the self-evaluation in the identification of required information by the scholars. Based on this the following research questions are framed.

RQ1 what is the level of use of libraries by research scholars

RQ2 what is the level of use of IT based gadgets by the scholars in the changing information environment

RQ3How far the scholars are capable of identifying their skills and knowledge in their own research areas

Scope and Limitation of Study

The study is conducted among the research scholars of two autonomous colleges namely Bishop Heber College (co-education College) and Holy Cross College (Women's College).

Methods

Questionnaire method is used to collect relevant data. Keeping in view the overall objectives of the present study a set of 7 set of questions as a part questionnaire was prepared on the basis of standards and performance indicators in the Information Literacy Competency Standards for Higher Education (ACRL 1-20). The total scholars of these two colleges is 391. Questionnaires were distributed to all the 391 scholars and the response rate is 53.45.

S. No.	Colleges	Bishop Heber College	Holy Cross College
	Departments		
1.	Languages	74	26
2.	Arts	42	63
3.	Management	18	-
4.	Sciences	108	61
	Total	241	150

DISCUSSION

Table 1 shows the distribution of respondents by college. Among the respondents, 57.89 per cent belong to Bishop Heber College while the rest of 42.11 per cent are from Holy Cross College. The scholars belong to the category of full time as well as part-time. It is found that nearly 50 per cent of the scholars visit the college library regularly (45.45 – Bishop Heber College and 45.59 – Holy Cross College. Here it is to be noted that women's college scholars visit the college libraries more frequently than Co-education College and those visiting rarely is very less compared to co-ed colleges. Also the chi-square value at 3 degrees of freedom is 0.11 which is less than the critical value of 7.815 and hence the null hypothesis is rejected. That is, there is no association between the type of college and the frequency of visit by the scholar to the libraries of these colleges.

**David Prabahar et al.,**

Use of cell phones has become the trend of the day. Any information can be got from the mobile phones if the internet facility is available. Handling the cell phones effectively is one of the parameters for measuring the information literacy competency. Table 3 shows the use of cell phones with internet connectivity. It can be seen that use of cell phones with internet connectivity is more in case of co-ed colleges. The chi-square value at 1 degrees of freedom is 1.64 which is less than the critical value of 3.841 and hence the null hypothesis is rejected. That is, there is no association between the type of college and the use of cell phones with internet connectivity. Information technology has enabled the scholars to use laptops having internet connectivity for getting information anywhere anytime. Use of laptops effectively is one of the parameters for measuring the information literacy competency. Table 4 shows the use of laptops with internet connectivity. It is found that that use of laptops with internet connectivity is more in case of women's colleges. The chi-square value at 1 degrees of freedom is 3.19 which is less than the critical value of 3.841 and hence the null hypothesis is rejected. That is, there is no association between the type of college and the use of laptops with internet connectivity.

Information Literacy Competency Measures

Information literacy is a set of abilities requiring individuals to “recognize when information is needed and have the ability to locate, evaluate, and use effectively the needed information. Information literacy competency extends learning beyond formal classroom settings and provides practice with self-directed investigations as individuals move into internship. Because information literacy augments students' competency with evaluating, managing and using information, it is now considered by several regional and discipline-based accreditation associations as a key outcome for college students. Though there are a number of measures for evaluating information literacy competencies, the following seven parameters are considered in this research:

- Can identify lack of knowledge in the subject area.
- Can identify a search topic / question and define it using simple terminology.
- Can articulate current knowledge on a topic
- Can recognise the need for information and data to achieve a specific end and define limits to the information need.
- Can use background information to underpin the search.
- Can take personal responsibility for an information search.
- Can manage time effectively to complete a search.

A psychological analysis of the scholars reveal the fact that the scholars are not fully well versed in their own subject area. Table 5 shows that only 57 percent of the scholars from Bishop Heber College and 49.8 percent of the scholars of Holy Cross College strongly agree or agree with their own lack of knowledge and the score is 32.8 and 30.6 respectively. Here the score is more in case of co-ed colleges than women's college. The calculated chi-square value is 4.535 at 5 degrees of freedom (Table value 11.070) showing no relationship between the type of college and the scholars knowledge in their subject area. Table 6 shows that 78.8 percent of the scholars from Bishop Heber College and 72.5 percent of the scholars of Holy Cross College strongly agree or agree with their own lack of ability to identify a search topic/term and the score is 39.2 and 37.2 respectively. Here the score is more in case of co-ed colleges than women's college. The calculated chi-square value is 2.465 showing no relationship between the type of college and the scholars' ability to identify a search topic. From table 7 it can be inferred that only 76.1 percent of the scholars from Bishop Heber College and 73.9 percent of the scholars of Holy Cross College strongly agree or agree with their ability to articulate current knowledge on a topic and the score is 53.2 and 37.3 respectively. Here also, the score is more in case of co-ed colleges than women's college. The calculated chi-square value is 4.524 showing no relationship between the type of college and the scholars' ability to articulate current knowledge on a topic a search topic.

From table 8 it is found inferred that 75.8 percent of the scholars from Bishop Heber College and 77.2 percent of the scholars of Holy Cross College strongly agree or agree with their ability to recognise the need for information and data to achieve a specific end and define limits to the information need and the score is 53.0 and 38.0 respectively. Here the score is more in case of co-ed colleges than women's college. The calculated chi-square value is 4.524

David Prabahar et al.,

showing no relationship between the type of college and the scholars' ability to recognise the need for information and data to achieve a specific end and define limits to the information need. From table 9 it is inferred that 76.7 percent of the scholars from Bishop Heber College and 77.3 percent of the scholars of Holy Cross College strongly agree or agree with their ability to use background information to underpin the search and the score is 52.6 and 37.8 respectively. Here the score is more in case of co-ed colleges than women's college. The calculated chi-square value is 1.757 showing no relationship between the type of college and the scholars' ability to use background information to underpin the search. From table 10 it is found that 72.6 percent of the scholars from Bishop Heber College and 75 percent of the scholars of Holy Cross College strongly agree or agree with their ability to take personal responsibility for an information search and the score is 52.6 and 38.2 respectively. Here the score is more in case of co-ed colleges than women's college. The calculated chi-square value is 0.859 showing no relationship between the type of college and the scholars' ability to take personal responsibility for an information search.

From table 10 it is found that 75.2 percent of the scholars from Bishop Heber College and 76.1 percent of the scholars of Holy Cross College strongly agree or agree with their ability to manage time effectively to complete a search and the score is 51.9 and 37.7 respectively. Here the score is more in case of co-ed colleges than women's college. The calculated chi-square value is 0.515 showing no relationship between the type of college and the scholars' ability to manage time effectively to complete a search. On the whole it is found that the scholars of co-ed colleges have higher scores in the self-assessment of their own capabilities in their own subject area. That is the scholars of co-ed colleges have higher information competency level than the women's colleges.

CONCLUSION

Academic librarians should find out new methods to for the assessment of information literacy skills of scholars. Satisfaction surveys and input/output measures do not provide librarians with adequate information about what scholars know and can do. Hence it is the need of the day to develop various new techniques that suit the Artificial intelligence environment.

ABSTRACT

Efficient job scheduling in cloud computing environments is crucial to optimize resource allocation, minimize processing time, and enhance system performance. This paper presents a hybrid Cuckoo approach to cloud-based job scheduling, integrating the Cuckoo Search Optimization (CSO) algorithm with other metaheuristic techniques to enhance scheduling efficiency. The hybrid model leverages the global search capabilities of CSO alongside local optimization strategies to improve load balancing and reduce task execution time. The proposed approach dynamically allocates resources based on task requirements and system states, ensuring an optimal balance between computational workloads and available resources. Experimental results, validated on a cloud simulation platform, show significant improvements in job scheduling performance, reducing overall latency and improving throughput when compared to conventional scheduling techniques. This approach holds promise for advancing cloud infrastructure management, offering a scalable and adaptive solution for real-time job scheduling in diverse cloud environments.

Keywords: Technique, computing, CSO, global.

INTRODUCTION

A metaphor, "cloud computing" is similar to the internet. As a service, resources in cloud computing are made available through a network. In Figure 1, you can see that several cloud providers like Google, Amazon, and Yahoo! offer their customers cloud storage, applications, and data. Data can now be accessible from any location at any time

**Kalaiselvi and Chandrabose**

thanks to the rise of cloud computing. The necessity for a shared physical location has been rendered obsolete by cloud computing. For smaller businesses without the capital to purchase their own storage infrastructure, the cloud is a godsend. Companies can now save money on storage devices by storing all of their data on remote servers in the cloud. Any computer, phone, or tablet with an internet connection can access data stored in the cloud. Through cloud computing, users have access to a plethora of third-party services. Once a user signs up for a cloud service, data is sent between the user and the supplier. Users who use cloud computing can avoid storing data on their personal computers by utilizing a remote virtual platform. There is also the option for customers to host their apps in the cloud, which gives them access to servers where they may process and manipulate data. Cloud computing's tremendous scalability and the convenience of having data accessible from any web browser at any time are driving a lot of interest right now. In general, there are three distinct kinds of cloud computing architectures:

The SaaS model of cloud computing describes the practice of distributing software to end users through subscription. Numerous devices, such as smartphones, tablets, laptops, desktop computers, workstations, and servers, are able to access software stored in the cloud. The platform and infrastructure are completely out of the users' hands. Look at Mail, Google Drive, and Google Talk as examples. The idea of software as a service, sometimes abbreviated as PaaS, is one way to approach cloud computing. The creation and deployment of services can be facilitated by the several programming languages and development environments that service providers offer. Although users may lack control over the underlying infrastructure, they do have the ability to install applications of their own. Google App Engine and Microsoft Azure are two examples. The cloud computing model known as infrastructure as a service, or IaaS, is essentially SaaS. Service providers offer a wide variety of services to their customers, including computing, storage, and networking infrastructure. Users do not have control over storage, deployed apps, operating systems, or anything else related to infrastructure. Rack Space and Amazon Web Services are two instances of cloud services.

Division of Labor

Optimal performance in cloud computing is dependent on well-planned workloads. The purpose of task scheduling is to establish start and end times for various tasks while considering requirements and restrictions. Time and resource constraints both exist. Task scheduling is an essential component of cloud computing. To make the most of available resources and reduce execution time, jobs can be scheduled across many CPUs. The two primary varieties of scheduling are static and dynamic. The scheduling system has been approached from multiple angles. To get the most out of your resources, you need a well-thought-out scheduling approach. The basic procedures for scheduling work are shown in Figure 2. The cloud organizes all of your tasks into queues, each with its own priority. Based on their relative significance, the scheduler assigns tasks to different processors.

Interrelated Duties

In recent times, numerous scheduling methods have emerged to address the issue of cloud computing work scheduling. When it came to task scheduling, I proposed a way to organize various jobs more efficiently. Considering the shortcomings of earlier protocols, this approach organizes tasks that occur on the cloud. The server's throughput, performance, and resource usage are all improved. It solves the issue of task scheduling optimally by using evolutionary algorithms. The Hadoop framework was crucial in completing the mission. A subclass of the scheduler class for work queues is the Genetic Scheduler. This work aims to construct a scheduler for Hadoop that use a genetic algorithm to address the specified issue, thus enhancing Hadoop's capabilities. Introduced the cuckoo search algorithm (CSA), an innovative evolutionary approach to scheduling tasks in remote computing. Not only do cuckoos choose their nests at random, but they also only ever deposit one egg at a time. The host bird's likelihood of finding and identifying an egg of a different species, P_a , might take on values between 0 and 1. A moderate value for P_a greatly improves the algorithm's speed and coverage. In an effort to boost cloud providers' bottom lines, this study introduces a task scheduling strategy based on genetic algorithms.

The GA scheduling function uses the fitness function, which considers user happiness and virtual machine availability, to generate a set of job plans for the population evaluation. In order to find the best time to finish each work, the program repeatedly goes over all populations. A genetic algorithm outperforms other work scheduling

**Kalaiselvi and Chandrabose**

models, including the ABC-based approach and the round robin model, when it comes to efficiency and effectiveness. A system that prioritizes the satisfaction of its users. Prioritizing jobs according to their distinct attributes, the algorithm employs a sorting approach to distribute them to services that are capable of completing them. Has offered an enhanced cost-based strategy. Optimal utilization of cloud resources is achieved by this program through the use of an efficient allocation technique. More people are able to communicate using computers. When comparing the two algorithms, the higher cost algorithm produces far better results than the ABC algorithm. Minimizing wait times for workload activities is the primary goal of the scheduling technique.

Expected Modeling

In order to maximize resource utilization and decrease runtime and power consumption, we require an immediate scheduling approach. This study is centered around optimal scheduling. The hybrid cuckoo method is used for scheduling in this work. When cuckoo and genetic algorithms are combined, the result is a hybrid algorithm. When compared to both the cuckoo method and the genetic algorithm, the hybrid cuckoo algorithm produces far better outcomes. Visual Studio 2010 used as the simulation tool for this investigation. Visual Studio is used for the development of all jobs using the web. Microsoft Azure is used to set up the cloud infrastructure.

In this article, we'll look closely at these traits:

- schedule
- Assets implementation
- vitality exhaustion

A few things are accomplished by the hybrid cuckoo algorithm:

- Tasks executed in the cloud function without a hitch.
- Efficient use of assets.
- It is less probable that the system will fail.
- The method of dividing up tasks among a large number of CPUs in an efficient manner.
- The goal is to reduce wait times.

System basic architecture

The system's basic architecture is shown in Figure 3. It checks if data about available resources is present before allocating jobs. The system swiftly classifies the tasks according to their workload, and then decides whether they are CPU or memory intensive, provided that the necessary data is available. The next step is to sort the tasks according to the nature of the work. Allotting resources, assigning priorities, and determining when jobs will run are all decisions made by the scheduler. This is not the case while initializing resources. In this step, you'll input a temperature value and then create a virtual machine whose capabilities are dependent on that temperature. A resource database stores the results of data sorting algorithms such as genetic, cuckoo, and hybrid cuckoo. The scheduler takes the needs of the jobs into consideration while distributing resources. Next, you should see if there is any outstanding work that needs doing. Until it stops, it continues to run the burden. The loop is restarted if a task cannot be located.

Kalaiselvi and Chandrabose

A Hybrid Cuckoo's Phraseology

Initialize population of n host nests

Set maximum number of iterations (MaxGen)

Define discovery rate of alien eggs/solutions (pa)

While (t < MaxGen)

Generate new solutions (cuckoos) using Lévy flights

Evaluate the fitness of each cuckoo

Select the best solution among new cuckoos

Compare the new solution with a randomly selected nest (host nest)

If the new solution is better, replace the host nest with the new solution

Abandon a fraction pa of the worst nests and build new ones

Keep the best solutions/nests

Apply additional optimization technique (e.g., genetic algorithm, particle swarm optimization) to improve the solutions

Evaluate the fitness of the new solutions from the hybrid method

Combine the new solutions with the current population

Select the best solutions to form the new population

Update the current generation (t = t + 1)

End While

Return the best solution found

Select the response that has been deemed most suitable.

The hybrid cuckoo algorithm combines the best parts of cuckoo search methods with genetic algorithms, and it achieves amazing results. In optimization, the cuckoo search looks for the best possible value of x to maximize or minimize the function f(x). The cuckoo bird's habit of laying its eggs in the nests of other birds likely played a role in shaping this behavior. Applying ideas from natural selection and evolutionary biology, Genetic Algorithms (GAs) are a type of probabilistic approach. In their quest to find novel answers, genetic algorithms (GA) scour both previously known and uncharted parts of the search space. By combining the strengths of the cuckoo and GA algorithms, we may create a new method that overcomes their respective shortcomings.

CONCLUSIONS AND REVIEW

Here you can see the results of our investigation on the time and resources used by various C# in Visual Studio projects. Windows Azure, a platform as a service (PaaS) from Microsoft, allows users to relocate web-based processes to a local cloud environment. The current state of Visual Studio is depicted in Figure 4, which is a screenshot. You can use cuckoo algorithms, hybrid cuckoo algorithms, or genetic algorithms (GAs) to organize your resources. We may then compare the results of various methods. The capacity of the machine is shown by the view machine. Figure 5 shows the time graph showing the accomplished activities.

Approaches Used

We use the Restrigin Function to check how well this analysis works. The way it is described is as follows:

$$f(x) = A_n + \sum_{l=1}^n [x_l^2 - \text{Acos}(2\pi x_l)]$$

Kalaiselvi and Chandrabose

$$\text{Time} = \frac{\text{Number of instruction jobs } (i)}{\frac{\text{MIPS rating (machine } i)}{\text{Tot temperature}}}$$

$$\text{Energy} = \frac{\text{Tot temperature}}{\text{Avg temperature}}$$

$$* \frac{1}{\text{Tot no of resources used}}$$

Because here,

$$\text{Energ}(\Delta E) \propto \text{Temperature}$$

And $\Delta E \propto \frac{1}{\text{resources}}$

Analysis

These criteria are used to conduct the analysis. It is plausible to conclude from these findings that the suggested research is an improvement above the prior models.

- schedule
- Assets implementation
- vitality exhaustion

As illustrated in Figure 5, the hybrid cuckoo method outperforms the Cuckoo, Genetic, and First Come, First serve (FCFS) algorithms in terms of execution time. So, the hybrid cuckoo algorithm gets the job done quickly and efficiently while still producing top-notch results. The hybrid cuckoo algorithm takes 48.72 seconds to finish 50 jobs, as shown in Table 1. Algorithms such as the cuckoo (61.46 seconds), GA (101.8 seconds), and FCFS(109.18 seconds) require significantly more time. In terms of runtime performance, the hybrid cuckoo algorithm outperforms its predecessors. Compared to cuckoo and GA algorithms, the hybrid cuckoo algorithm is more energy efficient. Table 2 shows that the hybrid cuckoo algorithm improves system performance while drastically reducing energy usage. The numerical data is illustrated visually in Figure 6.

The best use of available resources

In this case, our three integers are -1, 0, and 1. Underutilization of resources is indicated by a score of -1. When it's zero, we're maximizing efficiency; when it's one, we're wasting resources. The resource utilization for 90 jobs is shown in Table 4, while for 50 jobs utilizing the hybrid cuckoo method, it is shown in Table 3. Neither the cuckoo algorithm nor the extended technique are perfect when it comes to resource utilization.

CONCLUSION

“Cloud computing” describes an emerging trend in program and data management that makes use of the internet and a distributed network of computers located in faraway locations. Complexity abounds in the cloud computing challenge of task scheduling. An approach to scheduling that is both simple and effective, the hybrid cuckoo algorithm is known for its reliability and ease of use. This method offers a great plan for scheduling within the framework of Visual Studio. whether it comes to execution time, energy consumption, and optimizing resource use, this method outperforms the GA, FIFO, and cuckoo algorithms, respectively, whether dealing with 50, 90, or 120 jobs. It was determined how well the hybrid cuckoo algorithm performed by comparing its output to that of the GA and cuckoo algorithms. The best algorithm after extensive testing was the hybrid cuckoo approach. We can confirm the results for more than 120 more professions with further study. Various methods of task scheduling can be investigated using the hybrid cuckoo algorithm.

ABSTRACT

Sentiment analysis, a crucial aspect of Natural Language Processing (NLP), has gained significant attention in recent years due to its applications in fields such as social media monitoring, customer feedback analysis, and market prediction. This literature review explores the evolution of sentiment analysis through the integration of traditional machine learning algorithms, deep learning models, and advanced NLP techniques. Early approaches relied on manual feature extraction combined with classical machine learning models like Naïve Bayes, Support Vector Machines (SVM), and Random Forests to classify sentiments. However, with the advent of deep learning, architectures such as Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), and more recently, transformers like BERT (Bidirectional Encoder Representations from Transformers), have drastically improved sentiment classification accuracy by enabling automatic feature extraction and handling complex linguistic patterns. The review also highlights the growing use of hybrid models that combine NLP techniques with machine learning and deep learning, enhancing the overall performance in sentiment polarity detection, emotion classification, and subjectivity analysis. The review concludes by discussing current challenges in sentiment analysis, such as handling sarcasm, context-aware sentiment interpretation, and multilingual sentiment analysis, while outlining potential directions for future research to further enhance accuracy and scalability.

Keywords: Sentiment Analysis, Natural Language Processing, Machine Learning, Deep Learning, Classification, Pre-Processing

INTRODUCTION

Sentiment analysis, also known as opinion mining, is a critical area of research within Natural Language Processing (NLP) that focuses on identifying and extracting subjective information from textual data [1]. The proliferation of online platforms, such as social media, e-commerce websites, and review forums, has led to an exponential increase in user-generated content, making sentiment analysis essential for understanding public opinion, market trends, and customer feedback. By transforming unstructured text into structured sentiment scores or categories, sentiment analysis provides valuable insights for businesses, governments, and researchers across various domains [2]. Traditional sentiment analysis techniques relied on lexicon-based approaches and manual feature extraction, which were often labor-intensive and lacked the ability to capture the complexities of natural language. Machine learning models such as Naïve Bayes, Support Vector Machines (SVM), and Logistic Regression were then introduced, significantly improving the classification of sentiment by automating feature selection. These models, however, faced limitations in handling large-scale data, contextual understanding, and non-linear linguistic relationships [3] [4].

The emergence of deep learning has revolutionized sentiment analysis by leveraging advanced neural networks that automatically learn features from raw text data. Deep learning architectures, such as Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), including Long Short-Term Memory (LSTM) models, have shown remarkable success in capturing complex patterns in language. Additionally, the introduction of transformers, particularly the BERT (Bidirectional Encoder Representations from Transformers) model, has set new benchmarks for state-of-the-art sentiment analysis, enabling context-aware interpretation and improving the classification of sentiments in nuanced textual inputs [5]. This review aims to explore the application of NLP techniques, machine learning, and deep learning in sentiment analysis, tracing their evolution and highlighting their strengths and limitations. The study also examines hybrid approaches that combine these techniques to achieve higher accuracy in sentiment classification tasks. Additionally, we identify key challenges in sentiment analysis, such as sarcasm detection, multilingual text processing, and context-aware sentiment interpretation, and provide insights into future research directions that could address these issues.

Background Study On Sentiment Analysis

Sentiment analysis, a subset of Natural Language Processing (NLP), focuses on identifying the emotional tone, polarity (positive, negative, neutral), or attitude expressed in a body of text. The origins of sentiment analysis date back to early attempts at extracting subjective information from text through lexicon-based methods and manual rule-based systems. The exponential growth of digital content, particularly in the form of social media posts, reviews, and forums, has made sentiment analysis increasingly important for analyzing public opinion, brand perception, and customer satisfaction across numerous industries.

Early Approaches in Sentiment Analysis

The initial methods for sentiment analysis were primarily lexicon-based, using pre-defined dictionaries of words associated with positive or negative sentiments. These methods classified text by counting sentiment-laden words, which were then aggregated to determine the overall polarity of the text [6]. Though relatively simple, lexicon-based approaches were effective in specific domains where domain-specific dictionaries could be created. However, they struggled with challenges like sarcasm, ambiguity, and context.

Traditional Machine Learning Techniques

To overcome the limitations of lexicon-based approaches, traditional machine learning algorithms were introduced to sentiment analysis. In these approaches, text was first converted into feature vectors using methods such as Bag of Words (BoW) and Term Frequency-Inverse Document Frequency (TF-IDF). These feature vectors were then fed into classifiers like Naïve Bayes, Support Vector Machines (SVM), Random Forest, and Logistic Regression to predict sentiment labels [11].

Roja and Durairaj

Naïve Bayes: One of the earliest machine learning models used for sentiment analysis, Naïve Bayes relies on probabilistic models. It assumes independence among features and performs well in binary classification tasks.

Support Vector Machines (SVM): SVM works by finding the hyperplane that best separates different sentiment classes. It often performs well in high-dimensional feature spaces but can struggle with handling very large datasets efficiently.

Random Forest: As an ensemble method, Random Forest aggregates decisions from multiple decision trees, improving robustness and accuracy in sentiment classification.

These traditional machine learning approaches marked a significant improvement over lexicon-based techniques by automating feature extraction and making the analysis more scalable. However, they still had limitations in capturing the semantic and syntactic nuances of language and often required manual feature engineering[7].

The Rise of Deep Learning in Sentiment Analysis

Deep learning techniques, particularly neural networks, brought about a paradigm shift in sentiment analysis by automatically learning hierarchical features from raw text data. Unlike traditional models, deep learning approaches could capture both shallow and deep semantic structures in language, making them well-suited for sentiment classification.

Convolutional Neural Networks (CNNs): Initially used in image processing, CNNs were later adapted for text classification tasks like sentiment analysis. CNNs use convolutional layers to extract local features from text data and have been effective in identifying sentiment indicators such as key phrases or word patterns.

Recurrent Neural Networks (RNNs) and Long Short-Term Memory (LSTM): RNNs, particularly LSTMs, were developed to handle sequential data and capture dependencies across time steps. LSTMs address the issue of vanishing gradients and are especially useful for processing longer sentences or paragraphs where contextual relationships between words affect sentiment.

Transformers (e.g., BERT): The introduction of transformer architectures, especially BERT (Bidirectional Encoder Representations from Transformers), has set new performance benchmarks in sentiment analysis. BERT captures word relationships bidirectionally, meaning it can consider both the left and right contexts of a word, improving sentiment classification in nuanced or ambiguous text. BERT-based models can also handle complex tasks such as sarcasm detection and emotion classification.

Hybrid Approaches in Sentiment Analysis

Recently, hybrid models that combine traditional machine learning, deep learning, and NLP techniques have emerged to improve the accuracy and robustness of sentiment analysis. These models leverage the strengths of different techniques to address the limitations of individual approaches [8]. For instance, feature selection techniques such as TF-IDF may be used alongside word embeddings like Word2Vec or GloVe, while a deep learning classifier, such as an LSTM, processes the input to predict sentiment.

Background Study On NLP Techniques

Natural Language Processing (NLP) plays a pivotal role in sentiment analysis by enabling computers to understand, interpret, and manipulate human language. Sentiment analysis involves classifying text into predefined sentiment categories, such as positive, negative, or neutral. Over the years, NLP techniques have evolved significantly, ranging from rule-based methods to modern deep learning-based approaches, allowing more accurate sentiment detection in diverse and complex datasets [9] [10].

**Roja and Durairaj****Feature Engineering and Traditional NLP Techniques**

As sentiment analysis grew in complexity, more advanced NLP techniques involving feature engineering and traditional machine learning were introduced. Feature engineering focuses on converting raw text into numerical features that machine learning models can process. Common NLP techniques used for this process include:

Bag of Words (BoW): A popular text representation technique, BoW treats text as a collection of words, disregarding grammar and word order. The frequency of each word in the text is counted, and the text is represented as a feature vector. BoW is effective for basic sentiment classification but ignores semantic relationships between words.

Term Frequency-Inverse Document Frequency (TF-IDF): An improvement over BoW, TF-IDF gives weight to words based on their frequency in a document relative to their occurrence across a larger corpus. Words that appear frequently in a document but less frequently across other documents are given higher weight, helping to identify important sentiment-carrying terms. However, TF-IDF, like BoW, lacks contextual understanding and word order information [11].

N-grams: N-grams capture sequences of N words in the text and are used to incorporate some degree of word order and local context into feature representations. Bigram (2-word) and trigram (3-word) models are commonly used to detect sentiment-related phrases, such as "not bad" or "very good."

Part-of-Speech (POS) Tagging: POS tagging identifies the grammatical role of each word in a sentence (e.g., noun, verb, adjective). In sentiment analysis, POS tagging helps identify sentiment-laden words, especially adjectives and adverbs, which often indicate emotional tone (e.g., "happy," "angry") [13].

Named Entity Recognition (NER): NER identifies and classifies named entities (e.g., people, organizations, locations) in text. While NER is not directly used for sentiment analysis, it can improve performance by identifying contextually important entities, allowing the model to better understand the subject of sentiment.

LITERATURE REVIEW

Naithani, Kanchan, and Yadav Prasad Raiwani [11] This study examined simple situations that make use of important methods and information that can be applied to sentiment analysis. An overview of the work completed up to this point is carried out, noting the findings and conclusions pertaining to different parameters of different researchers who worked on previously known as well as unique and hybrid algorithms using legion techniques. In order to obtain practice percentage and accuracy score in the fields of NLP, sentiment analysis, and text analytics, basic algorithms like Support Vector Machine (SVM), Bayesian Networks (BN), Maximum Entropy (MaxEnt), Conditional Random Fields (CRF), and Artificial Neural Networks (ANN) are also covered. William, P., *et al* [12] explained the initial attempts at sentiment analysis using twitter. The goal of this research is to identify sentiment in tweets based on their subject matter. It makes use of natural language processing techniques to identify the feeling connected to a particular problem. In our study, we classified emotions using three distinct methods: subjectivity-based classification, semantic association-based classification, and polarity-based classification. By determining the grammatical connection between emotion lexicons and the participant, the experiment takes advantage of them. The suggested approach works better than the state-of-the-art text sentiment analysis techniques because of tweets' distinct structure.

Omuya, Erick Odhiambo, George Okeyo, and Michael Kimwele [13] intended to create a sentiment analysis model for social media data that integrates natural language processing with part-of-speech tagging and dimensionality reduction. The model is evaluated against the performance of two different sentiment analysis models utilising the Naïve Bayes, support vector machine, and K-nearest neighbour algorithms. The model uses machine learning approaches to increase sentiment analysis performance, according to experimental results. Balli, Cagla, *et al* [14]

**Roja and Durairaj**

sought to analyse sentiment using a number of machine learning algorithms using Turkish language datasets gathered from the Twitter platform. In this study, in addition to utilising public datasets for broader generalisation, a new dataset is generated to comprehend the pandemic's effects on individuals and get insights into public sentiment. As a result, a new dataset called SentimentSet was created using Turkish tweets that had been manually categorised as good, negative, or neutral based on the inclusion of terms like "pandemic" and "corona." SentimentSet may also serve as a standard dataset for upcoming studies. Results demonstrate up to around 87% classification accuracy using test data from datasets of both datasets and trained models, and up to approximately 84% using small "Sample Test Data" created using the same techniques as the SentimentSet dataset. These study findings helped to show that sentiment analysis particular to the Turkish language depends on linguistic parameters.

Das, Jay Krishna, Anupam Das, and Joann Rosak-Szyrocka [15] The main objective of this work is to use natural language processing techniques to design a new sentiment analysis model for an e-learning platform. First, benchmark resources are used to collect standard text data on e-learning platforms with user reviews. The collected data is transferred to a pre-processing procedure, which removes superfluous content to optimise sentiment analysis results. Additionally, the glove embedding approach is used to convert words to vectors in order to obtain pertinent data for sentiment analysis. Additionally, Convolutional Neural Networks (CNN) equipped with Gated Recurrent Units (GRU) do sentiment categorisation. Lastly, in the e-learning domain, the feelings are examined using hybrid deep learning. The analysis shows encouraging outcomes for sentiment analysis tasks. Tunca, Sezai, Bulent Sezen, and Violetta Wilk. [16] The purpose of this study was to better comprehend the metaverse concept by revealing the linkages between the metaverse concept and other related concepts, as well as by determining the features of positive and negative attitude. This study employed computational qualitative analysis and artificial intelligence (AI) with natural language processing (NLP) techniques to achieve this goal. The information included metaverse stories from 2021–2022, which were posted on The Guardian website, a significant worldwide mainstream media source. The Natural Language Toolkit (NLTK) from NLP libraries was utilised to determine sentiment, and Leximancer software was utilised to do thematic content analysis of the qualitative data. Additionally, sectoral classifications of the primary themes that surfaced in the Leximancer research were created using an AI-powered Monkeylearn API. Four major themes came out of the Leximancer analysis: "games," "platforms," "Facebook," "metaverse," and "games."

Bari, Anasse, *et al* [17] Artificial intelligence in the form of natural language processing sentiment analysis was used to construct a real-time big data analytics system. Real-time sentiment and content themes, such natural health or personal independence, are ingested, processed, and analysed by the framework. A subsequent dataset assessed the correlation between sentiment scores on Twitter and US immunisation rates. Ruskanda, Fariska Zakhralativa, *et al* [18] suggested a different ansatz for the quantum representation task of sentiment categorisation. In particular, it expands on earlier research in the field of quantum sentiment categorisation by putting forth the Simple Sentiment Analysis (SimpleSA) ansatz, which is a substitute for the Instantaneous Quantum Polytime ansatz. The SimpleSA ansatz's choice to disregard noun parameterisation is a fundamental component. In terms of the amount of parameters and gates, the suggested SimpleSA is less complex than the other ansätze. Furthermore, the H-CNOT-Rz-H compound block construction used in the SimpleSA ansatz works better than the Instantaneous Quantum Polytime (IQP) ansatz at 85.00% accuracy, according to experimental results. In addition, SimpleSA optimisation converges 20.89% faster for the Simultaneous Perturbation Stochastic Approximation (SPSA) approach with 130 iterations than Instantaneous Quantum Polytime (IQP). Applications of quantum computers for sentiment analysis and classification can benefit from the suggested study.

Sadanand, Vijaya Shetty, *et al*. [19] Proposing and training an LSTM model with a dataset of hand graded essays with scores is one of the research's primary goals. Sentiment analysis is used to identify whether the essay's sentiment is neutral, positive, or negative. A sentiment classifier that evaluates sentiment according to students' approaches to a topic is built using the Twitter sample dataset. Every essay is also examined for grammatical mistakes and plagiarism in order to determine how original it is. Ounacer, Soumaya, *et al*. [20] recommended extracting reviews from travel websites like Booking and TripAdvisor and using the Aspect-Based Sentiment Analysis method to them. This method is based on two primary steps: each aspect's sentiment classification and aspect extraction. A topic modeling-

**Roja and Durairaj**

based method is suggested for aspect extraction that makes use of the semi-supervised CorEx (Correlation Explanation) technique for classifying word sequences into entities. Regarding sentiment classification, a variety of supervised machine learning methods are applied to link a given aspect expression to a sentiment (positive, negative, or neutral). Opinion corpus experiments have produced very positive results.

Hasan, Mahmud, *et al.* [21] Submitted a dataset with annotations in Bangla for sentiment analysis on the recent conflict between Russia and Ukraine. The dataset was created by gathering comments in Bangla from a variety of videos that three well-known Bangladeshi YouTube TV news channels posted while reporting on the ongoing crisis. 10,861 Bangla comments in total were gathered and classified into three polarity sentiments: neutral, pro-Russia (negative), and pro-Ukraine (positive). By testing with various transformer-based language models that had all been pre-trained on an unlabelled Bangla corpus, a benchmark classifier was created. The dataset we acquired was used to refine the models. All five transformer language models—BanglaBERT, XLM-RoBERTa-base, XLM-RoBERTa-large, Distil-mBERT, and mBERT—were subjected to hyperparameter optimisation. Several assessment criteria, such as the F1 score, accuracy, and AIC (Akaike Information Criterion), were used to assess and analyse each model. With an F1 score of 0.82, the top-performing model obtained the highest accuracy of 86%. BanglaBERT surpasses the baseline and all other transformer-based classifiers in terms of accuracy, F1 score, and AIC.

Gunasekaran, Karthick Prasad [22] discussed the opportunities and difficulties in SA, including how to handle irony and sarcasm, analyse data that is multilingual, and address ethical issues. Twitter was selected as one of the biggest online social media networks to offer a real-world case study. The researchers also clarified the various fields in which SA is applied, such as social media, healthcare, marketing, banking, and politics. Additionally, a thorough and comparative study of current methodologies, datasets, and evaluation criteria is included in the paper. The final objective is to provide academics and practitioners with a thorough analysis of SA approaches, point out any gaps in the field, and make recommendations for potential enhancements. The goal of this research is to improve the accuracy and efficiency of SA procedures, producing results that are more error-free and seamless. Mishra, Shreyash, *et al.* [23] Sentiment analysis and opinion mining is a field of study that looks into people's attitudes, judgements, sentiments, and opinions in order to derive meaning from their written words. One of the most active research areas in text, online, and data mining is natural language processing. Sentiment analysis has several applications, including measuring public opinion on goods and services and evaluating the effects of events on social networks. Sentiment analysis is becoming more and more significant, much as blogs, forums, microblogs, and social networks like Facebook and Twitter have increased in popularity. Digitally recorded sentiments can be quantified by lexical-based methods and supervised machine learning.

Khaiser, Fareed Kaleem, Amna Saad, and Cordelia Mason [24] In this study, student opinions regarding institutional facilities are gathered by sentiment analysis, often known as opinion mining or emotional artificial intelligence (AI). An online text must first be analysed to determine whether it has a positive, negative, or neutral emotional tone. Sentiment analysis is a subfield of natural language processing (NLP), which can be utilised with machine learning techniques to extract and classify data. Since students are customers in an educational context, it is crucial to find out if they are happy with the facilities or services offered. This study examined how college students felt about the books, audio CDs, and video CDs; the services that the library personnel offered; and the personal computers that are available to them as part of the library's amenities. Surveys were used in the current study to collect data and evaluate the degree to which students' requirements are met. Shinde, Varun [25] This covers issues like languages and missing data in addition to solutions like multilingual models and transfer learning. Additionally covered are developments in multilingual perceptual analysis models for natural language processing. The techniques employed were gathering multilingual Twitter data, using that data to pre-train language models, generating sentiment analysis data sets for every language, and fine-tuning the developed models in comparison to the originals.

Gupta, Shelley, Archana Singh, and Vivek Kumar [26] 1,68,548 tweets expressing the opinions of 650 well-known people have been downloaded from all around the world. The findings demonstrate how the suggested framework for natural language processing demonstrates that the presence of emojis in sentiments frequently appears to alter

**Roja and Durairaj**

the sentiment's overall polarity. By extension, a dictionary of sentiments is used to assess the polarity of text, and the CLDR name of the emoji is used to assess the correct polarity of emoji patterns. Finally, the suggested distinguishing language features are assessed based on the performances of three machine learning classifiers: SVM, DT, and Naïve Bayes. The reliable tests show that when compared to other ML classifiers, the suggested method performs better than the SVM classifier. The suggested polarity detection generator outperformed current state-of-the-art methods in achieving an outstanding view of the sentiments expressed in the sentence by utilising the concept flow established based on linguistic features, polarity inversion, coordination, and discourse patterns. Li, Yan [27] created a text sentiment analysis model and a picture-text multimodal sentiment analysis model in social networks, respectively, after studying the sentiment analysis algorithms in social networks at two levels: unimodal and multimodal. The efficiency of the two models was confirmed by comparing the experiments with the current models on a number of datasets. The accuracy of the two models outperformed the benchmark models by 4.45% and 5.2%, respectively. By practically applying the optimised convolutional neural network recurrent optimisation network to single task and multitask and comparing it with other deep learning classifiers currently in use, the viability of applying the network to social network sentiment analysis is confirmed.

Kasula, Balam Yadav [28] explored the field of sentiment analysis using a variety of approaches and strategies derived from machine learning and natural language processing. The search for the best accurate model is still ongoing, despite earlier efforts examining binary (positive or negative), ternary (containing neutral), or even more complicated sentiment classifications (such as joyful, sad, afraid, astonished, or wrathful). As a result, this study looks into using sentiment analysis to analyse comments on YouTube videos, concentrating on polarity identification. Researchers studying data mining and sentiment analysis can benefit greatly from the research's clarification and classification of these methodologies. Thimmapuram, Madhuri, Devasish Pal, and Gouse Baig Mohammad [29] Analysing polarity in noisy Twitter feeds is the primary objective. This study details the idea behind a data analysis that pulls out a large number of tweets. Results employ tweets to categorise people' perceptions into positive and negative groups. By inputting a keyword, the user can discover its nature based on the most recent tweets that contain the inputted keyword. Every tweet is categorised based on whether it makes you feel good or unhappy. Information about movie reviews is gathered from the IMDB website. Naive Bayes, a machine learning algorithm, was applied. The outcome of this model was tested using several test methodologies. Furthermore, our algorithm performs quite well when mining sentences that are directly extracted from Twitter. The accuracy was 92.50%, and the execution speed and generalisation were also strong points. Sv, Praveen, *et al.* [30] In this study, sentiment analysis and topic modeling—two methods often used in natural language processing—were used to examine Indian perspectives on COVID-19 booster dosage vaccinations. For this study, we examined tweets written by Indian nationals. The Indian government expedited the COVID-19 booster dose immunisation protocol in late July 2022. The government, health policy officials, and policymakers will be able to implement the health policy more effectively and achieve the desired outcomes if they have a thorough understanding of the feelings and worries that the public has regarding it.

Research Gap

Despite the significant advances in sentiment analysis, there remain several challenges:

Sarcasm and Irony: Detecting sarcasm and irony is one of the most challenging aspects of sentiment analysis. The literal meaning of words in sarcastic statements often contradicts their intended sentiment, making it difficult for models to correctly classify such text.

Context-Awareness: Traditional sentiment analysis methods often fail to capture the context in which a sentiment is expressed, leading to inaccurate classifications. Context-aware models, such as transformers, aim to address this issue.

**Roja and Durairaj**

Multilingual Sentiment Analysis: Analyzing sentiment across multiple languages presents challenges due to differences in grammar, syntax, and cultural nuances. Pretrained multilingual models like mBERT have been developed to address this, but they still require further refinement.

Future Research Direction

The future of sentiment analysis lies in further advancements in deep learning, transfer learning, and hybrid models. Researchers are increasingly focusing on building more context-aware models, improving the handling of sarcasm and irony, and creating robust multilingual sentiment analysis systems. Moreover, the integration of sentiment analysis with other AI techniques, such as emotion recognition and cognitive computing, promises to expand its applications in fields like healthcare, finance, and social media analysis. This background study provides a comprehensive understanding of the development of sentiment analysis techniques, highlighting the transition from traditional lexicon-based methods to sophisticated deep learning approaches. The continuous improvement of NLP, machine learning, and deep learning techniques has made sentiment analysis an indispensable tool for extracting meaningful insights from large-scale text data.

ABSTRACT

The rapid advancement of healthcare technology has led to an explosion of multi-modal data, including electronic health records, medical imaging, genomics, and wearable device outputs. This diverse data landscape poses significant challenges in terms of dimensionality reduction, which is essential for effective analysis and interpretation. This literature review explores various multi-modal data fusion techniques aimed at enhancing dimensionality reduction in healthcare analytics. We categorize the existing approaches into three main frameworks: feature-level fusion, decision-level fusion, and hybrid methods, each exhibiting unique strengths and limitations. The review critically evaluates recent studies that leverage machine learning algorithms, deep learning architectures, and statistical methods for integrating multi-modal data. By synthesizing findings from various domains, we highlight the impact of dimensionality reduction on predictive modeling, disease diagnosis, and personalized treatment strategies. Furthermore, we discuss the challenges and future directions in the field, emphasizing the need for robust methodologies that ensure data integrity and interpretability while maintaining patient privacy. This review aims to provide a comprehensive understanding of current trends and advancements in multi-modal data fusion techniques, offering insights for researchers and practitioners in the realm of healthcare analytics.

Keywords: Healthcare Analytics, Dimensionality Reduction, Data Fusion Technique

Chitra and Hari Ganesh

INTRODUCTION

In recent years, the healthcare sector has experienced a profound transformation driven by technological advancements and the proliferation of data [1] [2]. The integration of diverse data sources—ranging from electronic health records (EHRs) and medical imaging to genomic sequences and data from wearable devices—has created a multi-modal data landscape. Each of these modalities provides unique insights into patient health, but they also introduce significant complexity due to their inherent heterogeneity in format, structure, and information content. Multi-modal data fusion refers to the process of integrating data from multiple sources to achieve a more comprehensive understanding of a given phenomenon. In the context of healthcare analytics, effective data fusion is crucial for enhancing clinical decision-making, improving patient outcomes, and advancing personalized medicine. However, the diverse nature of these data sources often results in high dimensionality, making it challenging to extract meaningful patterns and insights. High-dimensional datasets can lead to issues such as the "curse of dimensionality," where the volume of the feature space increases exponentially, potentially diminishing the performance of machine learning algorithms and complicating the interpretability of models.

Dimensionality reduction techniques play a pivotal role in addressing these challenges by reducing the number of features while preserving the essential information required for analysis. By minimizing dimensionality, these techniques can improve computational efficiency, reduce storage costs, and enhance model performance. Moreover, effective dimensionality reduction can mitigate overfitting, improve generalization, and facilitate the visualization of complex data structures. Various methodologies have been proposed to achieve dimensionality reduction in the context of multi-modal data fusion. These can broadly be categorized into feature-level fusion, where data from different modalities is combined at the feature level before analysis, and decision-level fusion, where models built on individual modalities are combined to form a consensus decision. Hybrid approaches that integrate both feature-level and decision-level fusion techniques have also gained traction, promising to leverage the strengths of each method [3] [4].

Despite the significant progress in multi-modal data fusion techniques, several challenges remain. Issues such as data inconsistency, missing values, and the need for effective alignment of disparate data sources complicate the fusion process. Additionally, the selection of appropriate dimensionality reduction techniques that suit the specific characteristics of each data modality is critical for achieving optimal results [5] [6]. This literature review aims to synthesize the current state of research on multi-modal data fusion techniques for enhanced dimensionality reduction in healthcare analytics. By critically examining the existing methodologies, we will identify trends, challenges, and opportunities in this evolving field. Our review will provide insights into how these techniques can be effectively applied to improve predictive modeling, disease diagnosis, and personalized treatment strategies, ultimately contributing to the advancement of healthcare analytics. The findings of this review will serve as a valuable resource for researchers and practitioners seeking to harness the potential of multi-modal data in healthcare.

Background Study on Healthcare Analytics

Healthcare analytics is the systematic analysis of healthcare data to derive actionable insights that enhance decision-making, improve patient outcomes, and optimize operational efficiency. The integration of data science techniques and healthcare information systems has paved the way for the emergence of analytics as a vital tool in the healthcare sector. It encompasses a wide range of methodologies, including descriptive, predictive, and prescriptive analytics, each serving distinct purposes in analyzing healthcare data [7] [8].

Descriptive Analytics provides insights into historical data, allowing stakeholders to understand trends, patterns, and correlations within healthcare datasets. It typically involves the use of data visualization tools to present findings in an understandable format.

**Chitra and Hari Ganesh**

Predictive Analytics utilizes statistical algorithms and machine learning techniques to forecast future events based on historical data. In healthcare, predictive models are employed for various applications, such as predicting disease outbreaks, patient readmissions, and treatment outcomes.

Prescriptive Analytics goes a step further by recommending actions based on predictive insights. This form of analytics helps healthcare providers optimize resource allocation, enhance treatment plans, and improve patient care protocols. The effectiveness of healthcare analytics is heavily dependent on the quality and variety of data available. Data sources in healthcare are diverse, encompassing:

Electronic Health Records (EHRs): Digital versions of patients' paper charts, EHRs contain a wealth of information, including patient demographics, medical history, medications, treatment plans, and laboratory results.

Medical Imaging: Imaging modalities such as X-rays, MRIs, and CT scans generate complex data that require advanced analytics for interpretation. Techniques such as image recognition and analysis have emerged to extract valuable information from medical images.

Genomic Data: The advent of genomics has provided insights into individual genetic makeups, paving the way for personalized medicine. Analyzing genomic data enables healthcare providers to tailor treatments based on genetic predispositions.

Wearable Devices: Devices such as smartwatches and fitness trackers collect real-time health data, including heart rate, physical activity, and sleep patterns. This data is increasingly used to monitor chronic conditions and promote preventive care. The landscape of healthcare analytics has evolved significantly over the past few decades:

Early Days: Initially, healthcare analytics focused primarily on descriptive statistics to report on patient outcomes and operational efficiency. Data was often siloed, with limited integration across departments.

Emergence of Predictive Analytics: With the advent of advanced statistical methods and machine learning algorithms, predictive analytics gained traction in the late 2000s. Healthcare organizations began employing predictive models to forecast patient needs and identify high-risk patients.

Current Trends: Today, the integration of artificial intelligence (AI) and machine learning in healthcare analytics has revolutionized the field. AI-driven tools can analyze complex datasets, identify patterns, and provide real-time insights, leading to improved clinical decision-making and personalized treatment approaches.

Background Study on Dimensionality Reduction Techniques

Dimensionality reduction refers to a set of techniques aimed at reducing the number of input variables or features in a dataset while retaining its essential information. In the context of healthcare analytics, the explosion of data from diverse sources—such as electronic health records, medical imaging, genomic studies, and wearable devices—has resulted in high-dimensional datasets. While this wealth of data can provide rich insights into patient health and treatment outcomes, high dimensionality often leads to challenges such as overfitting, increased computational costs, and difficulties in visualization and interpretation. Dimensionality reduction techniques serve to simplify these complex datasets by extracting relevant features and eliminating redundant or irrelevant information. This simplification not only enhances the performance of machine learning algorithms but also aids healthcare practitioners in making more informed decisions based on the underlying patterns present in the data. Dimensionality reduction techniques can be broadly categorized into two main types: feature selection methods and feature extraction methods.

**Chitra and Hari Ganesh**

Feature Selection: This approach involves selecting a subset of the most relevant features from the original dataset [9][10]. It is particularly useful when the original features contain irrelevant or redundant information that can obscure meaningful patterns. Common feature selection techniques include:

Filter Methods: These methods evaluate the relevance of features based on their statistical properties, independent of the machine learning algorithm used. Examples include chi-square tests, correlation coefficients, and mutual information.

Wrapper Methods: These techniques use a predictive model to evaluate the performance of feature subsets. They iteratively select features based on model accuracy, often employing techniques like recursive feature elimination.

Embedded Methods: These approaches perform feature selection during the model training process, integrating the selection with the learning algorithm. Examples include Lasso regression and decision tree-based methods like Random Forest.

Feature Extraction: This approach transforms the original features into a new feature space with reduced dimensionality. Feature extraction techniques create composite features that capture the underlying structure of the data. Common feature extraction methods include:

Principal Component Analysis (PCA): A linear transformation technique that reduces dimensionality by projecting the data onto a lower-dimensional space while maximizing variance.

t-distributed Stochastic Neighbor Embedding (t-SNE): A nonlinear technique particularly suited for visualizing high-dimensional data in a lower-dimensional space. It emphasizes preserving local structures in the data.

Linear Discriminant Analysis (LDA): A supervised method that seeks to find the linear combinations of features that best separate different classes in the dataset.

Autoencoders: A type of neural network used for unsupervised feature extraction, where the model learns to encode the input data into a lower-dimensional representation and then reconstruct it. \ The application of dimensionality reduction techniques in healthcare is vast and varied, with implications across several areas:

Disease Diagnosis and Prediction: Dimensionality reduction techniques are often employed to enhance the performance of predictive models in disease diagnosis. By reducing the number of features, these techniques help mitigate overfitting and improve model interpretability, which is crucial in clinical settings. For example, PCA has been used to analyze genomic data for predicting cancer outcomes, while LDA has been applied to differentiate between various types of diseases based on clinical parameters.

Medical Imaging: In medical imaging, dimensionality reduction techniques are used to extract relevant features from high-dimensional image data, facilitating the identification of patterns indicative of specific conditions. For instance, PCA and autoencoders have been utilized to enhance image quality and reduce noise in MRI and CT scans.

Personalized Medicine: The integration of multi-modal data, including genomic, clinical, and lifestyle data, is essential for advancing personalized medicine. Dimensionality reduction techniques enable the identification of significant biomarkers that can inform tailored treatment plans, enhancing the efficacy of interventions.

Patient Monitoring and Wearable Devices: Data collected from wearable devices, which often include numerous features related to physical activity, heart rate, and sleep patterns, can be analyzed using dimensionality reduction techniques. This analysis helps in identifying trends and anomalies in patient health, facilitating timely interventions.

LITERATURE REVIEW

Rani, Ridhima, *et al* [11] In the era of big data, diverse data types characterised by extensive samples and high dimensionality are proving essential across various domains, including data mining, pattern recognition, machine learning, and the Internet of Things (IoT), among others. The intricacy of data processing escalates with the augmentation of the dataset's size. The term "complexity" denotes the challenge of identifying and utilising correlations among many elements of a dataset. Consequently, employing a dimensionality reduction (DR) method can eliminate the complexity among various features. This article examines the literature on data recovery approaches in the context of enhancing storage and processing of large data across various IoT applications, highlighting its advantages, characteristics, classification, and evaluation criteria. Moreover, the essay delineates prospective research issues and provides insights into the applications of data reduction (DR) across several areas, thereby informing readers about the relevance of a specific data reduction technique. Rashid, Lubaba, *et al* [12] intended to ascertain the impact of dimensionality reduction on IoT data on storage and communication expenses. It also examines the impact of dimensionality reduction of IoT data on the efficacy of various classification algorithms applied to it. Dimension reduction has been shown to decrease the storage and communication expenses of IoT data, albeit at the expense of the performance of classification algorithms applied to the reduced-dimensional data. Nonetheless, this decline in performance is insignificant relative to the optimisation of storage and transmission costs.

Ashraf, Mohsena, *et al* [13] Contemporary data analysis entails managing extensive datasets, including time-series data. This data is distinguished by its high dimensionality, substantial volume, and the existence of noise and redundant features. Nevertheless, the "curse of dimensionality" frequently presents challenges for learning methodologies, which may struggle to recognise the temporal correlations inherent in time-series data. To resolve this issue, it is imperative to diminish dimensionality while maintaining the inherent characteristics of temporal dependencies. This will mitigate diminished learning and prediction performance. This paper introduces twelve distinct dimensionality reduction techniques tailored for time-series data, categorised by supervision, linearity, time and memory complexity, hyper-parameters, and limitations. Vinutha, M. R., *et al* [14] An Enhanced Principal Component Analysis (EPCA) is proposed, which minimises the dimensions of the medical dataset while meticulously preserving critical information, thereby attaining superior outcomes. The notable dimensionality reduction approaches, including Principal Component Analysis (PCA), Singular Value Decomposition (SVD), Partial Least Squares (PLS), Random Forest, Logistic Regression, Decision Tree, and the proposed EPCA, are examined in relation to the following Machine Learning (ML) algorithms: Support Vector Machine (SVM), Artificial Neural Networks (ANN), Naïve Bayes (NB), and Ensemble ANN (EANN) evaluated by statistical metrics including F1 score, precision, accuracy, and recall. EPCA directly transferred the data to a lower-dimensional space to enhance the distribution of the data in that form.

Henouda, Salah Eddine, *et al* [15] This study aims to examine the impact of dimensionality reduction methods (DRTs) on the classification of breast cancer (BC). We concentrated on the following five dimensionality reduction techniques (DRTs): Auto-Encoders (AE), T-Distributed Stochastic Neighbour Embedding (T-SNE), Recursive Feature Elimination (RFE), Isometric Feature Mapping (Isomap), and Principal Component Analysis (PCA). These methods are integrated with two renowned classifiers: Support Vector Machine (SVM) and Multilayer Perceptron (MLP). They are utilised for BC categorisation. The Breast Cancer Wisconsin Diagnostic (WDBC) dataset was utilised to validate the experiments conducted in this study. The former was supplied by the machine learning repository of the University of California, Irvine (UCI). Ahmad, Noor, and Ali Bou Nassif [16] Dimensionality reduction strategies are essential for the analysis and interpretation of high-dimensional data. These strategies collect various data attributes of significance, including dynamic structure, input-output linkages, inter-data set correlation, covariance, and others. Dimensionality reduction involves transforming a collection of high-dimensional data features into a lower-dimensional representation. This study addresses the inadequate performance of learning models caused by high-dimensional data by examining five distinct dimensionality reduction techniques. A comprehensive comparison is

**Chitra and Hari Ganesh**

made between reduced dimensionality data and the original dataset utilising statistical and machine learning algorithms.

Rafieian, Bardia, Pedro Hermosilla, and Pere-Pau Vázquez [17] presented a straightforward yet potent transformation for vector datasets that alters their values according to weight frequencies. This strategy greatly enhances the efficacy of dimensionality reduction algorithms in many contexts. We analyse a selection of renowned labelled datasets to illustrate the effectiveness of our methods. The results indicate enhanced clustering efficacy in classifying data within the limited space. The idea offers a thorough and flexible strategy to improve the results of dimensionality reduction for visual data analysis. Ali, Mehak, *et al* [18] This paper combines Principal Component Analysis (PCA) with eigenvector integration techniques to present a new approach for dimensionality reduction in time-domain optimisation. Effective dimensionality reduction is increasingly obstructed by data complexity, which is crucial for enhancing computational efficiency and improving model performance. Principal Component Analysis (PCA) is a crucial instrument in machine learning and data processing, particularly advantageous for high-resolution data. This study examines the influence of Principal Component Analysis (PCA) on the efficacy and precision of three classification algorithms: Support Vector Machine (SVM), Random Forest (RF), and Convolutional Neural Network (CNN) in the context of medical image categorisation. Data photos of melanoma and eczema were utilised, with Visual Geometry Group 16 (VGG16) employed for feature extraction, followed by Principal Component Analysis (PCA) for dimensionality reduction. The findings indicate that Principal Component Analysis (PCA) enhances processing speed without significantly impacting accuracy or other performance metrics.

Mwanga, Emmanuel P., *et al* [19] Fourier transform infrared spectrometers, categorised into two distinct age classes. The dimensionality of the spectral data was diminished by unsupervised principal component analysis or t-distributed stochastic neighbour embedding, subsequently employed to train deep learning and conventional machine learning classifiers. The efficacy of transfer learning was assessed to enhance the transferability of models in predicting mosquito age classes from novel populations. Kabir, Md Faisal, Tianjie Chen, and Simone A. Ludwig [20] Examined the effects of various dimensionality reduction strategies on machine learning models employed for cancer prediction. Dimensionality reduction methods, including principal component analysis (PCA), kernel PCA, and autoencoders, were employed to diminish the dimensionality of the RNA sequencing data. Two machine learning classifiers, specifically a neural network and a support vector machine, were trained and evaluated utilising the original, dimensionally reduced, and cancer-relevant datasets. Multiple metrics, including accuracy, precision, recall, F-measure, receiver operating characteristic curve, and area under the curve, were employed to evaluate classifier performance.

Bharadiya, Jasmin Praful [21] Anomaly detection has emerged as an essential technology across various application domains, particularly in network security. This document outlines the categorisation difficulty of anomaly detection utilising machine learning algorithms on network data. The KDD99 dataset is utilised to explore and evaluate dimensionality reduction and classification algorithms for network intrusion detection systems (IDS). Principal Component Analysis for dimensionality reduction and Support Vector Machine for classification have been utilised in the application of network data, and the outcomes have been analysed. The results indicate a reduction in execution time for classification when the dimensionality of the input data is diminished. Additionally, the precision and recall metrics of the classification algorithm demonstrate that the SVM with PCA technique exhibits greater accuracy, evidenced by a decrease in misclassifications. The vast data in health research is highly intriguing, as data-driven studies can progress more rapidly than hypothesis-driven research, despite the increasing prevalence of large databases, which complicates interpretation. Principal Component Analysis (PCA) can be employed to reduce the dimensionality of certain datasets. improves interpretability while preserving the majority of the information. It accomplishes this by introducing novel variables that are independent of each other. Saheed, Yakub Kayode [22] Intended to offer machine learning-based methodologies for the classification of acute myeloid leukaemia and acute lymphoblastic leukaemia utilising microarray gene expression patterns. We utilised logistic regression, very randomised trees classifier, ridge classifier, AdaBoost classifier, linear discriminant analysis, random forest, gradient boosting, and k-nearest neighbours classifier. Principal component analysis was employed for dimensionality

**Chitra and Hari Ganesh**

reduction. We utilise two separate cross-validation methods in this work as they yield more precise skill evaluations than prior approaches. Six unique performance metrics for categorisation were employed to assess these methodologies.

Pandey, Rajiv, *et al* [23] offered an investigation employing Principal Component investigation (PCA), a prevalent dimensionality reduction technique, to address the dimensionality issue of data. We evaluate the importance of employing PCA to diminish the dimensions of the dataset utilised in an IoMT-enabled system, integrating our research with a previously established framework titled "Prenatal Healthcare System of Remote Mother and Foetal Surveillance via IoMT." The prenatal device enhances the probability of a safe and healthy delivery while mitigating pregnancy hazards. The survival of a foetus relies on regular health evaluations, which are both beneficial and crucial. The information utilised in the experiments comprises essential prenatal device parameters for a foetus, potentially assisting medical professionals with real-time health updates. We employ PCA to emphasise variance and reveal major patterns in the dataset to reliably predict outcomes. Saidulu, D., and R. Sasikala [24] developed a computationally efficient approach for dimensionality reduction and categorisation of healthcare-related data. The developed framework is capable of handling data with both discrete and continuous properties. The experimental assessment is conducted on the Parkinson's disease categorisation database (Sakar *et al.*, 2018). The statistical performance metrics employed include validation and test accuracy, precision, recall, F1-score, among others. The decreased dimensional data will confer computational complexity advantages when processed for modelling and constructing prediction systems. To demonstrate the optimality of the proposed framework, a comparative analysis is conducted with notable existing techniques.

Hussein, Safa Saad, *et al* [25] This work examined the efficacy of data dimensionality reduction approaches and machine learning algorithms in enhancing the detection accuracy of cardiac anomalies in WBAN sensors. Dimensionality reduction was executed utilising principal component analysis (PCA), independent component analysis (ICA), and spatial correlation techniques. Decision Tree and Multilayer Perceptron algorithms were employed for arrhythmia prediction, and their performances were compared. Numerical simulations and Python code analysis shown that the implementation of data reduction strategies markedly enhanced the reliability and efficacy of WBAN sensors in managing extensive datasets. Moreover, the implementation of PCA, ICA, and spatial correlation techniques significantly diminished the battery energy consumption of WBAN sensors, as well as the requirements for data storage, computational complexity, and processing duration. These realistic methods may enable healthcare practitioners to react proactively before patients face life-threatening diseases. Karthikeyani, S., S. Sasipriya, and M. Ramkumar [26] This study examined the amalgamation of dimensionality reduction techniques with diverse deep learning classifiers to enhance the precision and efficacy of cardiac illness classification. Uniform Manifold Approximation and Projection, in conjunction with Principal Component Analysis, is employed for dimensionality reduction, effectively capturing both global and local data structures. Classification is performed using deep learning classifiers, including convolutional neural networks, capsule networks, recurrent neural networks, graph neural networks, deep long short-term memory networks, and attention-based convolutional neural networks. The Adaptive Spiral Flying Sparrow Search algorithm optimises classifier parameters to boost accuracy. Performance is assessed using multiple criteria, including the area under the receiver operating characteristic curve, accuracy, F1-Score, precision, and recall.

Kherwa, Pooja, *et al* [27] Conducted an extensive literature review to furnish a comprehensive application-oriented understanding of diverse dimensionality reduction strategies, serving as a reference for selecting the appropriate dimensionality reduction approach to enhance performance across distinct applications. The authors conducted comprehensive tests on two distinct datasets to compare the efficacy of several linear and non-linear dimensionality reduction strategies. PCA, a linear dimensionality reduction method, surpassed all other strategies included in the studies. Indeed, nearly all linear dimensionality reduction methods far surpassed the non-linear strategies on both datasets, exhibiting a substantial margin of error. Dessureault, Jean-Sébastien, and Daniel Massicotte [28] provided a novel approach for selecting the optimal dimensionality reduction technique inside a supervised learning framework. It is also beneficial to eliminate or reconstruct features until the desired resolution is attained. The target

Chitra and Hari Ganesh

resolution may be user-defined or automatically determined by the algorithm. The method employs regression or classification, assesses the outcomes, and provides a diagnosis for the optimal dimensionality reduction technique inside this particular supervised learning framework. The primary algorithms employed are the random forest method, the principal component analysis technique, and the multilayer perceptron neural network algorithm. Six use cases are delineated, each grounded in a recognised approach for generating synthetic data. This research examines each option available in the process, seeking to elucidate the complexities surrounding the overall decision-making process of feature selection or extraction.

Mehrpooya, Adel, *et al* [29] employed matrix factorisation (MF) as a method for high-dimensional reduction in systems pharmacology. We have introduced three innovative feature selection methods based on the mathematical concept of a basis for features. We employed these strategies together with three additional MF methods to analyse eight distinct gene expression datasets in order to examine and compare their efficacy for feature selection. Our findings indicate that these techniques can effectively diminish feature spaces and identify predictive features related to phenotypic determination. The three proposed methodologies surpass the alternative methods employed and can isolate a 2-gene signature indicative of a response to tyrosine kinase inhibitor treatment in the Cancer Cell Line Encyclopaedia. Hernández-Carnerero, Àlvar, *et al* [30] Concentrated on forecasting antibiotic resistance in *Pseudomonas aeruginosa* nosocomial infections within the ICU, employing Long Short-Term Memory (LSTM) artificial neural networks as the predictive approach. The data analysed were sourced from the Electronic Health Records (EHR) of patients admitted to the University Hospital of Fuenlabrada between 2004 and 2019 and were structured as Multivariate Time Series. A data-driven dimensionality reduction method is developed by modifying three feature importance methodologies from the literature to the specific data and presenting an algorithm for determining the optimal number of features. This is accomplished through the sequential capabilities of LSTM, allowing for the consideration of the temporal dimension of features. Additionally, a collection of LSTMs is employed to mitigate performance volatility.

Challenges in the Healthcare Analytics

Despite their advantages, dimensionality reduction techniques in healthcare face several challenges:

Data Quality and Integrity: The effectiveness of dimensionality reduction methods is contingent on the quality of the input data. Incomplete, inconsistent, or noisy data can lead to misleading results, necessitating robust preprocessing steps to ensure data integrity.

Interpretability: While dimensionality reduction can simplify data, it may also complicate interpretability. For instance, the new features generated by PCA may not have clear clinical relevance, making it difficult for healthcare practitioners to derive actionable insights.

Choice of Technique: The choice of dimensionality reduction technique can significantly impact the outcomes of analyses. The effectiveness of different methods may vary based on the specific characteristics of the dataset and the goals of the analysis, necessitating careful evaluation and validation.

Computational Complexity: Some dimensionality reduction techniques, particularly those involving complex algorithms like deep learning-based autoencoders, can be computationally intensive. This complexity can pose challenges in real-time applications or when processing large datasets.

Future Research Direction

As the healthcare landscape continues to evolve, several future directions can enhance the application of dimensionality reduction techniques:

**Chitra and Hari Ganesh**

Integration of AI and Machine Learning: The incorporation of advanced machine learning and artificial intelligence techniques into dimensionality reduction processes can lead to improved performance and efficiency. Hybrid models that combine dimensionality reduction with predictive analytics are likely to yield significant insights.

Developing Robust Algorithms: Continued research is needed to develop robust algorithms that can handle diverse data types and maintain interpretability. Techniques that account for missing values and outliers will be particularly beneficial in clinical settings.

Focus on Interpretability and Explainability: As healthcare decisions increasingly rely on data-driven insights, ensuring that dimensionality reduction techniques produce interpretable and explainable results will be crucial. This focus will help bridge the gap between data science and clinical practice.

Interdisciplinary Collaboration: Collaboration between data scientists, healthcare professionals, and domain experts will be essential to effectively apply dimensionality reduction techniques in real-world scenarios. Such interdisciplinary efforts can enhance the development and validation of methods tailored to specific healthcare challenges.

ABSTRACT

Human Activity Recognition (HAR) is a fundamental part of many supportive applications among these Healthcare, Supervising System and Human – Computer Interaction. The very popular traditional method for HAR suffering from a large computational burden is high feature extraction complexity. In this paper, we present a deep learning-based ensemble model and as well as suggest an innovative Deer Hunting Optimization Algorithm (DHOA) to bolster human movements identification adversity. The DHOA tunes the hyperparameters of deep learning ensemble to improve its overall quality. Experiments show that DHOA ensemble model with outstanding results significantly surpasses other solutions in accuracy, precision, recall and F1-score performance. Therefore it is a strong candidate solution to real time HAR applications

Keywords: Deer Hunting Optimization Algorithm, Human Activity Recognition, Ensemble Deep Learning, Hyperparameter Optimization, Classification

Mahesh et al.,

INTRODUCTION

Human Activity Recognition (HAR) is an important area of research in healthcare, smart environments and surveillance systems [1]. Accurate recognition and classification human activities using sensors have numerous implications such as monitoring elderly patients in health care environment, personalized services on smart phones or wearable devices. Characterizing the evolution of HAR methods, there has been a shift from classical machine learning (ML) approaches to more sophisticated deep-learning models [2]. Manual feature extraction is one of the traditional ways to approach such problems, but it has high dimensionality and variety in data hence error-prone plus time-consuming. While well-performing on smaller and simpler datasets, the accuracy and generalization of these methods may reduce when applied to larger scale or more challenging datasets. Deep learning models, especially Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), have been well suited for HAR as they are capable of automatically capturing features from raw sensor data. Convolutional Neural Networks are good for extracting patterns from spatial features, on the other hand Recurrent neural networks (RNNs), including Long Short-Term Memory (LSTM) units capturing temporal dependencies in sequences. These models are not without their challenges, though. One of the more major issues is extensive hyperparameter tuning, that can be computationally expensive and time consuming. These challenges have led to the operation of optimization algorithms which can automate hyperparameter tuning. Of the approaches, meta-heuristic algorithms which are inspired in practically all cases by natural phenomena have been developed flatteringly to find near-optimal solutions of problems with complex search spaces. Nevertheless, the current algorithms (e.g., Particle Swarm Optimization (PSO) and Genetic Algorithms (GA)) usually converge too early or consume many computational resources [3]. In this research, a new Deer Hunting Optimization Algorithm (DHOA) is proposed to solve optimization problems based on the foraging and caginess hunting behaviors of deer in nature. Considering this work, we introduce the DHOA, which is an ensemble model optimization framework that aims to exploit the strengths of both CNNs and sequence-based models (RNN/LSTM) to improve HAR accuracy and efficiency. The ensemble method is used to merge these models that are strongly complementary with each other, resulting in higher accuracy in recognition and classification of human activities [4]. The goal of the proposed DHOA-ensemble model is to address these limitations and offer a versatile, high-performance method for HAR that combines good performance with computational efficiency [5]. Contributions This paper (1) outlines the derivation of DHOA; (2) formulates its combination with our other devised ensemble deep learning model; and then, examines the effectiveness in classifying activities simulated from benchmark HAR datasets. We verify through comprehensive experiments that the DHOA-ensemble model can extract more effective discriminative feature characteristics of human activities than traditional methods, and it could be a promising method for real-time human activity recognition.

LITERATURE REVIEW

Over the last two decades, Human Activity Recognition (HAR) has progressed considerably from previously simple handcrafted solutions to relying on sensor data and modern machine learning or deep neural network techniques [6]. In the second-generation literature review, we summarize and discuss a few fundamental optimization techniques of machine learning proposed in HAR research and ensemble models that have gradually become more important methods.

HAR based on Traditional Machine Learning

The initial work in HAR predominantly used traditional machine learning algorithms like SVM, k-NNs, and decision trees [7]. These approaches were mainly based on feature extraction, manually extracted from accelerometer sensor data and classified with the algorithm selected [7]. For example, it adopted SVMs for HAR from accelerometer and gyroscope data, getting good accuracy but using intensive feature engineering. Nevertheless, the performance of these traditional methods was often restricted by their reliance on handcrafted features which may not be able to

**Mahesh et al.,**

fully extract human activity complexities [8]. They also suffered from the curse of dimensionality, meaning they did not scale or generalize very well.

Deep Learning Models for HAR

Deep learning has redefined the status of HAR to some degree by allowing models to learn deep features from raw sensor data. Convolutional Neural Networks (CNNs) were a big breakthrough in capturing spatial hierarchies in data [9]. For instance, Yang et al. Further developments include the application of CNNs to HAR which resulted in accuracy that significantly surpassed traditional machine learning methods. The same goes for the development of algorithms such as Recurrent Neural Networks (RNNs) and Long Short-Term Memory (LSTM) networks which were designed to record relationships oriented temporally in sequential data thereby improving recognition activities across time sequences. Even with all these advancements, introduction of deep learning models was no cakewalk as it came along many issues and the foremost reason is hyperparameter tuning [10]. The performance of these models is very sensitive to the hyper-parameters, such as learning rates, batch sizes and network architectures used with them. Given that manual tuning is a tedious and often suboptimal process, several automated optimization techniques have been introduced to aid in the design of cheaper filters.

Competitive HAR Optimization Algorithms

Different optimization algorithms have been suggested to address the issues of hyperparameter tuning in modern day deep learning models. The two widely utilized metaheuristic techniques include Genetic Algorithm (GA) and Particle Swarm Optimization (PSO) [11]. The idea behind this process is that of natural selection and it has been employed in HAR to optimize the parameters of neural network, thereby making model efficient for better accuracy. Party swarm optimization based on birds flocking social behaviors has also been used to optimize deep learning models, but the algorithm is susceptible to premature convergence and falling into local optimum [12]. In the past decade, Differential Evolution (DE), Grey Wolf Optimizer (GWO) etc. have been proposed which are claimed to better explore search space and not suffer from all limitation of GA or PSO. Nevertheless, such algorithms can be computationally demanding and do not always converge to the global optimal solution.

Ensemble Learning in HAR

Because ensemble learning, combining multiple models to increase prediction accuracy, has become popular in HAR. Bagging, boosting and stacking are such techniques to combine the power of different models [13]. For example, it utilized a CNN followed by an LSTM as well as ensemble of the model for human activity recognition (HAR). This is because the ensemble methods can be more robust in making predictions as each model may catch a different space of data thus an overall improves [14]. However, ensemble models also bring a higher level of complexity mainly in the context of model selection and hyperparameter tuning. The complexity itself entails that very complex optimization is necessary to make an ensemble model not only accurate but also computationally economical.

Deer Hunting Optimization Algorithm (DHOA)

Traditional optimization algorithms have limitations, and in response to these shortcomings new research took abstract ideas from nature, for example, the birds flocking behavior. This work presents a novel optimization method based on the recent Deer Hunting Optimization Algorithm (DHOA), inspired by behavior of hunting deer. While still in its infancy, initial results suggest DHOA has balance properties that are beneficial for exploration and exploitation trade off which makes it an attractive candidate to optimize sophisticated models like deep learning ensembles [15]. The author had previously employed the DHOA in feature selection and parameter optimization where its performance was quite promising. Nonetheless, its use in HAR and deep learning models have not been thoroughly explored leading to a novel line of research for potential enhancement in model quality.

Mahesh et al.,

METHODOLOGY

This section explains the methodology used to implement and test out newly proposed Deer Hunting Optimization Algorithm (DHOA) based ensemble deep learning model for Human Activity Recognition (HAR) [16]. We describe our methodology, which encompasses the construction and deployment of a DHOA, ensemble deep learning model architecture, data pre-processing and experimental setup for evaluating the performance of the resulting models.

Deer Hunting Optimization Algorithm (DHOA)

Deer Hunting Optimization Algorithm (DHOA): DHO is a new metaheuristic that takes the hunting behavior of deer as it features adaptability, accuracy and collaboration. They used the DHOA approach to tune hyperparameters of deep learning algorithms for accurately classifying human activities. The steps of the DHOA process are as follows [17]:

Population Initialization

Optimization is initiated through the creation and initialization of a population of candidate solutions, each representing hyperparameters for deep learning models. The population size depends on the complexity of a problem and computational resources.

Fitness Evaluation

The fitness of a candidate solution is the classification accuracy given a set of hyperparameters, how accurate can we classify using this specific HAR model. Depending on the optimization goals, it may also include other performance metrics like precision, recall or computational efficiency.

Hunting Strategy

The nucleus of the DHOA can be found in its hunting style which closely follows deer behavior. Basically, there are two steps in this strategy [18]: Exploration Phase: At the beginning of its lifetime, an optimization algorithm searches a vast solution space. This is the wildlife equivalent of a deer scopes its surrounds where it hopes to discover half-starved prey. The algorithm adds randomness to the hyperparameters and sees other areas of search space. Exploitation Phase: As the algorithm identifies such promising regions in search space, it transitions to exploitation mode and hones-in on these Areas for hyper Param tuning. Here, the deer is behaving analogous to a cat stalking and preying. It helps the algorithm reduce variations in hyperparameters and focus more on fine-tuning to attain better results.

Selection and Update

After every iteration, a solution's fitness is evaluated and only the best solutions are selected to become parents to generate (or spawn) offsprings of generation [19]. The population is updated by merging successful solutions from all the generations, adding a small random perturbation to make these points unique and avoid trapping into locally optimal spots.

Termination Criteria

The DHOA process repeats until a predetermined termination criterion is satisfied. It could be some maximum number of iterations, a convergence threshold where the improvement in fitness hits 0 or close to it), etc.

Ensemble Deep Learning Model

The ensemble model consists of several deep learning models integrated to exploit their complementary virtues; this adds an edge for our approach towards HAR.

**Mahesh et al.,****Model Selection**

It is a combination of Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs) and Long Short-Term Memory or LSTM networks. A different model type is chosen based upon the way it highlights a certain aspect of the data:

CNNs: Great at capturing spatial features from sensor data

RNNs: Able to model sequential dependencies in time-series data

LSTM Networks: LSTM is designed to retain long-term dependencies and process sequential data well.

Model Training

For each HAR task synthesized by the DHOA, we train an ensemble of models independently on hyperparameters optimized for that constant [20]. This process undergoes a few epochs and the models from them recognize/learn patterns, features which are related to various forms of human activity.

Ensemble Strategy

Ensemble: The output of the individual models is combined using an ensemble strategy. Common techniques include:

Voting: Every model predicts on the activity predicted and whichever has majority votes is given as a final prediction. This makes sure that their strengths are combined, and the overall performance is improved.

Dataset and Preprocessing

Performance of the model is assessed on hand-crafted datasets like UCI HAR dataset, which possesses sensor data collected from smartphone-based accelerators and gyroscopes [21].

Data Collection

It is a dataset in which human-for example, walking-sitting stand-lying etc. actions are recorded. For each activity, you will see time-series data for different noisy and realistic sensors.

Data Preprocessing

Data Preprocessing: Data preprocessing is an important step in preparing the dataset for model training. Following are the steps to be done [22]:

Normalization: Sensor data is normalized to common scales for the models are provided with identical input.

Noise Filtering: This is done in low pass filtering to help extract softer signs from data on which noise may be causing your model's efficacy dwindling.

Segmentation: Continuous times-series data broken down into smaller windows, each window representing a fixed period. These are divided into segments accordingly and given as input to the models corresponding to their activity.

Experimental Setup & Evaluation Metrics

Different evaluation metrics are used to evaluate the performance of our proposed DHOA-ensemble model [23].

Experimental Setup

Experiments are performed on a high-performance computing platform using GPU acceleration to train deep learning models. Except that the dataset also gets divided into training, validation and test sets for evaluating generalization.

Evaluation Metrics

Then these metrics are used to evaluate model performance,

Precision: The overall percentage of correctly classified activities.

Precision: True positive to total number of predicted positives

Recall: The fraction of total actual positive instances that the model predicts are positive.

Mahesh et al.,

F1-Score: F-Measure of a test is an F-score the weighted harmonic mean between precision and recall.

Computational Complexity: The time it takes to train and inference the models, a crucial factor for real-time applications.

Comparative Analysis

To verify the efficiency of DHOA-ensemble model, a comparative analysis is accomplished with other state-of-the-art HAR models (single deep learning or those optimized by traditional algorithms like GA and PSO).

RESULTS

In this section, experimental results of the proposed Deer Hunting Optimization Algorithm (DHOA) ensemble deep learning model for Human Activity Recognition (HAR) [24]. Results are analyzed using different evaluation matrices like accuracy, precision, recall and f1score and computational time is measured. Moreover, we compare the DHOA-ensemble model with other state-of-the-art algorithms.

Model Performance

Evaluation on UCI HAR dataset We have evaluated the performance of our DHOA-ensemble model using a widely used benchmark in Human Activity Recognition (HAR) research, i.e., UCI HAR -dataset [25]. The dataset was divided into training, validation and test sets with a model being trained on the train set then validated using valid before a final un-seen evaluation by passing in our test data.

Accuracy

The DHOA-ensemble model yielded 96.7% of test accuracy integrally, which means it could recognize correctly the types in majority as human activities This high-level of accuracy suggests that the ensemble model, with hyperparameter tuning can effectively learn spatial and temporal features from sensor data [26].

Precision and Recall

We then compute precision and recall metrics for each activity class to evaluate the model by how well it can identify positive instances, without false positives or negatives [27].

Precision: The average precision for all classes was 95.8%, indicating that the likely hood of false alarm prediction is low

Recall: The mean recall was 96.2% indicating that the model correctly identified almost all true positive instances of activities, and the high precision and recall values among the various classes demonstrate that our framework can effectively classify different human activities.

F1-Score

F1-score representing the balance between precision and recall was high on all activity classes with an average F1 score of 96.0% across model experiments, Fig(cursor over) This careful balance of performance should indicate that the trade-off between precision and recall is handled properly by DHOA-ensemble model, ultimately providing a consistent classification capability.

Computational Efficiency

The major goals of the DHOA are to improve computational efficiency and this code implements an ensemble model in deep learning [28]. The authors measured and compared training and inference time with other optimization algorithms.

Training Time: The DHOA-ensemble model showed a 20% lower training time compared to models tuned with Genetic Algorithms (GA) and Particle Swarm Optimization (PSO). This division of responsibility leads to faster learning due to the balance between exploration and exploitation, resulting in reduced training time [29].

**Mahesh et al.,**

Inference Time: The time it took to infer in between the input and eventually getting an output for DHOA-ensemble model was around seconds which suggests that this is a real-time application gesture recognition. This model can provide a high level of accuracy with lower computational load which can act as an alternative for resource constraint environments [30].

Comparative Analysis

To establish the performance of DHOA-ensemble model, a comparative analysis was performed based on various baseline models including single deep learning (CNN, RNN and LSTM) as well as ensemble optimized with swarm optimization algorithms such GA & PSO.

Accuracy Comparison

Single Models: The accuracy of the single models varied between 90.5% (CNN) to 93.2% (LSTM). Despite these models doing well, they did not have the same level of accuracy as DHOA-ensemble model.

Ensemble Models with GA/PSO: The ensemble models optimized using GA and PSO had 94.3% and 94.8%, respectively, accuracy (micro-level F1 Scores). Nevertheless, the DHOA-ensemble model still outperformed them with an accuracy of 96.7%.

Result of Precision

When compared to all other models, the precision, recall and F1-scores were constantly better for the DHOA-ensemble model. While each model and GA-PSO-infused optimization improved upon individual models, neither alone could out-compete the balanced performance of DHOA ensemble across all metrics.

Computational Efficiency Comparisons

Training and Inference Times: The DHOA ensemble model had lower requirements for training time in contrast to both the GA and PSO optimized models, thus suggesting better computational efficiency. It also has comparable or slightly better inference time as the other models, so it could be a good choice for real-time HAR tasks.

Generalization Capability

Results also indicated that the generalization capacity of DHOA-ensemble models was generally better than those of other model types and toward different test sets/a activity classes. The guiding principle of approximate inference using Deep HO are [31]: To use some type of less-effective proposal distribution or otherwise intractable variational approximation, with low complexity encoding the structure that makes it easy for successful sampling. Train while making maintaining tractability even under unstable contortions. This seems a very promising trend which suggests higher robustness possible from the DHOA-ensemble model due to its weaker dependence on exact data distributions necessary if one wishes usage within real-world applications. The DHOA-ensemble model performance was further examined for individual activity classes, e.g. walking, sitting wearing a rucksack standing lying flat or worn on wrist Walking (97.5% precision, 98% recall): This model performed well in recognizing dynamic activities because the intensity of this type of activity is higher than that for other types and moving sequences are continuous without a big gap between two motions like biking or up/down the stairs. In the first activity, we found greater than 95% precision and recall across these exhaustive activities (Sitting/standing: static) which is an even more difficult task between similar classes. Lying Down: The model successfully classified lying down activity with a precision of 96.8% and recall of 97.2%. These findings demonstrate the ability of our approach to classify dynamic and static human activities with high accuracy.

DISCUSSION

This ensemble deep learning model has achieved great improvements on Human Activity Recognition (HAR) task in the research results from proposed Deer Hunting Optimization Algorithm (DHOA) [32]. We also consider the

**Mahesh et al.,**

implications of these results and compare them to similar literature, as well as discuss strengths, limitations and areas for further research.

Implications of the Results

The high accuracy, precision, recall and F1-score gained by the DHOA-ensemble also prove its capability to accurately detect human activities summaries. The performance evaluation of the model on real-life datasets indicates that it performs significantly better than single models and those optimized using standard algorithms (Genetic Algorithms [GA] or Particle Swarm Optimization [PSO]) thus, amply demonstrating the benefits from combining ensemble learning with a new optimization method. One particularly notable feature of the DHOA is how rapidly it transits through hyperparameter space [33]. By modeling the strategic hunting behavior of deer, this algorithm balances exploration and exploitation well to find near-optimal hyperparameter configuration with minimal computation power. This balance is what plays into large and complex deep learning models, where having less than the optimal hyperparameters can lead to hilariously inaccurate results—or astronomically long training times. A potential practical importance of the DHOA-ensemble model is its significantly lesser training and inference time. The task of gesture recognition is timing sensitive and computationally efficient processing needs to be considered for real-time HAR applications, such as wearables or smart environments, health monitoring systems. With the ability to deploy a model that not only does well but also works with scarce computational resources, one could look forward towards applications deployment on the ground.

Comparison To Previous Studies

As you can see the DHOA-ensemble model does take and improves on many existing HAR research-based models along with optimization algorithms. Although traditional machine learning models work well in some scenarios, often they had glitches coping with the high dimensionality (600 features) & complexity of our sensor data. While moving to deep learning models dramatically improved the situation, tuning hyperparameters was still a major bottleneck. It is known from previous studies that optimization algorithms as GA and PSO manage to help in the obtaining of hyperparameters for deep learning models but performing an automatized search process [34]. But these algorithms are prone to problems like prematurity and computational overheads. In contrast to previous slicing methods, the DHOA shows better capability in expanding search as fellrunning sample is selected regarding whole population space so that exploring more efficiently and achieves improved performance with faster convergence.

This ensemble approach even greatly boosts its robustness, The DHOA-ensemble model combines CNN, RNN and LSTM to capture spatial features from sensor data which dealt with similar approach limitation using a single model type. It demonstrates the superior performance of our ensemble strategy, which is in comparison with various existing state-of-the-art models, and it surely shows that this DHOA-based optimization significantly improves the outcome reliability as well interpretability among all HAR-models.

DHOA-Ensemble Model

Key strengths of DHOA-ensemble model are summarized below:

High Accuracy and Robustness: The model consistently achieves high accuracy across different classes of activities, indicating its capability to work well for both dynamic as well as static activities.

Real-time Operation: The speed factor is an important constriction in many HAR deployments, so the decreased time to train and apply our model makes it viable for real-time applications.

State-of-the-Art Hyperparameter Optimization: By having strides in balancing exploration and exploitation, the DHOA is also able to outperform other hyper-parameter configurations resulting in a more performant model.

Versatile: The ensemble-based architecture of the model let it capitalize over advantages from various deep learning models which makes it versatile to be used for any HAR task.

Limitations

Complexity of Ensemble Models: Ensemble models, while they yield better results over single model counterparts, are complex due to the additional complexity involved in selecting and integrating various models. Merging multiple

**Mahesh et al.,**

models/hyperparameters can be quite difficult, too much of a burden to process due to running more computationally than single models.

Generalization Performance: While the model did a great job at UCI infernal device dataset, it remains to be seen if that success will span different far more diverse datasets. The variations in sensor types, data collection procedures and activity classes from one dataset to another might negatively affect the model's performance.

Parameter Sensitivity: although DHOA helps hyperparameter optimization, it brings its parameters (examples include the population size and exploration-exploitation balance), making this too a parameter sensitive algorithm. If not, then the performance obtained by mistuning these parameters could be worse than what is expected.

Future Directions

Recommendations for future research could also be developed based on the results of this study:

Testing on Diverse Datasets: Future research could test the generalization capabilities of our model over a broader set of datasets, with additional complex activities or different sensor types in various environments for HAR.

Integration with Other Optimization Algorithms: The integration of DHOA in combination with other optimization techniques like Bayesian-optimization or reinforcement-learning may boost the performance even more and mitigating parametric sensitivity

Real-World Use: By deploying the DHOA-ensemble model in real-world HAR contexts (e.g., wearable devices and smart homes), insights can be gained on its viability, limitations, etc.

Generalization to Other Domains: Finally, while the DHOA was developed for HAR it is not domain specific and will be adaptable to other domains (i.e., image classification, IR) given appropriate re-training.

COMPARISON STUDY

The comparative study section shows how the performance of proposed ensemble deep learning model, that is Deer Hunting Optimization Algorithm based (DHOA), used for Human Activity Recognition (HAR) compared to other models and optimization techniques. We begin with an important comparison that elucidates both (1) the strengths and weaknesses of DHOA-ensemble model and (2) where it falls within the larger continuum of HAR research.

Baseline Models

General Comparison with Baselines: In general, the DHOA-ensemble model is compared to several baselines baseline models both traditional machine learning and deep learning. The baselines we selected are as follows:

Support Vector Machines (SVM): A widely known classical machine learning model; it has been heavily employed in HAR applications. SVMs have historically been found to be effective for binary classification tasks yet are not always ideal solutions given the complexity and dimensionality of HAR data.

Random Forest (RF): It is an ensemble learning method that constructs multiple decision trees during training and outputs the mode of the classes for classification type tasks. RF is an ensemble method which uses many decision trees, and because of that it are more robust model (less a overfitting) then individual decision tree but still may failed to learn the temporal dependences in HAR data.

Convolutional Neural Networks (CNN): A special kind of deep learning model that is primarily useful for extracting spatial features from data such as images, hence common in image recognition tasks. We then apply Convolutional Neural Networks (CNNs) in human activity recognition where CNN performs very well when there is spatial patterns e.g. accelerometer data;

Recurrent Neural Networks (RNN): A deep learning model for sequence prediction that treats a tensor as a multi-dimensional array is well informed about the time component. Notwithstanding, RNNs can run into vanishing gradient issues that degrade their efficiency when sequences are large.

Long Short-Term Memory Networks (LSTM): A type of RNN that is capable of learning long-term dependencies in data sequences. In turn, LSTMs are never the worst choice when it comes to HAR tasks that imply recognition of activities over long sequences.

Mahesh et al.,

Optimization Algorithms

The work also provides a comparison of the DHOA-ensemble model with several other optimization algorithms for deep learning models fine-tuning, including:

Genetic Algorithms (GA) - Another famous sort of evolutionary algorithm that simulates the process of natural selection. While GAs is successful in optimizing deep learning model hyperparameters, they tend to be computationally intensive and often converge too quickly on poor solutions.

Particle Swarm Optimization (PSO): An optimization technique based upon the social behaviour of birds flocking. While PSO is one of the most straightforward and effective optimization algorithms when it comes to continuous problems, dealing with a search space as complex (and high-dimensional) as those presented by human-activity recognition can be highly challenging.

Comparison of Accuracy

Compared to the baseline models and GA or PSO optimized ones: The SVM model the light blue bars among mean cross-validation was permuted to show testing-HAR and were the Seventh Column containing 100 random observations ACC accuracy of 28.5049%. For simple classification problems, SVMs work well but not as effective for HAR data due to its complex nature of spatial and temporal patterns.

Random Forest: The one with RF model was somewhat better, it gave 87.8% accuracy RF is an ensemble method which makes it more robust than SVM in dealing with the variety of data but less effective in exploiting known temporal dependencies.

CNN: The model for the spatial features generated an accuracy of 90.5%. Although, these results demonstrate the power of this method to learn out-of-sample patterns from sensor data in general but not sufficient for HAR due to lack of temporal analysis.

RNN: The RNN, which is the leading model, designed mainly for sequence data, outperformed CNN with 91.8% accuracy as shown in Table just above Figure. But the vanishing gradient problem could still be a concern for longer sequences.

LSTM: The model performed better than the CNN and RNN models, with accuracy of 93.2%, reflecting its long-term memory in handling sequence dependent input data.

GA-Optimized Models: The GA-optimized ensemble model was able to achieve an accuracy of 94.3%, showcasing the potential benefit that evolutionary optimization brings in improving deep learning results.

PSO Optimized Models: The model optimized via Particle Swarm Optimization reported a slightly better accuracy of 94.8%, by taking advantage of the swarm intelligence approach to scan over hyperparameter space for neighborhood region discovery process.

DHOA Ensemble Model: the best performed model is a ranked ensemble on all features (96.7% accuracy) which demonstrates not only an improvement in searching of possible hyperparameters spaces by using DHOA, but also more valuable strengths from this approach enabling to make good use of the advantages that come with building ensembles for better prediction powers over just single scores from similar models.

Precision, Recall and F1-Score Comparison

These are essential metrics for evaluating the performance of classification algorithms, especially in an imbalanced data set:

SVM: Precision (84.0%), recall (83.5%) and F1-score also of the SVM, this is more enough low to deal with complexity inherent in HAR data [34]

SVM -Precision=83.6%, Recall =82.5% and F1-score. = 81.2%- Random Forest: Similar to SVM-f Precision, Recall, And F1 score are about 86%.

CNN: The CNN resulted in high precision, recall and an F1-score of 89.6%, indicating it can detect important patterns within the data.

RNN: The RNN achieves 91.0% precision, 91.2% recall and an F1-score of 91.1%, demonstrating its ability to capture temporal dependencies but still with some difficulties on complex sequences in the application domain.

Mahesh et al.,

LSTM – This model achieved precision (92.5%), recall (92.8%) and F1-score(92.6%), it clearly performed better due to the long-term dependencies to learned during training [STO]

GA Optimized Models

Precision (93.5%) recall (93.8%), F1-score, show how much it is beneficial to have GA in tuning the model performance:

PSO-Optimized Models: The minimal improvement in this part shows how PSO is of a better use to fine-tune the final model.

DHOA-Ensemble Model: The DHOA ensemble model once again performed very well in terms of precision (95.8%), recall (96.2%) and F1-score (96.0%). So, it is one step ahead by confirming strong compatibility across all metrics compared to ordinary classifiers models far off against the state-of-the-art performers used for comparison analysis [22–24].

Computational Cost Comparison

Efficient computation of training and inference time for our HAR models is crucial so that they can be adapted to a real-world scenario.

SVM and Random Forest: Both are computationally efficient over the training, inference with good working order but less accurately to fall in terms of finding users model on a complex task such as human activity recognition.

CNN, RNN, LSTM: These are deep learning Model which require higher computational resources for training and out of these three LSTMs have more because they are complex.

GA-Optimized Models: Using GA will lead to better model performance, but it is computationally expensive since the process of optimization becomes an iterative one, hence more types required in training.

PSO-Optimized Models: PSO does give a marginal increase in computational efficiency as compared to GA but still needs significant resources for training of models.

DHOA-Ensemble Model: The new model of this paper, the DHOA-ensemble model gives better trade-off between computational cost and performance and our results confirm that it shrinks training time by around 20% against GA and PSO counterparts without losing much in accuracy.

Generalization Capability

The ability of a model to generalize refers to how well the trained data performs on unseen data, i.e., it shows its robustness and reliability:

SVM and Random Forest: Since they require handcrafted features, these models have a broader generalization error.

CNN, RNNs and LSTMs: Deep learning models like LSTMs generalize well across different test sets but can overfit if not properly regularized.

GA & PSO-optimized Models: While GA and PSO also significantly increase model generalization by improving the hyperparameter settings, they may be overfit to training data. DHOA-Ensemble Model DHOA-ensemble model has powerful generalization where outperforms other models on diversity test sets and alleviates the risk of over-fitting due to its balanced optimization.

Summary of Comparative Study

Comparison with other Traditional models and Optimization techniques, the DHOA-ensemble deep learning model provides strong benefits. The DHOA-ensemble model showed well-balanced performance in terms of accuracy, compared to other models and outperformed all the base classifiers suggesting its ability at learning more intricate patterns from HAR data.

Balanced Performance Metrics: They also reported balanced results (precision, recall and F1-scores) achieved by the DHOA-ensemble model over number of activity classes.

Computational Efficiency: The model manages to strike a balance between computational efficiency and performance that makes it viable for real-time applications.

Robust Generalization: We demonstrated that the DHOA-en ensemble model generalizes well on unseen data, mitigating overfitting risk which makes experiments ideal for practical deployment.

Mahesh et al.,

CONCLUSION

Here, a novel DHOA-ensemble deep learning model for human activity recognition and classification is proposed in present paper. The DHOA allows the ensemble model to optimally adjust its hyperparameters based on entropy deindex updating and as a result, it achieves better performance than existing algorithms. By combining a set of deep learning architectures, the model is able to learn many distinct features which increase its accuracy and robustness. This model is very expensive computationally, however its advantages in precision and reliability justify the use of this approach for HAR. We look to future work in further accelerating the DHOA as well as applications of it outside generative modeling.

ABSTRACT

Feature selection is a critical step in the preprocessing of clinical datasets, where the goal is to identify the most relevant features that contribute to accurate and efficient predictive modeling. This study proposes a novel hybrid feature selection method that combines Information Gain (IG), ReliefF algorithm, and Whale Optimization Algorithm (WOA) to enhance the performance of clinical data analysis. The proposed method begins with the application of IG and ReliefF, two well-established filter-based techniques, to evaluate and rank features based on their relevance and redundancy. Information Gain measures the reduction in entropy, thus quantifying the importance of each feature in predicting the target variable, while ReliefF assesses the quality of features by considering their ability to distinguish between instances that are near each other. Subsequently, the Whale Optimization Algorithm, a nature-inspired metaheuristic technique, is employed to perform a wrapper-based search that optimizes the subset of features. WOA mimics the social behavior of humpback whales and their unique hunting mechanism known as bubble-net feeding, providing a robust exploration and exploitation balance in the search space. By integrating IG and ReliefF for preliminary filtering and WOA for optimal subset selection, the proposed method aims to reduce the dimensionality of clinical datasets effectively while preserving or improving the accuracy of predictive models.

Keywords: Feature Selection, Filter based Feature Selection, Wrapper Approach, Optimization Technique, Clinical dataset

INTRODUCTION

Healthcare is a fundamental pillar of societal well-being, playing a crucial role in maintaining and improving the health of individuals and communities. The significance of healthcare extends beyond the direct treatment of illness and injury; it encompasses preventive care, health education, and the promotion of healthy lifestyles, all of which contribute to a higher quality of life and increased life expectancy [1] [2]. In recent years, the importance of effective healthcare systems has become even more pronounced, highlighted by global challenges such as the COVID-19 pandemic, aging populations, and the rise of chronic diseases. Effective healthcare systems are essential for several reasons. Firstly, they provide critical services that ensure early detection and timely treatment of diseases, thereby reducing mortality and morbidity rates. Preventive measures such as vaccinations, screenings, and public health campaigns play a vital role in mitigating the spread of infectious diseases and managing chronic conditions [3]. Additionally, comprehensive healthcare services support mental health, maternal and child health, and geriatric care, addressing the diverse needs of the population at different life stages. Secondly, healthcare has a profound impact on economic stability and development. Healthy populations are more productive, with fewer workdays lost to illness and disability, leading to greater economic output and reduced healthcare costs. Investment in healthcare infrastructure and services also generates employment opportunities and drives innovation in medical research and technology [4]. Furthermore, healthcare is integral to social equity and justice. Access to quality healthcare is a fundamental human right, and disparities in healthcare access and outcomes are often reflective of broader social inequalities. Ensuring that all individuals, regardless of socioeconomic status, geographic location, or cultural background, have access to essential health services is crucial for building inclusive and equitable societies [5]. The intersection of healthcare with technology has ushered in a new era of possibilities for improving patient outcomes and operational efficiency. Advances in medical technologies, digital health solutions, and data analytics have revolutionized the way healthcare is delivered and managed. In particular, the utilization of clinical datasets has the potential to transform healthcare by enabling personalized medicine, improving diagnostic accuracy, and optimizing treatment plans [6]. However, the complexity and high dimensionality of clinical data necessitate sophisticated analytical methods to extract meaningful insights and support decision-making processes. In this context, feature selection methods become indispensable tools for handling large clinical datasets. By identifying the most relevant and informative features, these methods enhance the interpretability and predictive performance of clinical models, facilitating better patient care and resource allocation [7]. This study proposes a novel feature selection approach that leverages Information Gain, ReliefF algorithm, and Whale Optimization Algorithm, aiming to address the challenges associated with clinical data analysis and contribute to the advancement of healthcare research and practice.

IMPORTANCE OF FEATURE SELECTION TECHNIQUES

Feature selection is a fundamental process in the preparation of data for machine learning and data mining, particularly for high-dimensional datasets such as those encountered in clinical research [8]. This process involves identifying and selecting the most relevant features from a dataset, which can significantly enhance the performance and efficiency of predictive models [9]. Here are the key reasons why feature selection techniques are important:

- **Dimensionality Reduction:** Reduces the number of features, simplifying models and making them more computationally efficient. Decreases training time and resource requirements, which is crucial when dealing with large-scale datasets [10].
- **Improved Model Performance:** Enhances the predictive power of models by focusing on the most informative features. Eliminates irrelevant or redundant features that introduce noise, thereby improving model accuracy and robustness.
- **Enhanced Interpretability:** Produces simpler models that are easier to understand and interpret. Facilitates clinical decision-making by providing insights into the most important factors influencing predictions.
- **Reduction of Overfitting:** Helps in preventing overfitting by removing features that contribute to noise rather than the actual signal. Ensures that models generalize better to new, unseen data.
- **Cost and Resource Efficiency:** Reduces the cost and effort associated with data collection and processing. Is particularly beneficial in clinical settings where some features may be expensive or difficult to measure.

LITERATURE REVIEW

Vommi, Amukta Malyada, and Tirumala Krishna Battula [11] proposed a hybrid filter-wrapper approach for feature selection. An ensemble of filter methods, ReliefF and Fuzzy Entropy (RFE) is developed, and the union of top-n features from each method are considered. The Equilibrium Optimizer (EO) technique is combined with Opposition Based Learning (OBL), Cauchy Mutation operator and a novel search strategy to enhance its capabilities. The OBL strategy improves the diversity of the population in the search space. The Cauchy Mutation operator enhances its ability to evade the local optima during the search, and the novel search strategy improves the exploration capability of the algorithm. This enhanced form of EO is integrated with eight time-varying S and V-shaped transfer functions to convert the solutions into binary form, Binary Enhanced Equilibrium Optimizer (BEE). The features from the ensemble are given as input to the Binary Enhanced Equilibrium Optimizer to extract the essential features. Fuzzy KNN based on Bonferroni mean is used as the learning algorithm. Atteia, Ghada, et al [12] propose a new algorithm for feature selection based on a hybrid between powerful and recently emerged optimizers, namely, guided whale and dipper throated optimizers. The proposed algorithm is evaluated using four publicly available breast cancer datasets. The evaluation results show the effectiveness of the proposed approach from the accuracy and speed perspectives. To prove the superiority of the proposed algorithm, a set of competing feature selection algorithms were incorporated into the conducted experiments. In addition, a group of statistical analysis experiments was conducted to emphasize the superiority and stability of the proposed algorithm.

Mostafa, Reham R., et al [13] introduced the Adaptive Hybrid-Mutated Differential Evolution (A-HMDE) method, targeting the inherent drawbacks of the Differential Evolution (DE) algorithm. The A-HMDE incorporates four distinct strategies. Firstly, it integrates the mechanics of the Spider Wasp Optimization (SWO) algorithm into DE's mutation strategies, yielding enhanced performance marked by high accuracy and swift convergence towards global optima. Secondly, adaptive mechanisms are applied to key DE parameters, amplifying the efficiency of the search process. Thirdly, an adaptive mutation operator ensures a harmonious balance between global exploration and local exploitation during optimization. Lastly, the concept of Enhanced Solution Quality (ESQ), rooted in the RUN algorithm, guides DE to elude local optima, thus heightening the accuracy of obtained solutions. Masood, Fawad, et al [14] used three feature selection filter algorithms (FSFAs): relief filter, step disc filter, and Fisher filter algorithm and 15 classifiers using a free data mining Tanagra software having UCIMachine Learning Repository.

This process is done on a medical dataset with 20 attributes and 155 instances. As a result, the error rate is obtained in terms of accuracy, which shows the performance of algorithms regarding patient survival. This work also shows the independent comparison of FSFAs with classification algorithms using continuous values and the FSFA without using classification algorithms. This paper shows that the obtained result of the classification algorithm gives promising results in terms of error rate and accuracy. Vommi, Amukta Malyada, and Tirumala Krishna Battula [15] A novel hybrid wrapper-based feature selection method is proposed to tackle these issues effectively. In order to improve the exploration ability of the particles, the Sine factor is integrated with the Equilibrium Optimizer (EO) technique. A Bi-phase Mutation (BM) scheme is integrated to enhance the exploitation phase of the EO algorithm (BM-based Hybrid EO, BMHEO). The BMHEO method is evaluated by employing four different classifiers – KNN, SVM, Random Forest (RF) and Discriminant Analysis (DA). It is observed that the Random Forest classifier exhibits superior performance compared to the other three classifiers. Eight S-shaped and V-shaped transfer functions are integrated to convert the solutions to binary form. García-Domínguez, Antonio, et al. [16] presented a comprehensive investigation into diabetes detection models by integrating two feature selection techniques: the Akaike information criterion and genetic algorithms. These techniques are combined with six prominent classifier algorithms, including support vector machine, random forest, k-nearest neighbor, gradient boosting, extratrees, and naive Bayes. By leveraging clinical and paraclinical features, the generated models are evaluated and compared to existing approaches. The results demonstrate superior performance, surpassing accuracies of 94%. Furthermore, the use of feature selection techniques allows for working with a reduced dataset. The significance of feature selection is

**Shanthi**

underscored in this study, showcasing its pivotal role in enhancing the performance of diabetes detection models. Grisci, Bruno I., et al [17] The use of feature selection in gene expression studies began at the end of the 1990s with the analysis of human cancer microarray datasets. Since then, gene expression technology has been perfected, the Human Genome Project has been completed, new microarray platforms have been created and discontinued, and RNA-seq has gradually replaced microarrays. However, most feature selection methods in the last two decades were designed, evaluated, and validated on the same datasets from the microarray technology's infancy. In this review of over 1200 publications regarding feature selection and gene expression, published between 2010 and 2020, we found that 57% of the publications used at least one outdated dataset, 23% used only outdated data, and 32% did not cite data sources. Biswas, Niloy, et al [18] This study is aimed at building a potential machine learning model to predict heart disease in early stage employing several feature selection techniques to identify significant features. Three different approaches were applied for feature selection such as chi-square, ANOVA, and mutual information, and the selected feature subsets were denoted as SF1, SF2, and SF3, respectively. Then, six different machine learning models such as logistic regression (C1), support vector machine (C2), K-nearest neighbor (C3), random forest (C4), Naive Bayes (C5), and decision tree (C6) were applied to find the most optimistic model along with the best-fit feature subset. Noroozi, Zeinab, Azam Orooji, and Leila Erfannia [19] The present study examines the role of feature selection methods in optimizing machine learning algorithms for predicting heart disease. The Cleveland Heart disease dataset with sixteen feature selection techniques in three categories of filter, wrapper, and evolutionary were used. Then seven algorithms Bayes net, Naïve Bayes (BN), multivariate linear model (MLM), Support Vector Machine (SVM), logit boost, j48, and Random Forest were applied to identify the best models for heart disease prediction. Precision, F-measure, Specificity, Accuracy, Sensitivity, ROC area, and PRC were measured to compare feature selection methods effect on prediction algorithms. Manikandan, G., et al. [20] Machine learning algorithms are now crucial in the medical field, especially when using medical databases to diagnose diseases. Such efficient algorithms and data processing techniques are applied to predict various diseases and offer much potential for accurate heart disease prognosis. Therefore, this study compares the performance logistic regression, decision tree, and support vector machine (SVM) methods with and without Boruta feature selection. The Cleveland Clinic Heart Disease Dataset acquired from Kaggle, which consists of 14 features and 303 instances, was used for the investigation. It was found that the Boruta feature selection algorithm, which selects six of the most relevant features, improved the results of the algorithms. Mahto, Rajul, et al [21] proposed a hybrid novel technique CSSMO-based gene selection for cancer classification. First, we made alteration of the fitness of spider monkey optimization (SMO) with cuckoo search algorithm (CSA) algorithm viz., CSSMO for feature selection, which helps to combine the benefit of both metaheuristic algorithms to discover a subset of genes which helps to predict a cancer disease in early stage. Further, to enhance the accuracy of the CSSMO algorithm, we choose a cleaning process, minimum redundancy maximum relevance (mRMR) to lessen the gene expression of cancer datasets. Next, these subsets of genes are classified using deep learning (DL) to identify different groups or classes related to a particular cancer disease.

Razzaque, Abdul, and Abhishek Badholia [22] a novel Multi Class based Feature Extraction (MC-FE) method has been proposed for medical data classification. Genomic datasets, or gene expression-based microarray medical datasets, are categorised for cancer diagnosis. The first stage involves applying a feature extraction technique. The Principal Component Analysis (PCA) is used to extract the features for medical data classification to detect leukemia, colon tumors, and prostate cancer. The MPSO (modified particle swarm optimization) technique is used at the second stage to pick features from high-dimensional microarray medical datasets like prostate cancer, leukemia, and colon tumors. Finally, SVM, KNN, and Naive Bayes classifiers are used to classify medical data. Pham, Tin H., and Bijan Raahemi [23] A systematic literature review is conducted on five major digital databases of science and engineering. Results: The primary search included 695 articles. After removing 263 duplicated articles, 432 studies remained to be screened. Among those, 317 irrelevant papers were removed. We then excluded 77 studies according to the exclusion criteria. Finally, 38 articles were selected for this study. Conclusion: Out of 38 studies, 28 papers discussed Swarm-based algorithms, 2 papers studied Genetic Algorithms, and 8 papers covered algorithms in both categories. Considering the application domains, 21 of the articles focused on problems in the healthcare sector, while the rest mainly investigated issues in cybersecurity, text classification, and image processing. Hybridization with other BIAs was employed by approximately 18.5% of papers, and 13 out of 38 studies used S-shaped transfer

Shanthi

functions. The majority of studies used supervised classification methods such as k-NN and SVM for building fitness functions.

INFORMATION GAIN BASED FEATURE SELECTION METHOD

Information Gain (IG) [24] [25] is a popular feature selection method used primarily in the context of classification problems. It measures the reduction in uncertainty or entropy in the target variable due to the presence of a feature.

Understanding Entropy

Entropy is a measure of the unpredictability or impurity in a dataset. In the context of feature selection, it quantifies the amount of disorder or randomness in the target variable.

For a target variable Y with n possible values, the entropy $H(Y)$ is defined as:

$$H(Y) = - \sum_{i=1}^n P(y_i) \log_2 P(y_i) \quad (1)$$

Where $P(y_i)$ is the probability of occurrence of the i -th value of y .

Conditional Entropy

Conditional entropy quantifies the amount of entropy (uncertainty) in the target variable Y given the presence of another variable X . It is defined as:

$$H(Y|X) = - \sum_{j=1}^m P(x_j) \sum_{i=1}^n P(y_i|x_j) \log_2 P(y_i|x_j) \quad (2)$$

Where $P(x_j)$ is the probability of the j -th value of X , and $P(y_i|x_j)$ is the conditional probability of y_i given x_j .

Information Gain Calculation

Information Gain (IG) is the reduction in entropy of the target variable Y after observing the feature X . It measures how much knowing the feature X reduces the uncertainty about the target variable Y . The IG is calculated as:

$$IG(Y, X) = H(Y) - H(Y|X) \quad (3)$$

Feature Selection using Information Gain

The steps involved in selecting features using Information Gain are as follows:

- **Calculate Entropy of the Target Variable:** Compute the entropy $H(Y)$ of the target variable Y using the formula mentioned above.
- **Calculate Conditional Entropy for each feature:** For each feature X_i in the dataset, calculate the conditional entropy $H(Y|X_i)$ of the target variable given the feature.
- **Compute Information Gain for each feature:** For each feature X_i , compute the $IG(Y, X_i)$ using the formula:

$$IG(Y, X_i) = H(Y) - H(Y|X_i) \quad (4)$$
- **Rank features based on Information Gain:** Rank the features based on their Information Gain values. Features with higher Information Gain are considered more informative and relevant for predicting the target variable.
- **Select Top features:** Select the top k features with the highest IG values as the most relevant features for the model.

RELIEFF BASED FEATURE SELECTION METHOD

The ReliefF algorithm [26] [27] is an extension of the original Relief algorithm and is designed to handle multi-class problems and noisy data. It is a feature weighting method that evaluates the importance of features based on their ability to distinguish between instances that are near each other.

Initialization

Relief F starts by initializing a weight vector W for all features, setting each weight to Zero:

$$W[f_i] = 0 \quad (5)$$

for each feature f_i in the dataset.

Shanthi

Random Sampling

Relief F iteratively samples instances from the dataset. For each iteration, it randomly selects an instance R from the dataset.

Finding Nearest Neighbors

For the selected instance R, Relief F identifies:

- k nearest neighbors from the same class as R (called “nearest hits”)
- k nearest neighbors from the same class as R (called “nearest hits”)

Updating Feature Weights

Relief F updates the weights of the features based on how well they can distinguish between R and its nearest hits and misses. The update rule for the weight of a feature f is:

$$W[f] = W[f] - \frac{1}{m} \sum_{i=1}^k \left(\frac{|f(R) - f(H_i)|}{k} \right) + \frac{1}{m} \sum_{c \neq \text{class}(R)} \left(\frac{P(c)}{1 - P(\text{class}(R))} \sum_{j=1}^k \left(\frac{|f(R) - f(M_j^c)|}{k} \right) \right) \quad (6)$$

Where $W[f]$ is the weight of feature f , m is the number of iterations, H_i is the i -th nearest hit, M_j^c is the j -th nearest miss from class c , $P(c)$ is the prior probability of class c , $f(R)$ is the value of feature f for instance R. The update increases the weight of a feature if it helps distinguish between instances of different classes (i.e., if the difference between R and nearest misses is large) and decreases the weight if it does not help distinguish between instances of the same class (i.e., if the difference between R and nearest hits is large).

Iteration

Steps 2-4 are repeated for a predefined number of iterations or until convergence. Each iteration refines the weights, improving the ranking of features based on their ability to discriminate between instances of different classes.

Ranking and Selecting Features

After completing the iterations, the features are ranked based on their final weights. Features with higher weights are considered more important and relevant for the classification task. ReliefF is a powerful feature selection method that evaluates feature importance based on their ability to discriminate between instances of different classes, considering local information around each instance. This method is particularly useful for handling multi-class problems and noisy data, providing a robust way to select relevant features that contribute to accurate and efficient predictive modeling.

WHALE OPTIMIZATION ALGORITHM BASED FEATURE SELECTION METHOD

The Whale Optimization Algorithm (WOA) [28] [29] is a nature-inspired metaheuristic optimization algorithm based on the social hunting behavior of humpback whales, specifically their bubble-net feeding strategy. In feature selection, WOA can be employed to find an optimal subset of features that maximizes the performance of a predictive model. Here's a detailed explanation of how the WOA-based feature selection method works:

Stage 1: Initialization

- **Population Initialization:** Initialize a population of whales (solutions), where each whale represents a potential solution (a subset of features). The size of the population is N , and each whale's position in the search space is represented as a binary vector indicating the presence (1) or absence (0) of features.
- **Fitness Function:** Define a fitness function to evaluate the quality of each solution. This function typically measures the predictive accuracy of a machine learning model using the selected features.

Stage 2: Whale Behavior Modeling

WOA mimics two main behaviors of humpback whales: the encircling prey mechanism and the bubble-net attacking method.

Shanthi

Stage 2.1: Encircling Prey

- Whales perceive the position of the best solution (whale) found so far, updating their positions to move towards this optimal solution.

- Update the position of each whale according to the following equations:

$$\bar{D} = |\bar{C} \cdot \bar{X}^*(t) - \bar{X}(t)| \quad (7)$$

$$\bar{X}(t+1) = \bar{X}^*(t) - \bar{A} \cdot \bar{D} \quad (8)$$

Where $\bar{X}^*(t)$ is the position vector of the best solution, $\bar{X}(t)$ is the position vector of the current whale, \bar{A} and \bar{C} are coefficient vector calculated as:

$$\bar{A} = 2\bar{a} \cdot \bar{r} - \bar{a} \quad (9)$$

$$\bar{C} = 2 \cdot \bar{r} \quad (10)$$

Where \bar{a} decreases linearly from 2 to 0 over the course of iterations, and \bar{r} is a random vector in [0,1].

Stage 2.2: Bubble – Net Attacking Model

This method includes two strategies: shrinking encircling mechanism and spiral updating position.

- Shrinking Encircling Mechanism:** This is controlled by \bar{A} . When $|\bar{A}| < 1$, the whales move towards the best solution.

- Spiral Updating Position:** This models the helix-shaped movement of whales around their prey.

$$\bar{X}(t+1) = \bar{D}' \cdot e^{bl} \cdot \cos(2\pi l) + \bar{X}^*(t) \quad (11)$$

Where $\bar{D}' = |\bar{X}^*(t) - \bar{X}(t)|$, b is a constant defining the spiral shape, and l is the random number in $[-1,1]$. The probability p is used to switch between the shrinking encircling mechanism and the spiral model. Typically, $p = 0.50$.

Stage 3: Exploration Phase

To enhance exploration, whales search for prey randomly based on the positions of other whales. When $|\bar{A}| \geq 1$, the whales move towards random positions in the search space, facilitating exploration.

Stage 4: Fitness Evaluation

Evaluate the fitness of each whale (solution) using the defined fitness function. This step assesses how well the selected subset of features performs in terms of model accuracy.

Stage 5: Updating Best Solution

Identify the whale with the best fitness score. Update the best-known position $\bar{X}^*(t)$ if a better solution is found.

Stage 6: Iteration

Repeat steps 2-5 for a predefined number of iterations or until convergence criteria are met.

Stage 7: Selection of Optimal Feature Subset

After the iterations, the position vector of the best whale represents the optimal subset of features. Features corresponding to 1s in the binary vector are selected for the final model.

PROPOSED TWICE FILTER OPTIMIZATION BASED FEATURE SELECTION (TTO-FS) METHOD

The proposed hybrid TTO-FS method integrates Information Gain (IG), ReliefF, and Whale Optimization Algorithm (WOA) to identify the most relevant features from high-dimensional datasets. The hybrid method is designed to leverage the strengths of each individual technique, thereby enhancing the overall performance and robustness of the feature election process.

Phase 1: Initial Feature Ranking using IG and ReliefF

Step 1: Information Gain (IG) Calculation

- Step 1.1: Compute the Entropy of the target variable:** The entropy $H(Y)$ of the target variable Y is calculated to measure its uncertainty using equation (1).

Shanthi

- **Step 1.2: Calculate Conditional Entropy for Each Feature:** For each feature X, the conditional entropy $H(Y|X)$ is computed to measure the remaining uncertainty about Y given X using the equation (2).
- **Step 1.3: Calculate Information Gain for Each Feature:** Information Gain (IG) is calculated for each feature to determine how much information about Y is gained by knowing X using equation (3).
- **Step 1.4: Rank Features Based on Information Gain:** Rank the features from highest to lowest based on their IG values. Higher IG values indicate more relevant features.

Step 2: Relief F Calculation

- **Step 2.1: Initialize Weights for All Features:** Initialize a weight vector W for all features using equation (5).
- **Step 2.2: Random Sampling:** For each iteration, randomly select an instance R from the dataset.
- **Step 2.3: Find Nearest Neighbors:** For the selected instance R, identify k nearest hits (same class as R) and k nearest misses (different classes).
- **Step 2.4: Update Weights:** Update the weight of each feature based on its ability to distinguish between R and its nearest hits and misses using equation (6).
- **Step 2.5: Rank Features Based on Weights:** Rank the features from highest to lowest based on their weights. Higher weights indicate more relevant features.

Phase 2: Combined Ranking of Features

Step 3: Normalize Rankings

- **Step 3.1: Normalize IG and ReliefF Rankings:** Normalize the ranks obtained from IG and ReliefF to a common scale (e.g., 0 to 1) to ensure they are comparable.

Step 4: Aggregate Rankings

- **Step 4.1: Combine the Normalized Ranks:** Aggregate the normalized ranks by averaging or using a weighted sum:

$$Rank_{combined}(f_i) = \alpha \cdot Rank_{IG}(f_i) + (1 - \alpha) \cdot Rank_{ReliefF}(f_i) \quad (12)$$

Where α is a weighting factor (e.g., 0.5)

- **Step 4.2: Select Top features:** Select the top k features based on the combined ranking. This subset of features will be used in the next phase.

Phase 3: Refinement Using Whale Optimization Algorithm (WOA)

Step 5: Initialization

- **Step 5.1: Population Initialization:** Initialize a population of whales (solutions), where each whale represents a subset of the top k features. Each whale's position is represented by a binary vector indicating the presence (1) or absence (0) of features.
- **Step 5.2: Fitness Function:** Define a fitness function to evaluate the quality of each subset. This function typically measures the predictive accuracy of a machine learning model using the selected features. For instance, accuracy, precision, recall, or F1-score can be used as metrics.

Step 6: Whale Behavior Modeling

- **Step 6.1: Encircling the prey**
 - Update position of each whale from equation (7) to equation (10).
- **Step 6.2: Bubble-Net Attacking Method**
 - Shrinking Encircling Mechanism: When $|\vec{A}| \geq 1$ whales move towards the best solution.
 - Spiral Updating Position using equation (11).
 - Exploration phase: Random search: When $|\vec{A}| \geq 1$, whales move towards random positions to enhance exploration and avoid local optimal.

Step 7: Fitness Evaluation

- **Step 7.1: Evaluate Fitness of Each Whale:** Use the fitness function to assess the quality of each subset of features. This involves training a machine learning model with the selected features and measuring its performance.

Shanthi

Step 8: Updating Best Solution

- **Step 8.1: Identify the Best Whale:** Find the whale with the best fitness score in the current population and update the best-known solution $\bar{X} * (t)$ if a better solution is found.

Step 9: Iteration

- **Step 9.1: Repeat the Process:** Repeat the optimization process for a predefined number of iterations or until convergence criteria are met. Each iteration refines the selection of features by updating the whales' positions.

Phase 4: Final Selection of Features

Step 10: Select Optimal Feature Subset

- **Step 10.1: Final Whale Solution:** After the completion of iterations, the position vector of the best whale represents the optimal subset of features. The selected features correspond to the positions with 1s in the binary vector.

RESULT AND DISCUSSION

Dataset Description

In this research work, the three different clinical datasets are considered to evaluate the performance of the Proposed TTO-FS method. Dermatology [30], Lung Cancer [31] and Hepatitis [32] datasets are considered in this work. Table 1 depicts the number of features in the given considered datasets.

Performance Metrics

Table 2 gives the performance metrics used in this research work, to evaluate the performance of the Proposed TTO-FS methods using Classification techniques, Artificial Neural Network (ANN), Random Forest (RF) and Support Vector Machine (SVM). The performance of the Proposed TTO-FS method is evaluated with the existing feature selection techniques like Information Gain (IG), ReliefF(RFF), Whale Optimization Algorithm (WOA), Artificial Bee Colony Optimization (ABO).

Performance Analysis of the Proposed TTO-FS Method for Dermatology Dataset

Table 1 give the number of features obtained by the Proposed TTO-FS method and existing feature selection methods. From the table 1, it is clear that the proposed TTO-FS method gives less number of features than the existing feature selection methods. Table 2 gives the Classification Accuracy (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques. From the table 3.2, Original Dataset: The baseline accuracies without any feature selection are the lowest across all classifiers, ranging from 43.10% (SVM) to 48.32% (ANN). Proposed TTO-FS: This method significantly outperforms all other feature selection techniques, achieving the highest accuracies for SVM (93.55%), RF (94.86%), and ANN (95.06%). WOA: The second-best performing method with accuracies of 71.76% (SVM), 72.30% (RF), and 72.87% (ANN). IG: Performs well with accuracies of 69.63% (SVM), 69.97% (RF), and 70.84% (ANN), slightly better than RFF and ABC. RFF: Moderate performance with accuracies of 66.54% (SVM), 66.86% (RF), and 68.75% (ANN). ABC: Shows lower accuracies compared to IG and WOA but still better than the original dataset, with 65.46% (SVM), 65.77% (RF), and 67.64% (ANN). Table 3 gives the True Positive Rate (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques. From the table 3.3, Original Dataset: The baseline TPRs without any feature selection are the lowest across all classifiers, ranging from 52.61% (SVM) to 52.94% (RF). Proposed TTO-FS: This method achieves the highest TPRs for SVM (93.35%), RF (94.99%), and ANN (94.97%), significantly outperforming all other feature selection techniques. WOA: The second-best performing method with TPRs of 75.37% (SVM), 76.37% (RF), and 70.54% (ANN). IG: Performs well with TPRs of 76.07% (SVM), 74.59% (RF), and 71.35% (ANN), slightly better than WOA for SVM. RFF: Moderate performance with TPRs of 69.18% (SVM), 67.68% (RF), and 65.45% (ANN). ABC: Shows lower TPRs compared to IG and WOA but still better than the original dataset, with 64.34% (SVM), 66.57% (RF), and 68.29% (ANN). Table 4 gives the False Positive Rate (in %) obtained by the Proposed

**Shanthi**

and Existing Feature Selection methods using ANN, RF and SVM classification techniques. From the table 3.4, Original Dataset: The baseline FPRs without any feature selection are the highest across all classifiers, ranging from 56.83% (ANN) to 67.17% (SVM). Proposed TTO-FS: This method achieves the lowest FPRs for SVM (6.21%), RF (5.26%), and ANN (4.84%), significantly outperforming all other feature selection techniques. WOA: The second-best performing method with FPRs of 32.18% (SVM), 32.80% (RF), and 24.22% (ANN). IG: Performs well with FPRs of 35.62% (SVM), 34.77% (RF), and 29.73% (ANN), slightly higher than WOA. RFF: Moderate performance with FPRs of 46.53% (SVM), 45.66% (RF), and 40.82% (ANN). ABC: Shows higher FPRs compared to IG and WOA but still lower than the original dataset, with 47.42% (SVM), 46.75% (RF), and 41.71% (ANN). Table 5 gives the Precision (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques. From the table 3.5, Original Dataset: The baseline precision without any feature selection is the lowest across all classifiers, ranging from 45.81% (SVM) to 51.72% (ANN). Proposed TTO-FS: This method achieves the highest precision for SVM (94.30%), RF (95.16%), and ANN (95.50%), significantly outperforming all other feature selection techniques. WOA: The second-best performing method with precision values of 71.97% (SVM), 71.45% (RF), and 78.97% (ANN). IG: Performs well with precision values of 68.79% (SVM), 68.81% (RF), and 73.60% (ANN), slightly lower than WOA. RFF: Moderate performance with precision values of 59.68% (SVM), 59.72% (RF), and 62.51% (ANN). ABC: Shows lower precision compared to IG and WOA but still higher than the original dataset, with 58.57% (SVM), 58.61% (RF), and 61.43% (ANN). Table 6 gives the Miss Rate (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques. From the table 3.6, Original Dataset: The baseline miss rates without any feature selection are the highest across all classifiers, ranging from 47.06% (RF) to 47.39% (SVM). Proposed TTO-FS: This method achieves the lowest miss rates for SVM (6.65%), RF (5.01%), and ANN (5.03%), significantly outperforming all other feature selection techniques. WOA: The second-best performing method with miss rates of 24.63% (SVM), 23.63% (RF), and 29.46% (ANN). IG: Performs well with miss rates of 23.93% (SVM), 25.41% (RF), and 28.65% (ANN), slightly higher than WOA. RFF: Moderate performance with miss rates of 32.82% (SVM), 36.52% (RF), and 39.76% (ANN). ABC: Shows higher miss rates compared to IG and WOA but still lower than the original dataset, with 33.91% (SVM), 37.61% (RF), and 40.85% (ANN). Table 7 gives the Specificity (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques. From the table 3.7, Original Dataset: The baseline specificity without any feature selection is the lowest across all classifiers, ranging from 32.83% (SVM) to 43.17% (ANN). Proposed TTO-FS: This method achieves the highest specificity for SVM (93.79%), RF (94.74%), and ANN (95.16%), significantly outperforming all other feature selection techniques. WOA: The second-best performing method with specificity values of 67.82% (SVM), 67.20% (RF), and 75.78% (ANN). IG: Performs well with specificity values of 64.38% (SVM), 65.23% (RF), and 70.27% (ANN), slightly lower than WOA. RFF: Moderate performance with specificity values of 53.49% (SVM), 54.32% (RF), and 59.38% (ANN). ABC: Shows lower specificity compared to IG and WOA but still higher than the original dataset, with 52.38% (SVM), 53.21% (RF), and 58.24% (ANN).

Performance Analysis of the Proposed TTO-FS Method for Lung Cancer Dataset

Table 8 give the number of features obtained by the Proposed TTO-FS method and existing feature selection methods. From the table 4.1, it is clear that the proposed TTO-FS method gives less number of features than the existing feature selection methods. Table 9 gives the Classification Accuracy (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques for Lung Cancer dataset. From the table 4.2, Original Dataset: The baseline accuracies without any feature selection are the lowest across all classifiers, ranging from 43.97% (SVM) to 48.32% (ANN). Proposed TTO-FS: This method achieves the highest classification accuracies for SVM (93.46%), RF (94.09%), and ANN (94.91%), significantly outperforming all other feature selection techniques. WOA: The second-best performing method with accuracies of 71.67% (SVM), 71.47% (RF), and 72.59% (ANN). IG: Performs well with accuracies of 69.34% (SVM), 70.94% (RF), and 70.84% (ANN), slightly lower than WOA. RFF: Moderate performance with accuracies of 58.43% (SVM), 59.85% (RF), and 59.73% (ANN). ABC: Shows lower accuracies compared to IG and WOA but still higher than the original dataset, with 57.34% (SVM), 58.74% (RF), and 58.64% (ANN). Table 10 gives the True Positive Rate (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques for Lung Cancer dataset. From the table 4.3, Original Dataset: The baseline TPRs without any feature selection are varied across

**Shanthi**

classifiers, ranging from 47.68% (RF) to 52.76% (ANN). Proposed TTO-FS: This method achieves the highest TPRs for SVM (92.42%), RF (94.51%), and ANN (95.51%), significantly outperforming all other feature selection techniques. IG: Performs well with TPRs of 73.05% (SVM), 75.50% (RF), and 74.45% (ANN), slightly lower than the proposed TTO-FS method. WOA: Shows strong performance with TPRs of 82.30% (SVM), 74.90% (RF), and 71.19% (ANN). RFF: Moderate performance with TPRs of 62.16% (SVM), 64.41% (RF), and 63.34% (ANN). ABC: Shows lower TPRs compared to IG and WOA but still higher than the original dataset, with 61.27% (SVM), 63.32% (RF), and 62.25% (ANN).

Table 11 gives the False Positive Rate (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques for Lung Cancer dataset. From the table 4.4, Original Dataset: The baseline FPRs without any feature selection are relatively high across classifiers, ranging from 56.58% (ANN) to 63.80% (SVM). Proposed TTO-FS: This method achieves the lowest FPRs for SVM (5.36%), RF (6.36%), and ANN (5.72%), significantly outperforming all other feature selection techniques. WOA: The second-best performing method with FPRs of 31.91% (SVM), 32.31% (RF), and 25.60% (ANN). IG: Performs well with FPRs of 35.31% (SVM), 33.75% (RF), and 32.87% (ANN), slightly higher than WOA. RFF: Moderate performance with FPRs of 44.42% (SVM), 42.84% (RF), and 43.78% (ANN). ABC: Shows higher FPRs compared to IG and WOA but still lower than the original dataset, with 45.53% (SVM), 43.75% (RF), and 44.69% (ANN). Table 12 gives the Precision (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques for Lung Cancer dataset. From the table 4.5, Original Dataset: The baseline precision without any feature selection varies across classifiers, ranging from 46.11% (SVM) to 52.34% (RF). Proposed TTO-FS: This method achieves the highest precision for SVM (95.11%), RF (94.16%), and ANN (94.17%), significantly outperforming all other feature selection techniques. WOA: The second-best performing method with precision values of 72.76% (SVM), 71.92% (RF), and 78.18% (ANN). IG: Performs well with precision values of 69.21% (SVM), 69.77% (RF), and 70.04% (ANN), slightly lower than WOA. RFF: Moderate performance with precision values of 58.32% (SVM), 58.68% (RF), and 61.13% (ANN). ABC: Shows lower precision compared to IG and WOA but still higher than the original dataset, with 57.43% (SVM), 57.79% (RF), and 60.24% (ANN). Table 13 gives the Miss Rate (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques for Lung Cancer dataset. From the table 4.6, Original Dataset: The baseline miss rates without any feature selection are varied across classifiers, ranging from 47.24% (ANN) to 52.32% (RF). Proposed TTO-FS: This method achieves the lowest miss rates for SVM (7.58%), RF (5.49%), and ANN (4.49%), significantly outperforming all other feature selection techniques. WOA: The second-best performing method with miss rates of 17.70% (SVM), 25.10% (RF), and 28.81% (ANN). IG: Performs well with miss rates of 29.65% (SVM), 24.50% (RF), and 25.55% (ANN), slightly higher than TTO-FS. RFF: Moderate performance with miss rates of 38.54% (SVM), 35.56% (RF), and 36.67% (ANN). ABC: Shows higher miss rates compared to IG and WOA but still lower than the original dataset, with 39.45% (SVM), 36.67% (RF), and 37.78% (ANN). Table 14 gives the Specificity (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques for Lung Cancer dataset. From the table 4.7, Original Dataset: The baseline specificities without any feature selection are relatively low across classifiers, ranging from 36.20% (SVM) to 43.42% (ANN). Proposed TTO-FS: This method achieves the highest specificities for SVM (94.64%), RF (93.64%), and ANN (94.28%), significantly outperforming all other feature selection techniques. WOA: The second-best performing method with specificities of 68.09% (SVM), 67.69% (RF), and 74.40% (ANN). Information Gain (IG): Performs well with specificities of 64.91% (SVM), 66.25% (RF), and 67.13% (ANN), slightly lower than TTO-FS. RFF: Moderate performance with specificities of 55.82% (SVM), 55.34% (RF), and 56.24% (ANN). ABC: Shows lower specificities compared to IG and WOA but still higher than the original dataset, with 54.71% (SVM), 54.45% (RF), and 55.35% (ANN).

Performance Analysis of the Proposed TTO-FS Method for Hepatitis Dataset

Table 15 give the number of features obtained by the Proposed TTO-FS method and existing feature selection methods. From the table 5.1, it is clear that the proposed TTO-FS method gives less number of features than the existing feature selection methods. Table 16 gives the Classification Accuracy (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques for Hepatitis dataset. From the

**Shanthi**

table 5.2, Original Dataset: The baseline accuracies without any feature selection are varied across classifiers, ranging from 44.93% (SVM) to 50.16% (ANN). Proposed TTO-FS: This method achieves the highest classification accuracies for SVM (95.15%), RF (95.85%), and ANN (95.15%), significantly outperforming all other feature selection techniques. WOA: Shows strong performance with accuracies of 74.04% (SVM and ANN) and 72.20% (RF). IG: Performs well with accuracies of 68.81% (SVM), 67.11% (RF), and 66.19% (ANN), slightly lower than the proposed TTO-FS method. RFF: Moderate performance with accuracies of 57.92% (SVM), 58.22% (RF), and 55.28% (ANN). ABC: Shows lower accuracies compared to IG and WOA but still higher than the original dataset, with 56.81% (SVM), 57.32% (RF), and 54.19% (ANN). Table 17 gives the True Positive Rate (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques for Hepatitis dataset. From the table 5.3, Original Dataset: The baseline true positive rates without any feature selection vary across classifiers, ranging from 49.44% (RF) to 55.11% (SVM). Proposed TTO-FS: This method achieves the highest true positive rates for SVM (96.53%), RF (96.90%), and ANN (95.02%), significantly outperforming all other feature selection techniques. WOA: Shows strong performance with true positive rates of 84.55% (SVM), 80.57% (RF), and 81.74% (ANN). IG: Performs well with true positive rates of 67.35% (SVM), 69.42% (RF), and 70.57% (ANN), slightly lower than the proposed TTO-FS method. RFF: Moderate performance with true positive rates of 56.43% (SVM), 58.31% (RF), and 60.46% (ANN). ABC: Shows lower true positive rates compared to IG and WOA but still higher than the original dataset, with 55.65% (SVM), 57.53% (RF), and 59.68% (ANN).

Table 18 gives the False Positive Rate (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques for Hepatitis dataset. From the table 5.4, Original Dataset: The baseline false positive rates without any feature selection vary significantly across classifiers, ranging from 54.40% (ANN) to 64.74% (SVM). Proposed TTO-FS: This method achieves the lowest false positive rates for SVM (6.32%), RF (5.305%), and ANN (4.704%), significantly outperforming all other feature selection techniques. WOA: Shows strong performance with false positive rates of 35.76% (SVM), 36.21% (RF), and 34.56% (ANN). IG: Performs well with false positive rates of 28.79% (SVM), 35.32% (RF), and 38.08% (ANN), notably higher than TTO-FS. RFF: Moderate performance with false positive rates of 37.88% (SVM), 36.43% (RF), and 39.19% (ANN). ABC: Shows slightly higher false positive rates compared to WOA but generally lower than the original dataset, with 38.06% (SVM), 37.65% (RF), and 40.32% (ANN). Table 19 gives the Precision (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques for Hepatitis dataset. Original Dataset: The baseline precisions without any feature selection are varied across classifiers, ranging from 44.75% (SVM) to 52.80% (RF). Proposed TTO-FS: This method achieves the highest precision scores for SVM (94.24%), RF (95.11%), and ANN (95.56%), significantly outperforming all other feature selection techniques. WOA: Shows strong performance with precision scores of 68.81% (SVM), 69.09% (RF), and 72.55% (ANN). IG: Performs well with precision scores of 74.80% (SVM), 67.58% (RF), and 64.97% (ANN), slightly lower than the proposed TTO-FS method. RFF: Moderate performance with precision scores of 63.91% (SVM), 57.47% (RF), and 53.86% (ANN). ABC: Shows lower precision scores compared to IG and WOA but still higher than the original dataset, with 61.13% (SVM), 56.69% (RF), and 52.08% (ANN). Table 20 gives the Miss Rate (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques for Hepatitis dataset. From the table 5.6, Original Dataset: The baseline miss rates without any feature selection vary across classifiers, ranging from 44.89% (SVM) to 50.56% (RF). Proposed TTO-FS: This method achieves the lowest miss rates for SVM (3.47%), RF (3.10%), and ANN (4.98%), significantly outperforming all other feature selection techniques. WOA: Shows strong performance with miss rates of 15.45% (SVM), 19.43% (RF), and 18.26% (ANN). IG: Performs well with miss rates of 32.65% (SVM), 30.58% (RF), and 29.43% (ANN), notably higher than the proposed TTO-FS method. RFF: Moderate performance with miss rates of 41.57% (SVM), 41.69% (RF), and 39.42% (ANN). ABC: Shows higher miss rates compared to IG and WOA but generally lower than the original dataset, with 42.79% (SVM), 42.81% (RF), and 40.64% (ANN). Table 21 gives the Specificity (in %) obtained by the Proposed and Existing Feature Selection methods using ANN, RF and SVM classification techniques for Hepatitis dataset. From the table 5.7, Original Dataset: The baseline specificity scores without any feature selection are varied across classifiers, ranging from 35.26% (SVM) to 45.6% (ANN). Proposed TTO-FS: This method achieves the highest specificity scores for SVM (93.68%), RF (94.70%), and ANN (95.29%), significantly outperforming all other feature selection techniques. WOA: Shows strong performance with specificity

Shanthi

scores of 64.24% (SVM), 63.79% (RF), and 65.44% (ANN).IG: Performs well with specificity scores of 71.21% (SVM), 64.68% (RF), and 61.92% (ANN), higher than the proposed TTO-FS method.RFF: Moderate performance with specificity scores of 60.12% (SVM), 55.79% (RF), and 50.81% (ANN).ABC: Shows lower specificity scores compared to IG and WOA but generally higher than the original dataset, with 59.35% (SVM), 56.91% (RF), and 49.05% (ANN).

CONCLUSION
