## ABSTRACT

To solve the Fuzzy Multi Transportation Problem (FMTP) and Intuitionistic Fuzzy Multi Transportation Problem (IFMTP) with the Decagonal Fuzzy Multi number (DFMN) and Intuitionistic Fuzzy Multi number (DIFMN), the Ranking Technique was considered in this paper. The DFMN and DIFMN were first transformed to a crisp data by ranking measures and then the initial, Optimal solution of the FMTP and IFMTP were analysed. And, as this is a new and it can be applied to the Initial and Final optimal solution of any multi-criteria decision-making analysis. The efficiency of the proposed Technique is illustrated with numerical examples.

**Keywords:** Fuzzy Sets; Fuzzy Numbers; Intuitionistic Fuzzy Number; Decagonal Fuzzy Number; Decagonal Intuitionistic Fuzzy Number; Transportation Problem; Ranking Measure.

## INTRODUCTION

[Zadeh] Proposed the Fuzzy set theory concept in 1965. Zadeh introduced a Mathematical method with decision making fuzzy concept. Zadeh proposed the membership function and non-membership function with a range of covering the interval (0, 1) for any sets. The value 0 means that  $x$  is not a member of the fuzzy set. The value 1 means that  $x$  is fully a member of the fuzzy set. [Yager] initiated the theory of fuzzy multi sets in 1986, the case where objects possess a particular property to a certain degree. Fuzzy set and its extensions techniques, methodologies mixed approaches and research directions focusing on unsolved issues. Ranking of fuzzy numbers were first proposed by [Jain] for decision making in fuzzy situations by representing the ill-defined quantity as a fuzzy set.

**Vivek et al.,**

In decision making problems, the ranking of intuitionistic fuzzy numbers plays an important role in comparison analysis was referred by S. K. Bharati [5]. Intuitionistic Fuzzy Transportation Problem with the Decagonal Intuitionistic Fuzzy Number was introduced by A.Thamariselvi & R.Santhi [7]. Also, G.Uthra [8] proposed the Generalized Intuitionistic Pentagonal, Hexagonal, Octagonal, Nonagonal Fuzzy Numbers defined and a new Ranking formula by finding the area of the centroid from the origin method. Later, A.Anju [1] presented a solution for fractional transportation problem where the cost functions are Decagonal intuitionistic fuzzy numbers by the method of Ranking and Russell's. The distinctive representation, ranking and defuzzification technique of Decagonal fuzzy number was illustrated by Avishek [4]. As the Ranking technique solves the Fuzzy Multi Transportation Problem (FMTP) and Intuitionistic Fuzzy Multi Transportation Problem (IFMTP) in which the costs, supplies and demands are of the triangular intuitionistic fuzzy numbers was introduced earlier [9] and this paper is an attempt to introduce the ranking technique to solve the Fuzzy Multi Transportation Problem (FMTP) and Intuitionistic Fuzzy Multi Transportation Problem (IFMTP) with Decagonal Fuzzy Multi Number (DFMN) and Decagonal Intuitionistic Fuzzy Multi Number (DIFMN).

The organization of this paper is as follows: In section 2, Fuzzy sets, Intuitionistic Fuzzy sets and Fuzzy Multi Number, Intuitionistic Fuzzy Multi Number, Decagonal Intuitionistic Fuzzy Multi Number, Ranking of Fuzzy Multi and Intuitionistic Fuzzy Multi Number are explained. The Fuzzy Multi Transportation Problem and Intuitionistic Fuzzy Multi Transportation problem procedures of the Ranking Technique in DFMN & Ranking Technique DIFMN are proposed in the section 3. The section 4, analyses the numerical examples of (DFMTP under DFMN)&(IFMTP under DIFMN). And in section 5, the analysis of fuzzy set by using Decagonal fuzzy Multi number and Decagonal Intuitionistic Multi fuzzy number methods and numerical example to define the ranking measures to satisfy the following ranking properties and conditions.

## PRELIMINARIES

The basic concepts and definitions are reviewed in this section

### Definition 2.1

If  $X$  is a collection of objects denoted by  $z$ , then the **fuzzy set**  $A$  is defined as set of ordered pair  $A = \{(z, \mu_A(z)) / z \in X\}$ , where  $\mu_A(z)$  is called a membership function of  $z$  of the fuzzy set  $A$ . The membership function maps each element of  $X$  to a membership value between 0 and 1.

### Definition 2.2

The Cardinality of a fuzzy set is the sum of all the membership values of the elements in the Set. This is also known as the sigma-count.

### Definition 2.3

The fuzzy set  $A$  is said to be **Fuzzy Multi number** if it satisfies the following properties

1.  $A$  must have a normal fuzzy set,
2.  $\alpha$ - cut must be piecewise continuous,
3.  $A$  must be convex set

### Definition 2.4

If  $X$  be a non-empty set then the **fuzzy multi number**  $A$  on  $X$  is defined as  $A = \{(z, \mu_A^1(z), \mu_A^2(z), \dots, \mu_A^n(z)) / z \in X\}$ , where  $\mu_A^1(z), \mu_A^2(z), \dots, \mu_A^n(z)$  is called membership function and this membership function maps each element of  $X$  to a membership value between 0 and 1  $\exists \mu_A^1(z) \geq \mu_A^2(z) \geq \dots \geq \mu_A^n(z)$  for  $z \in X$

**Vivek et al.,**

**Decagonal Fuzzy Multi Number**

**Definition 2.5**

A **Decagonal Intuitionistic fuzzy multi number** is specified by 10 tuples

$A_H = (a_1^i, a_2^i, a_3^i, a_4^i, a_5^i, a_6^i, a_7^i, a_8^i, a_9^i, a_{10}^i), (b_1^i, b_2^i, b_3^i, b_4^i, b_5^i, b_6^i, b_7^i, b_8^i, b_9^i, b_{10}^i)$  where  $(a_1^i, a_2^i, a_3^i, a_4^i, a_5^i, a_6^i, a_7^i, a_8^i, a_9^i, a_{10}^i), (b_1^i, b_2^i, b_3^i, b_4^i, b_5^i, b_6^i, b_7^i, b_8^i, b_9^i, b_{10}^i)$  are real numbers and  $a_1^i \leq a_2^i \leq a_3^i \leq a_4^i \leq a_5^i \leq a_6^i \leq a_7^i \leq a_8^i \leq a_9^i \leq a_{10}^i, (b_1^i \leq b_2^i \leq b_3^i \leq b_4^i \leq b_5^i \leq b_6^i \leq b_7^i \leq b_8^i \leq b_9^i, \leq)$

$$\mu_A = \begin{cases} \frac{1}{4} \left[ \frac{z - a_1^i}{a_2^i - a_1^i} \right] & a_1^i \leq z \leq a_2^i \\ \frac{1}{4} + \frac{1}{4} \left[ \frac{z - a_1^i}{a_2^i - a_1^i} \right] & a_2^i \leq z \leq a_3^i \\ \frac{1}{2} + \frac{1}{4} \left[ \frac{z - a_2^i}{a_3^i - a_2^i} \right] & a_3^i \leq z \leq a_4^i \\ \frac{3}{4} + \frac{1}{4} \left[ \frac{z - a_3^i}{a_4^i - a_3^i} \right] & a_4^i \leq z \leq a_5^i \\ 1 & a_5^i \leq z \leq a_6^i \\ 1 - \frac{1}{4} \left[ \frac{z - a_6^i}{7 - 6} \right] & a_6^i \leq z \leq a_7^i \\ \frac{3}{4} - \frac{1}{4} \left[ \frac{a_7^i - z}{a_7^i - a_6^i} \right] & a_7^i \leq z \leq a_8^i \\ \frac{1}{2} - \frac{1}{4} \left[ \frac{z - a_1^i}{a_2^i - a_1^i} \right] & a_8^i \leq z \leq a_9^i \\ \frac{1}{2} \left[ \frac{a_7^i - z}{a_7^i - a_6^i} \right] & a_9^i \leq z \leq a_{10}^i \\ 0 & \text{otherwise} \end{cases} \quad \mu_A = \begin{cases} \frac{1}{4} \left[ \frac{z - b_1^i}{b_2^i - b_1^i} \right] & b_1^i \leq z \leq b_2^i \\ \frac{1}{4} + \frac{1}{4} \left[ \frac{z - a_1^i}{b_2^i - b_1^i} \right] & b_2^i \leq z \leq b_3^i \\ \frac{1}{2} + \frac{1}{4} \left[ \frac{z - b_2^i}{b_3^i - b_2^i} \right] & b_3^i \leq z \leq a_4^i \\ \frac{3}{4} + \frac{1}{4} \left[ \frac{z - b_3^i}{b_4^i - b_3^i} \right] & b_4^i \leq z \leq b_5^i \\ 1 & b_5^i \leq z \leq b_6^i \\ 1 - \frac{1}{4} \left[ \frac{z - b_6^i}{7 - 6} \right] & b_6^i \leq z \leq b_7^i \\ \frac{3}{4} - \frac{1}{4} \left[ \frac{b_7^i - z}{b_7^i - b_6^i} \right] & b_7^i \leq z \leq b_8^i \\ \frac{1}{2} - \frac{1}{4} \left[ \frac{z - a_1^i}{b_2^i - b_1^i} \right] & b_8^i \leq z \leq b_9^i \\ \frac{1}{2} \left[ \frac{b_7^i - z}{b_7^i - b_6^i} \right] & b_9^i \leq z \leq b_{10}^i \\ 0 & \text{otherwise} \end{cases}$$

**RANKING MEASURES OF DECAGONAL FUZZY MULTI -NUMBER AND DECAGONAL INTUITIONISTIC FUZZY MULTI NUMBER**

Many Ranking Measures are available for Fuzzy Numbers (FN), where the membership and are considered only once. But, in Fuzzy Multi Numbers (FMN) and Intuitionistic Fuzzy Multi Number because of their multi membership functions, it should be considered more than once. And, their considerations are combined together by means of Summation concept based on their cardinality. Few new Ranking Measures for the Decagonal Fuzzy Multi Number (DFMN) and Decagonal Intuitionistic Fuzzy Multi Number(DIFMN) are proposed in this section. The **Graded Mean Representation Method, Helipern’s Expected Value Method, Sub Interval Average Method and Extended Method of DFMNs & DIFMNs** were presented.

**Method I: Graded Mean Integration**

The Ranking Measure by the **Graded Mean Integration Representation** of Decagonal Fuzzy Multi Number (DFMN) $A_i$  is defined for as follows

$$R = \frac{1}{n} \sum_{i=1}^n \left[ \frac{a_1^i + a_2^i + a_3^i + a_4^i + 2a_5^i + 2a_6^i + a_7^i + a_8^i + a_9^i + a_{10}^i}{12} \right]$$

The Ranking Measure by the **Graded Mean Integration Representation** of Decagonal Intuitionistic Fuzzy Multi Number (DIFMN) $A_i$  is defined for as follows

$$R = \frac{1}{n} \sum_{i=1}^n \left[ \frac{a_1^i + a_2^i + a_3^i + a_4^i + 2a_5^i + 2a_6^i + a_7^i + a_8^i + a_9^i + a_{10}^i}{12} \right], \left[ \frac{b_1^i + b_2^i + b_3^i + b_4^i + 2b_5^i + 2b_6^i + b_7^i + b_8^i + b_9^i + b_{10}^i}{12} \right]$$

**Vivek et al.,**

**Method II: Heilpern’s Expected Value**

Here, another method using the **Heilpern’s Expected Value** using the notions of the expected value is introduced. These are based on the upper expected values of  $A_i$ , Fuzzy Multi Number for decagonal with its membership function is defined as follows

$$R = \frac{1}{n} \sum_{i=1}^n \left[ \frac{a_1^i + a_2^i + a_3^i + a_4^i + a_5^i + a_6^i + a_7^i + a_8^i + a_9^i + a_{10}^i}{10} \right]$$

**Method III: Sub Interval Average**

Another Ranking Measure based on **Sub-Interval Average** for Ranking of Linear Decagonal Fuzzy Multi Number  $A_i$  is also proposed as follows

$$R = \frac{1}{n} \sum_{i=1}^n \left[ \frac{a_1^i + a_2^i + a_3^i + a_4^i + a_5^i + a_6^i + a_7^i + a_8^i + a_9^i + a_{10}^i}{10} \right]$$

**Method IV: Extended Ranking Measure**

Extended Ranking Measure Decagonal Fuzzy Multi Number  $A_i$  based on is proposed as follows:

$$R = \frac{1}{n} \sum_{i=1}^n [A_{\mu}^i] \text{ where } A_{\mu}^i = \left[ \frac{2a_1^i + 3a_2^i + 4a_3^i + 5a_4^i + 6a_5^i + 6a_6^i + 5a_7^i + 4a_8^i + 3a_9^i + 2a_{10}^i}{40} \right]$$

The two Ranking measures, Graded Mean Integration Representation Method and Expected Value Method of the Fuzzy Multi Numbers and Intuitionistic Fuzzy Multi Numbers lead to proposal of other Ranking Measure of *DFMNs* and *DIFMNs*. By the introduced Ranking Measures, the *DFMNs* & *DIFMNs* are transformed to crisp data, which can use for any multi criteria decision making problems.

**ANALYSIS OF THE RANKING MEASURE**

**Definition 4.1**

The properties of the general ranking measures are

- $R(A_i) > 0$
- $R(A_i, B_i) > 0 \leftrightarrow R(A_i) > R(B_i) \leftrightarrow A_i > B_i$
- $R(A_i, B_i) < 0 \leftrightarrow R(A_i) < R(B_i) \leftrightarrow A_i < B_i$
- $R(A_i, B_i) = 0 \leftrightarrow R(A_i) = R(B_i) \leftrightarrow A_i = B_i$

The Ranking measures of *DFMN* and *DIFMN* satisfies the properties of the ranking measure, even though, the extended ranking measures slightly differ in the  $a_1^i, a_2^i, a_3^i, a_4^i, a_5^i, a_6^i, a_7^i, a_8^i, a_9^i, a_{10}^i$  their formula, they give the same result. To justify the concept to analysis the properties,  $A_i = (a_1^i, a_2^i, a_3^i, a_4^i, a_5^i, a_6^i, a_7^i, a_8^i, a_9^i, a_{10}^i)$ ,  $(b_1^i, b_2^i, b_3^i, b_4^i, b_5^i, b_6^i, b_7^i, b_8^i, b_9^i, b_{10}^i)$  and  $A_i = \{(a_1^i, a_2^i, a_3^i, a_4^i, a_5^i, a_6^i, a_7^i, a_8^i, a_9^i, a_{10}^i) (b_1^i, b_2^i, b_3^i, b_4^i, b_5^i, b_6^i, b_7^i, b_8^i, b_9^i, b_{10}^i)\}$  which the membership function are real numbers of *DFMN* and *DIFMN* the following numerical examples are consider.

**NUMERICAL EXAMPLES OF FUZZY MULTI AND INTUITIONISTIC FUZZY MULTI TRANSPORTATION PROBLEM**

The Transportation problem is associated with day-to-day activities in our real life. Transportation Problem helps insolving problem on distribution and transportation of resources from one place to another and the main objective is to minimize the transportation cost possible by satisfying the demand at destination from supply constraint. But in present situation, due to several uncontrolled reasons, the transportation parameters like demand, supply and unit transportation cost are uncertain. Hence, the fuzzy and intuitionistic fuzzy Multi transportation problem was formulated and solved. Here, we consider the Intuitionistic Fuzzy Transportation Problem (IFMTP) of Decagonal Intuitionistic Fuzzy Multi Number (DIFMN) and intend to describe a methodology and solve. The Intuitionistic Fuzzy Multi Transportation Problem with  $m$  origins (rows) and  $n$  destinations (columns) is considered with  $C_{ij}$ , the cost of transporting one unit of the product from  $i$ th origin to  $j$ th destination.

\_ DECA

$a_i = (a_1^i, a_2^i, a_3^i, a_4^i, a_5^i, a_6^i, a_7^i, a_8^i, a_9^i, a_{10}^i)$  be the quantity of commodity available at origin  $I$  of DECA

\_ DECA

$b_j = (b_j^1, b_j^2, b_j^3, b_j^4, b_j^5, b_j^6, b_j^7, b_j^8, b_j^9, b_j^{10})$  be the quantity of commodity needed a intuitionistic fuzzy destination j of DECA

\_ DECA

$x_{ij} = i = (x_{ij}^1, x_{ij}^2, x_{ij}^3, x_{ij}^4, x_{ij}^5, x_{ij}^6, x_{ij}^7, x_{ij}^8, x_{ij}^9, x_{ij}^{10})$  be the quantity )is the quantity transported from i th origin to j th destination, and using these the minimization of the DIFN transportation cost is formulated as follows, for  $j = 1, 2, \dots, n$  where m is the number of supplies and n is the number of demands.

### METHODOLOGY

Step1: In Intuitionistic Fuzzy Transportation Problem (IFTP) with Hexagonal Intuitionistic Fuzzy Number (HIFN), the HIFN quantities are reduced into an integer using the sign distance ranking number.

Step 2: LCM method is used to find the initial basic feasible solution

Step 3: VCM method is applied to find the optimal solution.

Example 5.1: The **Balanced FMTP** of **category 1** (DFN Supply & Demand parameters).

Example 5.2: The **Balanced IFMTP** of **category 2** (DIFNs Supply & Demand parameters)

**Example: 5.1**

The **Balanced FMTP** of **category1** with **DFMNs** in all Supply & Demand parameters has been considered with three sources and four destinations.

By Applying, the Graded Mean Integration of Decagonal Fuzzy Number, Demand (D1, D2, D3) & Supply (S1, S2, S3) the Ranking Measure Calculations Given below.

$$R = \frac{1}{n} \sum_{i=1}^n \frac{[a_1^i + a_2^i + a_3^i + a_4^i + 2a_5^i + 2a_6^i + a_7^i + a_8^i + a_9^i + a_{10}^i]}{12} + \frac{[b_1^i + b_2^i + b_3^i + b_4^i + 2b_5^i + 2b_6^i + b_7^i + b_8^i + b_9^i + b_{10}^i]}{12}$$

$$R = \frac{1}{2} \sum_{i=1}^n \frac{[14 + 16 + 17 + 19 + 2(20) + 2(21) + 22 + 23 + 24 + 25]}{12} + \frac{[17 + 18 + 19 + 20 + 2(21) + 2(22) + 23 + 24 + 25 + 28]}{12}$$

$$R = \frac{1}{2} \sum_{i=1}^n \frac{[201]}{12} + \frac{[215]}{12} \quad R = \frac{1}{2} \sum_{i=1}^n \frac{[20.1]}{1} + \frac{[21.5]}{1} \quad R = \sum_{i=1}^n \frac{[41.85]}{2} \quad R = 20.85 \quad R = 21$$

By solving in this way obtain the Table5.1, and then use the **LCM method** and obtain the initial basic feasible solution The total transportation cost of the initial solution by LCM is calculated as given below:

Total cost =  $(11*3 + 5*17 + 8*14 + 1*32 + 6* 27 + 12*20) = 664$

and also found the Optimal Solution of Fuzzy Transportation Problem using MODI method is 664.

**Example: 5.2**

The **Balanced IFMTP** of **category1** with **IDFMNs** in all Supply & Demand parameters has been considered with three sources and four destinations.

By Applying, the Graded Mean Integration of Decagonal Fuzzy Number, Demand (D1, D2, D3) & Supply (S1, S2, S3) the Ranking Measure Calculations Given below.

$$R = \frac{1}{n} \sum_{i=1}^n \frac{[a_1^i + a_2^i + a_3^i + a_4^i + 2a_5^i + 2a_6^i + a_7^i + a_8^i + a_9^i + a_{10}^i]}{12} + \frac{[a_1^i + a_2^i + a_3^i + a_4^i + 2a_5^i + 2a_6^i + a_7^i + a_8^i + a_9^i + a_{10}^i]}{12}$$

$$R = \frac{1}{2} \sum_{i=1}^n \frac{[1 + 2 + 2 + 3 + 8 + 10 + 6 + 7 + 8 + 10]}{12} + \frac{[0 + 0 + 1 + 2 + 8 + 10 + 6 + 7 + 9 + 11]}{12} +$$

**Vivek et al.,**

$$\sum_{i=1}^n \frac{[1+2+3+4+5+6+7+8+9+10]}{12}, \frac{[0+2+3+4+5+6+7+8+10+11]}{12}$$

$$R = \frac{1}{2} \sum_{i=1}^n \frac{[66]}{12} + \frac{[66]}{12} \quad R = \frac{1}{2} \sum_{i=1}^n \frac{[5.5]}{1} + \frac{[5.5]}{1} \quad R = \sum_{i=1}^n \frac{[11]}{2} \quad R = 5.5 \quad R = 6$$

By solving in this way obtain the Table 5.2, and then use the **North West Corner method** and obtain the initial basic feasible solution. The total transportation cost of the initial solution by NWC is calculated as given below:

Total cost = (6\*6 + 4\*8 + 9\*2 + 2\*4 + 6\* 1 + 2\*4) = 108

and also found the Optimal Solution of Fuzzy Transportation Problem using MODI method is 108

### CONCLUSION

Fuzzy Multi Transportation Problem (FMTP) and Intuitionistic Fuzzy Multi Transportation Problem (IFMTP) with the Decagonal Fuzzy Multi number (DFMN) and Intuitionistic Fuzzy Multi number (DIFMN) were considered in this article. The presented numerical examples 5.1 and 5.2 for balanced FMTP and IFMTP were under consideration and which shows the efficiency of the proposed methodology. The Ranking Technique was used to transform the DFMN & DIFMN values into the crisp value. Ranking measures defined where found to satisfy all the properties of ranking condition. And it was clear that the results were closer to one another and hence we conclude that these measures are suited for any multi decision-making applications.

## ABSTRACT

In statistical process control, using control charts to analyze any course of action is a common technique. A process may be represented and tracked using a control chart. A control chart can also identify abnormal circumstances and process changes. When the underlying normalcy assumption is not fulfilled, a new six-sigma based control chart that uses the interquartile range (IQR) under normal and exponential distributions for the mean is presented in this research paper in place of the Shewhart (1931) chart. This allows for simpler outlier spotting. Additionally, based on numerical examples and the presumptions of normal and exponential distributions, the performances of these charts were compared. The Shewhart control chart for mean with an illustration performs worse than the suggested robust control chart using IQR.

**Keywords:** Control limit interval, Interquartile range, process capability and six sigma.

## INTRODUCTION

The control chart, which was created in the early 1920s, has become the most widely used and efficient tool for statistical process control (SPC) in business operations. Shewhart (1931) control charts show the process's capability and are used to track changes in mean and variation. There are two sorts of control charts: attribute and variable. Statistical process control techniques are widely used in the industrial sector to detect and eliminate production problems. It's general known that control charts are a crucial tool for manufacturing process monitoring. Through the detection and reduction of variation, statistical process control has been successfully used in the industrial sector to increase process productivity (Deming, 1982). When the variance swings in a predictable or natural way, a stable pattern of several random causes of variation appears. There will always be random sources for variance. When there

### Sivakumaran and Kanneswari

is an assignable source of variation that leads to excessive variation, the process is classified as being out of control or beyond the expected natural variation. In a control chart, control limits can be utilized to pinpoint common or assignable causes of variance.

#### Robust measures

When the fundamental premise of normalcy is broken, this is one of the statistical techniques that is most frequently applied. If the normal assumption is true, these techniques provide a valuable and feasible substitute for conventional statistical approaches and can produce more accurate findings, frequently leading to higher statistical power and sensitivity while remaining efficient (Moustafa Omar Ahmed Abu-Shawiesh, 2008). Spread around the mean is measured by the standard deviation. Therefore, while utilizing the median as the central tendency metric, it is not feasible to compute the standard deviation. When figuring out the dispersion around the median, other data can be more helpful. Calculating the range is one metric that is frequently used to assess the spread. The smallest value in the sample,  $y_1$ , is subtracted from the biggest value,  $y_n$ , to find the range. The range has an issue as it possesses the worst characteristics of both the mean and the median. It is not resistant, just like the mean. The value of the range will be greatly impacted by any outlier, regardless of direction. It disregards the majority of the data's numerical values, much like the median does. That being said, the range offers some valuable information, and calculating it is not too difficult. Instead of having to deal with the outliers, though, we may compute an alternative dispersion measure known as the interquartile range (IQR). Subtracting the first quartile value ( $q_1$ ) from the third quartile value ( $q_3$ ) yields the interquartile range. We define  $q_1$  as the order statistic below which 25% of the data for a sample of observations sits. Similarly, the order statistic, or  $q_3$ , is defined as the value below which 75% of the data falls.

#### Concept of six sigma

Motorola, a large American telecommunications company, is credited with developing the first set of Six Sigma practices and objectives. The folks at Motorola admitted that their superior products seldom ever broke down while being used (www.motorola.com). This discovery led to the development of the Six Sigma strategy, which attempts to systematically improve processes by eliminating defects. Six Sigma is the ability of very skilled procedures to provide results within requirements. More specifically, in terms of faults, Six Sigma quality-driven operations produce less than 3.4 defects per one million opportunities (dpmo). It was proposed by Radhakrishnan (2009) to use the weighted Poisson distribution and the intervening random effect Poisson distribution as the basis line distributions to index a single sample plan to six sigma quality levels (SSQLs). Using the six-sigma concept, Radhakrishnan and Sivakumaran (2009) created mixed sample plans that are indexed by six sigma quality levels and include both an attribute plan and a Chsp-2 plan. Using the Poisson distribution as the foundation line distribution, they developed single, double, and repeated group sampling plans that were indexed by six sigma quality levels (SSQLs) using the six-sigma concept.

Motorola was the pioneer of the corporate management methodology known as Six Sigma, which is now extensively applied across several sectors. By identifying and removing the underlying causes of mistakes, Six Sigma seeks to minimize variation and faults in manufacturing and commercial operations. It creates a distinctive human capital infrastructure within the business and uses a range of quality control methods, including statistical methods.

According to Six Sigma, the following:

- Eliminating volatility in process outputs is a crucial aspect of running a successful business.
- The organization as a whole, and higher management in particular, must be dedicated to attaining consistent quality improvement.
- Business and manufacturing processes are open to measurement, analysis, control, and improvement.

#### Conditions for Application

- The company implements Six Sigma with strong measures quality efforts in its processes;
- There should be less human participation in the overall process/system.

### Sivakumaran and Kanneswari

#### Process capability (C<sub>p</sub>)

An Estimating the process parameters on a regular basis is necessary for quality improvement projects. Keeping an eye on these variables will guarantee that the procedure functions as effectively as feasible. If the process isn't naturally competent, remedial measures need to be implemented, according to Montgomery (2008). These may include putting the process average in the middle of the desired value and determining whether purchasing new machinery or better raw materials can lower the process spread. Another option is to analyze the specs' flexibility by determining the client's preferences.

$$C_p = \frac{USL - LSL}{6\sigma}$$

where USL - Upper specification limit and LSL - Lower specification limit

#### Interquartile range (IQR)

The interquartile range (IQR) is a measurement of variability based on a data set's quartile partition. These quartiles split a rank-ordered data collection into four equal halves. The values that split each section are denoted by the letters Q<sub>1</sub>, Q<sub>2</sub>, and Q<sub>3</sub>, respectively, and are the first, second, and third quartiles (Adekeye, 2012).

- Q<sub>1</sub> is the "middle" value in the first half of the rank-ordered data set
- Q<sub>2</sub> is the median value in the set
- Q<sub>3</sub> is the "middle" value in the second half of the rank-ordered data set

The interquartile range is equal to Q<sub>3</sub> minus Q<sub>1</sub>.

## METHODS AND MATERIALS

The  $\bar{X}_1, \bar{X}_2, \dots, \bar{X}_r$  subgroup represents a sample of size 'r' from a normal population with mean  $\mu$  and standard deviation  $\sigma$ . The data is normally distributed, with a mean of  $\mu$  and a standard deviation that encompasses over 99% of all observations. Since  $\mu$  and  $\sigma$  are unknown, we need to replace them with their unbiased estimators. The unbiased estimator of  $\mu$  is given as

$$\hat{\mu} = \frac{\bar{X}_1 + \bar{X}_2 + \dots + \bar{X}_k}{k} = \bar{\bar{X}}$$

and the biased estimator of  $\sigma$  is given by  $\bar{s} = \frac{s_1 + s_2 + \dots + s_r}{r}$ ,

where

$$s_i^2 = \frac{1}{n} \sum_{j=1}^n (X_{ij} - \bar{X}_i)^2, i = 1, 2, \dots, r$$

Shewhart (1931) proposed the three-sigma probability level under normal distribution  $p(z \leq z_{3\sigma}) = 1 - \alpha_1, \alpha_1 = 0.0027$  for constructing a control chart based on  $3\sigma$ .

$$UCL_{\bar{X}}^{3\sigma} = \bar{\bar{X}} + \left( \frac{3\sigma_{3\sigma}}{\sqrt{n}} \right)$$

$$CL_{\bar{X}}^{3\sigma} = \bar{\bar{X}}$$

$$LCL_{\bar{X}}^{3\sigma} = \bar{\bar{X}} - \left( \frac{3\sigma_{3\sigma}}{\sqrt{n}} \right)$$

The standard deviation  $\left( \sigma_{N,3\sigma}^{\bar{X}-IQR} \right)$  for constructing control limits with three-sigma by using IQR for mean under normal distribution as follows:

**Sivakumaran and Kanneswari**

$$UCL_{N.\bar{X}-IQR}^{3\sigma} = \bar{\bar{X}} + 3 \left( \frac{\sigma_{N.3\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right)$$

$$CL_{N.\bar{X}-IQR}^{3\sigma} = \bar{\bar{X}}$$

$$LCL_{N.\bar{X}-IQR}^{3\sigma} = \bar{\bar{X}} - 3 \left( \frac{\sigma_{N.3\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right)$$

The standard deviation  $\left( \sigma_{E.3\sigma}^{\bar{X}-IQR} \right)$  for constructing control limits with three-sigma by using IQR for mean under exponential distribution as follows:

$$UCL_{E.\bar{X}-IQR}^{3\sigma} = \bar{\bar{X}} + 3 \left( \frac{\sigma_{E.3\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right)$$

$$CL_{E.\bar{X}-IQR}^{3\sigma} = \bar{\bar{X}}$$

$$LCL_{E.\bar{X}-IQR}^{3\sigma} = \bar{\bar{X}} - 3 \left( \frac{\sigma_{E.3\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right)$$

The mean control chart uses the average of subgroup Downton estimator  $\left( D_{n.3\sigma}^{\bar{X}} \right)$  to define control boundaries and the centre line based on the process standard deviation.

In addition to the assumption that the underlying distribution is normal, the process mean and standard deviation are not assigned a standard value. Instead, there are 'r' subgroups, each with 'n' units, from which the process mean and standard deviation will be computed. As is customary, the process mean will be determined by taking the average of the subgroup averages, and the process standard deviation  $\left( D_{n.3\sigma}^{\bar{X}} \right)$  will be derived from the subgroup to lessen the impact of outliers on the control limits under normal distribution.

$$UCL_{Dn.\bar{X}}^{3\sigma} = \bar{\bar{X}} + 3 \left( \frac{D_{n.3\sigma}^{\bar{X}}}{\sqrt{n}} \right)$$

$$CL_{Dn.\bar{X}}^{3\sigma} = \bar{\bar{X}}$$

$$LCL_{Dn.\bar{X}}^{3\sigma} = \bar{\bar{X}} - 3 \left( \frac{D_{n.3\sigma}^{\bar{X}}}{\sqrt{n}} \right)$$

Uma and Balamurugan (2021) proposed the six-sigma probability level under normal distribution  $p(z \leq z_{6\sigma}) = 1 - \alpha_1, \alpha_1 = 3.4 \times 10^{-6}$  for constructing a mean control chart based on  $6\sigma$ .

$$UCL_{\bar{X}}^{6\sigma} = \bar{\bar{X}} + \phi_{6\sigma} \left( \frac{\sigma_{6\sigma}}{\sqrt{n}} \right)$$

$$CL_{\bar{X}}^{6\sigma} = \bar{\bar{X}}$$

$$LCL_{\bar{X}}^{6\sigma} = \bar{\bar{X}} - \phi_{6\sigma} \left( \frac{\sigma_{6\sigma}}{\sqrt{n}} \right)$$

where  $\phi_{6\sigma}$  is the quality control constant based on the six-sigma probability threshold for the normal distribution.

**Sivakumaran and Kanneswari**

The six-sigma mean control chart defines control limits and the centre line based on the process standard deviation  $(D_{n,6\sigma}^{\bar{X}})$  by taking the average of the subgroup Downton estimator.

$$\begin{aligned}
 UCL_{Dn,\bar{X}}^{6\sigma} &= \bar{\bar{X}} + \left( \frac{\phi_{6\sigma} D_{n,6\sigma}^{\bar{X}}}{\sqrt{n}} \right) \\
 CL_{Dn,\bar{X}}^{6\sigma} &= \bar{\bar{X}} \\
 LCL_{Dn,\bar{X}}^{6\sigma} &= \bar{\bar{X}} - \left( \frac{\phi_{6\sigma} D_{n,6\sigma}^{\bar{X}}}{\sqrt{n}} \right)
 \end{aligned}$$

The suggested process standard deviation  $(\tau_{N,6\sigma}^{\bar{X}-IQR})$  for constructing mean control limits with six sigma by using interquartile range (IQR) under normal distribution is used to establish the tolerance level (TL) and process capability. Using the process standard deviation  $(\tau_{N,6\sigma}^{\bar{X}-IQR})$  instead of the standard deviation ( $\sigma$ ) from the control chart for mean yields:

$$\begin{aligned}
 UCL_{N,\bar{X}-IQR}^{6\sigma} &= \bar{\bar{X}} + \left( \frac{\phi_{6\sigma} \tau_{N,6\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right) \\
 CL_{N,\bar{X}-IQR}^{6\sigma} &= \bar{\bar{X}} \\
 LCL_{N,\bar{X}-IQR}^{6\sigma} &= \bar{\bar{X}} - \left( \frac{\phi_{6\sigma} \tau_{N,6\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right)
 \end{aligned}$$

The proposed process standard deviation  $(\tau_{E,6\sigma}^{\bar{X}-IQR})$  for generating mean control limits with six sigma using IQR under exponential distribution is used to determine the tolerance level (TL) and process capabilities. To calculate mean yields, use the process standard deviation  $(\tau_{E,6\sigma}^{\bar{X}-IQR})$  rather than the control chart's standard deviation ( $\sigma$ ).

$$\begin{aligned}
 UCL_{E,\bar{X}-IQR}^{6\sigma} &= \bar{\bar{X}} + \left( \frac{\phi_{6\sigma} \tau_{E,6\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right) \\
 CL_{E,\bar{X}-IQR}^{6\sigma} &= \bar{\bar{X}} \\
 LCL_{E,\bar{X}-IQR}^{6\sigma} &= \bar{\bar{X}} - \left( \frac{\phi_{6\sigma} \tau_{E,6\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right)
 \end{aligned}$$

**Example**

The following data are collected based on temperature at which thermostatic switch operates (temperature units not specified).

**Sivakumaran and Kanneswari**

(i) The control chart for mean based on  $3\sigma$ , then the control limits are as follows:

$$UCL_{\bar{X}}^{3\sigma} = \bar{\bar{X}} + \left( \frac{3\sigma_{3\sigma}}{\sqrt{n}} \right) = 54.32 + \left( \frac{3 \times 1.79}{\sqrt{5}} \right) = 56.72$$

$$CL_{\bar{X}}^{3\sigma} = \bar{\bar{X}} = 54.32$$

$$LCL_{\bar{X}}^{3\sigma} = \bar{\bar{X}} - \left( \frac{3\sigma_{3\sigma}}{\sqrt{n}} \right) = 54.32 - \left( \frac{3 \times 1.79}{\sqrt{5}} \right) = 51.92$$

(ii) The control chart for mean by using interquartile range (IQR) based on  $3\sigma$  under normal distribution, then the control limits are as follows:

$$UCL_{N.\bar{X}-IQR}^{3\sigma} = \bar{\bar{X}} + 3 \left( \frac{\sigma_{N.3\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right) = 54.32 + 3 \left( \frac{1.28}{\sqrt{5}} \right) = 56.03$$

$$CL_{N.\bar{X}-IQR}^{3\sigma} = \bar{\bar{X}} = 54.32$$

$$LCL_{N.\bar{X}-IQR}^{3\sigma} = \bar{\bar{X}} - 3 \left( \frac{\sigma_{N.3\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right) = 54.32 - 3 \left( \frac{1.28}{\sqrt{5}} \right) = 52.61$$

(iii) The control chart for mean by using interquartile range (IQR) based on  $3\sigma$  under exponential distribution, then the control limits are as follows:

$$UCL_{E.\bar{X}-IQR}^{3\sigma} = \bar{\bar{X}} + 3 \left( \frac{\sigma_{E.3\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right) = 54.32 + 3 \left( \frac{1.57}{\sqrt{5}} \right) = 56.42$$

$$CL_{E.\bar{X}-IQR}^{3\sigma} = \bar{\bar{X}} = 54.32$$

$$LCL_{E.\bar{X}-IQR}^{3\sigma} = \bar{\bar{X}} - 3 \left( \frac{\sigma_{E.3\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right) = 54.32 - 3 \left( \frac{1.57}{\sqrt{5}} \right) = 52.22$$

(iv) The control chart for mean by using Downton statistic based on  $3\sigma$ , then the control limits are as follows:

$$UCL_{Dn.\bar{X}}^{3\sigma} = \bar{\bar{X}} + 3 \left( \frac{D_{n.3\sigma}^{\bar{X}}}{\sqrt{n}} \right) = 54.32 + 3 \left( \frac{1.88}{\sqrt{5}} \right) = 56.84$$

$$CL_{Dn.\bar{X}}^{3\sigma} = \bar{\bar{X}} = 54.32$$

$$LCL_{Dn.\bar{X}}^{3\sigma} = \bar{\bar{X}} - 3 \left( \frac{D_{n.3\sigma}^{\bar{X}}}{\sqrt{n}} \right) = 54.32 - 3 \left( \frac{1.88}{\sqrt{5}} \right) = 51.80$$

(v) The six-sigma based control chart for mean, then the control limits are as follows:

$$UCL_{\bar{X}}^{6\sigma} = \bar{\bar{X}} + \phi_{6\sigma} \left( \frac{\sigma_{6\sigma}}{\sqrt{n}} \right) = 54.32 + 4.831 \left( \frac{0.30}{\sqrt{5}} \right) = 54.97$$

$$CL_{\bar{X}}^{6\sigma} = \bar{\bar{X}} = 54.32$$

$$LCL_{\bar{X}}^{6\sigma} = \bar{\bar{X}} - \phi_{6\sigma} \left( \frac{\sigma_{6\sigma}}{\sqrt{n}} \right) = 54.32 - 4.831 \left( \frac{0.30}{\sqrt{5}} \right) = 53.67$$

## Sivakumaran and Kanneswari

(vi) The six-sigma based control chart for mean by using Downton statistic, then the control limits are as follows:

$$UCL_{Dn.\bar{X}}^{6\sigma} = \bar{\bar{X}} + \left( \frac{\phi_{6\sigma} D_{n,6\sigma}^{\bar{X}}}{\sqrt{n}} \right) = 54.32 + \left( \frac{4.831 \times 0.33}{\sqrt{5}} \right) = 55.02$$

$$CL_{Dn.\bar{X}}^{6\sigma} = \bar{\bar{X}} = 54.32$$

$$LCL_{Dn.\bar{X}}^{6\sigma} = \bar{\bar{X}} - \left( \frac{\phi_{6\sigma} D_{n,6\sigma}^{\bar{X}}}{\sqrt{n}} \right) = 54.32 - \left( \frac{4.831 \times 0.33}{\sqrt{5}} \right) = 53.62$$

(vii) The six-sigma based control chart for mean by using interquartile range (IQR) under normal distribution, then the control limits are as follows:

$$UCL_{N.\bar{X}-IQR}^{6\sigma} = \bar{\bar{X}} + \left( \frac{\phi_{6\sigma} \tau_{N,6\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right) = 54.32 + \left( \frac{4.831 \times 0.19}{\sqrt{5}} \right) = 54.72$$

$$CL_{N.\bar{X}-IQR}^{6\sigma} = \bar{\bar{X}} = 54.32$$

$$LCL_{N.\bar{X}-IQR}^{6\sigma} = \bar{\bar{X}} - \left( \frac{\phi_{6\sigma} \tau_{N,6\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right) = 54.32 - \left( \frac{4.831 \times 0.19}{\sqrt{5}} \right) = 53.92$$

(viii) The six-sigma based control chart for mean by using interquartile range (IQR) under exponential distribution, then the control limits are as follows:

$$UCL_{E.\bar{X}-IQR}^{6\sigma} = \bar{\bar{X}} + \left( \frac{\phi_{6\sigma} \tau_{E,6\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right) = 54.32 + \left( \frac{4.831 \times 0.23}{\sqrt{5}} \right) = 54.81$$

$$CL_{E.\bar{X}-IQR}^{6\sigma} = \bar{\bar{X}} = 54.32$$

$$LCL_{E.\bar{X}-IQR}^{6\sigma} = \bar{\bar{X}} - \left( \frac{\phi_{6\sigma} \tau_{E,6\sigma}^{\bar{X}-IQR}}{\sqrt{n}} \right) = 54.32 - \left( \frac{4.831 \times 0.23}{\sqrt{5}} \right) = 53.83$$

The ensuing Table-3, Figure=1 and Figure-2 show that the process is out of control based on six sigma for mean by using interquartile range under normal distribution, since only eight samples fall inside the control limits, with a control limit interval (CLI) of 0.80 compared with other control limits for the sample size n=5. The Table-4 and Figure-3 demonstrate that the six-sigma control chart utilizing interquartile range under normal distribution for mean based on average run length is effective than the existing three-sigma and other control charts.

## CONCLUSION

The previously described findings demonstrate that the process is not statistically controlled when Shewhart 3-Sigma, IQR, and six-sigma based IQR control limits are applied under normal and exponential distributions for mean. Furthermore, there is less space between the Shewhart and IQR control limits and the gap between the six-sigma based control chart. It is obvious that the system or procedure has to be changed since the product or service is not up to grade.

## ABSTRACT

Diabetes has emerged as a critical global health challenge, necessitating more accurate and efficient approaches for identifying optimal treatment methods. This research paper presents a novel approach that combines Hesitant Fuzzy Decision-Making Involving Multiple Criteria (MCDM) with Artificial Intelligence (AI) Supervised Learning Algorithms, specifically Logistic Regression, to determine the most effective diabetes treatment. Hesitant fuzzy sets are employed to address the inherent uncertainty and hesitation in medical decision-making, particularly when diagnostic information is conflicting or imprecise. The proposed model is validated using real-world diabetes datasets, and experimental results demonstrate superior performance in terms of accuracy and uncertainty management when compared to traditional methods. This hybrid approach offers a promising tool for enhancing clinical decision support and delivering more personalized patient care.

**Keywords:** Multi-Criteria Decision Making (MCDM), Hesitant fuzzy (HF), Artificial Intelligence (AI), **Logistic Regression**, Diabetes.

## INTRODUCTION

Diabetes is a long-term condition marked by high blood sugar levels, caused by either inadequate insulin production, the body's inability to use insulin effectively, or a combination of both. Regular monitoring, patient education, and a personalized treatment plan are essential components of successful diabetes management. Making decisions based on multiple criteria (MCDM) is an essential approach for assessing complex alternatives based on multiple conflicting criteria. However, these methods often encounter difficulties in addressing the uncertainties and imprecisions

**Iswariya and Sahaya Sudha**

commonly found in real-world scenarios (Yildirim & Yildirim, 2021)[14]. To address these challenges, recent advancements in MCDM have focused on integrating fuzzy and hesitant fuzzy frameworks, which help accommodate the complexities inherent in decision-making environments (Mishra et al., 2021)[8]. The literature indicates that these advancements significantly improve decision accuracy and reliability, resulting in more effective solutions for problems ranging from supplier selection to risk management (Hadi & Abdullah, 2022) [3].

Fuzzy logic has emerged as a vital methodology for addressing the uncertainties present in decision-making processes. Pioneered by Zadeh (1965), fuzzy logic allows for the representation of vague or imprecise information through degrees of truth, enabling more nuanced decision-making than traditional binary logic. For instance, fuzzy logic has been used in healthcare for diagnostic purposes, where symptoms may not clearly correlate with specific conditions (Dey et al., 2018) [2]. Additionally, its flexibility extends to educational contexts, where fuzzy logic aids in assessing student performance and learning outcomes in uncertain environments (Jain & Kumar, 2019)[5]. This adaptability highlights the significance of fuzzy logic in developing advanced decision-making frameworks capable of accommodating the complexities of real-world scenarios.

H Hesitant fuzzy sets (HFS) are an important advancement in fuzzy set theory, enabling the representation of multiple membership values to capture the uncertainty and hesitation often faced by decision-makers. Introduced by Torra and Narukawa (2009)[13], HFS provides a mathematical framework that acknowledges the complexity of human judgment. For example, Rani et al. (2021)[11] applied HFS in supplier selection, demonstrating its capability to enhance decision accuracy by capturing the nuances of expert assessments. Hesitant fuzzy sets have been extensively utilized in MCDM frameworks, enhancing the evaluation process by incorporating the hesitance of decision-makers. For instance, Hadi and Abdullah (2022) [3] introduced a hybrid MEREC-TOPSIS method that integrates hesitant fuzzy sets to improve the selection of IoT-based hospital locations. Similarly, Mishra et al. (2022)[9] employed hesitant fuzzy frameworks to evaluate alternative fuels concerning sustainability. One significant challenge is the need for suitable aggregation methods to combine multiple hesitant fuzzy evaluations, as traditional techniques may inadequately capture the complexities of expert judgments (Zheng et al., 2018)[15]. Furthermore, the computational complexity of hesitant fuzzy decision-making models can hinder practical applications, particularly in scenarios involving large datasets or numerous criteria (Nguyen et al., 2020)[10].

Logistic classification technique is a versatile model that works with both categorical and continuous predictor variables, making it useful in diverse fields like healthcare, finance, and social sciences. Numerous studies have demonstrated its efficiency as a classification method across these areas. In healthcare, **Hosmer and Lemeshow (2000) [4]** emphasized the utility of logistic regression for predicting disease outcomes based on risk factors, illustrating its role in developing clinical decision support systems. Furthermore, logistic regression has been integrated into multi-criteria decision-making frameworks, enhancing its applicability in complex decision environments. **Kahraman et al. (2009) [6]** explored the combination of logistic regression with fuzzy logic to improve decision-making under uncertainty, showcasing its adaptability to various contexts. For instance, **Chawla et al. (2002) [1]** highlighted the performance of logistic regression in imbalanced datasets, demonstrating its robustness when combined with resampling techniques.

Integrating hesitant fuzzy sets helps to better manage the uncertainties and hesitations common in medical decision-making, enabling a more refined assessment of different options. This hybrid approach combines the strengths of logistic regression and fuzzy logic, facilitating better clinical decision support and enabling healthcare professionals to make informed, patient-centered choices. Ultimately, this research highlights the potential of advanced MCDM frameworks in improving diabetes management and outcomes, offering a promising direction for future studies in this critical area of healthcare.

**Iswariya and Sahaya Sudha**

**PRELIMINARIES**

**Definition 2.1[12]**

Let S be a fixed set, a fuzzy set with hesitant membership values on S is defined by a function that maps each element in S returns a subset of [0,1]. As introduced by Torra, this concept is described as follows

$$H = \{ \langle x, g_G(s) \rangle | s \in S \}$$

where  $g_G(s)$  is a set of some values in [0,1], denoting the possible membership degrees of the element  $s \in S$  to the set H. In this context, a fuzzy set with hesitant membership values is represented as  $g_G(s)$ .

**Definition 2.2[12]**

For three fuzzy sets characterized by hesitant membership values, represented as  $g, g_1, g_2$ , the following operations are proposed:

- (i)  $g^c = \bigcup_{\gamma \in g} \{1 - \gamma\}$ ;
- (ii)  $g_1 \cup g_2 = \bigcup_{\gamma \in g_1, \gamma \in g_2} \max\{\gamma_1, \gamma_2\}$ ;
- (iii)  $g_1 \cap g_2 = \bigcap_{\gamma \in g_1, \gamma \in g_2} \min\{\gamma_1, \gamma_2\}$ ;
- (iv)  $g^\lambda = \bigcup_{\gamma \in g} \{\gamma^\lambda\}$ ;
- (v)  $\lambda g = \bigcup_{\gamma \in g} \{1 - (1 - \gamma)^\lambda\}$ ;
- (vi)  $g_1 \oplus g_2 = \bigcup_{\gamma \in g_1, \gamma \in g_2} \{\gamma_1 + \gamma_2 - \gamma_1 \gamma_2\}$ ;
- (vii)  $g_1 \otimes g_2 = \bigcup_{\gamma \in g_1, \gamma \in g_2} \{\gamma_1 \cdot \gamma_2\}$ ;

**Definition 2.3 [12]**

For a fuzzy set with hesitant membership values  $g_G(s)$ , the score function  $F(g_G(s))$  is defined as follows:

$$Z(g_G(s)) = \frac{\sum_{j=1}^{l(g_G(s))} g_G^{\sigma(j)}(s)}{l(g_G(s))}, \quad Z(g_G(s)) \in [0,1]$$

Using the above function, fuzzy set with hesitant membership values can be ranked based on the following rules:

- $g_1 > g_2$ , if  $z(g_1) > z(g_2)$  ;
- $g_1 < g_2$ , if  $z(g_1) < z(g_2)$  ;
- $g_1 = g_2$ , if  $z(g_1) = z(g_2)$ .

$g_1$  and  $g_2$  are two elements in fuzzy set with hesitant membership values.

**PROPOSED FUZZY DECISION-MAKING METHOD WITH HESITANT MEMBERSHIP INVOLVING MULTIPLE CRITERIA WITH LOGISTIC ANALYSIS:**

In this part, a new decision-making method designed to tackle MCDM challenges in the fuzzy set with hesitant membership values domain. The following outlines the steps of the hybrid framework:

**STEP 1: Define Alternatives, Criteria, and Decision Experts**

In an MCDM problem within the HF domain, consider a set of alternatives  $O = \{O_1, O_2, \dots, O_m\}$  and the Parameters  $K = \{K_1, K_2, \dots, K_n\}$ . A group of decision experts  $E = \{DE_1, DE_2, \dots, DE_l\}$  provides their assessments of each alternative  $A_i$  concerning each parameters  $P_j$  using linguistic values. The linguistic matrices are then transformed into hesitant fuzzy matrices. Following this, an aggregated hesitant decision matrix is constructed. The matrix of fuzzy values with hesitant membership values is transformed into a clear value matrix by applying a below formula.

**Iswariya and Sahaya Sudha**

$$R(B) = \frac{1}{2}[a_1 + a_2] \quad (3.1.1)$$

**STEP 2: Normalize Criteria using Min-Max Scaling**

The min-max normalization technique adjusts the data to fit within a range of 0 to 1, employing the following formula:

$$B' = \frac{B - B_{\min}}{B_{\max} - B_{\min}} \quad (3.1.2)$$

**STEP 3: Initialize the weights and bias**

Calculate the weights ( $\sigma$ ), as given by

$$\sigma_j = \frac{\sum_{i=1}^m d_{ij}}{\sum_{i=1}^m \sum_{j=1}^n d_{ij}} \quad (3.1.3)$$

Initialize the bias  $b$  to a small random value.

**STEP 4: Predicted Probability using Logistic Regression Formula**

The logistic regression equation for Predicted Probability is:

$$P(O_i) = \frac{1}{1 + e^{z_i}} \quad (3.1.4)$$

Where  $z_i = \sum_{j=1}^n \sigma_j x_{ij} + b$

**STEP 5: Rank the Alternatives**

Order the alternatives by arranging them in descending order based on their predicted probabilities.

**4. CASE ANALYSIS BY IMPLEMENTING THE SUGGESTED MCDM APPROACH:**

**STEP 1:** Establish the alternatives and Parameters

**STEP 2: Normalize Criteria using Min-Max Scaling**

After performing the min-max scaling for all alternatives and criteria, the normalized values are

**STEP 3: Initialize the weights and bias**

Calculate the weight using the formula (3.1.2) and initialize the bias  $b$  to a small random value, such as 0.01.

Then the weights are  $W = (0.1008, 0.0954, 0.1218, 0.0976, 0.0758, 0.1228, 0.1019, 0.0919, 0.1043, 0.0878)$

**STEP 4: Predicted Probability using Logistic Regression Formula**

Calculate the logistic regression equation for Predicted Probability using the formula 3.1.3

**STEP 5: Rank the Alternatives**

Based on the analysis of alternatives for diabetes management, Insulin Therapy ( $A_1$ ) ranks the highest with the highest probability of success  $P(A_1) = 0.3516$ , indicating it may be the most effective option among the evaluated methods. This ranking helps prioritize treatment approaches based on their perceived likelihood of success.

## CONCLUSION

This research underscores the need for innovative approaches to diabetes treatment selection, combining Hesitant Fuzzy Multi-Criteria Decision Making (MCDM) with AI-driven Logistic Regression. Hesitant fuzzy sets are employed to address the inherent uncertainty and hesitation in medical decision-making, particularly when diagnostic information is conflicting or imprecise. The proposed model effectively manages uncertainties in medical

**Iswariya and Sahaya Sudha**

decision-making, showing superior performance in diagnostic accuracy compared to traditional methods. Analysis of treatment alternatives identifies Insulin Therapy and Bariatric Surgery as the most effective options. This systematic ranking aids in prioritizing treatment modalities based on effectiveness. Overall, this hybrid approach enhances clinical decision support and promotes personalized patient care, paving the way for future research in chronic disease management.

### ABSTRACT

A directed graph, also known as a digraph, is a graph that consists of vertices joined by directed edges, which can also be referred to as arcs. In this study, the idea of minimum dominating energy is expanded to digraphs. A subset of vertex set is dominating set of a digraph if the union of closed out-neighborhoods of vertices in dominating set equals vertex set of digraph. The minimum dominating matrix of digraph is defined and eigen values of minimum dominating matrix are calculated. The minimum dominating energy is determined using these eigen values. Further, the properties of eigen values are stated and boundaries of minimum dominating energy of digraphs are computed.

**Key words:** digraph, domination, minimum dominating matrix.

**2020 AMS subject classification:** 05C20,05C50, 05C69, 05C90, 15A18

### INTRODUCTION

A directed graph  $\vec{R} = (\mathfrak{X}, \mathfrak{z})$  has a limited number of vertices and an ordered set of pairs of distinct vertices, referred to as arcs. If an arc connects two vertices, then they are considered adjacent. We write  $\vec{pq}$  if there is an arc from  $p$  to  $q$ , which is also given by  $pq$ . A directed walk of length  $x$  from  $p$  to  $q$  is given by  $p = p_0, p_1, \dots, p_x = q$ , where  $p_{y-1}p_y$  is an arc of  $\vec{R}$  for all  $1 \leq y \leq x$ . A walk is closed if  $p = q$ . In digraph  $\vec{R}$ , there are arcs pointing in the direction towards a

**Maheswari and Lincy**

node and arcs pointing away from a node. This is known as the indegree and outdegree of the nodes respectively.  $\vec{R}$  is symmetric if  $pq \in \mathfrak{z}$  then  $qp \in \mathfrak{z}$ , where  $p, q \in \mathfrak{z}$ . An orientated graph is a digraph that does not have symmetric pairs of arcs. Between the graphs and symmetric digraphs, there exists a one to one correspondence, which is given by  $R \rightsquigarrow \vec{R}$ , where  $\vec{R}$  and  $R$  has the same vertices, and a pair of symmetric arcs,  $pq$  and  $qp$ , substitute each edge,  $pq$ , of  $R$ .

The adjacency matrix  $\mathfrak{B}$  of  $\vec{R}$  with  $\mathfrak{X} = \{p_1, p_2, \dots, p_b\}$  is an  $b \times b$  matrix whose entry  $b_{ij}$  is given by

$$b_{ij} = \begin{cases} 1 & \text{if } p_i p_j \in \mathfrak{z} \\ 0 & \text{otherwise} \end{cases}$$

The characteristic polynomial of  $\vec{R}$  is calculated by  $|zI - \mathfrak{B}|$ . The eigen values of  $\vec{R}$  is given by eigen values of  $\mathfrak{B}$ . Since  $\mathfrak{B}$  is not necessarily a symmetric matrix, eigen values of  $\mathfrak{B}$  are complex numbers. These eigen values form the spectrum of  $\vec{R}$ , which is denoted by  $Spec(\vec{R}) = \{z_1, z_2, \dots, z_b\}$ . The energy of  $\vec{R}$ [6] is given by

$$\mathcal{E}(\vec{R}) = \sum_{t=1}^b |Re z_t|$$

where  $z_t$  are complex(possibly) eigen values of  $\vec{R}$  and  $Re z_t$  denotes the real part of  $z_t$ . Domination in digraph is dealt with in [1,2,3]. In this study, the idea of minimum dominating energy[7] is expanded to digraphs.

**The minimum dominating energy of a digraph**

Let  $\vec{R}$  be digraph with  $\mathfrak{X} = \{p_1, p_2, \dots, p_b\}$  and arc set  $\mathfrak{z}$ . A set  $\mathcal{S} \subseteq \mathfrak{X}(\vec{R})$  is dominating set[4] of  $\vec{R}$  if for each  $q \notin \mathcal{S}$ , there exists  $p \in \mathcal{S}$  such that  $(p, q)$  is an arc of  $\vec{R}$ . A dominating set of  $\vec{R}$  which has the smallest cardinality is termed as minimum dominating set[5] of  $\vec{R}$  and its cardinality is domination number  $\eta$  of  $\vec{R}$ . The minimum dominating matrix of  $\vec{R}$  is a  $b \times b$  matrix given by  $\mathfrak{B}_\mathcal{S}(\vec{R}) := (b_{uv})$ , where

$$b_{uv} = \begin{cases} 1 & \text{if } p_u p_v \in \mathfrak{z} \\ 1 & \text{if } u = v \text{ and } p_u \in \mathcal{S} \\ 0 & \text{otherwise} \end{cases}$$

The characteristic polynomial of  $\mathfrak{B}_\mathcal{S}(\vec{R})$  is calculated by  $\psi(\vec{R}, \lambda) = |\lambda I - \mathfrak{B}_\mathcal{S}(\vec{R})|$ . The minimum dominating eigen values of  $\vec{R}$  is given by eigen values of  $\mathfrak{B}_\mathcal{S}(\vec{R})$ . Since  $\mathfrak{B}_\mathcal{S}(\vec{R})$  is not necessarily a symmetric matrix, eigen values of  $\mathfrak{B}_\mathcal{S}(\vec{R})$  are complex(possibly) numbers. The spectrum of  $\vec{R}$  is  $Spec(\vec{R}) = \left\{ \begin{matrix} \lambda_1 & \lambda_2 & \dots & \lambda_b \\ m_1 & m_2 & \dots & m_b \end{matrix} \right\}$  where  $m_j$  indicates algebraic multiplicity of  $\lambda_j$ . The minimum dominating energy of  $\vec{R}$  is given by

$$E_\mathcal{S}(\vec{R}) = \sum_{u=1}^b |Re \lambda_u|$$

where  $\lambda_u$  are the complex(possibly) eigen values of  $\vec{R}$  and  $Re \lambda_u$  indicates the real part of  $\lambda_u$ .

**Example:**

Consider a directed cycle graph  $\vec{C}_4$  with vertex set  $\mathfrak{X} = \{p_1, p_2, p_3, p_4\}$  and arc set  $\mathfrak{z} = \{p_1 p_2, p_2 p_3, p_3 p_4, p_4 p_1\}$ . The minimum dominating matrix of  $\vec{C}_4$  is the  $4 \times 4$  matrix given by

$$\mathfrak{B}_\mathcal{S}(\vec{C}_4) = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix}$$

Then the minimum dominating set of the digraph  $\vec{C}_4$  is  $\mathcal{S} = \{p_1, p_3\}$ .

The characteristic polynomial of  $\mathfrak{B}_\mathcal{S}(\vec{C}_4)$  is  $\psi(\vec{C}_4, \lambda) = |\lambda I - \mathfrak{B}_\mathcal{S}(\vec{C}_4)| = (\lambda^2 - \lambda - 1)(\lambda^2 - \lambda + 1)$ . The minimum dominating eigen values of  $\vec{C}_4$  are  $\lambda = 1.618, 0.618, 0.5 + 0.866025i, 0.5 - 0.866025i$ . Hence  $E_\mathcal{S}(\vec{C}_4) = 1.618 + 0.618 + 0.5 + 0.5 = 3.236$ .

**Minimum dominating energy of some oriented digraphs**

**Definition 3.1.**

A directed path  $\vec{P}_b$  is a path, with  $b$  vertices and  $b - 1$  arcs, wherein every edge is oriented in a clockwise manner. The arc set of  $\vec{P}_b$  is given by  $\{p_i p_{i+1} | i = 1, 2, \dots, b - 1\}$ .

**Maheswari and Lincy**

**Theorem 3.2.**

Let  $\vec{P}_\delta$  be a directed path where  $\delta \geq 3$ . Then  $E_S(\vec{P}_\delta) = \delta = \lfloor \frac{\delta}{2} \rfloor$ .

**Proof:**

Let  $\vec{P}_\delta$  be directed path with  $\mathfrak{X} = \{p_1, p_2, \dots, p_\delta\}$  and arc set  $\mathfrak{z} = \{p_i p_{i+1} | i = 1, 2, \dots, \delta - 1\}$ . Then  $\mathcal{S} = \{p_i, i = 1 \leq i \leq \lfloor \frac{\delta}{2} \rfloor\}$ . Hence  $\mathfrak{B}_S(\vec{P}_\delta)$  is given by the Jordan matrix, which is a  $\delta \times \delta$  matrix of zeros everywhere except for the diagonal, which is filled with  $\rho$  and for the super diagonal, which is composed of ones and  $\rho = a_{ii} = \begin{cases} 1 & i \text{ is odd} \\ 0 & i \text{ is even} \end{cases}$ .

The characteristic equation is given in two cases

**Case i:**  $\delta$  is even

The characteristic equation of  $\vec{P}_\delta$  is given by  $\lambda^\delta (\lambda - 1)^\delta = 0$ .

Spectrum of  $\vec{P}_\delta = \begin{pmatrix} 0 & 1 \\ \delta & \delta \end{pmatrix}$ . The minimum dominating eigen values of  $\vec{P}_\delta$  are  $\lambda = 0$  [ $\delta$  times] and  $\lambda = 1$  [ $\delta$  times].

Therefore,  $E_S(\vec{P}_\delta) = |0|(\delta) + |1|(\delta) = \delta = \lfloor \frac{\delta}{2} \rfloor$ .

**Case ii:**  $\delta$  is odd

The characteristic equation of  $\vec{P}_\delta$  is given by  $\lambda^{\delta-1} (\lambda - 1)^\delta = 0$ .

Spectrum of  $\vec{P}_\delta = \begin{pmatrix} 0 & 1 \\ \delta - 1 & \delta \end{pmatrix}$ . The minimum dominating eigen values of  $\vec{P}_\delta$  are  $\lambda = 0$  [ $\delta - 1$  times] and  $\lambda = 1$  [ $\delta$  times].

Therefore,  $E_S(\vec{P}_\delta) = |0|(\delta - 1) + |1|(\delta) = \delta = \lfloor \frac{\delta}{2} \rfloor$ .

**Definition 3.3.**

A directed star  $\vec{K}_{1,\delta-1}$  is known as directed in-star, denoted by  $\vec{iK}_{1,\delta-1}$ , if all the arcs are directed towards the central vertex.

**Theorem 3.4.**

Let  $\vec{iK}_{1,\delta-1}$  be a directed in-star where  $\delta \geq 3$ . Then  $E_S(\vec{iK}_{1,\delta-1}) = \delta - 1$ .

**Proof:**

Consider the directed in-star  $\vec{iK}_{1,\delta-1}$  with vertex set  $\mathfrak{X} = \{p_1, p_2, \dots, p_\delta\}$  and arc set  $\mathfrak{z} = \{p_1 p_0, p_2 p_0, \dots, p_\delta p_0\}$ . Then  $\mathcal{S} = \{p_i, i = 1 \leq i \leq \delta - 1\}$ . Hence  $\mathfrak{B}_S(\vec{iK}_{1,\delta-1})$  is given by

$$\mathfrak{B}_S(\vec{iK}_{1,\delta-1}) = \begin{bmatrix} \mathcal{O}_{1 \times 1} & \mathcal{O}_{1 \times (\delta-1)} \\ \mathcal{J}_{(\delta-1) \times 1} & I_{(\delta-1) \times (\delta-1)} \end{bmatrix}_{\delta \times \delta}$$

The characteristic equation of  $\vec{iK}_{1,\delta-1}$  is  $\lambda(\lambda - 1)^{\delta-1} = 0$ . Spectrum of  $\vec{iK}_{1,\delta-1} = \begin{pmatrix} 0 & 1 \\ 1 & \delta - 1 \end{pmatrix}$ . The minimum dominating eigen values of  $\vec{iK}_{1,\delta-1}$  are  $\lambda = 0$  [one time] and  $\lambda = 1$  [ $(\delta - 1)$  times]. Therefore  $E_S(\vec{iK}_{1,\delta-1}) = |0|(1) + |1|(\delta - 1) = \delta - 1$ .

**Definition 3.5.**

A directed star  $\vec{K}_{1,\delta-1}$  is known as directed out-star, denoted by  $\vec{\sigma K}_{1,\delta-1}$ , if every arc is pointed in the opposite direction of the central vertex.

**Theorem 3.6.**

Let  $\vec{\sigma K}_{1,\delta-1}$  be a directed out-star where  $\delta \geq 3$ . Then  $E_S(\vec{\sigma K}_{1,\delta-1}) = 1$ .

**Proof:**

Consider the directed out-star  $\vec{\sigma K}_{1,\delta-1}$  with vertex set  $\mathfrak{X} = \{p_0, p_1, p_2, \dots, p_{\delta-1}\}$  and arc set  $\mathfrak{z} = \{p_0 p_1, p_0 p_2, \dots, p_0 p_{\delta-1}\}$ . Then  $\mathcal{S} = \{p_0\}$ . Hence  $\mathfrak{B}_S(\vec{\sigma K}_{1,\delta-1})$  is given by

$$\mathfrak{B}_S(\vec{\sigma K}_{1,\delta-1}) = \begin{bmatrix} \mathcal{J}_{1 \times \delta} \\ \mathcal{O}_{(\delta-1) \times \delta} \end{bmatrix}_{\delta \times \delta}$$

The characteristic equation of  $\vec{\sigma K}_{1,\delta-1}$  is  $\lambda^{\delta-1} (\lambda - 1) = 0$ . Spectrum of  $\vec{\sigma K}_{1,\delta-1} = \begin{pmatrix} 0 & 1 \\ \delta - 1 & 1 \end{pmatrix}$ . The minimum dominating eigen values of  $\vec{\sigma K}_{1,\delta-1}$  are  $\lambda = 0$  [ $(\delta - 1)$  times] and  $\lambda = 1$  [one time]. Therefore,  $E_S(\vec{\sigma K}_{1,\delta-1}) = |0|(\delta - 1) + |1|(1) = 1$ .

**Maheswari and Lincy**

**Definition 3.7.**

A digraph obtained by subdividing  $p(1 \leq p < d)$  arcs of the directed star  $\vec{K}_{1,d-1}$  is known as directed wounded spider  $\vec{S}_{d,p}$  of order  $d + p + 1$ . If  $d = p$ , then the digraph  $\vec{S}_{d,d}$  is called directed spider.

**Theorem 3.8.**

Let  $\vec{S}_{d,d}$  be a directed spider where  $d \geq 2$ . Then  $E_S(\vec{S}_{d,d}) = d + 1$ .

**Proof:**

Consider the directed spider  $\vec{S}_{d,d}$  with vertex set  $\mathfrak{X} = \{p_1, p_2, \dots, p_d\}$  and arc set  $\mathfrak{z} = \{p_1p_2, p_1p_3, \dots, p_1p_{d+1}, p_2p_{d+2}, p_3p_{d+3}, \dots, p_{d+1}p_{2d+1}\}$ . Then  $\mathcal{S} = \{p_i, 1 \leq i \leq d + 1\}$ . Hence  $\mathfrak{B}_S(\vec{S}_{d,d})$  is given by

$$\mathfrak{B}_S(\vec{S}_{d,d}) = \begin{bmatrix} \mathcal{J}_{1 \times (d+1)} & \mathcal{O}_{1 \times d} \\ \mathcal{O}_{d \times (d+1)} & \mathcal{I}_{d \times d} \\ \mathcal{O}_{d \times (d+1)} & \mathcal{I}_{d \times d} \end{bmatrix}_{(2d+1) \times (2d+1)}$$

The characteristic equation of  $\vec{S}_{d,d}$  is  $\lambda^d(\lambda - 1)^{d+1} = 0$ . Spectrum of  $\vec{S}_{d,d} = \begin{pmatrix} 0 & 1 \\ d & d + 1 \end{pmatrix}$ . The minimum dominating eigen values of  $\vec{S}_{d,d}$  are  $\lambda = 0$  [ $d$  times] and  $\lambda = 1$  [ $d + 1$  times]. Therefore,  $E_S(\vec{S}_{d,d}) = |0|(d) + |1|(d + 1) = d + 1$ .

**Definition 3.9**

The directed globe graph  $\vec{G}_d$  is a digraph that is made by connecting two isolated vertices  $u, v$  with  $d$  paths of length 2 with arc set  $\{up_1, \dots, up_d, p_1v, \dots, p_dv\}$ .

**Theorem 3.10.**

Let  $\vec{G}_d$  be a directed globe graph where  $d \geq 2$ . Then  $E_S(\vec{G}_d) = 2$ .

**Proof:**

Consider the directed globe graph  $\vec{G}_d$  with vertex set  $\mathfrak{X} = \{u, v, p_1, p_2, \dots, p_d\}$  and arc set  $\mathfrak{z} = \{up_1, \dots, up_d, p_1v, \dots, p_dv\}$ . Then  $\mathcal{S} = \{u, v\}$ . Hence  $\mathfrak{B}_S(\vec{G}_d)$  is given by

$$\mathfrak{B}_S(\vec{G}_d) = \begin{bmatrix} \mathcal{J}_{1 \times (d+1)} & \mathcal{O}_{1 \times 1} \\ \mathcal{O}_{(d+1) \times (d+1)} & \mathcal{J}_{(d+1) \times 1} \end{bmatrix}_{(d+2) \times (d+2)}$$

The characteristic equation of  $\vec{G}_d$  is  $\lambda^d(\lambda - 1)^2 = 0$ . Spectrum of  $\vec{G}_d = \begin{pmatrix} 0 & 1 \\ d & 2 \end{pmatrix}$ . The minimum dominating eigen values of  $\vec{G}_d$  are  $\lambda = 0$  [ $d$  times] and  $\lambda = 1$  [ $2$  times]. Therefore  $E_S(\vec{G}_d) = |0|(d) + |1|(2) = 2$ .

**Definition 3.11.**

The directed comb graph, denoted as  $\vec{C}_d$ , is given by using pendant edge to join each vertex of  $\vec{P}_d$ . It has  $2d$  vertices and  $2d - 1$  arcs.

**Theorem 3.12.**

Let  $\vec{C}_d$  be a directed comb graph where  $d \geq 2$ . Then  $E_S(\vec{C}_d) = d$ .

**Proof:**

Consider the directed comb graph  $\vec{C}_d$  with vertex set  $\mathfrak{X} = \{p_1, p_2, \dots, p_d, q_1, q_2, \dots, q_d\}$  where  $\{p_1, p_2, \dots, p_d\}$  are the vertices of  $\vec{P}_d$ .

**Case i** If arc set  $\mathfrak{z} = \{q_1p_1, q_2p_2, \dots, q_dp_d\} \cup \{p_i p_{i+1} | i = 1, 2, \dots, d - 1\}$ . Then  $\mathcal{S} = \{q_1, q_2, \dots, q_d\}$ . Hence  $\mathfrak{B}_S(\vec{C}_d)$  is given by

$$\mathfrak{B}_S(\vec{C}_d) = \begin{bmatrix} \mathcal{W}_{d \times d} & \mathcal{O}_{d \times d} \\ \mathcal{I}_{d \times d} & \mathcal{I}_{d \times d} \end{bmatrix}_{2d \times 2d}$$

where  $\mathcal{W}$  is a  $d \times d$  matrix of zeros everywhere except for the super diagonal with value 1. The characteristic equation of  $\vec{C}_d$  is  $\lambda^d(\lambda - 1)^d = 0$ . Spectrum of  $\vec{C}_d = \begin{pmatrix} 0 & 1 \\ d & d \end{pmatrix}$ . The minimum dominating eigen values of  $\vec{C}_d$  are  $\lambda = 0$  [ $d$  times] and  $\lambda = 1$  [ $d$  times]. Therefore  $E_S(\vec{C}_d) = |0|(d) + |1|(d) = d$ .

**Case ii** If arc set  $\mathfrak{z} = \{p_1q_1, p_2q_2, \dots, p_dq_d\} \cup \{p_i p_{i+1} | i = 1, 2, \dots, d - 1\}$ . Then  $\mathcal{S} = \{p_1, p_2, \dots, p_d\}$ . Hence  $\mathfrak{B}_S(\vec{C}_d)$  is given by

$$\mathfrak{B}_S(\vec{C}_d) = \begin{bmatrix} \mathcal{J}_{d \times d} & \mathcal{I}_{d \times d} \\ \mathcal{O}_{d \times d} & \mathcal{O}_{d \times d} \end{bmatrix}_{2d \times 2d}$$

where  $\mathcal{J}$  is a  $d \times d$  Jordan matrix of zeros everywhere except for the diagonal, which is filled with  $\rho = 1$  and for the super diagonal, which is composed of ones. The characteristic equation of  $\vec{C}_d$  is  $\lambda^d(\lambda - 1)^d = 0$ . Spectrum of  $\vec{C}_d =$

**Maheswari and Lincy**

$\begin{pmatrix} 0 & 1 \\ \delta & \delta \end{pmatrix}$ . The minimum dominating eigen values of  $\vec{C}_\delta$  are  $\lambda = 0$  [ $\delta$  times] and  $\lambda = 1$  [ $\delta$  times]. Therefore  $E_S(\vec{C}_\delta) = |\delta| + |\delta| = 2\delta$ .

**Corollary 3.13.**

$E_S(\vec{C}_\delta)$  is independent of direction of the pendant vertices which are joined to every vertex of  $\vec{P}_\delta$ .

**Minimum dominating energy of some symmetric digraphs**

**Theorem 4.1.**

Let  $R$  be a graph and  $\vec{R}$  be its symmetric digraph. Then the minimum dominating energy of  $R$  and  $\vec{R}$  are equal.

**Proof:**

Let  $\{p_1, p_2, \dots, p_\delta\}$  be the vertex set of  $R$  and  $\vec{R}$ . If there is an edge in  $R$ , say  $p_u p_v$ , then in a symmetric digraph  $\vec{R}$  we have two arcs namely  $p_u p_v, p_v p_u$ . Hence we get same adjacency matrix for both  $R$  and  $\vec{R}$ . We can infer from the graphs of  $R$  and  $\vec{R}$  that dominating set (minimum) of  $R$  and symmetric digraph  $\vec{R}$  are the same. Therefore, we have the same minimum dominating matrix for both  $R$  and  $\vec{R}$ . This implies that the eigen values of  $R$  and  $\vec{R}$  are equal with one spectrum. Hence we conclude that  $E_S(\vec{R}) = E_S(R)$ .

**Corollary 4.2.**

$E_S(\vec{R})$  of some symmetric digraphs – cocktail party digraph  $\vec{CP}_\delta$ , star digraph  $\vec{S}_\delta$ , complete digraph  $\vec{K}_\delta$ , crown graph  $\vec{S}^0_\delta$  are

$$\begin{aligned} E_S(\vec{CP}_\delta) &= (2\delta - 3) + \sqrt{4\delta^2 - 4\delta - 9} \\ E_S(\vec{S}_\delta) &= \sqrt{4\delta - 3} \\ E_S(\vec{K}_\delta) &= (\delta - 2) + \sqrt{\delta^2 - 2\delta + 5} \\ E_S(\vec{S}^0_\delta) &= 2(\delta - 2) + \sqrt{\delta^2 - 2\delta + 5} + \sqrt{\delta^2 + 2\delta - 3} \end{aligned}$$

**Application:**

**Construction of airports**

To construct a directed graph, flights are used as the input. The vertices of the digraph are all the serviced cities, and a directed edge will link the flight's departure and arrival locations. The weights on the arcs match the amount of crew members needed for the trip. It is necessary to add a source vertex and sink vertex to finish flow network. The source is placed at airport's base city, which supplies workers, while sink vertex is placed at every terminal city.

By using minimum domination matrix in digraph, the airport may be constructed in the cities in dominating vertices so that it covers all remaining vertices. Consequently, the cost of construction is minimized.

**CONCLUSION**

In this paper,  $\mathfrak{B}_S(\vec{R})$  is defined and  $E_S(\vec{R})$  of some digraphs are computed using eigen values of  $\mathfrak{B}_S(\vec{R})$ .

### ABSTRACT

In this paper, we define and introduce a Soft  $\alpha\omega$  – Closed sets in soft ideal space. Furthermore, we introduce to Enlightenment and Edification of some theorems, properties and remarks with examples, which is the extension of the concepts of soft  $\alpha\omega$  - Closed sets in Soft topological space.

**Keywords :** Soft set, Soft ideal space, Soft- $\omega$ -Closed set, Soft- $\alpha$ - $\omega$ -open set.

## INTRODUCTION

The concept of Soft set theory was introduced by Molodstov [6] in 1990 and the concept of theory of ideal topological spaces were introduced by kuratowski [5] and vaidyanathswamy [12] in 1945 and 1996. The concept of soft ideal theory, soft local function was introduced by A.Kandil, et.al [4]. In this paper we define and study the extension of soft  $\alpha\omega$ -Closed sets in soft topological spaces.

### PRELIMINARIES

Let  $V$  be an initial universe and  $Q$  be a set of parameters. Let  $P(V)$  denote the powerset of  $V$ .

**DEFINITION 2.1 [1]** Let  $D$  be a non-empty subset of  $Q$  and a soft set over  $V$  is a parameterized family of subsets of an initial universe  $V$ . For a particular  $q \in Q$ ,  $f(q)$  may be considered the set of  $q$ -approximate elements of the soft set  $(f, q)$  and if  $q \notin Q$ ,

then  $f(q) = \emptyset$  that is,  $(f, Q) = \{f(q) : q \in D \subseteq Q, f: Q \rightarrow P(V)\}$  is called a soft set over  $V$ . Then the family of all these soft sets denoted by  $SS(V)_Q$ .

**Chandramathi and Kiruthika**

**DEFINITION 2.2**[13] Let  $C_s$  be the collection of soft sets over  $V$ . Then  $C_s$  is said to be a soft topology on  $V$  if satisfies the following axioms:

- a.  $(\{\}, Q), (V, Q)$  belongs to  $C_s$
- b. The union of any number of soft sets in  $C_s$  belongs to  $C_s$
- c. The intersection of two number of soft sets in  $C_s$  belongs to  $C_s$ .

The triplet  $(V, C_s, Q)$  is said to be soft topological space and we note that the member of  $C_s$  are said to be  $C_s$ -soft open sets.

**DEFINITION 2.3** [1] Let  $\tilde{I}_s$  be a non-null collection of soft sets over an initial universe  $V$  with the same set of parameter  $Q$ . Then  $\tilde{I}_s$  containing  $SS(V)_Q$  is called as a soft Ideal on  $V$  with same set  $Q$  if,

- a.  $(F, Q) \in \tilde{I}_s$  and  $(G, Q) \in \tilde{I}_s$  then  $(F, Q) \cup (G, Q) \in \tilde{I}_s$ .
- b.  $(F, Q) \in \tilde{I}_s$  and  $(G, Q) \subseteq (F, Q)$  then  $(G, Q) \in \tilde{I}_s$ .

That is  $\tilde{I}_s$  is Closure under finite soft unions and soft subsets.

**SOFT  $\alpha\omega\tilde{I}_s$ - CLOSED SETS IN SOFT IDEAL TOPOLOGICAL SPACE**

In this section we introduce and study a new type of sets are known as soft  $\alpha\omega\tilde{I}_s$ - closed sets in Soft Ideal topological space and we work out some basic theorems.

**REMARK 3.1a.** A subset  $(F, Q)$  of a soft Ideal topological space  $(V, C_s, Q)$  and A soft  $\alpha\tilde{I}_s$ -open set, if  $(F, Q) \subseteq \text{int}^s(\text{Cl}^{*s}(\text{int}^s(F, Q)))$ .

b.  $\omega\text{Cl}^{*s}(F, Q) = (F, Q) \cup (F, Q)^{\omega*}$  defines a kuratowski Closure operator with respect to  $\omega$ -Closed. Where  $(F, Q)^{\omega*} = \cup \{(v, q) \in (V, Q) : (H, Q) \cap (F, Q) \notin \tilde{I}_s \text{ for every soft-}\omega\text{-open set } (H, Q) \text{ containing } (v, q)\}$ .

**DEFINITION 3.2** A subset  $(F, Q)$  of a soft Ideal topological space  $(V, C_s, \tilde{I}_s)$  is called Soft  $\alpha\omega\tilde{I}_s$ -closed set if  $\omega\text{Cl}^{*s}(F, Q) \subseteq (H, Q)$  whenever  $(F, Q) \subseteq (H, Q)$  and  $(H, Q)$  is soft

$\alpha\tilde{I}_s$ -open in  $(V, C_s, \tilde{I}_s)$ . The complement of a soft  $\alpha\omega\tilde{I}_s$ -closed set is called as soft  $\alpha\omega\tilde{I}_s$ -open set in  $(V, C_s, \tilde{I}_s)$ .

**EXAMPLE 3.3**  $V = \{\alpha, \beta, \gamma\}, Q = \{\otimes_1, \otimes_2\}, C_s = \{(\{\}, Q), (V, Q), (F_1, Q), (F_2, Q)\}$  That is,  $C_s = \{(\{\}, V, \{\alpha\}, \{\gamma\}, \{\alpha, \gamma\})\}, \tilde{I}_s = \{(\{\}, Q), (F_3, Q), (F_4, Q)\} = \{(\{\}, \{\beta\}, \{\gamma\}, \{\beta, \gamma\})\}$ , where  $(F_1, Q) = \{(\{\}, \{\alpha\})\}, (F_2, Q) = \{(\{\gamma\}, \{\alpha, \gamma\})\}, (F_3, Q) = \{(\{\beta\}, \{\beta, \gamma\})\}, (F_4, Q) = \{(\{\}, \{\alpha, \beta\})\}$  are soft sets over  $V$ . Let  $(F, Q) = (F_5, Q) = \{(\{\alpha\}, \{\alpha, \gamma\})\}$ . Therefore,  $\omega\text{Cl}^{*s}(F, Q) \subseteq (H, Q)$ , whenever  $(F, Q) \subseteq (H, Q)$  and  $(H, Q)$  is  $\alpha\tilde{I}_s$ -open. Hence,  $(F, Q)$  is soft  $\alpha\omega\tilde{I}_s$ -closed in  $(V, C_s, \tilde{I}_s)$ .

**THEOREM 3.4** Every soft closed set is soft  $\alpha\omega\tilde{I}_s$ -closed in  $(V, C_s, \tilde{I}_s)$ .

**PROOF.** Let  $(F, Q)$  be any soft closed set and  $(H, Q)$  be any soft  $\alpha\tilde{I}_s$ -open set containing a soft set  $(F, Q)$ . Since  $(F, Q)$  is soft closed set in  $(V, C_s, \tilde{I}_s)$ . Then  $\text{Cl}^s(F, Q) = (F, Q) \subseteq (H, Q)$ , but  $\omega\text{Cl}^{*s}(F, Q) \subseteq \text{Cl}^s(F, Q)$ . Thus, we have  $\omega\text{Cl}^{*s}(F, Q) \subseteq (H, Q)$ , whenever  $(F, Q) \subseteq (H, Q)$ . Hence,  $(F, Q)$  is soft  $\alpha\omega\tilde{I}_s$ -closed in  $(V, C_s, \tilde{I}_s)$ .

The converse of the above theorem is not true as seen in the following example.

**EXAMPLE 3.5** Let  $V = \{\alpha, \beta, \gamma\}, Q = \{\otimes_1, \otimes_2\}, C_s = \{(\{\}, Q), (V, Q), (F_1, Q)\} = \{(\{\}, V, \{\alpha\})\}, C_s^c = \{(\{\}, Q), (V, Q), (F_2, Q)\} = \{(\{\}, V, \{\beta, \gamma\})\}, \tilde{I}_s = \{(\{\}, Q), (F_3, Q)\} = \{(\{\}, \{\beta\})\}$  and  $(F, Q) = \{(\{\gamma\}, \{\alpha, \gamma\})\}$  where  $(F_1, Q) = \{(\{\}, \{\alpha\})\}, (F_2, Q) = \{(\{\}, \{\beta, \gamma\})\}, (F_3, Q) = \{(\{\}, \{\beta\})\}$  and  $(F_4, Q) = \{(\{\gamma\}, \{\alpha, \gamma\})\}$  are soft sets over  $V$ . Then  $\text{int}^s(\text{Cl}^s(\text{int}^s(\{\}, Q))) = (\{\}, Q) = \{\}, \text{int}^s(\text{Cl}^s(\text{int}^s(V, Q))) = (V, Q), \text{int}^s(\text{Cl}^s(\text{int}^s(\{\alpha\})) = \{\alpha\}$ , therefore, it is soft  $\alpha\tilde{I}_s$ -open in  $(V, C_s, \tilde{I}_s)$ . Then  $(F, Q) \subseteq \text{Cl}^s(F, Q)$ . Hence, it is not soft closed set in  $(V, C_s, \tilde{I}_s)$ .

**THEOREM 3.6** Every soft- $\omega$ -closed set is soft  $\alpha\omega\tilde{I}_s$ -closed in  $(V, C_s, \tilde{I}_s)$ .

**PROOF.** Let  $(F, Q)$  be any soft- $\omega$ -closed set and  $(H, Q)$  is any soft  $\alpha\tilde{I}_s$ -open set in  $(V, C_s, \tilde{I}_s)$ . Such that  $(F, Q) \subseteq (H, Q)$ . Since  $(F, Q)$  is soft closed and  $\omega\text{Cl}^{*s}(F, Q) \subseteq \text{Cl}^s(F, Q) \subseteq (H, Q)$ . Thus, we have  $\omega\text{Cl}^{*s}(F, Q) \subseteq (H, Q)$ , whenever  $(F, Q) \subseteq (H, Q)$ . This shows that  $(F, Q)$  is soft  $\alpha\omega\tilde{I}_s$ -closed in  $(V, C_s, \tilde{I}_s)$ .

The converse of the above theorem is not true as seen in the following example.

**EXAMPLE 3.7** Let  $V = \{\alpha, \beta, \gamma\}, Q = \{\otimes_1, \otimes_2\}, C_s = \{(\{\}, Q), (V, Q), (F_1, Q)\} = \{(\{\}, V, \{\alpha\}, \{\alpha, \beta\})\}$ ,

**Chandramathi and Kiruthika**

$C_s^c = \{(\{ \}, Q), (V, Q), (F_2, Q), (F_3, Q)\} = \{ \{ \}, V, \{ \gamma \}, \{ \beta, \gamma \} \}$ , where  $(F_1, Q) = \{ \{ \alpha \}, \{ \alpha, \beta \} \}$ ,  $(F_2, Q) = \{ \{ \}, \{ \gamma \} \}$ ,  $(F_3, Q) = \{ \beta, \gamma \}$  are soft sets over  $V$ . Then  $Cl^s(int^s(\{ \}, Q)) = (\{ \}, Q), Cl^s(int^s(V, Q)) = (V, Q)$ ,

$Cl^s(int^s\{\alpha\}) = (V, Q), Cl^s(int^s\{\alpha, \beta\}) = (V, Q)$  which implies that,  $(F, Q) \notin Cl^s(int^s(F, Q))$ .

Therefore, it is not soft-semi-open and Hence it is not soft- $\omega$ -closed set.

**LEMMA 3.8** For any two soft sets  $(F, Q)$  and  $(G, Q)$ ,

- a.  $\omega Cl^{*s}((F, Q) \cup (G, Q)) = \omega Cl^{*s}(F, Q) \cup \omega Cl^{*s}(G, Q)$
- b.  $\omega Cl^{*s}((F, Q) \cap (G, Q)) \subseteq \omega Cl^{*s}(F, Q) \cap \omega Cl^{*s}(G, Q)$ .

PROOF OF a.  $\omega Cl^{*s}((F, Q) \cup (G, Q)) = ((F, Q) \cup (G, Q)) \cap ((F, Q) \cup (G, Q))^*$   
 $= ((F, Q) \cup (G, Q)) \cup ((F, Q)^* \cup (G, Q)^*)$   
 $= ((F, Q) \cup (F, Q)^*) \cup ((G, Q) \cup (G, Q)^*)$

Hence,  $\omega Cl^{*s}((F, Q) \cup (G, Q)) = \omega Cl^{*s}(F, Q) \cup \omega Cl^{*s}(G, Q)$ .

PROOF OF b.  $\omega Cl^{*s}((F, Q) \cap (G, Q)) = ((F, Q) \cap (G, Q)) \cup ((F, Q) \cap (G, Q))^*$   
 $\subseteq ((F, Q) \cap (G, Q)) \cup ((F, Q)^* \cap (G, Q)^*)$   
 $= ((F, Q) \cap (F, Q)^*) \cup ((G, Q) \cap (G, Q)^*)$

Hence,  $\omega Cl^{*s}(F, Q) \cap \omega Cl^{*s}(G, Q) \subseteq \omega Cl^{*s}((F, Q) \cap (G, Q))$ .

**THEOREM 3.9** Finite union of soft  $\alpha\omega\check{I}_s$ -closed sets are soft  $\alpha\omega\check{I}_s$ -closed sets in  $(V, C_s, \check{I}_s)$ .

PROOF. Let  $(F, Q)$  and  $(G, Q)$  are two soft  $\alpha\omega\check{I}_s$ -closed sets and let  $(F, Q) \cup (G, Q) \subseteq (H, Q)$ ,

$(H, Q)$  is soft  $\alpha\check{I}_s$ -open in  $(V, C_s, \check{I}_s)$ . Then  $(F, Q) \subseteq (H, Q)$  and  $(G, Q) \subseteq (H, Q)$ . Since,  $(F, Q)$  and  $(G, Q)$  are soft  $\alpha\omega\check{I}_s$ -closed sets,  $\omega Cl^{*s}(F, Q) \subseteq (H, Q)$  and  $\omega Cl^{*s}(G, Q) \subseteq (H, Q)$ .

Therefore, by Lemma 3.7 (a),  $\omega Cl^{*s}(F, Q) \cup \omega Cl^{*s}(G, Q) = \omega Cl^{*s}((F, Q) \cup (G, Q)) \subseteq (H, Q)$ .

Hence,  $(F, Q) \cup (G, Q)$  is soft  $\alpha\omega\check{I}_s$ -closed set in  $(V, C_s, \check{I}_s)$ .

**REMARK 3.10** Every soft  $\alpha\omega\check{I}_s$ -closed set is not finite intersection of soft  $\alpha\omega\check{I}_s$ -closed set as shown by the following example.

**EXAMPLE 3.11**  $V = \{ \alpha, \beta, \gamma \}$ ,  $Q = \{ \circ_1, \circ_2 \}$ ,  $C_s = \{ (\{ \}, Q), (V, Q), (F_1, Q), (F_4, Q) \} = \{ \{ \}, V, \{ \alpha \}, \{ \gamma \}, \{ \alpha, \gamma \} \}$ ,  $C_s^c = \{ (\{ \}, Q), (V, Q), (F_5, Q), (F_6, Q), (F_7, Q) \} = \{ \{ \}, V, \{ \beta \}, \{ \alpha, \beta \}, \{ \beta, \gamma \} \}$ ,  $\check{I}_s = \{ (\{ \}, Q), (F_5, Q), (F_6, Q) \} = \{ \{ \}, \{ \beta \}, \{ \alpha, \beta \} \}$ , where  $(F_1, Q) = \{ \{ \}, \{ \alpha \} \}$ ,  $(F_2, Q) = \{ \{ \}, \{ \beta \} \}$ ,  $(F_3, Q) = \{ \alpha \}$ ,  $(F_4, Q) = \{ \{ \gamma \}, \{ \alpha, \gamma \} \}$ ,  $(F_5, Q) = \{ \beta \}$ ,  $(F_6, Q) = \{ \{ \}, \{ \beta, \gamma \} \}$ ,  $(F_7, Q) = \{ \{ \}, \{ \alpha, \beta \} \}$  are soft set over  $V$ . Clearly,  $(F_5, Q)$  and  $(F_6, Q)$  are soft  $\alpha\omega\check{I}_s$ -closed but  $(F_5, Q) \cap (F_6, Q) = (F_2, Q)$  which is not soft  $\alpha\omega\check{I}_s$ -closed set in  $(V, C_s, \check{I}_s)$ .

**THEOREM 3.12** If  $(F, Q)$  and  $(F, Q)$  are soft- $\omega$ -closed sets in  $(V, C_s, \check{I}_s)$ . Then  $(F, Q) \cup (F, Q)$  is also soft- $\omega$ -closed set.

PROOF. Let  $(H, Q)$  be a soft- $\alpha\check{I}_s$ -open set and  $(F, Q) \cup (F, Q) \subseteq (H, Q)$ . Since,  $(F, Q)$  and  $(F, Q)$  are soft  $\alpha\omega\check{I}_s$ -closed set. Then  $\omega Cl^{*s}(F, Q) \subseteq (H, Q)$  and  $\omega Cl^{*s}(F, Q) \subseteq (H, Q)$ . Hence,  $\omega Cl^{*s}(F, Q) \cup \omega Cl^{*s}(F, Q) \subseteq \omega Cl^{*s}((F, Q) \cup (F, Q)) \subseteq (H, Q)$ .

**THEOREM 3.13** If  $(F, Q)$  is soft  $\alpha\check{I}_s$ -open and soft  $\alpha\omega\check{I}_s$ -closed set in  $(V, C_s, \check{I}_s)$ . Then  $(F, Q)$  is a soft- $\omega$ -closed in  $(V, C_s, \check{I}_s)$ .

PROOF. Since,  $(F, Q) \subseteq (F, Q)$  and  $(F, Q)$  is soft  $\alpha\check{I}_s$ -open and soft  $\alpha\omega\check{I}_s$ -closed, Then we have  $\omega Cl^{*s}(F, Q) \subseteq (H, Q)$ . Thus  $Cl^s(F, Q) \subseteq (F, Q)$  and  $(F, Q)$  is soft-semi-open, which implies that  $(F, Q)$  is soft- $\omega$ -closed in  $(V, C_s, \check{I}_s)$ .

**THEOREM 3.14** Let  $(V, C_s, \check{I}_s)$  be a soft Ideal topological space. For every  $(F, Q) \in \check{I}_s$ , and  $(F, Q)$  is soft  $\alpha\omega\check{I}_s$ -closed.

PROOF. Let  $(F, Q) \subseteq (H, Q)$ , where  $(H, Q)$  is soft  $\alpha\check{I}_s$ -open. Since,  $(F, Q)_{\omega^*} = \{ \}$ ,

For every  $(F, Q) \in \check{I}_s$ , Then  $\omega Cl^{*s}(F, Q) = (F, Q) \cup (F, Q)_{\omega^*} \subseteq (H, Q)$ . Hence,  $(F, Q)$  is soft  $\alpha\omega\check{I}_s$ -closed in  $(V, C_s, \check{I}_s)$ .

**THEOREM 3.15** Let  $(V, C_s, \check{I}_s)$  be a soft Ideal topological space, then  $(F, Q)_{\omega^*}$  is always a soft  $\alpha\omega\check{I}_s$ -closed for every subset  $(F, Q)$  of  $(V, C_s, \check{I}_s)$ .

PROOF. Let  $(F, Q)_{\omega^*} \subseteq (H, Q)$ , where  $(H, Q)$  is a soft  $\alpha\check{I}_s$ -open. Since,  $((F, Q)_{\omega^*})^* = (F, Q)^*$ , we have  $\omega Cl^{*s}((F, Q)_{\omega^*}) \subseteq (H, Q)$ , whenever  $(F, Q)_{\omega^*} \subseteq (H, Q)$  and  $(H, Q)$  is soft  $\alpha\check{I}_s$ -open. Hence,  $(F, Q)_{\omega^*}$  is soft  $\alpha\omega\check{I}_s$ -closed in  $(V, C_s, \check{I}_s)$ .

**THEOREM 3.16** Let  $(V, C_s, \check{I}_s)$  be a soft Ideal topological space and  $(F, Q) \subseteq V$ ,

- a. Let  $\check{I}_s = \{ \}$ , Then  $(F, Q)$  is soft  $\alpha\omega\check{I}_s$ -closed if and only if  $(F, Q)$  is soft- $\omega$ -closed.
- b. Let  $\check{I}_s = P(V)$ , Then  $(F, Q)$  is soft-closed if and only if  $(F, Q)$  is soft  $\alpha\omega\check{I}_s$ -closed.

**Chandramathi and Kiruthika**

**PROOF OF a.** Let  $\check{I}_s = \{\}$ , Then  $(F, Q)_{\omega^*} = \omega Cl^{*s}(F, Q)$ , and  $\omega Cl^{*s}(F, Q) = (F, Q) \cup (F, Q)_{\omega^*}$  for every subset  $(F, Q)$  of  $V$ . Therefore, we have soft  $\alpha$ - $\check{I}_s$ -open  $(V, C_s, \check{I}_s)$  which is equal to the soft open  $(V, C_s, \check{I}_s)$  and  $(F, Q)$  is soft  $\alpha\omega\check{I}_s$ -closed if and only if  $(F, Q)$  is a soft- $\omega$ -closed.

**PROOF OF b.** Let  $\check{I}_s = P(V)$ , Then  $(F, Q)_{\omega^*} = \{\}$  and  $\omega Cl^{*s}(F, Q) = (F, Q)$  for every subset  $(F, Q)$  of  $(V, C_s, \check{I}_s)$ . Let  $(F, Q)$  belongs to soft  $\alpha$ - $\check{I}_s$ -open in  $(V, C_s, \check{I}_s)$ . Then  $(F, Q) \subseteq \omega Cl^{*s}(int^s(F, Q))$  which is equal to  $int^s(F, Q)$  and Hence,  $(F, Q)$  is soft open in  $(V, C_s, \check{I}_s)$ .

**THEOREM 3.17** If  $(F, Q)$  is soft  $\alpha\omega\check{I}_s$ -closed set in  $(V, C_s, \check{I}_s)$  and  $(F, Q) \subseteq (G, Q) \subseteq \omega Cl^{*s}(F, Q)$ . Then  $(G, Q)$  is also a soft  $\alpha\omega\check{I}_s$ -closed set in  $(V, C_s, \check{I}_s)$ .

**PROOF.** Suppose  $(F, Q)$  is soft  $\alpha\omega\check{I}_s$ -closed set in  $(V, C_s, \check{I}_s)$ . Let  $(G, Q) \subseteq (H, Q)$ , such that  $(H, Q)$  is soft  $\alpha\omega\check{I}_s$ -closed in  $(V, C_s, \check{I}_s)$ . Since,  $(F, Q) \subseteq (G, Q)$ , we have  $(F, Q) \subseteq (H, Q)$ . Since,  $(F, Q)$  is soft  $\alpha\omega\check{I}_s$ -closed and  $\omega Cl^{*s}(G, Q) \subseteq \omega Cl^{*s}(\omega Cl^{*s}(F, Q)) = \omega Cl^{*s}(F, Q) \subseteq (H, Q)$ . Therefore,  $\omega Cl^{*s}(G, Q) \subseteq (H, Q)$ . Hence,  $(G, Q)$  is soft  $\alpha\omega\check{I}_s$ -closed set in  $(V, C_s, \check{I}_s)$ .

**THEOREM 3.18** Let  $(F, Q)$  is soft  $\omega$ -closed set in  $(V, C_s, \check{I}_s)$ . Then  $(F, Q)$  is soft- $\omega$ -closed if and only if  $\omega Cl^{*s}(F, Q) - (F, Q) = \{\}$  is soft  $\alpha$ - $\check{I}_s$ -closed.

**PROOF.** Suppose  $(F, Q)$  is soft- $\omega$ -closed. Then  $\omega Cl^{*s}(F, Q) - (F, Q)$  and  $\omega Cl^{*s}(F, Q) - (F, Q) = \{\}$  Which is soft  $\alpha$ - $\check{I}_s$ -closed. Conversely,  $\omega Cl^{*s}(F, Q) - (F, Q)$  is soft  $\alpha$ - $\check{I}_s$ -closed. Then  $\omega Cl^{*s}(F, Q) - (F, Q) = \{\}$ , Since,  $(F, Q)$  is soft  $\alpha\omega\check{I}_s$ -closed set in  $(V, C_s, \check{I}_s)$ . That is,  $\omega Cl^{*s}(F, Q) - (F, Q)$  (or)  $(F, Q)$  is soft- $\omega$ -closed.

**THEOREM 3.19** Every soft  $\alpha\omega\check{I}_s$ -closed sets in  $(V, C_s, \check{I}_s)$  is  $\check{I}_s$ -g-closed in  $(V, C_s, \check{I}_s)$ .

**PROOF.** Let  $(F, Q) \subseteq (H, Q)$  and  $(H, Q)$  is soft open, Hence, it is soft  $\alpha$ - $\check{I}_s$ -open. Since,  $(F, Q)$  is soft  $\alpha\omega\check{I}_s$ -closed, we have  $\omega Cl^{*s}(F, Q) \subseteq (H, Q)$ . But  $(F, Q)_{\omega^*} \subseteq \omega Cl^{*s}(F, Q) \subseteq (H, Q)$ .

Hence,  $(F, Q)$  is soft  $\check{I}_s$ -g-closed in  $(V, C_s, \check{I}_s)$ .

The converse of the above theorem is not true as seen in the following example.

**EXAMPLE 3.20** Let  $V = \{\alpha, \beta, \gamma\}$ ,  $Q = \{\otimes_1, \otimes_2\}$ ,  $C_s = \{(\{\}, Q), (V, Q), (F_1, Q)\} = \{\{\}, V, \{\alpha\}\}$  and  $\check{I}_s = \{\}$ , where  $(F_1, Q) = \{\{\}, \{\alpha\}\}$  and  $(F_2, Q) = \{\beta\}$  are soft sets over  $V$ . Here  $(F_2, Q) = \{\beta\}$  is soft  $\check{I}_s$ -g-closed but not soft  $\alpha\omega\check{I}_s$ -closed in  $(V, C_s, \check{I}_s)$ .

**THEOREM 3.21** Every  $\omega^*$ -soft closed set is soft  $\alpha\omega\check{I}_s$ -closed in  $(V, C_s, \check{I}_s)$ .

**PROOF.** Let  $(F, Q)$  is  $\omega^*$ -soft closed set. Then  $(F, Q)_{\omega^*} \subseteq (F, Q)$  implies  $(F, Q) \cup (F, Q)_{\omega^*} \subseteq (F, Q) \cup (F, Q) = (F, Q)$ . Let  $(F, Q) \subseteq (H, Q)$ , where  $(H, Q)$  is soft  $\alpha$ - $\check{I}_s$ -open. Hence,  $\omega Cl^{*s}(F, Q) \subseteq (H, Q)$ , Whenever  $(F, Q) \subseteq (H, Q)$  and  $(H, Q)$  is soft  $\alpha$ - $\check{I}_s$ -open. Therefore,  $(F, Q)$  is soft  $\alpha\omega\check{I}_s$ -closed in  $(V, C_s, \check{I}_s)$ .

The converse of the above theorem is not true as seen in the following example.

**EXAMPLE 3.22** Let  $V = \{\alpha, \beta, \gamma\}$ ,  $Q = \{\otimes_1, \otimes_2\}$ ,  $C_s = \{(\{\}, Q), (V, Q), (F_3, Q)\} = \{\{\}, V, \{\gamma\}, \{\alpha, \beta\}\}$ ,  $\check{I}_s = \{(\{\}, Q), (V, Q), (F_1, Q)\} = \{\{\}, V, \{\alpha\}\}$ . Then  $(F, Q) = \{\beta, \gamma, \delta\}$  is soft  $\alpha\omega\check{I}_s$ -closed but not  $\omega^*$ -soft closed in  $(V, C_s, \check{I}_s)$ .

**THEOREM 3.23** If  $(F, Q)$  is soft  $\alpha$ - $\check{I}_s$ -open and soft  $\alpha\omega\check{I}_s$ -closed set, then  $(F, Q)$  is

$\omega^*$ -soft closed in  $(V, C_s, \check{I}_s)$ .

**PROOF.** Since,  $(F, Q) \subseteq (F, E)$ , then  $(F, Q)$  is soft  $\alpha$ - $\check{I}_s$ -open and soft  $\alpha\omega\check{I}_s$ -closed set, we have  $\omega Cl^{*s}(F, Q) \subseteq (F, Q)$ . Therefore,  $\omega Cl^{*s}(F, Q) = (F, Q)$  and  $(F, Q)$  is  $\omega^*$ -soft closed set in  $(V, C_s, \check{I}_s)$

## ABSTRACT

This study explores the use of a Topological Median Filter (TMF) in medical image processing to effectively reduce noise while preserving essential image structures. The proposed hybrid method integrates TMF with adaptive Kalman filters and non-local means techniques, optimized through a Latin square design. This innovative combination achieves efficient noise reduction without compromising the diagnostic quality of medical images, including MRI, CT, and radiographic scans. Experimental results demonstrate that this approach surpasses traditional methods in maintaining image details, making it particularly valuable for clinical applications. Furthermore, multigranular segmentation is employed to detect topological variations, enhancing feature extraction for improved diagnosis and treatment.

**Keywords:** Topological Median Filter, MRI, CT, Feature extraction.

## INTRODUCTION

Medical imaging techniques, such as Magnetic Resonance Imaging (MRI), Computed Tomography (CT), and radiographic scans, are crucial in diagnostic medicine, enabling detailed visualization of anatomical and pathological structures. However, noise—often stemming from acquisition processes, environmental interference, or limitations in sensor precision—can degrade image quality, complicating interpretation and potentially affecting diagnostic

**Marudhachalam et al.,**

outcomes. Problem Statement: Traditional denoising techniques can reduce noise effectively but frequently lead to blurring or loss of critical anatomical details essential for accurate diagnosis. The delicate balance between noise reduction and structural preservation remains a key challenge, as excessive smoothing risks erasing fine features while insufficient noise reduction may render the images unusable. This study proposes a hybrid noise reduction method combining a Topological Median Filter (TMF) with adaptive Kalman filtering and Non-Local Means (NLM) denoising techniques, optimized via a Latin square design. The hybrid model aims to enhance image clarity while retaining key diagnostic details, thereby improving the quality of medical images for clinical analysis. The proposed method's ability to maintain structural integrity while effectively denoising could greatly enhance diagnostic confidence and enable better patient outcomes through clearer and more informative imaging results.

## LITERATURE REVIEW

Medical imaging noise reduction has advanced significantly, focusing on reducing noise while preserving diagnostically relevant details. Approaches to image denoising often include median filtering, Gaussian blurring, wavelet transforms, and statistical filtering techniques, each with unique benefits and limitations. Median filtering [3] is a popular technique due to its ability to preserve edges, an important feature in medical images. Traditional median filters operate by replacing pixel values with the median of neighbouring pixels, which effectively reduces noise, particularly impulse noise. However, conventional median filters can underperform in maintaining structural details, especially in complex textures typical of medical images. The TMF, an advanced form of median filtering, incorporates topological information to enhance edge preservation. Unlike standard median filters, TMF adapts to the spatial distribution of noise and structure, using topological constraints to avoid excessive smoothing. Studies have shown TMF to be particularly useful in scenarios requiring high-detail preservation, making it a promising foundation for medical image denoising. Kalman filters, traditionally applied in signal processing, are used in image processing for predictive smoothing and noise reduction. Adaptive Kalman filters, which adjust filter parameters based on noise variance, are suitable for real-time noise reduction in dynamic imaging contexts, allowing for finer control over the denoising process. NLM filters work by averaging similar pixel patches across the entire image, achieving high levels of noise reduction while preserving textures. Unlike local filters, NLM leverages global information, thus reducing the risk of blurring structures. This makes NLM an ideal addition to the hybrid approach, especially in preserving image textures in medical scans. While TMF, Kalman, and NLM filters each have their strengths, none alone can sufficiently balance noise reduction and structure preservation across various medical imaging types. The limitations lie in over-smoothing, computational demands, or loss of critical image details in high-noise conditions. Automatic medical image segmentation [1] is crucial for accurate disease diagnosis and treatment planning, especially in cancer detection. The U-Net model, while effective, struggles with long-range dependencies due to its CNN layers. To address this, we propose a dual-path encoder model combining CNN for local features and Transformer for global context, achieving superior segmentation performance. Denoising and filtering line-scan images are crucial for improving recognition and classification quality in industrial applications. An improved adaptive Kalman-median filter (IAKMF) [6] was developed for dual-energy X-ray transmission (DE-XRT) line-scan images, addressing various noise types. This filter offers high precision, real-time control, and effective noise reduction while preserving important signal features, making it practical for diverse line-scan image filtering scenarios. To refine denoised images, we use a non-local means (NLM) method and a median filter. NLM [5] reduces noise by leveraging similarities between image patches, while the median filter suppresses residual noise and preserves details. To optimize these methods efficiently, we employ Latin square optimization, reducing computational complexity.

## METHODOLOGY

The proposed method combines TMF, adaptive Kalman filtering, and NLM denoising to leverage the strengths of each. This hybrid approach enables dynamic noise reduction suitable for complex medical images, ensuring structural integrity while effectively removing noise.

**Marudhachalam et al.,**

The TMF component is implemented by adapting median filtering to emphasize structural details. The TMF applies a neighborhood-based approach, using the median of pixel values constrained by local topological patterns. This results in noise reduction without sacrificing edge clarity, a critical requirement for medical imaging. The Kalman filter is incorporated to predict noise trends and smooth out fluctuations, using adaptive parameter adjustment to cater to different noise levels. Kalman's predictive capabilities are especially valuable in CT and MRI images, where specific noise patterns (e.g., Gaussian or Poisson) require targeted reduction techniques. NLM denoising is applied after TMF and Kalman filtering to refine noise reduction. By averaging similar pixel patches, NLM further enhances texture clarity, complementing the edge-preserving benefits of TMF and Kalman. This combination ensures a balanced denoising effect suitable for both high-noise and fine-detail regions. The Latin square design is used to optimize the parameters of the hybrid filter, such as neighborhood size in TMF, adaptation rates in Kalman filtering, and patch size in NLM. This statistical method ensures a balanced and systematic exploration of parameter configurations, leading to an optimal setup for each imaging modality. To further enhance feature extraction, multigranular segmentation is introduced to analyze topological variations. By segmenting images at different scales, this approach captures both coarse and fine structures, assisting in noise reduction while aiding in feature recognition for improved diagnostic outcomes. Experiments are conducted on a dataset including MRI, CT, and radiographic images. Performance is evaluated using Peak Signal-to-Noise Ratio (PSNR) and Structural Similarity Index Measure (SSIM), comparing the hybrid method against conventional denoising methods.

## RESULTS AND DISCUSSION

The hybrid filter shows substantial improvements in PSNR and SSIM scores compared to traditional filters. Tables and figures illustrating PSNR and SSIM across imaging types (MRI, CT, radiographs) demonstrate the method's robustness in preserving details. Visual results confirm that the hybrid approach maintains edge sharpness and structural details across different imaging types. MRI images, in particular, show enhanced contrast between regions with and without noise, making the method especially suitable for soft tissue imaging. Statistical analysis using paired t-tests indicates that the hybrid filter's performance improvement is statistically significant ( $p < 0.05$ ). The Latin square optimization further substantiates that the optimal parameter settings effectively balance denoising and detail preservation.

## DISCUSSION

The hybrid filter's integration of TMF, Kalman, and NLM elements provides a unique balance between noise reduction and detail preservation, outperforming traditional methods. Its adaptability across different imaging types makes it a versatile tool for clinical applications, potentially enhancing diagnostic confidence.

## CONCLUSION

This study presented a novel hybrid denoising method combining TMF, adaptive Kalman filtering, and NLM, optimized through Latin square design, achieving superior noise reduction in medical imaging. The method advances the field by providing a tool that reduces noise effectively while preserving essential structures, applicable across MRI, CT, and radiographic images. Its segmentation-enhanced feature extraction further adds value by improving diagnostic image quality. Future research could extend this approach to real-time applications and explore machine learning techniques for automatic parameter adjustment. Additionally, applying this method to other imaging modalities, such as ultrasound, could further expand its clinical utility. The experimental results show that the proposed Hybrid Topological Median Filter (HTMF) outperforms many existing techniques, delivering the best results. Additionally, this method is simple and easy to implement.

## ABSTRACT

In this paper, we study some distance based topological indices, such as, Wienerindex(W), hyper-Wiener index(WW), Harary index(H), Reciprocal Complementary Wienerindex(RCW) of  $K_m \odot P_n$ .

MSC:05C76, 05C10, 05C38

**Keywords:** Wiener index, Hyper-Wienerindex, Hararyindex, Reciprocal Complementary Wienerindex and Corona Product.

## INTRODUCTION

Only finite, undirected, connected, and simple graphs are examined in this study. The numbers of vertices and edges in a graph  $G = (V, E)$  are represented by  $|V(G)|$  and  $|E(G)|$ , respectively. If there is no ambiguity in the graph under discussion, we simply denote it by  $d(u, v)$ . If  $u, v \in V(G)$ , the length of the shortest distance between  $u$  and  $v$  in  $G$  is given by  $d_G(u, v)$ . A vertex  $u$  in a graph  $G$  has eccentricity  $e(u) = \max \{d(u, v) : v \in V(G)\}$ .  $r = \text{rad}(G) = \min \{e(v) : v \in V(G)\}$  is the radius (or, more accurately, the diameter) of  $G$  (resp.  $d = \text{diam}(G) = \max \{e(v) : v \in V(G)\}$ ).

Topological indices derive from graph theory, which represents molecules as graphs. Atoms correspond to vertices, whereas bonds correspond to edges. Distance-based topological indices are topological indices that are calculated from the distances between vertices (atoms) in a molecular network. These indices concentrate on the graph's structure by measuring the distance between atoms, which can offer information about numerous chemical characteristics and behaviors.

**Giridharan and Maragathavalli**

The Wiener index is the distance based topological index introduced by the chemist Harry Wiener in 1947[3] and also known as the “Wiener number”[4,5], and defined as

$$W(G) = \sum_{u,v \in V(G)} d(u, v)$$

The hyper – Wiener index introduced by Milan Randić in 1993[7] and is defined as follows:

$$WW(G) = \frac{1}{2} \sum_{u,v \in V(G)} [d(u, v) + d(u, v)^2]$$

In [8] Plavšić et. al., and in [9] Ivancine et. al., independently introduced the Harary index, and defined as,

$$H(G) = \sum_{u,v \in V(G)} \frac{1}{d(u, v)}$$

In[10,11]Ivancineet.al., introduced the Reciprocal Complementary Wiener index, denoted by  $RCW(G)$  and given by,

$$RCW(G) = \sum_{u,v \in V(G)} \frac{1}{d + 1 - d(u, v)}$$

Where  $d$  is the diameter of a graph  $G$ .

**Definition 1.1:**

The corona product of two graphs  $G$  and  $H$  is defined as the graph obtained by taking one copy of  $G$  and  $|V(G)|$  copies of  $H$  and joining the  $i^{th}$  vertex of  $G$  to every vertex in the  $i^{th}$  copy of  $H$ . See Figure1

**MAIN RESULTS**

In this section, we compute some degree based topological indices of corona product of  $K_m \odot P_n$ .

**Definition 2.1:**

The graph that results from taking  $m$  copies of  $P_n$ , one copy of  $K_m$  and linking each vertex in the  $i^{th}$  copy of  $P_n$ , to every vertex in the  $i^{th}$  copy of  $K_m$  is known as the corona product of two complete graphs,  $K_m$  and  $P_n$ .

**Theorem 2.2:** Let  $K_m$  and  $P_n$  be two graphs with  $m \geq 2$  and  $n \geq 1$ . Then

- i.  $W(K_m \odot P_n) = \frac{m(m-1)}{2}[1 + 4n + 3n^2] + m[4n - 5]$
- ii.  $WW(K_m \odot P_n) = m(m - 1)[1 + 6n + 6n^2] + m[10n - 14]$ .

**Proof:** Let  $K_m$  and  $P_n$  be two graphs with  $m \geq 2$  and  $n \geq 1$ . Then  $K_m \odot P_n$  is the corona of  $K_m$  and  $P_n$ . Let  $V(K_m \odot P_n) = V_1 \cup V_2 \cup \dots \cup V_n$ , where  $V_i = \{v_{i,0}, v_{i,1}, \dots, v_{i,m+1}\}$ , for  $1 \leq i \leq m$ .

**Giridharan and Maragathavalli**

For  $i, j = 1, 2, \dots, m$  and  $p, q = 1, 2, \dots, n$ , the distance between any pair of vertices in  $K_m \odot P_n$  are given by  
 $d(v_i, v_j) = 1$  for  $i \neq j$ ,  $d(v_i, v_{i,p}) = 1$   
 $d(v_{i,p}, v_{i,q}) = 1$  where  $q = p + 1$ ,  $d(v_i, v_{j,p}) = 2$   
 $d(v_{i,p}, v_{i,q}) = 2$  where  $q \neq p + 1$ ,  $d(v_{i,p}, v_{i,q}) = 3$  where  $i \neq j$

Here  $\text{diam}(G) = 3$  and the distance between any pair of vertices varies from  $1, 2, \dots, \text{diam}(G)$ .

The number of 1 distance, pair of vertices is  $\frac{m(m-1)}{2} + mn + m(n-1)$

The number of 2 distance, pair of vertices is  $mn(m-1) + m(n-2)$

The number of 3 distance, pair of vertices is  $n^2 \binom{m-1}{2}$

Then,

$$\begin{aligned} \text{i. } W(K_m \odot P_n) &= \left[ \binom{m}{2} + mn + m(n-1) \right] (1) + [mn(m-1) + m(n-2)](2) + \\ &\quad n^2 \binom{m}{2} (3) \\ &= \frac{m(m-1)}{2} + mn + m(n-1) + 2mn(m-1) + 2m(n-2) + \frac{3n^2 m(m-1)}{2} \\ &= \frac{m(m-1)}{2} [1 + 4n + 3n^2] + m[n + (n-1) + 2(n-2)] \\ &= \frac{m(m-1)}{2} [1 + 4n + 3n^2] + m[n + n - 1 + 2n - 4] \end{aligned}$$

$$\begin{aligned} W(K_m \odot P_n) &= \frac{m(m-1)}{2} [1 + 4n + 3n^2] + m[4n - 5] \\ \text{ii. } WW(K_m \odot P_n) &= \left[ \binom{m}{2} + mn + m(n-1) \right] (1 + 1^2) + \\ &\quad [mn(m-1) + m(n-2)](2 + 2^2) + \left[ n^2 \binom{m}{2} \right] (3 + 3^2) \\ &= \\ 2 \left[ \frac{m(m-1)}{2} + mn + m(n-1) \right] &+ 6[mn(m-1) + m(n-2)] + \qquad 12 \left[ \frac{n^2 m(m-1)}{2} \right] \\ &= \frac{2m(m-1)}{2} + 2mn + 2m(n-1) + 6mn(m-1) + 6m(n-2) + 6n^2 m(m-1) \\ &= m(m-1)[1 + 6n + 6n^2] + 2mn + 2mn - 2m + 6mn - 12m \\ &= m(m-1)[1 + 6n + 6n^2] + 10mn - 14m \\ WW(K_m \odot P_n) &= m(m-1)[1 + 6n + 6n^2] + m[10n - 14]. \end{aligned}$$

**Theorem 2.3:** Let  $K_m$  and  $P_n$  be two graphs with  $m \geq 2$  and  $n \geq 1$ . Then

$$\begin{aligned} \text{i. } H(K_m \odot P_n) &= \frac{m(m-1)}{2} \left[ 1 + n + \frac{n^2}{3} \right] + mn \left[ \frac{5}{2} \right] - 2m \\ \text{ii. } RCW(K_m \odot P_n) &= \frac{m(m-1)}{2} \left[ \frac{1}{3} + n + n^2 \right] + \frac{m}{3} \left[ \frac{7n}{2} - 4 \right] \end{aligned}$$

**Proof:**

Let  $K_m$  and  $P_n$  be two graphs with  $m \geq 2$  and  $n \geq 1$ . Then  $K_m \odot P_n$  is the corona of  $K_m$  and  $P_n$ . Let  $V(K_m \odot P_n) = V_1 \cup V_2 \cup \dots \cup V_n$ , where  $V_i = \{v_{i,0}, v_{i,1}, \dots, v_{i,m+1}\}$ , for  $1 \leq i \leq m$ .

For  $i, j = 1, 2, \dots, m$  and  $p, q = 1, 2, \dots, n$ , the distance between any pair of vertices in  $K_m \odot P_n$  are given by  
 $d(v_i, v_j) = 1$  for  $i \neq j$ ,  $d(v_i, v_{i,p}) = 1$   
 $d(v_{i,p}, v_{i,q}) = 1$  where  $q = p + 1$ ,  $d(v_i, v_{j,p}) = 2$   
 $d(v_{i,p}, v_{i,q}) = 2$  where  $q \neq p + 1$ ,  $d(v_{i,p}, v_{i,q}) = 3$  where  $i \neq j$

Here  $\text{diam}(G) = 3$  and the distance between any pair of vertices varies from  $1, 2, \dots, \text{diam}(G)$ .

The number of 1 distance, pair of vertices is  $\frac{m(m-1)}{2} + mn + m(n-1)$

The number of 2 distance, pair of vertices is  $mn(m-1) + m(n-2)$

## Giridharan and Maragathavalli

The number of 3distance, pair of vertices is  $n^2 \binom{m-1}{2}$

Then,

$$\begin{aligned}
 \text{i. } H(K_m \odot P_n) &= \left[ \binom{m}{2} + mn + m(n-1) \right] \cdot \frac{1}{3} + [mn(m-1) + m(n-2)] \cdot \frac{1}{2} + \left[ n^2 \binom{m}{2} \right] \cdot \frac{1}{3} \\
 &= \frac{m(m-1)}{2} + mn + m(n-1) + \frac{mn(m-1)}{2} + \frac{m(n-2)}{2} + \frac{n^2 m(m-1)}{6} \\
 &= \frac{m(m-1)}{2} \left[ 1 + n + \frac{n^2}{3} \right] + mn + mn - m + \frac{mn}{2} \\
 &= \frac{m(m-1)}{2} \left[ 1 + n + \frac{n^2}{3} \right] + 2m + \frac{mn}{2} - 2m \\
 H(K_m \odot P_n) &= \frac{m(m-1)}{2} \left[ 1 + n + \frac{n^2}{3} \right] + mn \left[ \frac{5}{2} \right] - 2m \\
 \text{ii. } RCW(K_m \odot P_n) &= \left[ \binom{m}{2} + mn + m(n-1) \right] \cdot \frac{1}{3} + [mn(m-1) + m(n-2)] \cdot \frac{1}{2} + \left[ n^2 \binom{m}{2} \right] \cdot \frac{1}{1} \\
 &= \frac{m(m-1)}{2 \times 3} + \frac{mn}{3} + \frac{m(n-1)}{3} + \frac{mn(m-1)}{2} + \frac{m(n-2)}{2} + \frac{n^2 m(m-1)}{2} \\
 &= \frac{m(m-1)}{2} \left[ \frac{1}{3} + n + n^2 \right] + \frac{mn}{3} + \frac{mn}{3} - \frac{m}{3} + \frac{mn}{2} - \frac{2m}{2} \\
 &= \frac{m(m-1)}{2} \left[ \frac{1}{3} + n + n^2 \right] + \frac{2mn}{3} + \frac{mn}{2} - \frac{m}{3} - m \\
 &= \frac{m(m-1)}{2} \left[ \frac{1}{3} + n + n^2 \right] + \frac{4mn + 3mn}{6} - \frac{m - 3m}{3} \\
 RCW(K_m \odot P_n) &= \frac{m(m-1)}{2} \left[ \frac{1}{3} + n + n^2 \right] + \frac{m}{3} \left[ \frac{7n}{2} - 4 \right]
 \end{aligned}$$

### ABSTRACT

Interval valued Game problem (IVGP) is used in which the payoff matrix are all interval numbers. First IVGP is converted into pentagonal numbers and using the Robust ranking techniques Secondly it is converted the normal fuzzy number and find the value of the game. Various procedures for solving interval valued game problem (IVGP) are discussed with numerical examples.

**Keywords:** Interval numbers , pentagonal fuzzy number ,saddle point , Robust ranking technique, Dominance, game value.

## INTRODUCTION

The fuzzy number is used in various applications and departments. Interval-valued numbers used and converted into pentagonal fuzzy number (PFN ) and solving the game problem. Game theory is generally used many fields such as economics, political science , politics , and computer science , and also can be used to many real- world problems. It is very interesting ,enthusiastic and useful concept of operations research.

### Definition : 1

Pentagonal fuzzy number :

A fuzzy number  $A = (p_1, p_2, p_3, p_4, p_5)$  is called a pentagonal fuzzy number (PFN) , if its membership function is given by

**Rajeswari and Maryshanthi**

$$= \left\{ \begin{array}{l} 0, \text{ for } x < p_1, p_5 \leq x \\ \frac{x-p_1}{p_2-p_1}; \text{ for } p_1 \leq x \leq p_2 \\ \frac{x-p_2}{p_3-p_2}; \text{ for } p_2 \leq x \leq p_3 \\ 1, \text{ for } x = p_3 \\ \frac{p_4-x}{p_4-p_3}; \text{ for } p_3 \leq x \leq p_4 \\ \frac{p_5-x}{p_5-p_4}; \text{ for } p_5 \leq x \leq p_4 \end{array} \right.$$

**Definition: 2**

An interval number A is defined as  $A = [r, s] = \{ x / r \leq x \leq s, x \in \mathcal{R} \}$ . Here  $r, s \in \mathcal{R}$  are lower and upper bound of the intervals.

**Definition: 3**

An approach is used to fuzzify the given interval data into a pentagonal fuzzy number. Consider an interval number  $[\bar{S}, \bar{L}]$ . The difference of this interval is  $d = \frac{\bar{L}-\bar{S}}{4}$ . The required pentagonal fuzzy number will be  $\bar{S}, \bar{S} + d, \bar{S} + 2d, \bar{S} + 3d, \bar{L}$ .

**Definition:4**

Robust ranking technique is the one of the pentagonal fuzzy number ranking concept. If  $\bar{F}$  is a convex fuzzy number, the robust ranking index is defined by

$$\rho(\bar{F}) = \int_0^1 \frac{1}{2} [a_\alpha^S, a_\alpha^L] d\alpha$$

Where  $[a_\alpha^S, a_\alpha^L] = [ \{ (p_2 - p_1) \alpha + p_1, p_5 - (p_5 - p_4) \alpha \} ]$  is a  $\alpha$  – level cut of a fuzzy number  $\bar{a}$ .

Sub interval addition method for Pentagonal Fuzzy number

$$\rho(p_1, p_2, p_3, p_4, p_5) = \left[ \frac{6(p_1 + p_2 + p_3 + p_4 + p_5)}{15} \right]$$

**Numerical example :**

Take the following interval entries problem

[-4,4]	[3,11]	[5,17]	[0,4]	
[-1,3]	[6,14]	[5,25]	[4,36]	
[-6,2]	[13,25]	[1,5]	[3,11]	
[-5,11]	[0,8]	[16,20]	[2,6]	

Solution:

Convert of interval numbers to pentagonal numbers using definition 4

Consider [-4,4]

$$d = (4+4)/4 = 2$$

$$[-4,4] = (-4, -4 + 1(2), -4 + 2(2), -4 + 3(2), 4) \\ = (-4, -2, 0, 2, 4)$$

All the interval numbers are converted into pentagonal fuzzy numbers and it is given in the table

Pentagonal fuzzy Numbers

[-4,4]	(-4, -2, 0, 2, 4)	[-6,2]	(-6, -4, -2, 0, 2)
[3,11]	(3, 5, 7, 9, 11)	[13,25]	(13, 16, 19, 22, 25)
[5,17]	(5, 8, 11, 14, 17)	[1,5]	(1, 2, 3, 4, 5)
[0,4]	(0, 1, 2, 3, 4)	[3,11]	(3, 5, 7, 9, 11)
[-1,3]	(-1, 0, 1, 2, 3)	[-5,11]	(-5, -1, 3, 7, 11)
[6,14]	(6, 8, 10, 12, 14)	[0,8]	(0, 2, 4, 6, 8)
[5,25]	(5, 10, 15, 20, 25)	[16,20]	(16, 17, 18, 19, 20)
[4,36]	(4, 12, 20, 28, 36)	[2,6]	(2, 3, 4, 5, 6)

Apply Robust ranking technique to convert pentagonal numbers into numbers, we have  $\rho(\bar{F}) = \int_0^1 \frac{1}{2} [a_\alpha^S, a_\alpha^L] d\alpha$

**Rajeswari and Maryshanthi**

$$\begin{aligned} \rho (-4, -2, 0, 2, 4) &= \int_0^1 0.5 [ (-2+4)\alpha - 4, 4 - (4 - 2) \alpha ] d\alpha \\ &= \int_0^1 0.5 [0] d\alpha \\ &= 0 \end{aligned}$$

Similarly, all the values are converted into numbers and given in the below table  
I. Numbers using Robust ranking :

0	7	11	2
1	10	15	20
-2	19	3	7
3	4	18	4

**Method [1]**

Saddle point method:

- Step 1 : In each row the minimum element and also the minimum of maximum element.
- Step 2 : In each column the maximum element and also the maximum of minimum element
- Step 3: Minimum of maximum equal to maximum of minimum equal to saddle point
- Step 4 : Saddle point is value of the game
- Row minimum of [ ( 0 , 7 , 11 , 2 ) , ( 1 , 10 , 15 , 20 ) , ( -2 , 19 , 3 , 7 ) , ( 3.75 , ( 3 , 4 , 18 , 4 ) ] . Maximum of minimum ( 0 , 1 , -2 , 3 ) is 3 .
- Column maximum of [ ( 0 , 1 , -2 , 3 ) , ( 7 , 10 , 19 , 4 ) , ( 11 , 15 , 3 , 18 ) , ( 2 , 20 , 7 , 4 ) ] . Minimum of maximum ( 3 , 19 , 18 , 20 ) is 3 .
- Value of the game V = 3 .

**Method [2]**

Dominance method :

Step 1 :  $R_1$  is dominated by the  $R_2$  .The reduced game is

1	10	15	20
-2	19	3	7
3	4	18	4

Step 2 :  $C_2, C_3$  and  $C_4$  is dominated by the  $C_1$  . The reduced game is

1
-2
3

Step 3 :  $R_1, R_2$  is dominated by the  $R_3$  . The reduced game is

3
---

Step 4 : Value of the game V = 3

**Method [3]**

**Arithmetic method :**

Step 1:  $A = (a_{ij})$  be an  $n \times n$  payoff matrix .Obtain a new matrix C , whose column is obtained from A by subtracting its 2<sup>nd</sup> column from 1<sup>st</sup> , second column is obtained by subtracting A's 3<sup>rd</sup> column from 2<sup>nd</sup> and so on till the last column of A has been taken care of . Thus C is an  $n \times (n-1)$  matrix.

Step 2 : Obtain a row matrix R ,from A by subtracting its successive rows from the proceeding ones , in exactly the same manner as was done for column in step 1. Thus R is an  $n \times (n-1)$  matrix.

Step 3: Determine the magnitude of oddments corresponding to each row and each column of A . The oddment corresponding to ith row of A is defined as the determinant  $|C_i|$ , Where  $C_i$  is obtained from C by deleting its ith row.

Similarly ,oddment (jth column of A ) =  $|R_j|$ , where  $R_j$  is obtained from R by deleting its jth column .

Step 4 : Write the magnitude of oddments ( after ignoring negative signs, if any against their respective rows and columns ).

**Rajeswari and Maryshanthi**

Step 5 : Check whether the sum of row oddments is equal to the sum of column oddments , If so the oddments expressed as fraction of the grand total yield the optimum stragies. If not the method fails.

Step 6 : Calculate the expected value of game corresponding to the optimum mixed strategy determined above for the Row player ( against any move of the column player).

-7	-4	9
-9	-5	-5
-21	16	-4
-1	-14	14

C =

$$c_1 = \begin{pmatrix} 9 & -5 & -5 \\ -21 & 16 & -4 \\ -1 & -14 & 14 \end{pmatrix} c_2 = \begin{pmatrix} -7 & -4 & 9 \\ -21 & 16 & -4 \\ -1 & -14 & 14 \end{pmatrix} c_3 = \begin{pmatrix} -7 & -4 & 9 \\ -9 & -5 & -5 \\ -1 & -14 & 14 \end{pmatrix}$$

$$c_4 = \begin{pmatrix} -7 & -4 & 9 \\ -9 & -5 & -5 \\ -21 & 16 & -4 \end{pmatrix}$$

$$|C_1| = 1572, |C_2| = 422, |C_3| = 565, |C_4| = 3217$$

<b>-1</b>	<b>-3</b>	<b>-4</b>	<b>-18</b>
<b>3</b>	<b>-9</b>	<b>12</b>	<b>13</b>
<b>-5</b>	<b>15</b>	<b>-15</b>	<b>3</b>

R =

$$R_1 = \begin{pmatrix} -3 & -4 & -18 \\ -9 & 12 & 13 \\ 15 & -15 & 3 \end{pmatrix} R_2 = \begin{pmatrix} -1 & -4 & -18 \\ 3 & 12 & 13 \\ -5 & -15 & 3 \end{pmatrix} R_3 = \begin{pmatrix} -1 & -3 & -18 \\ 3 & -9 & 13 \\ -5 & 15 & 3 \end{pmatrix}$$

$$R_4 = \begin{pmatrix} -1 & -3 & -4 \\ 3 & -9 & 12 \\ -5 & 15 & -15 \end{pmatrix} |R_1| = 771, |R_2| = 205, |R_3| = 444, |R_4| = 90$$

Value of the game V = 2.7

**II .Pentagonal Ranking Technique :**

For given pentagonal fuzzy number , the ranking formula is applied and converted to numbers .

$$R(-4, -2, 0, 2, 4) = \left[ \frac{6(-4 + -2 + 0 + 2 + 4)}{15} \right] = 0$$

Similarly converting all the Pentagonal fuzzy numbers into numbers we have

Values using sub interval addition ranking

0	14	22	4
2	20	30	40
-4	38	6	14
6	8	36	8

**Method [1]**

Saddle point method :

Row minimum of [ ( 0 , 14 , 22 , 4 ) , ( 2 , 20 , 30 , 40 ) , ( -4 , 38 , 6 , 14 ) , ( 6 , 8 , 36 , 8 ) ]

Maximum of minimum ( 0 , 2 , -4 , 6 ) is 6 . Value of game V = 6 .

**Method [2]**

Dominance method :

R<sub>1</sub> is dominated by the R<sub>2</sub>. The reduced game is

**Rajeswari and Maryshanthi**

2	20	30	40
-4	38	6	14
6	8	36	8

$C_2, C_3, C_4$  is dominated by  $C_1$  . The reduced game is

2
-4
6

$R_1$  and  $R_2$  is dominated by  $R_3$  . The reduced game is

6
---

Value of the game  $V = 6$  .

Method [3]

Arithmetic method :

-14	-8	18
-18	-10	-10
-42	32	-8
-2	-28	28

$C =$

$$C_1 = \begin{pmatrix} -18 & -10 & -10 \\ -42 & 32 & -8 \\ -2 & -28 & 28 \end{pmatrix} C_2 = \begin{pmatrix} -14 & -8 & 18 \\ -42 & 32 & -8 \\ -2 & -28 & 28 \end{pmatrix} C_3 = \begin{pmatrix} -14 & -8 & 18 \\ -18 & -10 & -10 \\ -2 & -28 & 28 \end{pmatrix}$$

$$C_4 = \begin{pmatrix} -14 & -8 & 18 \\ -18 & -10 & -10 \\ -42 & 32 & -8 \end{pmatrix}$$

$$|C_1| = 9104, |C_2| = 844, |C_3| = 3090, |C_4| = 6434$$

-2	-6	-8	-36
6	-18	24	26
-10	30	-30	6

$R =$

$$R_1 = \begin{pmatrix} -6 & -8 & -36 \\ -18 & 24 & 26 \\ 30 & -30 & 6 \end{pmatrix} R_2 = \begin{pmatrix} -2 & -8 & -36 \\ 6 & 24 & 26 \\ -10 & -30 & 6 \end{pmatrix} R_3 = \begin{pmatrix} -2 & -6 & -36 \\ 6 & -18 & 26 \\ -10 & 30 & 6 \end{pmatrix}$$

$$R_4 = \begin{pmatrix} -2 & -6 & -8 \\ 6 & -18 & 24 \\ -10 & 30 & -30 \end{pmatrix}$$

$$|R_1| = 205, |R_2| = 205, |R_3| = 205, |R_4| = 205$$

Value of the game  $V = 5.4$  .

**Rajeswari and Maryshanthi**

## RESULT

**Comparison Table**

Ranking Technique	Value of the game		
	Saddle point Method	Dominance Method	Arithmetic Method
Robust Ranking	3	3	2.7
Pentagonal Ranking	6	6	5.4

## CONCLUSION

Pentagonal ranking technique , Robust ranking technique are applied to convert pentagonal numbers to numbers . Different methods available for solving the game problem are applied to find the optimum solution of the game problem . We see that Pentagonal ranking technique gives two times that all the methods when compared to Robust ranking technique.

## ABSTRACT

In this paper we have introduced the concept of Neutrosophic  $\alpha\pi$  generalized closed sets in Neutrosophic topological spaces. We analyze some of its properties with the existing sets in Neutrosophic topological spaces.

**Key words:** Neutrosophic Topological spaces, Neutrosophic open sets, Neutrosophic Closed sets, Neutrosophic  $\alpha$  Closed sets and Neutrosophic  $\alpha\pi$ -generalized Closed sets.

## INTRODUCTION

The concept of fuzzy sets, introduced by Zadeh [3] in 1965, allow each element to have a degree of membership. This concept was expanded by K. Atanassov [1] in 1986 with the introduction of Intuitionistic Fuzzy sets, which assign both a degree of membership and a degree of non-membership to each element. Florentin Samarandache [5] introduced Neutrosophic Sets as a further generalization, which adds more flexibility. Later, A.A. Salama and S.A. Albowi [6] extended the idea by developing Neutrosophic Topological Spaces. In this paper we introduced Neutrosophic  $\alpha\pi$  generalized Closed sets in Neutrosophic topological spaces.

### Preliminaries

In this section the basic Definitions for Neutrosophic sets and its operations are given. Herein this paper the neutrosophic topological space is denoted by  $(X, \tau_\alpha)$ . Also the neutrosophic interior, neutrosophic closure of a neutrosophic set  $A$  are denoted by  $\text{Int}_\alpha(A)$  and  $\text{Cl}_\alpha(A)$ . The complement of a neutrosophic set  $A$  is denoted by  $A^c$  and the empty and whole sets are denoted by  $0_\alpha$  and  $1_\alpha$  respectively.

**Sakthivel and Kavipriya**

**Definition 2.1:[6]**

Let  $X$  be a non-empty fixed set. A neutrosophic set ( $\check{N}\check{S}$ )  $\check{A}$  is an object having the form  $\check{A} = \{ \langle x, \mu_{\check{A}}(x), \sigma_{\check{A}}(x), \nu_{\check{A}}(x) \rangle : x \in X \}$  where  $\mu_{\check{A}}(x), \sigma_{\check{A}}(x)$  and  $\nu_{\check{A}}(x)$  represent the degree of membership, degree of indeterminacy and the degree of non-membership respectively of each element  $x \in X$  to the set  $\check{A}$ .

A neutrosophic set  $\check{A} = \{ \langle x, \mu_{\check{A}}(x), \sigma_{\check{A}}(x), \nu_{\check{A}}(x) \rangle : x \in X \}$  can be identified as an ordered triple  $\langle \mu_{\check{A}}, \sigma_{\check{A}}, \nu_{\check{A}} \rangle$  in  $]^{-0}, 1^{+}[$  on  $X$ .

**Definition 2.2:[6]**

Let  $\check{A} = \langle \mu_{\check{A}}, \sigma_{\check{A}}, \nu_{\check{A}} \rangle$  be a  $\check{N}\check{S}$  on  $X$ , then the complement ( $\check{A}^c$ ) may be defined as

$$1. \quad \check{A}^c = \{ \langle x, \nu_{\check{A}}(x), 1 - \sigma_{\check{A}}(x), \mu_{\check{A}}(x) \rangle : x \in X \}$$

Note that any two neutrosophic sets  $\check{A}$  and  $B$ ,

2.  $(\check{A} \cup B)^c = \check{A}^c \cap B^c$
3.  $(\check{A} \cap B)^c = \check{A}^c \cup B^c$

**Definition 2.3:[6]**

For any two neutrosophic sets  $\check{A} = \{ \langle x, \mu_{\check{A}}(x), \sigma_{\check{A}}(x), \nu_{\check{A}}(x) \rangle : x \in X \}$  and  $B = \{ \langle x, \mu_B(x), \sigma_B(x), \nu_B(x) \rangle : x \in X \}$  we may have,

1.  $\check{A} \subseteq B \Leftrightarrow \mu_{\check{A}}(x) \leq \mu_B(x), \sigma_{\check{A}}(x) \leq \sigma_B(x)$  and  $\nu_{\check{A}}(x) \geq \nu_B(x) \forall x \in X$
2.  $\check{A} \cap B = \langle \mu_{\check{A}}(x) \wedge \mu_B(x), \sigma_{\check{A}}(x) \wedge \sigma_B(x), \nu_{\check{A}}(x) \vee \nu_B(x) \rangle$
3.  $\check{A} \cup B = \langle \mu_{\check{A}}(x) \vee \mu_B(x), \sigma_{\check{A}}(x) \vee \sigma_B(x), \nu_{\check{A}}(x) \wedge \nu_B(x) \rangle$

**Definition 2.4:[6]**

A Neutrosophic topology ( $\check{N}\check{T}$ ) on a non-empty set  $X$  is a family  $\tau_{\check{N}}$  of neutrosophic subsets in  $X$  satisfies the following axioms:

- ( $\check{N}\check{T}_1$ )  $0_{\check{N}}, 1_{\check{N}} \in \tau_{\check{N}}$
- ( $\check{N}\check{T}_2$ )  $\check{W}_1 \cap \check{W}_2 \in \tau_{\check{N}}$  for any  $\check{W}_1, \check{W}_2 \in \tau_{\check{N}}$
- ( $\check{N}\check{T}_3$ )  $\cup \check{W}_j \in \tau_{\check{N}} \forall \{ \check{W}_j : j \in I \} \subseteq \tau_{\check{N}}$

In this case the pair  $(X, \tau_{\check{N}})$  is a neutrosophic topological space ( $\check{N}\check{T}\check{S}$ ) and any neutrosophic set in  $\tau_{\check{N}}$  is known as a neutrosophic open set ( $\check{N}\check{O}\check{S}$ ) in  $X$ . A neutrosophic set  $\check{A}$  is a neutrosophic Closed set ( $\check{N}\check{C}\check{S}$ ) if and only if complement ( $\check{A}^c$ ) is a neutrosophic open set in  $X$ .

Here the empty set ( $0_{\check{N}}$ ) and the whole set ( $1_{\check{N}}$ ) may be defined as follows:

$$(0_{\check{N}}) \quad 0_{\check{N}} = \{ \langle x, 0, 0, 1 \rangle : x \in X \}$$

$$(1_{\check{N}}) \quad 1_{\check{N}} = \{ \langle x, 1, 1, 0 \rangle : x \in X \}$$

**Definition 2.5:[6]**

Let  $(X, \tau_{\check{N}})$  be a  $\check{N}\check{T}\check{S}$  and  $\check{A} = \{ \langle x, \mu_{\check{A}}(x), \sigma_{\check{A}}(x), \nu_{\check{A}}(x) \rangle : x \in X \}$  be a  $\check{N}\check{S}$  in  $X$ . Then the neutrosophic interior and the neutrosophic closure of  $\check{A}$  are defined by

$$\check{N}jnt(\check{A}) = \cup \{ H : H \text{ is an } \check{N}\check{O}\check{S} \text{ in } X \text{ and } H \subseteq \check{A} \}$$

$$\check{N}el(\check{A}) = \cap \{ M : M \text{ is an } \check{N}\check{C}\check{S} \text{ in } X \text{ and } \check{A} \subseteq M \}$$

Note that for any  $\check{N}\check{S}$   $\check{A}$ ,  $\check{N}el(\check{A})^c = (\check{N}jnt(\check{A}))^c$  and  $\check{N}jnt(\check{A})^c = (\check{N}el(\check{A}))^c$ .

**Definition 2.6:[11]**

A subset of  $\check{A}$  of a space  $(X, \tau_{\check{N}})$  is called:

- (i) Neutrosophic Regular open if  $\check{A} = \check{N}jnt(\check{N}el(\check{A}))$ .
- (ii) Neutrosophic  $\pi$  open if  $\check{A}$  is the union of Neutrosophic Regular open sets.

**Definition 2.7:[13]**

An  $\check{N}\check{S}$   $\check{A} = \langle x, \mu_{\check{A}}, \sigma_{\check{A}}, \nu_{\check{A}} \rangle$  in a  $\check{N}\check{T}\check{S}$   $(X, \tau_{\check{N}})$  is said to be a Neutrosophic Semi closed set ( $\check{N}\check{S}\check{C}\check{S}$  in short) if  $\check{N}jnt(\check{N}el(\check{A})) \subseteq \check{A}$ .

An  $\check{N}\check{S}$   $\check{A} = \langle x, \mu_{\check{A}}, \sigma_{\check{A}}, \nu_{\check{A}} \rangle$  in a  $\check{N}\check{T}\check{S}$   $(X, \tau_{\check{N}})$  is said to be a Neutrosophic Semi open set ( $\check{N}\check{S}\check{O}\check{S}$  in short) if  $\check{A} \subseteq \check{N}el(\check{N}jnt(\check{A}))$ .

**Definition 2.8:[8]**

**Sakthivel and Kavipriya**

An  $\mathcal{N}\mathcal{S}\mathcal{A}$  in an  $\mathcal{N}\mathcal{T}\mathcal{S}(\mathcal{X}, \tau_{\mathcal{N}})$  is,

- (i) Neutrosophic Pre closed set ( $\mathcal{N}\mathcal{P}\mathcal{C}\mathcal{S}$  in short) if  $\mathcal{N}\mathcal{e}\mathcal{l}(\mathcal{N}\mathcal{j}\mathcal{i}\mathcal{n}\mathcal{t}(\mathcal{A})) \subseteq \mathcal{A}$ ,
- (ii) Neutrosophic Pre open set ( $\mathcal{N}\mathcal{P}\mathcal{O}\mathcal{S}$  in short) if  $\mathcal{A} \subseteq \mathcal{N}\mathcal{j}\mathcal{i}\mathcal{n}\mathcal{t}(\mathcal{N}\mathcal{e}\mathcal{l}(\mathcal{A}))$ .

**Definition 2.9:[14]**

A  $\mathcal{N}\mathcal{S}\mathcal{A}$  in an  $\mathcal{N}\mathcal{T}\mathcal{S}(\mathcal{X}, \tau_{\mathcal{N}})$  is,

- (i) Neutrosophic  $\alpha$  open set ( $\mathcal{N}\alpha\mathcal{O}\mathcal{S}$  in short) if  $\mathcal{A} \subseteq \mathcal{N}\mathcal{j}\mathcal{i}\mathcal{n}\mathcal{t}(\mathcal{N}\mathcal{e}\mathcal{l}(\mathcal{N}\mathcal{j}\mathcal{i}\mathcal{n}\mathcal{t}(\mathcal{A})))$ ,
- (ii) Neutrosophic  $\alpha$  closed set ( $\mathcal{N}\alpha\mathcal{C}\mathcal{S}$  in short) if  $\mathcal{N}\mathcal{e}\mathcal{l}(\mathcal{N}\mathcal{j}\mathcal{i}\mathcal{n}\mathcal{t}(\mathcal{N}\mathcal{e}\mathcal{l}(\mathcal{A}))) \subseteq \mathcal{A}$ .

**Definition 2.10:[8]**

An  $\mathcal{N}\mathcal{S}\mathcal{A}$  in an  $\mathcal{N}\mathcal{T}\mathcal{S}(\mathcal{X}, \tau_{\mathcal{N}})$  is,

- (i) Neutrosophic Semi Pre open set ( $\mathcal{N}\mathcal{S}\mathcal{P}\mathcal{O}\mathcal{S}$  in short) if  $\mathcal{A} \subseteq \mathcal{N}\mathcal{e}\mathcal{l}(\mathcal{N}\mathcal{j}\mathcal{i}\mathcal{n}\mathcal{t}(\mathcal{N}\mathcal{e}\mathcal{l}(\mathcal{A})))$ ,
- (ii) Neutrosophic Semi Pre closed set ( $\mathcal{N}\mathcal{S}\mathcal{P}\mathcal{C}\mathcal{S}$  in short) if  $\mathcal{N}\mathcal{j}\mathcal{i}\mathcal{n}\mathcal{t}(\mathcal{N}\mathcal{e}\mathcal{l}(\mathcal{N}\mathcal{j}\mathcal{i}\mathcal{n}\mathcal{t}(\mathcal{A}))) \subseteq \mathcal{A}$ .

**Definition 2.11:[14]**

An  $\mathcal{N}\mathcal{S}\mathcal{A}$  of an  $\mathcal{N}\mathcal{T}\mathcal{S}(\mathcal{X}, \tau_{\mathcal{N}})$  is,

- (i) Neutrosophic Regular open set ( $\mathcal{N}\mathcal{R}\mathcal{O}\mathcal{S}$  in short) if  $\mathcal{A} = \mathcal{N}\mathcal{j}\mathcal{i}\mathcal{n}\mathcal{t}(\mathcal{N}\mathcal{e}\mathcal{l}(\mathcal{A}))$ ,
- (ii) Neutrosophic Regular closed set ( $\mathcal{N}\mathcal{R}\mathcal{C}\mathcal{S}$  in short) if  $\mathcal{A} = \mathcal{N}\mathcal{e}\mathcal{l}(\mathcal{N}\mathcal{j}\mathcal{i}\mathcal{n}\mathcal{t}(\mathcal{A}))$ .

**Definition 2.12:[12]**

An  $\mathcal{N}\mathcal{S}\mathcal{A}$  of an  $\mathcal{N}\mathcal{T}\mathcal{S}(\mathcal{X}, \tau_{\mathcal{N}})$  is an Neutrosophic Generalized closed set ( $\mathcal{N}\mathcal{G}\mathcal{C}\mathcal{S}$  in short) if  $\mathcal{N}\mathcal{e}\mathcal{l}(\mathcal{A}) \subseteq U$  whenever  $\mathcal{A} \subseteq U$  and  $U$  is an  $\mathcal{N}\mathcal{O}\mathcal{S}$  in  $\mathcal{X}$ .

**Definition 2.13:[9]**

An  $\mathcal{N}\mathcal{S}\mathcal{A}$  of an  $\mathcal{N}\mathcal{T}\mathcal{S}(\mathcal{X}, \tau_{\mathcal{N}})$  is an Neutrosophic Generalized Semi closed set ( $\mathcal{N}\mathcal{G}\mathcal{S}\mathcal{C}\mathcal{S}$  in short) if  $\mathcal{N}\mathcal{S}\mathcal{e}\mathcal{l}(\mathcal{A}) \subseteq U$  whenever  $\mathcal{A} \subseteq U$  and  $U$  is an  $\mathcal{N}\mathcal{O}\mathcal{S}$  in  $\mathcal{X}$ .

**Result 2.14:[9]**

Let  $(\mathcal{X}, \tau_{\mathcal{N}})$  be an  $\mathcal{N}\mathcal{S}$ . If  $\mathcal{A}$  is an  $\mathcal{N}\mathcal{S}$  of  $\mathcal{X}$  then  $\mathcal{N}\mathcal{S}\mathcal{e}\mathcal{l}(\mathcal{A})^c = (\mathcal{N}\mathcal{S}\mathcal{j}\mathcal{i}\mathcal{n}\mathcal{t}(\mathcal{A}))^c$

**Remark 2.15:[10]**

- (i)  $\mathcal{N}\mathcal{S}\mathcal{e}\mathcal{l}(\mathcal{A}) = \mathcal{A} \cup \mathcal{N}\mathcal{j}\mathcal{i}\mathcal{n}\mathcal{t}(\mathcal{N}\mathcal{e}\mathcal{l}(\mathcal{A}))$ ,
- (ii)  $\mathcal{N}\mathcal{S}\mathcal{j}\mathcal{i}\mathcal{n}\mathcal{t}(\mathcal{A}) = \mathcal{A} \cap \mathcal{N}\mathcal{e}\mathcal{l}(\mathcal{N}\mathcal{j}\mathcal{i}\mathcal{n}\mathcal{t}(\mathcal{A}))$ .

**NEUTROSOPHIC  $\alpha\pi$  GENERALIZED CLOSED SETS IN NEUTROSOPHIC TOPOLOGICAL SPACES**

In this section, we have introduced Neutrosophic  $\alpha\pi$  Generalized closed sets and explored some of their properties.

**Definition 3.1:**

An  $\mathcal{N}\mathcal{S}\mathcal{A}$  in  $(\mathcal{X}, \tau_{\mathcal{N}})$  is said to be a Neutrosophic  $\alpha\pi$  Generalized closed set ( $\mathcal{N}\alpha\pi\mathcal{G}\mathcal{C}\mathcal{S}$  in short) if  $\mathcal{N}\alpha\mathcal{e}\mathcal{l} \subseteq U$  whenever  $\mathcal{A} \subseteq U$  and  $U$  is an  $\mathcal{N}\pi\mathcal{O}\mathcal{S}$  in  $(\mathcal{X}, \tau_{\mathcal{N}})$ . Here the family of all  $\mathcal{N}\alpha\pi\mathcal{G}\mathcal{C}\mathcal{S}$  of an  $\mathcal{N}\mathcal{T}\mathcal{S}(\mathcal{X}, \tau_{\mathcal{N}})$  is denoted by  $\mathcal{N}\alpha\pi\mathcal{G}\mathcal{C}\mathcal{S}(\mathcal{X}, \tau_{\mathcal{N}})$ .

**Example 3.2:**

Let  $\mathcal{X} = \{p, q\}$  with  $\tau_{\mathcal{N}} = \{0_{\mathcal{N}}, \mathcal{W}, 1_{\mathcal{N}}\}$  be an  $\mathcal{N}\mathcal{T}\mathcal{S}$  on  $\mathcal{X}$ , where  $\mathcal{W} = \{(x, (0.7, 0.6, 0.7), (0.2, 0.3, 0.2))\}$ . Let us consider the  $\mathcal{N}\mathcal{S}\mathcal{A} = \{(x, (0.2, 0.2, 0.2), (0.7, 0.6, 0.7))\}$ . Clearly  $\mathcal{A} \subseteq 1_{\mathcal{N}}$ , then  $\mathcal{N}\alpha\mathcal{e}\mathcal{l}(\mathcal{A}) \subseteq 1_{\mathcal{N}}$ . Hence  $\mathcal{N}\alpha\mathcal{e}\mathcal{l}(\mathcal{A}) \subseteq U$  whenever  $\mathcal{A} \subseteq U$  and  $U$  is an  $\mathcal{N}\pi\mathcal{O}\mathcal{S}$  in  $(\mathcal{X}, \tau_{\mathcal{N}})$ . Therefore the  $\mathcal{N}\mathcal{S}\mathcal{A}$  is an  $\mathcal{N}\alpha\pi\mathcal{G}\mathcal{C}\mathcal{S}$  in  $(\mathcal{X}, \tau_{\mathcal{N}})$ .

**Sakthivel and Kavipriya**

**Theorem 3.3:**

Every  $\hat{N}CSin(X, \tau_\mu)$  is an  $\hat{N}\pi\hat{G}CS(X, \tau_\mu)$  but not conversely.

**Proof:**

Assume that  $\hat{A}$  is an  $\hat{N}CS$  in  $(X, \tau_\mu)$ . Let us consider an  $\hat{N}SA \subseteq U$  and  $U$  be an  $\hat{N}\pi OSin(X, \tau_\mu)$ . Since  $\hat{N}ael(\hat{A}) \subseteq \hat{N}el(\hat{A})$  and  $\hat{A}$  is an  $\hat{N}CS$  in  $X$ ,  $\hat{N}ael(\hat{A}) \subseteq \hat{N}el(\hat{A}) = \hat{A} \subseteq U$ . That is  $\hat{N}ael(\hat{A}) \subseteq U$ . Therefore,  $\hat{A}$  is an  $\hat{N}\pi\hat{G}CSin(X, \tau_\mu)$ .

**Example 3.4:**

Let  $X = \{p, q\}$  with  $\tau_\mu = \{0_\mu, \hat{W}, 1_\mu\}$  be an  $\hat{N}TSonX$ , where  $\hat{W} = (x, (0.4, 0.2, 0.4), (0.5, 0.6, 0.5))$ . Consider the  $\hat{N}SA = (x, (0.5, 0.3, 0.3), (0.5, 0.6, 0.4))$ . Clearly  $\hat{A} \subseteq 1_\mu$  and  $\hat{N}ael(\hat{A}) \subseteq 1_\mu$ . Hence  $\hat{A}$  is an  $\hat{N}\pi\hat{G}CS$ . But  $\hat{A}$  is not an  $\hat{N}CSin(X, \tau_\mu)$ .

**Theorem 3.5:**

Every  $\hat{N}ACS$  in  $(X, \tau_\mu)$  is an  $\hat{N}\pi\hat{G}CS(X, \tau_\mu)$  but not conversely.

**Proof:**

Let us consider an  $\hat{N}SA$ .  $\hat{A} \subseteq U$  and  $U$  be an  $\hat{N}OSin(X, \tau_\mu)$ . Also let  $\hat{A}$  is an  $\hat{N}ACSinX$ . This implies  $\hat{N}ael(\hat{A}) = \hat{A}$ . Hence  $\hat{N}ael(\hat{A}) \subseteq \hat{U}$ . Therefore  $\hat{A}$  is an  $\hat{N}\pi\hat{G}CSin(X, \tau_\mu)$ .

**Example 3.6:**

Let  $X = \{p, q\}$  and  $\tau_\mu = \{0_\mu, \hat{W}_1, \hat{W}_2, 1_\mu\}$  be an  $\hat{N}TSonX$ , where  $\hat{W}_1 = (x, (0.8, 0.6, 0.3), (0.6, 0.8, 0.4))$ ,  $\hat{W}_2 = (x, (0.3, 0.2, 0.4), (0.2, 0.8, 0.6))$ . Consider the  $\hat{N}SA = (x, (0.9, 0.6, 0.5), (0.2, 0.8, 0.6))$ . Clearly  $\hat{A} \subseteq 1_\mu$  and  $\hat{N}ael(\hat{A}) \subseteq 1_\mu$ . Hence  $\hat{A}$  is an  $\hat{N}\pi\hat{G}CS$ . But  $\hat{A}$  is not an  $\hat{N}ACSin(X, \tau_\mu)$  because  $\hat{N}el(\hat{N}jnt(\hat{N}el(\hat{A}))) \not\subseteq \hat{A}$ .

**Theorem 3.7:**

Every  $\hat{N}RCSin(X, \tau_\mu)$  is an  $\hat{N}\pi\hat{G}CSin(X, \tau_\mu)$  but not conversely.

**Proof**

Let  $\hat{A}$  be an  $\hat{N}RCSin(X, \tau_\mu)$ . Since every  $\hat{N}RCS$  is an  $\hat{N}CS$ . Let us consider an  $\hat{N}SA \subseteq U$  and  $U$  be an  $\hat{N}\pi OSin(X, \tau_\mu)$ . Since  $\hat{N}ael(\hat{A}) \subseteq \hat{N}el(\hat{A})$  and  $\hat{A}$  is an  $\hat{N}CS$  in  $X$ .  $\hat{A}$  is an  $\hat{N}\pi\hat{G}CSin(X, \tau_\mu)$ .

**Example 3.8:**

Let  $X = \{p, q\}$  with  $\tau_\mu = \{0_\mu, \hat{W}, 1_\mu\}$  be an  $\hat{N}TSonX$ , where  $\hat{W} = (x, (0.6, 0.7, 0.8), (0.2, 0.4, 0.3))$ . Consider the  $\hat{N}SA = (x, (0.7, 0.4, 0.6), (0.3, 0.5, 0.1))$ . Clearly  $\hat{A} \subseteq 1_\mu$  and  $\hat{N}ael(\hat{A}) \subseteq 1_\mu$ . Hence  $\hat{A}$  is an  $\hat{N}\pi\hat{G}CS$ . But  $\hat{A}$  is not an  $\hat{N}RCSin(X, \tau_\mu)$  because  $0_\mu \neq \hat{A}$ .

**Theorem 3.9:**

Every  $\hat{N}GCSin(X, \tau_\mu)$  is an  $\hat{N}\pi\hat{G}CSin(X, \tau_\mu)$  but its conversely may not be true in general.

**Proof:**

Assume that  $\hat{A}$  be an  $\hat{N}GCSin(X, \tau_\mu)$ . Let  $\hat{A} \subseteq U$  and  $U$  be an  $\hat{N}\pi OS$  in  $(X, \tau_\mu)$ . By hypothesis  $\hat{N}el(\hat{A}) \subseteq \hat{U}$ . Clearly  $\hat{N}ael(\hat{A}) \subseteq \hat{N}el(\hat{A})$ . This implies  $\hat{N}ael(\hat{A}) \subseteq U$  whenever  $\hat{A} \subseteq U$  and  $U$  is an  $\hat{N}\pi OSin(X, \tau_\mu)$ . Hence  $\hat{A}$  is an  $\hat{N}\pi\hat{G}CSin(X, \tau_\mu)$ .

**Example 3.10:**

Let  $X = \{p, q\}$  with  $\tau_\mu = \{0_\mu, \hat{W}, 1_\mu\}$  be an  $\hat{N}TSonX$ , where  $\hat{W} = (x, (0.9, 0.5, 0.1), (0.8, 0.5, 0.7))$ . Consider the  $\hat{N}SA = (x, (0.2, 0.3, 0.8), (0.3, 0.2, 0.7))$ . Clearly  $\hat{A} \subseteq 1_\mu$  and  $\hat{N}ael(\hat{A}) \subseteq 1_\mu$ . Hence  $\hat{A}$  is an  $\hat{N}\pi\hat{G}CS$  but  $\hat{A}$  is not an  $\hat{N}GCSin(X, \tau_\mu)$ , as  $\hat{N}el(\hat{A}) \not\subseteq \hat{W}$  even though  $\hat{A} \subseteq \hat{W}$  and  $\hat{W}$  is an  $\hat{N}\pi OSin(X, \tau_\mu)$ .

**Theorem 3.11:**

Every  $\hat{N}GSCS(X, \tau_\mu)$  is an  $\hat{N}\pi\hat{G}CSin(X, \tau_\mu)$  but its conversely may not be true in general.

**Sakthivel and Kavipriya**

**Proof:**

Assume that  $\hat{A}$  is an  $\hat{N}\hat{G}\hat{S}\hat{C}\hat{S}$  in  $(X, \tau_u)$ . Let us an  $\hat{N}\hat{S}\hat{A} \subseteq U$  and  $U$  be an  $\hat{N}\hat{\pi}\hat{O}\hat{S}$  in  $(X, \tau_u)$ . By hypothesis  $\hat{N}\hat{\alpha}\hat{e}l(\hat{A}) \subseteq \hat{N}\hat{e}l(\hat{A})$ . This implies  $\hat{N}\hat{\alpha}\hat{e}l(\hat{A}) \subseteq U$  whenever  $\hat{A} \subseteq U$  and  $U$  is an  $\hat{N}\hat{\pi}\hat{O}\hat{S}$  in  $(X, \tau_u)$ .

**Example 3.12:**

Let  $X = \{p, q\}$  with  $\tau_u = \{0_u, \hat{W}, 1_u\}$  be an  $\hat{N}\hat{T}\hat{S}$  on  $X$ , where  $\hat{W} = (x, (0.7, 0.6, 0.5), (0.4, 0.8, 0.3))$ . Consider the  $\hat{N}\hat{S}\hat{A} = (x, (0.7, 0.5, 0.5), (0.3, 0.7, 0.5))$ . Clearly  $\hat{A} \subseteq 1_u$  and  $\hat{N}\hat{\alpha}\hat{e}l(\hat{A}) \subseteq 1_u$ . Hence  $\hat{A}$  is an  $\hat{N}\hat{\alpha}\hat{\pi}\hat{G}\hat{C}\hat{S}$ . But  $\hat{A}$  is not an  $\hat{N}\hat{G}\hat{S}\hat{C}\hat{S}$  in  $(X, \tau_u)$ , because  $\hat{N}\hat{S}\hat{e}l(\hat{A}) \not\subseteq \hat{W}$ .

**Remark 3.13:**

An  $\hat{N}\hat{G}\hat{S}\hat{P}\hat{C}\hat{S}$  in  $(X, \tau_u)$  is need not be an  $\hat{N}\hat{\alpha}\hat{\pi}\hat{G}\hat{C}\hat{S}$  in  $(X, \tau_u)$ .

**Example 3.14:**

Let  $X = \{p, q\}$  with  $\tau_u = \{0_u, \hat{W}, 1_u\}$  be an  $\hat{N}\hat{T}\hat{S}$  on  $X$ , where  $\hat{W} = (x, (0.2, 0.5, 0.7), (0.3, 0.5, 0.8))$ . Consider the  $\hat{N}\hat{S}\hat{A} = (x, (0.2, 0.3, 0.8), (0.1, 0.4, 0.9))$  is an  $\hat{N}\hat{G}\hat{S}\hat{P}\hat{C}\hat{S}$  but  $\hat{A}$  is not an  $\hat{N}\hat{\alpha}\hat{\pi}\hat{G}\hat{C}\hat{S}$  in  $(X, \tau_u)$ . Since  $\hat{N}\hat{\alpha}\hat{e}l(\hat{A}) \not\subseteq \hat{W}$  even though  $\hat{A} \subseteq \hat{W}$  and  $\hat{W}$  is an  $\hat{N}\hat{\pi}\hat{O}\hat{S}$  in  $(X, \tau_u)$ .

**Remark 3.15:**

An  $\hat{N}\hat{\pi}$  closedness is independent of an  $\hat{N}\hat{\alpha}\hat{\pi}\hat{G}$  closedness.

**Example 3.16:**

Let  $X = \{p, q\}$  with  $\tau_u = \{0_u, \hat{W}, 1_u\}$  be an  $\hat{N}\hat{T}\hat{S}$  on  $X$ , where  $\hat{W} = (x, (0.2, 0.5, 0.7), (0.3, 0.5, 0.8))$ . Consider the  $\hat{N}\hat{S}\hat{A} = (x, (0.2, 0.3, 0.8), (0.1, 0.4, 0.9))$  is an  $\hat{N}\hat{P}\hat{C}\hat{S}$  but  $\hat{A}$  is not an  $\hat{N}\hat{\alpha}\hat{\pi}\hat{G}\hat{C}\hat{S}$  in  $(X, \tau_u)$ . Since  $\hat{N}\hat{\alpha}\hat{e}l(\hat{A}) \not\subseteq \hat{W}$  even though  $\hat{A} \subseteq \hat{W}$  and  $\hat{W}$  is an  $\hat{N}\hat{\pi}\hat{O}\hat{S}$  in  $(X, \tau_u)$ .

**Example 3.17:**

Let  $X = \{p, q\}$  with  $\tau_u = \{0_u, \hat{W}, 1_u\}$  be an  $\hat{N}\hat{T}\hat{S}$  on  $X$ , where  $\hat{W} = (x, (0.5, 0.3, 0.4), (0.6, 0.5, 0.4))$ . Consider the  $\hat{N}\hat{S}\hat{A} = (x, (0.6, 0.4, 0.3), (0.7, 0.5, 0.3))$  is an  $\hat{N}\hat{\alpha}\hat{\pi}\hat{G}\hat{C}\hat{S}$  but not an  $\hat{N}\hat{P}\hat{C}\hat{S}$  in  $(X, \tau_u)$ , as  $\hat{N}\hat{e}l(\hat{N}\hat{j}\hat{i}\hat{n}\hat{t}(\hat{A})) \not\subseteq \hat{A}$ .

**Remark 3.18:**

An  $\hat{N}\hat{S}\hat{P}$  closedness is independent of an  $\hat{N}\hat{\alpha}\hat{\pi}\hat{G}$  closedness.

**Example 3.19:**

Let  $X = \{p, q\}$  with  $\tau_u = \{0_u, \hat{W}, 1_u\}$  be an  $\hat{N}\hat{T}\hat{S}$  on  $X$ , where  $\hat{W} = (x, (0.3, 0.4, 0.8), (0.5, 0.4, 0.7))$ . Consider the  $\hat{N}\hat{S}\hat{A} = (x, (0.1, 0.3, 0.9), (0.2, 0.3, 0.8))$  is an  $\hat{N}\hat{S}\hat{P}\hat{C}\hat{S}$  but  $\hat{A}$  is not an  $\hat{N}\hat{\alpha}\hat{\pi}\hat{G}\hat{C}\hat{S}$  in  $(X, \tau_u)$ . Since  $\hat{N}\hat{\alpha}\hat{e}l(\hat{A}) \not\subseteq \hat{W}$  even though  $\hat{A} \subseteq \hat{W}$  and  $\hat{W}$  is an  $\hat{N}\hat{\pi}\hat{O}\hat{S}$  in  $(X, \tau_u)$ .

**Example 3.20:**

Let  $X = \{p, q\}$ ,  $\tau_u = \{0_u, \hat{W}, 1_u\}$  be an  $\hat{N}\hat{T}\hat{S}$  on  $X$ , where  $\hat{W} = (x, (0.3, 0.2, 0.5), (0.7, 0.8, 0.6))$ . Consider the  $\hat{N}\hat{S}\hat{A} = (x, (0.7, 0.8, 0.3), (0.8, 0.9, 0.4))$  is an  $\hat{N}\hat{\alpha}\hat{\pi}\hat{G}\hat{C}\hat{S}$  but not an  $\hat{N}\hat{S}\hat{P}\hat{C}\hat{S}$  in  $(X, \tau_u)$ . Since  $\hat{N}\hat{j}\hat{i}\hat{n}\hat{t}(\hat{N}\hat{e}l(\hat{N}\hat{j}\hat{i}\hat{n}\hat{t}(\hat{A}))) = 1_u \not\subseteq \hat{A}$ .

**Theorem 3.21:**

The union of  $\hat{N}\hat{\alpha}\hat{\pi}\hat{G}\hat{C}\hat{S}$   $\hat{A}$  and  $B$  is an  $\hat{N}\hat{\alpha}\hat{\pi}\hat{G}\hat{C}\hat{S}$  in  $(X, \tau_u)$ , if  $\hat{A}$  and  $B$  are  $\hat{N}\hat{C}\hat{S}$  in  $(X, \tau_u)$ .

**Proof:**

Since  $\hat{A}$  and  $B$  are  $\hat{N}\hat{C}\hat{S}$  in  $X$ ,  $\hat{N}\hat{e}l(\hat{A}) = \hat{A}$  and  $\hat{N}\hat{e}l(B) = B$ . Assume that  $\hat{A}$  and  $B$  are  $\hat{N}\hat{\alpha}\hat{\pi}\hat{G}\hat{C}\hat{S}$  in  $(X, \tau_u)$ . Let  $\hat{A} \cup B \subseteq U$  and  $U$  be  $\hat{N}\hat{\pi}\hat{O}\hat{S}$  in  $(X, \tau_u)$ . Then  $\hat{N}\hat{e}l(\hat{N}\hat{j}\hat{i}\hat{n}\hat{t}(\hat{N}\hat{e}l(\hat{A} \cup B))) = \hat{N}\hat{e}l(\hat{N}\hat{j}\hat{i}\hat{n}\hat{t}(\hat{A} \cup B)) \subseteq \hat{N}\hat{e}l(\hat{A} \cup B) = \hat{A} \cup B \subseteq U$ . That is  $\hat{N}\hat{\alpha}\hat{e}l(\hat{A} \cup B) \subseteq U$ . Therefore the union of  $\hat{A}$  and  $B$  is an  $\hat{N}\hat{\alpha}\hat{\pi}\hat{G}\hat{C}\hat{S}$  in  $(X, \tau_u)$ .

**Theorem 3.22:**

Let  $(X, \tau)$  be an  $\hat{N}\hat{T}\hat{S}$ . Then  $\hat{N}\hat{\alpha}\hat{O}(X) = \hat{N}\hat{\alpha}\hat{C}(X)$  if and only if  $\hat{N}\hat{S}$  in  $(X, \tau_u)$  is an  $\hat{N}\hat{\alpha}\hat{\pi}\hat{G}\hat{C}\hat{S}$  in  $(X, \tau_u)$ .

**Proof:**

**Necessity:** Suppose that  $\hat{N}\hat{\alpha}\hat{O}(X) = \hat{N}\hat{\alpha}\hat{C}(X)$ . Let  $\hat{A} \subseteq U$  and  $U$  be an  $\hat{N}\hat{O}\hat{S}$  in  $X$ . This implies  $\hat{N}\hat{\alpha}\hat{e}l(\hat{A}) \subseteq \hat{N}\hat{\alpha}\hat{e}l(U)$ . Since  $U$  is an  $\hat{N}\hat{O}\hat{S}$ ,  $U$  is an  $\hat{N}\hat{\alpha}\hat{O}\hat{S}$  in  $X$ . Since by hypothesis  $U$  is an  $\hat{N}\hat{\alpha}\hat{C}\hat{S}$  in  $X$ ,  $\hat{N}\hat{\alpha}\hat{e}l(U) = U$ . This implies  $\hat{N}\hat{\alpha}\hat{e}l(U) \subseteq U$ . Therefore  $\hat{A}$  is an  $\hat{N}\hat{\alpha}\hat{\pi}\hat{G}\hat{C}\hat{S}$  in  $(X, \tau_u)$ .

**Sakthivel and Kavipriya**

**Sufficiency:** Suppose that every  $\tilde{N}\tilde{S}$  in  $(X, \tau_u)$  is an  $\tilde{N}\alpha\pi\hat{G}\tilde{C}\tilde{S}$  in  $(X, \tau_u)$ . Let  $U \in \tilde{N}\tilde{O}(X)$ , then  $U \in \tilde{N}\alpha\tilde{O}(X)$ . Since  $U \subseteq U$  and  $U$  is  $\tilde{N}\tilde{O}\tilde{S}$  in  $X$ , by hypothesis  $\tilde{N}\alpha\text{el}(U) \subseteq U$ . But clearly  $U \subseteq \tilde{N}\alpha\text{el}(U)$ . Hence  $U = \tilde{N}\alpha\text{el}(U)$ . That is  $U \in \tilde{N}\alpha C(X)$ . Hence  $\tilde{N}\alpha\tilde{O}(X) \subseteq \tilde{N}\alpha C(X)$ .

Let  $\tilde{A} \in \tilde{N}\alpha C(X)$  then  $\tilde{A}^c$  is an  $\tilde{N}\alpha\tilde{O}\tilde{S}$  in  $X$ . But  $\tilde{N}\alpha\tilde{O}(X) \subseteq \tilde{N}\alpha C(X)$ . Therefore  $\tilde{A}^c \in \tilde{N}\alpha C(X)$ . Hence  $\tilde{A} \in \tilde{N}\alpha\tilde{O}(X)$ . This implies  $\tilde{N}\alpha C(X) \subseteq \tilde{N}\alpha\tilde{O}(X)$ . Thus  $\tilde{N}\alpha\tilde{O}(X) = \tilde{N}\alpha C(X)$ .

**Theorem 3.23:**

If  $\tilde{A}$  is  $\tilde{N}\tilde{O}\tilde{S}$  and an  $\tilde{N}\alpha\pi\hat{G}\tilde{C}\tilde{S}$  in  $(X, \tau_u)$ , then

- (i)  $\tilde{A}$  is  $\tilde{N}\tilde{R}\tilde{O}\tilde{S}$  in  $X$ ,
- (ii)  $\tilde{A}$  is  $\tilde{N}\tilde{R}\tilde{C}\tilde{S}$  in  $X$ .

**Proof:**

- (i) Let  $\tilde{A}$  be an  $\tilde{N}\pi\tilde{O}\tilde{S}$  and  $\tilde{N}\alpha\pi\hat{G}\tilde{C}\tilde{S}$  in  $X$ . This implies  $\tilde{N}\text{el}(\tilde{N}\text{jnt}(\tilde{N}\text{el}(\tilde{A}))) \subseteq \tilde{A}$ . That is  $\tilde{N}\text{jnt}(\tilde{N}\text{el}(\tilde{A})) \subseteq \tilde{A}$ . Since  $\tilde{A}$  is an  $\tilde{N}\tilde{O}\tilde{S}$ ,  $\tilde{A}$  is an  $\tilde{N}\tilde{P}\tilde{O}\tilde{S}$  in  $X$ . Hence  $\tilde{A} \subseteq \tilde{N}\text{jnt}(\tilde{N}\text{el}(\tilde{A}))$ . Therefore  $\tilde{A} = \tilde{N}\text{jnt}(\tilde{N}\text{el}(\tilde{A}))$ . Hence  $\tilde{A}$  is an  $\tilde{N}\tilde{R}\tilde{O}\tilde{S}$  in  $X$ .
- (ii) Let  $\tilde{A}$  be an  $\tilde{N}\tilde{O}\tilde{S}$  and an  $\tilde{N}\alpha\pi\hat{G}\tilde{C}\tilde{S}$  in  $X$ . Then  $\tilde{N}\text{el}(\tilde{N}\text{jnt}(\tilde{N}\text{el}(\tilde{A}))) \subseteq \tilde{A}$ . That is  $\tilde{N}\text{el}(\tilde{N}\text{jnt}(\tilde{A})) \subseteq \tilde{A}$ . Since  $\tilde{A}$  is an  $\tilde{N}\tilde{O}\tilde{S}$ ,  $\tilde{A}$  is an  $\tilde{N}\tilde{S}\tilde{O}\tilde{S}$  in  $X$ . Hence  $\tilde{A} \subseteq \tilde{N}\text{el}(\tilde{N}\text{jnt}(\tilde{A}))$ . Therefore  $\tilde{A} = \tilde{N}\text{el}(\tilde{N}\text{jnt}(\tilde{A}))$ ,  $\tilde{A}$  is an  $\tilde{N}\tilde{R}\tilde{C}\tilde{S}$  in  $X$ .

### ABSTRACT

In this paper ,we introduce the notion of Fermatean m-Polar Anti Fuzzy Subgroup(FmPAFSG).we define algebraic structure of a Fermatean m-Polar Anti Fuzzy Subgroup(FmPAFSG) and related properties are investigated.

**Keywords:** Fermatean m-Polar Anti Fuzzy Subgroups, some results.

## INTRODUCTION

Fuzzy set theory was first introduced by Zadeh[12] to solve the uncertainty problems in our real life. Using the concept of fuzzy set Rosenfeld[8] first define the notion of fuzzy subgroup. Chowdry[2] proved varies properties of fuzzy subgroups. The notion of Characterization of Phythagorean fuzzy subgroups was developed by Bhunia[3].Fermatean fuzzy set was introduced by T.Senapathi[9] .Using this sets ilambarasan[10] developed Fermatean fuzzy subgroups. The notion ofm-polar fuzzy sets was introduce by J.Chen[4].Solairaju[11] investigated some algebraic properties on m-polar neutrosophic fuzzy subgroups. R.Muthuraj[6] introduced Intuitionistic Multi-Anti fuzzy sub groups. The notion of some novel features of Phythagorean m-Polar fuzzy sets with applications was investigated by Khalid Naem[5].The notion of anti fuzzy subgroups was first proposed by Biwas[1].B.O.Onasanya[7] proved some results of fuzzy subgroups. In this paper we introduce the concept of Fermatean m Polar Anti Fuzzy Subgroups and prove some results.

**Radharamani and Rajarajeswari**

**PRELIMINARIES**

**Definition :2.1[12]**Let  $U$  be an universal set. A *fuzzy set*  $F$  on  $U$  is defined by  $F = \{ \langle u, \varphi(u) \rangle : \text{for all } u \in U \}$ , where  $\varphi$  is a function from  $U$  to  $[0,1]$  and it is called the membership function .

**Definition :2.2[8]**Let  $G$  be a group and  $U$  be an universal set. The fuzzy subset :  $U \rightarrow [0,1]$  of a group  $G$  is said to be a fuzzy subgroup of  $G$  if it satisfies the following conditions

- (i)  $\varphi(u,v) \geq \min\{ \varphi(u), \varphi(v) \}$
- (ii)  $\varphi(u^{-1}) \geq \varphi(u)$  , for all  $u,v \in G$

**Definition :2.3[1]** Let  $G$  be a group and  $U$  be an universal set. The fuzzy subset :  $U \rightarrow [0,1]$  of a group  $G$  is said to be a anti fuzzy subgroup of  $G$  if it satisfies the following conditions

- (i)  $\varphi(u,v) \leq \max\{ \varphi(u), \varphi(v) \}$
- (ii)  $\varphi(u^{-1}) = \varphi(u)$  , for all  $u,v \in G$

**Definition :2.4[5]** Let  $m$  be any positive integer. A *Pythagorean m-polar fuzzy set (PmFS)* on  $U$  is defined by  $P = \{ \langle u, ((\varphi_p^{(1)}(u), \Psi_p^{(1)}(u)), (\varphi_p^{(2)}(u), \Psi_p^{(2)}(u)), \dots, (\varphi_p^{(m)}(u), \Psi_p^{(m)}(u))) \rangle : \forall u \in U \}$ , where  $\varphi_p^{(i)} : U \rightarrow [0,1]$  is the membership function  $\Psi_p^{(i)} : U \rightarrow [0,1]$  is the non membership function which satisfies the condition  $(\varphi_p^{(i)}(u))^2 + (\Psi_p^{(i)}(u))^2 \leq 1$ . The set  $P = \{ \langle u, ((\varphi_p^{(1)}(u), \Psi_p^{(1)}(u)), (\varphi_p^{(2)}(u), \Psi_p^{(2)}(u)), \dots, (\varphi_p^{(m)}(u), \Psi_p^{(m)}(u))) \rangle : \forall u \in U \}$  is rewrite as  $P = \{ \langle u, (\varphi_p^{(i)}(u), \Psi_p^{(i)}(u)) \rangle : i=1,2,\dots,m \text{ and } \forall u \in U \}$

**Definition :2.5[9]** Let  $U$  be an universal set. An *Fermatean fuzzy set*  $F$  on  $U$  is defined by  $F = \{ \langle u, (\varphi(u), \Psi(u)) \rangle : \text{for all } u \in U \}$ , where the membership function  $\varphi : U \rightarrow [0,1]$  and the non membership function  $\Psi : U \rightarrow [0,1]$  which satisfies the condition  $(\varphi(u))^3 + (\Psi(u))^3 \leq 1, \forall u \in U$

**Fermatean m-Polar Anti-Fuzzy Subgroup**

**Definition :3.1**Let  $m$  be any positive integer and  $U$  be an universal set. A *Fermatean m-Polar fuzzy set (FmFS)* on  $U$  is defined as

$F = \{ \langle u, ((\varphi_F^{(1)}(u), \Psi_F^{(1)}(u)), (\varphi_F^{(2)}(u), \Psi_F^{(2)}(u)), \dots, (\varphi_F^{(m)}(u), \Psi_F^{(m)}(u))) \rangle : \forall u \in U \}$ , where  $\varphi_F^{(i)}(u) : U \rightarrow [0,1]$  is the membership function  $\Psi_F^{(i)}(u) : U \rightarrow [0,1]$  is the non membership function which satisfies the condition  $(\varphi_F^{(i)}(u))^3 + (\Psi_F^{(i)}(u))^3 \leq 1$ .

$F = \{ \langle u, ((\varphi_F^{(1)}(u), \Psi_F^{(1)}(u)), (\varphi_F^{(2)}(u), \Psi_F^{(2)}(u)), \dots, (\varphi_F^{(m)}(u), \Psi_F^{(m)}(u))) \rangle \}$   
 $= \{ \langle u, (\varphi_F^{(i)}(u), \Psi_F^{(i)}(u)) \rangle : i=1,2,3,\dots,m \}$

$$= \left\{ \frac{u}{((\varphi_F^{(i)}(u), (\Psi_F^{(i)}(u)))} \right\}$$

**Definition :3.2**Let  $(G, *)$  be a group and  $F = (\varphi_F^{(i)}(u), \Psi_F^{(i)}(u)) , i=1,2,\dots,m$  be a FmFS .Then  $F$  is said to be a Fermatean m Polar Anti Fuzzy Subgroup (FmAFSG) of  $G$  if it satisfies the following conditions

- (i)  $(\varphi_F^{(i)})^3(u * v) \leq (\varphi_F^{(i)})^3(u) \vee (\varphi_F^{(i)})^3(v)$
- (ii)  $(\varphi_F^{(i)})^3(u^{-1}) = (\varphi_F^{(i)})^3(u)$
- (iii)  $(\Psi_F^{(i)})^3(u * v) \geq (\Psi_F^{(i)})^3(u) \wedge (\Psi_F^{(i)})^3(v)$
- (iv)  $(\Psi_F^{(i)})^3(u^{-1}) = (\Psi_F^{(i)})^3(u)$  ,  $i=1,2,\dots,m$  and for all  $u \in G$

Here  $(\varphi_F^{(i)})^3(u) = (\varphi_F^{(i)}(u))^3$  and  $(\Psi_F^{(i)})^3(u) = (\Psi_F^{(i)}(u))^3$

**Example:3.3**Consider the set  $G = \{1, -1, i, -i\}$  .Then  $G$  is a group under usual multiplication ' . '

Now we define the F3FASG  $F = (\varphi_F^{(i)}, \Psi_F^{(i)}) , i=1,2,3$  on  $G$  is

$\varphi_F^{(1)}(1) = 0.6$  ,  $\varphi_F^{(2)}(1) = 0.5$   $\varphi_F^{(3)}(1) = 0.8$

$\Psi_F^{(1)}(1) = 0.3$  ,  $\Psi_F^{(2)}(1) = 0.7$  ,  $\Psi_F^{(3)}(1) = 0.4$

Radharamani and Rajarajeswari

$$\varphi_F^{(1)}(-1)=0.2, \varphi_F^{(2)}(-1)=0.3, \varphi_F^{(3)}(-1)=0.1$$

$$\Psi_F^{(1)}(-1)= 0.5, \Psi_F^{(2)}(-1)=0.8, \Psi_F^{(3)}(-1)=0.7$$

$$\varphi_F^{(1)}(i)=0.7, \varphi_F^{(2)}(i) =0.8, \varphi_F^{(3)}(i)=0.9$$

$$\Psi_F^{(1)}(i)=0.2, \Psi_F^{(2)}(i)=0.6, \Psi_F^{(3)}(i)=0.3$$

$$\varphi_F^{(1)}(-i)=0.7, \varphi_F^{(2)}(-i)=0.8, \varphi_F^{(3)}(-i)=0.9$$

$$\Psi_F^{(1)}(-i)= 0.2, \Psi_F^{(2)}(-i)=0.6, \Psi_F^{(3)}(-i)=0.3$$

$$(i)(\varphi_F^{(1)})^3(i \cdot -i) = (\varphi_F^{(1)})^3(1) = (0.6)^3, (\varphi_F^{(1)})^3(i) \vee (\varphi_F^{(1)})^3(-i) = (0.7)^3 \vee (0.7)^3 = (0.7)^3. \text{Therefore } (\varphi_F^{(1)})^3(i \cdot -i) \leq (\varphi_F^{(1)})^3(i) \vee (\varphi_F^{(1)})^3(-i)$$

$$(\varphi_F^{(2)})^3(i \cdot -i) = (\varphi_F^{(2)})^3(1) = (0.5)^3, (\varphi_F^{(2)})^3(i) \vee (\varphi_F^{(2)})^3(-i) = (0.8)^3 \vee (0.8)^3 = (0.8)^3. \text{Therefore } (\varphi_F^{(2)})^3(i \cdot -i) \leq (\varphi_F^{(2)})^3(i) \vee (\varphi_F^{(2)})^3(-i)$$

$$(\varphi_F^{(3)})^3(i \cdot -i) = (\varphi_F^{(3)})^3(1) = (0.8)^3, (\varphi_F^{(3)})^3(i) \vee (\varphi_F^{(3)})^3(-i) = (0.9)^3 \vee (0.9)^3 = (0.9)^3. \text{Therefore } (\varphi_F^{(3)})^3(i \cdot -i) \leq (\varphi_F^{(3)})^3(i) \vee (\varphi_F^{(3)})^3(-i)$$

$$(ii)(\varphi_F^{(1)})^3(i) = (\varphi_F^{(1)})^3(-i) = 0.7, (\varphi_F^{(2)})^3(i) = (\varphi_F^{(2)})^3(-i) = 0.8,$$

$$(\varphi_F^{(3)})^3(i) = (\varphi_F^{(3)})^3(-i) = 0.9$$

$$(iii)(\Psi_F^{(1)})^3(i \cdot -i) = (\Psi_F^{(1)})^3(1) = (0.3)^3, (\Psi_F^{(1)})^3(i) \wedge (\Psi_F^{(1)})^3(-i) = (0.2)^3 \wedge (0.2)^3 = (0.2)^3. \text{Therefore } (\Psi_F^{(1)})^3(i \cdot -i) \geq \Psi_F^{(1)} i \wedge \Psi_F^{(1)} -i$$

$$(\Psi_F^{(2)})^3(i \cdot -i) = (\Psi_F^{(2)})^3(1) = (0.3)^3, (\Psi_F^{(2)})^3(i) \wedge (\Psi_F^{(2)})^3(-i) = (0.2)^3 \wedge (0.2)^3 = (0.2)^3. \text{Therefore } (\Psi_F^{(2)})^3(i \cdot -i) \geq (\Psi_F^{(2)})^3(i) \wedge (\Psi_F^{(2)})^3(-i)$$

$$(\Psi_F^{(3)})^3(i \cdot -i) = (\Psi_F^{(3)})^3(1) = (0.4)^3, (\Psi_F^{(3)})^3(i) \wedge (\Psi_F^{(3)})^3(-i) = (0.3)^3 \wedge (0.3)^3 = (0.3)^3. \text{Therefore } (\Psi_F^{(3)})^3(i \cdot -i) \geq (\Psi_F^{(3)})^3(i) \wedge (\Psi_F^{(3)})^3(-i)$$

$$(iv)(\Psi_F^{(1)})^3(i) = (\Psi_F^{(1)})^3(-i) = 0.2, (\Psi_F^{(2)})^3(i) = (\Psi_F^{(2)})^3(-i) = 0.6,$$

$$(\Psi_F^{(3)})^3(i) = (\Psi_F^{(3)})^3(-i) = 0.3$$

Similarly we can check for other elements in G .

Hence F is F3FASG of (G,·)

**Proposition:3.4** Let  $F=(\varphi_F^{(i)}, \Psi_F^{(i)}), i=1,2,3, \dots, m$  be a FmPAFSG of a group (G,\*). Then the following are true

$$(i)(\varphi_F^{(i)})^3(e) \leq (\varphi_F^{(i)})^3(u) \text{ and } (\Psi_F^{(i)})^3(e) \geq (\Psi_F^{(i)})^3(u), i=1,2, \dots, m$$

$$(ii) (\varphi_F^{(i)})^3(e) \leq (\varphi_F^{(i)})^3(u^{-1}) \text{ and } (\Psi_F^{(i)})^3(e) \geq (\Psi_F^{(i)})^3(u^{-1}), i=1,2, \dots, m, \text{ for all } u \text{ in } G.$$

*Proof:* Let  $F=(\varphi_F^{(i)}, \Psi_F^{(i)}), i=1,2,3, \dots, m$  is FmPAFSG of (G,\*).

$$(i)(\varphi_F^{(i)})^3(e) = (\varphi_F^{(i)})^3(u * u^{-1}) \leq (\varphi_F^{(i)})^3(u) \vee (\varphi_F^{(i)})^3(u^{-1}) = (\varphi_F^{(i)})^3(u) \vee (\varphi_F^{(i)})^3(u) = (\varphi_F^{(i)})^3(u). \text{Therefore } (\varphi_F^{(i)})^3(e) \leq (\varphi_F^{(i)})^3(u)$$

$$\text{Again } (\Psi_F^{(i)})^3(e) = (\Psi_F^{(i)})^3(u * u^{-1}) \geq (\Psi_F^{(i)})^3(u) \wedge (\Psi_F^{(i)})^3(u^{-1}) = (\Psi_F^{(i)})^3(u) \wedge (\Psi_F^{(i)})^3(u) = (\Psi_F^{(i)})^3(u)$$

$$\text{Therefore } (\Psi_F^{(i)})^3(e) \geq (\Psi_F^{(i)})^3(u).$$

$$(ii) \text{ by our definition } (\varphi_F^{(i)})^3(u) = (\varphi_F^{(i)})^3(u^{-1}) \text{ and } (\Psi_F^{(i)})^3(u) = (\Psi_F^{(i)})^3(u^{-1})$$

Hence proved (ii)

**Proposition:3.5** Let (G,\*) be a group and  $F=(\varphi_F^{(i)}, \Psi_F^{(i)}), i=1,2,3, \dots, m$  be a FmPFS.

**Radharamani and Rajarajeswari**

F is FmPAFSG of a group  $(G,*)$  iff  $(\varphi_F^{(i)})^3(u * v^{-1}) \leq (\varphi_F^{(i)})^3(u) \vee (\varphi_F^{(i)})^3(v)$  and  $(\Psi_F^{(i)})^3(u * v^{-1}) \geq (\Psi_F^{(i)})^3(u) \wedge (\Psi_F^{(i)})^3(v)$

*Proof:* Let F is Fm PAFSG of a group  $(G,*)$ .

Now  $(\varphi_F^{(i)})^3(u * v^{-1}) \leq (\varphi_F^{(i)})^3(u) \vee (\varphi_F^{(i)})^3(v^{-1}) = (\varphi_F^{(i)})^3(u) \vee (\varphi_F^{(i)})^3(v)$  and

$(\Psi_F^{(i)})^3(u * v^{-1}) \geq (\Psi_F^{(i)})^3(u) \wedge (\Psi_F^{(i)})^3(v^{-1}) = (\Psi_F^{(i)})^3(u) \wedge (\Psi_F^{(i)})^3(v)$

Converse :Let us assume that  $(\varphi_F^{(i)})^3(u * v^{-1}) \leq (\varphi_F^{(i)})^3(u) \vee (\varphi_F^{(i)})^3(v)$  and

$(\Psi_F^{(i)})^3(u * v^{-1}) \geq (\Psi_F^{(i)})^3(u) \wedge (\Psi_F^{(i)})^3(v)$

Now  $(\varphi_F^{(i)})^3(e) = (\varphi_F^{(i)})^3(u * u^{-1}) \leq (\varphi_F^{(i)})^3(u) \vee (\varphi_F^{(i)})^3(u^{-1}) = (\varphi_F^{(i)})^3(u)$

$(\varphi_F^{(i)})^3(e) = (\varphi_F^{(i)})^3(u^{-1} * u) = (\varphi_F^{(i)})^3(u^{-1} * (u^{-1})^{-1}) \leq (\varphi_F^{(i)})^3(u^{-1}) \vee (\varphi_F^{(i)})^3(u^{-1}) = (\varphi_F^{(i)})^3(u^{-1})$

$(\varphi_F^{(i)})^3(u) = (\varphi_F^{(i)})^3(e * (u^{-1})^{-1}) \leq (\varphi_F^{(i)})^3(e) \vee (\varphi_F^{(i)})^3(u^{-1}) \leq (\varphi_F^{(i)})^3(u^{-1}) \vee (\varphi_F^{(i)})^3(u^{-1}) = (\varphi_F^{(i)})^3(u^{-1})$

Therefore  $(\varphi_F^{(i)})^3(u) \leq (\varphi_F^{(i)})^3(u^{-1})$

$(\varphi_F^{(i)})^3(u^{-1}) = (\varphi_F^{(i)})^3(e * u^{-1}) \leq (\varphi_F^{(i)})^3(e) \vee (\varphi_F^{(i)})^3(u) \leq (\varphi_F^{(i)})^3(u) \vee (\varphi_F^{(i)})^3(u) = (\varphi_F^{(i)})^3(u)$

Therefore  $(\varphi_F^{(i)})^3(u^{-1}) \leq (\varphi_F^{(i)})^3(u)$

Combining these ,we get  $(\varphi_F^{(i)})^3(u) = (\varphi_F^{(i)})^3(u^{-1})$

$(\varphi_F^{(i)})^3(u * v) = (\varphi_F^{(i)})^3(u * (v^{-1})^{-1}) \leq (\varphi_F^{(i)})^3(u) \vee (\varphi_F^{(i)})^3(v^{-1}) = (\varphi_F^{(i)})^3(u) \vee (\varphi_F^{(i)})^3(v)$

$(\Psi_F^{(i)})^3(e) = (\Psi_F^{(i)})^3(u * u^{-1}) \geq (\Psi_F^{(i)})^3(u) \wedge (\Psi_F^{(i)})^3(u^{-1}) = (\Psi_F^{(i)})^3(u)$

$(\Psi_F^{(i)})^3(e) = (\Psi_F^{(i)})^3(u^{-1} * u) = (\Psi_F^{(i)})^3(u^{-1} * (u^{-1})^{-1}) \geq (\Psi_F^{(i)})^3(u^{-1}) \wedge (\Psi_F^{(i)})^3(u^{-1}) = (\Psi_F^{(i)})^3(u^{-1})$

$(\Psi_F^{(i)})^3(u) = (\Psi_F^{(i)})^3(e * (u^{-1})^{-1}) \geq (\Psi_F^{(i)})^3(e) \wedge (\Psi_F^{(i)})^3(u^{-1}) \geq (\Psi_F^{(i)})^3(u^{-1}) \wedge (\Psi_F^{(i)})^3(u^{-1}) = (\Psi_F^{(i)})^3(u^{-1})$

Therefore  $(\Psi_F^{(i)})^3(u) \geq (\Psi_F^{(i)})^3(u^{-1})$

$(\Psi_F^{(i)})^3(u^{-1}) = (\Psi_F^{(i)})^3(e * u^{-1}) \geq (\Psi_F^{(i)})^3(e) \wedge (\Psi_F^{(i)})^3(u) \geq (\Psi_F^{(i)})^3(u) \wedge (\Psi_F^{(i)})^3(u) = (\Psi_F^{(i)})^3(u)$

Therefore  $(\Psi_F^{(i)})^3(u^{-1}) \geq (\Psi_F^{(i)})^3(u)$

Again  $(\Psi_F^{(i)})^3(u * v) = (\Psi_F^{(i)})^3(u * (v^{-1})^{-1}) \geq (\Psi_F^{(i)})^3(u) \wedge (\Psi_F^{(i)})^3(v^{-1}) = (\Psi_F^{(i)})^3(u) \wedge (\Psi_F^{(i)})^3(v)$

Hence F is Fm PAFSG of  $(G,*)$

**Proposition:3.6** Let  $(G,*)$  be a group and  $F_1 = (\varphi_{F_1}^{(i)}, \Psi_{F_1}^{(i)}(u)), F_2 = (\varphi_{F_2}^{(i)}, \Psi_{F_2}^{(i)}(u)), i=1,2,3,\dots,m$  and for all u in G be aFmPAFSG of  $(G,*)$ . Then  $F_1 \cup F_2$  is a FmPAFSG of  $(G,*)$ .

*Proof:* Let  $F_1 = (\varphi_{F_1}^{(i)}(u), \Psi_{F_1}^{(i)}(u))$  and  $F_2 = (\varphi_{F_2}^{(i)}(u), \Psi_{F_2}^{(i)}(u)), i=1,2,3,\dots,m$  and u in G be two FmPAFSG of  $(G,*)$ . Let  $F = F_1 \cup F_2 = (\varphi_F^{(i)}(u), \Psi_F^{(i)}(u)), i=1,2,3,\dots,m$  and u in G ,where  $\varphi_F^{(i)}(u) = \varphi_{F_1}^{(i)}(u) \vee \varphi_{F_2}^{(i)}(u)$  and  $\Psi_F^{(i)}(u) = \Psi_{F_1}^{(i)}(u) \wedge \Psi_{F_2}^{(i)}(u), i=1,2,3,\dots,m$  and u in G

Let  $u, v \in G$ . Now

$$(\varphi_F^{(i)})^3(u * v^{-1}) = (\varphi_{F_1}^{(i)})^3(u * v^{-1}) \vee (\varphi_{F_2}^{(i)})^3(u * v^{-1}) \leq$$

**Radharamani and Rajarajeswari**

$$\left( (\varphi_{F_1}^{(i)})^3(u) \vee (\varphi_{F_1}^{(i)})^3(v) \right) \vee \left( (\varphi_{F_2}^{(i)})^3(u) \vee (\varphi_{F_2}^{(i)})^3(v) \right) = \left( (\varphi_{F_1}^{(i)})^3(u) \vee (\varphi_{F_2}^{(i)})^3(u) \right) \vee \left( (\varphi_{F_1}^{(i)})^3(v) \vee (\varphi_{F_2}^{(i)})^3(v) \right) = (\varphi_F^{(i)})^3(u) \vee (\varphi_F^{(i)})^3(v) \quad , i=1,2,\dots,m$$

Therefore  $(\varphi_F^{(i)})^3(u * v^{-1}) \leq (\varphi_F^{(i)})^3(u) \vee (\varphi_F^{(i)})^3(v)$  ,  $i=1,2,\dots,m$  and for all  $u, v$  in  $G$ .

Again  $(\Psi_F^{(i)})^3(u * v^{-1}) = (\Psi_{F_1}^{(i)})^3(u * v^{-1}) \wedge (\Psi_{F_2}^{(i)})^3(u * v^{-1}) \geq \left( (\Psi_{F_1}^{(i)})^3(u) \wedge (\Psi_{F_1}^{(i)})^3(v) \right) \wedge \left( (\Psi_{F_2}^{(i)})^3(u) \wedge (\Psi_{F_2}^{(i)})^3(v) \right) = \left( (\Psi_{F_1}^{(i)})^3(u) \wedge (\Psi_{F_2}^{(i)})^3(u) \right) \wedge \left( (\Psi_{F_1}^{(i)})^3(v) \wedge (\Psi_{F_2}^{(i)})^3(v) \right) = (\Psi_F^{(i)})^3(u) \wedge (\Psi_F^{(i)})^3(v) \quad , i=1,2,\dots,m$

Therefore  $(\Psi_F^{(i)})^3(u * v^{-1}) \geq (\Psi_F^{(i)})^3(u) \wedge (\Psi_F^{(i)})^3(v)$  ,  $i=1,2,\dots,m$  and for all  $u, v$  in  $G$ .

Hence  $F = F_1 \cup F_2 = (\varphi_F^{(i)}(u), \Psi_F^{(i)}(u))$  ,  $i=1,2,\dots,m$  and for all  $u, v$  in  $G$  is a FmPAFSG of  $(G, *)$ .

**Corollary:3.7** Union of a family of FmPAFSGs of a group  $(G, *)$  is also a FmPAFSG of a group  $(G, *)$

Proof: Let  $K = \{F_1, F_2, F_3, \dots, F_n\}$  be a family of FmPAFSGs of a group  $(G, *)$ .

To prove  $F = \bigcup_{i=1}^n F_i$  is a FmPAFSG of a group  $(G, *)$

Let  $F = (\varphi_F^{(i)}(u), \Psi_F^{(i)}(u))$  ,  $i=1,2,\dots,m$  , where  $\varphi_F^{(i)}(u) = \varphi_{F_1}^{(i)}(u) \vee \varphi_{F_2}^{(i)}(u) \vee \dots \vee \varphi_{F_n}^{(i)}(u)$  and  $\Psi_F^{(i)}(u) = \Psi_{F_1}^{(i)}(u) \wedge \Psi_{F_2}^{(i)}(u) \wedge \dots \wedge \Psi_{F_n}^{(i)}(u)$  ,  $i=1,2,3,\dots,m$  and  $u$  in  $G$

Let  $u, v \in G$ .

Now

$$\begin{aligned} (\varphi_F^{(i)})^3(u * v^{-1}) &= (\varphi_{F_1}^{(i)})^3(u * v^{-1}) \vee (\varphi_{F_2}^{(i)})^3(u * v^{-1}) \vee \dots \vee (\varphi_{F_n}^{(i)})^3(u * v^{-1}) \leq \\ &\left( (\varphi_{F_1}^{(i)})^3(u) \vee (\varphi_{F_1}^{(i)})^3(v) \right) \vee \left( (\varphi_{F_2}^{(i)})^3(u) \vee (\varphi_{F_2}^{(i)})^3(v) \right) \vee \dots \vee \left( (\varphi_{F_n}^{(i)})^3(u) \vee (\varphi_{F_n}^{(i)})^3(v) \right) \\ &= \left( (\varphi_{F_1}^{(i)})^3(u) \vee (\varphi_{F_2}^{(i)})^3(u) \vee \dots \vee (\varphi_{F_n}^{(i)})^3(u) \right) \vee \left( (\varphi_{F_1}^{(i)})^3(v) \vee (\varphi_{F_2}^{(i)})^3(v) \vee \dots \vee (\varphi_{F_n}^{(i)})^3(v) \right) = (\varphi_F^{(i)})^3(u) \vee (\varphi_F^{(i)})^3(v) \end{aligned}$$

$, i=1,2,\dots,m$

Therefore  $(\varphi_F^{(i)})^3(u * v^{-1}) \leq (\varphi_F^{(i)})^3(u) \vee (\varphi_F^{(i)})^3(v)$  ,  $i=1,2,\dots,m$  and for all  $u, v$  in  $G$ .

Again

$$\begin{aligned} (\Psi_F^{(i)})^3(u * v^{-1}) &= (\Psi_{F_1}^{(i)})^3(u * v^{-1}) \wedge (\Psi_{F_2}^{(i)})^3(u * v^{-1}) \wedge \dots \wedge (\Psi_{F_n}^{(i)})^3(u * v^{-1}) \geq \\ &\left( (\Psi_{F_1}^{(i)})^3(u) \wedge (\Psi_{F_1}^{(i)})^3(v) \right) \wedge \left( (\Psi_{F_2}^{(i)})^3(u) \wedge (\Psi_{F_2}^{(i)})^3(v) \right) = \left( (\Psi_{F_1}^{(i)})^3(u) \wedge (\Psi_{F_2}^{(i)})^3(u) \right) \wedge \left( (\Psi_{F_1}^{(i)})^3(v) \wedge (\Psi_{F_2}^{(i)})^3(v) \right) = \\ &(\Psi_F^{(i)})^3(u) \wedge (\Psi_F^{(i)})^3(v) \quad , i=1,2,\dots,m \end{aligned}$$

Therefore  $(\Psi_F^{(i)})^3(u * v^{-1}) \geq (\Psi_F^{(i)})^3(u) \wedge (\Psi_F^{(i)})^3(v)$  ,  $i=1,2,\dots,m$  and for all  $u, v$  in  $G$ .

Therefore  $F = F_1 \cup F_2 = (\varphi_F^{(i)}(u), \Psi_F^{(i)}(u))$  ,  $i=1,2,\dots,m$  and for all  $u, v$  in  $G$  is a FmPAFSG of  $(G, *)$ .

Hence family of union of FmPAFSG is also a FmPAFSG.

**Remark:3.7** Intersection of two FmPAFSG is need not be a FmPAFSG  $(G, *)$ .

**Example:3.8** Let  $G = (Z, +)$  be a group and Let  $i=2$  and  $u$  in  $G$ ,  $F_1 = \langle (\varphi_{F_1}^{(1)}(u), \Psi_{F_1}^{(1)}(u)), (\varphi_{F_1}^{(2)}(u), \Psi_{F_1}^{(2)}(u)) \rangle$ ,  $F_2 = \langle (\varphi_{F_2}^{(1)}(u), \Psi_{F_2}^{(1)}(u)), (\varphi_{F_2}^{(2)}(u), \Psi_{F_2}^{(2)}(u)) \rangle$  be a FmPAFSG of  $(G, *)$ , where

$$\begin{aligned} \varphi_{F_1}^{(1)}(u) &= \begin{cases} 0, & u \in 5z \\ 0.5, & \text{elsewhere} \end{cases}, \Psi_{F_1}^{(1)}(u) = \begin{cases} 0.3, & u \in 5z \\ 0, & \text{elsewhere} \end{cases}, \varphi_{F_1}^{(2)}(u) = \begin{cases} 0.1, & u \in 5z \\ 0.7, & \text{elsewhere} \end{cases} \\ \varphi_{F_2}^{(1)}(u) &= \begin{cases} 0.6, & u \in 5z \\ 0, & \text{elsewhere} \end{cases}, \varphi_{F_2}^{(2)}(u) = \begin{cases} 0.2, & u \in 3z \\ 0.3, & \text{elsewhere} \end{cases}, \Psi_{F_2}^{(1)}(u) = \begin{cases} 0.15, & u \in 3z \\ 0, & \text{elsewhere} \end{cases} \\ \varphi_{F_2}^{(2)}(u) &= \begin{cases} 0.3, & u \in 3z \\ 0.5, & \text{elsewhere} \end{cases}, \Psi_{F_2}^{(2)}(u) = \begin{cases} 0.3, & u \in 3z \\ 0, & \text{elsewhere} \end{cases} \end{aligned}$$

$F = F_1 \cap F_2 = \langle (\varphi_F^{(1)}(u), \Psi_F^{(1)}(u)), (\varphi_F^{(2)}(u), \Psi_F^{(2)}(u)) \rangle$  , for all  $u$  in  $G$ , where

$$(\varphi_F^{(1)}(u) = \varphi_{F_1}^{(1)}(u) \wedge \varphi_{F_2}^{(1)}(u) , (\varphi_F^{(2)}(u) = \varphi_{F_1}^{(2)}(u) \wedge \varphi_{F_2}^{(2)}(u) , \Psi_F^{(1)}(u) = \Psi_{F_1}^{(1)}(u) \vee \Psi_{F_2}^{(1)}(u) , \Psi_F^{(2)}(u) = \Psi_{F_1}^{(2)}(u) \vee \Psi_{F_2}^{(2)}(u)$$

**Radharamani and Rajarajeswari**

$$\varphi_F^{(1)}(u) = \begin{cases} 0, & u \in 5z \\ 0.2, & u \in 3z - 5z \\ 0.3, & \text{elsewhere} \end{cases}, \varphi_F^{(2)}(u) = \begin{cases} 0.1, & u \in 5z \\ 0.3, & u \in 3z - 5z \\ 0.5, & \text{elsewhere} \end{cases}$$

$$\varphi_F^{(1)}(5 + (-3)) = \varphi_F^{(1)}(2) = 0.3, \varphi_F^{(1)}(5) = 0, \varphi_F^{(1)}(-3) = 0.2. \text{ Then } 0.3 \notin \max\{0.0.2\}$$

$$\varphi_F^{(2)}(5 + (-3)) = \varphi_F^{(2)}(2) = 0.5, \varphi_F^{(2)}(5) = 0.1, \varphi_F^{(2)}(-3) = 0.3. \text{ Then } 0.5 \notin \max\{0.1.0.3\}$$

$$\Psi_F^{(1)}(5 + (-3)) = \Psi_F^{(1)}(2) = 0, \Psi_F^{(1)}(5) = 0.3, \Psi_F^{(1)}(-3) = 0.15. \text{ Then } 0 \notin \min\{0.3.0.15\}$$
 Hence intersection of two FmPAFSG is not a FmPAFSG.

**Proposition:3.9** Let  $(G,*)$  be a group and  $F=(\varphi_{F^{(i)}},\Psi_{F^{(i)}}),i=1,2,3,\dots,m$  be a FmPAFSG of a group  $(G,*)$ . Then  $\varphi_{F^{(i)}}(u^n) \leq \varphi_{F^{(i)}}(u)$  and  $\Psi_{F^{(i)}}(u^n) \geq \Psi_{F^{(i)}}(u), i=1,2,..m$  and  $u$  in  $G$ .  
 Proof: Let  $n=2. \varphi_{F^{(i)}}(u^2) = \varphi_{F^{(i)}}(u * u) \leq \varphi_{F^{(i)}}(u) \forall \varphi_{F^{(i)}}(u) = \varphi_{F^{(i)}}(u)$  and  $\Psi_{F^{(i)}}(u^2) = \Psi_{F^{(i)}}(u * u) \geq \Psi_{F^{(i)}}(u) \wedge \Psi_{F^{(i)}}(u) = \Psi_{F^{(i)}}(u)$ . Then we can prove by induction  $\varphi_{F^{(i)}}(u^n) \leq \varphi_{F^{(i)}}(u)$  and  $\Psi_{F^{(i)}}(u^n) \geq \Psi_{F^{(i)}}(u), i=1,2,..m$  and  $u$  in  $G$ .

## ABSTRACT

This paper investigates the Hyers-Ulam-Rassias stability for mixed-type additive and quadratic functional equations in neutrosophic normed spaces. Neutrosophic normed spaces extend classical normed spaces by incorporating degrees of truth, indeterminacy, and falsity, making them suitable for handling uncertain, inconsistent, or incomplete information. We establish the general solution of the mixed additive-quadratic equation and analyze its stability using fixed-point methods and direct techniques. The results show how mappings behave under modifications and give the circumstances in which these mappings show stability in neutrosophic normed spaces.

**Keywords:** matrix neutrosophic normed spaces, neutrosophic stability, mixed type additive quadratic functional equation, direct method, fixed point method.

Mathematics Subject Classification: 39B82, 47L25, 39B72, 54H25.

## INTRODUCTION

By 1965, Lotfi A. Zadeh[26] invented fuzzy set theory. With respect to the idea of partial truth a concept in which truth values vary from fully true to fully false he put out this argument. This method was especially helpful for handling ambiguous or inaccurate data, which was outside the scope of classical binary logic. Krassimir T. Atanassov[2][3] proposed intuitionistic fuzzy set theory in 1986 and developed that concept in the year of 1989. With the addition of a degree of membership and a degree of non-membership, this theory expands upon the conventional fuzzy set theory. Neutrosophic sets were introduced by Florentin Smarandache[21][22] as an extension of the

**Jenifer et al.,**

intuitionistic fuzzy set. He introduced the idea of the neutrosophic set (NS) and the degree of indeterminacy as independent components in his 1995 manuscript, which was published in 1998. Compared to ordinary fuzzy sets, this enables the representation of imprecision and uncertainty, which makes it especially helpful in situations where judgements must take into account missing or ambiguous information. Fuzzy norms on a linear space were later introduced by Chun- Kai Cheng and John N. Moderson. In 2006, Saadati and Park[20] developed the idea of intuitionistic fuzzy normed space. Ulam[24] first raised the stability issue with group homomorphisms. Hyers[6][7] found a solution to the problem for Banach spaces in the case of approximation additive mappings. Next, for additive mappings and linear mappings, respectively, Aoki [1] and Rassias[18][19] expanded on Hyers' findings. Gavruta[5] found another further generalisation in 1994, which is known as the generalised Hyer-Ulam stability. A number of stability findings for various functional equations and inequalities were examined and expanded upon in a variety of matrix normed spaces, including matrix non-Archimedean random normed spaces, matrix fuzzy normed spaces, and matrix paranormed spaces[4, 12, 13, 16, 17]. Later Wang [25] developed this concept in matrix intuitionistic fuzzy normed spaces and then Jeyaraman, Mangayarkkarasi, Jeyanthi and Pandiselvi[9] established Hyers-Ulam-Rassias stability for functional equation in neutrosophic normed spaces. Also, Mangayarkkarasi, Jeyaraman and Jeyanthi[14] enhanced the idea of stability of a cubic functional equation in neutrosophic normed spaces.

This research aims to first present terminology of matrix neutrosophic normed spaces, which can then be used to study the Hyers-Ulam stability results for the mixed type additive-quadratic functional equation

$$2\ell[g(x + \ell y) + g(\ell x + y)] \\ = \ell(1 - s + \ell + \ell s + 2\ell^2)g(x + y) + \ell(1 - s - 3\ell + \ell s + 2\ell^2)g(x - y) + 2\ell g(\ell x) + 2\ell(s \\ + \ell - \ell s - 2\ell^2)g(x) + 2(1 - \ell - s)g(\ell y) + 2\ell s g(y)$$

in matrix neutrosophic normed spaces using the fixed point and direct methods, where  $s \neq 1 - 2\ell$  and  $\ell$  is a parameter,  $\ell > 1$ .

**Preliminaries**

To study the Hyer – Ulam stability results in matrix neutrosophic normed spaces, we present a few fundamental definitions and early findings in this section.

Definition:2.1. [14]The seven-tuple  $(\mathfrak{X}, \mu, \nu, \omega, *, \diamond, \odot)$  is a neutrosophic normed space  $(\mathfrak{NN}\mathfrak{S})$  if  $\mathfrak{X}$  is a vector space,  $*$  is a continuous t-norm,  $\diamond$  and  $\odot$  are continuous t-conorms, and  $\mu, \nu$  and  $\omega$  are fuzzy sets on  $\mathfrak{X} \times (0, \infty)$  meet the following conditions.

For every  $x, y \in \mathfrak{X}$  and  $\zeta, \lambda > 0$ ,

- (i)  $\mu(x, \lambda) + \nu(x, \lambda) + \omega(x, \lambda) \leq 3$ ;
- (ii)  $\mu(x, \lambda) > 0$ ,
- (iii)  $\mu(x, \lambda) = 1$  if and only if  $x = 0$ ;
- (iv)  $\mu(\alpha x, \lambda) = \mu\left(x, \frac{\lambda}{|\alpha|}\right)$  for each  $\alpha \neq 0$ ,
- (v)  $\mu(x, \lambda) * \mu(y, \zeta) \leq \mu(x + y, \lambda + \zeta)$ ;
- (vi)  $\mu(x, \cdot) : (0, \infty) \rightarrow [0, 1]$  is continuous;
- (vii)  $\lim_{\lambda \rightarrow \infty} \mu(x, \lambda) = 1$  and  $\lim_{\lambda \rightarrow 0} \mu(x, \lambda) = 0$ ;
- (viii)  $\nu(x, \lambda) < 1$ ,
- (ix)  $\nu(x, \lambda) = 0$  if and only if  $x = 0$ ;
- (x)  $\nu(\alpha x, \lambda) = \nu\left(x, \frac{\lambda}{|\alpha|}\right)$  for each  $\alpha \neq 0$ ,
- (xi)  $\nu(x, \lambda) \diamond \nu(y, \zeta) \geq \nu(x + y, \lambda + \zeta)$ ;
- (xii)  $\nu(x, \cdot) : (0, \infty) \rightarrow [0, 1]$  is continuous;
- (xiii)  $\lim_{\lambda \rightarrow \infty} \nu(x, \lambda) = 0$  and  $\lim_{\lambda \rightarrow 0} \nu(x, \lambda) = 1$ .
- (xiv)  $\omega(x, \lambda) < 1$ ,
- (xv)  $\omega(x, \lambda) = 0$  if and only if  $x = 0$ ;
- (xvi)  $\omega(\alpha x, \lambda) = \omega\left(x, \frac{\lambda}{|\alpha|}\right)$  for each  $\alpha \neq 0$ ,

**Jenifer et al.,**

- (xvii)  $\omega(x, \lambda) \otimes \omega(y, \zeta) \geq \omega(x + y, \lambda + \zeta)$ ;
  - (xviii)  $\omega(x, \cdot) : (0, \infty) \rightarrow [0, 1]$  is continuous;
  - (ixx)  $\lim_{\lambda \rightarrow \infty} \omega(x, \lambda) = 0$  and  $\lim_{\lambda \rightarrow 0} \omega(x, \lambda) = 1$ .
- In this case,  $(\mu, \nu, \omega)$  is called a  $\mathfrak{NN}$ .

**Definition:2.2.** [9] Let  $(\mathfrak{X}, \mu, \nu, \omega, *, \circ, \otimes)$  be a  $\mathfrak{NN}$ . Then, a sequence  $\{x_j\}$  is said to be convergent to  $x \in \mathfrak{X}$  w.r.to  $\mathfrak{NN}(\mu, \nu, \omega)$  if  $\forall \varepsilon > 0$  and  $\lambda > 0, \exists j_0 \in \mathbb{N}$ :  
 $\mu(x_j - x, \lambda) > 1 - \varepsilon, \nu(x_j - x, \lambda) < \varepsilon$  and  $\omega(x_j - x, \lambda) < \varepsilon$  for all  $j \geq j_0$ .  
 In this case we write  $(\mu, \nu, \omega) - \lim x_j = x$ .

**Definition:2.3.** [9] The sequence  $\{x_j\}$  is said to be a Cauchy sequence with respect to  $\mathfrak{NN}(\mu, \nu, \omega)$  if  $\forall \varepsilon > 0$  and  $\lambda > 0, \exists j_0 \in \mathbb{N}$  such that

$$\mu(x_j - x_k, \lambda) > 1 - \varepsilon, \nu(x_j - x_k, \lambda) < \varepsilon, \text{ and } \omega(x_j - x_k, \lambda) < \varepsilon \text{ for all } j, k \geq j_0.$$

A  $\mathfrak{NN}(\mathfrak{X}, \mu, \nu, \omega, *, \circ, \otimes)$  is said to be complete if every Cauchy sequences in  $(\mathfrak{X}, \mu, \nu, \omega, *, \circ, \otimes)$  is convergent in  $(\mathfrak{X}, \mu, \nu, \omega, *, \circ, \otimes)$ .

**Remark:** The following notations will also be used:

$E_{i,j}(\mathfrak{X})$  will represent the set of all  $i \times j$ -matrices in  $\mathfrak{X}$ . The matrix  $E_{i,j}(\mathfrak{X})$  is written as  $E_j(\mathfrak{X})$  when  $i = j$ . The row vector whose  $n$ th component is 1 and the other components are 0 shall be shown by the symbols  $e_n \in E_{1,j}(\mathbb{C})$ . The  $j \times j$  matrix whose  $(m,n)$ -component is 1 and the other components are 0 is denoted by  $\mathfrak{M}_{mn} \in E_j(\mathbb{C})$ .  $\mathfrak{M}_{mn} \otimes x \in E_j(\mathfrak{X})$  represents the  $j \times j$  matrix whose  $(m,n)$ -component is  $x$  and the remaining components are 0.

**Definition: 2.4.**[25] Let  $(\mathfrak{X}, \|\cdot\|)$  be a  $\mathfrak{NS}$ . Note that  $(\mathfrak{X}, \{\|\cdot\|_j\})$  is a  $\mathfrak{NN}$  iff  $(E_j(\mathfrak{X}), \|\cdot\|_j)$  is a  $\mathfrak{NS}$  for each positive integer  $j$  and  $\|\mathfrak{A} \times \mathfrak{B}\|_k \leq \|\mathfrak{A}\| \|\mathfrak{B}\|$  holds for  $\mathfrak{A} \in E_{k,j}, x = [x_{mn}] \in E_j(\mathfrak{X})$  and  $\mathfrak{B} \in E_{j,k}$ , and that  $(\mathfrak{X}, \{\|\cdot\|_j\})$  is a matrix Banach space  $(\mathfrak{MB})$  iff  $\mathfrak{X}$  is a  $\mathfrak{NS}$  and  $(\mathfrak{X}, \{\|\cdot\|_j\})$  is a  $\mathfrak{NN}$ .

Now, we introduce the concept of a  $\mathfrak{MNN}$  as follows:

**Definition: 2.5.** Consider a  $\mathfrak{NN}(\mathfrak{X}, \mu, \nu, \omega, *, \circ, \otimes)$  with a rectangular matrix of zero elements over  $\mathfrak{X}$  represented by  $\vartheta$ . Then:

(1)  $(\mathfrak{X}, \{\mu_n\}, \{\nu_n\}, \{\omega_n\}, *, \circ, \otimes)$  is said to be a  $\mathfrak{MNN}$  if for each positive integer  $j, (E_j(\mathfrak{X}), \mu_j, \nu_j, \omega_j, *, \circ, \otimes)$  is a  $\mathfrak{NN}$ ,  $\mu_j, \nu_j$  and  $\omega_j$  satisfy the following conditions:

(i)  $\mu_{j+i}(\vartheta + x, \lambda) = \mu_j(x, \lambda), \nu_{j+i}(\vartheta + x, \lambda) = \nu_j(x, \lambda)$  and  $\omega_{j+i}(\vartheta + x, \lambda) = \omega_j(x, \lambda)$  for all  $\lambda > 0, x = [x_{mn}] \in E_j(\mathfrak{X}), \vartheta \in E_j(\mathfrak{X})$ ;

(ii)  $\mu_\ell(\mathfrak{A} \times \mathfrak{B}, \lambda) \geq \mu_j\left(x, \frac{\lambda}{\|\mathfrak{A}\| \cdot \|\mathfrak{B}\|}\right), \nu_\ell(\mathfrak{A} \times \mathfrak{B}, \lambda) \leq \nu_j\left(x, \frac{\lambda}{\|\mathfrak{A}\| \cdot \|\mathfrak{B}\|}\right)$  and

$\omega_\ell(\mathfrak{A} \times \mathfrak{B}, \lambda) \leq \omega_j\left(x, \frac{\lambda}{\|\mathfrak{A}\| \cdot \|\mathfrak{B}\|}\right) \forall \lambda > 0, \mathfrak{A} \in E_{\ell,j}(\mathbb{R}), x = [x_{mn}] \in E_j(\mathfrak{X})$  and  $\mathfrak{B} \in E_{j,\ell}(\mathbb{R})$  with  $\|\mathfrak{A}\| \cdot \|\mathfrak{B}\| \neq 0$ .

(2)  $(\mathfrak{X}, \{\mu_j\}, \{\nu_j\}, \{\omega_j\}, *, \circ, \otimes)$  is called a  $\mathfrak{MNNB}$  if  $(\mathfrak{X}, \mu, \nu, \omega, *, \circ, \otimes)$  is a  $\mathfrak{NN}$  and  $(\mathfrak{X}, \{\mu_j\}, \{\nu_j\}, \{\omega_j\}, *, \circ, \otimes)$  is a  $\mathfrak{MNN}$ .

**Lemma: 2.6.** Let  $(\mathfrak{X}, \{\mu_j\}, \{\nu_j\}, \{\omega_j\}, *, \circ, \otimes)$  be a  $\mathfrak{MNN}$ . Then,

(1)  $\mu_j(\mathfrak{M}_{\ell s} \otimes x, \lambda) = \mu(x, \lambda), \nu_j(\mathfrak{M}_{\ell s} \otimes x, \lambda) = \nu(x, \lambda)$  and  $\omega_j(\mathfrak{M}_{\ell s} \otimes x, \lambda) = \omega(x, \lambda)$  for all  $\lambda > 0$  and  $x \in \mathfrak{X}$ .

(2) For all  $[x_{mn}] \in E_j(\mathfrak{X})$  and  $\sum_{m,n=1}^j \lambda_{mn} > 0$ ,

$$\begin{aligned} \mu(x_{\ell s}, \lambda) &\geq \mu_j([x_{mn}], \lambda) \geq \min\{\mu(x_{mn}, \lambda_{mn}) : m, n = 1, 2, \dots, j\}, \\ \mu(x_{\ell s}, \lambda) &\geq \mu_j([x_{mn}], \lambda) \geq \min\left\{\mu\left(x_{mn}, \frac{\lambda}{j^2}\right) : m, n = 1, 2, \dots, j\right\}, \\ \nu(x_{\ell s}, \lambda) &\leq \nu_j([x_{mn}], \lambda) \leq \max\{\nu(x_{mn}, \lambda_{mn}) : m, n = 1, 2, \dots, j\}, \\ \nu(x_{\ell s}, \lambda) &\leq \nu_j([x_{mn}], \lambda) \leq \max\left\{\nu\left(x_{mn}, \frac{\lambda}{j^2}\right) : m, n = 1, 2, \dots, j\right\} \text{ and} \\ \omega(x_{\ell s}, \lambda) &\leq \omega_j([x_{mn}], \lambda) \leq \max\{\omega(x_{mn}, \lambda_{mn}) : m, n = 1, 2, \dots, j\}, \\ \omega(x_{\ell s}, \lambda) &\leq \omega_j([x_{mn}], \lambda) \leq \max\left\{\omega\left(x_{mn}, \frac{\lambda}{j^2}\right) : m, n = 1, 2, \dots, j\right\}. \end{aligned}$$

(3)  $\lim_{i \rightarrow \infty} x_i \stackrel{\mathfrak{M}}{=} x$  iff  $\lim_{i \rightarrow \infty} x_{mni} \stackrel{\mathfrak{M}}{=} x_{mn}$  for  $x_i = [x_{mni}], x = [x_{mn}] \in E_j(\mathfrak{X})$ .

**Jenifer et al.,**

Lemma: 2.7. Let  $\mathbb{C}: \mathfrak{M} \rightarrow \mathfrak{M}$  be a strictly contractive mapping with Lipschitz constant  $\varrho < 1$  and let  $(\mathfrak{M}, \mathfrak{d})$  be a complete generalised  $\mathfrak{M}\mathfrak{S}$ . Then for every fixed element  $\mathfrak{x}$  in  $\mathfrak{M}$ , either  $\mathfrak{d}(\mathbb{C}^j \mathfrak{x}, \mathbb{C}^{j+1} \mathfrak{x}) = \infty, \forall j \geq 0$ , or  $\mathfrak{d}(\mathbb{C}^j \mathfrak{x}, \mathbb{C}^{j+1} \mathfrak{x}) < \infty, \forall j \geq j_0$ , for some natural number  $j_0$ . Furthermore, in the event that the second option is true, then

- (i) The sequence  $\{\mathbb{C}^j \mathfrak{x}\}$  is convergent to a fixed point  $\eta^*$  of  $\mathbb{C}$ .
- (ii)  $\eta^*$  is the unique fixed point of  $\mathbb{C}$  in the set  $\mathfrak{M}^* = \{\eta \in \mathfrak{M} : \mathfrak{d}(\mathbb{C}^0 \eta, \eta) < +\infty\}$
- (iii)  $\mathfrak{d}(\eta, \eta^*) \leq \frac{1}{1-\varrho} \mathfrak{d}(\eta, \mathbb{C}\eta), \forall \eta, \eta \in \mathfrak{M}^*$ .

**Neutrosophic Stability with Direct Method**

Let  $(\mathfrak{X}, \{\mu_j\}, \{\nu_j\}, \{\omega_j\}, *, \circ, \oplus)$  be a  $\mathfrak{M}\mathfrak{N}\mathfrak{S}$  and  $(\mathfrak{Y}, \{\mu_j\}, \{\nu_j\}, \{\omega_j\}, *, \circ, \oplus)$  be a  $\mathfrak{M}\mathfrak{N}\mathfrak{B}\mathfrak{S}$ . Using the direct method, we shall demonstrate the Hyer-Ulam stability of the functional equation in  $\mathfrak{M}\mathfrak{N}\mathfrak{S}$  in this section. Given a mapping  $g: \mathfrak{X} \rightarrow \mathfrak{Y}$ , we introduce the difference operators  $\mathfrak{D}g: \mathfrak{X}^2 \rightarrow \mathfrak{Y}$  and  $\mathfrak{D}g_n: E_j(\mathfrak{X}^2) \rightarrow E_j(\mathfrak{Y})$  of the functional Equation by

$$\begin{aligned} \mathfrak{D}g(u, v) &:= 2\ell[g(u + \ell v) + g(\ell u + v)] - \ell(1 - t + \ell + \ell t + 2\ell^2)g(u + v) \\ &\quad - \ell(1 - t - 3\ell + \ell t + 2\ell^2)g(u - v) - 2\ell g(\ell u) - 2\ell(t + \ell - \ell t - 2\ell^2)g(u) - 2(1 - \ell - t)g(\ell v) - 2\ell t g(v), \\ \mathfrak{D}g_j([\mathfrak{x}_{mn}], [\mathfrak{y}_{mn}]) &:= 2\ell[g_j([\mathfrak{x}_{mn}] + \ell[\mathfrak{y}_{mn}]) + g_j(\ell[\mathfrak{x}_{mn}] + [\mathfrak{y}_{mn}])] \\ &\quad - \ell(1 - t + \ell + \ell t + 2\ell^2)g_j([\mathfrak{x}_{mn}] + [\mathfrak{y}_{mn}]) - \ell(1 - t - 3\ell + \ell t + 2\ell^2)g_j([\mathfrak{x}_{mn}] - [\mathfrak{y}_{mn}]) - 2\ell g_j(\ell[\mathfrak{x}_{mn}]) \\ &\quad - 2\ell(t + \ell - \ell t - 2\ell^2)g_j([\mathfrak{x}_{mn}]) - 2(1 - \ell - t)g_j(\ell[\mathfrak{y}_{mn}]) - 2\ell t g_j([\mathfrak{y}_{mn}]) \end{aligned}$$

$\forall u, v \in \mathfrak{X}$  and all  $\mathfrak{x} = [\mathfrak{x}_{mn}], \eta = [\eta_{mn}] \in E_j(\mathfrak{X})$ .

Lemma: 3.1. Consider two real vector spaces,  $\mathfrak{X}$  and  $\mathfrak{U}$ . An odd function  $g: \mathfrak{X} \rightarrow \mathfrak{U}$  is additive if it fulfils the functional equation.

Lemma: 3.2. Consider two real vector spaces,  $\mathfrak{X}$  and  $\mathfrak{U}$ . An even function  $g: \mathfrak{X} \rightarrow \mathfrak{U}$  is quadratic if it fulfils the functional equation.

Theorem: 3.3. Given a function  $\psi_o: \mathfrak{X}^2 \rightarrow [0, \infty)$  such that, for a given real integer  $\delta$ , where  $0 < \delta < \ell$ ,

$$\psi_o(\ell u, \ell v) = \delta \psi_o(u, v) \tag{3.3.1}$$

$\forall u, v \in \mathfrak{X}$ . Suppose the following inequality is satisfied by an odd function  $g: \mathfrak{X} \rightarrow \mathfrak{Y}$ ,

$$\begin{cases} \mu_j(\mathfrak{D}g_j([\mathfrak{x}_{mn}], [\mathfrak{y}_{mn}]), \lambda) \geq \frac{\lambda}{\lambda + \sum_{m,n=1}^j \psi_o(\mathfrak{x}_{mn}, \mathfrak{y}_{mn})}, \\ \nu_j(\mathfrak{D}g_j([\mathfrak{x}_{mn}], [\mathfrak{y}_{mn}]), \lambda) \leq \frac{\sum_{m,n=1}^j \psi_o(\mathfrak{x}_{mn}, \mathfrak{y}_{mn})}{\lambda + \sum_{m,n=1}^j \psi_o(\mathfrak{x}_{mn}, \mathfrak{y}_{mn})} \text{ and} \\ \omega_j(\mathfrak{D}g_j([\mathfrak{x}_{mn}], [\mathfrak{y}_{mn}]), \lambda) \leq \frac{\sum_{m,n=1}^j \psi_o(\mathfrak{x}_{mn}, \mathfrak{y}_{mn})}{\lambda} \end{cases} \tag{3.3.2}$$

$\forall \mathfrak{x} = [\mathfrak{x}_{mn}], \eta = [\eta_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ . Then, an additive function  $\mathfrak{A}: \mathfrak{X} \rightarrow \mathfrak{Y}$  exists such that

$$\begin{cases} \mu_j(g_j([\mathfrak{x}_{mn}]) - \mathfrak{A}_j([\mathfrak{x}_{mn}]), \lambda) \geq \frac{(\ell - \delta)(2\ell + s - 1)\lambda}{(\ell - \delta)(2\ell + s - 1)\lambda + j^2 \sum_{m,n=1}^j \psi_o(0, \mathfrak{x}_{mn})}, \\ \nu_j(g_j([\mathfrak{x}_{mn}]) - \mathfrak{A}_j([\mathfrak{x}_{mn}]), \lambda) \leq \frac{j^2 \sum_{m,n=1}^j \psi_o(0, \mathfrak{x}_{mn})}{(\ell - \delta)(2\ell + s - 1)\lambda + j^2 \sum_{m,n=1}^j \psi_o(0, \mathfrak{x}_{mn})}, \\ \omega_j(g_j([\mathfrak{x}_{mn}]) - \mathfrak{A}_j([\mathfrak{x}_{mn}]), \lambda) \leq \frac{j^2 \sum_{m,n=1}^j \psi_o(0, \mathfrak{x}_{mn})}{(\ell - \delta)(2\ell + s - 1)\lambda} \end{cases} \tag{3.3.3}$$

$\forall \mathfrak{x} = [\mathfrak{x}_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ .

Proof. In the case where  $n = 1$ , (3.3.2) equals

$$\begin{aligned} \mu(\mathfrak{D}g(u, v), \lambda) &\geq \frac{\lambda}{\lambda + \psi_o(u, v)}, \nu(\mathfrak{D}g(u, v), \lambda) \leq \frac{\psi_o(u, v)}{\lambda + \psi_o(u, v)} \text{ and} \\ \omega(\mathfrak{D}g(u, v), \lambda) &\leq \frac{\psi_o(u, v)}{\lambda} \end{aligned} \tag{3.3.4}$$

$\forall u, v \in \mathfrak{X}$  and all  $\lambda > 0$ . If we put  $u = 0$  in (3.3.4), we get

$$\begin{cases} \mu(2(2\ell + s - 1)g(\ell v) - 2(2\ell + s - 1)\ell g(v), \lambda) \geq \frac{\lambda}{\lambda + \psi_o(0, v)}, \\ \nu(2(2\ell + s - 1)g(\ell v) - 2(2\ell + s - 1)\ell g(v), \lambda) \leq \frac{\psi_o(0, v)}{\lambda + \psi_o(0, v)} \text{ and} \\ \omega(2(2\ell + s - 1)g(\ell v) - 2(2\ell + s - 1)\ell g(v), \lambda) \leq \frac{\psi_o(0, v)}{\lambda} \end{cases} \tag{3.3.5}$$

**Jenifer et al.,**

$\forall v \in \mathfrak{X}$  and all  $\lambda > 0$ . Using (3.3.1) and changing  $u$  by  $\ell^q u$  in (3.3.5), we get

$$\begin{cases} \mu \left( \frac{g(\ell^{q+1}u)}{\ell^{q+1}} - \frac{g(\ell^q a)}{\ell^q}, \frac{\lambda}{2\ell(2\ell+s-1)\ell^q} \right) \geq \frac{\lambda}{\lambda + \delta^q \psi_o(0,u)}, \\ v \left( \frac{g(\ell^{q+1}u)}{\ell^{q+1}} - \frac{g(\ell^q u)}{\ell^q}, \frac{\lambda}{2\ell(2\ell+s-1)\ell^q} \right) \leq \frac{\delta^q \psi_o(0,u)}{\lambda + \delta^q \psi_o(0,u)}, \\ \omega \left( \frac{g(\ell^{q+1}u)}{\ell^{q+1}} - \frac{g(\ell^q u)}{\ell^q}, \frac{\lambda}{2\ell(2\ell+s-1)\ell^q} \right) \leq \frac{\delta^q \psi_o(0,u)}{\lambda} \end{cases} \quad (3.3.6)$$

$\forall u \in \mathfrak{X}$  and all  $\lambda > 0$ . From (3.3.6), it is evident that

$$\begin{cases} \mu \left( \frac{g(\ell^{q+1}u)}{\ell^{q+1}} - \frac{g(\ell^q u)}{\ell^q}, \frac{\delta^q \lambda}{2\ell(2\ell+s-1)\ell^q} \right) \geq \frac{\lambda}{\lambda + \psi_o(0,u)}, \\ v \left( \frac{g(\ell^{q+1}u)}{\ell^{q+1}} - \frac{g(\ell^q u)}{\ell^q}, \frac{\delta^q \lambda}{2\ell(2\ell+s-1)\ell^q} \right) \leq \frac{\psi_o(0,u)}{\lambda + \psi_o(0,u)} \text{ and} \\ \omega \left( \frac{g(\ell^{q+1}u)}{\ell^{q+1}} - \frac{g(\ell^q u)}{\ell^q}, \frac{\delta^q \lambda}{2\ell(2\ell+s-1)\ell^q} \right) \leq \frac{\psi_o(0,u)}{\lambda} \end{cases} \quad (3.3.7)$$

$\forall u \in \mathfrak{X}$  and all  $\lambda > 0$ . It follows from

$$\frac{g(\ell^q u)}{\ell^q} - f(u) = \sum_{r=0}^{q-1} \left( \frac{g(\ell^{q+1}u)}{\ell^{q+1}} - \frac{g(\ell^q u)}{\ell^q} \right) \text{ and (3.3.7) that}$$

$$\begin{cases} \mu \left( \frac{g(\ell^q u)}{\ell^q} - g(u), \sum_{r=0}^{q-1} \frac{\delta^r \lambda}{2\ell(2\ell+s-1)\ell^r} \right) \geq \prod_{r=0}^{q-1} \mu \left( \frac{g(\ell^{r+1}u)}{\ell^{r+1}} - \frac{g(\ell^r u)}{\ell^r}, \frac{\delta^r \lambda}{2\ell(2\ell+s-1)\ell^r} \right) \geq \frac{\lambda}{\lambda + \psi_o(0,u)}, \\ v \left( \frac{g(\ell^q u)}{\ell^q} - g(u), \sum_{r=0}^{q-1} \frac{\delta^r \lambda}{2\ell(2\ell+s-1)\ell^r} \right) \leq \prod_{r=0}^{q-1} v \left( \frac{g(\ell^{r+1}u)}{\ell^{r+1}} - \frac{g(\ell^r u)}{\ell^r}, \frac{\delta^r \lambda}{2\ell(2\ell+s-1)\ell^r} \right) \leq \frac{\psi_o(0,u)}{\lambda + \psi_o(0,u)}, \\ \omega \left( \frac{g(\ell^q u)}{\ell^q} - g(u), \sum_{r=0}^{q-1} \frac{\delta^r \lambda}{2\ell(2\ell+s-1)\ell^r} \right) \leq \prod_{r=0}^{q-1} v \left( \frac{g(\ell^{r+1}u)}{\ell^{r+1}} - \frac{g(\ell^r u)}{\ell^r}, \frac{\delta^r \lambda}{2\ell(2\ell+s-1)\ell^r} \right) \leq \frac{\psi_o(0,u)}{\lambda} \end{cases} \quad (3.3.8)$$

$\forall u \in \mathfrak{X}$  and all  $\lambda > 0$ , where  $\prod_{n=0}^p u_n = u_1 * u_2 * \dots * u_p$ ,

$$\prod_{n=0}^p u_n = u_1 \diamond u_2 \diamond \dots \diamond u_p \text{ and } \prod_{n=0}^p u_n = u_1 \diamond u_2 \diamond \dots \diamond u_p.$$

By replacing  $u$  with  $\ell^p u$  in (3.3.8), we have

$$\begin{cases} \mu \left( \frac{g(\ell^{q+p}u)}{\ell^{q+p}} - \frac{g(\ell^p u)}{\ell^p}, \sum_{r=0}^{q-1} \frac{\delta^r \lambda}{2\ell(2\ell+s-1)\ell^{r+q}} \right) \geq \frac{\lambda}{\lambda + \delta^q \psi_o(0,u)}, \\ v \left( \frac{g(\ell^{q+p}u)}{\ell^{q+p}} - \frac{g(\ell^p u)}{\ell^p}, \sum_{r=0}^{q-1} \frac{\delta^r \lambda}{2\ell(2\ell+s-1)\ell^{r+q}} \right) \leq \frac{\delta^q \psi_o(0,u)}{\lambda + \delta^q \psi_o(0,u)}, \\ \omega \left( \frac{g(\ell^{q+p}u)}{\ell^{q+p}} - \frac{g(\ell^p u)}{\ell^p}, \sum_{r=0}^{q-1} \frac{\delta^r \lambda}{2\ell(2\ell+s-1)\ell^{r+q}} \right) \leq \frac{\delta^q \psi_o(0,u)}{\lambda} \end{cases} \quad (3.3.9)$$

$\forall u \in \mathfrak{X}, \lambda > 0, q > 0$  and  $p > 0$ . Thus

$$\begin{cases} \mu \left( \frac{g(\ell^{q+p}u)}{\ell^{q+p}} - \frac{g(\ell^p u)}{\ell^p}, \sum_{r=p}^{q+p-1} \frac{\delta^r \lambda}{2\ell(2\ell+s-1)\ell^r} \right) \geq \frac{\lambda}{\lambda + \psi_o(0,u)}, \\ v \left( \frac{g(\ell^{q+p}u)}{\ell^{q+p}} - \frac{g(\ell^p u)}{\ell^p}, \sum_{r=q}^{q+p-1} \frac{\delta^r \lambda}{2\ell(2\ell+s-1)\ell^r} \right) \leq \frac{\psi_o(0,u)}{\lambda + \psi_o(0,u)}, \\ \omega \left( \frac{g(\ell^{q+p}u)}{\ell^{q+p}} - \frac{g(\ell^p u)}{\ell^p}, \sum_{r=q}^{q+p-1} \frac{\delta^r \lambda}{2\ell(2\ell+s-1)\ell^r} \right) \leq \frac{\psi_o(0,u)}{\lambda} \end{cases} \quad (3.3.10)$$

$\forall u \in \mathfrak{X}, \lambda > 0, q > 0$  and  $p > 0$ . Hence

$$\begin{cases} \mu \left( \frac{g(\ell^{q+p}u)}{\ell^{q+p}} - \frac{g(\ell^p u)}{\ell^p}, \lambda \right) \geq \frac{\lambda}{\lambda + \sum_{r=p}^{q+p-1} \frac{\delta^r}{2\ell(2\ell+s-1)\ell^r} \psi_o(0,u)}, \\ v \left( \frac{g(\ell^{q+p}u)}{\ell^{q+p}} - \frac{g(\ell^p u)}{\ell^p}, \lambda \right) \leq \frac{\sum_{r=p}^{q+p-1} \frac{\delta^r}{2\ell(2\ell+s-1)\ell^r} \psi_o(0,u)}{\lambda + \sum_{r=p}^{q+p-1} \frac{\delta^r}{2\ell(2\ell+s-1)\ell^r} \psi_o(0,u)}, \\ \omega \left( \frac{g(\ell^{q+p}u)}{\ell^{q+p}} - \frac{g(\ell^p u)}{\ell^p}, \lambda \right) \leq \frac{\sum_{r=p}^{q+p-1} \frac{\delta^r}{2\ell(2\ell+s-1)\ell^r} \psi_o(0,u)}{\lambda} \end{cases} \quad (3.3.11)$$

$\forall u \in \mathfrak{X}, \lambda > 0, p > 0$  and  $q > 0$ . Given that  $0 < \delta < \ell$  and  $\sum_{r=0}^{\infty} \frac{\delta^r}{2\ell(2\ell+s-1)\ell^r} < \infty$ .

It can be shown that  $\left\{ \frac{g(\ell^q u)}{\ell^q} \right\}$  is a Cauchy sequence in  $(\mathfrak{Y}, \mu, v, \omega, *, \diamond, \odot)$  via the Cauchy criterion for convergence in  $\mathfrak{N}\mathfrak{F}\mathfrak{S}$ . Since  $(\mathfrak{Y}, \mu, v, \omega, *, \diamond, \odot)$  is a  $\mathfrak{N}\mathfrak{F}\mathfrak{B}\mathfrak{S}$  (neutrosophic fuzzy banach space), this sequence converges to a point  $\mathfrak{A}(u) \in \mathfrak{Y}$ .

The function  $\mathfrak{A}: \mathfrak{X} \rightarrow \mathfrak{Y}$  can so be defined as follows:  $\mathfrak{A}(u) = (\mu, v, \omega) - \lim_{q \rightarrow \infty} \frac{g(\ell^q u)}{\ell^q} \text{ [17]}$

Furthermore, when we put  $q = 0$  in (3.3.11), we get

Jenifer et al.,

$$\left\{ \begin{aligned} \mu \left( \frac{g(\ell^q u)}{\ell^q} - g(u), \lambda \right) &\geq \frac{\lambda}{\lambda + \sum_{r=0}^{q-1} \frac{\delta^r}{2\ell(2\ell+s-1)\ell^r} \psi_0(0, u)}, \\ \nu \left( \frac{g(\ell^q u)}{\ell^q} - g(u), \lambda \right) &\leq \frac{\sum_{r=0}^{q-1} \frac{\delta^r}{2\ell(2\ell+s-1)\ell^r} \psi_0(0, u)}{\lambda + \sum_{r=0}^{q-1} \frac{\delta^r}{2\ell(2\ell+s-1)\ell^r} \psi_0(0, u)}, \\ \omega \left( \frac{g(\ell^q u)}{\ell^q} - g(u), \lambda \right) &\leq \frac{\sum_{r=0}^{q-1} \frac{\delta^r}{2\ell(2\ell+s-1)\ell^r} \psi_0(0, u)}{\lambda} \end{aligned} \right. \tag{3.3.12}$$

For  $u \in \mathfrak{X}, \lambda > 0$  and  $q > 0$ . Thus, we get

$$\left\{ \begin{aligned} \mu(g(u) - \mathfrak{A}(u), \lambda) &\geq \mu \left( g(u) - \frac{g(\ell^q u)}{\ell^q}, \frac{\lambda}{2} \right) * \mu \left( \frac{g(\ell^q u)}{\ell^q} - \mathfrak{A}(u), \frac{\lambda}{2} \right) \geq \frac{\lambda}{\lambda + \sum_{r=0}^{q-1} \frac{\delta^r}{2\ell(2\ell+s-1)\ell^r} \psi_0(0, u)}, \\ \nu(g(u) - \mathfrak{A}(u), \lambda) &\leq \nu \left( g(u) - \frac{g(\ell^q u)}{\ell^q}, \frac{\lambda}{2} \right) \diamond \nu \left( \frac{g(\ell^q u)}{\ell^q} - \mathfrak{A}(u), \frac{\lambda}{2} \right) \leq \frac{\sum_{r=0}^{q-1} \frac{\delta^r}{2\ell(2\ell+s-1)\ell^r} \psi_0(0, u)}{\lambda + \sum_{r=0}^{q-1} \frac{\delta^r}{2\ell(2\ell+s-1)\ell^r} \psi_0(0, u)}, \\ \omega(g(u) - \mathfrak{A}(u), \lambda) &\leq \omega \left( g(u) - \frac{g(\ell^q u)}{\ell^q}, \frac{\lambda}{2} \right) \otimes \omega \left( \frac{g(\ell^q u)}{\ell^q} - \mathfrak{A}(u), \frac{\lambda}{2} \right) \leq \frac{\sum_{r=0}^{q-1} \frac{\delta^r}{2\ell(2\ell+s-1)\ell^r} \psi_0(0, u)}{\lambda} \end{aligned} \right. \tag{3.3.13}$$

with large  $p$  and  $\forall u \in \mathfrak{X}, \lambda > 0$ . Taking the limit as  $q \rightarrow \infty$ , we obtain the following by applying the  $\mathfrak{N}\mathfrak{N}\mathfrak{S}$  definition,

$$\left\{ \begin{aligned} \mu(g(u) - \mathfrak{A}(u), \lambda) &\geq \frac{(\ell-\delta)(2\ell+s-1)\lambda}{(\ell-\delta)(2\ell+s-1)\lambda + \psi_0(0, u)}, \\ \nu(g(u) - \mathfrak{A}(u), \lambda) &\leq \frac{\psi_0(0, u)}{(\ell-\delta)(2\ell+s-1)\lambda + \psi_0(0, u)}, \\ \omega(g(u) - \mathfrak{A}(u), \lambda) &\leq \frac{\psi_0(0, u)}{(\ell-\delta)(2\ell+s-1)\lambda}. \end{aligned} \right. \tag{3.3.14}$$

Using (3.3.1) and substituting  $\ell^q u$  and  $\ell^q v$  for  $u$  and  $v$ , respectively in (3.3.4), we obtain

$$\left\{ \begin{aligned} \mu \left( \frac{1}{\ell^q} \mathfrak{D}g(\ell^q u, \ell^q v), \lambda \right) &\geq \frac{\lambda}{\lambda + \left(\frac{\alpha}{\ell}\right)^q \psi_0(u, v)}, \\ \nu \left( \frac{1}{\ell^q} \mathfrak{D}g(\ell^q u, \ell^q v), \lambda \right) &\leq \frac{(\delta^\ell)^q \psi_0(u, v)}{\lambda + \left(\frac{\alpha}{\ell}\right)^q \psi_0(u, v)} \text{ and} \\ \omega \left( \frac{1}{\ell^q} \mathfrak{D}g(\ell^q u, \ell^q v), \lambda \right) &\leq \frac{(\delta^\ell)^q \psi_0(u, v)}{\lambda} \end{aligned} \right. \tag{3.3.15}$$

For  $u, v \in \mathfrak{X}$  and all  $\lambda > 0$ . If we allow  $p \rightarrow \infty$  in (3.3.15), we obtain

$$\mu(\mathfrak{D}\mathfrak{A}(u, v), \lambda) = 1, \nu(\mathfrak{D}\mathfrak{A}(u, v), \lambda) = 0 \text{ and } \omega(\mathfrak{D}\mathfrak{A}(u, v), \lambda) = 0 \tag{3.3.16}$$

For  $u, v \in \mathfrak{X}$  and all  $\lambda > 0$ . Thus, the functional equation is satisfied by  $\mathfrak{A}$ . Given that  $g: \mathfrak{X} \rightarrow \mathfrak{Y}$  is an odd function, we may use definition  $\mathfrak{A}$  to show that, for every  $u$  in  $\mathfrak{X}$ ,  $\mathfrak{A}(-u) = -\mathfrak{A}(u)$ . Lemma (3.1) states that the function  $\mathfrak{A}: \mathfrak{X} \rightarrow \mathfrak{Y}$  is additive.

Let  $\mathfrak{A}': \mathfrak{X} \rightarrow \mathfrak{Y}$  be an additive function that satisfies (3.3.14) in order to prove the uniqueness of  $\mathfrak{A}$ . Assume  $j = 1$ .

Following that, we have

$$\left\{ \begin{aligned} \mu(\mathfrak{A}(u) - \mathfrak{A}'(u), \lambda) &= \mu \left( \frac{\mathfrak{A}(\ell^q u)}{\ell^q} - \frac{\mathfrak{A}'(\ell^q u)}{\ell^q}, \lambda \right) \\ &\geq \mu \left( \frac{\mathfrak{A}(\ell^q u)}{\ell^q} - \frac{g(\ell^q u)}{\ell^q}, \frac{\lambda}{2} \right) * \mu \left( \frac{g(\ell^q u)}{\ell^q} - \frac{\mathfrak{A}'(\ell^q u)}{\ell^q}, \frac{\lambda}{2} \right) \geq \frac{(\ell-\alpha)(2\ell+s-1)\lambda}{(\ell-\delta)(2\ell+s-1)\lambda + 2\left(\frac{\alpha}{\ell}\right)^q \psi_0(0, u)}, \\ \nu(\mathfrak{A}(u) - \mathfrak{A}'(u), \lambda) &= \nu \left( \frac{\mathfrak{A}(\ell^q u)}{\ell^q} - \frac{\mathfrak{A}'(\ell^q u)}{\ell^q}, \lambda \right) \\ &\leq \nu \left( \frac{\mathfrak{A}(\ell^q u)}{\ell^q} - \frac{g(\ell^q u)}{\ell^q}, \frac{\lambda}{2} \right) \diamond \nu \left( \frac{g(\ell^q u)}{\ell^q} - \frac{\mathfrak{A}'(\ell^q u)}{\ell^q}, \frac{\lambda}{2} \right) \leq \frac{2\left(\frac{\alpha}{\ell}\right)^q \psi_0(0, u)}{(\ell-\delta)(2\ell+s-1)\lambda + 2\left(\frac{\alpha}{\ell}\right)^q \psi_0(0, u)}, \\ \omega(\mathfrak{A}(u) - \mathfrak{A}'(u), \lambda) &= \omega \left( \frac{\mathfrak{A}(\ell^q u)}{\ell^q} - \frac{\mathfrak{A}'(\ell^q u)}{\ell^q}, \lambda \right) \\ &\leq \omega \left( \frac{\mathfrak{A}(\ell^q u)}{\ell^q} - \frac{g(\ell^q u)}{\ell^q}, \frac{\lambda}{2} \right) \otimes \omega \left( \frac{g(\ell^q u)}{\ell^q} - \frac{\mathfrak{A}'(\ell^q u)}{\ell^q}, \frac{\lambda}{2} \right) \leq \frac{2\left(\frac{\alpha}{\ell}\right)^q \psi_0(0, u)}{(\ell-\delta)(2\ell+s-1)\lambda} \end{aligned} \right. \tag{3.3.17}$$

For  $u \in \mathfrak{X}, \lambda > 0$  and  $q > 0$ . After allowing  $q \rightarrow \infty$  in (3.3.17), we get

$$\mu(\mathfrak{A}(u) - \mathfrak{A}'(u), \lambda) = 1, \nu(\mathfrak{A}(u) - \mathfrak{A}'(u), \lambda) = 0 \text{ and } \omega(\mathfrak{A}(u) - \mathfrak{A}'(u), \lambda) = 0$$

For  $u \in \mathfrak{X}$  and  $\lambda > 0$ . Hence, for all  $u$  in  $\mathfrak{X}$ , we have  $\mathfrak{A}(u) = \mathfrak{A}'(u)$ . As a result, there is only one additive function,  $\mathfrak{A}: \mathfrak{X} \rightarrow \mathfrak{Y}$ . Lemma 2.6 and (3.3.14) provide us with

Jenifer et al.,

$$\left\{ \begin{aligned} \mu_j(g_j([x_{mn}]) - \mathfrak{A}_j([x_{mn}]), \lambda) &\geq \min \left\{ \mu \left( g(x_{mn}) - \mathfrak{A}(x_{mn}), \frac{\lambda}{j^2} \right) : m, n = 1, \dots, j \right\} \\ &\geq \frac{(\ell - \delta)(2\ell + s - 1)\lambda}{(\ell - \delta)(2\ell + s - 1)\lambda + j^2 \sum_{m,n=1}^j \psi_o(0, x_{mn})}, \\ \nu_j(g_j([x_{mn}]) - \mathfrak{A}_j([x_{mn}]), \lambda) &\leq \max \left\{ \nu \left( g(x_{mn}) - \mathfrak{A}(x_{mn}), \frac{\lambda}{j^2} \right) : m, n = 1, \dots, j \right\} \\ &\leq \frac{j^2 \sum_{m,n=1}^j \psi_o(0, x_{mn})}{(\ell - \delta)(2\ell + s - 1)\lambda + j^2 \sum_{m,n=1}^j \psi_o(0, x_{mn})} \\ \omega_j(g_j([x_{mn}]) - \mathfrak{A}_j([x_{mn}]), \lambda) &\leq \max \left\{ \omega \left( g(x_{mn}) - \mathfrak{A}(x_{mn}), \frac{\lambda}{j^2} \right) : m, n = 1, \dots, j \right\} \\ &\leq \frac{j^2 \sum_{m,n=1}^j \psi_o(0, x_{mn})}{(\ell - \delta)(2\ell + s - 1)\lambda} \end{aligned} \right.$$

$\forall x = [x_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ . As a result,  $\mathfrak{A}: \mathfrak{X} \rightarrow \mathfrak{Y}$  is a unique additive function that fulfils (3.3.3), just as needed. This concludes the theorem's proof.

Theorem: 3.4. Let  $\psi_e: \mathfrak{X}^2 \rightarrow [0, \infty)$  be a function such that for a given real integer  $\delta$ , where  $0 < \delta < \ell^2$ ,  $\psi_e(\ell u, \ell v) = \delta \psi_e(u, v) \forall u, v \in \mathfrak{X}$ . (3.4.1)

Assume that the following inequality is satisfied by an even function  $g: \mathfrak{X} \rightarrow \mathfrak{Y}$  with  $g(0) = 0$

$$\left\{ \begin{aligned} \mu_n(\mathfrak{D}g_n([x_{mn}], [y_{mn}]), \lambda) &\geq \frac{\lambda}{\lambda + \sum_{m,n=1}^j \psi_e(x_{mn}, y_{mn})}, \\ \nu_n(\mathfrak{D}g_n([x_{mn}], [y_{mn}]), \lambda) &\leq \frac{\sum_{m,n=1}^j \psi_e(x_{mn}, y_{mn})}{\lambda + \sum_{m,n=1}^j \psi_e(x_{mn}, y_{mn})} \text{ and} \\ \omega_n(\mathfrak{D}g_n([x_{mn}], [y_{mn}]), \lambda) &\leq \frac{\sum_{m,n=1}^j \psi_e(x_{mn}, y_{mn})}{\lambda} \end{aligned} \right. \quad (3.4.2)$$

$\forall x = [x_{mn}], y = [y_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ . Following that, there is an unique quadratic function  $Q: \mathfrak{X} \rightarrow \mathfrak{Y}$  such that

$$\left\{ \begin{aligned} \mu_j(g_j([x_{mn}]) - Q_j([x_{mn}]), \lambda) &\geq \frac{(\ell^2 - \delta)(2\ell + s - 1)\lambda}{(\ell^2 - \delta)(2\ell + s - 1)\lambda + j^2 \sum_{m,n=1}^j \psi_e(0, x_{mn})}, \\ \nu_j(g_j([x_{mn}]) - Q_j([x_{mn}]), \lambda) &\leq \frac{j^2 \sum_{m,n=1}^j \psi_e(0, x_{mn})}{(\ell^2 - \delta)(2\ell + s - 1)\lambda + j^2 \sum_{m,n=1}^j \psi_e(0, x_{mn})} \text{ and} \\ \omega_j(g_j([x_{mn}]) - Q_j([x_{mn}]), \lambda) &\leq \frac{j^2 \sum_{m,n=1}^j \psi_e(0, x_{mn})}{(\ell^2 - \delta)(2\ell + s - 1)\lambda} \end{aligned} \right. \quad (3.4.3)$$

$\forall x = [x_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ .

Proof. In the case where  $j = 1$ , (3.4.2) equals

$$\left\{ \begin{aligned} \mu(\mathfrak{D}g(u, v), \lambda) &\geq \frac{\lambda}{\lambda + \psi_e(u, v)}, \\ \nu(\mathfrak{D}g(u, v), \lambda) &\leq \frac{\psi_e(u, v)}{\lambda + \psi_e(u, v)} \text{ and} \\ \omega(\mathfrak{D}g(u, v), \lambda) &\leq \frac{\psi_e(u, v)}{\lambda} \end{aligned} \right. \quad (3.4.4)$$

$\forall u, v \in \mathfrak{X}$  and all  $\lambda > 0$ . If we allow  $u = 0$  in (3.4.4), we get

$$\left\{ \begin{aligned} \mu(2(2\ell + s - 1)g(\ell v) - 2(2\ell + s - 1)\ell^2 g(v), \lambda) &\geq \frac{\lambda}{\lambda + \psi_e(0, v)}, \\ \nu(2(2\ell + s - 1)g(\ell v) - 2(2\ell + s - 1)\ell^2 g(v), \lambda) &\leq \frac{\psi_e(0, v)}{\lambda + \psi_e(0, v)}, \\ \omega(2(2\ell + s - 1)g(\ell v) - 2(2\ell + s - 1)\ell^2 g(v), \lambda) &\leq \frac{\psi_e(0, v)}{\lambda} \end{aligned} \right. \quad (3.4.5)$$

$\forall v \in \mathfrak{X}$  and all  $\lambda > 0$ . Using (3.4.1) and changing  $u$  to  $\ell^q u$  in (3.4.5), we obtain

$$\left\{ \begin{aligned} \mu \left( \frac{g(\ell^{q+1}u)}{\ell^{2(q+1)}} - \frac{g(\ell^q u)}{\ell^{2q}}, \frac{\lambda}{2\ell^2(2\ell + s - 1)\ell^{2q}} \right) &\geq \frac{\lambda}{\lambda + \delta^q \psi_e(0, u)}, \\ \nu \left( \frac{g(\ell^{q+1}u)}{\ell^{2(q+1)}} - \frac{g(\ell^q u)}{\ell^{2q}}, \frac{\lambda}{2\ell^2(2\ell + s - 1)\ell^{2q}} \right) &\leq \frac{\delta^q \psi_e(0, u)}{\lambda + \delta^q \psi_e(0, u)} \text{ and} \\ \omega \left( \frac{g(\ell^{q+1}u)}{\ell^{2(q+1)}} - \frac{g(\ell^q u)}{\ell^{2q}}, \frac{\lambda}{2\ell^2(2\ell + s - 1)\ell^{2q}} \right) &\leq \frac{\delta^q \psi_e(0, u)}{\lambda} \end{aligned} \right. \quad (3.4.6)$$

$\forall u \in \mathfrak{X}$  and all  $\lambda > 0$ . From (3.4.6), it is evident that

Jenifer et al.,

$$\left\{ \begin{aligned} \mu \left( \frac{g(\ell^{q+1}u)}{\ell^{2(q+1)}} - \frac{g(\ell^q u)}{\ell^{2q}}, \frac{\delta^q \lambda}{2\ell^2(2\ell+s-1)\ell^{2q}} \right) &\geq \frac{\lambda}{\lambda + \psi_e(0, u)}, \\ \nu \left( \frac{g(\ell^{q+1}u)}{\ell^{2(q+1)}} - \frac{g(\ell^q u)}{\ell^{2q}}, \frac{\delta^q \lambda}{2\ell^2(2\ell+s-1)\ell^{2q}} \right) &\leq \frac{\psi_e(0, u)}{\lambda + \psi_e(0, u)} \text{ and} \\ \omega \left( \frac{g(\ell^{q+1}u)}{\ell^{2(q+1)}} - \frac{g(\ell^q u)}{\ell^{2q}}, \frac{\delta^q \lambda}{2\ell^2(2\ell+s-1)\ell^{2q}} \right) &\leq \frac{\psi_e(0, u)}{\lambda} \end{aligned} \right. \tag{3.4.7}$$

$\forall u \in \mathfrak{X}$  and all  $\lambda > 0$ . It derives from

$$\frac{g(\ell^q u)}{\ell^{2q}} - g(u) = \sum_{r=0}^{q-1} \left( \frac{g(\ell^{r+1}u)}{\ell^{2(r+1)}} - \frac{g(\ell^r u)}{\ell^{2r}} \right) \text{ and (3.4.7) that}$$

$$\left\{ \begin{aligned} \mu \left( \frac{g(\ell^q u)}{\ell^{2q}} - g(u), \sum_{r=0}^{q-1} \frac{\delta^r \lambda}{2\ell^2(2\ell+s-1)\ell^{2r}} \right) &\geq \prod_{r=0}^{q-1} \mu \left( \frac{g(\ell^{r+1}u)}{\ell^{2(r+1)}} - \frac{g(\ell^r u)}{\ell^{2r}}, \frac{\delta^r \lambda}{2\ell^2(2\ell+s-1)\ell^{2r}} \right) \geq \frac{\lambda}{\lambda + \psi_e(0, u)}, \\ \nu \left( \frac{g(\ell^q u)}{\ell^{2q}} - g(u), \sum_{r=0}^{q-1} \frac{\delta^r \lambda}{2\ell^2(2\ell+s-1)\ell^{2r}} \right) &\leq \prod_{r=0}^{q-1} \nu \left( \frac{g(\ell^{r+1}u)}{\ell^{2(r+1)}} - \frac{g(\ell^r u)}{\ell^{2r}}, \frac{\delta^r \lambda}{2\ell^2(2\ell+s-1)\ell^{2r}} \right) \leq \frac{\psi_e(0, u)}{\lambda + \psi_e(0, u)} \text{ and} \\ \omega \left( \frac{g(\ell^q u)}{\ell^{2q}} - g(u), \sum_{r=0}^{q-1} \frac{\delta^r \lambda}{2\ell^2(2\ell+s-1)\ell^{2r}} \right) &\leq \prod_{r=0}^{q-1} \omega \left( \frac{g(\ell^{r+1}u)}{\ell^{2(r+1)}} - \frac{g(\ell^r u)}{\ell^{2r}}, \frac{\delta^r \lambda}{2\ell^2(2\ell+s-1)\ell^{2r}} \right) \leq \frac{\psi_e(0, u)}{\lambda} \end{aligned} \right. \tag{3.4.8}$$

$\forall u \in \mathfrak{X}$  and all  $\lambda > 0$ , where  $\prod_{n=0}^q u_n = u_1 * u_2 * \dots * u_q$ ,

$$\prod_{n=0}^q u_n = u_1 \diamond u_2 \diamond \dots \diamond u_q \text{ and } \prod_{n=0}^q u_n = u_1 \otimes u_2 \otimes \dots \otimes u_q$$

with  $\ell^p u$  in place of  $u$  in (3.4.8), we obtain

$$\left\{ \begin{aligned} \mu \left( \frac{g(\ell^{q+p}u)}{\ell^{2(q+p)}} - \frac{g(\ell^p u)}{\ell^{2p}}, \sum_{r=0}^{q-1} \frac{\delta^r \lambda}{2\ell^2(2\ell+s-1)\ell^{2(r+p)}} \right) &\geq \frac{\lambda}{\lambda + \delta^p \psi_e(0, u)}, \\ \nu \left( \frac{g(\ell^{q+p}u)}{\ell^{2(q+p)}} - \frac{g(\ell^p u)}{\ell^{2p}}, \sum_{r=0}^{q-1} \frac{\delta^r \lambda}{2\ell^2(2\ell+s-1)\ell^{2(r+p)}} \right) &\leq \frac{\delta^p \psi_e(0, u)}{\lambda + \delta^p \psi_e(0, u)} \text{ and} \\ \omega \left( \frac{g(\ell^{q+p}u)}{\ell^{2(q+p)}} - \frac{g(\ell^p u)}{\ell^{2p}}, \sum_{r=0}^{q-1} \frac{\delta^r \lambda}{2\ell^2(2\ell+s-1)\ell^{2(r+p)}} \right) &\leq \frac{\delta^p \psi_e(0, u)}{\lambda} \end{aligned} \right. \tag{3.4.9}$$

$\forall u \in \mathfrak{X}, \lambda > 0, q > 0$  and  $p > 0$ . Hence

$$\left\{ \begin{aligned} \mu \left( \frac{g(\ell^{q+p}u)}{\ell^{2(q+p)}} - \frac{g(\ell^p u)}{\ell^{2p}}, \sum_{r=p}^{q+p-1} \frac{\delta^r \lambda}{2\ell^2(2\ell+s-1)\ell^{2r}} \right) &\geq \frac{\lambda}{\lambda + \psi_e(0, u)}, \\ \nu \left( \frac{g(\ell^{q+p}u)}{\ell^{2(q+p)}} - \frac{g(\ell^p u)}{\ell^{2p}}, \sum_{r=p}^{q+p-1} \frac{\delta^r \lambda}{2\ell^2(2\ell+s-1)\ell^{2r}} \right) &\leq \frac{\psi_e(0, u)}{\lambda + \psi_e(0, u)} \text{ and} \\ \omega \left( \frac{g(\ell^{q+p}u)}{\ell^{2(q+p)}} - \frac{g(\ell^p u)}{\ell^{2p}}, \sum_{r=p}^{q+p-1} \frac{\delta^r \lambda}{2\ell^2(2\ell+s-1)\ell^{2r}} \right) &\leq \frac{\psi_e(0, u)}{\lambda} \end{aligned} \right. \tag{3.4.10}$$

$\forall u \in \mathfrak{X}, \lambda > 0, q > 0$  and  $p > 0$ . Hence

$$\left\{ \begin{aligned} \mu \left( \frac{g(\ell^{q+p}u)}{\ell^{2(q+p)}} - \frac{g(\ell^p u)}{\ell^{2p}}, \lambda \right) &\geq \frac{\lambda}{\lambda + \sum_{r=p}^{q+p-1} \frac{\delta^r}{2\ell^2(2\ell+s-1)\ell^{2r}} \psi_e(0, u)}, \\ \nu \left( \frac{g(\ell^{q+p}u)}{\ell^{2(q+p)}} - \frac{g(\ell^p u)}{\ell^{2p}}, \lambda \right) &\leq \frac{\sum_{r=q}^{q+p-1} \frac{\delta^r}{2\ell^2(2\ell+s-1)\ell^{2r}} \psi_e(0, u)}{\lambda + \sum_{r=p}^{q+p-1} \frac{\delta^r}{2\ell^2(2\ell+s-1)\ell^{2r}} \psi_e(0, u)} \text{ and} \\ \omega \left( \frac{g(\ell^{q+p}u)}{\ell^{2(q+p)}} - \frac{g(\ell^p u)}{\ell^{2p}}, \lambda \right) &\leq \frac{\sum_{r=p}^{q+p-1} \frac{\delta^r}{2\ell^2(2\ell+s-1)\ell^{2r}} \psi_e(0, u)}{\lambda} \end{aligned} \right. \tag{3.4.11}$$

$\forall u \in \mathfrak{X}, \lambda > 0, q > 0$  and  $p > 0$ . Given that  $0 < \delta < \ell^2$  and  $\sum_{r=0}^{\infty} \frac{\delta^r}{2\ell^2(2\ell+s-1)\ell^{2r}} < \infty$ .

It is demonstrated that  $\left\{ \frac{g(\ell^q u)}{\ell^{2q}} \right\}$  is a Cauchy sequence in  $(\mathfrak{Y}, \mu, \nu, \omega, *, \diamond, \otimes)$  via the Cauchy criterion for convergence in  $\mathfrak{N}\mathfrak{N}\mathfrak{S}$ . This sequence converges to a point  $Q(u) \in \mathfrak{Y}$  since  $(\mathfrak{Y}, \mu, \nu, \omega, *, \diamond, \otimes)$  is a  $\mathfrak{N}\mathfrak{N}\mathfrak{S}\mathfrak{B}\mathfrak{S}$ .

Thus,  $Q: \mathfrak{X} \rightarrow \mathfrak{Y}$  can be defined in such a way that  $Q(u) := (\mu, \nu, \omega) - \lim_{p \rightarrow \infty} g(\ell^q u) / \ell^{2q}$

Additionally, if we write  $p = 0$  in (3.4.11), we obtain

$$\left\{ \begin{aligned} \mu \left( \frac{g(\ell^q u)}{\ell^{2q}} - g(u), \lambda \right) &\geq \frac{\lambda}{\lambda + \sum_{r=0}^{q-1} \frac{\delta^r}{2\ell^2(2\ell+s-1)\ell^{2r}} \psi_e(0, u)}, \\ \nu \left( \frac{g(\ell^q u)}{\ell^{2q}} - g(u), \lambda \right) &\leq \frac{\sum_{r=0}^{q-1} \frac{\delta^r}{2\ell^2(2\ell+s-1)\ell^{2r}} \psi_e(0, u)}{\lambda + \sum_{r=0}^{q-1} \frac{\delta^r}{2\ell^2(2\ell+s-1)\ell^{2r}} \psi_e(0, u)} \text{ and} \\ \omega \left( \frac{g(\ell^q u)}{\ell^{2q}} - g(u), \lambda \right) &\leq \frac{\sum_{r=0}^{q-1} \frac{\delta^r}{2\ell^2(2\ell+s-1)\ell^{2r}} \psi_e(0, u)}{\lambda} \end{aligned} \right. \tag{3.4.12}$$

$\forall u \in \mathfrak{X}, \lambda > 0$  and  $q > 0$ . Hence, we can get

Jenifer et al.,

$$\left\{ \begin{aligned} \mu(g(u) - Q(u), \lambda) &\geq \mu\left(g(u) - \frac{g(\ell^q u)}{\ell^{2q}}, \frac{\lambda}{2}\right) * \mu\left(\frac{g(\ell^q u)}{\ell^{2q}} - Q(u), \frac{\lambda}{2}\right) \geq \frac{\lambda}{\lambda + \sum_{r=0}^{q-1} \frac{\delta^r}{\ell^{2(2\ell+s-1)\ell^{2r}} \psi_e(0, u)}}, \\ v(g(u) - Q(u), \lambda) &\leq v\left(g(u) - \frac{g(\ell^q u)}{\ell^{2q}}, \frac{\lambda}{2}\right) \diamond v\left(\frac{g(\ell^q u)}{\ell^{2q}} - Q(u), \frac{\lambda}{2}\right) \leq \frac{\sum_{r=0}^{q-1} \frac{\delta^r}{\ell^{2(2\ell+s-1)\ell^{2r}} \psi_e(0, u)}}{\lambda + \sum_{r=0}^{q-1} \frac{\delta^r}{\ell^{2(2\ell+s-1)\ell^{2r}} \psi_e(0, u)}} \text{ and} \\ \omega(g(u) - Q(u), \lambda) &\leq \omega\left(g(u) - \frac{g(\ell^q u)}{\ell^{2q}}, \frac{\lambda}{2}\right) \otimes \omega\left(\frac{g(\ell^q u)}{\ell^{2q}} - Q(u), \frac{\lambda}{2}\right) \leq \frac{\sum_{r=0}^{q-1} \frac{\delta^r}{\ell^{2(2\ell+s-1)\ell^{2r}} \psi_e(0, u)}}{\lambda} \end{aligned} \right. \tag{3.4.13}$$

with large q and  $\forall u \in \mathfrak{X}, \lambda > 0$ . Using the  $\mathfrak{N}\mathfrak{N}\mathfrak{S}$  formulation and using the limit as  $q \rightarrow \infty$ , we obtain

$$\left\{ \begin{aligned} \mu(g(u) - Q(u), \lambda) &\geq \frac{(\ell^2 - \delta)(2\ell + s - 1)\lambda}{(\ell^2 - \delta)(2\ell + s - 1)\lambda + \psi_e(0, u)}, \\ v(g(u) - Q(u), \lambda) &\leq \frac{\psi_e(0, u)}{(\ell^2 - \delta)(2\ell + s - 1)\lambda + \psi_e(0, u)} \text{ and} \\ \omega(g(u) - Q(u), \lambda) &\leq \frac{\psi_e(0, u)}{(\ell^2 - \delta)(2\ell + s - 1)\lambda} \end{aligned} \right. \tag{3.4.14}$$

Replacing  $u$  and  $v$  by  $\ell^q u$  and  $\ell^q v$  in (3.4.14), respectively, and using (3.3.11), we can get Using (3.4.1) and substituting  $\ell^q u$  and  $\ell^q v$  for  $u$  and  $v$ , respectively, in (3.4.4), we may obtain

$$\left\{ \begin{aligned} \mu\left(\frac{1}{\ell^{2q}} \mathfrak{D}g(\ell^q u, \ell^q v), \lambda\right) &\geq \frac{\lambda}{\lambda + \left(\frac{\delta}{\ell^2}\right)^q \psi_e(u, v)}, \\ v\left(\frac{1}{\ell^{2q}} \mathfrak{D}g(\ell^q u, \ell^q v), \lambda\right) &\leq \frac{\left(\frac{\delta}{\ell^2}\right)^q \psi_e(u, v)}{\lambda + \left(\frac{\delta}{\ell^2}\right)^q \psi_e(u, v)} \text{ and} \\ \omega\left(\frac{1}{\ell^{2q}} \mathfrak{D}g(\ell^q u, \ell^q v), \lambda\right) &\leq \frac{\left(\frac{\delta}{\ell^2}\right)^q \psi_e(u, v)}{\lambda} \end{aligned} \right. \tag{3.4.15}$$

$\forall u, v \in \mathfrak{X}$  and all  $\lambda > 0$ . If we assume  $q \rightarrow \infty$  in (3.4.15), we get

$$\mu(\mathfrak{D}Q(u, v), \lambda) = 1, v(\mathfrak{D}Q(u, v), \lambda) = 0 \text{ and } \omega(\mathfrak{D}Q(u, v), \lambda) = 0 \tag{3.4.16}$$

$\forall u, v \in \mathfrak{X}$  and all  $\lambda > 0$ . This indicates that the functional equation is satisfied by  $Q$ .

Using the concept of  $Q$  and the fact that  $g: \mathfrak{X} \rightarrow \mathfrak{Y}$  is an even function, we can show that for all  $u$  in  $\mathfrak{X}, Q(-u) = -Q(u)$ .

Therefore, the function  $Q: \mathfrak{X} \rightarrow \mathfrak{Y}$  is quadratic by Lemma (3.2). Let  $Q': \mathfrak{X} \rightarrow \mathfrak{Y}$  be other quadratic function that satisfies (3.4.14) in order to show the uniqueness of  $Q$ .

Assume  $j = 1$ . Next, we have

$$\left\{ \begin{aligned} \mu(Q(u) - Q'(u), \lambda) &= \mu\left(\frac{Q(\ell^q u)}{\ell^{2q}} - \frac{Q'(\ell^q u)}{\ell^{2q}}, \lambda\right) \\ &\geq \mu\left(\frac{Q(\ell^q u)}{\ell^{2q}} - \frac{g(\ell^q u)}{\ell^{2q}}, \frac{\lambda}{2}\right) * \mu\left(\frac{g(\ell^q u)}{\ell^{2q}} - \frac{Q'(\ell^q u)}{\ell^{2q}}, \frac{\lambda}{2}\right) \\ &\geq \frac{(\ell^2 - \delta)(2\ell + s - 1)\lambda}{(\ell^2 - \delta)(2\ell + s - 1)\lambda + 2\left(\frac{\delta}{\ell^2}\right)^q \psi_e(0, u)}, \\ v(Q(u) - Q'(u), \lambda) &= v\left(\frac{Q(\ell^q u)}{\ell^{2q}} - \frac{Q'(\ell^q u)}{\ell^{2q}}, \lambda\right) \\ &\leq v\left(\frac{Q(\ell^q u)}{\ell^{2q}} - \frac{g(\ell^q u)}{\ell^{2q}}, \frac{\lambda}{2}\right) \diamond v\left(\frac{g(\ell^q u)}{\ell^{2q}} - \frac{Q'(\ell^q u)}{\ell^{2q}}, \frac{\lambda}{2}\right) \\ &\leq \frac{2\left(\frac{\delta}{\ell^2}\right)^q \psi_e(0, u)}{(\ell^2 - \delta)(2\ell + s - 1)\lambda + 2\left(\frac{\delta}{\ell^2}\right)^q \psi_e(0, u)}, \\ \omega(Q(u) - Q'(u), \lambda) &= \omega\left(\frac{Q(\ell^q u)}{\ell^{2q}} - \frac{Q'(\ell^q u)}{\ell^{2q}}, \lambda\right) \\ &\leq \omega\left(\frac{Q(\ell^q u)}{\ell^{2q}} - \frac{g(\ell^q u)}{\ell^{2q}}, \frac{\lambda}{2}\right) \otimes \omega\left(\frac{g(\ell^q u)}{\ell^{2q}} - \frac{Q'(\ell^q u)}{\ell^{2q}}, \frac{\lambda}{2}\right) \\ &\leq \frac{2\left(\frac{\delta}{\ell^2}\right)^q \psi_e(0, u)}{(\ell^2 - \delta)(2\ell + s - 1)\lambda} \end{aligned} \right. \tag{3.4.17}$$

$\forall u \in \mathfrak{X}, \lambda > 0$  and  $q > 0$ . Assuming  $q \rightarrow \infty$  in (3.4.17), we obtain

$$\mu(Q(u) - Q'(u), \lambda) = 1 \text{ and } v(Q(u) - Q'(u), \lambda) = 0 \text{ and } \omega(Q(u) - Q'(u), \lambda) = 0$$

$\forall u \in \mathfrak{X}$  and  $\lambda > 0$ . Therefore,  $Q: \mathfrak{X} \rightarrow \mathfrak{Y}$  is a unique quadratic function as a result. For any  $u$  in  $\mathfrak{X}$ , we obtain  $Q(u) = Q'(u)$  via Lemma 2.6 and (3.4.14).

Jenifer et al.,

$$\left\{ \begin{aligned} \mu_j(g_j([x_{mn}]) - Q_j([x_{mn}]), \lambda) &\geq \min \left\{ \mu \left( g(x_{mn}) - Q(x_{mn}), \frac{\lambda}{j^2} \right) : m, n = 1, \dots, j \right\} \\ &\geq \frac{(\ell^2 - \delta)(2\ell + s - 1)\lambda}{(\ell^2 - \delta)(2\ell + s - 1)\lambda + j^2 \sum_{m,n=1}^j \psi_e(0, x_{mn})}, \\ \nu_j(g_j([x_{mn}]) - Q_j([x_{mn}]), \lambda) &\leq \max \left\{ \nu \left( g(x_{mn}) - Q(x_{mn}), \frac{\lambda}{j^2} \right) : m, n = 1, \dots, j \right\} \\ &\leq \frac{j^2 \sum_{m,n=1}^j \psi_e(0, x_{mn})}{(\ell^2 - \delta)(2\ell + s - 1)\lambda + j^2 \sum_{m,n=1}^j \psi_e(0, x_{mn})} \text{ and} \\ \omega_j(g_j([x_{mn}]) - Q_j([x_{mn}]), \lambda) &\leq \max \left\{ \omega \left( g(x_{mn}) - Q(x_{mn}), \frac{\lambda}{j^2} \right) : m, n = 1, \dots, j \right\} \\ &\leq \frac{j^2 \sum_{m,n=1}^j \psi_e(0, x_{mn})}{(\ell^2 - \delta)(2\ell + s - 1)\lambda} \end{aligned} \right.$$

$\forall x = [x_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ . Therefore,  $Q: \mathfrak{X} \rightarrow \mathfrak{Y}$  is a unique quadratic function that, as needed, satisfies (3.4.3). This concludes the theorem's proof.

Theorem:3.5. Let  $\psi: \mathfrak{X}^2 \rightarrow [0, \infty)$  be a function such that for a given real integer  $\delta$  with  $0 < \delta < \ell$ ,  $\psi(\ell u, \ell v) = \delta \psi(u, v)$

(3.5.1)

$\forall u, v \in \mathfrak{X}$ . Assume the inequality is satisfied by a function:  $\mathfrak{X} \rightarrow \mathfrak{Y}$  with  $g(0) = 0$ ,

$$\left\{ \begin{aligned} \mu_j(\mathfrak{D}g_j([x_{mn}], [y_{mn}]), \lambda) &\geq \frac{\lambda}{\lambda + \sum_{m,n=1}^j \psi(x_{mn}, y_{mn})} \\ \nu_j(\mathfrak{D}g_j([x_{mn}], [y_{mn}]), \lambda) &\leq \frac{\sum_{m,n=1}^j \psi(x_{mn}, y_{mn})}{\lambda + \sum_{i,j=1}^n \psi(x_{mn}, y_{mn})} \\ \omega_j(\mathfrak{D}g_j([x_{mn}], [y_{mn}]), \lambda) &\leq \frac{\sum_{m,n=1}^j \psi(x_{mn}, y_{mn})}{\lambda} \end{aligned} \right. \tag{3.5.2}$$

$\forall x = [x_{mn}], y = [y_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ . A unique additive function  $\mathfrak{A}: \mathfrak{X} \rightarrow \mathfrak{Y}$  and a unique quadratic function  $Q: \mathfrak{X} \rightarrow \mathfrak{Y}$  are therefore exist such that

$$\left\{ \begin{aligned} \mu_j(g_j([x_{mn}]) - Q_j([x_{mn}]) - \mathfrak{A}_j([x_{mn}]), \lambda) &\geq \frac{(\ell - \delta)(2\ell + s - 1)\lambda}{(\ell - \delta)(2\ell + s - 1)\lambda + 2j^2 \sum_{m,n=1}^j \tilde{\psi}(0, x_{mn})}, \\ \nu_j(g_j([x_{mn}]) - Q_j([x_{mn}]) - \mathfrak{A}_j([x_{mn}]), \lambda) &\leq \frac{2j^2 \sum_{m,n=1}^j \tilde{\psi}(0, x_{mn})}{(\ell - \delta)(2\ell + s - 1)\lambda + 2j^2 \sum_{m,n=1}^j \tilde{\psi}(0, x_{mn})} \text{ and} \\ \omega_j(g_j([x_{mn}]) - Q_j([x_{mn}]) - \mathfrak{A}_j([x_{mn}]), \lambda) &\leq \frac{2j^2 \sum_{m,n=1}^j \tilde{\psi}(0, x_{mn})}{(\ell - \delta)(2\ell + s - 1)\lambda} \end{aligned} \right. \tag{3.5.3}$$

$\forall x = [x_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ ,  $\tilde{\psi}(u, v) = \tilde{\psi}(u, v) + \tilde{\psi}(-u, -v)$  for all  $u, v \in \mathfrak{X}$ .

Proof. In the case where  $n = 1$ , (3.5.2) equals

$$\mu(\mathfrak{D}g(u, v), \lambda) \geq \frac{\lambda}{\lambda + \psi(u, v)}, \nu(\mathfrak{D}g(u, v), \lambda) \leq \frac{\psi(u, v)}{\lambda + \psi(u, v)} \text{ and } \omega(\mathfrak{D}g(u, v), \lambda) \leq \frac{\psi(u, v)}{\lambda} \tag{3.5.4}$$

for all  $u, v \in \mathfrak{X}$  and all  $\lambda > 0$ . Consider  $g_e(u) = \frac{g(u) + g(-u)}{2}$  for all  $u \in \mathfrak{X}$ .

Thus,  $g_e(0) = 0, g_e(-u) = g_e(u)$ . Also, we have

$$\left\{ \begin{aligned} \mu(\mathfrak{D}g_e(u, v), \lambda) &= \mu \left( \frac{1}{2} \mathfrak{D}g(u, v) + \frac{1}{2} \mathfrak{D}g(-u, -v), \lambda \right) \\ &= \mu(\mathfrak{D}g(u, v) + \mathfrak{D}g(-u, -v), 2\lambda) \geq \mu(\mathfrak{D}g(u, v), \lambda) * \mu(\mathfrak{D}g(-u, -v), \lambda) \\ &\geq \min\{\mu(\mathfrak{D}g(u, v), \lambda), \mu(\mathfrak{D}g(-u, -v), \lambda)\} \geq \frac{\lambda}{\lambda + \tilde{\psi}(u, v)}, \\ \nu(\mathfrak{D}g_e(u, v), \lambda) &= \nu \left( \frac{1}{2} \mathfrak{D}g(u, v) + \frac{1}{2} \mathfrak{D}g(-u, -v), \lambda \right) \\ &= \nu(\mathfrak{D}g(u, v) + \mathfrak{D}g(-u, -v), 2\lambda) \leq \nu(\mathfrak{D}g(u, v), \lambda) \circ \nu(\mathfrak{D}g(-u, -v), \lambda) \\ &\leq \max\{\nu(\mathfrak{D}g(u, v), \lambda), \nu(\mathfrak{D}g(-u, -v), \lambda)\} \leq \frac{\tilde{\psi}(u, v)}{\lambda + \tilde{\psi}(u, v)} \text{ and} \\ \omega(\mathfrak{D}g_e(u, v), \lambda) &= \omega \left( \frac{1}{2} \mathfrak{D}g(u, v) + \frac{1}{2} \mathfrak{D}g(-u, -v), \lambda \right) \\ &= \omega(\mathfrak{D}g(u, v) + \mathfrak{D}g(-u, -v), 2\lambda) \leq \omega(\mathfrak{D}g(u, v), \lambda) \oplus \omega(\mathfrak{D}g(-u, -v), \lambda) \\ &\leq \max\{\omega(\mathfrak{D}g(u, v), \lambda), \omega(\mathfrak{D}g(-u, -v), \lambda)\} \leq \frac{\tilde{\psi}(u, v)}{\lambda} \end{aligned} \right. \tag{3.5.5}$$

$\forall u \in \mathfrak{X}$  and all  $\lambda > 0$ . Consider  $g_o(u) = \frac{g(u) - g(-u)}{2} \forall u \in \mathfrak{X}$ .

Thus,  $g_o(0) = 0, g_o(-u) = -g_o(u)$ . Also we get

**Jenifer et al.,**

$$\left\{ \begin{aligned}
 & \mu(\mathfrak{D}g_0(u, v), \lambda) = \mu\left(\frac{1}{2}\mathfrak{D}g(u, v) + \frac{1}{2}\mathfrak{D}g(-u, -v), \lambda\right) \\
 & = \mu(\mathfrak{D}g(u, v) + \mathfrak{D}g(-u, -v), 2\lambda) \geq \mu(\mathfrak{D}g(u, v), \lambda) * \mu(\mathfrak{D}g(-u, -v), \lambda) \\
 & \geq \min\{\mu(\mathfrak{D}g(u, v), \lambda), \mu(\mathfrak{D}g(-u, -v), \lambda)\} \geq \frac{\lambda}{\lambda + \tilde{\psi}(u, v)}, \\
 & \nu(\mathfrak{D}g_0(u, v), \lambda) = \nu\left(\frac{1}{2}\mathfrak{D}g(u, v) + \frac{1}{2}\mathfrak{D}g(-u, -v), \lambda\right) \\
 & = \nu(\mathfrak{D}g(u, v) + \mathfrak{D}g(-u, -v), 2\lambda) \leq \nu(\mathfrak{D}g(u, v), \lambda) \circ \nu(\mathfrak{D}g(-u, -v), \lambda) \\
 & \leq \max\{\nu(\mathfrak{D}g(u, v), \lambda), \nu(\mathfrak{D}g(-u, -v), \lambda)\} \leq \frac{\tilde{\psi}(u, v)}{\lambda + \tilde{\psi}(u, v)} \text{ and} \\
 & \omega(\mathfrak{D}g_0(u, v), \lambda) = \omega\left(\frac{1}{2}\mathfrak{D}g(u, v) + \frac{1}{2}\mathfrak{D}g(-u, -v), \lambda\right) \\
 & = \omega(\mathfrak{D}g(u, v) + \mathfrak{D}g(-u, -v), 2\lambda) \leq \omega(\mathfrak{D}g(u, v), \lambda) \diamond \omega(\mathfrak{D}g(-u, -v), \lambda) \\
 & \leq \max\{\omega(\mathfrak{D}g(u, v), \lambda), \omega(\mathfrak{D}g(-u, -v), \lambda)\} \leq \frac{\tilde{\psi}(u, v)}{\lambda}
 \end{aligned} \right. \tag{3.5.6}$$

$\forall u \in \mathfrak{X}$  and all  $\lambda > 0$ . According to the definition of  $\tilde{\psi}$ ,  $\tilde{\psi}(\ell u, \ell v) = \delta \tilde{\psi}(u, v)$ ,  $u, v \in \mathfrak{X}$ , it follows. Verifying that the conditions of Theorems (3.3) and (3.4) are met is an easy task. Following that, using the Theorems (3.3) and (3.4) proofs, we may conclude that there is only one quadratic function  $Q: \mathfrak{X} \rightarrow \mathfrak{Y}$  and one additive function  $\mathfrak{A}: \mathfrak{X} \rightarrow \mathfrak{Y}$  which satisfy

$$\left\{ \begin{aligned}
 & \mu(g_e(u) - Q(u), \lambda) \geq \frac{(\ell^2 - \delta)(2\ell + s - 1)\lambda}{(\ell^2 - \delta)(2\ell + s - 1)\lambda + \tilde{\psi}(0, u)}, \\
 & \nu(g_e(u) - Q(u), \lambda) \leq \frac{\tilde{\psi}(0, u)}{(\ell^2 - \delta)(2\ell + s - 1)\lambda + \tilde{\psi}(0, u)} \text{ and} \\
 & \omega(g_e(u) - Q(u), \lambda) \leq \frac{\tilde{\psi}(0, u)}{(\ell^2 - \delta)(2\ell + s - 1)\lambda}
 \end{aligned} \right. \tag{3.5.7}$$

and

$$\left\{ \begin{aligned}
 & \mu(g_o(u) - \mathfrak{A}(u), \lambda) \geq \frac{(\ell - \delta)(2\ell + s - 1)\lambda}{(\ell - \delta)(2\ell + s - 1)\lambda + \tilde{\psi}(0, u)}, \\
 & \nu(g_o(u) - \mathfrak{A}(u), \lambda) \leq \frac{\tilde{\psi}(0, u)}{(\ell - \delta)(2\ell + s - 1)\lambda + \tilde{\psi}(0, u)} \text{ and} \\
 & \omega(g_o(u) - \mathfrak{A}(u), \lambda) \leq \frac{\tilde{\psi}(0, u)}{(\ell - \delta)(2\ell + s - 1)\lambda}
 \end{aligned} \right. \tag{3.5.8}$$

$\forall u \in \mathfrak{X}$  and all  $\lambda > 0$ . Hence

Jenifer et al.,

$$\left\{ \begin{aligned}
 & \mu(g(u) - Q(u) - \mathfrak{A}(u), \lambda) \\
 &= \mu(g_e(u) - Q(u) + g_o(u) - \mathfrak{A}(u), \lambda) \\
 &\geq \mu\left(g_e(u) - Q(u), \frac{\lambda}{2}\right) * \mu\left(g_o(u) - \mathfrak{A}(u), \frac{\lambda}{2}\right) \\
 &= \min\left\{\mu\left(g_e(u) - Q(u), \frac{\lambda}{2}\right), \mu\left(g_o(u) - \mathfrak{A}(u), \frac{\lambda}{2}\right)\right\} \\
 &\geq \min\left\{\frac{(\ell^2 - \delta)(2\ell + s - 1)\lambda}{(\ell^2 - \delta)(2\ell + s - 1)\lambda + 2\tilde{\psi}(0, u)}, \frac{(\ell - \delta)(2\ell + s - 1)\lambda}{(\ell - \delta)(2\ell + s - 1)\lambda + 2\tilde{\psi}(0, u)}\right\} \\
 &= \frac{(\ell - \delta)(2\ell + s - 1)\lambda}{(\ell - \delta)(2\ell + s - 1)\lambda + 2\tilde{\psi}(0, u)} \\
 & \quad v(g(u) - Q(u) - \mathfrak{A}(u), \lambda) \\
 &= v(g_e(u) - Q(u) + g_o(u) - \mathfrak{A}(u), \lambda) \\
 &\leq v\left(g_e(u) - Q(u), \frac{\lambda}{2}\right) \circ v\left(g_o(u) - \mathfrak{A}(u), \frac{\lambda}{2}\right) \\
 &= \max\left\{v\left(g_e(u) - Q(u), \frac{\lambda}{2}\right), v\left(g_o(u) - \mathfrak{A}(u), \frac{\lambda}{2}\right)\right\} \\
 &\leq \max\left\{\frac{2\tilde{\psi}(0, u)}{(\ell^2 - \delta)(2\ell + s - 1)\lambda + 2\tilde{\psi}(0, u)}, \frac{2\tilde{\psi}(0, u)}{(\ell - \delta)(2\ell + s - 1)\lambda + 2\tilde{\psi}(0, u)}\right\} \\
 &= \frac{2\tilde{\psi}(0, u)}{(\ell - \delta)(2\ell + s - 1)\lambda + 2\tilde{\psi}(0, u)} \text{ and} \\
 & \quad \omega(g(u) - Q(u) - \mathfrak{A}(u), \lambda) \\
 &= \omega(g_e(u) - Q(u) + g_o(u) - \mathfrak{A}(u), \lambda) \\
 &\leq \omega\left(g_e(u) - Q(u), \frac{\lambda}{2}\right) \otimes \omega\left(g_o(u) - \mathfrak{A}(u), \frac{\lambda}{2}\right) \\
 &= \max\left\{\omega\left(g_e(u) - Q(u), \frac{\lambda}{2}\right), \omega\left(g_o(u) - \mathfrak{A}(u), \frac{\lambda}{2}\right)\right\} \\
 &\leq \max\left\{\frac{2\tilde{\psi}(0, u)}{(\ell^2 - \delta)(2\ell + s - 1)\lambda + 2\tilde{\psi}(0, u)}, \frac{2\tilde{\psi}(0, u)}{(\ell - \delta)(2\ell + s - 1)\lambda + 2\tilde{\psi}(0, u)}\right\} \\
 &= \frac{2\tilde{\psi}(0, u)}{(\ell - \delta)(2\ell + s - 1)\lambda}
 \end{aligned} \right. \tag{3.5.9}$$

Lemma (2.6) and (3.5.9) provide us

$$\left\{ \begin{aligned}
 & \mu_j(g_j([x_{mn}]) - Q_j([x_{mn}]) - \mathfrak{A}_j([x_{mn}]), \lambda) \\
 &\geq \min\left\{\mu\left(g(x_{mn}) - Q(x_{mn}) - \mathfrak{A}(x_{mn}), \frac{\lambda}{2}\right) : m, n = 1, \dots, j\right\} \\
 &\geq \frac{(\ell - \delta)(2\ell + s - 1)\lambda}{(\ell - \delta)(2\ell + s - 1)\lambda + 2j^2 \sum_{m,n=1}^j \tilde{\psi}(0, x_{mn})}, \\
 & \quad v_j(g_j([x_{mn}]) - Q_j([x_{mn}]) - \mathfrak{A}_j([x_{mn}]), \lambda) \\
 &\leq \max\left\{v\left(g(x_{mn}) - Q(x_{mn}) - \mathfrak{A}(x_{mn}), \frac{\lambda}{2}\right) : m, n = 1, \dots, n\right\} \\
 &\leq \frac{2j^2 \sum_{i,j=1}^j \tilde{\psi}(0, x_{mn})}{(\ell - \delta)(2\ell + s - 1)\lambda + 2j^2 \sum_{m,n=1}^j \tilde{\psi}(0, x_{mn})} \text{ and} \\
 & \quad \omega_j(g_j([x_{mn}]) - Q_j([x_{mn}]) - \mathfrak{A}_j([x_{mn}]), \lambda) \\
 &\leq \max\left\{\omega\left(g(x_{mn}) - Q(x_{mn}) - \mathfrak{A}(x_{mn}), \frac{\lambda}{2}\right) : m, n = 1, \dots, n\right\} \\
 &\leq \frac{2j^2 \sum_{m,n=1}^j \tilde{\psi}(0, x_{mn})}{(\ell - \delta)(2\ell + s - 1)\lambda}
 \end{aligned} \right.$$

$\forall x = [x_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ . As expected,  $Q: \mathfrak{X} \rightarrow \mathfrak{Y}$  is a unique quadratic function and  $\mathfrak{A}: \mathfrak{X} \rightarrow \mathfrak{Y}$  is a unique additive function satisfying (3.5.3).

This concludes the theorem's proof.

Corollary: 3.6. Give positive real values  $t$  and  $\vartheta$  such that  $t < 1$ . Suppose the condition is satisfied by a function  $g: \mathfrak{X} \rightarrow \mathfrak{Y}$  with  $g(0) = 0$ ,

Jenifer et al.,

$$\begin{cases} \mu_j(\mathcal{D}g_j([\mathbf{x}_{mn}], [\mathbf{y}_{mn}]), \lambda) \geq \frac{\lambda}{\lambda + \sum_{m,n=1}^j (\|\mathbf{x}_{mn}\|^t + \|\mathbf{y}_{mn}\|^t)}, \\ \nu_j(\mathcal{D}g_j([\mathbf{x}_{mn}], [\mathbf{y}_{mn}]), \lambda) \leq \frac{\sum_{m,n=1}^j \vartheta (\|\mathbf{x}_{mn}\|^t + \|\mathbf{y}_{mn}\|^t)}{\lambda + \sum_{m,n=1}^j \vartheta (\|\mathbf{x}_{mn}\|^t + \|\mathbf{y}_{mn}\|^t)} \text{ and} \\ \omega_j(\mathcal{D}g_j([\mathbf{x}_{mn}], [\mathbf{y}_{mn}]), \lambda) \leq \frac{\sum_{m,n=1}^j \vartheta (\|\mathbf{x}_{mn}\|^t + \|\mathbf{y}_{mn}\|^t)}{\lambda} \end{cases} \quad (3.6.1)$$

$\forall \mathbf{x} = [\mathbf{x}_{mn}], \mathbf{y} = [\mathbf{y}_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ . Therefore, there are only one quadratic function  $Q: \mathfrak{X} \rightarrow \mathfrak{Y}$  and one additive function  $\mathfrak{A}: \mathfrak{X} \rightarrow \mathfrak{Y}$  that are unique such that

$$\begin{cases} \mu_j(g_j([\mathbf{x}_{mn}]) - Q_j([\mathbf{x}_{mn}]) - \mathfrak{A}_j([\mathbf{x}_{mn}]), \lambda) \geq \frac{(\ell - \ell^t)(2\ell + s - 1)\lambda}{(\ell - \ell^t)(2\ell + s - 1)\lambda + 4j^2 \sum_{m,n=1}^j \vartheta \|\mathbf{x}_{mn}\|^t}, \\ \nu_j(g_j([\mathbf{x}_{mn}]) - Q_j([\mathbf{x}_{mn}]) - \mathfrak{A}_j([\mathbf{x}_{mn}]), \lambda) \leq \frac{4j^2 \sum_{m,n=1}^j \vartheta \|\mathbf{x}_{mn}\|^t}{(\ell - \ell^t)(2\ell + s - 1)\lambda + 4j^2 \sum_{i,j=1}^j \vartheta \|\mathbf{x}_{mn}\|^t} \text{ and} \\ \omega_j(g_j([\mathbf{x}_{mn}]) - Q_j([\mathbf{x}_{mn}]) - \mathfrak{A}_j([\mathbf{x}_{mn}]), \lambda) \leq \frac{4j^2 \sum_{m,n=1}^j \vartheta \|\mathbf{x}_{mn}\|^t}{(\ell - \ell^t)(2\ell + s - 1)\lambda} \end{cases} \quad (3.6.2)$$

$\forall \mathbf{x} = [\mathbf{x}_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ .

Proof. Assuming  $\psi(u, v) = \vartheta(\|u\|^t + \|v\|^t) \forall u, v \in \mathfrak{X}$ , we derive the proof from Theorem 3.5 and arrive at the intended outcome.

#### 4. Neutrosophic Stability with fixed point method

This section will use the fixed point method to show the Hyers-Ulam stability of the functional equation in  $\mathfrak{MNNS}$ .

Theorem: 4.1. Let  $\psi_o: \mathfrak{X}^2 \rightarrow [0, \infty)$  be a function such that for some real integer  $\mathcal{T}$  with  $0 < \mathcal{T} < 1$  and

$$\psi_o(u, v) = \frac{\mathcal{T}}{\ell} \psi_o(\ell u, \ell v) \quad (4.1.1)$$

$\forall u, v \in \mathfrak{X}$ . Assume the following inequality is satisfied by an odd function:  $\mathfrak{X} \rightarrow \mathfrak{Y}$

$$\begin{cases} \mu_j(\mathcal{D}g_j([\mathbf{x}_{mn}], [\mathbf{y}_{mn}]), \lambda) \geq \frac{\lambda}{\lambda + \sum_{m,n=1}^j \psi_o(\mathbf{x}_{mn}, \mathbf{y}_{mn})}, \\ \nu_j(\mathcal{D}g_j([\mathbf{x}_{mn}], [\mathbf{y}_{mn}]), \lambda) \leq \frac{\sum_{m,n=1}^j \psi_o(\mathbf{x}_{mn}, \mathbf{y}_{mn})}{\lambda + \sum_{i,j=1}^j \psi_o(\mathbf{x}_{mn}, \mathbf{y}_{mn})}, \\ \omega_j(\mathcal{D}g_j([\mathbf{x}_{mn}], [\mathbf{y}_{mn}]), \lambda) \leq \frac{\sum_{m,n=1}^j \psi_o(\mathbf{x}_{mn}, \mathbf{y}_{mn})}{\lambda} \end{cases} \quad (4.1.2)$$

$\forall \mathbf{x} = [\mathbf{x}_{mn}], \mathbf{y} = [\mathbf{y}_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ .

Then, a unique additive function  $\mathfrak{A}: \mathfrak{X} \rightarrow \mathfrak{Y}$  exists, such that

$$\begin{cases} \mu_j(g_j([\mathbf{x}_{mn}]) - \mathfrak{A}_n([\mathbf{x}_{mn}]), \lambda) \geq \frac{2\ell(2\ell + s - 1)(1 - \mathcal{T})\lambda}{2\ell(2\ell + s - 1)(1 - \mathcal{T})\lambda + \mathcal{T}j^2 \sum_{m,n=1}^j \psi_o(0, \mathbf{x}_{mn})}, \\ \nu_j(g_j([\mathbf{x}_{mn}]) - \mathfrak{A}_n([\mathbf{x}_{mn}]), \lambda) \leq \frac{\mathcal{T}j^2 \sum_{m,n=1}^j \psi_o(0, \mathbf{x}_{mn})}{2\ell(2\ell + s - 1)(1 - \mathcal{T})\lambda + \mathcal{T}j^2 \sum_{m,n=1}^j \psi_o(0, \mathbf{x}_{mn})} \text{ and} \\ \omega_j(g_j([\mathbf{x}_{mn}]) - \mathfrak{A}_n([\mathbf{x}_{mn}]), \lambda) \leq \frac{\mathcal{T}j^2 \sum_{m,n=1}^j \psi_o(0, \mathbf{x}_{mn})}{2\ell(2\ell + s - 1)(1 - \mathcal{T})\lambda} \end{cases} \quad (4.1.3)$$

$\forall \mathbf{x} = [\mathbf{x}_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ .

Proof. In the case when  $j = 1$ , as in the Theorem (3.3) proof, we obtain

$$\begin{cases} \mu(2(2\ell + s - 1)g(\ell u) - 2(2\ell + s - 1)\ell g(u), \lambda) \geq \frac{\lambda}{\lambda + \psi_o(0, u)}, \\ \nu(2(2\ell + s - 1)g(\ell u) - 2(2\ell + s - 1)\ell g(u), \lambda) \leq \frac{\psi_o(0, u)}{\lambda + \psi_o(0, u)} \text{ and} \\ \omega(2(2\ell + s - 1)g(\ell u) - 2(2\ell + s - 1)\ell g(u), \lambda) \leq \frac{\psi_o(0, u)}{\lambda} \end{cases} \quad (4.1.4)$$

$\forall u \in \mathfrak{X}$  and all  $\lambda > 0$ . Let  $\mathcal{L}_1 = \{f_1: \mathfrak{X} \rightarrow \mathfrak{Y}\}$ , and introduce a generalized metric  $\mathfrak{d}_1$  on  $\mathcal{L}_1$  as follows:

Let  $\mathcal{L}_1 = \{f_1: \mathfrak{X} \rightarrow \mathfrak{Y}\}$ . Then, assign a generalised metric  $\mathfrak{d}_1$  to  $\mathcal{L}_1$  in the following way:

$$\mathfrak{d}_1(f_1, \mathfrak{k}_1) = \inf \left\{ \lambda \in \mathbb{R}_+ \left| \left\{ \begin{aligned} \mu(f_1(u) - \mathfrak{k}_1(u), \delta\lambda) &\geq \frac{\lambda}{\lambda + \psi_o(0, u)} \\ \nu(f_1(u) - \mathfrak{k}_1(u), \delta\lambda) &\leq \frac{\psi_o(0, u)}{\lambda + \psi_o(0, u)} \forall u \in \mathfrak{X}, \forall \lambda > 0 \\ \omega(f_1(u) - \mathfrak{k}_1(u), \delta\lambda) &\leq \frac{\psi_o(0, u)}{\lambda} \end{aligned} \right. \right\} \right\}. (\mathcal{L}_1, \mathfrak{d}_1) \text{ is a complete generalised}$$

metric space. The function  $\mathcal{G}_1: \mathcal{L}_1 \rightarrow \mathcal{L}_1$  is now defined for all  $f_1 \in \mathcal{L}_1$  and  $u \in \mathfrak{X}$  as

**Jenifer et al.,**

$$J_1 f_1(u) = \ell f_1\left(\frac{u}{\ell}\right) \tag{4.1.5}$$

Assume that  $f_1, k_1 \in L_1$  and that  $\delta \in \mathbb{R}_+$ , where  $d_1(f_1, k_1) \leq \delta$ . Based on  $d_1$ 's definition, we obtain

$$\begin{cases} \mu(f_1(u) - k_1(u), \delta\lambda) \geq \frac{\lambda}{\lambda + \psi_o(0, u)}, \\ \nu(f_1(u) - k_1(u), \delta\lambda) \leq \frac{\psi_o(0, u)}{\lambda + \psi_o(0, u)} \text{ and} \\ \omega(f_1(u) - k_1(u), \delta\lambda) \leq \frac{\psi_o(0, u)}{\lambda} \end{cases}$$

$\forall u \in \mathfrak{X}$  and  $\lambda > 0$ . Thus, utilizing (4.1.1), we obtain

$$\begin{cases} \mu(G_1 f_1(u) - G_1 k_1(u), \delta\mathcal{T}\lambda) = \mu\left(\ell f_1\left(\frac{u}{\ell}\right) - \ell k_1\left(\frac{u}{\ell}\right), \delta\mathcal{T}\lambda\right) \\ = \mu\left(f_1\left(\frac{u}{\ell}\right) - k_1\left(\frac{u}{\ell}\right), \frac{\delta\mathcal{T}\lambda}{\ell}\right) \geq \frac{\frac{\mathcal{T}\lambda}{\ell}}{\frac{\mathcal{T}\lambda}{\ell} + \frac{\psi_o(0, u)}{\ell}} = \frac{\lambda}{\lambda + \psi_o(0, u)}, \\ \nu(G_1 f_1(u) - G_1 k_1(u), \delta\mathcal{T}\lambda) = \nu\left(\ell f_1\left(\frac{u}{\ell}\right) - \ell k_1\left(\frac{u}{\ell}\right), \delta\mathcal{T}\lambda\right) \\ = \nu\left(f_1\left(\frac{u}{\ell}\right) - k_1\left(\frac{u}{\ell}\right), \frac{\delta\mathcal{T}\lambda}{\ell}\right) \leq \frac{\frac{\mathcal{T}\psi_o(0, u)}{\ell}}{\frac{\mathcal{T}\lambda}{\ell} + \frac{\mathcal{T}\psi_o(0, u)}{\ell}} = \frac{\psi_o(0, u)}{\lambda + \psi_o(0, u)} \text{ and} \\ \omega(G_1 f_1(u) - G_1 k_1(u), \delta\mathcal{T}\lambda) = \omega\left(\ell f_1\left(\frac{u}{\ell}\right) - \ell k_1\left(\frac{u}{\ell}\right), \delta\mathcal{T}\lambda\right) \\ = \omega\left(f_1\left(\frac{u}{\ell}\right) - k_1\left(\frac{u}{\ell}\right), \frac{\delta\mathcal{T}\lambda}{\ell}\right) \leq \frac{\frac{\mathcal{T}\psi_o(0, u)}{\ell}}{\frac{\mathcal{T}\lambda}{\ell} + \frac{\mathcal{T}\psi_o(0, u)}{\ell}} = \frac{\psi_o(0, u)}{\lambda} \end{cases} \tag{4.1.6}$$

$\forall u \in \mathfrak{X}$  and all  $\lambda > 0$  for some  $\mathcal{T} < 1$ . Therefore, it may be stated that

$d_1(G_1 f_1, G_1 k_1) \leq \delta\mathcal{T}$ , meaning that  $\forall f_1, k_1 \in L_1, d_1(G_1 f_1, G_1 k_1) \leq \mathcal{T}d_1(f_1, k_1)$ . Additionally, we derive the following inequality from (4.1.1) and (4.1.4)

$$d(g, G_1 g) \leq \frac{\mathcal{T}}{2\ell(2\ell + s - 1)}.$$

The sequence  $G_1^q g$  converges to a fixed point  $\mathfrak{A}$  of  $G_1$ , that is,  $\forall u \in \mathfrak{X}$  and all  $\lambda > 0$ , this may be inferred from Lemma (2.7) that

$$\mathfrak{A}: \mathfrak{X} \rightarrow \mathfrak{Y}, \mathfrak{A}(u) := (\mu, \nu, \omega)\text{-}\lim_{q \rightarrow \infty} \ell^q f\left(\frac{u}{\ell^q}\right) \tag{4.1.7}$$

and

$$\mathfrak{A}(\ell u) = \ell \mathfrak{A}(u). \tag{4.1.8}$$

In the meantime,  $\mathfrak{A}$  represents  $G_1$ 's only fixed point in the collection

$L_1^* = \{g_1 \in L_1 : d_1(g, f_1) < \infty\}$ . Therefore,  $\exists$  a  $\delta \in \mathbb{R}_+$  so that

$$\begin{cases} \mu(g(u) - \mathfrak{A}(u), \delta\lambda) \geq \frac{\lambda}{\lambda + \psi_o(0, u)} \\ \nu(g(u) - \mathfrak{A}(u), \delta\lambda) \leq \frac{\psi_o(0, u)}{\lambda + \psi_o(0, u)} \text{ and} \\ \omega(g(u) - \mathfrak{A}(u), \delta\lambda) \leq \frac{\psi_o(0, u)}{\lambda} \end{cases}$$

$\forall u \in \mathfrak{X}$  and all  $\lambda > 0$ .

$$\text{Also, } d_1(g, \mathfrak{A}) \leq \frac{1}{1 - \mathcal{T}} d(g, G_1 g) \leq \frac{\mathcal{T}}{2\ell(1 - \mathcal{T})(2\ell + s - 1)}.$$

As a result, the following inequality

$$\begin{cases} \mu(g(u) - \mathfrak{A}(u), \lambda) \geq \frac{2\ell(2\ell + s - 1)(1 - \mathcal{T})\lambda}{2\ell(2\ell + s - 1)(1 - \mathcal{T})\lambda + \mathcal{T}\psi_o(0, u)}, \\ \nu(g(u) - \mathfrak{A}(u), \lambda) \leq \frac{\mathcal{T}\psi_o(0, u)}{2\ell(2\ell + s - 1)(1 - \mathcal{T})\lambda + \mathcal{T}\psi_o(0, u)} \text{ and} \\ \omega(g(u) - \mathfrak{A}(u), \lambda) \leq \frac{\mathcal{T}\psi_o(0, u)}{2\ell(2\ell + s - 1)(1 - \mathcal{T})\lambda} \end{cases} \tag{4.1.9}$$

that true for every  $\lambda > 0$  and  $\forall u \in \mathfrak{X}$ . From (3.3.4) and (4.1.1), it is evident that

$$\begin{aligned} \mu\left(\ell^q \mathfrak{D}g\left(\frac{u}{\ell^q}, \frac{v}{\ell^q}\right), \lambda\right) &\geq \frac{\lambda}{\lambda + \mathcal{T}^q \psi_o(u, v)}, \\ \nu\left(\ell^q \mathfrak{D}g\left(\frac{u}{\ell^q}, \frac{v}{\ell^q}\right), \lambda\right) &\leq \frac{\mathcal{T}^q \psi_o(u, v)}{\lambda + \mathcal{T}^q \psi_o(u, v)} \text{ and} \\ \omega\left(\ell^q \mathfrak{D}g\left(\frac{u}{\ell^q}, \frac{v}{\ell^q}\right), \lambda\right) &\leq \frac{\mathcal{T}^q \psi_o(u, v)}{\lambda} \end{aligned} \tag{4.1.10}$$

**Jenifer et al.,**

$\forall u, v \in \mathfrak{X}$  and all  $\lambda > 0$ . When we let  $q \rightarrow \infty$  in (4.1.10), we get  
 $\mu(\mathfrak{D}\mathfrak{A}(u, v), \lambda) = 1, \nu(\mathfrak{D}\mathfrak{A}(u, v), \lambda) = 0$  and  $\omega(\mathfrak{D}\mathfrak{A}(u, v), \lambda) = 0$  (4.1.11)

$\forall u, v \in \mathfrak{X}$  and all  $\lambda > 0$ . Thus, the functional equation is satisfied by  $\mathfrak{A}$ .  
 Given that  $g: \mathfrak{X} \rightarrow \mathfrak{Y}$  is an odd function, we may use definition  $\mathfrak{A}$  to show that, for every  $u \in \mathfrak{X}, \mathfrak{A}(-u) = -\mathfrak{A}(u)$ .  
 Hence, the function  $\mathfrak{A}: \mathfrak{X} \rightarrow \mathfrak{Y}$  is additive according to Lemma (3.1). Lemma (2.6) and (4.1.9) provide us with

$$\left\{ \begin{array}{l} \mu_j(g_j([x_{mn}]) - \mathfrak{A}_j([x_{mn}]), \lambda) \geq \min \left\{ \mu \left( g(x_{mn}) - \mathfrak{A}(x_{mn}), \frac{\lambda}{j^2} \right) : m, n = 1, \dots, j \right\} \\ \geq \frac{2\ell(2\ell + s - 1)(1 - \mathcal{T})\lambda}{2\ell(2\ell + s - 1)(1 - \mathcal{T})\lambda + \mathcal{T}j^2 \sum_{m,n=1}^j \psi_o(0, x_{mn})}, \\ \nu_j(g_j([x_{mn}]) - \mathfrak{A}_j([x_{mn}]), \lambda) \leq \max \left\{ \nu \left( g(x_{mn}) - \mathfrak{A}(x_{mn}), \frac{\lambda}{j^2} \right) : m, n = 1, \dots, j \right\} \\ \leq \frac{\mathcal{T}j^2 \sum_{i,j=1}^n \psi_o(0, x_{mn})}{2\ell(2\ell + s - 1)(1 - \mathcal{T})\lambda + \mathcal{T}j^2 \sum_{m,n=1}^j \psi_o(0, x_{mn})} \text{ and} \\ \omega_j(g_j([x_{mn}]) - \mathfrak{A}_j([x_{mn}]), \lambda) \leq \max \left\{ \omega \left( g(x_{mn}) - \mathfrak{A}(x_{mn}), \frac{\lambda}{j^2} \right) : m, n = 1, \dots, j \right\} \\ \leq \frac{\mathcal{T}j^2 \sum_{m,n=1}^j \psi_o(0, x_{mn})}{2\ell(2\ell + s - 1)(1 - \mathcal{T})\lambda} \end{array} \right.$$

$\forall x = [x_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ . As a result,  $\mathfrak{A}: \mathfrak{X} \rightarrow \mathfrak{Y}$  is a unique additive function that satisfies (4.1.3), just as needed.

This completes the theorem's proof.

Theorem: 4.2. For some real integer  $\mathcal{T}$  with  $0 < \mathcal{T} < 1$ , let  $\psi_e: \mathfrak{X}^2 \rightarrow [0, \infty)$  be a function such that  $\psi_e(u, v) = \frac{\mathcal{T}}{\ell^2} \psi_e(\ell u, \ell v)$  (4.2.1)

$\forall u, v \in \mathfrak{X}$ . Assume that the inequality is satisfied by an even function  $g: \mathfrak{X} \rightarrow \mathfrak{Y}$ ,

$$\left\{ \begin{array}{l} \mu_j(Dg_j([x_{mn}], [y_{mn}]), \lambda) \geq \frac{\lambda}{\lambda + \sum_{m,n=1}^j \psi_e(x_{mn}, y_{mn})}, \\ \nu_j(Dg_j([x_{mn}], [y_{mn}]), \lambda) \leq \frac{\sum_{m,n=1}^j \psi_e(x_{mn}, y_{mn})}{\lambda + \sum_{m,n=1}^j \psi_e(x_{mn}, y_{mn})} \text{ and} \\ \omega_j(Dg_j([x_{mn}], [y_{mn}]), \lambda) \leq \frac{\sum_{m,n=1}^j \psi_e(x_{mn}, y_{mn})}{\lambda} \end{array} \right. \quad (4.2.2)$$

$\forall x = [x_{mn}], y = [y_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ . Then  $\exists$  a unique quadratic function  $Q: \mathfrak{X} \rightarrow \mathfrak{Y}$  such that

$$\left\{ \begin{array}{l} \mu_j(g_j([x_{mn}]) - Q_j([x_{mn}]), \lambda) \geq \frac{2\ell^2(2\ell + s - 1)(1 - \mathcal{T})\lambda}{2\ell^2(2\ell + s - 1)(1 - \mathcal{T})\lambda + \mathcal{T}j^2 \sum_{m,n=1}^j \psi_e(0, x_{mn})}, \\ \nu_j(g_j([x_{mn}]) - Q_j([x_{mn}]), \lambda) \leq \frac{\mathcal{T}j^2 \sum_{m,n=1}^j \psi_e(0, x_{mn})}{2\ell^2(2\ell + s - 1)(1 - \mathcal{T})\lambda + \mathcal{T}j^2 \sum_{m,n=1}^j \psi_e(0, x_{mn})} \text{ and} \\ \omega_j(g_j([x_{mn}]) - Q_j([x_{mn}]), \lambda) \leq \frac{\mathcal{T}j^2 \sum_{m,n=1}^j \psi_e(0, x_{mn})}{2\ell^2(2\ell + s - 1)(1 - \mathcal{T})\lambda} \end{array} \right. \quad (4.2.3)$$

$\forall x = [x_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ .

Proof. When  $j = 1$ , as in Theorem (3.4)'s proof, we obtain

$$\left\{ \begin{array}{l} \mu(2(2\ell + s - 1)g(\ell a) - 2(2\ell + s - 1)\ell^2 g(u), \lambda) \geq \frac{\lambda}{\lambda + \psi_e(0, u)}, \\ \nu(2(2\ell + s - 1)g(\ell a) - 2(2\ell + s - 1)\ell^2 g(u), \lambda) \leq \frac{\psi_e(0, u)}{\lambda + \psi_e(0, u)} \text{ and} \\ \omega(2(2\ell + s - 1)g(\ell a) - 2(2\ell + s - 1)\ell^2 g(u), \lambda) \leq \frac{\psi_e(0, u)}{\lambda} \end{array} \right. \quad (4.2.4)$$

$\forall u \in \mathfrak{X}$  and all  $\lambda > 0$ .

Let  $\mathcal{L}_2 = \{f_2: \mathfrak{X} \rightarrow \mathfrak{Y}\}$ . Then, assign a generalised metric  $d_2$  to  $\mathcal{L}_2$  in the following way:

**Jenifer et al.,**

$$d_2(f_2, k_2) = \inf \left\{ \delta \in \mathbb{R}_+ \left\{ \begin{aligned} &\mu(f_2(u) - k_2(u), \delta\lambda) \geq \frac{\lambda}{\lambda + \psi_e(0, u)} \\ &\nu(f_2(u) - k_2(u), \delta\lambda) \leq \frac{\psi_e(0, u)}{\lambda + \psi_e(0, u)} \forall u \in \mathfrak{X}, \forall \lambda > 0 \\ &\omega(f_2(u) - k_2(u), \delta\lambda) \leq \frac{\psi_e(0, u)}{\lambda} \end{aligned} \right. \right\}.$$

The existence of a complete generalized metric space  $(\mathcal{L}_2, d_2)$  is easily proved. The mapping  $G_2: \mathcal{L}_2 \rightarrow \mathcal{L}_2$  is now defined by

$$G_2 f_2(u) = \ell^2 f_2\left(\frac{u}{\ell}\right), \forall G_2 \in \mathcal{L}_2 \text{ and } u \in \mathfrak{X}. \tag{4.2.5}$$

Let  $\delta \in \mathbb{R}_+$  with  $d_2(f_2, k_2) \leq \delta$  where  $f_2, k_2 \in \mathcal{L}_2$ . The definition of  $d_2$  gives us

$$\left\{ \begin{aligned} &\mu(f_2(u) - k_2(u), \delta\lambda) \geq \frac{\lambda}{\lambda + \psi_e(0, u)}, \\ &\nu(f_2(u) - k_2(u), \delta\lambda) \leq \frac{\psi_e(0, u)}{\lambda + \psi_e(0, u)} \text{ and} \\ &\omega(f_2(u) - k_2(u), \delta\lambda) \leq \frac{\psi_e(0, u)}{\lambda} \end{aligned} \right.$$

$\forall u \in \mathfrak{X}$  and  $\lambda > 0$ . Thus, utilizing (4.2.1), we obtain

$$\left\{ \begin{aligned} &\mu(G_2 f_2(u) - G_2 k_2(u), \delta T \lambda) = \mu\left(\ell^2 f_2\left(\frac{u}{\ell}\right) - \ell^2 k_2\left(\frac{u}{\ell}\right), \delta T \lambda\right) \\ &= \mu\left(f_2\left(\frac{u}{\ell}\right) - k_2\left(\frac{u}{\ell}\right), \frac{\delta T \lambda}{\ell^2}\right) \geq \frac{\frac{T}{\ell^2} \lambda}{\frac{T}{\ell^2} \lambda + \psi_e(0, u)} = \frac{\lambda}{\lambda + \psi_e(0, u)}, \\ &\nu(G_2 f_2(u) - G_2 k_2(u), \delta T \lambda) = \nu\left(\ell^2 f_2\left(\frac{u}{\ell}\right) - \ell^2 k_2\left(\frac{u}{\ell}\right), \delta T \lambda\right) \\ &= \nu\left(f_2\left(\frac{u}{\ell}\right) - k_2\left(\frac{u}{\ell}\right), \frac{\delta T \lambda}{\ell^2}\right) \leq \frac{\frac{T}{\ell^2} \psi_e(0, u)}{\frac{T}{\ell^2} \lambda + \frac{T}{\ell^2} \psi_e(0, u)} = \frac{\psi_e(0, u)}{\lambda + \psi_e(0, u)} \text{ and} \\ &\omega(G_2 f_2(u) - G_2 k_2(u), \delta T \lambda) = \omega\left(\ell^2 f_2\left(\frac{u}{\ell}\right) - \ell^2 k_2\left(\frac{u}{\ell}\right), \delta T \lambda\right) \\ &= \omega\left(f_2\left(\frac{u}{\ell}\right) - k_2\left(\frac{u}{\ell}\right), \frac{\delta T \lambda}{\ell^2}\right) \leq \frac{\frac{T}{\ell^2} \psi_e(0, u)}{\frac{T}{\ell^2} \lambda + \frac{T}{\ell^2} \psi_e(0, u)} = \frac{\psi_e(0, u)}{\lambda}, \end{aligned} \right. \tag{4.2.6}$$

for all  $u \in \mathfrak{X}$  and all  $\lambda > 0$  for some  $T < 1$ . Therefore, it occurs that  $d_2(G_2 f_2, G_2 k_2) \leq \delta T$ , that is,  $d_2(G_2 f_2, G_2 k_2) \leq T d_2(f_2, k_2) \forall f_2, k_2 \in \mathcal{L}_2$ .

Additionally, we establish the inequality  $d(g, G_2 g) \leq \frac{T}{2\ell^2(2\ell + s - 1)}$  from (4.2.1) and (4.2.4).

Lemma (2.7) indicates that the sequence  $G_2^q g$  converges to a fixed point  $Q$  of  $G_2$ , meaning that all  $\lambda > 0$  and  $\forall u \in \mathfrak{X}$   $Q: \mathfrak{X} \rightarrow \mathfrak{Y}$ ,  $Q(u) := (\mu, \nu, \omega) - \lim_{p \rightarrow \infty} \ell^{2q} g\left(\frac{u}{\ell^q}\right)$  (4.2.7)

and

$$Q(\ell u) = \ell^2 Q(u). \tag{4.2.8}$$

At the same time,  $Q$  represents the unique fixed point of  $G^2$  in the collection

$\mathcal{L}_2^* = \{f_2 \in \mathcal{L}_2: d_2(g, f_2) < \infty\}$ . Therefore, there is a  $\delta \in \mathbb{R}_+$  such that

$$\left\{ \begin{aligned} &\mu(g(u) - Q(u), \delta\lambda) \geq \frac{\lambda}{\lambda + \psi_e(0, u)}, \\ &\nu(g(u) - Q(u), \delta\lambda) \leq \frac{\psi_e(0, u)}{\lambda + \psi_e(0, u)} \text{ and} \\ &\omega(g(u) - Q(u), \delta\lambda) \leq \frac{\psi_e(0, u)}{\lambda} \end{aligned} \right.$$

$\forall u \in \mathfrak{X}$  and all  $\lambda > 0$ .

$$\text{Also, } d_2(g, Q) \leq \frac{1}{1 - \ell} d(g, G_2 g) \leq \frac{T}{2\ell^2(1 - T)(2\ell + s - 1)}.$$

Thus, the resulting inequality

$$\left\{ \begin{aligned} &\mu(g(u) - Q(u), \lambda) \geq \frac{2\ell^2(2\ell + s - 1)(1 - T)\lambda}{2\ell^2(2\ell + s - 1)(1 - T)\lambda + T\psi_e(0, u)}, \\ &\nu(g(u) - Q(u), \lambda) \leq \frac{T\psi_e(0, u)}{2\ell^2(2\ell + s - 1)(1 - T)\lambda + T\psi_e(0, u)} \text{ and} \\ &\omega(g(u) - Q(u), \lambda) \leq \frac{T\psi_e(0, u)}{2\ell^2(2\ell + s - 1)(1 - T)\lambda} \end{aligned} \right. \tag{4.2.9}$$

**Jenifer et al.,**

true  $\forall u \in \mathfrak{X}$  and all  $\lambda > 0$ . The other half of the proof is similar to the Theorem (4.1) proof. This completes the proof of the theorem.

Theorem: 4.3. Let  $\psi: \mathfrak{X}^2 \rightarrow [0, \infty)$  be a function such that for some real integer  $\mathcal{T}$  with  $0 < \mathcal{T} < \ell$ ,  

$$\psi(u, v) = \frac{\mathcal{T}}{\ell^2} \psi(\ell u, \ell v) \tag{4.3.1}$$

$\forall u, v \in \mathfrak{X}$ . Assume the following inequality is satisfied by a function  $g: \mathfrak{X} \rightarrow \mathfrak{Y}$  with  $g(0) = 0$

$$\begin{cases} \mu_j(\mathfrak{D}g_j([\mathfrak{x}_{mn}], [\mathfrak{y}_{mn}]), \lambda) \geq \frac{\lambda}{\lambda + \sum_{m,n=1}^j \psi(x_{mn}, y_{mn})}, \\ \nu_j(\mathfrak{D}g_j([\mathfrak{x}_{mn}], [\mathfrak{y}_{mn}]), \lambda) \leq \frac{\sum_{m,n=1}^j \psi(x_{mn}, y_{mn})}{\lambda + \sum_{m,n=1}^j \psi(x_{mn}, y_{mn})} \text{ and} \\ \omega_j(\mathfrak{D}g_j([\mathfrak{x}_{mn}], [\mathfrak{y}_{mn}]), \lambda) \leq \frac{\sum_{m,n=1}^j \psi(x_{mn}, y_{mn})}{\lambda} \end{cases} \tag{4.3.2}$$

$\forall \mathfrak{x} = [\mathfrak{x}_{mn}], \mathfrak{y} = [\mathfrak{y}_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ . Following that, there's a unique quadratic function  $Q: \mathfrak{X} \rightarrow \mathfrak{Y}$  and a unique additive function  $\mathfrak{A}: \mathfrak{X} \rightarrow \mathfrak{Y}$ , so that

$$\begin{cases} \mu_j(g_j([\mathfrak{x}_{mn}]) - Q_j([\mathfrak{x}_{mn}]) - \mathfrak{A}_j([\mathfrak{x}_{mn}]), \lambda) \geq \frac{\ell(2\ell+s-1)(1-\mathcal{T})\lambda}{\ell(2\ell+s-1)(1-\mathcal{T})\lambda + \mathcal{T}j^2 \sum_{m,n=1}^j \tilde{\psi}(0, x_{mn})}, \\ \nu_j(g_j([\mathfrak{x}_{mn}]) - Q_j([\mathfrak{x}_{mn}]) - \mathfrak{A}_j([\mathfrak{x}_{mn}]), \lambda) \leq \frac{\mathcal{T}j^2 \sum_{m,n=1}^j \tilde{\psi}(0, x_{mn})}{\ell(2\ell+s-1)(1-\mathcal{T})\lambda + \mathcal{T}j^2 \sum_{m,n=1}^j \tilde{\psi}(0, x_{mn})} \text{ and} \\ \omega_j(g_j([\mathfrak{x}_{mn}]) - Q_j([\mathfrak{x}_{mn}]) - \mathfrak{A}_j([\mathfrak{x}_{mn}]), \lambda) \leq \frac{\mathcal{T}j^2 \sum_{m,n=1}^j \tilde{\psi}(0, x_{mn})}{\ell(2\ell+s-1)(1-\mathcal{T})\lambda} \end{cases} \tag{4.3.3}$$

$\forall \mathfrak{x} = [\mathfrak{x}_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ ,  
 $\tilde{\psi}(u, v) = \psi(u, v) + \psi(-u, -v)$  for all  $u, v \in \mathfrak{X}$ .

Proof. The proof is derived from Theorems (4.1) and (4.2), as well as an approach related to Theorem (3.5). This concludes the theorem's proof.

Corollary: 4.4. Let  $\lambda, \vartheta$  be positive real numbers with  $t > 2$ . Suppose that a function  $g: \mathfrak{X} \rightarrow \mathfrak{Y}$  with  $g(0) = 0$  satisfies the inequality

$$\begin{cases} \mu_j(\mathfrak{D}g_j([\mathfrak{x}_{mn}], [\mathfrak{y}_{mn}]), \lambda) \geq \frac{\lambda}{\lambda + \sum_{m,n=1}^j \vartheta (\|x_{mn}\|^t + \|y_{mn}\|^t)}, \\ \nu_j(\mathfrak{D}g_j([\mathfrak{x}_{mn}], [\mathfrak{y}_{mn}]), \lambda) \leq \frac{\sum_{m,n=1}^j \vartheta (\|x_{mn}\|^t + \|y_{mn}\|^t)}{\lambda + \sum_{m,n=1}^j \vartheta (\|x_{mn}\|^t + \|y_{mn}\|^t)} \text{ and} \\ \omega_j(\mathfrak{D}g_j([\mathfrak{x}_{mn}], [\mathfrak{y}_{mn}]), \lambda) \leq \frac{\sum_{m,n=1}^j \vartheta (\|x_{mn}\|^t + \|y_{mn}\|^t)}{\lambda} \end{cases} \tag{4.4.1}$$

$\forall \mathfrak{x} = [\mathfrak{x}_{mn}], \mathfrak{y} = [\mathfrak{y}_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ . A unique additive function  $\mathfrak{A}: \mathfrak{X} \rightarrow \mathfrak{Y}$  and a unique quadratic function  $Q: \mathfrak{X} \rightarrow \mathfrak{Y}$  are exist such that

$$\begin{cases} \mu_j(g_j([\mathfrak{x}_{mn}]) - Q_j([\mathfrak{x}_{mn}]) - \mathfrak{A}_j([\mathfrak{x}_{mn}]), \lambda) \geq \frac{(2\ell+s-1)(\ell^t - \ell^2)\lambda}{(2\ell+s-1)(\ell^t - \ell^2)t + 2\ell j^2 \sum_{m,n=1}^j \vartheta \|x_{mn}\|^t}, \\ \nu_j(g_j([\mathfrak{x}_{mn}]) - Q_j([\mathfrak{x}_{mn}]) - \mathfrak{A}_j([\mathfrak{x}_{mn}]), \lambda) \leq \frac{2\ell j^2 \sum_{m,n=1}^j \vartheta \|x_{mn}\|^t}{(2\ell+s-1)(\ell^t - \ell^2)\lambda + 2\ell j^2 \sum_{m,n=1}^j \vartheta \|x_{mn}\|^t} \text{ and} \\ \omega_j(g_j([\mathfrak{x}_{mn}]) - Q_j([\mathfrak{x}_{mn}]) - \mathfrak{A}_j([\mathfrak{x}_{mn}]), \lambda) \leq \frac{2\ell j^2 \sum_{m,n=1}^j \vartheta \|x_{mn}\|^t}{(2\ell+s-1)(\ell^t - \ell^2)\lambda} \end{cases} \tag{4.4.2}$$

$\forall \mathfrak{x} = [\mathfrak{x}_{mn}] \in E_j(\mathfrak{X})$  and all  $\lambda > 0$ .

Proof. The expected result is obtained by taking  $\varphi(u, v) = \vartheta (\|u\|^t + \|v\|^t)$  for all  $u, v \in \mathfrak{X}$  and  $\mathcal{T} = \ell^{2-t}$  in Theorem (4.3).

## CONCLUSION

We examine the Hyers-Ulam stability of the functional equation within the context of matrix neutrosophic normed spaces using the direct and fixed point techniques. Thus, we offer a connection between two different fields of study: functional equations and matrix neutrosophic normed spaces. From quasi-Banach spaces to matrix neutrosophic normed spaces, we extended the Hyers-Ulam stability results of the functional Equation. These criteria can be extended to other important functional equations.

Jenifer et al.,

### ABSTRACT

**Abstract:** For a connected graph  $G = (V, E)$ , a connected monophonic hull set  $S \subseteq V$  is a monophonic hull set such that the subgraph  $\langle S \rangle$  induced by  $S$  is connected. The minimum cardinality of a connected monophonic hull set of  $G$  is the connected monophonic hull number of  $G$  and is denoted by  $mh_c(G)$ . A connected monophonic hull set of cardinality  $mh_c(G)$  is called a  $mh_c$ -set of  $G$  or a minimum connected monophonic hull set of  $G$ . Connected monophonic hull number of certain classes of graphs are determined. Connected graph of order  $p$  with connected monophonic hull number 2 or  $p$  are characterized. It is shown that for every three positive integers  $a, b, c$  with  $2 \leq a < b < c$ , there exists a connected graph  $G$  such that  $mh(G) = a$ ,  $mh_c(G) = b$  and  $m(G) = c$ , where  $mh(G)$ ,  $m(G)$  are the monophonic hull number and monophonic number of a graph respectively.

**Keywords:** Hull Number, Monophonic Hull Number, Connected Monophonic Hull Number.

**AMS Subject Classification:** 05C05, 05C12.

## INTRODUCTION

Let  $G = (V, E)$  be a graph that is finite and undirected, without loops or multiple edges. Let  $p$  and  $q$  indicate the order and size of  $G$  and we refer Harary [7], for basic graph theoretic terminology. The length of the shortest  $u-v$  path in a connected graph  $G$  is the distance between the vertices  $u$  and  $v$ , which is denoted by  $d(u, v)$ . A  $u-v$  geodesic is a  $u-v$  path with length  $d(u, v)$ . A vertex  $x$  is said to lie on a  $u-v$  geodesic  $P$  if  $x$  is one of the vertices included in  $P$ , encompassing both endpoints  $u$  and  $v$ . Let  $I[u, v]$  denote the set of all vertices that are part of the  $u-v$  geodesic. This collection includes every vertex that lies on the path connecting  $u$  and  $v$ . The *eccentricity*  $e(v)$  of a vertex  $v$  in a graph  $G$  is defined as the maximum distance from  $v$  to any other vertex in  $G$ . The minimum eccentricity among all vertices in  $G$  is referred to as the *radius*, denoted as  $rad(G)$  or  $r(G)$ , while the maximum eccentricity is known as the *diameter*,

**Mary Gleeta and Celine Priya**

$diam(G)$ . A chord of a path  $u_0, u_1, u_2, \dots, u_n$  is an edge  $u_i u_j$ , with  $j \geq i + 2$ . The neighborhood of a vertex  $v$  in  $G$ , denoted by  $N(v)$ , is defined as the set  $N(v) = \{u \in V(G) : uv \in E(G)\}$ .

For any set  $M$  of vertices in  $G$ , the induced sub graph  $\langle M \rangle$  is the maximal sub graph of  $G$  that includes only the vertices in  $M$ . A vertex  $v$  is considered an *extreme vertex* of  $G$  if the induced subgraph  $\langle N(v) \rangle$  is complete. A vertex  $v$  is termed a *central vertex* if its eccentricity  $e(v)$  equals the radius of  $G$ . The induced subgraph  $\langle S \rangle$  is the maximal subgraph of  $G$  with the given edge set  $S$  of  $G$ . If one of the ends of an edge in a connected graph  $G$  is an extreme vertex in the graph, that edge is said to be an extreme edge of  $G$ . For a graph  $G$  that is not complete, the vertex-connectivity  $\kappa(G)$  of  $G$  is defined as the cardinality of a minimum vertex-cut of  $G$ . Let  $I[S] = \bigcup_{u,v \in S} I[u, v]$ , for a set  $S$  of vertices. If  $I[S] = S$ , the set  $S$  is convex.  $S$  is convex if  $S = \{v\}$  or  $S = V$ , which is obvious [8]. The convexity number is the cardinality of a maximum proper convex subset of  $V$  which is denoted by  $C(G)$  [9,10,11,12]. A  $C$ -set of  $G$  is a convex set with cardinality  $C(G)$ . In [9], the convexity number was first introduced.

The smallest set that contains  $S$  and is convex is represented by  $I_h(S)$  and is known as the *convex hull* of  $S$ . The convex hull is well defined as the intersection of two convex sets is also convex. It's important to note that  $S$  is a subset of  $I[S]$  and thereby  $I_h(S)$  which is a subset of  $V$ . A subset  $S$  of  $V$  is referred to as a hull set if it is equal to  $I_h(S)$ . The hull number  $h(G)$  of  $G$  represents the minimum order of its hull sets. Any hull set of order  $h(G)$  is considered a *minimum hull set* or simply an *h-set* of  $G$ . The concept of the hull number of a graph was first introduced in [3] and has been explored in [1,2,14,15]. If  $e = \{u, v\}$  is an edge of a graph  $G$  with  $d(u)$  equals 1 and  $d(v)$  greater than 1, then we call  $e$  a pendent edge,  $u$  an end vertex and  $v$  a support vertex. If  $uv$  is an edge of a graph  $G$  with  $u$  and  $v$  as its endpoints, then  $uv$  is called a pendent edge,  $u$  is an end vertex, and  $v$  is a support vertex. For any connected graph  $G$ , a vertex  $v$  is classified as a cut vertex of  $G$  if  $G - v$  is no longer connected.

A  $u$ - $v$  path  $P$  is termed a monophonic path if it is a chordless path. A vertex  $x$  is considered to lie on a  $u$ - $v$  monophonic path  $P$  if  $x$  is a vertex of  $P$ , including the vertices  $u$  and  $v$ . For two vertices  $u$  and  $v$ , let  $J[u, v]$  denote the set of all vertices that lie on the  $u$ - $v$  monophonic path. For a set  $M$  of vertices, let  $J[M]$  denote the union of all vertices that lie on  $u$ - $v$  monophonic paths, that is  $J[M] = \bigcup_{u,v \in M} J[u, v]$ . The set  $M$  is monophonic convex, or  $m$ -convex, if  $J[M] = M$ . It is clear that if  $M = \{v\}$  or  $M = V$ , then  $M$  is  $m$ -convex. The  $m$ -convexity number, denoted by  $C_m(G)$ , is the cardinality of a maximum proper  $m$ -convex subset of  $V$ . The smallest  $m$ -convex set containing  $M$  is denoted by  $J_h(M)$  and is called the monophonic convex hull or *m-convex hull* of  $M$ . Since the intersection of two  $m$ -convex sets is  $m$ -convex, the  $m$ -convex hull is well defined. Note that  $M$  is a subset of  $J[M]$ , which is a subset of  $J_h(M)$ , which is a subset of  $V$ . When  $J[M] = V$  for a subset  $M$  of  $V$ ,  $M$  is said to be a monophonic set and when  $J_h(M) = V$ ,  $M$  is said to be a  $m$ -hull set. The minimum order of the monophonic sets is the monophonic number  $m(G)$  of  $G$  and a monophonic set that has its order as  $m(G)$  is a *minimum monophonic set*, or simply a *m-set* of  $G$ . In the same way we can define the monophonic hull number  $mh(G)$  to be the minimum order of its  $m$ -hull sets and a minimum monophonic hull set or a *mh-set* is any  $m$ -hull set whose order is  $mh(G)$ . A graph's monophonic number is examined in [4,5,6], and its monophonic hull number is examined in [5,13]. If a vertex  $v$  of  $G$  belongs to every minimum monophonic set of  $G$ , then that vertex is said to be a monophonic vertex. Throughout the following  $G$  stands for a connected graph with at least two vertices. The following theorems are used in sequel.

**Theorem 1.1.** [4] Each extreme vertex of  $G$  belongs to every monophonic set of  $G$ .

**Observation 1.2.** Let  $G$  be a connected graph. Then each extreme vertex of  $G$  belongs to every monophonic hull set of  $G$ .

**Theorem 1.3.** [13] Let  $G$  be a connected graph with cut-vertices and let  $S$  be a minimal monophonic hull set of  $G$ . If  $v$  is a cut-vertex of  $G$ , then every component of  $G - v$  contains an element of  $S$ .

### Mary Gleeta and Celine Priya

#### The Connected Monophonic Hull Number of a Graph

**Definition 2.1.** Let  $G$  be a connected graph with at least two vertices. A *connected monophonic hull set*  $S$  of a graph  $G$  is a monophonic hull set such that the subgraph  $\langle S \rangle$  induced by  $S$  is connected. The *connected monophonic hull number* of  $G$ , denoted by  $mh_c(G)$  is the minimum cardinality of a connected monophonic hull set of  $G$ . A *mh<sub>c</sub>-set* of  $G$  or a *minimum connected monophonic hull set* of  $G$  is defined as a connected monophonic hull set of cardinality  $mh_c(G)$ .

**Example 2.2.** For Figure 2.1, a graph  $G$  with 9 vertices,  $mh_c(G) = 6$  as  $S = \{v_1, v_2, v_4, v_5, v_8, v_9\}$  is the only minimum connected monophonic hull set ( $mh_c$ -set) of  $G$ .

**Theorem 2.3.** In a connected graph  $G$ , every extreme vertex belongs to every connected monophonic hull set of  $G$ . Specifically, each end-vertex of  $G$  is a member of every connected monophonic hull set of  $G$ .

**Proof.** We use Observation 1.2 to prove this result. Since every connected monophonic hull set is also a monophonic hull set, every extreme vertex belongs to every connected monophonic hull set of  $G$ .

**Corollary 2.4.**  $mh_c(K_p) = p$  for the complete graph  $K_p$  ( $p \geq 2$ ).

**Theorem 2.5.** For a connected graph  $G$  with cut-vertices, let  $S$  be a connected monophonic hull set. If  $v$  is a cut-vertex of  $G$ , then every component of  $G - v$  contains an element of  $S$ .

**Proof.** We know that from Theorem 1.3, the result is true for a monophonic hull set. Since every connected monophonic hull set is also a monophonic hull set, the result is true for a connected monophonic hull set too.

**Theorem 2.6.** Every cut-vertex of a connected graph  $G$  belongs to every connected monophonic hull set of  $G$ .

**Proof.** Consider any cut-vertex  $v$  of  $G$  and we name the components of  $G - v$  as  $G_1, G_2, \dots, G_r$  ( $r \geq 2$ ). Let  $S$  be any connected monophonic hull set of  $G$ . Then  $S$  contains at least one element from each  $G_i$  ( $1 \leq i \leq r$ ), by theorem 2.5. Since  $\langle S \rangle$  is connected, it follows that  $v \in S$ .

**Corollary 2.7.** If  $G$  is a connected graph with  $k$  extreme vertices and  $l$  cut-vertices then  $mh_c(G) \geq \max\{2, k + l\}$ .

**Proof.** The result follows from Theorems 2.3 and 2.6.

**Corollary 2.8.** For any non-trivial tree  $T$  of order  $p$ ,  $mh_c(T) = p$ .

**Proof.** This follows from Corollary 2.7.

**Theorem 2.9.** Let  $G$  be a connected graph of order  $p$ . Then  $2 \leq mh(G) \leq mh_c(G) \leq p$ .

**Proof.** Since the minimum number of vertices in any hull set is two,  $mh(G) \geq 2$ . As every connected monophonic hull set is also a monophonic hull set, it follows that  $mh(G) \leq mh_c(G)$ . Also, since  $V[G]$  induces a connected monophonic hull set of  $G$ , it is clear that  $mh_c(G) \leq p$ .

**Remark 2.10.** The bounds in Theorem 2.9 are sharp. For any non-trivial path  $P$ ,  $mh(P) = 2$ . For the complete graph  $K_p$ ,  $mh(K_p) = mh_c(K_p)$ . For any non-trivial tree  $T$ ,  $mh_c(T) = p$  by Corollary 2.8. Also, all the inequalities in the theorem are strict. For the graph  $G$  given in Figure 2.1,  $mh(G) = 3$ ,  $mh_c(G) = 6$  and  $p = 9$  so that  $2 < mh(G) < mh_c(G) < p$ .

**Corollary 2.11.** If  $mh_c(G) = 2$  for any connected graph  $G$ , then the monophonic hull number,  $mh(G)$ , is also 2.

**Proof.** This follows from Theorem 2.9.

The graphs with connected monophonic hull numbers 2 and  $p$  are characterized in the following theorems 2.12 and 2.13 respectively.

**Theorem 2.12.** If  $G$  is a connected graph of order  $p \geq 2$ , then  $G = K_2$  if and only if  $mh_c(G) = 2$ .

**Proof.** In case of  $G = K_2$ ,  $mh_c(G) = 2$ . Conversely, let  $mh_c(G) = 2$ . Let  $S = \{u, v\}$  be a minimum connected monophonic hull set of  $G$ . Then  $uv$  is an edge. If  $G \neq K_2$ , then there exists a vertex  $w$  other than  $u$  and  $v$ . Thus  $w$  cannot lie on any  $J^k[u, v]$ , ( $k \geq 1$ ) and thereby  $S$  is not a  $mh_c$ -set, which is a contradiction. Thus  $G = K_2$ .

**Mary Gleeta and Celine Priya**

**Theorem 2.13.** For a connected graph  $G$ , every vertex of  $G$  is either a cut-vertex or an extreme vertex if and only if  $mh_c(G) = p$ .

**Proof.** Let  $G$  be a connected graph with every vertex of  $G$  either a cut-vertex or an extreme vertex. Then the result is an immediate consequence of Theorem 2.3 and Theorem 2.6. Conversely, let  $mh_c(G) = p$ . Suppose that there is a vertex  $x$  in  $G$  which is neither a cut-vertex nor an extreme vertex. Since  $x$  is not an extreme vertex,  $N(x)$  does not induce a complete subgraph and hence there exist  $u$  and  $v$  in  $N(x)$  such that  $d_m(u, v) = 2$ . Clearly,  $x$  lies on a  $u-v$  monophonic path in  $G$ . Also, we get  $G - x$  to be connected as  $x$  is not a cut-vertex of  $G$ . Thus  $V(G) - \{x\}$  is a connected monophonic hull set of  $G$  and so  $mh_c(G) \leq |V(G) - \{x\}| = p - 1$ , which is a contradiction.

**Theorem 2.14.** Let  $G$  be a non-complete connected graph which has a minimum cut set, then  $mh_c(G) \leq p - \kappa(G) + 1$ .

**Proof.** Since  $G$  is non-complete,  $1 \leq \kappa(G) \leq p - 2$ . Consider a minimum cut set  $U = \{u_1, u_2, \dots, u_\kappa\}$  of  $G$ . Let  $G_1, G_2, \dots, G_r$  ( $r \geq 2$ ) be the components of  $G - U$  and let  $S = V(G) - U$ . Then every vertex  $u_i$  ( $1 \leq i \leq \kappa$ ) is adjacent to at least one vertex of  $G_j$  for every  $j$  ( $1 \leq j \leq r$ ). It is clear that  $S$  is a monophonic hull set of  $G$  and  $\langle S \rangle$  is not connected. Also,  $\langle S \cup \{x\} \rangle$  is a connected monophonic hull set for any vertex  $x$  in  $U$  so that  $mh_c(G) \leq p - \kappa(G) + 1$ .

**Remark 2.15.** The bound in Theorem 2.14 is sharp. For the cycle  $G = C_4$ ,  $mh_c(G) = 3$ . Also,  $\kappa(G) = 2$ ,  $p - \kappa(G) + 1 = 3$ . Thus  $mh_c(G) = p - \kappa(G) + 1$ .

**Theorem 2.16.** For positive integers  $r_m, d_m$  and  $l \geq d_m - r_m + 3$  with  $r_m < d_m \leq 2r_m$ , there exists a connected graph  $G$  with  $rad_m G = r_m$ ,  $diam_m G = d_m$  and  $mh_c(G) = l$ .

**Proof.** For our convenience, we denote  $r_m$  as  $r$  and  $d_m$  as  $d$ . In case of  $r = 1$ , we assume  $G = K_{1,l}$ . The result is immediate from Corollary 2.8. Let  $r \geq 2$ . Let  $v_1, v_2, \dots, v_{r+2}$  be a cycle of length  $r+2$  and let  $u_0, u_1, \dots, u_{d-r}$  be a path of length  $d-r$  and we denote them by  $C_{r+2}$  and  $P_{d-r+1}$  respectively. Let  $H$  be the graph obtained from  $C_{r+2}$  and  $P_{d-r+1}$  by adding a new vertex  $x$  and joining the edges  $xv_{r-1}$  and  $xv_{r+1}$  and identifying  $v_1$  in  $C_{r+2}$  and  $u_0$  in  $P_{d-r+1}$ . We add  $l - d + r - 3$  new vertices to  $H$  namely  $w_1, w_2, \dots, w_{l-d+r-3}$  and join each  $w_i$  ( $1 \leq i \leq l - d + r - 3$ ) to the vertex  $u_{d-r-1}$  and thus obtain the graph  $G$  of Figure 2.2. It is clear that  $rad_m G = r = r_m$  and  $diam_m G = d = d_m$ . Consider  $S = \{w_1, w_2, \dots, w_{l-d+r-3}, v_1, u_1, u_2, \dots, u_{d-r}\}$  to be the set of all extreme and cut vertices of  $G$ . By Theorems 2.3 and 2.6, every connected monophonic hull set of  $G$  contains  $S$ . Clearly,  $S$  is not a connected  $mh$ -set of  $G$ . Also it is easily verified that  $S \cup \{x\}$ , where  $x \notin S$  is not a connected  $mh$ -set of  $G$  so that  $mh_c(G) \geq l$ . On the other hand,  $S_1 = S \cup \{v_2, v_{r+2}\}$  is a connected monophonic hull set of  $G$  so that  $mh_c(G) = l$ .

**Realization results**

**Theorem 3.1.** There exists a connected graph  $G$  such that  $mh(G) = a$ ,  $mh_c(G) = b$  and  $m(G) = c$  where  $a, b, c$  are any three positive integers such that  $2 \leq a < b < c$ .

**Proof.** Let  $2 \leq a < b < c$ . Consider a path of length  $b - a + 1$  say  $P_{b-a+2}: v_1, v_2, \dots, v_{b-a+2}$ . We add to  $P_{b-a+2}$ ,  $2c - a - 1$  new vertices  $w_1, w_2, \dots, w_{c-a}, u_1, u_2, \dots, u_{c-a}, z_1, z_2, \dots, z_{a-1}$  and each  $z_i$  ( $1 \leq i \leq a - 1$ ) is joined with  $v_1$  and  $v_2$ , each  $w_i$  ( $1 \leq i \leq c - a$ ) is joined with  $v_1$  and  $v_3$  and each  $u_i$  ( $1 \leq i \leq c - a$ ) is joined with  $v_2$  and each  $w_i$  ( $1 \leq i \leq c - a$ ) which results in the graph  $G$  of Figure 3.1. First, we demonstrate that  $mh(G) = a$ . Let  $\{v_{b-a+2}, z_1, z_2, \dots, z_{a-1}\}$  be the set of all extreme vertices of  $G$  and we denote it by  $S$ . By Observation 1.2, every monophonic hull set of  $G$  contains  $S$  and so  $mh(G) \geq a$ . Clearly,  $S$  is a monophonic hull set of  $G$  and so  $mh(G) = a$ . Now, we demonstrate that  $mh_c(G) = b$ . Let  $S_1 = S \cup \{v_3, v_4, \dots, v_{b-a+1}\}$  be the set of all extreme vertices and cut vertices of  $G$ . By Theorems 2.3 and 2.6, each connected monophonic hull set contains  $S_1$ . It is clear that  $S_1$  is not a connected  $mh$ -set of  $G$  and so  $mh_c(G) \geq b$ . However  $S_1 \cup \{v_2\}$  is a connected  $mh$ -set of  $G$  so that  $mh_c(G) = b$ . Now our aim is to show that  $m(G) = c$ . By Theorem 1.1, every monophonic set of  $G$  contains  $S$ . We can easily observe that every monophonic set contains each  $u_i$  ( $1 \leq i \leq c - a$ ). Let  $S_2 = S \cup \{u_1, u_2, \dots, u_{c-a}\}$ . Clearly,  $S_2$  is a monophonic set of  $G$  and so  $m(G) = c$ .

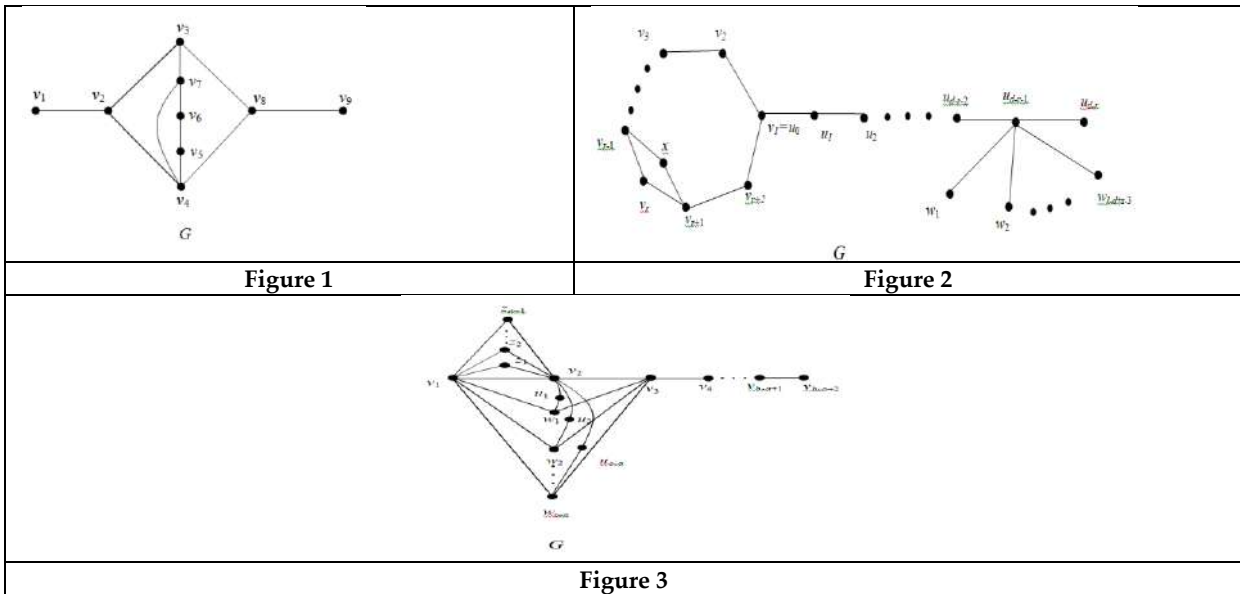

**Mary Gleeta and Celine Priya**

**CONCLUSION**

We have encountered the connected monophonic hull number of certain graphs in this article and these results are extended to other distance related parameters in graphs.

### ABSTRACT

Here, we proposed and analyzed a non-delayed HIV pathogenesis model with saturation incidence, incorporating both from virus to the cell and from one cell to the next cell transmission mechanisms. The proposed model draws inspiration from a prey-predator system, with the predator affected by disease, and interactions represented using a Holling type II functional response. For the non-delayed system, we first established the conditions for the existence of feasible equilibria and performed a local stability analysis. Additionally, we investigated the occurrence of Hopf bifurcation, using the infected prey rate as the bifurcation parameter.

## INTRODUCTION

In various approaches to studying real-world systems, one can create physical or iconic models to analyze their behavior, though this may be expensive and complex. Experimenting directly with the system, especially biological ones, is often impractical or impossible. A more efficient approach is to represent the system using mathematical equations, known as a mathematical model. The process of deriving these equations is referred to as mathematical modeling. Mathematical formulations can take various forms, including algebraic, transcendental, differential, or integral equations. In differential equations, we seek solutions as functions, where the derivative of the unknown function is involved. These models are particularly useful when the behavior of a dependent variable changes smoothly with respect to an independent variable, and the rate of change is quantified through the derivative. Differential equation models are essential tools in science and engineering, as they are used to express physical laws

### Magudeeswaran and Bhuvanika

and relationships. Over the past few decades, the study of HIV dynamics has drawn considerable attention from researchers, given the complexity and importance of understanding its behavior.

HIV is an infectious disease that affects the immune system. If ignored, untreated HIV can lead to AIDS (Acquired Immunodeficiency Syndrome), and there is presently no effective therapy. Individuals who develop HIV carry the virus for life; but, with correct medical care, the condition can be properly treated. HIV infection in humans is supposed to have originated in a particular kind of chimp in Central Africa. Based on studies, HIV might have been transmitted to individuals as early as the last decade of the 1800s. The virus's chimp equivalent is known as SIV. This transmission was most likely initiated when humans hunted chimps for flesh and came into contact with tainted blood. HIV spread gradually across Africa for centuries before spreading across various parts of the globe as well. The virus has been floating around in the United States since at least the mid to late 1970s.

HIV is a major global public health issue, accounting for around 40.4 million deaths [32.9-51.3 million] up to this point, with transmission continuing in countries around the world. Several nations have recently noticed increased infection rates after previously witnessing reductions. As of the conclusion of 2022, approximately 39.0 million persons [33.1-45.7 million] were HIV positive, with three quarters (25.6 million) living in the WHO's African country. In 2022, 6,30,000 [48000-88000 million] persons died of HIV-related causes, while 1.3 million [1.0-1.7 million] people became infected. While there is no curative for HIV infection, enhanced early detection, therapy, and care, including the control of opportunistic infections, have made HIV a tolerable chronic health condition. This progress enables people who suffer from HIV to live a healthy and long life. Organizations such as WHO, the Global Fund for Survivors, and UNAIDS (Joint United Nations Programme on HIV/AIDS) have developed worldwide strategy aligned with the SDG (Sustainable Development Goals) target 3.3, which aims to end the HIV epidemic by 2030. HIV/AIDS is one of the oldest and most extensively investigated viral illnesses, with almost 260,000 papers referencing the issue indexed by GoPubMed [1] and over 42,000 publications with "HIV/AIDS" in the heading discovered in the Public Library of Science [2], representing over three decades of scientific investigation. Numerous studies have been conducted on HIV infection from various perspectives, as highlighted in references [3–9]. Mathematical models serve as essential tools for elucidating complex processes, formulating assumptions, and guiding new experimental investigations.

In this paper, we will discuss the possibility of equilibria and the local stability of the infected prey in the context of HIV pathogenesis, incorporating both from the virus to the cell and one cell to the next cell transmission. Additionally, we will explore the existence of Hopf bifurcation analysis using the infected prey rate for this model. The outline for this article is as described below: The previous section presented a historical summary of the research. In Section 2, we shall analyze the suggested model's equilibria and local stability. The appearance of a Hopf bifurcation is discussed in Section 3. Sections 4 and 5 present the conclusion and acknowledgement, respectively. Following this, we provided some references.

#### Existence of equilibria and local stability of the infected prey with the Holling type II functional response

In recent decades, academics have focused heavily on the investigation of HIV dynamics. Numerous research, including [6, 7, 10], have investigated HIV infection from diverse angles. Mathematical models are essential for understanding complex biological functions, developing hypotheses, and leading future investigations.

The basic mathematical model for studying HIV dynamics in terms of healthy cells, infected cells, and viral load can be expressed as:

$$\begin{aligned}\frac{dT}{dt} &= s - aT - \alpha TV, \\ \frac{dI}{dt} &= \alpha TV - cI, \\ \frac{dV}{dt} &= NcI - eV,\end{aligned}$$

**Magudeeswaran and Bhuvanika**

AIDS (Acquired Immunodeficiency Syndrome), brought on by HIV, is a major worldwide medical challenge. HIV, lacking a cell wall, is parasitic and requires a host cell to replicate [11]. Upon entering the body, the virus primarily targets CD4+ T-cells, thereby destroying key white blood cells of the immune system. Despite extensive research, a definitive cure for HIV/AIDS remains elusive.

The above equation can be reformulated as:

$$\begin{aligned} \frac{dT}{dt} &= s - aT + bT \left(1 - \frac{T}{K}\right) - \alpha TV, \\ \frac{dI}{dt} &= \alpha TV - cI, \\ \frac{dV}{dt} &= NcI - eV. \end{aligned}$$

F. Li and J. Wang [12] proposed the following model to explore the effect of bifurcation analysis, which included both from the virus to cell and cell-to-cell spreading mechanisms:

$$\begin{aligned} \frac{dT}{dt} &= s - aT + bT \left(1 - \frac{T}{K}\right) - \alpha_1 TV - \alpha_2 TI, \\ \frac{dI}{dt} &= \alpha_1 TV + \alpha_2 TI - cI, \\ \frac{dV}{dt} &= NcI - eV. \end{aligned}$$

Motivated by [12], we modified their model, which considered only three components: uninfected cells, infected CD4+ T-cells, and the free viral particles. Our modified HIV pathogenesis model, which includes saturation frequency, from virus to the cell and one cell to the next cell spreading, is as follows:

$$\begin{aligned} \frac{dT}{dt} &= s - aT + bT \left(1 - \frac{T}{K}\right) - \frac{\alpha_1 TV}{1 + \beta_1 V} - \frac{\alpha_2 TI}{1 + \beta_2 I} \\ \frac{dI}{dt} &= \frac{\alpha_1 TV}{1 + \beta_1 V} + \frac{\alpha_2 TI}{1 + \beta_2 I} - cI, \\ \frac{dV}{dt} &= NcI - eV. \end{aligned} \tag{1}$$

In the model,  $T$  and  $I$  represents the amount of target and infected cells, correspondingly, while  $V$  represents the viral load. The parameter  $s$  indicates the amount at which fresh T-cells are produced from the source. The death rates of target and infected cells are denoted by  $a$  and  $c$ , respectively, and  $e$  represents the clearance virions rate.

The infection rates are given by  $\alpha_1$  (from virus to the cell spreading) and  $\alpha_2$  (one cell to the cell spreading), with  $\beta_1$  and  $\beta_2$  being the half-saturation constants. The population densities  $K$  and  $N$  represent the average amount of virus particles created by infected cells.

**Existence of equilibria**

This system (1) has two non negative equilibria exists. An infected free equilibrium  $E_0 = [T_0, 0, 0]$  and infected equilibrium  $E^* = [T^*, I^*, V^*]$ ,

where,  $T_0 = \frac{K}{2b} \left[ (b - a) \pm \sqrt{(b - a)^2 + 4bsK^{-1}} \right]$ ,  
 $I^* = \frac{K(s - aT + bT) - bT^*}{Kc}$ ,

$V^* = \frac{NcI}{e}$ ,

$T^* = p_4 T^4 + p_3 T^3 + p_2 T^2 + p_1 T + p_0 = 0$ , (2)

where,

$$\begin{aligned} p_4 &= \beta_1 \beta_2 N b^2 c^2, \\ p_3 &= \alpha_1 \beta_2 KNbc^2 + \alpha_2 \beta_1 KNbc^2 + 2\beta_1 \beta_2 KNabc^2 - 2\beta_1 \beta_2 KNb^2 c^2, \\ p_2 &= \alpha_1 \beta_2 K^2 Nac^2 + \alpha_2 \beta_1 K^2 Nac^2 - \alpha_1 \beta_2 K^2 Nbc^2 - \alpha_2 \beta_1 K^2 Nbc^2 - \beta_1 KNbc^3 \\ &\quad - \beta_2 Kbc^2 e + \beta_1 \beta_2 K^2 Nb^2 c^2 + \beta_1 \beta_2 K^2 Na^2 c^2 - 2\beta_1 \beta_2 Nabc^2 - 2\beta_1 \beta_2 Kbc^2 s, \\ p_1 &= \beta_1 K^2 Nbc^3 + \beta_2 K^2 bc^2 e - \alpha_1 K^2 Nc^3 - \alpha_1 K^2 Nc^3 - \alpha_2 K^2 c^2 e - \alpha_1 \beta_2 K^2 Nc^2 s \\ &\quad - \alpha_2 \beta_1 K^2 Nc^2 s - \beta_1 K^2 Nac^3 - \beta_2 K^2 ac^2 e + 2\beta_1 \beta_2 K^2 Nbc^2 s - 2\beta_1 \beta_2 K^2 Nac^2 s, \\ p_0 &= \beta_1 \beta_2 K^2 Nc^2 s^2 + K^2 c^3 e + \beta_1 K^2 Nc^3 s + \beta_2 K^2 c^2 es. \end{aligned}$$

**Magudeeswaran and Bhuvanika**

The basic reproductive number is given by  $R_0 = \frac{T_0}{T^*}$ , this reflects the amount of fresh infected cells created by single infected cell over the course of its life. To demonstrate the local asymptotic stability of the free of infection equilibrium  $E_0$ , we proceed with the following analysis.

**Local stability analysis**

We have identified two equilibrium points for the proposed model: the infection-free equilibrium  $E_0 = [T_0, 0, 0]$  and the infected equilibrium  $E^* = [T^*, I^*, V^*]$ . We examine the local stability properties of these equilibrium points. To do so, we compute the Jacobian matrix at an arbitrary equilibrium point  $E (T, I, V)$ , which is presented below:

$$J(T, I, V) = \begin{pmatrix} \theta_{11} & \theta_{12} & \theta_{13} \\ \theta_{21} & \theta_{22} & \theta_{23} \\ \theta_{31} & \theta_{32} & \theta_{33} \end{pmatrix}, \tag{3}$$

where

$$\begin{aligned} \theta_{11} &= b - a - \frac{2bT}{K} - \frac{\alpha_1 V}{1+\beta_1 V} - \frac{\alpha_2 I}{1+\beta_2 I}, \theta_{12} = -\frac{\alpha_2 T}{(1+\beta_2 I)^2}, \theta_{13} = -\frac{\alpha_1 T}{(1+\beta_1 V)^2}, \\ \theta_{21} &= \frac{\alpha_1 V}{1+\beta_1 V} + \frac{\alpha_2 I}{1+\beta_2 I}, \theta_{22} = \frac{\alpha_2 T}{(1+\beta_2 I)^2} - cI, \theta_{23} = \frac{\alpha_1 T}{(1+\beta_1 V)^2}, \\ \theta_{31} &= 0, \theta_{32} = Nc, \theta_{33} = -e. \end{aligned}$$

**Theorem 1:**

1. The infected free equilibrium point,  $E_0 = [T_0, 0, 0]$  is locally asymptotically stable.
2. The infected equilibrium point  $E^* = [T^*, I^*, V^*]$  is locally asymptotically stable, if

$\vartheta_1 > 0, \vartheta_3 > 0$  and  $\vartheta_1 \vartheta_2 > \vartheta_3$

*Proof:*

1. The Jacobian matrix at the  $E_0 = [T_0, 0, 0]$  is

$$J(E_0) = \begin{bmatrix} b - a - \frac{2bT_0}{K} & -\alpha_2 T_0 & -\alpha_1 T_0 \\ 0 & \alpha_2 T_0 & \alpha_1 T_0 \\ 0 & Nc & -e \end{bmatrix}$$

The following two equations are the eigenvalues of the Jacobian matrix at  $E_0$

$$\lambda_1 = b - a - \frac{2bT_0}{K}, \lambda_2 = \frac{\alpha_2 T_0 - c - e}{2} \pm \sqrt{\frac{c^2 e^2 + \alpha_1^2 T_0^2 + 4\alpha_1 Nc T_0 - 2ce + 2\alpha_2 e T_0 - 2\alpha_2 c T_0}{2}}$$

It implies that the  $\lambda_{2,3}$  should have a real part as negative. Hence the equilibrium  $E_0 = (T_0, 0, 0)$  is locally asymptotically stable for any time t.

2. The Jacobian matrix at  $E^* = [T^*, I^*, V^*]$  is

$$J(T, I, V) = \begin{bmatrix} Q_{11} & Q_{12} & Q_{13} \\ Q_{21} & Q_{22} & Q_{23} \\ Q_{31} & Q_{32} & Q_{33} \end{bmatrix}, \tag{4}$$

where

$$\begin{aligned} Q_{11} &= b - a - \frac{2bT^*}{K} - \frac{\alpha_1 V^*}{1+\beta_1 V^*} - \frac{\alpha_2 I^*}{1+\beta_2 I^*}, Q_{12} = -\frac{\alpha_2 T^*}{(1+\beta_2 I^*)^2}, Q_{13} = -\frac{\alpha_1 T^*}{(1+\beta_1 V^*)^2}, \\ Q_{21} &= \frac{\alpha_1 V^*}{1+\beta_1 V^*} + \frac{\alpha_2 I^*}{1+\beta_2 I^*}, Q_{22} = \frac{\alpha_2 T^*}{(1+\beta_2 I^*)^2} - cI^*, Q_{23} = \frac{\alpha_1 T^*}{(1+\beta_1 V^*)^2}, \\ Q_{31} &= 0, Q_{32} = N^*c, Q_{33} = -e. \end{aligned}$$

The characteristic equation of (4) is

$$\omega^3 + \vartheta_1 \omega^2 + \vartheta_2 \omega + \vartheta_3 = 0, \tag{5}$$

where

$$\begin{aligned} \vartheta_1 &= R + c + e - \frac{\alpha_2 T^*}{(1+\beta_2 I^*)^2}, \\ \vartheta_2 &= R \left( c + e - \frac{\alpha_2 T^*}{(1+\beta_2 I^*)^2} \right) + ce - \frac{\alpha_2 T^* e}{(1+\beta_2 I^*)^2} - \frac{\alpha_1 T^* Nc}{(1+\beta_1 V^*)^2} + \frac{\alpha_1 \alpha_2 T^* V^*}{(1+\beta_2 I^*)^2 (1+\beta_1 V^*)} + \frac{\alpha_2^2 T^* I^*}{(1+\beta_1 I^*)^3}, \\ \vartheta_3 &= R \left[ ce - \frac{\alpha_2 T^* e}{(1+\beta_2 I^*)^2} + \frac{\alpha_1 T^* Nc}{(1+\beta_1 V^*)^2} \right] + \frac{\alpha_1 \alpha_2 T^* V^*}{(1+\beta_2 I^*)^2 (1+\beta_1 V^*)} + \frac{\alpha_2^2 T^* I^*}{(1+\beta_1 I^*)^3}, \\ R &= a - b + \frac{2bT^*}{K} + \frac{\alpha_1 V^*}{1+\beta_1 V^*} + \frac{\alpha_2 I^*}{1+\beta_2 I^*}. \end{aligned}$$

By Routh – Hurwitz criteria [13],  $E^*$  is locally asymptotically stable, if  $\vartheta_1 > 0, \vartheta_3 > 0$  and  $\vartheta_1 \vartheta_2 > \vartheta_3$ .

**Magudeeswaran and Bhuvanika**

**Hopf bifurcation analysis for non-delayed system**

In the present section, we analyze the model’s bifurcation behavior analytically, focusing on the Hopf bifurcation parameter  $\alpha_1$ . The following theorem demonstrates the presence of a Hopf bifurcation, when the amount of parameter  $\alpha_1$  varies.

**Theorem 2.** *If the bifurcation component  $\alpha_1$  approaches a critical value, the model (1) experiences Hopf bifurcation. Hopf-bifurcation conditions occur at  $\alpha_1 = \alpha_1^*$  as follows:*

$$1. H(\alpha_1^*) = \vartheta_1(\alpha_1^*)\vartheta_2(\alpha_1^*) - \vartheta_3(\alpha_1^*) = 0,$$

$$2. \frac{d}{d\alpha_1} \left( Re(\varpi(\alpha_1)) \right) |_{\alpha_1=\alpha_1^*} \neq 0, \quad 1$$

where,  $\rho$  is the zero of characteristic equation associated with interior equilibrium point.

**Proof.** For  $\alpha_1 = \alpha_1^*$ , characteristic equation must be of the form

$$(\varpi^2(\alpha_1^*) + \vartheta_2(\alpha_1^*))(\varpi(\alpha_1^*) + \vartheta_1(\alpha_1^*)) = 0. \tag{6}$$

The solution of the above equation are  $\pm i\sqrt{\vartheta_2(\alpha_1^*)}$  and  $-\vartheta_1(\alpha_1^*)$ . To prove that the Hopf-bifurcation appearance at  $\alpha_1 = \alpha_1^*$ , the following transversality requirement must be satisfied:

$$\frac{d}{d\alpha_1} \left( Re(\varpi(\alpha_1)) \right) |_{\alpha_1=\alpha_1^*} \neq 0,$$

For all  $\alpha_1$ , the roots are generally in the form

$$\varpi_1(\alpha_1) = \varrho(\alpha_1) + i\hbar(\alpha_1),$$

$$\varpi_2(\alpha_1) = \varrho(\alpha_1) - i\hbar(\alpha_1),$$

$$\varpi_3(\alpha_1) = -\vartheta_1(\alpha_1).$$

Now, we check

$$\frac{d}{d\alpha_1} \left( Re(\varpi_j(\alpha_1)) \right) |_{\alpha_1=\alpha_1^*} \neq 0, j = 1, 2.$$

Let  $\varpi_1(\alpha_1) = \varrho(\alpha_1) + i\hbar(\alpha_1)$  in (6), we get

$$\mathcal{A}(\alpha_1) + i\mathcal{B}(\alpha_1) = 0.$$

Where,

$$\mathcal{A}(\alpha_1) = \varrho^3(\alpha_1) + \varrho^2(\alpha_1)\vartheta_1(\alpha_1) - 3\varrho(\alpha_1)\hbar^2(\alpha_1) - \hbar^2(\alpha_1)\vartheta_1(\alpha_1) + \vartheta_2(\alpha_1)\varrho(\alpha_1) + \vartheta_1(\alpha_1)\vartheta_2(\alpha_1),$$

$$\mathcal{B}(\alpha_1) = 3\varrho^2(\alpha_1)\hbar(\alpha_1) + \vartheta_2(\alpha_1)\hbar(\alpha_1) + 2\varrho(\alpha_1)\hbar(\alpha_1)\vartheta_1(\alpha_1) - \hbar^3(\alpha_1).$$

To fulfill equation (6), we must have  $\mathcal{A}(\alpha_1) = 0$  and  $\mathcal{B}(\alpha_1) = 0$ .

Then differentiating  $\mathcal{A}$  and  $\mathcal{B}$  with respect to  $\alpha_1$ , we have

$$\frac{d\mathcal{A}}{d\alpha_1} = \varphi_1(\alpha_1)\varrho'(\alpha_1) - \varphi_2(\alpha_1)\hbar'(\alpha_1) + \varphi_3(\alpha_1) = 0, \tag{7}$$

### Magudeeswaran and Bhuvanika

$$\frac{dB}{d\alpha_1} = \varphi_2(\alpha_1)g'(\alpha_1) + \varphi_1(\alpha_1)h(\alpha_1) + \varphi_4(\alpha_1) = 0, \quad (8)$$

where,

$$\begin{aligned} \varphi_1(\alpha_1) &= 3g^2(\alpha_1) + 2g(\alpha_1)\vartheta_1(\alpha_1) - 3h^2(\alpha_1) + \vartheta_2(\alpha_1), \\ \varphi_2(\alpha_1) &= 6g(\alpha_1) + h(\alpha_1) + 2h(\alpha_1)\vartheta_1(\alpha_1), \\ \varphi_3(\alpha_1) &= g^2(\alpha_1)\vartheta_1'(\alpha_1) + \vartheta_2'(\alpha_1)g(\alpha_1), \\ \varphi_4(\alpha_1) &= 2g(\alpha_1)h(\alpha_1)\vartheta_1'(\alpha_1) + \vartheta_2'(\alpha_1)h(\alpha_1). \end{aligned}$$

On multiplying (7) and (8) by  $\varphi_1(\alpha_1)$  and  $\varphi_2(\alpha_1)$  respectively, then adding those two equations, we have

$$g'(\alpha_1) = -\frac{\varphi_1(\alpha_1)\varphi_3(\alpha_1) + \varphi_2(\alpha_1)\varphi_4(\alpha_1)}{\varphi_1^2(\alpha_1) + \varphi_2^2(\alpha_1)} \quad (9)$$

Substituting  $g(\alpha_1) = 0$  and  $s(\alpha_1) = \sqrt{\vartheta_2(\alpha_1)}$  at  $\alpha_1 = \alpha_1^*$  on  $\varphi_1(\alpha_1)$ ,  $\varphi_2(\alpha_1)$ ,  $\varphi_3(\alpha_1)$  and  $\varphi_4(\alpha_1)$  we obtain

$$\begin{aligned} \varphi_1(\alpha_1^*) &= -2\vartheta_2(\alpha_1^*), \\ \varphi_2(\alpha_1^*) &= 2\vartheta_1(\alpha_1^*)\sqrt{\vartheta_2(\alpha_1^*)}, \\ \varphi_3(\alpha_1^*) &= \vartheta_3'(\alpha_1^*) - \vartheta_2(\alpha_1^*)\vartheta_1'(\alpha_1^*), \\ \varphi_4(\alpha_1^*) &= \vartheta_2'(\alpha_1^*)\sqrt{\vartheta_2(\alpha_1^*)}. \end{aligned}$$

The equation (9), implies

$$g'(\alpha_1^*) = \frac{\vartheta_3'(\alpha_1^*) - (\vartheta_1(\alpha_1^*)\vartheta_2(\alpha_1^*))'}{2(\vartheta_2(\alpha_1^*) + \vartheta_1^2(\alpha_1^*))}.$$

If  $\vartheta_3'(\alpha_1^*) - (\vartheta_1(\alpha_1^*)\vartheta_2(\alpha_1^*))' \neq 0$ , which implies that

$$\frac{d}{d\alpha_1} \left( \text{Re}(\varpi_j(\alpha_1)) \right) \Big|_{\alpha_1 = \alpha_1^*} = g'(\alpha_1^*) \neq 0, j = 1, 2.$$

and

$$\varpi_3(\alpha_1^*) = -\vartheta_1(\alpha_1^*) \neq 0.$$

Therefore, the condition  $\vartheta_3'(\alpha_1^*) - (\vartheta_1(\alpha_1^*)\vartheta_2(\alpha_1^*))' \neq 0$  is guaranteed that the condition for transversality is satisfied, hence the model (1) under goes Hopf-bifurcation at  $\alpha_1 = \alpha_1^*$ .

## CONCLUSION

In the present research, we studied a non-delayed model of HIV pathogenesis incorporating saturation frequency, from virus to the cell spreading, and the one cell to next cell transfer. The model also considers intrinsic dynamics without delay, which describe the time between the virus getting into a desired and concurrent direct cell-to-cell transformation. We modified the mathematics framework to analyze the presence of equilibria and the local stability of the infected steady state. Furthermore, we investigated the conditions for the occurrence of Hopf bifurcation, providing insights into the system's dynamic behavior.

### ABSTRACT

This paper focus on introducing the product of simplicial complexes to form a simplicial topological space namely  $\mathcal{S}_T$  space. A new approach and characteristics of simplices are studied under this space. Furthermore, we discussed the properties of simplicial homology, singular homology and homotopic invariance under the  $\mathcal{S}_T$  space.

**Keywords:**  $\mathcal{S}_T$  space, Simplicial Homology, Singular Homology, Homotopic Invariance.

## INTRODUCTION

Algebraic topology is an interconnection between continuous and discrete mathematics. Continuous mathematics is formulated in the language of continuous maps and topological spaces. Whereas, Discrete mathematics is expressed in the concepts of algebra and combinations. Classical algebraic topology was arisen in the construction of functions from any category of topological spaces into the algebraic category(groups). Consequently, the two important viewpoints of algebraic topology are homology and homotopy. The most ingenious and influential inventions in mathematics is homology, which is invented by Henry Poincare. The basic concept of homology is about to start with a geometric structure or a space which is derived from combinational data or a simplicial complex. Then the homology groups are produced by the data determined from the boundary relations and linear algebra. The homotopy arise with the construction of functors from the topology to algebra. This exhibits the category of a topological space has a kind of algebraic structure. This manuscript is initiate with these spaces. Simplicial sets were first defined by Samuel Eilenberg and Joseph A. Zilber in 1950 [4]. They proved the properties of simplicial

**Sasikala and Renukadevi**

complexes under singular homology and homotopy. The concepts and properties of simplicial complex were extracted from the elements of algebraic topology by James R. Munkres [2] and Algebraic topology by Allen Hatcher [1]. In this paper, we extended the simplices to the product space with few restrictions to make it simplicial topological space as  $\mathcal{S}_T$  space. Investigations were carried out with some properties of algebraic statements under the simplicial homology, singular homology and homotopic invariance.

**PRELIMINARIES**

**Definition 2.1:** Let  $[a_0, \dots, a_n]$  be a geometrically independent set in  $\mathbb{R}^n$ . We define the  $n$  – **simplex** spanned by  $a_0, \dots, a_n$  to be set of all points  $x$  of  $\mathbb{R}^n$  such that  $x = \sum_{i=0}^n t_i a_i$ , where  $\sum_{i=0}^n t_i = 1$  and  $t_i \geq 0$  for all  $i$ .

**Notations:** We denote the ordered  $n$  – **simplex** as  $|\Delta^n|$ . We label the vertices of  $n$  – **simplex** with the numbers  $0, 1, \dots, n$ . So that  $|\Delta^n| = [0, 1, \dots, n]$ .

Structure of  $n$  – **simplex**:

- 0 – **simplex** : 1 Independent point:  $|\Delta^0| = [0]$
- 1 – **simplex** : 2 Independent point:  $|\Delta^1| = [0, 1]$
- 2 – **simplex** : 3 Independent point:  $|\Delta^2| = [0, 1, 2]$
- 3 – **simplex** : 4 Independent point:  $|\Delta^3| = [0, 1, 2, 3]$
- .
- $n$  – **simplex** :  $(n + 1)$  Independent point:  $|\Delta^n| = [0, 1, \dots, n]$

**Definition 2.2:** A **simplicial complex**  $X$  which is in  $\mathbb{R}^n$  is a collection of simplices in  $\mathbb{R}^n$  such that

- (i) Every face in a simplex of  $X$  is in  $X$ .
- (ii) For any two simplices of  $X$ , its non-empty intersection is a face of each.

**Definition 2.3:** In the standard  $n$  – **simplex**  $|\Delta^n| = [0, 1, \dots, n]$ , there are  $n + 1$  **face maps**  $d_0, \dots, d_n$ , defined by  $d_j[0, \dots, n] = [0, \dots, \hat{j}, \dots, n]$  where the  $\hat{j}$  denotes the term, which is being ignored and then applying  $d_j$  to  $[0, \dots, n]$  results in  $n - 1$  faces (by missing  $j^{th}$  vertex).

**Definition 2.4:** In the standard  $n$  – **simplex**  $|\Delta^n| = [0, 1, \dots, n]$ , there will be  $n + 1$  **degeneracy maps**  $s_0, \dots, s_n$ , defined by  $s_j[0, \dots, n] = [0, \dots, j, j, \dots, n]$ . Thus  $s_j[0, \dots, n]$  gives the  $n + 1$  unique degenerate simplices in  $|\Delta^n|$  (with the repetition of  $j^{th}$  vertex).

**Definition 2.5:** A **simplicial set**  $X$  which contains a sequence of set  $X_0, X_1, \dots$  and for every  $n \geq 0$ , functions  $d_i: X_n \rightarrow X_{n-1}$  and  $s_i: X_n \rightarrow X_{n+1}$  where  $0 \leq i \leq n$  for each  $i$ , such that

- (i)  $d_i d_j = d_{j-1} d_i$  if  $i < j$
- (ii)  $s_i s_j = s_{j+1} s_i$  if  $i \leq j$
- (iii)  $d_i s_j = s_{j-1} d_i$  if  $i < j$
- (iv)  $d_j s_j = d_{j+1} s_j = \text{identity}$
- (v)  $d_i s_j = s_j d_{i-1}$  if  $i > j + 1$

**Definition 2.6:** A **simplicial map**  $\sigma: X \rightarrow Y$  is a map of simplicial sets which commutes with its face and degeneracy maps i.e.,  $\sigma$  consists of  $\sigma_n: X_n \rightarrow Y_n$  and

- (i)  $\sigma_n d_i = d_i \sigma_{n+1}$
- (ii)  $\sigma_n s_i = s_i \sigma_{n-1}$

**Definition 2.7:** A **degenerate simplex** is a  $[x_{i_0}, \dots, x_{i_n}]$  for which the  $x_{i_j}$  are not all distinct, though require  $i_k \leq i_l$  if  $k < l$ .

**Sasikala and Renukadevi**

**Definition 2.8:** A simplex  $X \in X_n$  is known as **non-degenerate** if  $X \neq s_i Y$  for any  $Y \in X_{n-1}$  and any  $i$ .

**Definition 2.9: Euler characteristic**  $\chi(X)$  defines the alternate sum of  $\sum_n (-1)^n C_n$ , where  $C_n$  denotes the count of  $n$ -cells of  $X$ .

**Definition 2.10:** A mapping  $F$  from  $C$  to  $D$  is said to be a **functor** when it

- (i) Associates each object  $X$  in  $C$  with an object  $F(X)$  in  $D$ ,
- (ii) Associates each morphism  $f: X \rightarrow Y$  in  $C$  to a morphism  $F(f): F(X) \rightarrow F(Y)$  in  $D$  such that, it should hold the following two conditions:
  - $F(id_X) = id_{F(X)}$  for every object  $X$  in  $C$
  - $F(g \circ f) = F(g) \circ F(f)$  for all morphism  $f: X \rightarrow Y$  and  $g: Y \rightarrow Z$  in  $C$ .

Thus, functors must preserve identity morphism and composition of morphisms

**$\mathcal{S}_T$  space**

**Definition 3.1:** Let  $\delta_a$  and  $\delta_b$  be two simplicial sets, then the cartesian product of  $\delta_a \times \delta_b$  is said to be a simplicial topological space as  $\mathcal{S}_T$  space ( $\delta_{ab}$ ) which satisfies the following conditions:

- (i) It forms a countable number of  $n$  – simplex in  $\mathbb{R}^n$  where  $n > 1$ .
- (ii) Formation of  $n$  – simplex will consist only the non-degenerate simplices.
- (iii) Existence of compactness.

**Example 3.2:** Let  $|\delta_a^1 \times \delta_b^1|$  be a  $\mathcal{S}_T$  space, where  $\delta_a^1 = [v_{a0}, v_{a1}]$ ,  $\delta_b^0 = [v_{b0}, v_{b1}]$  are 1–simplices.

Let us take  $\delta_{ab} = |\delta_a^1 \times \delta_b^1|$  and consider  $\Omega_{ab}^n$  be the finite collection of  $n$  – simplices in  $\delta_{ab}$ .

- Then,
- $\Omega_{ab}^0 = \{\emptyset, [v_{a0}], [v_{a1}], [v_{b0}], [v_{b1}]\}$
  - $\Omega_{ab}^1 = [v_{a0}, v_{b0}], [v_{a0}, v_{b1}], [v_{a0}, v_{a1}], [v_{b0}, v_{a1}], [v_{b0}, v_{b1}], [v_{b1}, v_{a1}]$
  - $\Omega_{ab}^2 = [v_{a0}, v_{b0}, v_{a1}], [v_{a0}, v_{b0}, v_{b1}], [v_{a0}, v_{a1}, v_{b1}], [v_{b0}, v_{a1}, v_{b1}]$
  - $\Omega_{ab}^3 = [v_{a0}, v_{a1}, v_{b0}, v_{b1}]$

- (i) It forms a 3 – simplex in  $\mathbb{R}^3$ .
- (ii) It has non-degenerate 0 – simplex (including the origin point), 1 – simplex in  $\mathbb{R}^1$ , 2 – simplex in  $\mathbb{R}^2$  and 3 – simplex in  $\mathbb{R}^3$ .
- (iii) It is compact.

Since, all the above  $\Omega_{ab}^n$  are open covering of  $\delta_{ab} = |\delta_a^1 \times \delta_b^1|$  but the subcollection  $\Omega_{ab}^2$  is enough to cover  $\delta_{ab}$ . Therefore,  $\delta_{ab} = |\delta_a^1 \times \delta_b^1|$  is a  $\mathcal{S}_T$  space.

**Proposition 3.3:** Let  $C_n(\delta_{ab})$  be the number of elements in  $\Omega_{ab}^n$  of  $\mathcal{S}_T$  space  $\delta_{ab}$  such that  $C_n$  has the Euler characteristic “1”.

**Proof:** Let  $\delta_{ab}$  be the  $\mathcal{S}_T$  space and  $\Omega_{ab}^n$  be the finite collection of  $n$  – simplices of  $\delta_{ab}$

$$C_n(\delta_{ab}) = \{C_0(\Omega_{ab}^0), C_1(\Omega_{ab}^1), \dots, C_n(\Omega_{ab}^n)\}$$

Euler characteristic is defined to be the alternating sum of  $C_n(\delta_{ab})$ .

$$\text{i.e., } \sum_n (-1)^n C_n(\delta_{ab}) = C_0(\Omega_{ab}^0) - C_1(\Omega_{ab}^1) + C_2(\Omega_{ab}^2) - \dots + C_n(\Omega_{ab}^n)$$

This proposition can be verified by taking the  $C_n$  values from the example 3.2.

$$\begin{aligned} C_0(\Omega_{ab}^0) &= 4 \\ C_1(\Omega_{ab}^1) &= 6 \\ C_2(\Omega_{ab}^2) &= 4 \\ C_3(\Omega_{ab}^3) &= 1 \end{aligned}$$

$$\begin{aligned} \text{Now } \sum_n (-1)^n C_n(\delta_{ab}) &= C_0(\Omega_{ab}^0) - C_1(\Omega_{ab}^1) + C_2(\Omega_{ab}^2) - C_3(\Omega_{ab}^3) \\ &= 4 - 6 + 4 - 1 \\ &= 1 \end{aligned}$$

**Sasikala and Renukadevi**

**Simplicial Homology on  $\mathcal{S}_T$  space**

Let the free abelian group be  $\Delta_{ab}^n(\delta_{ab})$  with the basis  $\Omega_{ab}^n$  of  $\delta_{ab}$  as open  $n - simplices$ .

The elements of  $\Delta_{ab}^n(\delta_{ab})$  called  $n_{ab}$ - chains and is represented as  $\sum_{ab} n_{ab} \Omega_{ab}^n$  with coefficients  $n_{ab} \in \mathbb{Z}$

Let  $\varphi_{ab} : \Delta_{ab}^n \rightarrow \delta_{ab}$  be the characteristic map restricting to a homeomorphism from the interior of  $\Delta_{ab}^n$  onto  $\Omega_{ab}^n$  of  $\delta_{ab}$ .

Let  $\partial_{ab}^n : \Delta_{ab}^n(\delta_{ab}) \rightarrow \Delta_{ab}^{n-1}(\delta_{ab})$  be the boundary homeomorphism on the basis element specifying  $\partial_{ab}^n(\varphi_{ab}) = \sum_k (-1)^k \varphi_{ab} [v_{a0}, \dots, \hat{v}_{(a/b)k}, \dots, v_{bn}]$

**Lemma 3.4:** The composition  $\Delta_{ab}^n(\delta_{ab}) \xrightarrow{\partial_{ab}^n} \Delta_{ab}^{n-1}(\delta_{ab}) \xrightarrow{\partial_{ab}^{n-1}} \Delta_{ab}^{n-2}(\delta_{ab})$  is zero.

**Proof:** We have  $\partial_{ab}^n(\varphi_{ab}) = \sum_k (-1)^k \varphi_{ab} [v_{a0}, \dots, \hat{v}_{(a/b)k}, \dots, v_{bn}]$

Then,  $\partial_{ab}^{n-1} \circ \partial_{ab}^n(\varphi_{ab}) = \sum_{l < k} (-1)^k (-1)^l \varphi_{ab} [v_{a0}, \dots, \hat{v}_{(a/b)k}, \dots, \dots, \hat{v}_{(a/b)l}, \dots, v_{bn}] +$

$$\sum_{l > k} (-1)^k (-1)^{l-1} \varphi_{ab} [v_{a0}, \dots, \hat{v}_{(a/b)k}, \dots, \dots, \hat{v}_{(a/b)l}, \dots, v_{bn}] = 0$$

By shifting  $k$  and  $l$  in the second sum, it becomes the negative of the previous one. Therefore, the above two summations get cancelled each other.

Hence, we have the composition  $\Delta_{ab}^n(\delta_{ab}) \xrightarrow{\partial_{ab}^n} \Delta_{ab}^{n-1}(\delta_{ab}) \xrightarrow{\partial_{ab}^{n-1}} \Delta_{ab}^{n-2}(\delta_{ab})$  is 0

**Remark 3.5**

We now have the chain complex which is sequence of homeomorphism of abelian groups.

$$\dots \rightarrow \mathbb{C}_{ab}^{n+1} \xrightarrow{\partial_{ab}^{n+1}} \mathbb{C}_{ab}^n \xrightarrow{\partial_{ab}^n} \mathbb{C}_{ab}^{n-1} \rightarrow \dots \rightarrow \mathbb{C}_{ab}^1 \xrightarrow{\partial_{ab}^1} \mathbb{C}_{ab}^0 \xrightarrow{\partial_{ab}^0} 0 \text{ with } \partial_{ab}^n \circ \partial_{ab}^{n+1} = 0 \text{ for each } n.$$

This follows that  $Im \partial_{ab}^{n+1} \subset Ker \partial_{ab}^n$ , where  $Im$  and  $Ker$  denote image and kernel. We now define the  $n^{th}$  simplicial homology group as  $H_{ab}^n = \frac{Ker \partial_{ab}^n}{Im \partial_{ab}^{n+1}}$ .

Elements of  $Ker \partial_{ab}^n$ : Cycles

Elements of  $Im \partial_{ab}^{n+1}$ : Boundaries

Elements of  $H_{ab}^n$ : Cosets of  $Ker \partial_{ab}^n$ : Homology Classes

**Singular Homology on  $\mathcal{S}_T$  space**

A singular  $n - simplex$  is a continuous map of  $\sigma_{ab} : \Delta_{ab}^n \rightarrow \delta_{ab}$  in  $\mathcal{S}_T$  space.

Let the free abelian group be  $\mathbb{C}_{ab}^n(\delta_{ab})$  with the basis of singular  $n - simplices$  in  $\delta_{ab}$ . The elements of  $\mathbb{C}_{ab}^n(\delta_{ab})$  called singular  $n_{ab}$ - chains and is represented as  $\sum_{ab} n_{ab} \sigma_{ab}^k$  with coefficients  $n_{ab} \in \mathbb{Z}$

Let  $\partial_{ab}^n : \mathbb{C}_{ab}^n(\delta_{ab}) \rightarrow \mathbb{C}_{ab}^{n-1}(\delta_{ab})$  be the boundary homeomorphism on the basis element specifying  $\partial_{ab}^n(\sigma_{ab}) = \sum_k (-1)^k \sigma_{ab} [v_{a0}, \dots, \hat{v}_{(a/b)k}, \dots, v_{bn}]$

**Remark 3.6:** The lemma 3.4 is applied equally to the singular simplices, showing that

$\partial_{ab}^{n-1} \circ \partial_{ab}^n = 0$ . So, we can define singular homology group as follows.

**Definition 3.7:** Let  $H_{ab}^n$  be the **singular homology group** of  $\delta_{ab}$  and is defined as

$$H_{ab}^n = \frac{Ker \partial_{ab}^n}{Im \partial_{ab}^{n+1}}$$

**Proposition 3.8:** There is an isomorphism of  $H_{ab}^n(\delta_{ab})$  with direct sum of  $\bigoplus_{\alpha} H_{ab}^n(P_{\alpha})$  corresponding to the decomposition of  $\mathcal{S}_T$  space  $\delta_{ab}$  into its path components  $P_{\alpha}$ .

**Proof:** Since, singular simplex has always path connected image,

$\mathbb{C}_{ab}^n(\delta_{ab})$  splits the direct sum of subgroups  $H_{ab}^n(P_{\alpha})$ .

The boundary map preserves the direct sum decomposition by  $\partial_{ab}^n : \mathbb{C}_{ab}^n(P_{\alpha}) \rightarrow \mathbb{C}_{ab}^{n-1}(P_{\alpha})$ .

Therefore,  $Ker \partial_{ab}^n$  and  $Im \partial_{ab}^{n+1}$  splits similarly as direct sums. Hence,  $H_{ab}^n$  also splits.

This implies  $H_{ab}^n(\delta_{ab}) \approx \bigoplus_{\alpha} H_{ab}^n(P_{\alpha})$ .

**Sasikala and Renukadevi**

**Proposition 3.9:** If  $\delta_{ab}$  be a point then  $H_{ab}^n(\delta_{ab}) = 0$ , for  $n > 0$  and  $H_{ab}^0(\delta_{ab}) \approx \mathbb{Z}$ .

**Proof:** There is a unique singular  $n$  – simplex  $\sigma_{ab}$  for each  $n$ .

$$\text{Then } \partial_{ab}(\sigma_{ab}^n) = \sum_k (-1)^k \sigma_{ab}^n = \begin{cases} 0 & \text{for } n \text{ is odd} \\ \sigma_{ab}^{n-1} & \text{for } n \text{ is even, } n \neq 0 \end{cases}$$

Thus, we have chain complex with boundary maps as

$$\dots \rightarrow \mathbb{Z} \xrightarrow{\approx} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \xrightarrow{\approx} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \rightarrow 0$$

This implies,

$H_{ab}^n(\delta_{ab})$  is trivial except for  $H_{ab}^0(\delta_{ab}) \approx \mathbb{Z}$ .

**Homotopic Invariance on  $\mathcal{S}_T$  space:**

Here the cartesian product of two simplicial sets  $\delta_{ab}$  and the simplicial topological space  $\delta'_{ab}$  are homotopic equivalent spaces. It can be proved by introducing a map  $f: \delta_{ab} \rightarrow \delta'_{ab}$  which induces a homomorphism  $f^*$  and that induces an isomorphism if  $f$  is a homotopic equivalence.

**Lemma 3.10:** A map  $f: \delta_{ab} \rightarrow \delta'_{ab}$  induces a homomorphism  $f^*: H_{ab}^n(\delta_{ab}) \rightarrow H_{ab}^n(\delta'_{ab})$  for each  $n$ .

**Proof:** Let us consider a map  $f: \delta_{ab} \rightarrow \delta'_{ab}$ .

This induces a homomorphism  $f_{\#}: \mathbb{C}_{ab}^n(\delta_{ab}) \rightarrow \mathbb{C}_{ab}^n(\delta'_{ab})$  which is defined by composing each singular  $n$  – simplex  $\sigma_{ab}: \Delta_{ab}^n \rightarrow \delta_{ab}$  with  $f$ .

We get  $f_{\#}(\sigma_{ab}) = f \circ \sigma_{ab}: \Delta_{ab}^n \rightarrow \delta'_{ab}$ .

Then extending  $f_{\#}$  linearly, it satisfies  $f_{\#} \partial_{ab} = \partial_{ab} f_{\#}$ .

$$\begin{aligned} \text{Since, } f_{\#} \partial_{ab}(\sigma_{ab}) &= f_{\#}(\sum_k (-1)^k \sigma_{ab} [v_{a0}, \dots, \hat{v}_{(a/b)k}, \dots, v_{bn}]) \\ &= \sum_k (-1)^k f(\sigma_{ab} [v_{a0}, \dots, \hat{v}_{(a/b)k}, \dots, v_{bn}]) \\ &= \partial_{ab} f_{\#}(\sigma_{ab}) \end{aligned}$$

Thus, we say that  $f_{\#}$  define a chain map from the singular chain complex of  $\delta_{ab}$  to that of  $\delta'_{ab}$ .

This implies,  $f_{\#}$  takes boundaries to boundaries and cycles to cycles.

Hence  $f: \delta_{ab} \rightarrow \delta'_{ab}$  induces a homomorphism  $f^*: H_{ab}^n(\delta_{ab}) \rightarrow H_{ab}^n(\delta'_{ab})$

**Theorem 3.11:** If the two maps  $f, g: \delta_{ab} \rightarrow \delta'_{ab}$  are homotopic then they induce the same homomorphism  $f_* = g_*: H_{ab}^n(\delta_{ab}) \rightarrow H_{ab}^n(\delta'_{ab})$ .

**Proof:** Let  $\Delta_{ab}^n$  be the  $n$  – simplex of  $\delta_{ab}$

We subdivided the product  $\Delta_{ab}^n \times I$  into  $(n + 1)$  – simplices

Let  $\Delta_a^n \times I = [v_{a0}, \dots, v_{an}]$  and  $\Delta_b^n \times I = [v_{b0}, \dots, v_{bn}]$ , where  $v_{ai}$  and  $v_{bi}$  has the same image under projection  $\Delta_{ab}^n \times I \rightarrow \Delta_{ab}^n$ . The  $n$  – simplex  $[v_{a0}, \dots, v_{ai}, v_{bi+1}, \dots, v_{bn}]$  is the graph of the linear function  $\varphi_k: \Delta_{ab}^n \rightarrow I$  defined in barycentric coordinate by  $\varphi_k(t_0, \dots, t_n) = t_{k+1} + \dots + t_n$ . Since, all the vertices are on graph of  $\varphi_k$  and this simplex is homeomorphic under projection  $\Delta_{ab}^n \times I \rightarrow \Delta_{ab}^n$ . Since  $\varphi_k \leq \varphi_{k-1}$ , the area between two graphs is also the simplex  $[v_{a0}, \dots, v_{ai}, v_{bi}, \dots, v_{bn}]$  which is  $(n + 1)$  simplex.

From string of inequalities  $0 = \varphi_k \leq \varphi_{k-1} \leq \dots \leq \varphi_0 \leq \varphi_{-1} = 1$ , we deduce that  $\Delta_{ab}^n \times I$  is the union of the  $(n + 1)$  simplex  $[v_{a0}, \dots, v_{ai}, v_{bi}, \dots, v_{bn}]$ , for which each one intersects the face of the next  $n$  – simplex.

Let  $\mathcal{F}: \delta_{ab} \times I \rightarrow \delta'_{ab}$  from  $f$  to  $g$ . We now define a prism operator

$$\mathbb{P}(\sigma_{ab}) = \sum_k (-1)^k \mathcal{F} \circ (\sigma_{ab} \times 1) [v_{a0}, \dots, v_{ai}, v_{bi}, \dots, v_{bn}] \text{ for } \sigma_{ab}: \Delta_{ab}^n \rightarrow \delta_{ab}$$

where  $\mathcal{F} \circ (\sigma_{ab} \times 1)$  is the composition  $\Delta_{ab}^n \times I \rightarrow \delta_{ab} \times I \rightarrow \delta'_{ab}$ .

Operator  $\mathbb{P}$  satisfies the relation  $\partial \mathbb{P} = g_{\#} - f_{\#} - \mathbb{P} \partial$  where  $\partial \mathbb{P}$ : boundary of prism,  $g_{\#} \Rightarrow \Delta_b^n \times I$  and  $f_{\#} \Rightarrow \Delta_a^n \times I$

Now,  $\partial \mathbb{P}(\sigma_{ab}) = \sum_{k \leq i} (-1)^i (-1)^k \mathcal{F} \circ (\sigma_{ab} \times 1) [v_{a0}, \dots, \hat{v}_{ak}, \dots, v_{ai}, v_{bi}, \dots, v_{bn}] +$

$$\sum_{k \geq i} (-1)^i (-1)^{k+1} \mathcal{F} \circ (\sigma_{ab} \times 1) [v_{a0}, \dots, v_{ai}, v_{bi}, \dots, \hat{v}_{bk}, \dots, v_{bn}]$$

The terms along with  $i = k$  in the above two sums gets cancelled except

for  $\mathcal{F} \circ (\sigma_{ab} \times 1) [\hat{v}_{a0}, v_{b0}, \dots, v_{bn}]$  which is  $g \circ \sigma_{ab} = g_{\#}(\sigma_{ab})$

### Sasikala and Renukadevi

and  $-\mathcal{F} \circ (\sigma_{ab} \times 1)[v_{a0}, \dots, v_{an}, \hat{v}_{bn}]$  which is  $-f \circ \sigma_{ab} = -f_{\#}(\sigma_{ab})$

If  $\alpha_{ab} \in \mathbb{C}_{ab}^n(\delta_{ab})$  be a cycle then  $g_{\#}(\alpha_{ab}) - f_{\#}(\alpha_{ab}) = \partial \mathbb{P}(\alpha_{ab}) + \mathbb{P} \partial(\alpha_{ab})$

Since  $\partial(\alpha_{ab}) = 0$ , implies  $g_{\#}(\alpha_{ab}) - f_{\#}(\alpha_{ab})$  is a boundary.

So,  $g_{\#}(\alpha_{ab})$  and  $f_{\#}(\alpha_{ab})$  indicates the same homology class, implies that  $g_* = f_*$  on the same homology class.

**Corollary 3.12:** The map  $f: \delta_{ab} \rightarrow \delta'_{ab}$  is homotopic and induces the homomorphism  $f_*: H_{ab}^n(\delta_{ab}) \rightarrow H_{ab}^n(\delta'_{ab})$ , then  $f_*$  is isomorphism for all  $n$ .

### ABSTRACT

In this paper the idea of  $f\pi gb$ -closed sets is introduced and certain properties of these sets have been studied.  $f\pi gb$ -closure,  $f\pi gb$ -interior,  $f\pi gb$ -limit points are defined and properties are studied. The authors have introduced a new class of functions in fine-topological space and investigated some of their properties. The concept of  $f\pi gb$ -irresolute function is introduced and the relationship between  $f\pi gb$ -continuous function and  $f\pi gb$ -irresolute function is studied. Furthermore, certain types of  $f\pi gb$ -separation axioms are introduced and some of their properties are investigated. Also, the concept of  $f\pi gb$ -connectedness is introduced and their properties are studied.

**Keywords :**  $f\pi gb$ -closed sets,  $f\pi gb$ -open sets,  $f\pi gb$ -continuous functions,  $f\pi gb$ -irresolute functions,  $f\pi gb$ -separation axioms,  $f\pi gb$ -connectedness.

**AMS Subject Classification :** 54C08, 54C10

### INTRODUCTION

Andrijevic[2] introduced a new class of generalized open sets in a topological space called b-open sets ( $\gamma$ -open sets in the sense of Ekici et.al). The class of b-open sets is contained in the class of semi-preopen sets and contains the class of semi-open and pre-open sets. In 1968, Zaitsev[18] defined  $\pi$ -open sets. Dontchev and Noiri[5] introduced the notion of  $\pi gb$ -closed sets. D.Sreeja and C. Janaki[16] introduced the idea of  $\pi gb$  closed sets. P.L.Powar and K. Rajak[9,10] have introduced fine topological space which is a special case of generalized topological space. In this space, they have defined a new class of open sets namely fine-open sets, fine-continuous mappings and fine-irresolute mappings.

### Geethapadmini and Janaki

In this paper the authors have defined a new set called  $f\pi gb$ -closed sets,  $f\pi gb$ -open sets and some new continuous functions. We have also introduced  $f\pi gb$ -separation axioms and  $f\pi gb$ -connectedness in fine-topological space and studied their properties.

#### Preliminaries

Throughout this paper  $(X, \tau, \tau')$ ,  $(Y, \sigma, \sigma')$  and  $(z, \eta, \eta')$  represents fine topological spaces on which no separation axioms are assumed unless otherwise stated.

**Definition 2.1** :[9] Let  $(X, \tau)$  be a topological space. Define  $\tau(A_\alpha) = \tau_\alpha = \{G_\alpha (\neq X) / G_\alpha \cap A_\alpha \neq \phi, \text{ for } A_\alpha \in \tau \text{ and } A_\alpha \neq \phi, X \text{ for some } \alpha \in J, \text{ where } J \text{ is the indexed set.}\}$ . Define  $\tau_f = \{\phi, X\} \cup \tau_\alpha$ . This collection  $\tau_f$  of subsets of  $X$  is called the fine collection of subsets of  $X$  and  $(X, \tau, \tau_f)$  and is called the fine space  $X$  and is generated by the topology  $\tau$  on  $X$ .

**Definition 2.2**:[9] A subset  $U$  of a fine space  $X$  is said to be a fine-open set of  $X$ , if  $U$  belongs to the collection  $\tau_f$  and the complement of every fine-open sets of  $X$  is called the fine-closed sets of  $X$  and we denote the collection by  $F_f$ .

**Remark 2.3**:[9] The arbitrary union of fine-open sets is fine-open.

**Remark 2.4** :[9] The intersection of two fine-open sets need not be a fine open set.

**Definition 2.5**:[10] Let  $A$  be the subset of a fine space  $X$ . The fine interior of  $A$  is defined as the union of all fine-open sets contained in the set  $A$  i.e. the largest fine-open set contained in the set  $A$  and is denoted by  $fintA$ .

**Definition 2.6**:[10] Let  $A$  be the subset of a fine space  $X$ , the fine closure of  $A$  is defined as the intersection of all fine-closed sets containing the set  $A$  i.e. the smallest fine-closed set containing the set  $A$  and is denoted by  $fclA$ .

**Definition 2.7**:[10] A subset  $A$  of a space  $(X, \tau, \tau_f)$  is called

- fine pre-open if  $S \subseteq f \text{ int}(fcl(A))$ .
- fine semi-open if  $A \subseteq fcl(fint(A))$ .
- fine  $\alpha$ -open if  $A \subseteq fint(fcl(fint(A)))$ .
- fine  $\beta$ -open if  $A \subseteq fcl(f \text{ int}(fcl(S)))$ .
- fine regular-open if  $A = fint(fcl(A))$
- fine  $\gamma$ -open (or fine b-open) if  $A \subseteq fcl(fint(A)) \cup fint(fcl(A))$

**Definition 2.8**[9] : A function  $f : (X, \tau, \tau_f) \rightarrow (Y, \tau', \tau'_f)$  is called fine-continuous if  $f^{-1}(V)$  is open in  $X$  for every fine-open set  $V$  of  $Y$ .

**Definition 2.9**:[9] A function  $f : (X, \tau, \tau_f) \rightarrow (Y, \tau', \tau'_f)$  is called fine-irresolute (or  $f$ -irresolute) if  $f^{-1}(V)$  is fine-open in  $X$  for every fine-open set  $V$  of  $Y$ .

**Remark 2.10**:[9] (i)  $fcl(A) \subseteq cl(A)$  (ii)  $int(A) \subseteq fint(A)$

#### 3. Fine $\pi$ generalized b-closed sets

**Definition 3.1**: Let  $(X, \tau, \tau_f)$  be a fine space. A subset  $A$  of a fine space  $X$  is said to be fine  $\pi$ -open ( $f\pi$ -open) if  $A$  is a finite union of fine regular-open sets.

**Remark 3.2** : fine regular open  $\Rightarrow$  fine  $\pi$ -open.

**Theorem 3.3**: Every fine  $\pi$ -open set is fine open.

**Proof** : Obvious.

**Remark 3.4** : The converse of the above theorem need not be true.

**Example 3.5**: Let  $X = \{1,2,3,4\}$ .  $\tau = \{\phi, \{1\}, X\}$ ,  $\tau_f = \{\phi, \{1\}, \{1,2\}, \{1,3\}, \{1,4\}, \{1,2,3\}, \{1,2,4\}, \{1,3,4\}, X\}$ . The set  $\{1\}$  is fine open but not fine  $\pi$ -open.

**Definition 3.6**: Let  $(X, \tau, \tau_f)$  be a fine space. A subset  $A$  of a fine space  $X$  is said to be

- (i)  $f\pi gp$ -closed set if  $fpc(A) \subseteq U$ , whenever  $A \subseteq U$  and  $U$  is  $f\pi$ -open.
- (ii)  $f\pi g\alpha$ -closed set if  $f\alpha cl(A) \subseteq U$ , whenever  $A \subseteq U$  and  $U$  is  $f\pi$ -open.
- (iii)  $f\pi gs$ -closed set if  $fsc(A) \subseteq U$ , whenever  $A \subseteq U$  and  $U$  is  $f\pi$ -open.

**Remark 3.7**: (i)  $fbcl(A) \subseteq bcl(A) \subseteq scl(A) \subseteq pcl(A)$  (ii)  $fbcl(A) \subseteq \alpha cl(A)$

**Example 3.8** : Let  $(X, \tau, \tau_f)$  be a fine space. Let  $X = \{1,2,3\}$ ,  $\tau = \{\phi, \{1\}, \{1,3\}, X\}$ .

$\tau_f = \{\phi, \{1\}, \{3\}, \{1,2\}, \{1,3\}, \{2,3\}, X\}$ . Let  $A = \{1\}$ .  $bcl(A) = scl(A) = pcl(A) = X$  and  $fbcl(A) = A$ .

**Geethapadmini and Janaki**

**Definition 3.9 :** Let  $(X, \tau, \tau_f)$  be a fine space. A subset  $A$  of a fine space  $X$  is said to be  $\pi$  generalized  $b$ -closed set (shortly  $f\pi gb$ -closed) if  $fbcl(A) \subseteq U$ , whenever  $A \subseteq U$  and  $U$  is  $f\pi$ -open in fine space  $X$ .

**Example 3.10:** Let  $(X, \tau, \tau_f)$  be a fine space. Let  $X = \{1,2,3\}$ ,  $\tau = \{ \phi, \{1\}, \{1,3\}, X \}$ ,  $\tau_f = \{ \phi, \{1\}, \{3\}, \{1,2\}, \{1,3\}, \{2,3\}, X \}$ . The  $f\pi gb$ -closed sets are  $\{ \phi, \{1\}, \{2\}, \{3\}, \{1,2\}, \{2,3\}, X \}$ .

**Theorem 3.11:** If  $A$  is  $f\pi$ -open and  $f\pi gb$ -closed then  $A$  is fine  $b$ -closed.

**Proof :** Let  $A$  is  $f\pi$ -open and  $f\pi gb$ -closed. Therefore  $fbcl(A) \subset A$ . But  $A \subset fbcl(A)$ . Therefore  $A = fbcl(A)$ . Hence  $A$  is fine  $b$ -closed.

**Remark 3.12:** The finite union of  $f\pi gb$ -closed sets need not be  $f\pi gb$ -closed.

**Example 3.13:** In example 3.10  $\{1\}$  and  $\{3\}$  are fine- $\pi gb$ -closed sets but  $\{1,3\}$  is not a  $f\pi gb$ -closed set.

**Definition 3.14:** The  $f\pi gb$ -closure of a subset  $A$  of a space  $X$  is the intersection of all  $f\pi gb$ -closed sets that contains  $A$  and is denoted by  $f\pi gb-cl(A)$ .

**Theorem 3.15:** If  $A$  is a  $f\pi gb$ -closed set, then  $fbcl(A) - A$  does not contain any non-empty  $f\pi$ -closed sets.

**Proof :** Let  $H$  be a non-empty  $f\pi$ -closed set such that  $H \subset fbcl(A) - A$ . Since  $A$  is  $f\pi gb$ -closed,  $A \subset X - H$  where  $X - H$  is  $f\pi$ -open. This implies  $fbcl(A) \subset X - H$ . Hence  $H \subset X - fbcl(A)$ .

$H \subset fbcl(A) \cap (X - fbcl(A))$  implies that  $H = \phi$  which is a contradiction. Therefore  $fbcl(A)$  does not contain any non-empty  $f\pi$ -closed sets.

**Theorem 3.16:** If  $A$  is  $f\pi gb$ -closed and  $B$  is any set such that  $A \subset B \subset fbcl(A)$ , then  $B$  is  $f\pi gb$ -closed.

**Proof :** Let  $B \subset U$  and  $U$  is  $f\pi$ -open. Since  $A \subset B$ ,  $A \subset U$ . Since  $A$  is  $f\pi gb$ -closed,  $A \subset U$  implies  $fbcl(A) \subset U$ . By our assumption it follows that  $fbcl(B) \subset fbcl(A) \subset U$ . Therefore  $B$  is  $f\pi gb$ -closed.

**Definition 3.17 :** Let  $(X, \tau, \tau_f)$  be a fine space. A subset  $A$  of a fine space  $X$  is said to be  $f\pi gb$ -open set if its complement is a  $f\pi gb$ -closed set.

**Remark 3.18:** By  $f\pi GBO(\tau_f)$  we mean the family of all  $f\pi gb$ -open subsets of the fine space  $(X, \tau, \tau_f)$ .

**Definition 3.19:** The fine- $\pi gb$ -interior of a subset  $A$  of a space  $X$  is the union of all fine  $\pi gb$ -open sets that contained  $A$  and is denoted by  $f\pi gb-int(A)$ .

**Lemma 3.20:** (i)  $f\pi gb-cl(X - A) = X - f\pi gb-int(A)$

(ii)  $f\pi gb-cl(f\pi gb-cl(A)) = f\pi gb-cl(A)$

(iii)  $f\pi gb-int(X - A) = X - f\pi gb-cl(A)$

(iv)  $f\pi gb-int(f\pi gb-int(A)) = f\pi gb-int(A)$

**Theorem 3.21:** If  $fbint(A) \subset B \subset A$  and  $A$  is  $f\pi gb$ -open then  $B$  is  $f\pi gb$ -open.

**Proof :** Let  $fbint(A) \subset B \subset A$ . Then  $X - A \subset X - B \subset fbcl(X - A)$ . Since  $A$  is  $f\pi gb$ -open,  $X - A$  is  $f\pi gb$ -closed. Then by theorem (3.16)  $X - B$  is  $f\pi gb$ -closed.

**Definition 3.22:** A fine space  $X$  is called a  $f\pi gb-T_{1/2}$  space if every  $f\pi gb$ -closed set is  $fb$ -closed.

**Theorem 3.23:** A fine space  $(X, \tau, \tau_f)$  is  $f\pi gb-T_{1/2}$  if and only if  $fBO(\tau) = f\pi GBO(\tau)$ .

**Proof :** Let  $(X, \tau, \tau_f)$  be  $f\pi gb-T_{1/2}$  space. Let  $A \in f\pi GBO(\tau)$ . Then  $X - A$  is  $f\pi gb$ -closed. By hypothesis,  $X - A$  is  $fb$ -closed. Therefore  $A \in fBO(\tau)$ . Thus  $f\pi GBO(\tau) = fBO(\tau)$ .

Conversely, let us assume that  $fBO(\tau) = f\pi GBO(\tau)$ . Let  $A$  be a  $f\pi gb$ -closed set. Then  $X - A$  is  $f\pi gb$ -open.  $X - A \in f\pi GBO(\tau) = fBO(\tau)$ . Hence the result.

**Theorem 3.24:** For a fine space  $(X, \tau, \tau_f)$  the following statements are equivalent.

(i)  $X$  is  $f\pi gb-T_{1/2}$  space.

(ii) Every singleton set is either  $f\pi$ -closed or  $fb$ -open.

**Proof :** Let  $X$  be a  $f\pi gb-T_{1/2}$  space. Let  $a \in X$  and assume  $\{a\}$  is not  $f\pi$ -closed. Then  $X - \{a\}$  is not  $f\pi$ -open. Hence  $X - \{a\}$  is  $f\pi gb$ -closed. As  $X$  is  $f\pi gb-T_{1/2}$  space,  $X - \{a\}$  is  $fb$ -closed which implies  $\{a\}$  is  $fb$ -open. Hence (i)  $\Rightarrow$  (ii).

Now assume every singleton set is either  $f\pi$ -closed or  $fb$ -open. Let  $A$  be a  $f\pi gb$ -closed set. Let  $\{a\} \in fbcl(A)$ .

Case1: Let  $\{a\}$  be  $f\pi$ -closed. Suppose  $\{a\} \notin A$ , then  $\{a\} \in fb-cl(A) - A$ . By theorem (3.23)  $\{a\} \in A$ . Hence  $fbcl(A) \subset A$ .

### Geethapadmini and Janaki

Case 2: Let  $\{a\}$  be  $\text{fb-open}$ . As  $\{a\} \in \text{fbcl}(A)$ ,  $\{a\} \cap A \neq \emptyset \Rightarrow \{a\} \in A$ . Therefore  $\text{fbcl}(A) \subset A$ . Therefore  $A$  is  $\text{fb-closed}$ .

**Definition 3.25:** Let  $(X, \tau, \tau_f)$  be a fine space. A point  $x$  in  $X$  is said to be  $\text{f}\pi\text{gb-limit}$  point of a subset  $A$  of a fine space  $X$  if every  $\text{f}\pi\text{gb-open}$  set containing  $x$  must contain atleast one point of  $A$  other than  $x$ .

**Definition 3.26:** The set of all  $\text{f}\pi\text{gb-limit}$  point of  $A$  is called  $\text{f}\pi\text{gb-derived}$  set of  $A$  and is denoted by  $D_{\text{f}\pi\text{gb}}(A)$

#### **f** $\pi$ **gb-continuous functions and f** $\pi$ **gb-irresolute functions**

**Definition 4.1 :** A function  $f : (X, \tau, \tau_f) \rightarrow (Y, \sigma, \sigma_f)$  is called a  $\text{f}\pi\text{gb-continuous}$  if  $f^{-1}(V)$  is  $\text{f}\pi\text{gb-closed}$  set in fine space  $X$  for every fine-closed set  $V$  of a fine space  $Y$ .

**Example 4.2 :** let  $f : (X, \tau, \tau_f) \rightarrow (Y, \sigma, \sigma_f)$  where  $X = \{a, b, c\}$  with topology  $\tau = \{\emptyset, \{a\}, \{a, b\}, \{b, c\}, X\}$   $\tau_f = \{\emptyset, \{a\}, \{b\}, \{c\}, \{a, b\}, \{a, c\}, \{b, c\}, X\}$  and  $Y = \{1, 2, 3\}$  with topology  $\sigma = \{\emptyset, \{1\}, Y\}$  with  $\sigma_f = \{\emptyset, \{1\}, \{1, 2\}, \{1, 3\}, Y\}$ . Define  $f(a) = 2, f(b) = 3, f(c) = 1$ . The function  $f$  is  $\text{f}\pi\text{gb-continuous}$ .

**Definition 4.3 :** A function  $f : (X, \tau, \tau_f) \rightarrow (Y, \sigma, \sigma_f)$  is called a  $\text{f}\pi\text{gb-irresolute}$  if  $f^{-1}(V)$  is  $\text{f}\pi\text{gb-closed}$  in the fine space  $X$  for every  $\text{f}\pi\text{gb-closed}$  set  $V$  of fine space  $Y$ .

**Proposition 4.4 :** Every  $\text{f}\pi\text{gb-irresolute}$  function is  $\text{f}\pi\text{gb-continuous}$ .

**Remark 4.5 :** The converse need not be true.

**Example 4.6:** Let  $X = Y = \{1, 2, 3\}$ ,  $\tau = \{\emptyset, \{1\}, \{b\}, \{1, 2\}, X\}$ ,  $\sigma = \{\emptyset, \{1\}, Y\}$ ,  $\tau_f = \{\emptyset, \{1\}, \{2\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, X\}$ ,  $\sigma_f = \{\emptyset, \{1\}, \{1, 2\}, \{1, 3\}, Y\}$ . The identity function  $i : (X, \tau, \tau_f) \rightarrow (Y, \sigma, \sigma_f)$  is  $\text{f}\pi\text{gb-continuous}$  but not  $\text{f}\pi\text{gb-irresolute}$  as  $\{1, 2\}$  is  $\text{f}\pi\text{gb-closed}$  in the fine space  $Y$  but  $f^{-1}\{1, 2\}$  is not  $\text{f}\pi\text{gb-closed}$  in the fine space  $X$ .

**Theorem 4.7:** If  $f : (X, \tau, \tau_f) \rightarrow (Y, \sigma, \sigma_f)$  and  $g : (Y, \sigma, \sigma_f) \rightarrow (Z, \eta, \eta_f)$  be any two functions. Then

- (i)  $g \circ f$  is  $\text{f}\pi\text{gb-continuous}$  if  $f$  is  $\text{f}\pi\text{gb-continuous}$  and  $g$  is fine continuous.
- (ii)  $g \circ f$  is  $\text{f}\pi\text{gb-continuous}$  if  $f$  is  $\text{f}\pi\text{gb-irresolute}$  and  $g$  is  $\text{f}\pi\text{gb-continuous}$ .

**Definition 4.8:** A map  $h : (X, \tau, \tau_f) \rightarrow (Y, \sigma, \sigma_f)$  is called a  $\text{f}\pi\text{gb-closed}$  map if for each fine closed set  $V$  of a fine space  $X$ ,  $h(V)$  is  $\text{f}\pi\text{gb-closed}$  in fine space  $Y$ .

**Definition 4.9 :** A function  $f : (X, \tau, \tau_f) \rightarrow (Y, \sigma, \sigma_f)$  is called a fine-strongly- $\pi\text{gb-open}$  if  $f(V)$  is  $\text{f}\pi\text{gb-closed}$  in the fine space  $Y$  for every  $\text{f}\pi\text{gb-open}$  set  $V$  in fine space  $X$ .

#### **f** $\pi$ **gb-separation axioms**

**Definition 5.1:** A topological space  $X$  is said to be

1.  $\text{f}\pi\text{gb-T}_0$  space if for each pair of distinct points  $x$  and  $y$  in  $X$ , there exist a  $\text{f}\pi\text{gb-open}$  set containing one point but not the other.
2.  $\text{f}\pi\text{gb-T}_1$  space if for each pair of distinct points  $x$  and  $y$  in  $X$ , there exist two  $\text{f}\pi\text{gb-open}$  sets  $G$  and  $H$  such that  $x \in G, y \notin G$  and  $x \notin H, y \in H$ .
3.  $\text{f}\pi\text{gb-T}_2$  space if for any pair of distinct points  $x$  and  $y$ , there exists  $\text{f}\pi\text{gb-open}$  sets  $G$  and  $H$  such that  $x \in G, y \in H$  and  $G \cap H = \emptyset$ .

**Theorem 5.2:** A space  $X$  is  $\text{f}\pi\text{gb-T}_0$  space iff  $\text{f}\pi\text{gb-closure}$  of a distinct points are distinct.

**Proof :** Let  $X$  be a  $\text{f}\pi\text{gb-T}_0$  space and  $p$  and  $q$  be any two distinct points of  $X$ . Therefore, there exists a  $\text{f}\pi\text{gb-open}$  set  $G$  such that  $p \in G$  and  $q \notin G$ . Then  $X - G$  is a  $\text{f}\pi\text{gb-closed}$  set containing  $q$  but not  $p$ . But  $\text{f}\pi\text{gb-cl}(q)$  is the intersection of all  $\text{f}\pi\text{gb-closed}$  sets containing  $q$ . Hence  $q \in \text{f}\pi\text{gb-cl}(q)$  but  $p \notin \text{f}\pi\text{gb-cl}(q)$  as  $p \notin X - G$ . Therefore  $\text{f}\pi\text{gb-cl}(p) \neq \text{f}\pi\text{gb-cl}(q)$ .

Conversely, let  $\text{f}\pi\text{gb-cl}(p) \neq \text{f}\pi\text{gb-cl}(q)$  for  $p \neq q$ . Then there exists atleast one point  $z \in X$  such that  $z \in \text{f}\pi\text{gb-cl}(p)$  but  $z \notin \text{f}\pi\text{gb-cl}(q)$ . We have to prove  $p \notin \text{f}\pi\text{gb-cl}(q)$ . For, if  $p \in \text{f}\pi\text{gb-cl}(q)$  then  $\{p\} \subset \text{f}\pi\text{gb-cl}(q)$  which implies  $\text{f}\pi\text{gb-cl}(p) \subset \text{f}\pi\text{gb-cl}(q)$ . So  $z \in \text{f}\pi\text{gb-cl}(q)$  which is a contradiction. Hence  $p \notin \text{f}\pi\text{gb-cl}(q)$ . That is  $p \in X - \text{f}\pi\text{gb-cl}(q)$  which is a  $\text{f}\pi\text{gb-open}$  set containing  $p$  but not  $q$ . Hence  $X$  is a  $\text{f}\pi\text{gb-T}_0$ -space.

**Theorem 5.3:** If  $f : X \rightarrow Y$  is a bijection,  $\text{f}\pi\text{gb-irresolute}$  map and  $Y$  is  $\text{f}\pi\text{gb-T}_0$  space, then  $X$  is also a  $\text{f}\pi\text{gb-T}_0$ -space.

**Proof :** Let  $x_1, x_2 \in X$  with  $x_1 \neq x_2$ . Since  $f$  is a bijection, there exists  $y_1, y_2 \in Y$  such that  $f(x_1) = y_1$  and  $f(x_2) = y_2 \Rightarrow x_1 = f^{-1}(y_1)$  and  $x_2 = f^{-1}(y_2)$ . Since  $Y$  is a  $\text{f}\pi\text{gb-T}_0$ -space there exists a  $\text{f}\pi\text{gb-open}$  set  $G$  in  $Y$  such that  $y_1 \in G$  and  $y_2 \notin G$ . Since  $f$  is

**Geethapadmini and Janaki**

$f\pi gb$ -irresolute,  $f^{-1}(G)$  is  $f\pi gb$ -open set in  $X$ . Now  $y_1 \in G \Rightarrow f^{-1}(y_1) \in f^{-1}(G) \Rightarrow x_1 \in f^{-1}(G)$ .  $y_2 \notin G \Rightarrow f^{-1}(y_2) \notin f^{-1}(G) \Rightarrow x_2 \notin f^{-1}(G)$ . Hence for any two distinct points  $x_1$  and  $x_2$  in  $X$  there exists a  $f\pi gb$ -open set  $f^{-1}(G)$  such that  $x_1 \in f^{-1}(G)$  and  $x_2 \notin f^{-1}(G)$ . Hence  $X$  is a  $f\pi gb-T_0$ -space.

**Theorem 5.4:** A space  $X$  is  $f\pi gb-T_1$ -space iff the singletons are  $f\pi gb$ -closed sets.

**Proof :** Let  $X$  be a  $f\pi gb-T_1$  space and  $x \in X$ . Let  $y \in X - \{x\}$ . then for  $x \neq y$ , there exists  $f\pi gb$ -open set  $G$  such that  $y \in G$  and  $x \notin G$ . Consequently,  $y \in G \subset X - \{x\}$ , that is  $X - \{x\} = \cup \{ G : y \in X - \{x\} \}$  which is  $f\pi gb$ -open. Hence  $\{x\}$  is  $f\pi gb$ -closed set.

Conversely, suppose  $\{x\}$  is  $f\pi gb$ -closed set for every  $x \in X$ . Let  $x, y \in X$  with  $x \neq y$ . Now  $x \neq y \Rightarrow y \in X - \{x\}$ . Hence  $X - \{x\}$  is  $f\pi gb$ -open set containing  $y$  but not  $x$ . Similarly  $X - \{y\}$  is a  $f\pi gb$ -open set containing  $x$  but not  $y$ . Therefore  $X$  is a  $f\pi gb-T_1$  space.

**Theorem 5.5:** If  $f : X \rightarrow Y$  is a injection,  $f\pi gb$ -continuous map and  $Y$  is a  $T_1$ -space then  $X$  is  $f\pi gb-T_1$ -space.

**Proof :** Let  $x_1, x_2$  be any two distinct points of  $X$ . Since  $f$  is injective there exists  $y_1, y_2$  such that  $f(x_1) = y_1$  and  $f(x_2) = y_2$ . Since  $Y$  is a  $T_1$ -space, there exists open sets  $G$  and  $H$  in  $Y$  such that  $y_1 \in G, y_2 \notin G$  and  $y_1 \notin H, y_2 \in H$ . That is,  $x_1 \in f^{-1}(G), x_1 \notin f^{-1}(H)$  and  $x_2 \in f^{-1}(H), x_2 \notin f^{-1}(G)$ . Since  $f$  is  $f\pi gb$ -continuous  $f^{-1}(G)$  and  $f^{-1}(H)$  are  $f\pi gb$ -open sets in  $X$ . Thus, for any two distinct points  $x_1, x_2$  of  $X$ , there exists  $f\pi gb$ -open sets  $f^{-1}(G)$  and  $f^{-1}(H)$  such that  $x_1 \in f^{-1}(G), x_2 \notin f^{-1}(G)$  and  $x_1 \notin f^{-1}(H), x_2 \in f^{-1}(H)$ . Therefore  $X$  is  $f\pi gb-T_1$ -space.

**Theorem 5.6:** If  $f : X \rightarrow Y$  is a bijection,  $f\pi gb$ -irresolute map and  $Y$  is  $f\pi gb-T_1$  space, then  $X$  is also a  $f\pi gb-T_1$ -space.

**Proof :** Let  $x_1, x_2$  be any two distinct points of  $X$ . Since  $f$  is injective there exists  $y_1, y_2$  such that  $f(x_1) = y_1$  and  $f(x_2) = y_2$ . Since  $Y$  is a  $f\pi gb-T_1$ -space, there exists  $f\pi gb$ -open sets  $G$  and  $H$  in  $Y$  such that  $y_1 \in G, y_2 \notin G$  and  $y_1 \notin H, y_2 \in H$ . That is,  $x_1 \in f^{-1}(G), x_1 \notin f^{-1}(H)$  and  $x_2 \in f^{-1}(H), x_2 \notin f^{-1}(G)$ . Since  $f$  is  $f\pi gb$ -irresolute,  $f^{-1}(G)$  and  $f^{-1}(H)$  are  $f\pi gb$ -open sets in  $X$ . Thus, for any two distinct points  $x_1, x_2$  of  $X$ , there exists  $f\pi gb$ -open sets  $f^{-1}(G)$  and  $f^{-1}(H)$  such that  $x_1 \in f^{-1}(G), x_2 \notin f^{-1}(G)$  and  $x_1 \notin f^{-1}(H), x_2 \in f^{-1}(H)$ . Therefore  $X$  is  $f\pi gb-T_1$ -space.

**Theorem 5.7:** Every  $f\pi gb-T_2$ -space is  $f\pi gb-T_1$ -space

**Proof :** Straight forward.

**Remark 5.8:** This example shows that the converse of the above need not be true.

Let  $X = \{1,2,3\}, \tau = \{ \phi, \{1\}, \{2\}, \{1,2\}, X \}, \tau_1 = \{ \phi, \{1\}, \{2\}, \{1,2\}, \{1,3\}, \{2,3\}, X \}$  is  $f\pi gb-T_1$ -space but not  $f\pi gb-T_2$ -space

**Theorem 5.9:** If  $f : X \rightarrow Y$  is a injection,  $f\pi gb$ -continuous map and  $Y$  is a  $T_2$ -space then  $X$  is  $f\pi gb-T_2$ -space.

**Proof :** Let  $x_1, x_2$  be any two distinct points of  $X$ . Since  $f$  is injective there exists  $y_1, y_2$  in  $Y$  such that  $f(x_1) = y_1$  and  $f(x_2) = y_2$ . Since  $Y$  is a  $T_2$ -space, there exists disjoint open sets  $G$  and  $H$  in  $Y$  such that  $y_1 \in G$ , and  $y_2 \in H$ . That is,  $x_1 \in f^{-1}(G)$  and  $x_2 \in f^{-1}(H)$ . Since  $f$  is  $f\pi gb$ -continuous  $f^{-1}(G)$  and  $f^{-1}(H)$  are  $f\pi gb$ -open sets in  $X$ . Also  $f^{-1}(G) \cap f^{-1}(H) = f^{-1}(G \cap H) = \phi$ . Thus, for any two distinct points  $x_1, x_2$  of  $X$ , there exists  $f\pi gb$ -open sets  $f^{-1}(G)$  and  $f^{-1}(H)$  such that  $x_1 \in f^{-1}(G)$  and  $x_2 \in f^{-1}(H)$ . Therefore  $X$  is  $f\pi gb-T_2$ -space.

**Theorem 5.10:** If  $f : X \rightarrow Y$  is a injective,  $f\pi gb$ -irresolute map and  $Y$  is  $f\pi gb-T_2$ -space, then  $X$  is also a  $f\pi gb-T_2$ -space.

**Proof :** Let  $x_1, x_2$  be any two distinct points of  $X$ . Since  $f$  is injective there exists  $y_1, y_2$  with  $y_1 \neq y_2$  in  $Y$  such that  $f(x_1) = y_1$  and  $f(x_2) = y_2$ . Since  $Y$  is a  $f\pi gb-T_2$  space, there exists disjoint  $f\pi gb$ -open sets  $G$  and  $H$  in  $Y$  such that  $y_1 \in G$  and  $y_2 \in H$ . That is,  $x_1 \in f^{-1}(G)$ , and  $x_2 \in f^{-1}(H)$ . Since  $f$  is  $f\pi gb$ -irresolute,  $f^{-1}(G)$  and  $f^{-1}(H)$  are disjoint  $f\pi gb$ -open sets in  $X$ . Thus, for any two distinct points  $x_1, x_2$  of  $X$ , there exists disjoint  $f\pi gb$ -open sets  $f^{-1}(G)$  and  $f^{-1}(H)$  such that  $x_1 \in f^{-1}(G)$  and  $x_2 \in f^{-1}(H)$ . Therefore  $X$  is  $f\pi gb-T_2$ -space.

**Theorem 5.11:** For any topological space, the following statements are equivalent.

- (i)  $X$  is a  $f\pi gb-T_2$ -space
- (ii) For each  $x \neq y$ , there exists a  $f\pi gb$ -open set  $G$  such that  $x \in G$  and  $y \notin f\pi gb-cl(G)$
- (iii) For each  $x \in X, \{x\} = \cap \{ f\pi gb-cl(G) / G \text{ is a } f\pi gb\text{-open sets in } X \text{ and } x \in G \}$ .

### Geethapadmini and Janaki

**Proof :** (i)  $\Rightarrow$  (ii) . Assume  $X$  is a  $f\pi gb-T_2$ -space. Let  $x, y \in X$  with  $x \neq y$ . Then there exists disjoint  $f\pi gb$ -open sets  $G$  and  $H$  such that  $x \in G$  and  $y \in H$ . Then  $X - V$  is  $f\pi gb$ -closed set. Since  $G$  and  $H$  are disjoint,  $G \subset X - H$ . Therefore  $f\pi gb-cl(G) \subset f\pi gb-cl(X - H)$ .  $y \notin X - H \Rightarrow y \notin f\pi gb-cl(X - H) \Rightarrow y \notin f\pi gb-cl(G)$ .

(ii)  $\Rightarrow$  (iii) let us assume that for each  $x \neq y$ , there exists a  $f\pi gb$ -open set  $G$  such that  $x \in G$  and  $y \notin f\pi gb-cl(G)$ . Therefore  $y \notin \{f\pi gb-cl(G) / G \text{ is a } f\pi gb\text{-open sets in } X \text{ and } x \in G\} = \{x\}$ .

(iii) $\Rightarrow$ (i) Let  $x, y \in X$  and  $x \neq y$ . By hypothesis there exists a  $f\pi gb$ -open set  $G$  such that  $x \in G$  and  $y \notin f\pi gb-cl(G)$ . This implies there exists a  $f\pi gb$ -closed set  $H$  such that  $y \notin H$ . Therefore,  $y \in X - H$  and  $X - H$  is  $f\pi gb$ -open set. Thus there exists two disjoint  $f\pi gb$ -open sets  $G$  and  $X - H$  such that  $x \in G$  and  $y \in X - H$ . Hence  $X$  is a  $f\pi gb-T_2$ -space.

#### **$f\pi gb$ -Connectedness**

**Definition 6.1:** Let  $(X, \tau, \tau_f)$  be a fine topological space. Two non-empty subsets  $A$  and  $B$  are said to be  $f\pi gb$ -separated if and only if  $[A \cap f\pi gb-cl(B)] \cup [B \cap f\pi gb-cl(A)] = \phi$ .

**Definition 6.2:** A topological space  $(X, \tau, \tau_f)$  is said to be  $f\pi gb$ -space if every  $f\pi gb$ -closed set is fine-closed in  $X$ .

**Definition 6.3 :** The space  $X = A \cup B$  such that  $A$  and  $B$  are non-empty  $f\pi gb$ -separated sets then  $A, B$  form a  $f\pi gb$ -separation of  $X$ .

**Definition 6.4:** A fine-topological space  $(X, \tau, \tau_f)$  is said to be  $f\pi gb$ -connected if there does not exist a separation of  $X$ . If  $X$  is not  $f\pi gb$ -connected then it is  $f\pi gb$ -disconnected.

**Theorem 6.5:** A fine-topological space  $(X, \tau, \tau_f)$  is  $f\pi gb$ -disconnected if there exists a non-empty proper subset of  $X$  which is both  $f\pi gb$ -open and  $f\pi gb$ -closed.

**Proof :** Let  $A$  be a non-empty proper subset of  $X$  which is both  $f\pi gb$ -open and  $f\pi gb$ -closed.

Then clearly  $A^c$  is a non-empty proper subset of  $X$  which is both  $f\pi gb$ -open and  $f\pi gb$ -closed.

Thus  $A \cap A^c = \phi$  and also  $X = A \cup A^c$ . Thus  $X$  is the union of two non-empty  $f\pi gb$ -open sets. Hence  $X$  is  $f\pi gb$ -disconnected.

**Theorem 6.5:** A fine-topological space  $(X, \tau, \tau_f)$  is  $f\pi gb$ -disconnected if and only if  $X$  is the union of two non-empty disjoint  $f\pi gb$ -open sets.

**Proof :** Let  $(X, \tau, \tau_f)$  be  $f\pi gb$ -disconnected. Then, there exists a non-empty proper subset  $A$  of  $X$  that is both  $f\pi gb$ -open and  $f\pi gb$ -closed. Thus  $X = A \cup A^c$  and  $A \cap A^c = \phi$ . This shows that  $X$  is the union of two non-empty disjoint  $f\pi gb$ -open sets.

Conversely, let  $X$  be the union of two disjoint non-empty  $f\pi gb$ -open sets  $A$  and  $B$ . Then  $B^c = A$ . Now  $B$  is  $f\pi gb$ -open,  $A$  is  $f\pi gb$ -closed. Since  $B$  is non-empty,  $A$  is non-empty proper subset of  $X$  that is both  $f\pi gb$ -open and  $f\pi gb$ -closed. Thus  $X$  is  $f\pi gb$ -disconnected.

**Theorem 6.6:** If  $f : (X, \tau, \tau_f) \rightarrow (Y, \sigma, \sigma_f)$  is  $f\pi gb$ -continuous, surjection and  $(X, \tau, \tau_f)$  is  $f\pi gb$ -connected  $(Y, \sigma, \sigma_f)$  is fine-connected.

**Proof :** Suppose that  $Y$  is not fine-connected. Let  $Y = A \cup B$ , where  $A$  and  $B$  are disjoint non-empty open sets in  $Y$ . Since  $f$  is  $f\pi gb$ -continuous and surjection,  $X = f^{-1}(A) \cup f^{-1}(B)$  where  $f^{-1}(A)$  and  $f^{-1}(B)$  are disjoint non-empty  $f\pi gb$ -open sets in  $X$ . This is a contradiction to the fact that  $X$  is  $f\pi gb$ -connected. Hence  $Y$  is fine-connected.

**Theorem 6.7:** If  $f : (X, \tau, \tau_f) \rightarrow (Y, \sigma, \sigma_f)$  is  $f\pi gb$ -irresolute, surjection and  $(X, \tau, \tau_f)$  is  $f\pi gb$ -connected then  $(Y, \sigma, \sigma_f)$  is  $f\pi gb$ -connected.

**Proof :** Suppose that  $Y$  is not  $f\pi gb$ -connected. Let  $Y = A \cup B$ , where  $A$  and  $B$  are disjoint non-empty  $f\pi gb$ -open sets in  $Y$ . Since  $f$  is  $f\pi gb$ -irresolute and surjection,  $X = f^{-1}(A) \cup f^{-1}(B)$  where  $f^{-1}(A)$  and  $f^{-1}(B)$  are disjoint non-empty  $f\pi gb$ -open sets in  $X$ . This is a contradiction to the fact that  $X$  is  $f\pi gb$ -connected. Hence  $Y$  is  $f\pi gb$ -connected.

### Geethapadmini and Janaki

**Theorem 6.8:** For a fine-topological space  $(X, \tau, \tau_f)$ , the following conditions are equivalent:

- (i)  $(X, \tau, \tau_f)$  is  $f\pi gb$ -connected.
- (ii) The only subsets of  $(X, \tau, \tau_f)$  which are both  $f\pi gb$ -open and  $f\pi gb$ -closed are  $\phi$  and  $X$ .

**Proof :** (i)  $\Rightarrow$  (ii) : Let  $G$  be a  $f\pi gb$ -open and  $f\pi gb$ -closed subset of  $X$ . Then  $G^c$  is both  $f\pi gb$ -open and  $f\pi gb$ -closed in  $X$ . Since  $X$  is a disjoint union of  $f\pi gb$ -open sets  $G$  and  $G^c$ , one of these must be empty. That is  $U = \phi$  or  $U = X$ .

(ii)  $\Rightarrow$  (i) : Suppose that  $X$  is  $f\pi gb$ -disconnected. Then there exists a proper subset of  $X$ , which are both  $f\pi gb$ -open and  $f\pi gb$ -closed, which is a contradiction. Hence,  $X$  is  $f\pi gb$ -connected.

## CONCLUSION

Many forms of fine-closed sets are introduced over the years. The authors have introduced a new form of closed set called  $f\pi gb$ -closed set in fine-topological spaces. This notion of closed sets will be used for further research investigations focusing on applications.

## ABSTRACT

The concept of compactness in Pythagorean fuzzy topological spaces extends the traditional idea of closed sets. In this context, a Generalized Pythagorean fuzzy compact space has been introduced, and its various properties have been explored. Additionally, this framework can be applied in real-world scenarios, such as analysing preferred cities in Southern India by using real-time temperature data. The analysis involves determining membership and non-membership degrees based on temperature preferences, which can help identify the most suitable cities.

**Keywords:** GPF closed sets, GPF compact space, Pythagorean fuzzification, Pythagorean Defuzzification

## INTRODUCTION

The concept of fuzzy sets, first introduced by L.A. Zadeh[19], has significantly influenced various branches of mathematics. Fuzzy sets have found applications in fields like information theory and control systems. The notion of fuzzy topological spaces was pioneered by C.L. Chang[4], and since then, many classical topological concepts, such as open and closed sets, continuity, and compactness, have been extended to the fuzzy domain. Atanassov[1] later introduced intuitionistic fuzzy sets, while G. Balasubramanian and P. Sundaram[2] developed the idea of generalized fuzzy closed sets. In 1997, Coker[5] provided an introduction to intuitionistic fuzzy topological spaces. Yager[18] proposed Pythagorean fuzzy sets as another variation of non-standard fuzzy sets. In 2010, R. Dhavaseelan, E. Roja, and M.K. Uma[6] introduced generalized intuitionistic fuzzy closed sets and continuous functions. Later, Murat Olgun,

### Rameshkumar and Maragathavalli

Mehmet Unver, and Seyhmus Yardimici[11] contributed to the development of Pythagorean fuzzy topological spaces. In 2020, Taha Yasin Ozturk and Adem Yolcu[15] further expanded the field by defining Pythagorean fuzzy interior, closure, boundary, as well as introducing fuzzy open and closed functions, and studying Pythagorean fuzzy homeomorphisms. The concepts of Generalized Pythagorean fuzzy closed sets and Generalized Pythagorean fuzzy continuous functions were introduced by T. Rameshkumar and S. Maragathavalli [13] in 2022. Pythagorean fuzzy  $G^*$  compact space was defined and its properties were investigated by N.B. Gnanachristy and G.K. Revathi[6] in 2023. In this paper, an application of the Generalized Pythagorean fuzzy compact space is anticipated for examining preferred cities in Southern India using real time data by considering the temperatures of the cities. An algorithm is proposed and explained in detail for identifying preferable places to lead a better life through a Generalized Pythagorean fuzzy compact space.

## PRELIMINARIES

**Definition 2.1:** Let  $X$  be the non empty universe of discourse. A Pythagorean fuzzy set (PFS)  $P$  in  $X$  is given by  $P = \{(x, \mu_P(x), \nu_P(x)) : x \in X\}$  where the functions  $\mu_P(x) \in [0, 1]$  and  $\nu_P(x) \in [0, 1]$  denote the degree of membership and degree of non membership of each element  $x \in X$  to the set  $P$ , respectively, and  $0 \leq \mu_P^2(x) + \nu_P^2(x) \leq 1$  for each  $x \in X$ . The degree of indeterminacy  $I_P = \sqrt{1 - (\mu_P^2(x) + \nu_P^2(x))}$  for each  $x \in X$ .

**Definition 2.2:** A Pythagorean fuzzy topology (PFT for short) on a nonempty set  $X$  is a family  $\tau$  of PFSs in  $X$  satisfying the following axioms:

- (i)  $0_P, 1_P \in \tau$
- (ii)  $G_1 \cap G_2 \in \tau$  for any  $G_1, G_2 \in \tau$
- (iii)  $\bigcup G_i \in \tau$  for any arbitrary family  $\{G_i : i \in J\} \subseteq \tau$

In this case, the pair  $(X, \tau)$  is called a Pythagorean fuzzy topological space (PFTS in short). Each member of  $\tau$  is called Pythagorean fuzzy open subset. The complement of Pythagorean fuzzy open subset is called Pythagorean fuzzy closed subset.

**Definition 2.3** Let  $A = \langle \mu_A(x), \nu_A(x) \rangle$  and  $B = \langle \mu_B(x), \nu_B(x) \rangle$  be two Pythagorean fuzzy subsets of a set  $X$ . Then,

- (i) The complement of  $A$  is defined by  $A^c = \langle \nu_A(x), \mu_A(x) \rangle$
- (ii) The intersection of  $A$  and  $B$  is defined by  $A \cap B = \langle \{\mu_A, \mu_B\}, \max\{\nu_A, \nu_B\} \rangle$
- (iii) The union of  $A$  and  $B$  is defined by  $A \cup B = \langle \{\mu_A, \mu_B\}, \min\{\nu_A, \nu_B\} \rangle$ .

**Definition 2.4** Let  $(X, \tau)_P$  be an Pythagorean Fuzzy topological space and  $P = \{(x, \mu_P(x), \nu_P(x)) : x \in X\}$  be a Pythagorean fuzzy set over  $X$ . Then the Pythagorean fuzzy interior, Pythagorean fuzzy closure and Pythagorean fuzzy boundary of  $P$  are defined by;

1.  $int(P) = \bigcup \{G : G \text{ is a PFOS in } X \text{ and } G \subseteq P\}$
2.  $cl(P) = \bigcap \{K : K \text{ is a PFCS in } X \text{ and } P \subseteq K\}$
3.  $Fr(P) = cl(P) \cap cl(P^c)$

**Definition 2.5** Let  $(X, \tau)_P$  be a Pythagorean fuzzy topological space. A Pythagorean fuzzy set  $A$  in  $(X, \tau)_P$  is said to be generalized Pythagorean fuzzy closed (shortly GPFC) if  $PFcl(A) \subseteq P$  whenever  $A \subseteq P$  and  $P$  is PFO. The complement of GPFC is GPFO

**Definition 2.6** Let  $(X, \tau)_P$  be a Pythagorean Fuzzy topological space. Let  $A$  be a PFS in  $X$ . Then Generalized Pythagorean fuzzy closure and Generalized Pythagorean Fuzzy interior of  $A$  are defined by

- (i)  $GPFcl(A) = \bigcap \{G : G \text{ is GPF closed set in } X \text{ and } A \subseteq G\}$
- (ii)  $GPFint(A) = \bigcup \{G : G \text{ is GPF open set in } X \text{ and } A \supseteq G\}$

### Rameshkumar and Maragathavalli

**Definition 2.7** Let  $(X, \tau)_P$  be any Pythagorean fuzzy topological space.  $(X, \tau)_P$  is said to be Pythagorean fuzzy disconnected if there exists Pythagorean fuzzy open and Pythagorean fuzzy closed set  $G$  such that  $G = 0_X$  and  $G = 1_X$ .  $(X, \tau)_P$  is said to be a Pythagorean fuzzy connected space if it is not Pythagorean fuzzy disconnected.

**Definition 2.8** Let  $(X, \tau)_P$  be any Pythagorean fuzzy topological space.  $(X, \tau)_P$  is said to be Generalized Pythagorean fuzzy disconnected if there exists a generalized Pythagorean fuzzy open and generalized Pythagorean fuzzy closed set  $G$  such that  $G = 0_X$  and  $G = 1_X$ .  $(X, \tau)_P$  is said to be a generalized Pythagorean fuzzy connected space if it is not generalized Pythagorean fuzzy disconnected.

**Definition 2.9** Let  $(X, \tau)_P$  be a Pythagorean fuzzy topological space. If a family  $\{(x, \mu_{G_i}, \nu_{G_i}) : i \in J\}$  of generalized Pythagorean fuzzy open sets in  $(X, \tau)_P$  satisfies the condition  $\bigcup \{(x, \mu_{G_i}, \nu_{G_i})\} = 1_P$ , then it is called a generalized Pythagorean fuzzy open cover of  $(X, \tau)_P$ . A finite subfamily of a generalized Pythagorean fuzzy open cover  $\{(x, \mu_{G_i}, \nu_{G_i}) : i \in J\}$  of  $(X, \tau)_P$  which is also a generalized Pythagorean fuzzy open cover of  $(X, \tau)_P$  is called a finite subcover.

**Definition 2.10** A Pythagorean fuzzy topological space  $(X, \tau)_P$  is called generalized Pythagorean fuzzy compact space if every generalized Pythagorean fuzzy open cover of  $(X, \tau)_P$  has a finite subcover.

#### Identification of Preferred Place to Lead a Better Life Through Generalized Pythagorean Fuzzy Compact Space

In this section, we describe an application of a generalized Pythagorean fuzzy compact space to identify preferred place to live in Southern India using the temperature. Temperature is a measure of how warm or cold an object or environment is. It plays a crucial role in determining the climate of a region; lower temperatures generally indicate a colder climate, while higher temperatures suggest a warmer one. Daily life is heavily influenced by temperature, impacting decisions on clothing, activities, and more. Accurate temperature readings are essential for planning and comfort. Analysing the temperatures of various cities, data from 2011 to 2023 was examined using the Pythagorean fuzzy trapezoidal membership function to assign values of membership and non-membership. This method led to the identification of Generalized Pythagorean fuzzy closed sets. From this data, cover and subcover were derived, contributing to the formulation of a Generalized Pythagorean fuzzy compact.

#### ALGORITHM

**Step 1:** The temperature of the four cities Chennai, Bangalore, Hyderabad and Trivandrum has been collected from the year 2011 to 2023 (from January to December)

**Step 2:** PFSs were framed by using Pythagorean fuzzy trapezoidal membership function for each year by assigning  $\langle \mu_{PF(x)}, \nu_{PF(x)} \rangle$  to the corresponding temperature value.

**Step 3:** The PFS obtained satisfies the condition that is provided in the definition of Generalized Pythagorean fuzzy closed sets and the graph of PFSs are using MATLAB (Figure 3.3)

**Step 4:** Generalized Pythagorean fuzzy closed cover of the PFSs obtained.

**Step 5:** Generalized Pythagorean Fuzzy compact space is obtained.

**Step 6:** Using the mean of maxima method preference is given for the value obtained  $p_{MOM} = \frac{\sum_{j=1}^M P_j^m}{2M} + \frac{\sum_{j=1}^K P_j^k}{2K}$ , where  $P^m = \{P \mid \mu_{P^m} = \max_i^M \mu_{P_i}\}$  and  $P^k = \{P \mid \nu_{P^k} = \max_i^K \nu_{P_i}\}$ .

**Step 7:** Preferences have been assigned based on the values obtained through this decision-making method.

#### DETAILED STUDY OF THE PROPOSED ALGORITHM TO FIND AN OPTIMAL CITY

**Step 1:** The data were collected from online sources. Temperature data for the four major cities of Chennai, Bangalore, Hyderabad and Trivandrum were collected between 2011 and 2023 (from January to December). The average of the 12 months was then computed for each year. Average Temperatures in Chennai, Bangalore, Hyderabad and Trivandrum were determined. In Table 3.1, Average Temperature of Cities of Southern India were listed from 2011 to 2023.

**Step 2:** PFSs were obtained using the Pythagorean fuzzy trapezoidal function by assigning  $p_1 = 78, p_2 = 81, p_3 = 83, p_4 = 85.5$

**Rameshkumar and Maragathavalli**

$$\mu_{PF(x)} = \begin{cases} 0, & x \leq p_1 \\ \sqrt{\frac{x-p_1}{p_2-p_1}}, & p_1 < x \leq p_2 \\ \frac{1, \quad p_2 \leq x \leq p_3}{0, \quad x \geq p_4}, & \sqrt{\frac{p_4-x}{p_4-p_3}}, \quad p_3 \leq x \leq p_4 \end{cases}$$

$$\nu_{PF(x)} = \begin{cases} 1, & x \leq p_1 \\ \sqrt{1 - \frac{x-p_1}{p_2-p_1}}, & p_1 < x \leq p_2 \\ \frac{0, \quad p_2 \leq x \leq p_3}{1, \quad x \geq p_4}, & \sqrt{1 - \frac{p_4-x}{p_4-p_3}}, \quad p_3 \leq x \leq p_4 \end{cases}$$

where  $\mu_{PF(x)}$  the Membership Value and  $\nu_{PF(x)}$  the Non-Membership value.

In table 6.2, columns 1, 4, 7 and 10 represent the average temperature of the cities Chennai, Bangalore, Hyderabad and Trivandrum respectively. Columns 2, 3, 5, 6, 8, 9, 11 and 12 show the membership and non-membership values for Chennai, Bangalore, Hyderabad and Trivandrum respectively. A Pythagorean fuzzy set graph was created using MATLAB, and each point on the graph represents the PFS and the related membership and non-membership values of the temperature.

**Step 3:** In Chennai city, it is possible to get GPFCS between the PFSs (0.801314, 0.598244) and (0.905702, 0.423913) and also between the PFSs (0.478572, 0.878047) and (0.675342, 0.737504). Also, it is possible to obtain GPFCS in Bangalore between the PFSs (0.801314, 0.598244) and (0.905702, 0.423913). Similarly, it is possible to obtain GPFCS in Trivandrum between the PFSs (0.5582711, 0.8296586) and (0.2503331, 0.9681598) and also between the PFSs (0.2503331, 0.9681598) and (0.5205766, 0.853815).

**Step 4 :** Generalized Pythagorean fuzzy cover is obtained for the cities Chennai, Bangalore and Trivandrum. However Generalized Pythagorean fuzzy cover is not obtained for Hyderabad.

**Step 5:** Therefore, Generalized Pythagorean fuzzy compact space is obtained except for Hyderabad city because Generalized Pythagorean fuzzy cover is not obtained for Hyderabad.

**Step 6:** Mean of maxima method for PFSs fuzzy-rule-based systems use fuzzification, inference, and composition processes to evaluate linguistic if, then rules. They produce fuzzy results that must be converted into crisp outputs. Defuzzification was used to transform the fuzzy findings into crisp findings. Defuzzification is the process of transforming fuzzy output into a single crisp value for a given fuzzy set. Many defuzzification techniques are used in decision-making. This method is suitable and effective for this real time data. To provide preferences for the city based on the temperature mean of maxima method, a PFS was defined and used. The mean of maxima for PFS is given by

$$p_{MOM} = \frac{\sum_{j=1}^M p_j^m}{2M} + \frac{\sum_{j=1}^K p_j^k}{2K},$$

where  $P^m = \{P \mid \mu_{p^m} = \max_i^M \mu_{p_i}\}$  and  $P^k = \{P \mid \nu_{p^k} = \max_i^K \nu_{p_i}\}$ .

**Step 7:** Based on the above formula,  $p_{MOM}$  is calculated for various cities; the maximum in Membership value and minimum non-membership value are taken. The average was used for all the values, and we obtained 84.54266. Similarly, for other cities, the preferences have been fixed (Table 6.3). It was concluded that Chennai is the preferred place to live using the temperature parameter for all seasons. The interpretation of preferences can also be observed by using the Mamdani fuzzy inference system (FIS).

## CONCLUSION

From these results, it is recognized that many factors are related to temperature, even though urbanization has an impact on temperature. Another significant reason for this increase in temperature is pollution. Chakraborty [3] concluded that urbanization and pollution are the reasons for the increase in temperature. The Air Quality Index (AQI) in Hyderabad has become poorer. This causes pollution, leading to an increase in temperature, Compared with the data and sources available regarding Hyderabad’s temperature, it was identified that Hyderabad the least

### Rameshkumar and Maragathavalli

preferred place to live among the cities, and temperature is the basis factor needed for the place to live in. According to the sources average temperature to live in india is between  $77^{\circ}$  to  $86^{\circ}$ . From the inference of the value computed using  $P_{MOM}$ , Chennai is the first place to reside based on temperature and Hyderabad is the least favored (Table 3.4).

### ABSTRACT

In this presentation, we have extended the concept of bipolar intuitionistic fuzzy graphs to bipolar interval valued intuitionistic fuzzy line graphs. We have also proposed and verified some propositions and theorems related to BIVIFLG, which are originated from intuitionistic fuzzy line graphs(IFLG). Bipolar interval valued intuitionistic fuzzy line graphs can be applied in fields like social networks, decision- making, and optimization, where uncertainty and opposing values (like positive and negative sentiments) are prevalent.

**Keywords:** Fuzzy set, line graphs, intuitionistic fuzzy graph, intuitionistic fuzzy line graph, Bipolar interval valued intuitionistic fuzzy line graph.

## INTRODUCTION

After Euler was presented with the impression of Konigsberg bridge problem, Graph theory has become recognized in different academic fields like engineering, social science medical science and natural science. A few operations of graphs like line graph, Wiener index of graph, cluster and corona operations of graph, total graph, semi-total line and edge join of graphs have been valuable in graph theory and chemical graph theory to consider the properties of boiling point, heat of evaporation, surface tension, vapour pressure, total electron energy of polymers, partition coefficients, ultrasonic sound velocity and internal energy [1-4]. The degree sequence of a graph and algebraic structure of different graphs operations were determined and its result is to the join and corona products of any number of graphs [5]. These operations are not only in classical graphs, they are more useful in fuzzy and generalizations of fuzzy graphs. The real "World Problems are often full of uncertainty and impreciseness, Zadeh introduced fuzzy sets and membership degree [6]. Based on Zedeh's work, Kaufman introduced the notion of fuzzy relations [7]. Then Rosen feld [8] followed the Kaufman work and he introduced fuzzy graphs.

### Kokila and Manonmani

Later, Atanassov witnessed that many problems with uncertainty and imprecision were not handled by fuzzy sets [FS] [9]. Then considering this, he added the falsehood degree to membership degree and presented intuitionistic fuzzy sets [IFS] with relations and IFG which is a generalization of FS and their applications [9-11]. In 1993, Mordeson examined the idea of fuzzy line graphs (FLG) for the first time by proofing both sufficient and necessary conditions for FLG to be bijective homomorphism to its FG. And also some theorems and prepositions are developed [12]. In 2011 IVFG and its properties were discussed by Akram and Dudek [13]. After that, Akram innovated IVGFLG [14]. Afterward, Akram and Davvaz introduced ideas of intuitionistic fuzzy line graphs [IFLG] [15]. Moreover, IFLG and its properties are investigated in [16]. The notion of bipolar fuzzy graphs was introduced by Akram [17]. Bipolar Interval-Valued Intuitionistic Fuzzy Line Graphs (BIVIFLGs) are a mathematical structure that combines bipolar fuzzy sets, interval-valued fuzzy sets, and intuitionistic fuzzy sets to model complex relationships.

#### BASIC DEFINITIONS

**Definition 2.1** A fuzzy graph is a tuple  $G = (V, E, \mu, \nu)$ , where:

1.  $V$  is a set of vertices (nodes).
2.  $E$  is a set of edges.
3.  $\mu: V \times V \rightarrow [0, 1]$  is a fuzzy membership function, assigning a membership degree to each edge.
4.  $\nu: V \times V \rightarrow [0, 1]$  is a fuzzy non-membership function, assigning a non-membership degree to each edge.

**Definition 2.2** An Intuitionistic Fuzzy Line Graph (IFLG) is a tuple  $G = (V, E, \mu, \nu, \pi)$ , where:

1.  $V$  is a set of vertices (nodes).
2.  $E$  is a set of edges.
3.  $\mu: E \rightarrow [0, 1]$  is an intuitionistic fuzzy membership function, assigning a membership degree to each edge.
4.  $\nu: E \rightarrow [0, 1]$  is an intuitionistic fuzzy non-membership function, assigning a non-membership degree to each edge.
5.  $\pi: E \rightarrow [0, 1]$  is an intuitionistic fuzzy hesitation degree function.

#### Intuitionistic Fuzzy Membership Function:

$\mu(e)$  represents the degree of membership of edge  $e$ , satisfying:  $0 \leq \mu(e) \leq 1$

#### Intuitionistic Fuzzy Non-Membership Function:

$\nu(e)$  represents the degree of non-membership of edge  $e$ , satisfying:  $0 \leq \nu(e) \leq 1$

#### Intuitionistic Fuzzy Hesitation Degree Function:

$\pi(e)$  represents the degree of hesitation or uncertainty, satisfying:

$$0 \leq \pi(e) \leq 1$$

#### Definition 2.3:

An Interval-Valued Intuitionistic Fuzzy Line Graph (IVIFLG) is a tuple  $G = (V, E, \mu, \nu, \pi)$ , where:

1.  $V$  is a set of vertices (nodes).
2.  $E$  is a set of edges.
3.  $\mu: E \rightarrow [0, 1] \times [0, 1]$  is an interval-valued intuitionistic fuzzy membership function.
4.  $\nu: E \rightarrow [0, 1] \times [0, 1]$  is an interval-valued intuitionistic fuzzy non-membership function.
5.  $\pi: E \rightarrow [0, 1] \times [0, 1]$  is an interval-valued intuitionistic fuzzy hesitation degree function.

#### BIPOLAR INTERVAL-VALUED INTUITIONISTIC FUZZY LINE GRAPH (BIVIFLG)

A Bipolar Interval-Valued Intuitionistic Fuzzy Line Graph (BIVIFLG) is a tuple  $G = (V, E, \mu^+, \mu^-, \nu^+, \nu^-, \pi^+, \pi^-)$  where

1.  $V$ : A set of vertices (nodes).
2.  $E$ : A set of edges.

**Kokila and Manonmani**

3.  $\mu$ : A bipolar interval-valued intuitionistic fuzzy membership function,  
 $\mu: E \rightarrow [0, 1] \times [0, 1]$ , assigning a positive membership degree to each edge.
  4.  $\mu$ : A bipolar interval-valued intuitionistic fuzzy membership function,  
 $\mu: E \rightarrow [-1, 0] \times [-1, 0]$ , assigning a negative membership degree to each edge.
  5.  $\nu$ : A bipolar interval-valued intuitionistic fuzzy non-membership function,  
 $\nu: E \rightarrow [0, 1] \times [0, 1]$ , assigning a positive non-membership degree to each edge.
  6.  $\nu$ : A bipolar interval-valued intuitionistic fuzzy non-membership function,  
 $\nu: E \rightarrow [-1, 0] \times [-1, 0]$ , assigning a negative non-membership degree to each edge.
- 
1.  $\pi$ : A bipolar interval-valued intuitionistic fuzzy hesitation degree function,  
 $\pi: E \rightarrow [0, 1] \times [0, 1]$ , assigning a positive hesitation degree to each edge.
  2.  $\pi$ : A bipolar interval-valued intuitionistic fuzzy hesitation degree function,  
 $\pi: E \rightarrow [-1, 0] \times [-1, 0]$ , assigning a negative hesitation degree to each edge.

**Properties:**

1. Reflexivity:  $\mu(v, v) = [1, 1]$  and  $\mu(v, v) = [-1, -1]$  for all  $v \in V$ .
2. Symmetry:  $\mu(u, v) = \mu(v, u)$  and  $\mu(u, v) = \mu(v, u)$  for all  $u, v \in V$ .
3. Transitivity:  $\mu(u, w) \geq \mu(u, v) \otimes \mu(v, w)$  and  $\mu(u, w) \leq \mu(u, v) \oplus \mu(v, w)$  for all  $u, v, w \in V$ .

**Additional Conditions:**

1.  $\mu(e) + \mu(e) = 0$  for all  $e \in E$ .
2.  $\nu(e) + \nu(e) = 0$  for all  $e \in E$ .
3.  $\pi(e) + \pi(e) = 0$  for all  $e \in E$ .

**Examples**

1.  $\mu_1(e)=[0.4, 0.6]$ ,  $\mu_1(e)=[-0.4,-0.6]$   
 $\mu_1(e) + \mu_1(e)=[0.4, 0.6] + [-0.4,-0.6] = 0$
2.  $\nu_1(e)=[0.2, 0.8]$ ,  $\nu_1(e) = [-0.2, -0.8]$   
 $\nu_1(e) + \nu_1(e)=[0.2, 0.8] + [-0.2, -0.8] = 0$
3.  $\pi_1(e)=[0.3,0.7]$ ,  $\pi_1(e) = [-0.3, -0.7]$   
 $\pi_1(e) + \pi_1(e)=[0.3,0.7] + [-0.3, -0.7]=0$

**Types of BIVIFLG:**

1. Simple BIVIFLG
2. Weighted BIVIFLG
3. Directed BIVIFLG
4. Undirected BIVIFLG

**Operations on Bipolar Interval-Valued Intuitionistic Fuzzy Line Graphs (BIVIFLG): Union**

1. Vertex Union:  $V(G_1 \cup G_2) = V(G_1) \cup V(G_2)$
2. Edge Union:  $E(G_1 \cup G_2) = E(G_1) \cup E(G_2)$
3. Membership Union:  $\mu(G_1 \cup G_2) = \max(\mu(G_1), \mu(G_2))$
4. Non-Membership Union:  $\nu(G_1 \cup G_2) = \min(\nu(G_1), \nu(G_2))$

**Proof:**

Let  $G_1 = (V_1, E_1, \mu_1^+, \mu_1^-, \nu_1^+, \nu_1^-, \pi_1^+, \pi_1^-)$  and  $G_2 = (V_2, E_2, \mu_2^+, \mu_2^-, \nu_2^+, \nu_2^-, \pi_2^+, \pi_2^-)$  be two BIVIFLGs. The union of  $G_1$  and  $G_2$  is defined as:  
 $G_1 \cup G_2 = (V_1 \cup V_2, E_1 \cup E_2, \mu^+, \mu^-, \nu^+, \nu^-, \pi^+, \pi^-)$   
 where:

### Kokila and Manonmani

$$\mu^*(e) = \max(\mu_1^*(e), \mu_2^*(e))$$

$$\mu_*(e) = \min(\mu_1^*(e), \mu_2^*(e))$$

$$v^*(e) = \min(v_1^*(e), v_2^*(e))$$

$$v_*(e) = \max(v_1^*(e), v_2^*(e))$$

$$\pi^*(e) = \max(\pi_1^*(e), \pi_2^*(e))$$

$$\pi_*(e) = \min(\pi_1^*(e), \pi_2^*(e))$$

#### Example:

Suppose we have two BIVIFLGs:

$$G_1 = \{ V_1, E_1, \mu_1^*(a, b), \mu_1^*(a, b), v_1^*(a, b), v_1^*(a, b), \pi_1^*(a, b), \pi_1^*(a, b) \}$$

Where,  $V_1 = \{a, b\}$

$$E_1 = \{(a, b)\}$$

$$\mu_1^*(a, b) = [0.6, 0.8]$$

$$\mu_1^*(a, b) = [-0.4, -0.2]$$

$$v_1^*(a, b) = [0.2, 0.4]$$

$$v_1^*(a, b) = [-0.8, -0.6]$$

$$\pi_1^*(a, b) = [0.4, 0.6]$$

$$\pi_1^*(a, b) = [-0.6, -0.4]$$

$$G_2 = \{ V_2, E_2, \mu_2^*(b, c), \mu_2^*(b, c), v_2^*(b, c), v_2^*(b, c), \pi_2^*(b, c), \pi_2^*(b, c) \}$$

Where  $V_2 = \{b, c\}$

$$E_2 = \{(b, c)\}$$

$$\mu_2^*(b, c) = [0.7, 0.9]$$

$$\mu_2^*(b, c) = [-0.3, -0.1]$$

$$v_2^*(b, c) = [0.1, 0.3]$$

$$v_2^*(b, c) = [-0.9, -0.7]$$

$$\pi_2^*(b, c) = [0.5, 0.7]$$

$$\pi_2^*(b, c) = [-0.7, -0.5]$$

$G_1 \cup G_2$ :

$$V = \{a, b, c\}$$

$$E = \{(a, b), (b, c)\}$$

$$\mu^*(a, b) = [0.6, 0.8]$$

$$\mu^*(a, b) = [-0.4, -0.2]$$

$$v^*(a, b) = [0.2, 0.4]$$

$$v^*(a, b) = [-0.8, -0.6]$$

$$\pi^*(a, b) = [0.4, 0.6]$$

$$\pi^*(a, b) = [-0.6, -0.4]$$

$$\mu^*(b, c) = [0.7, 0.9]$$

$$\mu^*(b, c) = [-0.3, -0.1]$$

$$v^*(b, c) = [0.1, 0.3]$$

$$v^*(b, c) = [-0.9, -0.7]$$

$$\pi^*(b, c) = [0.5, 0.7]$$

$$\pi^*(b, c) = [-0.7, -0.5]$$

**Kokila and Manonmani**

**Intersection**

1. Vertex Intersection:  $V(G1 \cap G2) = V(G1) \cap V(G2)$
2. Edge Intersection:  $E(G1 \cap G2) = E(G1) \cap E(G2)$
3. Membership Intersection:  $\mu^-(G1 \cap G2) = \min(\mu^-(G1), \mu^-(G2))$
4. Non-Membership Intersection:  $\nu^-(G1 \cap G2) = \max(\nu^-(G1), \nu^-(G2))$

**Proof**

Let  $G1 = (V1, E1, \mu1, \mu1, \nu1, \nu1, \pi1, \pi1)$  and  $G2 = (V2, E2, \mu2, \mu2, \nu2, \nu2, \pi2, \pi2)$  be two BIVIFLGs.

The intersection of  $G1$  and  $G2$  is defined as:

$$G1 \cap G2 = (V1 \cap V2, E1 \cap E2, \mu^-, \mu^-, \nu^-, \nu^-, \pi^-, \pi^-)$$

where:

$$\mu^-(e) = \min(\mu1^-(e), \mu2^-(e))$$

$$\mu^+(e) = \max(\mu1^+(e), \mu2^+(e))$$

$$\nu^-(e) = \max(\nu1^-(e), \nu2^-(e))$$

$$\nu^+(e) = \min(\nu1^+(e), \nu2^+(e))$$

$$\pi^-(e) = \min(\pi1^-(e), \pi2^-(e))$$

$$\pi^+(e) = \max(\pi1^+(e), \pi2^+(e)) \quad V1 \cap V2 = \{b\}$$

$$E1 \cap E2 = \emptyset$$

$$\mu1^- \cap \mu2^- = \min[\mu1^-(e), \mu2^-(e)] = [0.6, 0.8] \quad \mu1^+ \cap \mu2^+ = \max[\mu1^+(e), \mu2^+(e)] = [-0.3, -0.1] \quad \nu1^- \cap \nu2^- = \max[\nu1^-(e), \nu2^-(e)] = [0.2, 0.4]$$

$$\nu1^+ \cap \nu2^+ = \min[\nu1^+(e), \nu2^+(e)] = [-0.9, -0.7]$$

$$\pi1^- \cap \pi2^- = \min[\pi1^-(e), \pi2^-(e)] = [0.4, 0.6]$$

$$\pi1^+ \cap \pi2^+ = \max[\pi1^+(e), \pi2^+(e)] = [-0.6, -0.4]$$

**Cartesian Product**

1. Vertex Cartesian Product:  $V(G1 \times G2) = V(G1) \times V(G2)$
2. Edge Cartesian Product:  $E(G1 \times G2) = E(G1) \times E(G2)$
3. Membership Cartesian Product:  $\mu^-(G1 \times G2) = \mu^-(G1) \times \mu^-(G2)$
4. Non-Membership Cartesian Product:  $\nu^-(G1 \times G2) = \nu^-(G1) \times \nu^-(G2)$

**Projection**

1. Vertex Projection:  $V(G|V') = V(G) \cap V'$
2. Edge Projection:  $E(G|V') = E(G) \cap E(V')$
3. Membership Projection:  $\mu^-(G|V') = \mu^-(G) \cap \mu^-(V')$
4. Non-Membership Projection:  $\nu^-(G|V') = \nu^-(G) \cap \nu^-(V')$

**CONCLUSION**

In this paper, we introduced the concept of a bipolar interval valued intuitionistic fuzzy line graph and some properties are investigated. We can extend this concept to hyper graphs and in some more areas of graph theory.

### ABSTRACT

This study is an investigation of the oscillatory behavior of second - order neutral difference equation of the form

$$\Delta(r(l)(\Delta\varpi(l))^\gamma) + \sum_{j=1}^{n_2} \varphi_j(l)\Upsilon^{\beta_j}(v_j(l)) = 0, \quad l \geq l_0$$

we acquire new conditions for oscillation in the second order neutral difference equation. Some examples are discussed to illustrate the significance of the results.

**Keywords:** Oscillation, Neutral difference equation, Second order.

## INTRODUCTION

Consider the second order neutral difference equation of the following form

$$\Delta(r(l)(\Delta\varpi(l))^\gamma) + \sum_{j=1}^{n_2} \varphi_j(l)\Upsilon^{\beta_j}(v_j(l)) = 0, \quad l \geq l_0 \quad (1.1)$$

where

$$\varpi(l) = \Upsilon(l) + \sum_{i=1}^{n_1} \varrho_i(l)\Upsilon^{\alpha_i}(\zeta_i(l))$$

for all  $i = 1, \dots, n_1$  and  $j = 1, \dots, n_2$ ,  $\alpha_i, \gamma$  and  $\beta_j$  are quotients of odd positive integers.

We are assuming that :

H1)  $v_j(l) < l, \zeta_i(l) < l, \lim_{l \rightarrow \infty} v_j(l) = \infty, \lim_{l \rightarrow \infty} \zeta_i(l) = \infty$ .

H2)  $r(l), \varphi(l), \varrho(l)$  are sequence of positive real numbers,  
 $0 \leq \varphi_i(l)$  for all  $l \geq 0$  and  $\sum_{j=1}^{n_2} \varphi_j(l)$  is not identically zero.

H3)  $\lim_{l \rightarrow \infty} B(l) = \infty$ , where  $B(y) = \sum_{\tau=l_0}^{y-1} r^{-1}(\tau)$ .

**Masaniammal**

H4)  $0 < v_0(l) = \min_{j=1, \dots, n_2} \{v_j(l) : l \geq l^* > l_0\}$  and  $\Delta(v_0(l)) \geq v_0$   
for  $l \geq l^* > l_0, v_0 > 0$ .

**Preliminary Results**

Assume

$$R(l) = \left( 1 - \sum_{i=1}^n \alpha_i \varrho_i(l) - \frac{1}{\sigma(l)} \sum_{i=1}^n (1 - \alpha_i) \varrho_i(l) \right)$$

$$M_1(l) = \sum_{j=1}^{n_2} \varphi_j(l) R^{\beta_j}(v_j(l))$$

$$M_2(l) = \sum_{j=1}^{n_2} \varphi_j(l) R^{\beta_j}(v_j(l)) \sigma^{\beta_j-1}(v_j(l))$$

$$M_3(l) = \sum_{j=1}^{n_2} \varphi_j(l) R^{\beta_j}(v_j(l)) B^{\beta_j-1}(v_j(l))$$

$$M_4(l) = \sum_{j=1}^{n_2} \varphi_j(l) R^{\beta_j}(v_j(l)) B^{\beta_j}(v_j(l))$$

$$V(l) = \sum_{\zeta=l}^{\infty} \sum_{j=1}^{n_2} \varphi_j(\zeta) \Upsilon^{\beta_j}(v_j(\zeta))$$

**Lemma 2.1.** Assume that (H1)–(H4) hold for  $l \geq l_0$ . If  $\varpi$  satisfies  $\Upsilon$ , then a solution of (1.1) is eventually positive.  
 $\varpi(l) > 0, \Delta\varpi(l) > 0$  and  $\Delta(r(\Delta(\varpi)^\varpi)) \leq 0$  for  $l \geq l_1$ . (2.1)

**Lemma 2.2.** Assume that for  $l \geq l_0$ , (H1) – (H4) hold.  $\varpi$  satisfies if a solution  $\Upsilon$  of (1.1) is eventually positive.  
 $\varpi(l) \geq (r(l))^{1/\gamma} \Delta\varpi(l) B(l)$  for  $l \geq l_1$ .

and

$$\frac{\varpi(l)}{B(l)} \text{ is decreasing for } l \geq l_1.$$

**Lemma 2.3.** Assume that (H1) – (H4) hold for  $l \geq l_0$ .  $\varpi$  satisfies if a solution  $\Upsilon$  of (1.1) is eventually positive.  
 $\Upsilon(l) \geq R(l)\varpi(l)$  for  $l \geq l_1$  (2.2)

**Lemma 2.4.** Assume that (H1) – (H4) hold for  $l \geq l_0$ . There exist  $l_1 > l_0$  and  $\delta > 0$  such that, if a solution  $\Upsilon$  of (1.1) is eventually positive

$$0 < \varpi(l) \leq \delta B(l) \text{ and (2.3)}$$

$$B(l) V^{1/\gamma}(l) \leq \varpi(l) \text{ (2.4)}$$

holds for all  $l \geq l_1$ .

**Theorem 2.5.** Assume that there exists a constant  $\delta_1$ , quotient of odd positive integers, such that  $0 < \beta_j < \delta_1 < \gamma$ , and (H1) – (H4) hold for  $l \geq l_0$ . If

$$\sum_{\tau=0}^{\infty} M_4(\tau) = \infty \text{ (2.5)}$$

holds, then every solution of (1.1) is oscillatory.

**Theorem 2.6.** Assume that there exists a constant  $\delta_2$ , quotient of odd positive integers, such that  $\gamma < \delta_2 < \beta_j$ . Furthermore, assume that (H1) - (H5) hold for  $l \geq l_0$  and  $r(l)$  is non-decreasing. If

$$\sum_{\tau=0}^{\infty} \left[ \frac{1}{r(\tau)} \sum_{\zeta=\tau}^{\infty} M_1(\zeta) \right]^{1/\gamma} = \infty \text{ (2.6)}$$

holds, then every solution of (1.1) is oscillatory.

**Masaniammal**

**MAIN RESULTS**

**Theorem 3.1.** Assume that (H1) – (H4) hold for  $l \geq l_0$ . Every solution to (1.1) is oscillatory if

$$\sum_{\tau=0}^{\infty} M_1(\tau) = \infty(3.1)$$

holds.

**Proof:** Assume that  $\Upsilon$  is eventually positive. Afterwards,  $l_0 > 0$  exists such that  $\Upsilon(l) > 0$ ,  $\Upsilon(\zeta_i(l)) > 0$  and  $\Upsilon(v_j(l)) > 0$  for all  $l \geq l_0$  and for all  $i = 1, 2, \dots, n_1$  and  $j = 1, 2, \dots, n_2$ . Applying lemmas 2.1 and 2.3 for  $l \geq l_1 > l_0$ .

We determine that, for every  $l \geq l_1$ ,  $\varpi$  satisfies (2.1),  $\varpi$  is increasing, and  $\Upsilon(l) \geq R(l)\varpi(l)$ .

From (1.1), we have

$$\Delta(r(l)(\Delta\varpi(l))^\gamma) + \sum_{j=1}^{n_2} \varphi_j(l)R^{\beta_j}(v_j(l))\varpi^{\beta_j}(v_j(l)) \leq 0(3.2)$$

for  $l \geq l_1$ .

Using (2.1), we get the following results there exists  $l_2 > l_1, \varpi(l) \geq d$  for  $l \geq l_2$ , and  $\lim_{l \rightarrow \infty} (r(l)(\Delta w(l)^\gamma))$ . Summing (3.2) from  $l_2$  to  $l - 1$ , for a suitable constant  $d$ , we have

$$d \sum_{l_2}^{l-1} \sum_{j=1}^{n_2} \varphi_j(\tau)R^{\beta_j}(v_j(\tau)) \leq -[r(l)(\Delta\varpi(l))^\gamma - r(l_2)(\Delta\varpi(l_2))^\gamma] < \infty \text{ as } l \rightarrow \infty$$

which is absurd to (3.1). That completes the proof.

**Theorem 3.2.** Assume that for  $l \geq l_0$  and  $\beta_j > 1$ , (H1)–(H4) hold. Every solution to (1.1) is oscillatory if

$$\sum_{\tau=0}^{\infty} M_2(\tau) = \infty(3.3)$$

holds.

**Proof:** Following the procedure used in theorem 3.1, we obtain (3.2).

Since  $\varpi(l)$  is positive and increasing,  $\sigma$  is positive and decreasing to zero, there exists  $l_0 \geq l_1$  such that  $\varpi(l) > \sigma(l)$  for  $l \geq l_1$ (3.4)

Applying (3.4) in (3.2) we have

$$\Delta(r(l)(\Delta\varpi(l))^\gamma) + \sum_{j=1}^{n_2} \varphi_j(l)R^{\beta_j}(v_j(l))\sigma^{\beta_j-1}(v_j(l))\varpi(v_j(l)) \leq 0(3.5)$$

The remaining portion of the proof has been omitted because it parallels Theorem 3.1.

**Theorem 3.3.** Suppose that (H1)–(H4) hold for  $l \geq l_0$  and  $0 < \beta_j < 1$ . Every solution of (1.1) is oscillatory if

$$\sum_{\tau=0}^{\infty} M_3(\tau) = \infty(3.6)$$

holds.

**Proof:** From following the procedure explained in the theorem 3.1 proof, it follows to (3.2).

Thus, (3.2) can be expressed as

$$\Delta(r(l)(\Delta\varpi(l))^\gamma) + \sum_{j=1}^{n_2} \varphi_j(l)R^{\beta_j}(v_j(l))B^{\beta_j-1}(v_j(l)) \frac{\varpi^{\beta_j-1}(v_j(l))}{B^{\beta_j-1}(v_j(l))} \varpi(v_j(l)) \leq 0(3.7)$$

for  $l \geq l_2 > l_1$ .

Since  $\frac{\varpi(l)}{B(l)}$  is decreasing, there exists a constant  $k$  such that

$$\frac{\varpi(l)}{B(l)} \leq k \text{ for } l \geq l_2(3.8)$$

**Masaniammal**

Using (3.8) and  $\beta_j < 1$  in (3.7), it follows that

$$\Delta(r(l)(\Delta\varpi(l))^r) + \sum_{j=1}^{m_2} \varphi_j(l) \frac{R^{\beta_j}(v_j(l))B^{\beta_j-1}(v_j(l))}{k^{1-\beta_j}} \varpi(v_j(l)) \leq 0.$$

The remaining portion of the proof is omitted since it is similar to theorem 3.2.

**Example**

We provide a few examples at the conclusion of the paper to show the usefulness and effectiveness of the main results.

**Example 4.1.** Let us examine the second-order neutral difference equation, which is expressed as follows:

$$\Delta \left( 1 \left( \Upsilon(l) + ((l + 1)\Upsilon^3(l - 2) + 2l\Upsilon^5(l - 4)) \right)^3 \right) + (2246l^3 + 12546l^2 + 21438l + 43252)\Upsilon^5(l - 2)$$

$$+ (1210l^3 + 9738l^2 + 12546l + 14256) \Upsilon^5(l - 4) = 0. (4.1)$$

where,  $r(l) = 1, \varphi_1 = 2246l^3 + 12546l^2 + 21438l + 43252,$

$$\varphi_2 = 1210l^3 + 9738l^2 + 12546l + 14256, \rho_1 = l + 1, \rho_2 = 2l, \zeta_1 = l - 2,$$

$$\zeta_2 = l - 4, \beta_1 = 5,$$

$$\beta_2 = 5, v_1 = l - 2, v_2 = l - 4, \alpha_1 = 3, \alpha_2 = 5.$$

Hence all the conditions of theorem 3.1 are satisfied. Hence every solution of (4.1) oscillates.  $\Upsilon(l) = (-1)^l$  is one such solutions of (4.1).

**Example 4.2.** Let us examine the second-order neutral difference equation, which is expressed as follows:

$$\Delta \left( l \left( \Delta \left( \Upsilon(l) + (l\Upsilon^3(l - 2) + 2l\Upsilon^5(l - 4)) \right)^3 \right) \right)$$

$$+ (2202l^4 + 112280l^3 + 38772l^2 + 44826l + 12208)\Upsilon^3(l - 2)$$

$$+ (1254l^4 + 8456l^3 + 1548l^2 + 1254l + 5648)\Upsilon^5(l - 4) (4.2)$$

where,  $r(l) = l, \varphi_1 = 2202l^4 + 112280l^3 + 38772l^2 + 44826l + 12208,$

$$\varphi_2 = 1254l^4 + 8456l^3 + 1548l^2 + 1254l + 5648, \rho_1 = l, \rho_2 = 2l, \zeta_1 = l - 2,$$

$$\zeta_2 = l - 4, \beta_1 = 3, \beta_2 = 5, v_1 = l - 2, v_2 = l - 4, \alpha_1 = 3, \alpha_2 = 5.$$

Hence all the conditions of theorem 3.2 are satisfied. Hence every solution of (4.2) oscillates.  $\Upsilon(l) = (-1)^l$  is one such solutions of (4.2).

**CONCLUSION**

This paper is an analysis of the oscillation criteria for second - order neutral difference equation. New oscillation criteria has been discovered that enhanced various earlier efforts. Two examples were in the demonstration of the relevance and reliability of the obtained results.

### ABSTRACT

A space that is complete in relation to the norm generated by its inner product is known as Hilbert space. In this paper, we introduce a new class of Fuzzy operators called Fuzzy Q(S) in Fuzzy Hilbert Space including some key characteristics of this operator, as well as a discussion of various theorems and properties related to this operator.

**Keywords:** Operator, Fuzzy operators, Q(S) Operator, Hilbert space, Fuzzy Q(S) Operator, Fuzzy Hilbert space.

## INTRODUCTION

In 1984, Katsaras [6] first introduced the notation of fuzzy norm on a vector space. In 1992, Felbin [7] offered an alternative definition of a fuzzy norm on a linear space by assigning a fuzzy real number to each element of the linear space. In 1994, Cheng and Mordeson [8] considered a fuzzy norm on a linear space with its associated metric. Many mathematicians consider the fuzzy metric spaces in different view. Saadati and Vaezpour [9] have given fuzzy normed spaces, fuzzy metric spaces and fuzzy banach spaces and their relations. Later, in 2002, Xiao and Zhu [10] modified this definitions by restricting the definition of fuzzy real numbers to give a concise as well as general definition of a fuzzy normed linear space. Following Cheng and Mordeson, in 2003, Bag and samanta [11] introduced another notion of fuzzy norm using the min triangular norm. The novelty of this definition is the validity of a decomposition theorem for this type of fuzzy norm into a family of crisp norms and using the same. It has been possible to establish many important results of fuzzy functional analysis. Many authors studied the notions and results of classical functional analysis in fuzzy normed linear spaces. During the last few years of existence of fuzzy normed linear spaces, some of the extensive study has been made in several areas.

**Radharamani and Jayakumar**

Studies on fuzzy inner product spaces are relatively new and few works have been done in fuzzy inner product spaces. In 1991, headmost start of the definition of fuzzy inner product space (FIP-space) was given by Biswas [16] and after that according to the chronological in Majumder and Samanta [17], Hasankhani, Nazari and Saheli [18], Mukherjee and Bag [19], Abyad et al [20] etc. Modified definition of FIP-space has been inserted by Goudarzi and Vaezpour in [21]. The new modification can help us to prove the results with fewer restrictions.

**PRELIMINARIES**

This section we examined some recent findings on Fuzzy Q(S) and Q(S\*) operators in this part using certain fundamental theorems and notions.

**DEFINITION 2.1.** Let  $(\mathbb{H}, \mathcal{F}, *)$  be a Fuzzy Hilbert Space (FHS - space) with an inner product  $IP : \langle u, v \rangle = \sup\{t \in \mathbb{R} : \mathcal{F}(u, v, t) < 1\}$  for all  $u, v \in \mathbb{H}$ . Let  $S \in FB(\mathbb{H})$ . Then S is called the class of Fuzzy Q(S) if there exist  $W \in B(\mathbb{H}), W \neq 0, I$  such that  $\|S^*SW\| = \|WSS\|$ .  $FQ(S) = \{W \in FB(\mathbb{H}) : \|SSW\| = \|WS^*S\|\}$ .

**REMARKS 2.2**  $FQ(S) \neq \emptyset$  because  $0, I \in FQ(S)$

**PROPOSITION 2.3.**  $FQ(S)$  is a closed subspace of  $FB(\mathbb{H})$ .

**PROOF.** Let  $W_1, W_2 \in FQ(S)$ . Then

$$\|S^*S(\alpha W_1 + \beta W_2)\| = \|\alpha W_1 S^*S + \beta W_2 S^*S\| = \|(\alpha W_1 + \beta W_2) S^*S\|$$

Therefore  $\|(\alpha W_1 + \beta W_2)\| \in FQ(S)$ . Let  $W_n \in FQ(S)$  such that  $W_n \rightarrow W$ . Therefore,

$$\|S^*SW_n\| \rightarrow \|S^*SW\| \quad \text{and} \quad \|W_n S^*S\| \rightarrow \|W S^*S\|.$$

Since  $\|S^*SW_n\| = \|W_n S^*S\| \forall n, \|S^*SW\| = \|W S^*S\|$ . Then  $W \in FQ(S)$ .

**PROPOSITION 2.4.**

1. If  $W_1, W_2 \in FQ(S)$ , then  $W_1 W_2 \in FQ(S)$
2. If  $W \in FQ(S), W^n \in FQ(S), \forall n$ .
3.  $W \in FQ(S)$  iff  $W^* \in FQ(S)$ .
4. If  $W \in FQ(S)$  is an invertible operator, then  $W^{-1} \in FQ(S)$ .

**THEOREM 2.5.** If  $\|S_1^* S_2^*\| + \|S_2^* S_1^*\| = 0$ , then  $FQ(S_1) \cap FQ(S_2) \subseteq FQ(S_1 + S_2)$

**PROOF.** Let  $W \in FQ(S_1) \cap FQ(S_2)$ . Then

$$\begin{aligned} \|(S_1 + S_2)^*(S_1 + S_2)W\| &= \|(S_1^* S_1 + S_1^* S_2 + S_2^* S_1 + S_2^* S_2)W\| \\ &= \|S_1^* S_1 W + S_2^* S_2 W\| = \|W S_1^* S_1 + W S_2^* S_2\| = \|W(S_1 + S_2)^*(S_1 + S_2)\|. \end{aligned}$$

**THEOREM 2.6.** If  $\|S_1^* S_2^*\| - \|S_2^* S_1^*\| = 0$ , then  $FQ(S_1) \cap FQ(S_2) \subseteq FQ(S_1 + S_2)$

**PROOF.** Let  $W \in FQ(S_1) \cap FQ(S_2)$ . Then

$$\begin{aligned} \|(S_1 - S_2)^*(S_1 - S_2)W\| &= \|(S_1^* S_1 - S_1^* S_2 - S_2^* S_1 + S_2^* S_2)W\| \\ &= \|S_1^* S_1 W + S_2^* S_2 W\| = \|W S_1^* S_1 + W S_2^* S_2\| = \|W(S_1 + S_2)^*(S_1 + S_2)\|. \end{aligned}$$

**PROPOSITION 2.7.** If  $W \in FQ(S)$ , then  $\|SUS^*\| \in FQ(S^*)$  i.e.  $\|SFQ(S)S^* \subseteq FQ(S^*)\|$

**PROOF.** We have  $\|SS^*(SUS^*)\| = \|(SUS^*)SS^*\|$ . Then  $\|SUS^*\| \in FQ(S^*)$ .

**REMARK 2.8.**

1. If  $W \in FQ(S)$ , then  $W^* \in FQ(S)$  and  $W^{*n} \in FQ(S), \forall n$ .
2.  $\|(S^*S)^n\| \in FQ(S), \forall n$ .

**PROPOSITION 2.9.**

1. S is a quasi-normal operator [5] iff  $S \in FQ(S)$
2. If  $S \in FQ(S)$ , then  $S^n \in FQ(S)$ .
3.  $(FQ(S), +, 0)$  is a ring with an identity.

**Radharamani and Jayakumar**

**THEOREM 2.10.**  $S \in FQ(S)$  iff  $\|S+S^*\|$  and  $\|S-S^*\| \in FQ(S)$ .

**PROOF.** Assume that  $S \in FQ(S) \Rightarrow \|S(S^*S)\| = \|(S^*S)S\|$ .

Therefore  $\|S^*SS^*\| = \|S^2S\|$  So,  $\|(S+S^*)S^*S\| = \|S^*SS+S^*SS^*\| = \|(S^*S)[S+S^*]\|$ . Then  $\|(S+S^*)\| \in FQ(S)$ . Moreover,

$$\|(S-S^*)S^*S\| = \|SS^*S-S^2S\| = \|S^*SS-S^*SS^*\|$$

$= \|(S^*S)[S-S^*]\|$ . Thus  $\|(S-S^*)\| \in FQ(S)$  On the other hand, Assume that

$$\|(S+S^*)S^*S\| = \|S^*S(S+S^*)\| \text{ and } \|(S-S^*)S^*S\| = \|S^*S(S-S^*)\|.$$

$$\text{Then } \|SS^*S+S^2S\| = \|S^*S^2+S^*SS^*\| \dots\dots (2.1)$$

$$\text{And } \|SS^*S-S^2S\| = \|S^*S^2-S^*SS^*\| \dots\dots (2.2)$$

From (2.1) and (2.2), we get  $\|2S^*(SS^*)\| = \|2(SS^*)S^*\|$ . Then  $S \in FQ(S)$ . The general theorem that follows comes from the above theorem.

**THEOREM 2.11.**  $S \in FQ(S)$  iff  $\alpha S + \beta S^*$  and  $\alpha S - \beta S^* \in FQ(S)$ , where  $\alpha, \beta \in \mathbb{C}$  are not both equal zero.

**Proof.** Let  $S \in FQ(S)$  then  $\|S(S^*S)\| = \|S^*SS\|$ . So  $\|S^2S\| = \|S^*SS^*\|$ . Then

$$\|(\alpha S + \beta S^*)S^*S\| = \|\alpha SS^*S + \beta S^2S\| = \|\alpha S^*SS + \beta S^*SS^*\| = \|(S^*S)[\alpha S + \beta S^*]\|.$$

Therefore  $\alpha S + \beta S^* \in FQ(S)$ . In the same way  $\|(\alpha S - \beta S^*)S^*S\| = \|\alpha SS^*S - \beta S^2S\|$

$$= \|\alpha S^*SS - \beta S^*SS^*\| = \|(S^*S)[\alpha S - \beta S^*]\|.$$

Therefore  $\alpha S - \beta S^* \in FQ(S)$ . Let  $\alpha S + \beta S^* \in FQ(S)$  and  $\alpha S - \beta S^* \in FQ(S)$ . If  $\alpha = 0$ , then  $\beta S^* \in FQ(S)$ . Since  $\beta = 0, S^* \in FQ(S)$ .

Therefore  $S \in FQ(S)$ .

Assume that  $\alpha \neq 0$ . Then  $\|(\alpha S \pm \beta S^*)S^*S\| = \|S^*S(\alpha S \pm \beta S^*)\|$

$$\|\alpha S^*S \pm \beta S^2S\| = \|\alpha S^*S^2 \pm \beta S^*SS^*\|$$

$$\text{Thus } \|\alpha SS^*S + \beta S^2S\| = \|\alpha S^*S^2 + \beta S^*SS^*\| \dots (2.3)$$

$$\text{And } \|\alpha SS^*S - \beta S^2S\| = \|\alpha S^*S^2 - \beta S^*SS^*\| \dots (2.4)$$

This implies that  $\|2\alpha S^*S\| = \|2\alpha S^*S^2\|$ . Since  $\alpha \neq 0$ , we have  $\|S(S^*S)\| = \|(S^*S)S\|$ . This shows that  $S \in FQ(S)$ .

**PROPOSITION 2.12.**  $\sigma(S) \cap \sigma(S^*) = \emptyset$  and  $\|S+S^*\| \in FQ(S)$  iff  $S \in FQ(S)$

**THEOREM 2.13.** If  $\|Ker S^*S\| = \mathbb{H}$ , then  $FQ(S) = FB(\mathbb{H})$

**PROOF.** Let  $K \in FB(\mathbb{H})$ . Since  $\|KS^*S(x)\| = 0$  and  $\|S^*SK(x)\| = 0, \forall x \in \mathbb{H}, \|KS^*S\| = \|S^*SK\|$ .

Thus,  $K \in FQ(S)$ , for all  $K \in FB(\mathbb{H})$ .

**COROLLARY 2.14** 1. If  $S$  is a zero operator, then  $FQ(S) = FB(\mathbb{H})$

2.  $\|S^*S\| = 0$  iff  $S=0$ .

**REMARK 2.15.** If  $S$  is a self adjoint operator [6], then  $FQ(S) = \|\dot{S}^2\|$ , where  $\|\dot{S}^2\|$  is commutes of  $S^2$ .

**THEOREM 2.16.** Let  $S$  be an operator with  $\|Ker S^*S\| = 0$ . Then  $FQ(S) = FB(\mathbb{H})$  iff  $\|S^*S\| = \alpha I$ , where  $\alpha$  is a non-zero constant.

**PROOF.** Let  $\{e_i\}$  be a basis for  $\mathbb{H}$ . Suppose that  $\|WS^*S\| = \|S^*SW\|, \forall W \in FB(\mathbb{H})$ . Let  $M = \text{span}\{S^*S(e_i)\}$ , then  $\mathbb{H} = M \oplus M^\perp$  and  $\|P_{M^\perp}S^*S(e_i)\| = \|S^*SP_{M^\perp}(e_i)\|$ .

This implies that  $\|S^*SP_{M^\perp}(e_i)\| = 0$ , but  $\|Ker S^*S\| = 0$ . So  $\|P_{M^\perp}(e_i)\| = 0$ . Thus,  $e_i \in M$ . Therefore  $e_i = \|\alpha_1 S^*S(e_i)\|, \alpha_1 \neq 0$ .

In the same way  $e_i = \|\alpha_i S^*S(e_i)\|, i=1,2,\dots$  Also

$$e_i + e_j = \|\alpha S^*S(e_i + e_j)\| = \|\alpha S^*S e_i + \alpha S^*S e_j\|. \text{ So, } \|\alpha_i S^*S e_i + \alpha_j S^*S e_j\| = \|\alpha S^*S e_i + \alpha S^*S e_j\|$$

$$= \|S^*S(\alpha_i e_i + \alpha_j e_j)\| = \|S^*S(\alpha e_i + \alpha e_j)\|.$$

Therefore  $\|(\alpha_i e_i + \alpha_j e_j)\| = \|(\alpha e_i + \alpha e_j)\|$ . Hence,  $\|(\alpha_i - \alpha) e_i + (\alpha_j - \alpha) e_j\| = 0$ .

Therefore,  $\|(\alpha_i - \alpha)\| = 0$  and  $\|(\alpha_j - \alpha)\| = 0$ . Hence,  $\|\alpha_i\| = \|\alpha\| = \|\alpha_j\|$  Thus,

$$\|T^*T(e_i)\| = \frac{1}{\alpha} (e_i) \text{ for all } i. \text{ This means that } \|T^*T\| = \frac{1}{\alpha} I. \text{ The converse part definitely holds.}$$

**THEOREM 2.17.**  $FQ(S)$  is invariant subspace of  $S$  iff  $S \in FQ(S)$ .

**Radharamani and Jayakumar**

**PROOF.** Since  $\|I\| \in FQ(S)$ ,  $\|SI\| \in FQ(S) \Rightarrow \|S\| \in FQ(S)$ . On the other hand, let  $W \in FQ(S)$ . Since  $\|S\| \in FQ(S)$ ,  $\|SW\| \in FQ(S)$ . Hence  $FQ(S)$  is invariant subspace.

**THEOREM 2.18** Let  $\{0\} \neq \text{Ker } S^*S \notin \mathbb{H}$ . Then  $\{0\} \neq \overline{FQ(S)(h)} \notin \mathbb{H}$ ,

$\forall h \in \text{Ker } S^*S$  and  $h \neq 0$ .

**PROOF.** Let  $0 \neq h \in \text{Ker } S^*S$ . Since  $I \in \overline{FQ(S)}$ ,  $h = I(h) \in FQ(S)(h) \subseteq \overline{FQ(S)(h)}$ .

Therefore,  $\{0\} \neq \overline{FQ(S)(h)}$ .

If  $W \in FQ(S)$ , then  $\|S^*SW\| = \|WS^*S\|$ . Therefore

$$\|S^*SW(h)\| = \|WS^*S(h)\|.$$

This implies that  $\|S^*SW(h)\| = 0$ . Therefore

$$W(h) \in \text{Ker } S^*S.$$

Thus,  $FQ(S)(h) \subseteq \text{Ker } S^*S$  and so  $\overline{FQ(S)(h)} \subseteq \text{Ker } S^*S$ . Therefore  $\overline{FQ(S)(h)} \notin \mathbb{H}$ .

**PROPOSITION 2.19.** If  $S$  is quasi normal operator [26], then  $\overline{S FQ(S)(h)} \subseteq \overline{FQ(S)(h)}$ ,  $\forall h \in \mathbb{H}$ .

**PROOF.** Since  $S \in FQ(S)$ ,  $S \in FQ(S) \subseteq FQ(S)$ . Let  $Z \in \overline{FQ(S)(h)}$ , so there exist

$W_n(h) \in FQ(S)(h)$  such that  $W_n(h) \rightarrow Z$  and  $\|SW_n(h)\| \rightarrow \|S(Z)\|$ .

Therefore  $W_n \in FQ(S) \Rightarrow \|SW_n\| \in FQ(S)$ . But  $\|SW_n(h)\| \in FQ(S)(h)$ . Therefore

$\|S(Z)\| \in \overline{FQ(S)(h)}$  and consequently  $\overline{S FQ(S)(h)} \subseteq \overline{FQ(S)(h)}$ .

**THEOREM 2.20.**  $FQ(S)(h)$  is a subspace of  $\mathbb{H}$ , for all  $h \in \mathbb{H}$ .

**PROOF.** Let  $W_1(h), W_2(h) \in FQ(S)(h) \Rightarrow W_1, W_2 \in FQ(S)$ . Hence,  $W_1 + W_2 \in FQ(S)$  and

$W_1(h) + W_2(h) = (W_1 + W_2)(h) \in FQ(S)(h)$ .

Let  $\alpha \in \mathbb{C}, W(h) \in FQ(S)(h) \Rightarrow \alpha(W(h)) = (\alpha W)(h) \in FQ(S)(h)$ .

**COROLLARY 2.21.**  $\overline{FQ(S)(h)}$  is a subspace of  $\mathbb{H}$ , for all  $h \in \mathbb{H}$

**PROOF.** Let  $Z_1, Z_2 \in \overline{FQ(S)(h)}$ . Then there exist  $W^1(h), W^2(h) \in FQ(S)(h)$  such that

$W_n^1(h) \rightarrow Z_1, W_n^2(h) \rightarrow Z_2$

Therefore  $W_n^1(h) + W_n^2(h) \rightarrow Z_1 + Z_2$  and  $W_n^1 + W_n^2(h) \rightarrow Z_1 + Z_2$ .

Since  $W_n^1 + W_n^2 \in FQ(S) \rightarrow Z_1 + Z_2 \in \overline{FQ(S)(h)}$ . Let  $Z \in \overline{FQ(S)(h)}$  and  $\alpha$  is constant.

Therefore,  $W_n(h) \rightarrow Z$  and  $\alpha W_n(h) \rightarrow \alpha Z$ . This shows that

$\alpha W_n \in FQ(S) \Rightarrow \alpha Z \in \overline{FQ(S)(h)}$ .

## CONCLUSION

The ideas of the operators in normed space and Hilbert space provide the operators in fuzzy normed and fuzzy Hilbert space are updates. The fuzzy operators in fuzzy Hilbert space have a wide range of applications.

### ABSTRACT

This study investigates the seasonal and interannual variations in groundwater levels and their relationship with rainfall, temperature, and potential evapotranspiration in Coimbatore, India, from 1994 to 2022. Groundwater sustainability is crucial in this semi-arid region, where monsoon patterns significantly impact groundwater recharge. Data analysis was conducted for four seasons—Winter, Pre-Monsoon, Monsoon, and Post-Monsoon—to assess seasonal effects on groundwater levels. The methodology involved analyzing rainfall (RF), average temperature (AVGT), and potential evapotranspiration (PET) alongside groundwater table depth (GWT) to understand groundwater fluctuations. Results indicate that monsoon rainfall plays a dominant role in groundwater recharge, as evidenced by higher GWT levels post-monsoon. Additionally, high PET values, especially in the pre-monsoon season, were correlated with groundwater depletion, emphasizing the impact of evaporation and temperature on groundwater availability. The study concludes that groundwater sustainability in Coimbatore is heavily influenced by monsoon rainfall, with increased temperature and evapotranspiration exacerbating seasonal groundwater stress. These findings provide valuable insights for water resource management and planning in Coimbatore, highlighting the need for effective strategies to mitigate groundwater depletion during dry seasons.

**Keywords:** evapotranspiration, monsoon, rainfall, groundwater, seasons.

## INTRODUCTION

Water is the world's most crucial and invaluable natural resource, essential for sustainable development. Groundwater, another significant natural resource, plays a vital role in industrial and domestic applications. In arid and semi-arid regions, groundwater becomes the primary source for fulfilling agricultural requirements. Over the past 20-25 years, global climate change has brought about rapid alterations in temperatures, rainfall patterns, weather conditions, and atmospheric pressure. Consequently, these changes have had a direct impact on groundwater levels. Furthermore, the increasing intensification of growth, heightened pollution levels, and decreased rainfall further intensify the reliance on groundwater resources.

## LITERATURE REVIEW

In the past few years, a multitude of studies have explored various simulation approaches to predict groundwater levels quantitatively and qualitatively. These methods encompass a diverse array of physically based conceptual models [1, 2] and experimental models. Numerical models have found extensive application in simulating groundwater quality and quantity within aquifers [3, 4, 32]. However, these numerical groundwater models, such as MODFLOW [33, 34], necessitate the determination of various parameters, which can be a time-consuming task. Obtaining reliable values for these parameters requires fieldwork and substantial expertise. Additionally, the computational time required for numerical model simulations is a notable concern, often taking several days to generate accurate results. To address these limitations, soft computing techniques offer a reliable alternative that delivers enhanced accuracy with reduced computational time for groundwater level prediction [5]. Approximately 70% of areas worldwide, including polar regions like Russia, have not extensively utilized Groundwater Level (GWL) studies due to an abundance of surface water or sparser populations. Furthermore, certain underdeveloped regions like Africa, parts of Asia, and North America may have yet to explore the potential of AI techniques [1]. In the past few decades, machine learning models have emerged as valuable tools for modeling complex nonlinear processes [6]. Specifically, artificial neural networks (ANN) [17-21] have gained wide popularity in flow prediction problems [7]. Alongside neural networks, several other advanced techniques have shown promise in modeling a diverse range of nonlinear functions. These include Support Vector Machines (SVM) [9, 25, 28], genetic programming [10, 29, 30], and probabilistic graphical models like Bayesian networks [8, 35]. Bayesian networks provide a statistical consideration of the causal relationships between random variables. Comparatively, Support Vector Machines have exhibited superior performance when compared to other techniques. Gong, Y et al., [11] introduced three hybrid models that combine ensemble empirical mode decomposition (EEMD) with data-driven models to forecast variations in groundwater levels. The research assessed the predictive capabilities of the EEMD-ANN, EEMD-SVM, and EEMD-ANFIS hybrid models [31]. These models were evaluated using a monthly time series of groundwater levels obtained from two monitoring wells located near Lake Okechobee in Florida. Ahmad Sharafati et al. [13] presented a prediction approach for monthly groundwater levels with both short- and long-lead times in the Rafsanjan aquifer, located in Iran. The proposed method employed an ensemble machine learning technique known as Gradient Boosting Regression (GBR) to forecast the groundwater levels. The study aimed to enhance the accuracy of groundwater level predictions within the Rafsanjan aquifer using this ensemble approach.

Jianchong Sun et al. [14] introduced three commonly employed data-driven models: autoregressive integrated moving average (ARIMA) [22-24], back-propagation artificial neural network (BP-ANN), and long short-term memory (LSTM). These models were established in five zones with distinct hydrogeological characteristics in the Northern Plain of China. The research aimed to evaluate the accuracy of these models in predicting groundwater level (GWL) at both monthly and daily scales. P. D. Sreekanth et al. [15] investigated the effectiveness of the artificial neural network (ANN) model, specifically a standard feed-forward neural network trained with the Levenberg-Marquardt algorithm, for predicting groundwater levels in the Maheshwaram watershed located in Hyderabad, India. The research aimed to evaluate the performance of the ANN model in forecasting groundwater levels in the specified region. Nilesh N. Maltare et al. [16] examined the rainfall pattern and groundwater level dynamics in the

**Marudhachalam et al.,**

Banaskantha district of Gujarat. The study further included predictions of an increase in groundwater levels using several models, namely SARIMA (Seasonal Autoregressive Integrated Moving Average), multi-variable regression, ridge regression, and KNN (K-Nearest Neighbors) regression. In their study, Chandra Mohan Shakya et al. [12] proposed several machine learning algorithms to predict groundwater levels in the Vidisha district, a semi-arid region of Central India. The ML algorithms used in the research included Multivariate Linear Regression (MLR) model, Multivariate Polynomial Regression (MPR) model, Support Vector Regression (SVR) model, Decision Tree Regression (DTR)[27] model, Random Forest Regression (RFR) model, Artificial Neural Network (ANN) model, and Adaptive Neuro-Fuzzy Inference System (ANFIS)[26]. These algorithms were employed to analyze and forecast groundwater levels in the mentioned region.

**Research Problem:**

Based on an extensive literature review, numerous studies have focused on predicting groundwater level (GWL) in various regions worldwide. Among these studies, two prominent areas of research have been identified: accuracy enhancement and feature expansion. These areas play a crucial role in GWL prediction and offer substantial scope for further exploration. In order to address these aspects, the adoption of a hybrid model is suggested as a preferable alternative to other models such as ANN, MLR, SVR, MPR, DTR, etc., due to the advantages it offers. The suitability of a prediction depends on the accuracy of the model and the extent of feature expansion. In the current study, a GWL prediction is proposed using a hybrid model incorporating new algorithms that aim to achieve high accuracy. Additionally, novel features such as sea level and groundwater level abstraction are incorporated to enhance the prediction process.

**Research Area: Arid region of Southern India**

The absence of consistent temperature changes across India introduces variations in microclimates, rendering weather predictions increasingly challenging. As greenhouse gas emissions contribute to climate warming, accelerated evaporation of seawater intensifies atmospheric moisture, leading to condensed and heavy rainfall. This shift towards intense precipitation, accompanied by a decline in moderate rainfall, has the potential to reduce groundwater recharge and soil moisture, thereby impacting agricultural activities.

This research focused on estimating the groundwater table in Coimbatore, a district in Tamil Nadu, India. Coimbatore is situated in the far west of Tamil Nadu, near the state of Kerala. The district is located at latitude 11°0'98" North and longitude 76°57'03" East in the Indian subcontinent. The elevation of this location is approximately 411 meters above sea level. It is encompassed by the Western Ghats mountain range, which surrounds it from the west and north. The northern side is particularly notable, housing the Nilgiri Biosphere Reserve and reserve forests. Coimbatore district boasts a wealth of natural resources, including hills, forests, rivers, and diverse wildlife. The Western Ghats in the district are home to important rivers like Bhavani, Noyyal River, Aliyar, and Siruvani, which provide essential drinking water and irrigation for the local population and farmers. The forests in Coimbatore district cover an area of 693.48 km<sup>2</sup>, accounting for a small portion of the total district area of 7433.72 km<sup>2</sup>. These forests play a crucial role in maintaining the pleasant weather, lush green landscape, and clean air of the district. The forest tract falls within the geographical coordinates of 10°37' to 11°31' north latitudes and 76°39' to 77°5' east longitudes. Coimbatore possesses significant water resources, including Singanallur, Valankulam, UkaadamPariyakulam, Kurichi Lake, Krishnampathi, Kumaraswami Lake, and Selvachinthamani. These play a vital role in the availability of water in the area. The average maximum temperature in Coimbatore ranges from 27.5 °C to 38 °C, while the average minimum temperature varies between 14.5 °C and 26.5 °C. The average relative humidity at this location is 69.2%. The annual rainfall distribution in Coimbatore accumulates to 859.5 mm. Among the months, May and October are the warmest and receive the highest amount of rainfall, respectively. December is considered the coldest month in this region.

Marudhachalam et al.,

## METHODOLOGY AND ANALYSIS

The following table contains groundwater and climatic data for Coimbatore from 1994 to 2022. This data covers various parameters, segmented by year and season (Winter, Pre-Monsoon, Monsoon, and Post-Monsoon). Here is a breakdown of the columns and what each represents:

1. Year: Indicates the year for which the data is recorded, ranging from 1994 to 2022.
2. Groundwater Table (GWT): This column records the groundwater levels, representing the water table depth. Groundwater levels are influenced by seasonal rainfall, temperature, and evapotranspiration rates.
3. Seasonal Rainfall (RF): Rainfall data recorded in millimeters for each season (Winter, Pre-Monsoon, Monsoon, and Post-Monsoon) each year. Rainfall is a key factor in groundwater recharge, with the Monsoon season generally showing the highest rainfall.
4. Average Temperature (AVGT): Seasonal average temperature in degrees Celsius. Temperature affects evapotranspiration rates, which, in turn, influence groundwater levels, particularly in drier seasons.
5. Potential Evapotranspiration (PET): Potential evapotranspiration values are recorded in millimeters, representing the amount of water that would evaporate and transpire if sufficient water was available. PET provides insights into the demand for water, with higher PET values generally indicating higher water loss, which can affect groundwater levels, especially in pre-monsoon and dry seasons.

This dataset (Table 3.1) is useful for studying the impacts of seasonal and climatic factors on groundwater levels in Coimbatore. By examining trends in GWT, RF, AVGT, and PET across different seasons, we can identify patterns, understand the role of monsoon rainfall in groundwater recharge, and explore how temperature and evapotranspiration contribute to groundwater depletion.

### Seasonal Analysis of Groundwater Levels (GWT):

- **Methodology:** We segment the data by season (Winter, Pre-Monsoon, Monsoon, Post-Monsoon) and analyze the patterns in groundwater levels across these seasons each year. This helps in understanding how groundwater levels respond to seasonal changes.
- **Analysis:**
  - **Monsoon Season:** The monsoon consistently shows the highest GWT values, which is directly influenced by high rainfall amounts. For instance, in years like 2011 (305.23 mm) and 2019 (185.55 mm), monsoon GWT levels reached peak values due to effective groundwater recharge.
  - **Post-Monsoon Season:** This season generally shows slightly decreased GWT compared to the monsoon season but still reflects the residual recharge effect. For example, in 2000 and 2022, post-monsoon GWT levels were high, showing sustained recharge after the monsoon.
  - **Pre-Monsoon and Winter Seasons:** Lower GWT values in these seasons indicate reduced rainfall and higher groundwater extraction. These seasons typically show declining trends in groundwater, especially in years with high pre-monsoon PET values (e.g., 2016 and 2021), which increases water loss.

### Correlation Between Rainfall (RF) and Groundwater Levels (GWT):

**Methodology:** Using a comparative analysis between rainfall (RF) and groundwater levels (GWT) across seasons, we determine the effectiveness of rainfall in recharging groundwater. Specifically, we focus on monsoon and post-monsoon seasons where rainfall is higher.

#### Analysis:

**High Rainfall Years:** Monsoon rainfall correlates with increases in GWT, as seen in years with high rainfall, such as 2011 (305.23 mm) and 2019 (185.55 mm). This trend shows the positive impact of heavy monsoon rainfall on groundwater recharge.

**Low Rainfall Years:** During years with lower rainfall, like 2001 and 2002, GWT levels are lower, especially in the post-monsoon period, showing the dependency of groundwater levels on sufficient rainfall during the monsoon season.

Marudhachalam *et al.*,

### Impact of Temperature (AVGT) and Potential Evapotranspiration (PET):

**Methodology:** We examine the seasonal average temperature (AVGT) and potential evapotranspiration (PET) to understand how climatic factors influence groundwater levels. High PET values, particularly in the pre-monsoon season, reduce the effectiveness of rainfall in recharging groundwater.

#### Analysis:

**Pre-Monsoon High PET:** PET values in the pre-monsoon season are generally high, correlating with reduced groundwater levels due to increased water loss. For instance, years like 2013 and 2021 show high PET values, resulting in decreased GWT even with some rainfall.

**Monsoon and Post-Monsoon Lower PET:** PET values tend to decrease in the monsoon and post-monsoon seasons, which supports groundwater retention from rainfall. This pattern is evident in years with low PET and moderate GWT levels, such as 2012 and 2017.

#### Trend Analysis Over Time:

**Methodology:** A longitudinal analysis across years highlights trends in groundwater levels, rainfall, and temperature, indicating shifts in climate patterns and groundwater sustainability.

#### Analysis:

**Declining Groundwater Trend:** Certain years, particularly from 2000 to 2004, exhibit a decline in GWT. This could be due to insufficient recharge from monsoon rainfall and increasing groundwater extraction.

**Recent Patterns (2018–2022):** In recent years, GWT levels have shown a slight increase post-monsoon, suggesting potential improvements in rainfall patterns or water management. However, rising PET values in recent pre-monsoon seasons indicate a risk of increased groundwater depletion if trends continue.

## CONCLUSION

The study of groundwater levels in Coimbatore from 1994 to 2022 reveals clear seasonal and climatic influences on groundwater sustainability:

- **Rainfall as a Primary Factor:** Monsoon rainfall is critical for groundwater recharge. The correlation between high monsoon rainfall and increased GWT highlights the importance of adequate rainfall for maintaining groundwater levels.
- **Temperature and Evapotranspiration Effects:** High temperatures and evapotranspiration rates, especially during the pre-monsoon season, contribute to groundwater depletion by increasing water loss. This seasonal dynamic underscores the need for efficient water management, especially before the monsoon season.
- **Recommendations for Sustainable Water Management:**
  - **Enhance Rainwater Harvesting:** Harvesting rainwater during monsoon and post-monsoon seasons can improve groundwater recharge and counteract the effects of high PET in pre-monsoon seasons.
  - **Reduce Groundwater Extraction During Low-Rainfall Periods:** Limiting groundwater use in winter and pre-monsoon seasons can help maintain sustainable levels.
  - **Climate-Responsive Planning:** Given the rising PET trends in recent years, implementing adaptive water management practices could mitigate the risk of groundwater scarcity.

This analysis highlights the need for season-specific groundwater management strategies that account for rainfall variability, temperature, and evapotranspiration to ensure long-term water security in the Coimbatore region.

### ABSTRACT

The purpose of this paper is to introduce the notion of Nano Weakly  $g\#$  (NW $g\#$ ) Irresolute functions and Nano Weakly  $g\#$  (NW $g\#$ ) homeomorphisms in Nano topological spaces and studied some of their basic properties. The basic characterizations with nano interior and nano closure are discussed.

**Keywords:** NW $g\#$  open map, NW $g\#$  closed map, NW $g\#$  continuous functions, NW $g\#$  Irresolute functions, NW $g\#$  Homeomorphism.

## INTRODUCTION

The topological spaces have many applications for different types of sets like fuzzy sets, nano sets, permutation sets and soft sets. In 2013 Lellis Thivagar.M and Carmel Richard [6] established Nano topology and introduced Nano continuity, Nano irresolute, Nano open mappings and Nano homeomorphism. The term irresoluteness was introduced by Crossley S.G and Hildebrand S.K [3] in 1972. In 2016 Bhuvaneswari.K and Ezhilarasi.A [2] revealed the idea of nano semi generalized homeomorphisms in nano topological spaces. The definition of Nano Weakly  $g\#$  (NW $g\#$ ) closed sets in nano topological spaces was introduced by Kalaivani.P and Nithyakala .R [4].

The Nano Weakly  $g\#$  irresolute functions and Nano Weakly  $g\#$  homomorphism in nano topological spaces are introduced and investigated their relationship with other existing Nano homeomorphisms.

### Kalaivani and Nithyakala

#### PRELIMINARIES

**Definition 2.1.[5]** Let  $(U, \tau_R(X))$  and  $(V, \tau_{R'}(Y))$  be two Nano Topological Spaces. A function  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_{R'}(Y))$  is Nano Weakly  $g\#$  continuous (NW $g\#$  continuous) if the inverse image of every nano open set in  $(V, \tau_{R'}(Y))$  is NW $g\#$  open in  $(U, \tau_R(X))$ .

**Definition 2.2. [5]** A Nano Topological Space  $(U, \tau_R(X))$  is NW $g\#$  compact if every NW $g\#$  open cover of  $(U, \tau_R(X))$  has a finite sub cover.

**Definition 2.3. [5]** A Nano Topological Space  $(U, \tau_R(X))$  is NW $g\#$  connected if it cannot be expressed as the disjoint union of two nonempty NW $g\#$  open sets.

#### On Nano Weakly $g\#$ Irresolute Functions in Nano Topological Spaces

In this section a new form of irresolute functions called Nano Weakly  $g\#$  irresolute function in nano topological spaces is introduced and some of their properties are analyzed.

**Definition 3.1.** Let  $(U, \tau_R(X))$  and  $(V, \tau_{R'}(Y))$  be two nano topological spaces. A function  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_{R'}(Y))$  is Nano Weakly  $g\#$  irresolute (NW $g\#$  irresolute) if the inverse image of every NW $g\#$  open set in  $(V, \tau_{R'}(Y))$  is NW $g\#$  open set in  $(U, \tau_R(X))$ .

**Example 3.2.** Let  $U = \{a, b, c, d\}$  with  $U/R = \{\{a\}, \{d\}, \{b, c\}\}$  and  $X = \{a, c\}$  then the nano topology  $\tau_R(X) = \{U, \Phi, \{a\}, \{b, c\}, \{a, b, c\}\}$ . Let  $V = \{x, y, z, w\}$  with  $V/R' = \{\{y\}, \{w\}, \{x, z\}\}$  and  $Y = \{x, y\}$  then the nanotopology  $\tau_{R'}(Y) = \{V, \phi, \{y\}, \{x, z\}, \{x, y, z\}\}$ .

Define  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_{R'}(Y))$  by  $f(a) = y, f(b) = x, f(c) = z, f(d) = w$ . Then  $f^{-1}(y) = \{a\}, f^{-1}(x, z) = \{b, c\}$  and  $f^{-1}(x, y, z) = \{a, b, c\}$ . Thus the inverse image of every NW $g\#$  open set in  $(V, \tau_{R'}(Y))$  is NW $g\#$  open in  $(U, \tau_R(X))$ . Hence  $f$  is NW $g\#$  irresolute map.

**Theorem 3.3.** If  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_{R'}(Y))$  and  $g : (V, \tau_{R'}(Y)) \longrightarrow (W, \tau_{R''}(Z))$  are two NW $g\#$  irresolute functions then their composition is also NW $g\#$  irresolute.

**Proof:** Let  $(U, \tau_R(X)), (V, \tau_{R'}(Y))$  and  $(W, \tau_{R''}(Z))$  be any three nano topological spaces and let  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_{R'}(Y))$  and  $g : (V, \tau_{R'}(Y)) \longrightarrow (W, \tau_{R''}(Z))$  be two NW $g\#$  irresolute functions. The composition of two functions  $(g \circ f) : (U, \tau_R(X)) \longrightarrow (W, \tau_{R''}(Z))$ . Assume that  $H$  is NW $g\#$  open set in  $(W, \tau_{R''}(Z))$ . Since  $g$  is NW $g\#$  irresolute,  $g^{-1}(H)$  is NW $g\#$  open in  $(V, \tau_{R'}(Y))$ . Also  $f$  is NW $g\#$  irresolute,  $f^{-1}(g^{-1}(H)) = (g \circ f)^{-1}(H)$  is NW $g\#$  open in  $(U, \tau_R(X))$ . Then for each NW $g\#$  open set  $H$  in  $(W, \tau_{R''}(Z))$ ,  $(g \circ f)^{-1}(H)$  is NW $g\#$  open in  $(U, \tau_R(X))$ . Hence  $(g \circ f)$  is NW $g\#$  irresolute in nano topological spaces.

**Theorem 3.4.** Let  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_{R'}(Y))$  and  $g : (V, \tau_{R'}(Y)) \longrightarrow (W, \tau_{R''}(Z))$  be such that  $g \circ f : (U, \tau_R(X)) \longrightarrow (W, \tau_{R''}(Z))$  is NW $g\#$  closed function.

- (i) If  $f$  is nano continuous and injective then  $g$  is NW $g\#$  closed.
- (ii) If  $g$  is NW $g\#$  irresolute and injective then  $f$  is NW $g\#$  closed.
- (iii)

**Proof : (i)** Assume that  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_{R'}(Y))$  is nano continuous and injective. Let  $g : (V, \tau_{R'}(Y)) \longrightarrow (W, \tau_{R''}(Z))$  be such that  $g \circ f : (U, \tau_R(X)) \longrightarrow (W, \tau_{R''}(Z))$  is NW $g\#$  closed function. Let  $A$  be a nano closed subset of  $(V, \tau_{R'}(Y))$ . Since  $f$  is nano continuous,  $f^{-1}(A)$  is nano closed in  $(U, \tau_R(X))$ . Since  $(g \circ f)$  is NW $g\#$  closed and  $f$  is injective,  $(g \circ f)(f^{-1}(A)) = g(A)$  is NW $g\#$  closed in  $(W, \tau_{R''}(Z))$ . Hence the map  $g$  is NW $g\#$  closed.

**(ii)** Assume that  $g : (V, \tau_{R'}(Y)) \longrightarrow (W, \tau_{R''}(Z))$  is NW $g\#$  irresolute and injective. Let  $H$  be a nano closed set of  $(U, \tau_R(X))$ . Then  $U - H$  is nano open set of  $(U, \tau_R(X))$ . Since  $(g \circ f)$  is NW $g\#$  closed,  $(g \circ f)(H)$  is NW $g\#$  closed in  $(W, \tau_{R''}(Z))$ .  $(W - (g \circ f)(H))$  is NW $g\#$  open in  $(W, \tau_{R''}(Z))$ . Since  $g$  is NW $g\#$  irresolute,  $g^{-1}(W - (g \circ f)(H)) = V - g^{-1}(g \circ f(H)) = V - f(H)$  is NW $g\#$  open in  $(V, \tau_{R'}(Y))$ . Therefore  $f(H)$  is NW $g\#$  closed in  $(V, \tau_{R'}(Y))$ . Thus for every nano closed set  $H$  of  $(U, \tau_R(X))$ ,  $f(H)$  is NW $g\#$  closed in  $(V, \tau_{R'}(Y))$ . Hence  $f$  is NW $g\#$  closed function in nano topological spaces.

**Kalaivani and Nithyakala**

**Theorem 3.5.** Iff:  $(U, \tau_R(X)) \longrightarrow (V, \tau_R'(Y))$  is  $NWg^\#$  irresolute then it is  $NWg^\#$  continuous but not conversely.

**Proof :** Let  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_R'(Y))$  be  $NWg^\#$  irresolute and let  $G$  be a nano open set in  $(V, \tau_R'(Y))$ . Since every nano open set is  $NWg^\#$  open,  $G$  is  $NWg^\#$  open in  $(V, \tau_R'(Y))$ . Also  $f$  is  $NWg^\#$  irresolute  $f^{-1}(G)$  is  $NWg^\#$  open in  $(U, \tau_R(X))$ . Thus the inverse image of every nano open set in  $(V, \tau_R'(Y))$  is  $NWg^\#$  open in  $(U, \tau_R(X))$ . Hence  $f$  is  $NWg^\#$  continuous.

**The contrary of the preceding theorem is not true as evidenced by the following example.**

**Example 3.6.** In example 3.2 define  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_R'(Y))$  by  $f(a) = x, f(b) = y, f(c) = z, f(d) = w$ . The map  $f$  is  $NWg^\#$  continuous. Now  $f^{-1}(y, z, w) = \{b, c, d\}$  which is not  $NWg^\#$  open in  $(U, \tau_R(X))$ . Hence  $f$  is not  $NWg^\#$  irresolute.

**Theorem 3.7.** Let  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_R'(Y))$  be a bijective function such that the image of every nano  $\alpha g$ -open set in  $(U, \tau_R(X))$  is nano  $\alpha g$ -open set in  $(V, \tau_R'(Y))$  and  $NWg^\#$  continuous, then  $f$  is  $NWg^\#$  irresolute.

**Proof :** Assume that  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_R'(Y))$  is bijective function such that the image of every nano  $\alpha g$ -open set in  $(U, \tau_R(X))$  is nano  $\alpha g$ -open set in  $(V, \tau_R'(Y))$  and  $NWg^\#$  continuous. Let  $G$  be a  $NWg^\#$  closed set in  $(V, \tau_R'(Y))$ . Let  $f^{-1}(G) \subseteq K$ , where  $K$  is nano  $\alpha g$  open set in  $(U, \tau_R(X))$  which implies  $G \subseteq f(K)$ . By assumption  $f(K)$  is nano  $\alpha g$  open set in  $(V, \tau_R'(Y))$ . Since  $G$  is  $NWg^\#$  closed in  $(V, \tau_R'(Y))$ ,  $Ncl(Nint(G)) \subseteq f(K) \implies f^{-1}(Ncl(Nint(G))) \subseteq K$ . Since  $f$  is  $NWg^\#$  continuous and  $Ncl(Nint(G))$  is nano closed in  $(V, \tau_R'(Y))$ .  $f^{-1}(Ncl(Nint(G)))$  is  $NWg^\#$  closed in  $(U, \tau_R(X))$ . Since  $f^{-1}(Ncl(Nint(G))) \subseteq K$  and  $f^{-1}(Ncl(Nint(G)))$  is  $NWg^\#$  closed,  $Ncl(Nint(f^{-1}(Ncl(Nint(G)))) \subseteq K \implies Ncl(Nint(f^{-1}(G))) \subseteq K \implies f^{-1}(G)$  is  $NWg^\#$  closed in  $(U, \tau_R(X))$ . Hence  $f$  is  $NWg^\#$  irresolute.

**Theorem 3.8.** Let  $(U, \tau_R(X)), (V, \tau_R'(Y))$  and  $(W, \tau_R''(Z))$  be any three nano topological spaces. Iff:  $(U, \tau_R(X)) \longrightarrow (V, \tau_R'(Y))$  is  $NWg^\#$  irresolute and  $g : (V, \tau_R'(Y)) \longrightarrow (W, \tau_R''(Z))$  is  $NWg^\#$  continuous then  $g \circ f : (U, \tau_R(X)) \longrightarrow (W, \tau_R''(Z))$  is  $NWg^\#$  continuous.

**Proof :** Assume  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_R'(Y))$  is  $NWg^\#$  irresolute and  $g : (V, \tau_R'(Y)) \longrightarrow (W, \tau_R''(Z))$  is  $NWg^\#$  continuous. Let  $A$  be a nano open set in  $(W, \tau_R''(Z))$ . Since  $g$  is  $NWg^\#$  continuous, for each open set  $A$  in  $(W, \tau_R''(Z))$ ,  $g^{-1}(A)$  is  $NWg^\#$  open in  $(V, \tau_R'(Y))$ . Since  $f$  is  $NWg^\#$  irresolute,  $f^{-1}(g^{-1}(A))$  is  $NWg^\#$  open in  $(U, \tau_R(X))$ . Thus  $f^{-1}(g^{-1}(A)) = (g \circ f)^{-1}(A)$  is  $NWg^\#$  open in  $(U, \tau_R(X))$ . Therefore,  $g \circ f$  is  $NWg^\#$  continuous.

**Theorem 3.9.** If  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_R'(Y))$  is a surjective,  $NWg^\#$  irresolute function. If  $(U, \tau_R(X))$  is  $NWg^\#$  compact then  $(V, \tau_R'(Y))$  is  $NWg^\#$  compact.

**Proof :** Let  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_R'(Y))$  be surjective and  $NWg^\#$  irresolute. By theorem 3.5  $f$  is  $NWg^\#$  continuous. The function  $f$  is surjective,  $NWg^\#$  continuous function if  $(U, \tau_R(X))$  is  $NWg^\#$  compact then  $(V, \tau_R'(Y))$  is nano compact. Every nano compact set is  $NWg^\#$  compact. Hence  $(V, \tau_R'(Y))$  is  $NWg^\#$  compact in nano topological spaces.

**Theorem 3.10.** If  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_R'(Y))$  is surjective,  $NWg^\#$  irresolute and  $(U, \tau_R(X))$  is  $NWg^\#$  connected then  $(V, \tau_R'(Y))$  is  $NWg^\#$  connected.

**Proof :** Let  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_R'(Y))$  be surjective,  $NWg^\#$  irresolute and  $(U, \tau_R(X))$  is  $NWg^\#$  connected. Suppose  $(V, \tau_R'(Y))$  is not  $NWg^\#$  connected then  $V = A \cup B$  and  $A \cap B = \{\emptyset\}$  where  $A$  and  $B$  are  $NWg^\#$  open sets in  $(V, \tau_R'(Y))$ . Since  $f$  is  $NWg^\#$  irresolute and surjection,  $X = f^{-1}(A) \cup f^{-1}(B)$  where  $f^{-1}(A)$  and  $f^{-1}(B)$  are disjoint non empty  $NWg^\#$  open subsets of  $(U, \tau_R(X))$ . This contradicts the fact that  $(U, \tau_R(X))$  is  $NWg^\#$  connected. Therefore  $(V, \tau_R'(Y))$  is  $NWg^\#$  connected.

**Nano Weakly  $g^\#$  Homeomorphism in Nano Topological Spaces**

In this section we define and study the concept of Nano Weakly  $g^\#$  homeomorphism in nano topological spaces and obtain some of its properties.

**Definition 4.1.** The function  $f : (U, \tau_R(X)) \longrightarrow (V, \tau_R'(Y))$  is said to be Nano Weakly  $g^\#$  homeomorphism ( $NWg^\#$  homeomorphism) if

- (i)  $f$  is bijective
- (ii)  $f$  is  $NWg^\#$  continuous
- (iii)  $f$  is  $NWg^\#$  open map

**Kalaivani and Nithyakala**

**Example 4.2.** Let  $U = \{a, b, c, d\}$  with  $U / R = \{\{a\}, \{d\}, \{b, c\}\}$  and  $X = \{a, c\}$  then the Nano topology  $\tau_R(X) = \{U, \Phi, \{a\}, \{b, c\}, \{a, b, c\}\}$ . Let  $V = \{x, y, z, w\}$  with  $V / R'(Y) = \{\{y\}, \{w\}, \{x, z\}\}$  and  $Y = \{x, y\}$ . Then the nano topology  $\tau_{R'}(Y) = \{V, \Phi, \{y\}, \{x, z\}, \{x, y, z\}\}$ . Define the bijective function  $f : (U, \tau_R(X)) \rightarrow (V, \tau_{R'}(Y))$  by  $f(a) = \{y\}, f(b) = \{x\}, f(c) = \{z\},$  and  $f(d) = \{w\}$ . Now  $f(a) = y, f(b, c) = \{x, z\}, f(a, b, c) = \{x, y, z\}$ . Thus  $f$  is NWg# open map. Then  $f^{-1}(y) = \{a\}, f^{-1}(x, z) = \{b, c\}$  and  $f^{-1}(x, y, z) = \{a, b, c\}$ . Thus  $f$  is NWg# continuous.  $\longrightarrow$  Hence  $f$  is NWg# homeomorphism in Nano Topological Spaces.

**Theorem 4.3.** Every nano homeomorphism is a NWg# homeomorphism

**Proof:** Let  $f : (U, \tau_R(X)) \rightarrow (V, \tau_{R'}(Y))$  be a nano homeomorphism. The mapping  $f$  is bijective, nano continuous and nano open map. Every nano continuous function is NWg# continuous function. Let  $S$  be a nano open set in  $V$  then  $f^{-1}(S)$  NWg# open in  $U$ . Thus  $f$  is NWg# continuous and every nano open map is NWg# open map. Thus for every open set  $G$  in  $U, f(G)$  is NWg# open in  $V$ . Hence  $f$  is NWg# homeomorphism.

**The contrary of the preceding theorem is not true as evidenced by the following example.**

**Example 4.4.** In example 4.2 define the bijective function  $f : (U, \tau_R(X)) \rightarrow (V, \tau_{R'}(Y))$  by  $f(a) = \{x\}, f(b) = \{z\}, f(c) = \{y\},$  and  $f(d) = \{w\}$ . Then  $f(a) = \{x\}, f(b, c) = \{y, z\}, f(a, b, c) = \{x, y, z\}$  are NWg# open set in  $(V, \tau_{R'}(Y))$ . Then  $f$  is NWg# homeomorphism. The function  $f$  is not nano open map since  $f(a) = \{x\}$  is not nano open in  $(V, \tau_{R'}(Y))$ . The map  $f$  is not nano continuous since  $f^{-1}(y) = \{c\}$  is not nano open in  $(U, \tau_R(X))$ . Hence  $f$  is not nano homeomorphism.

**Theorem 4.5.** Let  $(U, \tau_R(X))$  and  $(V, \tau_{R'}(Y))$  be two nano topological spaces and if  $f : (U, \tau_R(X)) \rightarrow (V, \tau_{R'}(Y))$  then the following statements are true.

- (i) Every Nano  $\alpha$ -homeomorphism is NWg# homeomorphism.
- (ii) Every Nano regular homeomorphism is NWg# homeomorphism but not conversely.
- (iii) Every Nano  $g\alpha$ -homeomorphism is NWg# homeomorphism but not conversely.
- (iv) Every Nano  $ag$ -homeomorphism is NWg# homeomorphism but not conversely.

**Proof:** The proof is similar to theorem 4.3.

**The contrary of the preceding theorem is not true as evidenced by the following example.**

**Example 4.6.** In example 4.2 the function  $f$  is NWg# homeomorphism. The function  $f$  is not nano  $\alpha$  homeomorphism since  $f(a) = \{x\}$  is not nano  $\alpha$  open in  $(V, \tau_{R'}(Y))$  for the nano open set  $\{a\}$  in  $(U, \tau_R(X))$ . Also  $f$  is not nano  $\alpha$  continuous since  $f^{-1}(y) = \{c\}$  is not nano  $\alpha$  open in  $(U, \tau_R(X))$  for the nano open set  $\{y\}$  in  $(V, \tau_{R'}(Y))$ .

**Example 4.7.** Let  $U = \{a, b, c, d\}$  with  $U / R = \{\{a\}, \{d\}, \{b, c\}\}$  and  $X = \{a, c\}$  then the nano topology  $\tau_R(X) = \{U, \Phi, \{a\}, \{b, c\}, \{a, b, c\}\}$ . Let  $V = \{x, y, z, w\}$  with  $V / R'(Y) = \{\{y\}, \{w\}, \{x, z\}\}$  and  $Y = \{x, y\}$  then  $\tau_{R'}(Y) = \{V, \Phi, \{y\}, \{x, z\}, \{x, y, z\}\}$ . Define the bijective function  $f : (U, \tau_R(X)) \rightarrow (V, \tau_{R'}(Y))$  by  $f(a) = y, f(b) = x, f(c) = z$  and  $f(d) = w$ . Then  $f$  is NWg# homeomorphism. Then  $f$  is not nano regular open map since  $f(a, b, c) = \{x, y, z\}$  is not nano regular open set in  $(V, \tau_{R'}(Y))$ .  $\longrightarrow$  Hence  $f$  is not Nano regular homeomorphism.

**Example 4.8.** Let  $U = \{a, b, c, d\}$  with  $U / R = \{\{a\}, \{c\}, \{b, d\}\}$  and  $X = \{b, d\}$  then the Nano open sets of  $U$  with respect to  $X$  is  $\tau_R(X) = \{U, \Phi, \{b, d\}\}$ . Let  $V = \{x, y, z, w\}$  with  $V / R'(Y) = \{\{y\}, \{w\}, \{x, z\}\}$  and  $Y = \{x, y\}$  then the Nano open sets of  $V$  with respect to  $Y$  is  $\tau_{R'}(Y) = \{V, \Phi, \{y\}, \{x, z\}, \{x, y, z\}\}$ . Define bijective function  $f : (U, \tau_R(X)) \rightarrow (V, \tau_{R'}(Y))$  by  $f(a) = w, f(b) = x, f(c) = y$  and  $f(d) = z$ . Hence  $f$  is NWg# homeomorphism but  $f$  is not nano  $ag$  continuous since the open set  $\{y\}$  in  $(V, \tau_{R'}(Y)), f^{-1}(y) = \{c\}$  is not nano  $ag$  open in  $(U, \tau_R(X))$ . Hence  $f$  is not Nano  $ag$  homeomorphism.

**Example 4.9.** Let  $U = \{a, b, c, d\}$  with  $U / R = \{\{b\}, \{d\}, \{a, c\}\}$  and  $X = \{a, b\}$  then the Nano topology with respect to  $X$  is  $\tau_R(X) = \{U, \Phi, \{b\}, \{a, c\}, \{a, b, c\}\}$ . Let  $V = \{x, y, z, w\}$  with  $V / R'(Y) = \{\{x\}, \{z\}, \{y, w\}\}$  and  $Y = \{x, y\}$  then the Nano topology with respect to  $Y$  is  $\tau_{R'}(Y) = \{V, \Phi, \{x\}, \{y, w\}, \{x, y, w\}\}$ . Define bijective function:  $f : (U, \tau_R(X)) \rightarrow (V, \tau_{R'}(Y))$  by  $f(a) = \{x\}, f(b) = \{y\}, f(c) = \{w\}$  and  $f(d) = z$ . Then  $f$  is NWg# homeomorphism but  $f$  is not nano  $g\alpha$  continuous since  $f^{-1}(y, w) = \{b, c\}$  is not nano  $g\alpha$  open in  $(U, \tau_R(X))$ . Hence  $f$  is not Nano  $g\alpha$  homeomorphism.

**Kalaivani and Nithyakala**

**Theorem 4.10.** Let  $(U, \tau_R(X))$  and  $(V, \tau'_R(Y))$  be two nano topological spaces and if  $f : (U, \tau_R(X)) \longrightarrow (V, \tau'_R(Y))$  then  $\longrightarrow$

- (i) Every  $NWg\#$  homeomorphism is Nano  $\beta$ homeomorphism but not conversely.
- (ii) Every  $NWg\#$  homeomorphism is Nano  $gsp$ homeomorphism but not conversely .

Proof of (i) : Let  $f : (U, \tau_R(X)) \longrightarrow (V, \tau'_R(Y))$  be a nano  $NWg\#$  homeomorphism. The map  $f$  is bijective,  $NWg\#$  continuous and  $NWg\#$  open map. Every  $NWg\#$  continuous function is  $N\beta$ -continuous function and every  $NWg\#$  open map is Nano  $\beta$ - open map. Hence  $f$  is Nano  $\beta$  continuous, Nano  $\beta$ - open map and bijective. Therefore  $f$  is Nano  $\beta$ - homeomorphism.

The proof of (ii) is similar to proof of (i).

**The contrary of the preceding theorem is not true as evidenced by the following example.**

**Example 4.11.** Let  $U = \{a, b, c, d\}$  with  $U / R = \{\{a\}, \{c\}, \{b, d\}\}$  and  $X = \{a, b\}$ . Then the Nano topology  $\tau_R(X) = \{U, \Phi, \{a\}, \{b, d\}, \{a, b, d\}\}$ . Let  $V = \{x, y, z, w\}$  with  $V / R' = \{\{y\}, \{w\}, \{x, z\}\}$  and  $Y = \{x, y\}$  and the nano topology  $\tau'_R(Y) = \{V, \Phi, \{y\}, \{x, z\}, \{x, y, z\}\}$ . Define the bijective map  $f : (U, \tau_R(X)) \longrightarrow (V, \tau'_R(Y))$  by  $f(a) = \{y\}, f(b) = \{z\}, f(c) = \{x\}, f(d) = \{w\}$ . Then. Hence  $f$  is Nano  $\beta$ -homeomorphism and Nano  $gsp$ - homeomorphism. But it is not  $NWg\#$  homeomorphism since  $f^{-1}(x, z) = \{b, c\}$  is not  $NWg\#$  open in  $(U, \tau_R(X))$ .

**Theorem 4.12.** Let the bijective function  $f : (U, \tau_R(X)) \longrightarrow (V, \tau'_R(Y))$  be  $NWg\#$  homeomorphism if and only if  $f$  is  $NWg\#$  continuous and  $NWg\#$  closed map.

**Proof:** Assume that the bijective function  $f : (U, \tau_R(X)) \longrightarrow (V, \tau'_R(Y))$  is  $NWg\#$  homeomorphism. Then  $f$  is  $NWg\#$  continuous and  $NWg\#$  open map. Let  $G$  be a nano closed set in  $(U, \tau_R(X))$ . Now  $U - G$  is nano open set in  $(U, \tau_R(X))$ . By assumption  $f$  is  $NWg\#$  open map then  $f(U - G)$  is  $NWg\#$  open set in  $(V, \tau'_R(Y))$ . Now  $f(U) - f(G) = V - f(G)$  is  $NWg\#$  open set in  $(V, \tau'_R(Y))$ . Therefore  $f(G)$  is  $NWg\#$  closed set in  $(V, \tau'_R(Y))$  for every nano closed set  $G$  in  $(U, \tau_R(X))$ . Hence the function  $f$  is  $NWg\#$  closed map.

Conversely assume that  $f : (U, \tau_R(X)) \longrightarrow (V, \tau'_R(Y))$  is  $NWg\#$  continuous and  $NWg\#$  closed. Let  $A$  be a nano open set in  $(U, \tau_R(X))$ . Now  $U - A$  is nano closed in  $(U, \tau_R(X))$ . By assumption  $f$  is  $NWg\#$  closed map,  $f(U - A)$  is  $NWg\#$  closed in  $(V, \tau'_R(Y))$ . Now  $f(U - A) = f(U) - f(A) = V - f(A)$  is  $NWg\#$  closed in  $(V, \tau'_R(Y))$ . Therefore  $f(A)$  is  $NWg\#$  open in  $(V, \tau'_R(Y))$  for every nano open set  $A$  in  $(U, \tau_R(X))$ . Thus  $f$  is  $NWg\#$  open map. Hence  $f$  is  $NWg\#$  homeomorphism.

**Theorem 4.13.** A bijective function  $f : (U, \tau_R(X)) \longrightarrow (V, \tau'_R(Y))$  is  $NWg\#$  continuous the following statements are equivalent.

- (i)  $f$  is  $NWg\#$  open map.
- (ii)  $f$  is  $NWg\#$  homeomorphism.
- (iii)  $f$  is  $NWg\#$  closed map.

**proof: (i)  $\rightarrow$  (ii)** The bijective function  $f : (U, \tau_R(X)) \longrightarrow (V, \tau'_R(Y))$  is  $NWg\#$  continuous and  $NWg\#$  open map. By definition 6.1,  $f$  is  $NWg\#$  homeomorphism.

**(ii)  $\rightarrow$  (iii)** Assume that  $f$  is  $NWg\#$  homeomorphism  $\Rightarrow f$  is bijective,  $NWg\#$  continuous and  $NWg\#$  open map. Let  $A$  be a nano closed set in  $(U, \tau_R(X))$ . Now  $U - A$  is nano open set in  $(U, \tau_R(X))$ . By assumption  $f$  is  $NWg\#$  open map,  $f(U - A)$  is  $NWg\#$  open in  $(V, \tau'_R(Y))$  and  $f(U - A) = f(U) - f(A) = V - f(A)$  is  $NWg\#$  open in  $(V, \tau'_R(Y))$ . Thus  $f(A)$  is  $NWg\#$  closed in  $(V, \tau'_R(Y))$  for every nano closed set  $A$  in  $(U, \tau_R(X))$ . Hence the map  $f$  is  $NWg\#$  closed map.

**(iii)  $\rightarrow$  (i)** Assume that  $f$  is  $NWg\#$  closed map. Let  $B$  be a nano open set in  $(U, \tau_R(X))$ . Then  $U - B$  is nano closed set in  $(U, \tau_R(X))$ . By assumption,  $f(U - B)$  is  $NWg\#$  closed set in  $(V, \tau'_R(Y))$ . Now  $f(U - B) = f(U) - f(B) = V - f(B)$  is  $NWg\#$  closed set in  $(V, \tau'_R(Y))$ . Hence  $f(B)$  is  $NWg\#$  open set in  $(V, \tau'_R(Y))$  for every nano open set  $B$  in  $(U, \tau_R(X))$ . Hence  $f$  is  $NWg\#$  open map.

**Remark 4.14.** The composition of two  $NWg\#$  homeomorphism is  $NWg\#$  homeomorphism as seen in the following example.

### Kalaivani and Nithyakala

**Example 4.15.** Let  $U = \{a, b, c, d\}$  with  $U / R = \{\{a\}, \{d\}, \{b, c\}\}$  and  $X = \{a, c\}$  then the Nano topology  $\tau_R(X) = \{U, \Phi, \{a\}, \{b, c\}, \{a, b, c\}\}$ . Let  $V = \{x, y, z, w\}$  with  $V / R' = \{\{y\}, \{w\}, \{x, z\}\}$  and  $Y = \{x, y\}$  then the nano topology  $\tau_{R'}(Y) = \{V, \Phi, \{y\}, \{x, z\}, \{x, y, z\}\}$ .

Define the bijective map  $f: (U, \tau_R(X)) \longrightarrow (V, \tau_{R'}(Y))$  by  $f(a) = y, f(b) = x, f(c) = z$  and  $f(d) = w$ . Now  $f(a) = y, f(b, c) = \{x, z\}, f(a, b, c) = \{x, y, z\}$ . Then  $f$  is  $NWg\#$  homeomorphism.

Let  $W = \{p, q, r, s\}$  with  $W / R'' = \{\{p\}, \{r\}, \{q, s\}\}$  and  $Z = \{p, q\}$  then the nano topology with respect to  $W$  is  $\tau_{R''}(W) = \{W, \Phi, \{p\}, \{q, s\}, \{p, q, s\}\}$ .

Define the bijective map  $g: (V, \tau_{R'}(Y)) \longrightarrow (W, \tau_{R''}(Z))$  by  $g(x) = q, g(y) = p, g(z) = s$ , and  $g(w) = r$ . Now  $g(y) = \{p\}, g(x, z) = \{q, s\}, g(x, y, z) = \{p, q, s\}$ . Then  $g$  is  $NWg\#$  homeomorphism.

The composition of two homeomorphisms  $g$  and  $f$  is given by  $(g \circ f): (U, \tau_R(X)) \longrightarrow (W, \tau_{R''}(Z))$  by  $(g \circ f)(a) = \{p\}, (g \circ f)(b) = \{q\}, (g \circ f)(c) = \{s\}, (g \circ f)(d) = \{r\}$ . Then  $\longrightarrow (g \circ f): (U, \tau_R(X)) \longrightarrow (W, \tau_{R''}(Z))$  is  $NWg\#$  homeomorphism.

## CONCLUSION

In this article we have introduced the concept of new classes of functions Nano weakly  $g\#$  irresolute functions and Nano weakly  $g\#$  homeomorphisms in nano topological spaces. Some of its properties have been discussed with suitable examples. The proposed definitions can be applied and extended to future research with some applications.

## ABSTRACT

In this article, we introduced the concept of defuzzification to transform interval-valued Pythagorean fuzzy soft matrix values into crisp values. This was achieved by utilizing three methods: Arithmetic Mean, Geometric Mean, and Harmonic Mean. We provided illustrative examples for each of these methods. Additionally, a new algorithm was developed using the defuzzification technique for medical diagnosis. A numerical example was included to demonstrate how this approach can be applied to diagnose a patient's disease.

**Keywords:** Soft sets, Fuzzy soft set, Pythagorean fuzzy set, Pythagorean fuzzy soft set, interval-valued Pythagorean fuzzy set, interval valued Pythagorean fuzzy soft set, interval valued Pythagorean fuzzy soft matrix.

## INTRODUCTION

The application of engineering, social science, economics, medical science, decision-making, and other fields that entail a great deal of uncertainty to real-world situations presents us with numerous challenges. The classical set theory and its techniques are insufficient for resolving these issues. To address this kind of issue, Zadeh[1] created the notion of a classical fuzzy set. Atanassov [2] developed the idea of an intuitionistic fuzzy set for further research in this area. The intuitionistic fuzzy set was expanded by Atanassov and Gargov [3] to the interval valued intuitionistic fuzzy set, which is defined by a membership function and a non membership function with interval-

**Rajarajeswari et al.,**

like values. Molodtsov [4] established the soft set theory, which aids in object parameterization. In the future, Maji P. K., Biswas R., and Roy A. R.[6] presented the idea of fuzzy soft sets and later developed it into IFSS (Intuitionistic Fuzzy Soft Sets). Following this because of the scientific environment's increasing complexity. Interval valued intuitionistic fuzzy soft set theory, an expansion of intuitionistic fuzzy soft set theory, was introduced by Y. Jiang et al. [7].

In research and engineering, matrices are essential tools. The traditional matrix theory is inadequate for dealing with problems containing uncertainties. In order to express the fuzzy soft set in matrix form and apply it to specific decision-making issues, Yong et al. [9] studies a few outcomes of the intuitionistic fuzzy soft matrix theory. Interval valued intuitionistic fuzzy soft matrices and their types were introduced by Rajarajeswari et al. [10], who also examined several operations based on weights. PFS, which is the membership and non-membership degree whose square sum is less than or equal to one was introduced by Yager R. R.[11]because IVIFSM cannot contain more information for decision making. Abhishek Guleria and Rakesh Kumar Bajaj defined the PFSM for a certain set of MCDM issues[12]. Later IVPFSS and IVPFSM were defined by Rajarajeswari and MathiSujitha[13, 14] for better decision making. In this research paper, a new algorithm is developed for finding the optimal solution in the field of medical diagnosis using defuzzification technique.

**PRELIMINARIES**

In this section, we recall some basic definitions such as soft set, fuzzy soft set, Pythagorean fuzzy set, Pythagorean fuzzy soft set and interval valued Pythagorean fuzzy set and soft set.

**Definition 2.1.[4]**Suppose that U is an initial Universe set and E is a set of parameters, let P(U) denotes the power set of U. A pair(F,E) is called a soft set over U where F is a mapping given by F: E →P(U). Clearly, a soft set is a mapping from parameters to P(U) and it is not a set, but a parameterized family of subsets of the Universe.

**Definition 2.2.[5]** Let U be an initial Universe set and E be the set of parameters. Let A ⊆ E. A pair (F,A) is called fuzzy soft set over U where F is a mapping given by F: A → I<sup>U</sup> where I<sup>U</sup> denotes the collection of all fuzzy subsets of U.

**Definition 2.3.[8]** Let U = {c<sub>1</sub>,c<sub>2</sub>,c<sub>3</sub>,...,c<sub>m</sub>} be the Universal set and E be the set of parameters given by E = {e<sub>1</sub>,e<sub>2</sub>,e<sub>3</sub>,...,e<sub>n</sub>}. Let A ⊆ E and (F,A) be a fuzzy soft set in the fuzzy soft class (U,E). Then fuzzy soft set (F,A) in a matrix form as A<sub>m×n</sub>

$$= [a_{ij}]_{m \times n} \text{ or } A = [a_{ij}] \text{ } i = 1,2,\dots,m, j = 1,2,3,\dots,n \text{ where } a_{ij} = \begin{cases} \mu_j(c_i) & \text{if } e_j \in A \\ 0 & \text{if } e_j \notin A \end{cases}$$

$\mu_j(c_i)$  represents the membership of  $c_i$  in the fuzzy set  $F(e_j)$ .

**Definition 2.4[11]:**Pythagorean fuzzy set,A is defined as a set of ordered pairs over a universal set X given by  $A = \{ \langle x, \mu_A(x), \vartheta_A(x) \rangle \mid x \in X \}$ , where  $\mu_A, \vartheta_A: X \rightarrow [0, 1]$  are the degrees of membership and nonmembership of the element  $x \in X$ , respectively, with the condition that  $(\mu_A(x))^2 + (\vartheta_A(x))^2 \leq 1$ . Corresponding to its membership

functions, the degree of indeterminacy is given by  $\pi_A(x) = \sqrt{1 - (\mu_A(x))^2 - (\vartheta_A(x))^2}$ .

**Definition 2.5[15]:**A pair (F,E) is called Pythagorean fuzzy soft set if a map F : E → P<sup>U</sup> defined as  $F_{u_i}(e_j) = \{(u_i, \zeta_j(u_i), \vartheta_j(u_i)) : u_i \in U \text{ where } P^U \text{ is the Pythagorean fuzzy subset of } U \text{ and } \zeta, \vartheta \text{ satisfies } \zeta^2 + \vartheta^2 \leq 1 \text{ for all } u_i \in U. \text{ A pair } (F,E) \text{ is termed as Pythagorean soft set and denote } F_{u_i}(e_j) = \{(u_i, \zeta_j(u_i), \vartheta_j(u_i)) \text{ called as Pythagorean fuzzy soft number (PFSN) with } \zeta_{F(e_j)}^2 + \vartheta_{F(e_j)}^2 \leq 1 \text{ for } \zeta_{F(e_j)}^2, \vartheta_{F(e_j)}^2 \in [0,1].$

**Definition 2.6[16]:**Let X be the universe of discourse. An interval-valued Pythagorean fuzzy set (IVPFS) A defined in X is given as  $A = \{ \langle x, [\mu_A^L(x), \mu_A^U(x)], [\vartheta_A^L(x), \vartheta_A^U(x)] \rangle : x \in X \}$ , where  $0 \leq \mu_A^L(x) \leq \mu_A^U(x) \leq 1, 0 \leq \vartheta_A^L(x) \leq$

$\vartheta_A^U(x) \leq 1$  and  $(\mu_A^U(x))^2 + (\vartheta_A^U(x))^2 \leq 1$  for all  $x \in X$ . Similar to PFSs, corresponding to interval-valued membership values, its hesitation interval relative to A is given as

$$\pi_A(x) = \left[ \sqrt{1 - (\mu_A^U(x))^2 - (\vartheta_A^U(x))^2}, \sqrt{1 - (\mu_A^L(x))^2 - (\vartheta_A^L(x))^2} \right].$$

**Rajarajeswari et al.,**

If for every  $x \in X$ ,  $\mu_A(x) = \mu_A^L(x) = \mu_A^U(x)$ ,  $\vartheta_A(x) = \vartheta_A^L(x) = \vartheta_A^U(x)$ , then IVPFS reduces to PFS. For an IVPFS  $A$ , the pair  $\langle [\mu_A^L(x), \mu_A^U(x)], [\vartheta_A^L(x), \vartheta_A^U(x)] \rangle$  is called an interval-valued Pythagorean fuzzy number (IVPFN). For convenience, this pair is often denoted by  $\alpha = \langle [a, b], [c, d] \rangle$ , where  $[a, b] \subseteq [0, 1]$ ,  $[c, d] \subseteq [0, 1]$ , and  $b^2 + d^2 \leq 1$ .

**Definition 2.7[13]:** Let the parameter set be  $\mathbb{E}$ . Let  $\mathcal{A} \subseteq \mathbb{E}$ . A pair  $(f, \mathcal{A})$  is called an interval-valued Pythagorean fuzzy soft set (IVPFSS) over  $\mathbb{U}$ , where  $\mathbb{U}$  is the universe and  $f$  is a mapping given by  $f: \mathcal{A} \rightarrow IP^{\mathbb{U}}$ , where  $IP^{\mathbb{U}}$  denotes the collection of all interval-valued Pythagorean fuzzy subsets of  $\mathbb{U}$ .

**Definition 2.8[12]:** If  $(F_A, E)$  be a Pythagorean fuzzy soft set over  $X$ , then the subset  $X \times E$  is uniquely defined by  $R_A = \{(x, e), e \in A, x \in F_A(e)\}$ . The  $R_A$  can be characterized by its membership function and non membership function given by  $\mu_{R_A}: X \times E \rightarrow [0,1]$  and  $\vartheta_{R_A}: X \times E \rightarrow [0,1]$ , respectively.

If  $(\mu_{ij}, \vartheta_{ij}) = (\mu_{R_A}(x_i, e_j), \vartheta_{R_A}(x_i, e_j))$ , where  $\mu_{R_A}(x_i, e_j)$  is the membership of  $x_i$  in the Pythagorean fuzzy set  $F(e_j)$  and  $\vartheta_{R_A}(x_i, e_j)$  is the non membership of  $x_i$  in the Pythagorean fuzzy set  $F(e_j)$ , respectively, then we define a

matrix given by  $[M] = [m_{ij}]_{m \times n} = [(\mu_{ij}^M, \vartheta_{ij}^M)]_{m \times n} = \begin{bmatrix} (\mu_{11}, \vartheta_{11}) & (\mu_{12}, \vartheta_{12}) & \dots & (\mu_{1n}, \vartheta_{1n}) \\ (\mu_{21}, \vartheta_{21}) & (\mu_{22}, \vartheta_{22}) & \dots & (\mu_{2n}, \vartheta_{2n}) \\ \vdots & \vdots & \vdots & \vdots \\ (\mu_{m1}, \vartheta_{m1}) & (\mu_{m2}, \vartheta_{m2}) & \dots & (\mu_{mn}, \vartheta_{mn}) \end{bmatrix}$  which is called

Pythagorean fuzzy soft matrix of order  $m \times n$  over  $X$ .

**Definition 2.9[14]:** Let  $\mathcal{A} \subseteq \mathbb{E}$ ,  $\mathbb{E} = \{e_1, e_2, \dots, e_n\}$  being the parameter set. A pair  $(f, \mathcal{A})$  is called an interval-valued Pythagorean fuzzy soft set (IVPFSS) over  $\mathbb{U}$ , where  $\mathbb{U} = \{u_1, u_2, \dots, u_m\}$  is the universe and  $f$  is a mapping given by  $f: \mathcal{A} \rightarrow IP^{\mathbb{U}}$ , where  $IP^{\mathbb{U}}$  characterize the collection of all interval-valued Pythagorean fuzzy subsets of  $\mathbb{U}$ . Then the IVPFSS can be symbolized in the matrix form as  $\mathcal{A}_{m \times n}^* = [a_{ij}]_{m \times n}$  where

$$a_{ij} = \begin{cases} ([\mu_j^L(u_i), \mu_j^U(u_i)], [\vartheta_j^L(u_i), \vartheta_j^U(u_i)]) & \text{if } e_j \in \mathcal{A} \\ ([0, 0], [1, 1]) & \text{if } e_j \notin \mathcal{A} \end{cases}$$

$[\mu_j^L(u_i), \mu_j^U(u_i)]$  is the membership of  $u_i$  in  $f(e_j)$ ,  $[\vartheta_j^L(u_i), \vartheta_j^U(u_i)]$  is the non - membership of  $u_i$  in  $f(e_j)$  with the condition  $(\mu_j^U(u_i))^2 + (\vartheta_j^U(u_i))^2 \leq 1$ .

**Application of interval valued Pythagorean fuzzy soft matrix using defuzzification in medical diagnosis**

Throughout this segment, an algorithm is developed to diagnose a patient 's disease in a hospital using medical records. This algorithm is based on a defuzzification technique that employs Arithmetic Mean, Geometric Mean, and Harmonic Mean to convert interval valued Pythagorean fuzzy values into crisp values. This conversion facilitates a more precise and straightforward interpretation of the medical data, enhancing the accuracy and reliability of the diagnosis.

**Definition 3.1:** If  $A^* = [a_{ij}]_{m \times n} \in$  IVPFSM then

- i) Arithmetic mean of IVPFSM  $A^*$  is  $A_{AM}^* = [c_{ij}] = \frac{\mu_{a_{ij}}^L + \mu_{a_{ij}}^U + \vartheta_{a_{ij}}^L + \vartheta_{a_{ij}}^U}{4}$
- ii) Geometric mean of IVPFSM  $A^*$  is  $A_{GM}^* = [c_{ij}] = [\mu_{a_{ij}}^L \times \mu_{a_{ij}}^U \times \vartheta_{a_{ij}}^L \times \vartheta_{a_{ij}}^U]^{\frac{1}{4}}$
- iii) Harmonic mean of IVPFSM  $A^*$  is  $A_{HM}^* = [c_{ij}] = \frac{4}{\frac{1}{\mu_{a_{ij}}^L} + \frac{1}{\mu_{a_{ij}}^U} + \frac{1}{\vartheta_{a_{ij}}^L} + \frac{1}{\vartheta_{a_{ij}}^U}}$

**Example 3.2.** Consider  $A^* = [a_{ij}]_{m \times n} \in$  IVPFSM the

$$A^* = \begin{pmatrix} [0.4,0.6][0.6,0.8] & [0.6,0.7][0.4,0.5] \\ [0.6,0.8][0.3,0.5] & [0.7,0.85][0.3,0.5] \end{pmatrix}$$

Then i) Arithmetic mean of IVPFSM  $A^*$  is  $A_{AM}^* = \begin{pmatrix} 0.6 & 0.55 \\ 0.55 & 0.58754 \end{pmatrix}$

Rajarajeswari et al.,

- ii) Geometric mean of IVPFSM  $A^*$  is  $A_{GM}^* = \begin{pmatrix} 0.5825 & 0.5383 \\ 0.5780 & 0.5465 \end{pmatrix}$
- iii) Harmonic mean of IVPFSM  $A^*$  is  $A_{HM}^* = \begin{pmatrix} 0.5647 & 0.5266 \\ 0.4848 & 0.5038 \end{pmatrix}$

## METHODOLOGY

Let there be a set of ‘m’ patients  $\mathbb{P} = \{p_1, p_2, \dots, p_m\}$  with a set of ‘n’ symptoms  $\mathbb{S} = \{s_1, s_2, \dots, s_n\}$  related to k’ diseases,  $\mathbb{D} = \{d_1, d_2, \dots, d_k\}$ . To diagnosis the disease of a patient, IVPFSM is employed.

Construct an IVPFSS (f,  $\mathbb{P}$ ) over  $\mathbb{S}$  and (g,  $\mathbb{S}$ ) over  $\mathbb{D}$ , where f and g is a mapping given by  $f : \mathbb{P} \rightarrow IV\ PF^S$  and  $g : \mathbb{S} \rightarrow IV\ PF^D$ ,  $IV\ PF^S$ ,  $IV\ PF^D$  is the collection of all intervalvalued Pythagorean fuzzy subsets of  $\mathbb{S}$  and  $\mathbb{D}$ . Hence this IVPFSS gives the matrix  $A^*_{m \times n}$  which relates patient to symptoms and the matrix  $B^*_{m \times n}$  which relates symptoms to diseases. Construct the complement of IVPFSS (f,  $\mathbb{P}$ ) and (g,  $\mathbb{S}$ ) and their corresponding IVPFSMA<sup>\*c</sup> and B<sup>\*c</sup>. Find the product of  $A^*$  and  $B^*$  which represents the maximum membership of occurrence of symptoms of the diseases. Also, find the product of  $A^{*c}$  and  $B^{*c}$  which represents the maximum membership of non-occurrence of symptoms of the diseases. Compute the value of the matrix. Hence by using the maximum value of the matrix, we can conclude that the patient  $p_i$  is suffering from the disease  $d_j$ .

### Algorithm

Step 1: Input the IVPFSS (f,  $\mathbb{E}$ ) and (g,  $\mathbb{E}$ ) and obtain the IVPFSM  $A^*_{m \times n}$  and  $B^*_{m \times n}$  corresponding to (f,  $\mathbb{E}$ ) and (g,  $\mathbb{E}$ ) respectively.

Step 2: Compute the complement matrices  $A^{*c}$  and  $B^{*c}$  corresponding to IVPFSS (f,  $\mathbb{E}$ )<sup>c</sup> and (g,  $\mathbb{E}$ )<sup>c</sup>.

Step 3: Compute the product of  $A^* \times B^*$  and  $A^{*c} \times B^{*c}$ .

Step 4: Convert the product of IVPFSM  $A^* \times B^*$  and  $A^{*c} \times B^{*c}$  into crisp values by defuzzification using Arithmetic mean, Geometric mean and Harmonic mean defined in the Definition mentioned above.

Step 5: Compute the value of matrices between  $A^* \times B^*$  and  $A^{*c} \times B^{*c}$ .

Step 6: Find the maximum score from the score matrix to identify that the patient  $p_i$  is affected by the disease  $d_j$ .

**Example 3.3.** Let us consider that there are four patients  $\mathbb{P} = \{p_1, p_2, p_3, p_4\}$  with set of symptoms  $\mathbb{S} = \{s_1, s_2, s_3, s_4\}$ , where  $s_1$  = headache,  $s_2$  = temperature,  $s_3$  = cough,  $s_4$  = body pain, related to the diseases  $\mathbb{D} = \{d_1, d_2, d_3, d_4\}$  where  $d_1$  = malaria,  $d_2$  = typhoid,  $d_3$  = viral fever,  $d_4$  = stomach problem.

Let the IVPFSS (f,  $\mathbb{S}$ ) over  $\mathbb{D}$ , where f is a mapping  $f : \mathbb{S} \rightarrow IV\ PFS$  which provides a detailed overview of patient symptoms observed in a hospital.

**Step 1:** Input the IVPFSS (f,  $\mathbb{S}$ ) and (g,  $\mathbb{D}$ ) and obtain the IVPFSM  $A^*_{m \times n}$  and  $B^*_{m \times n}$  corresponding to (f,  $\mathbb{S}$ ) and (g,  $\mathbb{D}$ ) respectively.

$$f(s_1) = \{p_1/[0.7,0.9][0.1,0.4] + p_2/[0.3,0.5][0.6,0.8] + p_3/[0.5,0.7][0.4,0.6] + p_4/[0.6,0.8][0.3,0.5]\},$$

$$f(s_2) = \{p_1/[0.7,0.9][0.1,0.4] + p_2/[0.5,0.7][0.4,0.6] + p_3/[0.1,0.3][0.7,0.9] + p_4/[0.1,0.4][0.7,0.9]\},$$

$$f(s_3) = \{p_1/[0.7,0.9][0.1,0.4] + p_2/[0.4,0.6][0.5,0.7] + p_3/[0.3,0.5][0.7,0.85] + p_4/[0.3,0.5][0.6,0.8]\},$$

$$f(s_4) = \{p_1/[0.8,0.95][0.2,0.3] + p_2/[0.7,0.85][0.4,0.5] + p_3/[0.6,0.7][0.3,0.5] + p_4/[0.4,0.6][0.5,0.7]\}.$$

The above mentioned IVPFSS can be depicted in matrix form as,

$$A^*_{m \times n} = \begin{pmatrix} ([0.1,0.4], [0.7,0.9]) & ([0.7,0.9], [0.1,0.4]) & ([0.8,0.95], [0.2,0.3]) & ([0.8,0.95], [0.2,0.3]) \\ ([0.3,0.5], [0.6,0.8]) & ([0.5,0.7], [0.4,0.6]) & ([0.4,0.6], [0.5,0.7]) & ([0.7,0.85], [0.4,0.5]) \\ ([0.5,0.7], [0.4,0.6]) & ([0.1,0.3], [0.8,0.95]) & ([0.3,0.5], [0.7,0.85]) & ([0.6,0.7], [0.3,0.5]) \\ ([0.6,0.8], [0.3,0.5]) & ([0.1,0.4], [0.7,0.9]) & ([0.3,0.5], [0.6,0.8]) & ([0.4,0.6], [0.5,0.7]) \end{pmatrix}$$

**Rajarajeswari et al.,**

Next, consider the IVPFSS (g , D) over S where g isa mapping  $g : D \rightarrow IVPF^D$  which provides a comprehensive description of medical knowledge of the diagnosis and this symptoms.

$$(g, \mathbb{D}) = \{g(d_1) = \{s_1/[0.4,0.6][0.6,0.8] + s_2/[0.6,0.8][0.3,0.4] + s_3/[0.3,0.5][0.7,0.85] + s_4/[0.3,0.4][0.8,0.9]\}, \\ g(d_2) = \{s_1/[0.3,0.5][0.6,0.8] + s_2/[0.4,0.6][0.5,0.7] + s_3/[0.6,0.8][0.3,0.5] + s_4/[0.8,0.9][0.3,0.4]\}, \\ g(d_3) = \{s_1/[0.7,0.85][0.4,0.5] + s_2/[0.3,0.5][0.6,0.8] + s_3/[0.2,0.35][0.8,0.9] + s_4/[0.7,0.85][0.4,0.5]\}\}.$$

The above collection can be arranged in matrix format as,

$$B^*_{m \times n} = \begin{pmatrix} ([0.4,0.6], [0.6,0.8]) & ([0.3,0.5], [0.6,0.8]) & ([0.7,0.85], [0.4,0.5]) \\ ([0.6,0.8], [0.3,0.4]) & ([0.4,0.6], [0.5,0.7]) & ([0.3,0.5], [0.6,0.8]) \\ ([0.3,0.5], [0.7,0.85]) & ([0.6,0.8], [0.3,0.5]) & ([0.2,0.35], [0.8,0.9]) \\ ([0.3,0.4], [0.8,0.9]) & ([0.8,0.9], [0.3,0.4]) & ([0.7,0.85], [0.4,0.5]) \end{pmatrix}$$

**Step 2:** To find the complement matrix

$$A^{*m \times n^c} = \begin{pmatrix} ([0.7,0.9], [0.1,0.4]) & ([0.1,0.4], [0.7,0.9]) & ([0.2,0.3], [0.8,0.95]) & ([0.2,0.3], [0.8,0.95]) \\ ([0.6,0.8], [0.3,0.5]) & ([0.4,0.6], [0.5,0.7]) & ([0.5,0.7], [0.4,0.6]) & ([0.7,0.85], [0.4,0.5]) \\ ([0.4,0.6], [0.5,0.7]) & ([0.8,0.95], [0.1,0.3]) & ([0.7,0.85], [0.3,0.5]) & ([0.3,0.5], [0.6,0.7]) \\ ([0.3,0.5], [0.6,0.8]) & ([0.7,0.9], [0.1,0.4]) & ([0.6,0.8], [0.3,0.5]) & ([0.5,0.7], [0.4,0.6]) \end{pmatrix}$$

$$B^{*c}_{m \times n} = \begin{pmatrix} ([0.6,0.8], [0.4,0.6]) & ([0.6,0.8], [0.3,0.5]) & ([0.4,0.5], [0.7,0.85]) \\ ([0.3,0.4], [0.6,0.8]) & ([0.5,0.7], [0.4,0.6]) & ([0.6,0.8], [0.3,0.5]) \\ ([0.7,0.85], [0.3,0.5]) & ([0.3,0.5], [0.6,0.8]) & ([0.8,0.9], [0.2,0.35]) \\ ([0.8,0.9], [0.3,0.4]) & ([0.3,0.4], [0.8,0.9]) & ([0.4,0.5], [0.7,0.85]) \end{pmatrix}$$

**Step 3:** Compute the product of these matrices

$$A_{m \times n}^* \times B_{m \times n}^* = \begin{pmatrix} ([0.6,0.8], [0.3,0.4]) & ([0.8,0.9], [0.3,0.4]) & ([0.7,0.85], [0.4,0.5]) \\ ([0.5,0.7], [0.4,0.6]) & ([0.7,0.85], [0.4,0.5]) & ([0.7,0.85], [0.4,0.5]) \\ ([0.4,0.6], [0.6,0.8]) & ([0.6,0.7], [0.3,0.5]) & ([0.6,0.7], [0.4,0.5]) \\ ([0.4,0.6], [0.6,0.8]) & ([0.4,0.6], [0.5,0.7]) & ([0.6,0.8], [0.4,0.5]) \end{pmatrix}$$

$$A_{m \times n}^{*c} \times B_{m \times n}^{*c} = \begin{pmatrix} ([0.6,0.8], [0.4,0.6]) & ([0.6,0.8], [0.3,0.5]) & ([0.4,0.5], [0.7,0.85]) \\ ([0.6,0.8], [0.4,0.6]) & ([0.6,0.8], [0.3,0.5]) & ([0.5,0.7], [0.5,0.6]) \\ ([0.7,0.85], [0.3,0.5]) & ([0.5,0.7], [0.4,0.6]) & ([0.7,0.85], [0.3,0.5]) \\ ([0.6,0.8], [0.3,0.5]) & ([0.5,0.7], [0.4,0.6]) & ([0.6,0.8], [0.3,0.5]) \end{pmatrix}$$

**Step 4:** Convert the product of IVPFSM ( $A^* \times B^*$ ) and  $A^{*c} \times B^{*c}$  into crisp values by defuzzification using Arithmetic mean, Geometric mean and Harmonic mean.

**Defuzzification using Arithmetic mean:**

The above product matrices  $A^*_{m \times n} \times B^*_{m \times n}$  and  $A^{*c}_{m \times n} \times B^{*c}_{m \times n}$  can be defuzzified using Arithmetic mean as follows:

$$(A_{m \times n}^* \times B_{m \times n}^*)_{AM} = \begin{pmatrix} 0.525 & 0.6 & 0.6125 \\ 0.55 & 0.6125 & 0.5875 \\ 0.6 & 0.525 & 0.55 \\ 0.6 & 0.55 & 0.55 \end{pmatrix}$$

$$(A_{m \times n}^{*c} \times B_{m \times n}^{*c})_{AM} = \begin{pmatrix} 0.6 & 0.55 & 0.6125 \\ 0.6 & 0.55 & 0.575 \\ 0.5875 & 0.55 & 0.5875 \\ 0.55 & 0.55 & 0.55 \end{pmatrix}$$

The value of the matrices is V =

$$(A^* \times B^*)_{AM} - (A^{*c} \times B^{*c})_{AM} = \begin{pmatrix} -0.075 & 0.05 & 0 \\ -0.05 & 0.0625 & 0.0125 \\ 0.0125 & -0.025 & -0.0375 \\ 0.05 & 0 & 0.025 \end{pmatrix}$$

Clearly from the value of the matrix, the patients  $p_1, p_2$  is affected by the disease  $d_2$  since  $d_2$  has the maximum value 0.05 and 0.0625 and the patients  $p_3, p_4$  is affected by the disease  $d_1$  since  $d_1$  has the maximum value 0.0125 and 0.05.

**Defuzzification using geometric mean:**

The above product matrices  $A^*_{m \times n} \times B^*_{m \times n}$  and  $A_{m \times n}^{*c} \times B_{m \times n}^{*c}$  can be defuzzified using Geometric mean as follows:

Rajarajeswari et al.,

$$(A_{m \times n} * \times B_{m \times n} *)_{GM} = \begin{pmatrix} 0.4898 & 0.5421 & 0.5873 \\ 0.5383 & 0.5873 & 0.5651 \\ 0.5825 & 0.5009 & 0.5383 \\ 0.5825 & 0.5383 & 0.5566 \end{pmatrix}$$

$$(A_{m \times n} *^C \times B_{m \times n} *^C)_{GM} = \begin{pmatrix} 0.5825 & 0.5280 & 0.5813 \\ 0.5825 & 0.5180 & 0.5692 \\ 0.5465 & 0.5383 & 0.5465 \\ 0.5180 & 0.5383 & 0.5180 \end{pmatrix}$$

The value of the matrices is V =

$$(A * \times B *)_{GM} - (A *^C \times B *^C)_{GM} = \begin{pmatrix} -0.0927 & 0.0241 & 0 \\ -0.0442 & 0.0693 & -0.004 \\ 0.0360 & -0.0374 & -0.0082 \\ 0.0645 & 0 & 0.0386 \end{pmatrix}$$

Clearly from the value of the matrix, the patients  $p_1, p_2$  is affected by the disease  $d_2$  since  $d_2$  has the maximum value 0.0241 and 0.0693 and the patients  $p_3, p_4$  is affected by the disease  $d_1$  since  $d_1$  has the maximum value 0.0360 and 0.0645.

**Defuzzification using Harmonic mean:**

The above product matrices  $A *_{m \times n} \times B *_{m \times n}$  and  $A *^C_{m \times n} \times B *^C_{m \times n}$  can be defuzzified using Harmonic mean as follows:

$$(A_{m \times n} * \times B_{m \times n} *)_{HM} = \begin{pmatrix} 0.4571 & 0.4881 & 0.5629 \\ 0.5266 & 0.5629 & 0.5447 \\ 0.5647 & 0.4745 & 0.5244 \\ 0.5647 & 0.5226 & 0.5393 \end{pmatrix}$$

$$(A_{m \times n} *^C \times B_{m \times n} *^C)_{HM} = \begin{pmatrix} 0.5647 & 0.4848 & 0.5629 \\ 0.5647 & 0.4848 & 0.5637 \\ 0.5038 & 0.5266 & 0.5038 \\ 0.4848 & 0.5266 & 0.4848 \end{pmatrix}$$

The value of the matrices is V=

$$(A * \times B *)_{HM} - (A *^C \times B *^C)_{HM} = \begin{pmatrix} -0.1076 & 0.0033 & 0 \\ -0.0381 & 0.0442 & -0.0190 \\ 0.0609 & -0.0521 & 0.0228 \\ 0.0799 & 0 & 0.0545 \end{pmatrix}$$

Clearly from the value of the matrix, the patients  $p_1, p_2$  is affected by the disease  $d_2$  since  $d_2$  has the maximum value 0.0033 and 0.0442 and the patients  $p_3, p_4$  is affected by the disease  $d_1$  since  $d_1$  has the maximum value 0.0609 and 0.0799.

**CONCLUSION**

In this article, the IVPFSM is converted into crisp values through the process of defuzzification using three different means: Arithmetic mean, Geometric mean, and Harmonic mean. An algorithm has been developed to diagnose whether the patient  $p_i$  affected by the disease  $d_j$ . The analysis reveals that, regardless of the defuzzification method used, patients  $p_1$  and  $p_2$  are affected by disease  $d_2$ , and patients  $p_3$  and  $p_4$  are affected by disease  $d_1$ , as these diseases have the maximum values in the defuzzified results.

### ABSTRACT

**Abstract.** A topological index is a derived numerical index- analytically for the graph structure. In this paper, we study some of the distance-based indices of  $K_m\{K_n\}$  and  $K_m\{\bar{K}_n\}$

MSC : 05C12, 05C76

**Keywords:** Topological indices, Cluster graph.

## INTRODUCTION

In this paper, we consider only finite simple connected undirected graphs [3] and [4]. The eccentricity of a vertex  $u$  in a graph  $G$  is  $e(u) = \max \{d(u, v) : v \in V(G)\}$ . The radius (resp. diameter) of  $G$  is  $r = \text{rad}(G) = \min \{e(v) : v \in V(G)\}$  (resp.  $d = \text{diam}(G) = \max \{e(v) : v \in V(G)\}$ ). The Complement of a graph  $G$  is a graph  $\bar{G}$  on the same set of vertices as of  $G$  such that there will be an edge between two vertices in  $\bar{G}$  iff there is no edge in between in  $G$ . A graph  $G$  in which every pair of vertices is joined by exactly one edge is called complete graph. A complete graph on  $n$  vertices is denoted by  $K_n$  and complement of the complete graph on  $n$  vertices is denoted by  $\bar{K}_n$ . The Wiener index is the distance based topological index introduced by the chemist Harry Wiener in 1947 [20] and also known as the "Wiener number" [4, 6]. The Wienerindex [5,7,20] is defined by the sum of distances between all unordered pairs of vertices of a graph  $G$ ,

Sivasankar et al.,

$$W(G) = \sum_{\{u,v \in V(G)\}} d(u, v).$$

The hyper-Wiener index is introduced by Milan Randić in 1993 [19] and is defined as follows :

$$WW(G) = \frac{1}{2} \sum_{\{u,v \in V(G)\}} [d(u, v) + d(u, v)^2]$$

In [17] Plavšić et. al., and in [12] Ivanciuet. al., independently introduced the Harary index and denoted by

$$H(G) = \sum_{\{u,v \in V(G)\}} \frac{1}{d(u, v)}$$

In [11, 13] Ivanciuet. al., introduced the Reciprocal Complementary Wiener index, denoted by RCW(G) and given by

$$RCW(G) = \sum_{\{u,v \in V(G)\}} \frac{1}{d + 1 - d(u, v)}$$

Where  $d$  is the diameter of a graph  $G$ .

The Wiener polarity index  $W_p$  is introduced by Wiener in 1947 [6] and is defined as follows

$$W_p(G) = |\{(u, v) \mid d(u, v) = 3, u, v \in V(G)\}|$$

The terminal Wiener index of a graph  $G$  is defined by Gutman et.al., in [8], as the sum of distance between all pairs of pendant vertices of  $G$ ,

$$TW(G) = \sum_{\substack{u,v \in V(G) \\ deg(u)=deg(v)=1}} d(u, v)$$

The reverse Wiener index was proposed by Balaban et. al., in 2000 [2], is defined as follows

$$\Lambda(G) = \frac{n(n-1)d}{2} - W(G)$$

where  $n = |V(G)|$  and  $d$  is the diameter of  $G$ .

In [14], the Reciprocal Reverse Wiener (RRW) index  $R \Lambda(G)$  of a connected graph  $G$  is defined as

$$R \Lambda(G) = \begin{cases} \sum_{\{u,v \in V(G)\}} \frac{1}{d - d(u, v)} & \text{for } 0 < d(u, v) < d, \\ 0, & \text{for otherwise} \end{cases}$$

where  $d$  is the diameter of a graph  $G$ .

Various indices are studied by [10, 15, 16]. In this paper we calculate  $W(G)$ ,  $WW(G)$ ,  $H(G)$ ,  $RCW(G)$ ,  $W_p(G)$ ,  $TW(G)$ ,  $\Lambda(G)$  and  $R \Lambda(G)$  of  $K_m\{K_n\}$  and  $K_m\{\bar{K}_n\}$ . In [19] the computation of distance-based topological indices have been studied for the corona product of two complete graphs.

**Definition 1.1.** The cluster  $G\{H\}$  of two graphs  $G$  and  $H$  is defined as the graph obtained by taking one copy of  $G$  and  $|V(G)|$  copies of a rooted graph  $H$  and by identifying the root of the  $i$ <sup>th</sup> vertex of  $G$  to every vertex in the  $i$ <sup>th</sup> copy of  $H$ .

**Theorem 1.2.** [9] Let  $G_1$  and  $G_2$  be connected graphs. Let  $r$  be the root-vertex of  $G_2$ . Then  $W(G_1\{G_2\}) = |G_2|^2 W(G_1) + |G_1| W(G_2) + (|G_1|^2 - |G_1|) |G_2| d(r|G_2)$ , where  $d(r|G_2)$  is the sum of distances of all the vertices of  $G_2$  from the root vertex of  $G_2$ .

## MAIN RESULTS

### Indices of $K_m\{K_n\}$

**Definition 2.1.** The cluster  $K_m\{K_n\}$  of two graphs  $K_m$  and  $K_n$  is defined as the graph obtained by taking one copy of  $K_m$  and  $m$  copies of a rooted graph  $K_n$  and by identifying the root of the  $i^{th}$  vertex of  $K_m$  to every vertex in the  $i^{th}$  copy of  $K_n$ , see Figure 2.1 for  $K_4\{K_2\}$ .

**Theorem 2.2.** For  $m \geq 2$  and  $n \geq 1$ , we have

- i.  $W(K_m\{K_n\}) = \frac{m(m-1)}{2} [(5n^2+8n+4) + \frac{mn}{2}(6m+n-1) + m(2m-1)]$
- ii.  $WW(K_m\{K_n\}) = \frac{1}{2}\{m(m-1)(15n^2+32n+13) + m(n^2+7n+2)\}$
- iii.  $H(K_m\{K_n\}) = \frac{m(m-1)}{60}(6n^2+15n+70) + \frac{mn}{6}(3n+2m+4) + m$
- iv.  $RCW(K_m\{K_n\}) = \frac{m(m-1)}{60}(30n^2+30n+31) + \frac{mn}{60}(6n+20m+1) + \frac{m}{5}$

**Proof.** For  $m \geq 2$  and  $n \geq 1$ , the  $K_m\{K_n\}$  is the cluster of  $K_m$  and  $K_n$ . Let  $V(K_m\{K_n\}) = V_1 \cup V_2 \cup \dots \cup V_m$ , where  $V_i = \{v_{i,0}, v_{i,1}, \dots, v_{i,n+1}\}$ ,  $1 \leq i \leq m$

For  $i, j = 1, 2, \dots, m$  and  $k, \ell = 1, 2, \dots, n + 1$  the distance between any two vertices in  $K_m\{K_n\}$  are given by

- $d(v_{i,0}, v_{i,1}) = 1,$
- $d(v_{i,0}, v_{j,0}) = 1, \quad \text{for } i \neq j$
- $d(v_{i,k}, v_{i,\ell}) = 1, \quad \text{for } k \neq \ell$
- $d(v_{i,0}, v_{i,k}) = 2 \quad \text{for } k \neq 1$
- $d(v_{i,0}, v_{j,1}) = 2 \quad \text{for } i \neq j$
- $d(v_{i,0}, v_{j,k}) = 3, \quad \text{for } k \neq 1$
- $d(v_{i,1}, v_{j,1}) = 3, \quad \text{for } i \neq j$
- $d(v_{i,1}, v_{j,k}) = 4, \quad \text{for } k \neq 1$
- $d(v_{i,k}, v_{j,\ell}) = 5, \quad \text{for } i \neq j$

Here  $diam(G) = 5$  and the distance between any pair of vertices varies from  $1, 2, \dots, diam(G)$ . The number of pair of vertices receives distance  $1, 2, 3, 4$  and  $5$  are  $\binom{m}{2} + m\binom{n+1}{2} + m, m(m-1) + mn, (m-1)mn + \binom{m}{2}$ ,  $2n\binom{m}{2}$  and  $n^2\binom{m}{2}$  respectively. By using these we derive the following

$$(i) W(K_m\{K_n\}) = [(\binom{m}{2} + m\binom{n+1}{2} + m) + [m(m-1) + mn]2 + [(m-1)mn + \binom{m}{2}]3 + [2n\binom{m}{2}]4 + [n^2\binom{m}{2}]5$$

$$= \frac{m(m-1)}{2} [(5n^2+8n+4) + \frac{mn}{2}(6m+n-1) + m(2m-1)]$$

$$(ii) WW(K_m\{K_n\}) = \frac{1}{2}\{[\binom{m}{2} + m\binom{n+1}{2} + m](1+1^2) + [m(m-1) + mn](2+2^2)$$

$$+ [(m-1)mn + \binom{m}{2}](3+3^2) + [2n\binom{m}{2}](4+4^2) + [n^2\binom{m}{2}](5+5^2)\}$$

$$= \frac{1}{2}\{m(m-1)(15n^2+32n+13) + m(n^2+7n+2)\}$$

$$(iii) H(K_m\{K_n\}) = [(\binom{m}{2} + m\binom{n+1}{2} + m) + [m(m-1) + mn]\frac{1}{2} + [(m-1)mn + \binom{m}{2}]\frac{1}{3} + [2n\binom{m}{2}]\frac{1}{4} + [n^2\binom{m}{2}]\frac{1}{5}$$

$$= \frac{m(m-1)}{60}(6n^2+15n+70) + \frac{mn}{6}(3n+2m+4) + m$$

Sivasankar et al.,

$$(iv) RCW(K_m\{K_n\}) = \left[ \binom{m}{2} + m \binom{n+1}{2} + m \right] \frac{1}{5} + [m(m-1) + mn] \frac{1}{4} + [(m-1)mn + \binom{m}{2}] \frac{1}{3} + \left[ 2n \binom{m}{2} \right] \frac{1}{2} + \left[ n^2 \binom{m}{2} \right]$$

$$= \frac{m(m-1)}{60} (30n^2 + 30n + 31) + \frac{mn}{60} (6n + 20m + 1) + \frac{m}{5}$$

**Remark 2.3.** In Theorem 2.2, when  $m = 1$ , here the diameter of graph  $K_m\{K_n\}$  is 2 hence  $RCW(K_m\{K_n\})$  is invalid but  $W(K_m\{K_n\})$ ,  $WW(K_m\{K_n\})$  and  $H(K_m\{K_n\})$  are valid.

**Corollary 2.4.** For  $m \geq 2$  and  $n \geq 1$ ,  $W_p(K_m\{K_n\}) = \frac{m(m-1)}{2} (2n + 1)$ .

**Proof.** The number of 3 distance pair of vertices is  $(m-1)mn + \binom{m}{2}$  by Theorem 2.2. So,  $W_p(K_m\{K_n\}) = \frac{m(m-1)}{2} (2n + 1)$ .

**Corollary 2.5.** For  $m \geq 2$  and  $n = 1$ ,  $TW(K_m\{K_n\}) = \frac{5}{2} mn^2 (m - 1)$ .

**Proof.** For  $m \geq 2$  and  $n = 1$ , by Theorem 2.2 we have  $TW(K_m\{K_n\}) = [n^2 \binom{m}{2}] 5 = \frac{5}{2} mn^2 (m - 1)$

**Lemma 2.6.** For  $m \geq 1$  and  $n \geq 1$ ,  $\Delta(K_m\{K_n\}) = \frac{5}{2} [m(n+2)][m[(n+2) - 1] - \frac{m(m-1)}{2} (5n^2 + 8n + 4) + \frac{mn}{2} (6m + n - 1) + m(2m - 1)]$

**Proof.** For  $m \geq 1$  and  $n \geq 1$ ,  $|V(K_m\{K_n\})| = m(n+2)$ , the diameter of  $K_m\{K_n\}$  is 5 (that is,  $d = 5$ ) by Theorem 2.2 and  $W(K_m\{K_n\}) = \frac{m(m-1)}{2} (5n^2 + 8n + 4) + \frac{mn}{2} (6m + n - 1) + m(2m - 1)$ , hence  $\Delta(K_m\{K_n\}) = \frac{5}{2} [m(n+2)][m[(n+2) - 1] - \frac{m(m-1)}{2} (5n^2 + 8n + 4) + \frac{mn}{2} (6m + n - 1) + m(2m - 1)]$

**Lemma 2.7.** For  $m \geq 2$  and  $n \geq 1$ ,  $R \Delta(K_m\{K_n\}) = \frac{m(m-1)}{24} (12n + 17) + \frac{mn}{24} (24m + 3n - 13) + \frac{m}{4}$

**Proof.** For  $m \geq 2$  and  $n \geq 1$ , the diameter of  $K_m\{K_n\}$  is 5 and the distance between any pair of vertices varies from  $0 < d(u, v) < d$ . The number of pair of vertices receives distance 1, 2, 3, and 4 are  $\binom{m}{2} + m \binom{n+1}{2} + m$ ,  $m(m-1) + mn$ ,  $(m-1)mn + \binom{m}{2}$ , and  $2n \binom{m}{2}$  respectively. Then we have

$$R \Delta(K_m\{K_n\}) = \left[ \binom{m}{2} + m \binom{n+1}{2} + m \right] \frac{1}{4} + [m(m-1) + mn] \frac{1}{3} + [(m-1)mn + \binom{m}{2}] \frac{1}{2} + \left[ 2n \binom{m}{2} \right]$$

$$= \frac{m(m-1)}{24} (12n + 17) + \frac{mn}{24} (24m + 3n - 13) + \frac{m}{4}$$

**Indices of  $K_m\{\bar{K}_n\}$**

**Theorem 2.8.** For  $m \geq 2$  and  $n \geq 2$ , we have

- i.  $W(K_m\{\bar{K}_n\}) = \frac{m}{2} [(m-1)(5n^2+4)+2(2m-1)+2n(7m+n-5)]$
- ii.  $WW(K_m\{\bar{K}_n\}) = \frac{1}{2} \{m(m-1)(15n^2+32n+13) + mn(3n+5) + 2m\}$
- iii.  $H(K_m\{\bar{K}_n\}) = \frac{m(m-1)}{60} (6n^2 + 35n + 70) + \frac{mn}{4} (n + 5) + m$
- iv.  $RCW(K_m\{\bar{K}_n\}) = \frac{m(m-1)}{60} (30n^2 + 50n + 31) + \frac{mn}{40} (5n + 3) + \frac{m}{5}$

**Proof.** For  $m \geq 2$  and  $n \geq 1$ , the  $K_m\{\bar{K}_n\}$  is the cluster of  $K_m$  and  $\bar{K}_n$ . Let  $V(K_m\{\bar{K}_n\}) = V_1 \cup V_2 \cup \dots \cup V_m$ , where  $V_i = \{v_{i,0}, v_{i,1}, \dots, v_{i,n+1}\}$ ,  $1 \leq i \leq m$

For  $i, j = 1, 2, \dots, m$  and  $k, l = 1, 2, \dots, n + 1$  the distance between any two vertices in  $K_m\{\bar{K}_n\}$  are given by

$$\begin{aligned} d(v_{i,0}, v_{i,1}) &= 1, \quad d(v_{i,0}, v_{j,0}) = 1 \quad \text{for } i \neq j \\ d(v_{i,1}, v_{i,k}) &= 1 \quad \text{for } k \neq 1 \\ d(v_{i,0}, v_{i,k}) &= 2 \quad \text{for } k \neq 1 \\ d(v_{i,0}, v_{j,1}) &= 2 \quad \text{for } i \neq j \\ d(v_{i,k}, v_{i,\ell}) &= 2 \quad \text{for } k \neq \ell \\ d(v_{i,0}, v_{j,k}) &= 3, \quad \text{for } k \neq 1 \\ d(v_{i,1}, v_{j,1}) &= 3, \quad \text{for } i \neq j \\ d(v_{i,1}, v_{j,k}) &= 4, \quad \text{for } k \neq 1 \\ d(v_{i,k}, v_{j,\ell}) &= 5, \quad \text{for } i \neq j \end{aligned}$$

Here  $diam(G) = 5$  and the distance between any pair of vertices varies from  $1, 2, \dots, diam(G)$ . The number of pair of vertices receives distance  $1, 2, 3, 4, 5$  are  $\binom{m}{2} + m\binom{n+1}{2} + m, m(m-1) + mn, (m-1)mn + \binom{m}{2}, 2n\binom{m}{2}$  and  $n^2\binom{m}{2}$  respectively. By using these we derive the following

$$\begin{aligned} \text{(i) } W(K_m\{\bar{K}_n\}) &= \left[\binom{m}{2} + m + mn\right] + \left[mn + m\binom{n}{2} + m(m-1)\right]2 + \left[(m-1)mn + \binom{m}{2}\right]3 + \left[2n\binom{m}{2}\right]4 + \left[n^2\binom{m}{2}\right]5 \\ &= \frac{m}{2}[(m-1)(5n^2+4)+2(2m-1)+2n(7m+n-5)] \end{aligned}$$

$$\begin{aligned} \text{(ii) } WW(K_m\{\bar{K}_n\}) &= \frac{1}{2}\left\{\left[\binom{m}{2} + m + mn\right](1 + 1^2) + \left[mn + m\binom{n}{2} + m(m-1)\right](2 + 2^2) \right. \\ &+ \left. \left[(m-1)mn + \binom{m}{2}\right](3 + 3^2) + \left[2n\binom{m}{2}\right](4 + 4^2) + \left[n^2\binom{m}{2}\right](5 + 5^2)\right\} \\ &= \frac{1}{2}\{m(m-1)(15n^2 + 32n + 13) + mn(3n + 5) + 2m\} \end{aligned}$$

$$\begin{aligned} \text{(iii) } H(K_m\{\bar{K}_n\}) &= \left[\binom{m}{2} + m + mn\right] + \left[mn + m\binom{n}{2} + m(m-1)\right]\frac{1}{2} \\ &+ \left[(m-1)mn + \binom{m}{2}\right]\frac{1}{3} + \left[2n\binom{m}{2}\right]\frac{1}{4} + \left[n^2\binom{m}{2}\right]\frac{1}{5} \\ &= \frac{m(m-1)}{60}(6n^2 + 35n + 70) + \frac{mn}{4}(n + 5) + m \end{aligned}$$

$$\begin{aligned} \text{(iv) } RCW(K_m\{\bar{K}_n\}) &= \left[\binom{m}{2} + m + mn\right]\frac{1}{5} + \left[mn + m\binom{n}{2} + m(m-1)\right]\frac{1}{4} \\ &+ \left[(m-1)mn + \binom{m}{2}\right]\frac{1}{3} + \left[2n\binom{m}{2}\right]\frac{1}{2} + \left[n^2\binom{m}{2}\right] \\ &= \frac{m(m-1)}{60}(30n^2 + 50n + 31) + \frac{mn}{40}(5n + 3) + \frac{m}{5} \end{aligned}$$

**Remark 2.9.** In Theorem 2.8, when  $m = 1, K_m\{\bar{K}_n\} \cong K_{1,m+n}$ , here the diameter of graph  $K_m\{\bar{K}_n\}$  is 2 hence  $RCW(K_m\{\bar{K}_n\})$  is invalid but  $W(K_m\{\bar{K}_n\}), WW(K_m\{\bar{K}_n\})$  and  $H(K_m\{\bar{K}_n\})$  are valid.

**Corollary 2.10.** For  $m \geq 2$  and  $n \geq 1, W_p(K_m\{\bar{K}_n\}) = \frac{m(m-1)}{2}(2n + 1)$ .

**Proof.** The number of 3 distance pair of vertices is  $(m-1)mn + \binom{m}{2}$  by Theorem 2.8. So,  $W_p(K_m\{\bar{K}_n\}) = \frac{m(m-1)}{2}(2n + 1)$

**Corollary 2.11.** For  $m \geq 2$  and  $n \geq 1, TW(K_m\{\bar{K}_n\}) = \frac{mn}{2}[n(5m + 2) - 7]$

Sivasankar et al.,

**Proof.** For  $m \geq 2$  and  $n \geq 1$ , by Theorem 2.8 we have  $TW(K_m\{\bar{K}_n\}) = [m\binom{n}{2} + \binom{m}{2}n^2]5 = \frac{mn}{2}(n(5m+2) - 7)$

**Lemma 2.12.** For  $m \geq 1$  and  $n \geq 1$ ,  $\wedge (K_m\{\bar{K}_n\}) = \frac{5}{2}[m(n+2)][m[(n+2) - 1] - \frac{m}{2}[(m-1)(5n^2+4) + 2(2m-1) + 2n(7m+n-5)]$

**Proof.** For  $m, m \geq 2$  and  $n \geq 1$ ,  $|V(K_m\{\bar{K}_n\})| = m(n+2)$ , the diameter of  $K_m\{\bar{K}_n\}$  is 5 (that is,  $d = 5$ ) by Theorem 2.8 and  $W(K_m\{\bar{K}_n\}) = \frac{m}{2}(m-1)(5n^2+4) + 2(2m-1) + 2n(7m+n-5)$  hence  $\wedge (K_m\{\bar{K}_n\}) = \frac{5}{2}[m(n+2)][m(n+2) - 1] - [\frac{m}{2}(m-1)(5n^2+4) + 2(2m-1) + 2n(7m+n-5)]$

**Lemma 2.13.** For  $m \geq 2$  and  $n \geq 1$   $R \wedge (K_m\{\bar{K}_n\}) = \frac{m(m-1)}{24}(36n+17) + \frac{mn}{24}(2n+5) + \frac{m}{4}$

**Proof.** For  $m \geq 2$  and  $n \geq 1$ , the diameter of  $K_m\{\bar{K}_n\}$  is 5 and the distance between any pair of vertices varies from  $0 < d(u, v) < d$ . The number of pair of vertices receives distance 1, 2, 3, and 4 are  $\binom{m}{2} + m + mn, mn + m\binom{n}{2} + m(m-1), (m-1)mn + \binom{m}{2}$ , and  $2n\binom{m}{2}$  respectively. Then we have

$$R \wedge (K_m\{\bar{K}_n\}) = [\binom{m}{2} + m + mn] \frac{1}{4} + [mn + m\binom{n}{2} + m(m-1)] \frac{1}{3} + [(m-1)mn + \binom{m}{2}] \frac{1}{2} + [2n\binom{m}{2}]$$

$$= \frac{m(m-1)}{24}(36n+17) + \frac{mn}{12}(2n+5) + \frac{m}{4}$$

### ABSTRACT

In this paper, the definition of  $\mathcal{M}$ -intuitionistic fuzzy hyponormal operator is introduced and some important properties of  $\mathcal{M}$ -intuitionistic fuzzy hyponormal operator from intuitionistic fuzzy hyponormal operators in intuitionistic fuzzy Hilbert space are examined. For an intuitionistic fuzzy continuous linear operator  $S$  on an intuitionistic fuzzy Hilbert space  $\mathbb{H}$  there exists a real number  $\mathcal{M}$  such that  $\mathcal{P}_{\mu, \nu}((S - \lambda I)^* a, t) \leq \mathcal{M} \mathcal{P}_{\mu, \nu}((S - \lambda I) a, t), \forall a \in \mathcal{H}$ . Some definitions and theorems have been given, which are related to  $\mathcal{M}$ -intuitionistic fuzzy hyponormal operator in intuitionistic fuzzy Hilbert space.

**Keywords:** Intuitionistic Fuzzy Adjoint operator (IFA-operator), Intuitionistic Fuzzy Hilbert space (IFH-space), Intuitionistic Fuzzy Hyponormal operator (IFHN-operator), Intuitionistic Fuzzy Normal operator,  $\mathcal{M}$ -Intuitionistic Fuzzy Hyponormal operator ( $\mathcal{M}$ -IFHN-operator), Intuitionistic Fuzzy Self-Adjoint operator (IFSA-operator).

## INTRODUCTION

The notion of intuitionistic fuzzy set first introduced by Atanossou [3] in 1986. In 2004, the notion of intuitionistic fuzzy metric space  $(\mathcal{H}, \mu, \nu, *, \diamond)$  with the use of continuous t-norm  $*$  and continuous t-conorm  $\diamond$  imported by Park [4]. Saadati and Park [5] introduced and established modulation of the intuitionistic fuzzy metric space in IFIP-space using continuous t-representable in 2006. The new idea of intuitionistic fuzzy normed spaces initiated by Goudarzi et al. [7] in 2009 and also introduced the modified definition of intuitionistic fuzzy inner product space (IFIP-space) with the help of continuous t-representable ( $\mathcal{T}$ ).

**Maheswari and Brindha**

Radharamani et al.[15],[16] first introduced the definition of intuitionistic fuzzy Hilbert space (IFH-space) in 2018, and also introduced IFA and IFSA-operators and some properties using IFH-space. Also in 2020,Radharamani et al. [17]introduced the concept of intuitionistic fuzzy normal operator. An operator  $S \in IFB(\mathcal{H})$  if it commutes with its intuitionistic fuzzy adjointoperator.i.e,  $SS^* = S^*S$  and their some properties. Then Radharamani et al. [18], [19] have given the definition of intuitionistic fuzzy unitary operator (IFU-operator) and intuitionistic fuzzy partial isometry (IFPI-operator) on IFH-space $\mathcal{H}$  and some properties of these operators in IFH-space.Also,the relation with isometric isomorphism of  $\mathcal{H}$ onto itself. In 2020,Radharamani et al. [20] introduced the definition of intuitionistic fuzzy hyponormal operator (IFHN-operator), $S \in IFB(\mathcal{H})$ if  $\mathcal{P}_{\mu,v}(S^*a, t) \leq \mathcal{P}_{\mu,v}(Sa, t), \forall a \in \mathcal{H}$  or equivalently  $S^*S - SS^* \geq 0$ , and gave some properties of IFHN-operator on IFH-space. Also, definitions and some theorems of intuitionistic fuzzy invariant, eigenvalue, eigenvectors and eigenspaces related to IFHN-operator in IFH-space have been discussed.

In this paper, $\mathcal{M}$ -intuitionistic fuzzy hyponormal operator ( $\mathcal{M}$ -IFHN-operator), some theorems and properties of  $\mathcal{M}$ -IFHN-operator are introduced. Also, a few numerical examples  $\mathcal{M}$ -IFHN-operator are presented.

**PRILIMINARIES**

**Definition 2.1: [7]**

Let  $\mu, v$  be fuzzy sets from  $\mathcal{H} \times (0, +\infty)$  to  $[0,1]$  such that  $\mu(a, t) + v(a, t) \leq 1, \forall a \in \mathcal{H} \ \& \ t > 0$ . The three tuple  $(\mathcal{H}, \mathcal{P}_{\mu,v}, \mathcal{T})$  is said to be an IFNL-space if  $\mathcal{H}$  is a vector space,  $\mathcal{T}$  is a continuous t-representable and  $\mathcal{P}_{\mu,v}$  is a mapping  $\mathcal{H} \times (0, +\infty) \rightarrow [0,1]$ satisfying the following conditions  $\forall a, b \in \mathcal{H}$  and  $u, v > 0$ :

- (a)  $\mathcal{P}_{\mu,v}(a, t) > 0$ .
- (b)  $\mathcal{P}_{\mu,v}(a, t) = 1$  if and only if  $a = 0$
- (c)  $\mathcal{P}_{\mu,v}(\alpha a, t) = \mathcal{P}_{\mu,v}(a, \frac{t}{|\alpha|})$  for each  $\alpha \neq 0$
- (d)  $\mathcal{P}_{\mu,v}(a + b, t + v) \geq \mathcal{T}(\mathcal{P}_{\mu,v}(a, t), \mathcal{P}_{\mu,v}(b, v))$
- (e)  $\mathcal{P}_{\mu,v}(a, \cdot): (0, \infty) \rightarrow [0,1]$  is continuous.
- (f)  $\lim_{t \rightarrow \infty} \mathcal{P}_{\mu,v}(a, t) = 1$  and  $\lim_{t \rightarrow 0} \mathcal{P}_{\mu,v}(a, t) = 0$

In this case,  $\mathcal{P}_{\mu,v}$  is called an intuitionistic fuzzy norm. Here,  $\mathcal{P}_{\mu,v}(a, t) = (\mu(a, t), v(a, t))$ .

**Definition 2.2: [7]**

Let  $\mu: \mathcal{H}^2 \times (0, +\infty) \rightarrow [0,1]$  and  $v: \mathcal{H}^2 \times (0, +\infty) \rightarrow [0,1]$  be the fuzzy sets, such that  $\mu(a, b, t) + v(a, b, t) \leq 1, \forall a, b \in \mathcal{H} \ \& \ t > 0$ . An intuitionistic fuzzy inner product space (IFIP-space) is a triplet  $(\mathcal{H}, \mathcal{F}_{\mu,v}, \mathcal{T})$ , where  $\mathcal{H}$  is a real vector space,  $\mathcal{T}$  is a continuous t-representable and  $\mathcal{F}_{\mu,v}$  is an intuitionistic fuzzy set on  $\mathcal{H}^2 \times \mathbb{R}$  satisfying the following conditions  $\forall a, b, z \in \mathcal{H}$  and  $u, v, w \in \mathbb{R}$ :

- (IFI - 1)  $\mathcal{F}_{\mu,v}(a, b, 0) = 0$  and  $\mathcal{F}_{\mu,v}(a, b, t) > 0, \forall t > 0$ .
- (IFI - 2)  $\mathcal{F}_{\mu,v}(a, b, t) = \mathcal{F}_{\mu,v}(b, a, t)$ .
- (IFI - 3)  $\mathcal{F}_{\mu,v}(a, b, t) \neq H(t)$  for some  $t \in \mathbb{R}$  iff  $a \neq 0$ , where  $H(t) = \begin{cases} 1, & \text{if } t > 0 \\ 0, & \text{if } t \leq 0 \end{cases}$
- (IFI - 4). For any  $\alpha \in \mathbb{R}$ ,

$$\mathcal{F}_{\mu,v}(\alpha a, b, t) = \begin{cases} \mathcal{F}_{\mu,v}(a, b, \frac{t}{\alpha}), & \alpha > 0 \\ H(t), & \alpha = 0 \\ \mathfrak{N}_s\left(\mathcal{F}_{\mu,v}(a, b, \frac{t}{\alpha})\right), & \alpha < 0 \end{cases}$$

- (IFI - 5)  $\sup \left\{ \mathcal{T} \left( \mathcal{F}_{\mu,v}(a, z, v), \mathcal{F}_{\mu,v}(b, z, w) \right) \right\} = \mathcal{F}_{\mu,v}(a + b, z, t)$ .
- (IFI - 6)  $\mathcal{F}_{\mu,v}(a, b, \cdot): \mathbb{R} \rightarrow [0,1]$  is continuous on  $\mathbb{R} \setminus \{0\}$ .
- (IFI - 7)  $\lim_{t \rightarrow \infty} \mathcal{F}_{\mu,v}(a, b, t) = 1$ .

**Maheswari and Brindha**

**Theorem 2.3:[7]**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFIP-space, where  $\mathcal{T}$  is a continuous-t-representable for every  $a, b \in \mathcal{H}$ ,  $\sup\{t \in \mathbb{R}: \mathcal{F}_{\mu, \nu}(a, b, t) < 1\} < \infty$ . Define  $\langle \cdot, \cdot \rangle: \mathcal{H} \times \mathcal{H} \rightarrow \mathbb{R}$  by  $\langle a, b \rangle = \sup\{t \in \mathbb{R}: \mathcal{F}_{\mu, \nu}(a, b, t) < 1\} < \infty$ . Then  $(\mathcal{H}, \langle \cdot, \cdot \rangle)$  is an IFIP-space, so that  $(\mathcal{H}, \mathcal{P}_{\mu, \nu})$  is a normed space, where  $\mathcal{P}_{\mu, \nu}(a, t) = \langle a, b \rangle^{\frac{1}{2}} \forall a \in \mathcal{H}$ .

**Theorem 2.4: [15]**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFH-space. For any  $\tau_{\mathcal{F}_{\mu, \nu}}$ -continuous linear functional  $f \exists$  unique  $b \in \mathcal{H}$ , such that for all  $a \in \mathcal{H}$ , we have  $f(a) = \sup\{t \in \mathbb{R}: \mathcal{F}_{\mu, \nu}(a, b, t) < 1\}$ .

**Theorem 2.5: [15]**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFIP-space, where  $\mathcal{T}$  is a continuous t-representable and  $\sup\{t \in \mathbb{R}: \mathcal{F}_{\mu, \nu}(a, b, t) < 1\} < \infty$  for all  $a, b \in \mathcal{H}$ . Then  $\sup\{t \in \mathbb{R}: \mathcal{F}_{\mu, \nu}(a + b, c, t) < 1\} = \sup\{t \in \mathbb{R}: \mathcal{F}_{\mu, \nu}(a, c, t) < 1\} + \sup\{t \in \mathbb{R}: \mathcal{F}_{\mu, \nu}(b, c, t) < 1\} \forall a, b, c, z \in \mathcal{H}$ .

**Remark 2.6**

Let  $IFB(\mathcal{H})$  be the set of all intuitionistic fuzzy bounded linear operators on  $\mathcal{H}$ .

**Theorem 2.7: [15]**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFH-space and let  $S \in IFB(\mathcal{H})$  be a  $\tau_{\mathcal{F}_{\mu, \nu}}$ -continuous linear functional. Then  $\exists$  unique  $S^* \in IFB(\mathcal{H})$  such that  $\langle Sa, b \rangle = \langle a, S^*b \rangle \forall a, b \in \mathcal{H}$ .

**Theorem 2.8: [15]**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFIP-space with  $IP: \sup\{t \in \mathbb{R}: \mathcal{F}_{\mu, \nu}(a, b, t) < 1\} \forall a, b \in \mathcal{H}$ . Then  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  is called an intuitionistic fuzzy Hilbert space (IFH-space) if it is complete in the norm  $\mathcal{P}_{\mu, \nu}(\cdot, t)$ .

**Theorem 2.9: [16]**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFH-space with  $IP: \langle a, b \rangle = \sup\{t \in \mathbb{R}: \mathcal{F}_{\mu, \nu}(a, b, t) < 1\} \forall a, b \in \mathcal{H}$  and let  $S \in IFB(\mathcal{H})$ . Then  $S$  is IFSA-operator, if  $S = S^*$  where  $S^*$  is intuitionistic fuzzy adjoint of  $S$ .

**Theorem 2.10: [16]**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFH-space with  $IP: \langle a, b \rangle = \sup\{t \in \mathbb{R}: \mathcal{F}_{\mu, \nu}(a, b, t) < 1\} \forall a, b \in \mathcal{H}$  and let  $S \in IFB(\mathcal{H})$ . Then  $S$  is an IFSA-operator.

**Theorem 2.11: [16]**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFH-space with  $IP: \langle a, b \rangle = \sup\{t \in \mathbb{R}: \mathcal{F}_{\mu, \nu}(a, b, t) < 1\} \forall a, b \in \mathcal{H}$  and let  $S^*$  be the IFA-operator of  $S \in IFB(\mathcal{H})$ . Then

- (i)  $(S^*)^* = S$
- (ii)  $(\beta S)^* = \beta S^*$
- (iii)  $(\beta S + \gamma W)^* = \beta S^* + \gamma W^*$  where  $\beta, \gamma$  are scalars and  $W \in IFB(\mathcal{H})$ .
- (iv)  $(SW)^* = W^* S^*$

**Theorem 2.12: [16]**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFH-space and  $S \in IFB(\mathcal{H})$ . Then  $S = 0$  if and only if  $\sup\{t \in \mathbb{R}: \mathcal{F}_{\mu, \nu}(Sa, Sa, t) < 1\} \forall a \in \mathcal{H}$ .

**Definition 2.13: [17]**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFH-space with  $IP: \langle a, b \rangle = \sup\{t \in \mathbb{R}: \mathcal{F}_{\mu, \nu}(a, b, t) < 1\} \forall a, b \in \mathcal{H}$  and let  $S \in IFB(\mathcal{H})$ . Then  $S$  is an intuitionistic fuzzy normal operator (IFN-operator) if it commutes with its IF-adjoint. i.e.  $SS^* = S^*S$ .

**Theorem 2.14: [17]**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFH-space with  $IP: \langle a, b \rangle = \sup\{t \in \mathbb{R}: \mathcal{F}_{\mu, \nu}(a, b, t) < 1\} \forall a, b \in \mathcal{H}$  and let  $S \in IFB(\mathcal{H})$ .  $S$  is IFN-operator if and only if  $\mathcal{P}_{\mu, \nu}(S^*a, t) = \mathcal{P}_{\mu, \nu}(Sa, t) \forall a \in \mathcal{H}$ .

**Theorem 2.15: [17]**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFH-space with  $IP: \langle a, b \rangle = \sup\{t \in \mathbb{R}: \mathcal{F}_{\mu, \nu}(a, b, t) < 1\} \forall a, b \in \mathcal{H}$  and let  $S \in IFB(\mathcal{H})$ . Then  $\mathcal{P}_{\mu, \nu}(S^2a, t) = \mathcal{P}_{\mu, \nu}^2(Sa, t) \forall a \in \mathcal{H}$ .

**Maheswari and Brindha**

**Definition 2.16: [18]**

Let  $\mathcal{H}_1$  and  $\mathcal{H}_2$  be two IFH-spaces. An intuitionistic fuzzy isometric isomorphism of  $\mathcal{H}_1$  into  $\mathcal{H}_2$  is a one to one linear transformation  $\mathbb{S}$  of  $\mathcal{H}_1$  into  $\mathcal{H}_2$  such that  $\mathcal{P}_{\mu, \nu}(\mathbb{S}a, t) = \mathcal{P}_{\mu, \nu}(a, t)$  for every  $a \in \mathcal{H}_1$ .

**Theorem 2.17: [18]**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFH-space with  $IP: \langle a, b \rangle = \sup\{t \in \mathbb{R} : \mathcal{F}_{\mu, \nu}(a, b, t) < 1\} \forall a, b \in \mathcal{H}$  and let  $\mathbb{S} \in IFB(\mathcal{H})$ . If  $\mathbb{S}$  is IFU-operator if and only if it is an isometric isomorphism of  $\mathcal{H}$  onto itself.

**Theorem 2.18: [18]**

If  $\mathbb{S} \in IFB(\mathcal{H})$  is IFU-operator on  $\mathcal{H}$ , then the following conditions are all equivalent to one another.

- (i)  $\mathbb{S}\mathbb{S}^* = I$
- (ii)  $\langle \mathbb{S}a, \mathbb{S}b \rangle = \langle a, b \rangle$
- (iii)  $\mathcal{P}_{\mu, \nu}(\mathbb{S}a, t) = \mathcal{P}_{\mu, \nu}(a, t) \forall a \in \mathcal{H}$ .

**Definition 2.19:**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFH-space with  $IP: \langle a, b \rangle = \sup\{t \in \mathbb{R} : \mathcal{F}_{\mu, \nu}(a, b, t) < 1\} \forall a, b \in \mathcal{H}$  and let  $\mathbb{S} \in IFB(\mathcal{H})$ . Then  $\mathbb{S}$  is IFU-operator if it satisfies  $\mathbb{S}\mathbb{S}^* = 1 = \mathbb{S}^*\mathbb{S}$ .

**Definition 2.20:**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFH-space with  $IP: \langle a, b \rangle = \sup\{t \in \mathbb{R} : \mathcal{F}_{\mu, \nu}(a, b, t) < 1\} \forall a, b \in \mathcal{H}$  and let  $\mathbb{S} \in IFB(\mathcal{H})$ . Then  $\mathbb{S}$  is an IFHN-operator on  $\mathcal{H}$  if  $\mathcal{P}_{\mu, \nu}(\mathbb{S}^*a, t) \leq \mathcal{P}_{\mu, \nu}(\mathbb{S}a, t) \forall a \in \mathcal{H}$  or equivalently  $\mathbb{S}^*\mathbb{S} - \mathbb{S}\mathbb{S}^* \geq 0$ .

**Theorem 2.21: [18]**

Let  $\mathbb{S} \in IFB(\mathcal{H})$  be an IFHN-operator with  $\mathbb{S}a_1 = \lambda_1 a_1, \mathbb{S}a_2 = \lambda_2 a_2$  and  $\lambda_1 \neq \lambda_2$  then  $\langle a_1, a_2 \rangle \geq 0$ .

## MAIN RESULTS

**Definition 3.1:**

Let  $(\mathcal{H}, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFH-Space with Inner Product:  $\langle a, b \rangle = \sup\{t \in \mathbb{R} : \mathcal{F}_{\mu, \nu}(a, b, t) < 1\} \forall a, b \in \mathcal{H}$ . An operator  $\mathbb{S}$  is called  $\mathcal{M}$ -IFHN-Operator if there exists a real number  $\mathcal{M}$ , such  $\mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda I)^*a, t) \leq \mathcal{M} \mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda I)a, t), \forall a \in \mathcal{H}$  and for all  $\lambda \in \mathbb{C}$ .

**Example 3.2:**

Let  $\mathbb{S} \in IFB(\mathbb{R}^2)$  and there exists  $\mathbb{S}^* \in IFB(\mathbb{R}^2)$ . Define  $\mathbb{S}: \mathbb{R}^2 \rightarrow \mathbb{R}^2$  by  $\mathbb{S} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \lambda I = \begin{pmatrix} \lambda & 0 \\ 0 & \lambda \end{pmatrix} \ni, (\mathbb{S} - \lambda I)a =$

$$\begin{aligned} \begin{pmatrix} -\lambda & 1 \\ -1 & -\lambda \end{pmatrix} \begin{pmatrix} a_1 \\ a_2 \end{pmatrix} &= \begin{pmatrix} -\lambda a_1 + a_2 \\ -a_1 - \lambda a_2 \end{pmatrix} \\ &= (-\lambda a_1 + a_2, -a_1 - \lambda a_2) \\ (\mathbb{S} - \lambda I)^*a &= \begin{pmatrix} -\lambda & -1 \\ 1 & -\lambda \end{pmatrix} \begin{pmatrix} a_1 \\ a_2 \end{pmatrix} = \begin{pmatrix} -\lambda a_1 - a_2 \\ a_1 - \lambda a_2 \end{pmatrix} \\ &= (-\lambda a_1 - a_2, a_1 - \lambda a_2) \forall a_1, a_2 \in \mathbb{R}^2 \end{aligned}$$

Then  $\mathbb{S}$  is an  $\mathcal{M}$ -IFHN-Operator.

**Example 3.3:**

Let  $(\mathbb{R}^2, \mathcal{F}_{\mu, \nu}, \mathcal{T})$  be an IFH-Space and  $\mathbb{S} \in IFB(\mathbb{R}^2)$  and  $\exists \mathbb{S}^* \in IFB(\mathbb{R}^2)$ .

Define  $\mathbb{S}: \mathbb{R}^2 \rightarrow \mathbb{R}^2$  by  $\mathbb{S} = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}, \lambda I = \begin{pmatrix} -\lambda & 0 \\ 0 & -\lambda \end{pmatrix}$  such that

$$\begin{aligned} (\mathbb{S} - \lambda I)a &= \begin{pmatrix} -\lambda & 0 \\ 0 & -\lambda \end{pmatrix} \begin{pmatrix} a_1 \\ a_2 \end{pmatrix} = \begin{pmatrix} -\lambda a_1 \\ -\lambda a_2 \end{pmatrix} \\ &= (-\lambda a_1, -\lambda a_2) \forall a_1, a_2 \in \mathbb{R}^2 \\ (\mathbb{S} - \lambda I)^*a &= \begin{pmatrix} -\lambda & 0 \\ 0 & -\lambda \end{pmatrix} \begin{pmatrix} a_1 \\ a_2 \end{pmatrix} = \begin{pmatrix} -\lambda a_1 \\ -\lambda a_2 \end{pmatrix} \\ &= (-\lambda a_1, -\lambda a_2) \forall a_1, a_2 \in \mathbb{R}^2 \end{aligned}$$

Then  $\mathbb{S}$  is an  $\mathcal{M}$ -IFHN-Operator.

**Maheswari and Brindha**

**Theorem 3.4:**

$\mathbb{S}$  is an  $\mathcal{M}$ -IFHN-Operator iff  $\mathcal{M}^2(\mathbb{S} - \lambda I)^*(\mathbb{S} - \lambda I) - (\mathbb{S} - \lambda I)(\mathbb{S} - \lambda I)^* \geq 0 \forall \lambda \in \mathbb{C}$ .

Proof:

Given  $\mathbb{S}$  is an  $\mathcal{M}$ -IFHN-Operator. Then by the definition  $\mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda I)^* a, \mathfrak{t}) \leq \mathcal{M} \mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda I) a, \mathfrak{t})$

Consider  $\mathcal{M}^2(\mathbb{S} - \lambda I)^*(\mathbb{S} - \lambda I) - (\mathbb{S} - \lambda I)(\mathbb{S} - \lambda I)^* \geq 0$

$$\Leftrightarrow \langle \mathcal{M}^2(\mathbb{S} - \lambda I)^*(\mathbb{S} - \lambda I) - (\mathbb{S} - \lambda I)(\mathbb{S} - \lambda I)^* a, a \rangle \geq 0$$

$$\Leftrightarrow \mathcal{M}^2 \text{Sup}\{\mathfrak{t} \in \mathbb{R}: \mathcal{F}_{\mu, \nu}((\mathbb{S} - \lambda I)^*(\mathbb{S} - \lambda I) a, a, \mathfrak{t}) < 1\} -$$

$$\text{sup}\{\mathfrak{t} \in \mathbb{R}: \mathcal{F}_{\mu, \nu}((\mathbb{S} - \lambda I) a, a, \mathfrak{t}) < 1\} \geq 0$$

$$\Leftrightarrow \mathcal{M}^2 \text{Sup}\{\mathfrak{t} \in \mathbb{R}: \mathcal{F}_{\mu, \nu}((\mathbb{S} - \lambda I) a, (\mathbb{S} - \lambda I) a, \mathfrak{t}) < 1\} -$$

$$\text{Sup}\{\mathfrak{t} \in \mathbb{R}: \mathcal{F}_{\mu, \nu}((\mathbb{S} - \lambda I)^* a, (\mathbb{S} - \lambda I)^* a, \mathfrak{t}) < 1\} \geq 0$$

$$\Leftrightarrow \mathcal{M}^2 \mathcal{P}_{\mu, \nu}^2((\mathbb{S} - \lambda I) a, \mathfrak{t}) - \mathcal{P}_{\mu, \nu}^2((\mathbb{S} - \lambda I)^* a, \mathfrak{t}) \geq 0$$

$$\Leftrightarrow \mathcal{M}^2 \mathcal{P}_{\mu, \nu}^2((\mathbb{S} - \lambda I) a, \mathfrak{t}) \geq \mathcal{P}_{\mu, \nu}^2((\mathbb{S} - \lambda I)^* a, \mathfrak{t})$$

$$\Leftrightarrow \mathcal{M} \mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda I) a, \mathfrak{t}) \geq \mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda I)^* a, \mathfrak{t})$$

$$\Leftrightarrow \mathbb{S} \text{ is an } \mathcal{M}\text{-IFHN-Operator}$$

**Theorem 3.5:**

Let  $\mathbb{S}$  be  $\mathcal{M}$ -IFHN-Operator. Then  $\mathcal{M} \geq 1$ .  $\mathbb{S}$  is an IFHN-Operator iff  $\mathcal{M} = 1$ .

Proof:

Given  $\mathbb{S}$  be  $\mathcal{M}$ -IFHN-Operator. Then  $\mathcal{M} \geq 1$ . i.e.  $\mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda I)^* a, \mathfrak{t}) \leq \mathcal{M} \mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda I) a, \mathfrak{t}), \forall a \in \mathcal{H}$  and for all  $\lambda \in \mathbb{C}$ .

If  $\mathcal{M} = 1$ , then  $\mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda I)^* a, \mathfrak{t}) \leq 1 \cdot \mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda I) a, \mathfrak{t}), \forall a \in \mathcal{H}$  and for all  $\lambda \in \mathbb{C}$ , by the definition.

$\Leftrightarrow \mathbb{S}$  is  $\mathcal{M}$ -IFHN-Operator.

**Theorem 3.6:**

Let  $\mathbb{S}$  be  $\mathcal{M}$ -IFHN-Operator. Then for any  $\lambda' \in \mathbb{C}$ ,  $\mathbb{S} - \lambda' I$  and  $\lambda' \mathbb{S}$  are  $\mathcal{M}$ -IFHN-Operators.

Proof:

Given that  $\mathbb{S}$  is  $\mathcal{M}$ -IFHN-Operator. Then by the definition

$$\mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda I)^* a, \mathfrak{t}) \leq \mathcal{M} \mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda I) a, \mathfrak{t})$$

Consider  $\mathcal{P}_{\mu, \nu}(((\mathbb{S} - \lambda' I) - \lambda I)^* a, \mathfrak{t})$ ,

$$\mathcal{P}_{\mu, \nu}(((\mathbb{S} - \lambda' I) - \lambda I)^* a, \mathfrak{t}) = \mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda' I - \lambda I)^* a, \mathfrak{t})$$

$$= \mathcal{P}_{\mu, \nu}((\mathbb{S} - (\lambda' + \lambda) I)^* a, \mathfrak{t})$$

Since  $\mathbb{S}$  is an  $\mathcal{M}$ -IFHN-Operator, we have

$$\mathcal{P}_{\mu, \nu}((\mathbb{S} - (\lambda' + \lambda) I)^* a, \mathfrak{t}) \leq \mathcal{M} \mathcal{P}_{\mu, \nu}((\mathbb{S} - (\lambda' + \lambda) I) a, \mathfrak{t})$$

$$\mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda' I - \lambda I)^* a, \mathfrak{t}) \leq \mathcal{M} \mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda' I - \lambda I) a, \mathfrak{t}) \forall a \in \mathcal{H}$$

Therefore,  $\mathbb{S} - \lambda' I$  is an  $\mathcal{M}$ -IFHN-Operator.

ii). To prove that  $\lambda' \mathbb{S}$  is  $\mathcal{M}$ -IFHN-Operator

If  $\lambda' = 0$ , then  $\lambda' \mathbb{S} = 0$ .

Since  $\mathbb{S}$  is an  $\mathcal{M}$ -IFHN-Operator then

$$\mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda I)^* a, \mathfrak{t}) \leq \mathcal{M} \mathcal{P}_{\mu, \nu}((\mathbb{S} - \lambda I) a, \mathfrak{t})$$

For  $\lambda' \neq 0$ ,

$$\mathcal{P}_{\mu, \nu}((\lambda' \mathbb{S} - \lambda I)^* a, \mathfrak{t}) \leq |\lambda'| \mathcal{P}_{\mu, \nu}((\mathbb{S} - \frac{\lambda}{\lambda'}) I)^* a, \mathfrak{t})$$

$$\leq |\lambda'| \mathcal{P}_{\mu, \nu}((\mathbb{S} - \frac{\lambda}{\lambda'}) I) a, \mathfrak{t})$$

$$\leq \mathcal{M} \mathcal{P}_{\mu, \nu}((\lambda' \mathbb{S} - \lambda I) a, \mathfrak{t})$$

Therefore,  $\lambda' \mathbb{S}$  is an  $\mathcal{M}$ -IFHN-Operator.

**Theorem 3.7:**

If  $\mathbb{S}$   $\mathcal{M}$ -IFHN-Operator such that  $\mathbb{S} a = \lambda a$ , then  $\mathbb{S} a - \lambda a = 0$

Proof:

Given  $\mathbb{S}$  an  $\mathcal{M}$ -IFHN-Operator. Let  $a$  be an eigen vector of  $\mathbb{S}$  corresponding to the Eigen value  $\lambda$ .

Since  $\mathbb{S} a = \lambda a$ , we get  $\mathbb{S} a - \lambda a = 0$

**Maheswari and Brindha**

$$\begin{aligned} &\Rightarrow Sa - \lambda a = 0 \\ &\Rightarrow (S - \lambda I)a = 0 \\ &\Rightarrow (S - \lambda I) = 0 \\ &\Rightarrow \text{Sup}\{t \in \mathbb{R} : \mathcal{F}_{\mu, \nu}((S - \lambda I)a, (S - \lambda I)a, t) < 1\} = 0 \quad \forall a, t \in \mathcal{H} \\ &\Rightarrow \text{Sup}\{t \in \mathbb{R} : \mathcal{F}_{\mu, \nu}((S - \lambda I)^*a, (S - \lambda I)^*a, t) < 1\} = 0 \\ &\Rightarrow (S - \lambda I)^*a = 0 \quad \text{since by theorem 2.12} \\ &\Rightarrow (S^* - \bar{\lambda}I)a = 0 \\ &\Rightarrow S^*a - \bar{\lambda}a = 0 \\ &\Rightarrow S^*a = \bar{\lambda}a \end{aligned}$$

Therefore,  $a$  is an Eigen vector of  $S^*$  corresponding to a Eigen value  $\bar{\lambda}$ .

**Result 3.8:**

Let  $S$  be an  $\mathcal{M}$ -IFHN-operator.

[1]. If  $Sa = \lambda_1 a$  and  $Sb = \lambda_2 b$ ,  $\lambda_1 \neq \lambda_2$ , then  $\langle a, b \rangle = 0$ .

[2]. If  $(S - \lambda I)^*a = 0$ , then  $(S - \lambda I)a = 0$ .

**Theorem 3.9:**

If  $S$  is an  $\mathcal{M}$ -IFHN-Operator, then  $\mathcal{P}_{\mu, \nu}((S^* - \bar{\lambda}I)^{-1}a, t) \leq \mathcal{M} \mathcal{P}_{\mu, \nu}((S - \lambda I)^{-1}a, t), \forall a \in \mathcal{H}$ .

Proof:

$$\begin{aligned} &\text{Consider } \mathcal{P}_{\mu, \nu}^2((S^* - \bar{\lambda}I)^{-1}a, t), \\ &\mathcal{P}_{\mu, \nu}^2((S^* - \bar{\lambda}I)^{-1}a, t) = \langle (S^* - \bar{\lambda}I)^{-1}a, (S^* - \bar{\lambda}I)^{-1}a \rangle \\ &= \text{Sup}\{t \in \mathbb{R} : \mathcal{F}_{\mu, \nu}((S^* - \bar{\lambda}I)^{-1}a, (S^* - \bar{\lambda}I)^{-1}a, t) < 1\} \\ &= \text{Sup}\{t \in \mathbb{R} : \mathcal{F}_{\mu, \nu}(((S - \lambda I)^*)^{-1}a, ((S - \lambda I)^*)^{-1}a, t) < 1\} \\ &= \langle ((S - \lambda I)^*)^{-1}a, ((S - \lambda I)^*)^{-1}a \rangle \\ &\leq \mathcal{P}_{\mu, \nu}^2(((S - \lambda I)^*)^{-1}a, t) \\ &\leq \mathcal{P}_{\mu, \nu}^{-2}((S - \lambda I)a, t) \mathcal{P}_{\mu, \nu}^2(a, t) \\ &\leq \mathcal{M} \mathcal{P}_{\mu, \nu}^{-2}((S - \lambda I)a, t) \mathcal{P}_{\mu, \nu}^2(a, t) \quad [\because S \text{ is } \mathcal{M}\text{-IFHN-Operator}] \\ &\leq \mathcal{M}^{-2} \mathcal{P}_{\mu, \nu}^{-2}((S - \lambda I)a, t) \mathcal{P}_{\mu, \nu}^2(a, t) \\ &\leq \frac{1}{\mathcal{M}^2} \mathcal{P}_{\mu, \nu}^2((S - \lambda I)a, t) \mathcal{P}_{\mu, \nu}^2(a, t) \\ &\leq \frac{1}{\mathcal{M}^2} \mathcal{P}_{\mu, \nu}^2((S - \lambda I)^{-1}a, t) \mathcal{P}_{\mu, \nu}^2(a, t) \\ &\mathcal{P}_{\mu, \nu}^2((S^* - \bar{\lambda}I)^{-1}a, t) \leq \frac{1}{\mathcal{M}^2} \mathcal{P}_{\mu, \nu}^2((S - \lambda I)^{-1}a, t) \\ &\Rightarrow \mathcal{P}_{\mu, \nu}((S^* - \bar{\lambda}I)^{-1}a, t) \leq \frac{1}{\mathcal{M}} \mathcal{P}_{\mu, \nu}((S - \lambda I)^{-1}a, t) \leq \mathcal{M} \mathcal{P}_{\mu, \nu}((S - \lambda I)^{-1}a, t) \end{aligned}$$

This implies  $\mathcal{P}_{\mu, \nu}((S^* - \bar{\lambda}I)^{-1}a, t) \leq \mathcal{M} \mathcal{P}_{\mu, \nu}((S - \lambda I)^{-1}a, t)$  for any  $\mathcal{M}$  in  $\mathbb{R}$ .

**Theorem 3.10:**

If  $S$ , an  $\mathcal{M}$ -IFHN-Operator, then  $\mathcal{P}_{\mu, \nu}((S - \lambda I)a, t)^{(n+1)} \leq \mathcal{M}^{\binom{n(n+1)}{2}} \mathcal{P}_{\mu, \nu}((S - \lambda I)^{(n+1)}a, t)$ , each  $a \in \mathcal{H}$ .

Proof:

Given  $S$  is an  $\mathcal{M}$ -IFHN-Operator. Then there exist  $\mathcal{M}$  in  $\mathbb{R}$  such that  $\mathcal{P}_{\mu, \nu}((S - \lambda I)^*a, t) \leq 1 \cdot \mathcal{P}_{\mu, \nu}((S - \lambda I)a, t), \forall a \in \mathcal{H}$  and for all  $\lambda \in \mathbb{C}$ .

To prove  $\mathcal{P}_{\mu, \nu}^{(n+1)}((S - \lambda I)a, t) \leq \mathcal{M}^{\binom{n(n+1)}{2}} \mathcal{P}_{\mu, \nu}((S - \lambda I)^{(n+1)}a, t), \forall a \in \mathcal{H}$ .

We use induction hypothesis.

For  $n=1$ ,  $\mathcal{P}_{\mu, \nu}^2((S - \lambda I)a, t) \leq \mathcal{M} \mathcal{P}_{\mu, \nu}((S - \lambda I)^2a, t)$

Assume for  $n=k$ ,  $\mathcal{P}_{\mu, \nu}^{(k+1)}((S - \lambda I)a, t) \leq \mathcal{M}^{\binom{k(k+1)}{2}} \mathcal{P}_{\mu, \nu}((S - \lambda I)^{(k+1)}a, t)$

To prove for  $n=k+1$

Consider  $\mathcal{P}_{\mu, \nu}^{((k+1)+1)}((S - \lambda I)a, t)$ , we have

Maheswari and Brindha

$$\begin{aligned} & \mathcal{P}_{\mu,v}^{((k+1)+1)}((\mathbb{S} - \lambda I)a, \mathfrak{t}) = \mathcal{P}_{\mu,v}^{(k+1)}((\mathbb{S} - \lambda I)a, \mathfrak{t})\mathcal{P}_{\mu,v}((\mathbb{S} - \lambda I)a, \mathfrak{t}) \\ & \leq \mathcal{M}^{\binom{k(k+1)}{2}}\mathcal{P}_{\mu,v}^{(k+1)}((\mathbb{S} - \lambda I)a, \mathfrak{t})\mathcal{P}_{\mu,v}((\mathbb{S} - \lambda I)a, \mathfrak{t}) \\ & \leq \mathcal{M}^{\binom{k(k+1)}{2}}\mathcal{P}_{\mu,v}^k((\mathbb{S} - \lambda I)a, \mathfrak{t})\mathcal{P}_{\mu,v}^2((\mathbb{S} - \lambda I)a, \mathfrak{t}) \\ & \mathcal{P}_{\mu,v}((\mathbb{S} - \lambda I)^{(k+1)+1}a, \mathfrak{t}) \leq \mathcal{M}^{\binom{k(k+1)}{2}+1}\mathcal{P}_{\mu,v}^{(k+1)+1}((\mathbb{S} - \lambda I)a, \mathfrak{t}) \end{aligned}$$

**Theorem 3.11:**

Let  $\mathbb{S}$  is  $\mathcal{M}$ -IFHN-operator and let  $\lambda_1, \lambda_2$  be in  $\sigma_{ap}(\mathbb{S})$  with  $\lambda_1 \neq \lambda_2$ . If the sequences  $\{a_n\}$  and  $\{b_n\}$  are of unit vectors of  $\mathcal{H}$  such that  $\mathcal{P}_{\mu,v}((\mathbb{S} - \lambda_1 I)a_n) \rightarrow 0$  and  $\mathcal{P}_{\mu,v}((\mathbb{S} - \lambda_2 I)b_n) \rightarrow 0$  then  $\langle a_n, b_n \rangle \rightarrow 0$ .

Proof:

Let  $\mathbb{S}$  is  $\mathcal{M}$ -IFHN-operator. Let  $\lambda_1, \lambda_2$  be eigen values in  $\sigma_{ap}(\mathbb{S})$  with  $\lambda_1 \neq \lambda_2$ .

Let  $(\lambda_1 - \lambda_2)\langle a_n, b_n \rangle = \langle (\lambda_1 - \lambda_2)a_n, b_n \rangle$ . Then

$$\begin{aligned} & (\lambda_1 - \lambda_2)\langle a_n, b_n \rangle = \langle (\lambda_1 - \lambda_2)a_n, b_n \rangle \\ & = \text{Sup}\{\mathfrak{t} \in \mathbb{R} : \mathcal{F}_{\mu,v}((\lambda_1 - \lambda_2)a_n, b_n, \mathfrak{t}) < 1\} \\ & = \text{Sup}\{\mathfrak{t} \in \mathbb{R} : \mathcal{F}_{\mu,v}((\mathbb{S} - \lambda_1 I) - (\mathbb{S} - \lambda_2 I)a_n, b_n, \mathfrak{t}) < 1\} \\ & = \text{Sup}\{\mathfrak{t} \in \mathbb{R} : \mathcal{F}_{\mu,v}((\mathbb{S} - \lambda_1 I)a_n, b_n, \mathfrak{t}) < 1\} - \\ & \text{Sup}\{\mathfrak{t} \in \mathbb{R} : \mathcal{F}_{\mu,v}((\mathbb{S} - \lambda_2 I)a_n, b_n, \mathfrak{t}) < 1\} \\ & = \text{Sup}\{\mathfrak{t} \in \mathbb{R} : \mathcal{F}_{\mu,v}((\mathbb{S} - \lambda_1 I)a_n, b_n, \mathfrak{t}) < 1\} - \\ & \text{Sup}\{\mathfrak{t} \in \mathbb{R} : \mathcal{F}_{\mu,v}(a_n, (\mathbb{S} - \lambda_2 I)^*b_n, \mathfrak{t}) < 1\} \\ & (\lambda_1 - \lambda_2)\langle a_n, b_n \rangle = \langle (\mathbb{S} - \lambda_1 I)a_n, b_n \rangle - \langle a_n, (\mathbb{S} - \lambda_2 I)^*b_n \rangle \\ & \mathcal{P}_{\mu,v}((\lambda_1 - \lambda_2)\langle a_n, b_n \rangle) = \mathcal{P}_{\mu,v}(\langle (\mathbb{S} - \lambda_1 I)a_n, b_n \rangle - \langle a_n, (\mathbb{S} - \lambda_2 I)^*b_n \rangle) \\ & \mathcal{P}_{\mu,v}((\lambda_1 - \lambda_2)\langle a_n, b_n \rangle) \leq \mathcal{P}_{\mu,v}(\langle (\mathbb{S} - \lambda_1 I)a_n \rangle) + \mathcal{P}_{\mu,v}(\langle (\mathbb{S} - \lambda_2 I)^*b_n \rangle) \\ & \mathcal{P}_{\mu,v}((\lambda_1 - \lambda_2)\langle a_n, b_n \rangle) \leq \mathcal{P}_{\mu,v}(\langle (\mathbb{S} - \lambda_1 I)a_n \rangle) + \mathcal{M}\mathcal{P}_{\mu,v}(\langle (\mathbb{S} - \lambda_2 I)^*b_n \rangle) \rightarrow 0 \end{aligned}$$

Since,  $\mathcal{P}_{\mu,v}((\mathbb{S} - \lambda_1 I)a_n) \rightarrow 0$  and  $\mathcal{P}_{\mu,v}((\mathbb{S} - \lambda_2 I)b_n) \rightarrow 0$

$$\mathcal{P}_{\mu,v}((\lambda_1 - \lambda_2)\langle a_n, b_n \rangle) \rightarrow 0 \text{ as } \langle a_n, b_n \rangle \rightarrow 0.$$

**CONCLUSION**

From this work, it is concluded that, the conception of  $\mathcal{M}$ -Intuitionistic Fuzzy Hyponormal Operators are initiated. Moreover, significant characteristics with suitable numerical examples have been discussed. Furthermore, some of their essential properties have been defined.

## ABSTRACT

In this article, we present a novel approach for brain tumor classification using both traditional image processing and topological data analysis (TDA). By integrating persistence images derived from topological features into neural network training, the model captures both pixel-level and topological information from MRI scans. We contrast the results with models trained without topological data, illustrating the enhanced performance due to the combination of features.

**Keywords:** Topological data analysis (TDA), Persistent homology, Persistence images, Persistence diagrams, Convolutional neural networks

## INTRODUCTION

One of the most challenging problems in computer science is processing and extracting information from noisy, large-scale data sources. For a long time, scientists have been interested in algebraic topology, which has led to the emergence of TDA provides insights into the geometric and topological structure of data by analyzing its "shape" [3, 4]. TDA represents datasets using simplicial complexes—combinatorial algebraic structures that capture relationships between data points. A fundamental aspect of TDA is the extraction of invariant features through the continuous transformations of simplicial complexes, a technique referred to as persistent homology [4]. In contrast to traditional data analysis methods that focus primarily on metrics or features, TDA identifies topological

### Revathi and Gnanambal Ilango

characteristics like clusters, holes, and voids that remain consistent across different scales. Persistent homology measures the lifespan of these features, revealing hidden structures in complex datasets. In the context of classification, TDA has been applied to high-resolution diabetic retinopathy images using a TDA-based technique, as detailed in [5]. This approach involved a preprocessing step to construct persistent homology, which facilitated the extraction of topological characteristics embedded in persistence diagrams. These persistence descriptors were then used as input for a convolutional neural network (CNN) to classify patients with brain tumors versus healthy individuals. For image-based datasets like brain MRI scans, TDA enhances feature extraction by identifying structures that may be overlooked by conventional methods. By constructing persistence diagrams and converting them into topological representations, TDA enables the study of underlying data topology, which can be combined with pixel-based features to improve classification accuracy. In modern medical diagnostics, particularly brain tumor classification, the integration of advanced computational techniques like deep learning and TDA has proven valuable. Deep learning is highly effective at classifying medical images, but TDA provides an innovative approach by focusing on the shape and configuration of the data. Persistent homology, in particular, identifies topological features like connected components and loops, providing additional insights. By merging topological signatures from brain MRI images with pixel-level data, this study creates a richer dataset, ultimately enhancing neural network-based tumor classification. Comparing models with and without topological information demonstrates the potential of TDA to improve diagnostic accuracy. A brain tumor is an abnormal cell mass that can cause severe brain damage due to limited skull space. Early detection and classification are vital for treatment. This study uses a CNN-based model with MRI images and topological features from persistent homology for tumor classification. The combined model outperforms image-only models, improving accuracy and recall in detecting tumors.

#### Mathematical Definition of Persistent Images with Vietoris-Rips Complex

##### Persistence Diagram[1]

Given a dataset, we compute the persistent homology, which yields a **persistence diagram**. A persistence diagram  $D$  consists of points  $(b_i, d_i)$ , where each  $(b_i, d_i) \in \mathbb{R}^2$  corresponds to the birth  $b_i$  and death  $d_i$  of a topological feature:

$$D = \{(b_i, d_i) | i = 1, 2, \dots, n\}$$

where  $b_i \leq d_i$ , and  $n$  is the number of features captured in the homology group (e.g., connected components, loops).

##### Vietoris-Rips Complex[8]

To compute persistent homology from a point cloud or "finite metric space, the **Vietoris-Rips (VR) complex** is often used. The Vietoris-Rips complex"[8]  $VR(\epsilon)$  for a finite metric space  $X$  and a fixed parameter  $\epsilon > 0$  is defined as follows:

- **0-Simplices (Vertices):** The **0-simplices** of the VR complex are the elements of  $X$ , meaning each point is considered a vertex.
- **q-Simplices (Higher-dimensional simplices):** A set of vertices  $\{v_0, v_1, \dots, v_q\}$  forms a  $q$ -simplex  $\sigma = [v_0, v_1, \dots, v_q]$  if

$$diam(\sigma) \leq \max_{0 \leq i, j \leq q} d(v_i, v_j) \leq 2\epsilon$$

That is the diameter of the set, defined by the maximum pairwise distance between points is less than or equal to  $2\epsilon$ .

As  $\epsilon$  increases the VR complex becomes more connected and start to include higher dimensional simplices, capturing topological characteristics, including connected components, loops, and voids across multiple scales. These characteristics are tracked in the persistent diagram.

##### Weight Function[1]

Each point in the persistence diagram can be assigned a weight based on its persistence (i.e., the difference between birth and death times). A typical weight function  $w(b, d)$  is based on the persistence  $p = d - b$ . One common weight is:

$$w(b, d) = \exp\left(-\frac{(d - b)^2}{\sigma^2}\right)$$

where  $\sigma$  is a parameter controlling the spread of the weighting.

### Revathi and Gnanambal Ilango

#### Binning into a Grid

Next, the persistence diagram points are placed into a regular grid. Let  $G \in R^{m \times m}$  be the persistent image grid of size  $m \times m$ . The domain  $[b_{min}, b_{max}] \times [d_{min}, d_{max}]$  is partitioned into grid cells.

Let  $x_i \in G$  be a cell in the grid, and let  $\phi(x_i)$  denote a mapping from the persistence diagram coordinates to the grid. The value of the grid at position  $x_i$  is:

$$G(x_i) = \sum_{(b_j, d_j) \in D} w(b_j, d_j) \cdot K(x_i, \phi(b_j, d_j))$$

where  $K$  is a kernel function, such as the Gaussian kernel:

$$K(x_i, \phi(b_j, d_j)) = \exp\left(-\frac{\|\phi(b_j, d_j) - x_i\|^2}{2\sigma^2}\right)$$

This kernel-based smoothing converts the persistence diagram points into a continuous image by distributing the weight of each point across the grid.

#### Final Persistent Image

The resulting matrix  $G$  is the **persistent image**, where each grid cell contains a value corresponding to the weighted topological features' persistence in that region of the persistence diagram. The output image can now be treated as a 2D matrix suitable for use in machine learning models, particularly in convolutional neural networks (CNNs) or other image-based classifiers. In Figure 1, there is an example of construction of Rips complex from the data together with persistent homology. Black dots are represent connected components ( $H_0$ ) and red triangles represent loops ( $H_1$ )[3].

#### Combining Persistent homology with image data set

The main objective of this study is to perform a classification assignment by combining original images with the topological characteristics of the images. We begin with a dataset of digitized images. In this paper, digital images in gray scale are utilized. A two-dimensional matrix is used to represent each image in the collection. First, each image in the collection has to undergo preprocessing. Following preprocessing, two distinct datasets are created. The first dataset is set up so that each image is represented as a series of three two-dimensional matrices, or what we'll refer to as three channels. Each matrix in this series is the matrix that originally represented the image. Stated differently, each image in the newly created dataset has a three-channel matrix, and within each channel lies the original grey-scale image matrix. Persistent Homology can be represented with persistence diagrams [4]. In Figure 2, For the circle dataset Persistent Homology is computed and persistent diagram is constructed. The diagram is shown in the middle picture in Figure 2. In the persistent diagrams, the red dots represent the loops with dimension 1, while the black dots represent connected components with dimension 0. More about the persistence diagram as a TDA tool can be in [4]. The persistent images for dimensions 0 and 1, which are displayed in Figure 2, are then computed from the persistent diagrams. A stable depiction of persistence diagrams is provided by persistent images. To construct the second dataset, an additional step involves computing the persistent homology of each image to capture topological features. For each image, a persistence diagram is generated, followed by the creation of persistence images for dimensions 0 and 1. These persistence images have the same dimensions as the original image matrix. The final dataset comprises sequences of three matrices for each image: the original image, the persistence image associated with dimension 0 and the persistence image associated with dimension 1.

#### Application of the Brain Tumor Images

A brain tumor is an abnormal mass of cells within the brain. Due to the limited space inside the skull, any growth can lead to increased pressure, causing brain damage and potentially life-threatening complications. Early detection and classification of brain tumors are critical in medical imaging research. Accurate classification helps to determine the most appropriate treatment, which can be life-saving for patients. Deep learning approaches have brought significant advancements in healthcare diagnosis. According to the World Health Organization (WHO)[6], accurate brain tumor diagnosis requires detecting the tumor, identifying its location, and classifying it by malignancy, grade, and type. This study focuses on diagnosing brain tumors using Magnetic Resonance Imaging (MRI), employing a single

### Revathi and Gnanambal Ilango

Convolutional Neural Network (CNN)-based multi-task model for tumor detection and classification. In a normal MRI (left panel), the brain appears clear with no visible signs of abnormalities, such as unusual masses, distortions, or clouding in the image. The tissue structures, including the gray matter, white matter, and ventricles, are distinct and well-defined, indicating healthy brain function. In contrast, the MRI on the right panel shows an affected brain, where a tumor is present. The tumor typically appears as an irregular, clouded, or mass-like area, disrupting the normal brain structure. This abnormality may cause distortion of surrounding tissues, swelling (edema), and increased pressure, indicating the presence of a pathological condition. The contrast between the two images highlights the impact of the tumor on the brain's normal architecture. The MRI image dataset [9] contains 253 JPEG images, categorized into two classes: "Tumor" and "Normal." The "Tumor" class represents images from patients with brain tumors, while the "Normal" class represents images from patients without brain tumors. In our processing, we label the "Tumor" class as "1" and the "Normal" class as "0." The dataset consists of two folders: "yes," containing 155 images, and "no," containing 98 images.

#### Preprocessing of Data

The original dataset contains grayscale images with varying dimensions, where the pixel values range from 0 to 255. As part of the preprocessing, all images were resized to 64x64 pixels. Additionally, the pixel values were normalized to a range between 0 and 1. This preprocessing was performed using R, and further process was done by Python.

#### Constructing the Persistent Images

Persistent images were constructed for dimensions 0 and 1 from the original images in the dataset, and each persistent image was resized to 64x64 to match the original image dimensions. These persistent images were then concatenated with the original images to create a second dataset incorporating both pixel-based and topological features. The aim was to evaluate whether a neural network classifier trained on this augmented dataset would perform better than one trained solely on the original images.

#### Classification of images

The dataset was segmented into training (80%), validation (20%), and test sets to enable a thorough evaluation of the model's performance. A simple neural network architecture with two hidden dense layers (128 neurons each) and a softmax output layer was used for binary classification into 'yes' (tumor) or 'no' (no tumor). The model was optimized with the 'adam' optimizer and trained using the 'sparse\_categorical\_crossentropy' loss function. It was trained for 30 epochs, and the results were compared with models trained only on the original image dataset. This comparison aimed to determine if the inclusion of topological features improved classification accuracy. There are relatively sophisticated neural architectures for classifying images in this task; these neural designs mostly use convolutional networks and transfer learning. This model, on the other hand, is straightforward and consists of a two-layered neural network. The outcomes are equivalent. In our tests, the topological characteristic calculation is a longest procedure. But even with this set of data, it can be completed in hours using relatively low-end hardware devoid of GPU and related technology. While the test set that we used in our studies with TDA was accurate, the test set that we used without TDA was not. It is as anticipated that our TDA Model has improved. It is clear from looking at Tables 1 and 3 that our model with topological signatures classifies images of patients without brain tumors better than the model without topological signatures. Tables 2 and 4 provide the remaining outcomes for the metrics. After analyzing them, we can conclude that our model performed better for this data set in terms of the parameters of recall, accuracy, and F1-metric.

## CONCLUSION

In this work, a summary of topological data analysis (TDA) and its fundamental tools are given, along with an example of how to apply them on basic datasets to show how they work. In addition to the original photos, a novel model is provided for classifying brain tumors that includes topological features. This model doesn't require a lot of computing power because it uses a fully connected neural network. Topological feature-based models outperformed

**Revathi and Gnanambal Ilango**

those based solely on the source images, in tests conducted on a brain tumor dataset, improving important machine learning metrics.

### ABSTRACT

Star edge coloring of a graph is a proper edge coloring of graph such that any path on three edges is not bicolored. Star edge chromatic number is the minimum number of colors which exhibits star edge coloring. Graph products are useful in many situations. The corona of two graphs  $G_1$  and  $G_2$  is the graph  $G = G_1 \circ G_2$  formed from one copy of  $G_1$  and  $|V(G_1)|$  copies of  $G_2$  where  $i$ th vertex of  $G_1$  is adjacent to every vertex in  $i$ th copy of  $G_2$ . In this paper, we investigate the star edge chromatic number of corona product of path and star graph.

**Keywords:** Star edge coloring, Star edge chromatic number, Corona product, Path, Cycle.

## INTRODUCTION

In graph theory, star coloring has been introduced by Grunbaum in 1973. The star edge coloring was introduced by Liu and Deng[2] motivated by the vertex coloring version[1,3,4,5]. Star edge coloring of a graph  $G$  is a proper edge coloring of graph such that any path on three edges is not bicolored. The minimum number of colors needed to star edge color the graph  $G$  is called the star edge chromatic index and it is denoted by  $\chi'_s(G)$ . Guillaume Fertin et al.[3] gave the exact value of the star chromatic number of different graph families such as cycles, trees, 2-dimensional grids, complete outerplanar graphs and bipartite graphs. They also gave for the star chromatic number of other graph families including planar graphs,  $d$ -dimensional grids, hypercubes, tori and graphs with restricted treewidth. Harary and Frucht[6,7] have studied and introduced the corona product of two graphs. Hou et al[8] gave another type of corona product called the edge corona product. In this is paper, we investigate the star edge chromatic number of corona product of path and star graph.

**Kowsalya and Keerthana**

**PRELIMINARIES**

The  $G_1$  and  $G_2$  are the two graphs, the corona graph is the graph  $G=G_1 \circ G_2$  formed from the one copy of  $G_1$  and  $|V(G_1)|$  copies of  $G_2$  where  $i$ th vertex of  $G_1$  is adjacent to every vertex in the  $i$ th copy of  $G_2$ . This type of graph have been studied and introduced by Harary and Frucht[6,7]and referred[9].

**THEOREM:**

The star edge chromatic number of corona product of path and star graph is  $\chi'_s(P_n \circ K_{1,n})=2n+5, n \geq 4$

**PROOF:**

Let  $V(P_n) = \{v_1, v_2, \dots, v_n\}$

$V(K_{1,n}) = \{u_i, u_{ij}; 1 \leq i \leq n; 1 \leq j \leq n\}$

&  $V(P_n \circ K_{1,n}) = \{v_i : 1 \leq i \leq n\} \cup \{u_i : 1 \leq i \leq n\} \cup \{u_{ij} : 1 \leq j \leq n; 1 \leq i \leq n\}$

By the definition of corona graph , each vertex of  $P_n$  is adjacent to every vertex of a copy of  $K_{1,n}$ .

Let the edge sets be,

$E(P_n) = \{e_1, e_2, e_3, \dots, e_{n-1}\}$

$E(K_{1,n}) = \{e_{ij} : 1 \leq i \leq n; 1 \leq j \leq n\}$

And  $E(P_n \circ K_{1,n}) = \{e_i : 1 \leq i \leq n-1\} \cup \{e_{ij} : 1 \leq i \leq n; 1 \leq j \leq n\}$

The graph  $P_n \circ K_{1,n}$  consists of  $2n^2+2n-1$  edges.

Assign the edges of the corona graph with colors as follows:

Let  $f$  be the coloring which assigns the colors for the edges as

$f(e_{ij}) = c_i, 1 \leq i \leq 2n+1$  for each odd copy of  $K_{1,n}$ .

$f(e_{ij}) = c_i, 2 \leq i \leq 2n+2$  for each even copy of  $K_{1,n}$ .

$$f(e_i) = \begin{cases} C_{2n+3} & \text{for } i \equiv 1 \pmod 3 \\ C_{2n+4} & \text{for } i \equiv 2 \pmod 3 \\ C_{2n+5} & \text{for } i \equiv 0 \pmod 3 \end{cases}$$

Each of the  $i$ th copy of  $K_{1,n}$  requires  $2n+1$  distinct colors to proper star color the edges of  $K_{1,n}$ .The edges  $\{e_i; 1 \leq i \leq n-1\}$  requires atleast 3 distinct colors from the definition of star edge coloring and since  $\deg(v_i)=n+3$  for  $2 \leq i \leq n-1$ , the minimum number of colors needed to star edge color the corona product  $P_n \circ K_{1,n}$  is  $2n+5$ .

Hence  $\chi'_s(P_n \circ K_{1,n}) = 2n+5, n \geq 4$ .

**CONCLUSION**

In this paper, we found the star edge chromatic number of corona product of path and star graph. The study of star edge coloring has increased in significance due to its real life application. In future, we would like to find the star edge chromatic number for graph families.

## ABSTRACT

This research introduces a mathematics-based approach for optimizing diabetes prediction models using the Firefly Algorithm (FA) in computer science. The FA, inspired by the flashing behavior of fireflies, is applied to both feature selection and hyperparameter tuning of classifiers like Random Forest and SVM. By formulating the optimization problem mathematically, the FA algorithm seeks to minimize the classification error through iterative updates based on attraction and randomness. Evaluated on the Pima Indian Diabetes Dataset, the optimized models show enhanced accuracy and robustness. This study demonstrates the effectiveness of mathematical optimization techniques, like FA, in computational healthcare analytics.

**Keywords:** Firefly Algorithm, Mathematical Optimization, Feature Selection, Hyperparameter Tuning, Computational Healthcare.

## INTRODUCTION

In recent years, the intersection of mathematics and computer science has led to significant advancements in predictive modeling, especially in healthcare analytics. One critical application is diabetes prediction, a crucial aspect of early diagnosis and management of this chronic disease. Diabetes Mellitus affects millions globally, and its early detection can help prevent severe complications such as cardiovascular diseases, kidney failure, and neuropathy. Machine learning (ML) models have been extensively used to develop predictive models for diabetes, utilizing

**Ravina and Karunya**

clinical and demographic data. However, the challenge lies in optimizing these models for accuracy, interpretability, and computational efficiency. This research explores the use of the Firefly Algorithm (FA), a nature-inspired optimization technique, for optimizing feature selection and hyperparameters of ML models for diabetes prediction. The Firefly Algorithm, introduced by Xin-She Yang in 2008, is a metaheuristic algorithm inspired by the bioluminescent communication behaviour of fireflies. The algorithm leverages the concept of the attractiveness and movement towards brighter, more attractive fireflies to explore and exploit the solution space effectively. In mathematical terms, each firefly represents a potential solution, and its brightness (fitness) is determined by an objective function. The FA's iterative process involves adjusting the positions of fireflies in the search space, guided by a combination of attraction, randomness, and distance between fireflies. This behaviour enables FA to perform global optimization, making it a powerful tool for solving complex problems in computer science, such as feature selection and hyperparameter tuning. Feature selection is a critical step in developing ML models, particularly in high-dimensional datasets. In diabetes prediction, features like Pregnancies, Glucose, BloodPressure, SkinThickness, Insulin, BMI, DiabetesPedigreeFunction, and Age may have varying levels of significance. Selecting the most relevant features not only improves the model's accuracy but also reduces computational cost and enhances the interpretability. Traditional feature selection methods, such as filter, wrapper, and embedded methods, often fail to balance the trade-off between accuracy and computational efficiency.

The FA offers a novel solution by dynamically adjusting the weights assigned to each feature based on its contribution to minimizing classification error. This adaptive mechanism ensures that only the most significant features are selected, leading to a more streamlined and effective predictive model. In addition to feature selection, hyperparameter tuning is crucial for optimizing the performance of ML models. Hyperparameters, such as the number of estimators in Random Forest, the kernel type in the Support Vector Machines (SVM), and the number of hidden layers in Neural Networks, significantly impact a model's ability to generalize to unseen data. Traditional grid search or random search methods are computationally expensive and may miss optimal combinations. The FA provides a more efficient approach by navigating the hyperparameter space using a guided random search mechanism. By iteratively refining hyperparameter values to minimize the classification error, the FA enhances the model's predictive performance while reducing the risk of overfitting. This study utilizes the Pima Indian Diabetes Dataset, a widely-used benchmark for diabetes prediction tasks, to evaluate the effectiveness of the FA in optimizing feature selection and the hyper parameters. The dataset consists of various medical and demographic attributes, making it an ideal candidate for testing the FA's capability in handling multi-dimensional optimization problems. By implementing FA for both the feature and hyperparameter optimization, this research aims to develop a robust, accurate, and interpretable model for diabetes prediction. Furthermore, this study compares the performance of FA-optimized models with those optimized using other metaheuristic algorithms, such as Genetic Algorithms (GA) and Particle Swarm Optimization (PSO). The results demonstrate that the FA not only improves prediction accuracy but also converges faster to optimal solutions, thereby reducing computational cost. This research highlights the potential of integrating mathematical optimization techniques like the FA in computer science applications, particularly in healthcare analytics, where precision and efficiency are paramount.

**RESEARCH PROBLEM**

Diabetes prediction using machine learning involves complex data analysis and model optimization, requiring efficient feature selection and hyperparameter tuning. For mathematics students, the challenge lies in applying mathematical principles to enhance these model's performance. Traditional methods for optimizing machine learning models often address feature selection and hyperparameter tuning separately, leading to inefficiencies and suboptimal results. The Firefly Algorithm (FA), a metaheuristic optimization technique inspired by the behaviour of fireflies, offers a novel approach to addressing these challenges. FA utilizes a combination of attractiveness and randomness to explore solution spaces, making it suitable for optimizing both feature weights and hyperparameters simultaneously. However, the effectiveness of FA in this dual optimization task for diabetes prediction has not been thoroughly investigated from a mathematical perspective.

**Ravina and Karunya**

The core research problem is to develop and mathematically validate a framework that leverages the Firefly Algorithm to concurrently optimize feature selection and hyperparameters for diabetes prediction models. This involves formulating the optimization problem mathematically, analyzing FA's performance theoretically, and comparing it with other optimization methods. The objective is to demonstrate how mathematical optimization techniques can enhance machine learning model's accuracy, interpretability, and computational efficiency, thus offering practical insights for improving diabetes prediction. This research aims to bridge the gap between mathematical theory and practical applications in healthcare analytics, providing valuable insights for students and researchers in the field of applied mathematics.

**RESEARCH OBJECTIVE****Apply the Firefly Algorithm for Feature Selection**

Investigate how the Firefly Algorithm can be used to identify and select the most relevant features from the diabetes dataset to improve prediction accuracy. This objective focuses on simplifying the feature set to enhance model performance and reduce complexity.

**Optimize Hyperparameters Using the Firefly Algorithm**

Explore the use of the Firefly Algorithm to fine-tune hyperparameters of machine learning models for diabetes prediction. The goal is to determine the optimal settings for model parameters that maximize prediction accuracy and efficiency.

**Evaluate the Performance of FA-Optimized Models**

Assess the effectiveness of models optimized using the Firefly Algorithm compared to baseline models. This involves comparing prediction accuracy and computational efficiency to understand the benefits of using FA for feature selection and hyperparameter optimization.

**Diagrammatic Representation**

This flowchart provides a clear visualization of the steps involved in feature selection and hyperparameter optimization using the Firefly Algorithm and how to evaluate the performance of the models. Here is a high-level flowchart of the entire process: To provide a comprehensive analysis, including graphical representations, you can use libraries like matplotlib and seaborn to visualize the results of feature selection, hyperparameter optimization, and model performance.

**Feature Selection Convergence Plot**

Shows how the best fitness score evolves over iterations during feature selection. This helps to visualize how the algorithm converges to the optimal feature subset.

**Hyperparameter Optimization Convergence Plot**

Displays the best fitness score achieved during hyperparameter over iterations. This demonstrates how the algorithm improves its parameter selection over time.

**Accuracy Comparison Bar Chart**

Compares the accuracy of the baseline model (trained with all features) against the FA-optimized model (trained with selected features and optimized hyperparameters). This illustrates the improvement (if any) achieved through feature selection and hyperparameter tuning.

**Ravina and Karunya**

## CONCLUSION

The Firefly Algorithm (FA) has demonstrated its efficiency in enhancing diabetes prediction models through both feature selection and hyperparameters optimization. By applying FA for feature selection, the most relevant features were identified, leading to improved model accuracy and reduced complexity. This is evident from the convergence plots, which show that the algorithm effectively refines feature subsets over iterations. Similarly, FA's role in hyperparameter optimization yielded better settings for the SVM model, resulting in superior performance compared to the baseline model. The accuracy comparison confirms that FA can significantly enhance model performance through both optimized feature selection and hyperparameter tuning.

### Future Work

#### Extended Testing

FA to larger, more complex datasets to evaluate its scalability and effectiveness in diverse scenarios.

### Hybrid Approaches

Investigate combining FA with other optimization techniques, such as Genetic Algorithms or Particle Swarm Optimization, to potentially achieve better results.

### Real-World Applications

Test FA-based methods on different real-world problems to validate their generalizability and robustness.

### Enhanced Metrics

Incorporate additional evaluation metrics like precision, recall, and F1-score to gain a comprehensive understanding of model performance.

### Parameter Sensitivity

Perform sensitivity analysis to determine how variations in FA parameters (e.g., alpha, beta, gamma) affect the outcomes, optimizing the algorithm for different types of problems.

### Computational Efficiency

Explore parallelization techniques to improve FA's computational efficiency, especially for large-scale datasets and complex models. These future directions aim to refine and expand the application of the Firefly Algorithm, potentially leading to more robust, efficient, and scalable solutions in machine learning and optimization tasks.

### ABSTRACT

This paper introduces the notion of a constant anti fuzzy graph, regular anti fuzzy line graph and claw anti fuzzy graph. The features of claw anti-fuzzy graph and regular anti-fuzzy line graph are presented. This paper investigates properties of anti fuzzy line graph when it is computed n-times for the regular anti fuzzy graph.

**Keywords:** constantanti fuzzy graph, regular anti-fuzzy graph, clawanti fuzzy graph

**Mathematical Classification:** 0C572, 05C07, 05C99.

## INTRODUCTION

[1]Fuzzy logic, introduced by Lotfi A. Zadeh in the 1960s, provides a framework for dealing with imprecise and uncertain information. It is particularly valuable in control systems, artificial intelligence, and decision-making where crisp, binary logic falls short. In conventional graph theory, graphs are used to model relationships between objects or entities, with crisp or binary edges to indicate whether there is a connection (edge)between two nodes (vertices). Fuzzy graphs are particularly useful in situations where the relationships between entities are not well-defined and can vary in strength or intensity. They provide a more flexible framework for modeling complex relationships by allowing edges in the graph to have varying degrees of membership in fuzzy sets, rather than just being binary (either present or absent). [2]Rosenfeld considered the fuzzy relations on fuzzy sets and developed the theory of fuzzy graphs in1975. The concept of fuzzy trees, blocks, bridgesand cut nodes in fuzzy graph has been studied in [2]. A fuzzy line graph, also known as a fuzzy line chart or a fuzzy time series graph, provides a visual representation of the fuzzy set's characteristics. It allows seeing how the degrees of membership change within the chosen interval, providing insights into the uncertainty and vagueness of the data. Here's a simple example to illustrate the concept.

**Kousalya and Radhika**

Suppose a fuzzy set representing "tallness" of people in a certain population, and want to create a fuzzy line graph for this set over the height range of 150 cm to 200 cm. It might assign membership degrees using a triangular membership function, with a peak at 175 cm. The graph would then show how tallness membership varies across this height range. [6] The concept of fuzzy line graph was introduced by J.N.Mordeson in 1993 by the base of [7] fuzzy intersection graph.

[10]Akram defines a new concept of fuzzy graph known as Fuzzy Anti Graph. This concept is relatively new in the development of fuzzy graph studies, and is a promising study material. Some anti-fuzzy graphs include in [11] which introduced the concept of anti fuzzy graph, regular degree and irregular anti fuzzy graph. The concept of anti fuzzy line graph has a recent origin. Anti fuzzy line graph is a mathematical and graphical representation used to describe uncertainty or imprecision in data or relationships between variables. It is a specialized form of a line graph, which typically displays the relationship between two or more variables over a continuous range obtained from anti fuzzy graph. [12] Introduced the anti fuzzy line graphs.

Regular graphs are important in graph theory because they often exhibit symmetrical and predictable properties, which can make them easier to study and analyze. It can help to solve problems related to network design, routing, and optimization in various practical applications. This work contributes to finding the constant anti fuzzy graphs, regular anti fuzzy line graphs, claw anti fuzzy graph and their potential applications. It insist to computing n-times anti fuzzy line graph can lead to improved decision-making tools, better network analysis techniques, and more robust models for complex systems.

**PRELIMINARIES**

This topic includes some fundamental definitions to derive the results of this paper. This paper considers an undirected simple and connected graph.  $G(\sigma, \mu)$  is a fuzzy graph and  $G_A(\sigma, \mu)$  is noted as anti fuzzy graph with underlying set S. Where, S is a fuzzy subset of non empty set.

1. The crisp graph of  $G(\sigma, \mu)$  is denoted as  $G^*(\sigma^*, \mu^*)$  where  $\sigma^* = \text{supp}(\sigma) = \{a \in S / \sigma(a) > 0\}$  and  $\mu^* = \text{supp}(\mu) = \{(a,b) \in S \times S / \mu(a,b) > 0\}$ .
2. A Fuzzy Graph  $G(\sigma, \mu)$  consist of vertices ( $\sigma: S \rightarrow [0,1]$ ) and edges ( $\mu: S \times S \rightarrow [0,1]$ ) such that  $\mu(x,y) \leq \min(\sigma(x), \sigma(y))$  for all x and y in S.
3. The order of fuzzy graph G is defined as  $p = \sum \sigma(x) x \in S$  and the size of G is defined as  $q = \sum \mu(x,y) x, y \in S$ .

Anti Fuzzy Graph  $G_A(\sigma, \mu)$  consist of vertices ( $\sigma: S \rightarrow [0,1]$ ) and edges ( $\mu: S \times S \rightarrow [0,1]$ ) such that  $\mu(x,y) \geq \max(\sigma(x), \sigma(y))$  for all x and y in S.

Example: 1

Consider,  $G_A: (\sigma, \mu)$  be a graph with  $\sigma = \{a/0.2, b/0.3, c/0.8, d/0.6\}$  and  $\mu = \{p, q, r, s / (a,b), (a,c), (b,d), (c,d) / 0.6, 0.9, 0.8, 1 \text{ respectively}\}$  such that  $\mu(a,b) \geq \max(\sigma(a), \sigma(b))$ .

**Kousalya and Radhika**

5. The degree of a vertex  $\sigma(x)$  of an anti fuzzy graph is  $dGA(\sigma(x)) = \sum_{x \neq y} \mu(x,y)$ .
6. Two vertices  $x$  and  $y$  are adjacent in  $GA:(\sigma, \mu)$ , if  $\mu(x,y) \geq [\sigma(x) \vee \sigma(y)]$ .
7. Anti fuzzy graph  $GA(\sigma, \mu)$  is strong if  $\mu(x,y) = \max(\sigma(x), \sigma(y)) \forall (x,y)$  in  $\mu$ .
8. Anti fuzzy graph  $GA(\sigma, \mu)$  is complete if  $\mu(x,y) = \max(\sigma(x), \sigma(y)) \forall (x,y)$  in  $\sigma$ .
9. Some kinds of AFG
  - v-nodal graph: In a graph, every vertex  $\sigma(x)$  has a distinct membership value.
  - e-nodal graph: In a graph every edge  $\mu(x,y)$  has a distinct membership value.
  - Uninodal graph: Every  $\sigma(x)$  and  $\mu(x,y)$  are distinct in a graph.
  - Partially uninodal graph: Any one of  $\sigma(x)$  or  $\mu(x,y)$  have the unique value.
  - Binodal graph: In a graph  $GA:(\sigma, \mu)$ ,  $\sigma(x) = c1$  and  $\mu(x,y) = c2$ .
10. The complement of AFG is denoted by  $GA(\bar{\sigma}, \bar{\mu})$  and is derived from  $GA(\sigma, \mu)$ . in which,  $\sigma = \bar{\sigma}$  and  $\bar{\mu}(x,y) = 0$  if  $\mu(x,y) > 0$  and  $\bar{\mu}(x,y) = \max(\sigma(x), \sigma(y))$ .

A line graph  $L(G)$  (also called an adjoint, conjugate, covering, derivative, derived, edge, edge-to-vertex dual, interchange, representative, or theta-obrazom graph) of a simple graph  $G$  is obtained by associating a vertex with each edge of the graph and connecting two vertices with an edge iff the corresponding edges of  $G$  have a vertex in common. Taking the line graph twice does not return the original graph unless the line graph of a graph  $G$  is isomorphic to  $G$  itself. 12.  $GA$  is the anti fuzzy graph with the set of vertices  $V$  and the set of edges  $E$ . [12]The line graph of  $GA$ , denoted by  $L(GA) = (X, Z)$ , is the graph with the set of vertices  $X = \{x\} \cup \{uv\} / x \in E, u, v \in V, x = uv\}$  & set of edges  $Z = \{SxSy / Sx \cap Sy \neq \emptyset, x, y \in E, x \neq y\}$ ,

where  $Sx = \{x\} \cup \{uv\} / x \in E, u, v \in V$ . Let  $(\sigma, \mu)$  be an anti fuzzy sub graph  $GA$ . Define the anti fuzzy subset  $(\lambda, \omega)$  of  $(X, Z)$  respectively as follows,

$$\forall Sx \in X, \lambda(Sx) = \mu(x);$$

$$\forall SxSy \in Z, \omega(SxSy) = \max \{ \mu(x), \mu(y) \}.$$

$(\lambda, \omega)$  is an anti fuzzy sub graph of  $L(GA)$  called the anti fuzzy line graph corresponding to  $(\sigma, \mu)$ . it is denoted by  $L(GA): (\lambda, \omega)$ .

**Example 2**

From Example (1), the anti fuzzy line graph  $L(GA) = (X, Z)$  is derived shown below.

$GA:(\sigma, \mu)$  is said to be  $k$ -regular if  $dGA(\sigma(x)) = k$  [15], where  $\delta = \Delta = k$ . Any connected anti fuzzy graph with two vertices is regular. If  $dGA(\sigma(x)) \neq k$  then AFG is irregular.  $\delta$  and  $\Delta$  are the minimum and maximum degree of a vertex on anti fuzzy graph.

**MAIN RESULTS**

This part defines the regular anti fuzzy line graph, caw anti fuzzy graph and constant anti fuzzy graph related with  $k$ -regular anti fuzzy graph. Some of the characteristics are analysed.

**Kousalya and Radhika**

**1. Constant Anti Fuzzy Graph**

Let  $GA:(\sigma,\mu)$  be an anti fuzzy graph on  $G^*(\sigma^*,\mu^*)$ . if  $dGA(\sigma(x)) = k$  for all  $\sigma(x)$  in GA. That is the graph is called as constant anti fuzzy graph of degree (k) or k- anti fuzzy graph. It is denoted by the symbol  $cGA$ . where  $c$  denotes the degree of  $\sigma(x)$ .

**Example 3**

Consider,  $GA:(\sigma,\mu)$  be a graph with  $\sigma = \{a/0.2, b/0.3, c/0.8, d/0.6\}$  and  $\mu = \{p, q, r, s / (a,b), (a,c), (b,d), (c,d) / 0.7, 0.8, 0.8, 0.7$  respectively} such that  $\mu(a,b) \geq \max(\sigma(a),\sigma(b))$ .

In this Example, the degree of vertices a, b, c, d is (1.5). where  $\delta=\Delta=1.5$ . This graph is also called 1.5GA or 1.5- regular anti fuzzy graph.

**Regular Anti Fuzzy Line Graph**

Consider  $GA$  is the anti fuzzy graph with the set of vertices  $V$  and the set of edges  $E$ . The regular anti fuzzy line graph of  $GA$ , denoted by  $RL(GA) = (X,Z)$ . Define the anti fuzzy subset  $(\lambda,\omega)$  of  $(X,Z)$  respectively as follows,

For all  $x \in X, \lambda(x) = GA(\mu)$

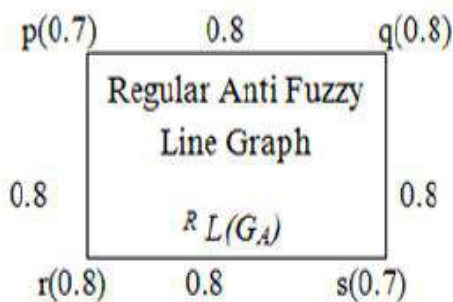

For all  $xy \in Z, \omega(xy) = \max\{\mu_i(x), \mu_j(x)\} = \max\{\lambda(x), \lambda(y)\}$ .

Such that  $d(\sigma_i(x)) = k$ , constant.

it is denoted by  $RL(GA):(\lambda,\omega)$ .

**Example 4**

From Example (3), The regular anti fuzzy line graph is derived. The obtained graph contains the unique edges and 1.6-regular.

Remark: Every regular anti fuzzy line graphs are regular and constant anti fuzzy graph.  $RL(GA):(\lambda,\omega) \rightarrow cGA:(\sigma,\mu)$ . But all the constant AFG need not be corresponding to regular AFLG.  $RL(GA):(\lambda,\omega)$  is also obtained from some anti fuzzy graph with more weighted edges adjacent to other vertices.

**Theorem 3.1**

Any uninodal GA with  $|\sigma|=|\mu|=3, Ln(GA)$ , is complete regular for  $n \geq 2$ .

**Kousalya and Radhika**

**Proof:**

By the consideration of statement, edges are adjacent to each other in  $GA$ .  $L(GA):(\lambda, \omega)$  hold the edges which are effective.  $L(GA)$  is strong and complete.  $max(\sigma)$  can assign 2 times with an incident edges.  $L2(GA) = L(L(GA))$  is exist with unique vertices and edges.

This implies that,  $\lambda(Se) = \omega(SeSf) = constant$ . Therefore,  $d(\lambda) = k$  for all  $\lambda$  in  $L2(GA)$ .

That is,  $L2(GA)$  is strong, complete and  $k$ -regular anti fuzzy graph.

Remark: The above result is also true for strong and complete  $GA:(\sigma, \mu)$ . That is, if  $GA$  is strong / complete with  $|\sigma|=|\mu|=3$ , then  $L(GA):(\lambda, \omega)$  is also strong, complete and  $k$ -regular AFLG.

**Illustration 3.2**

Consider,  $GA:(\sigma, \mu) : \sigma = \{a/0.7, b/0.3, c/0.5\} ; \mu = \{(a,b)/0.8, (b,c)/0.6, (a,c)/0.9\}$   
 $L(GA):(\lambda, \omega) : \lambda = \{ab/0.8, bc/0.6, ac/0.9\} ; \omega = \{(ab,ac)/0.9, (ab,bc)/0.8, (ac,bc)/0.9\}$   
 $L2(GA):(\lambda, \omega) : \lambda = \{abac/0.9, abbc/0.8, acbc/0.9\} ; \omega = \{0.9, 0.9, 0.9\} = 1.8$ -regular.  
 In this example,  $L2(GA)$  is strong, complete and 1.8-regular AFLG

Fig. (a) Uninodal AFG

Fig. (b) AFLG –  $L^1(G_A)$

Fig. (c)  $AFLG - L^2(G_A) = L(L(G_A))$

**Theorem 3.3**

For any  $GA:(\sigma, \mu)$  with  $|\sigma| > 3$ ,  $\{Ln(GA), n \geq 2\}$  is  $k$ -regular.

**Proof:**

The proof of this theorem is given by two cases. Consider the underlying graph when one is strong and another is complete. The suitable example is provided at the end of this theorem.

Case: 1  $GA:(\sigma, \mu)$  is Strong (SAFG)

Consider SAFG with  $|\sigma| > 3$  as shown in example (3.4). If  $|\sigma| = m$  &  $|\mu| = n$  then  $L1(G)$  having  $|\lambda| = n$  and  $|\omega| = Deg(incident\ edges)/2$ .

By theorem 3.1,  $\lambda(Se) = \omega(SeSf) = constant\ k$  for all  $\lambda$ .

Computing  $L2(G)$  from  $L1(G)$ , its line graph is exists the unique values of  $\lambda$  &  $\omega$ .

**Kousalya and Radhika**

Hence, SAFG with  $|\sigma| = 4$  then  $L_2(G)$  is  $k$ -regular AFLG.

Case: 2  $GA:(\sigma, \mu)$  is Complete

Consider any  $GA:(\sigma, \mu)$  for  $(|\sigma| > 3)$ , edges are adjacent with each other. If it is Complete AFG, all the edges are effective.

Based on case-1,  $L_2(G)$  is  $k$ -regular  $L(GA):(\lambda, \omega)$ .

If  $GA:(\sigma, \mu)$  is not complete with uninodal then, only one vertex having  $max(\mu)$ .

To attain the  $k$ -regular graph, we compute  $L_n(GA)$  until  $max(\mu)$  is project as a maximum number of vertices within the line graph.

This happens only after  $n > 2$ .

Remark: For any  $GA:(\sigma, \mu)$ ,  $|\sigma| > 3$  with strong and complete,  $\{L_n(G), n = 2\}$  is  $k$ -regular  $L(GA):(\lambda, \omega)$ . For uninodal AFG  $(|\sigma| > 3)$ ,  $\{L_n(G), n > 2\}$  is  $k$ -regular AFLG.

**Illustration 3.4**

Consider,  $GA:(\sigma, \mu) : \sigma = \{a/0.6, b/0.3, c/0.5, d/0.8\} ; \mu = \{(a,b)/0.6, (b,c)/0, (a,c)/0.7, (a,d)/0.8, (b,d)/0.8, (c,d)/0.8\}$

**Fig. (a) Uninodal Strong Anti Fuzzy Graph**

It's Line graph  $L(GA):(\lambda, \omega) : \lambda = \{ab/0.6, ad/0.8, ac/0.7, cd/0.8, bd/0.8\} ; \omega = \{(ab,ac)/0.7, (ab,bd)/0.8, (ab,ac)/0.7, (bd,cd)/0.8, (ad,bd) = (ad,ac) = (ad,cd) = (ad,ab) = 0.8, (ac,cd)/0.8\}$

**Fig. (b) Anti Fuzzy Line Graph**

**Anti Fuzzy Line Graph in Claw Graph**

The complete bipartite graph  $K_{1,3}$  is a tree known as the "claw." It is isomorphic to the star graph  $S_4$  and is sometimes known as the Y graph. This topic applied the features of claw graph in anti fuzzy graph. A graph that does not contain the claw as an induced sub graph is called a claw-free graph. The anti fuzzy line graph  $L(GA)$  of any anti fuzzy graph  $GA$  is claw-free because three edges  $\mu_1, \mu_2$  and  $\mu_3$  in  $GA$  share the endpoints with another edge  $\mu_4$  then, at least two of  $\mu_1, \mu_2$  and  $\mu_3$  must share one of those endpoints with each other. Every edges of the base graph correspond to the vertices of line graph whenever the edges share endpoints in  $GA$ . The purpose of anti fuzzy graph is to solve the uncertainty when it attains maximum. In this regard, one can observe the simplest form of claw graph where the membership values are categorised by two cases.  $K_{m,n}$  is a claw graph if the following conditions can hold.

©  $K_{1,3}$  is bipartite AFG.

**Kousalya and Radhika**

©  $K_{1,3}$  is complete bipartite AFG.

The aim of this section is to claim both the above graphs are claw graph and it is isomorphic to  $C_3$  line graph. It explained by the following section.

**Theorem 3.5**

A claw graph cannot be a  $k$ -regular graph.

**Proof:**

Consider  $K_{m,n}$  be the claw anti fuzzy graph.

Then,  $K_{1,3} = B/GA:(\sigma, \mu) = \{\sigma_1(x_1), \sigma_3(x_j)/j=1,2,3; \mu \geq \max(\sigma_1(x_1), \sigma_3(x_j))\}$

Take,  $\sigma(x_i) = \{a/0.9\}$  and  $\sigma(x_j) = \{x/0.9, y/0.9, z/1\}$  and  $\mu = \{(a,x)/1, (a,y)/0.9, (a,z)/1\}$

$d(\sigma(x_i)) = d(a) = 2.9 = \text{Size}(K_{m,n})$ .

$d(\sigma(x_j)) : d(x) = 1, d(y) = 0.9 \text{ and } d(z) = 1$ .

Because, a single vertex in  $\sigma(x_i)$  is adjacent to other three vertices. It is increase the degree which is nothing but the size of the graph.

Therefore, the claw graph cannot be a  $k$ -regular graph. See Illustration 3.7.

**Theorem 3.6**

$L(GA):(\lambda, \omega)$  of a claw graph  $GA:(\sigma, \mu)$  can be a  $k$ -regular graph.

**Proof:**

Consider  $K_{m,n}$  be the claw anti fuzzy graph.

Then,  $K_{1,3} = B/GA:(\sigma, \mu) = \{\sigma_1(x_1), \sigma_3(x_j)/j=1,2,3; \mu \geq \max(\sigma_1(x_1), \sigma_3(x_j))\}$

$L(GA):(\lambda, \omega)$  is a triangular graph ( $C_3$ ) such that,

$\lambda = \{\sigma_3(x_j)/j=1,2,3\}$  and  $\omega = \{\sigma(x_i, x_j) / i \neq j\}$ .

By the characteristics of AFLG, the triangular graph  $C_3$  must be strong  $GA:(\sigma, \mu)$ .

Case 1:  $K_{1,3}$  is unique [that is,  $\mu((\sigma_1(x_1), \sigma_3(x_j))) = \text{constant}$ ] then, triangular line graph [ $C_3$ ] must be strong and complete.

By theorem 3.1,  $L(GA):(\lambda, \omega)$  is complete then it must be  $k$ -regular.

Case 2:  $K_{1,3}$  is not unique [ that is,  $\mu((\sigma_1(x_1), \sigma_3(x_j))) \neq \text{constant}$  ] then, triangular line graph [ $C_3$ ] must be strong not complete.

By theorem 3.1 of Remark-1,  $L_2(GA)$  is  $k$ -regular.

**Illustration 3.7**

Case – 1 : Anti fuzzy line graph of claw graph is  $k$ -regular AFG

$K_{1,3}$  is never  $k$ -regular AFG

$L(K_{1,3})$  is  $k$ -regular AFG

Fig (a) Claw [ $K_{1,3}$ ]Anti fuzzy Graph

Fig (b) AFLG of [ $K_{1,3}$ ] - Triangular graph

**Kousalya and Radhika**

Case – 2 :  $L_2(GA)$  of claw graph is  $k$ -regular AFG

Fig (c) Claw graph with distinct edges

AFLG of  $[K_{1,3}]$

$L[L[K_{1,3}]] = L^2[K_{1,3}]$

From the above two cases, this theorem concludes  $L(GA):(\lambda, \omega)$  of a claw graph can be a  $[C_3]$   $k$ -regular graph.

From Illustration 3.7 (b),  $L[K_{1,3}] =$  complete and 2-regular anti fuzzy graph.

From Illustration 3.7 (c)  $L[L[K_{1,3}]] = L^2[K_{1,3}] =$  complete and 1.8-regular AFG.

**Theorem 3.8**

Line graph of a regular square ( $C_4$ )  $GA:(\sigma, \mu)$  is  $k$ -regular.

**Proof:**

$GA:(\sigma, \mu)$  be the regular square AFG ( $C_4$ ) then,  $\sigma = \{a,b,c,d\}$  and  $\mu = \{a,b\}, \{b,c\}, \{c,d\}, \{a,d\}$  such that,  $d(\sigma(xi)) = k$  (constant) for  $i = 1$  to 4. Then,  $L(GA):(\lambda, \omega)$  such that,  $d(\lambda(yj)) = k$  (constant) for  $j = 1$  to 4. Hence,  $L(C_4)$  is a complete and  $k$ -regular AFG.

**Theorem 3.9**

In a  $v$ -nodal AFG,  $Ln[C_4]$  is  $k$ -regular anti fuzzy graph for  $n \geq 3$ .

**Proof:**

Consider,  $GA:(\sigma, \mu)$  is a square ( $C_4$ ) AFG is strong then the following condition holds. That is,  $\mu(x, y) = \max(\sigma(x), \sigma(y))$  for all  $x$  and  $y$  in  $GA$ .

If,  $\sigma(xi) =$  distinct ( $v$ -nodal AFG), then at least one of  $\sigma(x) =$  maximum (choose it as  $k$ )

This  $k$  appear 2 incident edges in  $L(GA)$ , 3 times of  $L_2(GA)$  and 4 times of  $L_3(GA)$ .

Hence all the edges of  $L(GA) = k$ .

This shows that  $Ln[C_4]$  is strong and  $k$ -regular for  $n \geq 3$ .

From Illustration 3.10,  $L_3[C_4] = 2$ -regular  $GA:(\sigma, \mu)$ .

**Illustration 3.10**

The following graph is the example for the above theorem

Fig. (a)  $C_4$ - Square AFG

Fig (b) AFLG -  $L(C_4)$

**Kousalya and Radhika**

Fig (c)  $L[L[C_4]]$

Fig (d)  $L[L[L[C_4]]]$

**Theorem 3.11**

Every  $L_n-1[C_n]$  is  $k$ -regular AFG in a  $v$ -nodal anti fuzzy graph.

**Proof:**

Consider  $GA:(\sigma, \mu)$  is a  $(C_n)$  anti fuzzy graph.

In  $(C_n)$  anti fuzzy graph, every edge is incident with exactly two edges.

If,  $\sigma(x_i) = \text{distinct}$ , then at least one of  $\sigma(x) = \text{maximum} = \text{choose it as } k$ .

This  $k$  appear 2 incident edges in  $L(GA):(\lambda, \omega)$ , 3 times of  $L_2(GA)$  and 4 times of  $L_3(GA)$  and so on. Hence all the edges of  $L(GA):(\lambda, \omega) = k$  for  $(n-1)$  times of computing Line graph.

This shows that,  $L_n-1[C_n]$  is  $k$ -regular anti fuzzy graph.

**Claw Anti Fuzzy Graph in Human Anatomy**

Conventionally, every claw graph is corresponding to its triangle line graph. Take the following example for describing a claw graph. In human anatomy, the head is considered as an initial node denoted as  $K_m(\sigma) = K_m(H)$ . Head is linked with two arms denoted as  $K_n(LA)$ ,

$RA$ ). The end of the two legs on which a person normally stands and walks denotes foot, pointed as  $K_n(L)$ .  $K_m, n$  is the considered as an example of human anatomy such that  $K_m(H)$  is the head,  $K_n(LA, RA, L)$  denotes the left arm, right arm and legs respectively. Human body have 12 different cranial nerves that pass the electrical signal to sensory and motor functions. They connect the brain to different parts of the body. So, we take  $K(\sigma) = \text{cranial nerves on the body whose membership value is taken as } 1$ . There are 5 major nerves which extend from the shoulder to the arm. Take it as,  $K_n(LA, RA) = 0.5$ . The lumbar plexus is an essential collection of nerves that arise from mostly the lumbar spinal cord. The term plexus refers to a "web" of nerves. Each of the major nerves from the web is divided into many smaller nerve branches. So, take it as,  $K_n(L) = 1$ . Consider an edge of the graph is associated with the sensory and motor function of the body. In a healthy person, all the nerves were active well in a body, so that the function is normal to the regular activities. That is every link can take the full support from the brain. That is,  $\mu(H, LA) = \mu(H, RA) = \mu(H, L) = 1$ . Then it must be the representation of  $K_{1,3}$  graph.

**Human Anatomy in Claw Anti Fuzzy Graph**

The line graph of this graph becomes a triangle graph and it is normalized (means, the height of the fuzzy set / graph attains the maximum value 1). It is also called 2-regular graph.

### Kousalya and Radhika

If the human body suffers from its regular activities (abnormal), it might have nerves injury or some other problems. So, the affected nerves cannot support the motor function. If the right brain neurons are affected then the left body activities lead to problems. In this case, consider,  $K_m(H) = 0.7$ ,  $K_n(LA) = 0.4$ ,  $K_n(RA) = 0.5$  and  $K_n(L) = 0.6$ . then  $\mu(H, LA) = 0.7$ ,  $\mu(H, RA) = 1$  and  $\mu(H, L) = 0.7$ . This kind of graph also gives the triangle graph with the vertices,  $\{0.7, 1$  and  $0.7\}$ . It says that, every activities of a human body is inter connected to the nerves system. If the vertices of  $L(GA)$  is 1, there is no injury of nerves and if  $L(GA) < 1$ , there is a problem in nerve system which causes the issue. It is not necessarily said that, if the claw graph is 2-regular line graph, the person is healthy. Because they may have some other issue apart from this case. However, the human anatomy can be represented by claw anti fuzzy graph. Its line graph gives the triangle graph. It is 2-regular whenever the edges are effective. Moreover  $K_{1,3}$  is a claw anti fuzzy graph whenever the underlying graph is either bipartite AFG or complete bipartite AFG.

#### Complement of Claw AFG

Complement of claw graph is not isomorphic to triangle graph for some cases.

- ⊙  $GA: (\sigma, \mu)$  is the claw AFG is strong / complete then its complement graph does not possess any edges.
- ⊙ AFLG of claw graph is a null graph for the two case.
- ⊙  $K_{1,3}$  AFG is existing with height 1. That is  $K_{m,n} = 1 \forall \sigma$  and  $\mu$ .
- ⊙  $K_{m,n}$  such that  $\sigma(GA) = 1$  for  $m = 1$ .
- ⊙ From the above section, the complement graph does not possess any edges.

### CONCLUSION

This paper concludes that the obtained results are played a major role in decision making. The computation of n-time line graph can lead to trace out the Applications of various domains, including pattern recognition, and network analysis. By incorporating anti-fuzzy graphs into the structure of regular anti fuzzy line graphs, it becomes possible to capture and analyze uncertainty and imprecision in a more detailed and expressive manner.

## ABSTRACT

This groundbreaking study introduces Euclidean and Hamming similarity measures for Spherical Picture Fuzzy Sets (SPFS), a novel framework extending Intuitionistic Fuzzy Sets, Circular Intuitionistic Fuzzy Sets, Picture Fuzzy Sets, and Zadeh's Fuzzy Sets. SPFS overcomes limitations of existing Circular Intuitionistic Fuzzy Sets, effectively addressing uncertainty in complex decision-making environment. By providing a generalized distance metric representation, SPFS enables comprehensive evaluation process understanding and more precise decision-making. Notably, this research proposes a pioneering score function for SPFS, facilitating criteria ranking. This innovative approach significantly contributes to Multiple Criteria Decision Making (MCDM) research, a rapidly evolving field tackling intricate decision making problems. An illustrative example demonstrates the Spherical Picture Fuzzy approach's efficacy, highlighting its potential to enhance decision support tools.

**Keywords:** Circular Intuitionistic Fuzzy sets, Picture Fuzzy Sets, Spherical Picture Fuzzy Sets and Multiple Criteria decision making.

Rajarajeswari Palanisamy et al.,

## INTRODUCTION

In everyday life, uncertainty poses challenges that traditional mathematical tools can't fully address. To tackle this, Fuzzy Set theory was introduced by Zadeh[15] in 1965, assigning a membership degree to each element, representing its degree of belonging. Building on this, Atanassov developed Intuitionistic Fuzzy Sets (IFSs)[1] in 1983, which describe elements with both membership and non-membership values, subject to the condition that their sum does not exceed one. However, IFSs lacked neutrality degree consideration. To address this gap, Coung[4] introduced Picture Fuzzy Sets (PFS) in 2014, extending Fuzzy Sets and IFSs by incorporating neutrality degree alongside membership and non-membership degrees, with a combined total not exceeding one. Coung and Kreinovich[5] subsequently explored new PFS operations and properties. Nguyen Van Dinh and Nguyen Xuan Thao[10] introduced measures for comparing PFS-sets, including difference, distance, and dissimilarity, along with calculation formulas in 2018 and they demonstrated applications in Multi-Attribute Decision Making. Chunyong Wang et al[8] developed geometric operators for PFS, exploring their properties and applying them to Multiple Attribute Decision Making in Picture Fuzzy environments in 2017. Atanassov [2] expanded the Intuitionistic Fuzzy Sets (IFS) concept by introducing Circular Intuitionistic Fuzzy Sets (C-IFS) in 2020. C-IFS represents a circle with radius  $r$ , centralizing membership and non-membership degrees. This extension enables C-IFS to be applied in various Multi-Criteria Decision Making (MCDM) methods. Researchers have made significant strides in integrating Circular Intuitionistic Fuzzy Sets (C-IFS) with established Multi-Criteria Decision Making (MCDM) models. Specifically, Cakir and et al [6,7] introduced a novel circular intuitionistic fuzzy multi-criteria decision-making (MCDM) in 2021 approach and applied it to various case studies, including the optimal selection of medical waste landfill sites, evaluating health tourism destinations, and assessing businesses for industrial symbiosis opportunities. Otay and Kahraman[11] utilized the Combined Interval Fuzzy Set (C-IFS) approach in conjunction with the Analytic Hierarchy Process (AHP) and VIKOR methods to optimize supplier selection in 2021. In 2021, Imanov and Aliyev explored the application of Circular Intuitionistic Fuzzy Sets in evaluating human capital. In this paper, discussed Similarity measures for Spherical Picture Fuzzy Sets and introduces a novel score function for Spherical Picture Fuzzy Sets (SPFS), enabling criteria ranking in Multiple Criteria Decision Making (MCDM). This innovative approach enhances decision support tools and addresses complex decision-making problems.

## PRELIMINARIES

In this section, few pre-requisites that are needed for this study overviewed.

### Definition 2.1. [15] Fuzzy Set

Let  $X$  be a non-empty universal set. Each set is mapped to  $[0,1]$  by membership function is defined as

$$E = \{(x, \mu_E(x)) / x \in X\}$$

where  $\mu_E: X \rightarrow [0, 1]$  is the degree of membership function of the fuzzy set  $E$  and  $\mu_E(x) \in [0, 1]$  is the membership value of the element  $x \in X$  in the fuzzy set  $E$ .

### Definition 2.2. [1] IFS

Let  $X$  be a non-empty universal set. An intuitionistic fuzzy set (IFS)  $E$  in  $X$  is defined as

$$E = \{(x, \mu_E(x), \vartheta_E(x)) / x \in X\}$$

where  $\mu_E: X \rightarrow [0, 1]$  and  $\vartheta_E: X \rightarrow [0, 1]$  with  $0 \leq \mu_E(x) + \vartheta_E(x) \leq 1$  for all  $x \in X$  represents the degrees of membership and non-membership of the element  $x$  to the IFS  $E$ . For each IFS, the intuitionistic index or hesitancy degree of the element  $x$  in  $X$  to the IFS  $E$  is  $\pi_E(x) = 1 - \mu_E(x) - \vartheta_E(x)$ .

### Definition 2.3. [2] C-IFS

Let  $X$  be the universe and  $E$  be its subset then, the set C-IFS is defined as,

$$E_r^* = \{(x, \mu_E(x), \vartheta_E(x); r) / x \in X\}$$

**Rajarajeswari Palanisamy et al.,**

where  $\iota_E: X \rightarrow [0, 1]$  and  $\vartheta_E: X \rightarrow [0, 1]$  with  $0 \leq \iota_E(x) + \vartheta_E(x) \leq 1$  and  $r \in [0, \sqrt{2}]$  is the radius of the circle around each element  $x \in E$ , and functions  $\iota_E: X \rightarrow [0, 1]$  and  $\vartheta_E: X \rightarrow [0, 1]$  represent membership degree and non-membership degree of element  $x \in X$  to a fixed set  $E \subseteq X$ . We also define the hesitancy margin  $\pi_E: X \rightarrow [0, 1]$  by  $\pi_E(x) = 1 - \iota_E(x) - \vartheta_E(x)$  which corresponds to the degree of indeterminacy. The radius  $r$  defined in C-IFS takes on values from the interval  $[0, 1]$ .

**Definition 2.4.** [4] PFS

A Picture Fuzzy Set (PFS)  $E$  on a universe  $X$  is an object in the form of

$$P = \{ \langle x, \iota_E(x), \psi_E(x), \vartheta_E(x) \rangle / x \in X \}$$

where  $\iota_E(x) \in [0, 1]$  is called the degree of positive membership of  $x$  in  $E$ ,  $\psi_E(x) \in [0, 1]$  is called the degree of neutral membership of  $x$  in  $E$  and  $\vartheta_E(x) \in [0, 1]$  is called the degree of negative membership of  $x$  in  $E$ . where  $\iota_E(x)$ ,  $\psi_E(x)$  and  $\vartheta_E(x)$  satisfy the following condition ( $x \in X$ )  $0 \leq \iota_E(x) + \psi_E(x) + \vartheta_E(x) \leq 1$  Now,  $\sigma_E(x) = (1 - (\iota_E(x) + \psi_E(x) + \vartheta_E(x)))$  could be called the degree of refusal membership of  $x$  in  $E$ .

**Definition 2.5.**[12](Spherical Picture Fuzzy Sets (SPFSs))

Let us have a fixed universe  $X$  and  $E$  be its subset then, the set SPFSs is defined as,

$P_r^* = \{ \langle x, \iota_E(x), \psi_E(x), \vartheta_E(x); r \rangle / x \in X \}$  where functions  $\iota_E: X \rightarrow [0, 1]$ ,  $\psi_E: X \rightarrow [0, 1]$  and  $\vartheta_E: X \rightarrow [0, 1]$  with  $0 \leq \iota_E(x) + \psi_E(x) + \vartheta_E(x) \leq 1$  and  $r \in [0, \sqrt{2}]$  is the radius of the sphere around each element  $x \in E$ , represent membership degree, neutral degree and non-membership degree of element  $x \in X$  to a fixed set  $E \subseteq X$ . We also define the hesitancy margin  $\pi_E: X \rightarrow [0, 1]$  by  $\pi_E(x) = 1 - \iota_E(x) - \psi_E(x) - \vartheta_E(x)$  which corresponds to the degree of indeterminacy.

**Definition 2.6.**[14]

Let  $IFS(X)$  denote the set of all Intuitionistic Fuzzy Sets (IFSs) in  $X$ . A similarity measure between two IFSs  $A$  and  $B$  is a function  $S: IFS(X) \times IFS(X) \rightarrow [0, 1]$  that satisfies the following properties:

- i. Boundedness:  $0 \leq S(A, B) \leq 1$
- ii. Identity:  $S(A, B) = 1$  if and only if  $A = B$
- iii. Symmetry:  $S(A, B) = S(B, A)$
- iv. Monotonicity: If  $A \subseteq B \subseteq C$ , then  $S(A, C) \leq \min\{S(A, B), S(B, C)\}$
- v. Crisp set condition:  $S(A, A_c) = 0$  if and only if  $A$  is a crisp set.

**Definition 2.7.**[10]

Let  $\alpha = (\iota_\alpha, \psi_\alpha, \vartheta_\alpha)$  and  $\beta = (\iota_\beta, \psi_\beta, \vartheta_\beta)$  be two picture fuzzy numbers, then

- (i)  $\alpha \cdot \beta = ((\iota_\alpha + \psi_\alpha)(\iota_\beta + \psi_\beta) - \psi_\alpha\psi_\beta, \psi_\alpha\psi_\beta, 1 - (1 - \vartheta_\alpha)(1 - \vartheta_\beta))$ ;
- (ii)  $\alpha^\lambda = ((\iota_\alpha + \psi_\alpha)^\lambda - \psi_\alpha^\lambda, \psi_\alpha^\lambda, 1 - (1 - \vartheta_\alpha)^\lambda)$ ,  $\lambda > 0$ .

**Definition 2.8.**[9]

If we consider  $\alpha = (\iota_\alpha, \vartheta_\alpha, Q_\alpha; r)$  be a Intuitionistic fuzzy numbers with radius, we can define a score function  $S$  as  $S(\alpha) = \frac{\iota_\alpha - \vartheta_\alpha + \sqrt{2}r(2\rho - 1)}{3}$  and the accuracy function  $H$  as  $H(\alpha) = \iota_\alpha + \psi_\alpha + \vartheta_\alpha$ , where  $S(\alpha) \in [-1, 1]$  and  $H(\alpha) \in [0, 1]$  respectively. We can take two picture fuzzy numbers  $\alpha$  and  $\beta$

- (i) if  $S(\alpha) > S(\beta)$ , then  $\alpha$  is superior to  $\beta$ , denoted by  $\alpha > \beta$ ;
- ii) if  $S(\alpha) = S(\beta)$ , then
  - (1)  $H(\alpha) = H(\beta)$ , implies that  $\alpha$  is equivalent to  $\beta$ , represented by  $\alpha \sim \beta$ ;
  - (2)  $H(\alpha) > H(\beta)$ , implies that  $\alpha$  is superior to  $\beta$ , represented by  $\alpha > \beta$ .

**Definition 2.9**

Let us assume that  $p_j$  ( $j = 1, 2, \dots, n$ ) is a set of PFNs, then the picture fuzzy weighted geometric(PFWG) operator is defined as follow:

$$PFWG_w(p_1, p_2, \dots, p_n) = \prod_{j=1}^n p_j^{w_j}, \text{ where } w = (w_1, w_2, w_3, \dots, w_n), \text{ and } w_j > 0$$

**Rajarajeswari Palanisamy et al.,**

**Definition 2.10.**[3](Distance Measures for C-IFSs)

The radius of the  $(\iota(x), \vartheta(x))$  is the maximum of the Euclidean distance

$$r_i = \max \sqrt{[(\iota(x) - m_{i,j})^2 + (\vartheta(x) - n_{i,j})^2]}$$

$$\text{Euclidean Distance } E_2(E, F) = \frac{1}{2} \left( \frac{|r_E - r_F|}{\sqrt{2}} + \sqrt{\frac{1}{2} \sum_{x \in E} [(\iota_E(x) - \iota_F(x))^2 + (\vartheta_E(x) - \vartheta_F(x))^2]} \right)$$

$$E_3(E, F) = \frac{1}{2} \left( \frac{|r_E - r_F|}{\sqrt{2}} + \sqrt{\frac{1}{2} \sum_{x \in E} [(\iota_E(x) - \iota_F(x))^2 + (\vartheta_E(x) - \vartheta_F(x))^2 + (\pi_E(x) - \pi_F(x))^2]} \right)$$

Hamming Distance

$$H_2(E, F) = \frac{1}{2} \left( \frac{|r_E - r_F|}{\sqrt{2}} + \frac{1}{2} \sum_{x \in E} [|\iota_E(x) - \iota_F(x)| + |\vartheta_E(x) - \vartheta_F(x)|] \right)$$

$$H_3(E, F) = \frac{1}{2} \left( \frac{|r_E - r_F|}{\sqrt{2}} + \frac{1}{2} \sum_{x \in E} [|\iota_E(x) - \iota_F(x)| + |\vartheta_E(x) - \vartheta_F(x)| + |\pi_E(x) - \pi_F(x)|] \right)$$

Hausdorff Distance

$$HD_2(E, F) = \frac{1}{2} \left( \frac{|r_E - r_F|}{\sqrt{2}} + \frac{1}{n} \sum_{x \in E} \max [|\iota_E(x) - \iota_F(x)|, |\vartheta_E(x) - \vartheta_F(x)|] \right)$$

$$HD_3(E, F) = \frac{1}{2} \left( \frac{|r_E - r_F|}{\sqrt{2}} + \frac{1}{n} \sum_{x \in E} \max [|\iota_E(x) - \iota_F(x)|, |\vartheta_E(x) - \vartheta_F(x)|, |\pi_E(x) - \pi_F(x)|] \right)$$

$$HD_4(E, F) = 1 - \frac{1}{n} \sum_{x \in E} \max[|\iota_E(x) - \iota_F(x)|, |\vartheta_E(x) - \vartheta_F(x)|, |\psi_E(x) - \psi_F(x)|, |\pi_E(x) - \pi_F(x)|]$$

**Similarity measures for Spherical Picture Fuzzy Sets**

In this section, we have defined the Similarity measures for Spherical Picture Fuzzy Sets which is an extension of Circular Intuitionistic Fuzzy Sets is given as follows. Additionally, we have defined a novel score function for Spherical Picture Fuzzy Sets.

Euclidean Distance

$$E_3(E, F) = 1 - \left(\frac{1}{2} \left(\frac{|r_E - r_F|}{\sqrt{2}}\right) + \sqrt{\frac{1}{2} \sum_{x \in E} [(\iota_E(x) - \iota_F(x))^2 + (\psi_E(x) - \psi_F(x))^2 + (\vartheta_E(x) - \vartheta_F(x))^2]}\right)$$

$$E_4(E, F) = 1 - \left(\frac{1}{2} \left(\frac{|r_E - r_F|}{\sqrt{2}}\right) + \sqrt{\frac{1}{2} \sum_{x \in E} [(\iota_E(x) - \iota_F(x))^2 + (\psi_E(x) - \psi_F(x))^2 + (\vartheta_E(x) - \vartheta_F(x))^2 + (\pi_E(x) - \pi_F(x))^2]}\right)$$

Hamming Distance  $H_3(E, F) = 1 - \left(\frac{1}{2} \left(\frac{|r_E - r_F|}{\sqrt{2}}\right) + \frac{1}{2} \sum_{x \in E} [|\iota_E(x) - \iota_F(x)| + |\psi_E(x) - \psi_F(x)| + |\vartheta_E(x) - \vartheta_F(x)|]\right)$

$$H_4(E, F) = 1 - \left(\frac{1}{2} \left(\frac{|r_E - r_F|}{\sqrt{2}}\right) + \frac{1}{2} \sum_{x \in E} [|\iota_E(x) - \iota_F(x)| + |\psi_E(x) - \psi_F(x)| + |\vartheta_E(x) - \vartheta_F(x)| + |\pi_E(x) - \pi_F(x)|]\right)$$

Hausdorff Distance

$$HD_3(E, F) = 1 - \left(\frac{1}{2} \left(\frac{|r_E - r_F|}{\sqrt{2}}\right) + \frac{1}{n} \sum_{x \in E} \max[|\iota_E(x) - \iota_F(x)|, |\psi_E(x) - \psi_F(x)|, |\vartheta_E(x) - \vartheta_F(x)|]\right)$$

$$HD_4(E, F) = 1 - \left(\frac{1}{2} \left(\frac{|r_E - r_F|}{\sqrt{2}}\right) + \frac{1}{n} \sum_{x \in E} \max[|\iota_E(x) - \iota_F(x)|, |\psi_E(x) - \psi_F(x)|, |\vartheta_E(x) - \vartheta_F(x)|, |\pi_E(x) - \pi_F(x)|]\right)$$

The radius of the  $(\mu(x), \psi(x), \vartheta(x))$  is the maximum of the Euclidean distance

**Rajarajeswari Palanisamy et al.,**

$$r_i = \max \sqrt{[(\iota(x) - m_{i,j})^2 + (\psi(x) - m_{i,j})^2 + (\vartheta(x) - n_{i,j})^2]}$$

**Score function for Spherical Picture Fuzzy Sets:**

If we consider  $\alpha = (\iota_\alpha, \psi_\alpha, \vartheta_\alpha, \pi_\alpha : r)$  be a Picture fuzzy numbers with radius, we can define a score function S as  $S(\alpha) = \iota_\alpha - \vartheta_\alpha - \frac{\psi_\alpha}{2}$  and the accuracy function H as  $H(\alpha) = \iota_\alpha + \psi_\alpha + \vartheta_\alpha$ , where  $S(\alpha) \in [-1, 1]$  and  $H(\alpha) \in [0, 1]$  respectively. We can take two picture fuzzy numbers  $\alpha$  and  $\beta$

(i) if  $S(\alpha) > S(\beta)$ , then  $\alpha$  is superior to  $\beta$ , denoted by  $\alpha > \beta$ ;

(ii) if  $S(\alpha) = S(\beta)$ , then  $\alpha = \beta$

(1)  $H(\alpha) = H(\beta)$ , implies that  $\alpha$  is equivalent to  $\beta$ , represented by  $\alpha \sim \beta$

(2)  $H(\alpha) > H(\beta)$ , implies that  $\alpha$  is superior to  $\beta$ , represented by  $\alpha > \beta$ .

Here, a new score ( $S_{SPFS}$ ) and an accuracy ( $H_{SPFS}$ ) function for SPFS are defined by using Picture Fuzzy Score Function. Consider an Spherical Picture Fuzzy Value (SPFV)  $(\iota_c, \psi_c, \vartheta_c; r)$ , with pessimistic and optimistic points defined as:

Pessimistic:  $\langle \iota_c - r/\sqrt{2}, \psi_c - r/\sqrt{2}, \vartheta_c + r/\sqrt{2} \rangle$

Optimistic:  $\langle \iota_c + r/\sqrt{2}, \psi_c + r/\sqrt{2}, \vartheta_c - r/\sqrt{2} \rangle$ . A score function  $S_{SPFS}$  and an accuracy function  $H_{SPFS}$  of the SPFV, c are defined as follows with respect to the decision-maker's (or manager's) preference information  $\lambda \in [0, 1]$

$$S_{SPFS(c)} = (\lambda * S_{SPFS}(\langle \iota_c + \frac{r}{\sqrt{2}}, \psi_c + \frac{r}{\sqrt{2}}, \vartheta_c - \frac{r}{\sqrt{2}} \rangle) + (1 - \lambda) * S_{SPFS}(\langle \iota_c - \frac{r}{\sqrt{2}}, \psi_c - \frac{r}{\sqrt{2}}, \vartheta_c + \frac{r}{\sqrt{2}} \rangle)) / 3$$

$$= \frac{\iota_c - \vartheta_c + \frac{3r}{2\sqrt{2}}(2\rho - 1)}{3} \text{ where } S_{SPFS(c)} \in [-1, 1] \quad (1)$$

$$H_{SPFS(c)} = \lambda * H_{SPFS}(\langle \iota_c + \frac{r}{\sqrt{2}}, \psi_c + \frac{r}{\sqrt{2}}, \vartheta_c - \frac{r}{\sqrt{2}} \rangle) + (1 - \lambda) * H_{SPFS}(\langle \iota_c - \frac{r}{\sqrt{2}}, \psi_c - \frac{r}{\sqrt{2}}, \vartheta_c + \frac{r}{\sqrt{2}} \rangle) = \iota_c + \psi_c + \vartheta_c, \text{ where } H_{SPFS(c)} \in [0, 1]$$

**A Method for Multiple Criteria Decision Making with spherical picture fuzzy information**

Consider a multiple criteria decision-making (MCDM) problem with spherical picture fuzzy information, represented as follows:

Let  $C = \{C_1, C_2, \dots, C_m\}$ : set of m criteria,  $D = \{D_1, D_2, \dots, D_n\}$ : set of n attributes,  $P =$  picture fuzzy decision matrix, where  $P = (p_{ij})_{m \times n}$ , and  $p_{ij}$  ( $i = 1, 2, \dots, m; j = 1, 2, \dots, n$ ) are picture fuzzy numbers (PFNs).

Evaluation Process:

1. Calculate overall preference values for each criterion  $C_i$  using the PFWG operator and decision matrix P.
2. Compute scores  $S(\tilde{P}_i)$  for each overall picture fuzzy value  $\tilde{P}_i$  using Eq. (1) and sum it for ranking.
3. Rank criteria  $R_i$  ( $i = 1, 2, \dots, m$ ) based on scores  $S(\tilde{P}_i)$  and select the optimal criterion.

**Numerical example**

This study involves evaluating five projects ( $D_i, i=1-5$ ) using a multi-criteria decision analysis framework. Four evaluation criteria have been identified: relevance ( $D_1$ ), effectiveness ( $D_2$ ), creativity ( $D_3$ ), impact ( $D_4$ ) and logical evaluation ( $D_5$ ). To maintain objectivity, expert evaluations will be conducted anonymously. The decision matrix (Table 1) presents the evaluation parameters.

Now, we use the proposed strategy to evaluate a project with spherical picture fuzzy information.

Step 1: utilize the decision information given in matrix  $P_i$  and

$$\tilde{p}_i = PFWG_w (P_{i1}, P_{i2}, P_{i3}, \dots, P_{in})$$

We have,

$$\tilde{p}_1 = (0.379196, 0.154140, 0.198920)$$

$$\tilde{p}_2 = (0.204767, 0.371910, 0.272260)$$

$$\tilde{p}_3 = (0.44769, 0.199820, 0.175130)$$

$$\tilde{p}_4 = (0.447769, 0.178200, 0.175130)$$

$$\tilde{p}_5 = (0.414387, 0.239750, 0.241610)$$

Step 2: Evaluate the overall picture fuzzy values  $\tilde{p}_i$  ( $i=1,2,3,4$ ) using Equation (1) to obtain scores  $S(\tilde{p}_i)$  and sum them.

**Rajarajeswari Palanisamy et al.,**

$S(\tilde{p}_1)=0.17198$ ,  $S(\tilde{p}_2)=0.42247$ ,  $S(\tilde{p}_3)=0.28788$ ,  $S(\tilde{p}_4)=0.30589$  and  $S(\tilde{p}_5)=0.08813$

Step 3: Rank all the Criteria  $R_i$  ( $i=1,2,3,4$ ) in accordance with the values of  $S(\tilde{p}_i)$ :  $R_3 > R_1 > R_4 > R_5 > R_2$ .

### Comparison Analysis.

First, when the input arguments are Picture Fuzzy Numbers, our method can be applied as already stated, Spherical Picture Fuzzy Sets are extensions of the standard Intuitionistic Fuzzy Sets, Circular Intuitionistic Fuzzy Sets and hence of Zadeh's Fuzzy Sets. This method can be plays predominant role in decision making situations. Our method facilitates comparison with the Intuitionistic Fuzzy Weighted Geometric (IFWG) operator. To illustrate, data from Table 1 is converted from picture fuzzy numbers (PFNs) to intuitionistic fuzzy numbers (IFNs). For example, PFN (0.2, 0.3, 0.1, 0.4) is transformed into IFN (0.2, 0.1). The detailed calculations are not shown, but the results are summarized in Table 2. Our approach seamlessly accommodates picture fuzzy numbers as input arguments, leveraging the generalized nature of picture fuzzy sets, which encompass fuzzy sets (FS) and intuitionistic fuzzy sets (IFS) as special cases. This ensures broad applicability. Next, our approach can be examined with IFWG and PFWG in Table 3. Finally, we conclude that, Circular Intuitionistic fuzzy sets scores deviation between candidates  $D_3$  and  $D_4$  is tie which is difficult for us to rank. By using Spherical Picture Fuzzy Sets scores, it improves the accuracy and enhance the deviation between  $D_3$  and  $D_4$ . Therefore, the ranking process is simplified. Our method's value is shown as PFWG with radius distinguishes  $D_3$  and  $D_4$ , whereas IFWG with radius cannot, highlighting picture fuzzy sets' richer information content.

## CONCLUSION

This study has pioneered the introduction of Euclidean and Hamming similarity measures for Spherical Picture Fuzzy Sets (SPFS), a novel extension of Intuitionistic Fuzzy Sets, Circular Intuitionistic Fuzzy Sets, Picture Fuzzy Sets, and Zadeh's Fuzzy Sets. By effectively addressing uncertainty in complex decision-making environments and overcoming limitations of existing Circular Intuitionistic Fuzzy Sets, SPFS has demonstrated its potential to enhance decision support tools. The proposed score function for SPFS has facilitated criteria ranking, contributing significantly to Multiple Criteria Decision Making (MCDM) research. The illustrative example has validated the efficacy of the Spherical Picture Fuzzy approach, showcasing its ability to enable comprehensive evaluation and precise decision-making. The findings of this study have important implications for decision-making in complex, uncertain environments. The SPFS framework offers a robust tool for decision analysts, enabling more accurate and efficient decision-making. Future research directions include exploring applications of SPFS in various domains and further developing its theoretical foundations.

## ABSTRACT

A mathematical model for climate change is a representation of the Earth's climate system using mathematical equations to describe interactions between the atmosphere, ocean, land, ice, and living organisms. When an atmospheric river makes landfall, the moisture it carries can be released as precipitation, sometimes leading to heavy rain or snow, particularly in mountainous regions. The most famous type of atmospheric river is known as the "Pineapple express," which brings moisture from the tropical pacific near Hawaii to the western coast of North America.

**Keywords:** mathematical model, climate change, atmospheric river, moisture, atmosphere, sky, water vapor, tropical, subtropical regions, landfall, heavy rain, snow, mountainous regions, beneficial rainfall, destructive flooding, excessive, Pineapple express, tropical pacific, western coast, North America.

## INTRODUCTION

An atmospheric river is a narrow corridor of concentrated moisture in the atmosphere, often "described as a river in the sky". Moisture transport can carry as much water as large terrestrial rivers, typically transporting water vapor equivalent to 7-15 times the flow of the Mississippi River. Length and Width of these systems are usually about 250-375 miles(400-600km) wide and can stretch over 1,000 miles (1,600km). Heavy precipitation when an atmospheric river hits a landmass, the water vapor condenses into rain or snow, often resulting in intense precipitation events.

### Vasanth Kumar Boniface and Harinee

Geographical Impact while common on the U.S. West Coast, especially California, atmospheric rivers occur globally and play a critical role in the water supply of many regions.

#### Atmospheric River

An atmospheric river is a narrow, concentrated band of moisture in the atmosphere that acts like a river in the sky. These systems carry large amounts of water vapor, often from tropical or subtropical regions and transport it across various distances. Atmospheric rivers are important for global water distribution and are a key factor in providing beneficial rainfall in some areas, but they can also lead to destructive flooding if the moisture they carry is excessive.

#### How Does Atmospheric River Affect the Earth

Atmospheric Rivers (ARs) significantly impact the earth in both positive and negative ways, affecting weather patterns, ecosystems, and even human activities.

**1. Water Supply :** Atmospheric rivers are a crucial source of precipitation, particularly in regions like the western United States, South America, and Europe.

**2. Drought Relief :** In areas experiencing drought, the arrival of an atmospheric river can provide much-needed rainfall, helping to alleviate dry conditions and supporting plant growth and agriculture.

#### Negative effects :

**1. Flooding :** When atmospheric rivers carry excessive moisture, they can lead to intense rainfall over short periods, overwhelming rivers and infrastructure, and causing flash floods, landslides, and erosion.

**2. Mudslides and Landslides:** In areas with steep terrain, prolonged rain from atmospheric rains can saturate the soil, triggering mudslides and landslides.

#### Key Components of the Mathematical Model

##### Numerical weather prediction models(nwp)

- **Equations of Motion :** These are derived from the Navier-Stokes equations, which describe the movement of air (wind), moisture, and pressure in the atmosphere.
- **Thermodynamic Equations:** These include the conservation of energy and mass, accounting for moisture, temperature, and the heat released during phase changes of water.

##### Hydrological Model

- **Runoff Models:** Hydrological models like the Hydrologic Engineering Center (HEC) models are used to predict how rainfall will translate into surface water runoff.
- **River Flooding Models:** River dynamics are modelled using the Saint-Venant equations, which are derived from the principles of mass and momentum conservation, predicting water flow in channels and rivers.

##### Statistical and Machine Learning

- **Ensemble Forecasting:** Multiple weather forecasts are combined using statistical techniques to account for uncertainties in predictions.
- **Machine Learning:** AI models, trained on large datasets of past Atmospheric River events and their impacts, can improve prediction accuracy.

##### Topographical and Geospatial Models

- **Digital Elevation Models:** These are used to model terrain and predict where water will flow, pooling in valleys or low-lying areas.
- **Landslides Risk Models:** These models predict the likelihood of landslides based on slope stability equations, soil moisture content, and rainfall intensity, helping authorities pre-emptively evacuate or fortify vulnerable areas.

### Vasanth Kumar Boniface and Harinee

#### Integral Earth System Models

- These models combine atmosphere, oceans, and land surface interactions to simulate the full life cycle of an atmospheric river. By incorporating factors like sea surface temperatures (SSTs), large scale pressure systems (e.g., the Pacific high-pressure system), and moisture sources (e.g., tropical regions), they improve overall predictions.

#### Examples of a workflow for preventing atmospheric river disaster:

**Data Collection:** Continuous monitoring of weather variables like pressure, temperature, moisture, wind speed, and direction from satellites, weather stations, and buoys.

#### Forecasting and simulation

Run numerical weather prediction (NWP) models to forecast Atmospheric River development and path.

#### Risk Assessment:

- Run extreme value theory (EVT) and machine learning models on past Atmospheric River data to estimate flood risks and the likelihood of extreme outcomes.
- Incorporate topographical models to predict localized flooding, landslides, and infrastructure damage.

#### Early Warning System

Issue early warnings based on the forecast models outputs, identifying areas most at risk.

#### Mitigations And Response

Use floodplain management and infrastructure planning to mitigate the impacts of heavy rainfall.

#### Mathematical Equations To Prevent Atmospheric River Disaster

##### Navier-Stokes Equations (Atmospheric Motion)

The Navier-Stokes equations are used to describe fluid motion, including the atmosphere. These equations are critical for modelling the movement of air masses, moisture transport, and the dynamic of atmospheric rivers.

The general form of the Navier-Stokes equations for a compressible fluid is:

$$\frac{\partial \mathbf{u}}{\partial t} + \mathbf{u} \cdot \nabla \mathbf{u} = -\frac{1}{\rho} \nabla p + \nu \nabla^2 \mathbf{u} + \mathbf{f}$$

- $\mathbf{u}$  is the velocity field (wind velocity in the case of Atmospheric Rivers).
- $t$  is time.
- $\nabla p$  is the gradient of pressure.
- $\rho$  is the density of air.
- $\nu$  is the kinematic viscosity.
- $\mathbf{f}$  is the external

##### Moisture Transport Equation (Atmospheric Rivers)

The transport of moisture in an atmospheric river can be modeled by the advection equation:

$$\frac{\partial q}{\partial t} + \mathbf{u} \cdot \nabla q = S$$

Where:

- $q$  is the specific humidity (moisture content of the air).
- $\mathbf{u}$  is the wind velocity.
- $S$  is the source/sink term (evaporation or condensation).

This equation tracks how moisture is carried by winds and forms the backbone of predicting how much water vapor will be available for precipitation. These equations are part of large-scale Numerical Weather Prediction (NWP) models like the Global Forecast System (GFS) and European Centre for Medium-Range Weather Forecasts (ECMWF), which predict weather systems, including Atmospheric Rivers.

### Vasanth Kumar Boniface and Harinee

#### Clausius-Clapeyron Equation (Moisture Capacity)

The Clausius-Clapeyron equation describes the relationship between temperature and the saturation vapor pressure of water

$$\frac{DPs}{dT} = \frac{LvPs}{T^2Rv}$$

Where:

- $P_s$  is the saturation vapor pressure.
- $T$  is temperature.
- $L_v$  is the latent heat of vaporization.
- $R_v$  is the specific gas constant for water vapor.

This equation helps to estimate the potential moisture content in the air mass of an Atmospheric River based on temperature, important for predicting how much precipitation will occur.

#### Hydrological Runoff Models (Flood Prediction)

Once an atmospheric river delivers precipitation, it is necessary to model how this water will behave on the ground

The equation for runoff depth  $Q$  is:

$$Q = \frac{(P - I_a)^2}{(P - I_a + S)}$$

Where:

- $P$  is the total rainfall.
- $I_a$  is the initial abstraction (e.g., surface storage, interception).
- $S$  is the potential maximum retention, calculated as:

$$S = \frac{1000}{CN}$$

Where  $CN$  is the curve number, which depends on land use, soil type, and moisture conditions.

#### Saint-Venant Equations (Flood Flow In Rivers)

The Saint-Venant equations are used to model the flow of water in rivers and streams, which is critical for predicting floods after an Atmospheric River event.

Continuity Equation:

$$\frac{\partial A}{\partial t} + \frac{\partial Q}{\partial x} = 0$$

Where:

- $A$  is denoted as the cross-sectional area of the flow
- $Q$  is the discharge (volume of water flowing per unit time).
- $x$  is represented as the spatial coordinate along the river.

Momentum Equation:

$$\frac{\partial Q}{\partial t} + \frac{\partial (\frac{Q^2}{A} + g A h)}{\partial x} = g A (S_0 - S_f)$$

Where:

$h$  is the water depth.

$g$  is the acceleration due to gravity.

$S_0$  is the channel bed slope.

$S_f$  is the friction slope, which represents energy losses due to friction.

These equations are solved using numerical methods to predict river levels and possible flooding.

#### Slope Stability Equation (Landslides)

Landslides are a common disaster resulting from Atmospheric Rivers in steep terrain, where rainfall saturates the soil.

$$Fs = \frac{c' + (\sigma - u) \tan \phi'}{\gamma h \sin \theta}$$

### Vasanth Kumar Boniface and Harinee

$F_s$  is the factor of safety (a value  $F_s < 1$  indicates instability).

- $c'$  is the effective cohesion of the soil.
- $\sigma$  is the normal stress.
- $u$  is the pore water pressure.
- $h$  is the soil depth.
- $\theta$  is the slope angle.

This model helps predict where landslides might occur by analyzing soil conditions and the amount of rainfall.

#### Extreme Value Theory (Flood Risk Assessment)

For predicting the likelihood of extreme floods, Extreme Value Theory (EVT) is used to model rare, high-impact events.

$$F(x; \mu, \sigma, \xi) = \exp\left(-\left[1 + \frac{\xi(x - \mu)}{\sigma}\right]^{-1/\xi}\right)$$

Where:

- $\mu$  is the location parameter.
- $\sigma$  is the scale parameter.
- $\xi$  is the shape parameter, which determines the tail behavior of the distribution.
- $x$  is the variable of interest (e.g., maximum rainfall or river discharge).

This allows for predicting the probability of extreme flood events that may result from intense atmospheric rivers.

## CONCLUSION

While we cannot prevent Atmospheric Rivers (ARs) from occurring, we can significantly mitigate their impacts by leveraging predictive models, infrastructure improvements, and adaptive management strategies. Here are the key conclusions for preventing future atmospheric river disasters. Advanced Predictive Model, Continued development and integration of numerical weather prediction (NWP), hydrological models, and machine learning tools are essential. This will improve the accuracy of Atmospheric River forecasts, allowing for timely warnings and better resource allocation.

## ABSTRACT

This paper presents a groundbreaking Genetic Algorithm-Driven Fuzzy Expert System (GAFES) designed to optimize control processes in complex, uncertain environments. By synergistically integrating genetic algorithms and fuzzy logic, GAFES enhances decision-making efficiency, adaptability, and precision. The proposed system addresses intricate optimization challenges by: Optimizing fuzzy membership functions and rule bases using genetic algorithms, Utilizing adaptive genetic algorithm-driven fuzzy inference for enhanced decision-making, Ensuring robustness in handling noisy and uncertain data. The contributions of this research are multifaceted: A novel hybrid GAFES architecture combining genetic algorithms and fuzzy expert systems, an optimized fuzzy membership function and rule base generation method, insights into GAFES's potential applications in control system, Future research directions include exploring GAFES's capabilities in multi-objective optimization, dynamic environments and integration with other artificial intelligence techniques.

**Keywords :** Genetic Algorithm, Fuzzy Expert System, Optimization Control, Decision-Making, Hybrid Intelligence, Uncertainty Handling.

## INTRODUCTION

As technological advancements lead to increasingly complex and dynamic control systems, there is a growing demand for methods that can optimize decision-making under uncertain conditions. Traditional control systems often struggle to cope with environmental variability, especially when subjected to noisy data or incomplete information. Fuzzy Expert Systems (FES) have been instrumental in addressing these challenges due to their ability to model uncertainty and handle imprecise information. However, one of the primary limitations of FES is the manual tuning of fuzzy membership functions and rule bases, which can be time-consuming and inefficient.

**Karen Felicita and Sahaya Sudha**

To overcome this limitation, Genetic Algorithms (GAs) offer a powerful solution. Inspired by the principles of natural evolution, GAs are widely recognized for their capacity to search through large solution spaces and optimize complex problems. The hybridization of GAs and FES—referred to as Genetic Algorithm-Driven Fuzzy Expert Systems (GAFES)—creates a robust framework for decision-making in uncertain environments. This hybrid approach leverages the strengths of both GAs and FES, with GAs optimizing the fuzzy parameters, while FES handles the decision-making process under uncertainty.

The aim of this paper is to investigate the efficacy of GAFES in optimizing control systems operating in uncertain environments. Through a detailed case study and extensive literature review, this paper provides insights into the strengths and limitations of GAFES and suggests areas for future research.

**LITERATURE REVIEW**

The combination of Genetic Algorithms and Fuzzy Expert Systems has emerged as a powerful approach for optimization and control in environments with uncertainty. This section outlines the fundamental principles of GAs and FES and reviews previous research on their hybridization for effective control and optimization.

**Genetic Algorithms**

Genetic Algorithms (GAs), developed by Holland (1975), are inspired by the process of natural selection, where solutions to optimization problems evolve over generations through selection, crossover, and mutation (Holland, 1975). These algorithms are renowned for their ability to search through large solution spaces, making them valuable for complex optimization tasks. GAs have proven effective in avoiding local minima, providing a global approach to optimization that is particularly useful in control systems requiring adaptive solutions. Early research by Goldberg (1989) expanded GAs into domains such as search, optimization, and machine learning, demonstrating the adaptability of GAs for solving complex industrial problems (Goldberg, 1989). Deb (2001) further advanced GA applications through multi-objective optimization, focusing on problems that require balancing multiple conflicting objectives, a common need in control and automation applications (Deb, 2001).

**Fuzzy Expert Systems**

Fuzzy Expert Systems (FES) were introduced by Zadeh (1965) to handle imprecision and uncertainty by allowing partial truth values rather than binary decisions, which is especially beneficial in control systems. Fuzzy logic provides a basis for expert systems that can interpret and process complex, uncertain data, making it well-suited for applications in robotics, industrial automation, and decision support systems (Zadeh, 1965).

In 1974, Mamdani applied fuzzy algorithms to control systems, specifically for a dynamic steam plant, setting the foundation for using FES in real-time industrial processes (Mamdani, 1974). More recent advancements by Ross (2009) have expanded the theory and application of fuzzy logic in engineering, improving FES applications in fields that require high adaptability and flexibility (Ross, 2009).

**Hybrid Systems: GAs and FES**

Hybrid systems that integrate Genetic Algorithms and Fuzzy Expert Systems (GAFES) have gained attention due to their potential to improve control accuracy, adaptability, and optimization in uncertain environments. The combination of GAs and FES allows for the tuning and learning of fuzzy parameters, enhancing system performance. Herrera (1995) examined the application of GAs in fuzzy rule-based systems, demonstrating how GAs can optimize fuzzy rules for more efficient control (Herrera, 1995). Cordon, Herrera, and Hoffmann (2001) advanced this concept by studying genetic fuzzy systems for tuning and learning fuzzy knowledge bases, leading to improved decision-making in dynamic environments (Cordon et al., 2001). Melin and Castillo (2005) further explored hybrid systems in pattern recognition and control applications, highlighting their effectiveness in handling soft computing and uncertain data (Melin & Castillo, 2005).

**Karen Felicita and Sahaya Sudha****Uncertainty Handling in Control Systems**

Control systems must often operate under uncertain conditions, where data may be incomplete, noisy, or imprecise. Traditional control methods can struggle with such uncertainties, whereas fuzzy logic provides a flexible framework for managing them effectively. GAs enhance this framework by refining fuzzy rules and membership functions, leading to robust control in complex, variable environments.

Kosko (1993) discussed the foundational principles of fuzzy logic as a method to manage uncertainty, illustrating its applications across various fields (Kosko, 1993). Castillo and Melin (2008) emphasized hybrid intelligent systems, particularly in the context of handling uncertainty, where they applied GAFES to maintain system robustness despite fluctuating data quality (Castillo & Melin, 2008). Multiobjective evolutionary studies by Zitzler and Deb (2000) offer insights into how GAs can handle multiple objectives under uncertainty, making them particularly useful for evolving fuzzy rules in complex environments (Zitzler & Deb, 2000).

**Applications of GAFES**

The application of Genetic Algorithm-Driven Fuzzy Expert Systems (GAFES) spans various fields, from industrial automation to robotics. In industrial settings, GAFES has been used to optimize processes, especially under varying conditions that require adaptive control. In autonomous robotics, GAFES has improved navigation by allowing robots to adapt to dynamic environments, proving advantageous in real-time decision-making scenarios.

**Wang (1997)** explored fuzzy systems in control, showing how GAs can optimize fuzzy rule-based controllers, especially in applications requiring adaptability and real-time response (Wang, 1997). **Karr (1991)** applied GAs to optimize fuzzy controllers, demonstrating their effectiveness in refining control parameters for precision and accuracy (Karr, 1991). **Bonissone (2001)** highlighted the role of soft computing, including GAFES, in industrial applications, particularly in cases that demand flexibility and adaptability under varying operational conditions (Bonissone, 2001).

**METHODOLOGY****System Design**

The proposed Genetic Algorithm-Driven Fuzzy Expert System (GAFES) integrates GAs and FES to optimize control processes under uncertainty. The system follows the following workflow:

1. **Initialization:** A set of initial fuzzy membership functions and rule bases is generated.
2. **Optimization with GA:** GAs are applied to optimize the fuzzy rule base and membership functions. The fitness function is designed to minimize errors and maximize decision accuracy.
3. **Fuzzy Inference System (FIS):** The optimized fuzzy rules are applied to the FIS to drive decision-making processes.
4. **Adaptation:** GAFES continuously adjusts its parameters based on real-time feedback from the control environment.

**Fitness Function**

The fitness function is designed to evaluate system performance across several metrics, including:

- Error minimization
- Robustness in handling noisy data
- Speed of decision-making
- System adaptability to changing conditions

**Simulation Environment**

A MATLAB-based simulation environment is used to implement and test GAFES. The control system simulates a robotic arm operating in a noisy environment. Various levels of noise and uncertainty are introduced to assess the robustness and adaptability of the system.

**Karen Felicita and Sahaya Sudha****Case Study: Operation of an Industrial Production Line****Objective**

The goal of this paper is to demonstrate how GAFES can optimize the operation of an industrial production line, with a focus on maximizing output while minimizing downtime and material waste. Due to varying product requirements and fluctuations in the availability of resources, conventional control systems struggle to maintain optimal production levels. GAFES, with its adaptive and flexible framework, offers a potential solution.

**System Overview**

In the context of this paper, the production line involves multiple stages:

1. **Raw Material Preparation:** Incoming raw materials need to be sorted and checked for quality.
2. **Assembly Line:** The prepared materials are fed into the assembly line, which involves multiple machines working in sync.
3. **Quality Control:** The final product is checked for defects, with the defective products reprocessed or discarded.
4. **Packaging and Distribution:** Packaged products are prepared for shipment.

Each stage of the production line has its own uncertainties, such as variable quality in raw materials, machine malfunctions, and changing demand levels. The traditional control systems are configured for fixed parameters and struggle with dynamic adaptations when unexpected variations occur.

**Application of GAFES****Fuzzy Expert System (FES) Setup**

The FES was designed to manage various stages in the production line. Key variables controlled by the FES include:

- **Material Quality (MQ):** Fuzzy parameters include "Low," "Medium," and "High."
- **Machine Efficiency (ME):** Indicates the operational status of machines, with fuzzy states such as "Inefficient," "Nominal," and "Optimal."
- **Product Quality (PQ):** Fuzzy states are "Defective," "Acceptable," and "High Quality."

Each fuzzy state has a membership function assigned to it. For example, "Low Material Quality" could have a triangular membership function defined over the range  $[0, 0.3, 0.6]$  on a scale of 0 to 1, with a peak at 0.3. Similarly, "Optimal Machine Efficiency" has a trapezoidal membership function with a range  $[0.7, 0.8, 1.0, 1.0]$ .

**Genetic Algorithm (GA) Optimization**

The GA was applied to optimize the fuzzy rules and membership functions to improve system performance. The optimization process involved the following steps:

1. **Initialization:** An initial population of fuzzy rule sets and membership functions was generated.
2. **Selection and Crossover:** Rule sets with higher fitness scores (evaluated by system performance) were selected and combined through crossover to create a new generation.
3. **Mutation:** Minor random changes were introduced in the membership functions or rule structures to ensure diversity in the solutions.
4. **Fitness Evaluation:** Each generation of fuzzy rule sets was evaluated based on a multi-objective fitness function. The fitness function included metrics for:

- **Production Output (PO):** Higher output scores increased fitness.
- **Material Waste (MW):** Lower waste levels increased fitness.
- **Downtime (DT):** Lower downtime levels contributed positively to fitness.

**Simulation Results**

Using a MATLAB-based simulation environment, the GAFES was tested across various scenarios representing different levels of material quality and machine efficiency. The outcomes demonstrated that GAFES achieved:

1. **20% Higher Production Output:** Compared to traditional control systems, GAFES could dynamically adapt to changes in material quality and demand, optimizing output.

### Karen Felicita and Sahaya Sudha

2. **15% Reduction in Material Waste:** The system's adaptability in real-time reduced defective products and rework.
3. **10% Decrease in Downtime:** Machines operated at optimal efficiency more consistently due to GAFES's dynamic tuning of control parameters.

The hybrid system's ability to adapt fuzzy parameters in real-time allowed the production line to remain efficient and responsive to changes. The GAFES optimization, driven by GA-tuned fuzzy rules, outperformed standard fuzzy control systems in robustness and adaptability, confirming findings by Castillo and Melin (2008) on the reliability of hybrid systems under uncertain conditions.

## CONCLUSION

This paper highlights the effectiveness of GAFES in optimizing production line efficiency under uncertainty. By combining GAs and FES, GAFES dynamically adjusts control rules and membership functions, leading to improved output, lower waste, and reduced downtime. This approach provides a scalable solution adaptable to various industrial settings and confirms the potential of GAFES in real-world applications.

### ABSTRACT

This paper explores the Interval-Valued Intuitionistic Fuzzy Transportation Problem (IVIFTP), advancing the traditional transportation model that incorporates interval-valued intuitionistic fuzzy sets. IVIFTP provides a more comprehensive framework for modelling uncertainty in transportation scenarios by allowing for a range of membership and non-membership degrees. We have developed an innovative solution methodology that combines optimization techniques with IVIFNs, enabling decision-makers to handle fluctuating costs, supply, and demand effectively. Through illustrative examples, we demonstrate the practicality and efficiency of our approach, highlighting its superiority over conventional models in terms of flexibility and accuracy.

**Keywords:** Transportation problem (TP), Arithmetic operations, Interval-valued triangular intuitionistic fuzzy number (IVTrIFN), Interval-valued trapezoidal intuitionistic fuzzy number (IVTrIFN), optimal solution.

## INTRODUCTION

The TP, a specific type of LPP, was first introduced by Hitchcock[1]. TP deals with optimizing the movement of goods from various sources to different destinations, aiming to minimize transportation costs while maximizing profits. Several key contributions to solving TP include: Dantzig and Thappa[2], enhanced the understanding of optimal solutions using the simplex method. Charnes and Cooper[3] devised the stepping-stone method to address TP efficiently. In situations where defining precise parameters for TP is challenging, fuzzy set theory offers a solution. Zadeh[4] introduced fuzzy sets in 1965, characterized by degrees of membership, to handle vagueness and uncertainty. In 1986, Atannasov[5] expanded on this concept by developing intuitionistic fuzzy sets (IFS), which incorporate non-membership and hesitation to manage different types of uncertainty. Later, Atannasov and

Gargov[6] further refined this by introducing IVIFS, where both membership & non-membership are represented as intervals, offering greater flexibility in dealing with uncertainties. The IVIFS is a significant advancement of the IFS. Its unique structure has attracted considerable research interest, particularly in decision-making contexts. Since IVIFS combines the concepts of intervals and IFS, analyzing the TP with IVIFNs provides more comprehensive information than IFS alone, offering greater flexibility and insight when dealing with uncertainty. Recent research has concentrated on the operations of IVIFSs as well as various intriguing properties associated with them. Also, extensive research has been conducted on the TP under fuzzy environments, particularly focusing on IVIFS due to their ability to handle uncertainties more effectively. Bharati and Singh [7-8] made significant contributions by exploring TP within the framework of IVIF environments, providing insights into optimizing distribution costs under uncertain conditions. They further developed a ranking methodology for IVIFNs and applied it in real-world scenarios, showcasing its practical relevance. Dhanasekaret al[9] extended these concepts by incorporating IVTIFNs into TP, further enhancing the model's ability to address complex uncertainties. These studies underscore the importance of IVIFNs and IVTIFNs in decision-making and optimization problems. Bharati [10] introduced ranking methods for intuitionistic fuzzy numbers, providing a systematic approach to comparing fuzzy values in decision-making processes. Xu [11] further contributed to this area by defining weighted aggregation operators for IVIFNs, which are essential for combining multiple IVIFNs into a single representative value, enhancing the effectiveness of fuzzy-based models in handling uncertainty and complexity.

In this article, we have introduced a method for solving TP under IVIFN. In IVIFTPP, the transportation costs are expressed using triangular and trapezoidal IVIFNs. To find optimal solutions, we employ a novel, computationally simple technique. This method is expected to garner significant attention because it bypasses the need to determine the initial basic feasible solution (IBFS) using Vogel's Approximation Method (VAM) and avoids checking optimality through the modified distribution method. In contrast to traditional fuzzy set and intuitionistic fuzzy set approaches, the proposed method directly provides optimal solutions with improved accuracy and efficiency, leading to more realistic and higher-quality outcomes. The structure followed is: Section 2 presents the fundamental definitions and operations of IFS. Section 3 introduces the ordering methods for IVTIFN and IVTrIFN. Section 4 discusses the IVIFTP along with the suggested algorithm. In Section 5, numerical examples are provided to validate the algorithm. Finally, Section 6 presents the results and discussion.

**Preliminaries**

**Definition 1**

Let  $X$  be a universal set. An IFSA in  $X$  is a set of form  $\tilde{A} = \{(x, \mu_A(x), \delta_A(x))\}$ , where  $\mu_A(x) : X \rightarrow [0, 1]$  and  $\delta_A(x) : X \rightarrow [0, 1]$  define the degree of membership and non – membership of the element  $x \in X$ , respectively, and for every  $x \in X$ ,  $0 \leq \mu_A(x) + \delta_A(x) \leq 1$ . The value of  $\pi_A(x) = 1 - \mu_A(x) - \delta_A(x)$  is called the degree of uncertainty of the element  $x \in X$  to the intuitionistic fuzzy set  $A$ . In IFS, if  $\pi_A(x) = 0$ , then an IFS becomes FS and it takes the form  $A = \{(x, \mu_A(x), 1 - \mu_A(x))\}$ .

**Definition 2**

An intuitionistic fuzzy set  $A = \{(a, b, c), [\mu, \delta]\}$  where  $a, b, c \in \mathbb{R}$  such that  $a \leq b \leq c$ . Then  $A$  is called a TIFN if its membership function  $\mu_A(x)$  and non-membership function  $\delta_A(x)$  are as follows:

$$\mu_A(x) = \begin{cases} \mu, & x = b \\ 0, & x \geq c, x \leq a \\ \frac{x - a}{b - a} \mu, & a < x < b \\ \frac{c - x}{c - b} \mu, & b < x < c \end{cases}$$

$$\delta_A(x) = \begin{cases} \delta, x = b \\ 1, x \geq c, x \leq a \\ 1 - \frac{(1-\delta)(x-a)}{b-a}, a < x < b \\ \delta - \frac{(1-\delta)(x-b)}{c-b}, b < x < c \end{cases}$$

**Definition 3**

Let  $X$  be a universal set. An IVIF  $A$  in  $X$  is expressed as  $A = \{(x, [\mu_A^-(x), \mu_A^+(x)], [\delta_A^-(x), \delta_A^+(x)]) : x \in X\}$ , where  $\mu_A^-(x) : X \rightarrow [0, 1]$ ,  $\mu_A^+(x) : X \rightarrow [0, 1]$ ,  $\delta_A^-(x) : X \rightarrow [0, 1]$ ,  $\delta_A^+(x) : X \rightarrow [0, 1]$  define both extreme degrees of memberships and non – memberships of the element  $x \in X$ ,  $0 \leq \mu_A^+(x) + \delta_A^+(x) \leq 1$ .

**Definition 4**

An INIFN is expressed as:  $A = \{(a, b, c) : [\mu^-, \mu^+], [\delta^-, \delta^+]\}$ , where  $\mu^- : X \rightarrow [0, 1]$ ,  $\mu^+ : X \rightarrow [0, 1]$  and  $\delta^- : X \rightarrow [0, 1]$ ,  $\delta^+ : X \rightarrow [0, 1]$  defines both extremedegrees of memberships & non – memberships, and these are:

$$\mu_A^-(x) = \begin{cases} \mu^- \frac{(x-a)}{(b-a)}, a < x < b \\ \mu^-, x = b \\ \mu^- \frac{(c-x)}{(c-b)}, b < x < c \end{cases}$$

$$\mu_A^+(x) = \begin{cases} \mu^+ \frac{(x-a)}{(b-a)}, a < x < b \\ \mu^+, x = b \\ \mu^+ \frac{(c-x)}{(c-b)}, b < x < c \end{cases}$$

$$\delta_A^-(x) = \begin{cases} 1 - (1 - \delta^-) \frac{(x-a)}{(b-a)}, a < x < b \\ \delta^-, x = b \\ \delta^- + (1 - \delta^-) \frac{(x-b)}{(c-b)}, b < x < c \end{cases}$$

$$\delta_A^+(x) = \begin{cases} 1 - (1 - \delta^+) \frac{(x-a)}{(b-a)}, a < x < b \\ \delta^+, x = b \\ \delta^+ + (1 - \delta^+) \frac{(x-b)}{(c-b)}, b < x < c \end{cases}$$

**Arithmetic Operations**

Arithmetic operations for the triangular IVIFNs. For this, let  $A = \{(a_1, b_1, c_1), [\mu_A^-, \mu_A^+], [\delta_A^-, \delta_A^+]\}$  and  $B = \{(a_2, b_2, c_2), [\mu_B^-, \mu_B^+], [\delta_B^-, \delta_B^+]\}$  be two TIVIFNs, then

$$A \oplus B = \{(a_1 + a_2, b_1 + b_2, c_1 + c_2), [\min\{\mu_A^-, \mu_B^-\}, \min\{\mu_A^+, \mu_B^+\}], [\max\{\delta_A^-, \delta_B^-\}, \max\{\delta_A^+, \delta_B^+\}]\}$$

$$A \ominus B = \{(a_1 - c_2, b_1 - b_2, c_1 - a_2), [\min\{\mu_A^-, \mu_B^-\}, \min\{\mu_A^+, \mu_B^+\}], [\max\{\delta_A^-, \delta_B^-\}, \max\{\delta_A^+, \delta_B^+\}]\}$$

$$A \odot B = \begin{cases} \{(a_1 a_2, b_1 b_2, c_1 c_2); [\min\{\mu_A^-, \mu_B^-\}, \min\{\mu_A^+, \mu_B^+\}], [\max\{\delta_A^-, \delta_B^-\}, \max\{\delta_A^+, \delta_B^+\}]\} \text{ if } a_1, a_2 \in \mathbb{R}^+ \\ \{(a_1 c_2, b_1 b_2, c_1 a_2); [\min\{\mu_A^-, \mu_B^-\}, \min\{\mu_A^+, \mu_B^+\}], [\max\{\delta_A^-, \delta_B^-\}, \max\{\delta_A^+, \delta_B^+\}]\} \text{ if } a_1 < 0 \text{ and } a_2 > 0 \\ \{(c_1 c_2, b_1 b_2, a_1 a_2); [\min\{\mu_A^-, \mu_B^-\}, \min\{\mu_A^+, \mu_B^+\}], [\max\{\delta_A^-, \delta_B^-\}, \max\{\delta_A^+, \delta_B^+\}]\} \text{ if } c_1 < 0 \text{ and } c_2 > 0 \end{cases}$$

$$k\dot{A} = \begin{cases} \{(ka, kb, kc), [\mu_A^-, \mu_A^+], [\delta_A^-, \delta_A^+]\} \text{ if } k > 0 \\ \{(kc, kb, ka), [\mu_A^-, \mu_A^+], [\delta_A^-, \delta_A^+]\} \text{ if } k < 0 \end{cases}$$

$$A^{-1} = \left\{ \left( \frac{1}{c}, \frac{1}{b}, \frac{1}{a} \right) [\mu_A^-, \mu_A^+], [\delta_A^-, \delta_A^+] \right\} \text{ if } a > 0$$

**Definition 5**

An IVTrIFNA<sup>IVF</sup> for the fixed set  $E$  is defined as  $A^{IVF} = \{(a_1, a_2, a_3, a_4); [\mu_{A^{IVF}}^-(x), \mu_{A^{IVF}}^+(x)]; [\delta_{A^{IVF}}^-(x), \delta_{A^{IVF}}^+(x)]\}$ , where  $\mu_{A^{IVF}}^-(x) : E \rightarrow [0, 1]$ ,  $\mu_{A^{IVF}}^+(x) : E \rightarrow [0, 1]$  and  $\delta_{A^{IVF}}^-(x) : E \rightarrow [0, 1]$ ,  $\delta_{A^{IVF}}^+(x) : E \rightarrow [0, 1]$  denotes both extremedegrees of membership, non – membership, respectively. It is defined as

$$\mu_{A^{IVF}}^{-}(x) = \begin{cases} \mu_{A^{IVF}}^{-} \frac{(x-a_1)}{(a_2-a_1)}, & a_1 \leq x < a_2 \\ \mu_{A^{IVF}}^{-}, & a_2 \leq x \leq a_3 \\ \mu_{A^{IVF}}^{-} \frac{(a_4-x)}{(a_4-a_3)}, & a_3 < x \leq a_4 \\ 0, & \text{otherwise} \end{cases}$$

$$\mu_{A^{IVF}}^{+}(x) = \begin{cases} \mu_{A^{IVF}}^{+} \frac{(x-a_1)}{(a_2-a_1)}, & a_1 \leq x < a_2 \\ \mu_{A^{IVF}}^{+}, & a_2 \leq x \leq a_3 \\ \mu_{A^{IVF}}^{+} \frac{(a_4-x)}{(a_4-a_3)}, & a_3 < x \leq a_4 \\ 0, & \text{otherwise} \end{cases}$$

$$\delta_{A^{IVF}}^{-}(x) = \begin{cases} \frac{a_2-x+v_{A^{IVF}}^{-}(x-a_1)}{a_2-a_1}, & a_1 \leq x < a_2 \\ v_{A^{IVF}}^{-}, & a_2 \leq x \leq a_3 \\ \frac{x-a_3+v_{A^{IVF}}^{-}(a_4-x)}{a_4-a_3}, & a_3 < x \leq a_4 \\ 0, & \text{otherwise} \end{cases}$$

$$\delta_{A^{IVF}}^{+}(x) = \begin{cases} \frac{a_2-x+v_{A^{IVF}}^{+}(x-a_1)}{a_2-a_1}, & a_1 \leq x < a_2 \\ v_{A^{IVF}}^{+}, & a_2 \leq x \leq a_3 \\ \frac{x-a_3+v_{A^{IVF}}^{+}(a_4-x)}{a_4-a_3}, & a_3 < x \leq a_4 \\ 0, & \text{otherwise} \end{cases}$$

**Operations of IVTrIFN**

Let  $A^{IVF} = \{(a_1, a_2, a_3, a_4); [\mu_{A^{IVF}}^{-}(x), \mu_{A^{IVF}}^{+}(x)]; [\delta_{A^{IVF}}^{-}(x), \delta_{A^{IVF}}^{+}(x)]\}$  and  $B^{IVF} = \{(b_1, b_2, b_3, b_4); [\mu_{B^{IVF}}^{-}(x), \mu_{B^{IVF}}^{+}(x)]; [\delta_{B^{IVF}}^{-}(x), \delta_{B^{IVF}}^{+}(x)]\}$  be two IVTrIFNs. Then,

1.  $A^{IVF} + B^{IVF} = \{(a_1 + b_1, a_2 + b_2, a_3 + b_3, a_4 + b_4); [\min\{\mu_{A^{IVF}}^{-}, \mu_{B^{IVF}}^{-}\}, \min\{\mu_{A^{IVF}}^{+}, \mu_{B^{IVF}}^{+}\}], [\max\{\delta_{A^{IVF}}^{-}, \delta_{B^{IVF}}^{-}\}, \max\{\delta_{A^{IVF}}^{+}, \delta_{B^{IVF}}^{+}\}]\}$
2.  $A^{IVF} - B^{IVF} = \{(a_1 - b_4, a_2 - b_3, a_3 - b_2, a_4 - b_1); [\min\{\mu_{A^{IVF}}^{-}, \mu_{B^{IVF}}^{-}\}, \min\{\mu_{A^{IVF}}^{+}, \mu_{B^{IVF}}^{+}\}], [\max\{\delta_{A^{IVF}}^{-}, \delta_{B^{IVF}}^{-}\}, \max\{\delta_{A^{IVF}}^{+}, \delta_{B^{IVF}}^{+}\}]\}$
3.  $kA^{IVF} = \{(ka_1, ka_2, ka_3, ka_4); [1 - (1 - \mu_{A^{IVF}}^{-})^k, 1 - (1 - \mu_{A^{IVF}}^{+})^k]; [(\delta_{A^{IVF}}^{-})^k, (\delta_{A^{IVF}}^{+})^k]\} k > 0;$
4.  $(A^{IVF})^k = \{(a_1^k, a_2^k, a_3^k, a_4^k); [(\mu_{A^{IVF}}^{-})^k, (\mu_{A^{IVF}}^{+})^k]; [1 - (1 - \delta_{A^{IVF}}^{-})^k, 1 - (1 - \delta_{A^{IVF}}^{+})^k]\} k > 0.$

**Ordering of IVTIFNs & IVTrIFNs**

**Definition 3.1**

The ranking of IVTIFN  $A = \{(a_1, b_1, c_1), [\mu_{A}^{-}, \mu_{A}^{+}], [\delta_{A}^{-}, \delta_{A}^{+}]\}$  is defined as

$$R(A) = \frac{1}{16}(a_1 + 2b_1 + c_1)(\mu_{A}^{-} + \mu_{A}^{+} + 2 - \delta_{A}^{-} - \delta_{A}^{+})$$

Then one of the below conditions applies

- If  $R(A_1) < R(A_2)$ , then  $A_1 < A_2$ .
- If  $R(A_1) > R(A_2)$ , then  $A_1 > A_2$ .
- If  $R(A_1) = R(A_2)$ , then  $A_1 = A_2$

**Definition 3.2**

Let  $A = \{(a_1, a_2, a_3, a_4); [\mu_{A}^{-}(x), \mu_{A}^{+}(x)]; [\delta_{A}^{-}(x), \delta_{A}^{+}(x)]\}$  be an IVTrIFN. Subsequently, the score function is defined as

$$S(A) = \frac{\mu_{A}^{-}(x) + \mu_{A}^{+}(x) - \delta_{A}^{-}(x) - \delta_{A}^{+}(x)}{2}$$

**Maheswari et al.,**

**Definition 3.3**

Let  $A = \{(a_1, a_2, a_3, a_4); [\mu_A^-(x), \mu_A^+(x)]; [\delta_A^-(x), \delta_A^+(x)]\}$  be an IVTrIFN. Then, the score expectation function is defined as

$$I(S(A)) = \frac{S(A)}{2} ((a_1 + a_2)(1 - \alpha) + (a_3 + a_4)\alpha); (\alpha \text{ denotes the preference value})$$

**4.Interval-valued intuitionistic fuzzy transportation problem**

The mathematical formulation of IVIFTP is

Minimize

$$\tilde{Z} = \sum_{i=1}^m \sum_{j=1}^n \tilde{C}_{ij} * x_{ij}$$

Subject to,

$$\sum_{j=1}^n x_{ij} = a_i, i = 1, 2, \dots, m$$

$$\sum_{i=1}^m x_{ij} = b_j, j = 1, 2, \dots, n$$

$x_{ij} \geq 0$  for all  $i = 1, 2, \dots, m$  and  $j = 1, 2, \dots, n$ .

where

$m$  denotes the available number of supply points which is indexed by  $i$ .

$n$  denotes the available number of demand points which is indexed by  $j$ .

The cost of transporting the product from the  $i$ th source of  $j$ th destination is represented as IVTIFN or IVTrIFN and denoted by  $\tilde{C}_{ij}$ .

Total availability and demand are denoted by  $a_i$  &  $b_j$ .

As a special case, the cost of the transportation problem is considered here in Table 1 as IVTIFNs or IVTrIFNs. Also, the problem should have  $(n + m - 1)$  basic variables for the solution and all the remaining variables should be treated as non-basis. The IVIFTP is balanced if

$$\sum_{i=1}^m a_i = \sum_{j=1}^n b_j$$

**Proposed Algorithm for Solving IVIFTP**

Step 1

- Form the IVIFTP with cost parameters are IVTIFNs or IVTrIFNs.

Step 2

- Check the feasibility condition. If not, add a row or column with zero cost.

Step 3

- Choose the first source row and check which column (destination) has a minimum cost.
- Enter that source row in column 1 and the corresponding destination under column 2. Continue this process for each source.
- If a source has the same minimum value for multiple destinations, list all those destinations in column 2.

Step 4

- Select the rows from column 1 that have unique destinations.
- For each row, determine the minimum cost and allocate the corresponding value.
- Afterwards, eliminate the row or column where the supply or demand is completely met.
- If the destinations are not unique, proceed to step 5.

Step 5

- If the destination under column 2 is not unique, select sources with identical destinations.
- Next, subtract the minimum cost from the next minimum unit cost for all sources with identical destinations.

Step 6

- Check the source which has the maximum difference. Select that source and allot a least amount of either supply or demand to the appropriate destination.
- Delete that row/column where supply/demand is exhausted.

Step 7

- Continue the process, till the rim requirements are met.

Remark 1:

- If two or more sources have the same maximum difference, determine the difference between the minimum and the next-to-next minimum costs for those sources, and select the source with the maximum difference.
- Allocate the least rim values to that cell and delete the row/column where supply/demand is exhausted.

**Numerical Example**

This section presents two numerical examples to validate the proposed approach.

**Illustration**

Consider the numerical example of [34]

Step 1: We express the transportation table 1 with IVTrIFN as costs.

Step 2:  $\sum_{i=1}^m a_i = \sum_{j=1}^n b_j = 32$ .

Step 3: Calculate row penalties.

$$R(C_{11}) < R(C_{13}) < R(C_{12}) \Rightarrow C_{11} < C_{13} < C_{12}$$

$$R(C_{21}) < R(C_{22}) < R(C_{23}) \Rightarrow C_{21} < C_{22} < C_{23}$$

$$R(C_{31}) < R(C_{32}) < R(C_{33}) \Rightarrow C_{31} < C_{32} < C_{33}$$

Step 4: Finding row penalties

$$C_{13} \ominus C_{11} = \{(-5, 2, 15), [0.1, 0.4], [0.03, 0.07]\}$$

$$C_{22} \ominus C_{21} = \{(-2, 5, 11), [0.2, 0.4], [0.01, 0.04]\}$$

$$C_{32} \ominus C_{31} = \{(-1, 10, 20), [0.3, 0.4], [0.03, 0.04]\}$$

The optimum allocations are  $x_{13}=7, x_{23}=6, x_{33}=9, x_{31}=8, x_{32}=2$  and

Total cost is  $7 * \{(4,6,16), [0.3,0.4],[0.03,0.07]\} + 6 * \{(5,10,15),[0.2,0.5],[0.01,0.04]\} + 9 * \{(7,16,24),[0.3,0.5],[0.02,0.03]\} + 8 * \{(1,3,6),[0.4,0.5],[0.01,0.02]\} +$

$2 * \{(8,18,27),[0.4,0.5],[0.05,0.05]\} = \{(145,306,520),[0.2,0.4],[0.03,0.07]\}$

Hence IVIF cost is given by  $z = \{(145,306,520), [0.2, 0.4], [0.03, 0.07]\}$

**Comparison:**

The result of [16] and our proposed method are the same.

**Illustration**

Consider the problem in [9]

Here  $m+n-1$ , the number of allocated cells= 5.

The optimum transportation cost =  $6([4, 5, 6, 8]; [0.3, 0.5]; [0.2, 0.4]) + 14([1, 4, 5, 6]; [0.1, 0.3]; [0.3, 0.5]) + 2([5, 6, 7, 8]; [0.3, 0.5]; [0.2, 0.4]) + 13([2, 4, 6, 7]; [0.1, 0.3]; [0.4, 0.6]) + 25([2, 3, 4, 5]; [0.1, 0.3]; [0.4, 0.6]) = \{(124,225,298,364), [0.51, 0.75], [0.04, 0.16]\}$

**RESULTS AND COMPARATIVE STUDY**

Table 14 shows that the transportation costs for IVTIF are the same for both methods, but the calculation time is much less in our method. Notably, the new method for IVTrIF yields a lower transportation cost compared to the current approach. A subtraction operation is utilized in both cases; however, the existing ranking is employed for

IVTIFTP, while the score function is applied for comparing IVTrIFNs. Additionally, the expected score function is implemented to robustly validate the comparison of IVTrIF costs in the transportation problem.

#### Advantages of the new method

- The new method involves fewer iterations, resulting in reduced computing time compared to existing approaches. Additionally, it is easy to understand and more flexible.
- This method can be used for TP involving different cost parameters.
- Both transportation problems are solved directly, without converting them into crisp values, yielding transportation costs as given.

## CONCLUSION

To address the uncertainties faced by decision-makers in predicting transportation costs in transportation problems (TPs), this study considers the costs as IVTFNs and IVTrIFNs. Additionally, IVTIFTP and IVTrIFN were compared with existing ranking methods to achieve an optimal solution using the proposed approach. Two numerical examples are given to showcase how effective the suggested method is, when results are compared to those obtained from existing methods. The suggested method is effective due to its simplicity and clarity in handling transportation problems under uncertain conditions. It can also be applied to various transportation problems involving different types of cost parameters.

### ABSTRACT

A Compartment model is an important tool for analyzing a dynamical system that describes the transport of material through several compartments, each containing well-mixed material and exchanging material with the others under certain rules. In this paper, we modeling on compartment based mixing problem with n tanks. One-Dimensional Differential Transform Method (ODDTM) has been used to solve the model.

**Keywords:** Differential equations, Modelling on compartments based mixing problem, Differential transform.

## INTRODUCTION

The mathematical modeling of mixing problems with n compartments has evolved through centuries of scientific inquiry and interdisciplinary collaboration. Beginning with early pioneers like Newton and Euler, the understanding of dynamic systems and diffusion laid the groundwork for subsequent developments. In the 19th and 20th centuries, figures such as Fourier, Poincare, and Prandtl advanced theories of heat transfer, fluid dynamics, and chemical kinetics, providing essential insights into mixing phenomena. As computational methods emerged, scientists gained the ability to model complex systems with greater accuracy, leading to applications in environmental science, biology, and engineering. Today, interdisciplinary teams continue to refine mathematical models and simulation techniques, driving innovation and deepening our understanding of mixing processes in diverse contexts. In that case, a solution may not be physically justified, so it is necessary to consider the proper initial approximation to

### Anuradha and Sabesh

obtain the physically realistic solution, which is a difficult task. The variational iteration method requires producing the correct function using Lagrange's multipliers and stationary conditions by using variational theory, which is problematic. Besides this, other disadvantages are repeated computation of unneeded terms, which consume time and effort. In the homotopy analysis method, an auxiliary linear operator is required to construct a continuous mapping of an initial guess approximation to the exact solution of the equation. An additional parameter is needed to show the convergences of series solutions obtained by this method, which are difficult to identify. This technique embeds a parameter  $p$ , which ranges from 0 to 1. When the embedding parameter is zero, the equation is a linear system, and when it is 1, the equation represents the original system. So, the embedded parameter  $p \in [0,1]$  can be considered as a small parameter. To overcome all the mentioned issues, we suggest an efficient semi-analytical approach, the differential transform method (DTM), for dealing with linear and nonlinear differential equations. The DTM has no unrealistic assumptions or restrictions, such as linearization, discretization, or small parameters which is used for nonlinear operators. It converts the system into a recursive formula which is easy to handle. Thus, the DTM addresses linear and nonlinear problems efficiently. Some authors consider the DTM as an iterative method or numerical method or semi-numerical analytic method. The DTM (Differential Transform Method) can be defined as a semi-numerical analytic iterative method that describes the solution of an ODEs and PDEs into a series form that further sometimes can be converted into a closed form, that is, an exact solution.

The DTM is derived from the traditional Taylor series method, which requires the complicated and tedious symbolic computation of higher-order derivatives. It transforms the differential equation or system of ODEs or PDEs into a recursive formula that calculates the series solution coefficient. The DTM reduces the span of the computational domain compared to the other techniques and doesn't require the unneeded parameters to start the solution procedure. The series solution obtained by using DTM shows rapid convergence. One of the most significant advantages of DTM is that it obtains the solution of the given differential equation on a continuous interval. Thus, its straightforward applicability, computational efficiency, and high accuracy make the DTM one of the powerful and efficient methods to solve the differential equations or system of differential equations. The One-dimensional differential transform method (ODDTM) is a numerical technique used to solve differential equations. Unlike traditional methods such as finite differences or finite element methods, ODDTM transforms the differential equations into algebraic equations, making them easier to solve. In ODDTM, the solution is represented as a series expansion, allowing of efficient computation and accurate result, particularly in problems with one independent variable. This method has gained popularity due to its simplicity, flexibility, and effectiveness in analysing various engineering and scientific problems. In this paper, we discuss the principle, applications and advancements of the One-Dimensional Differential Transformation Method (ODDTM), highlighting its significance in solving differential equation across different disciplines.

## PRILIMINARIES

This chapter presents the one-dimensional differential transform method (ODDTM) and its basic properties. Also discusses the solution of differential equations involved in different fields of science and technology.

### DEFINITION

If  $u(t)$  is analytic in the time domain  $T$ , then

$$\frac{d^k u(t)}{dt^k} = \phi(t, k), \quad \forall t \in T. \quad (2.1)$$

For  $t = t_i$ ,  $\phi(t, k) = \phi(t_i, k)$ . where  $k$  belongs to the non-negative integer, denoted as the  $K$ -domain. The equation (2.1) can become

$$U_i(k) = \phi(t_i, k) = \left[ \frac{d^k u(t)}{dt^k} \right]_{t=t_i}, \quad \forall t \in T. \quad (2.2)$$

where  $U_i(k)$  is called the spectrum of  $u(t)$  at  $t = t_i$  in the  $K$  domain.

**Anuradha and Sabesh**

**DEFINITION**

If  $u(t)$  is analytic, then  $u(t)$  can be expressed by Taylor's series expansion as

$$u(t) = \sum_{k=1}^{\infty} \frac{(t-t_i)^k}{k!} U(k) \tag{2.3}$$

Equation (2.3) is called the inverse transformation of  $U(k)$ . If  $U(k)$  is defined as

$$U(k) = M(k) \left[ \frac{d^k q(t) u(t)}{dt^k} \right]_{t=t_i}, \quad k = 0, 1, 2, 3, \dots \tag{2.4}$$

then the function  $u(t)$  can be described as  $u(t) = \frac{1}{q(t)} \sum_{k=0}^{\infty} \frac{(t-t_i)^k U(k)}{k! M(k)}$ , (2.5)

where  $M(k) \neq 0, q(t) \neq 0$ .  $M(k)$  is called the weighting factor, and  $q(t)$  is considered as a kernel corresponding to  $u(t)$ . If  $M(k) = 1$  and  $q(t) = 1$  in equation (2.5), then equations (2.3) and (2.5) are equivalent. Using the ODDTM, the given differential equation in the domain of interest can be transformed to be an algebraic equation in the  $K$  domain. Hence,  $u(t)$  can be obtained by finite-term Taylor series plus a remainder, as

$$\begin{aligned} u(t) &= \frac{1}{q(t)} \sum_{k=0}^{\infty} \frac{(t-t_i)^k}{k!} \frac{U(k)}{M(k)} + R_{n+1}(t) \\ &= \sum_{k=0}^{\infty} \frac{(t-t_i)^k U(k)}{k!} + R_{n+1}(t) \end{aligned}$$

where  $R_{n+1}(t) = \sum_{k=n+1}^{\infty} (t-t_0)^k U(k)$  is negligibly small

**BASIC PROPERTIES OF ODDTM**

In this section, the basic properties of the ODDTM were discussed. Assume that  $U(k), G(k), H(k)$  are the differential transform of the original function of  $u(x), g(x), h(x)$  respectively.

**PROBLEM DESCRIPTION AND MATHEMATICAL FORMULATION**

Mixing raw materials is an important task in processing a product. The ratio has to be fixed and obtained as per the requirement. Suppose raw materials P and Q has to be mixed to obtain a product. But the real scenario is in market the mixing of P and Q is available in different ratio by n different suppliers in fluid form. Our aim is to mix all using a 'n' compartment model. Consider n tanks  $A_1, A_2, A_3, \dots, A_n$  with volume  $V_1, V_2, V_3, \dots, V_n$ , respectively containing raw material  $R_1, R_2, R_3, \dots, R_n$ . Initially, the concentration of the raw material P in tank  $A_1, A_2, A_3, \dots, A_n$  is  $c_1, c_2, c_3, \dots, c_n$ , respectively. To keep the volume of the tank constant, it is assumed that the fluid flow from tank  $A_1$  to  $A_2, A_2$  to  $A_3, \dots, A_{n-1}$  to  $A_n$  and  $A_n$  to  $A_1$  at rate r. Furthermore, it is assumed that each tank is uniformly stirred so that the concentration is uniform. Due to recycling, no material is lost. Let  $x_1(t), x_2(t), x_3(t), \dots, x_n(t)$  denote the amount of raw material P in tanks  $A_1, A_2, A_3, \dots, A_n$  respectively at any time t. Using the balance law: rate of change = input rate – output rate, the mixing problem is modeled. The flux is flowing rate time the tank  $A_1$  is emptied with flux r times  $\frac{x_1(t)}{V_1}$ . Using the figure and the balance law gives the following coupled system of differential Equations:

$$\left. \begin{aligned} \frac{dx_1}{dt} &= \frac{rx_n}{V_n} - \frac{rx_1}{V_1} \\ \frac{dx_2}{dt} &= \frac{rx_1}{V_1} - \frac{rx_2}{V_2} \\ \frac{dx_3}{dt} &= \frac{rx_2}{V_2} - \frac{rx_3}{V_3} \\ &\vdots \\ &\vdots \\ \frac{dx_n}{dt} &= \frac{rx_{n-1}}{V_{n-1}} - \frac{rx_n}{V_n} \end{aligned} \right\} \text{-----(3.1)}$$

With the initial condition  $x_1(0) = c_1, x_2(0) = c_2, x_3(0) = c_3, \dots, x_n(0) = c_n$ .

**Anuradha and Sabesh**

Applying the basic properties of the ODDTM to the first equation in (3.1) gives

$$\begin{aligned}
 D\left(\frac{dx_1}{dt}\right) &= D\left(\frac{rx_n}{V_n} - \frac{rx_1}{V_1}\right) \\
 D\left(\frac{dx_1}{dt}\right) &= \frac{r}{V_n}D(x_n) - \frac{r}{V_1}D(x_1) \\
 \left(\frac{1}{k!}\left(\frac{dx_1}{dt}\right)\right) &= \frac{r}{V_n}\left(\frac{1}{k!}\left(\frac{dx_n}{dt}\right)\right) - \frac{r}{V_1}\left(\frac{1}{k!}\left(\frac{dx_1}{dt}\right)\right) \\
 \left. \begin{aligned}
 (k+1)X_1(k+1) &= \frac{rX_n(k)}{V_n} - \frac{rX_1(k)}{V_1} \\
 (k+1)X_2(k+1) &= \frac{rX_1(k)}{V_1} - \frac{rX_2(k)}{V_2} \\
 (k+1)X_3(k+1) &= \frac{rX_2(k)}{V_2} - \frac{rX_3(k)}{V_3} \\
 &\vdots \\
 &\vdots \\
 &\vdots \\
 (k+1)X_n(k+1) &= \frac{rX_{n-1}(k)}{V_{n-1}} - \frac{rX_n(k)}{V_n}
 \end{aligned} \right\} \text{-----(3.2)}
 \end{aligned}$$

Applying the ODDTM to the initial condition  $x_1(0) = c_1, x_2(0) = c_2, x_3(0) = c_3, \dots, x_n(0) = c_n$  and substituting  $k = 0$  in equation (3.2) and using the transformed initial condition.

Equation (3.2) will be reduced to

$$\begin{aligned}
 (0+1)X_1(0+1) &= \frac{rX_n(0)}{V_n} - \frac{rX_1(0)}{V_1} \\
 (1)X_1(1) &= \frac{rc_n}{V_n} - \frac{rc_1}{V_1} \\
 \left. \begin{aligned}
 X_1(1) &= \frac{rc_n}{V_n} - \frac{rc_1}{V_1} \\
 X_2(1) &= r\left(\frac{c_1}{V_1} - \frac{c_2}{V_2}\right) \\
 X_3(1) &= r\left(\frac{c_2}{V_2} - \frac{c_3}{V_3}\right) \\
 &\vdots \\
 &\vdots \\
 &\vdots \\
 X_n(1) &= r\left(\frac{c_{n-1}}{V_{n-1}} - \frac{c_n}{V_n}\right)
 \end{aligned} \right\} \text{-----(3.3)}
 \end{aligned}$$

Substituting  $k=1$  into equations (3.2) and using  $X_1(1) = r\left(\frac{c_n}{V_n} - \frac{c_1}{V_1}\right), X_2(1) = r\left(\frac{c_1}{V_1} - \frac{c_2}{V_2}\right), X_3(1) = r\left(\frac{c_2}{V_2} - \frac{c_3}{V_3}\right)$  up to  $n$  terms  $X_n(1) = r\left(\frac{c_{n-1}}{V_{n-1}} - \frac{c_n}{V_n}\right)$ .

Equation (3.3) reduce to

$$\begin{aligned}
 (1+1)X_1(1+1) &= \frac{rX_n(1)}{V_n} - \frac{rX_1(1)}{V_1} \\
 (2)X_1(2) &= \frac{r\left(\frac{rc_{n-1}}{V_{n-1}} - \frac{rc_n}{V_n}\right)}{V_n} - \frac{r\left(\frac{rc_n}{V_n} - \frac{rc_1}{V_1}\right)}{V_1} \\
 X_1(2) &= \frac{r\left(\frac{rc_{n-1}}{V_{n-1}} - \frac{rc_n}{V_n}\right)}{2V_n} - \frac{r\left(\frac{rc_n}{V_n} - \frac{rc_1}{V_1}\right)}{2V_1} \\
 (1+1)X_2(1+1) &= \frac{rX_1(1)}{V_1} - \frac{rX_2(1)}{V_2}
 \end{aligned}$$

Similarly,

$$X_2(2) = \frac{r\left(\frac{rc_n}{V_n} - \frac{rc_1}{V_1}\right)}{2V_1} - \frac{r\left(\frac{rc_1}{V_1} - \frac{rc_2}{V_2}\right)}{2V_2}$$

**Anuradha and Sabesh**

$$(1 + 1)X_3(1 + 1) = \frac{rX_2(1)}{V_2} - \frac{rX_3(1)}{V_3}$$

$$X_3(2) = \frac{r\left(\frac{rc_1}{V_1} - \frac{rc_2}{V_2}\right)}{2V_2} - \frac{r\left(\frac{rc_2}{V_2} - \frac{rc_3}{V_3}\right)}{2V_3}$$

and

$$(1 + 1)X_n(1 + 1) = \frac{rX_{n-1}(1)}{V_{n-1}} - \frac{rX_n(1)}{V_n}$$

$$X_n(2) = \frac{r\left(\frac{rc_{n-2}}{V_{n-2}} - \frac{rc_{n-1}}{V_{n-1}}\right)}{2V_{n-1}} - \frac{r\left(\frac{rc_{n-1}}{V_{n-1}} - \frac{rc_n}{V_n}\right)}{2V_n}$$

Continuing in the same manner, the remaining coefficient can be calculated. Using the definition of the inverse ODDTM, the amount of raw material P in the tanks are given by

$$x_1(t) = \sum_{k=0}^n X_1(k)t^k,$$

$$x_1(t) = c_1 - r\left(\frac{c_n}{V_n} - \frac{c_1}{V_1}\right)t + \left(\frac{r\left(\frac{rc_{n-1}}{V_{n-1}} - \frac{rc_n}{V_n}\right)}{2V_{n-1}} - \frac{r\left(\frac{rc_n}{V_n} - \frac{rc_1}{V_1}\right)}{2V_n}\right)t^2 - \dots$$

$$x_2(t) = \sum_{k=0}^n X_2(k)t^k,$$

$$x_2(t) = c_2 - r\left(\frac{c_1}{V_1} - \frac{c_2}{V_2}\right)t + \left(\frac{r\left(\frac{rc_n}{V_n} - \frac{rc_1}{V_1}\right)}{2V_1} - \frac{r\left(\frac{rc_1}{V_1} - \frac{rc_2}{V_2}\right)}{2V_2}\right)t^2 - \dots$$

$$x_3(t) = \sum_{k=0}^n X_3(k)t^k,$$

$$x_3(t) = c_3 - r\left(\frac{c_2}{V_2} - \frac{c_3}{V_3}\right)t + \left(\frac{r\left(\frac{rc_1}{V_1} - \frac{rc_2}{V_2}\right)}{2V_2} - \frac{r\left(\frac{rc_2}{V_2} - \frac{rc_3}{V_3}\right)}{2V_3}\right)t^2 - \dots$$

...

...

...

$$x_n(t) = \sum_{k=0}^n X_n(k)t^k,$$

$$x_n(t) = c_n - r\left(\frac{c_{n-1}}{V_{n-1}} - \frac{c_n}{V_n}\right)t + \left(\frac{r\left(\frac{rc_{n-2}}{V_{n-2}} - \frac{rc_{n-1}}{V_{n-1}}\right)}{2V_{n-1}} - \frac{r\left(\frac{rc_{n-1}}{V_{n-1}} - \frac{rc_n}{V_n}\right)}{2V_n}\right)t^2 - \dots$$

**CONCLUSION**

Mathematical modeling on compartment based mixing problem with n tanks has been arrived. One-Dimensional Differential Transform Method has been applied to solve the model. That is, the concentration of raw material on each tank has been obtained for time. An illustration has been shown by using MATLAB.

### ABSTRACT

The proposed paper introduces a new type of grill  $V -$  set namely;  $V_G - \mathcal{M}_p$  Open sets, which is analogous to the  $V_G -$  semiopen sets in a grill  $V -$  space  $(X, VO_X, \mathcal{G})$ . Further it, defines some relations between set of all  $V_G -$  opensets and the set of all  $V_G - \mathcal{M}_p$  Open sets in Grill  $V -$  Space. The Properties and theorems of  $V_G - \mathcal{M}_p$  Open sets are investigated and studied.

**Keywords:**  $V_G - \mathcal{M}_p$  open,  $V_G - \mathcal{M}_p$   $O(X)$ ,  $V_G -$  open,  $V_G -$  pre open.

## INTRODUCTION

Choquet, [1] introduced the notion of grill. After that, Roy [2] introduced the notion of grill topological space. In 2022, [3] introduced the concept of  $V -$  open set for the first time and named the ordered pair of the universal set and the family of all  $V -$  open sets a  $V -$  Sapce and prove that this space represents a topological space under the certain conditions. In 2023, Esmaeel [4] introduce grill into this  $V -$  Sapce as grill  $V -$  Sapce.

### Preliminaries

#### Definition 2.1

Let  $X$  represent a set that is non-empty and let  $\{\tau_j\}_{j \in \mathbb{N}}, J \geq 2$  be any topologies on  $X$  and let the family  $VO_X = \{\mathfrak{N} \subseteq X: \mathfrak{N} = \Phi \text{ or } \exists T \in \cap_{j \in \mathbb{N}} \tau_j \text{ such that } \Phi \neq T \subseteq \mathfrak{N}\}$  satisfying the following axioms:

1.  $X, \Phi \in VO_X$ .
2.  $\cup_{i \in \mathbb{N}} N_i \in VO_X \forall \{N_i\}_{i \in \mathbb{N}} \in VO_X$
3.  $\cap_{i=1}^n N_i \in VO_X \forall \{N_i\}_{i=1}^n \in VO_X$

Then  $(X, VO_X)$  is called to be  $V -$  Sapce and the elements of  $VO_X$  are called  $V -$  open

Sets and the complement of  $V -$  open set is called  $V -$  Closed.

**Manikandan and Chandramathi**

**Definition 2.2**

A non-empty family  $\mathcal{G}$  of sets of  $V - Space (X, VO_X)$  is named a grill on  $X$  if satisfies the following axioms

1.  $\Phi \notin \mathcal{G}$ .
2.  $\mathbb{M} \in \mathcal{G}$  and  $\mathbb{M} \subseteq \mathbb{P} \implies \mathbb{P} \in \mathcal{G}$ .
3.  $\mathbb{M} \notin \mathcal{G}$  and  $\mathbb{P} \notin \mathcal{G} \implies \mathbb{M} \cup \mathbb{P} \notin \mathcal{G}$ .

Any  $V - Space (X, VO_X)$  with a grill  $\mathcal{G}$  on  $X$  is named grill  $V - Space$  and is symbolize by  $(X, VO_X, \mathcal{G})$ .

**Example 2.1:**

Let

$X = \{\dagger_1, \dagger_2, \dagger_3, \dagger_4\}$ , and let  $\{\tau_i\}_{i=1}^3$  be a family of topologies defined on  $X$  follows:  $\tau_1 = P(X), \tau_2 = \{X, \Phi, \{\dagger_1\}, \{\dagger_1, \dagger_2\}, \{\dagger_3\}, \{\dagger_1, \dagger_3\}, \{\dagger_1, \dagger_2, \dagger_3\}\}, \tau_3 = \{X, \Phi, \{\dagger_1\}, \{\dagger_1, \dagger_2\}, \{\dagger_3, \dagger_4\}, \{\dagger_1, \dagger_3, \dagger_4\}\}$ .

Then  $\cap_{i=1}^3 \tau_i = \{X, \Phi, \{\dagger_1, \dagger_2\}, \{\dagger_1\}\}$

Now,

$VO_X = \{X, \Phi, \{\dagger_1\}, \{\dagger_1, \dagger_2\}, \{\dagger_1, \dagger_3\}, \{\dagger_1, \dagger_4\}, \{\dagger_1, \dagger_3, \dagger_4\}, \{\dagger_1, \dagger_2, \dagger_3\}, \{\dagger_1, \dagger_2, \dagger_4\}\}$

And grill  $\mathcal{G} = \{\{\dagger_1\}, \{\dagger_1, \dagger_2\}, \{\dagger_1, \dagger_3\}, \{\dagger_1, \dagger_4\}, \{\dagger_1, \dagger_2, \dagger_3\}, \{\dagger_1, \dagger_3, \dagger_4\}, \{\dagger_1, \dagger_2, \dagger_3, \dagger_4\}\}$ ,

Here  $(X, VO_X)$  is a  $V - Space$  and  $(X, VO_X, \mathcal{G})$  Grill  $V - Space$ .

**Closure operator in Grill  $V - Spaces$**

**Definition 3.1**

Let  $\mathcal{G}$  be a grill on  $V - Space (X, VO_X)$ . The map  $\Omega_{\mathcal{G}}: P(X) \rightarrow P(X)$  defined by  $\Omega_{\mathcal{G}}(\aleph) = \{x \in X: \mathbb{M} \cap \aleph \in \mathcal{G}, \forall \mathbb{M} \in VO_X\}$  for each  $\aleph \subseteq X$ , is named the local map commitment to grill  $\mathcal{G}$  with the topology  $VO_X$ .

**Definition 3.2:**

Let  $\mathcal{G}$  be a grill on  $V - Space (X, VO_X)$ . The map  $\Psi: P(X) \rightarrow P(X)$  defined by  $\Psi(\aleph) = \aleph \cup \Omega_{\mathcal{G}}(\aleph) = V_{\mathcal{G}} - cl(\aleph)$  is a Kuratowski's closure operator and hence induces a topology on  $X$  defined as  $V_{\mathcal{G}} = \{K \subseteq X: \Psi(X - K) = (X - K)\}$ .

**Definition 3.3:**

For a grill  $V - Space (X, VO_X, \mathcal{G})$ , and  $\aleph \subseteq X$

1.  $\aleph$  is named  $V_{\mathcal{G}} - preopen$  set if  $\aleph \subseteq V_{\mathcal{G}} int V_{\mathcal{G}} cl(\aleph)$ .
2.  $\aleph$  is named  $V_{\mathcal{G}} - semiopen$  set if  $\aleph \subseteq V_{\mathcal{G}} cl V_{\mathcal{G}} int(\aleph)$ .
3.  $\aleph$  is named  $V_{\mathcal{G}} - \alpha open$  set if  $\aleph \subseteq V_{\mathcal{G}} int V_{\mathcal{G}} cl V_{\mathcal{G}} int(\aleph)$ .

The family of all  $V_{\mathcal{G}} - \alpha open$  set (resp.  $V_{\mathcal{G}} - preopen, V_{\mathcal{G}} - semiopen$  set) is denoted by  $V_{\mathcal{G}} - \alpha O(X)$  (resp.  $V_{\mathcal{G}} - PO(X), V_{\mathcal{G}} - SO(X)$ ).

IN view of Mashhour[6], For any subset  $K$  in  $X$ , (i)  $V_{\mathcal{G}} - pint(K) = \cup \{M: M \in V_{\mathcal{G}} - PO(X) \text{ and } M \subseteq K\}$ ; (ii)  $V_{\mathcal{G}} - pcl(K) = \cap \{F: X - F \in V_{\mathcal{G}} - PO(X) \text{ and } K \subseteq F\}$ .

**$V_{\mathcal{G}} - \mathcal{M}_p$  Open Sets**

**Definition 4.1:**

Let  $(X, VO_X, \mathcal{G})$  be a grill  $V - Space$  and let  $\aleph$  be a subset of  $X$ . Then  $\aleph$  is said to be  $V_{\mathcal{G}} - \mathcal{M}_p$  open set if there exist a  $K \in V_{\mathcal{G}} - PO(X)$  such that  $K \subseteq \aleph \subseteq \Psi(K)$ . A set  $\aleph$  Of  $X$  is  $V_{\mathcal{G}} - \mathcal{M}_p$  closed if its complement  $X - \aleph$  is  $V_{\mathcal{G}} - \mathcal{M}_p$  open.

**Example 4.1:**

Let  $X = \{\dagger_1, \dagger_2, \dagger_3\}$ , and let  $\{\tau_i\}_{i=1}^3$  be a family of topologies defined on  $X$  follows:

$\tau_1 = \{X, \Phi, \{\dagger_1\}, \{\dagger_1, \dagger_2\}\}, \tau_2 = \{X, \Phi, \{\dagger_1\}, \{\dagger_1, \dagger_3\}\}, \tau_3 = \{X, \Phi, \{\dagger_1\}, \{\dagger_2, \dagger_3\}\}$ .  $\cap_{i=1}^3 \tau_i = \{X, \Phi, \{\dagger_1\}\}$

$VO_X = \{X, \Phi, \{\dagger_1\}, \{\dagger_1, \dagger_2\}, \{\dagger_1, \dagger_3\}\}$ , and grill  $\mathcal{G} = \{\{\dagger_1, \dagger_2, \dagger_3\}, \{\dagger_2\}, \{\dagger_1, \dagger_2\}, \{\dagger_2, \dagger_3\}\}$ . Here  $(X, VO_X, \mathcal{G})$  is a Grill  $V - Space$ . Then  $V_{\mathcal{G}} - \mathcal{M}_p O(X) = \{X, \Phi, \{\dagger_1\}, \{\dagger_3\}, \{\dagger_1, \dagger_2\}, \{\dagger_1, \dagger_3\}\}$ ,

**Manikandan and Chandramathi**

**Theorem 4.1:**

Let  $(X, VO_X, \mathcal{G})$  be a grill  $V$  – Space and let  $\aleph$  be a subset of  $X$ . Then  $\aleph \in V_G - \mathcal{M}_p O(X)$  if and

Only if  $\aleph \subseteq \Psi(V_G - \text{pint}(\aleph))$ .

Proof: If,  $\aleph \in V_G - \mathcal{M}_p O(X)$ , then there exist a  $K \in V_G - PO(X)$  such that  $K \subseteq \aleph \subseteq \Psi(K)$ . But  $K \subseteq \aleph$  implies that  $K \subseteq V_G - \text{pint}(\aleph)$ . Hence  $\Psi(K) \subseteq \Psi(V_G - \text{pint}(\aleph))$ . Therefore

$\aleph \subseteq \Psi(V_G - \text{pint}(\aleph))$ . Conversely, Let  $\aleph \subseteq \Psi(V_G - \text{pint}(\aleph))$ . To prove that  $\aleph \in V_G - \mathcal{M}_p O(X)$ , take  $K = V_G - \text{pint}(\aleph)$ , then  $K \subseteq \aleph \subseteq \Psi(K)$ . Hence  $\aleph \in V_G - \mathcal{M}_p O(X)$ .

**Corollary 4.1:** If  $\aleph \subseteq X$ , Then  $\aleph \in V_G - \mathcal{M}_p O(X)$  if and only if  $\Psi(\aleph) = \Psi(V_G - \text{pint}(\aleph))$ .

Proof: Let  $\aleph \in V_G - \mathcal{M}_p O(X)$ . Then as  $\Psi$  is monotonic and idempotent,  $\Psi(\aleph) \subseteq \Psi(\Psi(V_G - \text{pint}(\aleph))) = \Psi(V_G - \text{pint}(\aleph)) \subseteq \Psi(\aleph)$  implies that  $\Psi(\aleph) = \Psi(V_G - \text{pint}(\aleph))$ .

**Theorem 4.2:** Let  $(X, VO_X, \mathcal{G})$  be a grill  $V$  – Space and let  $\aleph$  be a subset of  $X$ . If  $\aleph \in V_G - \mathcal{M}_p O(X)$  and  $K \subseteq X$  such that  $\aleph \subseteq K \subseteq \Psi(V_G - \text{pint}(\aleph))$ . Then  $K \in V_G - \mathcal{M}_p O(X)$ .

Proof: Given  $\aleph \in V_G - \mathcal{M}_p O(X)$ . Then by theorem 4.1  $\aleph \subseteq \Psi(V_G - \text{pint}(\aleph))$ . But  $\aleph \subseteq K$  implies that  $V_G - \text{pint}(\aleph) \subseteq V_G - \text{pint}(K)$  and hence by theorem 2.4,  $\Psi(V_G - \text{pint}(\aleph)) \subseteq \Psi(V_G - \text{pint}(K))$ . Therefore  $K \subseteq V_G - \text{pint}(\aleph) \subseteq V_G - \text{pint}(K)$ . Hence  $K \in V_G - \mathcal{M}_p O(X)$ .

**Corollary 4.2:** If  $\aleph \in V_G - \mathcal{M}_p O(X)$  and  $K \subseteq X$  such that  $\aleph \subseteq K \subseteq \Psi(\aleph)$ , then  $K \in V_G - \mathcal{M}_p O(X)$ .

Proof: Proof is similar to above two theorems.

**Proposition 4.1:** If  $K \in V_G - PO(X)$ , then  $K \in V_G - \mathcal{M}_p O(X)$ .

Proof: Let  $K \in V_G - PO(X)$ , it implies that  $K = V_G - \text{pint}(K) \subseteq \Psi(V_G - \text{pint}(K))$ . Hence  $K \in V_G - \mathcal{M}_p O(X)$ .

Note that the already said proposition(4.1) is necessarily not be true. Let  $X = \{\#_1, \#_2, \#_3, \#_4\}$   
 $VO_X = \{\Phi, X, \{\#_2\}, \{\#_3\}, \{\#_1, \#_2\}, \{\#_2, \#_3\}, \{\#_1, \#_2, \#_3\}\}$ ,  $\mathcal{G} = \{\{\#_1\}, \{\#_2\}, \{\#_4\}, \{\#_1, \#_2\}, \{\#_1, \#_3\}, \{\#_1, \#_4\}, \{\#_2, \#_3\}, \{\#_2, \#_4\}, \{\#_3, \#_4\}, \{\#_1, \#_2, \#_3\}, \{\#_1, \#_2, \#_4\}, \{\#_1, \#_2, \#_3, \#_4\}\}$ . Then  $V_G - PO(X) = \{\Phi, X, \{\#_2\}, \{\#_3\}, \{\#_1, \#_2\}, \{\#_2, \#_3\}, \{\#_1, \#_2, \#_3\}\}$ .  $V_G - \mathcal{M}_p O(X) = \{\Phi, X, \{\#_2\}, \{\#_3\}, \{\#_1, \#_2\}, \{\#_2, \#_3\}, \{\#_2, \#_4\}, \{\#_1, \#_2, \#_3\}, \{\#_1, \#_2, \#_4\}, \{\#_2, \#_3, \#_4\}\}$ . Hear  $\{\#_2, \#_4\}$  and  $\{\#_1, \#_2, \#_4\}$  are  $V_G - \mathcal{M}_p$  open sets but not  $V_G - \text{pre open}$ .

**Theorem 4.3:** Let  $(X, VO_X, \mathcal{G})$  be a grill  $V$  – Space. If  $K \in V_G - SO(X)$ , then  $K \in V_G - \mathcal{M}_p O(X)$ .

Proof: Given  $K \in V_G - SO(X)$ . Then  $K \subseteq \Psi(V_G - \text{pint}(K))$ . Since  $V_G - \text{int}(K) \subseteq V_G - \text{pint}(K)$ .

We have that  $\Psi(V_G - \text{int}(K)) \subseteq \Psi(V_G - \text{pint}(K))$ . Hence  $K \subseteq \Psi(V_G - \text{pint}(K))$  and thus  $K \in V_G - \mathcal{M}_p O(X)$ .

Note: Converse of the theorem(4.3) which mentioned above is need not be true.

**Proposition 4.2:** If  $V_G - PO(X) = VO_X$ , then  $V_G - \mathcal{M}_p O(X) = V_G - SO(X)$ .

Proof: By theorem 4.3  $V_G - SO(X) \subseteq V_G - \mathcal{M}_p O(X)$ . Let  $K \in V_G - \mathcal{M}_p O(X)$ , then by theorem 4.1

$K \subseteq \Psi(V_G - \text{pint}(\aleph))$ . Since  $V_G - PO(X) = VO_X$ , we have  $V_G - \text{pint}(K) = V_G - \text{int}(K)$  implies that  $K \subseteq \Psi(V_G - \text{pint}(K)) = \Psi(V_G - \text{int}(K))$  and hence  $K \in V_G - SO(X)$ . Thus  $V_G - \mathcal{M}_p O(X) \subseteq V_G - SO(X)$ .

**Theorem 4.4:** Let  $(X, VO_X, \mathcal{G})$  be a grill  $V$  – Space

(i) If  $K_i \in V_G - \mathcal{M}_p O(X)$  for each  $i \in \mathbb{N}$ , then  $\bigcup_{i \in \mathbb{N}} K_i \in V_G - \mathcal{M}_p O(X)$ .

(ii) If  $K \in V_G - \mathcal{M}_p O(X)$  and  $\aleph \in V_G - PO(X)$ , then  $K \cap \aleph \in V_G - \mathcal{M}_p O(X)$

Proof: (i) since  $K_i \in V_G - \mathcal{M}_p O(X)$ , we have  $K_i \subseteq \Psi(V_G - \text{pint}(K_i))$  for each  $i \in \mathbb{N}$ . Thus we obtain  $K_i \subseteq \Psi(V_G - \text{pint}(K_i)) \subseteq \Psi(V_G - \text{pint}(\bigcup_{i \in \mathbb{N}} K_i))$  and hence  $\bigcup_{i \in \mathbb{N}} K_i \subseteq \Psi(V_G - \text{pint}(\bigcup_{i \in \mathbb{N}} K_i))$ . This

**Manikandan and Chandramathi**

Shows that  $\bigcup_{i \in \mathbb{N}} K_i \in V_G - \mathcal{M}_p O(X)$ .

(ii) Let  $K \in V_G - \mathcal{M}_p O(X)$  and  $\aleph \in V_G - PO(X)$ . Then  $K \subseteq \Psi(V_G - pint(K))$  and  $V_G - pint(K) = K$ .

Now  $K \cap \aleph \subseteq \Psi(V_G - pint(K)) \cap \aleph = (V_G - pint(K) \cup \Omega_G(V_G - pint(K))) \cap \aleph = (V_G - pint(K) \cap \aleph) \cup \Omega_G(V_G - pint(K) \cap \aleph) \subseteq V_G - pint(K \cap \aleph) \cup \Omega_G(V_G - pint(K) \cap \aleph) = V_G - pint(K \cap \aleph) \cup \Omega_G(V_G - pint(K \cap \aleph)) = \Psi(V_G - pint(K \cap \aleph))$ . Therefore  $K \cap \aleph \in V_G - \mathcal{M}_p O(X)$ .

**Theorem 4.5:** Let  $(X, VO_X, \mathcal{G})$  be a grill  $V$  – Space and let  $K$  be a subset of  $X$ . if  $K \in V_G - \mathcal{M}_p C(X)$  then  $V_G - pint(\Psi(K)) \subseteq K$ .

Proof: Suppose  $K \in V_G - \mathcal{M}_p C(X)$ . Then  $X - K \in V_G - \mathcal{M}_p O(X)$  and hence  $X - K \subseteq \Psi(V_G - pint(X - K)) \subseteq V_G - pcl(V_G - pint(X - K)) = X - V_G - pint(V_G - pcl(K))$ . implies that  $V_G - pint(\Psi(K)) \subseteq K$ .

**Theorem 4.6:** Let  $(X, VO_X, \mathcal{G})$  be a grill  $V$  – Space and let  $K$  be a subset of  $X$  such that  $X - (V_G - pint(\Psi(K))) = \Psi(V_G - pint(X - K))$ . Then  $K \in V_G - \mathcal{M}_p C(X)$  if and only if  $V_G - pint(\Psi(K)) \subseteq K$ .

Proof: The previous theorem(4.5) gives evidence for necessary part of the current theorem. Conversely, suppose that  $V_G - pint(\Psi(K)) \subseteq K$ . Then  $X - K \subseteq X - (V_G - pint(\Psi(K))) = \Psi(V_G - pint(X - K))$ , implies that  $X - K \in V_G - \mathcal{M}_p O(X)$ . Hence  $K \in V_G - \mathcal{M}_p C(X)$ .

**Definition 4.2:** Let  $(X, VO_X, \mathcal{G})$  be a grill  $V$  – Space and let  $K$  be a subset of  $X$ . Then

(i)  $V_G - \mathcal{M}_p$  – interieor of  $K$  is defied as union of all  $V_G - \mathcal{M}_p$  open sets contained in  $K$ .

Thus  $V_G - \mathcal{M}_p int(K) = \bigcup \{ \aleph : \aleph \in V_G - \mathcal{M}_p O(X) \text{ and } \aleph \subseteq K \}$ ;

(ii)  $V_G - \mathcal{M}_p$  – closure of  $K$  is defied as intersection of all  $V_G - \mathcal{M}_p$  closed sets containing  $K$ .

Thus  $V_G - \mathcal{M}_p cl(K) = \bigcap \{ \aleph : \aleph \in V_G - \mathcal{M}_p C(X) \text{ and } K \subseteq \aleph \}$ ;

**Theorem 4.7:** Let  $(X, VO_X, \mathcal{G})$  be a grill  $V$  – Space and let  $K$  be a subset of  $X$ . Then

(i)  $V_G - \mathcal{M}_p int(K)$  is a largest open set contined in  $A$ ;

(ii)  $V_G - \mathcal{M}_p cl(K)$  is a smallest closed set containing  $A$ ;

(iii)  $K$  is  $V_G - \mathcal{M}_p$  closed if and only if  $V_G - \mathcal{M}_p cl(K) = K$ .

(iv)  $K$  is  $V_G - \mathcal{M}_p$  open if and only if  $V_G - \mathcal{M}_p int(K) = K$

### Manikandan and Chandramathi

## CONCLUSIONS

This research article investigated  $V_G - \mathcal{M}_p$  open set,  $V_G - \mathcal{M}_p$  closed set,  $V_G - \mathcal{M}_p$  interior, and  $V_G - \mathcal{M}_p$  closure in this grill  $V - \text{Space}$ . The concept of  $V_G - \mathcal{M}_p$  open set along with the concept of  $V_G - \text{pre open sets}$  is discussed. Many theorems are discussed besides of counter examples. Some significant characteristics and key properties which are associated characteristics and key properties which are associated with these  $V_G - \mathcal{M}_p$  open sets are proved with the help of  $V_G - \mathcal{M}_p$  interior and  $V_G - \mathcal{M}_p$  closure.

### ABSTRACT

In this paper, we establish a new criteria for initiating the solution of oscillation behavior of third order advanced difference equation of the form,

$\Delta[\gamma(\zeta)\Delta^2\mu(\zeta)] + t(\zeta)\mu(\varepsilon(\zeta)) = 0$  We illustrate the results with suitable examples.

**Keywords:** Oscillation, third order advanced difference equation, monotonically increasing, advanced argument.

## INTRODUCTION

In this paper, we study the third order advanced difference equation

$$\Delta[\gamma(\zeta)\Delta^2\mu(\zeta)] + t(\zeta)\mu(\varepsilon(\zeta)) = 0 \quad (1.1)$$

where,  $\zeta \in \mathbb{N} = \{\zeta_0, \zeta_0 + 1, \zeta_0 + 2, \dots\}$ ,  $\zeta_0$  is a non-negative integer and

[Z<sub>1</sub>]  $\{\gamma(\zeta)\}$  and  $\{t(\zeta)\}$  are positive real sequences with  $\gamma(\zeta) \geq 1$  for  $\zeta \geq \zeta_0$ ;

[Z<sub>2</sub>]  $\varepsilon(\zeta)$  is a monotone non-decreasing sequence of integers with  $\varepsilon(\zeta) \geq \zeta + 1$  for  $\zeta \geq \zeta_0$ ;

[Z<sub>3</sub>]  $G(\zeta) = \sum_{s=\zeta_0}^{\zeta-1} \frac{1}{\gamma(s)}$  as  $\zeta \rightarrow \infty$ .

By a solution of (1.1), we mean a non-trivial sequence  $\{\mu(\zeta)\}$  that satisfies (1.1) for all  $\zeta \geq \zeta_0$ . A solution  $\{\mu(\zeta)\}$  of (1.1) is oscillatory, if it is neither eventually positive nor eventually negative, otherwise it is non-oscillatory. (1.1) is oscillatory, if all of its solutions are oscillatory.

Recently, there are too many studies in the literature on the oscillation theory of advanced type differential and difference equations, see [1,2,6,8,9,11,12] and the references cited therein. Another popular technique, appearing in

**Mohammed Ali Jaffer and M.Shankarakeerthana**

several studies also the Ricatti method; see [3,5,10] and see the examples in [4,7]. In particular, there is no comparison result for difference equation of advanced type except that of Zhang and Li[14], where the oscillation of the advanced difference Eq(1.1), follows from that of ordinary difference equation.

$$\Delta[\gamma(\zeta)\Delta^2\mu(\zeta)] + t(\zeta)\mu(\zeta + 1) = 0, \zeta \geq \zeta_0 \tag{1.2}$$

**Main Results**

Without loss of generality, in studying non-oscillatory solutions of (1.1), we can limit our attention only to positive solutions.

**Lemma 2.1 :** Let  $\{\mu(\zeta)\}$  be a positive solutions of (1.1). Then,  
 $\gamma(\zeta)[\Delta^2(\mu(\zeta))] > 0$  and  $\Delta[\gamma(\zeta)\Delta^2\mu(\zeta)] < 0$  eventually. (2.1)

**Proof :** From our assumption, it is easy to see that (1.1) implies  $\Delta[\gamma(\zeta)\Delta^2\mu(\zeta)] = -t(\zeta)\mu(\zeta) < 0$  and it means that  $\{\gamma(\zeta)\Delta^2\mu(\zeta)\}$  is decreasing. Assume that  $\Delta[\gamma(\zeta)\Delta^2\mu(\zeta)] < 0$  for  $\zeta \geq \zeta_1 \geq \zeta_0$ , then there exists a constant  $K > 0$  such that  $\Delta[\gamma(\zeta)\Delta^2\mu(\zeta)] \leq K$  for  $\zeta \geq \zeta_1$ .

Summing the above inequality from  $\zeta$  to  $\infty$ . we get,

$$\Delta(\mu(\zeta)) \leq K \sum_{s=\zeta}^{\infty} \frac{1}{\gamma(s)} .$$

Again summing the above from  $\zeta_1$  to  $(\zeta - 1)$ ,

$$\mu(\zeta) \leq \mu(\zeta_1) - K \sum_{l=s_1}^{\zeta-1} \sum_{s=\zeta}^{\infty} \frac{1}{\gamma(s)} \rightarrow -\infty \text{ as } \zeta \rightarrow \infty ,$$

This is a contradiction which leads us to conclude that  $\gamma(\zeta)[\Delta^2\mu(\zeta)] > 0$ . This completes the proof. Next, we establish an early oscillatory criterion which we will further improve in the subsequent theorems.

Let us define

$$E(\zeta; j) = \begin{cases} \sum_{s=\zeta}^{\infty} t(s) & j = 0 \text{ for } \zeta \geq \zeta_0 \\ \sum_{s=\zeta}^{\infty} \frac{E^2(s; j-1)}{E(s; j-1) + \gamma(s)} + E(\zeta; 0) & j \geq 1 \text{ for } \zeta \geq \zeta_0 \end{cases} \tag{2.2}$$

**Theorem 2.2 :**

Assume that  $G^2(\zeta) \sum_{s=\zeta}^{\infty} t(s) \geq \frac{\omega}{\gamma(\zeta)} > 0.25$  eventually. Then (1.1) is oscillatory. (2.3)

**Proof :** From (2.3) and (2.2) for  $j=0$ , we have  $E(\zeta; 0) \geq \frac{\omega}{\gamma(\zeta)G^2(\zeta)}$ . Since,  $h(x) = \frac{x^2}{d+x^2}$  is increasing for  $x > 0$  and  $d > 0$ , we have  $h(E(\zeta; 0)) \geq \left(\frac{\omega}{\gamma(\zeta)G^2(\zeta)}\right)$  and therefore,

$$\frac{E^2(\zeta; 0)}{E(\zeta; 0) + \gamma(\zeta)} \geq \frac{\frac{\omega^2}{\gamma(\zeta)G^4(\zeta)}}{\frac{\omega}{\gamma(\zeta)G^2(\zeta)} + \gamma(\zeta)} = \frac{\omega^2}{\gamma(\zeta)G^2(\zeta)[\omega + \gamma^2(\zeta)G^2(\zeta)]} ,$$

where  $d = \gamma(\zeta)$  from (2.2) for  $j=1$ , we have

$$E(\zeta; 1) = \sum_{s=\zeta}^{\infty} \frac{E^2(s; 0)}{E(s; 0) + \gamma(s)} + E(\zeta; 0) \geq \sum_{s=\zeta}^{\infty} \frac{\omega^2\gamma(s)\Delta G(s)}{\gamma(s)G^2(s)[\omega + \gamma^2(s)G^2(s)]} + \frac{\omega}{\gamma(\zeta)G^2(\zeta)} ,$$

where  $\gamma(\zeta)\Delta G(\zeta) = 1$ . Since,  $\frac{\omega}{\gamma(\zeta)} \leq \omega$  for all  $\zeta \geq \zeta_0$ , we have

$$E(\zeta; 1) \geq \sum_{s=\zeta}^{\infty} \frac{\omega^2\Delta G(s)}{G^2(s)(\omega + G^2(s))} + \frac{\omega}{G^2(\zeta)}$$

On the other hand,  $\sum_{s=\zeta}^{\infty} \frac{\omega^2\Delta G(s)}{G^2(s)[\omega + G^2(s)]} \geq \int_{G(\zeta)}^{\infty} \frac{\omega^2 ds}{s(\omega + s)} = \omega \ln \left(\frac{\omega + G^2(\zeta)}{G^2(\zeta)}\right)$

**Mohammed Ali Jaffer and M.Shankarakeerthana**

Hence,  $E(\zeta; j) \geq \frac{\omega}{G^2(\zeta)} + \omega \ln \left( \frac{\omega + G^2(\zeta)}{G^2(\zeta)} \right) = \frac{\omega}{G^2(\zeta)}$

where  $\omega_1 = \omega + G^2(\zeta)\omega \ln \left( \frac{\omega + G^2(\zeta)}{G^2(\zeta)} \right) > \omega$ .

In general,  $E(\zeta; j) = \sum_{s=\zeta}^{\infty} \frac{E^2(s; j-1)}{E(s; j-1) + \gamma(s)} + E(\zeta; 0) \geq \sum_{s=\zeta}^{\infty} \frac{\omega_{j-1} \Delta G(s)}{G^2(s)[\omega_{j-1} + G^2(s)]} + \frac{\omega}{G^2(\zeta)} \geq \omega_{j-1} \ln \left( \frac{\omega_{j-1} + G^2(\zeta)}{G^2(\zeta)} \right) + \frac{\omega}{G^2(\zeta)} = \frac{\omega}{G^2(\zeta)}$ ,

where,  $\omega_j = \omega + G^2(\zeta)\omega_{j-1} \ln \left( \frac{\omega_{j-1} + G^2(\zeta)}{G^2(\zeta)} \right)$  (2.4)

It is easy to observe that  $\omega_j > \omega_{j+1}$ , with  $\omega = \omega_0$ , for  $j = 0, 1, 2, \dots$

Now we claim that  $\lim_{j \rightarrow \infty} \omega_j = \infty$ . If not, let  $R = \lim_{j \rightarrow \infty} \omega_j < \infty$ . Then from (2.4), we get

$$R = \omega + G^2(\zeta)R \ln \left( \frac{R + G^2(\zeta)}{G^2(\zeta)} \right) = \omega + R \left( R - \frac{R^2}{2G^2(\zeta)} + \frac{R^3}{3G^4(\zeta)} - \dots \right),$$

Let  $\zeta \rightarrow \infty$ , we have  $G(\zeta) \rightarrow \infty$ . Then, the above equation yields,

$$R = \omega + R^2 \tag{2.5}$$

But (2.5) has no real solution if  $\omega > 0.25$ . Hence,  $\lim_{j \rightarrow \infty} \omega_j = \infty$ . Then, we have  $\lim_{j \rightarrow \infty} E(\zeta; j) = \infty$ . Thus, from Theorem 1.11.5 of [2], it follows that (1.2) is oscillatory. Now using Theorem 3.5 of [14], we see that (1.1) is oscillatory, which completes the proof.

**Remark 2.1:** Note that the above condition is independent of the advanced argument  $\{\varepsilon(\zeta)\}$  and thus, is more appropriate for (1.2).

Theorem 2.2 also implies that the opposite condition of (2.3) namely,

$$\gamma(\zeta)G^2(\zeta)\sum_{s=\zeta}^{\infty} t(s) \geq \omega \text{ but } \omega \leq 0.25 \text{ also holds.}$$

**Theorem 2.3** Let  $\{\mu(\zeta)\}$  be a positive solution of (1.1) and

$$G^2(\zeta)\sum_{s=\zeta}^{\infty} t(s) \geq \frac{\omega}{\gamma(\zeta)} > 0. \tag{2.6}$$

eventually. Then there is an integer  $I$  such that  $\zeta \geq I$ ,

$\left\{ \frac{\mu(\zeta)}{G^{\omega}(\zeta)} \right\}$  is monotonically non-decreasing.

**Proof:** Let  $\{\mu(\zeta)\} > 0$  be a positive solution of (1.1). Taking summation of (1.1), we get

$$\gamma(\zeta)\Delta^2(\mu(\zeta)) \geq \sum_{s=\zeta}^{\infty} t(s)\mu(\varepsilon(s)) \geq \frac{1}{\gamma(\zeta)} \sum_{s=\zeta}^{\infty} t(s).$$

Again summing up from  $s$  to  $\zeta - 1$ , we get,

$$\Delta(\mu(\zeta)) \geq \sum_{k=s}^{\zeta-1} \frac{1}{\gamma(k)} \sum_{s=\zeta}^{\infty} t(s).$$

$$\text{Thus, } \Delta \left( \frac{\mu(\zeta)}{G^{\omega}(\zeta)} \right) = \frac{G^{\omega}(\zeta)\Delta\mu(\zeta) - \mu(\zeta)\Delta G^{\omega}(\zeta)}{G^{\omega}(\zeta)G^{\omega}(\zeta+1)} \tag{2.7}$$

By the Mean value theorem,

$$\Delta G^{\omega}(\zeta) \leq \omega G^{\omega-1}(\zeta) \leq \frac{\omega G^{\omega-1}(\zeta)}{\gamma(\zeta)},$$

Since,  $\omega \leq 0.25$ . Using this in (2.7), we get,

$$\Delta \left( \frac{\mu(\zeta)}{G^{\omega}(\zeta)} \right) \geq \frac{1}{G^{\omega}(\zeta+1)G(\zeta)\gamma(\zeta)} [G^2(\zeta)\gamma(\zeta) \sum_{s=\zeta}^{\infty} t(s) - \mu(\zeta)\omega] > 0.$$

This completes the proof.

**Remark 2.2** Theorem 2.3, establishes a new monotonic property of the positive solution of (1.1), ensuring that  $\{\mu(\zeta)\}$  is increasing and  $\left\{ \frac{\mu(\zeta)}{G^{\omega}(\zeta)} \right\}$  is decreasing. This property leads to improve oscillation criteria for the advanced type equations. The next theorem states that a new comparison result, containing an advanced argument.

**Theorem 2.4** Let (2.6) holds. If the difference equation

**Mohammed Ali Jaffer and M.Shankarakeerthana**

$$\Delta[\gamma(\zeta)\Delta^2 \mu(\zeta)] + \left(\frac{G(\varepsilon(\zeta))}{G(\varepsilon + 1)}\right)^\omega t(\zeta)\mu(\zeta + 1) = 0 \tag{2.8}$$

is oscillatory, then (1.1) is oscillatory.

**Proof :** Assume to the contrast that (1.1) has an eventually positive solution  $\{\mu(\zeta)\}$ . Now (1.1) can be written as,

$$\Delta[\gamma(\zeta)\Delta^2 \mu(\zeta)] + t(\zeta)\left(\frac{G(\varepsilon(\zeta))}{G(\varepsilon(\zeta))}\right)^\omega \mu(\zeta + 1) = 0 .$$

Since,  $\frac{\mu(\zeta)}{G^\omega(\zeta)}$  is non-decreasing, and  $\varepsilon(\zeta) \geq \zeta + 1$ , we have

$$\frac{\mu(\varepsilon(\zeta))}{G^\omega(\varepsilon(\zeta))} \geq \frac{\mu(\zeta + 1)}{G^\omega(\zeta + 1)}$$

Using this relation in last equation, we see that  $\{\mu(\zeta)\}$  is a positive solution of the following inequality,

$$\Delta[\gamma(\zeta)\Delta^2 \mu(\zeta)] + \left(\frac{G(\varepsilon(\zeta))}{G(\varepsilon + 1)}\right)^\omega t(\zeta)\mu(\zeta + 1) \leq 0 .$$

This leads to a contradiction to our hypothesis, which completes the proof. Theorem 2.4, ensures that any oscillation criteria obtained for Eq.(2.8), leads to an oscillation criteria for (1.1).

**Theorem 2.5** Let (2.6) holds. Assume that there is a constant  $\omega_1$  such that

$$\gamma(\zeta)G^2(\zeta)\sum_{s=\zeta}^\infty \left(\frac{G(\varepsilon(s))}{G(s + 1)}\right)^\omega t(s) \geq \omega_1 > 0.25 \tag{2.9}$$

eventually. Then (1.1) is oscillatory.

**Proof :** Condition (2.9) guarantees that (2.8) oscillates which in turn implies that (1.1) oscillates. This completes the proof. ■

Next, we provide an example illustrating this result.

**Example 2.1** Consider the third order advanced difference equation,

$$\Delta^3 z(\zeta) + \frac{4\gamma}{(2\zeta - 1)(2\zeta + 1)} z(\lambda\zeta), \zeta \geq 1. \tag{2.10}$$

With  $\gamma > 0$  and  $\lambda > 1$  is an integer. Now  $\omega = \alpha$  and by theorem 2.5, (2.10) is oscillatory provided that  $2\gamma\lambda^\gamma > 0.25$ .

If  $\gamma = \frac{1}{8}$ , then it is required that  $\lambda = 2$  or conversely, for given  $\lambda = 2$ , we need  $\gamma = 0.1284$ . If condition fails, (ie),

$\omega_1 \leq 0.25$ , then we derive the following new criterion using the constant  $\omega_1$ .

**Theorem 2.6** Let (2.6) holds. Assume that  $\{\mu(\zeta)\}$  be a positive solution of (1.1) and  $\gamma(\zeta)G^2(\zeta)\sum_{s=\zeta}^\infty t(s) \geq \omega_1 > 0$ . eventually. Then there is an integer I such that  $\zeta \geq I$ , (2.11)

$$\left\{ \frac{\mu(\zeta)}{G^{\omega_1}(\zeta)} \right\} \text{ is monotonically nondecreasing.}$$

**Mohammed Ali Jaffer and M.Shankarakeerthana**

**Proof:** Let  $\{\mu(\zeta)\}$  be a positive solution of (1.1). Since  $\left\{ \frac{\mu(\zeta)}{G^{\omega_1}(\zeta)} \right\}$  is nondecreasing. We can see that

$$\gamma(\zeta)\Delta^2(\mu(\zeta)) \geq \sum_{s=\zeta}^{\infty} t(s)\mu(\varepsilon(s)) \geq \mu(\zeta) \sum_{s=\zeta}^{\infty} \left(\frac{G(\varepsilon(s))}{G(s)}\right)^{\omega} t(s).$$

Thus,

$$\Delta\left(\frac{\mu(\zeta)}{G^{\omega_1}(\zeta)}\right) = \frac{G^{\omega_1}(\zeta)\Delta\mu(\zeta) - \mu(\zeta)\Delta G^{\omega_1}(\zeta)}{G^{\omega_1}(\zeta)G^{\omega_1}(\zeta+1)}. \tag{2.12}$$

By the Mean value theorem,

$$\Delta G^{\omega_1}(\zeta) \leq \omega G^{\omega_1-1}(\zeta) \leq \frac{\alpha G^{\omega_1-1}(\zeta)}{\gamma(\zeta)},$$

Since,  $\omega \leq 0.25$ . Using this in (2.12), we get,

$$\Delta\left(\frac{\mu(\zeta)}{G^{\omega_1}(\zeta)}\right) \geq \frac{1}{G^{\omega_1}(\zeta+1)G(\zeta)\gamma(\zeta)} [G^2(\zeta)\gamma(\zeta) \sum_{s=\zeta}^{\infty} t(s) - \mu(\zeta)\omega_1] > 0.$$

This completes the proof.

**Theorem 2.7** Let (2.6) and (2.11) holds. If the difference equation

$$\Delta[\gamma(\zeta)\Delta^2\mu(\zeta)] + \left(\frac{G(\varepsilon(\zeta))}{G(\zeta+1)}\right)^{\omega_1} t(\zeta)\mu(\zeta+1) = 0 \tag{2.13}$$

is oscillatory, then (1.1) is oscillatory.

**Theorem 2.8** Let (2.6) and (2.11) holds. If there exists a constant  $\omega_2$  such that

$$\gamma(\zeta)G^2(\zeta) + \sum_{s=\zeta}^{\infty} \left(\frac{G(\varepsilon(s))}{G(s)}\right)^{\omega_1} t(s) \geq \omega_2 > 0.25 \tag{2.14}$$

eventually. Then (1.1) is oscillatory.

Theorem 2.7 and 2.8 can be proved similar to Theorem 2.4 and 2.5. Thus, we omit proofs.

**Example 2.2 :** Consider, again the difference equation (2.10). For this equation  $\omega_1 = 2\gamma\lambda^\lambda$ . By theorem 2.8, we see that (2.10) is oscillatory provided that  $2\gamma\lambda^{\omega_1} > 0.25$ .

Since,  $\omega_1 > \gamma$ , Theorem 2.8 improves Theorem 2.5. Now for  $\gamma = \frac{1}{8}$ , we need  $\lambda \geq 2$ .

Applying repeatedly the above process, we can get an improved oscillation criterion many times. Assume that there is a positive constant  $\lambda$  such that

$$\frac{G(\varepsilon(\zeta))}{G(\zeta+1)} \geq 1 \tag{2.15}$$

eventually. Thus, using (2.6) conditions (2.11) and (2.14) can be written in simpler form as

$$\omega_1 = 2\lambda^\omega \omega > 0.25,$$

$$\omega_2 = 2\lambda^{\omega_1} \omega > 0.25,$$

respectively. Repeating the above process, we get an increasing sequence  $\{\omega_j\}_{j=0}^{\infty}$  defined as follows:

$$\omega_0 = \omega$$

$$\omega_{j+1} = 2\omega\lambda^{\omega_j}$$

(2.16)

Now we can generalize the oscillatory criteria obtained in Theorem 2.5 and Theorem 2.8, in the following theorem.

**Theorem 2.9** Let (2.6) and (2.15) holds. Assume that there exists a positive integer  $m$  such that,

**Mohammed Ali Jaffer and M.Shankarakeerthana**

$\omega_j \leq 0.25$  for  $j = 0, 1, 2, \dots, m - 1$  and

$$\omega_m \geq 0.25,$$

then (1.1) is oscillatory.

**Example 2.3 :** Consider the third order advanced type difference equation

$$\Delta^3 z(\zeta) + \frac{0.452}{(2\zeta-1)(2\zeta+1)} z(1.5\zeta) = 0, \zeta \geq 1. \quad (2.17)$$

For this equation  $\omega_0 = 0.113$  and  $\lambda = 1.5$ . Simple computations, we get

$$\omega_1 = 0.2365956, \omega_2 = 0.2487544 \text{ and } \omega_3 = 0.2499838$$

Thus, Theorem 2.5 and 2.8 fail for (2.17). But

$$\omega_4 = 0.2501084 > 0.25$$

and Theorem 2.9 guarantees the oscillation of (2.17).

**Example 2.4 :** Consider the difference equation

$$\Delta \left[ \frac{1}{2\zeta-1} \Delta^2(\mu(\zeta)) \right] + \frac{8}{(2\zeta-1)(2\zeta+1)} \mu(\zeta + 1) = 0 \quad (2.18)$$

All the conditions  $[Z_1], [Z_2]$  and  $[Z_3]$  are satisfied. Hence, every solution of equation (2.18) is oscillatory. One such solution of (2.18) is  $\mu(\zeta) = \{(-1)^\zeta\}$ .

## CONCLUSION

In this study, by utilizing recently discovered monotonic characteristics of non-oscillatory solutions. We have developed an innovative comparison method to analyze the oscillatory behavior of third order advanced difference equations.

### ABSTRACT

Agriculture plays an important part by serving as the main source of revenue for a large section of the people in the economy. Fruit diseases are a major contributor to financial losses in agriculture and farming worldwide, leading to substantial reductions in both crop yield and quality. Timely identification of fruit diseases helps to prevent their spread, leading to cost savings for agricultural practitioners. In recent years, artificial intelligence techniques like Machine Learning algorithms (ML) and also many Deep Learning (DL) algorithms, were progressed to enable initial prediction and classification of fruit diseases using various imaging techniques. Various researchers have developed and tested numerous ML and DL methods for plant disease detection, often achieving significant results with both approaches. The results obtained from these techniques can aid farmers in identifying and managing fruit diseases. This review article proposes comprehensive assessment of various Machine Learning models and Deep Learning algorithms developed for predicting and also for classifying fruit diseases. Initially, it examines several fruit disease predictions and also fruit disease classification models created through various ML and DL models.

**Keywords:** Machine Learning, Deep Learning, Fruit Disease

### INTRODUCTION

Agriculture has consistently been a key contributor to economic growth, particularly in developing nations, where it holds significant importance for society. A major challenge today is addressing the continuously rising demands for high-quality food products. Although various factors, including climate change and other challenges, directly affect agricultural production, fruit diseases have been identified as the main causes of losses in food, suggestively harming moderate farmers. Human health has been negatively impacted by the deteriorating quality of food. Diseases in

**Kavitha and Sarojini**

fruits have been a leading cause of reduced production. Fruit diseases impact fruit production, and a decline in productivity ultimately affects the overall economy of a country [1]. Detecting diseases in fruit is the toughest task because each and every plant in the farm needs to be checked. This manual process consumes long period and also much human effort and hence automated computerized techniques were introduced [2]. Preprocessing, segmentation, feature extraction, feature selection, and classification are the primary processes in these automated systems. In order to help farmers improve the quality of their crops, researchers have been looking into ways to improve the effectiveness of machine learning and deep learning-based techniques as well as identifying diseases detection in crops, fruits, leaves and vegetables. The suggested article's primary goal is to present a thorough analysis of machine learning and deep learning techniques created for the intent of identifying and classifying fruit illnesses[3].

Now a comprehensive learning is provided in order to brief out the merits and shortcomings of the algorithms and also the techniques. The remainder is arranged as follows: Part II provides a thorough evaluation of various machine learning models / algorithms proposed for the purpose of prediction and classification of different types of diseases in fruits using the images. Part III provides a complete assessment of various deep learning models / algorithms created for predicting and also for classifying the diseases in fruit diseases using the images. Part IV summarizes the entire survey.

**SURVEY ON DIFFERENT ML BASED FRUIT DISEASE DETECTION METHODS**

Saranya et al. (2020) proposed a method using fuzzy c-means, histogram-based equalization, and ANN to classify leaf and fruit diseases in banana plants. The dataset included banana plant images, where fuzzy c-means separated diseased regions and histogram-based equalization transformed images without data loss. The ANN classified the diseases. The proposed method offered improved disease classification and higher yield production. However, it lacked the ability to handle complex image distortions. Future improvements could focus on enhancing the system's robustness for more accurate classification under varying environmental conditions [4]. Nandhini and Bhavani (2020) proposed a machine learning-based technique for identifying the disease in leaf. This technique used KNN, decision trees and SVM for classification. In order to extract color features, leaf images were transformed from RGB to lab color space. K-means clustering followed by Fourier transform were then performed. Shape features were extracted using scale-invariant feature transform and PCA reduced vector size. SVM outperformed KNN and decision trees in accuracy. The method offered high classification accuracy and efficient feature reduction but required significant computational resources. Future work suggested improving the method's efficiency for real-time applications in large-scale farming [5].

Bekkanti et al. (2020) proposed computer-based classification model for fruit disease prediction using a dataset of 400 fruit images. Initially, images were pre-processed to remove noise using the PSNR (Peak Signal-to-Noise Ratio) value. Median filtering was applied, achieving a PSNR value of 31, outperforming Gaussian (28) and Mean filtering (26). Sobel edge segmentation was applied in order to extract the region of interest, followed by texture feature extraction. BPNN, SVM, and PNN classifiers were used for the purpose of classification. The method improved accuracy in fruit images but required high computational resources. Future work focused on optimizing computational efficiency [6].

Khan and Narvekar (2020) developed an automated system for recognizing and categorizing infections in *Solanum lycopersicum* using a super pixel-based optimized partitioning approach. The images are taken from real time and also some from dataset of Plant Village. Input images were first converted to RGB format to mitigate uneven lighting effects. To remove the unwanted background, Histogram of Gradients (HOG) and also color channels were used for creating super pixels. K-means clustering isolated infected areas. An enhanced HOG approach, combining a pyramid of HOG and GLCM features, identified infected regions, while Random Forest (RF) classified infection types. However, the method was time-consuming due to initial seed selection [7].

**Kavitha and Sarojini**

Kumar et al. (2020) proposed the Whale Optimization-Based Artificial Neural Network (WOANN) for tomatoes disease detection. To undertake disease prediction analysis, a dataset comprising these four tomato types (ripe, sour, unripe, rot and blotchy ripening) was gathered. The process involved color image extraction using the Firefly Algorithm (FA) to improve the process of identifying disease. The ANN categorized different types of illnesses, while the Whale Optimization Algorithm (WOA) optimized weight variables in the neural network. The model demonstrated high accuracy and precision, effectively identifying diseases. However, the computational complexity was significant due to multiple phases. The study suggested further optimization to reduce complexity and improve real-time detection in future implementations [8].

Ramya et al. (2020) proposed a technique which applied K-means clustering and SVM techniques to classify and segment fruit images. The dataset included fruit pictures, which were used to extract and segment features, analyze diseases and identify optimal conditions. An alert box was provided for each disease and the database was stored in the cloud, accessible via a mobile application. The method improved disease detection accuracy but was limited by cloud dependency. Future work could enhance offline accessibility [9]. Nouri et al. (2020) proposed using the Electronic Nose (E-nose) scheme with a Back Propagation Neural Network (BPNN) to detect *Alternaria* fungus in pomegranate. The dataset included samples from healthy fruits and four stages of fungal infection. The workflow involved using BPNN for classification, which outperformed Linear Discriminant Analysis (LDA) and SVM in terms of accuracy. The method was quick, non-destructive and provided consistent results. However, it was noted that the approach was expensive and cumbersome. Future research could focus on optimizing cost and simplifying the system for broader applications in fruit quality detection [10]. Alharbi and Arif (2020) proposed an image processing method to identify the physiological conditions in apple and orange fruit X-ray pictures. They used a dataset collected from the local market, selecting apples that were already infected for analysis. The process involved applying different models based on KNN techniques to classify healthy apples and identify diseased ones. The proposed method achieved high accuracy in detection and enabled early identification of physiological decay, enhancing fruit quality assessment. However, a limitation was the dependency on a specific dataset, which may affect generalizability. Future research could explore broader datasets for improved robustness [11].

Benlachmi et al. (2022) proposed a ML model for an efficient smart farming strategy aimed at increasing productivity while reducing human effort. The dataset consisted of fruit images, which were analyzed for texture and skin color using three feature extractors: Haralick, Hu Moments and Color Histogram. Three machine learning classifiers were used in the workflow: Random Forest, Decision Tree and KNN. The system performance was assessed using a k-fold cross-validation technique. The model effectively classified fruit diseases at early stages, resulting in improved detection accuracy and reduced labour requirements. However, a disadvantage noted was the reliance on quality image data, which may not always be available. Future predictions suggested further enhancements in disease detection accuracy through advanced ML techniques [12].

Shakil et al. (2023) proposed an agro-based method for recognizing dragon diseases through a detailed analysis of techniques used for feature selection. They collected dragon images and those images were pre-processed using various processing methods. After segmentation, two significant features were saved. To evaluate feature ranks based on mutual scores, the analysis of variance (ANOVA) and least absolute shrinkage and selection operator (LASSO) were utilized. The key feature sets were subjected to six distinct machine learning classifiers, with AdaBoost and Random Forest achieving the highest accuracy of 96.29%. While the method demonstrated high accuracy and effective feature selection, it required extensive computational resources. Future enhancements may focus on optimizing computational efficiency [13].

Javidan et al. (2023) proposed an image processing algorithm to identify and categorize disease in grape leaf. K-means clustering was used to distinguish between damaged and healthy regions in the dataset, which included pictures of grape leaves. Features were extracted using  $I^*a^*b$ , HSV and RGB color models. SVM was used for classification whereas for dimension reduction of the feature Principal Component Analysis (PCA) was applied. The method

**Kavitha and Sarojini**

showed high accuracy. However, it had a limitation in processing time. Future research could explore real-time disease detection [14].

**SURVEY ON DIFFERENT DL BASED FRUIT DISEASE DETECTION METHODS**

Jiang et al. (2020) used the ResNet50 CNN model to extract disease characteristics from tomato leaves. This method's objective was to identify three prevalent diseases: Blight that appears late, Yellow leaf curl disease, spot blight. They utilized a dataset of 1,000 images per disease, dividing it into 900 for training and 100 for testing. The proposed method involved using convolutional layers for feature extraction, iterative learning for classification and random data augmentation to prevent overfitting. The advantages of this approach included enhanced feature capture and improved model robustness. However, it had the disadvantage of a higher computational cost [15]. Wang et al. (2020) proposed a detection technology using Mask R-CNN to identify various fruit disease spots. The dataset included apple, peach, orange, and pear images. The method involved introducing a Mask R-CNN-based model that detects surface disease spots on these fruits. This model improved detection accuracy once the picking robot identified and located the fruit. The main advantages of this method were its effective identification of surface defects and improved accuracy using path which is bottom-up in the pyramid structure of feature. However, the model's reliance on specific fruit types limited its generalizability. Future work could explore broader applications across different fruit varieties [16].

Khan et al. (2020) proposed a deep CNN-based model for identifying fruits diseases. They utilized a dataset of fruit leaf images, retrieving deep features through pre-trained networks like AlexNet, VGG-S then using the transfer learning techniques they were altered. A multi-level fusion methodology was introduced prior to feature selection, employing an entropy-controlled threshold based on the average of selected features. The proposed method achieved improved accuracy and enhanced feature extraction, but it was limited by the reliance on a single pre-trained model. Future work may involve integrating multiple models to further boost detection performance and robustness [17]. Ahmad et al. (2020) suggested a CNN-based disease detection technique for plums to enhance source-inhibited instruments in practical settings. The dataset used comprised images captured in the field, considering the important features of image like angle, orientation and ambient. To increase the dataset, data augmentation techniques were used. The approach demonstrated improved accuracy. Two main advantages of this method were its effectiveness in real-world scenarios and enhanced detection capabilities, while a noted disadvantage was its reduced accuracy for certain pathological instances. Future research could focus on refining the algorithm to address these limitations [18].

Yang et al. (2020) proposed the LFC-Net to identify relevant regions in tomato images without the need for manual annotations. The dataset comprised 16,486 images capturing various aspects of tomato health and disease, used for training and testing the model. The system comprised of a positioning module, a feedback module also a separation part, leveraging a method that eliminated the necessity for bounding boxes or labelled parts. This innovative training procedure focused on ensuring class integrity and enhancing image informativeness. The method demonstrated improved accuracy and reduced reliance on extensive labelled datasets. However, it was limited in its consideration of only a few types of pathologies. This shortcoming might be addressed in future studies by adding a wider variety of disease categories to improve the model's robustness and applicability [19]. Yao et al. (2021) proposed an improved XceptionNet which is united with the L2M error to classify the illnesses in *Prunus persica*. The model was trained using images of infected *Prunus persica* fruits. The dataset used was limited and unbalanced, affecting overall performance. The method achieved high accuracy and improved classification efficiency but was constrained by the small and uneven dataset. Future work might focus on increasing the dataset and employing data expansion methods to improve the model robustness and generalization across a broader range of fruit disorders [20]. Malathy et al. (2021) suggested a CNN-based image processing method that may identify fruit illnesses by identifying the areas that are contaminated. The dataset consisting of images of many fruits was sourced from Kaggle.com. The workflow involved processing the input images to extract relevant characteristics from the affected areas, followed by training and classification to yield accurate results. The method demonstrated two key advantages: precise infection detection and enhanced classification accuracy. However, a limitation was the model's

**Kavitha and Sarojini**

dependence on high-quality input images. For future work, the authors suggested improving the model's robustness to variations in image quality for more reliable detection across diverse conditions [21]. Khan et al. (2021) suggested a deep learning network to categorize citrus fruit diseases that affect fruit quality. A privately acquired dataset was augmented to increase its size and the augmented data was used to retrain lightweight methods, MobileNetV2 and SqueezeNet. Important Features were then improved using the Whale Optimization Algorithm. The approach demonstrated improved disease classification accuracy and model efficiency, with reduced computational cost as a key advantage. However, a limitation was the reliance on a private dataset. Future work could focus on testing the models on larger, publicly available datasets for broader applicability [22].

Elaraby et al. (2022) proposed a deep learning model in order to identify disease in citrus using pretrained models like AlexNet and VGG19. The method focuses on detecting lesion patches on citrus fruits and classifying diseases. Instead of training from scratch, the weights from pretrained networks are transferred, enhancing performance and reducing training time. Experiments show AlexNet outperforms other architectures in classification. Advantages include faster training and improved accuracy, though the reliance on pretrained models limits adaptability to new data. Future work may explore improving adaptability to unseen diseases or extending the approach to other plant species [23]. Wakhare et al. (2023) proposed a DL system for disease detection in pomegranate. The system allows farmers to upload fruit images using a trained dataset for analysis. To identify infections, image processing procedures include CNN-based clustering, SVM classification, and feature extraction based on color, morphology, and CCV. An intent search technique refines the user's intention. The Proposed tool provides timely and accurate disease identification, improving crop yield and benefiting agriculture. The model achieved 98.38% accuracy but may face challenges with highly similar disease symptoms. Future improvements could enhance the system's ability to differentiate subtle variations [24].

Zhu et al. (2023) proposed an identification system based on Raspberry Pi to identify pests and diseases in fruits like Longan and lychee. The system used a VGGNet model for image classification, leveraging a knowledge graph constructed from data collection and knowledge fusion. Images were captured via a Raspberry Pi-controlled camera and analyzed, with results broadcasted through a Bluetooth speaker in real-time. The method achieved high accuracy in pest and disease detection. Its advantages include real-time detection and portability, but it may struggle with complex image backgrounds. Future improvements could focus on enhancing recognition accuracy in diverse environments [25]. Jain et al. (2023) proposed a deep learning technique by combining LSTM and CNN for categorizing guava fruit images as healthy or diseased by focusing on guava canker, leaf spot, guava rust. Dataset of 6000 images were used for training this model. The workflow involves feature extraction through CNN followed by sequence learning using LSTM. It achieved an accuracy of 95.90%, offering efficient disease detection and potential for use in automated agricultural systems. However, the model may struggle with images outside the training data scope. Future improvements could focus on expanding the dataset for broader applicability [26].

Dhiman et al. (2023) proposed a fusion model combining LSTM and CNN using edge computing to detect citrus crop diseases. The model employs a feature-fusion system after a downsampling technique and an improved feature extraction process. It was evaluated on 2950 citrus fruit photos classified by diseases like melanosis, cankers, scabs, and greening black patches from the Kaggle and Plan Village datasets. The model improves detection accuracy while operating efficiently on edge devices. However, the model may face limitations in large-scale deployments. Future work could involve scaling the model for real-time large dataset processing [27]. Dhiman et al. (2023a) presented an edge computing setting a precise fruit disease diagnosis model that uses Faster-CNN context data fusion to identify four citrus diseases: canker, black spot, greening, scab, and melanosis. The model integrates multi-modal data using RGB and near-infrared (NIFR) patterns with early and late fusion approaches. Implemented without pruning, it uses transfer learning to enhance detection. The model's excellent detection accuracy and quick processing make it essential for autonomous manufacturing of food in robotic boundary platforms. However, the absence of pruning may lead to inefficiency [28].

**Kavitha and Sarojini****CONCLUSION**

This paper offers a complete review of various Machine Learning and Deep Learning models developed for predicting and classifying fruit diseases from different fruit images. Initially, it examines several fruit disease prediction and categorization systems created by various investigators utilizing ML and DL algorithms. Following this, a comparative analysis is conducted to evaluate the merits and shortcomings of these algorithms, highlighting their limitations in accurately classifying fruit diseases. Many researchers focused on optimizing accuracy, reducing computational complexity and improving real-time detection capabilities. Despite the significant advancements, there remains a need for improved standardization of datasets and evaluation metrics to enhance the applicability and comparability of findings. Future research should also focus on developing more scalable solutions that can be seamlessly integrated into practical, real-world systems. This article will be highly valuable to researchers aiming to explore this topic further and improve upon the existing models.

## ABSTRACT

A progressive neurological condition, Parkinson's disease (PD) seriously affects motor ability and presents difficulties for early identification and therapy. In this paper, we provide a novel approach using improved Recurrent Neural Network (RNN) architecture to predict Parkinson's disease. This design is intended to manage patient motor activity-generated wave frequency data. Long-term dependencies and sequence modeling in complicated datasets provide difficulties for traditional RNN models, therefore restricting their prediction accuracy. We therefore use a modified RNN model with gated mechanisms like Long Short-Term Memory (LSTM) or Gated Recurrent Units (GRU) to better grasp temporal relationships in wave frequency patterns. Subtle changes in motor signals linked with Parkinson's disease symptoms are analyzed using the wave frequency dataset, therefore giving a rich feature set for the model to learn from. Regarding accuracy, sensitivity, and specificity, the improved RNN beats conventional machine learning techniques in terms of anticipating Parkinson's disease onset. Our results suggest that a tool combining modern RNN architectures with wave frequency datasets might be helpful for early-stage Parkinson's disease detection and prediction, hence improving treatment choices and early interventions.

Sasirekha et al.,

## INTRODUCTION

In North America alone, about one million people suffer from psoriatic dementia [1]. One of how Parkinson's disease affects motor abilities is via its effects on language and literacy. Neurons, which are essential brain cells, malfunction and die [2-5]. A chemical messenger between two regions of the brain, dopamine is produced when neurons die and conveys instructions to the region of the brain responsible for movement and coordination [6-7]. A natural reduction in dopamine production in the brain renders the affected individual unable to regulate their motions [8]. The number of people diagnosed with PD is likely to rise in tandem with the global population. There is currently no cure for PD, despite the availability of drugs [9-10]. Patients can benefit greatly from an early diagnosis, which in turn enhances their quality of life. Parkinson's disease symptoms include tremors in the limbs, stiffness in the muscles, sluggish movement, trouble walking, problems with balance and coordination, impaired vocal abilities, and mental disorders [11-13]. Chronic, degenerative neuropathy is known as Parkinson's disease (PD). Exactly what triggers Parkinson's disease is a mystery. Nevertheless, studies have shown that PD is likely caused by a mix of hereditary and environmental factors [14-17]. At its core, Parkinson's disease is a CNS condition caused by the loss of neurons in different parts of the brain. The dopamine-producing substantia nigra cells are also a part of these cells [18-19]. When it comes to motor control, dopamine is king. It carries messages from one part of the brain to another using chemical messengers. Patients have mobility dysfunction as a result of these cells being lost [20-21]. There are two main categories of PD symptoms: motor and non-motor. Because they are visible to the naked eye, motor signs are well-known [22]. Resting tremors, sluggish movement, postural instability (balance issues), and stiffness are the four hallmark signs [23]. It has now been shown that there is a window of opportunity to notice the non-motor signs. The medical term for this symptom is symptoms that are not responsive to dopamine [24-25]. Cognitive impairment, trouble sleeping, olfactory loss, constipation, difficulty with eating and speaking, inexplicable aches, drooling, low blood pressure while standing, and other symptoms are included [26-27]. To be clear, none of these non-motor symptoms alone can rule out PD [28-29]. However, when combined with additional indicators derived from CSF measurements and dopamine transporter imaging, they can provide some insight.

### The main contribution of the paper is:

Parkinson's Disease Prediction Using Improved RNN The rest of the piece's table of contents is here. Section 2 covers many writers' approaches to Parkinson's disease diagnosis. Section 3 displays the suggested model. The findings of the study are summarized in Part 4. Results and future study goals are discussed in Section 5, which finishes the section.

### Motivation of the paper

The urgent need for rapid and efficient detection and treatment of PD, a neurodegenerative condition that progressively diminishes motor function, is the driving force behind our work. When PD is not detected early enough using conventional diagnostic procedures, treatment, and management might be postponed. This research seeks to improve prediction accuracy and sensitivity by using sophisticated RNN architectures that are specifically designed to interpret wave frequency data from patient motor activities. Gated methods like as LSTM and GRU are used to address the drawbacks of conventional RNNs in identifying long-term associations of complex datasets. The ultimate aim of this work is a strong instrument for the early detection and prognosis of Parkinson's disease.

### Background study

Arasteh, E et al. (2021)Computation of DC in the EEG provided us with a fresh approach for generating an image representation of the 1D signal. Authors obtained exceptional classification performance and latent areas better linked with clinical indications using transfer learning. Based on their results, classifying small-sample data sets should benefit from a technique including heat maps into an image classifier and using transfer learning. Khare, S. K., et al. (2021)Using EEG data as input, the work proposes an independent, exact, and reliable Parkinson's disease CNN (PDCNNet) model. Smoothed-Pseudo Wigner Ville distribution (SPWVD) plots are produced using Electroencephalogram (EEG) data. Integration of SPWVD plots with CNN produced the best accurate PD

**Sasirekha et al.,**

identification on two publicly accessible EEG datasets. By lowering interference from both time and frequency, the SPWVD was able to expose more precise and hitherto unrecorded data. Koch, M., et al. (2019) Authors of this work provide an automated method for EEG data categorization. Using a dataset of forty PD patients, their system finds and chooses the most significant attributes from time series automatically after a random forest model and hyperparameter optimization. The results show that incorporating the automatically computed characteristics much improved the performance of the model than depending only on recorded clinical variables. Maitin, A. M., et al. (2020) Crucially, the effectiveness of the model depended on its design and the methods it used to project the categorizing. Conversely, the EEG cleaning technique varied widely among trials and did not affect the results. An emerging and fast-growing field of study is the classification of neurodegenerative illnesses using EEG and ML techniques. Obayya, M. et al. (2023) Densely Linked Bidirectional Long Short-Term Memory (DLBLSTM) is a novel deep-learning model for automatic Parkinson's disease identification. To create more useful and interpretable spectrograms from raw EEG data, the model makes use of the Gabor transform. DLBLSTM employs the bidirectional LSTM RNN architecture. In this network design, the hidden states of the layers above and below it are combined. This model was used to update the levels below it recursively. The model was trained based on spectrograms. Experimental findings demonstrated that the proposed DLBLSTM model correctly recognized Parkinson's disease. Shaban, M. (2021) This research explored and verified the hypothesis that people can be screened and classified into controls and PD using resting state EEG with extremely high accuracy and sensitivity using Artificial Neural Networks (IRNN). With this, doctors will have a trustworthy resource to back up their diagnoses, and it can even be able to be further evaluated using resting state Electroencephalograms (EEGs) in individuals with pre-diabetic PD to identify those at increased risk of developing pharmaceutical PD.

Siuly, S. et al. (2024) The main purpose of the research was to find the part of the brain that responds well to EEG data to enhance current methods of Parkinson's disease identification. Two real datasets, one from San Diego and one from Iowa, were used to evaluate the framework's performance. Analyzing EEG data channel by channel revealed regions of the brain that provide more clues about Parkinson's disease. Xu, S., et al. (2020) the suggestion was for a new computer-assisted technique for PD identification using EEG data, which relies on a deep RNN network. They believe this is the first instance of deep learning used to address the difficulty of Parkinson's disease diagnosis based on EEG data. In the present study, the proposed model was able to achieve quite good efficiency despite the limited sample size. This paper addresses the challenge of early-stage Parkinson's disease (PD), a neurodegenerative illness that progressively compromises motor ability. Traditional diagnostic methods find it difficult to appropriately diagnose early-stage PD as motor symptoms are complex and vague, therefore delaying treatment. This work aims to overcome these constraints and increase the prediction accuracy, sensitivity, and specificity for early detection of Parkinson's disease by efficiently processing wave frequency data from patient motor activities using the architectural improvement of Recurrent Neural Networks (RNNs).

## MATERIALS AND METHODS

Here we detail the suggested approach to Parkinson's disease prediction based on an improved RNN architecture. Our approach begins with the collection and preprocessing of wave frequency data derived from patient motor activities, which captures subtle variations associated with PD symptoms. We then implement an advanced RNN model that incorporates gated mechanisms, specifically LSTM and GRU, to effectively model long-term dependencies and enhance sequence processing.

### Dataset collection

The dataset utilized in this study was sourced from Kaggle, a well-known platform for data science and machine learning resources. Specifically, we accessed the Parkinson's Disease Data Set available at <https://www.kaggle.com/datasets/vikasukani/parkinsons-disease-data-set>. This dataset is particularly valuable for research and analysis related to Parkinson's disease due to its comprehensive collection of features that reflect various motor symptoms associated with the condition.

Sasirekha et al.,

**LSTM**

By including more interactions per module, Hochreiter, and Schmidhuber's Long Short-Term Memory improved upon RNN and solved the issues with the RNN's aforementioned shortcomings. LSTMs are a subset of RNNs that, by design, can learn dependencies across lengthy periods and retain knowledge for very long durations. Olah asserts that the LSTM model follows a chain structure. Unlike traditional RNNs, which consist of a single neural network, this one has four interconnected layers that communicate in a novel way. The building components of an LSTM network are known as cells. Moving from one cell to another involves passing both the current state and the concealed state. The primary data flow chain that permits data to go substantially unaltered is the cell state. Nevertheless, certain linear changes might take place. To avoid the problem of long-term dependence, LSTMs use gates to control the memorization process. The sigmoid function determines how much data should be included or omitted in this method. A current input ( $X_t$ ) is taken in at time t, and the output ( $h_{t-1}$ ) of the LSTM unit before it is taken in at time t-1. Furthermore, the pruning-needed portion of the previous output is located using the sigmoid function. The term "ft" is an abbreviation for "forget gate" and it characterizes this entrance. The cell state denoted as  $C_t$ , is a vector with integer values ranging from 0 to 1.

$$f_t = \sigma(W_f[h_{t-1}, X_t] + b_f) \text{----- (1)}$$

Using these methods with the sigmoid and tanh layers adds extra. The sigmoid layer (0 or 1) either updates incoming data or ignores it; data that passes by is weighted using the tanh function (1 to 1) to ascertain its relevance degree.

$$i_t = \sigma(W_i[h_{t-1}, x_t] + b_i) \text{----- (2)}$$

$$N_t = \tanh(W_n[h_{t-1}, X_t] + b_n) \text{----- (3)}$$

$$C_t = C_{t-1}f_t + N_t i_t \text{----- (4)}$$

Afterward, the output values ( $h_t$ ) are calculated using the filtered version of the output cell state ( $O_t$ ). One more stage before output: a sigmoid layer chooses which cell state components to apply.

$$O_t = \sigma(W_o[h_{t-1}, X_t] + b_o) \text{----- (5)}$$

$$h_t = O_t \tanh(C_t) \text{----- (6)}$$

**Gated Recurrent Units**

Learning both short-term and long-term speech dependencies is best accomplished using recurrent neural networks (RNNs). RNNs have already demonstrated success in activity detection, voice augmentation, speech separation, and speech recognition among other speech-processing applications. Disappearing and bursting gradients, however, can complicate RNN training and impede learning long-term dependencies. Unlike exploding gradients, which can be managed with simple clipping methods, the vanishing gradient problem calls for specific structures. Usually referred to as gated RNNs, one common approach uses a gating device to control the information flow across the many timesteps. Constructing effective "shortcuts" that let gradients pass over many time steps reduces vanishing gradient difficulties in this class of designs. Long short-term memory (LSTMs) is the gold standard of gated RNNs because of their remarkable performance in several ML applications, including speech recognition. Long short-term memories (LSTMs) are derived from IN/OUT gate-controlled memory cells. Notwithstanding its efficiency, a very complicated model might result from such a sophisticated gating mechanism. Given the critical need for computational efficiency for RNNs, a lot of recent money has gone into researching and designing fresh ideas for these models. Emerging as a creative attempt to simplify long short-term memory (LSTMs) is a novel concept called the Gated Recurrent Unit (GRU). GRU depends on just two multiplicative gates. Especially, the following equations explain the traditional GRU design.

$$z_t = \sigma(W_z x_t + U_z h_{t-1} + b_z) \text{----- (7)}$$

$$r_t = \sigma(W_r x_t + U_r h_{t-1} + b_r) \text{----- (8)}$$

$$h_t = \tanh(W_h x_t + U_h (h_{t-1} \cdot r_t) + b_h) \text{----- (9)}$$

Here  $r_t$  and  $z_t$  indicate the update and reset gates, respectively;  $h_t$  stands for the state vector for time frame t. Element-wise multiplies are shown with the symbol  $\cdot$ . Both gates are triggered by logistic sigmoid functions.  $b_n$ , therefore restricting  $z_t$  and  $r_t$  to integers between 0 and 1. One uses a hyperbolic tangent on the candidate state  $e_{ht}$ . The model's parameters are the matrices  $U_z$ ,  $U_r$ , and  $U_h$ , which represent the recurrent weights, and the current input vector  $x_t$ , which represents the feedforward connections, feeds into the network. Include the trainable bias vectors  $b_z$ ,  $b_r$ , and  $b_h$  to finish the design process before applying non-linearities. Eq. 1d shows that the current

**Sasirekha et al.,**

candidate state  $e_{ht}$  and the preceding activation  $ht-1$  are linearly integrated to generate the current state vector  $ht$ . The update gate  $z_t$  determines the amount by which the units update their activations while also establishing the weighting components. This linear interpolation is crucial for learning long-term dependencies. The truth is that the previous state is retained and can remain unaltered for an infinite number of time steps as long as it is close to 1. At low values of  $z_t$ , on the other hand, the network is more likely to choose the candidate state  $e_{ht}$  based on the present input and neighboring hidden states. The reset gate is also critical to the candidate state  $e_{ht}$  since it enables the model to potentially erase its memory by disregarding the states that were calculated earlier.

**Improved RNN**

A subfield of artificial intelligence is machine learning. The goal is to construct a model that can solve classification or regression issues by learning from the given data. In machine learning, supervised and unsupervised approaches are the two most common types. Unsupervised learning makes use of unlabelled data to create an output, while supervised learning uses labeled data to create an output from inputs.<sup>34</sup> When it comes to regression and classification issues, IRNN, a supervised learning approach, works well. The core component of conventional ML methods, such as IRNN, is the construction of feature vectors from raw data to optimize learning accuracy. By fixing previous methods' problems with steady-state monitoring of speed and oscillations around the MPP, IRNN is now able to consistently follow the distinct peak even in uniform conditions. The range of 35–37 To get the GMP from the PV array instead of the LMP under the same PS, use IRNN with other conventional or AI MPPT methods if you are using IRNN for GMP area forecasting and another technique for GMP tracking. as an example, IRNN might be used with modified IC for GMP monitoring since it could provide VGMP to the latter.<sup>38</sup> To anticipate the GMP-seeking area, IRNN is used. The scanning method was used to identify the GMP and its accompanying voltage VGMP by comparing subsequent power levels. To determine the best duty cycle at GMP, a feed forward network is used to process both the GMP power and the VGMP. An IRNN can be trained to calculate VGMP by just having to input temperature and irradiance data for some PSCs. To modify the boost converter's duty cycle, FLC receives the output of IRNN and applies VGMP.<sup>41</sup> An ML method that is effective in solving nonlinear issues is the IRNN. Even though it is an expansion of the IRNN approach, it offers numerous advantages over IRNN. Input sequences can be completely random using IRNNs, making them a potent deep-learning tool. In IRNNs, the length of the input sequence is flexible. The depth of an IRNN can be as deep as the length of an input sequence, which is infinite. IRNN's short memory allows it to take into account the network's past states to influence the present choice based on the input sequence. A memory like this, which influences the present choice, uses sequence information to its advantage by retrieving the recurrence's sequential data from hidden states, a feature that feed forward networks lack. Additionally, IRNN was differentiated from feed forward neural networks by including recurrent connections into the hidden layers. Additionally, the network's weights are adjusted using the back propagation method to minimize errors during training.

$$h_i = H(Ux_i + Wh_{i-1} + b_n) \quad \text{----- (10)}$$

$$y_i = O(vh_i + b_o) \quad \text{----- (11)}$$

Every neuron in the same subsurface layer has the same weight (W) about the activation functions (H) of the hidden and output layers. The input layer bias is denoted by  $b_o$ , while the output layer bias is represented by  $b_n$ . An infinite number of input time series can be transformed into an infinite number of outputs, or even a single desired result, by use of a deep recurrent neural network. What gives IRNNs their "depth" is the hidden-to-hidden transition that is a part of RNN architecture.<sup>40, 44</sup> The suggested IRNN has an input layer, five hidden layers, and a final layer for output. Five neurons represent the feature vector in the input layer. We take three readings of irradiance, temperature, and duty ratio from the previous state. One important aspect of the IRNN method is that it is sequential. This is achieved by making an estimate of the duty ratio value (Dt) for the present state based on the actual value of the duty ratio in the previous state (Dt - 1). Time steps need inputs to be provided in a certain order, and this makes sure that happens. The ideal boost converter duty cycle (Dopt) is predicted by a single neuron in the output layer for each input vector. The following are some possible approaches to finding the optimal duty cycle for IRNN testing and training:

$$D_{opt} = \frac{V_{dc} - V_{MPP}}{V_{dc}} \quad \text{----- (12)}$$

Sasirekha et al.,

## Algorithm 1: Improved RNN

**Inputs:**

1. Wave Frequency Data:
  - Motor Activity Signals: Continuous data capturing the frequency of the patient's motor

**Steps:**

- Normalize the input wave frequency data.
- Encode categorical patient demographic data (if included).
- $h_i = H(Ux_i + Wh_{i-1} + b_n)$
- Construct feature vectors from the input data.
- Identify and select the most relevant features for model training.
- $y_i = O(vh_i + b_o)$
- Train the Improved RNN using the prepared dataset.
- Utilize backpropagation to minimize prediction error.
- Validate the model using a separate test dataset.
- Evaluate performance metrics: accuracy, sensitivity, specificity, and F-measure.
- Input the latest wave frequency data into the trained IRNN model.
- $D_{opt} = \frac{V_{dc} - V_{MPP}}{V_{dc}}$
- Obtain the prediction of Parkinson's disease onset.

**Output:**

1. Prediction of Parkinson's Disease Onset:
  - **Y**: Binary output indicating the presence (1) or absence (0) of Parkinson's disease.

## RESULTS AND DISCUSSIONS

In this section, we present the results and discussion of our study on predicting Parkinson's disease using the proposed improved RNN architecture. We begin by detailing the performance metrics achieved by our model, including accuracy, sensitivity, and specificity, comparing them against conventional machine learning techniques. Table 2 and Figure 3 exhibit the accuracy of several neural network approaches for a specific task, demonstrating a continuous development among the models. With 96.37%, the GRU model was followed by the LSTM model with 97.14%. Reaching 97.89%, the RNN model kept getting better. Nonetheless, the ERNN model obtained the best accuracy—98.65%, meaning it exceeded the others in terms of model precision. These findings imply that of the four methods, the ERNN one is the most efficient for this particular job as it provides better prediction accuracy. Consistent improvement across the models is shown in Table 3 and Figure 4 revealing the accuracy values of many neural network approaches. The LSTM model somewhat improved with 97.18%; the GRU model had an accuracy of 96.54%. The RNN model improved the accuracy yet more to 97.91%. With 98.87%, the ERNN model notably showed the best accuracy, proving its better capacity to accurately identify positive cases while lowering false positives. These numbers show that ERNN delivers correct results more precisely than the other models, so it is the most efficient model. As the models become more sophisticated, table 4 and Figure 5 displaying recall values across several neural network approaches indicate progress. Following the LSTM model with a notable rise to 97.21%, the GRU model attained a recall of 96.14%. Reaching a recall of 98.21%, the RNN model did even better. With a 98.41% recall value, the ERNN model proved to be most adept at accurately spotting real positive instances. This development shows how well the ERNN model captures as many relevant examples as feasible, thereby surpassing the other models in recall performance. Showing F-measure values—the harmonic mean of accuracy and recall—table 5 and Figure 6 demonstrate consistent improvement across many neural network techniques. Whereas the LSTM model improved to 97.51%, the GRU model has an F-measure of 96.61%. With an improved general balance between accuracy and recall, the RNN model raised this statistic even further to 98.23%. With an F-measure of 99.14%, the ERNN model demonstrated the best performance in preserving both high accuracy and recall. This makes the ERNN the most successful model as it performs especially in producing accurate and balanced forecasts.

Sasirekha et al.,

## CONCLUSION

This paper demonstrates the efficacy of an improved RNN architecture for Parkinson's disease prediction by the use of wave frequency data from patient motor movements. Using gated mechanisms including LSTM and GRU, our approach efficiently addresses the restrictions of traditional RNN models in capturing long-term dependencies and raising prediction accuracy. Since our improved RNN performs better than conventional machine learning methods in terms of accuracy, sensitivity, and specificity, the results suggest that it highlights its potential use as a powerful tool for early diagnosis and Parkinson's disease prediction. Ultimately, our findings highlight the importance of utilizing innovative neural network designs and wave frequency datasets to allow quick therapies, hence perhaps improving patient outcomes and quality of life for individuals with this disabling condition. Future studies will focus on enhancing the model and looking at its applicability in clinical settings to support early Parkinson's disease diagnosis and treatment.

### ABSTRACT

Decision-making systems are essential for solving difficult combinatorial issues in computational science and soft computing. Traditional fuzzy graphs can only be used with single-valued fuzzy data, which limits their use in situations that require both positive and negative perspectives. The bipolar fuzzy graph sets (BFGS) enhance decision-making by considering diverse views, but it is less successful at handling uncertainties that incorporate periods and more complicated choice requirements in real-world circumstances. We recommend using the bipolar interval-valued picture fuzzy graph (BIVPFG) to avoid these drawbacks. It combines interval-valued fuzzy sets with picture fuzzy logic, an enhancement on intuitionist fuzzy logic. Due to pervasive ambiguity, real-time decision-making must weigh several contradictory factors. Health outcomes, costs, and resources are considered. Treating conflicting issues including client tastes, risk factors, and therapy options can also help treatment planning. BIVPFG can help allocate assets for medical care frameworks. This paper discusses BIVPFG in real life applications.

**Keywords:** decision-making, fuzzy graphs, bipolar fuzzy graph, bipolar interval-valued picture fuzzy graph, intuitionist fuzzy logic

## INTRODUCTION

Technology and enterprises depend on decision-making systems [1]. In healthcare, finance, transportation, and industry automation, these technologies automate critical decisions, eliminate human error, and increase efficiency [2]. Conventional decision-making methods presume precise data and specific choices. Because they handle real-world problems better, uncertain, fuzzy logic, and AI-based systems have become more prevalent [3]. These systems learn from data, adapt to new expertise, and make more sophisticated judgments than rule-based models. IoT and big data have revolutionized decision-making systems by processing data in real time [4]. More advanced models that can handle unpredictability, adapt to changing situations, and make reliable choices quickly are needed as these systems progress. Systems that need precise decision-making and inexact data analysis benefit from fuzzy logic. Fuzzy logic was invented by LotfiZadeh in 1965 to handle unreliable vague, or vague real-world data. Fuzzy logic has degrees of truth, unlike binary [5]. In an environmental control system, fuzzy logic can represent a temperature as partly hot and partially cold, smoothing control. Graph theory models pairwise interactions using mathematical constructs [6]. Classical graph theory is extended to fuzzy graph theory, which uses fuzzy logic for expressing imprecise interactions. Fuzzy graphs fit complex systems with unclear variable relationships [7]. Fuzzy network models assign participation degrees to node edges depending on dynamic relationship strength. Social network analysis, security of networks, and transportation systems need this integration to make dynamic, complicated, and unpredictable decisions [8]. A new fuzzy graph, Bipolar Interval-Valued Picture Fuzzy Graphs (BIVPFG), is used for uncertain and imprecise decision-making. These graphs bring bipolarity, interval values, and picture fuzzy sets to fuzzy logic [9]. Supportive and opposing factors affect real-world decision-making, making bipolarity crucial [10].

Doctors may have information for and against a specific diagnosis. Due to its dual nature, BIVPFG allows balanced input decisions. Interval-valued fuzzy sets improve this by capturing input data uncertainty and providing a range of truth values rather than a fixed degree of membership. Current applications like dynamic supply chain management and budgeting require this since data is often inadequate or changing [11]. The picture fuzzy set's unpredictability enhances decision-making when neither positive nor negative judgments are reliable [12]. In incomplete, unclear, or contradictory settings, real-time decision-making is challenging [13]. Managing large, dynamic data is another challenge. Many real-time systems use IoT, sensors, and social media [14]. Conventional decision-making models struggle with noisy, incomplete, or fast-changing data and sophisticated models like fuzzy logic or hybrid techniques are needed to understand and act on uncertain data [15]. Complex choices demand more processing and storage. Urban traffic management and disaster response real-time systems must scale to cope with more data and more complex choices without slowing down [16]. Because they handle data ambiguity, vagueness, and imprecision, fuzzy network models are used in many real-world applications [17]. Contradictory diagnostic indicators have been utilized to identify cancer and cardiovascular problems using bipolar interval-valued fuzzy graphs [18]. Another crucial use is network security. Security systems can categorize traffic as benign or hazardous with limited data using fuzzy graph models [19][20]. In this study, the Bipolar Interval-valued Picture Fuzzy Graph (BIVPFG) is introduced as a decision-making framework for real-time applications. This model integrates interval-valued fuzzy sets with picture fuzzy logic, an advanced form of intuitionist fuzzy logic. Given the inherent uncertainty in real-time decision-making, it is crucial to balance multiple conflicting factors. Key considerations include health outcomes, costs, and resource availability. Addressing divergent issues such as patient preferences, risk variables, and treatment options can enhance planning for medical care. The BIVPFG offers a valuable tool for optimizing resource allocation within healthcare systems.

## PRELIMINARIES

In this section, we present some basic concept related to fuzzy graphs. However, we refer [21] for the basics of the classical graphs theory.

**Definition 2.1:** A fuzzy set (FS)  $T$  on a nonempty set  $U$  is described by

**Sakkthisri and Manonmani**

$T u = \{(u, \rho(u)) : u \in U, \rho(u) \in [0, 1]\}$ .

**Definition 2.2:** A bipolar fuzzy set (BPFS) T on a non empty py set U is given by

$T = \{(w, \rho^+(w), \rho^-(w)) : w \in U\}$ , where  $\rho^+ : U \rightarrow [0, 1]$  and  $\rho^- : U \rightarrow [-1, 0]$  are the mappings.

**Definition 2.3:** A PFST on U is the collection  $T = \{(u, \rho_T(u), \varphi_T(u), \tau_T(u)) : u \in U\}$ , where  $\rho_T(u), \varphi_T(u)$  and  $\tau_T(u)$  are lying in the interval  $[0, 1]$  and represent the positive, neutral and negative membership degrees of u in T, respectively with  $\rho_T(u) + \varphi_T(u) + \tau_T(u) \leq 1$ , for all  $u \in U$ .

**Definition 2.4:** A fuzzy graph (FG) is a pair  $G^* = (C, D)$ , where  $C = \{\rho_C\}$  and  $D = \{\rho_D\}$  such that  $\rho_C : V \rightarrow [0, 1]$  and  $\rho_D : V \times V \rightarrow [0, 1]$ . We have  $\rho_D(x, w) \leq \rho_C(w) \wedge \rho_C(x)$ .

**Definition 2.5:** A BPF is a pair  $G^* = (C, D)$ , where  $C = \{\rho_C^+, \rho_C^-\}$  and  $D = \{\varphi_D^+, \varphi_D^-\}$ , where  $\rho_C^+ : W \rightarrow [0, 1], \rho_C^- : W \rightarrow [-1, 0], \varphi_D^+ : W \rightarrow [0, 1], \varphi_D^- : W \rightarrow [-1, 0]$ , is said to be a BPF of underlying set W, if  $\varphi_D^+(w, z) \leq \min(\rho_C^+(w), \rho_C^+(z))$  and  $\varphi_D^-(w, z) \geq \min(\rho_C^-(w), \rho_C^-(z))$ , for all  $w, z \in D = C \times C$ .

**Definition 2.6:** A pair  $G = (C, D)$  is called a PFG on  $G^* = (C, D)$ , where  $C = (\rho_C, \varphi_C, \tau_C)$  is a PFS on V and  $D = (\rho_D, \varphi_D, \tau_D)$  is a PFS on  $D \subseteq V \in C$  with

$$\rho_D(w, z) \leq \min(\rho_C(w), \rho_C(z))$$

$$\varphi_D(w, z) \leq \min(\varphi_C(w), \varphi_C(z))$$

$$\tau_D(w, z) \geq \max(\tau_C(w), \tau_C(z))$$

**BIPOLAR INTERVAL-VALUED PICTURE FUZZY GRAPH**

In this section, the concepts of the bipolar interval-valued picture fuzzy graph is introduced and the working process of BIVPFG are discussed. Bipolar Interval-Valued Picture Fuzzy Graph (BIVPFG) combines the concepts of bipolar fuzzy sets, interval-valued fuzzy sets, and picture fuzzy logic to represent and analyze complex relationships between multiple factors in decision-making systems. Picture fuzzy logic, an extension of intuitionistic fuzzy logic, was introduced to handle the uncertainty and imprecision in a more comprehensive way. The combination of these concepts led to the development of BIVPFG. It is inspired by the need to develop a more comprehensive and robust decision-making system that can handle complex relationships between multiple factors, including conflicting and uncertain information. It is inspired by the limitations of traditional fuzzy graphs and the need to incorporate both positive and negative aspects of a phenomenon, as well as the uncertainty and imprecision associated with real-world data.

**Definition :** Let  $G^* = (V, E)$  be a graph. A pair  $G = (C, D)$  is said to be a BIVPFG on  $G^*$ , where  $C = \{\alpha_C^+(w), \alpha_C^-(w), \gamma_C^+(w), \gamma_C^-(w), \beta_C^+(w), \beta_C^-(w), \rho_C^+(w), \rho_C^-(w)\}$  is a BIVPF set on V and

$D = \{\alpha_D^+(w, z), \alpha_D^-(w, z), \gamma_D^+(w, z), \gamma_D^-(w, z), \beta_D^+(w, z), \beta_D^-(w, z), \rho_D^+(w, z), \rho_D^-(w, z)\}$  is a BIVPF set on  $E \subseteq V \times V$  such that for every edge  $w, z \in E$ ,

$$\alpha_D^+(w, z) \leq \min(\alpha_C^+(w), \alpha_C^+(z)) \quad \alpha_D^-(w, z) \geq \max(\alpha_C^-(w), \alpha_C^-(z))$$

$$\gamma_D^+(w, z) \leq \min(\gamma_C^+(w), \gamma_C^+(z)) \quad \gamma_D^-(w, z) \geq \max(\gamma_C^-(w), \gamma_C^-(z))$$

$$\beta_D^+(w, z) \geq \max(\beta_C^+(w), \beta_C^+(z)) \quad \beta_D^-(w, z) \leq \min(\beta_C^-(w), \beta_C^-(z))$$

$$\rho_D^+(w, z) = (\rho_C^+(w), \rho_C^+(z)) \quad \rho_D^-(w, z) = (\rho_C^-(w), \rho_C^-(z))$$

Satisfying  $0 \leq \alpha_D^+(w, z) + \gamma_D^+(w, z) + \beta_D^+(w, z) \leq 1$

$$-1 \leq \alpha_D^+(w, z) + \gamma_D^+(w, z) + \beta_D^+(w, z) \leq 0$$

$$\rho_D^-(w, z) = (\alpha_D^+(w, z) + \gamma_D^+(w, z) + \beta_D^+(w, z)) \leq 1$$

**EXAMPLE**

In Figure 1, X has 30% good acquaintances, 20% bad acquaintances, and 30% casual acquaintances in his social group. Meanwhile, the edges of the graph reflect a person's acquaintanceship with others. The degrees of membership, non-membership, and neutral membership of an edge can be interpreted as the proportions of good acquaintances, bad acquaintances, and non-acquaintances. It is also easy to check whether the edge values in the graph in Figure 1.

**Sakkthisri and Manonmani**

The working process of BIVPFG involves the following steps:

- Collect data on the factors involved in the decision-making process, including their relationships and interactions.
- Convert the collected data into fuzzy numbers, which represent the uncertainty and imprecision associated with each factor.
- Construct interval-valued fuzzy sets for each factor, which capture the uncertainty and imprecision in a more nuanced way.
- Apply picture fuzzy logic to the interval-valued fuzzy sets to capture the uncertainty and imprecision in a more comprehensive way.
- Construct a bipolar fuzzy graph, which represents the relationships between the factors, including both positive and negative aspects.
- Use the BIVPFG to make decisions by analyzing the relationships between the factors and identifying the optimal solution.

Consider a shape with  $n$  vertices  $\{\rho_1, \rho_2, \dots, \rho_m\}$  and no equal edges. Let's call the arrangement of its continuity relationships the 'continuity lattice.' Symbolically, this can be denoted as  $\alpha_{uh}$  for some condition involving  $\alpha_{uh} \notin \{-1, 0, 1\}$  for  $u, h = 1, 2, \dots, m$ , aiming to achieve a particular outcome

$$\alpha_{uh} = \begin{cases} 1 & \text{if } \rho_u \rho_h \text{ is a positive edge.} \\ -1 & \text{if } \rho_u \rho_h \text{ is a negative edge.} \\ 0 & \text{if } \rho_u \rho_h \text{ is not an edge.} \end{cases} \quad (1)$$

The continuity structure related to a labeled diagram is symmetrical. This symmetry implies that in the diagram's representation, the upper triangular matrix  $U$  is identical to the transpose of the lower triangular matrix  $L$ . Therefore, if  $L$  is given, it implies the construction of  $U$ ."

$$\alpha = \begin{pmatrix} 0 & \alpha_{12} & \dots & \alpha_{1m} \\ \alpha_{21} & 0 & \dots & \alpha_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ \alpha_{1m} & \alpha_{2m} & \dots & 0 \end{pmatrix} \quad (2)$$

where  $\alpha_{uh} = \alpha_{uh}$  to understand the continuity structure, it's enough to focus on either the upper or lower triangular system. For encryption and decryption, let's consider only the upper triangular grid. In the next step, we add 1 to both the beginning and end of every identical number. Then, we convert all the binary numbers into decimal numbers, treating -1 as a decimal number itself. This process results in a sequence of decimal numbers, where  $f_1, f_2, \dots, f_l$ . This sequence is used for encryption. The qualities  $f_1, f_2, \dots, f_l$ , where  $1 \leq l \leq e$ , are scrambled by applying RSA calculation to get the encoded numbers  $s_1, s_2, \dots, s_k$  (say), to such an extent that  $(\text{mod } m)$ , where  $1 \leq l \leq e$ , and this ciphertext is shipped off collector who can infer the first framework by applying some converse cycle. For decoding, in the wake of getting the scrambled qualities (figure text)  $s_1, s_2, \dots, s_k$ , where  $1 \leq l \leq e$  is unscrambled to get the upsides of  $f_1, f_2, \dots, f_l$ , to such an extent that  $f_i = (s_i) f$ , where  $1 \leq l \leq e$ . Further, every  $f_i = 1, \dots, l$  aside from -1 is switched over completely too twofold numbers to build the upper three-sided network  $U$ . Each line corresponds to the rightmost digits, representing the final part from the top section to the last line. In the participation capability layer, each information  $x_i$  is input into  $q_i$  different enrollment capabilities. Every enrollment capability addresses a sort of semantics, and its result is the participation degree that the information  $z_1$  fulfills this semantics, and its worth is somewhere in the range of 0 and 1.

**Sakkthisri and Manonmani**

IF  $z_1$  is  $S_1^{h_1}$  and  $z_2$  is  $S_2^{h_2} \dots$  and  $z_m$  is  $S_m^{h_m}$ , THEN  $t$  is  $v^{h_1, h_2, \dots, h_m}$ , (3)

where  $z_1$  is the contribution of FNN,  $t$  is  $v^{h_1, h_2, \dots, h_m}$ , I addresses a sort of fluffy semantics, for example, "quick", "slow", "high" or "low" that can't be precisely communicated, which is numerically addressed as a participation capability,  $z_m$  is  $S_m^{h_m}$ , the standard boundary  $z_2$  is  $S_2^{h_2} \dots$  is an exact worth. The result of the standard hub is the enactment strength  $d_l^{h_1, h_2, \dots, h_m}$  of the standard, and the recipe for working out  $d_l^{h_1, h_2, \dots, h_m}$  is:

$$d_l^{h_1, h_2, \dots, h_m} = \prod_{h_u=1}^m \mu_{h_u}(z_u(l)). \tag{4}$$

where,  $\mu_{h_u}$  addresses the participation capability that addresses the fluffy semantic  $S_m^{h_m}$ . The articulation  $\mu_{h_u}(z_u(l))$  implies the enrollment level of the l-th test for the fluffy recommendation  $z_2$  is  $S_2^{h_2} \dots$ . The image  $\prod$  addresses the fluffy crossing point administrator, and that signifies "and". Subsequently, the actuation strength  $d_l^{h_1, h_2, \dots, h_m}$  addresses how much the information meets the preconditions of the standard "Assuming that  $z_2$  is  $S_2^{h_2} \dots$  and  $z_m$  is  $S_m^{h_m}$ ,

$$t = \sum_{h_1=1}^{w_1} \dots \sum_{h_m=1}^{w_m} v^{h_1, h_2, \dots, h_m} \times d_l^{h_1, h_2, \dots, h_m}. \tag{5}$$

Given M preparing input-yield information coordinates, every information pair is signified as:

$$[z_1(l), z_2(l), \dots, z_m(l); t(l)] \tag{6}$$

where  $z_1(l)$  is the contribution of information,  $t(l)$  is the preset number of enrollment capabilities for each info aspect  $z_1(l)$ , ex-squeezed as. The  $z_m$  is a connected with the actual significance of the info aspect. In particular, the more complicated the information aspect, the bigger the  $m_i$  ought to be set. Work out the most extreme worth and least worth of each dimensional variable  $z$  of the info information, and gap the locale blocks:

$$[z_1, z_2], [z_2, z_3], \dots, [z_{n_1-1}, z_{n_1}] \tag{7}$$

where  $z_1$  Compute the difference of result  $y(k)$  comparing to the example in every area  $[z_1, z_2], [z_2, z_3], \dots, [z_{n_1-1}, z_{n_1}]$  in and record it as  $MSE_k(t)$ ,

$$MSE(t) = \min MSE_k(t) + f \times (\max MSE_k(t) - \min MSE_k(t)), \tag{8}$$

where  $\max MSE_k(t)$  and  $\min MSE_k(t)$  are the most extreme and least qualities in  $\max MSE_k(t)$ , separately, and  $d$  is a hyper parameter,  $0 < f < 1$ . The  $MSE_k(t)$  will be utilized as a pruning related edge in resulting steps. Step 3: For the aspect whose segment number  $m_i$  fulfills  $m_i > m_0$ , we play out a pruning activity, where  $m_0$  is a hyper parameter. We navigate all locales from the primary area  $[z_1, z_2]$ . On the off chance that the ongoing crossing district is  $[z_1, z_2]$ , and the locale  $[z_1, z_2]$  has not been navigated, and fulfill:

$$MSE_{s\beta}(t) \leq MSE(t) \tag{9}$$

$$MSE_{s\beta}(t) \leq MSE(t) \tag{10}$$

$$z_v - z_s \leq x' \times \frac{\max z_u - \min z_u}{n_u} \tag{11}$$

Then merge region  $[z_v - z_s]$  and region  $[z_v, z_s]$  into region  $[z_v, z_s]$  as

$$MSE_{sv}(t) = \frac{MSE_{sv}(t) + MSE_{sv}(t)}{2} \tag{12}$$

**Sakkthisri and Manonmani**

where  $(t)$  are the differences of the result of relating districts  $MSE_{sv}(t) + MSE_{sv}(t)$  is a hyper parameter. The blended locale should be not exactly  $sv$  seasons of the original many districts consolidating, we will check whether  $[Z_v - Z_s]$  can be converged with the following area  $[Z_v - Z_s]$ . If not, we will cross the following district until all locales are navigated.

$$d_l^{h_1^*, h_2^*, \dots, h_m^*} = \max_{h_1, h_2, \dots, h_m} d_l^{h_1, h_2, \dots, h_m} \tag{13}$$

In the wake of crossing all M preparing tests, in the event that a standard has saved something like  $d_l^{h_1^*, h_2^*, \dots, h_m^*}$  information pair, the standard boundary  $d_l^{h_1, h_2, \dots, h_m}$  .n of this standard can be determined by the adhere to condition:

$$v^{h_1^*, h_2^*, \dots, h_m^*} = \frac{\sum_{l=1}^M d_l^{h_1^*, h_2^*, \dots, h_m^*} \times t_l}{\sum_{l=1}^M d_l^{h_1^*, h_2^*, \dots, h_m^*}} \tag{14}$$

where N is the all out number of preparing tests,  $d_l^{h_1^*, h_2^*, \dots, h_m^*}$  n addresses the directions of this standard in the standard space, and  $d_l^{h_1^*, h_2^*, \dots, h_m^*}$  n k is the actuation power of the l-th test on the standard, and is the greatest enactment force among all rules set off by the l-th test.  $t_l$  is the result of the l-th test.

**Real-time application of BIVPFG decision making**

The utilization of graph modeling has far-reaching implications in various disciplines, including computer science, mathematics, chemistry, physics, and social sciences. Typically, such models necessitate more intricate arrangements beyond mere adjacency among vertices. In the realm of social network analysis, it is crucial to ascertain the nature of relationships between individuals, such as familiarity, friendship, or acquaintanceship, whether in the physical or virtual world. By assigning a vertex to each individual within a group, we can represent their connections through undirected edges, devoid of multiple edges and loops. The presence of an edge between vertices signifies a level of acquaintanceship between the corresponding individuals. However, classical graphs are limited in their ability to accurately model social networks, as they assign equal importance to each vertex and edge, neglecting the nuances of real-world relationships. In reality, social units, whether individuals or organizations, possess varying levels of influence and connection strengths. To address this limitation, we propose the use of fuzzy graphs, which can effectively capture the ambiguity and uncertainty inherent in social relationships. Specifically, we introduce fuzzy acquaintanceship graphs, bipolar fuzzy acquaintanceship graphs, and bipolar picture fuzzy acquaintanceship graphs to quantify an individual's level of socialization within a group. The bipolar picture fuzzy acquaintanceship graph model, in particular, offers a more sophisticated approach to detecting symmetries and asymmetries in relationships, enabling a deeper understanding of social dynamics in networks, computer networks, and beyond.

**CONCLUSION**

This study presents the Bipolar Interval-Valued Picture Fuzzy Graph (BIVPFG) as an innovative approach to decision-making systems, particularly in scenarios marked by uncertainty, complexity, and conflicting factors. Traditional decision-making models, such as fuzzy graphs, fall short in their ability to address both positive and negative perspectives simultaneously, especially when real-world applications demand consideration of nuanced and interval-based uncertainties. While bipolar fuzzy graph sets (BFGS) improve decision-making by accommodating dual perspectives, they still struggle with more intricate, real-time decision processes where uncertainty is pervasive. The proposed BIVPFG model justifies its value by overcoming these limitations, combining the strengths of interval-valued fuzzy sets with picture fuzzy logic—an enhancement of intuitionistic fuzzy logic. This hybrid approach allows the BIVPFG to model real-world decision environments more comprehensively by capturing not just degrees of membership, non-membership, and hesitancy, but also by considering the bipolar

### Sakkthisri and Manonmani

nature of choices, accounting for both positive and negative influences. BIVPFG improves decision accuracy by effectively managing uncertainty through its interval-valued picture fuzzy representation, allowing stakeholders to make better-informed, nuanced decisions.

## ABSTRACT

This study introduces the notion of Interval-Valued Intuitionistic Fuzzy Nano Topological Spaces (IVIFNTS), an advanced framework that combines Interval-valued Intuitionistic Fuzzy sets with Nano Topology to characterize uncertainty and granularity at a very localized level. The major impetus for creating this framework originates from the requirement to manage imprecise data in complicated, real-world systems where classic topological approaches fail. The formal description of IVIFNTS is provided, emphasizing the fundamental qualities that distinguish this structure in dealing with fuzziness and precision at the nanoscale level. We next investigate various essential aspects of IVIFNTS, including interval-valued intuitionistic fuzzy nano-open sets, closures, interior operators, and continuous mappings.

**Keywords :** Interval valued intuitionistic fuzzy nano topological spaces, Interval valued intuitionistic fuzzy nano open sets, Interval valued intuitionistic fuzzy nano closed sets.

## INTRODUCTION

Lellis Thilagavar[1] proposed the notion of nano topological spaces, which discuss and define the terms of approximations, border region, and equivalence relation of subsets. Zadeh[2] introduced the fuzzy set in 1905, and it indicates a degree of membership for each member of the set in a subset of it. In 1986, Atanassov [3] introduced

**Malathi and Manonmani**

intuitionistic fuzzy sets to cope with accuracy in the face of uncertainty. In this study, we introduce the idea of Interval valued Intuitionistic Fuzzy Nano Topological Space.

**Preliminaries**

**Definition 2.1 Fuzzy set [4]:**

Let  $X$  be a non-empty set. A Fuzzy Set  $I$  of  $X$  is defined as  $I = \{(x, A(x)) | x \in X\}$  where  $A: X \rightarrow [0,1]$ .

**Definition 2.2 Interval Valued Fuzzy set [5]:**

Let  $X$  be a non-empty set. An Interval Valued Fuzzy Set  $I$  of  $X$  is defined as  $I = \{(x, A(x)) | x \in X\}$  where  $A: X \rightarrow D[0,1]$ , where  $D[0,1]$  denotes the family of all closed subintervals of  $[0,1]$ .

**Definition 2.3 Intuitionistic Fuzzy set [6]:**

An Intuitionistic Fuzzy set  $I$  in  $X$ , a universe of discourse is defined as  $I = \{(x, \mu_A(x), \nu_A(x)) | x \in X\}$  where the membership function  $\mu_A(x): X \rightarrow [0,1]$  and the non-membership function  $\nu_A(x): X \rightarrow [0,1]$  satisfies the condition  $0 \leq \mu_A(x) + \nu_A(x) \leq 1$  for every  $x \in X$ .

**Definition 2.4 Interval valued Intuitionistic Fuzzy set [7]:**

An Interval valued Intuitionistic Fuzzy set  $I$  in  $X$ , a universe of discourse is defined as  $I = \{(x, \mu_A(x), \nu_A(x)) | x \in X\}$  where the membership function  $\mu_A(x): X \rightarrow Int[0,1]$  and the non-membership function  $\nu_A(x): X \rightarrow Int[0,1]$  satisfy the condition  $0 \leq \sup \mu_A(x) + \sup \nu_A(x) \leq 1$  for every  $x \in X$ . Which means  $\mu_A(x) = [\mu_A^l(x), \mu_A^u(x)]$  and  $\nu_A(x) = [\nu_A^l(x), \nu_A^u(x)]$

**Definition 2.5 [8]:**

Let  $U$  be a universe of a non-empty finite set of objects and  $R$  be the equivalence relation defined on  $U$  called discernibility relation. Then  $U$  as disjoint equivalence classes. Elements involving the same equivalence class are named to be indiscernible with each other. The order pair  $(U, R)$  is called as the approximation space. Let  $X \subseteq U$ . Then,

The lower approximation of  $x$  with  $R$  of all objects for further classified as  $X$  and denoted by  $L_R(x)$ .

$$L_R(x) = \cup \{R(x) : R(x) \subseteq X, x \in U\}$$

where  $R(x)$  denotes the equivalence class denoted by  $x \in U$

The upper approximation of  $X$  with  $R$  of all objects are classified as  $X$  is denoted by  $U_R(x) = \cup \{R(x) : R(x) \cap X \neq \emptyset, x \in U\}$ .

The boundary region of  $X$  with respect to  $R$  is the set of all objects which can be classified neither as  $X$  or as not  $X$  with respect to  $R$  and is denoted by  $B_R(x)$ .

$$B_R(x) = U_R(x) - L_R(x)$$

**Definition 2.6 Nano Topology [8]**

Let  $U$  be the universe of a set,  $R$  be an equivalence relation on  $U$  and  $\tau_R(X) = \{U, \emptyset, L_R(x), U_R(x), B_R(x)\}$  where  $X \subseteq U$ .

Then  $\tau_R(X)$  satisfies the following

$U$  and  $\emptyset \in \tau_R(X)$ .

The union of the elements of any sub-collection of  $\tau_R(X)$  is in  $\tau_R(X)$ .

The intersection of the elements of any finite sub collection of  $\tau_R(X)$  is in  $\tau_R(X)$ .

Then  $\tau_R(X)$  is a topology on universe called the Nano topology to  $X$ .  $(U, \tau_R(X))$

is called the Nano topological space. Elements of the nano topology are known as nano open sets in  $U$ .

**Malathi and Manonmani**

**Interval valued Intuitionistic Fuzzy Nano topological Spaces**

Definition 3.1 Interval valued Intuitionistic Fuzzy Nano set

An Interval Valued Intuitionistic Fuzzy Nano set U on A is defined as  $U = \{ \langle x, [\mu_A^L(x), \mu_A^U(x)], [v_A^L(x), v_A^U(x)] \rangle \mid x \in A \}$

Where  $[\mu_A^L(x), \mu_A^U(x)] \subseteq [0,1]$  is the membership interval

$[v_A^L(x), v_A^U(x)] \subseteq [0,1]$  is the non-membership interval

$$0 \leq \mu_A^L(x) + \mu_A^U(x) \leq 1$$

$$0 \leq v_A^L(x) + v_A^U(x) \leq 1$$

$$0 \leq \mu_A^U(x) + v_A^L(x) \leq 1 \text{ for all } x \in A.$$

**Definition 3.2 Index of IVIFNS**

The IVIFNS index or hesitation margin of x in an IVIFNS A is defined as  $\pi_A(x) = [1 - \mu_A^U(x) - v_A^L(x), 1 - \mu_A^L(x) - v_A^U(x)]$

**Example**

Let  $A = \{ \langle x, [0.5,0.6], [0.1,0.3] \rangle \mid x \in X \}$  be an IVIFNS on X, then

$$\pi_A(x) = [1 - \mu_A^U(x) - v_A^L(x), 1 - \mu_A^L(x) - v_A^U(x)]$$

$$\pi_A(x) = [1 - 0.6 - 0.1, 1 - 0.5 - 0.3]$$

$$= [0.3,0.2]$$

The hesitation margin of IVIFNS A of x is [0.3,0.2].

Definition 3.3 Interval-Valued Intuitionistic Fuzzy Nano Topological Space (IVIFNTS)

Let X be a non-empty set. An IVIFNTS on X is a family  $\tau$  of interval-valued intuitionistic fuzzy nano sets (IVIFNS) satisfying

$$\emptyset, X \in \tau$$

$$A, B \in \tau \text{ implies } A \cap B \in \tau$$

$$\{A_i \mid i \in I\} \subseteq \tau \text{ implies } \cup \{A_i \mid i \in I\} \in \tau$$

The pair  $(X, \tau(X))$  is called interval-valued intuitionistic fuzzy nano topological space (IVIFNTS) and IVIFNS in  $\tau(X)$  is said to be Interval-valued intuitionistic fuzzy nano open sets (IVIFNOS) in X .

The complement of  $A^c$  of an IVIFNOS A in IVIFNTS  $(X, \tau(X))$  is called an interval-valued intuitionistic fuzzy nano closed set (IVIFNCS) in X.

Example 1:

Let  $X = \{x_1, x_2, x_3\}$  and  $\tau(X) = \{\emptyset, X, A, B, C\}$  be a family of IVIFNS. where

$$A = \{ \langle x_1, [0.4,0.6], [0.3,0.5] \rangle, \langle x_2, [0.2,0.4], [0.6,0.8] \rangle, \langle x_3, [0.1,0.3], [0.7,0.9] \rangle \}$$

$$B = \{ \langle x_1, [0.6,0.8], [0.2,0.4] \rangle, \langle x_2, [0.4,0.6], [0.4,0.6] \rangle, \langle x_3, [0.3,0.5], [0.5,0.7] \rangle \}$$

$$C = \{ \langle x_1, [0.8,1], [0.1,0.3] \rangle, \langle x_2, [0.6,0.8], [0.3,0.5] \rangle, \langle x_3, [0.5,0.7], [0.4,0.6] \rangle \}$$

Then  $(X, \tau(X))$  is an IVIFNTS.

**Definition 3.4**

Let  $(X, \tau(X))$  be an IVIFNTS and  $A = \{ \langle x, [\mu_A^L(x), \mu_A^U(x)], [v_A^L(x), v_A^U(x)] \rangle \}$  be an IVIFNS in X. Then the interval valued intuitionistic fuzzy nano interior and interval valued intuitionistic fuzzy nano closure are denoted by  $int(A) = \cup \{G \mid G \text{ is an IVIFNOS in } X \text{ and } G \subseteq A\}$

$$cl(A) = \cap \{G \mid G \text{ is an IVIFNCS in } X \text{ and } G \subseteq K\}$$

$$cl(A) = \cap \{G \mid G \text{ is an IVIFNCS in } X \text{ and } G \subseteq K\}$$

**3.5 Operations on Interval-valued Intuitionistic Fuzzy Nano Sets**

Let X be a non-empty set, and let A and B be two IVIFNS in IVIFNTS of the form

$$A = \{ \langle x, [\mu_A^L(x), \mu_A^U(x)], [v_A^L(x), v_A^U(x)] \rangle \mid x \in X \}$$

$$B = \{ \langle x, [\mu_B^L(x), \mu_B^U(x)], [v_B^L(x), v_B^U(x)] \rangle \mid x \in X \}$$

$$\bar{A} = \{ \langle x, [v_A^L(x), v_A^U(x)], [\mu_A^L(x), \mu_A^U(x)] \rangle \mid x \in X \}$$

$$A \cup B = \{ \langle x, [\mu_{A \cup B}^L(x), \mu_{A \cup B}^U(x)], [v_{A \cup B}^L(x), v_{A \cup B}^U(x)] \rangle \mid x \in X \}$$

where  $\mu_{A \cup B}^L(x) = \max \{ \mu_A^L(x), \mu_B^L(x) \}$

$$\mu_{A \cup B}^U(x) = \max \{ \mu_A^U(x), \mu_B^U(x) \}$$

$$v_{A \cup B}^L(x) = \min \{ v_A^L(x), v_B^L(x) \}$$

$$v_{A \cup B}^U(x) = \min \{ v_A^U(x), v_B^U(x) \}$$

**Malathi and Manonmani**

Example2:

Let  $X = \{x_1, x_2, x_3\}$ , and A, B be two IVIFNS

$$A = \{(x_1, [0.4, 0.5], [0.3, 0.5]), (x_2, [0.2, 0.4], [0.6, 0.4]), (x_3, [0.1, 0.3], [0.7, 0.9])\}$$

$$B = \{(x_1, [0.6, 0.3], [0.2, 0.4]), (x_2, [0.2, 0.4], [0.2, 0.6]), (x_3, [0.3, 0.5], [0.5, 0.7])\}$$

$$A \cup B = \{(x_1, [0.6, 0.5], [0.2, 0.4]), (x_2, [0.4, 0.6], [0.2, 0.6]), (x_3, [0.3, 0.5], [0.5, 0.7])\}$$

Then,  $A \cup B$  is also an

IVIFNS.  $A \cap B = \{ \langle x, [\mu_{A \cap B}^L(x), \mu_{A \cap B}^U(x)], [v_{A \cap B}^L(x), v_{A \cap B}^U(x)] \mid x \in X \}$

where  $\mu_{A \cap B}^L(x) = \min \{ \mu_A^L(x), \mu_B^L(x) \}$

$$\mu_{A \cap B}^U(x) = \min \{ \mu_A^U(x), \mu_B^U(x) \}$$

$$v_{A \cap B}^L(x) = \max \{ v_A^L(x), v_B^L(x) \}$$

$$v_{A \cap B}^U(x) = \max \{ v_A^U(x), v_B^U(x) \}$$

**Example 2**

Let  $X = \{x_1, x_2, x_3\}$ , and A, B be two IVIFNS

$$A = \{(x_1, [0.4, 0.5], [0.3, 0.5]), (x_2, [0.2, 0.4], [0.6, 0.4]), (x_3, [0.1, 0.3], [0.7, 0.9])\}$$

$$B = \{(x_1, [0.6, 0.3], [0.2, 0.4]), (x_2, [0.2, 0.4], [0.2, 0.6]), (x_3, [0.3, 0.5], [0.5, 0.7])\}$$

$$A \cap B = \{(x_1, [0.4, 0.3], [0.3, 0.5]), (x_2, [0.2, 0.4], [0.6, 0.6]), (x_3, [0.1, 0.3], [0.7, 0.9])\}$$

Then,  $A \cap B$  is also an IVIFNS.

**PREPOSITIONS**

**Commutative Law**

Let A and B be two IVIFNS in IVIFNTS then,  $A \cup B = B \cup A$

$$A \cap B = B \cap A$$

Proof:

$$A = \{ \langle x, [\mu_A^L(x), \mu_A^U(x)], [v_A^L(x), v_A^U(x)] \mid x \in X \rangle \text{ and}$$

$$B = \{ \langle x, [\mu_B^L(x), \mu_B^U(x)], [v_B^L(x), v_B^U(x)] \mid x \in X \rangle \text{ be two IVIFNS}$$

$$A \cup B = \{ \langle x, [\mu_{A \cup B}^L(x), \mu_{A \cup B}^U(x)], [v_{A \cup B}^L(x), v_{A \cup B}^U(x)] \mid x \in X \rangle$$

$$= \{ \langle x, [\max(\mu_A^L(x), \mu_B^L(x)), \max(\mu_A^U(x), \mu_B^U(x))],$$

$$[\min(v_A^L(x), v_B^L(x)), \min(v_A^U(x), v_B^U(x))] \mid x \in X \rangle$$

$$= \{ \langle x, [\max(\mu_B^L(x), \mu_A^L(x)), \max(\mu_B^U(x), \mu_A^U(x))],$$

$$[\min(v_B^L(x), v_A^L(x)), \min(v_B^U(x), v_A^U(x))] \mid x \in X \rangle$$

$$= \{ \langle x, [\mu_{B \cup A}^L(x), \mu_{B \cup A}^U(x)], [v_{B \cup A}^L(x), v_{B \cup A}^U(x)] \mid x \in X \rangle$$

$$= B \cup A$$

$$\Rightarrow A \cup B = B \cup A$$

$$A \cap B = \{ \langle x, [\mu_{A \cap B}^L(x), \mu_{A \cap B}^U(x)], [v_{A \cap B}^L(x), v_{A \cap B}^U(x)] \mid x \in X \rangle$$

$$= \{ \langle x, [\max(\mu_A^L(x), \mu_B^L(x)), \max(\mu_A^U(x), \mu_B^U(x))],$$

$$[\min(v_A^L(x), v_B^L(x)), \min(v_A^U(x), v_B^U(x))] \mid x \in X \rangle$$

$$= \{ \langle x, [\max(\mu_A^L(x), \mu_B^L(x)), \max(\mu_A^U(x), \mu_B^U(x))],$$

$$[\min(v_A^L(x), v_B^L(x)), \min(v_A^U(x), v_B^U(x))] \mid x \in X \rangle$$

$$= \{ \langle x, [\mu_{B \cap A}^L(x), \mu_{B \cap A}^U(x)], [v_{B \cap A}^L(x), v_{B \cap A}^U(x)] \mid x \in X \rangle$$

$$= B \cap A$$

$$\Rightarrow A \cap B = B \cap A$$

Hence the commutative law is Verified

**Example3.**

Let  $X = \{x_1, x_2, x_3\}$ ,

$$A = \{(x_1, [0.4, 0.5], [0.3, 0.5]), (x_2, [0.2, 0.4], [0.6, 0.4]), (x_3, [0.1, 0.3], [0.7, 0.9])\}$$

$$B = \{(x_1, [0.6, 0.3], [0.2, 0.4]), (x_2, [0.2, 0.4], [0.2, 0.6]), (x_3, [0.3, 0.5], [0.5, 0.7])\}$$

### Malathi and Manonmani

$$A \cup B = \{(x_1, [0.6, 0.5], [0.2, 0.4]), (x_2, [0.4, 0.6], [0.2, 0.6]), (x_3, [0.3, 0.5], [0.5, 0.7])\}$$

$$B \cup A = \{(x_1, [0.6, 0.5], [0.2, 0.4]), (x_2, [0.4, 0.6], [0.2, 0.6]), (x_3, [0.3, 0.5], [0.5, 0.7])\}$$

$$\Rightarrow A \cup B = B \cup A$$

$$A \cap B = \{(x_1, [0.4, 0.3], [0.3, 0.5]), (x_2, [0.2, 0.4], [0.6, 0.6]), (x_3, [0.1, 0.3], [0.7, 0.9])\}$$

$$B \cap A = \{(x_1, [0.4, 0.3], [0.3, 0.5]), (x_2, [0.2, 0.4], [0.6, 0.6]), (x_3, [0.1, 0.3], [0.7, 0.9])\}$$

$$\Rightarrow A \cap B = B \cap A$$

## CONCLUSION

In this paper, we have introduced the concept of interval-valued intuitionistic fuzzy nano topology (IVIFNT). We have explored its interior, closure and basic operations like union and intersection. IVIFNTS provides framework for modeling and uncertainty and vagueness in various domains, offering a new perspective on topological structures.

### ABSTRACT

This research article presents a novel algorithm and methodology for Multi Dimensional Chain Sampling for various processes from neutrosophic sources of production. In multidimensional chain sampling inspection the process parameter  $p$  and the index  $i$  are vague and hence parameters are neutrosophic. The measures of acceptance sampling plans are planned with fuzzy parameters and the corresponding probability functions are evaluated.

**Keywords:** Multi Dimensional Chain Sampling plan, Operating Characteristic Function and Neutrosophic Statistics.

### INTRODUCTION

Statistical Quality Control is a methodology used to monitor and control the quality of the products. The SQC tools and techniques are used to measure, analyze and monitor the process during manufacturing time. The main aim is to reduce or eliminate defects in a production process. A variable sampling plan is an acceptance sampling technique that is measured on a continue scale to monitor the quality characteristics. The sampling plans quality characteristics are assumed to follow normal distribution. A variable sampling plan provides more information compared to attribute plan. Neutrosophic Quality Environment is an extension of classical quality control division designed to handle uncertainty, imprecision, vagueness, and indeterminacy in a production process. Prof. Dodge (1955)

### Deva Arul and Shanthi

introduced the chain sampling plans (ChSP-1). The ChSP decision on lots depends upon the past lots results. The parameters of the acceptance sampling plans are not possible to define as crisp values if number defectives vary largely lot by lot. These parameters can be managed by neutrosophic variables. The fuzzy set theories can be successfully used to handle with the vagueness in these variables and hence neutrosophic acceptance samplings are being developed. Govindaraju and Subramani (1993) have studied the Chain Sampling Plans indexed through Acceptable Quality Level (AQL) and Limiting Quality Level (LQL). Ezzatallah BalouiJamkhaneh et.al. (2011) have specified the chain sampling plan when the proportion defective is a trapezoidal fuzzy number. Ebru Turanoglu et.al. (2012) have designed acceptance sampling plans with fuzzy parameters and derived its acceptance probability functions. DevaArul and Vijila Moses (2017) have studied the new development of RChSP(0,i). Elango et.al. (2017) have studied fuzzy acceptance sampling based on fuzzy gamma distribution and generalized distribution. Nandhini Devi and Uma (2018) have studied fuzzy on Quick Switching Systems using Poisson distribution. Deva Arul and Jothimani (2020) have studied some properties of TSRChSP. Ramya and Uma (2020) have studied Quick Switching Double Sampling System when the fraction defectives are fuzzy number and being modeled based on the Fuzzy Poisson distribution. Sangeetha and Karunya (2022) have designed chain sampling plans for two stage chain sampling. Kavi Priya and Subramani Ramasamy (2022) have studied two-sided complete chain sampling plan using fuzzy parameters. Julia Thampy Thomas and Mahesh Kumar (2023) have compared existing fuzzy acceptance sampling plans for attributes. Rebecca Jebaseeli Edna and Jemmy Joyce (2020) have derived the operating characteristic curve of the sampling plan using fuzzy probability.

#### Notation and Definition

Let, N = Lot size, n = Sample size

$\bar{x}$  = Mean where,  $\bar{x}_i = \frac{\sum x_i}{n}$

$\sigma$  = Standard Deviation where,  $\sigma = \sqrt{\frac{\sum(x_i - \mu)^2}{N}}$

U = Upper Specification Limit

i = Preceding isamples

1 -  $\alpha$  = Producer's Risk

$\beta$  = Consumer's Risk

AQL<sub>n</sub> = Neutrosophic Acceptable Quality Level

LQL<sub>n</sub> = Neutrosophic Limiting Quality Level

$\tilde{T}$ ,  $\tilde{I}$ ,  $\tilde{F}$  = Neutrosophic components expressed as fuzzy numbers for each quality dimension

$\tilde{w}$  = Fuzzy variable factor such that lot is accepted,

if  $\bar{x}_k + \tilde{w}_k \sigma_k \leq U_k$  (or)  $\bar{x}_k + \tilde{w}_k \sigma_k \geq L_k$

k defines the combination of fuzzy and neutrosophic parameter

Let AQL( $p_{1n}$ ) and LQL( $p_{2n}$ ) - Fuzzy membership function, it represent the degrees of quality level in neutrosophic quality environment.

#### Algorithm to Sentence a lot.

Step 1: Let U be the upper specification given by the consumer and  $\sigma$  is the known process standard deviation.

Step 2: Draw a sample of size n, for the known AQL<sub>n</sub> and index i.

Step 3: Calculate the sample mean, standard deviation, and fuzzy variable factor  $\tilde{w}$

Step 4: If  $\bar{x}_k \leq U_k - \tilde{w}_k \sigma_k$ , accept the lot.

Step 5: If  $\bar{x}_k > U_k - \tilde{w}_k \sigma_k$ , go to next step.

Step 6: Accept the current lot provided preceding i lots have been accepted on the criterion that  $\{\bar{x}_k \leq U_k - \tilde{w}_k \sigma_k\}$ . Otherwise reject the lot.

#### Neutrosophic Probability of acceptance:

The probability of acceptance of the lot for a multi-dimensional chain sampling plan with neutrosophic  $p_n$  can be expressed as:

**Deva Arul and Shanthi**

$$P_a(p_n) = \prod_{k=1}^K [P[\bar{x}_k \leq U_k - \tilde{w}_k \sigma_k] + P[\bar{x}_k > U_k - \tilde{w}_k \sigma_k] \{P[\bar{x}_k \leq U_k - \tilde{w}_k \sigma_k]\}^i]$$

The lot will be accepted if the following cases are satisfies.

Case (i): if  $\bar{x}_k \leq U_k - \tilde{w}_k \sigma_k$

Case (ii): if  $\bar{x}_k > U_k - \tilde{w}_k \sigma_k$  and  $\{\bar{x}_k \leq U_k - \tilde{w}_k \sigma_k\}^i$

Case (i) and Case (ii) are mutually exclusive events

Therefore,

$$P_a(p) = P(i) + P(ii)$$

$$\begin{aligned} &= P[\bar{x}_k \leq U_k - \tilde{w}_k \sigma_k] + P[\bar{x}_k > U_k - \tilde{w}_k \sigma_k] \{P[\bar{x}_k \leq U_k - \tilde{w}_k \sigma_k]\}^i \\ &= P_n[\bar{x}_k \leq U_k - \tilde{w}_k \sigma_k] + P_n[\bar{x}_k > U_k - \tilde{w}_k \sigma_k] \{P_n[\bar{x}_k \leq U_k - \tilde{w}_k \sigma_k]\}^i \\ &= \int_{-\infty}^{U_k - \tilde{w}_k \sigma_k} f(\bar{x}) dx + \int_{\bar{x}_k > U_k - \tilde{w}_k \sigma_k}^{\infty} f(\bar{x}) dx \cdot \int_{-\infty}^{(U_k - \tilde{w}_k \sigma_k)^i} f(\bar{x}) dx \end{aligned}$$

**Designing MDCh SP through AQL<sub>n</sub>:**

Let the index  $i=3$ . Then the parameters of MDChSP for known sigma are  $(n_1, n_2, n_3, \tilde{w}_1, \tilde{w}_2, \tilde{w}_3)$ . The sample size  $n_1, n_2, n_3$  and neutrosophic variable factors  $\tilde{w}_1, \tilde{w}_2, \tilde{w}_3$  are determined based on the following designing procedure.

**Step: 1** Let the probability of acceptance of the fraction defectives  $p_{1n}, p_{2n}, p_{3n}$  is

$1 - \alpha$  or  $P_a(p_{1n}, p_{2n}, p_{3n}) \geq 1 - \alpha$ , Let the level  $\alpha = 0.05$ .

**Step: 2** Now determine the sample of size  $n_1, n_2, n_3$  and fuzzy variable factor  $\tilde{w}_1, \tilde{w}_2, \tilde{w}_3$  for the given index  $i$ , from the following equation.

$$\prod_{k=1}^K [P[\bar{x}_k \leq U_k - \tilde{w}_k \sigma_k] + P[\bar{x}_k > U_k - \tilde{w}_k \sigma_k] \{P[\bar{x}_k \leq U_k - \tilde{w}_k \sigma_k]\}^i] \geq 0.95$$

A computer program is written to solve the above fuzzy equation and hence the table is constructed for the easy selection of sampling plans.

Similarly, one can design the sampling plans for neutrosophic LQL.

$$AQL(p_{1n}) = AQL(p_{1n}) = \begin{cases} 0, & x \leq p_{1n} \\ \frac{x - p_{1n}}{p_{2n} - p_{1n}}, & p_{1n} < x < p_{2n} \\ 1, & x = p_{2n} \\ \frac{p_{3n} - x}{p_{3n} - p_{2n}}, & p_{2n} < x < p_{3n} \\ 0, & x \geq p_{3n} \end{cases}$$

Similarly  $LQL(p_{2n})$  membership function can be determined.

**Illustration 1:** Obtain Neutrosophic MDChSP by variables if the known  $p_{1n} = 0.0002, p_{2n} = 0.0003, p_{3n} = 0.0004$  when index  $i = 3$

**Solution:** From the table 1, when  $i=3$ , the sample size  $n_{11} = 43, n_{12} = 50, n_{13} = 60$  and variable factor  $\tilde{w}_{11} = 3.4217, \tilde{w}_{12} = 3.2964, \tilde{w}_{13} = 3.2315$  and probability of acceptance  $P_a(p) = 0.95004$ .

**CONCLUSION**

A Multi-Dimensional Chain Sampling Plan (MDChSP) utilizing neutrosophic statistics to handle the vagueness and uncertainty in process parameters, such as the AQL<sub>n</sub> and LQL<sub>n</sub>. The integration of neutrosophic statistics and fuzzy sets allowed for a more flexible and comprehensive evaluation of product quality, particularly when dealing with multidimensional quality levels for an intermittent production sources.

### ABSTRACT

A new concept called fuzzy infra j open set, fuzzy infra j closed, and fuzzy infra j continuous function in fuzzy infra j topological spaces are introduced. Some basic properties concerning the infra j open set, infra j closed set, infra j continuous function are analyzed with suitable examples. We also investigate the relation and the converse relation among these new concepts. Further, we generalize this idea and characterize with existing sets.

**Keywords:** Fuzzy infra j open set, Fuzzy infra j closed set, Fuzzy infra j closure, Fuzzy infra j interior, Fuzzy infra j continuous function.

## INTRODUCTION

Lotfi A. Zadeh independently introduced fuzzy sets in 1965.[10], an extension classification of a set. Sets with degree of membership elements are called fuzzy sets. On Fuzzy topological sets, the hypothesis of the definition are termed as Fuzzy Topological spaces [chang][2]. Michalek pinpoint and look over further idea of fuzzy topological spaces in the paper respectively[6]. Latter on, hand full researchers came with the development in the theory and application of fuzzy topology. Considering fuzzy sets and various sets, functions that are stronger or weaker than these concepts are found to be very helpful and form a significant portion of the research in fuzzy topology and fuzzy analysis. The author [11] demonstrated that any closed has an accompanying open, then the converse is equally true. Wenzhong and kimfung[10] based the closure, interior and the idea of arithmetical topological fuzzy was established. D.Sasikala, Divya [8] discussed the concept of strong forms of generalized j-closed sets in ditopological texture spaces. The author [9] analyzed the decomposition of j-closed set in bigeneralized topological spaces.

In Infra topological spaces, the conception was distinctly acknowledged by Al-odhari[1]. On the flipside, infra topological spaces was practically studied by witzcak significant in [7]. The terms of witzcak & AL-odhari inspired the

Sasikala and Mahima

author to learn infra fuzzy topological spaces. Infra fuzzy semiopen sets was introduced by Hakeem A.Othman in 2016[4]. B. Ahmaddiscussed the concept of Fuzzy set, Fuzzy s-open and s- closed mapping [4]. In this paper, we investigate the class of infra j open set, infra j closed set, infra j closure,infra j interior and infra j continuous functionthe fuzzy infratopological space. The relation and the converse relation between these new concepts are studied. Farther, the notation of consider sets is to acquaint and explore several attentiveness properties of this new conception are explored.

PRELIMINARIES

Definition 2.1[14]

If X is a universe of discourse and x be any particular element of X, the fuzzy set A defined on X is a collection of ordered pairs  $A = \{(x, \mu_A(x)) / x \in X\}$ , where  $\mu_A(x): X \rightarrow [0,1]$  is called the membership function.

Definition 2.2 [14]

Let X is fuzzy topology  $X = \{ \mu: \mu \text{ is } x \}$  of fuzzy subset that fulfills the subsequent axioms.

- (i)  $0, 1 \in X$
- (ii)  $\sigma_1, \sigma_2 \in X, \sigma_1 \wedge \sigma_2 \in X$
- (iii) If  $\{ \sigma_i : i \in J \} \subset X$ , j is known to be index set, then  $\cup_j \sigma_i \in X$ .

Definition 2.3[1]

A subcollection X of  $\delta(Z)$  if there exists an IFTon z, then

- (i)  $0, 1 \in X$
- (ii)  $\sigma_1 \wedge \sigma_2 \in X$  Whenever  $\sigma_1, \sigma_2 \in X$ .

IFT (Z) is the set of infra-fuzzy topologies on Z; the pair (Z,T) constitutes an infra-fuzzy topological space. The infra-fuzzy closed sets are the complements of T, and members of T are referred to as the infra-fuzzy open subsets of Z. Each of the members of  $T^c$  are frequently referred to as "IF-closed".

Definition 2.4[5]

Ina topological spaces  $(X, \mathfrak{T})$  for any subset  $A \subseteq X, A$  is called a j - open set if  $A \subseteq \text{int } p(\text{cl } A)$ .

Definition 2.5[5]

Let  $(X, \mathfrak{T})$  be a topological space and  $A \subset G$ . Then j - closure of A, denoted by  $(jcl A)$  is defined as the smallest j-closed contains A .It is thus intersection of all j closed set that contain A.

Definition 2.6[5]

Fuzzy function  $f: G \rightarrow H$  is known as  $f(\sigma) \in FSO(Y), \forall \sigma \in FO(X)$ .  
 Fuzzy function  $f: G \rightarrow H$  is known as  $f(\sigma) \in FSC(Y), \forall \sigma \in FC(X)$ .

Definition 2.7[5]

Let  $f: G \rightarrow H$  be a function:  
 Let  $u \in H$ , for all fuzzy closed (open) set called fuzzy infra- $\alpha$ -continuous then  $f^{-1}(u) \in IF\alpha C(X) (IF\alpha O(X))$ .

Definition 2.8[1]

Let the point where fuzzy set union G and H is  $G \cup H$ , where  $\mu_{G \cup H} = \max \{ \mu_G(x), \mu_H(x) \}$ .

Definition 2.9[1]

Let the point where fuzzy set intersect G and H is  $G \cap H$ , where  $\mu_{G \cap H} = \min \{ \mu_G(x), \mu_H(x) \}$ .

Fuzzy infra j open set

Definition 3.1:

1. If  $(X, \mathfrak{T}_{fix})$  be FITS. A set  $\psi$  is supposed to be fuzzy infra jopen if  $\gamma \leq \psi \leq jcl(\gamma)$ , where  $\gamma$  is fuzzy open.
2. Let  $(X, \mathfrak{T}_{fix})$  known to be FITS. A set  $\psi$  is known to be fuzzy infra j closed if  $j \text{ int}(\gamma) \leq \psi \leq \gamma$ , where  $\gamma$  is fuzzy closed.

**Sasikala and Mahima**

3. If  $(X, \mathcal{T}_{fix})$  be a FITS then  $\sigma$  be fuzzy set if  $Ij\ cl\ \sigma = \wedge \{ \psi : \psi \geq \sigma, \psi \in FIjC(X) \}$  is called a fuzzy infra  $j$  closure.
4. If  $(X, \mathcal{T}_{fix})$  be FITS and  $\sigma$  be fuzzy set if  $Ij\ int\ \sigma = \vee \{ \psi : \psi \leq \sigma, \psi \in FIjO(X) \}$  called a fuzzy infra  $j$  interior.
5. If  $(X, \mathcal{T}_{fix})$  be FITS. A set  $\sigma$  is fuzzy infra generalized  $j$  closed set if  $Ijcp(\sigma) \subseteq \gamma$ , where  $\sigma \subseteq \gamma$  and  $\gamma$  is fuzzy  $j$  open.
6. Let  $(X, \mathcal{T}_{fix})$  be a FITS. A set  $\sigma$  is fuzzy infra  $j$  generalized closed set if  $Ijcp(\sigma) \subseteq \gamma$ , where  $\sigma \subseteq \gamma$  and  $\gamma$  is fuzzy open.

**EXAMPLE 3.2:**

If  $X = \{t, r\}$  and  $q_1, q_2, q_3$  and  $q_4$  of  $X$ :

$$q_1(t) = 0.2, q_1(r) = 0.3$$

$$q_2(t) = 0.3, q_2(r) = 0.4$$

$$q_3(t) = 0.4, q_3(r) = 0.7$$

$$q_4(t) = 0.6, q_4(r) = 0.4$$

$$\text{Let } \mathcal{T} = \{0_x, q_1, q_2, q_1 \vee q_2, q_1 \wedge q_2\}$$

$$j\ int\ (q_4^c) = \vee \binom{0.2 \leq g < 0.4}{0.4} \text{ But } j\ int\ (l) = l_2$$

$$\text{Then, } j\ int\ (q_4^c) \leq j\ int\ (q_4^c) \leq q_4^c$$

$$j\ cl\ (q_2) = \wedge \binom{0.2 < g \leq 0.4}{0.4} \text{ But } j\ cl\ (q_2) = q_4^c$$

$$\text{Then, } q_2 \leq j\ cl\ (q_2) \leq j\ cl\ (q_2).$$

**Theorem 3.3:**

For a fuzzy subset  $\sigma$  of  $X$ , subsequent criteria are true:

- (i)  $(Ij\ int\ \sigma)^c = Ij\ cl\ \sigma$
- (ii)  $(Ij\ cl\ \sigma)^c = Ij\ int\ \sigma$
- (iii)  $Ij\ int\ \sigma = \sigma \wedge cl\ p\ (int\ \sigma)$
- (iv)  $Ij\ cl\ \sigma = \sigma \vee int\ p\ (cl\ \sigma)$

**Proof:**

$$(i) \quad (Ij\ int\ \sigma)^c = Ij\ cl\ \sigma$$

$$(Ij\ int\ \sigma)^c = \vee \{ \psi : \psi \leq \sigma, \psi \in FIjO(X) \}^c$$

$$= \wedge \{ \psi^c : \psi^c \geq \sigma, \psi^c \in FIjC(X) \} = Ij\ cl\ \sigma.$$

$$(ii) \quad (Ij\ cl\ \sigma)^c = Ij\ int\ \sigma$$

$$(Ij\ cl\ \sigma)^c = \wedge \{ \psi : \psi \geq \sigma, \psi \in FIjC(X) \}^c = \vee \{ \psi^c : \psi^c \leq \sigma, \psi^c \in FIjO(X) \} = Ij\ int\ \sigma.$$

$$(iii) \quad Ij\ int\ \sigma = \sigma \wedge cl\ p\ (int\ \sigma)$$

$$Ij\ int\ \sigma \leq cl\ p\ (int\ (Ij\ int\ \sigma))$$

$$\leq cl\ p\ (int\ \sigma)$$

$$Ij\ int\ (\sigma) \leq \sigma \wedge cl\ p\ (int\ \sigma) \quad \dots (1)$$

$$int\ (\sigma) \leq \sigma \wedge cl\ p\ (int\ \sigma) \leq cl\ p\ (int\ \sigma)$$

$$\sigma \wedge cl\ p\ (int\ \sigma) \in FIjO(X) \text{ and } \sigma \wedge cl\ p\ (int\ \sigma) \leq \sigma$$

Then,

$$\sigma \wedge cl\ p\ (int\ \sigma) \leq Ij\ int\ (\sigma) \quad \dots (2)$$

From (1) along with (2)

$$Ij\ int\ \sigma = \sigma \wedge cl\ p\ (int\ \sigma)$$

$$(iv) \quad Ij\ cl\ \sigma = \sigma \vee cl\ p\ (int\ \sigma)$$

$$Ij\ cl\ \sigma \leq int\ p\ (cl\ (Ij\ cl\ \sigma)) \leq int\ p\ (cl\ (\sigma))$$

$$Ij\ cl\ \sigma \leq \sigma \vee int\ p\ (cl\ (\sigma)) \quad \dots (1)$$

$$cl\ (\sigma) \leq \sigma \vee int\ p\ (cl\ \sigma)$$

$$\sigma \vee int\ p\ (cl\ (\sigma)) \in FIjO(X), \sigma \vee int\ p\ (cl\ \sigma)$$

$$\sigma \vee int\ p\ (cl\ (\sigma)) \leq Ij\ cl\ (\sigma) \quad \dots (2)$$

**Sasikala and Mahima**

From (1) and (2)  
 $I j cl \sigma = \sigma \vee int p (cl \sigma)$

**Theorem 3.9:**

If  $\sigma \in FljO (X)$ , then  $I j cl (\sigma) \in FljO(X)$

**Proof:**

If  $\sigma \in FljO (X)$   
 $\sigma \leq cl p (int(\sigma)) \leq cl p (int \sigma)$   
 $I j cl (\sigma) \leq I j cl (cl p (int (I j cl (\sigma))))$   
 $= cl p (int (I j cl (\sigma)))$   
 $I j cl (\sigma) \in FljO(x)$

**Theorem 3.10:**

- i) If  $\psi \in FljO (X)$  and  $\psi \leq \sigma \leq cl \psi$ , then  $\sigma \in FljO (X)$
- ii) If  $\psi \in FljC (X)$  and  $int \psi \leq \sigma \leq \psi$ ,  $\sigma \in IFjC (X)$

**Proof:**

(i) If  $\psi \in FljO (X)$   
 $\gamma \leq \psi \leq cl(\gamma)$ ,  $\gamma \leq \sigma$ ,  $\psi \leq cl(\gamma)$ ,  
 $cl(\psi) \leq cl(\gamma)$   
 $\gamma \leq \sigma \leq cl(\gamma)$   
 Then,  $\sigma \in FljO (X)$   
 (ii) If  $\psi \in FljC (X)$   
 $int \psi \leq \psi \leq \gamma$ ,  $\gamma \leq \sigma$ ,  $\psi \leq int(\gamma)$ ,  
 $int(\psi) \leq int(\gamma)$   
 Therefore,  $int \gamma \leq \sigma \leq \gamma$   
 Then,  $\sigma \in IFjC (X)$ .

**Theorem 3.11:**

Let  $\sigma$  be a fuzzy subset of  $X$ , then  $int \sigma \leq I j int \sigma \leq \sigma \leq I j cl \sigma \leq cl \sigma$

**Proof:**

$int \sigma \leq \sigma$   
 $I j int (int \sigma) \leq I j int \sigma$   
 Then,  $int \sigma \leq I j int \sigma \leq \sigma$  .... (1)  
 $\sigma \leq I j cl \sigma \leq cl \sigma$  .....(2)  
 From (1) and (2)  
 $int \sigma \leq I j int \sigma \leq \sigma \leq I j cl \sigma \leq cl \sigma$ .

**Theorem 3.12:**

If  $\sigma$  is a subset of  $(X, \mathcal{U}_{fix})$ , then the declaration below is true

- (i) If  $\sigma$  fuzzy infra  $j$  closed set, if and only if  $\sigma$  is fuzzy  $j$  closed set.
- (ii) If  $\sigma$  will be fuzzy infra *pre*- closed (*pre – open*), then  $\sigma$  be fuzzy infra  $j$  closed set.
- (iii) If  $\sigma$  be fuzzy closed (open), then  $\sigma$  is  $Flj$  closed (infra  $j$  open) set.

**Proof:**

The Proof is obvious by the definition.

**Theorem 3.13:**

Each fuzzy infra  $j$  closed set is infra fuzzy generalized set is  $j$  closed

**Sasikala and Mahima**

**Proof:**

Let  $\sigma$  be Finfraset is  $j$  closed in  $(X, \mathbb{T}_{fix})$  such that  $\gamma$  be fuzzy infra open set containing  $\sigma$ ,  
 Since  $\sigma$  is fuzzyinfra  $j$  closed,  $j \text{ int } cp(\sigma) = \sigma$   
 $j \text{ int } cp(\sigma) \subseteq \gamma$   
 Hence  $\sigma$  is fuzzy infra generalized  $j$  closed set.

**Definition 3.14:**

A fuzzy infra union  $GUIH$  is said to be a union of fuzzy infra set  $G$  and  $H$  if  
 $\sigma_\chi GUIH = \max[\sigma_\chi G(x), \sigma_\chi H(x)]$  or  $\sigma_\chi G(x) \vee \sigma_\chi H(x)$

**Definition 3.15:**

A fuzzy infra intersection  $G \cap H$  is said to be a intersection of fuzzy infra set  $G$  and  $H$  if  
 $\sigma_\chi G \cap H = \min [\sigma_\chi G(x), \sigma_\chi H(x)]$  or  $\sigma_\chi G(x) \wedge \sigma_\chi H(x)$

**Theorem 3.16:**

- (i) A fuzzy infra  $j$  open set is equal to the union of any number of its members.
- (ii) A fuzzy infra  $j$  closed set is equal to the intersection of any number of its members.

**Proof:**

(i) Let  $\{\sigma_\chi\}$  be fuzzy infra  $j$  open.  
 Then for each  $\chi$ ,  
 $\sigma_\chi \leq \text{int } p(\text{cl } \sigma)$ ,  $\vee \sigma_\chi \leq \text{int } p(\text{cl } \sigma)$   
 $\leq \text{int } p(\text{cl } \sigma)$   
 Hence  $\vee \sigma_\chi$  is fuzzy infra  $j$  open set.

(ii) It is obvious.

**Example 3.17:**

Let  $A = \{x: 10 \leq x \leq 20\}$  and  $B = \{15 \leq x \leq 25\}$ .  
 $\sigma_\chi A \cup B = \max[\sigma_\chi A(x), \sigma_\chi B(x)]$   
 $= \max [\{x: 10 \leq x \leq 20\}, \{15 \leq x \leq 25\}]$   
 $= 1, \text{ when } 10 \leq x \leq 15$   
 $0 \text{ otherwise}$   
 $A \cap B = \min [A(x), B(x)]$   
 $= \min [\{x: 10 \leq x \leq 20\}, \{15 \leq x \leq 25\}]$   
 $= 1, \text{ When } 15 \leq x \leq 20$   
 $0 \text{ otherwise}$

**Theorem 3.18:**

Consider a fuzzy infra  $j$  closed  $\sigma$  of  $X$ , then  $\sigma \text{ be int } p \text{ cl } \sigma \leq \psi \leq \sigma$ .

**Proof:**

If  $\sigma \in FIjC(X)$ , then  $\text{int } p \text{ cl}(\text{int } \psi) \leq \psi$ , put  $\text{int } \psi = \text{int } p \text{ cl } \sigma \leq \psi \leq \sigma$ .  
 Conversely,  
 Let  $\sigma$  be fuzzy infra  $j$  closed set. such that  $\text{int } p \text{ cl } \sigma \leq \psi \leq \sigma \Rightarrow \text{int } p \text{ cl}(\text{int } \psi) \leq \text{int } p \text{ cl } \sigma$   
 Then,  
 $\text{int } p \text{ cl}(\text{int } \psi) \leq \psi$

**Theorem 3.19:**

A fuzzy set  $\sigma$  be a FTS  $X$ ,  $\sigma$  be a fuzzy infra  $j$  closed iff  $Ij \text{ int } p \text{ cl } \sigma \leq \sigma$ .

**Proof:**

If  $\sigma$  is a FIjCset, that is  $\sigma = Ij \text{ cl } \sigma$ , then  $Ij \text{ int } p \text{ cl } \sigma = Ij \text{ int } \sigma \leq \sigma$ .

**Sasikala and Mahima**

Suppose,

$Ij \text{ int } p \text{ cl } \sigma \leq \sigma$ . Since  $Ij \text{ cl } \sigma$  be a  $FIjC$ , so a closed set  $\psi$  contains that  $\psi \leq Ij \text{ cl } \sigma \leq \psi$ .

Thus  $I \text{ int } \psi \leq Ij \text{ int } p \text{ cl } \sigma \leq \sigma \leq Ij \text{ cl } \sigma \leq \psi$

(or)  $I \text{ int } \psi \leq \sigma \leq \psi$ .

As a result,  $\sigma = Ij \text{ cl } \psi$  as well as  $\sigma$  was fuzzy infraset is  $j$  closed.

**Theorem 3.20:**

Let  $G$  and  $H$  be subset of  $(X, \mathcal{T})$ . Then  $G$  and  $H$  satisfies the following

- (I)  $FIj \text{ cl}(\emptyset) = \emptyset$
- (II)  $G \subseteq Ij \text{ cl}(G)$
- (III) If  $G \subseteq H, Ij \text{ cl}(G) \subseteq Ij \text{ cl}(H)$
- (IV)  $Ij \text{ cl}(Ij \text{ cl}(G)) = Ij \text{ cl}(G)$
- (V)  $Ij \text{ cl}(G \cup H) = Ij \text{ cl}(G) \cup Ij \text{ cl}(H)$

**Theorem 3.21:**

Each fuzzy infra generalized closed set is a fuzzy infra generalized set is  $j$  closed.

**Proof:**

Let  $\sigma$  be a fuzzy infra  $j$  open set in  $(X, \tau_{fix})$  such that  $\psi \subseteq \sigma$ , by hypothesis,  $\psi$  is fuzzy infra generalized  $j$  closed set then  $Icp(\psi) \subseteq \sigma$ , which implies that  $Ijcp(\psi) \subseteq \sigma$

Therefore,  $\psi$  is fuzzy infra generalized  $j$  closed set.

**Fuzzy infra  $j$  continuous - function**

**Definition 4.1:**

Assume  $f: G \rightarrow H$  be map b/w fuzzy sets  $G$  and  $H$  and  $\sigma$  be any fuzzy infra  $j$  closed (open) set in  $H$ . Then  $f$  is said to be fuzzy infra  $j$  continuous if  $f^{-1}(\sigma) \in FIjC(G)$  ( $FIjO(G)$ ) are all fuzzy closed (open) set  $\sigma \in H$ .

**Theorem 4.2:**

The listed properties are equipollent  $f: G \rightarrow H$

- (i)  $f$  is a fuzzy infra  $j$  continuous.
- (ii) Every fuzzy singleton  $U \in G$  and all fuzzy open set  $\psi \in H$  then  $f(U) \leq \psi, \exists$  a fuzzy infra  $j$  open set  $\sigma \in G$ , contains that  $U \leq \sigma$  and  $\sigma \leq f^{-1}(\psi)$ .
- (iii) A fuzzy singleton  $U \in G$ , along for fuzzy open set  $\psi \in H, S.T f(U) \leq \psi \exists$  a fuzzy infra  $j$  open set  $\psi \in y \sigma cx, S.T U \leq \sigma$  and  $f(\sigma) \leq \psi$ .
- (iv)  $f^{-1}(\psi) \in FIjC(G)$ , for all  $\psi \in FC(H)$ .
- (v)  $F(Ijcl(\sigma)) \leq cl(f(\sigma))$  for all  $\sigma \in G$ .
- (vi)  $Ijcl(f^{-1}(\psi)) \leq f^{-1}(cl(\psi))$  for all  $\psi \in H$ .
- (vii)  $f^{-1}(int \psi) \leq Ijcl(f^{-1}(\psi))$  for all  $\psi \in H$ .

**Proof:**

i)  $\rightarrow$  ii)

$\psi \in FO(H)$  and fuzzy singleton  $U \in G$ , such that  $f(U) \subseteq \psi$ , then there exist  $n \in FO(H)$  such that  $f(U) \leq n \leq \psi$  Because  $f$  is a fuzzy infra  $j$  continuous,  $\sigma = f^{-1}(n)$  is fuzzy infra  $j$  open set and  $U \leq \sigma = f^{-1}(n) \leq f^{-1}(\psi)$ .

ii)  $\rightarrow$  iii)

Assume that  $U$  is a fuzzy singletons in  $G$  with the value  $f(U) \subseteq \psi$  as well as  $\psi \in FO(H)$ , then there exist a fuzzy infra  $j$  open set,  $\sigma$  such that  $U \leq \sigma$  and  $\sigma \leq f^{-1}(\psi)$  so we get  $(U \leq \sigma)$  and  $f(\sigma) \leq f^{-1}(f(\psi)) \leq \psi$ .

iii)  $\rightarrow$  iv)

Let  $U \leq f^{-1}(\psi)$  and  $\psi \in FO(H)$ ,  $f(U) \leq f(f^{-1}(\psi))$  a fuzzy infra  $j$  open set  $\sigma$ , contains that  $(U \leq \sigma)$  along with  $f(\sigma) \leq \psi$  we get  $U \leq \sigma \leq f^{-1}(f(\sigma)) \leq f^{-1}(\psi)$  then  $f^{-1}(\psi) \in G$  is fuzzy infra  $j$  open set, then  $f$  is fuzzy infra  $j$  continuous.

i)  $\rightarrow$  iv)

Let  $\psi \in FC(H)$ ,  $\psi^c \in FO(H)$

**Sasikala and Mahima**

Now,  
 $f^{-1}(\psi^c) \in FIjO(G)$  Hence,  $f^{-1}(\psi) \in FIjC(G)$   
 iv)  $\rightarrow$  v)  
 Let  $\sigma \subset G, \sigma \leq f^{-1}(f(\sigma)) \leq f^{-1}(cl f(\sigma))$   
 We get  $Ijcl(\sigma) \leq f^{-1}(cl f(\sigma)) = Ijcl(f^{-1}(cl f(\sigma)))$   
 v)  $\rightarrow$  vi)  
 Let  $\psi \in H, f^{-1}(\psi)$  in  $G$ , in (iv) we get  
 $f(Ijcl(f^{-1}(\psi))) \leq cl(f^{-1}(\psi)) \leq cl\psi, Ijcl(f^{-1}(\psi)) \leq f^{-1}(cl\psi)$ .  
 vi)  $\rightarrow$  vii)  
 Let  $\psi \in H$ , then  $\psi^c \in H$  by (vi)  $Ijcl(f^{-1}(\psi^c)) \leq f^{-1}(cl\psi^c)$ ,  
 $f^{-1}(int\psi) \leq Ijint(f^{-1}(\psi))$ .  
 vii)  $\rightarrow$  i)  
 Let  $\psi \in H$  by (vi) we get  $f^{-1}(\psi) = f^{-1}(int\psi) \leq Ijint(f^{-1}(\psi))$ .  
 Therefore,  
 $f^{-1}(\psi) \in FIjO(G)$ . Then  $f$  is fuzzy infra  $j$  continuous- function.

**Theorem 4.3:**

Every completely fuzzy infra  $j$  continuous - function is a fuzzy infra continuous - function

**Proof:**

If  $f: G \rightarrow H$  be totally fuzzy infra  $j$  continuous - function,  
 Let  $\sigma$  be fuzzy infra open in  $H$ . If  $\sigma$  is a fuzzy infra  $j$  open -set in  $H$  then  $f^{-1}(\sigma)$  is a pair of fuzzy infra  $j$  open set in  $G$ .  
 Therefore  $f^{-1}(\sigma)$  is a FI open in  $G$ .  
 $f$  is a FI continuous-function.

**Theorem 4.4:**

If  $g: G \rightarrow H$  be fuzzy infra  $j$  continuous and  $f: H \rightarrow Z$  be a FCF then  $(f \circ g): G \rightarrow Z$  is fog infra  $j$  continuous - function.

**Proof:**

If  $\psi \in Z$  be a fuzzy open- set.  
 Then,  $(f \circ g)^{-1}(\psi) = g^{-1}(f^{-1}(\psi))$ .  
 Therefore  $f^{-1}(g^{-1}(U)) \in X$  is a fuzzy infra  $j$  open set.

**Example 4.5:**

Let  $G=H=I=(k,m)$  and  $q_1, q_2, q_3, q_4, q_5, q_6$  be fuzzy set of  $X$ ,  

$q_1(k)=0.2$	$q_1(m)=0.2$
$q_2(k)=0.4$	$q_2(m)=0.4$
$q_3(k)=0.3$	$q_3(m)=0.5$
$q_4(k)=0.5$	$q_4(m)=0.7$
$q_5(k)=0.3$	$q_5(m)=0.5$
$q_6(k)=0.3$	$q_6(m)=0.3$

If  $T_G = \{0_G, q_1, q_2, 1_G\}$ ,  $T_H = \{0_H, q_3, q_4, 1_H\}$  and  $T_I = \{0_I, q_6, 1_I\}$  and the function  $h: (G, T_G) \rightarrow (H, T_H), f: (H, T_H) \rightarrow (I, T_I)$  be the identity function. We can say that  $f$  and  $h$  are infra  $j$  continuous function.

**Theorem 4.6:**

If  $f: (G, T) \rightarrow (H, S)$  is a fuzzy infra  $j$  continuous  $(G, T)$  and  $(H, S)$  fuzzy topological space then  $Int[f^{-1}(\sigma)] \neq \emptyset$  in  $(G, T)$  for fuzzy open set  $\sigma$  in  $(H, S)$

**Proof:**

Let  $\sigma$  a fuzzy infra  $j$  open set in  $(H, S)$ ,  $f: (G, T) \rightarrow (H, S)$  is a FIjCF1 –  $f^{-1}(\sigma)$  is not dense set in  $(G, T)$  that is  $cl[1 - f^{-1}(\sigma)] \neq 1$  in  $(G, T)$ . Therefore,  
 $int[f^{-1}(\sigma)] \neq \emptyset$ . Hence  $int[f^{-1}(\sigma)] \neq \emptyset$  in  $(G, T)$ .

**Sasikala and Mahima****CONCLUSION**

In this paper, we investigated fuzzy infra  $j$  open set, fuzzy infra  $j$  closed set and fuzzy infra  $j$  continuous function using fuzzy infra topological spaces. Basic properties of the concerned sets are studied using illustration. The study of relation and converse relation among these new concepts has been examined

### ABSTRACT

In decision-making processes, uncertainty and imprecision are inherent factors, particularly when complex, real-world situations are involved. Fuzzy set theory, which examines the variability and vagueness inherent in human judgment, is integrated into fuzzy decision-making analysis to give a flexible framework for handling those issues. This study examines how risk information functions in fuzzy decision-making, emphasizing the ways in which fuzzy logic can represent and measure decision-process uncertainty. We look into several methods for adding risk elements to fuzzy decision models so that decision-makers can assess and handle possible hazards more effectively. We also look at how linguistic evaluations and subjective impressions affect the way decisions turn out. We illustrate the usefulness and efficiency of fuzzy decision-making in domains including finance, project management, and strategic planning using case studies and simulations.

**Keywords:** Fuzzy decision-making, Risk Assessment, Fuzzy set theory, Decision analysis.

### INTRODUCTION

Decision-making in real-world scenarios often involves uncertainty and imprecision. Traditional decision-making models, which rely on precise numerical data, may not be well-suited for environments where information is vague, incomplete, or ambiguous. In such situations, fuzzy decision-making analysis provides an effective alternative. This approach integrates the notion of "fuzziness," whereby uncertainty is demonstrated using fuzzy sets, consequently allowing a more malleable and real analysis of real-world issues. A crucial component of organizational decision-

### Sangeetha and Sundar

making is risk management [1], [2], which tries to recognize, evaluate, and reduce possible risks that can have an influence on investments, initiatives, or business operations. Traditional strategies for risk management usually utilize deterministic methods, statistical models, and quantitative analysis to evaluate hazards. Still, the application of these methods in complex and dynamic risk situations is limited, as they are frequently unable to handle ambiguities, subjective assessments, and imprecise data. In order to improve risk management practices, fuzzy logic branch of mathematics that deals with imprecision and uncertainty has grown in popularity previously. Fuzzy logic provides an adaptable and user-friendly framework for gathering and analysing imprecise, uncertain, and ambiguous input. A more thorough and nuanced evaluation of hazards is made possible by its ability to reflect linguistic variables, subjective assessments, and linguistic norms. Since its introduction by Zadeh in (1965)[3], the concept of fuzzy sets has found extensive use across multiple fields, such as engineering, management, and economics, and is acknowledged as a valuable tool for addressing ambiguity and vagueness. Over the past few decades, numerous academics have used a variety of methodologies and novel inventions to build fuzzy sets theory. Subsequently, the notion of decision making difficulties including uncertainty was presented by Bellman, R.E. (1970)[4]. Zimmermann(1978) [5] uses fuzzy linear programming techniques to solve the linear vector maximum problem and shows how effective these solutions are. In order to arrive at the best answer by integrating various objective functions, they investigate the repercussions of doing so.

They also provide useful details on the effectiveness of fuzzy linear programming in resolving multi-objective issues and recommendations on how to apply various techniques to arrive at the best feasible compromise. Process industries are difficult, multidimensional domains with a multitude of socio technical processes and highly modern technology. Major accidents constitute a substantial risk to the process industries. One of the things investigators look into after major incidents is what activities contributed up to the accidents. The 2010 San Bruno gas transmission pipeline disaster is one example of a catastrophe that can be caused by choices made independently over a protracted period of time by staff at various levels of an organization (Hayes and Hopkins, 2014). This case involved many wrong operations from the development of inspection plans and maintenance and inspection cost-cutting strategies to the resolution of specific operational issues. These decisions might be considered to as risk-related decisions.[6]

. This essay investigates methods of fuzzy logic. The impact of fuzzy logic approaches on embedded control systems based on microcontrollers is examined in this work [7]. The remaining portions of the paper are arranged as follows: under Section 2 Given below are some fundamental definitions of Fuzzy Risk Index (FRI). In Section, mathematical expression is shown 3 and 4. The Part 5, The conclusions are presented in Section 5.

#### PRELIMINARIES

To effectively integrate risk information into fuzzy decision-making analysis, several key formulas and mathematical concepts from fuzzy set theory and risk analysis are used. Below are some foundational formulas relevant to this topic.

#### Membership Position

The fuzzy set A, membership position  $\mu_A(X)$  defines the connection between every element X. The membership position's value, which varies from 0 to 1, indicates an element's category of membership  $\mu_A(X) : X \rightarrow [0,1]$ .

For example, a triangular fuzzy number can be defined by three values e, f and g as follows:

$$\mu_A(X) = \begin{cases} 0, & x \leq e \\ \frac{x-e}{f-e}, & e \leq x \leq f \\ \frac{g-x}{g-f}, & f \leq x \leq g \\ 0, & g \leq x \end{cases}$$

Fuzzy decision-making utilizes this membership position to handle imprecise and uncertain comments.

**Sangeetha and Sundar**

**Language-Related Variables**

Language-related variables like "small," "average," and "extreme" can be represented using fuzzy sets. These fuzzy sets, which can be recognized by their membership position, enable meaningful representations of risk and other decision elements. As an example, the fuzzy set labelled "high risk" could be presented below.

:

$$\mu_{high\ risk}(x) = \begin{cases} 0, & x \leq a_1 \\ \frac{x-a_1}{a_2-a_1}, & a_1 < x \leq a_2 \\ 1, & x \geq a_2 \end{cases}$$

Here,  $a_1$  and  $a_2$  define the points at which "high risk" starts and reaches full membership, respectively.

**Fuzzy Expected Value**

In fuzzy decision-making, the expected value of a fuzzy number can be used to estimate the entire risk or outcome. The membership function  $\mu_{\tilde{R}}(x)$  can be utilized for expressing a fuzzy number  $\tilde{R}$ . The fuzzy desired value  $E(\tilde{R})$  can be obtained below.

$$E(\tilde{R}) = \frac{\int x \cdot \mu_{\tilde{R}}(x) \, dx}{\int \mu_{\tilde{R}}(x) \, dx}$$

When making fuzzy decisions, this formula can be utilized for determining the expected value of a fuzzy quantity. This is useful in determining risk.

**Fuzzy Multi-Criteria Decision-Making (FMCDM) Aggregation**

A few variables are combined in FMCDM to assess various possibilities. Weighted aggregation can be utilized to get the overall fuzzy score  $\tilde{s}_j$  of alternative j if  $\tilde{w}_i$  is the fuzzy weight of rules i and  $\tilde{x}_i^j$  is the fuzzy score of alternative j with considering criterion i.

$$\tilde{s}_j = \sum_{i=1}^m \tilde{w}_i \cdot \tilde{x}_i^j$$

This aggregation formula is fundamental for ranking alternatives in fuzzy decision-making, considering multiple risk factors and criteria.

**Defuzzification (Centroid Method)**

Defuzzification is the process of converting a fuzzy output into an exact value. Typically, defuzzification occurs by determining the managing point of the fuzzy set by utilizing the centroid (centre of gravity) method:

$$x_{defuzzified} = \frac{\int x \cdot \mu_A(x) \, dx}{\int \mu_A(x) \, dx}$$

This formula helps to interpret fuzzy results into actionable, crisp decisions.

**Fuzzy Risk Index (FRI)**

In fuzzy risk analysis, the Fuzzy Risk Index (FRI) is used to determine an amount of risk. A risk's fuzzy probability (L) and fuzzy impact ( $\tilde{I}$ ) are combined.

$$FRI = \tilde{L} \times \tilde{I}$$

This formula enables the evaluation of risks using fuzzy numbers for both likelihood and impact, making it suitable for uncertain environments.

**Mathematical Expression**

Fuzzy decision-making analysis, especially risk evaluation, utilizes mathematical methods to handle information confusion and imprecision. Fuzzy logic model uncertainty by assigning degrees of membership to sets. The primary mathematical techniques used in fuzzy risk decision-making analysis are:

**Fuzzy Sets and Membership Functions**

**Fuzzy Set A:** An ordered pair  $A = \{(x, \mu_A(X)) / x \in X\}$  is a fuzzy set; here,  $\mu_A(X)$  denotes the membership function of element x in set A. The degree of membership of x in A can be expressed by the membership function  $\mu_A(X)$ , which supports a value between 0 and 1.

### Sangeetha and Sundar

#### Triangular, Trapezoidal, Gaussian Membership Functions:

Commonly used functions to describe fuzzy sets. For instance, a triangular membership function might look like:

$$\mu_A(X) = \begin{cases} 0, & x < s \\ \frac{x-s}{t-s}, & s \leq x \leq t \\ \frac{u-x}{u-t}, & u \leq x \leq v \\ 0, & x > u \end{cases}$$

where a, b and c define the range of the membership function.

#### Fuzzy Operators (T-Norms and S-Norms):

**T-Norm (Intersection):** Used to represent fuzzy AND operations,

e.g.,  $\mu_{A \cap B}(x) = \min(\mu_A(x), \mu_B(x))$ , where the membership of an element in the intersection of two fuzzy sets is the minimum of the individual memberships.

**S-Norm (Union):** Used to represent fuzzy OR operations,

e.g.,  $\mu_{A \cup B}(x) = \max(\mu_A(x), \mu_B(x))$ , where the membership of an element in the union is the maximum of the individual memberships.

#### Fuzzy Aggregation Operators

In risk analysis, fuzzy numbers or linguistic variables are aggregated to assess the overall risk.

#### Weighted Averaging

A common way to aggregate fuzzy information:

$$\mu_{agg}(x) = \sum_{i=1}^n w_i \mu_{A_i}(x)$$

Where  $w_i$  is the weight assigned to the  $i^{\text{th}}$  criterion or decision factor, and  $\mu_{A_i}(x)$  is the membership function for each fuzzy set  $A_i$ .

#### Fuzzy Max-Min Composition

This is used for multi-criteria decision-making where the overall fuzzy risk is determined by taking the minimum or maximum of the memberships.

#### Defuzzification

Once a fuzzy risk evaluation has been done, the fuzzy results must be translated into a crisp value for decision-making. Common methods include:

#### Centroid Method

For the fuzzy set, the centre of gravity of the region under the curve is denoted by the defuzzified value  $x^*$ .

$$x^* = \frac{\int x \cdot \mu_A(x) dx}{\int \mu_A(x) dx}$$

#### Mean of Maxima

The defuzzified value is the average of the points where the membership function reaches its maximum value.

#### Bisector Method

The defuzzified value is where the fuzzy set is divided into two sub-areas of equal size.

#### Fuzzy Risk Index Calculation

In fuzzy risk evaluation, a risk index can be calculated using the fuzzy sets for probability and impact:

**Sangeetha and Sundar****Fuzzy Rule-Based Approach:**

Fuzzy IF-THEN rules are applied to evaluate the risk. As an illustration, if both likelihood and impact are high, then risk is also quite high. The rules are combined by the fuzzy logic system to create a fuzzy risk score, which is then defuzzified to give a crisp risk index.

**Example of a Fuzzy Risk Calculation**

- i) **Define Risk Parameters:** For instance, let the probability and impact of a certain event be defined as fuzzy sets.
- ii) **Apply Fuzzy Operators:** Use T-norms (AND) or S-norms (OR) to combine the probability and impact memberships.
- iii) **Aggregate Results:** Use weighted averages or other fuzzy aggregation techniques to get a fuzzy risk score.
- iv) **Defuzzify:** Compute the crisp value of the fuzzy score through using a defuzzification method such as the centroid strategy.

**CONCLUSION**

Incorporating risk information into fuzzy decision-making analysis provides a powerful framework for addressing uncertainty in complex decision environments. When challenged with uncertain or imprecise data, traditional decision models often come short; nevertheless, fuzzy set theory, fuzzy logic, and fuzzy multi-criteria decision-making (FMCDM) offers flexible options. By representing both uncertainty and risk through fuzzy numbers, linguistic variables, and membership functions, decision-makers can evaluate options more realistically, accounting for imprecision in both input data and risk factors. Fuzzy decision-making models allow for a nuanced understanding of trade-offs between multiple criteria, making them especially useful in domains like finance, engineering, healthcare, and project management where risks are inherent and outcomes uncertain. The integration of risk analysis into these models further enhances their applicability, enabling decision-makers to quantify and mitigate potential adverse outcomes even when the probabilities and impacts of those risks are not precisely known. Ultimately, fuzzy decision-making enriched with risk information leads to more informed, robust, and adaptable decision processes, contributing to better outcomes in real-world scenarios.

## ABSTRACT

Alzheimer's disease (AD) is a complex neurodegenerative disorder that leads to damage of neuronal cells. Accurate detection of AD at its early stages is critical for effective intervention so developing of deep learning models have been employed to facilitate the rapid and precise identification of the condition. This article presents an novel approach that compares various fuzzy clustering techniques combined with deep learning models, such as Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), and Deep Neural Networks (DNNs), for the segmentation and classification of brain imaging data. The methodology integrates different fuzzy clustering techniques alongside the Sea Lion Optimization Algorithm (SLOA), to segment Regions of Interest (ROIs) in preprocessed brain images. The preprocessing phase involves applying a Gaussian filter for noise reduction, followed by optimized fuzzy clustering to enhance the segmentation quality. The features extracted for classification encompass textural characteristics, deep convolutional features, and statistical features. Finally, the performance of deep learning models with SLOA model classifies AD into five types as Cognitive Impairment (MCI), Early Mild Cognitive Impairment (EMCI), AD, Mild Cognitively Normal (CN), and Late Early Mild Cognitive Impairment (LMCI). This comparative analysis identified the most effective combination of deep fuzzy clustering and network models gives the promising results in specificity, sensitivity, and accuracy for AD detection.

**Keywords:** Alzheimer's disease (AD), Deep fuzzy clustering (DFC), Sea Lion Optimization Algorithm (SLOA), Convolution neural networks (CNN), Recurrent neural networks (RNNs) and deep neural networks(DNNs).

**Sandhya Mohankumar and Dhanalakshmi Palanisami**

## INTRODUCTION

Alzheimer's Disease (AD) is a prevalent neurodegenerative disorder characterized by progressive cognitive decline and memory loss. It accounts for 60-70% of dementia cases globally and affects millions of elderly individuals, imposing a significant burden on healthcare systems and society. Early and accurate detection of AD is crucial to improve patient outcomes, slow disease progression, and enhance the quality of life through timely intervention and therapeutic strategies. Its diagnosis traditionally involves clinical evaluations, cognitive tests, and neuroimaging techniques like magnetic resonance imaging (MRI) and positron emission tomography (PET). MRI scans, in particular, are valuable for detecting structural brain changes associated with AD, such as hippocampal atrophy and ventricular enlargement. However, accurate identification of these changes, especially in early disease stages like Mild Cognitive Impairment (MCI), remains challenging due to the overlap of symptoms with normal aging and other neurological disorders. In recent years, deep learning techniques, including Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), and Deep Neural Networks (DNNs), have emerged as powerful tools in medical image analysis[1]. CNNs are particularly effective in automatically extracting complex features from large datasets, significantly reducing the need for manual feature engineering. They have demonstrated remarkable performance in various applications, including tumor detection, organ segmentation, and the classification of neurodegenerative diseases like Alzheimer's. RNNs, on the other hand, are well-suited for sequential data and have shown promise in analyzing time-series data from neuroimaging, allowing for insights into disease progression over time. DNNs further enhance the ability to model intricate patterns within the data, providing a comprehensive understanding of the relationships between features[20,21].

Despite the successes of deep learning, the inherent complexity and variability of brain imaging data present unique challenges. Issues such as noise, artifacts, and the presence of overlapping structures can hinder the performance of these neural networks[4]. To address these challenges, robust preprocessing and segmentation techniques are essential. This is where fuzzy clustering methods come into play, providing a flexible approach to handling uncertainty and overlapping data points within MRI images. By allowing for partial membership in multiple clusters, fuzzy clustering techniques can capture the subtleties of brain structure more effectively than traditional hard clustering approaches. Fuzzy C-means clustering and its variants are particularly noteworthy for their ability to segment images based on the concept of fuzzy sets[9]. These methods enable the classification of pixels into multiple classes, reflecting the inherent ambiguity present in medical imaging. By integrating fuzzy clustering techniques with deep learning architectures such as CNNs and RNNs, researchers can enhance segmentation accuracy and improve classification performance, paving the way for more reliable diagnostic tools. This article proposes a hybrid framework that combines fuzzy clustering-based segmentation with a deep learning techniques for the classification of Alzheimer's disease. The hybrid model aims to leverage the strengths of both methodologies, ensuring a more comprehensive analysis of MRI data. We will evaluate the proposed approach using the Alzheimer's Disease Neuroimaging Initiative (ADNI) dataset, a well-established resource that provides a rich repository of labeled MRI images, facilitating robust experimental validation. By optimizing fuzzy clustering techniques through advanced algorithms such as the Sea Lion Optimization Algorithm (SLOA), we aim to address the limitations of traditional classification methods. This study not only contributes to the understanding of Alzheimer's disease detection but also advocates for the integration of artificial intelligence in clinical practice, promising a future where automated tools can assist in the timely diagnosis and treatment of neurodegenerative diseases. In this research, a novel Deep Fuzzy Clustering (DFC) approach combined with the Sea Lion Optimization Algorithm (SLOA)-based deep learning model is implemented to enhance Alzheimer's disease (AD) detection. The use of a Gaussian filter plays a crucial role in preprocessing by reducing image artifacts and noise, which helps in refining the quality of MRI images and boosts the overall accuracy of the model. DFC is particularly advantageous for analyzing large-scale datasets due to its ability to accommodate the inherent ambiguity and uncertainty in medical images, making it a comprehensive solution for segmentation and feature extraction tasks.

**Sandhya Mohankumar and Dhanalakshmi Palanisami**

## METHODOLOGY

The structure of AD's segmentation and classification are described below.

### Dataset Description

Alzheimer's Disease Neuroimaging Initiative (ADNI) dataset which consists of neuroimaging data, including Magnetic Resonance Imaging (MRI) scans, which are used for the analysis and classification of AD. The dataset includes different stages of cognitive impairment associated with AD. Consider the ADNI dataset as  $K$  and it is mathematically represented as  $K = \{F_1, F_2, \dots, F_i, \dots, F_h\}$  where  $K$  denotes the dataset,  $h$  denotes the number of images and  $F_i$  denotes the  $i^{th}$  image of the input.

### Noise removal using Preprocessor

The preprocessing phase is essential to enhance the quality of the images in the dataset. This preprocessing phase significantly impacts the quality of ROI segmentation, feature extraction, and the overall performance of classification in AD. By reducing the noise in the images gives more accurate and reliable analysis. In this process gaussian filter is used to reduce the noise from the dataset.

### Gaussian filter

The gaussian filter is widely used to smoothing filter in image processing for noise reduction. It is based on the Gaussian function, which provides a weighted average of surrounding pixels with more weight given to the central pixels. This function is represented as,

$$G(m, n) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{m^2+n^2}{2\sigma^2}}$$

Where  $m, n$  are the points in the coordinates of the filter kernel,  $\sigma$  is the standard deviation of the gaussian function.

### Region of interest in segmentation

ROI segmentation increases the focus on relevant brain regions, thus improving the detection and classification of AD. By isolating specific areas for analysis, the process reduces computational complexity and enhances the accuracy of feature extraction, ultimately leading to better classification performance in the subsequent deep learning models. The ROI segmentation starts with the preprocessed brain MRI image, which has undergone Gaussian filtering to reduce noise and improve image quality. It is enhanced using deep fuzzy clustering (DFC) methods optimized by the Sea Lion Optimization Algorithm (SLOA). The fuzzy clustering helps in defining soft boundaries between different brain tissues by assigning pixels to clusters based on their membership values. This step is crucial because it allows partial membership to different clusters, which can be useful in dealing with the varying intensity levels found in medical images. SLOA fine-tunes the hyperparameters of the clustering process, such as the number of clusters and the fuzziness coefficient, to improve the segmentation quality. This optimization ensures that the clusters correspond to meaningful anatomical structures in the brain, enhancing the accuracy of the segmentation. After clustering the regions affected by AD are identified as ROI. These segmented regions are crucial for downstream tasks, such as feature extraction and classification, as they highlight areas with potential pathological changes.

### Deep fuzzy clustering

In this research, deep learning techniques such as CNN, RNN and DNN are integrated with fuzzy clustering methods to enhance the segmentation and classification of Alzheimer's Disease (AD). This combination aims to leverage the strengths of both deep learning and fuzzy clustering to achieve better performance in identifying and categorizing different stages of cognitive impairment. The output  $F'_i$  from the preprocessing phase are fed into the DFC as input. The DFC is achieved by integrating it with the SLOA, which facilitates the determination of DFC's hyperparameters[6]. The input preprocessed images  $K' = \{F'_1, F'_2, \dots, F'_i, \dots, F'_h\}$  consists of  $d$  clusters and a specified maximum number of iterations  $Iter_{max}$ . The fuzzy clustering methods integrated with deep learning models to extract deep features from the data and these deep features are performed as an input for the algorithms. The below fuzzy clustering techniques are

### Sandhya Mohankumar and Dhanalakshmi Palanisami

#### Fuzzy C-Means (FCM)

Fuzzy C-Means clustering[9] is commonly used for medical image segmentation, including brain scans in AD. FCM allows each data points belong to multiple clusters with varying degrees of membership. In AD segmentation, the clusters represent different tissue types like gray matter, white matter, cerebrospinal fluid, or potentially atrophied regions. The algorithm that allows each data point to belong to multiple clusters with varying degrees of membership. The loss function is given by

$$O(U, V) = \sum_{i=1}^n \sum_{j=1}^c u_{ij}^m \|x_i - v_j\|^2$$

where  $U$  is the membership matrix,  $V$  represents the cluster centers,  $m$  is the fuzziness parameter and  $d$  is the number of clusters.

#### Kernel-Based Fuzzy C-Means (KFCM)

KFCM[10,17] extends FCM by using a kernel function to map the data into a higher- dimensional space. This helps in handling non-linearly separable data, which is important in complex medical images where tissue intensities may not be easily distinguished in the original space. The use of a kernel function allows for better separation of the regions corresponding to different stages of brain tissue degeneration in AD. The extended loss function is given by

$$O(U, V) = \sum_{i=1}^n \sum_{j=1}^c u_{ij}^m K(x_i, v_j)$$

#### Entropy Weighted Fuzzy C-Means (EWFCM)

EWFCM adds an entropy term to the clustering process, which controls the uncertainty in the membership values. In AD segmentation, this helps in dealing with ambiguous regions where the intensity values are similar across different tissues. The entropy weighting ensures that the clustering solution is not overly sensitive to noise, which is common in medical imaging. The loss function can be expressed as:

$$O(U, V) = \sum_{i=1}^n \sum_{j=1}^c u_{ij}^m \|x_i - v_j\|^2 - \lambda \sum_{i=1}^n H(u_i)$$

where  $H(u_i)$  represents the entropy of membership,  $\lambda$  is a weighting factor that balances the clustering and entropy terms.

#### Spatial Fuzzy C-Means (SFCM)

SFCM [3] incorporates spatial information from neighboring pixels into the clustering process. In the case of brain imaging, it takes into account the spatial continuity of brain tissues, thus improving segmentation quality by reducing noise and preserving important structures. For AD segmentation, SFCM can be used to better delineate boundaries of brain regions affected by atrophy while ensuring that spatial coherence is maintained.

$$O(U, V) = \sum_{i=1}^n \sum_{j=1}^c u_{ij}^m \|x_i - v_j\|^2 + \beta \sum_{i=1}^n \sum_{j=1}^c \|x_i - x_j\|^2$$

where  $\beta$  controls the contribution of spatial information.

#### Sea Lion Optimization Algorithm

When the Sea Lion Optimization Algorithm (SLOA)[5] is fused with various deep fuzzy clustering methods, it serves to optimize the hyperparameters of the clustering techniques and enhance segmentation quality. In segmentation the aim is to partition an image into meaningful regions of interest (ROIs), such as brain structures that may show signs of AD. The **steps involved in the integration of SLOA with DFC are varied depends on the DFC method.** DFC techniques such as DFCM integrates with SLOA tunes the number of clusters and the fuzziness parameter to improve membership function estimation, DKFCM integrates with SLOA optimizes kernel parameters, enhancing the non-linear clustering capabilities, DEWFCM with SLOA adjusts weights associated with entropy to achieve a balance between fuzzy membership and entropy minimization, and DSFCM with SLOA determines the optimal spatial constraints for better segmentation, particularly in noisy images. After segmentation, the classification phase

### Sandhya Mohankumar and Dhanalakshmi Palanisami

involves categorizing the segmented brain regions into different stages of cognitive impairment such as CN, MCI, EMCI, LMCI, and AD. The Steps involved in SLOA are as follows,

#### Step 1: Initialization

The initial population of sea lions is generated randomly within a predefined search space for the hyperparameters.

#### Step 2: Fitness Evaluation

The fitness of each sea lion is evaluated based on the clustering performance, using the clustering objective function  $O(U, V)$ .

#### Step 3: Update Positions of Sea Lions

The position update in SLOA is based on both exploration and exploitation:

**Exploration Phase:** The movement of each sea lion is random, allowing a broader search over the solution space.

**Exploitation Phase:** When a prey (optimum solution) is identified, the sea lions converge towards it, refining the hyperparameters. The position update for each sea lion is mathematically given by:

$$X_i^{t+1} = X_i^t + \alpha(X_{best}^t - X_i^t) + \beta \text{rand}(-1,1)$$

where  $X_i^{t+1}$  is the new position for the  $i$ -th sea lion at iteration  $t+1$ ,  $X_i^t$  is the current position,  $X_{best}^t$  represents the best-known position,  $\alpha$  and  $\beta$  are weighting factors that control the influence of  $X_{best}$  and the random movement,  $\text{rand}(-1,1)$  is a random number between -1 and 1, adding stochastic behavior to the search process.

The algorithm converges when the change in fitness between iterations falls below a predefined threshold, or after a set number of iterations.

#### Feature Extraction

The extracted features from each segment are collected and play a vital role in classification of AD. These features compass textural features such as Local Gabor Binary Patterns (LGBP) and Spatial Local Intensity Features (SLIF) and various statistical features, including kurtosis, skewness, variance, standard deviation, mean, contrast, entropy, and energy[2].

#### Textural features

The textural features are extracted from segmented regions from the methods of LGBP and SLIP. The methods are as follows,

**(a) LGBP:** It is a texture descriptor that captures local texture information by combining Gabor filters with binary pattern encoding. The Gabor filters capture different frequency and orientation responses, allowing for the extraction of multi-scale texture features. The binary pattern is derived from the filter responses, making LGBP robust against variations in illumination and capable of capturing significant texture information from brain images.

**(b) SLIF:** It is another method that analyzes the local intensity distribution within an image. It evaluates the intensity values of pixels within a local neighborhood, capturing variations in texture. This method focuses on how pixel intensities are arranged spatially, making it particularly effective for identifying patterns in brain images associated with different stages of Alzheimer's Disease.

#### Statistical features

The statistical features play a vital role in analyzing and used to enhance deep learning techniques for classification. The features are illustrated below,

**(i)Mean:** Mean value represents the average pixel intensity within a region. It helps the overall brightness and texture of the image.

**(ii)Variance:** It measures the spread of pixel values around the mean. High variance indicates significant texture, while low variance suggests smoother areas.

**(iii)Standard Deviation:** The square root of variance, it quantifies the variation in pixel intensity. A higher standard deviation often reflects greater contrast.

### Sandhya Mohankumar and Dhanalakshmi Palanisami

**(iv)Energy:** Calculated as the sum of squared pixel values, energy reflects the amount of textures and high energy values correlated.

**(v)Entropy:** A measure of the unpredictability in the intensity distribution, higher entropy values indicate more complex textures. This can be particularly useful in distinguishing between different stages of cognitive impairment.

**(vi)Contrast:** Assesses the difference in intensity between neighboring pixels and higher contrast indicates sharper distinct features.

**(vii)Kurtosis:** Measures the "tailedness" of the intensity distribution. High kurtosis indicates more extreme values and significant textural patterns.

**(viii)Skewness:** Indicates the asymmetry of the distribution of pixel intensities. Positive skewness means a longer tail on the right side of the distribution gives the brighter pixels, while negative skewness indicates the opposite distribution gives the darker pixels.

The features are characterized into vectors  $V$  such as

$$V = \{V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8, V_9, V_{10}\}$$

where  $V_1$  refers LGBP,  $V_2$  refers SLIF,  $V_3$  refers mean,  $V_4$  refers variance,  $V_5$  refers standard deviation,  $V_6$  refers energy,  $V_7$  refers entropy,  $V_8$  refers contrast,  $V_9$  refers kurtosis,  $V_{10}$  refers skewness.

#### Data augmentation

The vectors are fed into the augmentation process. It involves creating additional training data by applying various transformations to the existing dataset and helps to improve the robustness of deep learning models. This involves in the process of feature standardization, whitening, rotation, flips and shifts. It leads to improved accuracy and reduced overfitting when working in small datasets[7,16].

#### AD classification

The AD classification is obtained by taking the augmentation inputs from the previous steps fed into the deep learning techniques. One of the significant combination of the deep fuzzy clustering technique with deep learning model gives the promising evaluation metrics.

## RESULTS AND DISCUSSIONS

The proposed DFC + SLOA-based deep learning models are evaluated on various training datasets, measuring its performance through metrics such as specificity, sensitivity, and accuracy.

#### Dataset Description

The Alzheimer's-Disease-5-Class-Dataset-ADNI [19] is used for the detection. This dataset is categorized into five stages of Alzheimer's disease as AD, Mild Cognitive Impairment (MCI), Late Mild Cognitive Impairment (LMCI), Early Mild Cognitive Impairment (EMCI), and Cognitively Normal (CN). This dataset is instrumental for both training and testing models aimed at detecting and understanding the progression of Alzheimer's disease.

#### Evaluation metrics

To evaluate Alzheimer's disease classification models using the ADNI dataset, three key metrics are used: accuracy, specificity, and sensitivity.

1. **Accuracy** measures the overall correctness of the model by calculating the proportion of true predictions (both positive and negative) out of the total number of predictions. It is expressed as:

$$Accuracy = \frac{X^p + X^n}{X^p + X^n + Y^n + Y^p}$$

where  $X^p$  is true positives,  $X^n$  is true negatives,  $Y^n$  is false positives, and  $Y^p$  is false negatives.

**Specificity** measures the model's ability to correctly identify negative cases, in this context, individuals without Alzheimer's disease or at a cognitively normal (CN) stage. It is given by:

$$Specificity = \frac{X^n}{X^n + Y^p}$$

**Sandhya Mohankumar and Dhanalakshmi Palanisami**

**Sensitivity** (or recall) measures the model's ability to correctly detect positive cases, i.e., identifying patients who do have Alzheimer's or a related cognitive impairment. It is calculated as:

$$\text{Sensitivity} = \frac{X^p}{X^p + Y^n}$$

Using these metrics together provides a comprehensive evaluation of the classification model's performance, balancing the ability to detect disease while minimizing misclassification.

**Performance analysis**

The experiments were conducted using a dataset split of 90% for training and 10% for testing. The experimental analysis of four fuzzy clustering methods of DFCM, DEWFCM, DSFCM and DKFCM when paired with deep learning architectures like CNN, RNN and DNN for AD detection with the sloa algorithm. The each combination of the model gives the analysis of the evaluation metrics.

**Comparative Analysis**

In this analysis, the performance metrics of various combinations of DFCM clustering methods with deep learning techniques CNN, RNN, DNN across different datasets. The evaluation metrics of accuracy, specificity, and sensitivity, which provide insights into the effectiveness of each model in classifying Alzheimer's Disease AD. From the Table.1, The DFCM + RNN model achieves an accuracy of **89.4%**. RNNs are adept at processing sequential data, which can be advantageous when analyzing temporal changes in medical imaging data. The model reports a specificity of **89%** and sensitivity of **89.8%**, indicating a balanced approach in identifying both true positives and true negatives. From the Table.2, This DKFCM+DNN combination achieves the highest accuracy at **93.08%**, making it the most effective among the DKFCM techniques for classifying AD. A high specificity of **92.1%** indicates excellent performance in minimizing false positives, suggest in with **91.2%**, it also shows robust capability in identifying actual AD cases, making it suitable for clinical applications. From the Table.3, The model DEWFCM+DNN in combination gives the highest accuracy of **96.94%** than overall other models, with highest prediction of specificity **95.4%** in AD cases and highest prediction of non-negative AD cases of sensitivity **93.7%**. From the Table.4, the DSFCM+RNN models combination predicts the highest accuracy **96.16%**, and the model's specificity **95.4%** and sensitivity **95.3%** identifying the AD and Non-AD by true positives and true negatives. From this analysis fig.1 and fig.2 shows the maximum accuracy with specificity and sensitivity of the DEWFCM and DSFCM .

**CONCLUSION**

The DFC methods combined with the deep learning techniques were used for segmentation and classification of AD. The initial stage involves preprocessing input images with a Gaussian filter to minimize noise. Subsequently, a modified DFC method is employed to segment the RoI and the SLOA is utilized for tuning the hyperparameters of DFC. Extracted features of textual features, statistical features are utilized. The model that classifies the dataset into AD disease and non-negative diseases using a combination of Deep Entropy Weighted Fuzzy Clustering (DEWFCM) and Deep Neural Network (DNN) with sloa achieves the highest classification accuracy of 96.94% with the maximum specificity and sensitivity of 95.4% and 93.7%, respectively. The promising results highlight the efficacy of combining advanced clustering techniques with deep learning models in the medical imaging domain.

### ABSTRACT

This paper presents the membership functions for performance metrics of Single Vacation Queues governed by an  $(e, d)$ -policy, incorporating fuzzy parameters where arrival rates, service rates, and vacation rates are treated as fuzzy numbers. Ranking techniques play a crucial role in the fuzzy number system for defuzzification. In this study, we propose the Incenter of Centroids ranking method to evaluate the performance measures of Single Vacation Queues under the  $(e, d)$  policy. Our proposed ranking method effectively converts fuzzy structures into crisp counterparts.

**Keywords:** Fuzzy set, Membership Functions, Single vacation, Incenter of Centroids Ranking Method

### INTRODUCTION

Queueing theory is a field within applied probability that studies waiting lines of customers seeking service from a service station. A queue forms when service isn't immediate. This concept was first introduced by A.K. Erlang[5] in 1909. The primary goal of analyzing queueing systems is to gain insights into their behaviors, facilitating informed decision-making for better organization. The vacation queueing model emerged in the 1970s, extending classical queueing theory by allowing servers to take breaks for maintenance or other tasks. Such vacations contribute to the long-term effectiveness of a queueing system. In practice, management often aims to ensure that some servers remain

**Syamala et al.,**

available, either actively serving or in a standby mode. This paper examines a single vacation model governed by an (e,d)-policy where some servers may be on break. Research by Baba[2] explored an  $M^*/G/1$  queue with vacation time, while Choudhry[4] analyzed a batch arrival queue under a single vacation policy. Ke[10] provided a brief overview of recent advancements in vacation queueing models, and Levy alongside Kleinrock[11] investigated queues featuring starters and vacations. Madan[13] and colleagues looked into a two-server queue utilizing Bernoulli schedules and a single vacation policy. Detailed studies on vacation queueing models with the (e-d) policy were conducted by Xiuli Xu and Zhe George Zhang[21], while Ayyappan[1] and others examined the effects of negative arrivals in a single-server fixed-batch service queue with multiple vacations. Fuzzy set theory helps address uncertainty, enhancing classical queueing models when represented in fuzzy terms. Fuzzy logic, introduced by Zadeh[22] in 1965, has evolved through contributions from researchers like Zimmermann[23], who expanded on fuzzy set theory and its applications. Klir and Yuwan[6] discussed various aspects of fuzzy sets and logic, while Kaufmann[8] introduced the theory of fuzzy subsets. In practical scenarios, parameters such as arrival rates and service rates are often uncertain, prompting the development of fuzzy queueing models by researchers like Li and Lee[12], Buckley[3], and Negi and Lee[14], who applied Zadeh's extension principle. Upadhaya[20] explored Bernoulli vacations in queues with fuzzy parameters. Ranking techniques play a crucial role in defuzzifying fuzzy number systems, with notable contributions from Jagatheesan[7] and others on fuzzy ranking methods. Ramesh and Kumaraghuru[15] proposed a centroid-based fuzzy ordering for priority queue systems. Ramesh and Kumaraghuru[19] examined the performance metrics of a fuzzy queueing model featuring an unreliable server by employing a ranking function method. Meanwhile, Ramesh and Hari Ganesh[16, 17] developed an innovative fuzzy ordering technique known as the Expansion and Wingspans Center approach for queueing systems. Additionally, Ramesh and Seenivasan[18] introduced the Centroid of Centroids ordering method specifically within an interval-valued Type-2 fuzzy environment. We propose a method for assessing the performances of Single Vacation Queues regulated by an (e, d)-policy, utilizing the Incenter of Centroids Ranking Method.

## PRELIMINARIES

### Definition: Fuzzy Set

A Fuzzy Set  $\tilde{A} = \{(x, \phi_{\tilde{A}}(x)); x \in U\}$  can have deliberated with the transformation  $\phi_{\tilde{A}} : U \rightarrow [0,1]$ , here  $\phi_{\tilde{A}}$  is membership function and  $U$  is the universal set.

### Definition: Fuzzy Number

A fuzzy number extends the concept of a standard real number by representing a range of values instead of a single fixed point. In this framework, each potential value is associated with a weight that ranges from 0 to 1, indicating its significance within the set of possibilities.

### Definition: Trapezoidal Fuzzy Number

A trapezoidal fuzzy number  $\tilde{A}(a_1, a_2, a_3, a_4; 1)$  is dictated by a membership function

$$\mu_{\tilde{A}}(z) = \begin{cases} \frac{z - a_1}{a_2 - a_1}, & a_1 \leq z \leq a_2 \\ 1, & a_2 \leq z \leq a_3 \\ \frac{z - a_4}{a_3 - a_4}, & a_3 \leq z \leq a_4 \\ 0, & \text{otherwise} \end{cases}$$

**Syamala et al.,**

**Multiserver Queueing Model with Single Vacation and (e, d)- Policy**

We analyze an M/M/c queue system where some idle servers can take vacations. When the count of idle servers drops to a critical threshold d, a group of ee (where e≤d) idle servers may take a vacation for an arbitrary duration. Upon returning from their vacation, these e servers rejoin the system simultaneously, regardless of the number of customers present, whether they are busy or idle. The arrival of customers is modeled as a Poisson process with a rate of λ, while the service times follow an exponential distribution with a rate parameter γ. The vacation periods are also modeled using an exponential distribution, characterized by a parameter v. This arrangement is termed a single vacation under the (e, d)-policy. The requirement for stability in this queueing model is  $\frac{\lambda}{c\mu} < 1$ .

The queue operates under a First-Come, First-Serve (FCFS) discipline. In this study, we explore the M/M/C queue system with a single vacation (e,d)-policy within a fuzzy context. Xiuli and Zhe [21] have provided precise findings for the mean queue length E(Lq) and the mean waiting time E(Wq) for this model. The conditional queue length (Lq) in this system can be broken down into two independent random variables:  $L_q=L_a+L_b$ . Here,  $L_a$  represents the number of customers waiting in the Typical M/M/c queue with continuous operation, while  $L_b$  reflects the overflow queue size caused by the vacation. Similarly, the waiting time based on conditions in the queue  $W_q$  can be divided into two independent components:  $W_q=W_a+W_b$ , where  $W_a$  refers to the holding time in the typical M/M/c queue with no vacations, and  $W_b$  accounts for the extra waiting duration caused by the vacation.

(ie).  $E(L_a) = \frac{\rho}{1-\rho}$

$E(W_a) = \frac{\rho}{c\gamma(1-\rho)}$

$E(L_b) = \frac{1-\sigma}{1-r}$

$E(W_b) = \frac{1-\sigma}{c\gamma(1-r)}$

$E(L_q) = \frac{\rho}{1-\rho} + \frac{1-\sigma}{1-r}$

$E(W_q) = \frac{\rho}{c\gamma(1-\rho)} + \frac{1-\sigma}{c\gamma(1-r)}$

Mean System length  $E(L_s) = \frac{1}{\rho} [\frac{\rho}{1-\rho} + \frac{1-\sigma}{1-r}]$

Mean waiting time in the System  $E(W_s) = \frac{L_s}{\lambda} [\frac{\rho}{c\gamma(1-\rho)} + \frac{1-\sigma}{c\gamma(1-r)}$

At the point  $r = \frac{\lambda+v+(c-e)\gamma - \sqrt{[\lambda+v+(c-e)\gamma]^2 - 4\lambda(c-e)\mu}}{2(c-e)\mu}$

Chance of added queue size  $L_b = 0$

(ie).  $\sigma = \frac{\pi_{c_1}}{H_1(1-\rho)}$

Probability of all servers working without vacation is  $H1 = \frac{1}{1-\rho} [\pi_{c_1} + \frac{vr}{c\gamma(1-r)^2} \pi_{c_0}]$

The steady state condition for this model  $\rho = \frac{\lambda}{c\gamma} < 1$

**Incenter of Centroids Fuzzy Ranking Method – Algorithm**

The centroid of a trapezoid (as illustrated in Figure 1) is regarded as its balancing point. The trapezoid can be divided into three distinct plane figures: a triangle (APB), a rectangle (BPQC), and another triangle (CQD). The centroids of these figures are denoted as  $G_1$ ,  $G_2$ , and  $G_3$  respectively. The incenter of these centroids  $G_1$ ,  $G_2$ , and  $G_3$  serves as the reference point for determining the ranking of generalized trapezoidal fuzzy numbers. The rationale behind using this point as the reference is that the centroid of each figure represents its individual balancing point. Meanwhile, the incenter of these centroid points offers a more stable balancing point for a generalized trapezoidal fuzzy number. Consequently, this incenter serves as a better reference point than the centroid of the trapezoid itself. Consider a generalized trapezoidal fuzzy number  $\tilde{A}(a, b, c, d; w)$ , We define the incenter  $I_{\tilde{A}}(\bar{x}_0, \bar{y}_0)$  of the triangle with vertices  $G_1, G_2,$  and  $G_3$  of the generalized trapezoidal fuzzy number  $\tilde{A}(a, b, c, d; w)$ ,

**Syamala et al.,**

$$I_{\tilde{a}}(\tilde{x}_0, \tilde{y}_0) = \left( \frac{\alpha \left( \frac{a+2b}{3} \right) + \beta \left( \frac{b+c}{2} \right) + \gamma \left( \frac{2c+d}{3} \right)}{\alpha + \beta + \gamma}, \frac{\alpha \left( \frac{w}{3} \right) + \beta \left( \frac{w}{2} \right) + \gamma \left( \frac{w}{3} \right)}{\alpha + \beta + \gamma} \right), \text{ Where}$$

$$\alpha = \frac{\sqrt{(c-3b+2d)^2 + w^2}}{6} \quad \beta = \frac{\sqrt{(2c+d-a-2b)^2}}{3} \quad \gamma = \frac{\sqrt{(3c-2a-b)^2 + w^2}}{6}$$

$$R(A) = (\tilde{x}_0 \ x \ \tilde{y}_0) = \left( \frac{\alpha \left( \frac{a+2b}{3} \right) + \beta \left( \frac{b+c}{2} \right) + \gamma \left( \frac{2c+d}{3} \right)}{\alpha + \beta + \gamma} \ x \ \frac{\alpha \left( \frac{w}{3} \right) + \beta \left( \frac{w}{2} \right) + \gamma \left( \frac{w}{3} \right)}{\alpha + \beta + \gamma} \right)$$

The ranking function for the fuzzy number  $\tilde{A}(a,b,c,d;w)$  maps the collection of all fuzzy numbers to the set of real numbers. The multi-server queuing model with a single vacation (e,d)-policy is represented using fuzzy set theory.

**Numerical example**

Suppose arrival rate, service rate, and vacation rates are trapezoidal fuzzy numbers represented by  $\tilde{\lambda}_1 = [3 \ 4 \ 5 \ 6; 1]$ ,  $\tilde{\lambda}_2 = [2 \ 3 \ 4 \ 5; 1]$ ,  $\tilde{\lambda}_3 = [6 \ 7 \ 8 \ 9; 1]$ ,  $\tilde{\lambda}_4 = [1 \ 2 \ 3 \ 4; 1]$ ,  $\tilde{\lambda}_5 = [4 \ 5 \ 6 \ 7; 1]$  and  $\tilde{\gamma}_1 = [12 \ 13 \ 14 \ 15; 1]$ ,  $\tilde{\gamma}_2 = [11 \ 12 \ 13 \ 14; 1]$ ,  $\tilde{\gamma}_3 = [13 \ 14 \ 15 \ 16; 1]$ ,  $\tilde{\gamma}_4 = [14 \ 15 \ 16 \ 17; 1]$ ,  $\tilde{\gamma}_5 = [15 \ 16 \ 17 \ 18; 1]$ ;  $\tilde{v} = [2 \ 6 \ 10 \ 21; 1]$  we take the number of servers  $c=8$ , we fix  $d=5$  and  $e=4$  i.e) When the number of inactive servers reaches five, then any three Inactive servers will undertake vacation together. Using the Incenter of Centroid Fuzzy Ranking Methods, we convert fuzzy numbers into crisp values through defuzzification, allowing us to determine the performance measures of the system  $E[L_q]$ ,  $E[W_q]$ ,  $E[L_s]$ ,  $E[W_s]$ .

Table 1 indicates that as the value of  $\tilde{\lambda}$  increases,  $E(L_q)$  also increases, whereas as the value of  $\tilde{\gamma}$  increases,  $E(L_q)$  decreases. Figure 2 indicates that as the value of  $\tilde{\lambda}$  increases,  $E(L_q)$  also increases, whereas as the value of  $\tilde{\gamma}$  increases,  $E(L_q)$  decreases. Table 2 indicates that as the value of  $\tilde{\lambda}$  increases,  $E(W_q)$  also increases, whereas as the value of  $\tilde{\gamma}$  increases,  $E(W_q)$  decreases. Figure 3 indicates that as the value of  $\tilde{\lambda}$  increases,  $E(W_q)$  also increases, whereas as the value of  $\tilde{\gamma}$  increases,  $E(W_q)$  decreases. Table 3 indicates that as the value of  $\tilde{\lambda}$  increases,  $E(L_s)$  also increases, whereas as the value of  $\tilde{\gamma}$  increases,  $E(L_s)$  decreases. Figure 4 indicates that as the value of  $\tilde{\lambda}$  increases,  $E(L_s)$  also increases, whereas as the value of  $\tilde{\gamma}$  increases,  $E(L_s)$  decreases. Table 4 indicates that as the value of  $\tilde{\lambda}$  increases,  $E(W_s)$  also increases, whereas as the value of  $\tilde{\gamma}$  increases,  $E(W_s)$  decreases. Figure 5 indicates that as the value of  $\tilde{\lambda}$  increases,  $E(W_s)$  also increases, whereas as the value of  $\tilde{\gamma}$  increases,  $E(W_s)$  decreases.

**CONCLUSION**

In this study, we analyzed a multi-server queuing model with a single vacation under the (e,d)-policy in a fuzzy environment. When the inter-arrival time, service time, and vacation time are treated as fuzzy variables, performance metrics such as the expected number of customers in the queue, expected waiting time in the queue, expected number of customers in the system, and expected waiting time in the system will also be fuzzy. From the numerical example, it was observed that as  $\tilde{\gamma}$  increases, the lower bound of the average queue length rises while the upper bound decreases a trend that is similarly reflected in the average waiting time in the queue. The graph illustrates this

**Syamala et al.,**

pattern, demonstrating the efficiency of the model. Vacation models are crucial in the planning and design of telecommunication networks. As the performance measures, such as waiting time and the expected number of customers in the queue and system, are crisp values, the proposed approach allows the decision-maker to make optimal and effective choices with great ease.

### ABSTRACT

The main focus of this paper is to introduce the concept of  $E^\sim$  and  $E_\alpha^\sim$  closed set and in intuitionistic topological spaces. Also, we study and establish more relationship between  $E^\sim$  and  $E_\alpha^\sim$  frontier sets in the intuitionistic topological concepts.

**Keywords:** Intuitionistic set,  $IE^\sim$  and  $IE_\alpha^\sim$ -closed set,  $IE^\sim$  and  $IE_\alpha^\sim$  frontier sets.

### INTRODUCTION

Coker [1][2] was introduced the concept of intuitionistic set and intuitionistic topological spaces. In 1963, Levine [3-4] was introduced the notions of semi open sets and g-closed sets and investigated it. In 2023, OchananNethaji and PitchaiJeyalakshmi [5] introduced new classes of sets called E-closed sets and  $E_\alpha$ -closed sets in topological spaces and some of its basic properties. In 2020, L.Vidyanani and R.Padma Priya [6], On Frontier and Exterior In Intuitionistic Supra  $-\alpha$  Closed Set has declared intuitionistic supra  $\alpha$ -frontier and  $\alpha$ -exterior in intuitionistic supra topological spaces. By using these concepts, we introduce  $IE^\sim$ -closed sets,  $IE_\alpha^\sim$ -closed sets,  $IE^\sim$  frontier and  $IE_\alpha^\sim$  frontier. The investigations got wider in the area of intuitionistic topology and its applications. In this paper, some of the properties of intuitionistic  $\tilde{E}$ -closed sets and  $\tilde{E}$  (Fr) are explored.

**Deepak and Santhiya**

**PRELIMINARIES**

**Definition 2.1** [6] Let  $X$  be a non-empty set, an intuitionistic set (IS in short)  $A$  is an object having the form  $A = \langle X, A_1, A_2 \rangle$  where  $A_1$  and  $A_2$  are subsets of  $X$  satisfying  $A_1 \cap A_2 = \emptyset$ . The set  $A_1$  is called the set members of  $A$ , while  $A_2$  is called the set of non-members of  $A$ .

**Definition 2.2** [6] Let  $X$  be a non-empty set,  $A = \langle X, A_1, A_2 \rangle$  and  $B = \langle X, B_1, B_2 \rangle$  be IS's on  $X$  and let  $\{A_i; i \in J\}$  be an arbitrary family of IS's in  $X$ , where  $A_i = \langle X, A_i^{(1)}, A_i^{(2)} \rangle$ . Then

- (i)  $A \subseteq B$  iff  $A_1 \subseteq B_1$  and  $A_2 \supseteq B_2$
- (ii)  $A = B$  iff  $A \subseteq B$  and  $B \subseteq A$ .
- (iii)  $\bar{A} = \langle X, A_2, A_1 \rangle$
- (iv)  $A \cup B = \langle X, A_1 \cup B_1, A_2 \cap B_2 \rangle$
- (v)  $A \cap B = \langle X, A_1 \cap B_1, A_2 \cup B_2 \rangle$
- (vi)  $A - B = A \cap \bar{B}$ .

**Definition 2.3** [6] an intuitionistic topology on a non-empty set  $X$  is a family  $\tau$  of IS's in  $X$  satisfying the following axioms:

- (i)  $X, \emptyset \in \tau$
- (ii)  $A_1 \cap A_2 \in \tau$  for any  $A_1, A_2 \in \tau$ .
- (iii)  $\cup A_i \in \tau$  for any arbitrary family  $\{A_i; i \in J\} \subseteq \tau$ .

The pair  $(X, \tau)$  is called an intuitionistic topological space (ITS in short) and IS in  $\tau$  is known as an intuitionistic open set (IOS in short) in  $X$ , the complement of IOS is called an intuitionistic closed set (ICS in short).

**Definition 2.4** [5] A subset  $A$  of a space  $(X, \tau)$  is called

- (i) I semi-open set if  $A \subseteq I \text{cl}(\text{int}(A))$ ;
- (ii) I preopen set if  $A \subseteq I \text{int}(\text{cl}(A))$ ;
- (iii) I  $\alpha$ -open set if  $A \subseteq I \text{int}(\text{cl}(\text{int}(A)))$ ;
- (iv) I  $\beta$ -open set (= semi-pre open set) if  $A \subseteq I \text{cl}(\text{int}(\text{cl}(A)))$ ;
- (v) I regular open set if  $A = I \text{int}(\text{cl}(A))$ .

**Definition 2.5** [5] A subset  $A$  of a space  $(X, \tau)$  is called

- (i) An intuitionistic generalized closed (briefly Ig-closed) set if  $I \text{cl}(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is I open in  $(X, \tau)$ . The complement of Ig-closed set is called Ig-open set;
- (ii) An intuitionistic semi-generalized closed (briefly Isg-closed) set if  $I \text{sgcl}(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is I semi-open in  $(X, \tau)$ . The complement of Isg-closed set is called Isg-open set.
- (iii) An intuitionistic semi-generalized closed (briefly Is-closed) set if  $I \text{sgcl}(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is I open in  $(X, \tau)$ . The complement of Isg-closed set is called Isg-open set;
- (iv) An intuitionistic  $\alpha$ generalized - closed (briefly I $\alpha$ g-closed) set if  $I \alpha \text{cl}(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is I open in  $(X, \tau)$ . The complement of I $\alpha$ g-closed set is called I $\alpha$ g-open set;
- (v) A  $\hat{g}$ -closed set if  $I \text{cl}(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is sI-open in  $(X, \tau)$ . The complement of  $\hat{g}$ -closed set is called  $\hat{g}$ -open set.
- (vi) A  $\hat{g}$ -closed set (=  $\omega$ -closed set) if  $\text{cl}(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is semi-open. The complement of  $\hat{g}$ -closed set is called  $\hat{g}$ -open

**ON I $\hat{E}$ -CLOSED SETS**

We introduce the following definitions.

**Deepak and Santhiya**

**Definition3.1.**

(i) A subset A of a space  $(X, \tau)$  is called an IA-closed set if  $Icl(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is  $Ig^2$ -open in  $(X, \tau)$ . The complement of an IA-closed set is called IA-open set.  
 (ii) A subset A of a space  $(X, \tau)$  is called an IB-closed set if  $IscI(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is IA-open in  $(X, \tau)$ . The complement of an IB-closed set is called IB-open set.  
 The collection of all IA-closed sets in  $X$  is denoted by  $IAC(X)$ .

**Definition3.2.** A subset A of a space  $(X, \tau)$  is called a  $\tilde{I\tilde{E}}$ -closed set if  $Icl(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is IB-open in  $(X, \tau)$ . The complement of  $\tilde{I\tilde{E}}$ -closed set is called  $\tilde{I\tilde{E}}$ -open set. The collection of all  $\tilde{I\tilde{E}}$  closed set in  $X$  is denoted by  $\tilde{I\tilde{E}}C(X)$ .

**Remark 3.3.**

Each I closed set is IB-closed but not conversely.

**Example3.4** Let  $X = \{q, r, s\}$  with  $\tau = \{X, \phi, \langle X, \{q\}, \phi \rangle, \langle X, \{r\}, \phi \rangle, \langle X, \{q, r\}, \phi \rangle, \langle X, \{q, s\}, \phi \rangle\}$   $IBC(X) = \{X, \phi, \langle X, \phi, \{q\} \rangle, \langle X, \phi, \{r\} \rangle, \langle X, \phi, \{q, r\} \rangle, \langle X, \phi, \{q, s\} \rangle, \langle X, \phi, \{r, s\} \rangle\}$  Here  $A = \{\langle X, \phi, \{r, s\} \rangle\}$  is IB-closed but not I closed.

**Proposition3.5.** Each I closed set is  $\tilde{I\tilde{E}}$ -closed in  $X$ .

**Proof:** If A is any, I closed set in  $X$  and G is any IB-open set containing A, then  $G \supseteq A = Icl(A)$ . Hence A is  $\tilde{I\tilde{E}}$ -closed.

**Example3.6.** Let  $X = \{q, r\}$ ,  $\tau = \{X, \phi, \langle X, \phi, \{q\} \rangle, \langle X, \{r\}, \phi \rangle, \langle X, \{q\}, \{r\} \rangle, \langle X, \{q\}, \phi \rangle\}$   
 Then,  $\tilde{I\tilde{E}}(X) = \{X, \phi, \langle X, \phi, \{q\} \rangle, \langle X, \phi, \{r\} \rangle\}$ . We have  $A = \{\langle X, \phi, \{q\} \rangle\}$  is  $\tilde{I\tilde{E}}$ -closed

**Definition3.7.** A subset A of a space  $(X, \tau)$  is called a  $\tilde{I\tilde{E}} \alpha$ -closed set if  $I\alpha cl(A) \subseteq U$  whenever  $A \subseteq U$  and  $U$  is IB-open in  $(X, \tau)$ . The complement of  $\tilde{I\tilde{E}} \alpha$ -closed set is called  $\tilde{I\tilde{E}} \alpha$ -open set. The collection of all  $\tilde{I\tilde{E}} \alpha$ -closed (respectively  $\tilde{I\tilde{E}} \alpha$ -open) sets in  $X$  are denoted by  $\tilde{I\tilde{E}} \alpha C(X)$  (respectively  $\tilde{I\tilde{E}} \alpha O(X)$ ).

**Proposition3.8.** Each  $\tilde{I\tilde{E}}$ -closed set is  $\tilde{I\tilde{E}} \alpha$ -closed in  $X$ .

**Proof:** If A is a  $\tilde{I\tilde{E}}$ -closed set in  $X$  and G is any IB-open set containing A, then  $G \supseteq Icl(A) \supseteq I\alpha cl(A)$ . Hence A is  $\tilde{I\tilde{E}} \alpha$ -closed. Converse of Proposition 3.8 need not be true as seen from the following example.

**Example3.9.** Let  $X = \{q, r, s\}$ ,  $\tau = \{X, \phi, \langle X, \{q, r\}, \{s\} \rangle, \langle X, \{r\}, \phi \rangle, \langle X, \{q\}, \{r\} \rangle, \langle X, \{q, r\}, \phi \rangle\}$   
 $\tilde{I\tilde{E}}C(X) = \{X, \phi, \langle X, \{r\}, \{q\} \rangle, \langle X, \phi, \{r\} \rangle, \langle X, \phi, \{q, r\} \rangle, \langle X, \{s\}, \{q, r\} \rangle\}$   
 $\tilde{I\tilde{E}} \alpha C(X) = \{X, \phi, \langle X, \phi, \{q\} \rangle, \langle X, \{r\}, \{q\} \rangle, \langle X, \phi, \{r\} \rangle, \langle X, \phi, \{q, r\} \rangle, \langle X, \phi, \{r, s\} \rangle, \langle X, \phi, \{q, s\} \rangle, \langle X, \{r\}, \{q, s\} \rangle, \langle X, \{s\}, \{q, r\} \rangle\}$   
 We have  $A = \{\langle X, \phi, \{q, s\} \rangle\}$  is  $\tilde{I\tilde{E}} \alpha$ -closed set but not  $\tilde{I\tilde{E}}$ -closed.

**Proposition3.10.** Each  $\tilde{I\tilde{E}}$ -closed set is Isg-closed in  $X$

**Proof:** If A is a  $\tilde{I\tilde{E}}$ -closed set in  $X$  and G is any I semi-open set containing A, since every I semi-open set is IB-open and A is  $\tilde{I\tilde{E}}$ -closed, we have  $G \supseteq Icl(A) \supseteq scl(A)$ . Hence A is Isg-closed. Converse of Proposition 3.10 need not be true as seen from the following example.

**Example3.11** Let  $X = \{q, r, s\}$  with  $\tau = \{X, \phi, \langle X, \{q\}, \phi \rangle, \langle X, \{r\}, \phi \rangle, \langle X, \{q, r\}, \phi \rangle, \langle X, \{q, s\}, \phi \rangle\}$   
 $\tilde{I\tilde{E}}C(X) = \{X, \phi, \langle X, \phi, \{q\} \rangle, \langle X, \phi, \{r\} \rangle, \langle X, \phi, \{q, s\} \rangle, \langle X, \phi, \{q, r\} \rangle\}$   
 $ISGC(X) = \{X, \phi, \langle X, \phi, \{q\} \rangle, \langle X, \phi, \{r\} \rangle, \langle X, \phi, \{r, s\} \rangle, \langle X, \phi, \{q, s\} \rangle, \langle X, \phi, \{q, r\} \rangle\}$   
 We have  $A = \{\langle X, \phi, \{r, s\} \rangle\}$  is Isg-closed set but not  $\tilde{I\tilde{E}}$ -closed.

**Deepak and Santhiya**

**Proposition 3.12** Each  $I\tilde{E}$ -closed set is  $I\alpha$  g-closed in  $X$ .

**Proof:** If  $A$  is an  $I\tilde{E}$ -closed set in  $X$  and  $G$  is any  $I$  open set containing  $A$ , since every  $I$  open set is  $IB$ -open, we have  $G \supseteq Icl(A) \supseteq I\alpha cl(A)$ . Hence  $A$  is  $I\alpha$  g-closed. Converse of Proposition 3.12 need not be true as seen from the following example.

**Example 3.13.** Let  $X = \{q, r\}$ ,  $\tau = \{X, \phi, \langle X, \phi, \{q\} \rangle, \langle X, \{r\}, \phi \rangle, \langle X, \{q\}, \{r\} \rangle, \langle X, \{q\}, \phi \rangle\}$

Then  $I\tilde{E}C(X) = \{X, \phi, \langle X, \phi, \{q\} \rangle, \langle X, \phi, \{r\} \rangle\}$

$I\alpha GC(X) = \{X, \phi, \langle X, \phi, \{q\} \rangle, \langle X, \{q\}, \phi \rangle, \langle X, \phi, \{r\} \rangle, \langle X, \{r\}, \{q\} \rangle\}$  We have  $A = \langle X, \{r\}, \{q\} \rangle$  is  $I\alpha$  g-closed set but not  $I\tilde{E}$ -closed

**Proposition 3.14.** Each  $I\tilde{E}$ -closed set is  $Igs$ -closed in  $X$ .

**Proof:** If  $A$  is a  $I\tilde{E}$ -closed set in  $X$  and  $G$  is any  $I$ open set containing  $A$ , since every  $I$ open set is  $IB$ -open, we have  $G \supseteq Icl(A) \supseteq Iscl(A)$ . Hence  $A$  is  $Igs$ -closed.

The converse of Proposition 3.14 need not be true as seen from the following example.

**Example 3.15** Let  $X = \{q, r, s\}$  with  $\tau = \{X, \phi, \langle X, \{q\}, \phi \rangle, \langle X, \{r\}, \phi \rangle, \langle X, \{q, r\}, \phi \rangle, \langle X, \{q, s\}, \phi \rangle\}$

$I\tilde{E}C(X) = \{X, \phi, \langle X, \phi, \{q\} \rangle, \langle X, \phi, \{r\} \rangle, \langle X, \phi, \{q, s\} \rangle, \langle X, \phi, \{q, r\} \rangle\}$

$IGSC(X) = \{X, \phi, \langle X, \phi, \{q\} \rangle, \langle X, \phi, \{r\} \rangle, \langle X, \phi, \{r, s\} \rangle, \langle X, \phi, \{q, s\} \rangle, \langle X, \phi, \{q, r\} \rangle\}$

We have  $A = \langle X, \phi, \{r, s\} \rangle$  is  $Igs$ -closed set but not  $I\tilde{E}$ -closed.

**Remark 3.16.** The following examples show that  $I\tilde{E}$ -closed sets are independent of  $I\alpha$ -closed sets and  $I$  semi-closed sets.

**Example 3.17** Let  $X = \{q, r, s\}$  with  $\tau = \{X, \phi, \langle X, \{q\}, \phi \rangle, \langle X, \{r\}, \phi \rangle, \langle X, \{q, r\}, \phi \rangle,$

$\langle X, \{q, s\}, \phi \rangle\}$   $I\tilde{E}C(X) = \{X, \phi, \langle X, \phi, \{q\} \rangle, \langle X, \phi, \{r\} \rangle, \langle X, \phi, \{q, s\} \rangle, \langle X, \phi, \{q, r\} \rangle\}$   $I\tilde{E}\alpha C(X) = ISC(X) = \{X, \phi, \langle X, \phi, \{q\} \rangle, \langle X, \phi, \{r\} \rangle, \langle X, \phi, \{q, r\} \rangle, \langle X, \phi, \{r, s\} \rangle, \langle X, \phi, \{q, s\} \rangle\}$

We have  $A = \langle X, \phi, \{r, s\} \rangle$  is both  $I\alpha$ -closed set and  $I$ semi-closed set but not  $I\tilde{E}$ -closed.

### INTUITIONISTISTIC $\tilde{E}$ FRONTIER SETS

**Definition 4.1** Let  $X$  be an ITS and for a subset  $A$  of an ITS  $X$ ,  $I\tilde{E} Fr(A) = I\tilde{E} cl(A) - I\tilde{E} int(A)$  is said to be Intuitionistic  $\tilde{E}$  Frontier of  $A$ .

**Theorem 4.2** Let  $X$  be an ITS then and for any a subset  $A$  of  $IS$  in ITS  $X$ ,

The following statements hold:

(i)  $I\tilde{E} Fr(A) = I\tilde{E} cl(A) \cap I\tilde{E} cl(X-A)$

(ii)  $I\tilde{E} Fr(A) = I\tilde{E} Fr(X-A)$

(iii)  $I\tilde{E} Fr(I\tilde{E} Fr(A)) \subseteq I\tilde{E} Fr(A)$ .

(iv)  $I\tilde{E} int(A) \cap I\tilde{E} Fr(A) = \phi$

(v)  $I\tilde{E} Fr(X) = \phi, I\tilde{E} Fr(\phi) = X$

**Proof.** Let  $A$  be a  $IS$  in ITS  $X$ .

(i)  $I\tilde{E} Fr(A) = I\tilde{E} cl(A) - I\tilde{E} int(A) = I\tilde{E} cl(A) \cap I\tilde{E} cl(X-A)$ .

(ii)  $I\tilde{E} Fr(A) = I\tilde{E} cl(A) - I\tilde{E} int(A) = (X - I\tilde{E} int(A)) - (X - I\tilde{E} cl(A)) = I\tilde{E} cl(X-A) - I\tilde{E} int(X-A) = I\tilde{E} Fr(X-A)$

(iii)  $I\tilde{E} Fr(I\tilde{E} Fr(A)) = I\tilde{E} cl(I\tilde{E} Fr(A)) \cap I\tilde{E} cl(X - I\tilde{E} Fr(A)) \subseteq I\tilde{E} cl(I\tilde{E} Fr(A)) = I\tilde{E} Fr(X-A)$ . Hence  $I\tilde{E} Fr(I\tilde{E} Fr(A)) \subseteq I\tilde{E} Fr(A)$ .

(iv)  $I\tilde{E} int(A) \cap I\tilde{E} Fr(A) = I\tilde{E} int(A) \cap (I\tilde{E} cl(A) - I\tilde{E} int(A)) = \phi$

(v)  $I\tilde{E} Fr(X) = \phi, I\tilde{E} Fr(\phi) = X$

**Example 4.3** Let  $X = \{q, r\}$ ,  $\tau = \{X, \phi, \langle X, \phi, \{q\} \rangle, \langle X, \{r\}, \phi \rangle, \langle X, \{q\}, \{r\} \rangle, \langle X, \{q\}, \phi \rangle\}$  Let  $A = \langle X, \phi, r \rangle$ ,  $X - A = \langle X, \{r\}, \phi \rangle$ ,  $I\tilde{E} int(A) = \phi$ ,  $I\tilde{E} cl(A) = \langle X, \phi, r \rangle$ ,  $I\tilde{E} Fr(A) = \langle X, \phi, r \rangle$ ,  $I\tilde{E} int(X - A) = \langle X, r, \phi \rangle$ ,  $I\tilde{E} cl(X - A) = X$ ,  $I\tilde{E} Fr(X - A) = \langle X, \phi, r \rangle$

(i)  $I\tilde{E} Fr(A) = I\tilde{E} cl(A) - I\tilde{E} int(A) = \langle X, \phi, r \rangle$  and  $I\tilde{E} cl(A) \cap I\tilde{E} cl(X - A) = \langle X, \phi, r \rangle$

(ii)  $I\tilde{E} Fr(A) = \langle X, \phi, r \rangle$  and  $I\tilde{E} Fr(X - A) = \langle X, \phi, r \rangle$

**Deepak and Santhiya**

(iii)  $I\tilde{E}Fr(A) = \langle X, \phi, r \rangle \Rightarrow I\tilde{E}Fr(I\tilde{E}Fr(A)) = \langle X, \phi, r \rangle$ .

Hence  $I\tilde{E}Fr(I\tilde{E}Fr(A)) \subseteq I\tilde{E}Fr(A)$ .

(iv)  $I\tilde{E}int(A) \cap I\tilde{E}Fr(A) = \phi$

(v)  $I\tilde{E}Fr(X) = \phi, I\tilde{E}Fr(\phi) = X$ .

**Definition 4.4** Let  $X$  be an ITS and for a subset  $A$  of an ITS,  $I\tilde{E}\alpha Fr(A) = I\tilde{E}\alpha cl(A) - I\tilde{E}\alpha int(A)$  said to be Intuitionistic  $\tilde{E}\alpha$ -Frontier of  $A$ .

**Theorem 4.5** For a subset  $A$  of ITS,  $I\tilde{E}\alpha Fr(A) \subseteq I\tilde{E}Fr(A)$

**Proof** Let  $x \in I\tilde{E}\alpha Fr(A)$  then  $x \in I\tilde{E}\alpha cl(A) - I\tilde{E}int(A)$ , implies  $x \in I\tilde{E}\alpha cl(A) - I\tilde{E}\alpha int(A)$ , since every intuitionistic  $\tilde{E}\alpha$  closed set is intuitionistic  $\tilde{E}\alpha$ -closed set. Hence,  $x \in I\tilde{E}Fr(A)$ . Therefore,  $I\tilde{E}\alpha Fr(A) \subseteq I\tilde{E}Fr(A)$ .

Converse of the above theorem need not be true. It is shown in the following example.

**Example 4.6** Let  $X = \{q, r, s\}; \tau = \{X, \phi, \langle X, \{q, r\}, \{s\} \rangle, \langle X, \{q\}, \{r\} \rangle, \langle X, \{r\}, \phi \rangle, \langle X, \{q, r\}, \phi \rangle\}$

Let  $A = \{X, \phi, \{s\}\}, I\tilde{E}Fr(A) = X$  and  $I\tilde{E}\alpha Fr(A) = \langle X, \phi, \{s\} \rangle$  Here  $I\tilde{E}\alpha Fr(A) \subseteq I\tilde{E}Fr(A)$  is true but converse is not true

**Theorem 4.7** Let  $X$  be an ITS then and for any a subset  $A$  of IS in ITS  $X$ , the following statements holds:

(i)  $I\tilde{E}\alpha Fr(I\tilde{E}\alpha Fr(A)) \subseteq I\tilde{E}\alpha Fr(A)$ .

(ii)  $I\tilde{E}\alpha cl(A) = I\tilde{E}\alpha int(A) \cup I\tilde{E}\alpha Fr(A)$ .

(iii)  $I\tilde{E}\alpha int(A) \cap I\tilde{E}\alpha Fr(A) = \phi$ .

(iv)  $I\tilde{E}\alpha Fr(X) = \phi, I\tilde{E}\alpha Fr(\phi) = X$ .

(v)  $I\tilde{E}\alpha Fr(I\tilde{E}\alpha cl(A)) \subseteq I\tilde{E}\alpha Fr(A)$

**Proof**

(i)  $I\tilde{E}\alpha Fr(I\tilde{E}\alpha Fr(A)) = I\tilde{E}\alpha cl(I\tilde{E}\alpha Fr(A)) \cap I\tilde{E}\alpha cl(X - I\tilde{E}\alpha Fr(A)) \subseteq I\tilde{E}\alpha cl(I\tilde{E}\alpha Fr(A)) = I\tilde{E}\alpha Fr(X - A)$ . Hence,  $I\tilde{E}\alpha Fr(I\tilde{E}\alpha Fr(A)) \subseteq I\tilde{E}\alpha Fr(A)$ .

(ii)  $I\tilde{E}\alpha int(A) \cup I\tilde{E}\alpha Fr(A) = I\tilde{E}\alpha int(A) \cup (I\tilde{E}\alpha cl(A) - I\tilde{E}\alpha int(A)) = (I\tilde{E}\alpha int(A) \cup I\tilde{E}\alpha cl(A)) - (I\tilde{E}\alpha int(A) \cup I\tilde{E}\alpha int(A)) = (I\tilde{E}\alpha int(A) \cup I\tilde{E}\alpha cl(A)) - I\tilde{E}\alpha int(A) = I\tilde{E}\alpha cl(A)$ .

(iii)  $I\tilde{E}\alpha int(A) \cap I\tilde{E}\alpha Fr(A) = I\tilde{E}\alpha int(A) \cap (I\tilde{E}\alpha cl(A) - I\tilde{E}\alpha int(A)) = \phi$

(iv)  $I\tilde{E}\alpha Fr(X) = \phi; I\tilde{E}\alpha Fr(\phi) = X$ .

(v)  $I\tilde{E}\alpha Fr(I\tilde{E}\alpha cl(A)) = I\tilde{E}\alpha cl(I\tilde{E}\alpha cl(A)) - I\tilde{E}\alpha int(I\tilde{E}\alpha cl(A)) \subseteq I\tilde{E}\alpha cl(A) - I\tilde{E}\alpha int(A) = I\tilde{E}\alpha Fr(A)$ . Hence,  $I\tilde{E}\alpha Fr(I\tilde{E}\alpha cl(A)) \subseteq I\tilde{E}\alpha Fr(A)$ .

**Example 4.8** Let  $X = \{q, r, s\}; \tau = \{X, \phi, \langle X, \{q, r\}, \{s\} \rangle, \langle X, \{q\}, \{r\} \rangle, \langle X, \{r\}, \phi \rangle, \langle X, \{q, r\}, \phi \rangle\}$

Let  $A = \langle X, \{q\}, \{r, s\} \rangle, X - A = \langle X, \{r, s\}, \{q\} \rangle, I\tilde{E}\alpha int(A) = \phi, I\tilde{E}\alpha cl(A) = \langle X, \{q\}, \{r, s\} \rangle, I\tilde{E}\alpha Fr(A) = \langle X, \{q\}, \{r, s\} \rangle, I\tilde{E}\alpha int(X - A) = \phi; I\tilde{E}\alpha cl(X - A) = \langle X, \{r, s\}, \{q\} \rangle; I\tilde{E}\alpha Fr(X - A) = \langle X, \{r, s\}, \{q\} \rangle$

(i)  $I\tilde{E}\alpha Fr(A) = \langle X, \{q\}, \{r, s\} \rangle, I\tilde{E}\alpha Fr(I\tilde{E}\alpha Fr(A)) = \langle X, \{q\}, \{r, s\} \rangle$ .

Hence,  $I\tilde{E}\alpha Fr(I\tilde{E}\alpha Fr(A)) \subseteq I\tilde{E}\alpha Fr(A)$ .

(ii)  $I\tilde{E}\alpha int(A) \cup I\tilde{E}\alpha Fr(A) = \langle X, \{q\}, \{r, s\} \rangle, I\tilde{E}\alpha cl(A) = \langle X, \{q\}, \{r, s\} \rangle$ . Hence  $I\tilde{E}\alpha cl(A) = I\tilde{E}\alpha int(A) \cup I\tilde{E}\alpha Fr(A)$

(iii)  $I\tilde{E}\alpha int(A) \cap I\tilde{E}\alpha Fr(A) = \phi$ .

(iv)  $I\tilde{E}\alpha Fr(X) = \phi, I\tilde{E}\alpha Fr(\phi) = X$

(v)  $I\tilde{E}\alpha Fr(I\tilde{E}\alpha cl(A)) = \langle X, \{q\}, \{r, s\} \rangle$ . Hence,  $I\tilde{E}\alpha Fr(I\tilde{E}\alpha cl(A)) \subseteq I\tilde{E}\alpha Fr(A)$ .

## CONCLUSION

In this paper we have established and studied some properties of  $I\tilde{E}$ -closed sets,  $I\tilde{E}\alpha$ -closed sets,  $I\tilde{E}$  Frontier and  $I\tilde{E}\alpha$  Frontier in Intuitionistic topological spaces, some of the properties satisfies  $I\tilde{E}$  and  $I\tilde{E}\alpha$  topological spaces.

### ABSTRACT

This paper deals with solving differential equation using Differential Transform Method (DTM) for both linear and nonlinear differential equations through numerical examples. algebraic equations, providing approximate solutions in the form of rapidly converging series. Several numerical problems are solved to demonstrate the accuracy, effectiveness, and computational simplicity of DTM.

**Keywords:** Differential transform method, linear equation, nonlinear equation, numerical problems.

## INTRODUCTION

Differential transform method is a semi numerical analytic iterative approach used to solve ordinary and partial differential equations, as well as system of these equations by expressing the solution in series form. The Differential Transform Method (DTM), initially introduced by Zhou is an iterative technique for deriving analytic Taylor series solutions to differential equations. The DTM is derived from traditional Taylor's series method, which requires a complicated and tedious symbolic computation of higher order derivatives. One of the most significant advantages solutions of the given differential equation on a continuous interval. DTM is very useful to solve equation in ordinary differential equation [1]. The DTM is the method to determine the coefficients of the Taylor series of the function by solving the induced recursive equation from the given differential equation [2]. The DTM has no unrealistic assumptions or restrictions, such as linearization, discretization or small parameters used for nonlinear operators. The differential transformation method approximates the exact solution using polynomials, and the high-order Taylor series method can also be applied to solve differential equations. However, the Taylor method requires the

**Rathi and Kaviya**

calculation of high-order derivatives, a difficult symbolic and complex problem[3]. The differential transform method reduces the span of the computational domain compared to the other techniques and doesn't require the unneeded parameters to start the solution procedure. The series solution obtained by using DTM shows rapid convergence. One of the most significant advantages of DTM is that it obtains the solution of the given differential interval on a continuous interval. Thus, the DTM addresses linear and non-linear problems efficiently.

This paper explores numerical approaches for finding solutions to both linear and nonlinear one-dimensional differential equations.

**FUNDAMENTAL PROPERTIES:**

Differential transform for the function  $y(x)$  is given by

$$Y(k) = \frac{1}{k!} \left\{ \frac{d^k y(x)}{dx^k} \right\}_{x=0}$$

The inverse differential transform of  $Y(k)$  can be expressed as:

$$y(x) = \sum_{k=0}^{\infty} Y(k)x^k$$

**Theorem 1:** If  $u(x) = g(x) \pm h(x)$ , then  $U(k) = G(k) \pm H(k)$

**Theorem 2:** If  $u(x) = \alpha g(x)$ , then  $U(k) = \alpha G(k)$ , where  $\alpha$  is a non zero constant.

**Theorem 3:** If  $u(x) = \frac{dg(x)}{dx}$ , then  $U(k) = (k + 1)G(k + 1)$

**Theorem 4:** If  $u(x) = \frac{d^2g(x)}{dx^2}$ , then  $U(k) = (k + 1)(k + 2)G(k + 2)$

**Theorem 5:** If  $u(x) = g(x)h(x)$ , then  $U(k) = \sum_{l=0}^k G(l)H(k - l)$ .

**Theorem 6:** If  $u(x) = g(x)h(x)l(x)$ , then  $U(k) = \sum_{n=0}^k \sum_{m=0}^n G(m)H(n - m)L(k - n)$

**Theorem 7:** If  $u(x) = x^m$ , then  $U(k) = \delta(k - m) = \begin{cases} 1, & \text{if } k = m \\ 0, & \text{if } k \neq m \end{cases}$

**IMPLEMENTATION OF TECHNIQUES IN PROBLEM-SOLVING LINEAR DIFFERENTIAL EQUATION**

1) Solve  $y'' + 4y = 0$  with an initial condition  $y(0) = 1$  and  $y'(0) = 6$

**Solution:**

**DIFFERENTIAL TRANSFORM METHOD**

Let  $Y(k)$  be the differential transform of the original function  $Y(x)$ .

Applying the fundamental properties of DTM

$$D(y'' + 4y) = 0$$

$$D(y'') + 4(y) = 0 \text{ (using theorem 1)}$$

$$(k + 1)(k + 2)Y(k + 2) + 4Y(k) = 0 \text{ (using theorem 4 and 2)}$$

$$Y(k + 2) = \frac{-4 * Y(k)}{(k + 1)(k + 2)}$$

Which is a required recursive formula with transformed initial condition  $Y(0)=1$  and  $Y(1)=6$

Putting  $k=0$  into the equation we get,

$$Y(0 + 2) = \frac{-4 * Y(0)}{1 * 2}$$

$$Y(2) = -2$$

Putting  $k=1$  into the equation we get,

$$Y(3) = \frac{-4 * Y(1)}{2 * 3}$$

$$Y(3) = -4$$

Putting  $k=2$  into the equation we get,

$$Y(4) = \frac{-4 * Y(2)}{3 * 4}$$

### Rathi and Kaviya

$$Y(4) = \frac{2}{3}$$

Putting  $k=3$  into the equation we get,

$$Y(5) = \frac{-4 * Y(3)}{4 * 5}$$

$$Y(5) = \frac{4}{5}$$

Using the definition of the inverse differential transformation for the set of values  $\{Y(k)\}_{k=0}^n$ , the analytic series solution is given as

$$Y(x) = \sum_{k=0}^n Y(k)x^k$$

$$Y(x) = Y(0) + Y(1)x + Y(2)x^2 + Y(3)x^3 + Y(4)x^4 + Y(5)x^5 + \dots$$

$$Y(x) = 1 + 6x - 2x^2 - 4x^3 + \frac{2}{3}x^4 + \frac{4}{5}x^5 + \dots$$

```

**Rathi and Kaviya**

**NON-LINEAR DIFFERENTIAL EQUATION**

2) Solve  $y' = y^2 + 1$  with initial condition  $y(0)=2$

**Solution:**

**DIFFERENTIAL TRANSFORM METHOD**

Let  $Y(k)$  be the differential transform of the original function  $Y(x)$ .

Applying the fundamental properties of DTM,

$$D(y') = D(y^2 + 1)$$

$$D(y') = D(y^2) + D(1)$$

$$(k + 1)Y(k + 1) = \sum_{m=0}^k Y(m)Y(k - m) + \delta(k - 0) \text{ (using theorem 3,5 and 7)}$$

$$Y(k + 1) = \frac{\sum_{m=0}^k Y(m)Y(k - m) + \delta(k - 0)}{(k + 1)}$$

Which is a required recursive formula with the transformed initial condition  $Y(0)=2$ .

According to the definition of the Kronecker delta  $\delta(k - m) = f(x) = \begin{cases} 1 & \text{if } k = m \\ 0 & \text{if } k \neq m \end{cases}$

For  $k=0$ , the value of  $\delta(k - 0) = 1$  and  $k \geq 1$ , the value of  $\delta(k - 0) = 0$ .

Putting  $k=0$  into the equation we get,

$$Y(1) = \sum_{m=0}^0 Y(0)Y(0 - 0) + \delta(0)$$

$$Y(1) = 2 * 2 + 1$$

$$Y(1) = 5$$

Putting  $k=1$  into the equation we get,

$$Y(2) = \frac{1}{2} \sum_{m=0}^1 y(m)Y(1 - m) + \delta(1 - 0)$$

$$= \frac{1}{2} [Y(0)Y(1) + Y(1)Y(0) + 0]$$

$$= \frac{1}{2} [2(5) + 5(2)]$$

$$Y(2) = \frac{20}{2}$$

$$Y(2) = 10$$

Putting  $k=2$  into the equation we get,

$$Y(3) = \frac{1}{3} \sum_{m=0}^2 Y(m)Y(2 - m) + \delta(2 - 0)$$

$$= \frac{1}{3} [Y(0)Y(2) + Y(1)Y(1) + Y(2)Y(0)]$$

$$= \frac{1}{3} [20 + 25 + 20]$$

$$= \frac{65}{3}$$

Putting  $k=3$  into the equation we get,

$$Y(4) = \frac{1}{4} \sum_{m=0}^3 Y(m)Y(3 - m) + \delta(3 - 0)$$

$$= \frac{1}{4} [Y(0)Y(3) + Y(1)Y(2) + Y(2)Y(1) + Y(3)Y(0)]$$

$$= \frac{1}{4} \left[ 2 \times \frac{65}{3} + 5 \times 10 + 10 \times 5 + \frac{65}{3} \times 2 \right]$$

$$= \frac{1}{4} \left[ 100 + \frac{260}{3} \right]$$

$$= \frac{1}{4} \left[ \frac{300 + 260}{3} \right]$$

## Rathi and Kaviya

$$= \frac{560}{4(3)}$$

$$= \frac{140}{3}$$

Using the definition of the inverse differential transformation for the set of values  $\{Y(k)\}_{k=0}^n$ , the analytic series solution is given as

$$Y(x) = \sum_{k=0}^n Y(k)x^k$$

$$Y(x) = Y(0) + Y(1)x + Y(2)x^2 + Y(3)x^3 + Y(4)x^4 + Y(5)x^5 + \dots$$

$$Y(x) = 2 + 5x + 10x^2 + \frac{65}{3}x^3 + \frac{140}{3}x^4 + \dots$$

**MATLAB CODING:**

```

clc;
clear all;
close all;
syms x
series(x) = sym(0);
Y = zeros(1, 100);
N = input('Enter number of coefficients: ');
Y(1) = 2;
for k = 1:N
    A = 0;
    for i = 1:k
        A = A + Y(i) * Y(k - i + 1);
    end
    if k == 1
        delta = 1;
    else
        delta = 0;
    end
    Y(k + 1) = (A + delta) / k;
end
for k = 1:N
    series(x) = series(x) + Y(k) * (x^(k - 1));
end
disp('The series is:');
disp(series(x));
x_range = linspace(-10, 10, 1000);
y_values = double(subs(series(x), x, x_range));
figure;
plot(x_range, y_values, 'LineWidth', 2);
grid on;
title('Plot of the Series');
xlabel('x');
ylabel('Series Value');
xlim([-10, 10]);
ylim([-max(abs(y_values)), max(abs(y_values))]);

```

**OUTPUT:**

```

Enter number of coefficients=5
series(x) =(140*x^4)/3 + (65*x^3)/3 + 10*x^2 + 5*x + 2

```

**Rathi and Kaviya**

**CONCLUSION**

DTM offers a systematic approach for solving differential equations. The numerical examples highlight the methods efficiency, precision and adaptability in handling both linear and nonlinear problems.

## ABSTRACT

Medical diagnosis frequently grapples with uncertainty due to inconclusive test results and ambiguous symptoms. This paper investigates the application of intuitionistic sets as a mathematical tool to address this uncertainty in diagnostics. By categorizing diseases into diagnosed, ruled out, and uncertain subsets, intuitionistic sets provide a systematic method for healthcare practitioners to handle ambiguous cases. Additionally, the paper explores the potential of integrating this approach into decision support systems (DSS) to automate diagnostic categorization, recommend further tests, and prioritize treatments. While this method offers a structured approach to managing diagnostic uncertainty, it also faces challenges related to complexity and practical implementation.

**Keywords:** Diagnostic Uncertainty, Intuitionistic Sets, Decision Support Systems (DSS), Medical Diagnostics

## INTRODUCTION

In the realm of medical diagnostics, healthcare practitioners frequently face uncertainties caused by inconclusive test results, unclear symptoms, and overlapping illness presentations. Traditional diagnostic procedures may fail to accurately identify patients, resulting in potential misdiagnoses or treatment delays. This diagnostic uncertainty can have a major impact on the choice of additional testing, therapy prioritization, and patient outcomes. Intuitionistic

Selvanayaki et al.,

sets, a mathematical construct under fuzzy set theory, provide a novel way to deal with such uncertainty. Unlike classical sets, intuitionistic sets allow elements to be classified not just into diagnosed and ruled-out categories, but also as "uncertain" subsets. This new level of uncertainty handling makes intuitionistic sets ideal for medical diagnostics, because incomplete knowledge must be managed on a continuous basis. By allowing for gradations in the membership of items (such as symptoms or test results) in a set, intuitionistic sets provide a more nuanced framework for capturing the complexity inherent in diagnostic processes. Intuitionistic sets, a mathematical construct under fuzzy set theory, provide a novel way to deal with such uncertainty. Unlike classical sets, intuitionistic sets allow elements to be classified not just into diagnosed and ruled-out categories, but also as "uncertain" subsets. This new level of uncertainty handling makes intuitionistic sets ideal for medical diagnostics, because incomplete knowledge must be managed on a continuous basis. By allowing for gradations in the membership of items (such as symptoms or test results) in a set, intuitionistic sets provide a more nuanced framework for capturing the complexity inherent in diagnostic processes. However, while intuitionistic sets hold potential for transforming diagnostic practices, they also present challenges. These include increased computational complexity and the need for adaptations in clinical workflows. This paper examines both the advantages and limitations of intuitionistic sets, assessing their practical feasibility and the implications for their implementation in medical settings. Through this exploration, we aim to offer insights into how intuitionistic sets can be effectively applied in diagnostics to support improved patient care in the face of uncertainty. In this paper, study on respiratory diseases illustrates how intuitionistic sets can streamline the diagnostic process. While this method offers a structured approach to managing diagnostic uncertainty, it also faces challenges related to complexity and practical implementation.

**PREMILINARIES**

**Definition 1. [2]** Let  $X$  be a non empty set. An intuitionistic set (IS for short)  $A$  is an object having the form  $A = \langle X, A_1, A_2 \rangle$ , where  $A_1$  and  $A_2$  are subsets of  $X$  satisfying  $A_1 \cap A_2 = \emptyset$ . The set  $A_1$  is called the set of members of  $A$ , while  $A_2$  is called the set of non-members of  $A$ .

**Definition 2. [2]** Let  $X$  be a non empty set and  $A, B$  are intuitionistic sets in the form  $A = \langle X, A_1, A_2 \rangle, B = \langle X, B_1, B_2 \rangle$  respectively. Then

- (a)  $A \subseteq B$  iff  $A_1 \subseteq B_1$  and  $A_2 \supseteq B_2$
- (b)  $A = B$  iff  $A \subseteq B$  and  $B \subseteq A$
- (c)  $\bar{A} = \langle X, A_2, A_1 \rangle$
- (d)  $[A] = \langle X, A_1, (A_1)^c \rangle$
- (e)  $A - B = A \cap \bar{B}$ .
- (f)  $\phi = \langle X, \emptyset, X \rangle, \bar{X} = \langle X, X, \emptyset \rangle$
- (g)  $A \cup B = \langle X, A_1 \cup B_1, A_2 \cap B_2 \rangle$ .
- (h)  $A \cap B = \langle X, A_1 \cap B_1, A_2 \cup B_2 \rangle$ .

Furthermore, let  $\{A_i : i \in J\}$  be an arbitrary family of intuitionistic sets in  $X$ , where  $A_i = \langle X, A_i^{(1)}, A_i^{(2)} \rangle$ . Then

- (i)  $\cap A_i = \langle X, \cap A_i^{(1)}, \cup A_i^{(2)} \rangle$ .
- (j)  $\cup A_i = \langle X, \cup A_i^{(1)}, \cap A_i^{(2)} \rangle$ .

**Definition 3.** An intuitionistic topology on a non empty set  $X$  is a family of IS's in  $X$  containing  $\phi, \bar{X}$  and closed

under finite infima and arbitrary suprema. The pair  $(X, \tau)$  is called an intuitionistic topological space. Any intuitionistic set in  $\tau$  is known as an intuitionistic open set in  $X$  and the complement of intuitionistic open set is called intuitionistic closed set.

Selvanayaki et al.,

### Diagnostic Uncertainty in Respiratory Diseases Using Intuitionistic Sets

Respiratory diseases like pneumonia, asthma, and chronic obstructive pulmonary disease (COPD) often present with overlapping symptoms, such as cough, wheezing, and shortness of breath. This overlap can lead to diagnostic uncertainty, particularly in cases where initial test results are inconclusive. Here, we apply intuitionistic sets to categorize the diagnostic possibilities for a patient presenting with respiratory symptoms, creating subsets to denote clear, uncertain, and ruled-out conditions. The application of intuitionistic set theory allows us to systematically manage the inherent ambiguity in the diagnosis.

### Mathematical Model of Diagnosis Using Intuitionistic Sets

Let  $X$  be the set of all possible diseases or conditions a patient might have, based on symptoms and medical history. The diagnosis process can be modeled using intuitionistic sets.

Each intuitionistic open set in the form  $\langle X, A_1, A_2 \rangle$  is represented by specifying its **membership set**  $A_1$  (the subset of diseases that are confidently diagnosed), **non-membership set**  $A_2$  (the subset of diseases that are confidently ruled out), and the set  $X \setminus (A_1 \cup A_2)$ : representing uncertainty.

### Setting Up the Universal Set $X$

Based on our disease set  $X = \{\text{COVID-19, Flu, Pneumonia, Asthma, Tuberculosis}\}$ , let's structure distinct intuitionistic open sets that capture the variety of diagnostic states without duplicates

### Define Intuitionistic Open Sets

We will now define each intuitionistic open set  $U_i = \langle X, A_1, A_2 \rangle$  based on the diagnostic categorization for membership  $A_1$ , non-membership  $A_2$ , and the subset representing uncertainty.

#### 1. Intuitionistic Open Set $U_1$ : Confirmed Diagnoses Only

- **Membership**  $A_1$ :  $\{\text{COVID-19, Pneumonia}\}$  – Diseases confidently diagnosed.
- **Non-membership**  $A_2$ :  $\emptyset$  – No diseases are confidently ruled out here.
- **Uncertainty**  $X \setminus (A_1 \cup A_2)$ :  $\{\text{Flu, Asthma, Tuberculosis}\}$

So,  $U_1 = \langle X, \{\text{COVID-19, Pneumonia}\}, \emptyset \rangle$

#### 2. Intuitionistic Open Set $U_2$ : Excluding Confidently Ruled-Out Diseases

- **Membership**  $A_1$ :  $\{\text{COVID-19, Pneumonia}\}$  – Diseases confidently diagnosed.
- **Non-membership**  $A_2$ :  $\{\text{Flu}\}$  – Disease confidently ruled out.
- **Uncertainty**  $X \setminus (A_1 \cup A_2)$ :  $\{\text{Asthma, Tuberculosis}\}$

So,  $U_2 = \langle X, \{\text{COVID-19, Pneumonia}\}, \{\text{Flu}\} \rangle$

#### 3. Intuitionistic Open Set $U_3$ : Including Suspected Disease Asthma

- **Membership**  $A_1$ :  $\{\text{COVID-19, Pneumonia, Asthma}\}$  – Includes both confirmed and suspected cases.
- **Non-membership**  $A_2$ :  $\{\text{Flu}\}$  – Disease confidently ruled out.
- **Uncertainty**:  $X \setminus (A_1 \cup A_2)$ :  $\{\text{Tuberculosis}\}$

So,  $U_3 = \langle X, \{\text{COVID-19, Pneumonia, Asthma}\}, \{\text{Flu}\} \rangle$

#### 4. Minimal Open Set $U_4$ : Empty Diagnosis and Non-diagnosis

- **Membership**  $A_1$ :  $\emptyset$
- **Non-membership**  $A_2$ :  $\emptyset$
- **Uncertainty**:  $X \setminus (A_1 \cup A_2)$ :  $X$

So,  $U_4 = \langle X, \emptyset, \emptyset \rangle$

#### 5. Intuitionistic Open Set $U_5$ : Entire Set as Diagnosed

- **Membership**  $A_1$ :  $X$
- **Non-membership**  $A_2$ :  $\emptyset$
- **Uncertainty**:  $X \setminus (A_1 \cup A_2)$ :  $X$

So,  $U_5 = \langle X, X, \emptyset \rangle$

**Selvanayaki et al.,**

This structured format allows the medical diagnostic process to clearly delineate which diseases are confidently diagnosed, confidently ruled out, or uncertain, facilitating a nuanced approach to handling diagnostic ambiguity using intuitionistic sets.

**Intuitionistic Topology  $\tau$**

The collection of these sets forms an intuitionistic topology  $\tau$  on  $X$  with the open sets:  
 $\tau = \{U_1, U_2, U_3, U_4, U_5\}$

**Verification**

This set  $\tau$  satisfies the properties of an intuitionistic topology, as it includes:

- The empty intuitionistic open set  $U_4 = \langle X, \emptyset, \emptyset \rangle$ ,
- The universal set  $U_5 = \langle X, X, \emptyset \rangle$ , and
- A sufficient number of unique open sets that represent different diagnostic scenarios on satisfying arbitrary union and finite intersection

**Definitions and Notations**

Given an intuitionistic set  $A \langle X, A_1, A_2 \rangle$ , where  $A_1$  is the membership set and  $A_2$  is the non-membership set, the definitions used will be:

**Intuitionistic Closure  $Icl(A)$  :**

- It is the smallest intuitionistic closed set containing  $A$ , incorporating points of uncertainty in relation to the open sets in  $\tau$ .

**Intuitionistic Interior  $Int(A)$ :**

- It is the largest intuitionistic open set contained in  $A$ , reflecting only those elements of  $X$  that fully belong to  $A_1$  without uncertainty.

**Intuitionistic Semiopen Set  $A$  :**

- This set contains elements of  $A_1$  and some additional elements in the boundary, allowing a mix of certainty and partial uncertainty.

**Intuitionistic Regular Open Set:**

- The regular open set associated with  $A$  is such that it's equal to the interior of its closure, ensuring that the set remains stable upon closure.

**Intuitionistic Preopen Set:**

- This set contains elements that almost certainly belong to  $A$  but may not strictly satisfy the full membership criteria.

**Given Example Data for  $A = \langle X, A_1, A_2 \rangle$**

Let's use the example given:

- **Universal Set**  $X = \{COVID-19, Flu, Pneumonia, Asthma, Tuberculosis\}$  **Membership Set**  $A_1$ :  
 $\{COVID-19, Pneumonia\}$
- **Non-Membership Set**  $A_2$ :  $\{Flu\}$

**Uncertainty:**  $X \setminus (A_1 \cup A_2)$ :  $\{Asthma, Tuberculosis\}$

Using the definitions:

1. **Intuitionistic Closure  $Icl(A)$ :**

- $Icl(A)$  includes all elements in  $A_1$ , any adjacent uncertain elements that could be within its boundary, and excludes  $A_2$ . Therefore:  
 $Icl(A) = \langle X, \{COVID-19, Pneumonia, Asthma, Tuberculosis\}, \{Flu\} \rangle$

2. **Intuitionistic Interior  $Int(A)$ :**

- The interior will strictly contain the elements in  $A_1$  that belong exclusively to  $A$  with no uncertainty, omitting any boundary elements. Therefore:  $Int(A) = \langle X, \{COVID-19, Pneumonia\}, \emptyset \rangle$

Selvanayaki et al.,

### Constructing Intuitionistic Semiopen, Regular Open, and Preopen Sets

#### 1. Intuitionistic Semiopen Set:

- This set allows partial inclusion of uncertain elements.
- Let's define it as follows, where we include part of the uncertainty set:  
Semiopen Set =  $\langle X, \{\text{COVID-19, Pneumonia, Asthma}\}, \{\text{Flu}\} \rangle$

#### 2. Intuitionistic Regular Open Set:

- This set is the interior of the closure of A. Given  $\text{Icl}(A) = \langle X, \{\text{COVID-19, Pneumonia, Asthma, Tuberculosis}\}, \{\text{Flu}\} \rangle$ , the interior of this set would retain only the fully diagnosed members without uncertainty: Regular Open Set =  $\langle X, \{\text{COVID-19, Pneumonia}\}, \emptyset \rangle$

#### 3. Intuitionistic Preopen Set:

- This set captures elements in  $A_1$  as well as additional members on the verge of being in A without full certainty. We can represent this as: Preopen Set =  $\langle X, \{\text{COVID-19, Pneumonia, Asthma}\}, \emptyset \rangle$

### Interpretation

1. **Semiopen Set** includes elements that are partially uncertain (Asthma) but avoids full closure, making it suitable for cases where certain conditions may be likely but not confirmed.
2. **Regular Open Set** reaffirms strict membership by removing all boundary points, useful for fully confirmed diagnoses.
3. **Preopen Set** retains elements in the boundary but treats them with cautious membership, allowing for flexibility in diagnostic consideration without full confirmation.

Each set provides a different lens on the diagnostic confidence, from strict confirmation to cautious inclusion of possible cases, allowing for nuanced decision-making in medical diagnostics.

### Decision Support System (DSS)

Integrating intuitionistic sets into a **Decision Support System (DSS)** for medical diagnostics can help manage diagnostic uncertainty, enabling more precise recommendations. Intuitionistic sets provide a flexible mathematical framework for categorizing diseases based on confidence, exclusion, and uncertainty, enhancing the system's ability to interpret ambiguous or partial data. Here's how intuitionistic sets can be effectively integrated into a DSS:

#### Structure of the DSS using Intuitionistic Sets

The DSS can use an underlying structure of intuitionistic sets to assess each disease for a given patient. Each disease D is represented as an intuitionistic  $D = \langle X, A_1, A_2 \rangle$ , where:

- $A_1$ : Set of diseases confidently diagnosed for the patient.
- $A_2$ : Set of diseases confidently ruled out for the patient.
- $X \setminus (A_1 \cup A_2)$ : Set of diseases with uncertain diagnostic status, either due to inconclusive test results or symptoms that overlap with multiple conditions.

This structure allows the DSS to dynamically adjust diagnoses based on updates in test results, new symptoms, or changes in patient history, with the intuitionistic sets helping to quantify and categorize levels of diagnostic confidence.

#### DSS Workflow for Diagnosis Using Intuitionistic Sets

The DSS diagnostic process can follow these steps:

- **Input Patient Data:** Collect patient data, including symptoms, test results, medical history, and demographic information.
- **Formulate Initial Intuitionistic Sets:**
  - Based on initial tests and evaluations, the system categorizes diseases into:
    - $A_1$ : Diagnosed diseases (with high confidence).
    - $A_2$ : Ruled-out diseases (with high confidence of non-existence).

### Selvanayaki et al.,

- $X \setminus (A_1 \cup A_2)$ : Diseases with uncertain status requiring further investigation.
- **Refine with Advanced Processing:**
  - The system re-evaluates  $A_1, A_2$  and uncertain diseases by integrating more data or new test results.
  - Adjustments to the intuitionistic sets can be made based on the likelihood that new results support or refute specific conditions.

#### Diagnostic Recommendations

Using the structured intuitionistic sets, the DSS can make diagnostic recommendations as follows:

- **For Diagnosed Diseases ( $A_1$ ):** Provide treatment recommendations and priority levels for these conditions.
- **For Ruled-Out Diseases ( $A_2$ ):** Avoid unnecessary treatments for these diseases, focusing resources on conditions in  $A_1$  or uncertain conditions.
- **For Uncertain Conditions ( $X \setminus (A_1 \cup A_2)$ ):** Recommend additional tests or observations, focusing on refining the status of these diseases within the intuitionistic framework.

#### Advanced Applications of Intuitionistic Sets in DSS

1. **Sequential Diagnosis:** As new data arrives, the DSS continuously updates the intuitionistic sets, allowing the system to refine diagnoses progressively.
2. **Priority-Setting and Resource Allocation:** Diseases in  $A_1$  (high confidence) get top priority for treatment, while uncertain cases are flagged for further testing, optimizing resource use and patient outcomes.
3. **Customizable Diagnostic Thresholds:** Intuitionistic parameters in  $A_1$  and  $A_2$  can be adjusted based on severity, patient history, and epidemiological data, enabling flexible decision-making.
4. **Patient Risk Profiling:** The DSS can use intuitionistic sets to categorize patients into risk groups, allowing healthcare providers to monitor patients with high uncertainty  $X \setminus (A_1 \cup A_2)$  for changes in their health status.

#### Example Workflow in the DSS with Intuitionistic Sets

Consider a patient with symptoms related to respiratory issues. Using intuitionistic sets, the DSS might categorize potential diseases as follows:

- **COVID-19 and Pneumonia** in  $A_1$  (Diagnosed confidently based on positive tests).
- **Flu** in  $A_2$  (Ruled out with high confidence).
- **Asthma and Tuberculosis** in  $X \setminus (A_1 \cup A_2)$  (Uncertain, needing further tests).

From this setup, the DSS will:

- Prioritize treatment and isolation measures for COVID-19 and Pneumonia.
- Suggest no intervention for the flu.
- Recommend further testing for Tuberculosis and Asthma.

#### Implementation Considerations

1. **User Interface:** The DSS should visualize the intuitionistic set structure, showing which diseases are diagnosed, ruled out, or uncertain, and the associated recommendations for each.
2. **Data Management:** Efficient data processing pipelines are necessary to handle updates to intuitionistic sets as new data becomes available.
3. **Integration with Electronic Health Records (EHR):** Synchronizing with EHR systems can enhance the DSS by using patient history for refining intuitionistic set membership over time.
4. **Training and Adaptation:** Medical staff should be trained to interpret the results of the DSS, especially the nuances of uncertain diagnoses, allowing them to make informed decisions.

#### Benefits of Using Intuitionistic Sets in DSS

- **Enhanced Diagnostic Accuracy:** By incorporating uncertainty, the DSS can avoid premature conclusions.
- **Efficient Resource Utilization:** Only uncertain cases get further testing, reducing redundant diagnostics.

Selvanayaki *et al.*,

- **Personalized Recommendations:** The DSS can adapt recommendations based on patient-specific uncertainty levels. Incorporating intuitionistic sets into a DSS thus provides a robust and flexible approach to managing diagnostic uncertainty, supporting a nuanced medical decision-making process that directly benefits both patients and healthcare providers

## CONCLUSION

Integrating intuitionistic sets into Decision Support Systems (DSS) provides an organized strategy to dealing with medical diagnostic uncertainty, especially in ambiguous or complex circumstances. Traditional binary diagnostic models frequently fail in circumstances when evidence is inadequate or inconclusive, whereas intuitionistic sets address this by dividing diseases into diagnosed, ruled-out, and unsure subsets. This study demonstrated how intuitionistic sets provide a good foundation for defining distinct diagnostic statuses, allowing for continuous refinement of diagnoses as new data becomes available. This study on respiratory disorders shows that intuitionistic sets can help prioritize treatments, prevent wasteful procedures, and offer focused follow-up diagnostics for unknown conditions. This framework not only simplifies the diagnostic procedure, but also allows for a dynamic, patient-specific model that can adapt to changing information, improving both accuracy and resource efficiency. The possibility for using this approach in real-world DSS applications is exciting because it enables healthcare providers to make more informed judgments while accounting for the complexities of medical ambiguity. Future research should concentrate on refining DSS user interfaces, assessing system efficacy in clinical situations, and investigating the advantages of combining intuitionistic sets with other types of soft computing to handle more complex diagnostic scenarios.

### ABSTRACT

The three-player Prisoner's Dilemma game is addressed in this study using an Intuitionistic fuzzy technique that employs a ranking procedure between triangular intuitionistic fuzzy numbers to arrive at the game's Nash Equilibrium solution.

**Keywords:** Intuitionistic fuzzy sets, Nash Equilibrium, Prisoner's Dilemma, Non-cooperative games, Triangular Intuitionistic Fuzzy Number.

## INTRODUCTION

A game is a decision-making situation in which one or more people pursue their own goals. The player could be an individual or a group. The concept of game theory was first introduced by Von Neumann and Morgenstern in their book *The Theory of Games and Economic Behaviour*. Participants in the game may be cooperative or non-cooperative in a given setting. J. Nash improved our understanding of non-cooperative games and equilibrium points [3]. The general strategies for selecting the best solution to a game are min-max and linear programming. Other considerations, such as philosophical motivations, moral aesthetics, environmental conditions, and a lack of information, can all influence the process of picking the optimal solutions in practice. To evaluate the game's outcome in the context of imprecision or ambiguity, we use L.A. Zadeh's concept of fuzzy numbers [8]. Atanassov [5] proposed the idea of intuitionistic fuzzy sets, which use membership and non-membership functions. The use of

**Sahathana Thasneem and Radharamani**

Triangular Intuitionistic Fuzzy Numbers (TIFNs) to solve Bi-matrix games involving two players has been introduced[6], with the inequality requirements between TIFNs being used to determine the optimal solution and equilibrium locations[7].The Prisoner's Dilemma is a classic game model in game theory that usually involves two players. In fuzzy game theory, the prisoner's dilemma game is solved with triangular fuzzy membership [1]. The Three Player Prisoner's Dilemma (3p-PD) game is an iterative variation of Prisoner's Dilemma that has more than two players[2]. In this paper, we introduce the concept of solving a 3p-PD game with triangular intuitionistic fuzzy numbers and calculating the game's Nash equilibrium solution. The paper is structured as follows: Section 2 defines TIFNs and describes their arithmetic operations; section 3 contains a model for solving the 3-PD game with TIFN payoffs; and section 4 provides a numerical example. Section 5 finishes the paper.

**PRELIMINARIES**

**Definition 2.1**

A Triangular Intuitionistic Fuzzy Number (TIFN) is defined as  $\tilde{l} = \langle (\underline{l}, \ell, \bar{l}); w_{\tilde{l}}, u_{\tilde{l}} \rangle$  in  $\mathbb{R}$  with membership function  $\mu_{\tilde{l}}(x)$  and non-membership function  $v_{\tilde{l}}(x)$  which are defined as

$$\mu_{\tilde{l}}(x) = \begin{cases} \frac{x - \underline{l}}{\ell - \underline{l}} w_{\tilde{l}}, & \underline{l} \leq x < \ell \\ w_{\tilde{l}}, & x = \ell \\ \frac{\bar{l} - x}{\bar{l} - \ell} w_{\tilde{l}}, & \ell < x \leq \bar{l} \\ 0, & x < \underline{l} \text{ or } x > \bar{l} \end{cases}, \quad v_{\tilde{l}}(x) = \begin{cases} \frac{(\underline{l} - x) + u_{\tilde{l}}(x - \underline{l})}{(\ell - \underline{l})}, & \underline{l} \leq x < \ell \\ u_{\tilde{l}}, & x = \ell \\ \frac{(x - \ell) + u_{\tilde{l}}(\bar{l} - x)}{(\bar{l} - \ell)}, & \ell < x \leq \bar{l} \\ 1, & x < \underline{l} \text{ or } x > \bar{l} \end{cases}$$

The values  $w_{\tilde{l}}, u_{\tilde{l}}$  represents the maximum degree of membership and minimum degree of non-membership, respectively. And they satisfy the condition  $0 \leq w_{\tilde{l}} \leq 1, 0 \leq u_{\tilde{l}} \leq 1$  and  $0 \leq w_{\tilde{l}} + u_{\tilde{l}} \leq 1$ .

**Definition 2.2:**

For a TIFN  $\tilde{l} = \langle (\underline{l}, \ell, \bar{l}); w_{\tilde{l}}, u_{\tilde{l}} \rangle$  the  $(\alpha, \beta)$ - cut set is a subset of R that is  $\tilde{l}_{\alpha, \beta} = \{x: \mu_{\tilde{l}}(x) \geq \alpha, v_{\tilde{l}}(x) \leq \beta\}$ , where  $0 \leq \alpha \leq w_{\tilde{l}}, u_{\tilde{l}} \leq \beta \leq 1$  and  $0 \leq \alpha + \beta \leq 1$ . and  $\tilde{l}_{\alpha}$  is defined by the closed interval  $[L_{\tilde{l}}(\alpha), R_{\tilde{l}}(\alpha)]$ ,

$$L_{\tilde{l}}(\alpha) = \frac{(w_{\tilde{l}} - \alpha)\underline{l} + \alpha\ell}{w_{\tilde{l}}}, \quad R_{\tilde{l}}(\alpha) = \frac{(w_{\tilde{l}} - \alpha)\bar{l} + \alpha\ell}{w_{\tilde{l}}}$$

$$\tilde{l}_{\alpha} = \left[ \frac{(w_{\tilde{l}} - \alpha)\underline{l} + \alpha\ell}{w_{\tilde{l}}}, \frac{(w_{\tilde{l}} - \alpha)\bar{l} + \alpha\ell}{w_{\tilde{l}}} \right]$$

Similarly the  $\beta$  -cut is defined as

$$\tilde{l}_{\beta} = \left[ \frac{(1 - \beta)\ell + (\beta - u_{\tilde{l}})\underline{l}}{1 - u_{\tilde{l}}}, \frac{(1 - \beta)\ell + (\beta - u_{\tilde{l}})\bar{l}}{1 - u_{\tilde{l}}} \right]$$

**Value and Ambiguity of TIFN**

For the TIFN  $\tilde{l} = \langle (\underline{l}, \ell, \bar{l}); w_{\tilde{l}}, u_{\tilde{l}} \rangle$  the value of membership and non-membership functions is denoted as  $S_{\mu}(\tilde{l})$  and  $S_{v}(\tilde{l})$ ,  $f(\alpha) = \frac{\alpha}{2w_{\tilde{l}}}$  and  $g(\beta) = \frac{1 - \beta}{2(1 - u_{\tilde{l}})}$  then

$$S_{\mu}(\tilde{l}) = \int_0^{w_{\tilde{l}}} \left[ \frac{(w_{\tilde{l}} - \alpha)\underline{l} + \alpha\ell + (w_{\tilde{l}} - \alpha)\bar{l} + \alpha\ell}{w_{\tilde{l}}} \right] \frac{\alpha}{2w_{\tilde{l}}} d\alpha = \frac{w_{\tilde{l}}(\underline{l} + \bar{l} + 4\ell)}{12}$$

$$S_{v}(\tilde{l}) = \int_{u_{\tilde{l}}}^1 \left[ \frac{(1 - \beta)\ell + (\beta - u_{\tilde{l}})\underline{l} + (1 - \beta)\ell + (\beta - u_{\tilde{l}})\bar{l}}{1 - u_{\tilde{l}}} \right] \frac{1 - \beta}{2(1 - u_{\tilde{l}})} d\beta = \frac{(\underline{l} + 4\ell + \bar{l})(1 - u_{\tilde{l}})}{12}$$

The ambiguity of the TIFN  $\tilde{l} = \langle (\underline{l}, \ell, \bar{l}); w_{\tilde{l}}, u_{\tilde{l}} \rangle$  are denoted as  $T_{\mu}(\tilde{l})$  and  $T_{v}(\tilde{l})$ , defined as

$$T_{\mu}(\tilde{l}) = \int_0^{w_{\tilde{l}}} \left[ \frac{(w_{\tilde{l}} - \alpha)\bar{l} + \alpha\ell - (w_{\tilde{l}} - \alpha)\underline{l} + \alpha\ell}{w_{\tilde{l}}} \right] \frac{\alpha}{2w_{\tilde{l}}} d\alpha = \frac{(\bar{l} - \underline{l})w_{\tilde{l}}}{12}$$

**Sahathana Thasneem and Radharamani**

$$T_v(\tilde{l}) = \int_{u_l}^1 \left[ \frac{(1-\beta)l + (\beta-u_l)\bar{l} - (1-\beta)l + (\beta-u_l)l}{1-u_l} \right] \frac{1-\beta}{2(1-u_l)} d\beta = \frac{(\bar{l}-l)(1-u_l)}{12}$$

**Definition 2.3**

For the TIFN  $\tilde{l} = \langle (l, \ell, \bar{l}); w_l, u_l \rangle$  and the ranking function or defuzzify function is defined as  $v: \mathcal{F}(R) \rightarrow R$  where  $\mathcal{F}(R)$  is the collection of all Triangular Intuitionistic fuzzy numbers defined on  $R$ , and the function maps each TIFN into the real line. And the ranking method also used to evaluate the relation between values and ambiguities of membership and non-membership functions of Triangular Intuitionistic fuzzy numbers defined as,

$$v(l) = \frac{\mathbb{P}(\tilde{l}) + \mathbb{Q}(\tilde{l})}{2} \tag{1}$$

$$\mathbb{P}(\tilde{l}) = C_\mu(\tilde{l}) + C_v(\tilde{l}) = \frac{(l + 4\ell + \bar{l})(w_l + 1 - u_l)}{12}$$

$$\mathbb{Q}(\tilde{l}) = D_\mu(\tilde{l}) + D_v(\tilde{l}) = \frac{(\bar{l} - l)(w_l + 1 - u_l)}{12}$$

**Definition 2.4**

The aggregated value of the Triangular Intuitionistic fuzzy numbers is defined as

$$Ag(\tilde{T}_{ij}^k) = \left\langle \left( \sum_{i,j,k=1}^n (t_{ij}^k)^p, \sum_{i,j,k=1}^n (t_{ij}^k)^p, \sum_{i,j,k=1}^n (\bar{t}_{ij}^k)^p \right); \bigwedge_{1 \leq i,j,k \leq n} \{w_{\tilde{T}_{ij}^k}\}, \bigvee_{1 \leq i,j,k \leq n} \{u_{\tilde{T}_{ij}^k}\} \right\rangle \tag{2}$$

Where  $p$  is the probability of the event, in the three dimensional payoff matrix the value of  $p$  is  $p = \frac{1}{8}$ . The aggregated value of TIFNs is also a TIFN.

**Equilibrium in Three player game**

The general structure of a three player game in which each player has two strategies is defined by the coalition of set of players  $N = \{1,2,3\}$ , strategies or actions  $s_i, i = 1,2,3$ , and the payoff function  $p_i \in R, i = 1,2,3$ , strategy space for each player  $i, S_i, i = 1,2,3$ , and strategy combinations between strategies  $(s_1, s_2)$ . According to Nash, a finite non-cooperative game has at least one equilibrium. In an n-person game, each participant selects a finite strategy set from the strategy space. Each strategy in the player's strategy space competes with each plan from the other player's strategy space in order to achieve the largest reward. In the non-cooperative game  $s_j$  are the strategy set of other players, and each player  $i$  have the knowledge about  $s_j, j \in N$  and  $p_j(s)$  is the payoff function in the strategy set  $s_j$ . So in the game each player  $i$  choose his best action according to  $j$  and  $p_i(s/t_i)$  is the best outcome of the player  $i$  with respect to  $s$ , and  $t_i(s)$  is the collection of best possible outcomes of  $i \in N$ . Because there may be more than one maximum payoff for  $s_i$ . So a strategy  $\bar{s}$  is said to be a best response if  $\bar{s} \in t_i(\bar{s})$  that is  $\bar{s}$  is the equilibrium if  $\bar{s} \in s_i$  and  $p_i(\bar{s}) = \max_{s_i} p_i(\bar{s}; s_i), i \in N$ .

**Prisoner's Dilemma with three players**

The Prisoner's Dilemma is a game in which two players are imprisoned for a crime and must spend their entire time alone in solitary confinement. When there is insufficient evidence to prosecute them, the authorities either offer each prisoner a deal to cooperate with them or place both in temporary imprisonment. In comparison to the inmate who refuses to cooperate with the authorities, the cooperative prisoner will receive a lower sentence. In this scenario, each person has two choices. They have the option of cooperating (C) or not. Noncooperation causes a defect (D). The classic version of the prisoner's dilemma (PD) game could have featured three or more players. When the PD game is extended to three players, the potential strategy combinations result in eight different coalitions: CCC, CCD, CDC, DCC, DCD, DDC, and DDD, each with six outcomes: R, K, S, T, L, or P. The payout values meet the inequality requirement  $T > R > L > K > P > S$ . Similar to the two-player PD game, T is regarded the maximum payment, which excludes the penalty or minimum prison time, and S is the minimum payoff. The three-player PD game allows for a variety of decision-making situations. Players may be allowed to engage, find a means to learn about other players' decisions, or have prior knowledge of other players' behaviours, etc. Previously, the three-player PD was solved using a model described as two-state automata[2]. In this manner, the above-mentioned strategy combination

### Sahathana Thasneem and Radharamani

contains a first position that represents the player under consideration, while the second and third positions represent the opponents. Intuitionistic fuzzy set theory[5] uses the membership and non-membership functions to illustrate decision maker's level of acceptance and hesitance regarding a strategy, which is significant in a setting for making decisions in real life situations. Three players making decisions at the same time are considered in this scenario. The reward values take the form of Triangular Intuitionistic fuzzy numbers. The Nash Equilibrium strategy for the game is determined using the procedure outlined below.

#### Example

The players 1,2 and 3 are given a choice to either cooperate or not- cooperate without knowing the choice of the other players. Each player's main goal is to maximize their own payoff. The payoff values are

$$R = \langle (37,43,48); 0.8,0.1 \rangle$$

$$K = \langle (86,90,96); 0.7,0.2 \rangle$$

$$S = \langle (135,140,144); 0.6,0.3 \rangle$$

$$T = \langle (-0 -) \rangle$$

$$L = \langle (62,66,72); 0.6,0.2 \rangle$$

$$P = \langle (105,114,120); 0.5,0.4 \rangle$$

The payoff values regarding the strategy combination are put together in the payoff table

Using the aggregation function(2) the payoff values become,

In the aggregated payoff value  $\tilde{t}_{ij}^k$ ,  $i, j, k = 1, 2, \dots, n$  denotes the strategy choices of the players. Here we have two strategy. While forming the payoff matrix  $i, j, k$  represents the row, column and page values of the matrix which leads to the three dimension form. So the aggregated payoff matrix for the three player PD game with TIFN payoffs is of the form

To find the Nash equilibrium of the game the ranking value of every payoff is calculated using the ranking function(1),

$$R(\tilde{t}_{11}^1) = 0.7838$$

$$R(\tilde{t}_{11}^2) = 0.7197$$

$$R(\tilde{t}_{12}^1) = 0.7197$$

$$R(\tilde{t}_{12}^2) = 0.6565$$

$$R(\tilde{t}_{21}^1) = 0.7197$$

$$R(\tilde{t}_{21}^2) = 0.6565$$

$$R(\tilde{t}_{22}^1) = 0.6565$$

$$R(\tilde{t}_{22}^2) = 0.5715$$

The maximum ranking value is  $R(\tilde{t}_{11}^1) = 0.7838$ , CCC is the equilibrium strategy for the game.

## CONCLUSION

After reviewing the created model for solving three-player Prisoner's Dilemma games with Triangular Intuitionistic Fuzzy payoffs, this strategy is suitable for decision makers who are unaware of their opponents' options and must deal with the game problem's ambiguity and uncertainty.

### ABSTRACT

This paper focuses on the application of three novel ranking formulas to solve the Fuzzy Linear Fractional Programming Problem (FLFPP), where coefficients are represented by fuzzy neutrosophic numbers. The proposed formulas effectively transform fuzzy neutrosophic quantities into crisp values, enabling the determination of optimal solutions using the simplex method. A decomposition technique is introduced, splitting the FLFPP into two Fuzzy Linear Programming (FLP) problem to simplify the process. The study evaluates the new ranking formulas by demonstrating their ability to rank fuzzy neutrosophic numbers through numerical examples. A comparative analysis is presented, using multiple bar diagrams to illustrate the performance of the new methods against existing ones in terms of fuzzy optimal results. The research highlights the convexity property of FLFPP, ensuring that integrated solutions can be obtained. The current work focuses on verifying the consistency of these solutions using the proposed approach. By addressing uncertainties inherent in neutrosophic fuzzy systems, the proposed formulas offer a structured methodology for solving FLFPP more effectively. Future research will investigate how these ranking methods can be extended and applied to various scientific fields, where uncertainty and fuzziness are significant challenges, to further enhance solution accuracy and reliability.

**Keywords:** Fuzzy Linear Programming, Fuzzy Linear Fractional Programming, Triangular, Trapezoidal, and Pentagonal Fuzzy Neutrosophic Numbers.

Rajarajeswari et al.,

## INTRODUCTION

Ballmen and Zadeh[2] first encountered the fuzzy system decision-making because of rapid growth in the linear programming theory and the theory of decisions. This led to the creation of a new area of study that integrates uncertainty and decision-making within fuzzy systems where the exact information may not readily be available. Later, Reza Ghanbari et al.[10] and others introduced the concept of (FLP) problem using fuzzy parameters, which brought much attention to this topic. In recent years, FLFP has attracted many researchers and a great deal of models have been developed to optimize Fuzzy Linear Programming(FLP) problem because fuzzy logic helps in dealing with uncertainties and imprecisions in different fields. Most ranking functions were introduced to handle the fuzzy numbers, which are used to rank fuzzy numbers representing uncertain values and help in making decisions when such values are involved. The more widely known types of fuzzy numbers are the Triangular, Trapezoidal, and Pentagonal Fuzzy Neutrosophic Numbers. These sets of numbers have been useful in solving various real-life problems concerning fuzzy decision-making. For example, FLFP may be used to solve finance, engineering, and many more complex problems involving uncertain data. Over the years, several authors have published different methods for solving fuzzy problems. Charnes and Cooper [3] formulated a mathematical approach for solving linear fractional problems; to such problems the data get translated in the terms of a linear programming problem which hence resolves the problem easily. Abass et.al.,[1] studied uncertainty case of linear fractional programming where the exactness of data cannot be identified, which hence discussed the methods of solving such problems. Li and Chen [8] incorporated the method of FLFP with fuzzy coefficients. Ganesan and Veeramani [7] explained solving FLP problem using trapezoidal fuzzy neutrosophic numbers. Such numbers are useful in representing unclear information in a clear and precise manner. The use of FLFP in the industrial sector was described by Das et.al.,[4]. Two methods have been proposed by Sapan Kumar Das et.al.,[11] and [12] for solving triangular neutrosophic LFPP and FLFP using trapezoidal fuzzy numbers, respectively. For instance, in business sectors, they are normally associated with cost, resource, or time uncertainties, fuzzy logic helps the uncertainty. Deepak Gupta et. al.,[5] presented rank function, which was used to solve the problems in fully FLFP. Thereby, the problem solving was enhanced. At the same time, Elhadidi et.al.,[6] studied trapezoidal neutrosophic number-based linear fractional programming problem; that is, another means of dealing with uncertainty in decisions.

This paper solves FLFP using new ranking methods. Here, Triangular, Trapezoidal, and Pentagonal Fuzzy Neutrosophic Numbers are considered. First, the coefficients of the objective function and the constraints, respectively, are represented by these fuzzy numbers, thus handling uncertainty at the problem site. Hence, triangular fuzzy neutrosophic number is applied in simple cases, the trapezoidal fuzzy neutrosophic number is used to apply cases that are a bit more complex and consequently in cases where there are layers of uncertainty, the pentagonal fuzzy neutrosophic number is used. In order to identify new approaches based on these different types of fuzzy numbers, the work is extended with these approaches. With the help of these proposed methods, it is shown how they operate by taking numerical examples useful for comparison of the effectiveness of new ranking methods versus older ones. The differences in the results obtained by means of new and old strategies are demonstrated with a bar diagram. However, it is proved that the presented methods can be comparatively better for FLFP. Those methods provide a better ranking approach of fuzzy numbers and find optimal solutions in cases of uncertainty. The new ranking strategies proved to be more effective in the fuzzy neutrosophic number as seen from the numerical examples. Results clearly show superiority in these methods when compared with existing ones. Methods

## PRELIMINARIES

This section intends to specify the general format of FLFP and an algorithm solution of proposed methodology to optimize FLFP are outlined.

**Rajarajeswari et al.,**

**The General format of FLFPP**

Maximize (or) Minimize  $F(x) = \frac{\sum_{j=1}^n c_j x_j + \alpha_j}{\sum_{j=1}^n d_j x_j + \beta_j}$

s.t

$\sum_{i=1}^m a_{ij} x_j \leq b_i$

$x_j \geq 0 \quad j=1,2,\dots,n.$

Where  $c_j, d_j, \alpha_j, \beta_j$  are represented as various types of fuzzy neutrosophic numbers.

**Algorithm to get the solution of FLFPP**

By using the following algorithm, we can solve Fuzzy LFPP using various types of fuzzy neutrosophic numbers namely TFNN, TrFNN and PFNN.

**Step 1:** Consider a FLFPP in which the coefficients associated with decision variables X1 and X2, both in the objective function and the constraint set, are modeled utilizing various types of fuzzy neutrosophic numbers namely TFNN, TrFNN and PFNN.

Maximize (or) Minimize  $F(x) = \frac{\sum_{j=1}^n c_j x_j + \alpha_j}{\sum_{j=1}^n d_j x_j + \beta_j}$  s.t

$\sum_{i=1}^m a_{ij} x_j \leq b_i$

$x_j \geq 0 \quad j=1,2,\dots,n.$

Where  $c_j, d_j, \alpha_j, \beta_j$  are represented as various types of fuzzy neutrosophic numbers.

**Step 2:** Convert above FLFPP into a fuzzy crisp value via new ranking function of various types of fuzzy neutrosophic numbers as below

(i) Ranking function R(A) for Triangular Fuzzy Neutrosophic Number[TFNN]

$R(A) = \frac{a+(9*b)+c}{16} (2+T-I-F)$

(ii) Ranking function R(A) for Trapezoidal Fuzzy Neutrosophic Number[TrFNN]

$R(A) = \frac{3a+(b*c)+3d}{16} (2+T-I-F)$

(iii) Ranking function for Pentagonal Fuzzy Neutrosophic Number[PFNN]

$R(A) = \frac{a+b+c+d+e}{15} (2+T-I-F)$

**Step 3:** Decompose the obtained FLFPP into two FLP problems as below.

**(F-1)**

Maximize (or) Minimize  $F_1(x) = \sum_{j=1}^n S(c_j x_j) + S(\alpha_j)$

s.t

$\sum_{i=1}^m S(a_{ij} x_j) \leq b_i$  where  $x_j \geq 0$  and  $j = 1,2, \dots, n.$

**(F-2)**

Maximize (or) Minimize  $F_2(x) = \sum_{j=1}^n S(d_j x_j) + S(\beta_j)$

s.t

$\sum_{i=1}^m S(a_{ij} x_j) \leq b_i$  where  $x_j \geq 0$  and  $j = 1,2, \dots, n.$

**Step 4:**The optimal fuzzy solutions of  $x_j$  for (F-1) and (F-2) in step3 is obtained by simplex method.

**Step 5:** Fuzzy optimal solution of given FLFPP is obtained by using the below formula.

Maximize (or) Minimize  $F(x) = \frac{F_1(x)}{F_2(x)}$

**Application of Proposed Three Ranking Functions to Optimize FLFPP**

Here, we try to demonstrate the effectiveness of proposed new solution algorithm methodology by solving the numerical problem solved by Rasha Jalal Mitlif .

**Numerical Example 1:[9]**

**Case-1: Solving FLFP using TFNN**

**Step 1:**

Consider a FLFP in which the coefficients associated with decision variables  $X_1$  and  $X_2$ , both in the objective function and the constraint set, are modeled utilizing TFNN.

$$\text{Maximize } F(x) = \frac{(3.6,4,5,6;0.4,0.6,0.5)X_1 + (7.6,8,9,6;0.2,0.3,0.5)X_2}{(0.6,1,2,6;0.4,0.6,0.5)X_1 + (1.6,2,3,6;0.5,0.4,0.9)X_2 + (2.6,3,4,6;0.4,0.6,0.5)}$$

S.t  $(1.6,2,3,6;0.5,0.4,0.9) X_1 + (0.6,1,2,6;0.4,0.6,0.5)X_2 \leq 10$ ,  $(2.6,3,4,6;0.4,0.6,0.5)X_1 + (1.6,4,6,6;0.2,0.5,0.6)X_2 \leq 26$  and  $X_1, X_2 \geq 0$

**Step 2:** Convert above FLFP in to a fuzzy crisp value via new ranking function of TFNN,  $R(A) = \frac{a+(9*b)+c}{16}$  (2+T-I-F).

$$\text{Maximize } F(x) = \frac{3.6725 X_1 + 7.8050 X_2}{0.9913 X_1 + 1.74 X_2 + 2.7788}$$

S.t  $1.74X_1 + 0.9913X_2 \leq 10$ ,  $2.7788 X_1 + 3.0388X_2 \leq 26$  and  $X_1, X_2 \geq 0$

**Step 3:**Decompose the obtained FLFP into two FLP problems as below.

**(F-1)**

$$\text{Maximize } F_1(x) = 3.6725 X_1 + 7.8050 X_2$$

S.t  $1.74X_1 + 0.9913X_2 \leq 10$ ,  $2.7788 X_1 + 3.0388X_2 \leq 26$  and  $X_1, X_2 \geq 0$

**(F-2)**

$$\text{Maximize } F_2(x) = 0.9913 X_1 + 1.74 X_2$$

S.t  $1.74X_1 + 0.9913X_2 \leq 10$ ,  $2.7788 X_1 + 3.0388X_2 \leq 26$  and  $X_1, X_2 \geq 0$

**Step 4:**The fuzzy optimal solutions of  $x_j$  got by simplex method for (F-1) is *Maximize*  $F_1(x) = 66.80$  where  $X_1 = 0, X_2 = 8.55$  and for (F-2) is *Maximize*  $F_2(x) = 17.66$  where  $X_1 = 0, X_2 = 8.55$  .

**Step 5:** The fuzzy optimal solution of FLFP is obtained by using the formula below.

$$\text{Maximize } F(x) = \frac{F_1(x)}{F_2(x)} = 3.7826$$

**Case-2: Solving FLFP using TrFNN**

**Step 1:** Consider a FLFP in which the coefficients associated with decision variables  $X_1$  and  $X_2$ , both in the objective function and the constraint set, are modeled utilizing TrFNN.

$$\text{Maximize } F(x) = \frac{(3.6,4,5,6,6;0.2,0.5,0.6)X_1 + (7.6,8,9,10,6;0.5,0.4,0.9)X_2}{(0.6,1,2,3,6;0.4,0.6,0.5)X_1 + (1.6,2,3,3,6;0.6,0.4,0.7)X_2 + (2.6,3,4,4,6;0.4,0.6,0.5)}$$

S.t

$(1.6,2,3,3,6;0.6,0.4,0.7) X_1 + (0.6,1,2,3,6;0.4,0.6,0.5)X_2 \leq 10$ ,  $(2.6,3,4,4,6;0.4,0.6,0.5)X_1 + (1.6,4,5,6,6;0.2,0.5,0.6)X_2 \leq 26$  and  $X_1, X_2 \geq 0$

**Step 2:** Convert above FLFP in to a fuzzy crisp value via new ranking function of TrFNN ,  $R(A) = \frac{(3a+(b*c)+3d)}{16}$  (2+T-I-F) .

$$\text{Maximize } F(x) = \frac{3.4788 X_1 + 9.4950 X_2}{1.1863 X_1 + 2.0250 X_2 + 2.73}$$

S.t  $2.0250X_1 + 1.1813X_2 \leq 10$ ,  $2.73 X_1 + 3.0663X_2 \leq 26$  and  $X_1, X_2 \geq 0$

**Step 3:**Decompose the obtained FLFP into two FLP problems as below.

**(F-1)**

$$\text{Maximize } F_1(x) = 3.4788 X_1 + 9.4950 X_2$$

S.t  $2.0250X_1 + 1.1813X_2 \leq 10$ ,  $2.73 X_1 + 3.0663X_2 \leq 26$  and  $X_1, X_2 \geq 0$

**(F-2)**

$$\text{Maximize } F_2(x) = 1.1813 X_1 + 2.0250 X_2 + 2.73$$

S.t  $2.0250X_1 + 1.1813X_2 \leq 10$ ,  $2.73 X_1 + 3.0663X_2 \leq 26$  and  $X_1, X_2 \geq 0$

**Rajarajeswari et al.,**

**Step 4:**The fuzzy optimal solutions of  $x_j$  got by simplex method for (F-1) is Maximize  $F_1(x) = 79.83$  where  $X_1 = 0, X_2 = 8.40$  and for (F-2) is Maximize  $F_2(x) = 19.79$  where  $X_1 = 0, X_2 = 8.40$ .

**Step 5:**The fuzzy optimal solution of FLFPF is obtained by using the formula below.

$$\text{Maximize } F(x) = \frac{F_1(x)}{F_2(x)} = 4.0339$$

**Case-3: Solving FLFPF using PFNN**

**Step 1:** Consider a FLFPF in which the coefficients associated with decision variables  $X_1$  and  $X_2$ , both in the objective function and the constraint set, are modeled utilizing PFNN.

Maximize  $F(x) =$

$$\frac{(3.6,4,5,6,7,6; 0.4,0.6,0.5)X_1 + (7.6,8,9,10,11,6; 0.8,0.6,0.4)X_2}{(0.6,1,2,3,4,6; 0.6,0.4,0.7)X_1 + (1.6,2,3,4,5,6; 0.2,0.5,0.6)X_2 + (2.6,3,4,5,6,6; 0.2,0.5,0.6)}$$

S.t

$$(1.6,2,3,4,5,6; 0.2,0.5,0.6) X_1 + (0.6,1,2,3,4,6; 0.6,0.4,0.7)X_2 \leq 10,$$

$$(2.6,3,4,5,6,6; 0.2,0.5,0.6)X_1 + (1.6,4,5,6,7,6; 0.2,0.5,0.6)X_2 \leq 26 \text{ and } X_1, X_2 \geq 0$$

**Step 2:** Convert above FLFPF in to a fuzzy crisp value via new ranking function of PFNN,  $R(A) = \frac{a+b+c+d+e}{15} (2 + T - I - F)$ .

$$\text{Maximize } F(x) = \frac{2.2707 X_1 + 5.5440 X_2}{1.1201 X_1 + 1.1880 X_2 + 1.5547}$$

S.t  $1.1880X_1 + 1.1201X_2 \leq 10, 1.5547 X_1 + 1.9360X_2 \leq 26$  and  $X_1, X_2 \geq 0$

**Step 3:**Decompose the obtained FLFPF into two FLP problems as below.

**(F-1)**

$$\text{Maximize } F_1(x) = 2.2707 X_1 + 5.5440 X_2$$

S.t  $1.1880X_1 + 1.1201X_2 \leq 10, 1.5547 X_1 + 1.9360X_2 \leq 26$  and  $X_1, X_2 \geq 0$

**(F-2)**

$$\text{Maximize } F_2(x) = 1.1201 X_1 + 1.1880 X_2 + 1.5547$$

S.t  $1.1880X_1 + 1.1201X_2 \leq 10, 1.5547 X_1 + 1.9360X_2 \leq 26$  and  $X_1, X_2 \geq 0$

**Step 4:**The fuzzy optimal solutions of  $x_j$  got by simplex method for (F-1) is Maximize  $F_1(x) = 49.46$  where  $X_1 = 0, X_2 = 8.93$  and for (F-2) is Maximize  $F_2(x) = 12.1847$  where  $X_1 = 0, X_2 = 8.93$ .

**Step 5:** The fuzzy optimal solution of FLFPF is obtained by using the formula below.

$$\text{Maximize } F(x) = \frac{F_1(x)}{F_2(x)} = 4.0592$$

**Numerical Example 2:[13]**

**Case-1: Solving FLFPF using TFNN**

**Step 1 :** Consider the Sumon Kumar Saha et.al.,[13] problem

$$\text{Minimize } F(x) = \frac{-2X_1 + X_2 + 2}{X_1 + 3X_2 + 4}$$

s.t  $-X_1 + X_2 \leq 4, 2X_1 + X_2 \leq 14, X_2 \leq 6$  and  $X_1, X_2 \geq 0$

Here, the coefficients associated with  $X_1$  and  $X_2$  in both the objective function and constraints are represented as TFNN like below.

$$\text{Minimize } F(x) = \frac{-(1,3,5; 0.2,0.3,0.5)x_1 + (0,2,4; 0.8,0.6,0.4)x_2 + (1,3,5; 0.2,0.3,0.5)}{(0,2,4; 0.8,0.6,0.4)x_1 + (2,3,4; 0.4,0.6,0.5)x_2 + (3,4,5; 0.2,0.5,0.6)}$$

s.t  $-(0,2,4; 0.8,0.6,0.4)X_1 + (0,2,4; 0.8,0.6,0.4)X_2 \leq 4,$

$$(1,3,5; 0.2,0.3,0.5) X_1 + (0,2,4; 0.8,0.6,0.4) X_2 \leq 14,$$

$$(0,2,4; 0.8,0.6,0.4)X_2 \leq 6 \text{ and } X_1, X_2 \geq 0$$

**Step 2:** Convert above FLFPF in to a fuzzy crisp value problem via new ranking function of TFNN,  $R(A) = \frac{a+(9*b)+c}{16} (2 + T - I - F)$ .

$$\text{Minimize } F(x) = \frac{-2.8875 X_1 + 2.4750 X_2 + 2.8875}{2.4750 X_1 + 2.6813 X_2 + 3.0250}$$

S.t  $-2.4750X_1 + 2.4750X_2 \leq 4,$

Rajarajeswari et al.,

$$2.8875 X_1 + 2.4750X_2 \leq 14 ,$$

$$2.4750X_2 \leq 6 \text{ and } X_1, X_2 \geq 0$$

**Step 3:**Decompose the obtained FLFP Problem into two FLP problems as below.

**(F-1)**

Minimize  $F_1(x) = -2.8875 X_1 + 2.4750 X_2 + 2.8875$

S.t

$$-2.4750X_1 + 2.4750X_2 \leq 4,$$

$$2.8875 X_1 + 2.4750X_2 \leq 14 ,$$

$$2.4750X_2 \leq 6 \text{ and } X_1, X_2 \geq 0$$

**(F-2)**

Maximize  $F_2(x) = 2.4750 X_1 + 2.6813 X_2 + 3.0250$  S.t

$$-2.4750X_1 + 2.4750X_2 \leq 4,$$

$$2.8875 X_1 + 2.4750X_2 \leq 14 ,$$

$$2.4750X_2 \leq 6 \text{ and } X_1, X_2 \geq 0$$

**Step 4:**The fuzzy optimal solutions of  $x_j$  got by simplex method for (F-1) is Minimize  $F_1(x) = -11.1125$  where  $X_1 = 4.84, X_2 = 0$  and for (F-2) is Minimize  $F_2(x) = 3.0250$  where  $X_1 = 0, X_2 = 0$ .

**Step 5:**The fuzzy optimal solution of FLFP is obtained by using the below formula

Minimize  $F(x) = \frac{F_1(x)}{F_2(x)} = -3.6736$

**Case2: Solving FLFP using TrFNN**

**Step 1 :** Consider the Sumon Kumar Saha et.al.,[13] problem

Minimize  $F(x) = \frac{-2X_1 + X_2 + 2}{X_1 + 3X_2 + 4}$  s.t  $-X_1 + X_2 \leq 4, 2X_1 + X_2 \leq 14, X_2 \leq 6$  and  $X_1, X_2 \geq 0$

Here, the coefficients associated with the decision variables  $X_1$  and  $X_2$  in both the objective function and constraints are represented as TrFNN like below.

Minimize  $F(x) = \frac{-(1,3,5,6; 0.2,0.3,0.5)x_1 + (0,2,4,5; 0.8,0.6,0.4)x_2 + (1,3,5,6; 0.2,0.3,0.5)}{(0,2,4,5; 0.8,0.6, 0.4)x_1 + (1,2,3,4; 0.4,0.6,0.5)x_2 + (1,3,4,5; 0.2,0.5,0.6)}$

s.t  $-(0,2,4,5; 0.8,0.6,0.4)X_1 + (0,2,4,5; 0.8,0.6,0.4)X_2 \leq 4,$   
 $(1,3,5,6; 0.2,0.3,0.5) X_1 + (0,2,4,5; 0.8,0.6,0.4) X_2 \leq 14 ,$   
 $(0,2,4,5; 0.8,0.6,0.4)X_2 \leq 6 \text{ and } X_1, X_2 \geq 0$

**Step 2:** Convert the above FLFP into a fuzzy crisp value via new ranking function of TrFNN,  $R(A) = \frac{(3a+(b*c)+3d)}{16}$  (2+T-I-F).

Minimize  $F(x) = \frac{-3.15 X_1 + 2.5875 X_2 + 3.15}{2.5875 X_1 + 1.7063 X_2 + 2.0625}$

S.t  $-2.5875X_1 + 2.5875X_2 \leq 4, 3.15 X_1 + 2.5875X_2 \leq 14 ,$   
 $2.5875X_2 \leq 6 \text{ and } X_1, X_2 \geq 0$

**Step 3:**Decompose the obtained FLFP into two FLP problems as below.

**(F-1)**

Minimize  $F_1(x) = -3.15 X_1 + 2.5875 X_2 + 3.15$

S.t

$$-2.5875X_1 + 2.5875X_2 \leq 4, 3.15 X_1 + 2.5875X_2 \leq 14 ,$$

$$2.5875X_2 \leq 6 \text{ and } X_1, X_2 \geq 0$$

**(F-2)**

Maximize  $F_2(x) = 2.5875 X_1 + 1.7063 X_2 + 2.0625$  S.t

$$-2.4750X_1 + 2.4750X_2 \leq 4, 2.8875 X_1 + 2.4750X_2 \leq 14 ,$$

$$2.4750X_2 \leq 6 \text{ and } X_1, X_2 \geq 0$$

**Step 4:**The fuzzy optimal solutions of  $x_j$  got by simplex method for (F-1) is Minimize  $F_1(x) = -10.85$  where  $X_1 = 4.44, X_2 = 0$  and for (F-2) is Minimize  $F_2(x) = 2.0625$  where  $X_1 = 0, X_2 = 0$ .

**Rajarajeswari et al.,**

**Step 5:**The fuzzy optimal solution of FLFPP is obtained by using the formula below.

$$\text{Minimize } F(x) = \frac{F_1(x)}{F_2(x)} = -5.2606$$

**Case3: Solving FLFPP using PFNN**

**Step 1 :**Consider the minimization problem below

$$\text{Minimize } F(x) = \frac{-2X_1 + X_2 + 2}{X_1 + 3X_2 + 4}$$

$$\text{s.t } -X_1 + X_2 \leq 4, 2X_1 + X_2 \leq 14, X_2 \leq 6 \text{ and } X_1, X_2 \geq 0$$

Here, the coefficients associated with the decision variables  $X_1$  and  $X_2$  in both the objective function and constraints are represented as PFNN like below.

$$\begin{aligned} \text{Minimize } F(x) = & \frac{-(1.6,3,5,6,7.6;0.2,0.3,0.5)X_1 + (0.6,2,4,5,7.6;0.4,0.6,0.5)X_2 + (1.6,3,5,6,7.6;0.2,0.3,0.5)}{(0.6,2,4,5,7.6; 0.4,0.6,0.5)X_1 + (1.6,2,5,6,7.6; 0.2,0.3,0.5)X_2 + (1.6,2,5,7,8.6;0.5,0.4,0.9)} \\ \text{s.t } & -(0.6,2,4,5,7.6; 0.4,0.6,0.5) X_1 + (0.6,2,4,5,7.6; 0.4, 0.6, 0.5) X_2 \leq 4 \\ & (1.6,3,5,6,7.6; 0.2,0.3,0.5) X_1 + (0.6,2,4,5,7.6; 0.4, 0.6, 0.5) X_2 \leq 14 \\ & (0.6,2,4,5,7.6; 0.4, 0.6, 0.5) X_2 \leq 6 \text{ and } X_1, X_2 \geq 0 \end{aligned}$$

**Step 2:** Convert above FLFPP into a fuzzy crisp value via new ranking function of PFNN,  $R(A) = \frac{(a+b+c+d+e)}{15} (2+T-I-F)$ .

$$\text{Minimize } F(x) = \frac{-2.1653 X_1 + 1.6640 X_2 + 2.1653}{1.6640 X_1 + 2.0720 X_2 + 1.9360}$$

$$\text{S.t } -1.6640X_1 + 1.6640X_2 \leq 4, 2.1653 X_1 + 1.6640X_2 \leq 14, 1.6640X_2 \leq 6 \text{ and } X_1, X_2 \geq 0$$

**Step 3:**Decompose the obtained FLFPP into two FLP problems as below.

**(F-1)**

$$\text{Minimize } F_1(x) = -2.1653 X_1 + 1.6640 X_2 + 2.1653$$

S.t

$$-1.6640X_1 + 1.6640X_2 \leq 4, 2.1653 X_1 + 1.6640X_2 \leq 14, 1.6640X_2 \leq 6 \text{ and } X_1, X_2 \geq 0$$

**(F-2)**

$$\text{Maximize } F_2(x) = 1.6640 X_1 + 2.0720 X_2 + 1.9360$$

S.t

$$-1.6640X_1 + 1.6640X_2 \leq 4, 2.1653 X_1 + 1.6640X_2 \leq 14, 1.6640X_2 \leq 6 \text{ and } X_1, X_2 \geq 0$$

**Step 4:**The fuzzy optimal solutions of  $x_j$  got by simplex method for (F-1) is Minimize  $F_1(x) = -11.84$  where  $X_1 = 6.45, X_2 = 0$  and for (F-2) is Minimize  $F_2(x) = 1.94$  where  $X_1 = 0, X_2 = 0$ .

**Step 5:** The fuzzy optimal solution of FLFPP is obtained by using the formula below.

$$\text{Minimize } F(x) = \frac{F_1(x)}{F_2(x)} = - 6.1031$$

The table that follows provides the fuzzy optimal solutions for the triangular, trapezoidal, and pentagonal fuzzy neutrosophic numbers.

## RESULTS AND DISCUSSION

We have created a brand-new technique that uses the PFNN, TrFNN and TFNN to solve FLFPP. After comparing the fuzzy optimal solutions of the objective function obtained for the aforementioned problems of Sumon Kumar Saha et.al.,[13] and Rasha Jalal Mitlif [9] using the FLFPP concept, we can conclude that the most optimal value is obtained

**Rajarajeswari et al.,**

from the solution obtained by our proposed ranking methods using the TFNN, TrFNN, and PFNN. In addition, the fuzzy optimal results are compared using multiple bar diagram and analyzed the fuzzy optimal solutions of FLFPP obtained using various fuzzy neutrosophic numbers.

## CONCLUSION

Three ranking formulas—the Pentagonal Fuzzy Neutrosophic Number, the Trapezoidal Fuzzy Neutrosophic Number, and the Triangular Fuzzy Neutrosophic Number—are investigated in this research study in order to optimize FLFPP using different fuzzy neutrosophic fuzzy numbers. The coefficients of the FLFPP in the objective function and constraints are represented by different fuzzy neutrosophic fuzzy numbers in this suggested technique. The fundamental FLFPP is divided into two equal FLP problems, and the resulting value is then transformed into a crisp value utilizing the three unique ranking functions of different fuzzy neutrosophic numbers. The fuzzy optimal solution is then produced by applying the simplex approach. We provide step-by-step explanations to demonstrate the effectiveness of our new ranking techniques. The outcomes obtained for the numerical examples show the efficiency of the investigated proposed methods, when compared with some of the existing outcomes of the base paper numerical examples. Hence, our proposed techniques appear to be more promising and gives efficient value. Overall, we were able to obtain the pentagonal fuzzy neutrosophic number's best fuzzy optimal solution. Additionally, academics may attempt to expand the idea of the PFNN approach in the future to create a variety of fuzzy neutrosophic numbers that represent the uncertainty in a different line of future path work.

### ABSTRACT

This paper focuses on  $\mathcal{NI}_{s\hat{g}}$ -closed sets (Nano  $I_{s\hat{g}}$ -closed sets) and  $\mathcal{NI}_{s\hat{g}}$ -open sets (Nano  $I_{s\hat{g}}$ -open sets) in nano ideal topological spaces and certain properties of these are investigated. We also investigate the concept of  $\mathcal{NI}_{s\hat{g}}$ -continuous functions,  $\mathcal{NI}_{s\hat{g}}$  irresolute functions and discussed their relationship with other existing nano continuous functions in nano ideal topological spaces.

**KEYWORDS:**  $\mathcal{N}_{s\hat{g}}$ -closed sets,  $\mathcal{N}_{s\hat{g}}$ -closed sets,  $\mathcal{NI}_{s\hat{g}}$ -closed,  $\mathcal{NI}_{s\hat{g}}$ -closed sets and  $\mathcal{NI}_{s\hat{g}}$ -open sets,  $\mathcal{NI}_{s\hat{g}}$  continuous functions,  $\mathcal{NI}_{s\hat{g}}$  irresolute functions.

## INTRODUCTION

In 1970, Levine [1] introduced the concept of generalized closed sets in topological spaces. The concepts of ideal topological spaces was introduced by Kuratowski [2]. Also he defined the local functions in ideal topological spaces. In 1990, Jonkovic and Hamlet [3] investigated further properties of ideal topological spaces. The notion of I-open sets was introduced by Jonkovic et al [4].

### Rajendran and Mangayarkarasi

In 2013 Lellis Thivagar and Carmal Richard [5] established the field of nano topological spaces which was defined in terms of approximation and boundary region of a subset of a universe using an equivalence relation on it. He has also defined a Nano continuous functions and . In 2016 Lellis Thivagar [5] defined ideal topological space. In Section 2, we recall some fundamental definitions and results which are useful to prove our main results. In Section 3, We define and study the notion of  $\mathcal{NI}_{s\hat{g}}$ -closed sets and  $\mathcal{NI}_{s\hat{g}}$ -open sets in nano topological spaces. In section 4, We also define the concepts of  $\mathcal{NI}_{s\hat{g}}$ -continuous functions and also  $\mathcal{NI}_{s\hat{g}}$ -irresolute functions and also discuss the relationship between the other existing nano continuous functions nano ideal topological spaces.

## PRELIMINARIES

**Definition 2.1.** [7] Let  $U$  be a non-empty finite set of objects called the universe and  $R$  be an equivalence relation on  $U$  named as the indiscernible relation. Elements belonging to the same equivalence class are said to be indiscernible with one another. The pair  $(U, R)$  is said to be the approximation space. Let  $X \subseteq U$ .

- (1) The Lower approximation of  $X$  with respect to  $R$  is the set of all objects, which can be for certain classified as  $X$  with respect to  $R$  and it is denoted by  $L_R(X)$ . That is,  $L_R(X) = \{\bigcup_{x \in U} \{R(x) : R(x) \subseteq X\}\}$ , where  $R(x)$  denotes the equivalence class determined by  $x \in U$ .
- (2) The Upper approximation of  $X$  with respect to  $R$  is the set of all objects, which can be for certain classified as  $X$  with respect to  $R$  and it is denoted by  $U_R(X)$ . That is,  $U_R(X) = \{\bigcup_{x \in U} \{R(x) : R(x) \cap X \neq \phi\}\}$
- (3) The Boundary region of  $X$  with respect to  $R$  is the set of all objects which can be classified as neither as  $X$  nor as not  $X$  with respect to  $R$  and it is denoted by  $B_R(X)$ . That is,  $B_R(X) = U_R(X) - L_R(X)$

**Definition 2.2.** [7] Let  $U$  be the universe,  $R$  be an equivalence relation on  $U$  and  $\tau_R(X) = \{U, \phi, L_R(X), U_R(X), B_R(X)\}$  where  $X \subseteq U$ . Then  $\tau_R(X)$  satisfies the following axioms:

- (1)  $U$  and  $\phi \in \tau_R(X)$
- (2) The union of elements of any subcollection of  $\tau_R(X)$  is in  $\tau_R(X)$
- (3) The intersection of the elements of any finite subcollection of  $\tau_R(X)$  is in  $\tau_R(X)$ .

### Rajendran and Mangayarkarasi

That is,  $\tau_R(X)$  is a topology on  $U$  is called the nano topology on  $U$  with respect to  $X$ . We call  $\{U, \tau_R(X)\}$  is called the nano topological space. Elements of the nano topology are known as nano open sets in  $U$ . Elements of  $[\tau_R(X)]^c$  are called nano closed sets. We denote a nano topological space by  $(U, \mathcal{N})$ , where  $\mathcal{N} = \tau_R(X)$ .

**Definition 2.3.** A subset  $A$  of a Nano topological space  $(U, \mathcal{N})$  is called a

- (1) Nano semi-open [7] if  $\mathcal{N}cl(\mathcal{N}int(A)) \subseteq A$ .
- (2) Nano generalized closed [8] if  $\mathcal{N}cl(A) \subseteq G$  whenever  $A \subseteq G$  and  $G$  is Nano open in  $U$ .
- (3) Nano  $\hat{g}$  closed [9] if  $\mathcal{N}cl(A) \subseteq G$  whenever  $A \subseteq G$  and  $G$  is Nano semi open in  $U$ .
- (4) Nano semi generalized closed [10] if  $\mathcal{N} scl(A) \subseteq G$  whenever  $A \subseteq G$  and  $G$  is Nano semi open in  $U$ .
- (5) Nano  $s\hat{g}$  closed [11] if  $\mathcal{N} scl(A) \subseteq G$  whenever  $A \subseteq G$  and  $G$  is Nano sg open in  $U$ .

**Definition 2.4.** [12] An ideal  $I$  on a topological space  $(X, \mathcal{N})$  is a non-empty collection of subset of  $X$  which satisfies the following properties

- (1)  $A \in I$  and  $B \subseteq A \Rightarrow B \in I$ .
- (2)  $A \in I$  and  $B \in I \Rightarrow A \cup B \in I$ .

**Definition 2.5.** [12] A nano topological space  $(U, \mathcal{N})$  with an ideal  $I$  on  $U$  is called a nano ideal topological space or nano ideal space and is denoted as  $(U, \mathcal{N}, I)$ .

**Definition 2.6.** [12] Let  $(U, \mathcal{N}, I)$  be a nano topological space. A set operator  $(A)^{*N} : P(U) \rightarrow P(U)$  is called the nano local function  $I$  on  $U$  with respect to  $I$  on  $\mathcal{N}$  is defined as  $(A)^{*N} = \{x \in U : U \cap A \notin I; \text{ for every } U \in \mathcal{N}\}$  and is denoted by  $(A)^{*N}$ , where nano closure operator is defined as  $\mathcal{N}cl^*(A) = A \cup (A)^{*N}$ .

**Result 2.7.** [6] Let  $(U, \mathcal{N}, I)$  be a nano ideal topological space and let  $A$  and  $B$  be subsets of  $U$ , then

- (1)  $(\phi)^{*N} = \phi$
- (2)  $A \subset B \rightarrow (A)^{*N} \subset (B)^{*N}$
- (3) For another  $J \supseteq I$  on  $U$ ,  $(A)^{*N}(J) \subset (A)^{*N}(I)$
- (4)  $(A)^{*N} \subset \mathcal{N}cl^*(A)$
- (5)  $(A)^{*N}$  is a nano closed set
- (6)  $((A)^{*N})^{\ast N} \subset (A)^{*N}$
- (7)  $(A)^{*N} \cup (B)^{*N} = (A \cup B)^{\ast N}$

**Rajendran and Mangayarkarasi**

- (8)  $(A \cap B)^{*N} = (A)^{*N} \cap (B)^{*N}$
- (9) For every nano open set  $V$ ,  $V \cap (V \cap A)^{*N} \subset (V \cap A)^{*N}$
- (10) For  $I \in I$ ,  $(A \cup I)^{*N} = (A)^{*N} = (A - I)^{*N}$

**Result 2.8.** [6] Let  $(U, \mathcal{N}, I)$  be a nano ideal topological space and let  $A$  be a subsets of  $U$ , If  $A \subset (A)^{*N}$ , then  $(A)^{*N} = \mathcal{N}cl(A^{*N}) = \mathcal{N}cl(A) = \mathcal{N}cl^*(A)$ .

**Definition 2.9.** [13] A subset  $A$  of a nano ideal topological space  $(U, \mathcal{N}, I)$  is called

- (1)  $\mathcal{N}I$  open if  $A \subseteq \mathcal{N}int((A)^{*N})$  and its complement is  $\mathcal{N}I$  closed.
- (2)  $\mathcal{N}I$  semi open if  $\mathcal{N}int^*(\mathcal{N}int A)$  and  $\mathcal{N}I$  semi closed if  $\mathcal{N}int(\mathcal{N}cl^*A) \subseteq A$
- (3)  $\mathcal{N}I\alpha$  open if  $A \subseteq \mathcal{N}int(\mathcal{N}cl^*(\mathcal{N}int(A)))$  and  $\mathcal{N}I\alpha$  closed if  $\mathcal{N}cl^*(\mathcal{N}int(\mathcal{N}cl^*(A))) \subseteq A$ .
- (4)  $\mathcal{N}I\beta$  open if  $A \subseteq \mathcal{N}cl^*(\mathcal{N}int(\mathcal{N}cl^*(A)))$  and  $\mathcal{N}I\beta$  closed if  $\mathcal{N}int(\mathcal{N}cl^*(\mathcal{N}int(A))) \subseteq A$ .

**Definition 2.10.** A subset  $A$  of a nano ideal topological space. Let  $(U, \mathcal{N}, I)$  is said to be

- (1) [4],  $*N$ - closed, If  $(A)^{*N} \subseteq A$ .
- (2) [4],  $*N$ - dense, If  $A \subseteq (A)^{*N}$ .
- (3) [4], Semi  $I$ -closed if  $int cl^1(A) \subseteq A$ .
- (4) [12], A Nano ideal generalized closed set  $\mathcal{N}I_g$ - closed, if  $\mathcal{N}Icl(A) \subseteq G$  whenever  $A \subseteq G$  and  $G$  is nano open.
- (5) [13], A Nano ideal generalized closed set  $\mathcal{N}I_{\hat{g}}$ - closed, if  $\mathcal{N}Icl(A) \subseteq G$  whenever  $A \subseteq G$  and  $G$  is nano semi open.

**Definition 2.11.** A function  $f:(U, \tau_R(X), I) \Rightarrow (V, \sigma_{R'}(Y))$  is said to be,

- (1) [4],  $\mathcal{N}I_g$ -continuous if  $f^{-1}(w)$  is  $\mathcal{N}I_g$ - closed in  $(U, \tau_R(X))$  for every nano closed set  $W$  in  $(V, \sigma_{R'}(Y))$
- (2) [14],  $\mathcal{N}I_{\hat{g}}$ -continuous if  $f^{-1}(w)$  is  $(\mathcal{N}I_{\hat{g}})$ - closed in  $(U, \tau_R(X))$  for every nano closed  $W$  in  $(V, \sigma_{R'}(Y))$

## NIsg-Closed Sets

In this section, we define and study the notion of  $\mathcal{N}I_{s\hat{g}}$ -closed sets and  $\mathcal{N}I_{s\hat{g}}$ -open sets in nano ideal topological spaces.

**Definition 3.1.** A subset  $A$  of a nano ideal topological space  $(U, \tau_R(X), I)$  is said to be  $\mathcal{N}I_{s\hat{g}}$ -closed sets, if  $\mathcal{N}SIcl(A) \subseteq G$  whenever  $A \subseteq G$  and  $G$  is nano  $\hat{g}$ -open.

**Theorem 3.2.** If  $(U, \tau_R(X), I)$  is any nano ideal topological space, then every nano closed set is  $\mathcal{N}I_{s\hat{g}}$ -closed but not conversely.

Let  $A$  be a nano closed set and  $G$  be any nano  $\hat{g}$  open set containing  $A$ . Then  $A \subseteq G$ . This implies that  $\mathcal{N}cl(A) \subseteq G$ . Also  $\mathcal{N}SIcl(A) \subseteq \mathcal{N}cl(A) \subseteq G$ . Therefore  $\mathcal{N}SIcl(A) \subseteq G$ . Hence  $A$  is  $\mathcal{N}I_{s\hat{g}}$ -closed set.

**Example 3.3.** Let  $U = \{a, b, c, d\}$ , with  $U/R = \{\{a\}, \{c\}, \{b, d\}\}$  and  $X = \{a, b\}$ . Then the nano topology  $\tau_R(X) = \{\phi, \{a\}, \{b, d\}, \{a, b, d\}, U\}$ , and  $I = \{\phi, \{a\}\}$ . Then  $\mathcal{N}I_{s\hat{g}}$ -closed set =  $\{\phi, \{a\}, \{c\}, \{a, b\}, \{a, c\}, \{b, d\}, \{a, c, d\}, \{b, c, d\}, U\}$  and nano closed set is  $\{\phi, \{c\}, \{a, c\}, \{b, c, d\}, U\}$ . It is clear that  $\{a, b\}$  is  $\mathcal{N}I_{s\hat{g}}$ -closed but it is not nano-closed set.

**Theorem 3.4.** If  $(U, \tau_R(X), I)$  is any nano ideal space, then every nano  $\hat{g}$  closed set is  $\mathcal{N}I_{s\hat{g}}$ -closed set but not conversely.

Let  $A$  be a nano  $\hat{g}$  closed set and  $G$  be any nano semi-open set containing  $A$ . Since  $A$  is nano  $\hat{g}$  closed. Therefore  $\mathcal{N}cl(A) \subseteq G$ . Since every nano semi open set is nano  $\hat{g}$  open set. That is  $\mathcal{N}cl(A) \subseteq G$  and  $\mathcal{N}SIcl(A) \subseteq \mathcal{N}cl(A) \subseteq G$ . This implies that  $\mathcal{N}SIcl(A) \subseteq G$ . Hence  $A$  is  $\mathcal{N}I_{s\hat{g}}$ -closed set.

**Example 3.5.** Let  $U = \{a, b, c, d\}$ , with  $U/R = \{\{a\}, \{b\}, \{c, d\}\}$  and  $X = \{a, b\}$ . Then the nano topology  $\tau_R(X) = \{\phi, \{a\}, \{b, d\}, \{a, b, d\}, U\}$ , and  $I = \{\phi, \{a\}, \{b\}, \{a, b\}\}$ . Then  $\mathcal{N}I_{s\hat{g}}$ -closed sets =  $\{\phi, \{a\}, \{c\}, \{a, b\}, \{a, c\}, \{b, d\}, \{c, d\}, \{a, b, c\}, \{a, c, d\}, \{b, c, d\}, U\}$  and nano  $\hat{g}$ -closed sets =  $\{\phi, \{c\}, \{a, c\}, \{b, c\}, \{c, d\}, \{a, b, c\}\}$ . It is clear that  $\{a\}$  is  $\mathcal{N}I_{s\hat{g}}$ -closed but it is not nano  $\hat{g}$ -closed set.

**Theorem 3.6.** If  $(U, \tau_R(X), I)$  is any nano ideal space, then every  $\mathcal{N}s\hat{g}$ -closed set in  $\mathcal{N}I_{s\hat{g}}$ -closed set but not conversely.

Let  $A$  be a  $\mathcal{N}s\hat{g}$  closed set of  $(U, \tau_R(X), I)$ . Let  $G$  be any nano semi-open set containing  $A$ . Since every nano semi open set is nano  $\hat{g}$  open set. Such that  $\mathcal{N} scl(A) \subseteq G$  and  $\mathcal{N}SIcl(A) \subseteq \mathcal{N} scl(A) \subseteq G$ . This implies that  $\mathcal{N}SIcl(A) \subseteq G$ . This shows that  $A$  is  $\mathcal{N}I_{s\hat{g}}$ -closed set.

**Rajendran and Mangayarkarasi**

**Example 3.7.** From example 6.2.3, Nano  $s\hat{g}$  closed sets are  $\{\phi, \{a\}, \{a, b\}, \{a, c\}, \{b, c, d\}, U\}$ . Here  $\{a\}$  is  $NI_{s\hat{g}}$ -closed but not in  $Ns\hat{g}$ -closed set.

**Theorem 3.8.** If  $(U, \tau_R(X), I)$  is any nano ideal topological space, then every  $NI_{s\hat{g}}$ -closed set is  $NI_{\hat{g}}$ -closed but not conversely.

Let  $A$  be a  $NI_{s\hat{g}}$ -closed set and  $G$  be a nano open set containing  $A$ . Then  $A \subseteq G$ . Since every nano open set is  $NI_{\hat{g}}$  open set. This implies that  $NSIcl(A) \subseteq Ncl(A) \subseteq G$  and  $(A^*)^N \subseteq G$  and from  $*^N$ -closed set,  $(A^*)^N \subseteq A = NSIcl(A) \subseteq G$ . Hence  $(A^*)^N \subseteq G$ . Therefore  $A$  is  $NI_{\hat{g}}$ -closed.

**Example 3.9.** Let  $U = \{a, b, c, d\}$ , with  $U/R = \{\{a\}, \{c\}, \{b, d\}\}$  and  $X = \{a, b\}$ . Then the nano topology  $\tau_R(X) = \{\phi, \{a\}, \{a, b, d\}, \{b, d\}, U\}$  and  $I = \{\phi, \{a\}\}$ . Then  $NI_{s\hat{g}}$ -closed set is  $\{\phi, \{a\}, \{c\}, \{a, b\}, \{a, c\}, \{b, d\}, \{a, c, b, d\}, \{c, d\}, \{a, b, c\}, \{a, b, d\}, \{a, c, d\}, \{b, c, d\}, U\}$ . Here,  $\{b\}$  is not in  $NI_{s\hat{g}}$ -closed set but in  $NI_{\hat{g}}$ -closed set.

**Theorem 3.10.** If  $(U, \tau_R(X), I)$  is any nano ideal topological space, then every  $NI_{s\hat{g}}$ -closed set is  $NI_{\hat{g}}$ -closed but not conversely.

Let  $A$  be a  $NI_{s\hat{g}}$ -closed set and  $G$  be a nano Semi-open set containing  $A$ . Then  $A \subseteq G$ . Since every nano Semi-open set is  $NI_{\hat{g}}$ -open set. This implies that  $NSIcl(A) \subseteq Ncl(A) \subseteq G$  and  $(A^*)^N \subseteq G$  and from  $*^N$  closed set,  $(A^*)^N \subseteq A = Ncl(A) \subseteq G$ . Hence  $(A^*)^N \subseteq G$ . Therefore  $A$  is  $NI_{\hat{g}}$ -closed.

**Example 3.11.** Let  $U = \{a, b, c, d\}$ , with  $U/R = \{\{a\}, \{c\}, \{c, d\}\}$  and  $X = \{a, b\}$ . Then the nano topology  $\tau_R(X) = \{\phi, \{a\}, \{a, b, d\}, \{b, d\}, U\}$  and  $I = \{\phi, \{a\}, \{b\}, \{a, b\}\}$ . Then  $NI_{s\hat{g}}$ -closed sets =  $\{\phi, \{a\}, \{c\}, \{a, b\}, \{a, c\}, \{b, c\}, \{b, d\}, \{c, d\}, \{a, b, c\}, \{a, c, d\}, \{b, c, d\}, U\}$ .  $NI_{\hat{g}}$ -closed sets are  $\{\phi, \{a\}, \{b\}, \{c\}, \{d\}, \{a, b\}, \{a, c\}, \{a, d\}, \{b, c\}, \{b, d\}, \{c, d\}, \{a, b, c\}, \{a, b, d\}, \{a, c, d\}, \{b, c, d\}, U\}$ . It's clear that  $\{a, b, d\}$  is not in  $NI_{s\hat{g}}$ -closed set but in  $NI_{\hat{g}}$ -closed set.

**Theorem 3.12.** Union of two  $NI_{s\hat{g}}$ -closed sets in  $NI_{s\hat{g}}$ -closed.

Let  $A$  and  $B$  be a  $NI_{s\hat{g}}$ -closed set in  $U$ . Let  $G$  be a nano  $\hat{g}$ -open in  $U$ . Then  $A \subseteq G, B \subseteq G$ . Since  $A$  and  $B$  are  $NI_{s\hat{g}}$ -closed sets,  $NSIcl(A) \subseteq G$  and  $NSIcl(B) \subseteq G$ . Hence  $NSIcl(A \cup B) = NSIcl(A) \cup NSIcl(B) \subseteq G$ . Therefore  $A \cup B$  is  $NI_{s\hat{g}}$ -closed.

**Remark 3.13.** The intersection of any two  $NI_{s\hat{g}}$ -closed set is  $NI_{s\hat{g}}$ -closed set.

**Rajendran and Mangayarkarasi**

**Example 3.14.** Let  $U = \{a, b, c, d\}$ , with  $U/R = \{\{a\}, \{c\}, \{b, d\}\}$  and  $X = \{a, b\}$ . Then the nano topology  $\tau_R(X) = \{\phi, \{a\}, \{b, d\}, \{a, b, d\}, U\}$  and  $I = \{\phi, \{a\}\}$ . Then  $A = \{a\}$  and  $B = \{a, c\}$  are  $\mathcal{N}I_{s\hat{g}}$ -closed set and  $A \cap B = \{a\} \cap \{a, c\} = \{a\}$  is also  $\mathcal{N}I_{s\hat{g}}$ -closed set.

**Theorem 3.15.** If  $A$  is  $\mathcal{N}I_{s\hat{g}}$ -closed set and  $A \subseteq B \subseteq \mathcal{N}I_{s\hat{g}}\text{-}\mathcal{N}cl(A)$ , then  $B$  is  $\mathcal{N}I_{s\hat{g}}$ -closed.

Let  $A$  be  $\mathcal{N}I_{s\hat{g}}$ -closed and  $B \subseteq G$ , Where  $B$  is  $\mathcal{N}I_{s\hat{g}}$ -closed. Then  $A \subseteq B$  implies  $A \subseteq G$ . Since  $A$  is  $\mathcal{N}I_{s\hat{g}}$ -closed,  $\mathcal{N}I_{s\hat{g}}\text{-}\mathcal{N}cl(A) \subseteq G$  and  $B \subseteq \mathcal{N}I_{s\hat{g}}\text{-}\mathcal{N}cl(A)$  implies  $\mathcal{N}I_{s\hat{g}}\text{-}\mathcal{N}cl(B) \subseteq \mathcal{N}I_{s\hat{g}}\text{-}\mathcal{N}cl(A)$ . Therefore  $\mathcal{N}I_{s\hat{g}}\text{-}\mathcal{N}cl(B) \subseteq G$  and hence  $B$  is  $\mathcal{N}I_{s\hat{g}}$ -closed set.

**Theorem 3.16.** Let  $(U, \tau_R(X), I)$  be a nano ideal topological space and  $A \subseteq R$ . Then the following are equivalent.

- (a):  $A$  is  $\mathcal{N}I_{s\hat{g}}$ -closed,
- (b):  $A \cup (U - A^*_n)$  is  $\mathcal{N}I_{s\hat{g}}$ -closed,
- (c):  $(A_n)^* - A$  is  $\mathcal{N}I_{s\hat{g}}$ -open.

(a)  $\Rightarrow$  (b) Suppose  $A$  is  $\mathcal{N}I_{s\hat{g}}$ -closed. If  $U$  is any nano  $\hat{g}$  open set such that  $A \cup (U - A^*_n) \subseteq U$ , then  $U - G \subseteq U - (A \cup (U - A^*_n)) = U \cap (A \cup A^*_n)^c = A_n^* \cap A^c = A^*_n - A$ . Since  $A$  is  $\mathcal{N}I_{s\hat{g}}$ -closed, it follows that  $U - G = \emptyset$  and so  $U = G$ . Therefore  $A \cup (U - A^*_n) \subseteq U$  which implies that  $A \cup (U - A^*_n) \subseteq U$  and so  $(A \cup (A \cup (U - A^*_n))) \subseteq U^*_n \subseteq U = G$ . Hence  $A \cup (U - A^*_n)$  is  $\mathcal{N}I_{s\hat{g}}$ -closed.

(b)  $\Rightarrow$  (a) Suppose  $A \cup (U - A^*_n)$  is  $\mathcal{N}I_{s\hat{g}}$ -closed. If  $F$  is any nano  $\hat{g}$  closed set such that  $F \subseteq A^*_n - A$ , then  $F \subseteq A^*_n - A$  and  $F \not\subseteq A$  which implies that  $U - A^*_n \subseteq U - F$  and  $A \subseteq U - F$  is nano  $\hat{g}$  open. Therefore  $A \cup (U - A^*_n) \subseteq A \cup (U - F) = U - F$  and  $U - F$  is nano  $\hat{g}$  open. Since  $(A \cup (U - A^*_n)) - n^* \subseteq U - F$  which implies that  $A^*_n \cup (U - A^*_n) \subseteq U - F$  and so  $A - n^* \subseteq U - F$  which implies that  $F \subseteq U - A^*_n$ . Since  $F \subseteq A^*_n$ , it follows that  $F = \emptyset$ . Hence  $A$  is  $\mathcal{N}I_{s\hat{g}}$ -closed.

(b)  $\Leftrightarrow$  (c) Since  $U - (A^*_n - A) = U \cap ((A^*_n)^c \cup A) \cup (U \cap A) = A \cup (U - A^*_n)$  is  $\mathcal{N}I_{s\hat{g}}$ -closed. Hence  $A^*_n - A$  is  $\mathcal{N}I_{s\hat{g}}$ -open.

**Theorem 3.17.** Let  $(U, \tau_R(X), I)$  be an nano ideal topological space. Then every subset of  $U$  is  $\mathcal{N}I_{s\hat{g}}$ -closed if and only if every nano  $\hat{g}$ -open set is  $n^*$  closed.

Suppose every subset of  $U$  is  $\mathcal{N}I_{s\hat{g}}$ -closed. If  $G \subseteq U$  is nano  $\hat{g}$ -open, then  $G$  is  $\mathcal{N}I_{s\hat{g}}$ -closed and so  $(G_n)^* \subseteq G$ . Hence  $G$  is  $n^*$  closed.

Conversely, Suppose that every nano  $\hat{g}$ -open set is  $n^*$  closed. If  $U$  is nano  $\hat{g}$ -open set such that is  $A \subseteq G \subseteq U$ , then  $(A_n)^* \subseteq (G_n)^* \subseteq G$  and so  $A$  is  $\mathcal{N}I_{s\hat{g}}$ -closed.

## NIsg-Open Sets

A subset  $A$  of a nano ideal space  $(U, \tau_R(X), I)$  is said to be  $\mathcal{NI}_{s\hat{g}}$ -open set if  $U - A$  is  $\mathcal{NI}_{s\hat{g}}$ -closed set.

**Theorem 4.1.** Let  $(U, \tau_R(X), I)$  be a nano ideal topological space. Then the following statements are hold

- (1) Every nano-open set is  $\mathcal{NI}_{s\hat{g}}$ -open set.
- (2) Every nano  $\hat{g}$ -open set is  $\mathcal{NI}_{s\hat{g}}$ -open set.
- (3) Every nano  $\mathcal{N}_{s\hat{g}}$ -open set is  $\mathcal{NI}_{s\hat{g}}$ -open.
- (4) Every nano  $\mathcal{NI}_{s\hat{g}}$ -open set is  $\mathcal{NI}_{\hat{g}}$ -open.
- (5) Every  $\mathcal{NI}_{s\hat{g}}$ -open set is  $\mathcal{NI}_{\hat{g}}$ -open.

**Proof.** Proof follows from the theorems 3.2, 3.4, 3.6, 3.8, 3.10 and 3.12.

$$\mathcal{NI}_{s\hat{g}}\text{-Ncl}(U - A) = U - \mathcal{NI}_{s\hat{g}}\text{-int}(A).$$

**Theorem 4.2.** A set  $A \subseteq U$  is  $\mathcal{NI}_{s\hat{g}}$ -open if and only if  $F \subseteq \mathcal{NI}_{s\hat{g}}\text{-int}(A)$  whenever  $F$  is nano  $\hat{g}$ -closed and  $F \subseteq A$ .

**Necessary Part:** Let  $A$  be a  $\mathcal{NI}_{s\hat{g}}$ -open, Let  $F$  be nano  $\hat{g}$ -closed set and  $F \subseteq A$ , then  $U - A \subseteq U - F$ , where  $U - F$  is nano  $\hat{g}$ -open. By assumption  $\mathcal{NI}_{s\hat{g}}\text{-cl}(U - A) \subseteq U - F$ . By the above remark  $U - \mathcal{NI}_{s\hat{g}}\text{-int}(A) \subseteq U - F$ . Then  $F \subseteq \mathcal{NI}_{s\hat{g}}\text{-Int}(A)$ .

**Sufficient Part:** Suppose  $F$  is  $\mathcal{NI}_{\hat{g}}$  closed and  $F \subseteq A$  such that  $F \subseteq \mathcal{NI}_{s\hat{g}}\text{-int}(A)$ . Let  $U - A \subseteq G$ , where  $G$  is nano  $\hat{g}$ -open. Then  $U - G \subseteq A$ , where  $U - G$  is nano  $\hat{g}$ -closed. By Hypothesis  $U - G \subseteq U - \mathcal{NI}_{s\hat{g}}\text{-int}(A)$  implies  $\mathcal{NI}_{s\hat{g}}\text{-int}(A) \subseteq G$  and  $\mathcal{NI}_{s\hat{g}}\text{-int}(A) \subseteq G$ . Then  $U - A$  is  $\mathcal{NI}_{s\hat{g}}$ -closed and  $A$  is  $\mathcal{NI}_{s\hat{g}}$ -open.

**Theorem 4.3.** If  $U - \mathcal{NI}_{s\hat{g}}\text{-int}(A) \subseteq B \subseteq A$  and  $A$  is  $\mathcal{NI}_{s\hat{g}}$ -open, then  $B$  is  $\mathcal{NI}_{s\hat{g}}$ -open set.

Let  $\mathcal{NI}_{s\hat{g}}\text{-int}(A) \subseteq B \subseteq A$ . Thus  $U - A \subseteq U - B \subseteq \mathcal{NI}_{s\hat{g}}\text{-cl}(U - A)$ . Since  $U - A$  is  $\mathcal{NI}_{s\hat{g}}$ -closed. By the theorem 6.3.4,  $U - A \subseteq U - B \subseteq \mathcal{NI}_{s\hat{g}}\text{-cl}(A)$  implies  $U - B$  is  $\mathcal{NI}_{s\hat{g}}$ -closed. Hence  $B$  is  $\mathcal{NI}_{s\hat{g}}$ -open set.

## NIsg-Continuous and NIsg Irresolute Function

In this section, we define and study the new class of nano function, namely  $\mathcal{NI}_{s\hat{g}}$ -continuous,  $\mathcal{NI}_{s\hat{g}}$ -irresolute functions in nano ideal topological space. Also study some of their properties, Further we investigated the relationships between the other existing nano continuous functions. A function  $f : (U, \tau_R(X), I) \rightarrow (V, \sigma_{R'}(Y))$  is said to be  $\mathcal{NI}_{s\hat{g}}$ -continuous if  $f^{-1}(w)$  is  $\mathcal{NI}_{s\hat{g}}$ -closed in  $(U, \tau_R(X), I)$  for every nano closed set  $W$  in  $(V, \sigma_{R'}(Y))$ .

A function  $f : (U, \tau_R(X), I_1) \rightarrow (V, \sigma_{R'}(Y), I_2)$  is said to be  $\mathcal{NI}_{s\hat{g}}$ -irresolute if  $f^{-1}(w)$  is  $\mathcal{NI}_{s\hat{g}}$ -closed in  $(U, \tau_R(X), I_1)$  for every nano closed set  $W$  in  $(V, \sigma_{R'}(Y), I_2)$ .

**Theorem 5.1.** *In a nano ideal topological space  $(U, \tau_R(X), I)$ , the following hold*

- : (a) *Every nano continuous function is  $\mathcal{NI}_{s\hat{g}}$ -continuous function.*
- : (b) *Every  $N\hat{g}$ -continuous function is  $\mathcal{NI}_{s\hat{g}}$ -continuous function.*
- : (c) *Every  $N_{s\hat{g}}$ -continuous function is  $\mathcal{NI}_{s\hat{g}}$ -continuous function.*
- : (d) *Every  $\mathcal{NI}_{s\hat{g}}$ -continuous function is  $\mathcal{NI}_{\hat{g}}$ -continuous function.*
- : (e) *Every  $\mathcal{NI}_{s\hat{g}}$ -continuous function is  $\mathcal{NI}_{\hat{g}}$ -continuous function.*

(a) Let  $f : (U, \tau_R(X), I) \rightarrow (V, \sigma_{R'}(Y))$  be nano continuous function and  $w$  be any nano closed set in  $(V, \sigma_{R'}(Y))$ , then  $f^{-1}(w)$  is nano closed set in  $(U, \tau_R(X), I)$  as  $f$  is nano continuous. Since every nano closed set is  $\mathcal{NI}_{s\hat{g}}$ -closed set,  $f^{-1}(w)$  is  $\mathcal{NI}_{s\hat{g}}$ -closed set in  $(U, \tau_R(X), I)$ . Therefore  $f$  is  $\mathcal{NI}_{s\hat{g}}$ -continuous function.

(b) Let  $f : (U, \tau_R(X), I) \rightarrow (V, \sigma_{R'}(Y))$  be  $N\hat{g}$ -continuous function and  $w$  be any nano closed set in  $(V, \sigma_{R'}(Y))$ . Then  $f^{-1}(w)$  is  $N\hat{g}$ -closed set in  $(U, \tau_R(X), I)$  as  $f$  is  $N\hat{g}$ -continuous. Since every  $N\hat{g}$ -closed set is  $\mathcal{NI}_{s\hat{g}}$ -closed set,  $f^{-1}(w)$  is  $\mathcal{NI}_{s\hat{g}}$ -closed in  $(U, \tau_R(X), I)$ . Therefore  $f$  is  $\mathcal{NI}_{s\hat{g}}$ -continuous function.

(c) Let  $f : (U, \tau_R(X), I) \rightarrow (V, \sigma_{R'}(Y))$  be  $N_{s\hat{g}}$ -continuous function and  $w$  be any nano closed set in  $(V, \sigma_{R'}(Y))$ . Then  $f^{-1}(w)$  is  $N_{s\hat{g}}$ -closed set in  $(U, \tau_R(X), I)$  as  $f$  is  $N_{s\hat{g}}$ -continuous. Since every  $N_{s\hat{g}}$ -closed set is  $\mathcal{NI}_{s\hat{g}}$ -closed set,  $f^{-1}(w)$  is  $\mathcal{NI}_{s\hat{g}}$ -closed in  $(U, \tau_R(X), I)$ . Therefore  $f$  is  $\mathcal{NI}_{s\hat{g}}$ -continuous function.

**Rajendran and Mangayarkarasi**

(d) Let  $f : (U, \tau_R(X), I) \rightarrow (V, \sigma_{R'}(Y))$  be nano  $\mathcal{N}I_{s\hat{g}}$ -continuous function and  $w$  be any nano closed set in  $(V, \sigma_{R'}(Y))$ . Then  $f^{-1}(w)$  is nano  $\mathcal{N}I_{s\hat{g}}$ -closed set in  $(U, \tau_R(X), I)$  as  $f$  is  $\mathcal{N}I_{s\hat{g}}$ -continuous. Since every  $\mathcal{N}I_{s\hat{g}}$ -closed set is  $\mathcal{N}I_{g}$ -closed set,  $f^{-1}(w)$  is  $\mathcal{N}I_{g}$ -closed set in  $(U, \tau_R(X), I)$ . Therefore  $f$  is  $\mathcal{N}I_{g}$ -continuous function.

(e) Let  $f : (U, \tau_R(X), I) \rightarrow (V, \sigma_{R'}(Y))$  be nano  $\mathcal{N}I_{s\hat{g}}$ -continuous function and  $w$  be any nano closed set in  $(V, \sigma_{R'}(Y))$ . Then  $f^{-1}(w)$  is  $\mathcal{N}I_{s\hat{g}}$ -closed set in  $(U, \tau_R(X), I)$  as  $f$  is  $\mathcal{N}I_{s\hat{g}}$ -continuous. Since every  $\mathcal{N}I_{s\hat{g}}$ -closed set is  $\mathcal{N}I_{\hat{g}}$ -closed set,  $f^{-1}(w)$  is  $\mathcal{N}I_{\hat{g}}$ -closed set in  $(U, \tau_R(X), I)$ . Therefore  $f$  is  $\mathcal{N}I_{\hat{g}}$ -continuous function.

**Example 5.2.** Let  $U = \{a, b, c, d\}$ , with  $U/R = \{\{a\}, \{c\}, \{b, d\}\}$ ,  $X = \{a, b\}$ . Then the nano topology  $\tau_R(X) = \{\phi, \{a\}, \{a, b, d\}, \{b, d\}, U\}$  and the ideal  $I = \{\phi, \{a\}\}$  and  $V = \{a, b, c, d\}$  with  $V/R = \{\{a\}, \{b\}, \{c, d\}\}$  and  $Y = \{a, b\}$ . Then the nano topology  $\sigma_{R'}(Y) = \{\phi, \{a\}, \{b, d\}, \{a, b, d\}, V\}$  and the ideal  $I = \{\phi, \{a\}, \{b\}, \{a, b\}\}$ . Let  $f : (U, \tau_R(X), I) \rightarrow (V, \sigma_{R'}(Y))$  be the identity function. Then  $f$  is  $\mathcal{N}I_{s\hat{g}}$ -continuous but not nano continuous,  $\mathcal{N}\hat{g}$ -continuous and  $\mathcal{N}s\hat{g}$ -continuous.

**Example 5.3.** Let  $U = \{a, b, c, d\}$ , with  $U/R = \{\{a\}, \{b\}, \{c, d\}\}$ ,  $X = \{a, b\}$ . Then the nano topology  $\tau_R(X) = \{\phi, \{a\}, \{a, b, d\}, \{b, d\}, U\}$  and the ideal  $I = \{\phi, \{a\}, \{b\}, \{a, b\}\}$  and  $V = \{a, b, c, d\}$  with  $V/R = \{\{a\}, \{c\}, \{b, d\}\}$  and  $Y = \{a, b\}$ . Then the nano topology  $\sigma_{R'}(Y) = \{\phi, \{a\}, \{b, d\}, \{a, b, d\}, V\}$ . Let  $f : (U, \tau_R(X), I) \rightarrow (V, \sigma_{R'}(Y))$  be the identity function. Then  $f$  is  $\mathcal{N}I_{g}$ -continuous but not  $\mathcal{N}I_{s\hat{g}}$ -continuous.

**Example 5.4.** Let  $U = \{a, b, c, d\}$ , with  $U/R = \{\{a\}, \{c\}, \{b, d\}\}$ ,  $X = \{a, b\}$ . Then the nano topology  $\tau_R(X) = \{\phi, U, \{a\}, \{a, b, d\}, \{b, d\}\}$  and the ideal  $I = \{\phi, \{a\}\}$  and let  $V = \{a, b, c, d\}$  with  $V/R = \{\{a\}, \{b\}, \{c, d\}\}$  and  $Y = \{a, b\}$ . Then the nano topology  $\sigma_{R'}(Y) = \{\phi, \{a\}, \{b, d\}, \{a, b, d\}, V\}$  and the ideal  $I = \{\phi, \{a\}, \{b\}, \{a, b\}\}$ . Let  $f : (U, \tau_R(X), I) \rightarrow (V, \sigma_{R'}(Y))$  be the identity function. Then  $f$  is  $\mathcal{N}I_{\hat{g}}$ -continuous but not  $\mathcal{N}I_{s\hat{g}}$ -continuous.

**Theorem 5.5.** A function  $f : (U, \tau_R(X), I) \rightarrow (V, \sigma_{R'}(Y))$  is  $\mathcal{N}I_{s\hat{g}}$ -continuous if and if the inverse image of every nano closed set in  $(V, \sigma_{R'}(Y))$  is  $\mathcal{N}I_{s\hat{g}}$ -closed set in  $(U, \tau_R(X), I)$ .

Necessary Part: Let  $W$  be a nano open set in  $(V, \sigma_{R'}(Y))$ . Since  $f$  is  $\mathcal{N}I_{s\hat{g}}$ -continuous,  $f^{-1}(W^c)$  is  $\mathcal{N}I_{s\hat{g}}$ -closed set in  $(U, \tau_R(X), I)$ . But  $f^{-1}(W^c) = U - f^{-1}(W)$ . Hence  $f^{-1}(W)$  is  $\mathcal{N}I_{s\hat{g}}$ -closed set in  $(U, \tau_R(X), I)$ .

### Rajendran and Mangayarkarasi

Sufficiency Part: Assume that the inverse image of every nano closed set in  $(V, \sigma_{R'}(Y))$  is  $\mathcal{NI}_{s\hat{g}}$ -closed set is  $(U, \sigma_R(X), I)$ . Let  $W$  be a nano open set in  $(V, \sigma_{R'}(Y))$ . By our assumption  $f^{-1}(W^c) = U - f^{-1}(W)$  is  $\mathcal{NI}_{s\hat{g}}$ -closed in  $(U, \tau_R(X), I)$ . Which implies that  $f^{-1}(W)$  is  $\mathcal{NI}_{s\hat{g}}$ -open set in  $(U, \tau_R(X), I)$ . Hence  $f$  is  $\mathcal{NI}_{s\hat{g}}$ -continuous.

**Theorem 5.6.** Let  $f : (U, \tau_R(X), I_1) \longrightarrow (V, \sigma_{R'}(Y), I_2)$  and  $g : (V, \sigma_{R'}(Y), I_2) \longrightarrow (Z, \eta_{R''}(Z), I_3)$  be any two functions. Then the following hold.

- (1)  $g \circ f$  is  $\mathcal{NI}_{s\hat{g}}$ -continuous if  $f$  is  $\mathcal{NI}_{s\hat{g}}$ -continuous and  $g$  is nano-continuous.
- (2)  $g \circ f$  is  $\mathcal{NI}_{s\hat{g}}$ -continuous if  $f$  is  $\mathcal{NI}_{s\hat{g}}$ -irresolute and  $g$  is  $\mathcal{NI}_{s\hat{g}}$ -continuous.
- (3)  $g \circ f$  is  $\mathcal{NI}_{s\hat{g}}$ -irresolute if  $f$  is  $\mathcal{NI}_{s\hat{g}}$ -irresolute and  $g$  is  $\mathcal{NI}_{s\hat{g}}$ -irresolute.

(1) Let  $W$  be a nano closed set in  $Z$ . Since  $g$  is nano continuous function,  $g^{-1}(W)$  is closed in  $V$ ,  $\mathcal{NI}_{s\hat{g}}$ -continuous of  $f$  implies  $f^{-1}(g^{-1}(W))$  is  $\mathcal{NI}_{s\hat{g}}$ -closed in  $U$  and hence  $g \circ f$  is  $\mathcal{NI}_{s\hat{g}}$ -continuous.

(2) Let  $W$  be a nano closed set in  $Z$ . Since  $g$  is  $\mathcal{NI}_{s\hat{g}}$ -continuous function,  $g^{-1}(W)$  is  $\mathcal{NI}_{s\hat{g}}$ -closed in  $V$ . Since  $f$  is  $\mathcal{NI}_{s\hat{g}}$ -irresolute  $f^{-1}(g^{-1}(W))$  is  $\mathcal{NI}_{s\hat{g}}$ -closed in  $U$  and hence  $g \circ f$  is  $\mathcal{NI}_{s\hat{g}}$ -continuous.

(3) Let  $W$  be a  $\mathcal{NI}_{s\hat{g}}$ -closed set in  $Z$ . Since  $g$  is  $\mathcal{NI}_{s\hat{g}}$ -irresolute,  $g^{-1}(W)$  is  $\mathcal{NI}_{s\hat{g}}$ -closed in  $V$ . Since  $f$  is  $\mathcal{NI}_{s\hat{g}}$ -irresolute  $f^{-1}(g^{-1}(W))$  is  $\mathcal{NI}_{s\hat{g}}$ -closed in  $U$ .

### ABSTRACT

Numbers of the form  $n(2n - 1)$  for all  $n \geq 1$  are called Hexagonal numbers . A graph  $G$  with " $p$ " vertices and " $q$ " edges is called a Hexagonal sum graph(HSG) if it admits a labeling known as *Hexagonal sum labeling*(HSL).HSL is an injective function  $h: V(G) \rightarrow \mathbb{N}$ , where  $\mathbb{N}$  represents the set of all non- negative integers that induces a bijection  $h^+ : E(G) \rightarrow \{P_6(1), P_6(2), \dots, P_6(q)\}$  of the edges of  $G$  defined by  $h^+(uv) = h(u) + h(v)$  for every  $e = uv \in E(G)$ . where  $P_6(1), P_6(2), \dots, P_6(q)$  are the first  $q$  hexagonal numbers. In this work, we prove HSL for various families of graphs, such as Caterpillars,  $(P_n; S_m)$ ,  $(S_n \cup P_m)$ , Union of paths , H- graph,  $P(m)\Delta P(n)$ , Olive trees ,Shrub  $St(n_1, n_2, \dots, n_m)$  and Banana tree  $Bt(n_1, n_2, \dots, n_m)$ .

**Keywords:** Hexagonal numbers, Hexagonal sum labeling, Hexagonal sum graph.

### INTRODUCTION

In this paper, we focus on non-trivial finite, simple undirected graphs. The vertex set and edge set of a graph  $G$  are denoted by  $V(G)$  and  $E(G)$  respectively. We adopt the graph theoretic notations and terminology from Bondy and Murty<sup>2</sup> and the number theory concepts from Burton<sup>1</sup>. Numerous types of labelings have been introduced and explored by various researchers, and an excellent review of graph labeling can be found in<sup>4</sup>.A pentagonal sum labeling(PSL) was introduced by S.Murugesan et al<sup>5</sup>.PSL is an injective function  $g: V(G) \rightarrow \mathbb{N}$ , where  $\mathbb{N}$  represents the set of all non- negative integers that induces a bijection  $g^+ : E(G) \rightarrow \{A_1, A_2, \dots, A_q\}$  of the edges of  $G$  defined by

**Sureshkumar and Maragathavalli**

$g^+(uv) = g(u) + g(v)$  for every  $e = uv \in E(G)$ . where  $A_1, A_2, \dots, A_q$  are the first  $q$  pentagonal numbers. A graph  $G$  is called a pentagonal sum graph(PSG) if it admits *PSL*.

In this work, we prove HSL for various families of graphs, such as Caterpillars,  $(P_n; S_m), (S_n UP_m)$ , Union of paths, H-graph,  $P(m)\Delta P(n)$ , Olive trees, Shrub  $St(n_1, n_2, \dots, n_m)$  and Banana tree  $Bt(n_1, n_2, \dots, n_m)$ .

**Definition 1.1**

Numbers of the form  $P_6(n) = n(2n - 1)$  for all  $n \geq 1$  are called Hexagonal numbers .

**Definition 1.2**

HSL is an injective function  $h: V(G) \rightarrow N$ , where  $N$  represents the set of all non- negative integers that induces a bijection  $h^+ : E(G) \rightarrow \{P_6(1), P_6(2), \dots, P_6(q)\}$  of the edges of  $G$  defined by  $h^+(uv) = h(u) + h(v)$  for every  $e = uv \in E(G)$ . where  $P_6(1), P_6(2), \dots, P_6(q)$  are the first  $q$  hexagonal numbers.

**Definition 1.3**

A graph  $G$  is called a Hexagonal Sum Graph if it admits *Hexagonal Sum Labeling* .

**Definition 1.4**

A graph  $(P_n; S_m)$  is obtained by taking  $n$  copies of the star  $S_m$  and the path  $P_n: u_1, u_2, \dots, u_n$  by joining  $u_j (1 \leq j \leq n)$  to the central vertex of the  $j^{th}$  copy of  $S_m$  via an edge.

**Definition 1.5**

Let  $P(m)$  and  $P(n)$  be two paths and  $V(P(m)) = \{w_1, w_2, \dots, w_m\}$ . Consider  $m$  isomorphic copies of  $P(n)$ . Let  $v$  be the end vertex in  $P(n)$ . Adjoin an isomorphic copy  $P_i(n)$  of  $P(n)$  to each  $w_i, i = 1, 2, \dots, m$  in such a way that  $v$  and  $w_i$  are identified. Such a graph is denoted by  $P(m)\Delta P(n)$ .

## MAIN RESULTS

**Theorem 2.1**

Caterpillars  $S(n_1, n_2, n_3, \dots, n_m)$  are Hexagonal sum graph for all  $n_s \geq 1$

**Proof**

Let  $P_m: u_1 u_2 u_3 \dots u_m$  be a path with  $m$  vertices . From each  $u_s, s = 1, 2, \dots, m$  there are  $n_r, r = 1, 2, 3, \dots, m$  pendent vertices say  $u_{s1}, u_{s2}, u_{s3}, \dots, u_{sn_r}$ . The resulting graph is known as caterpillar and is represented as  $S(n_1, n_2, n_3, \dots, n_m)$ .

The caterpillar graph  $S(n_1, n_2, n_3, \dots, n_m) = G$  has  $m + n_1 + n_2 + n_3 + \dots + n_m$  vertices and  $q = m - 1 + n_1 + n_2 + n_3 + \dots + n_m$  edges.

Define  $h: V(G) \rightarrow N$  by

$$h(u_1) = 0$$

$$h(u_s) = P_6(s - 1) - h(u_{s-1}) ; 2 \leq s \leq m$$

$$h(u_{1r}) = P_6(m - 1 + s) ; 1 \leq r \leq n_1$$

$$h(u_{sr}) = P_6(m - 1 + n_1 + n_2 + \dots + n_{s-1} + r) - h(u_s)$$

$$s = 2, 3, 4, \dots, m ; r = 1, 2, 3, \dots, n_s$$

and the induced edge labels are

$$h^+(u_1 u_2) = P_6(1)$$

$$h^+(u_s u_{s+1}) = h(s) + h(u_{s+1}) = P_6(r) ; r = 1, 2, 3, \dots, m - 1$$

$$h^+(u_1 u_{1r}) = P_6(m - 1 + r) ; r = 1, 2, 3, \dots, n_1$$

$$h^+(u_s u_{sr}) = h(u_s) + h(u_{sr}) = P_6(m - 1 + n_1 + n_2 + \dots + n_{s-1} + r) ;$$

$$r = 1, 2, \dots, n_s ; s = 2, 3, \dots, m$$

As a result, the induced edge labels represent the initial  $q$  Hexagonal numbers.

Hence Caterpillars  $S(n_1, n_2, n_3, \dots, n_m)$  are Hexagonal sum graph for all  $n_s \geq 1$

**Sureshkumar and Maragathavalli**

**Theorem 2.2**

The graph  $(P_n; S_m)$  admits HSL

**Proof**

Let  $v_1, v_2, v_3, \dots, v_n$  be the vertices of  $P_n$  and  $u_{r0} ; r = 1,2,3, \dots, n$   $w_{rs} ; r = 1,2,3, \dots, n$   $s = 1,2,3, \dots, m$  be the central and end vertices of  $S_m$ .

Define  $h: V(P_n; S_m) \rightarrow N$  as an injective function by

$$\begin{aligned} h(v_1) &= 0 \\ h(v_r) &= P_6(r - 1) - h(u_{r-1}) \quad 2 \leq r \leq n \\ h(u_{r0}) &= P_6(n + r - 1) \quad 1 \leq r \leq n \\ h(u_{rs}) &= P_6(2n + m(r - 1) + (l - 1)) - h(u_{r0}) ; 1 \leq r \leq n, 1 \leq s \leq m. \end{aligned}$$

By the definition of  $h$ , it is evident that for distinct  $r$  and  $s$ , the corresponding vertex labels are different. Consequently, the induced edge labels are also unique. They are  $\{P_6(1), P_6(2), P_6(3), \dots, P_6(n(m + 2) - 1)\}$ . There fore  $(P_n, S_m)$  is a HSG.

**Theorem 2.3**

$S_n \cup P_m$  is a HSG for  $n > 1$

**Proof**

Let  $v_0, v_1, v_2, \dots, v_n$  be the vertices of  $S_n$  and  $v_{n+1}, \dots, v_{n+m}$  be the vertices of  $P_m$ . The graph  $S_n \cup P_m$  has  $n + m + 1$  vertices and  $q = n + m - 1$  edges.

Define  $h: V(S_n \cup P_m) \rightarrow N$  as an injective function such that

$$\begin{aligned} h(v_0) &= 0 \\ h(v_r) &= P_6(r) \quad ; 1 \leq r \leq n \\ h(v_{n+1}) &= [\max f(V(S_n))] + 3 \quad \text{and} \quad h(v_s) = P_6(s - 1) - h(v_{s-1}) \quad ; s = n + 2, n + 3, \dots, n + m \end{aligned}$$

This  $h$  obviously generates  $h^+$  as required. Hence the proof

**Theorem 2.4**

Union of paths admits Hexagonal sum labeling.

**Proof**

Consider the graph  $P_1 \cup P_2 \cup P_3 \cup \dots \cup P_n$  where the number of edges  $q$  is given by  $1 + 2 + 3 + \dots + (n - 1) = \frac{n(n-1)}{2}$ . Let the vertices of the graph be denoted by  $v_r ; r = 1,2, \dots, \frac{n(n+1)}{2}$ . Define an injective mapping  $h: V(\cup_{i=1}^n P_n) \rightarrow N$  as follows, Label the single vertex of  $P_1$  by 1. Assign zero to the first vertex of  $P_2$ . The first vertices of each  $P_l, l \geq 3$  are labeled as  $[\max f(V(P_{l-1}))] + 3$  and the remaining vertices as  $P_6(r - (s - 1)) - h(u_{r-1}) ; 3 \leq r \leq \frac{n(n+1)}{2}$ . Based on the definition  $h$  on  $V(\cup_{i=1}^n P_n)$ , it is obvious that  $h$  is an injective function and  $h^+[E(\cup_{i=1}^n P_n)] = \{P_6(1), P_6(2), \dots P_6(q)\}$ . Hence  $\cup_{i=1}^n P_i$  is a Hexagonal sum graph.

**Theorem 2.5**

H – graphs are HSG.

**Proof**

Let  $u_1, u_2, u_3, \dots, u_n$  be the  $n$  vertices of the first copy of  $P_n$  and  $v_1, v_2, \dots, v_n$  be the  $n$  vertices in the second copy of  $P_n$ . Let  $u_r v_s ; r, s \in \{1,2, \dots, n\}$  be the connecting edge. Then this graph has  $2n - 1$  edges. Define  $h: V(H) \rightarrow N$  by

$$\begin{aligned} h(u_k) &= 0 \\ h(u_{r-i}) &= P_6(i) - h(u_{r-i+1}) \quad ; i = 1,2, \dots, k - 1 \\ h(u_{k+i}) &= P_6(r + i - 1) - f(u_{r+i-1}) \quad ; i = 1,2,3, \dots, n - k \\ h(v_s) &= P_6(n) \\ h(v_{s-i}) &= P_6(n + i) - h(v_{s-i+1}) \quad ; i = 1,2, \dots, s - 1 \\ h(v_{s+i}) &= P_6(n + s - 1 + i) - h(v_{l+i-1}) \quad ; i = 1,2,3, \dots, n - s \end{aligned}$$

**Sureshkumar and Maragathavalli**

Clearly  $h$  is an injective function that establishes  $h^+(E(G)) = \{P_6(1), P_6(2), \dots, P_6(2n - 1)\}$ . Hence the proof.

**Theorem 2.6**

$P(m)\Delta P(n)$  graph admits HSL

**Proof**

Let us label the vertices of  $P(m)$  by  $u_{r0}$  ;  $r = 1,2,3, \dots, m$  and those of  $m$  isomorphic copies of  $P(n)$  by  $u_{rs}$  ;  $1 \leq s \leq n - 1, 1 \leq r \leq m$ .

Define an injective function  $h: V(P(m)\Delta P(n)) \rightarrow N$  by

$$h(u_{10}) = 0$$

$$h(u_{k0}) = P_6((r - 1)n) - h(u_{r-1,0}) ; 2 \leq r \leq m$$

$$h(u_{rs}) = P_6((r - 1)n + s) - h(u_{r,s-1}) ; 1 \leq r \leq m, 1 \leq s \leq n - 1$$

Clearly the resulting edge labels correspond to the first  $mn - 1$  hexagonal numbers.

Hence the proof.

**Theorem 2.7**

Olive trees are pentagonal sum graphs

**Proof**

Let  $u_0$  be the root . Let  $u_{11}, u_{12}, \dots, u_{1n}$  be the vertices in the first level. Let  $u_{22}, u_{23}, \dots, u_{2n}$  be the  $n - 1$  vertices in the second level etc. Let  $u_{nm}$  be the unique vertex in the  $n^{th}$  level. Then

$u_0 u_{1r} 1 \leq r \leq n ; u_{1r} u_{2r} 2 \leq r \leq n ; u_{2r} u_{3r} 3 \leq r \leq n ; \dots u_{n-1n} u_{nm}$  are the edges in the corresponding levels.

Then  $G$  has  $\frac{n(n+1)}{2}$  edges and  $\frac{n(n+1)}{2} + 1$  vertices

Define  $h: V(G) \rightarrow N$  by

$$h(u_0) = h(u_{mr}) = P_6 \left[ (m - 1)n - \frac{m(m - 1)}{2} + r \right] - h(u_{m-1,r}) \text{ where } m(\text{represent each level}) = 1,2,3 \dots, n; r = m, m + 1, \dots, n$$

This induces the edge labels as follows

$$h^+(u_0 u_{1r}) = h(u_0) + h(u_{1r})$$

$$= 0 + P_6(r)$$

$$= P_6(r) 1 \leq r \leq n$$

$$h^+(u_{1r} u_{2r}) = h(u_{1r}) + h(u_{2r})$$

$$= h(u_{1r}) + P_6[n - 1 + r] - h(u_{1r})$$

$$= P_6[n - 1 + r] 1 \leq r \leq n - 1$$

$$h^+(u_{2r} u_{3r}) = h(u_{2r}) + h(u_{3r})$$

$$= h(u_{2r}) + P_6[2n - 3 + r] - h(u_{2r})$$

$$= P_6[2n - 3 + r] 1 \leq r \leq n - 2$$

⋮  
⋮  
⋮

$$h^+(u_{n-1n} u_{nm}) = h(u_{n-1n}) + h(u_{nm})$$

$$= h(u_{n-1n}) + P_6 \left[ (n - 1)n - \frac{n(n - 1)}{2} + n \right] - h(u_{n-1n})$$

$$= P_6 \left[ \frac{n(n + 1)}{2} \right]$$

Hence the injective function  $h$  induces first  $P_6 \left[ \frac{n(n+1)}{2} \right]$  edge labels . Therefore, Olive trees are HSG's

**Theorem 2.8**

Shrub  $St(n_1, n_2, \dots, n_m)$  is a HSG

**Sureshkumar and Maragathavalli**

**Proof**

Let  $V(St(n_1, n_2, \dots, n_m)) = \{v, v_r, v_{rs} : 1 \leq r \leq m, 1 \leq s \leq n_r\}$  and  $E(St(n_1, n_2, \dots, n_m)) = \{vv_r, v_r v_{rs} : 1 \leq r \leq m, 1 \leq s \leq n_r\}$ .  $St(n_1, n_2, \dots, n_m)$  has  $m + n_1 + n_2 + \dots + n_m + 1$  vertices and  $m + n_1 + n_2 + \dots + n_m$  edges.

Define  $h: V(St(n_1, n_2, \dots, n_m)) \rightarrow N$  by

$$h(v) = 0$$

$$h(v_r) = P_6(r)$$

$$h(v_{1s}) = P_6(m + s) - h(v_1) \quad 1 \leq s \leq n_1$$

$$h(v_{2s}) = P_6(m + n_1 + s) - h(v_2) \quad 1 \leq s \leq n_2 :$$

$$h(v_{rs}) = P_6(m + n_1 + n_2 + \dots + n_{r-1} + s) - h(v_r) \quad 1 \leq r \leq m, 1 \leq s \leq n_r$$

Clearly the edges labels are the first  $m + n_1 + n_2 + \dots + n_m$  Hexagonal numbers. Hence Shrub  $St(n_1, n_2, \dots, n_m)$  is a HSG.

**Theorem 2.9**

Banana tree  $Bt(n_1, n_2, \dots, n_m)$  is a HSG

**Proof**

Let  $V(Bt(n_1, n_2, \dots, n_m)) = \{v, v_r, w_r, w_{rs} : 1 \leq r \leq m, 1 \leq s \leq n_r - 1\}$  and  $E(Bt(n_1, n_2, \dots, n_m)) = \{vv_r, v_r w_r, w_r w_{rs} : 1 \leq r \leq m, 1 \leq s \leq n_r - 1\}$

$Bt(n_1, n_2, \dots, n_m)$  has  $m + n_1 + n_2 + \dots + n_m + 1$  vertices and  $m + n_1 + n_2 + \dots + n_m$  edges.

Define  $h: V(Bt(n_1, n_2, \dots, n_m)) \rightarrow N$  by

$$h(v) = 0$$

$$h(v_r) = P_6(r)$$

$$h(w_r) = P_6(m + r) - g(v_r)$$

$$h(w_{1s}) = P_6(2m + s) - h(w_1) \quad 1 \leq s \leq n_1 - 1$$

$$h(w_{2s}) = P_6(2m + n_1 - 1 + s) - f(w_2) \quad 1 \leq s \leq n_2 - 1$$

$$h(w_{3s}) = P_6(2m + n_1 + n_2 - 2 + l) - f(w_3) \quad 1 \leq s \leq n_3 - 1$$

⋮

$$h(w_{rs}) = P_6(2m + n_1 + n_2 + n_{r-1} - (r - 1) + s) - f(w_r) \quad 1 \leq r \leq m, \quad 1 \leq l \leq n_r - 1$$

Clearly the edges labels are the first  $m + n_1 + n_2 + \dots + n_m$  Hexagonal numbers. Hence  $Bt(n_1, n_2, \dots, n_m)$  HSG

## ABSTRACT

In the fields of information analysis, economic strategy, and dynamics, fuzzy numbers are essential. Determining the Positioning of numerous fuzzy values is a crucial step towards improving numerous numerical models. Using a fuzzy number of available strategies, the best solution for the transportation challenges was produced. In this research, we present a positioning technique that modifies the transportation problem of Hexagonal Intuitionistic Fuzzy to a brilliantly renowned one, which is after that applies to a further optional dealing to obtain the Fuzzy acceptable collection. Based on fuzzy calculations, the statistical depiction highlights the latest proposed method's fantastic and sensitive methods to solving the transportation issues.

**Keywords:** Fuzzy set, Hexagonal Fuzzy Number Ranking, Hexagonal Intuitionistic Fuzzy Number Ranking, Fuzzy Transportation Problem, Centroid Method.

## INTRODUCTION

Due to a variety of uncontrollable circumstances, there is always some reluctance while making decisions in many real-life situations. In the very first Prof. Zadeh [20] introduced fuzzy set theory. In the fuzzy set theory, the

Sakthivel et al.,

association point  $\mu(x)$  of a division in a fuzzy set lies  $(0, 1)$  and then on–membership point  $\nu(x)$  is  $1 - \mu(x)$ . But because of the level of hesitation, this is not feasible in many real-world scenarios. In intuitionistic fuzzy set theory, the point of membership and non-membership are defined concurrently such that the sum of the two values is  $(\leq 1)$ . Thus, the degree of hesitancy  $\pi(x)$  is  $1 - \mu(x) - \nu(x)$ . Unlike fuzzy set premise, intuitionistic fuzzy set hypothesis offered more information about the problem. Because of this, fuzzy set theory and intuitionistic fuzzy set theory have been applied by many academics in a variety of scientific fields [2–8, 17, 18]. It is frequently impossible to fully characterize the numerical data associated with a decision-making challenge. Therefore, it might be represented by fuzzy numbers. In the literature membership functions with trapezoidal and triangular shapes are commonly used to symbolize fuzzy numbers. R. Srinivasan and N. Karthikeyan [11, 12] looked into a two point cost preventive fuzzy transportation problem when supply and demand is both fuzzy figures, when things get complicated and ambiguous. Furthermore, to address transportation-related problems, Yahya Mohamed [19] implemented a suggested ranking technique utilizing triangular fuzzy numbers. Amalorpava et. al [1, 13, 14, 15] are suggested some graphical and fuzzy ideas for transportation problems. Ramesh et. al [9, 10, 16] are produced some ranking ideas for fuzzy numbers. In contrast, intuitionistic fuzzy numbers provide more information than fuzzy numbers provide, as well as indicating considerable uncertainty in unclear problem scenarios. The author presents hexagonal intuitionistic fuzzy numbers and their membership and non-membership functions in this research study. A proposed type of arithmetic operations for Hexagonal Intuitionistic Fuzzy Numbers has been proposed based on  $(\alpha, \beta)$  cuts.

## PRELIMINARIES

### Definition: Fuzzy Set

A set is considered fuzzy if its boundaries are abrupt or unclear. Fuzzy set theory is unable to connect the ends of classical set theory because it allows membership in a set to be a matter of degree. The degree of membership in a set is expressed as a number between 0 and 1, where 0 denotes complete absence of the value and 1 denotes complete presence. The number 0 denotes non-membership, the value 1 denotes membership, and values in between indicate intermediate degrees of membership. A mapping of a domain element by a membership function, such as Space of the cosmos of Discourse  $X$ , to the unit interval  $J = [0, 1]$ , provides a fuzzy set. i.e.  $\tilde{A} = \{(x, \mu_{\tilde{A}}(x); x \in X)\}$ . Here  $\mu_{\tilde{A}}: X \rightarrow J$  a mapping known as the fuzzy set's function point of membership  $\tilde{A}$  and  $\mu_{\tilde{A}}(x)$  is called the membership value of  $x \in X$  in a fuzzy set  $\tilde{A}$ . Often, these membership prerequisites are stated as actual values between  $J$ .

### Definition: Fuzzy Number

Let  $\tilde{A}$  be a fuzzy set on  $R$ , then it's satisfied the following conditions.

- i.  $\mu_{\tilde{A}}(x_0)$  is piecewise continuous
- ii. There exist at least one  $x_0 \in \mathfrak{R}$  with  $\mu_{\tilde{A}}(x_0) = 1$
- iii.  $\tilde{A}$  is a regular and convex

### Definition: Intuitionistic Fuzzy Number

An Intuitionistic fuzzy set  $\tilde{A}^I = \{ \langle x, \mu_{\tilde{A}^I}(x), \nu_{\tilde{A}^I}(x) \rangle \}$  is called an Intuitionistic fuzzy number of the real line  $R$  if the following conditions are meeting.

1. There is one  $m \in R$  such that  $\mu_{\tilde{A}^I}(m) = 1$  and  $\nu_{\tilde{A}^I}(m) = 1$  (where  $m$  is called the mean of  $\tilde{A}^I$ )
2.  $\mu_{\tilde{A}^I}(x)$  and  $\nu_{\tilde{A}^I}(x)$  are piecewise continuous functions derived from  $R \rightarrow [0, 1]$  such that  $0 \leq \mu_{\tilde{A}^I}(x) + \nu_{\tilde{A}^I}(x) \leq 1, \forall x \in R$
3. The membership and non-membership functions of  $\tilde{A}^I$  are as follows.

**Sakthivel et al.,**

$$\mu_{\tilde{A}^I}(x) = \begin{cases} f_1(x) & m - \alpha \leq x \leq m \\ 1 & x = m \\ g_1(x) & m \leq x \leq m + \beta \\ 0 & \text{otherwise} \end{cases}$$

$$\nu_{\tilde{A}^I}(x) = \begin{cases} f_2(x) & m - \alpha' \leq x \leq m \\ 0 & x = m \\ g_1(x) & m \leq x \leq m + \beta' \\ 1 & \text{otherwise} \end{cases}$$

This is how the Intuitionistic fuzzy number  $\tilde{A}^I$  is represented:  $\tilde{A}^I = (m : \alpha, \beta : \alpha', \beta')$ .

**Hexagonal Intuitionistic Fuzzy Number**

A group of intuitionistic fuzzy sets with the following membership and non-membership functions is called a hexagonal intuitionistic fuzzy number.

$$\mu_{\tilde{A}^I}(x) = \begin{cases} \frac{1}{2} \left( \frac{x - \tilde{a}_1}{\tilde{a}_2 - \tilde{a}_1} \right), & \tilde{a}_1 \leq x \leq \tilde{a}_2 \\ \frac{1}{2} + \frac{1}{2} \left( \frac{x - \tilde{a}_2}{\tilde{a}_3 - \tilde{a}_2} \right), & \tilde{a}_2 \leq x \leq \tilde{a}_3 \\ 1, & \tilde{a}_3 \leq x \leq \tilde{a}_4 \\ 1 - \frac{1}{2} \left( \frac{x - \tilde{a}_4}{\tilde{a}_5 - \tilde{a}_4} \right), & \tilde{a}_4 \leq x \leq \tilde{a}_5 \\ \frac{1}{2} \left( \frac{\tilde{a}_6 - x}{\tilde{a}_6 - \tilde{a}_5} \right), & \tilde{a}_5 \leq x \leq \tilde{a}_6 \\ 0, & \text{o.w} \end{cases} \text{-----(1) and}$$

$$\nu_{\tilde{A}^I}(x) = \begin{cases} 1 - \frac{1}{2} \left( \frac{x - \tilde{a}'_1}{\tilde{a}'_2 - \tilde{a}'_1} \right), & \tilde{a}'_1 \leq x \leq \tilde{a}'_2 \\ \frac{1}{2} \left( \frac{\tilde{a}'_3 - x}{\tilde{a}'_3 - \tilde{a}'_2} \right), & \tilde{a}'_2 \leq x \leq \tilde{a}'_3 \\ 0, & \tilde{a}'_3 \leq x \leq \tilde{a}'_4 \\ \frac{1}{2} \left( \frac{x - \tilde{a}'_4}{\tilde{a}'_5 - \tilde{a}'_4} \right), & \tilde{a}'_4 \leq x \leq \tilde{a}'_5 \\ \frac{1}{2} + \frac{1}{2} \left( \frac{x - \tilde{a}'_5}{\tilde{a}'_6 - \tilde{a}'_5} \right), & \tilde{a}'_5 \leq x \leq \tilde{a}'_6 \\ 1, & \text{o.w} \end{cases} \text{-----(2)}$$

Where  $\tilde{a}'_1 \leq \tilde{a}_1 \leq \dots \leq \tilde{a}_6 \leq \tilde{a}'_6$ . The symbol for this fuzzy Intuitionistic hexagonal number is  $\tilde{A}^I_H = (a_1, \dots, a_6 ; a'_1, \dots, a'_6)$ .

**Sakthivel et al.,**

**Transformation of Hexagonal Intuitionistic Fuzzy Number to a Hexagonal Fuzzy Number**

If  $a'_1 = a_1, a'_2 = a_2, a'_5 = a_5$  and  $a'_6 = a_6$  then the hexagonal Intuitionistic fuzzy number  $\tilde{A}_H^I = (a_1, \dots, a_6; a'_1, \dots, a'_6)$ . is changed to a fuzzy hexagonal number  $\tilde{A}_H = (a_1, \dots, a_6)$

**Proof:**

Put  $a'_1 = a_1, a'_2 = a_2, a'_5 = a_5$  and  $a'_6 = a_6$  in 1 and 2 we get

$$\mu_{\tilde{A}'}(x) = \begin{cases} \frac{1}{2} \left( \frac{x - \tilde{a}_1}{\tilde{a}_2 - \tilde{a}_1} \right), & \tilde{a}_1 \leq x \leq \tilde{a}_2 \\ \frac{1}{2} + \frac{1}{2} \left( \frac{x - \tilde{a}_2}{\tilde{a}_3 - \tilde{a}_2} \right), & \tilde{a}_2 \leq x \leq \tilde{a}_3 \\ 1, & \tilde{a}_3 \leq x \leq \tilde{a}_4 \\ 1 - \frac{1}{2} \left( \frac{x - \tilde{a}_4}{\tilde{a}_5 - \tilde{a}_4} \right), & \tilde{a}_4 \leq x \leq \tilde{a}_5 \\ \frac{1}{2} \left( \frac{\tilde{a}_6 - x}{\tilde{a}_6 - \tilde{a}_5} \right), & \tilde{a}_5 \leq x \leq \tilde{a}_6 \\ 0. & o.w \end{cases} \text{-----(3)}$$

and

$$\nu_{\tilde{A}'}(x) = \begin{cases} 1 - \frac{1}{2} \left( \frac{x - \tilde{a}_1}{\tilde{a}_2 - \tilde{a}_1} \right), & \tilde{a}_1 \leq x \leq \tilde{a}_2 \\ \frac{1}{2} \left( \frac{\tilde{a}_3 - x}{\tilde{a}_3 - \tilde{a}_2} \right), & \tilde{a}_2 \leq x \leq \tilde{a}_3 \\ 0, & \tilde{a}_3 \leq x \leq \tilde{a}_4 \\ \frac{1}{2} \left( \frac{x - \tilde{a}_4}{\tilde{a}_5 - \tilde{a}_4} \right), & \tilde{a}_4 \leq x \leq \tilde{a}_5 \\ \frac{1}{2} + \frac{1}{2} \left( \frac{x - \tilde{a}_5}{\tilde{a}_6 - \tilde{a}_5} \right), & \tilde{a}_5 \leq x \leq \tilde{a}_6 \\ 1. & o.w \end{cases} \text{-----(4)}$$

From 3 and 4, it is obvious that  $\nu_{\tilde{A}'}(x)$  is the match of  $\mu_{\tilde{A}'}(x)$  in each period.

ie  $\nu_{\tilde{A}'}(x) = 1 - \mu_{\tilde{A}'}(x) \quad \forall x \in R$ .

Hence it is a HFN (Hexagonal fuzzy number)  $\tilde{A}_H = (a_1, \dots, a_6)$

**Arithmetic Operations on Hexagonal Intuitionistic Fuzzy Numbers**

Let  $\tilde{A}_H^I = (a_1, \dots, a_6; a'_1, \dots, a'_6)$ . and  $\tilde{B}_H^I = (b_1, \dots, b_6; b'_1, \dots, b'_6)$  be a pair of intuitionistic, fuzzy hexagonal numbers. The following are the fundamental operations in mathematics, according per the Zadeh Extension principle:

**Sakthivel et al.,**

$$\tilde{A}_H^I \oplus \tilde{B}_H^I = (a_1 + b_1, \dots, a_6 + b_6; a_1' + b_1', \dots, a_6' + b_6')$$

$$\tilde{A}_H^I - \tilde{B}_H^I = (a_1 - b_6, \dots, a_6 - b_1; a_1' - b_6', \dots, a_6' - b_1')$$

$$\tilde{A}_H^I * \tilde{B}_H^I = (l_1, l_2, l_3, l_4, l_5, l_6; l_1', l_2', l_3', l_4', l_5', l_6') \text{ where}$$

$$l_1 = \min(a_1b_1, a_1b_6, a_6b_1, a_6b_6), \quad l_6 = \max(a_1b_1, a_1b_6, a_6b_1, a_6b_6)$$

$$l_2 = \min(a_2b_2, a_2b_5, a_5b_2, a_5b_5), \quad l_5 = \max(a_2b_2, a_2b_5, a_5b_2, a_5b_5)$$

$$l_3 = \min(a_3b_3, a_3b_4, a_4b_3, a_4b_4), \quad l_4 = \max(a_3b_3, a_3b_4, a_4b_3, a_4b_4)$$

$$l_1' = \min(a_1'b_1', a_1'b_6', a_6'b_1', a_6'b_6'), \quad l_6' = \max(a_1'b_1', a_1'b_6', a_6'b_1', a_6'b_6')$$

$$l_2' = \min(a_2'b_2', a_2'b_5', a_5'b_2', a_5'b_5'), \quad l_5' = \max(a_2'b_2', a_2'b_5', a_5'b_2', a_5'b_5')$$

$$k\tilde{A}_H^I = (ka_1, \dots, ka_6; ka_1', \dots, ka_6') \text{ if } k > 0$$

$$k\tilde{A}_H^I = (ka_6, \dots, ka_1; ka_6', \dots, ka_1') \text{ if } k < 0$$

$(\alpha, \beta)$  – cuts of Hexagonal Intuitionistic Fuzzy Number

Let  $\tilde{A}_H^I = (a_1, \dots, a_6; a_1', \dots, a_6')$  be a hexagonal Intuitionistic fuzzy number, then  $(\alpha, \beta)$  cuts of  $\tilde{A}_H^I$  are given by

$$\tilde{A}_H^I(\alpha) = \begin{cases} [a_1 + 2\alpha(a_2 - a_1), a_6 - 2\alpha(a_6 - a_5)] & \alpha \in [0, 0.5] \\ [2a_2 - a_3 + 2\alpha(a_3 - a_2), 2a_5 - a_4 - 2\alpha(a_5 - a_4)] & \alpha \in (0.5, 1] \end{cases}$$

$$\tilde{A}_H^I(\beta) = \begin{cases} [a_3 - 2\beta(a_3 - a_2'), a_4 + 2\beta(a_5' - a_4)] & \beta \in [0, 0.5] \\ [2a_2' - a_1' - 2\beta(a_2' - a_1'), 2a_5' - a_6' + 2\beta(a_6' - a_5')] & \beta \in (0.5, 1] \end{cases}$$

**Ranking of Hexagonal Intuitionistic Fuzzy Number**

For the fuzzy numbers of generalized hexagonal intuitionistic fuzzy number and hexagonal intuitionistic fuzzy number, we discuss the following Centroid ranking technique. Let

$\tilde{A}_{GH}^I = (a_1, \dots, a_6; a_1', \dots, a_6'; u_a, w_a)$  be fuzzy numbers of the generalized hexagonal intuitionistic; the ranking system is introduced here by using the Centroid ranking technique for GHIFNs.

$$R[\tilde{A}_{GH}^I] = \frac{R[\tilde{A}_{GH}^I(\mu)] + R[\tilde{A}_{GH}^I(v)]}{u_a + w_a} \text{ where}$$

$$R[\tilde{A}_{GH}^I(\mu)] = \left( \frac{2a_1 + 3a_2 + 4a_3 + 4a_4 + 3a_5 + 2a_6}{18} \right) \left( \frac{5u_a}{18} \right)$$

$$R[\tilde{A}_{GH}^I(v)] = \left( \frac{2a_1' + 3a_2' + 4a_3' + 4a_4' + 3a_5' + 2a_6'}{18} \right) \left( \frac{13 + 5w_a}{18} \right)$$

Let  $\tilde{A}_{GH}^I = (a_1, \dots, a_6; a_1', \dots, a_6')$  be fuzzy, hexagonal, intuitionistic numbers under the given criteria  $u_a = 1$  and  $w_a = 0$ , here, the ranking was introduced utilizing the Centroid Ranking technique for HIFNs.

**Sakthivel et al.,**

$$R[\tilde{A}'_H] = \left(\frac{5}{18}\right)\left(\frac{2a_1 + 3a_2 + 4a_3 + 4a_4 + 3a_5 + 2a_6}{18}\right) + \left(\frac{13}{18}\right)\left(\frac{2a'_1 + 3a'_2 + 4a_3 + 4a_4 + 3a'_5 + 2a'_6}{18}\right)$$

**MATHEMATICAL FORMULATION**

The IHFN's arithmetical design in the case where the whole source and the whole demand are equal is given below.

$$\text{Min } Z = \sum_{i=1}^s \sum_{j=1}^t \tilde{\alpha}_{ij} \tilde{x}_{ij}$$

To the constraints

$$\sum_{j=1}^t \tilde{x}_{ij} = \tilde{a}_i \quad j = 1, 2, \dots, t$$

$$\sum_{i=1}^s \tilde{x}_{ij} = \tilde{b}_j \quad i = 1, 2, \dots, s$$

$$\sum_{i=1}^s \tilde{a}_i = \sum_{j=1}^t \tilde{b}_j; \quad i = 1, 2, \dots, s; \quad j = 1, 2, \dots, t \text{ and}$$

$$\tilde{x}_{ij} \geq 0, \quad i = 1, 2, \dots, s, \quad j = 1, 2, \dots, t$$

The TP of fuzzy is openly denoted by the following way:

**Transportation Problem**

The transportation problem is the one where every limit is of the equality kind. The experiential data set usually has to be adjusted to meet one or more associations or requirements for many other transportation-related issues. Many of these times, the values of the variables, whether seen or inferred, are approximations. Nevertheless, a number of rigid relationships need to be met by the variables. The goals are incompatible and cannot be reconciled. Additionally, the cost coefficients in the transportation problem targets may refer to underutilized capacity, the amount of items transported, delivery time, distance, or other factors. Frequently, these criteria are inaccurate and ambiguous as a result of inadequate data.

A TP (Transportation Problem) mathematically, this can be stated as follows: 
$$\min z = \sum_{i=1}^m \sum_{j=1}^n c_{ij} x_{ij}$$

----- (5)

Subject to

$$\left. \begin{aligned} \sum_{j=1}^n x_{ij} &= a_i & j &= 1, 2, \dots, n \\ \sum_{i=1}^m x_{ij} &= b_j & i &= 1, 2, \dots, m \\ x_{ij} &\geq 0 & i &= 1, 2, \dots, m, \quad j = 1, 2, \dots, n \end{aligned} \right\} \text{----- (6)}$$

Where  $C_{ij}$  is the price of transport of a unit from the  $i^{th}$  starting place to the  $j^{th}$  endpoint, and the quantity  $x_{ij}$  is to be some +ve integer or 0, on or after which is to be transfer  $i^{th}$  starting point to  $j^{th}$  the objective. For the linear transportation problem discussed in (1) to contain a outcome, it is obviously shows that

**Sakthivel et al.,**

$$\sum_{i=1}^n a_i = \sum_{j=1}^m b_j \text{ -----(7)}$$

(i.e) Remember that there is an equal supply and demand overall. If a supply or destination is untrue, it can be replaced with a fictional one. It should be investigated to determine whether the issue can be resolved if and only if condition (2) is satisfied. The Transportation Problem (TP) at this point is to manage  $x_{ij}$ , in an effort to lower the overall cost of transportation.

**Fuzzy Transportation Problem**

Most of the time, the Transportation Problems' goals are inconsistent and non-measurable. Moreover, because of incomplete data and fuzziness in different possible suppliers and surroundings, the cost coefficients in objectives are never stated. The majority of these data are determined using basic forecasting techniques. Fuzzy algorithms are therefore more successful than crisp ones when handling transportation-related single- and multi-objective issues.

Mathematically, an FTP (fuzzy transportation problem) looks like this:

$$z = \sum_{i=1}^m \sum_{j=1}^n \tilde{c}_{ij} x_{ij} \text{ -----(8)}$$

Subject to

$$\left. \begin{aligned} \sum_{j=1}^n x_{ij} &= \tilde{a}_i & j = 1, 2, \dots, n \\ \sum_{i=1}^m x_{ij} &= \tilde{b}_j & i = 1, 2, \dots, m \\ x_{ij} &\geq 0 & i = 1, 2, \dots, m, \quad j = 1, 2, \dots, n \end{aligned} \right\} \text{ -----(9)}$$

Somewhere the rate of transport  $\tilde{c}_{ij}$ , supply  $\tilde{a}_i$ , and demand  $\tilde{b}_j$  values are fuzzy values. For the fuzzy linear transport issue obtainable in (4-5) to have a result, there is a obvious needed and satisfactory condition

$$\sum_{i=1}^n a_i = \sum_{j=1}^m b_j \text{ -----(10)}$$

**RECOMMENDED ALGORITHM**

**Step 1:**

Verify that the provided fuzzy transportation problem is a hexagonal intuitionistic problem that is fair. Whether or it is modified to be a balanced term by displaying an appropriate copy Horizontal or Vertical with hexagonal 0 expenses and its Supply/Demand represented as the difference between the full fuzzy supply and the complete fuzzy insist.

(i.e)  $\sum_{i=1}^s \tilde{a}_i = \sum_{j=1}^t \tilde{b}_j$ .

**Step 2:**

Using the centroid ranking value of the given HIFTP, create a clean transportation table. The ranking of both supply and demand is communicated by this transformation.

**Sakthivel et al.,**

**Step 3:**

In a reduced crisp cost matrix, the total quantity of rows and columns of the cost matrix is divided by the Horizontal wise maximum supply value subtracted by its nominal supply value for each individual line.

$$(i.e) \frac{\text{max} - \text{min}}{\text{row} + \text{column}}$$

**Step 4:**

In a condensed crisp cost matrix, the total number of rows and columns of the cost matrix is divided by the maximum demand value of each column, subtracted by its smallest demand value.

$$(i.e) \frac{\text{max} - \text{min}}{\text{row} + \text{column}}$$

**Step 5:**

In order to determine the maximum and minimum penalty numbers, respectively, assign a particular cost cell to the supplied problem after determining the corresponding minimum price value. We can select any of the various maximum/minimum values if there are any.

**Step 6:**

You can follow the steps 3, 4, and 5, upto  $(R + I - 1)$  collections are fixed. Suppose the condition is not reached; apply the Modi's method to find the most favorable level.

**EXAMPLE**

Consider a Hexagonal Intuitionistic fuzzy Transport exercise with the following data as given in table

**Solution**

We used the Centroid Ranking algorithm to turn the fuzzy hexagonal intuitionistic numbers into a crisp value. The specified troublesome phrase has been stabilized. Next, choose the maximum penalty amount, find the lowest price value that corresponds to it, and allocate the specified cost cell to the presented Exercise. We can choose from any of the highest-ranking results if there is more than one. The highest penalty value in the above table is found in the second row. Therefore, adjust the supply units and assign the smallest number of require units (8) to the smallest amount cost group (2, 2). of  $I_b$ .  $\times$  This table shows that the first column has the lowest penalty value. Thus, assign the lowest feasible require units (6) to the lowest possible price group (1, 1), and alter the make available units of  $I_a$ . the final assigned value. In this case, a entire of  $(3+4-1) = 6$  cells are selected. The projected Ranking algorithm might then be used to find the best solution.

$$\text{Min } Z = 5(24) + 5(12) + 14(10) + 6(13) + 2(29) + 8(8)$$

$$\text{Min } Z = 520$$

**DISCUSSION**

The innovative recommended level Procedure is check with to the optimality tests of the NWCM, LCM, VAM, and MODI in the graph under. The recently proposed Ranking Technique yields the best results.

**CONCLUSION**

The most important part of this Analysis is to find the optimal feasibility of a fuzzy transport problem for Hexagonal Intuitionistic fuzzy numbers using the recently introduced Ranking technique approach. You can use this method for any fuzzy transportation problem. The recently developed Ranking methodology is a straightforward, standardized approach that may be used to emphasize or minimize a desired function across all problem categories. This method might be extended to handle transportation-related issues by utilizing a second fuzzy algorithm.

### ABSTRACT

In this paper, we introduce a new class of operators called  $(\alpha, \beta)$ - quasi normal operator in Hilbert Spaces including some key characteristics of this operator, as well as a discussion of various theorems related to this operator and state various inequalities between the operator norm and the numerical radius. An operator  $T \in B(H)$  is said to be  $(\alpha, \beta)$ - quasi normal operator then  $T[\alpha^2 T^* T] \leq [T T^*] T \leq T[\beta^2 T^* T]$

**Keywords:** Operator, Hilbert space, Normal,  $(\alpha, \beta)$  - Quasi Normal,  $(\alpha, \beta)$  - Normal Operator,  $(\alpha, \beta)$  - Quasi Normal Operator.

**Mathematics Subject Classification:** 47B20, 47B37, 47B38.

## INTRODUCTION

Throughout this paper, we denote Hilbert space over the field of complex numbers  $\mathbb{C}$  and we write  $B(H)$  for the set of all bounded linear operators on  $H$ . An operator  $T \in B(H)$ , the adjoint, the kernel, and the range of  $T$  are denoted by  $T^*$ ,  $N(T)$  and  $R(T)$ , respectively. If  $T, S \in B(H)$ ,  $T$  is said to be positive if  $\langle Tx|x \rangle \geq 0$  for all  $x \in H$  and  $T \geq S$  iff  $T - S \geq 0$ . We are interested in introducing the  $(\alpha, \beta)$  - quasi normal operators, a novel notion of normality in Hilbert spaces, in this context. We demonstrate that numerous findings from [8] and [11] still apply to this new class. In the works [2], [3], [15], [16], [18] and other papers, these classes of operators have just lately been generalized in Hilbertian spaces. There have been some thorough research done on the class of normal operators on Hilbert spaces. J. B. Conway and C. R. Putnam in particular looked into the theory of these operators in their respective works [7] and

**Radharamani and Sathyavathi**

[17]. In this paper we prove some of the properties of  $(\alpha, \beta)$  quasi normal operators and also various inequalities between the operator norm and the numerical radius of the  $(\alpha, \beta)$  quasi normal operators in Hilbertian spaces.

**Preliminaries**

First, various notations are introduced and a complex Hilbert space with the inner products  $\langle \cdot, \cdot \rangle$  and  $\| \cdot \|$  represents by the sign  $H$ . Let  $B(H)$  stand for the complex Hilbert space  $H$ 's Banach algebra of all bounded linear operators.

**Definition 2.1**

It is referred to as an operator  $T \in B(H)$  is said to be Normal if  $T^*T = TT^* \Rightarrow [T] = 0 \Rightarrow \|Tx\| = \|T^*x\|, \forall x \in H$

**Definition 2.2[2,3]**

It is referred to as an operator  $T \in B(H)$  is said to be Hyponormal  $[T^*T] \geq 0 \Rightarrow \|Tx\| \geq \|T^*x\|, \forall x \in H$

**Definition 2.3 [14]**

It is referred to as an operator  $T \in B(H)$  is said to be  $(\alpha, \beta)$ - Normal if  $\beta^2 T^*T \geq TT^* \geq \alpha^2 T^*T$

or equivalently  $\alpha \|Tx\| \leq \|T^*x\| \leq \beta \|Tx\|, \forall x \in H$  where  $0 \leq \alpha \leq 1 \leq \beta$ .

If  $T$  is a normal operator then  $\alpha = 1 = \beta$ . If  $T^*$  is hyponormal when  $\alpha = 1$  and if  $T$  is hyponormal when  $\beta = 1$ .

An immediate consequence of the above definition is as follows

$$\beta^2 \langle T^*Tx, x \rangle \geq \langle T^*Tx, x \rangle \geq \alpha^2 \langle T^*Tx, x \rangle$$

Then we have  $\alpha \|Tx\| \leq \|T^*x\| \leq \beta \|Tx\|, \forall x \in H$ .

Observe that according to  $(\alpha, \beta)$ - Normal, if  $T$  is  $(\alpha, \beta)$ - Normal operator, then  $T$  and  $T^*$  dominate each other.

**Proposition 2.4[21]**

Let  $T = (T_1, \dots, \dots, T_m) \in B(H^m)$  be a  $m$ -tuple of operators and  $T$  is said to be jointly normal if  $T_i T_j = T_j T_i$  and an every  $T_i$  is a normal operator for all  $i, j = 1, \dots, \dots, m$ .

**Definition 2.5**

The numerical radius  $w(T)$  of an operator  $T$  on  $H$  is known as

$$w(T) = \sup\{|\langle Tx, x \rangle| : \|x\| = 1\} \tag{1}$$

Clearly by (1) for any  $x \in H$  then we have

$|\langle Tx, x \rangle| \leq w(T) \|x\|^2$  and it is well known that  $w(\cdot)$  is a norm on the Banach Algebra of all bounded linear operators.

Then we have

$$w(T) \leq \|T\| \leq 2w(T) \text{ where } T \in B(H).$$

The anti eigen value of an operator  $T \in B(H)$  defined by

$$\mu_1(T) := \inf_{Tx \neq 0} \frac{Re \langle Tx, x \rangle}{\|Tx\| \|x\|}$$

The vector  $x \in H$  which takes  $\mu_1(T)$  is called an antieigenvector of  $T$ .

**Proposition 2.6**

Let  $T$  be an  $(\alpha, \beta)$ - quasi normal then we have the following

- (i) If  $\mu_1(T) \geq 0$  then  $z + T$  is an  $(\alpha, \beta)$ - normal operator for any  $z > 0$ .
- (ii) If  $\mu_2(T) \leq 0$  then  $z + T$  is an  $(\alpha, \beta)$ - normal operator for any  $z < 0$ .

**Proof**

(i) By the definition of the first antieigenvalue of  $T \forall z > 0$ , then we have

$$\mu_1(zT) = \mu_1(zT) = \mu_1(T) \geq 0 \text{ implies that } z + T \text{ is an } (\alpha, \beta) \text{- normal.}$$

(ii) If  $z < 0$ , then

$$\mu_1(zT) = -\mu_2(T) \geq 0 \text{ implies that } z + T \text{ is an } (\alpha, \beta) \text{- normal.}$$

**Radharamani and Sathyavathi**

**Inequalities Involving Norms and Numerical Radius of  $(\alpha, \beta)$  –Quasi Normal Operators**

In this part, we defined some properties and also we stated some inequalities involving norms and numerical radius of  $(\alpha, \beta)$  - quasi normal operators. If  $T$  is an  $(\alpha, \beta)$  – quasi normal ( $\alpha > 0$ ) then  $T^*$  is  $(\frac{1}{\alpha}, \frac{1}{\beta})$ - quasi normal operators.

**Theorem 3.1**

If  $T$  be an  $(\alpha, \beta)$  – quasi normal operator such that  $T^{2^n}$  is  $(\alpha, \beta)$ – quasi normal operator for each  $n \in N$ . Then we have  $T [\frac{1}{\beta} \|T\|] \leq [r(T)]T \leq T[\|T\|]$  (2)

**Proof**

For any  $T \in B(H)$  we have

$$T\|T^*T\| = \|T\|^2T \tag{3}$$

In specific, if  $T$  is a self-adjoint operator then  $\|T^{*2}\| = \|T^*\|^2$  and by the definition of  $(\alpha, \beta)$  – quasi normal operator, we have

$$\|T^{*2}T^2\|T \geq T[\frac{1}{\beta^2}\|(T^*T)^2\|] = T[\frac{1}{\beta^2}\|T\|^4]$$

By the induction on  $n$ , implies that

$$\|T^{*2^n}T^{2^n}\|T \geq T[\frac{1}{\beta^{2^{n+1}-2}}\|T\|^{2^{n+1}}] \tag{4}$$

from which we get

$$\begin{aligned} [r(T)^2]T &= [r(T^*)r(T)]T = \lim_{n \rightarrow \infty} (\|T^{*2^n}\| \|T^{2^n}\|T)^{\frac{1}{2^n}} \geq \lim_{n \rightarrow \infty} \|(T^{*2^n}T^{2^n})T\|^{\frac{1}{2^n}} \\ &\geq T(\lim_{n \rightarrow \infty} (\frac{1}{\beta^{2^{n+1}-2}}\|T\|^{2^{n+1}})^{\frac{1}{2^n}}) = T[\frac{1}{\beta^2}\|T\|^2 \lim_{n \rightarrow \infty} \frac{1}{\beta^{-\frac{2}{2^n}}} = T[\frac{1}{\beta^2}\|T\|^2] \end{aligned}$$

Then we get,  $T [\frac{1}{\beta} \|T\|] \leq [r(T)]T \leq T[\|T\|]$

Hence the proof.

**Corollary 3.2**

Let  $T$  be an injective and  $(\alpha, \beta)$ – quasi normal operator with  $\alpha > 0$ . Then

- (i)  $R(T)$  is dense,
- (ii)  $T^*$  is injective
- (iii) If  $T$  is surjective then  $T^{-1}$  is also  $(\alpha, \beta)$ – quasi normal.

**Proof**

Since the known inequality is valid , we obtain  $N(T^*) = N(T)$  and therefore  $R(T)^{\perp} = N(T^*) = N(T) = 0$ , thus  $R(T)$  is dense subspace of  $H$  and  $T^*$  is injective. This proves the (i) and (ii).

To Prove (iii), we have the  $T$  is surjective implies that  $T$  is invertible. On the other part we have that  $(T^*)^{-1} = (T^{-1})^*$ . If  $A$  and  $B$  are two positive and invertible operators with  $0 \leq A \leq B$  then  $B^{-1} \leq A^{-1}$ . Since  $T$  is  $(\alpha, \beta)$ – quasi normal operator, taking inverse on both sides, we get

$$T[\frac{1}{\beta^2}T^{-1}(T^*)^{-1}] \leq [(T^*)^{-1}T^{-1}]T \leq T[\frac{1}{\alpha^2}T^{-1}(T^*)^{-1}] \tag{5}$$

Hence  $(T^{-1})^*$  is  $(\frac{1}{\beta}, \frac{1}{\alpha})$ – quasi normal then  $T^{-1}$  is  $(\alpha, \beta)$ – quasi normal operator.

**Theorem 3.3**

Let  $T \in B(H)$  be an  $(\alpha, \beta)$ – quasi normal operator

- (i) For positive real numbers  $p$  and  $q$  with  $p \geq 2$  and  $(\frac{1}{p}) + (\frac{1}{q}) = 1$

we have  $[\|T + T^*\|^p + \|T - T^*\|^p]T \geq 2$  (6)

- (ii) If  $0 \leq p \leq 1$  or  $p \geq 2$ , then we have

**Radharamani and Sathyavathi**

$T \{ [\|T + T^*\|^2 + \|T - T^*\|^2] T \}^p \geq [\|T\|^{2p} \varphi(\alpha, p)] T$ ,  
 where  $\varphi(\alpha, p) = 2^p [(1 + \alpha^p)^2 + (2^p - 2^2)\alpha^p]$  (7)

(iii) If  $N(t) = 0$  and for any  $x \in H$  with  $\|x\| = 1$  then we have

$$\left\| \frac{Tx}{\|Tx\|} - \frac{T^*x}{\|T^*x\|} \right\| T \leq \rho \tag{8}$$

then we have

$$T[\alpha \|T\|^2] \leq \left[ \omega(T^2) + \frac{\rho^2}{2} \beta \|T\|^2 \right] T$$

**Proof**

By the following known inequality

$$(i) \quad T[\|a + b\|^p + \|a - b\|^p] \geq (2(\|a\|^q + \|b\|^q)^{p-1}) T \tag{9}$$

which is for  $a, b \in H$ .

Here we can take  $a = Tx$  and  $b = T^*x$  in (9), then for any  $x \in H$  we get

$$\begin{aligned} T[\|Tx + T^*x\|^p + \|Tx - T^*x\|^p] &\geq (2(\|Tx\|^q + \|T^*x\|^q)^{p-1}) T \geq (2(\|Tx\|^q + \alpha^q \|T^*x\|^q)^{p-1}) T \tag{10} \\ &= [2(1 + \alpha^q)^{p-1} \|Tx\|^{q(p-1)}] T \\ &= [2(1 + \alpha^q)^{p-1} \|Tx\|^p] T \end{aligned}$$

Taking the supremum in (10) over  $x \in H$  with  $\|x\| = 1$ , we get the result of (6)

By using the following inequality  $T[\|a + b\|^2 + \|a - b\|^2] \geq [2^p((\|a\|^p + \|b\|^p)^2 + (2^p - 2^2)\|a\|^p \|b\|^p)]$  (11) where  $a$  and  $b$  are two vectors in Hilbert space where  $0 \leq p \leq 1$  or  $p \geq 2$ . Then, we put  $a = Tx$  and  $b = T^*x$  in (11), then we get  $\geq [2^p(\|Tx\|^p + \|T^*x\|^p)^2 + (2^p - 2^2)\|Tx\|^p \|T^*x\|^p] T \geq [2^p \|Tx\|^{2p} (1 + \alpha^p)^2 (2^p - 2^2) \alpha^p \|Tx\|^{2p}] T$

$$\geq [2^p \|Tx\|^{2p} \{(1 + \alpha^p)^2 + (2^p - 2^2)\alpha^p\}] T \tag{12} = [2^p \|Tx\|^{2p} \{\{(1 + \alpha^p)^2 + (2^p - 2^2)\alpha^p\} \varphi(\alpha, p)\}] T$$

Now, taking the supremum over  $\|x\| = 1$  in (12), we get the result (7).

By using the following reverse of Schwartz's inequality ,

$$T[\|a\| \|b\| - \text{Re}\langle a, b \rangle] \leq \frac{1}{2} \rho^2 \|a\| \|b\| \tag{13}$$

for  $a, b \in H$ . We can take  $a = Tx$  and  $b = T^*x$  in (13) to get  $T[\|Tx\| \|T^*x\|] \leq \{|\langle Tx, T^*x \rangle| + \frac{1}{2} \rho^2 [\|Tx\| \|T^*x\|]\}$

We get

$$T[\alpha \|Tx\|^2] \leq [|\langle Tx, T^*x \rangle| + \frac{1}{2} \rho^2 \beta \|Tx\|^2] T \tag{14}$$

Then we take the supremum over  $\|x\| = 1$  in (14), we get the desired result (8).

**Theorem 3.4**

Assume that  $T$  is an  $(\alpha, \beta)$ - quasi normal operator then we have

$$T[(1 + \alpha^2)\|T\|^2] \leq \left[ \frac{1}{2} \|T - T^*\|^2 + \omega(T^2) \right] T$$

**Proof**

By the known theorem, we have

$$T[2(1 + \alpha^p)\|T\|^2] \leq \left\{ \frac{1}{2} [\|T + T^*\|^p + \|T - T^*\|^p] \right\} T \tag{15}$$

and also

$$T\left[ \left\| \frac{T^*T + TT^*}{2} \right\|^{p/2} \right] \leq \left\{ \frac{1}{4} [\|T + T^*\|^p + \|T - T^*\|^p] \right\} T \tag{16}$$

By known [8] that for  $A, B \in B(H)$  we have

$$T\left[ \left\| \frac{A+B}{2} \right\|^2 \right] \leq \left\{ \frac{1}{2} \left[ \left\| \frac{A^*A + B^*B}{2} \right\| + \omega(B^*A) \right] \right\} T \tag{17}$$

By using the above inequality we get

$$T\left[ \left\| \frac{T+T^*}{2} \right\|^2 \right] \leq \left\{ \frac{1}{2} \left[ \left\| \frac{T^*T + TT^*}{2} \right\| + \omega(T^2) \right] \right\} T \tag{18}$$

Then we putting  $p = 2$  in (16) we get

**Radharamani and Sathyavathi**

$$T\left[\left\|\frac{T+T^*}{2}\right\|^2\right] \leq \left\{\frac{1}{4}\|T+T^*\|^2 + \|T-T^*\|^2 + \omega(T^2)\right\}T$$

$$= \left\{\frac{1}{2}\left[\left\|\frac{T+T^*}{2}\right\|^2 + \left\|\frac{T-T^*}{2}\right\|^2 + \omega(T^2)\right]\right\}T \quad (19)$$

Then we get

$$T\left\{\frac{1}{2}\left[\left\|\frac{T+T^*}{2}\right\|^2\right]\right\} \leq \left\{\frac{1}{2}\left\|\frac{T-T^*}{2}\right\|^2 + \frac{\omega(T^2)}{2}\right\}T \quad (20)$$

Then we take  $p = 2$  in (15) we get

$$T[(1 + \alpha^2)\|T\|^2] = \left[\left\|\frac{T+T^*}{2}\right\|^2 + \left\|\frac{T-T^*}{2}\right\|^2 + \omega(T^2)\right]T \quad (21)$$

$$= \frac{1}{2}[\|T-T^*\|^2 + \omega(T^2)]T$$

Hence the proof.

**Theorem 3.5**

Assume that  $T$  is an  $(\alpha, \beta)$ -quasi normal operator then for any real  $s$  with  $0 \leq s \leq 1$ , we have

$$T\left[\left(1-s\right)\left(\frac{1}{\beta^2}\right) + s\right]\left(1-s\right) + s\left(\frac{1}{\beta^2}\right)\|T\|^4 \leq \left[\left(1-s + s\beta^2\right)\|T\|^2\|T-T^*\|^2 + \omega(T^2)^2\right] \quad (22)$$

**Proof**

By the known theorem [9],[10] we have

$$T[(1-s)\|a\|^2 + s\|b\|^2][\|a\|^2 + s\|b\|^2] - |\langle a, b \rangle|^2$$

$$\leq \left[\left(1-s\right)\|a\|^2 + s\|b\|^2\right]\left[\left(1-s\right)\|b-ta\|^2 + s\|tb-a\|^2\right]T \quad (23)$$

where  $0 \leq s \leq 1, t \in R$  and  $a, b \in H$ . Take  $t = 1, a = Tx$  and  $b = T^*x$  in (23), we get

$$T\left\{\left(1-s\right)\|Tx\|^2 + s\|T^*x\|^2\right\}\left[\left(1-s\right)\|T^*x\|^2 + s\|Tx\|^2 - |\langle Tx, T^*x \rangle|^2\right]$$

$$\leq \left\{\left(1-s\right)\|Tx\|^2 + s\|T^*x\|^2\right\}\left[\left(1-s\right)\|T^*x-Tx\|^2 + s\|T^*x-Tx\|^2\right]T \quad (24)$$

Then we have

$$T\left\{\left[\frac{\left(1-s\right)}{\beta^2}\|T^*x\|^2\right] + s\|T^*x\|^2\right\}\left[\left(1-s\right)\|T^*x\|^2 + \frac{s}{\beta^2}\|T^*x\|^2\right] - |\langle T^2x, x \rangle|^2\}$$

$$\leq \left\{\left(1-s\right)\|Tx\|^2 + s\|T^*x\|^2\right\}\left[\left(1-s\right)\|T^*x\|^2 + s\|Tx\|^2\right] - |\langle T^2x, x \rangle|^2\}T$$

$$\leq \left\{\left(1-s\right)\|Tx\|^2 + s\|T^*x\|^2\right\}\left[\left(1-s\right)\|T^*x-Tx\|^2 + s\|T^*x-Tx\|^2\right]T$$

$$\leq \left\{\left(1-s\right)\|Tx\|^2 + s\beta^2\|Tx\|^2\right\}\|T^*x-Tx\|^2\}T$$

Now, taking supremum over  $\|x\| = 1$  from both sides

$$T\left[\left(1-s\right)\left(\frac{1}{\beta^2}\right) + s\right]\left(1-s\right) + s\left(\frac{1}{\beta^2}\right)\|T\|^4$$

$$\leq \left\{\left(1-s\right)\|Tx\|^2 + s\beta^2\|Tx\|^2\right\}\|T^*x-Tx\|^2 + |\langle T^2x, x \rangle|^2\}T \quad (25)$$

and by using triangle inequality for supremum we get the result.

**Corollary 3.6**

Let  $T$  be an  $(\alpha, \beta)$ -quasi normal operator then we have

$$T\left[\frac{1}{\beta}\|T\|^2\right] \leq \|T\|\|T-T^*\| + \omega(T^2) \quad (26)$$

**Proof**

By using the inequality (23) we get

$$T\left[\left(1-s\right) + s\alpha^2\right]\left(1-s\right)\alpha^2 + s\|T\|^4 \leq \left[\left(1-s + s\alpha^2\right)\|T\|^2\|T-T^*\|^2 + \omega(T^2)^2\right] \quad (27)$$

We take  $s = 0$  in the inequalities (22) and (27) implies that

$$T\left[\max\left\{\frac{1}{\beta^2}, \alpha^2\right\}\|Tx\|^4\right] \leq \left[\|Tx\|^2\|T-T^*\|^2 + \omega(T^2)^2\right]T$$

Then we have,

$$T\left[\max\left\{\frac{1}{\beta}, \alpha\right\}\|Tx\|^2\right] \leq \left[\|Tx\|\|T-T^*\| + \omega(T^2)\right]T$$

### Radharamani and Sathyavathi

Now taking the supremum for all  $x$  with  $\|x\| = 1$  then the desired result is obtained.

## CONCLUSION

We defined as the  $(\alpha, \beta)$  quasi normal operators in Hilbertian Spaces are relatively new. We attempted to prove some properties of  $(\alpha, \beta)$  quasi normal operators in complex Hilbert space. The results of this paper will be accessible for further research to develop application side of Functional Analysis.

## ABSTRACT

Present investigation explores the numerical solution of Magnetohydrodynamic laminar steady gray fluid flow with heat and mass transfer past a stretching permeable sheet, incorporating several factors such as heat source, radiation, viscous and joules dissipation effects, thermal radiation, chemical reactions, Soret and Dufour effects. The governing nonlinear PDE's are simplified to ODE's through similarity transformations. With the plate extending at a linearly changing velocity, the momentum equation is solved analytically, and the energy and species concentration equations are solved using nonhomogeneous confluent hypergeometric functions in the absence of Soret and Dufour effects. In contrast, when Soret and Dufour effects are present, the energy and species concentration equations are solved numerically using the Runge-Kutta shooting method, complemented by the Nachtsheim-Swigert iteration scheme to ensure appropriate asymptotic boundary conditions. Calculating skin friction, heat transfer rates, and mass transfer rates are important outcomes. Numerous factors are examined in detail, emphasising how they affect the system's thermal and concentration profiles. These factors include magnetic field strength, suction, internal heat generation, radiation, chemical reactions, and

Kayalvizhi *et al.*,

dissipative effects on flow characteristics and other physical quantities. This comprehensive analysis provides insights into the behaviour of the fluid flow under the specified conditions, which can be useful for applications in engineering and industrial processes.

**Keywords:** Viscous and Joule dissipation, Confluent Hypergeometric Functions, Soret and Dufour effects, Radiative Chemical Reactions, Magnetohydrodynamics, Heat Source.

## INTRODUCTION

Insights into intricate fluid dynamics situations have been gained from recent studies on the impact of Dufour and Soret effects in boundary layer, laminar gray fluid flow, which incorporate chemical processes and thermal radiation. These studies reveal that the Soret effect, which drives species migration in response to temperature gradients, and the Dufour effect, which induces thermal gradients due to concentration differences, significantly influence boundary layer behavior. When combined with thermal radiation, which alters heat transfer rates by adding radiative heat flux components, and chemical reactions, which affect species concentration and energy release or absorption, the resulting fluid dynamics become highly intricate. In a variety of applications, including chemical reactors, heat exchangers, and atmospheric research, these parameters jointly affect temperature distributions, reaction rates, and heat and mass transfer efficiency, as demonstrated by sophisticated numerical models and tests. The impact of these Dufour and Soret effects is the primary focus of the current study.

The intricacy and importance of heat and mass transport mechanisms have been highlighted by the numerous investigations conducted by researchers using a variety of geometries. Tewfik and Yang [1] conducted experimental investigations into thermodynamic convectional fluid flow with Helium suction, confirming the critical roles of Dufour and Soret effects in transpiration-cooled boundary layer flows. Goddard and Acrivos [2] analyzed forced convectional flow involving chemical reactions, laying foundational insights into the interactions of mass transfer and reaction kinetics.

Additional contributions consist of Gupta and Gupta [3] introduced the concept of porous stretched surfaces with mass and heat transmission. Chen and Strobel [4] also examined the combined effects of species diffusion and thermal buoyancy forces on laminar boundary layer flow on a horizontal flat plate. While Noor Afzal [6] investigated a constant surface temperature over a stretching surface using chemical processing equipment, Grubka and Bobba [5] concentrated on variable surface temperature over a stretching continuous surface. Kafoussias and Williams [7] examined the impact of Soret and Dufour effects on boundary layer fluid flow with temperature-dependent viscosity.

These studies collectively underscore the multifaceted nature of heat and mass transfer in various systems, offering valuable insights into the intricate interplay of fluid dynamics, thermal properties, and chemical reactions. Fluid flow over an accelerating porous surface with internal heat generation was analysed by Acharya *et al.* [8]. Atul Kumar Singh [9] analysed the Magnetohydrodynamics incompressible, viscous fluid flow over an infinite vertical plate with suction, internal heat generation and thermal diffusion. There was discussion about a nonlinear MHD electrically conducting viscous fluid with a power-law velocity passes a stretched sheet done by Anjalidevi and Thiyagarajan [10]. In order to incorporate the magnetic field by Postelnicu in [11], variable suction by Alam and Rahman in [12], and chemical reaction by Postelnicu in [13], the impact of Dufour and Soret on a vertical surface with convective heat and mass transfer was examined together with a number of additional factors. Natural and forced convectional boundary layer flows with thermal-diffusion and diffusion-thermo effects was analysed by Abreu *et al.* [14]. This investigation in saturated porous medium has been analysed by Lakshmi Narayana and Murthy [15] using the similarity solution technique. Many authors like Abd El-Aziz [16], Anwar Beg *et al.* [17], Abdel-Rahman [18] investigated the combined influence of Dufour and Soret Parameters on electrically conducting gray fluid over a continuous stretching porous sheet.

**Kayalvizhi et al.,**

Chien-Hsin Chen [19] further developed this topic by investigating the effects of viscous dissipation and Joule heating on magnetohydrodynamic gray fluid flow via a stretched permeable surface and including free convective heat transfer in the study. The thermal boundary layer flow across a non-isothermal, permeable stretching sheet under the impact of radiation and MHD gray fluid was examined by Anjalidevi and Kayalvizhi [20, 21]. Abdul Hakeem et al. [22] examined the MHD flow in this study with partial slip. The investigation by Ching Yang Cheng [23, 24], Sharma et al.[25], and Chandra Sekhar Bella et al.[26] have highlighted the significant impacts of influence of Soret and Dufour parameters on convection flow in porous media. These factors affect fluid flow as well as the properties of heat and mass transport and are related to the thermal and concentration gradients in the fluid. By investigating the consequences of magnetohydrodynamics in the setting of Hiemenz flow, specifically with respect to mass transfer over a stretched surface, recent studies have built upon these discoveries. Understanding how MHD interactions might change the behaviour of fluid flow and thermal fields has been made possible by the research conducted by Gandluru Sreedevi et al. [27], Shalini Jain et al. [28], and Seema Tinkar et al. [29]. Numerous physical phenomena are taken into account in their research.

Additional With an emphasis on heat and mass transfer, Verma and Sharma [30] recently investigated the impact of Soret and Dufour effects on MHD flow via a stretched surface. The numerical study of unsteady MHD mixed convective flow over a curved stretching surface by Temjennaro Jamir [31] included Dufour and Soret effects, chemical reactions, and Joule heating in addition to thermal and velocity slip effects; however, it did not take radiation and viscous dissipation effects into consideration. This work's primary goal is to analyse nonlinear MHD grey fluid flow across a stretched porous horizontal sheet while taking into account the Soret and Dufour effects as well as the impacts of internal heat generation, radiation, dissipation, and chemical reactions. This comprehensive study aims to enhance understanding of these complex interactions in practical applications.

**Formulation of the Problem**

Assuming that, the study involves a 2-D steady Magnetohydrodynamic (MHD) flow of a laminar, incompressible, gray viscous fluid. Consider the influences of chemical radiative heat transfer, heat source, viscous and Joule heating dissipation, Soret and Dufour effects. The flow direction is established as velocity *u* along the *x*-axis, and velocity *v* along the *y*-axis. A uniform transverse magnetic field, denoted as **B** = (0, B<sub>0</sub>, 0) is applied normal to a linear stretching permeable sheet. Given that the magnetic Reynolds number *R<sub>e</sub>* is sufficiently small, we can neglect the induced magnetic field in comparison to the applied uniform magnetic field.

Under these assumptions, the following are governing continuity, momentum, energy and diffusion equations:

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0 \tag{1}$$

$$u \frac{\partial u}{\partial x} + v \frac{\partial v}{\partial y} = \vartheta \frac{\partial^2 u}{\partial y^2} - \frac{\sigma B_0^2 u}{\rho} \tag{2}$$

$$\rho C_p \left( u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} \right) = K \frac{\partial^2 T}{\partial y^2} - \frac{\partial q_r}{\partial y} + Q_0(T - T_\infty) + \mu \left( \frac{\partial u}{\partial y} \right)^2 + \frac{j^2}{\sigma} + \frac{D_m K_T}{c_s c_p} \frac{\partial^2 C}{\partial y^2} \tag{3}$$

$$u \frac{\partial C}{\partial x} + v \frac{\partial C}{\partial y} = D_m \frac{\partial^2 C}{\partial y^2} - K_1 C + \frac{D_m K_T}{c_s c_p} \frac{\partial^2 T}{\partial y^2} \tag{4}$$

$$\text{and } q_r = \frac{-4\sigma^* \partial^2 T}{3\alpha^* \partial y} \tag{5}$$

Using Taylors Serious expansion Eqn.(3) becomes

$$u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \frac{K}{\rho c_p} \frac{\partial^2 T}{\partial y^2} + \frac{16 \sigma^* T_\infty^3}{3 \rho c_p \alpha^*} \frac{\partial^2 T}{\partial y^2} + \frac{Q_0(T - T_\infty)}{\rho c_p} + \frac{\mu}{\rho c_p} \left( \frac{\partial u}{\partial y} \right)^2 + \frac{\sigma B_0^2 u^2}{\rho c_p} + \frac{D_m K_T}{c_s c_p} \frac{\partial^2 C}{\partial y^2} \tag{7}$$

The boundary conditions are:

$$\begin{aligned} u = U_w = ax, \quad T = T_w(x) = T_\infty + A_0 x^r & \quad \text{at } y = 0 \\ v = -v_0, \quad C = C_w(x) = C_\infty + A_1 x^r & \quad \text{at } y = 0 \\ u \rightarrow 0, \quad T \rightarrow T_\infty \quad C \rightarrow C_\infty & \quad \text{as } y = \infty \end{aligned}$$

**Kayalvizhi et al.,**

Using stream function  $\psi(x, y)$  the relative parameters are introduced as;

$$\begin{aligned} \psi &= \sqrt{a\delta} x f(\eta), & \eta &= \sqrt{\frac{a}{\delta}} y \\ u &= axf'(\eta), & v &= -\sqrt{a\delta} f(\eta), \\ \theta(\eta) &= \frac{T - T_\infty}{T_w - T_\infty}, & \varphi(\eta) &= \frac{C - C_\infty}{C_w - C_\infty} \end{aligned}$$

The above similarity transformations transform the equations (2), (7) and (4) into a set of ODE's which are expressed as,

$$f''' + ff'' - f'^2 - M^2 f' = 0 \tag{9}$$

$$\theta'' + \beta f \theta' - r \beta f' \theta + S_h \beta \theta + D_f \beta \varphi'' = -Ec\beta[f''^2 + M^2 f'^2] \tag{10}$$

$$\varphi'' + Sc f \varphi' - Sc(r_0 f' + \beta_1) \varphi + S_r S_c \theta''(\eta) = 0 \tag{11}$$

together with boundary conditions

$$f(0) = S, \quad f'(0) = 1, \quad f'(\infty) = 0 \tag{12}$$

$$\theta(0) = \varphi(0) = 1, \quad \theta(\infty) = \varphi(\infty) = 0 \tag{13}$$

Where  $\beta = \frac{3Pr R_d}{3R_d + 4}$

**Exact Solution of Momentum Equation**

Equation(9)withboundaryconditions(12)admitsolutionoftheform[ChakrabarthiandGupta[3]]

$$f(\eta) = A + Be^{-\alpha\eta}$$

where  $A = S + \frac{1}{\alpha}$ ,  $B = \frac{-1}{\alpha}$  and  $\alpha = \frac{S + \sqrt{S^2 + 4(1 + M^2)}}{2}$ .

Hence the exact solution is  $f(\eta) = S + \frac{1}{\alpha}(1 - e^{-\alpha\eta})$  (14)

The velocity components are  $u = axe^{-\alpha\eta}$ ,  $v = -\sqrt{a\delta}[S + \frac{1}{\alpha}(1 - e^{-\alpha\eta})]$ .

**Numerical Solution for Temperature and Concentration**

Equations(10)and(11)withtheboundaryconditions(13) arenon-linearODE's that form the nonlinearBVP.Numerical solution is obtained by reducing the nonlinear BVP into IVP using RK shootingmethodalongwithNachtsheim-SwigertIteration Schemefor satisfaction of boundary conditions.Numerical results are obtainedfor different values of  $S, M^2, R_d, S_h, Ec, Pr, \beta_1, S_r, D_f$ and $Sc$ .

**Analytical Solution for Temperature and Concentration**

When there is no Soret and Dufour effects, the eqns. (10) and (11) solved analytically by introducing

$$\xi = \frac{-\beta}{\alpha^2} e^{-\alpha\eta} \quad \text{and} \quad \zeta = \frac{-Sc}{\alpha^2} e^{-\alpha\eta} \tag{15}$$

When  $S_r = 0$  and  $D_f = 0$  eqns. (10) and (11) becomes

$$\xi \frac{d^2\theta}{d\xi^2} + (1-\gamma - \xi) \frac{d\theta}{d\xi} + (r + \frac{\beta}{\xi\alpha^2} S_h) \theta = \frac{-Ec\alpha^2}{\beta} (\alpha^2 + M^2) \tag{16}$$

$$\zeta \frac{d^2\varphi}{d\zeta^2} + (1-\gamma_1 - \zeta) \frac{d\varphi}{d\zeta} + (r_0 + \frac{Sc}{\zeta\alpha^2} \beta_1) \varphi = 0 \tag{17}$$

where the wall temperature parameter  $r = 2$ and  $\gamma = \frac{\beta}{\alpha^2}(1 + S\alpha)$ ,  $\gamma_1 = \frac{Sc}{\alpha^2}(1 + S\alpha)$

The corresponding boundary condition are

$$\theta(\xi = 0) = 0, \theta(\xi = -\frac{\beta}{\alpha^2}) = 1 \tag{18}$$

$$\varphi(\zeta = 0) = 0, \varphi(\zeta = -\frac{Sc}{\alpha^2}) = 1 \tag{19}$$

Equation (16) is in the form of non-homogeneous confluent hypergeometric equation and Equation (17) is in the form of homogeneous

Kayalvizhi et al.,

confluent hypergeometric equation. Hence, the solutions for temperature and concentration are derived in terms of dependent variable  $\eta$  are

$$\theta(\eta) = b_0 \left( \frac{\beta(M^2 + \alpha^2)}{\alpha^2} \right) e^{-2\alpha \eta} + b_4 \left( -\frac{\beta}{\alpha^2} \right)^b e^{-\alpha b \eta} {}_1F_1[b - 2, A + 1; -\left( -\frac{\beta}{\alpha^2} \right) e^{-\alpha \eta}] \quad (20)$$

$$\varphi(\eta) = \frac{e^{-\alpha b_6 \eta} {}_1F_1[b_6 - r_0, 1 + b_5; \left( -\frac{Sc}{\alpha^2} \right) e^{-\alpha \eta}]}{{}_1F_1[b_6 - r_0, 1 + b_5; \left( -\frac{Sc}{\alpha^2} \right) e^{-\alpha \eta}]} \quad (21)$$

where,  $b = \frac{A + \gamma}{2}$ ,  $A = \sqrt{\gamma^2 - 4 \left( \frac{\beta}{\alpha^2} \right) S_h}$ ,  $b_4 = \frac{1 - b_0 \left( \frac{\beta(M^2 + \alpha^2)}{\alpha^2} \right)}{b_1 \left( -\frac{\beta}{\alpha^2} \right)^b}$

$$b_0 = \frac{-Ec}{(4 - 2\gamma + \frac{5h\beta}{\alpha^2})}, b_1 = {}_1F_1[b - 2, 1 + A; \left( -\frac{\beta}{\alpha^2} \right) e^{-\alpha \eta}], b_6 = \frac{b_5 + \gamma_1}{2} \text{ and } b_5 = \sqrt{\gamma_1^2 + 4 \left( \frac{\beta_1}{\alpha^2} \right) Sc}$$

**Skin Friction**

The shear stress at the wall is given by  $\tau^* = \mu \frac{\partial u}{\partial y}$  and the coefficient of skin friction is given by  $C_f = \theta''(0) = -\alpha$

**RESULTS AND DISCUSSION**

The numerical solution of nonlinear MHD flow with heat and mass transfer over a stretching surface with suction, heat source, Soret and Dufour effects including radiation, chemical reaction, viscous and joules dissipation has been obtained by fixing several values of the physical parameters and these results are displayed graphically. From the numerical computations adapted in the present investigation, in the absence of Soret and Dufour effects, the results for nondimensional rate of heat transfer and rate of mass transfer have been compared with the analytical results which are illustrated through Tables 3 and 4. The comparison shows excellent agreement, hence an encouragement for the use of the present numerical computations.

The transverse velocity for various values of  $M^2$  is depicted in Fig.1. The horizontal velocity for various values magnetic field is illustrated in Fig.2. It is discerned that fluid velocity decreases as the magnetic field increases. Fig.3 depicts the effect of  $M^2$  on  $C_f$  against porosity. The magnetic field has the effect of reducing the skin friction coefficient. Fig.4 displays the graph of temperature distribution for various  $R_d$ . It is revealed that an increase in  $R_d$  results in a decrease in  $\theta(\eta)$  which implies that radiation reduces the thermal boundary layer thickness. Since  $R_d$  is directly proportional to  $K$  and  $T_\infty$ , the Rosseland mean absorption coefficient  $\alpha^*$ . As  $\alpha^*$  is inversely proportional to  $\frac{\partial q_r}{\partial y}$ , this demonstrates that the rate of heat transfer increases. Therefore, temperature increases.  $\theta(\eta)$  for various values of  $Pr$  is shown in Fig.5. Clearly, it is concluded that the effect of  $Pr$  is to reduce thermal boundary layer thickness and the temperature. Fig. 6 presents the thermal-diffusion and diffusion-thermo effects on temperature distribution. The product  $SrDf$  is kept constant by selecting different values of  $Df$  and  $Sr$ . A simultaneous decrease in  $Df$  and an increase in  $Sr$  result in a decrease in temperature across the boundary layer.  $\varphi(\eta)$  for different values of suction parameter  $S$  is shown through Fig.7.

Porosity reduces the species concentration which is physically true. Concentration reaches its maximum value only near the wall. The influence of chemical reaction on the species concentration is clearly portrayed in Fig.8. It is noticed that for increasing values of  $\beta_1$ , the concentration decreases. i.e., The concentration boundary layer becomes thin as chemical reaction increases. Fig.9 depicts  $\varphi(\eta)$  for different values of  $Sc$ . It is inferred that the influence of  $Sc$  decreases the concentration. i.e., Schmidt number reduces the boundary layer thickness. The influence of  $S_r$  and  $D_f$  on the concentration distribution are shown in Fig.10. It is observed that the influence of thermal-diffusion (Soret) enhances the temperature whereas influence diffusion-thermo (Dufour) is to suppress it.

Kayalvizhi *et al.*,

## CONCLUSION

Generally, Influence of Physical parameters affects the fluid flow, temperature and concentration. In the absence of dissipation effects, internal heat generation, thermal diffusion effect and when there is no mass transfer, the results are same as that of Ouaf [32]. In the absence of thermal-diffusion (Soret) and diffusion-thermo (Dufour) effects and when there is no mass transfer, the results are similar to that of analytical results presented in Kayalvizhi [33] which justify our numerical results.

From the results and discussions, the following conclusions are arrived.

- The magnetic field decreases the dimensionless transverse velocity, skin friction coefficient, and non-dimensional horizontal velocity.
- Influence of porosity accelerate the transverse velocity whereas decelerate the horizontal velocity.
- Influence of magnetic field, Eckert number and heat source parameter enhances the temperature, however, the influence of porosity, radiation, Prandtl number and wall temperature parameter over temperature is to reduce it.
- The suction parameter, Schmidt number, chemical reaction parameter, and wall concentration parameter reduce the concentration in magnitude, while the magnetic field increases it.
- Influence of thermal-diffusion enhances the temperature whereas influence diffusion-thermo is to suppress it.

**Table : 1 Terminology**

Symbol	Abbreviation
T	Temperature
C	Concentration
$\rho$	Density
$\mu$	Coefficient of Viscosity
$C_p$	Specific Heat at Constant Pressure
K	Thermal Conductivity of the Medium
j	Current Density
$\vartheta$	Kinematic Viscosity
$\sigma$	Electrical Conductivity of the Fluid
$B_0$	Magnetic Field
$D_m$	Mass Diffusivity
$K_1$	Rate of Chemical Reaction
$Q_0$	Volumetric Rate of Heat Generation
$K_T$	Thermal - Diffusion Ratio
$C_s$	Concentration Susceptibility
$T_m$	Fluid Mean Temperature
$q_r$	Radiative Heat Flux
$\sigma^*$	Stefan – Boltzman constant
$\alpha^*$	Rosseland mean approximation coefficient.

**Table 2. Solution of the Problem**

Parameter	Description
$R_d = \frac{K\alpha^*}{4\sigma^*T_\infty^3}$	Radiation parameter
$Pr = \frac{\mu C_p}{K}$	Prandtl number
$M^2 = \frac{\sigma B_0^2}{\rho \alpha}$	Magnetic interaction parameter
$S_h = \frac{Q_0}{a\rho C_p}$	heat source parameter
$Ec = \frac{\alpha^2 x^2}{C_p(T_w - T_\infty)}$	Eckert number
$s = \left(\frac{v_0}{\sqrt{\vartheta a}}\right) (v_0 > 0)$	suction parameter
$\beta_1 = \frac{k_1}{a}$	Chemical reaction parameter
$Sc = \frac{\vartheta}{D}$	Schmidt number
$D_f = \frac{D_m K_T}{\vartheta c_s c_p}$	Dufour number
$S_f = \frac{D_m K_T}{\vartheta T_m}$	Soret number

### ABSTRACT

Minimal structure spaces are defined by a nonempty set with a minimal collection of subsets satisfying certain axiom. Biminimal structure spaces further generalize this concept by incorporating two distinct minimal structures on the same set. These concepts are extended into the neutrosophic domain by neutrosophic crisp minimal structure spaces, where sets are characterized by degrees of truth, indeterminacy, and falsehood. This study presents a unique framework that combines biminimal structures and neutrosophic logic known as Neutrosophic Crisp Biminimal Structure Space is presented. This work builds upon the foundations of minimal structure spaces and biminimal structure spaces, extending these ideas to the neutrosophic domain to deal precisely with falsehood, uncertainty, and indeterminacy.

**Keywords:** Neutrosophic crisp biminimal structure space,  $NC\mathcal{M}_1\mathcal{M}_2$ -closed,  $NC\mathcal{M}_1\mathcal{M}_2$ -open,  $NC\mathcal{M}_1\mathcal{M}_2\text{int}(Q)$ ,  $NC\mathcal{M}_1\mathcal{M}_2\text{cl}(Q)$ .

### INTRODUCTION

In 2010, mathematics saw the development of biminimal structure spaces. Noiri [8] used bitopology as inspiration to create bi-m-spaces, which are composed of two minimal structures on  $X$  and a non-empty set  $X$ . Subsequently, Boonpok [3] reestablished this in 2010 as biminimal structure spaces, and the majority of researchers are currently using this terminology. Although Popa and Noiri [9] first proposed the idea of minimal structure spaces in 1999, Maki et al. [7] developed the notion. Neutrosophic minimal structure spaces are the result of a recent

**Tharani and Kokilavan**

development in which the notion of neutrosophic has been implemented into minimal structure spaces. Karthika, Parimala, and Smarandache started this work [5]. They demonstrated an application by solving a decision-making problem with the score function. Neutrosophic biminimal structure space, or nbiss, was first proposed in 2021 by S. Ganesan and C. Alexander [4]. The notion of nbiss was also presented and investigated, along with  $N_{m_x}^1, N_{m_x}^2$ -closed sets and  $N_{m_x}^1, N_{m_x}^2$ -open sets. Additionally, the concept of nbiss served as inspiration for the real-world use of index numbers. A minimal structure, as described by [6], on a set  $X$  is a subfamily  $m_x$  of  $P(X)$  if and only if both  $X, \emptyset \in m_x$ . Any element within  $m_x$  is considered an  $m_x$ -open set, while the complement of an  $m_x$ -open set is referred to as an  $m_x$ -closed set. The pair  $(X, m_x)$  represents a minimal structure on the non-empty set  $X$ . If  $\phi_N \in \mathcal{M}, X_N \in \mathcal{M}$  then a family  $\mathcal{M}$  of neutrosophic crisp sets on  $X$  constitutes a neutrosophic crisp minimal structure (NCMS)[1]. The pair  $(X, \mathcal{M})$  is termed a (NCMS). Specifically, each element of  $\mathcal{M}$  is recognized as a neutrosophic crisp minimal open set (NCMOS), while the complement of any NCMOS is identified as a neutrosophic crisp minimal closed set (NCMCS). The union of all NCMOS elements within a set  $\mathcal{Q}$  is defined as the neutrosophic crisp minimal interior of  $\mathcal{Q}$ , denoted  $NCMint(\mathcal{Q})$ . Conversely, the intersection of all NCMCS elements within  $\mathcal{Q}$  forms the neutrosophic crisp minimal closure of  $\mathcal{Q}$ , expressed as  $NCMcl(\mathcal{Q})$ . Here,  $NCMOS(X)$  and  $NCMCS(X)$  represent the collections of all neutrosophic crisp minimal open sets and closed sets, respectively, within  $X$ .

**PRELIMINARIES**

**Definition 2.1.** [10] The element  $\mathcal{Q} = \langle Q_{11}, Q_{22}, Q_{33} \rangle$  can be classified as:

A Type1 Neutrosophic Crisp Set (NCS) if  $Q_{11} \cap Q_{22} = \emptyset, Q_{11} \cap Q_{33} = \emptyset$  and  $Q_{22} \cap Q_{33} = \emptyset$ .

A Type2 Neutrosophic Crisp Set (NCS) if  $Q_{11} \cap Q_{22} = \emptyset, Q_{11} \cap Q_{33} = \emptyset$  and  $Q_{22} \cap Q_{33} = \emptyset$  and  $Q_{11} \cup Q_{22} \cup Q_{33} = X$ .

A Type3 Neutrosophic Crisp Set (NCS) if  $Q_{11} \cap Q_{22} \cap Q_{33} = \emptyset$  and  $Q_{11} \cup Q_{22} \cup Q_{33} = X$ .

**Definition 2.2.** [10] The types of Neutrosophic Crisp Sets (NCS's) for  $\phi_N$  and  $X_N$  in  $X$  are defined as follow.

$\phi_N$  can be represented by  $\phi_N = \langle \emptyset, \emptyset, X \rangle$  or  $\langle \emptyset, X, X \rangle$  or  $\langle \emptyset, X, \emptyset \rangle$  or  $\langle \emptyset, \emptyset, \emptyset \rangle$ .

$X_N$  can be represented by  $X_N = \langle X, \emptyset, \emptyset \rangle$  or  $\langle X, X, \emptyset \rangle$  or  $\langle X, \emptyset, X \rangle$  or  $\langle X, X, X \rangle$ .

**Definition 2.3.** [10] Let  $X$  represent a non-empty set and the NCS's  $\mathcal{Q}$  and  $\mathcal{P}$  be expressed as  $\mathcal{Q} = \langle Q_{11}, Q_{22}, Q_{33} \rangle$   $\mathcal{P} = \langle P_{11}, P_{22}, P_{33} \rangle$ , then

(i)  $\mathcal{Q} \subseteq \mathcal{P}$  iff  $Q_{11} \subseteq P_{11}, Q_{22} \subseteq P_{22}$  and  $Q_{33} \subseteq P_{33}$  or  $Q_{11} \subseteq P_{11}, Q_{22} \supseteq P_{22}$  and  $Q_{33} \supseteq P_{33}$ .

(ii)  $\mathcal{Q} \cap \mathcal{P} = \langle Q_{11} \cap P_{11}, Q_{22} \cap P_{22}, Q_{33} \cap P_{33} \rangle$  or  $\langle Q_{11} \cap P_{11}, Q_{22} \cup P_{22}, Q_{33} \cup P_{33} \rangle$ .

(iii)  $\mathcal{Q} \cup \mathcal{P} = \langle Q_{11} \cup P_{11}, Q_{22} \cup P_{22}, Q_{33} \cup P_{33} \rangle$  or  $\langle Q_{11} \cup P_{11}, Q_{22} \cap P_{22}, Q_{33} \cap P_{33} \rangle$ .

**Definition 2.4.** [10] Let  $\mathcal{Q} = \langle Q_{11}, Q_{22}, Q_{33} \rangle$  a NCS on  $X$ , then the complement of  $\mathcal{Q}$  (in short,  $\mathcal{Q}^c$ ) may be characterized in three distinct ways:

(i)  $\mathcal{Q}^c = \langle Q_{11}^c, Q_{22}^c, Q_{33}^c \rangle$

(ii)  $\mathcal{Q}^c = \langle Q_{33}, Q_{22}, Q_{11} \rangle$

(iii)  $\mathcal{Q}^c = \langle Q_{33}, Q_{22}^c, Q_{11} \rangle$

**Definition 2.5.** [10] A Neutrosophic Crisp Topological Space NCTS on a non empty set  $X$  is defined as a collection( $\Gamma$ ) of neutrosophic crisp subsets of  $X$  that satisfy the following conditions:

(i)  $\phi_N$  and  $X_N \in \Gamma$ .

(ii)  $Q_1 \cap P_1 \in \Gamma$  for any  $Q_1, P_1 \in \Gamma$ .

(iii)  $\cup Q_j \in \Gamma$  for any arbitrary family  $\{Q_j : j \in J\} \subseteq (X, \Gamma)$

This structure is known as Neutrosophic Crisp Topological Space(NCTS) and the elements in  $\Gamma$  are referred to as neutrosophic crisp open set (NCSOS). The complement of NCSOS is neutrosophic crisp closed set(NCCS).

**Tharani and Kokilavan**

**Definition 2.6.** [10] Let  $(X, \Gamma)$  be a  $\mathcal{NCTS}$  on  $X$  and  $Q$  be a  $\mathcal{NCS}$  on  $X$ . Then the neutrosophic crisp closure of  $Q$ , denoted as  $\mathcal{NCcl}(Q)$  and neutrosophic crisp interior of  $Q$ , denoted as  $\mathcal{NCint}(Q)$  are defined as follows:

$$\mathcal{NCcl}(Q) = \cap \{G : Q \subseteq G \text{ \& } G \text{ is an } \mathcal{NCCS} \text{ in } X\}.$$

$$\mathcal{NCint}(Q) = \cup \{J : J \subseteq Q \text{ \& } J \text{ is an } \mathcal{NCS} \text{ in } X\}.$$

**Definition 2.7.** [2] A neutrosophic crisp supra topology ( $\mathcal{NCTS}$  for short) on a non empty set  $X$  is defined as family  $\tau^\mu$  of neutrosophic crisp subset of  $X$  that satisfies the following condition:

$$\emptyset_N \text{ and } X_N \in \tau^\mu$$

$$\cup E_j \in \tau^\mu, \text{ for any family } \{E_j : j \in J\} \subseteq \tau^\mu.$$

The pair  $(X, \tau^\mu)$  is called neutrosophic crisp supra topological space ( $\mathcal{NCSTS}$ ) on  $X$ , and the elements in  $\tau^\mu$  are referred to as neutrosophic crisp supra open sets ( $\mathcal{NCSOS}$ ). The complement of  $\tau^\mu$  is called neutrosophic crisp supra closed sets ( $\mathcal{NCSOS}$ ).

**Definition 2.8.** [2] Let  $\tau_1^\mu, \tau_2^\mu$  be any two neutrosophic crisp supra topology ( $\mathcal{NCST}$ ) on a non empty  $X$ . Then, the triple  $(X, \tau_1^\mu, \tau_2^\mu)$  forms a neutrosophic crisp supra bi-topological space ( $\mathcal{NCS} - \text{bi} - \mathcal{TS}$ ).

**Neutrosophic Crisp Minimal Structure Spaces**

Riad K. Al-Hamido[1] introduced the concept of  $\mathcal{NCMS}$ . Here, we present the additional properties of  $\mathcal{NCMOS}$  and  $\mathcal{NCMCS}$  within this  $\mathcal{NCMS}$  framework.

**Theorem 3.1.** Let  $X$  be a nonempty set and  $\mathcal{M}$  be a  $\mathcal{NCMS}$  on  $X$ . The following properties apply for neutrosophic crisp subsets  $Q$  and  $\mathcal{P}$  of  $X$ :

- (i)  $\mathcal{NCMint}(\emptyset) = \emptyset$  and  $\mathcal{NCMint}(X) = X$ .
- (ii)  $\mathcal{NCMcl}(\emptyset) = \emptyset$  and  $\mathcal{NCMcl}(X) = X$ .
- (iii)  $\mathcal{NCMcl}(X - Q) = X - \mathcal{NCMint}(Q)$ .
- (iv)  $\mathcal{NCMint}(X - Q) = X - \mathcal{NCMcl}(Q)$ .
- (v)  $Q$  is  $\mathcal{NCMCS}$  iff  $Q = \mathcal{NCMcl}(Q)$ .
- (vi)  $Q$  is  $\mathcal{NCMOS}$  iff  $Q = \mathcal{NCMint}(Q)$ .
- (vii)  $\mathcal{NCMcl}(\mathcal{NCMcl}(Q)) = \mathcal{NCMcl}(Q)$  and  $\mathcal{NCMint}(\mathcal{NCMint}(Q)) = \mathcal{NCMint}(Q)$

**Proof:**

(i) Since  $X$  and  $\emptyset$  are  $\mathcal{NCMOS}$ ,

$$\begin{aligned} \mathcal{NCMint}(X) &= \cup \{J : J \text{ is a } \mathcal{NCMO}, J \subset X\} \\ &= X \cup J \text{ is } \mathcal{NCMOS} \\ &= X \end{aligned}$$

(i.e)  $\mathcal{CMint}(X) = X$ . Since  $\emptyset$  is the only  $\mathcal{NCMOS}$  contained in  $\emptyset$ ,  $\mathcal{NCMint}(\emptyset) = \emptyset$ .

(ii) By the definition of  $\mathcal{NCMcl}(Q)$ ,  $X$  is the only  $\mathcal{NCMCS}$  containing  $X$ .

$$\begin{aligned} \therefore \mathcal{NCMcl}(X) &= \text{Intersection of all the } \mathcal{NCMCS} \text{ containing } X. \\ &= \cap \{X\} = X \end{aligned}$$

That is  $\mathcal{CMcl}(X) = X$ .

Consequently,

$$\begin{aligned} \mathcal{NCMcl}(\emptyset) &= \text{Intersection of all the } \mathcal{NCMCS} \text{ containing } \emptyset. \\ &= \cap \{\emptyset\} = \emptyset. \end{aligned}$$

That is  $\mathcal{NCMcl}(\emptyset) = \emptyset$ .

(iii) Let  $x \in \mathcal{NCMcl}(X - Q)$ . By definition,  $x \in \mathcal{NCMcl}(X - Q)$  if every  $\mathcal{NCMOS} J$  containing  $x$  must intersect  $X - Q$ . Suppose  $x \in \mathcal{NCMint}(Q)$ . Then,  $\exists \mathcal{NCMOS} J$  such that  $x \in J \subseteq Q$ . This

Tharani and Kokilavan

implies  $J \cap (X - Q) = \emptyset$ , which contradicts the condition that  $\in NCMcl(X - Q)$ . Thus,  $\notin NCMint(Q)$ , so  $x \in X - NCMint(Q)$ . Since,  $\in X - NCMint(Q)$ , it follows that  $NCMcl(X - Q) \subseteq X - NCMint(Q)$ .

Conversely, Let  $\in X - NCMint(Q)$ . Then,  $\notin NCMint(Q)$ , meaning there is no  $NCMOS J$  such that  $x \in J \subseteq Q$ . Consequently, every  $NCMOS J$  that contains  $x$  must intersect  $X - Q$ , implying  $x \in NCMcl(X - Q)$ . Since,  $X - NCMint(Q) \subseteq NCMcl(X - Q)$  and  $NCMcl(X - Q) \subseteq X - NCMint(Q)$ , we conclude that  $NCMcl(X - Q) = X - NCMint(Q)$ .

(iv) Let  $x \in NCMint(X - Q)$ . By definition,  $\exists NCMOS J$  such that  $x \in J \subseteq X - Q$ , which implies  $J \cap Q = \emptyset$ . If  $\in NCMcl(Q)$ , then every  $NCMOS$  containing  $x$  would intersect  $Q$ . However,  $J$  is a neutrosophic crisp minimal open set containing  $x$  and  $J \cap Q = \emptyset$ , which is a contradiction. Therefore,  $\notin NCMcl(Q)$ , so  $x \in X - NCMcl(Q)$ .

Conversely, Let  $x \in X - NCMcl(Q)$ . This means,  $x \notin NCMcl(Q)$ . By definition,  $\exists NCMOS J$  such that  $x \in J$  and  $J \cap Q = \emptyset$ , which implies  $J \subseteq X - Q$ . Since  $x \in J$  and  $J$  is  $NCMOS$ ,  $x$  is a neutrosophic crisp minimal interior point of  $X - Q$ . Hence,  $x \in NCMint(X - Q)$ .

(v) If  $Q$  is neutrosophic crisp minimal closed, then by definition, it is the smallest  $NCMCS$  containing itself. Therefore,  $Q = NCMcl(Q)$ . Conversely, if  $Q = NCMcl(Q)$ , then  $Q$  is the intersection of  $NCMCS$ . Since the intersection of  $NCMCS$  is neutrosophic crisp minimal closed,  $Q$  is neutrosophic crisp minimal closed.

(vi) If  $Q$  is an  $NCMOS$  over  $X$ , then  $Q$  is itself an  $NCMOS$  over  $X$  that contains  $Q$ . Thus,  $Q$  is the largest  $NCMOS$  within  $Q$  and  $NCMint(Q) = Q$ . Conversely, if  $NCMint(Q) = Q$ . Then,  $Q \in \mathcal{M}$ .

(vii) From the definition of  $NCMcl(Q)$  and  $NCMint(Q)$ , the proof is obvious.

Neutrosophic Crisp Biminimal Structure Spaces

We present the neutrosophic crisp biminimal structure in this section. Additionally, we present novel forms of  $NCM_1M_2$ -closed sets and  $NCM_1M_2$ -open sets in neutrosophic crisp biminimal structure spaces, analyze their characteristics, and extensively investigate their interrelationship.

**Definition 4.1.** Let  $X$  be a nonempty set and let  $NCM_1S$  and  $NCM_2S$  be neutrosophic crisp minimal structure on  $X$ . The triple  $(X, \mathcal{M}_1, \mathcal{M}_2)$  is called a neutrosophic crisp biminimal structure space ( $NCbiMSS$ ). Let  $(X, \mathcal{M}_1, \mathcal{M}_2)$  be  $NCbiMSS$  and  $Q$  be neutrosophic crisp subset of  $X$ , the neutrosophic crisp minimal interior and closure of  $X$  for  $\mathcal{M}_i$  are denoted as  $NCM_iint(Q)$  and  $NCM_icl(Q)$ , respectively, for  $i = 1, 2$ .

**Definition 4.2.** A neutrosophic crisp subset  $Q$  of a  $NCbiMSS (X, \mathcal{M}_1, \mathcal{M}_2)$  is called  $NCM_1M_2$ -closed set if  $\mathcal{CM}_1cl(NCM_2cl(Q)) = Q$ . The complement of an  $NCM_1M_2$ -closed set is called an  $NCM_1M_2$ -open set.

**Theorem 4.1.** Let  $NCM_1S$  and  $NCM_2S$  be neutrosophic crisp minimal structure on  $X$ . Then  $Q$  is a  $NCM_1M_2$  closed subset of neutrosophic crisp biminimal structure space  $(X, \mathcal{M}_1, \mathcal{M}_2)$  iff  $Q$  is both  $NCM_1$  closed and  $NCM_2$  closed.

**Example 4.1.** Let  $X = \{q_{11}, p_{22}\}$ . Define neutrosophic crisp minimal structure  $\mathcal{M}_1$  and  $\mathcal{M}_2$  on  $X$  as follows:  $\mathcal{M}_1 = \{\{\emptyset, \emptyset, X\}, \langle X, X, \emptyset \rangle, \langle \{q_{11}\}, \{p_{22}\}, \{q_{11}\} \rangle\}$ ,  $\mathcal{M}_2 = \{\{\emptyset, \emptyset, X\}, \langle X, X, \emptyset \rangle, \langle \{q_{11}\}, \{p_{22}\}, \{q_{11}\} \rangle, \langle \{p_{22}\}, \emptyset, \{q_{11}\} \rangle\}$ . Then  $\langle \{p_{22}\}, \{q_{11}\}, \{p_{22}\} \rangle$  is  $NCM_1M_2$  close

Let  $(X, \mathcal{M}_1, \mathcal{M}_2)$  be a neutrosophic crisp biminimal structure space and  $A$  be a neutrosophic crisp subset of  $X$ . Then  $A$  is  $NCM_1M_2$  closed iff  $NCM_1cl(Q) = Q$  and  $NCM_2cl(Q) = Q$ .

**Theorem 4.2.** Let  $(X, \mathcal{M}_1, \mathcal{M}_2)$  be  $NCbiMSS$ . If  $Q$  and  $P$  are  $NCM_1M_2$ -closed subsets of  $(X, \mathcal{M}_1, \mathcal{M}_2)$ , then their intersection  $Q \cap P$  is  $NCM_1M_2$ -closed.

*Proof.* Assume that  $Q$  and  $P$  be  $NCM_1M_2$ -closed.

By the definition, we have:  $NCM_1cl(NCM_1cl(Q)) = Q$  and  $NCM_1cl(NCM_1cl(P)) = P$ .

Since,  $Q \cap P \subseteq Q$  and  $Q \cap P \subseteq P$ , it follows that

Tharani and Kokilavan

$$NCM_1cl(NCM_1cl(Q \cap P)) \subseteq NCM_1cl(NCM_1cl(Q)) \text{ and } NCM_1cl(NCM_1cl(Q \cap P)) \subseteq NCM_1cl(NCM_1cl(P)).$$

Therefore,

$$NCM_1cl(NCM_1cl(Q \cap P)) \subseteq NCM_1cl(NCM_1cl(Q)) \cap NCM_1cl(NCM_1cl(P)) = Q \cap P.$$

Additional, we know that  $Q \cap P \subseteq NCM_1cl(NCM_1cl(Q \cap P))$ .

Thus, combining the two inclusion, we conclude that,  $NCM_1cl(NCM_1cl(Q \cap P)) = Q \cap P$ . □

Hence,  $Q \cap P$  is  $NCM_1M_2$ -closed.

**Remark 4.1.** The union of two  $NCM_1M_2$ -closed sets is not necessarily an  $NCM_1M_2$ -closed set, as demonstrated by the following example.

**Example 4.2.** Let  $X = \{q_{11}, p_{22}, r_{33}\}$ . Define  $NCMS$   $M_1$  and  $M_2$  on  $X$  as follows:  $M_1 = \{\{\emptyset, \emptyset, X\}, \langle X, X, \emptyset \rangle, \langle \{q_{11}, p_{22}\}, \{r_{33}\}, \{q_{11}\} \rangle, \langle \{r_{33}\}, \{q_{11}, p_{22}\}, \{p_{22}\} \rangle\}$ ,  $M_2 = \{\{\emptyset, \emptyset, X\}, \langle X, X, \emptyset \rangle, \langle \{q_{11}, p_{22}\}, \{r_{33}\}, \{q_{11}\} \rangle, \langle \{p_{22}\}, \emptyset, \{q_{11}\} \rangle, \langle \{r_{33}\}, \{q_{11}, p_{22}\}, \{p_{22}\} \rangle\}$ . Then  $\langle \{r_{33}\}, \{q_{11}, p_{22}\}, \{p_{22}, r_{33}\} \rangle, \langle \{q_{11}, p_{22}\}, \{r_{33}\}, \{q_{11}, r_{33}\} \rangle$  are  $NCM_1M_2$ -closed but  $\langle \{r_{33}\}, \{q_{11}, p_{22}\}, \{p_{22}, r_{33}\} \rangle \cup \langle \{q_{11}, p_{22}\}, \{r_{33}\}, \{q_{11}, r_{33}\} \rangle = \langle \{q_{11}, p_{22}, r_{33}\}, \{q_{11}, p_{22}, r_{33}\}, \{q_{11}, p_{22}, r_{33}\} \rangle$  is not  $NCM_1M_2$ -closed.

**Theorem 4.3.** Let  $(X, M_1, M_2)$  be  $NCbiMSS$ . Then  $Q$  is  $NCM_1M_2$ -open subsets of  $(X, M_1, M_2)$  iff  $Q = NCM_1int(NCM_2int(Q))$ .

*Proof.* Let  $Q$  be a  $NCM_1M_2$ -open subsets of  $(X, M_1, M_2)$ . Then  $X - Q$  is  $NCM_1M_2$ -closed. Therefore,  $NCM_1cl(NCM_2cl(X - Q)) = X - Q$ .

By theorem 3.1 (iii),  $X - NCM_1int(NCM_2int(Q)) = X - Q$ .

Consequently,  $Q = NCM_1int(NCM_2int(Q))$ .

Conversely, let  $Q = NCM_1int(NCM_2int(Q))$ .

Therefore,  $X - Q = X - NCM_1int(NCM_2int(Q))$ .

By theorem 3.1(iii)  $X - Q = NCM_1cl(NCM_2cl(X - Q))$ . □

Hence,  $X - Q$  is  $NCM_1M_2$ -closed. Consequently,  $Q$  is a  $NCM_1M_2$ -open.

**Theorem 4.4.** Let  $(X, M_1, M_2)$  be  $NCbiMSS$ . If  $Q$  and  $P$  are  $NCM_1M_2$ -open subsets of  $(X, M_1, M_2)$ , then  $Q \cup P$  is  $NCM_1M_2$ -open.

*Proof.* Let  $Q$  and  $P$  be  $NCM_1M_2$ -open. Then  $NCM_1int(NCM_2int(Q)) = Q$  and  $NCM_1int(NCM_2int(P)) = P$ . Since,  $Q \subseteq Q \cup P$  and  $Q \cup P, NCM_1int(NCM_2int(Q)) \subseteq NCM_1int(NCM_2int(Q \cup P))$  and

$$NCM_1int(NCM_2int(P)) \subseteq NCM_1int(NCM_2int(Q \cup P)).$$

$$\text{Therefore, } Q \cup P = NCM_1int(NCM_2int(Q)) \cup NCM_1int(NCM_2int(P)) \subseteq NCM_1int(NCM_2int(Q \cup P)).$$

But  $NCM_1int(NCM_2int(Q \cup P)) \subseteq Q \cup P$ .

Consequently,  $NCM_1int(NCM_2int(Q \cup P)) = Q \cup P$ . Hence,  $Q \cup P$  is  $NCM_1M_2$ -open.

**Remark 4.2.** The intersection of two  $NCM_1M_2$ -open sets is not necessarily an  $NCM_1M_2$ -open sets, as demonstrated by the following example.

**Example 4.3.** Let  $X = \{q_{11}, p_{22}, r_{33}\}$ . Define  $NCMS$   $M_1$  and  $M_2$  on  $X$  as follows:  $M_1 = \{\{\emptyset, \emptyset, X\}, \langle X, X, \emptyset \rangle, \langle \{q_{11}, p_{22}\}, \{r_{33}\}, \{q_{11}\} \rangle, \langle \{r_{33}\}, \{q_{11}, p_{22}\}, \{p_{22}\} \rangle\}$ ,  $M_2 = \{\{\emptyset, \emptyset, X\}, \langle X, X, \emptyset \rangle, \langle \{q_{11}, p_{22}\}, \{r_{33}\}, \{q_{11}\} \rangle, \langle \{p_{22}\}, \emptyset, \{q_{11}\} \rangle, \langle \{r_{33}\}, \{q_{11}, p_{22}\}, \{p_{22}\} \rangle\}$ . Then  $\langle \{q_{11}, p_{22}\}, \{r_{33}\}, \{q_{11}\} \rangle, \langle \{r_{33}\}, \{q_{11}, p_{22}\}, \{p_{22}\} \rangle$  are  $NCM_1M_2$ -open but  $\langle \{q_{11}, p_{22}\}, \{r_{33}\}, \{q_{11}\} \rangle \cap \langle \{r_{33}\}, \{q_{11}, p_{22}\}, \{p_{22}\} \rangle = \langle \emptyset, \emptyset, \{q_{11}, p_{22}\} \rangle$  is not  $NCM_1M_2$ -open.

### Tharani and Kokilavan

**Definition 4.3.** Let  $(X, \mathcal{M}_1, \mathcal{M}_2)$  be  $\mathcal{NCbiMSS}$  and  $\mathcal{V}$  be a neutrosophic crisp subset over  $X$ . Define neutrosophic crisp minimal structures  $Y_{\mathcal{V}_1}$  and  $Y_{\mathcal{V}_2}$  on  $\mathcal{V}$  are defined as follows:  $Y_{\mathcal{V}_1} = \{ \mathcal{V} \cap \mathcal{Q} : \mathcal{Q} \in \mathcal{M}_1 \}$  and  $Y_{\mathcal{V}_2} = \{ \mathcal{V} \cap \mathcal{P} : \mathcal{P} \in \mathcal{M}_2 \}$ . A triple  $(\mathcal{V}, Y_{\mathcal{V}_1}, Y_{\mathcal{V}_2})$  is called a neutrosophic crisp biminimal structure subspace of  $(X, \mathcal{M}_1, \mathcal{M}_2)$ .

Now, let  $(\mathcal{V}, Y_{\mathcal{V}_1}, Y_{\mathcal{V}_2})$  be a neutrosophic crisp biminimal structure subspace of  $(X, \mathcal{M}_1, \mathcal{M}_2)$  and let  $\mathcal{Q}$  be a neutrosophic crisp subset of  $\mathcal{V}$ . The  $\mathcal{NCM}_{\mathcal{V}}^i$ -closure and  $\mathcal{NCM}_{\mathcal{V}}^i$ -interior of  $\mathcal{Q}$  to  $\mathcal{M}_{\mathcal{V}}^i$  are denoted by  $\mathcal{NCM}_{\mathcal{V}}^i cl_i(\mathcal{Q})$  and  $\mathcal{NCM}_{\mathcal{V}}^i int_i(\mathcal{Q})$ , respectively, for  $i = 1, 2$ . The relationship are as follows:  $\mathcal{NCM}_{\mathcal{V}}^1 cl_1(\mathcal{Q}) = \mathcal{V} \cap \mathcal{NCM}_1 cl(\mathcal{Q})$  and  $\mathcal{NCM}_{\mathcal{V}}^2 cl_2(\mathcal{Q}) = \mathcal{V} \cap \mathcal{NCM}_2 cl(\mathcal{Q})$ .

**Theorem 4.5.** Let  $(\mathcal{V}, Y_{\mathcal{V}_1}, Y_{\mathcal{V}_2})$  be a neutrosophic crisp biminimal structure subspace of  $(X, \mathcal{M}_1, \mathcal{M}_2)$  and let  $C$  be a neutrosophic crisp subset of  $\mathcal{V}$ . If  $C$  is  $\mathcal{NCM}_1 \mathcal{M}_2$ -closed, then  $C$  is  $\mathcal{NCM}_{Y_{\mathcal{V}_1}, Y_{\mathcal{V}_2}}$ -closed.

*Proof:* Since  $C$  is  $\mathcal{NCM}_1 \mathcal{M}_2$ -closed. We known that  $\mathcal{CM}_1 cl(\mathcal{NCM}_1 cl(C)) = C$ , which implies that  $(\mathcal{NCM}_1 cl(C)) = C$  and  $(\mathcal{NCM}_2 cl(C)) = C$ . Therefore,  $\mathcal{V} \cap \mathcal{NCM}_1 cl(\mathcal{Q}) = C$  and  $\mathcal{V} \cap \mathcal{NCM}_2 cl(C) = C$ . Consequently,  $\mathcal{NCM}_{\mathcal{V}}^1 cl_1(\mathcal{NCM}_{\mathcal{V}}^2 cl_2(C)) = C$ . Hence,  $C$  is  $\mathcal{CM}_{Y_{\mathcal{V}_1}, Y_{\mathcal{V}_2}}$ -closed.

### ABSTRACT

This research study investigates the meaning of homomorphism, isomorphism, weak isomorphism, and strong co-isomorphism in the setting of cohesive fuzzy graphs with suitable graphical illustrations and also we look into the isomorphism of two cohesive fuzzy graphs and establishes that the relationship is an equivalence. We discuss some isomorphic properties of cohesive fuzzy graphs and self-complementary cohesive fuzzy graphs.

**Keywords:** Cohesive fuzzy graph, Homomorphism, Isomorphism, Weak isomorphism, Strong co-isomorphism, Self complementary.

## INTRODUCTION

Isomorphism is a branch of graph theory that has recently attracted considerable interest from researchers. In 2023, X. Xue [7] introduced the concept of cohesive fuzzy sets. This innovative concept of a cohesive fuzzy graph specifically addresses the grouping of favorable conditions associated with a particular ambiguous, higher-dimensional problem, incorporating a potentially broader range with a unit disk's phase component. This approach not only tackles the challenge of selecting the most suitable option among various choices but also aids in eliminating negative scenarios across a wide array of situations. Ismayil AM and N. Azhagendran [8] explored isomorphism on complex fuzzy graphs in their studies. This discussion delves into isomorphism on cohesive fuzzy graphs, focusing on cases that involve time-periodic phenomena. The topics covered include weak isomorphism, co-weak isomorphism,

**Sheelarani and Jon Arockiaraj**

isomorphism, and complementary aspects with their related findings. The application of isomorphism in complex fuzzy graphs involves examining the structural equivalence between two such graphs. In this context, isomorphism helps determine if there is a one-to-one correspondence between the vertex sets of two complex fuzzy graphs that preserves the edge connectivity and fuzzy relationships. This can be particularly useful in analyzing graph properties like symmetry, pattern recognition, and efficiency in network analysis. For instance, in complex systems modeling or information networks, identifying isomorphic complex fuzzy graphs allows for simplifying computations and understanding underlying patterns by reducing data redundancy.

**METHODOLOGY**

**Definition 2.1:[9]**Let an underlying set be  $U$ . A Cohesive fuzzy graph with  $U$  is an ordered pair  $\mathbb{G} = (\mathbb{X}, \mathbb{Y})$  where  $\mathbb{X} = (\lambda_{\mathbb{X}}e^{i\alpha_{\mathbb{X}}}, \gamma_{\mathbb{X}}e^{i\beta_{\mathbb{X}}}, \delta_{\mathbb{X}}e^{i\Omega_{\mathbb{X}}})$  and  $\mathbb{Y} = (\lambda_{\mathbb{Y}}e^{i\alpha_{\mathbb{Y}}}, \gamma_{\mathbb{Y}}e^{i\beta_{\mathbb{Y}}}, \delta_{\mathbb{Y}}e^{i\Omega_{\mathbb{Y}}})$  are the cohesive fuzzy vertex and edge set with  $\mathbb{X}:\mathbb{V} \rightarrow$

$H_u\{\xi \in C: |\xi| \leq 1\}$  and  $\mathbb{Y}:E \rightarrow H_u\{\xi \in C: |\xi| \leq 1\}$ , where  $H_u\{\xi \in C: |\xi| \leq 1\}$  is the set of all the unit disc's finite subsets, such that

$$\begin{aligned} \lambda_{\mathbb{Y}}(uv)e^{i\alpha_{\mathbb{Y}}(uv)} &\leq \min\{\lambda_{\mathbb{X}}(u), \lambda_{\mathbb{X}}(v)\}e^{i \min\{\alpha_{\mathbb{X}}(u), \alpha_{\mathbb{X}}(v)\}} \\ \gamma_{\mathbb{Y}}(uv)e^{i\beta_{\mathbb{Y}}(uv)} &\leq \min\{\gamma_{\mathbb{X}}(u), \gamma_{\mathbb{X}}(v)\}e^{i \min\{\beta_{\mathbb{X}}(u), \beta_{\mathbb{X}}(v)\}} \\ \delta_{\mathbb{Y}}(uv)e^{i\Omega_{\mathbb{Y}}(uv)} &\leq \min\{\delta_{\mathbb{X}}(u), \delta_{\mathbb{X}}(v)\}e^{i \min\{\Omega_{\mathbb{X}}(u), \Omega_{\mathbb{X}}(v)\}}, \forall u, v \in \mathbb{X}. \end{aligned}$$

**Definition 2.2:[9]**Let  $\mathbb{X} = \{(u, \lambda_{\mathbb{X}}(u)e^{i\alpha_{\mathbb{X}}}, \gamma_{\mathbb{X}}(u)e^{i\beta_{\mathbb{X}}}, \delta_{\mathbb{X}}(u)e^{i\Omega_{\mathbb{X}}}) : u \in \mathbb{X}\}$  and  $\mathbb{Y} = \{(uv, \lambda_{\mathbb{Y}}(uv)e^{i\alpha_{\mathbb{Y}}(uv)}, \gamma_{\mathbb{Y}}(uv)e^{i\beta_{\mathbb{Y}}(uv)}, \delta_{\mathbb{Y}}(uv)e^{i\Omega_{\mathbb{Y}}(uv)}) : uv \in \mathbb{Y}\}$  be a cohesive fuzzy graph the vertex and edge sets.

A cohesive fuzzy graph's order can be stated as follows,

$$O(\mathbb{G}) = (\sum_{u_i \in \mathbb{V}} \lambda_{\mathbb{X}}(u_i)e^{i\sum_{u_i \in \mathbb{V}} \alpha_{\mathbb{X}}(u_i)}, \sum_{u_i \in \mathbb{V}} \gamma_{\mathbb{X}}(u_i)e^{i\sum_{u_i \in \mathbb{V}} \beta_{\mathbb{X}}(u_i)}, \sum_{u_i \in \mathbb{V}} \delta_{\mathbb{X}}(u_i)e^{i\sum_{u_i \in \mathbb{V}} \Omega_{\mathbb{X}}(u_i)})$$

A cohesive fuzzy graph's size can be stated as follows:

$$S(\mathbb{G}) = (\sum_{u_i \neq v_i} \lambda_{\mathbb{Y}}(u_i v_i)e^{i\sum_{u_i \neq v_i} \alpha_{\mathbb{Y}}(u_i v_i)}, \sum_{u_i \neq v_i} \gamma_{\mathbb{Y}}(u_i v_i)e^{i\sum_{u_i \neq v_i} \beta_{\mathbb{Y}}(u_i v_i)}, \sum_{u_i \neq v_i} \delta_{\mathbb{Y}}(u_i v_i)e^{i\sum_{u_i \neq v_i} \Omega_{\mathbb{Y}}(u_i v_i)})$$

**Definition 2.3: [9]**Let  $\mathbb{G} = (\mathbb{X}, \mathbb{Y})$  be a cohesive fuzzy graph. Then its Complement of cohesive fuzzy graph  $\mathbb{G} = (\mathbb{X}, \mathbb{Y})$  is indicated by  $\overline{\mathbb{G}} = (\overline{\mathbb{X}}, \overline{\mathbb{Y}})$  is described as,

- (i)  $\overline{\mathbb{X}} = \mathbb{X}$ ,
- (ii)  $\lambda_{\overline{\mathbb{X}}}(u)e^{i\alpha_{\overline{\mathbb{X}}}(u)} = \lambda_{\mathbb{X}}(u)e^{i\alpha_{\mathbb{X}}(u)}$   
 $\gamma_{\overline{\mathbb{X}}}(u)e^{i\beta_{\overline{\mathbb{X}}}(u)} = \gamma_{\mathbb{X}}(u)e^{i\beta_{\mathbb{X}}(u)}$

$\delta_{\overline{\mathbb{X}}}(u)e^{i\Omega_{\overline{\mathbb{X}}}(u)} = \delta_{\mathbb{X}}(u)e^{i\Omega_{\mathbb{X}}(u)}$ , if  $u \in \mathbb{X}$ ,

$$\begin{aligned} \text{(iii)} \lambda_{\overline{\mathbb{Y}}}(uv)e^{i\alpha_{\overline{\mathbb{Y}}}(uv)} &= \begin{cases} 0 & \text{if } \lambda_{\mathbb{Y}}(uv)e^{i\alpha_{\mathbb{Y}}(uv)} \neq 0 \\ \min\{\lambda_{\mathbb{X}}(u), \lambda_{\mathbb{X}}(v)\}e^{i \min\{\alpha_{\mathbb{X}}(u), \alpha_{\mathbb{X}}(v)\}} & \text{if } \lambda_{\mathbb{Y}}(uv)e^{i\alpha_{\mathbb{Y}}(uv)} = 0 \end{cases} \\ \gamma_{\overline{\mathbb{Y}}}(uv)e^{i\beta_{\overline{\mathbb{Y}}}(uv)} &= \begin{cases} 0 & \text{if } \gamma_{\mathbb{Y}}(uv)e^{i\beta_{\mathbb{Y}}(uv)} \neq 0 \\ \min\{\gamma_{\mathbb{X}}(u), \gamma_{\mathbb{X}}(v)\}e^{i \min\{\beta_{\mathbb{X}}(u), \beta_{\mathbb{X}}(v)\}} & \text{if } \gamma_{\mathbb{Y}}(uv)e^{i\beta_{\mathbb{Y}}(uv)} = 0 \end{cases} \\ \delta_{\overline{\mathbb{Y}}}(uv)e^{i\Omega_{\overline{\mathbb{Y}}}(uv)} &= \begin{cases} 0 & \text{if } \delta_{\mathbb{Y}}(uv)e^{i\Omega_{\mathbb{Y}}(uv)} \neq 0 \\ \min\{\delta_{\mathbb{X}}(u), \delta_{\mathbb{X}}(v)\}e^{i \min\{\Omega_{\mathbb{X}}(u), \Omega_{\mathbb{X}}(v)\}} & \text{if } \delta_{\mathbb{Y}}(uv)e^{i\Omega_{\mathbb{Y}}(uv)} = 0 \end{cases} \end{aligned}$$

**Isomorphic properties of cohesive fuzzy graphs**

**Definition 3.1:**Let at wocohesive fuzzy graphs be  $\mathbb{G} = (P_1, Q_1)$  and  $\mathbb{G}' = (P_2, Q_2)$ . A homomorphism of cohesive fuzzy graphs  $r: \mathbb{G} \rightarrow \mathbb{G}'$  is a map  $r: \mathbb{V}_1 \rightarrow \mathbb{V}_2$  satisfies the following criteria.

**Sheelarani and Jon Arockiaraj**

$$\begin{aligned}
 & \text{(i)} \quad \mu_{P_1}(v_1)e^{i\alpha_{P_1}(v_1)} \leq \mu_{P_2}(r(v_1))e^{i\alpha_{P_2}(r(v_1))} \\
 & \gamma_{P_1}(v_1)e^{i\beta_{P_1}(v_1)} \leq \gamma_{P_2}(r(v_1))e^{i\beta_{P_2}(r(v_1))} \\
 & \delta_{P_1}(v_1)e^{i\Omega_{P_1}(v_1)} \leq \delta_{P_2}(r(v_1))e^{i\Omega_{P_2}(r(v_1))}, \text{ for all } v_1 \in \mathbb{V}_1. \\
 & \text{(ii)} \quad \mu_{Q_1}(v_1w_1)e^{i\alpha_{Q_1}(v_1w_1)} \leq \mu_{Q_2}(r(v_1)r(w_1))e^{i\alpha_{Q_2}(r(v_1)r(w_1))} \\
 & \gamma_{Q_1}(v_1w_1)e^{i\beta_{Q_1}(v_1w_1)} \leq \gamma_{Q_2}(r(v_1)r(w_1))e^{i\beta_{Q_2}(r(v_1)r(w_1))} \quad \delta_{Q_1}(v_1w_1)e^{i\Omega_{Q_1}(v_1w_1)} \leq \\
 & \delta_{Q_2}(r(v_1)r(w_1))e^{i\Omega_{Q_2}(r(v_1)r(w_1))}, \text{ for all } v_1w_1 \in \mathbb{E}_1.
 \end{aligned}$$

In Fig 1, a homomorphism  $r: \mathbb{V}_1 \rightarrow \mathbb{V}_2$  such that  $r(a) = u, r(b) = v, r(c) = w$ .

**Definition 3.2:** A weak isomorphism of a cohesive fuzzy graphs is defined by  $r: \mathbb{G} \rightarrow \mathbb{G}'$  is a map  $r: \mathbb{V}_1 \rightarrow \mathbb{V}_2$  which is one-to-one and onto homomorphism satisfies the following criteria.

$$\begin{aligned}
 & \text{(i)} \quad \mu_{P_1}(v_1)e^{i\alpha_{P_1}(v_1)} = \mu_{P_2}(r(v_1))e^{i\alpha_{P_2}(r(v_1))} \\
 & \gamma_{P_1}(v_1)e^{i\beta_{P_1}(v_1)} = \gamma_{P_2}(r(v_1))e^{i\beta_{P_2}(r(v_1))} \\
 & \delta_{P_1}(v_1)e^{i\Omega_{P_1}(v_1)} = \delta_{P_2}(r(v_1))e^{i\Omega_{P_2}(r(v_1))}, \text{ for all } v_1 \in \mathbb{V}_1.
 \end{aligned}$$

In Fig 2, the mapping  $r: \mathbb{V}_1 \rightarrow \mathbb{V}_2$  defined by  $r(v_1) = w_2, r(w_1) = v_2$  is a weak isomorphism.

**Definition 3.3:** A strong co-isomorphism of a cohesive fuzzy graphs is defined by  $r: \mathbb{G} \rightarrow \mathbb{G}'$  is a map  $r: \mathbb{V}_1 \rightarrow \mathbb{V}_2$  which is one-to-one and onto homomorphism satisfies the following criteria.

$$\begin{aligned}
 & \text{(i)} \quad \mu_{Q_1}(v_1w_1)e^{i\alpha_{Q_1}(v_1w_1)} = \mu_{Q_2}(r(v_1)r(w_1))e^{i\alpha_{Q_2}(r(v_1)r(w_1))} \\
 & \gamma_{Q_1}(v_1w_1)e^{i\beta_{Q_1}(v_1w_1)} = \gamma_{Q_2}(r(v_1)r(w_1))e^{i\beta_{Q_2}(r(v_1)r(w_1))} \quad \delta_{Q_1}(v_1w_1)e^{i\Omega_{Q_1}(v_1w_1)} = \\
 & \delta_{Q_2}(r(v_1)r(w_1))e^{i\Omega_{Q_2}(r(v_1)r(w_1))}, \text{ for all } v_1w_1 \in \mathbb{E}_1.
 \end{aligned}$$

In Fig3, a homomorphism  $r: \mathbb{V}_1 \rightarrow \mathbb{V}_2$  such that  $r(a) = x, r(b) = y, r(c) = z, r(d) = w$ .

**Definition 3.4:** An isomorphism of cohesive fuzzy graphs is defined by a mapping  $r: \mathbb{G} \rightarrow \mathbb{G}'$ , where  $r: \mathbb{V}_1 \rightarrow \mathbb{V}_2$  is a one-to-one and onto function that satisfies the condition outlined in definitions 3.2 and 3.3.

**Definition 3.5:** Let  $G$  be a cohesive fuzzy graph.  $G$  is considered self-complementary if its complement, denoted as  $\bar{G}$ ,  $G \approx \bar{G}$ .

**Theorem 3.6:** Cohesive fuzzy graphs isomorphism act as an equivalence relation.

**Proof:** we are going to prove isomorphism between cohesive fuzzy graphs is equivalence relation. To show equivalence relation, we prove that is reflexive, symmetric and transitive. The reflexive and symmetric properties are obvious. To prove transitive: We define a map  $h_1: \mathbb{V}_1 \rightarrow \mathbb{V}_2$  and  $h_2: \mathbb{V}_2 \rightarrow \mathbb{V}_3$  that represent isomorphisms from  $\mathbb{G}_1$  onto  $\mathbb{G}_2$  and from  $\mathbb{G}_2$  onto  $\mathbb{G}_3$ , respectively. Consequently, the composition  $h_2 \circ h_1: \mathbb{V}_1 \rightarrow \mathbb{V}_3$  is bijective. For each  $v_1 \in \mathbb{V}_1$ , the composition satisfies  $(h_2 \circ h_1)(v_1) = h_2(h_1(v_1))$ . The map  $h_1: \mathbb{V}_1 \rightarrow \mathbb{V}_2$ , described by  $h_1(v_1) = v_2$ , is itself an isomorphism. Then,

$$\begin{aligned}
 \mu_{P_1}(v_1)e^{i\alpha_{P_1}(v_1)} &= \mu_{P_2}(h_1(v_1))e^{i\alpha_{P_2}(h_1(v_1))} \\
 \mu_{P_1}(v_1)e^{i\alpha_{P_1}(v_1)} &= \mu_{P_2}(v_2)e^{i\alpha_{P_2}(v_2)}, \text{ for all } v_1 \in \mathbb{V}_1 \quad \dots \dots (1.1)
 \end{aligned}$$

$$\begin{aligned}
 \gamma_{P_1}(v_1)e^{i\beta_{P_1}(v_1)} &= \gamma_{P_2}(h_1(v_1))e^{i\beta_{P_2}(h_1(v_1))} \\
 \gamma_{P_1}(v_1)e^{i\beta_{P_1}(v_1)} &= \gamma_{P_2}(v_2)e^{i\beta_{P_2}(v_2)}, \text{ for all } v_1 \in \mathbb{V}_1 \quad \dots \dots (1.2)
 \end{aligned}$$

$$\begin{aligned}
 \delta_{P_1}(v_1)e^{i\Omega_{P_1}(v_1)} &= \delta_{P_2}(h_1(v_1))e^{i\Omega_{P_2}(h_1(v_1))} \\
 \delta_{P_1}(v_1)e^{i\Omega_{P_1}(v_1)} &= \delta_{P_2}(v_2)e^{i\Omega_{P_2}(v_2)}, \text{ for all } v_1 \in \mathbb{V}_1 \quad \dots \dots (1.3)
 \end{aligned}$$

$$\begin{aligned}

From equations (1.1) & (3.1),  $h_1(v_1) = v_2, v_1 \in \mathbb{V}_1$ , we have

$$\begin{aligned} \mu_{P_1}(v_1)e^{i\alpha_{P_1}(v_1)} &= \mu_{P_2}(h_1(v_1))e^{i\alpha_{P_2}(h_1(v_1))} = \mu_{P_2}(v_2)e^{i\alpha_{P_2}(v_2)} \\ &= \mu_{P_3}(h_2(v_2))e^{i\alpha_{P_3}(h_2(v_2))} \\ \mu_{P_1}(v_1)e^{i\alpha_{P_1}(v_1)} &= \mu_{P_3}(h_2(h_1(v_1)))e^{i\alpha_{P_3}(h_2(h_1(v_1)))} \end{aligned}$$

From equations (1.2) & (3.2),  $h_1(v_1) = v_2, v_1 \in \mathbb{V}_1$ , we have

$$\begin{aligned} \gamma_{P_1}(v_1)e^{i\beta_{P_1}(v_1)} &= \gamma_{P_2}(h_1(v_1))e^{i\beta_{P_2}(h_1(v_1))} \\ &= \gamma_{P_2}(v_2)e^{i\beta_{P_2}(v_2)} \\ &= \gamma_{P_3}(h_2(v_2))e^{i\beta_{P_3}(h_2(v_2))} \\ \gamma_{P_1}(v_1)e^{i\beta_{P_1}(v_1)} &= \gamma_{P_3}(h_2(h_1(v_1)))e^{i\beta_{P_3}(h_2(h_1(v_1)))} \end{aligned}$$

From equations (1.3) & (3.3),  $h_1(v_1) = v_2, v_1 \in \mathbb{V}_1$ , we have

$$\begin{aligned} \delta_{P_1}(v_1)e^{i\Omega_{P_1}(v_1)} &= \delta_{P_2}(h_1(v_1))e^{i\Omega_{P_2}(h_1(v_1))} \\ &= \delta_{P_2}(v_2)e^{i\Omega_{P_2}(v_2)} \\ &= \delta_{P_3}(h_2(v_2))e^{i\Omega_{P_3}(h_2(v_2))} \\ \delta_{P_1}(v_1)e^{i\Omega_{P_1}(v_1)} &= \delta_{P_3}(h_2(h_1(v_1)))e^{i\Omega_{P_3}(h_2(h_1(v_1)))} \end{aligned}$$

From equations (2.1) & (4.1), we have

$$\begin{aligned} \mu_{Q_1}(v_1w_1)e^{i\alpha_{Q_1}(v_1w_1)} &= \mu_{Q_2}(h_1(v_1)h_1(w_1))e^{i\alpha_{Q_2}(h_1(v_1)h_1(w_1))} \\ &= \mu_{Q_2}(v_2w_2)e^{i\alpha_{Q_2}(v_2w_2)} \\ &= \mu_{Q_3}(h_2(v_2)h_2(w_2))e^{i\alpha_{Q_3}(h_2(v_2)h_2(w_2))} \\ \mu_{Q_1}(v_1w_1)e^{i\alpha_{Q_1}(v_1w_1)} &= \mu_{Q_3}(h_2(h_1(v_1))h_2(h_1(w_1)))e^{i\alpha_{Q_3}(h_2(h_1(v_1))h_2(h_1(w_1)))} \end{aligned}$$

for all  $v_1w_1 \in \mathbb{E}_1$ .

From equations (2.2) & (4.2), we have,

$$\begin{aligned} \gamma_{Q_1}(v_1w_1)e^{i\beta_{Q_1}(v_1w_1)} &= \gamma_{Q_2}(h_1(v_1)h_1(w_1))e^{i\beta_{Q_2}(h_1(v_1)h_1(w_1))} \\ &= \gamma_{Q_2}(v_2w_2)e^{i\beta_{Q_2}(v_2w_2)} \\ &= \gamma_{Q_3}(h_2(v_2)h_2(w_2))e^{i\beta_{Q_3}(h_2(v_2)h_2(w_2))} \\ \gamma_{Q_1}(v_1w_1)e^{i\beta_{Q_1}(v_1w_1)} &= \gamma_{Q_3}(h_2(h_1(v_1))h_2(h_1(w_1)))e^{i\beta_{Q_3}(h_2(h_1(v_1))h_2(h_1(w_1)))} \end{aligned}$$

for all  $v_1w_1 \in \mathbb{E}_1$ .

**Sheelarani and Jon Arockiaraj**

From equations (2.3) & (4.3), we have,

$$\begin{aligned} \delta_{Q_1}(v_1w_1)e^{i\Omega_{Q_1}(v_1w_1)} &= \delta_{Q_2}(h_1(v_1)h_1(w_1))e^{i\Omega_{Q_2}(h_1(v_1)h_1(w_1))} \\ &= \delta_{Q_2}(v_2w_2)e^{i\Omega_{Q_2}(v_2w_2)} \\ &= \delta_{Q_3}(h_2(v_2)h_2(w_2))e^{i\Omega_{Q_3}(h_2(v_2)h_2(w_2))} \\ \delta_{Q_1}(v_1w_1)e^{i\Omega_{Q_1}(v_1w_1)} &= \delta_{Q_3}(h_2(h_1(v_1))h_2(h_1(w_1)))e^{i\Omega_{Q_3}(h_2(h_1(v_1))h_2(h_1(w_1)))} \end{aligned}$$

for all  $v_1w_1 \in \mathbb{E}_1$ .

Therefore  $h_2 \circ h_1$  is an isomorphism from  $\mathbb{G}_1$  to  $\mathbb{G}_3$ . Hence an isomorphism between cohesive fuzzy graphs is an equivalence.

**Theorem 3.7:**A weak isomorphism (co-isomorphism)between cohesive fuzzy graphs serves as a partial order relation.

**Proof:**We will demonstrate that a partial ordering relation exists between cohesive fuzzy networks through a weak isomorphism (co-isomorphism).To show partial order relation, we prove that is reflexive, anti-symmetric and transitive. The reflexive and transitive properties are obvious.

To prove anti-symmetric: we define a map  $h_1: \mathbb{V}_1 \rightarrow \mathbb{V}_2$ , the function  $h_1: \mathbb{V}_1 \rightarrow \mathbb{V}_2$  is a strong isomorphism from  $\mathbb{G}_1$  onto  $\mathbb{G}_2$ . Here  $h_1$  is a one to one and onto mapping which is described by  $h_1(v_1) = v_2$ , for all  $v_1 \in \mathbb{V}_1$  and the mapping satisfies the following conditions.

$$\begin{aligned} \mu_{P_1}(v_1)e^{i\alpha_{P_1}(v_1)} &= \mu_{P_2}(h_1(v_1))e^{i\alpha_{P_2}(h_1(v_1))}, \text{ for all } v_1 \in \mathbb{V}_1, \\ \gamma_{P_1}(v_1)e^{i\beta_{P_1}(v_1)} &= \gamma_{P_2}(h_1(v_1))e^{i\beta_{P_2}(h_1(v_1))}, \text{ for all } v_1 \in \mathbb{V}_1 \quad \delta_{P_1}(v_1)e^{i\Omega_{P_1}(v_1)} = \delta_{P_2}(h_1(v_1))e^{i\Omega_{P_2}(h_1(v_1))}, \text{ for all } v_1 \in \mathbb{V}_1 \\ \mu_{Q_1}(v_1w_1)e^{i\alpha_{Q_1}(v_1w_1)} &\leq \mu_{Q_2}(h_1(v_1)h_1(w_1))e^{i\alpha_{Q_2}(h_1(v_1)h_1(w_1))} \dots \dots (4.4) \\ \gamma_{Q_1}(v_1w_1)e^{i\beta_{Q_1}(v_1w_1)} &\leq \gamma_{Q_2}(h_1(v_1)h_1(w_1))e^{i\beta_{Q_2}(h_1(v_1)h_1(w_1))} \dots \dots (4.5) \\ \delta_{Q_1}(v_1w_1)e^{i\Omega_{Q_1}(v_1w_1)} &\leq \delta_{Q_2}(h_1(v_1)h_1(w_1))e^{i\Omega_{Q_2}(h_1(v_1)h_1(w_1))} \dots \dots (4.6) \end{aligned}$$

for all  $v_1w_1 \in \mathbb{E}_1$

We define a map  $h_2: \mathbb{V}_2 \rightarrow \mathbb{V}_1$  as a strong isomorphism of  $\mathbb{G}_2$  onto  $\mathbb{G}_1$ . This means that  $h_2$  is a bijection, characterized by  $h_2(v_2) = v_1$  for every  $v_2 \in \mathbb{V}_2$ . Additionally, this mapping adheres to the following conditions.

$$\begin{aligned} \mu_{P_2}(v_2)e^{i\alpha_{P_2}(v_2)} &= \mu_{P_1}(h_2(v_2))e^{i\alpha_{P_1}(h_2(v_2))}, \text{ for all } v_2 \in \mathbb{V}_2, \\ \gamma_{P_2}(v_2)e^{i\beta_{P_2}(v_2)} &= \gamma_{P_1}(h_2(v_2))e^{i\beta_{P_1}(h_2(v_2))}, \text{ for all } v_2 \in \mathbb{V}_2, \\ \delta_{P_2}(v_2)e^{i\Omega_{P_2}(v_2)} &= \delta_{P_1}(h_2(v_2))e^{i\Omega_{P_1}(h_2(v_2))}, \text{ for all } v_2 \in \mathbb{V}_2, \\ \mu_{Q_2}(v_2w_2)e^{i\alpha_{Q_2}(v_2w_2)} &\leq \mu_{Q_1}(h_2(v_2)h_2(w_2))e^{i\alpha_{Q_1}(h_2(v_2)h_2(w_2))} \dots \dots (4.7) \\ \gamma_{Q_2}(v_2w_2)e^{i\beta_{Q_2}(v_2w_2)} &\leq \gamma_{Q_1}(h_2(v_2)h_2(w_2))e^{i\beta_{Q_1}(h_2(v_2)h_2(w_2))} \dots \dots (4.8) \\ \delta_{Q_2}(v_2w_2)e^{i\Omega_{Q_2}(v_2w_2)} &\leq \delta_{Q_1}(h_2(v_2)h_2(w_2))e^{i\Omega_{Q_1}(h_2(v_2)h_2(w_2))} \dots \dots (4.9) \end{aligned}$$

for all  $v_2w_2 \in \mathbb{E}_2$

The inequalities (4.4) and (4.7), (4.5) and (4.8), as well as (4.6) and (4.9), apply to the finite sets  $\mathbb{V}_1$  and  $\mathbb{V}_2$  only if both  $\mathbb{G}_1$  and  $\mathbb{G}_2$  have the same number of edges and corresponding edges are of equal weight. Hence,  $\mathbb{G}_1$  and  $\mathbb{G}_2$  are identical. Therefore, the composition  $h_2 \circ h_1$  forms a strong isomorphism from  $\mathbb{G}_1$  to  $\mathbb{G}_3$ . This concludes the proof.

**Theorem 3.8:**If  $\mathbb{G}_1$  and  $\mathbb{G}_2$  are two cohesive fuzzy graphs, then  $\mathbb{G}_1$  and  $\mathbb{G}_2$  are strongly isomorphic if and only if their complements  $\overline{\mathbb{G}_1}$  and  $\overline{\mathbb{G}_2}$ , are also strongly isomorphic.

**Proof:** Let  $\mathbb{G}_1$  and  $\mathbb{G}_2$  be two cohesive fuzzy graphs. A strong isomorphism exists between  $\mathbb{G}_1$  and  $\mathbb{G}_1$ . We define the bijective map  $h_1: \mathbb{V}_1 \rightarrow \mathbb{V}_2$  such that  $h_1(v_1) = v_2$  for all  $v_1 \in \mathbb{V}_1$ , ensuring the condition is met.

$$\begin{aligned} \mu_{P_1}(v_1)e^{i\alpha_{P_1}(v_1)} &= \mu_{P_2}(h_1(v_1))e^{i\alpha_{P_2}(h_1(v_1))} \text{ for all } v_1 \in \mathbb{V}_1. \\ \gamma_{P_1}(v_1)e^{i\beta_{P_1}(v_1)} &= \gamma_{P_2}(h_1(v_1))e^{i\beta_{P_2}(h_1(v_1))} \text{ for all } v_1 \in \mathbb{V}_1. \\ \delta_{P_1}(v_1)e^{i\Omega_{P_1}(v_1)} &= \delta_{P_2}(h_1(v_1))e^{i\Omega_{P_2}(h_1(v_1))} \text{ for all } v_1 \in \mathbb{V}_1 \\ \mu_{Q_1}(v_1w_1)e^{i\alpha_{Q_1}(v_1w_1)} &\leq \mu_{Q_2}(h_1(v_1)h_1(w_1))e^{i\alpha_{Q_2}(h_1(v_1)h_1(w_1))} \text{ for all } v_1w_1 \in \mathbb{E}_1. \\ \gamma_{Q_1}(v_1w_1)e^{i\beta_{Q_1}(v_1w_1)} &\leq \gamma_{Q_2}(h_1(v_1)h_1(w_1))e^{i\beta_{Q_2}(h_1(v_1)h_1(w_1))} \text{ for all } v_1w_1 \in \mathbb{E}_1. \\ \delta_{Q_1}(v_1w_1)e^{i\Omega_{Q_1}(v_1w_1)} &\leq \delta_{Q_2}(h_1(v_1)h_1(w_1))e^{i\Omega_{Q_2}(h_1(v_1)h_1(w_1))} \text{ for all } v_1w_1 \in \mathbb{E}_1. \end{aligned}$$

**Sheelarani and Jon Arockiaraj**

Given that  $h_1: \mathbb{V}_1 \rightarrow \mathbb{V}_2$  is bijective, its inverse,  $h_1^{-1}: \mathbb{V}_2 \rightarrow \mathbb{V}_1$  is also bijective described by  $h_1^{-1}(v_2) = v_1$ , for every  $v_2 \in \mathbb{V}_2$ , adhering to the conditions outlined below.

$$\begin{aligned} \mu_{P_1}(h_1^{-1}(v_2))e^{i\alpha_{P_1}(h_1^{-1}(v_2))} &= \mu_{P_2}(v_2)e^{i\alpha_{P_2}(v_2)} \text{ for all } v_2 \in \mathbb{V}_2. \\ \gamma_{P_1}(h_1^{-1}(v_2))e^{i\beta_{P_1}(h_1^{-1}(v_2))} &= \gamma_{P_2}(v_2)e^{i\beta_{P_2}(v_2)} \text{ for all } v_2 \in \mathbb{V}_2. \\ \delta_{P_1}(h_1^{-1}(v_2))e^{i\Omega_{P_1}(h_1^{-1}(v_2))} &= \delta_{P_2}(v_2)e^{i\Omega_{P_2}(v_2)} \text{ for all } v_2 \in \mathbb{V}_2. \end{aligned}$$

By applying the complement definition,

$$\begin{aligned} \mu_{\overline{Q_1}}(v_1w_1)e^{i\alpha_{\overline{Q_1}}(v_1w_1)} &= \min\{\mu_{P_1}(v_1), \mu_{P_1}(w_1)\}e^{i \min\{\alpha_{P_1}(v_1), \alpha_{P_1}(w_1)\}} \\ &\leq \min\{\mu_{P_2}(h_1(v_2)), \mu_{P_2}(h_1(w_2))\}e^{i \min\{\alpha_{P_2}(h_1(v_2)), \alpha_{P_2}(h_1(w_2))\}} \\ &= \min\{\mu_{P_2}(v_2), \mu_{P_2}(w_2)\}e^{i \min\{\alpha_{P_2}(v_2), \alpha_{P_2}(w_2)\}} \\ \mu_{\overline{Q_1}}(v_1w_1)e^{i\alpha_{\overline{Q_1}}(v_1w_1)} &= \mu_{Q_2}(v_2w_2)e^{i\alpha_{Q_2}(v_2w_2)}. \\ \gamma_{\overline{Q_1}}(v_1w_1)e^{i\beta_{\overline{Q_1}}(v_1w_1)} &= \min\{\gamma_{P_1}(v_1), \gamma_{P_1}(w_1)\}e^{i \min\{\beta_{P_1}(v_1), \beta_{P_1}(w_1)\}} \\ &\leq \min\{\gamma_{P_2}(h_1(v_2)), \gamma_{P_2}(h_1(w_2))\}e^{i \min\{\beta_{P_2}(h_1(v_2)), \beta_{P_2}(h_1(w_2))\}} \\ &= \min\{\gamma_{P_2}(v_2), \gamma_{P_2}(w_2)\}e^{i \min\{\beta_{P_2}(v_2), \beta_{P_2}(w_2)\}} \quad \gamma_{\overline{Q_1}}(v_1w_1)e^{i\beta_{\overline{Q_1}}(v_1w_1)} = \gamma_{Q_2}(v_2w_2)e^{i\beta_{Q_2}(v_2w_2)}. \\ \delta_{\overline{Q_1}}(v_1w_1)e^{i\Omega_{\overline{Q_1}}(v_1w_1)} &= \min\{\delta_{P_1}(v_1), \delta_{P_1}(w_1)\}e^{i \min\{\Omega_{P_1}(v_1), \Omega_{P_1}(w_1)\}} \\ &\leq \min\{\delta_{P_2}(h_1(v_2)), \delta_{P_2}(h_1(w_2))\}e^{i \min\{\Omega_{P_2}(h_1(v_2)), \Omega_{P_2}(h_1(w_2))\}} \\ &= \min\{\delta_{P_2}(v_2), \delta_{P_2}(w_2)\}e^{i \min\{\Omega_{P_2}(v_2), \Omega_{P_2}(w_2)\}} \quad \delta_{\overline{Q_1}}(v_1w_1)e^{i\Omega_{\overline{Q_1}}(v_1w_1)} = \delta_{Q_2}(v_2w_2)e^{i\Omega_{Q_2}(v_2w_2)}. \end{aligned}$$

Therefore, a bijective map  $h_1^{-1}: \mathbb{V}_2 \rightarrow \mathbb{V}_1$  is strong isomorphism. Hence  $\overline{\mathbb{G}_1}$  and  $\overline{\mathbb{G}_2}$  are strongly isomorphic.

**Theorem 3.9:** If  $\mathbb{G}_1$  and  $\mathbb{G}_2$  are two cohesive fuzzy graphs, then  $\mathbb{G}_1$  and  $\mathbb{G}_2$  are isomorphic if and only if their complements,  $\overline{\mathbb{G}_1}$  and  $\overline{\mathbb{G}_2}$  are also isomorphic.

## CONCLUSION

This study introduces new concepts related to cohesive fuzzy graphs, specifically focusing on weak isomorphism, co-strong isomorphism, and isomorphism. It establishes that cohesive fuzzy graph isomorphism is an equivalence relation, while weak isomorphism is a partial ordering. Additionally, the study defines self-complementary cohesive fuzzy graphs and discusses some associated findings.

### ABSTRACT

Since mobile nodes have limited power resources, sustainability and performance of mobile ad hoc networks (MANET) rely mostly on energy efficiency. This paper presents a new approach aimed to maximize energy utilization in MANETS: the Stable Election Protocol with Energy-Aware Cluster Formation (SEP-EACF). Reliable election algorithms mixed with energy-aware clustering methods help to achieve balanced energy consumption and extend the operational lifetime of the network. By selecting cluster leaders based on communication reliability and residual energy, the protocol guarantees a more uniform allocation of network energy usage. The energy-aware cluster construction technique reduces needless transmissions and control message overhead, therefore saving yet more energy. The proposed SEP-EACF protocol significantly increases MANET energy efficiency, hence boosting their robustness and sustainability in dynamic, resource-limited wireless environments. Simulation results have been achieved using many performance criteria from present methods.

**Keywords:** Cluster Head, Cluster Formation, Energy, MANET, SEP-EACF

## INTRODUCTION

A self-organized MANET is a kind of dynamic network in which nodes can interact with one another and move about at random without relying on any preexisting network architecture [1–5]. When traditional wired or wireless

**Sivaranjani et al.,**

networks are down, overcrowded, damaged, or destroyed, MANETs can step in to help with things like schools and conferences. Rescue operations, disaster relief, tactical battlefields, schools, and emergency situations all fall within this category [6-7]. By using MANET, this dependence on static network architecture is reduced. In a MANET, every node serves as a switch in the network. There is complete freedom of movement and dynamic connection between all nodes [8-9]. Terminals within the network are free to relocate in relation to one another, and the whole network itself is movable [10]. The nodes that move about in dynamic networks also play the role of routers, finding and keeping track of connections to other nodes. The nodes might be situated in or on everything from aircraft and ships to trucks and vehicles, and even on humans or incredibly tiny electronics [11–12]. Because it is wireless and mobile, the network relies on batteries, which have a limit on how long they can last. Energy becomes critical for extending the network's lifespan [13–14] due to the finite battery power of a node. Node If a node's energy becomes too low or runs out entirely, it will not only limit the node's lifespan but also its capacity to transmit packets on behalf of other nodes. This is why creating energy sensitive routing methods has been the focus of so much study [15-16]. Both the network and node levels should be considered in energy efficient routing, which aims to decrease energy usage. The optimal path, from the viewpoint of the network, is the one that uses the least amount of energy; optimally, from the viewpoint of the nodes, it is the one that avoids the nodes with the lowest energy levels [17–18]. This study mostly makes three kinds of contributions. First, it suggests a new stable election mechanism based on residual energy and communication stability those results in more equal energy usage throughout the network. Second, it presents an energy-aware cluster building technique that lowers control overhead and lowers energy waste thereby increasing the operational lifespan of the network. At last, this work shows via large-scale simulations that in dynamic MANET contexts SEP-EACF beats current energy efficiency, latency, and PDR algorithms. Through addressing the important problem of energy efficiency, SEP-EACF opens the path for more durable and sustainable MANET installations, thus contributing significantly to wireless communication. This work is divided mainly as follows. Many authors cover several cluster head choosing techniques covered in Section 2. Section 3 features the proposed model. Section 4 compiled the findings of the research. Section 5 ends with a review of the outcome and the following tasks.

### Background Study

Aftab, F. et al. [1] One bio-inspired MANET clustering technique is SOCZBM, which is based on self-organization. The SOCZBM algorithm's zone-based node deployment technique guarantees stability in cluster-based topologies. The effectiveness and efficiency of SOCZBM are enhanced by its straightforward node deployment approach and CH selection process, which is inspired by bio-flocking mechanisms. Hamza, F., & Celestin Vigila, S. M. [5]The Hybrid PSO-GA methodology is used to develop an Energy-Efficient CH Selection method. Clustering makes use of the Soft k-means algorithm, which optimizes cluster formation by considering node location, speed, and distance. To cluster nodes according to characteristics like location, speed, and distance, the soft k-means algorithm is used. Sharada, K. A. et al. [9]these authors research shows that the AACDIC Algorithm outperforms its predecessors in wireless sensor networks (WSNs) and provide a thorough assessment of its performance. Extensive simulations and comparisons have shown that the technique is effective in improving network efficiency, especially when it comes to reducing the frequent CH re-elections, which have been a constant problem with previous clustering algorithms.

### Problem definition

The basic problem is that present MANET clustering and routing technologies might ignore the differential energy use across nodes. This results in certain nodes—especially those acting as cluster leaders—exhaust their energy faster than others. This reduces the efficiency of the network as well as increases the likelihood of network failures. Furthermore aggravating energy consumption and therefore taxing the already limited energy resources are frequent re-clustering and redundant data transfers resulting from node mobility. Therefore, the challenge is to design a protocol capable of effectively controlling and optimizing energy consumption across all nodes in a MANET thereby ensuring that energy usage is balanced and that the network is operational for as long as practically possible. While under node mobility and dynamic network conditions the recommended strategy must also reduce control overhead and redundant transmissions while maintaining good communication and connectivity.

**Sivaranjani et al.,**

**STABLE ELECTION PROTOCOL WITH ENERGY-AWARE CLUSTER FORMATION**

Among many parameters, cluster heads in SEP-EACF are selected based on residual energy, communication reliability, and node stability. This approach ensures that cluster heads—that is, nodes with sufficient power and dependable communication links—are chosen to help fairly distribute the energy consumption around the network. Included in the protocol there is an energy-aware cluster formation technique designed to cut pointless transmission. **The proposed architecture is represented in Figure 1.**

**NETWORK MODEL**

Assuming these things before network configuration:

- a)  $N_d$  is the set of all network nodes whereby  $n_i$  is a member of  $N_d$ . Referring to BS or the closest cluster head, a node  $n_i$  notes its neighbors ( $N_d$ ) and location  $I$  (LOC $_i$ ).
- b) Every network node  $N_d$  possesses equal functional and energy characteristics.
- c) Every  $N_d$  node is distributed at random. They do not move; they function as stationary nodes following deployment.
- d) Every network node possesses location awareness, granting access to every other node's locations.

**Model for Energy Utilization**

Comparable to those published in the literature, the energy consumption model presented in the proposed study reflects (Shamkuwar, Shukla, & Manjhi 2014). Equation 1 contains the definition of energy consumed in data transmission.

$$E_t(k, d) = \begin{cases} E_{elec} \cdot k + \epsilon_{fs} \cdot k \cdot d^2, & d < d_0 \\ E_{elec} \cdot k + \epsilon_{mp} \cdot k \cdot d^2, & d \geq d_0 \end{cases} \quad \text{----- (1)}$$

$d_0$  is expressed as mentioned in equation 2.

$$d_0 = \sqrt{\frac{\epsilon_{fs}^2}{\epsilon_{mp}}} \quad \text{----- (2)}$$

$$E_r(k) = E_{elec} \cdot k \quad \text{----- (3)}$$

Energy consumed while reception of data is defined as mentioned in equation 4.

$$E_o(k) = E_{elec} \cdot k \quad \text{----- (4)}$$

While  $d$  is less than  $d_0$  (threshold distance), the free space propagation model is used for power amplification; otherwise, the multipath fading model is used.

The formula used for calculating distance  $d$  using the RSSI measure is as described in equation 5

$$d = 10^{\frac{[RSSI - A]}{10 \cdot n}} \quad \text{----- (5)}$$

RSSI - Received Signal Strength Indicator,  $n$  - Path fading factor (value usually ranges from 2 to 5) where  $A$  - RSSI computed from one meter away from the transmitting point.

The total energy consumed by a node  $n_i$  is expressed as in equation 6.

$$E(n_i) = E_t(kn_i, d) + E_r(kn_i) + E_o(kn_i) \quad \text{----- (6)}$$

**STABLE ELECTION PROTOCOL**

Steady Election Protocol (SEP), a variant of the LEACH protocol, takes nodes' remaining energy into account prior to beginning the cluster head selection process. Whether cluster heads have energy over the threshold is determined independently of the cluster head selection procedure. For the next round, can keep the present cluster heads and use the same member nodes as cluster leaders. This procedure is repeated until all rounds have been completed. As a result of reducing the number of cluster heads chosen, this SEP technique reduces energy loss in each node by lowering the overhead of the selection process.

Sivaranjani et al.,

The Stable Cluster Head selection approach is shown in Figure 3.2 Based on the above assumptions, we can calculate the predicted number of Cluster heads selected in each Static LEACH cycle. We start with a network of Nd sensor nodes and a probability of PCH for picking cluster heads from that set.

$$CH_{Static} = P_{CH} \times N \tag{7}$$

Should R be the overall number of rounds, the total number of cluster chiefs chosen in LEACH is:

$$CH_{LEACH} = P_{CH} \times N \times R \tag{8}$$

The probability of nodes having energy greater than the threshold is  $P(E_R > E_{TH})$ , given that the residual energy threshold is  $E_{TH}$  and the energy in nodes is  $E_R$ . Following is the formula for calculating the new number of cluster heads selected ( $CH_{New}$ ) in SEP that satisfy the condition  $E_R > E_{TH}$ .

$$CH_{D-LEACH} = P(E_R > E_{TH}) \times P_{CH} \times N \times R \tag{9}$$

In the first phase of the SEP protocol, every node considers the likelihood of becoming a cluster leader and the remaining energy in the second round. This decision is driven by a value between 0 and 1, which is chosen at random by node n.

$$T(n) = \begin{cases} \frac{p}{1-p \times (r \bmod \frac{1}{p})} & \text{if } n \in G \text{ and } E_R(n) > E_{TH} \\ \text{else} & \end{cases} \tag{10}$$

Where  $E_R(n)$  is residual energy of node n and  $E_{TH}$  Is the threshold for residual energy.

$$E_{D-LEACH} = \sum_{R=1}^R P(E_R > E_{TH}) \cdot N \cdot P_{CH} \cdot E_o + E_{Data} \tag{11}$$

The quantity  $P(E_R > E_{TH})$  in the equation above determines the number of cluster chiefs chosen in each round. Reducing the threshold for residual energy in SEP lowers the overall number of cluster heads selected, thereby lowering the energy usage relative to Static LEACH and LEACH processes.

**ENERGY-AWARE CLUSTER FORMATION**

A new phase of cluster formation has begun in the SEP-EACF Protocol. At this stage, nodes that are not at the head of the cluster figure out how to be part of a cluster, with an eye toward maximizing energy efficiency while making use of features like Stable's long-range capabilities and the secure ledger system offered by Energy Efficiency. Nodes that are not part of the cluster head get improved ad messages with information about stability and energy efficiency. This is because these communications can go farther and more reliably than before. With the announced cluster heads in mind, nodes calculate the energy cost of connecting with them. Energy Efficiency calculations' extra energy demands and stable energy profiles both have an impact on the final price tag. Incorporating the components mentioned in Eqn. 12, the revised energy cost equation is

$$E_{cost} = E_{elec} \times d^2 + \epsilon_{amp} + E_{stable} \tag{12}$$

The decision-making process also takes into account the energy consumption caused by Energy Efficiency processes, such as cryptographic processing for safe data transfer. An association is noted on the Energy Efficiency after a node chooses a cluster leader. The node-cluster head relationship is protected by this immutable record, which prevents any attempt at revocation. This method is useful for building a reliable and extensible network, keeping it up and running for longer, and keeping data secure. Above, we can see an example of a simple cluster formed using the SEP-EACF Protocol. Here in this virtual setting. Cluster leaders, selected at random from the collection of nodes, are shown by the red triangles. Nodes outside of clusters are shown by the blue circles. The gray lines show the connections between nodes that are not cluster heads and the closest cluster head, according to the minimal communication energy requirement.

<b>Algorithm: Stable Election Protocol with Energy-Aware Cluster Formation</b>	
<b>Input:</b>	<ul style="list-style-type: none"> <li>• <math>G = (V, E)</math>: The graph representing the MANET, where <math>V</math> is the set of nodes, and <math>E</math> is the set of edges.</li> <li>• <math>E_{residual}(v)</math>: Residual energy levels of nodes in <math>V</math>.</li> <li>• <math>\alpha</math>: Weight factor for energy in cluster head election.</li> <li>• <math>\beta</math>: Weight factor for communication stability in cluster head election.</li> </ul>
<b>Steps:</b>	<ol style="list-style-type: none"> <li>1. Initialize cluster heads:             <ul style="list-style-type: none"> <li>○ Set <math>ClusterHeads = \emptyset</math></li> </ul> </li> <li>2. Compute Node Score:</li> </ol>

**Sivaranjani et al.,**

- For each node  $v$  in  $V$ :
    - Compute  $NodeScore(v) = \alpha \cdot Eresidual(v) + \beta \cdot CommunicationStability(v)$  where  $CommunicationStability(v)$  represents the stability of communication for node  $v$ .
  - 3. Elect Cluster Heads:
    - Sort nodes based on Node Score in descending order.
    - Start with the highest-scoring node:
      - If node  $v$  is not already a Cluster Head and does not interfere with existing Cluster Heads:
        - Add  $v$  to  $ClusterHeads$
        - Mark neighboring nodes of  $v$  as ineligible for Cluster Head election.
      - Continue this process until no eligible nodes remain.
  - 4. Output  $ClusterHeads$
- Output:**
- Cluster heads: Selected cluster heads in the network.

Algorithm 1 represents the Stable Election Protocol with the Energy-Aware Cluster Formation (SEP-EACF) algorithm, which selects cluster heads in a mobile ad hoc network (MANET) by prioritizing nodes based on a weighted score that balances residual energy and communication stability. Initially, the algorithm computes a score for each node using a combination of its residual energy and communication stability, with weights  $\alpha$  and  $\beta$  determining the importance of each factor. Nodes are then sorted by their scores, and the highest-scoring nodes are chosen as cluster heads, provided they do not interfere with existing cluster heads and their neighbors are marked as ineligible for further selection.

## RESULTS AND DISCUSSIONS

We assess our proposed approach using the NS2 Simulator. The assessment and understanding of the results produced by using the SEP-EACF algorithm in the context of MANETs rests fundamentally on the conclusions and discussion phase. This section clarifies the performance and implications of the algorithm for the MANET Process by means of actual data and concepts collected via simulations and experiments.

### Throughput Comparison

$$Throughput = \frac{Payload\ size}{Packet\ transmission\ time} \times 100 \quad \text{----- (13)}$$

Table 3 and Figure 4 demonstrate that in packet transmission time and throughput the proposed SEP-EACF system beats the DEEC and HPSO-GA protocols. With 3.3 milliseconds, SEP-EACF boasts the shortest packet transmission time among DEEC's 3.9 milliseconds and HPSO-GA's 3.4 milliseconds, therefore signaling speedier data delivery. Furthermore regularly achieving better performance throughout all payload sizes, SEP-EACF peaks at 757.58 Mbps for a 250-byte payload, exceeding both DEEC and HPSO-GA. This implies that because SEP-EACF provides faster and more consistent data transfer and is the most efficient protocol.

### Energy

$$EnergyConsumption (E) = Power (P) \times Time (t) \quad \text{----- (14)}$$

Over different running durations, Table 4 and Figure 5 show the energy consumption of three protocols—DEEC, HPSO-GA, and SEP-EACF—so stressing the efficiency of SEP-EACF. With its low power demand of 0.003 Watts, SEP-EACF constantly displays the lowest energy consumption, thereby greatly reduces energy use during all running hours. For example, SEP-EACF runs only 0.15 Joules in 50 hours of operation, whereas DEEC runs 1 Joule and HPSO-GA runs 0.5 Joules. This suggests that SEP-EACF is the most energy-efficient technique; hence it is perfect for uses where lowering energy usage is absolutely important.

### TIME DELAY

$$TransmissionDelay = \frac{packet\ size\ in\ bits}{transmission\ rate} \quad \text{----- (15)}$$

Sivaranjani et al.,

Emphasizing the efficiency of SEP-EACF, Table 5 and Figure 6 demonstrate the transmission delays for various packet sizes across three protocols—DEEC, HPSO-GA, and SEP-EACF. Given its greatest transmission rate of 10 Mbps, SEP-EACF often has the lowest transmission latency. With a 100-bit packet size, for instance, SEP-EACF has a 10-millisecond delay; DEEC and HPSO-GA have greater delays of 16.67 ms and 11.76 ms correspondingly. This shows that SEP-EACF is more efficient for uses needing speedy and effective data transfer as it can transport data faster.

#### Packet Delivery ratio

$$PDR = \frac{\text{Number of Packets Receive}}{\text{Total Packets}} * 100 \quad \text{----- (16)}$$

Emphasizing SEP-EACF's excellent performance, Table 6 and Figure 7 show the Packet Delivery Ratio (PDR) for DEEC, HPSO-GA, and SEP-EACF protocols. With minimum packet loss of only 0.1%, SEP-EACF routinely achieves the greatest PDR across various amounts of packets, hence producing almost flawless delivery rates (e.g., 99.9% for 100 packets and higher). Though it falls short of SEP-EACF, HPSO-GA performs quite well with a somewhat greater packet loss of 0.3%. Among the three DEEC has the lowest PDR with a 0.6% packet loss. This suggests that for applications with high delivery accuracy, SEP-EACF is the most dependable protocol guaranteeing data packets reach their target.

#### Packet Loss Ratio

$$\text{Packet Loss Ratio} = 100 - PDR \quad \text{----- (17)}$$

Table 7 and Figure 8 show the Packet Loss Ratio (PLR) for DEEC, HPSO-GA, and SEP-EACF protocols, thereby showing that SEP-EACF has the lowest packet loss throughout all circumstances. With a loss percentage as low as 0.1% for packet counts of 100 and more, SEP-EACF shows better dependability than HPSO-GA, which has somewhat greater losses (e.g., 0.6% for 100 packets), and DEEC, which shows the greatest packet loss (e.g., 2.4% for 50 packets). < This suggests that SEP-EACF is the most efficient method in reducing data loss, so it is especially helpful for uses requiring great data integrity and dependability.

## CONCLUSIONS

We presented in this study the Stable Election Protocol with Energy-Aware Cluster Formation (SEP-EACF), a novel technique designed to enhance MANET energy economy. Knowing the critical necessity of energy economy in MANETs, where nodes operate on limited battery life, SEP-EACF addresses the issue by aggregating dependable election protocols with an energy-aware cluster construction method. To achieve more uniform energy usage throughout the network and to increase the network's operational lifespan, the protocol selects cluster heads according to remaining energy and communication stability. Reducing unnecessary data transfers and control message overhead by the energy-aware cluster construction technique helps yet further in saving energy. Regarding energy efficiency, network lifetime, and overall network performance, our simulation results suggest that SEP-EACF far surpasses present approaches. Studies of transmission delays, energy consumption, packet delivery and loss ratios show that SEP-EACF outperforms DEEC and HPSO-GA in all significant performance categories. By means of a maximum transmission rate of 10 Mbps, SEP-EACF achieves the fastest transmission delays, therefore translating speedier data delivery. Its lowest energy usage also emphasizes its power use efficiency. Moreover displaying remarkable dependability in ensuring data integrity, SEP-EACF maintains the lowest Packet Loss Ratio (PLR) and the highest Packet Distribution Ratio (PDR). Although DEEC shows longer transmission delays, greater energy consumption, and a higher packet loss rate, HPSO-GA performs better than DEEC but does not suit SEP-EACF. SEP-EACF is therefore the most trustworthy and efficient protocol accessible for uses requiring fast, energy-efficient, and precise data transport. For further to concentrate on Black Hole attack detection using many ML techniques.

### ABSTRACT

Accurate rainfall forecasting is critical for water resource management, agricultural planning, and disaster preparedness. This study presents a comparative analysis of two advanced time series forecasting models Support Vector Regression (SVR) and Seasonal Auto Regressive Integrated Moving Average (SARIMA) to predict rainfall from 2022 to 2026. Historical rainfall data from 2008 to 2021 is used to model the temporal patterns SARIMA a traditional statistical model is compared with SVR, a machine learning approach that handles non-linear relationships in time series data. The results show that while both models provide reasonable forecasts, SVR demonstrates a higher accuracy in predicting complex patterns due to its ability to capture non-linear dependencies. The findings showcase the prominence of machine learning in enhancing rainfall prediction models offering valuable insights for stakeholders in agriculture, environment and water management.

**Keywords:** SARIMA, SVR, Time Series, Rainfall Prediction

Rithika et al.,

## INTRODUCTION

To predetermine certain aspects in agriculture, water resource management and disaster preparedness, accurate forecasting of rainfall plays a vital role. Due to the highly unpredictable nature of weather and climate patterns, developing robust models for rainfall prediction has become a pressing challenge, particularly in regions dependent on monsoons. Numerous statistical models have been developed over the years to forecast rainfall, with varying degrees of success. Recently, the use of ML techniques has formulated as a promising alternative as they capture both linear and non-linear dependencies in time series data. Traditionally, the Seasonal Auto Regressive Integrated Moving Average (SARIMA) model has been widely used for time series forecasting. SARIMA's key feature is that it accounts for both trend and seasonal components in time series data, making it an effective tool for forecasting climate variables like rainfall. Previous studies have demonstrated the effectiveness of SARIMA in rainfall prediction across different regions. For instance, Mukherjee et al. [1] used SARIMA to forecast monsoon rainfall in India, showing high accuracy in short-term predictions. Similarly, Ahmed and Abdalla [2] employed SARIMA for rainfall prediction in Sudan, achieving reliable seasonal forecasts. However, SARIMA is widely used, the complexity of climatic data may not be fully captured by its linear nature, which often exhibit non-linear patterns due to various environmental factors. In contrast, machine learning models such as Support Vector Regression (SVR) have gained attention for their ability to handle non-linearity and complex interactions within time series data. SVR is a supervised learning model that has shown significant promise in fields such as finance and meteorology. A recent study by Zhang et al. [4] applied SVR to temperature prediction, highlighting its superior performance compared to traditional methods. Additionally, Kumar et al. [5] explored SVR for long-term rainfall prediction in Southeast Asia, demonstrating its capacity to outperform classical models such as ARIMA. This study aims to provide a comparative analysis of the SARIMA model and the SVR algorithm for rainfall prediction. By leveraging historical rainfall data from 2008 to 2021, we forecast the rainfall for the years 2022 to 2026. The SARIMA model is employed to account for the seasonal nature of the rainfall data, while SVR is utilized to capture non-linear relationships. This comparative approach will help identify the model best suited for predicting complex, real-world time series data. The outcomes of this research will offer valuable insights for policymakers and stakeholders in water resource management and agricultural planning.

## LITERATURE REVIEW

Predicting rainfall is essential for applications like agriculture, water resource management, and disaster preparedness. Various statistical and machine learning models are employed for rainfall forecasting, each offering specific strengths and limitations. This section reviews the use of SARIMA and Support Vector Regression (SVR), along with insights into hybrid models and advanced approaches.

### SARIMA Models for Rainfall Forecasting

The SARIMA model, a statistical tool that is widely used for time series forecasting, especially for seasonal data like rainfall. Several studies have shown SARIMA's effectiveness in capturing seasonal patterns. For instance, Mukherjee et al. [1] applied SARIMA to forecast India's monsoon rainfall, while Ahmed and Abdalla [2] used it to predict seasonal rainfall in Sudan. Although SARIMA effectively models seasonal fluctuations, its limitations become evident in handling non-linear or irregular variations, such as those caused by climate change.

### Support Vector Regression (SVR) for Rainfall Prediction

The SVR is a powerful machine learning method used for time series forecasting, especially when traditional models like SARIMA fall short. SVR is known for handling complex, non-linear relationships in data, making it effective for rainfall prediction. Zhang et al. [4] demonstrated that SVR outperformed ARIMA in capturing non-linear trends. Kumar et al. [5] also found that SVR performed better than SARIMA for long-term rainfall forecasts in Southeast Asia.

**Rithika et al.,****Hybrid SARIMA-SVR Models**

Hybrid models that combine SARIMA and SVR have gained attention for their ability to predict rainfall more accurately by leveraging both linear and non-linear modelling capabilities. Guo et al. [7] and Liu and Zhang [8] demonstrated that hybrid SARIMA-SVR models outperformed standalone models in capturing irregular and seasonal patterns, making them highly effective for complex, unpredictable rainfall data.

**Other Advanced Methods for Rainfall Forecasting**

Other advanced techniques, including Random Forest, Gradient Boosting, and LSTM (Long Short-Term Memory) networks, have been applied to rainfall forecasting with success. Random Forest and Gradient Boosting handle large datasets and complex interactions, while LSTM networks excel in predicting time series data with long-term dependencies. Hybrid models combining LSTM and SARIMA further improve accuracy by addressing both seasonal trends and long-term dependencies.

**METHODOLOGY**

This outlines the methods used for predicting rainfall data from 2022 to 2026, focusing on the application of SARIMA and Support Vector Regression (SVR) models.

**Objectives of the Study**

- To apply the SARIMA and SVR models to historical rainfall data and compare their prediction accuracy.
- To evaluate the effectiveness of SVR in capturing non-linear patterns in rainfall data.
- To forecast rainfall for the years 2022 to 2026 and analyze the error metrics for both models.
- To provide recommendations on which model can be adopted for future climate data forecasting.

**Data Collection and Pre-processing**

The dataset consists of yearly rainfall data from 2008 to 2021. The data was normalized for use in the SVR model and seasonal components were identified for the SARIMA model.

**SARIMA Model**

The SARIMA model was employed to identify seasonal trends in the rainfall data. The parameters for the ARIMA part ( $p$ ,  $d$ ,  $q$ ) and ( $P$ ,  $D$ ,  $Q$ ,  $s$ ) were established through grid search and the Akaike Information Criterion (AIC). The model was fitted to the historical data and future values for 2022 to 2026 were forecasted.

**Support Vector Regression (SVR)**

SVR was utilised to analyse the non-linear aspects of the rainfall data. The radial basis function (RBF) kernel was chosen for its ability to effectively capture non-linear patterns. Hyper parameters such as  $C$ ,  $\gamma$ , and  $\epsilon$  were optimized using cross-validation. The SVR model was developed using past data and used to project future rainfall values for 2022 to 2026.

**Hybrid SARIMA-SVR Approach**

A hybrid SARIMA-SVR model was created, integrating the linear seasonal patterns identified by SARIMA with the non-linear residuals modelled by SVR. The SARIMA model predicted the seasonal component, and the SVR model was applied to the residuals for improved accuracy in forecasting.

**Performance Evaluation**

The models were assessed using metrics like Mean Absolute Error and Root Mean Squared Error. These metrics were used to compare the performance of SARIMA, SVR, and the hybrid model in predicting the rainfall from 2022 to 2026.

Rithika et al.,

### Model Description

#### SARIMA (Seasonal Auto Regressive Integrated Moving Average)

SARIMA extends of ARIMA by integrating seasonal components. It estimates future values of a time series based on its previous values, differencing, and moving averages of errors. The SARIMA model is denoted using the following notation:

#### SARIMA (p, d, q) x (P, D, Q, s)

The general SARIMA model is

$$y_t = \Phi_1 y_{t-1} + \Phi_2 y_{t-2} + \dots + \theta_1 \varepsilon_{t-1} + \theta_2 \varepsilon_{t-2} + \dots + \varepsilon_t \text{ ----- (i)}$$

Where:  $y_t$  represents value of the time series at time  $t$ ,  $\Phi$  refers to the coefficients of the autoregressive terms,  $\theta$  denotes the coefficients for the moving average terms,  $\varepsilon_t$  is the error term.

Seasonal components are similarly defined, just applied with a lag of  $s$ .

#### Support Vector Regression(SVR)

SVR is a regression technique that tries to find a hyperplane that best fits the data in a high- dimensional space. It's particularly effective for non- linear relationships.

The general form of SVR is:

$$f(x) = \sum_{i=1}^n (\alpha_i - \alpha_i^*) k(x_i, x) + b \text{ ----- (ii)}$$

where:  $x_i$  represents to support vectors,  $\alpha_i, \alpha_i^*$  are the Lagrange multipliers,  $K(x_i, x)$  is the kernel function, commonly the Radial Basis Function (RBF), which maps the data into higher dimensions and  $B$  is the bias term,

The RBF kernel is defined as:

$$k(x_i, x) = \exp(-\gamma \|x_i - x\|^2)$$

Where:  $\gamma$  controls the width of the RBF kernel and  $C$  is the regularization parameter, This parameters balancing the trade-off between maximizing the margin and minimizing the training error.

#### Enhanced Seasonal Regression Model (ESRM)

To combine predictions from both SARIMA and SVR models, we treat the hybrid model as a two- step process: the SARIMA model capture the linear and seasonal trends, while the SVR model handles the non-linear residual components. Here's how this works in theory:

A time series  $Y_t$  can generally be decomposed into:

$$Y_t = T_t + S_t + R_t \text{ ----- (iii)}$$

The SARIMA forecast for the future can be written as:

$$\hat{Y}_t^{SAR} = \hat{T}_t + \hat{S}_t \text{ ----- (iv)}$$

Where  $\hat{T}_t$  is the predicted trend and  $\hat{S}_t$  is the predicted seasonality for a future time point  $t$ .

Once the SARIMA model is fitted, we compute the residuals:

$$R_t = Y_t - \hat{Y}_t^{SAR} \text{ ----- (v)}$$

These residuals represent the portion of the data that the SARIMA model couldn't explain. These residuals contain the non-linear patterns or random fluctuations that SARIMA might miss due to its linear assumptions.

In other words, we use SVR to predict the non-linear patterns in the residuals:

$$\hat{R}_t^{SVR} = SVR(R_t) \text{ ----- (vi)}$$

To create the ESRM, we combine the predictions from  $\hat{Y}_t^{SAR}$  and  $\hat{R}_t^{SVR}$ :

$$\hat{Y}_t^{ESRM} = \hat{Y}_t^{SAR} + \hat{R}_t^{SVR} \text{ from (iv and vi)}$$

Where:  $\hat{Y}_t^{SAR}$  is the SARIMA prediction and  $\hat{R}_t^{SVR}$  is the SVR prediction

Thus, the hybrid model combines the linear and seasonal predictions from SARIMA and the non-linear predictions from SVR to create a more robust forecast.

Rithika et al.,

## CONCLUSIONS

In this paper when comparing SVR, SARIMA and the ESRM model for predicting rainfall. SARIMA offers stability, simplicity and effectively capturing seasonal patterns in linear data but may struggle with non-linear trends. SVR shows greater responsiveness to fluctuations, resulting in more variable predictions, particularly in the years 2024 and 2025 but can risk over fitted in small datasets. The ESRM model effectively combines the strength of both approaches, providing moderate predictions that balance linear and nonlinear adjustments Overall SVR may excel in capturing complex patterns, the ESRM model emerge as the most versatile option, offering robustness and accuracy for varied valid rainfall forecasting scenarios.

### ABSTRACT

The purpose of this paper is to introduce and the notion of  $\mathcal{N}\hat{g}\alpha$ -regular spaces and  $\mathcal{N}\hat{g}\alpha$ -normal spaces. Also discuss the basic properties of  $\mathcal{N}\hat{g}\alpha$ -Normal and  $\mathcal{N}\hat{g}\alpha$ -Regular spaces. Further, we introduce  $\mathcal{N}\hat{g}\alpha$ -regular spaces by using  $\mathcal{N}\hat{g}\alpha$ -closed sets and study some of its properties.

**Keywords:** Nano topological spaces,  $\mathcal{N}\hat{g}\alpha$ -open,  $\mathcal{N}\hat{g}\alpha$ -closed,  $\mathcal{N}\hat{g}\alpha$ -neighbourhood,  $\mathcal{N}\hat{g}\alpha$ -Normal and  $\mathcal{N}\hat{g}\alpha$ -Regular.

## INTRODUCTION

In 1985, Dorsett [2] introduced the notion of semi-normal spaces. In 1996 Arya et.al [1] introduced and investigates the concepts of S-normal spaces. Further, Govindappa Navalagi [3] investigate  $\beta\alpha$ - Regular Spaces and  $\beta\alpha$ - Normal spaces in topology. In 2013, Lellis Thivagar et.al [4] introduced the concept of nano forms of weakly open sets in nano topological spaces. In 2023, Nehmat et.al [5] introduced a novel view of regular and normal spaces via nano  $S_\beta$ -open sets in nano topological spaces. Also Ramesh Pandi [8] et.al, introduced the concepts of almost nano regular spaces.

The structure of this paper is as follows. In section 3 and 4 we defined and study the notion of  $\mathcal{N}\hat{g}\alpha$ -regular spaces and  $\mathcal{N}\hat{g}\alpha$ -normal spaces. Also discuss the basic properties of  $\mathcal{N}\hat{g}\alpha$ -normal and  $\mathcal{N}\hat{g}\alpha$ -regular spaces.

## PRELIMINARIES

**Rajendran et al.,**

In this section, we recollect some basic definitions and results which are used in the subsequent chapters.

**Definition 2.1.** [6] Let  $U$  be a non-empty finite set of objects called the universe and  $R$  be an equivalence relation on  $U$  named as indiscernibility relation. Then  $U$  is divided into disjoint equivalence classes. Elements belonging to the same equivalence class are said to be indiscernible with one another. The pair  $(U, R)$  is said to be the approximation space. Let  $X \subseteq U$ . Then, Let  $U$  be a non-empty finite set of objects called the universe and  $R$  be an equivalence relation on  $U$  named as indiscernibility relation. Then  $U$  is divided into disjoint equivalence classes. Elements belonging to the same equivalence class are said to be indiscernible with one another. The pair  $(U, R)$  is said to be the approximation space. Let  $X \subseteq U$ . Then,

The lower approximation of  $x$  with respect to  $R$  is the set of all objects, which can be for certain classified as  $X$  with respect to  $R$  and is denoted by  $L_R(X)$ .  $L_R(X) = \cup_{x \in U} \{R(x) : R(x) \subseteq X\}$  where  $R(x)$  denotes the equivalence class determined by  $x \in U$ .

The upper approximation of  $x$  with respect to  $R$  is the set of all objects which can be possibly classified as  $X$  with respect to  $R$  and is denoted by  $U_R(X)$ .  $U_R(X) = \cup_{x \in U} \{R(x) : R(x) \cap X \neq \emptyset\}$ .

The boundary region of  $x$  with respect to  $R$  is the set of all objects which can be classified neither as  $X$  nor as not  $X$  with respect to  $R$  and it is denoted by  $B_R(X)$ .  $B_R(X) = U_R(X) - L_R(X)$ .

**Definition 2.2.** [4] Let  $U$  be the universe,  $R$  be an equivalence relation on  $U$  and  $\tau_R(X) = \{U, \emptyset, L_R(X), U_R(X), B_R(X)\}$  where  $X \subseteq U$ . Then  $\tau_R(X)$  satisfies the following axioms

1.  $U$  and  $\emptyset \in \tau_R(X)$ .
2. The union of the elements of any sub-collection of  $\tau_R(X)$  is in  $\tau_R(X)$ .
3. The intersection of the elements of any finite sub collection of  $\tau_R(X)$  is in  $\tau_R(X)$ .

Then  $\tau_R(X)$  is a topology on  $U$  called the nano topology on  $U$  with respect to  $X$ . We call  $(U, \tau_R(X))$  as nano topological space. The elements of  $\tau_R(X)$  are called as nano-open sets. The complement of the nano-open sets are called nano-closed sets.

**Definition 2.3.** [4] Let  $(U, \tau_R(X))$  be a nano topological space and  $A \subseteq U$ . Then  $A$  is said to be

- Nano semi-open if  $A \subseteq Ncl(Nint(A))$ .
- Nano pre-open if  $A \subseteq Nint(Ncl(A))$ .
- Nano  $\alpha$ -open if  $A \subseteq Nint(Ncl(Nint(A)))$ .
- Nano semi pre-open if  $A \subseteq Ncl(Nint(Ncl(A)))$ .

Nano regular-open if  $A = Nint(Ncl(A))$ .

**Remark 2.4.** [4] If  $\tau_R$  is the nano topology on  $U$  with respect to  $X$ , then the set  $B = \{U, L_R(X), B_R(X)\}$  is the basis for  $\tau_R$ .

**Definition 2.5.** [4] If  $(U, \tau_R(X))$  is a nano topological space with respect to  $X$  where  $X \subseteq U$  and if  $A \subseteq U$ , then

The nano-interior of  $A$  is defined as the union of all nano-open subsets of  $A$  and is denoted by  $Nint(A)$ . That is,  $Nint(A)$  is the largest nano-open set contained  $A$ .

The nano-closure of  $A$  is defined as the intersection of all nano-closed sets containing  $A$  and is denoted by  $Ncl(A)$ . That is,  $Ncl(A)$  is the smallest nano-closed set containing  $A$ .

Rajendran et al.,

**Definition 2.6.** [7] A subset  $A$  of  $(U, \tau_{TR}(X))$  is called  $\mathcal{N}\hat{g}\alpha$ -closed if  $\mathcal{N}acl(A) \subseteq G$  whenever  $A \subseteq G$  and  $G$  is  $\mathcal{N}\hat{g}\alpha$ -open set in  $(U, \tau_{TR}(X))$ .

**$\mathcal{N}\hat{g}\alpha$ -REGULAR SPACES**

In this section, we introduce  $\mathcal{N}\hat{g}\alpha$ -regular spaces by using  $\mathcal{N}\hat{g}\alpha$ -closed sets and study some of its properties.

**Definition 3.1.** A nano topological space  $(U, \tau_{TR}(X))$  is said to be  $\mathcal{N}\hat{g}\alpha$ -Regular if for each  $\mathcal{N}\hat{g}\alpha$ -closed set  $F$  and for each  $x \in U - F$ , there exist disjoint nano open sets  $G$  and  $H$  such that  $F \subseteq G$  and  $x \in H$  and it is denoted by  $\mathcal{N}\hat{g}\alpha$ -Regular Space.

**Theorem 3.2.** Let  $(U, \tau_{TR}(X))$  be a nano topological space, then each nano regular space is  $\mathcal{N}\hat{g}\alpha$ -regular space.

**Proof:** Let  $U$  be a Nano-regular space. Let  $F$  be any nano closed set in  $(U, \tau_{TR}(X))$  not containing  $x$  implies  $F$  be  $\mathcal{N}\hat{g}\alpha$ -closed set not containing  $x$ . As  $U$  is  $\mathcal{N}\hat{g}\alpha$ -regular there exists disjoint  $\mathcal{N}\hat{g}\alpha$ -closed sets  $G$  and  $H$ . Such that  $x \in H$  and  $F \subseteq G$ . Therefore  $U$  is  $\mathcal{N}\hat{g}\alpha$ -regular space in  $(U, \tau_{TR}(X))$ .

The converse of the above theorem need not be true, as proved by the following example.

**Example 3.3.** Let  $U = \{a, b, c, d\}$ ,  $X = \{b, c\}$  and  $U/R = \{\{a, b, d\}, \{c\}\}$ . Then  $\tau_{TR}(X) = \{U, \emptyset, \{c\}, \{a, b, d\}\}$  and  $[\tau_{TR}(X)]^c = \{U, \emptyset, \{a, b, d\}, \{c\}\}$ . We have  $\mathcal{N}\hat{g}\alpha-cl(U, X) = \{U, \emptyset, \{c\}, \{a, b, d\}\}$ , then the point  $X = \{a\}$  and  $\mathcal{N}\hat{g}\alpha$ -closed set  $F = \{c\}$  there exists disjoint nano open sets  $G = \{a, b\}$  and  $H = \{c, d\}$  such that  $x \in G$  and  $F \subseteq H$ . Hence  $(U, \tau_{TR}(X))$  is a  $\mathcal{N}\hat{g}\alpha$ -regular space but not nano regular space.

**Theorem 3.4.** The following statements are equivalent for the nanotopological space  $(U, \tau_{TR}(X))$

- (i)  $(U, \tau_{TR}(X))$  is  $\mathcal{N}\hat{g}\alpha$ -regular space.
- (ii) For each  $x \in U$  and each  $\mathcal{N}\hat{g}\alpha$ -open neighbourhood  $A$  of  $X$  there exists a nano-open neighbourhood  $D$  of  $X$ , such that  $\mathcal{N}cl(D) \subseteq A$ .

**Proof:** (i)  $\Rightarrow$  (ii) Suppose  $(U, \tau_{TR}(X))$  is  $\mathcal{N}\hat{g}\alpha$ -regular space. Let  $A$  be any  $\mathcal{N}\hat{g}\alpha$ -open neighbourhood of  $X$ . Then there exists  $\mathcal{N}\hat{g}\alpha$ -open sets  $G$  such that  $x \in G \subseteq A$ . Now  $U - G$  is  $\mathcal{N}\hat{g}\alpha$ -Closed and  $x \notin U - G$ . Since  $(U, \tau_{TR}(X))$  is  $\mathcal{N}\hat{g}\alpha$ -regular. There exists nano open sets  $C$  and  $D$  such that  $U - G \subseteq C$ ,  $x \in D$  and  $C \cap D = \emptyset$  and so  $D \subseteq U - C$ . Now  $\mathcal{N}cl(D) \subseteq \mathcal{N}cl(U - C) \subseteq U - C$  and  $U - G \subseteq C$ . This implies  $U - C \subseteq G \subseteq A$ . Therefore  $\mathcal{N}cl(D) \subseteq A$ .

(ii)  $\Rightarrow$  (i) Suppose (ii) holds. To prove that  $(U, \tau_{TR}(X))$  is  $\mathcal{N}\hat{g}\alpha$ -regular space. Let  $F$  be any  $\mathcal{N}\hat{g}\alpha$ -closed set in  $(U, \tau_{TR}(X))$  and  $x \notin F$ . Then  $x \notin U - F$  and is a  $\mathcal{N}\hat{g}\alpha$ -open and so  $U - F$  is  $\mathcal{N}\hat{g}\alpha$ -neighbourhood of  $X$ . By the hypothesis, there exists a nano open neighbourhood  $D$  of  $X$ . Such that  $x \notin D$  and  $\mathcal{N}cl(D) \subseteq U - F$ . This implies  $F \subseteq U - \mathcal{N}cl(D)$  is a nano open set containing and  $D \cap U - \mathcal{N}cl(D) = \emptyset$ . Hence  $(U, \tau_{TR}(X))$  is  $\mathcal{N}\hat{g}\alpha$ -regular space.

**Theorem 3.5.** A nano topological space  $(U, \tau_{TR}(X))$  is  $\mathcal{N}\hat{g}\alpha$ -regular if and only if for each  $\mathcal{N}\hat{g}\alpha$ -Closed set  $F$  of  $(U, \tau_{TR}(X))$  and each  $x \in U - F$  there exists nano open sets  $G$  and  $H$  of  $(U, \tau_{TR}(X))$ . Such that  $x \in G$ ,  $F \subseteq H$  and  $\mathcal{N}cl(G) \cap \mathcal{N}cl(H) = \emptyset$ .

**Proof:** Suppose  $(U, \tau_{TR}(X))$  is  $\mathcal{N}\hat{g}\alpha$ -regular space. Let  $F$  be a  $\mathcal{N}\hat{g}\alpha$ -closed set in  $(U, \tau_{TR}(X))$  with  $x \notin F$ . Then there exists nano open sets  $M$  and  $H$  of  $(U, \tau_{TR}(X))$  such that  $x \in M$ ,  $F \subseteq H$  and  $M \cap H = \emptyset$ . This implies  $M \cap \mathcal{N}cl(H) = \emptyset$ . As  $(U, \tau_{TR}(X))$  is  $\mathcal{N}\hat{g}\alpha$ -regular, there exists nano open sets  $U$  and  $V$  such that  $x \in U$ ,  $\mathcal{N}cl(H) \subseteq V$  and  $U \cap V = \emptyset$ , So  $\mathcal{N}cl(U) \cap V = \emptyset$ . Let  $G = M \cap U$ , then  $G$  and  $H$  are nano open sets of  $(U, \tau_{TR}(X))$ . Such that  $x \in G$ ,  $F \subseteq H$  and  $\mathcal{N}cl(G) \cap \mathcal{N}cl(H) = \emptyset$ .

Conversely, if for each  $\mathcal{N}\hat{g}\alpha$ -closed set  $F$  of  $(U, \tau_{TR}(X))$  and each  $x \in U - F$ . There exists nano open sets  $G$  and  $H$  Such that  $x \in G$ ,  $F \subseteq H$  and  $\mathcal{N}cl(G) \cap \mathcal{N}cl(H) = \emptyset$ . This implies  $x \in G$ ,  $F \subseteq H$  and  $G \cap H = \emptyset$ . Hence  $(U, \tau_{TR}(X))$  is  $\mathcal{N}\hat{g}\alpha$ -regular.

**Theorem 3.6.** Every subspace of a  $\mathcal{N}\hat{g}\alpha$ -regular space is  $\mathcal{N}\hat{g}\alpha$ -regular.

**Proof:** Let  $(U, \tau_{TR}(X))$  be a  $\mathcal{N}\hat{g}\alpha$ -regular space. Let  $(V, \tau_{TR}(Y))$  be a subspace of  $(U, \tau_{TR}(X))$ . Let  $x \in V$  and  $F$  be a  $\mathcal{N}\hat{g}\alpha$ -closed set in  $(V, \tau_{TR}(Y))$ . Such that  $x \notin F$ . Then there is a nano closed set and so  $\mathcal{N}\hat{g}\alpha$ -closed set  $A$  of  $(U, \tau_{TR}(X))$  with  $F = V \cap A$  and  $x \notin A$  therefore we have  $x \in U$ ,  $A$  is  $\mathcal{N}\hat{g}\alpha$ -closed set in  $(U, \tau_{TR}(X))$ . Such that  $x \notin A$ .

Rajendran et al.,

Since  $(U, \tau_R(X))$  is  $\mathcal{N}\hat{g}\alpha$ -regular, there exists nano open sets  $G$  and  $H$ . Such that  $x \in G, A \subseteq H$  and  $G \cap H = \emptyset$ . Note that  $V \cap G$  and  $V \cap H$  are nano open sets in  $(V, \tau_{R'}(Y))$ . Also  $x \in G$  and  $x \in G \in V$  which implies  $x \in V \cap G$  and  $A \subseteq H$  implies  $V \cap A \subseteq V \cap H, F \subseteq V \cap H$ . Also  $(V \cap G) \cap (V \cap H) = \emptyset$ . Hence  $(V, \tau_{R'}(Y))$  is a  $\mathcal{N}\hat{g}\alpha$ -regular space.

**Theorem 3.7.** The following Statements about a nano topological space  $(U, \tau_R(X))$  are equivalent

- (i)  $(U, \tau_R(X))$  is a  $\mathcal{N}\hat{g}\alpha$ -regular.
- (ii) For each  $x \in U$  and each  $\mathcal{N}\hat{g}\alpha$ -open set  $A$  in  $(U, \tau_R(X))$ , Such that  $x \in A$  there exists a nano open set  $B$  in  $(V, \tau_{R'}(Y))$  Such that  $x \in B \subseteq \mathcal{N}cl(B) \subseteq A$ .
- (iii) For each point  $x \in U$  and for each  $\mathcal{N}\hat{g}\alpha$ -closed set  $F$  with  $x \notin F$ , there exists a nano open set  $B$  containing  $x$  such that  $\mathcal{N}cl(B) \cap F = \emptyset$ .

**Proof:**(i)  $\Rightarrow$  (ii) follows from theorem 3.4

(ii)  $\Rightarrow$  (iii) Suppose (ii) holds, Let  $x \in U$  and  $F$  be a  $\mathcal{N}\hat{g}\alpha$ -closed set of  $(U, \tau_R(X))$ . Such that  $x \notin F$ . Then  $U - F$  is  $\mathcal{N}\hat{g}\alpha$ -open set with  $x \in U - F$ . by the hypothesis, there exists a nano open set  $B$  such that  $x \in B \subseteq \mathcal{N}cl(B) \subseteq U - F$ . That is  $x \in B, B \subseteq \mathcal{N}cl(B)$  and  $\mathcal{N}cl(B) \subseteq U - F$ . So  $x \in B$  and  $\mathcal{N}cl(B) \cap F = \emptyset$ .

(iii)  $\Rightarrow$  (ii) Let  $x \in U$  and  $A$  be a  $\mathcal{N}\hat{g}\alpha$ -open set in  $(U, \tau_R(X))$ . Such that  $x \in A$ . Then  $U - A$  is a  $\mathcal{N}\hat{g}\alpha$ -closed set and  $x \notin U - A$ . Then by the hypothesis, there exists a nano open set  $B$  containing  $x$ . Such that  $\mathcal{N}cl(B) \cap (U - A) = \emptyset$ . Therefore  $x \in B, \mathcal{N}cl(B) \subseteq A$ . So  $x \in B \subseteq \mathcal{N}cl(B) \subseteq A$ .

**Theorem 3.8.**  $\mathcal{N}\hat{g}\alpha$ -regular space  $(U, \tau_R(X))$  into a nano topological space  $(V, \tau_{R'}(Y))$ , then  $(V, \tau_{R'}(Y))$  is  $\mathcal{N}\hat{g}\alpha$ -regular.

**Proof:** Let  $v \in V$  and  $F$  be a  $\mathcal{N}\hat{g}\alpha$ -closed set in  $(V, \tau_{R'}(Y))$  with  $v \notin F$ . Since  $F$  is  $\mathcal{N}\hat{g}\alpha$ -irresolute,  $f^{-1}(F)$  is  $\mathcal{N}\hat{g}\alpha$ -closed set in  $(U, \tau_R(X))$ . Let  $f(x) = v$  so that  $x = f^{-1}(v)$  and  $x \notin f^{-1}(F)$ . Again since  $(U, \tau_R(X))$  is  $\mathcal{N}\hat{g}\alpha$ -regular space, there exists nano open sets  $M$  and  $N$  Such that  $x \in M$  and  $f^{-1}(F) \subseteq N, M \cap N = \emptyset$ . Since  $f$  is nano open sets and bijective, we have  $v \in f(M), F \subseteq f(N)$  and  $f(M) \cap f(N) = f(M \cap N) = f(\emptyset) = \emptyset$ . Hence  $(V, \tau_{R'}(Y))$  is  $\mathcal{N}\hat{g}\alpha$ -regular space.

**Theorem 3.9.** If  $f : (U, \tau_R(X)) \rightarrow (V, \tau_{R'}(Y))$  is  $\mathcal{N}\hat{g}$ -irresolute, nano pre- $\mathcal{N}\hat{g}\alpha$ -closed, continuous injection and  $(V, \tau_{R'}(Y))$  is  $\mathcal{N}\hat{g}\alpha$ -regular, then  $(U, \tau_R(X))$  is  $\mathcal{N}\hat{g}\alpha$ -regular.

**Proof:** Let  $F$  be any  $\mathcal{N}\hat{g}\alpha$ -closed set in  $(U, \tau_R(X))$  with  $x \notin F$ . Since  $f$  is  $\mathcal{N}\hat{g}\alpha$ -irresolute, nano pre- $\mathcal{N}\hat{g}\alpha$ -closed,  $f(F)$  is  $\mathcal{N}\hat{g}\alpha$ -closed set in  $(V, \tau_{R'}(Y))$  and  $f(x) \notin f(F)$ . Since  $(V, \tau_{R'}(Y))$  is  $\mathcal{N}\hat{g}\alpha$ -regular, there exist disjoint open sets  $A$  and  $B$  such that  $f(x) \in A$  and  $f(F) \subseteq B$ . Thus  $x \in f^{-1}(A), F \subseteq f^{-1}(B)$  and  $f^{-1}(A) \cap f^{-1}(B) = \emptyset$ . Hence  $(U, \tau_R(X))$  is  $\mathcal{N}\hat{g}\alpha$ -regular.

**Theorem 3.10.** If  $f : (U, \tau_R(X)) \rightarrow (V, \tau_{R'}(Y))$  is nano continuous, nano  $\alpha$ -open and  $\mathcal{N}\hat{g}\alpha$ -closed, surjection, if  $(U, \tau_R(X))$  is nano regular, then  $(V, \tau_{R'}(Y))$  is nano  $\alpha$ -regular.

**Proof:** Let  $y \in Y$  and  $G$  be a nano open set containing  $y$  of  $(V, \tau_{R'}(Y))$ . Let  $x$  be a point of  $(U, \tau_R(X))$  such that  $y = f(x)$ . Since  $(U, \tau_R(X))$  is nano regular and  $f$  is nano continuous, there exists a nano open set  $A$  such that  $x \in A \subseteq \mathcal{N}cl(A) \subseteq f^{-1}(G)$ . Hence  $y \in f(A) \subseteq f(\mathcal{N}cl(A)) \subseteq G$ . Since  $f$  is a  $\mathcal{N}\hat{g}\alpha$ -closed,  $f(\mathcal{N}cl(A))$  is a  $\mathcal{N}\hat{g}\alpha$ -closed set contained in the nano open set  $G$ . Hence we have  $\mathcal{N}\alpha\text{-cl}(f(\mathcal{N}cl(A))) \subseteq G$ . Therefore  $y \in f(\mathcal{N}cl(A)) \subseteq \mathcal{N}\alpha\text{-cl}(f(A)) \subseteq \mathcal{N}\alpha\text{-cl}(f(\mathcal{N}cl(A))) \subseteq G$ . This implies  $y \in f(\mathcal{N}cl(A)) \subseteq \mathcal{N}\alpha\text{-cl}(f(A)) \subseteq G$  and  $f(A)$  is  $\mathcal{N}\alpha$ -open. Then  $(V, \tau_{R'}(Y))$  is  $\mathcal{N}\alpha$ -regular.

**$\mathcal{N}\hat{g}\alpha$ -NORMAL SPACES**

In this section, we introduce the concept of  $\mathcal{N}\hat{g}\alpha$ -normal spaces and study some of its characterizations.

**Definition 4.1.** A nano topological space  $(U, \tau_R(X))$  is called  $\mathcal{N}\hat{g}\alpha$ -Normal space if corresponding to every pair of disjoint  $\mathcal{N}\hat{g}\alpha$ -closed sets  $A$  and  $B$  of  $U$ , there exists  $\mathcal{N}\hat{g}\alpha$ -open sets  $G$  and  $H$  such that  $A \subseteq G, B \subseteq H$  and  $G \cap H = \emptyset$ . It is denoted by  $\mathcal{N}\hat{g}\alpha$ -normal space.

**Theorem 4.2.** Let  $(U, \tau_R(X))$  be a nano topological space, then each nano-normal space is  $\mathcal{N}\hat{g}\alpha$ -normal space.

**Example 4.3.** Let  $U = \{a,b,c,d\}, X = \{a,b\}$  and  $U/R = \{\{a\},\{c\},\{b,d\}\}$ . Then the nano-open set  $\tau_R(X) = \{U, \emptyset, \{a\}, \{a,b,d\}, \{b,d\}\}$  and the nano closed set  $[\tau_R(X)]^c = \{U, \emptyset, \{b,c,d\}, \{c\}, \{a,c\}\}$ . Then the space  $(U, \tau_R(X))$  is

$\mathcal{N}\hat{g}\alpha$ -normal but not nano-normal, since the pair of disjoint  $\mathcal{N}\hat{g}\alpha$ -closed set  $A = \{b\}$  and  $B = \{d\}$  there exist disjoint  $\mathcal{N}\hat{g}\alpha$ -open sets  $G=\{a,b\}$  and  $H=\{c,d\}$  such that  $A \subseteq G$  and  $B \subseteq H$ . Hence  $(U, \tau_R(X))$  is  $\mathcal{N}\hat{g}\alpha$ -normal space but not nano normal space.

**Theorem 4.4.** A  $\mathcal{N}\hat{g}\alpha$ -closed subspace of a  $\mathcal{N}\hat{g}\alpha$ -normal space is  $\mathcal{N}\hat{g}\alpha$ -normal.

**Proof:** Let  $(U, \tau_R(X))$  be a  $\mathcal{N}\hat{g}\alpha$ -normal. Let  $(V, \tau_{R'}(Y))$  be a  $\mathcal{N}\hat{g}\alpha$ -closed subspace of  $(U, \tau_R(X))$ . Let  $A$  and  $B$  be a pair of disjoint  $\mathcal{N}\hat{g}\alpha$ -closed sets in  $(V, \tau_{R'}(Y))$ . Then  $A$  and  $B$  are disjoint  $\mathcal{N}\hat{g}\alpha$ -closed sets in  $(U, \tau_R(X))$ . Since  $(U, \tau_R(X))$  is  $\mathcal{N}\hat{g}\alpha$ -normal, there exists disjoint nano-open sets  $G$  and  $H$  in  $(U, \tau_R(X))$ . Such that  $A \subseteq G$  and  $B \subseteq H$ . Since  $G$  and  $H$  are nano-open in  $(U, \tau_R(X))$ ,  $Y \cap G$  and  $Y \cap H$  are nano-open in  $(V, \tau_{R'}(Y))$ . Also we have  $A \subseteq G, B \subseteq H$  implies  $Y \cap A \subseteq Y \cap G, Y \cap B \subseteq Y \cap H$ . So  $A \subseteq Y \cap G, B \subseteq Y \cap H$  and  $(Y \cap G) \cap (Y \cap H) = Y \cap (G \cap H) = \emptyset$ . Thus for each pair of disjoint  $\mathcal{N}\hat{g}\alpha$ -closed sets  $A, B$  in  $(V, \tau_{R'}(Y))$ , there exist disjoint nano-open sets  $Y \cap G$  and  $Y \cap H$  such that  $A \subseteq Y \cap G$  and  $B \subseteq Y \cap H$ . Hence  $(V, \tau_{R'}(Y))$  is  $\mathcal{N}\hat{g}\alpha$ -normal.

**Theorem 4.5.** The following statements for a topological space  $(U, \tau_R(X))$  are equivalent:

- (i)  $(U, \tau_R(X))$  is  $\mathcal{N}\hat{g}\alpha$ -normal.
- (ii) For each  $\mathcal{N}\hat{g}\alpha$ -closed set  $A$  and each  $\mathcal{N}\hat{g}\alpha$ -open set  $R$  such that  $A \subseteq R$ , There exists a nano-open set  $S$ . Such that  $A \subseteq S \subseteq \mathcal{NCl}(S) \subseteq R$ .
- (iii) For any disjoint  $\mathcal{N}\hat{g}\alpha$ -closed sets  $A, B$ , there exists a nano-open set such that  $A \subseteq S$  and  $\mathcal{NCl}(S) \cap B = \emptyset$ .

**Proof:** (i)  $\Rightarrow$  (ii): Let  $A$  be a  $\mathcal{N}\hat{g}\alpha$ -closed set and  $R$  be a  $\mathcal{N}\hat{g}\alpha$ -open setsuch that  $A \subseteq R$ . Then  $A$  and  $U-R$  are disjoint  $\mathcal{N}\hat{g}\alpha$ -closed sets in  $(U, \tau_R(X))$ . Since  $(U, \tau_R(X))$  is  $\mathcal{N}\hat{g}\alpha$ -normal, there exist disjoint nano-open sets  $S$  and  $W$  in  $(U, \tau_R(X))$  such that  $A \subseteq S$  and  $U-R \subseteq W$ . Now  $U-W \subseteq U-(U-R)$ , So  $U-W \subseteq R$  also  $S \cap W = \emptyset$  implies  $S \subseteq U-W$ , so  $\mathcal{NCl}(S) \subseteq \mathcal{NCl}(U-W)$  which implies  $\mathcal{NCl}(S) \subseteq U-W$ . Therefore  $\mathcal{NCl}(S) \subseteq U-W \subseteq R$ . So  $\mathcal{NCl}(S) \subseteq R$ . Hence  $A \subseteq S \subseteq \mathcal{NCl}(S) \subseteq R$ .

(ii)  $\Rightarrow$  (iii): Let  $A$  and  $B$  be a pair of disjoint  $\mathcal{N}\hat{g}\alpha$ -closed sets in  $(U, \tau_R(X))$ . Now  $A \cap B = \emptyset$ , So  $A \subseteq U-B$ , where  $A$  is  $\mathcal{N}\hat{g}\alpha$ -closed and  $U-B$  is  $\mathcal{N}\hat{g}\alpha$ -open. Then by (ii), there exists a nano-open set  $S$  such that  $A \subseteq S \subseteq \mathcal{NCl}(S) \subseteq U-B$ . Now  $\mathcal{NCl}(S) \subseteq U-B$  implies  $\mathcal{NCl}(S) \cap B = \emptyset$ . Thus  $A \subseteq S$  and  $\mathcal{NCl}(S) \cap B = \emptyset$ .

(iii)  $\Rightarrow$  (i): Let  $A$  and  $B$  be a pair of disjoint  $\mathcal{N}\hat{g}\alpha$ -closed sets in  $(U, \tau_R(X))$ . Then form (iv) there exist nano-open sets  $R$  and  $S$  in  $(U, \tau_R(X))$  such that  $A \subseteq R, B \subseteq S$  and  $\mathcal{NCl}(R) \cap \mathcal{NCl}(S) = \emptyset$ . So  $A \subseteq R, B \subseteq S$  and  $R \cap S = \emptyset$ . Hence  $(U, \tau_R(X))$  is  $\mathcal{N}\hat{g}\alpha$ -normal.

**Theorem 4.6.** Let  $(U, \tau_R(X))$  be a nano topological space. Then the following are equivalent.

- (i)  $(U, \tau_R(X))$  is nano-normal.
- (ii) For any disjoint nano-closed sets  $A$  and  $B$ , there exist disjoint  $\mathcal{N}\hat{g}\alpha$ -opensets  $R$  and  $S$  such that  $A \subseteq R$  and  $B \subseteq S$ .
- (iii) For any closed set  $A$  and any nano-open set  $S$  such that  $A \subseteq R \subseteq \mathcal{N}\alpha cl(R) \subseteq S$ .

**Proof:**(i)  $\Rightarrow$  (ii): Suppose  $(U, \tau_R(X))$  is nano-normal. Since every nanoopen set is  $\mathcal{N}\hat{g}\alpha$ -open, (ii) follows.

(ii)  $\Rightarrow$  (iii): Suppose (ii) holds. Let  $A$  be a nano-closed set and  $S$  an nano-open set containing  $A$ . Then  $A$  and  $U-S$  are disjoint nano-closed sets. By (ii), there exist disjoint  $\mathcal{N}\hat{g}\alpha$ -open sets  $R$  and  $W$  such that  $A \subseteq R$  and  $U-S \subseteq W$ , Since  $U-S$  is nano-closed, so  $\mathcal{N}\hat{g}\alpha$ -closed. By theorem, we have  $U-S \subseteq \mathcal{N}\alpha int(W)$  and  $R \cap \mathcal{N}\alpha int(W) = \emptyset$  and so we have  $\mathcal{N}\alpha cl(R) \cap \mathcal{N}\alpha int(W) = \emptyset$ . Hence  $A \subseteq R \subseteq \mathcal{N}\alpha cl(R) \subseteq U-\mathcal{N}\alpha int(W) \subseteq S$ . Thus  $A \subseteq R \subseteq \mathcal{N}\alpha cl(R) \subseteq S$ .

(iii)  $\Rightarrow$  (i): Let  $A$  and  $B$  be disjoint nano-closed sets of  $(U, \tau_R(X))$ . Then  $A \subseteq U-B$  and  $U-B$  is nano-open. There exists a  $\mathcal{N}\hat{g}\alpha$ -open set  $G$  of  $(U, \tau_R(X))$  such that  $A \subseteq G \subseteq \mathcal{N}\alpha cl(G) \subseteq U-B$ . Since  $A$  is nano-closed, it is  $g$ -closed, we have  $A \subseteq \mathcal{N}\alpha int(G)$ . Take  $R = \mathcal{N}int(\mathcal{N}cl(\mathcal{N}int(\alpha(G))))$  and  $S = \mathcal{N}int(\mathcal{N}cl(\mathcal{N}int(U-\mathcal{N}\alpha cl(G))))$ . Then  $R$  and  $S$  are disjoint nano-open sets of  $(U, \tau_R(X))$  such that  $A \subseteq R$  and  $B \subseteq S$ . Hence  $(U, \tau_R(X))$  is nano-normal.

**Theorem 4.7.** Let  $(U, \tau_R(X))$  be a nano topological space. Then the following are equivalent.

- (i)  $(U, \tau_R(X))$  is  $\mathcal{N}\alpha$ -normal.
- (ii) For any pair of disjoint nano-closed sets  $A$  and  $B$ , there exist disjoint  $\mathcal{N}\hat{g}\alpha$ -open sets  $R$  and  $S$  such that  $A \subseteq R$  and  $B \subseteq S$  and  $R \cap S = \emptyset$ .

Rajendran et al.,

Proof:(i)  $\Rightarrow$  (ii): Let  $(U, \tau_R(X))$  be  $\mathcal{N}\alpha$ -normal. Let  $A$  and  $B$  be disjoint nano-closed sets in  $(U, \tau_R(X))$ . Since  $(U, \tau_R(X))$  is  $\mathcal{N}\alpha$ -normal there exist disjoint  $\mathcal{N}\alpha$ -open sets  $R$  and  $S$  such that  $A \subseteq R$ ,  $B \subseteq S$  and  $R \cap S = \emptyset$ . Then  $R$  and  $S$  are  $\mathcal{N}\hat{g}\alpha$ -open sets in  $(U, \tau_R(X))$  such that  $A \subseteq R$  and  $B \subseteq S$  and  $R \cap S = \emptyset$ .

(ii)  $\Rightarrow$  (i): Let  $A$  and  $B$  be disjoint nano-closed sets in  $(U, \tau_R(X))$ . Then by hypothesis there exist disjoint  $\mathcal{N}\hat{g}\alpha$ -open sets  $R$  and  $S$  such that  $A \subseteq R$  and  $B \subseteq S$  and  $R \cap S = \emptyset$ . Since  $A$  and  $B$  be disjoint nano-closed sets in  $(U, \tau_R(X))$ . So  $A$  and  $B$  are  $\mathcal{N}\hat{g}$ -closed sets in  $(U, \tau_R(X))$ . Then by the nano closed,  $A \subseteq \mathcal{N}\alpha\text{int}(R)$ ,  $B \subseteq \mathcal{N}\alpha\text{int}(S)$  and  $\mathcal{N}\alpha\text{int}(R) \cap \mathcal{N}\alpha\text{int}(S) = \emptyset$ . Hence  $(U, \tau_R(X))$  is  $\mathcal{N}\alpha$ -normal.

**Theorem 4.8.** Let  $(U, \tau_R(X))$  be  $\mathcal{N}\alpha$ -normal and  $F \cap A = \emptyset$  where  $F$  is closed and  $A$  is  $\mathcal{N}\hat{g}\alpha$ -closed, then there exist disjoint  $\mathcal{N}\alpha$ -open sets  $R$  and  $S$  such that  $A \subseteq R$  and  $F \subseteq S$ .

**Proof:** Since  $F$  is nano-closed and  $F \cap A = \emptyset$ , we have  $A \subseteq U - F$  and so  $\text{Cl}(A) \subseteq U - F$ . Thus  $\text{Cl}(A) \cap F = \emptyset$ . Since  $\text{Cl}(A)$  and  $F$  are disjoint nano closed and  $(U, \tau_R(X))$  is  $\mathcal{N}\alpha$ -normal. There exist disjoint  $\mathcal{N}\alpha$ -open sets  $R$  and  $S$  such that  $\text{Cl}(A) \subseteq R$  and  $F \subseteq S$ , that is  $A \subseteq R$  and  $F \subseteq S$ .

**Theorem 4.9.** Let  $(U, \tau_R(X))$  be  $\mathcal{N}\alpha$ -normal, then the following hold:

- (i) For each nano closed set  $A$  and every  $\mathcal{N}\hat{g}\alpha$ -open set  $B$  such that  $A \subseteq B$  there exists a  $\mathcal{N}\alpha$ -open set  $R$  such that  $A \subseteq R \subseteq \mathcal{N}\alpha\text{acl}(R) \subseteq B$ .
- (ii) For every  $\mathcal{N}\hat{g}\alpha$ -closed set  $A$  and every nano-open set  $B$  containing  $A$ , there exists a  $\mathcal{N}\alpha$ -open set  $R$  such that  $A \subseteq R \subseteq \mathcal{N}\alpha\text{acl}(R) \subseteq B$ .

**Proof:** (i) Let  $A$  be closed set and  $B$  be  $\mathcal{N}\hat{g}\alpha$ -open set  $B$  such that  $A \subseteq B$ . Then  $A \cap (U - B) = \emptyset$ , where  $A$  is nano-closed set and  $U - B$  is  $\mathcal{N}\hat{g}\alpha$ -closed set, By the theorem 7.3.8, there exist  $\mathcal{N}\alpha$ -open sets  $R$  and  $S$  such that  $A \subseteq R$ ,  $U - B \subseteq S$  and  $R \cap S = \emptyset$ . Then  $A \subseteq R \subseteq U - S \subseteq B$ . Since  $U - S$  is  $\mathcal{N}\alpha$ -closed,  $\mathcal{N}\alpha\text{acl}(R) \subseteq U - S$  and so  $A \subseteq R \subseteq \mathcal{N}\alpha\text{acl}(R) \subseteq B$ .

(ii) Let  $A$  be a  $\mathcal{N}\hat{g}\alpha$ -closed set and  $B$  be an nano-open set such that  $A \subseteq B$ . Then  $U - B \subseteq U - A$ . Since  $(U, \tau_R(X))$  is  $\mathcal{N}\alpha$ -normal and  $U - A$  is  $\mathcal{N}\hat{g}\alpha$ -open set containing the nano-closed  $U - B$ , by hypothesis there exists a  $\mathcal{N}\hat{g}\alpha$ -open set  $G$  such that  $U - B \subseteq G \subseteq \mathcal{N}\alpha\text{acl}(G) \subseteq U - A$ . Thus  $A \subseteq (\mathcal{N}\alpha\text{acl}(G))^c \subseteq U - G \subseteq B$ . Let  $R = (\mathcal{N}\alpha\text{acl}(G))^c$ . Then  $R$  is  $\mathcal{N}\alpha$ -open and  $A \subseteq R \subseteq \mathcal{N}\alpha\text{acl}(R) \subseteq B$ .

**Theorem 4.10.** Let  $(U, \tau_R(X))$  be  $\mathcal{N}\alpha$ -normal and  $\mathcal{N}\alpha$ -space, then for every pair of disjoint sets  $A$  and  $B$  one of which is nano-closed and other is  $\mathcal{N}\hat{g}\alpha$ -closed there exist  $\mathcal{N}\alpha$ -open sets  $R$  and  $S$  such that  $A \subseteq R$  and  $B \subseteq S$  and  $\mathcal{N}\alpha\text{acl}(R) \cap \mathcal{N}\alpha\text{acl}(S) = \emptyset$ .

**Proof:** Let  $A$  be a  $\mathcal{N}\hat{g}\alpha$ -closed and  $B$  be a nano-closed set in  $(U, \tau_R(X))$  such that  $A \cap B = \emptyset$ . Then  $A \subseteq U - B$  and  $U - B$  is nano-open. Since  $(U, \tau_R(X))$  is  $\mathcal{N}\alpha$ -normal, there exists a  $\mathcal{N}\alpha$ -open set  $M$  such that  $A \subseteq M \subseteq \mathcal{N}\alpha\text{acl}(M) \subseteq U - B$ . Since  $A$  is  $\mathcal{N}\hat{g}\alpha$ -closed and  $(U, \tau_R(X))$  is  $\mathcal{N}\alpha$ -space,  $M$  is nano-open and there exists a  $\mathcal{N}\alpha$ -open set  $R$  such that  $A \subseteq R \subseteq \mathcal{N}\alpha\text{acl}(R) \subseteq M \subseteq \mathcal{N}\alpha\text{acl}(M) \subseteq U - B$ . Let  $S = U - \mathcal{N}\alpha\text{acl}(M)$ . Thus  $S$  is  $\mathcal{N}\alpha$ -open,  $B \subseteq S$  and  $\mathcal{N}\alpha\text{acl}(R) \cap \mathcal{N}\alpha\text{acl}(S) = \emptyset$ .

### ABSTRACT

A sub set  $D \subseteq V(G)$  of a fuzzy graph  $G(\sigma, \mu)$  is said to be equitable dominating set if each  $v \in V - D$ , there exists a vertex  $u \in D$  such that  $uv \in E(G)$  and  $|\deg_s(u) - \deg_s(v)| \leq 1$ . An equitable dominating set  $D$  of  $V(G)$  is said to be 2-equitable dominating set in a fuzzy graphs  $G(\sigma, \mu)$ , if every vertex  $v \in V - D$  there exists a vertex  $u \in D$  or  $v$  is equitable dominated by at least two vertices in  $D$ . A sub set  $D \subseteq V(G)$  is said to be total 2-equitable dominating set if  $\forall u \in V$ , there exists  $v \in D$  such that  $u$  is 2-equitable with  $v$  in  $D$ . In this study, total 2-equitable equitable dominating set, its number in fuzzy graphs are introduced. Bounds and some theorems related to total 2-equitable equitable domination numbers are stated and proved.

**Keywords:** Fuzzy graph, equitable dominating set, equitable domination number, 2 - equitable dominating set, total 2 - equitable dominating set, total 2 - equitable dominating number.

2010 AMS Subject Classification: 05C72

## INTRODUCTION

Complementary nil g-eccentric domination fuzzy graphs concepts introduced in 2020. Divisor 2-equitable domination in fuzzy graphs in 2023. The concept isolate g-eccentric domination in fuzzy graph has been introduced in 2023. Upper g-eccentric domination in fuzzy graphs concepts

**Rabeeh Ahamed et al.,**

introduced in 2024. The concept complementary nil equitable domination in fuzzy graphs in 2024, Zadeh, L. A. (1965), Rosenfeld, A. (1975), Dharmalingam, K. M., & Rani, M. (2016), Ismayil, A. M., & Muthupandiyani, S. (2020), Catherine Grace John, J., Xavier, P., & Priyanka, G. B. (2023, March), Muthupandiyani, S., & Ismayil, A. M. (2023), Muthupandiyani, S., & Ismayil, A. M. (2024), Ahamed, T. R., Mohideen, S. I., & Hussain, R. J. (2024).

**Basic Definitions**

**Definition 2.1:** A fuzzy graph  $G = (\sigma, \mu)$  is characterized with two functions  $\sigma$  on  $V$  and  $\mu$  on  $E \subseteq V \times V$ , where  $\sigma: V \rightarrow [0,1]$  and  $\mu: E \rightarrow [0,1]$  such that  $\mu(x, y) \leq \sigma(x) \wedge \sigma(y) \forall x, y \in V$ . We expect that  $V$  is finite and non-empty,  $\mu$  is reflexive and symmetric. We indicate the crisp graph  $G^* = (\sigma^*, \mu)$  of the fuzzy graph  $G(\sigma, \mu)$  where  $\sigma^* = \{x \in V: \sigma(x) > 0\}$  and  $\mu = \{(x, y) \in E: \mu(x, y) > 0\}$ . The fuzzy graph  $G = (\sigma, \mu)$  is called *trivial in this case* if  $|\sigma^*| = 1$ , Ismayil, A. M., & Muthupandiyani, S. (2020).

**Definition 2.2:** A path  $P$  of length  $n$  is a sequence of distinct nodes  $u_0, u_1, \dots, u_n$  such that  $\mu(u_{i-1}, u_i) > 0, i = 1, 2, \dots, n$  and the degree of membership of a weakest arc is defined as its strength, Ismayil, A. M., & Muthupandiyani, S. (2020).

**Definition 2.3:** An edge is said to be strong if its weight is equal to the strength of connectedness of its end nodes. Symbolically,  $\mu(u, v) \geq \text{CONN}_{G-(u,v)}(u, v)$ , Ismayil, A. M., & Muthupandiyani, S. (2020).

**Definition 2.4:** The order and size of a fuzzy graph  $G(\sigma, \mu)$  are defined by  $p = \sum_{u \in V} \sigma(u)$  and  $q = \sum_{uv \in E} \mu(u, v)$  respectively, Muthupandiyani, S., & Ismayil, A. M. (2023).

**Definition 2.5:** Let  $G(\sigma, \mu)$  be a fuzzy graph. The strong degree of a vertex  $v \in \sigma^*$  is defined as the sum of membership values of all strong arcs incident at  $v$  and it is denoted by  $d_s(v)$ . Also, it is defined by  $d_s(v) = \sum_{u \in N_s(v)} \mu(u, v)$  where  $N_s(v)$  denotes the set of all strong neighbors of  $v$ , Ismayil, A. M., & Muthupandiyani, S. (2020).

**Definition 2.6:** A fuzzy graph  $G(\sigma, \mu)$  is connected if  $\text{CONN}(u, v) > 0$  where  $\text{CONN}(u, v)$  is strength of connectedness between two vertices  $u, v$  in  $G(\sigma, \mu)$ , Muthupandiyani, S., & Ismayil, A. M. (2023).

**Definition 2.7:** In a fuzzy graph  $G(\sigma, \mu)$ , strength of connectedness between two vertices  $u, v \in V(G)$  is maximum strength of all paths between  $u, v$  in  $V(G)$ , Muthupandiyani, S., & Ismayil, A. M. (2023).

**Definition 2.8** A subset  $D$  of  $V$  is called a dominating set (DS) in  $G$  if for every  $v \notin D$  there exist  $u \in D$  such that  $u$  dominates  $v$ . The minimum scalar cardinality taken over all dominating set is called domination number and is denoted by the symbol  $\gamma$ . The maximum scalar cardinality of a minimal dominating set is called upper domination number and is denoted by the symbol  $\Gamma$ , Muthupandiyani, S., & Ismayil, A. M. (2023).

**Definition 2.9:** A sub set  $D \subseteq V(G)$  of a fuzzy graphs  $G(\sigma, \mu)$  is said to be equitable dominating set (EDS) if each  $v \in V - D$ , there exists a vertex  $u \in D$  such that  $uv \in E(G)$  and  $|\deg_s(u) - \deg_s(v)| \leq 1$ , Dharmalingam, K. M., & Rani, M. (2016).

**Definition 2.10:** An equitable dominating set  $D \subseteq V$  of a fuzzy graph  $G = (\sigma, \mu)$  is called 2 – equitable dominating set if for every vertex  $v \in V - D$  there exist  $v \in D$  or  $v$  is equitable dominated by atleast two vertices in  $D$ , Catherine Grace John, J., Xavier, P., & Priyanka, G. B. (2023, March).

**Definition 2.11:** An equitable dominating set  $D \subseteq V(G)$  of a fuzzy graph  $G = (\sigma, \mu)$  is said to be total equitable dominating set if each vertex in  $V - D$  has at least an equitable vertex in  $D$ , Dharmalingam, K. M., & Rani, M. (2016).

**Rabeeh Ahamed et al.,**

**Main Results**

**Total 2- Equitable Domination in Fuzzy Graphs**

**Definition 3.1**

A sub set  $D \subseteq V(G)$  of a fuzzy graph  $G(\sigma, \mu)$  is said to be total 2-equitable dominating set if  $\forall u \in V$ , there exists  $v \in D$  such that  $u$  is 2-equitable with  $v$  in  $D$ . A total 2 – equitable dominating set  $D$  is said to be minimal if no proper subset of  $D$  is total 2 – equitable dominating set. The minimum scalar cardinality of a minimal total2 – equitable dominating set of  $G$  is called the total 2 – equitable dominating number of  $G$  and is denoted by  $\gamma_{t2eqd}(G)$ . The maximum scalar cardinality of a minimal total2 – equitable dominating set of  $G$  is called the upper total 2 – equitable dominating number of  $G$  and is denoted by  $\Gamma_{t2eqd}(G)$ .

**Note 3.1:** The minimum total 2 - equitable dominating set is denoted by  $\gamma_{t2eqd}$ -set.

**Example 3.1:** Consider the fuzzy graph  $G(\sigma, \mu)$ .

**Figure: Total 2-Equitable Dominating Set in a Fuzzy Graph**

From the fuzzy graph given in example 3.1, the followings are observed.

1. The minimum dominating set is  $D_1 = \{v_1, v_3\}$  and  $\gamma(G) = 0.4$ .
2. The minimum total dominating set is  $D_2 = \{v_2, v_3\}$  and  $\gamma_t(G) = 0.5$ .
3. The minimum 2-dominating set is  $D_3 = \{v_1, v_3, v_4\}$  and  $\gamma_{2d}(G) = 0.8$
4. The minimum total 2- dominating set is  $D_4 = \{v_1, v_2, v_3, v_4\}$  and  $\gamma_{t2eqd}(G) = 1.0$ .
5. The set  $D_4$  is also an upper total 2- equitable dominating set, then  $\Gamma_{t2eqd}(G) = 1.0$ .

**Observation 3.1: For any connected fuzzy graphs  $G(\sigma, \mu)$**

1.  $\gamma(G) \leq \gamma_{eqd}(G) \leq \gamma_{2eqd}(G) \leq \gamma_{t2eqd}(G)$
2.  $\gamma_{t2eqd}(G) \leq \Gamma_{t2eqd}(G)$ .

**Observation 3.2:** For any FG  $G = (\sigma, \mu)$ ,

1. Every super set of a total 2-equitable dominating set is also a total 2-equitable dominating set.
2. Complement of a total 2-equitable dominating set is no need to be a total 2-equitable dominating set
3.  $\gamma_{t2neqd}$  -set is need not be unique.

**Proposition 3.1:** For any fuzzy graph  $G$  with order  $p$ , then  $\sum_{\substack{v_i, v_j \in G \\ v_i \neq v_j}} \min(\sigma(v_i), \sigma(v_j)) \leq \gamma_{t2eqd}(G) \leq p$ .

**Proof**

Let  $D$  be a total dominating set of a fuzzy graph  $G$  having atleast two vertices has minimum of  $V$  which is a sum of minimum value of vertices  $v_i, v_j \in D, \gamma_{t2eqd}(G) \leq p$  it is obviously true.

**Theorem 3.1:** Let  $G$  be a fuzzy graph,  $\gamma_{t2eqd}(G) = p$  iff the fuzzy graph  $G$  has adjacent to less than two vertices.

**Rabeeh Ahamed et al.,**

**Proof**

Let  $G$  be a fuzzy graph then  $\gamma_{t2eqd}(G) = p$  then definition of fuzzy graph has all vertices in dominating set  $D$ . which shows that every vertex in  $G$  has adjacent to less than two vertices. Conversely,  $G$  be a fuzzy graph has adjacent to less than two vertices then every vertex is in total dominating set. Which is  $\gamma_{t2eqd}(G) = p$

**Theorem 3.2:** Let  $D$  is a minimal total 2 - equitable dominating set then  $V - D$  contains minimal total 2 - equitable dominating set if every vertex of  $V$  in a fuzzy graph  $G$  adjacent to more than two vertices in  $V$ .

**Proof**

Let  $D$  be a minimal total 2 - equitable set of  $G$  suppose that  $V - D$  is not total 2 - equitable dominating set, then there exists atleast one vertex  $v \in D$  which is not equitable adjacent to any vertex in  $V - D$ . Therefore  $V - D$  is 2 - equitable adjacent to atleast two vertices in  $D$  then  $D - \{v\}$  is a total 2 - equitable dominating set which is a contradiction. Hence every vertex in  $D$  must be equitable adjacent to at least two vertices in  $V - D$ . Hence  $V - D$  is total 2 - equitable dominating set which contains minimal 2 - equitable dominating set.

**Corollary 3.1:** Every connected fuzzy graph has minimum total 2 - equitable dominating set  $D$  then  $V - D$  need not be total 2 - equitable dominating set of  $G$ .

**Proof**

Let  $D$  be a total 2 - equitable dominating set of  $G$  satisfies the condition also  $|d(u) - d(v)| \leq 1$ , suppose  $v \in V$ , then  $v$  be in every 2 - equitable dominating set of a fuzzy graph  $G$ , since it has only one neighbor vertex. This one neighbor also strong neighbor of  $v$ . Which shows that every vertex in  $V - D$  does not has two strong neighbors for  $v$ . This implies that  $V - D$  is not a total 2 - equitable dominating set of  $G$ .

**Theorem 3.3:** Let  $G$  be a connected fuzzy graph has no non - equitable edge and  $H$  is spanning subgraph of  $G$  then  $\gamma_{t2eqd}(G) \leq \gamma_{t2eqd}(H)$ .

**Proof:**

Let  $G$  be a connected fuzzy graph and  $H$  is the spanning subgraph of  $H$ . consider  $D$  is minimum total 2 - equitable dominating set of  $G$ ,  $D$  also an total 2 - equitable dominate all the vertices in  $V(H) - D$  that is  $D$  is an total 2 - equitable dominating set in  $H$ . Hence  $\gamma_{t2eqd}(G) \leq \gamma_{t2eqd}(H)$ .

**Theorem 3.4:** For any fuzzy graph  $G$ ,  $\gamma_{2eqd} + \min\sigma(v_i) \leq \gamma_{t2eqd}(G)$ , for  $v_i \notin D$ .

**Proof:**

Let  $D$  be total 2 - equitable dominating set with minimum cardinality  $\gamma_{t2eqd}$ . for any vertex  $v_i \in D$ ,  $D - \{v_i\}$  is 2 - equitable dominating set. Hence  $\gamma_{2eqd} + \min\sigma(v_i) \leq \gamma_{t2eqd}(G)$ .

**Theorem 3.5:** For any fuzzy graph  $G$  without isolated vertices a fuzzy total 2-equitable dominating set  $D$  is minimal if and only if for every  $u \in D$ , one of the following two properties holds.

- (i) There exists a vertex  $v \in V - D$  such that  $N_s(v) \cap D = \{u\}$ ,  $|\deg_s(u) - \deg_s(v)| \leq 1$
- (ii)  $D - \{u\}$  contains no isolated vertices.

**Proof:**

Assume that  $D$  is a minimal fuzzy total 2- equitable dominating set and (i) and (ii) do not hold, then for some  $u \in D$ , there exists  $v \in V - D$  such that  $|\deg_s(u) - \deg_s(v)| \leq 1$  and for every  $v \in V - D$ , either  $N_s(v) \cap D \neq \{u\}$  or  $|\deg_s(u) - \deg_s(v)| \geq 2$ . or both. Therefore  $D - \{u\}$  contains an isolated vertex, which is contradiction to the minimality of  $D$ . Therefore (i) and (ii) holds. Conversely, if for every vertex  $u \in D$ , the statement (i) or (ii) holds and  $D$

Rabeeh Ahamed *et al.*,

is not minimal. Then there exists  $u \in D$ , such that  $D - \{u\}$  is a fuzzy total2- equitable dominating set. Therefore, there exists  $v \in D - \{u\}$  such that  $v$  2-equitable dominates  $u$ . that is,  $v \in N_s(u)$  and  $|\deg_s(u) - \deg_s(v)| \leq 1$ . Hence  $u$  does not satisfy (i). Then  $u$  must satisfy (ii) and there exists  $v \in V - D$  such that  $N_s(v) \cap D = \{u\}$ , and  $|\deg_s(u) - \deg_s(v)| \leq 1$ . And also, there exists  $w \in D - \{u\}$  such that  $w$  is adjacent to  $v$ . Therefore  $w \in N_s(v) \cap D$ ,  $|\deg_s(u) - \deg_s(v)| \leq 1$  and  $w \neq v$ , a contradiction to  $N_s(v) \cap D = \{u\}$ . Hence  $D$  is a minimal fuzzy total2- equitable dominating set.

**Theorem 3.6:** Let  $G$  be a fuzzy graph without isolated vertices. Then  $\gamma_t(G) \leq \gamma_{t2eqd}(G)$

**Proof:**

Every fuzzy total 2- equitable dominating set is a total dominating set. Thus  $\gamma_t(G) \leq \gamma_{t2eqd}(G)$ .

## CONCLUSION

In this research, total 2 - equitable dominating set, its number in fuzzy graphs are obtained. Theorems related to total 2 -equitable dominating set and number are stated and proved. Bounds and some points are observed and discussed.

### ABSTRACT

At currently, the use of the social networking website has grown exponentially. Social media site, Tweet, has generated a large amount of opinion data these times. The evaluation of the opinions is primarily concerned with the interpretation of the emotions and perceptions of the text. Text Mining is an established field in text analysis science. This article reflects on the numerous machine learning (ML) techniques used in opinion interpretation and opinion discovery. In this paper, I have studied various Machine Learning techniques and equated various machine learning algorithms like Decision Trees (DTs), Support Vector Regression (SVR) and Random Forest (RF). In this paper, comparison of some machine learning classifier to analysis and classify the twitters as three polarities such as positive negative and neutral. I used three machine learning model, which gives better classification performance in different polarity classes, that are measured by using different parametric metrics. This approach study will be give better clarification to our future work in machine learning background.

**Keywords:** Opinion analysis, Decision Trees (DTs), Twitter Sentiment Analysis. Support Vector Regression (SVR), and Random Forest (RF).

## INTRODUCTION

Swift creation of social media platforms for micro-blogging. Micro-blogging webtake been one of the main online communities for companies to connect their views, viewpoints and attitudes on various themes[1-2]. Twitter is a commonly used micro - blogging site and social media application that produces a huge volume of knowledge.In light of developments have preferably used social media to evaluate people's views on an invention, problem or case. Also, opinion mining is an essential issue for the production of natural languages. This mechanism decides the text's sentimental inclination as positive, neutral or negative [3-4]. Twitter opinion analysis is important. The purpose focus for science,such a study is useful as it collects and categorises public sentiment by analysing broad social records. However, Twitter data has many features that make it impossible to perform sentiment analysis, as opposed to other forms of data [14] [15] [16] [17] [18] [19]. Twitters are limited to 140 stories portrayed in casual English, with odd phrases and a variety of acronyms and slang terms.In this research, MLmethods are used to answer twitter sentiment analysis.Some classification methods concentrate on predicting trivial class data names. However a rule for forecasting divisions or marks on an ordinal scale includes a variety of problems related to information processing. This form of query, known as ordinal classified or does are. Ordinal regression has gained substantial coverage lately [20] [21] [22] [23] [24]. Linear regression problems in many areas of study are very popular and have mostly been seen as typical insignifcantlyharm that can lead to semi solutions. The current research focuses primarily on the emotion analysis of Twitter messages using various MLalgorithms to solve ordinal regression issues. In this article, I suggest a methodology that involves pre-processing messages, features extraction techniques, and developing a scoring and complementary scheme, and then utilising various MLapproaches to identify tweets in a variety of groups.

## RELATED WORK

Substantial research in the area of sentiment classification have been published on Twitter in recent decades. Dandannavar and Jain[6] checked several measures for Tweet sentiment using ml algorithms. They also presented descriptions of the planned approach to emotion investigation. The method gathered data but instead before the tweets using NLP-based systems. Subsequently, the extraction of features was done to export trend features. Lastly, a model was educated using classification algorithms, such as Naive Bayes, SVM, and DT classifiers. The suggested method carried out sentiment using multinomial DT algorithms. Outcomes have shown that DT perform successfully, demonstrating 100% achieved. M.Z. Asghar, et al, [7] proposed a hybrid classification framework to overcome the issues of incorrect classification. The performance of twitter-based SA systems were improved by using four classifiers such as a slang classifier, a moticon classifier, the Senti WordNet (SWN) classifier, and an better domain specific classifier algorithm. The input text was passed through the first two classifiers such as emoticon and slag, after applying the pre-processing stage. In the final step, SWN-based and domain-specific classification algorithms were used to specifically identify the language. The drawback of the method was the lack of automated domain specific word score even without SWN search process, which may improve the precision of the categorization. Go et al. [8] have a solution for opinion analysis based on twitters using remote supervision has been suggested. In their system, they used training data comprising emoticon tweets that were used as disruptive labels. They developed models using NB classifiers, maximum entropy and SVM. Their characteristics were unigrams, and POS. They decided that Contrast enhancement other prototypes and that unigrams were more powerful as features.

A key for opinion analysis based on posts using remote supervision has been suggested. In their system, they used training samples comprising emoticon tweets that were used as disruptive labels. They developed models using NB classifiers, max entropy (MaxEnt) and SVM. Their characteristics were bigrams, unigrams and POS. They decided that Contrast enhancement other prototypes and that unigrams were more powerful as features. I. Alsmadi and Gan Keng Hoon[10] have designed a supervised term weighting method (SW) to understand the specific qualities of short texts in high-dimensional vector space. The SW approach calculated the length of the paper in order to deal with the shortness of the text. Trials were performed on two datasets, such as a self-composed dataset, to verify the efficacy of SW. Compared to unsupervised methods, the SW system achieved varying and generally better results. The

**Senthil and Kasthuri**

drawback of this SW approach was its descriptive message in social networks, which incorporates the instant existence, the prevalence of misspellings and the high dimensionality of its feature space, which contributes to low results in recognition rate.

**PROPOSED SYSTEM**

In this part, I present the methodology used for this analysis. Essentially, the developed scheme consists of four major components. The first component is data collection, which is a method of capturing labelled tweets to conduct sentiment analysis; the secondary unit, this data set, undergoes multiple pre-processing steps to convert and optimise tweets it into set of data which can be conveniently used for data interpretation. The third unit involves the extraction of the necessary features for the creation of a classification algorithm. Then the method of balancing and ranking tweets is demonstrated. The last unit applies various ML classifiers that define given three tweets. Figure 1 demonstrates the different steps taken to evaluate emotions using ML techniques.

**DATA SOURCES AND COLLECTION**

After data gathering from the STC data set, data pre-processing is taken out in order to increase the accuracy of the data obtained. Tweets had to go through pre-processing phase classification results because the Twitter language has certain special characteristics that might not be important to the classification process, including such usernames, links and hashtags. Figure 2 displays the example twitter picture containing hashtags, the unofficial dialects are omitted.

**TWEETS PREPROCESSING**

Rare tweets are full of noise, misappropriation, and include various acronyms and slang terms. These noisy features also require the efficiency of sentiment analysis approaches. Any pre-processing methods are then implemented prior to the extraction of a function. Pre-processing of tweets contains the following procedures:

- Remove all links ("# hashtag"), retweet (RT) and account links ("@user") that occur in tweets;
- Allows the elimination of recurring letters (e.g., "loovee" became "love");
- sympathising for minimising misspellings and slang words;
- Failed to convert words to physical and financial meanings (conversion of case); replacement of widely used words that have no significant significance, such as nouns, prepositions, and conjunctures (stop elimination of words);
- Apply segmenting phrases into words and phrases called tokens by discarding those letters;
- Please delete redundant data tweets; and
- Replacement of all emoticons with their matching sentiment. Algorithm 1 shows the complete rocess used in the pre-processing of the data set in this paper.

**FEATURE DEMONSTRATION**

After pre-processing, the posts are converted into feature vectors. A commonly documented action recognition technique unigram is used in this study[11-12]. This approach is operating as follows. Suppose  $T = \{t_1, t_2, t_3, \dots, t_n\}$  List of tweets and  $C = \{c_1, c_2, \dots, c_l\}$  is the set of classes allocated to each tweet. The specific tokens (descriptions) that reflect the functionality will be created from this tweet array. Suppose  $F$  is the k-D function set to  $F = \{f_1, f_2, f_3, f_k\}$ . These attributes are defined as  $m \times n$  matrix, where  $m$  is the total of tweets and  $n$  is the number of characters. The interpretation of Unigram recognizes the individual words as features[13]. The Boolean method is used to weigh the concepts of this matrix. That is, if a phrase appears in a tweet, a Boolean value 1, then 0 will be given. Table 1 displays a chunk of the unigram Boolean character illustration for twelve pre-marked tweets, i.e.  $T = \{t_1, t_2, t_3, \dots, t_{12}\}$ , four characters  $F = \{f_1, f_2, f_3, f_4\}$  and two class labels  $C_l = \{c_1, c_2\}$  as an instance dataset. Imputed IT data will be obtained from current Twitter T data.

### Senthil and Kasthuri

#### ML TECHNIQUES

Two simple methods for detecting text-based (tweet) sentiment, namely Lexicon-based and ML-based methods, are available. I use a machine learning method in this analysis. For text categorization and TSA, various types of ML algorithms are used. ML strategies train algorithms with certain existing testing data with defined outputs, allowing new test data to be used. Several ML algorithms like SVR, DT, and RF that are used to construct a research ML classifier.

#### SVR

SVM a collection of supervised learning approaches facilitates the identification of grouping, regression and deviations that are useful for mathematical learning theory. In order to solve segmentation problem, it is possible to expand the help vector classification. This technique is called SVR, which retains all the key features of SVM and follows the same rules for classification as SVM, with just a few small improvements. The vector regression support has three separate architectures: Nu-SVR and Linear SVR.

#### DECISION TREE

DT is a non- feature supervised system widely used for task classification and task regression. It functions on both discrete and numerical response variable. The goal is to construct a template that forecasts the value of a target inconstant by studying the basic rules of judgement derived from the results. The training samples space is showed in a hierarchical model wherein the data is subdivided by the state of the attribute.

#### RANDOM FOREST

RF is a regression and classification methodology based on the set technique which is based on bootstrap tags. Boosting and hauling are the two widely known and used methods for tree classification. The random forest takes the form of trees which can be used to estimate the class mark based on the definite dependent variable for a given data point. Each DT is trained using random features characteristics. To evaluate the sample class, a new instance is used to identify the output mode of each tree. This process is used for numerous speech and language data processing.

## RESULTS AND CONVERSATION

This section outlines the experimental outcome and analysis of the suggested method and also describes the output metric, test configuration, quantitative analysis including comparative analysis. The suggested framework was introduced to use a Python 4GB RAM, 1TB hard disc, 3.0GHz Intel i5 cpu. The efficacy of the proposed system was contrasted with other classification methods and current academic papers focused on twitter databases in order to determine the efficacy of the proposed system. The presentation of the planned method was measured in terms of reliability, recall, recognition accuracy, and f-measurement.

#### EVALUATION METRICS

The classification of opinions can be measured using four indices determined on the two of the three equations: consistency, precision, recall and f-measurement. These efficiency metrics are used to measure our performance of the model.

$$Precision = TP / (TP + FP)$$

$$Recall = TP / (TP + FN)$$

$$F \text{ Measurement} = 2 * Precision * Recall / (Precision + Memory)$$

$$Accuracy = TP + TN / (TP + TN + FP + FN)$$

**Senthil and Kasthuri****PERFORMANCE ANALYSIS**

In this segment, I addressed the performance analysis of the proposed ML model for detecting sentiment study through tweets. The planned technological efficiency is calculated using different parametric parameters, such as precision, recall, F-measurement and accuracy. The table below displays the efficiency analysis of proposed model.

In table 1 displayed that the performance of proposed model. In this performance analysis of machine learning model by using STC dataset. In first SVM ML classifier model is used to classify the twitter data, in this model provide the better accuracy of 0.89% in neutral and F-measure value of 0.89% in neutral tweets. Also recall value of 0.51% in negative tweets. Then DT classifier attained the better accuracy of 0.90% in positive tweet and f-measure value of 0.42% in negative tweets. Finally the random forest classifier attained the better accuracy of 0.71% in positive case and better recall value positive case as 0.64% and F-measure value of 0.74% in neutral tweets. In this machine learning model classifier comparison conclude that the DT performs better classification performance in twitter sentimental data analysis.

**CONCLUSION**

The text of the emotional review is an established area of study in the mining industry. This article touches on many of the ML methods used in sentiment processing and opinion-taking. I correlated and evaluated DT and RF with their assessment parameters: accuracy, precision, recall, and f-measurement. In my research, I find that many writers have problems with consistency and are attempting to address data inconsistency and big data. In addition, I have found a problem with multilingual tweeting and treating strategies. The prospect of a possible study of emotions with other languages can be discussed. As most analysis work deals only with monolingual tweets. It is also important to review all possible tweets in various languages. In this study provide a better idea to implement the ML model to classify the tweets. Further, I will modify the decision Tree classifier to attain better classification in twitter sentimental analysis.

### ABSTRACT

Lung cancer remains a leading cause of cancer-related mortality worldwide, highlighting the critical need for advanced diagnostic tools. Traditional diagnostic methods, such as chest X-rays and CT scans, often face limitations in accuracy, sensitivity, and patient comfort. This study explores the use of machine learning techniques to analyze CT scan images for predicting lung diseases, including lung cancer. The proposed machine learning-based algorithm, leveraging convolutional neural networks (CNNs) and ensemble learning techniques, aims to enhance the accuracy of lung cancer detection and prediction. By analyzing a combination of CT images, patient data, and genetic information, the algorithm shows significant improvements in detection accuracy, sensitivity, and specificity. It incorporates advanced features such as data augmentation, dropout regularization, and RMSprop optimization to improve performance and generalization. The ability to provide precise percentage predictions can aid in personalized treatment planning, reduce unnecessary biopsies, and ultimately enhance patient outcomes. Future work will focus on refining the model, expanding datasets, and exploring new imaging technologies.

**Keywords:** Lung Cancer, Convolutional Neural Networks, Machine Learning, CT Imaging, Data Augmentation

## INTRODUCTION

Lung cancer is a formidable global health challenge, being the leading cause of cancer-related deaths worldwide. According to the World Health Organization (WHO), lung cancer accounts for approximately 2.2 million new cases and 1.8 million deaths annually, making it a significant public health concern (World Health Organization, 2023). The high mortality rate associated with lung cancer is largely due to late diagnosis, which limits treatment options and diminishes survival rates. Early and accurate detection is crucial for improving patient outcomes and survival rates, yet traditional diagnostic methods often fall short in accuracy, sensitivity, and patient comfort.

### Traditional Diagnostic Methods

Conventional diagnostic techniques for lung cancer typically include chest X-rays and computed tomography (CT) scans. Chest X-rays have been a standard tool for initial lung evaluation, but they are limited by their low sensitivity in detecting early-stage cancers and their susceptibility to false positives and negatives [13]. CT scans offer more detailed images and have higher sensitivity compared to X-rays, but they also have limitations. For instance, CT scans can be expensive, expose patients to higher doses of radiation, and may still yield ambiguous results in some cases [7].

### Machine Learning and its Role in Lung Cancer Detection

The integration of machine learning (ML) into medical diagnostics has introduced significant advancements, particularly in the analysis of medical imaging data. Machine learning, a subset of artificial intelligence (AI), enables systems to learn from data, identify patterns, and make predictions with minimal human intervention [8]. In the context of lung cancer, machine learning techniques, especially those involving convolutional neural networks (CNNs), have shown promising results in improving diagnostic accuracy and efficiency.

### Machine Learning Classification Techniques

Machine learning classification techniques are extensively used for diagnosing lung cancer. Traditional algorithms such as decision trees, random forests, and support vector machines (SVMs) have been employed to classify images based on features extracted from CT scans. Decision trees and random forests can handle complex datasets and are relatively easy to interpret, but they may not perform well with high-dimensional data without significant feature engineering [2][3]. SVMs, on the other hand, are effective in high-dimensional spaces and are known for their robustness in classification tasks, but they require careful parameter tuning and are computationally intensive [4].

### Deep Learning Models

Deep learning, a subset of machine learning, has revolutionized medical imaging with its ability to automatically learn features from raw data through multiple layers of processing. Convolutional Neural Networks (CNNs) are particularly adept at analyzing medical images due to their hierarchical structure, which mimics the human visual cortex's processing. CNNs can automatically extract and learn features from CT scans, significantly improving the accuracy of lung cancer detection and classification. Studies have demonstrated that CNNs outperform traditional methods in terms of both sensitivity and specificity in lung cancer diagnosis [10].

### Thermography and CNNs

While less commonly used for lung cancer detection, thermography combined with CNNs represents an innovative approach to identifying abnormal thermal patterns associated with tumors. Thermography measures the heat emitted from the body's surface, which can be indicative of underlying pathological changes. When combined with CNNs, this method could potentially enhance the early detection of lung tumors by analyzing thermal patterns and correlating them with cancerous changes [12]. However, this technique is still under investigation and requires further validation.

**Mohan Kumar and Ida Rose****Ensemble Learning Models**

Ensemble learning involves combining multiple models to improve overall performance. By integrating various machine learning algorithms, ensemble methods can leverage the strengths of individual models and mitigate their weaknesses. Techniques such as bagging, boosting, and stacking have been applied to improve lung cancer detection accuracy. For instance, combining CNNs with other classifiers can enhance the robustness of predictions and reduce the likelihood of false positives or negatives [14]. Ensemble learning has shown promise in various medical imaging tasks, including lung cancer detection, by providing a more comprehensive analysis of the data.

**Feature Selection Techniques**

Effective feature selection is crucial for enhancing model performance and interpretability. In the context of lung cancer detection, selecting the most relevant features from imaging data can significantly impact the accuracy of machine learning models. Techniques such as principal component analysis (PCA) and recursive feature elimination (RFE) are commonly used to reduce the dimensionality of data and focus on the most informative features [6][9]. By improving feature selection, models can achieve better performance and more accurate predictions.

**Emerging Biomarkers**

In addition to imaging data, emerging biomarkers are gaining attention as non-invasive diagnostic tools for lung cancer. Plasma metabolomics and microRNAs are being studied for their potential to provide early and accurate detection of lung cancer. Plasma metabolomics involves analyzing metabolic profiles in blood samples to identify biomarkers associated with cancer [16]. Similarly, microRNAs are small RNA molecules that regulate gene expression and have been identified as potential biomarkers for various cancers, including lung cancer [1]. These non-invasive methods, when combined with machine learning techniques, could offer new avenues for early detection and personalized treatment.

**LITERATURE SURVEY**

The use of machine learning in medical diagnostics, particularly for lung cancer detection, has seen significant advancements in recent years. This literature survey explores various methodologies, models, and applications of machine learning in the realm of lung cancer diagnosis, highlighting key contributions and identifying areas for further research. Machine learning (ML) has become a transformative tool in medical diagnostics due to its ability to handle large datasets, identify patterns, and provide predictions with high accuracy. Early studies demonstrated the potential of ML in diagnosing various cancers, including lung cancer, through the analysis of medical images and patient data [25]. Convolutional Neural Networks (CNNs) have revolutionized image analysis, including medical imaging. CNNs are designed to automatically and adaptively learn spatial hierarchies of features from input images. They have been widely applied to detect and classify lung cancer from CT scans due to their ability to capture intricate patterns in imaging data. A seminal work by [16] demonstrated the efficacy of CNNs in detecting lung cancer from CT images. Their model achieved high accuracy in classifying lung nodules, outperforming traditional methods. Similarly, the work of [21] illustrated that deep learning models, including CNNs, could achieve performance comparable to that of experienced radiologists in various diagnostic tasks. Various deep learning architectures have been explored to enhance lung cancer detection. For instance, the work by [10] introduced a deep learning model that integrates CNNs with Long Short-Term Memory (LSTM) networks to analyze sequential imaging data, improving temporal prediction capabilities. Their approach achieved superior performance in detecting lung cancer lesions compared to conventional CNN models. Additionally, researchers have investigated transfer learning, where pre-trained models are fine-tuned for specific tasks [27] utilized transfer learning with deep CNNs pre-trained on large datasets like ImageNet, significantly improving model performance in lung cancer detection and classification.

Ensemble learning combines multiple machine learning models to improve prediction accuracy and robustness. In the context of lung cancer detection, ensemble methods such as stacking, bagging, and boosting have been applied

**Mohan Kumar and Ida Rose**

to integrate various models and enhance diagnostic performance. A notable study by [32] explored the use of ensemble learning techniques to combine CNNs with Random Forests and SVMs for lung cancer detection. Their ensemble approach demonstrated improved accuracy and reduced false positives compared to individual models. Similarly, Zhang et al. [30] utilized a stacking ensemble method to combine multiple CNN architectures, achieving high sensitivity and specificity in detecting lung nodules. Effective feature extraction and selection are critical for improving machine learning model performance. Traditional methods often rely on manually engineered features, but recent advancements have focused on automatic feature learning through deep learning models. A study by Xu et al. [33] highlighted the importance of feature extraction in lung cancer detection, comparing various feature extraction methods, including Histogram of Oriented Gradients (HOG) and CNN-based features. Their results demonstrated that CNN-based features outperformed traditional methods, leading to better detection accuracy. Moreover, feature selection techniques, such as Principal Component Analysis (PCA) and Recursive Feature Elimination (RFE), have been employed to reduce dimensionality and enhance model performance. Yang et al. [31] utilized PCA in conjunction with SVMs for lung cancer classification, achieving notable improvements in accuracy and computational efficiency. Integrating patient data and genetic information with imaging data offers a comprehensive approach to lung cancer detection. Studies have shown that combining imaging data with clinical and genetic data can enhance prediction accuracy and provide a more holistic view of the disease. The research by Zhang et al. [29] explored the integration of clinical data, such as smoking history and demographic information, with CT imaging data to improve lung cancer prediction. Their model demonstrated improved performance in identifying high-risk patients and tailoring treatment plans. Similarly, genetic information has been integrated into predictive models to enhance accuracy. The study by Lee et al. [22] incorporated genomic data with imaging features to develop a multi-modal machine learning model for lung cancer detection. Their approach showed promise in identifying genetic markers associated with the disease, leading to more personalized diagnostic and treatment strategies. Emerging biomarkers and non-invasive methods are gaining attention as potential tools for lung cancer detection. Plasma metabolomics, microRNAs, and thermography are being explored as complementary diagnostic approaches. Plasma metabolomics involves analyzing metabolic profiles in blood samples to identify biomarkers associated with lung cancer. The study by Wang et al. [30] identified several metabolites with significant associations with lung cancer, demonstrating the potential of metabolomics in early detection and diagnosis. MicroRNAs, small RNA molecules that regulate gene expression, have also been investigated as biomarkers for lung cancer. The research by Yang et al. [31] identified specific microRNAs associated with lung cancer and integrated them into predictive models, enhancing diagnostic accuracy and providing insights into disease mechanisms. Thermography, which measures heat emitted from the body's surface, has been explored in combination with machine learning models to detect abnormal thermal patterns associated with lung tumors. Moshkforoush et al. [24] demonstrated the potential of thermography and CNNs in lung cancer detection, though this approach requires further validation and refinement. Despite the advancements in machine learning for lung cancer detection, several challenges remain. Data quality, availability, and diversity are critical issues that impact model performance and generalizability. Many studies rely on limited datasets, which may not represent the full spectrum of lung cancer cases [20] [34] [35] [36] [37] [38]. Additionally, integrating machine learning models into clinical practice requires addressing issues related to data privacy, model interpretability, and regulatory approval. Ensuring that models are transparent, explainable, and compliant with medical regulations is essential for their successful adoption [26] [39] [40] [41] [42] [43] [44].

**METHODOLOGY**

The proposed algorithm enhances lung cancer prediction using advanced machine learning techniques:

1. **Data Augmentation:** Creates varied training examples through transformations such as rotation, shifting, shearing, zooming, and flipping to improve model generalization.
2. **Enhanced Convolutional Neural Network (e-CNN):** Utilizes advanced CNN techniques with data augmentation, dropout layers, and RMSprop optimization for better performance [30].

**Mohan Kumar and Ida Rose**

3. **Integration of Data Sources:** Analyzes CT images, patient data, and genetic information to predict lung cancer percentages accurately.

**Algorithm for Lung Cancer Detection Using e-CNN****1. Load and Preprocess the Dataset:**

- Load the image and label datasets from the given path.
- Normalize pixel values (scale between 0 and 1).

**2. Split the Dataset:**

- Split the data into training (80%) and testing (20%) sets.

**3. Data Augmentation:**

- Apply random transformations (rotation, flip, zoom) on the training set to avoid overfitting.

**4. Build e-CNN Model:**

- Add Conv2D layers with ReLU activation.
- Use Batch Normalization after each Conv2D layer.
- Downsample with MaxPooling2D.
- Add Dropout for regularization.
- Flatten the output and add Dense layers with ReLU and Batch Normalization.
- Apply Dropout and use softmax in the output layer.

**5. Compile Model:**

- Use Adam optimizer with a defined learning rate and decay.
- Set loss to sparse categorical cross-entropy.

**6. Train Model:**

- Train the model on the augmented training data for a specified number of epochs.

**7. Evaluate Model:**

- Test the model on the test set to compute loss and accuracy.

**8. Save Model:**

- Save the trained model for future predictions.

**9. Print Evaluation Metrics:**

- Output loss and accuracy on the test set.

**Experiment**

The algorithm was evaluated against datasets obtained from Kaggle that contain images of lung nodules and tumors. Dataset Overview is given as follows

- Total Images: 1190 CT scan slices.
- Number of Cases: 110.
- Classes: Normal, Benign, Malignant.
- Class Distribution:
- Malignant: 40 cases.
- Benign: 15 cases.
- Normal: 55 cases.

Performance metrics accuracy is measured to validate the algorithm's effectiveness along with SVM and Random Forest. The experimental results demonstrated significant improvements over traditional methods, with high sensitivity and specificity. Comparison results show the following accuracies and it is represented in figure 2:

1. **Proposed Model Accuracy:** 0.9846
  2. **SVM Accuracy:** 0.9554
  3. **Random Forest Accuracy:** 0.9725
- **Proposed Model:**
    - **Accuracy:** 98.46%

**Mohan Kumar and Ida Rose**

- **Observation:** The proposed model performs exceptionally well compared to both SVM and Random Forest, achieving the highest accuracy. This is expected given CNN's ability to capture spatial hierarchies and features in images effectively.
- **SVM (Support Vector Machine):**
  - **Accuracy:** 95.54%
  - **Observation:** The SVM model performs well but is slightly less accurate than the proposed model. SVMs can be effective for smaller datasets and simpler tasks but may struggle with complex image data due to their inability to capture spatial features directly.
- **Random Forest:**
  - **Accuracy:** 97.25%
  - **Observation:** The Random Forest model shows good performance and is more accurate than SVM but less so than proposed. Random Forests are generally robust and handle a variety of data types well but might not perform as well as proposed model on image data.

**DISCUSSION**

The proposed model provides the best performance with the highest accuracy, making it the most suitable choice for this image classification task. Both **SVM and Random Forest** are strong performers, the proposed model's superior performance highlights its advantage in tasks involving complex image data due to its specialized architecture. The proposed machine learning algorithm shows substantial improvements in predicting lung cancer percentages. The integration of data augmentation, enhanced CNN techniques, and the incorporation of multiple data sources contribute to its effectiveness. This non-invasive approach provides a promising alternative to traditional diagnostic methods, potentially reducing unnecessary biopsies and improving patient outcomes [17]. Despite the advancements in machine learning and its applications in lung cancer detection, several challenges remain. One major challenge is the need for large and diverse datasets to train and validate models effectively. Current datasets may not always represent the full spectrum of lung cancer cases, which can impact the generalizability of models [20]. Additionally, integrating machine learning algorithms into clinical practice requires overcoming barriers related to data privacy, model interpretability, and regulatory approval. Future research should focus on expanding datasets, improving algorithm robustness, and exploring new imaging technologies. The development of 3D CT scans and other advanced imaging techniques could further enhance the accuracy of lung cancer detection [28]. Collaborative efforts between researchers, clinicians, and regulatory bodies will be essential for the successful integration of machine learning models into routine clinical practice, ultimately improving patient outcomes and advancing the field of lung cancer diagnostics.

**CONCLUSION**

The development of an advanced machine learning algorithm for predicting lung cancer percentages represents a significant advancement in cancer detection. By harnessing machine learning and analyzing comprehensive data, the algorithm offers a powerful tool for early diagnosis and personalized treatment, promising more effective management of lung cancer [18]. Future work will focus on refining the algorithm, expanding datasets, and exploring new imaging technologies to enhance detection and treatment further.

### ABSTRACT

Data mining is the process of examining systems that were previously used to investigate misconduct information that has recently been addressed from a variety of sources in order to find models and instances of violations. Additionally, it may be used to highlight the wrongdoings in a regular way and will generally be employed to build efficiency in resolving the infractions faster. In any case, there are several methods for information mining. Choosing the right information mining techniques is essential to increasing the efficiency of the wrongdoing area. This essay examines the literature on a range of information mining applications, with a focus on those that were used to address misconduct. Additionally, the review clarifies research opportunities and issues related to improper information mining. Furthermore, in order to aid beginners with the evaluation of wrongdoing data mining, this study provides insight into the information digging process for locating models and instances in wrongdoing to be utilized effectively.

**Keywords:** This essay examines the literature on a range of information mining applications, with a focus on those that were used to address misconduct.

## INTRODUCTION

Identification and prevention of crime become important trends in misconduct and very challenging to address infractions. Several studies have discovered several methods to address the wrongdoings that were employed in

**Imthiyas Ahamed et al.,**

many apps. These tests can help speed up the most popular method of resolving misconduct and help automated systems identify the offenders as a result. Additionally, the rapidly advancing technologies can help to resolve such problems. In any event, the designs of misbehavior are always evolving [1]. Information on misbehavior that has lately been stored from various sources tends to increase steadily. Because of this, managing and researching massive amounts of data is extremely difficult and intricate. Information mining techniques use numerous gaining computations to extract hidden information from vast amounts of data in order to address the problems already mentioned. Information mining is the process of dissecting data to find patterns and instances of misconduct. In addition to helping to alarm the criminal identification system, it can help to address the wrongdoings more quickly. This paper provides brief overviews of several information mining executions and guidelines for using information mining techniques to resolve wrongdoings. Additionally, it discusses research gaps and challenges in the field of misconduct information mining. The foundation and problems of information mining are discussed in the next section. In order to resolve the infractions, Segment III lavishly investigates the goals of information mining techniques. Segment IV shows the problems and challenges of the examination. Finally, Segment V completes the review.

**FOUNDATIONS OF DATA MINING**

The practice of examining historical data to identify trends, patterns, and knowledge is known as data mining. The following are the first crucial elements for examination in order to uncover the hidden knowledge: 1) the analysis's data must be accurate and sufficient. 2) Experts experiences and knowledge. Figure 1 show how the information gathered from data mining procedures is applied to help solve issues and make decisions. The next subsections provide an explanation of the data mining analysis approaches.

**ASSOCIATION MINING**

This process is an unassisted learning technique used to identify hidden proficiencies in unlabeled data. Assuming the students receive the unlabeled model information, it is used to resolve the problems. Furthermore, in relation to extensive informational collections, the affiliation rule can identify the intriguing co-occurrences of objects. Two components make up the standard for the fundamental affiliation rule. 1) The left side, often known as the left hand side (LHS), is the precursor. 2) The outcome also referred to as the right hand side (RHS), is on the right side. LHS → RHS is a kind of broad affiliation rule in which LHS and RHS are disjoint thing sets. The RHS thing set is likely to occur in the unlikely event that the LHS thing set occurs. The help and certainty measures, as well as the important factual estimations, should be used in tandem for the successful disclosure of affiliation leads. Such metrics have a value between 0 and 1. This standard is likely to be uninteresting if an affiliation rule has very little assistance. Therefore, the boring affiliation rules are organized using the help measure. The reliability of affiliation rules is examined using the certainty measure. With greater certainty, B will most likely be available in T that contains the specified rule An and B in an exchange set T. Backing and certainty findings should be more noticeable than client-indicated restrictions when identifying co-events between two informative indexes [3].

**CLUSTERING**

Clustering is an unsupervised method of data analysis. This method is used to separate distinct data into one group and the same data into another. There are many different notions in the clustering approaches. Applied fields determine how clustering algorithms are used [9]. Several algorithms, including K-means, Hierarchical Clustering, and Expectation-Minimization, are discussed here for straightforward and efficient clustering techniques.

**CLASSIFICATION**

This process is a controlled learning technique that assigns items to one of many predetermined categories. Generally speaking, the arrangement computations have been used for the few problems that involve a wide variety of applications. It is employed, for example, to classify the records, anticipate coronary sickness, and discriminate between suspicious cars and intruders. The following illustrates the basic concept of grouping: In a characterization task, a gather information also known as info information is used. Each record consists of a class name and the property set. Pre-resolved class is the class mark. Two pieces of information are separated from the collected data. 1)

**Imthiyas Ahamed et al.,**

The train set is randomly distributed and used to create a classifier, also known as a grouping model, to predict the class of the new cryptic record. 2) A test set is an excess set used to evaluate how well the order model exhibits itself. Many intentional approaches, including as choice trees, closest neighbors, Bayes' Hypothesis, brain structure, and others, are used to construct the grouping models.

**CLOUD STORAGE**

The on-demand delivery of processing power, data storage capacity, applications, and other IT resources via a cloud administration platform via the internet with pay-more-only-as-costs-appear pricing is known as cloud storage [1]. Cloud storage provides several forms of support, with information capacity serving as the core component of cloud management. Distributed storage operates in the background while we engage in daily activities, such as watching movies, playing games, exchanging messages, listening to music, and so forth. Distributed storage allows us to store, recover, and reinforce data, create new programs, send code when needed, have websites, and more. Clients can gradually access cloud services via the internet whenever they are interested [2].

**THE METHODS OF DATA MINING FOR CRIME PATTERN ANALYSIS**

These days, a variety of data mining techniques are employed for a variety of purposes, including email filtering, healthcare, science, finance and banking, and criminal activity. Nonetheless, the following categories of crime are the focus of this survey [14].

**Traffic Violation and Border Control**

The real-time traffic surveillance system Police Eyes [15] was created to improve the automatic detection of traffic infractions. They employed the Gaussian mixture model to separate the foreground from the background in the scene captured by IP cameras. The traffic infractions are then examined using violation conditions and the retrieved foreground. In order to establish stronger connections between the traffic offense and regular traffic violation data of large concealed data, Cheng et al. [16] employed rough set theory and association rules. Thongsataporn-watana and Chuenmanus [17] developed a suspect vehicle detection method in the realm of border control and security that uses association rules to examine vehicles with falsified license plates that may have been involved in criminal activity. In order to detect the possible criminal or suspect cars at the border, Reference [6] used association analysis by employing mutual information (MI) and updated the MI formulation with the time heuristic [3]. Sensors are one of the key instruments for data collection. To identify the criminal at the borders, the data gathered from the several sensors is examined. Additionally, the sensors' geographic data is generated with the aid of Geographic Information Systems (GIS). However, the geographic data cannot be used to extract valuable hidden knowledge if the system solely uses GIS techniques. In order to simulate the patterns and trends of crime, Kondaveeti et al. [18] combined GIS tools with data mining techniques (spatial and association data mining techniques).

**Violent Crime**

In order to categorize news items into different types of crimes and develop a criminal model, Reference [1] suggested using the naive bayes algorithm in conjunction with the named entity recognition (NER) approach, which is sometimes referred to as entity or element extraction. Additionally, by training crime data from many websites, the Apriori algorithm is used to identify and generate common patterns in crime. They applied the decision tree approach to crime prediction. According to test results, their technology has an accuracy of over 90% in classifying and predicting crimes. The hotspots are the most effective approach to crime forecasting suggested by [19] for a crime prediction model used in conjunction with the police department of a city in the Northeast of the United States. The segmented multiple metric similarity measure (SMMSM), which is used to identify crime suspects, is suggested by [20] as a way to increase the accuracy of the clustering technique.

**The Narcotics**

The core component of opiate organizations consists of hubs or entertainers and the relationships or connections between them. The depiction of the opiate network evolves throughout time, possibly as a result of hubs and connections being added and the network being evacuated. In order to prevent such attacks, Kaza et al. [21]

**Imthiyas Ahamed et al.,**

developed predictive criminal relationship calculations that were utilized to predict the automobiles that are at fault. They employed multivariate endurance research using the risk proportions of Cox relapse investigation and the special interpersonal organization examination (SNA) approaches. Reference [22] created rule-based classifiers and suggested using sophisticated brain structures. Opiate and response systems of activity (MOAs) of small atoms are useful tools for identifying hazardous substances. To differentiate between patients receiving opiates or other drugs and those with inescapable sepsis, the Fresh TDMn technique with assistance for worldly information mining, as suggested by [23], is used to identify a relationship between the pulse fluctuation (HRV) and the respiration rate inconstancy (RRV). To analyze the relationships between HRV and RRV, they used hourly briefings to make passing decisions. Chauet al. [24] have focused on text extraction and information assortment, which are important tests for information handling. They then used named-element extraction techniques, such as lexical query, artificial intelligence, and irrelevant hand-crafted criteria, to suggest a neural network-based substance extractor.

**Cyber Crime**

The performance of the event ontology approach as apriori knowledge and the method based on Support Vector Machine (SVM) to assess the properties and relations in web pages has been compared in Reference [25] for the detection and prevention of cybercrime for Chinese web sites. These techniques are also applied for reconstructing the criminal mining situation. [26] Suggests a web-based crime analysis system. The news article elements from news websites, blogs, etc., can be extracted using this method. After then, the newspaper stories are divided into two categories: crime and non-crime. To find exact or near duplicate news paper items and eliminate them from the database, it features a duplicate detector. The system identified the crimes and their frequencies using hot spot detection for the criminal analysis procedures. To categorize emails as either potentially suspicious or not, Sharma [27] suggested an updated feature selection technique, an improved ID3 algorithm, and an attribute priority factor. Additionally, they employed a program called Zero Crime to assist the system in identifying emails related to illegal activity. Using a centralized user feedback database and a categorization technique known as the sender reputation algorithm, the Framework of Marketing or Newsletter Sender Reputation System (FMNSRS) [28] was created.

**ISSUES AND CHALLENGES ON CRIME**

The summaries of research gaps and challenges in crime are shown in Table I.

**Data Collection and Integration**

In the purpose of training and testing, input data is crucial in crime analysis procedures. The crime model is implemented through the training process, and the algorithm is validated through the testing procedure. Numerous sources, including news, social media, various sensors, criminal histories retrieved from government agencies, etc., can provide input data. Large amounts of data have been gathered as a result. Furthermore, these data may be unstructured and come in a variety of formats. The gathered information is kept in several databases. The challenges of data preparation, transformation, and integration are a direct result of the problems with data gathering. Numerous studies are focused on finding solutions for these problems. One obstacle, though, is the complexity and difficulty of deciphering and uncovering hidden knowledge in massive amounts of data. Techniques like entity extraction [1] and grouping and filtering [29] may be helpful for gathering and integrating data [31] [32] [33] [34].

**Crime Patten**

Analyzing and forecasting the concealed crime is the focus of crime pattern issues. These days, crime rates are always rising, and crime trends are constantly shifting. As a result, it is challenging to forecast and explain the behaviors involved in crime. Finding and using the crime model to detect crimes is the focus of research on crime prevention and detection. Despite shifting crime trends, the difficulty lies in simulating the behaviors of criminal attacks to aid in crime detection. The crime model may be found and conducted with the use of statistical and predictive methods[35] [36] [37].

**Imthiyas Ahamed et al.,**

### Performance

The performance problems are related to processing time, accuracy, and dependability. The accuracy of crime detection is impacted by the unpredictability of crime trends. In addition, processing time is influenced by the processed data and appropriately used algorithms. Many studies try to create algorithms that can effectively detect crimes. The majority of them employed a mixture strategy. Even if crime trends and data are always evolving, the performance issue lies in creating detection algorithms that improve the accuracy of crime detection.

### Visualization

Developing pictures, graphs, or animations to summarize data is the primary duty of data visualization. It can make the text data and mining results more engaging and comprehensible. The present problem is that the volume of data is increasing quickly, making it more difficult and complex to show the hidden knowledge. Determining how to present data summaries of significant crime patterns and trends from massive amounts of data is one of the biggest issues. Numerous visualization techniques, including charts, maps, scatter diagrams, coxcomb plots, and more, are used to visualize low-dimensional data. Furthermore, multi-dimensional data visualization requires the employment of visualization techniques including distortion, pixel-oriented visualization, image-based visualization, geometric projection, etc. [30].

## CONCLUSION

Crime is defined by constant growth and change over time. Understanding criminal behavior, crime prediction, accurate detection, and managing vast amounts of data gathered from several sources are all made more difficult by the growing and changing crime rate. These problems have been attempted to be resolved by research interests. There are still gaps in the accuracy of crime detection, nonetheless, notwithstanding these studies. The difficulties in the field of criminal detection result from this. The difficulties include processing time, data preparation and transformation, accurate detection, and modeling crimes to identify appropriate algorithms for crime detection.

### ABSTRACT

In this paper, we introduce and study Regular I-V Atanassov soft intuitionistic fuzzy graphs (RAIVIFG). We discuss various regularity criteria for an interval valued intuitionistic fuzzy graph and produce  $f$ -morphism on an I-V Atanassov soft intuitionistic fuzzy graph and regular I-V Atanassov soft intuitionistic fuzzy graph. Some exquisite features are (2,H)-Regular and fully (2,H)-Regular I-V Atanassov soft intuitionistic fuzzy graphs.

**Keywords:** Soft Intuitionistic fuzzy graph(SIFG);  $f$ -morphism; (2,H)-regular graph,Atanassov soft intuitionistic fuzzy graphs.

### INTRODUCTION

Zadeh discovered the distinction between probability and possibility and developed the idea of fuzzy sets. This approach was highlighted by the researchers because it gives a mechanism for determining the uncertainty of any problem comprising linguistic parameters. Applications in computer science, electrical engineering, system analysis, mathematical modeling, economics, medical science, social networks, transportation, and other fields demonstrate its value. The trend of dealing with ambiguous information more correctly continues. Atanassov [4] proposed

### Vijaya and Anitha

intuitionistic fuzzy sets in 1986. This improved concept of fuzzy sets appears to be more appropriate for quantifying uncertainty. It allows for the detailed modeling of problems based on existing knowledge and observations. In 1989, Atanassov and Gargov [3] extended the notion to I-V Intuitionistic Fuzzy Set (IVIFS) after three years. It is more efficient than earlier theories and aids in the materialization of problems with ambiguous knowledge. When Rosenfeld established the concept of fuzzy graphs in 1975, significant improvements in classical graph theory became obvious. Fuzzy graphs appear to be beneficial for dealing with uncertainty in relationships that differ considerably from classical graphs. I-VFuzzy Graphs (IVFG) were introduced by Akram and Dudek [1] in 2011. Following that, Atanassov's [5] concept of intuitionistic fuzzy relations and Intuitionistic Fuzzy Graphs (IFG) handle ambiguity more correctly among relational objects and in their interactions. In fact, we use I-Vfuzzy graphs and I-VAtanassov soft intuitionistic fuzzy graphs to extend the idea of fuzzy graphs, which are two separate models for dealing with vague things. Mishra and Pal [6] proposed the I-VAtanassov soft intuitionistic fuzzy graphs product. Strong Intuitionistic Fuzzy Graphs (SIFG) were proposed by Akram and Davvaz [2]. Nowadays, numerous scholars have made significant contributions to this topic, obtaining several relations in fuzzy graphs and intuitionistic fuzzy graphs. Atanassov [5] presented the concept of intuitionistic fuzzy relations and intuitionistic fuzzy graphs, but Parvathy and Karunambigai elaborated on it and referred it adequately. In NagoorGani and Radha proposed various unique properties of fuzzy graphs such as regular fuzzy graphs, complete gradation, and regular fuzzy graphs. Some characteristics of (2,H)-regular fuzzy graphs were introduced by Alison Northup. Santhi Maheswari and Sekar developed d2 in fuzzy graphs and discovered various features. Seethalakshmi and Gnanajothi referred f -morphism on intuitionistic fuzzy graphs and investigated its behavior on strong regular intuitionistic fuzzy graphs.

#### BASIC PRELIMINARY OF REGULAR I-V ATANASSOV SOFT INTUITIONISTIC FUZZY GRAPH

We consider  $D[0,1]$  to be the set of all closed sub-intervals of the interval  $[0,1]$ , and elements of this set are denoted by uppercase letters throughout this work. If  $P \in D[0,1]$ , then this interval is  $P = [PL, PU]$ , where PL and PU are the bottom and upper boundaries of P. When these subintervals are grade of the elements of any set A, the grade values are denoted by PR, while the non-grade values are designated by QR.

##### Definition 2.1.

An I-V Atanassov soft intuitionistic fuzzy graph with fundamental graph  $\psi^* = (V, E)$  is referred to be a pair  $\psi = (R, S)$ , where (i) the functions  $P^R : t_2 \rightarrow D[0,1]$  and  $Q^R : t_2 \rightarrow D[0,1]$  denote the gradation of grade and non grade of the element correspondingly, such that  $0 \leq PR + QR \leq 1$  for all  $x \in V$ .

(ii) the functions  $P_S : E \subset V \times V \rightarrow D[0,1]$  and  $N_B : E \subset V \times V \rightarrow D[0,1]$  are referred by  $P_{SL}(x, y) \leq \inf(P_{RL}(x), P_{RL}(y))$  and

$$Q_{SL}(x, y) \geq \sup(Q_{RL}(x), Q_{RL}(y)),$$

$$P_{SU}(x, y) \leq \inf(P_{RU}(x), P_{RU}(y)) \text{ and}$$

$$Q_{SU}(x, y) \geq \inf(P_{RU}(x), P_{RU}(y)).$$

Such that  $0 \leq P_{SU}(x, y) + Q_{SU}(x, y) \leq 1, \forall (x, y) \in E$ .

##### Definition 2.2.

The I-V Atanassov soft intuitionistic fuzzy graph is said to be strong

$$\text{if } P_{SL}(t_i, t_j) = \inf\{P_{RL}(t_i), P_{RL}(t_j)\},$$

$$P_{SU}(t_i, t_j) = \inf\{P_{RU}(t_i), P_{RU}(t_j)\} \text{ and}$$

$$Q_{SL}(t_i, t_j) = \sup\{Q_{RL}(t_i), Q_{RL}(t_j)\},$$

$$Q_{SU}(t_i, t_j) = \sup\{Q_{RU}(t_i), Q_{RU}(t_j)\}.$$

##### Definition 2.3.

If the absolute gradation of each vertex of an I-V Atanassov soft intuitionistic fuzzy graph is constant, the graph is said to be regular. If each vertex's absolute gradation is k, we call the graph a k-regular I-V Atanassov soft intuitionistic fuzzy graph.

##### Definition 2.4.

Absolute gradation  $d(u)$  of any vertex u of an I-VAtanassov soft intuitionistic fuzzy graph  $\psi$  is

Vijaya and Anitha

$$d(u) = \left| \sum_{t_1 \neq t_2, t_2 \in T_2} P_{SU}(t_1, t_2) - \sum_{t_1 \neq t_2, t_2 \in T_2} Q_{SL}(t_1, t_2) \right|$$

Absolute grade of an edge  $e = t_1 t_2 \forall e \in G$  is referred as  $d(e) = |P_{SU} - Q_{SU}|$ , where  $e = (P, Q) \forall e \in G$ .

**Definition 2.5.**

Let  $\psi = (R, S)$  be an I-V Atanassov soft intuitionistic fuzzy graph on  $\psi^* (t_2, E)$ . The total gradation of a vertex  $u$  is referred as

$$td(u) = \left| \sum_{t_1 \neq t_2, t_2 \in T_2} P_{SU}(t_1, t_2) - \sum_{t_1 \neq t_2, t_2 \in T_2} Q_{SL}(t_1, t_2) \right| + |P_{RU}(t_1) - Q_{RL}(t_2)|$$

$$= d(u) + |PRU(t_1) - QAU(u)|; \forall uv \in E$$

If each vertex of has the same total gradation  $H$ , is said to be a completely regular intervalvalued intuitionistic fuzzy graph of gradation  $H$ , or an  $H$ -totally regular I-V Atanassov soft intuitionistic fuzzy graph.

**Definition 2.6.**

Let  $\psi = (R, S)$  be an I-V Atanassov soft intuitionistic fuzzy graph. The  $d_2$ -gradation of a vertex  $u \in \psi$  is

$$d_2(u) = \left| \sum_{t_1 \neq t_2, t_2 \in T_2} P^2_{SU}(t_1, t_2) - \sum_{t_1 \neq t_2, t_2 \in T_2} Q^2_{SL}(t_1, t_2) \right|$$

and precis runs over all such  $t \in t_2$  which are distance two apart from  $t_1$ ; where  $P^2_{SU}(t_1 t_2) = \inf\{P_{RU}(t_1 t_1), P_{RU}(t_1, t_2)\}$  and  $Q^2_{SU}(t_1 t_2) = \sup\{Q_{SU}(t_1 t_1), Q_{SU}(t_1, t_2)\}$ .

Also,  $P_{RU}(t_1 t_2) = 0$  and  $Q_{SU}(t_1 t_2) = 1$ ; for  $t_1 t_2 \notin E$ .

The infimum  $d_2$ -gradation of  $\psi$  is  $\delta_2(\psi) = \wedge\{d_2(t_2) : t_2 \in t_2\}$ . The supremum  $d_2$ -gradation of  $\psi$  is  $\Delta_2(G) = t_2\{d_2(t_2) : t_2 \in t_2\}$ .

**Definition 2.7.**

Let  $\psi = (R, S)$  be an I-V Atanassov soft intuitionistic fuzzy graph on  $\psi^* (t_2, E)$ . If  $d_2(t_2) = 2, \forall v \in t_2$  then  $\psi$  is said to be  $(2, H)$ -regular I-V Atanassov soft intuitionistic fuzzy graph.

**Definition 2.8.**

Let  $\psi_1 = (R_1, S_1)$  and  $\psi_2 = (R_2, S_2)$  be two I-V Atanassov soft intuitionistic fuzzy graphs on  $(t_2, E_1)$  and  $(T_2, E_2)$ , respectively. A bijective function  $f : R_1 \rightarrow R_2$  is called I-V intuitionistic fuzzy morphism or  $f$ -morphism of I-V Atanassov soft intuitionistic fuzzy graph if there exists some positive real number  $H_1$  and  $H_2$  such that

- (i)  $PR_2(f(t_1)) = H_1 PR_1(t_1)$  and  $QR_2(f(t_1)) = H_1 QR_1(t_1), \forall t_1 \in t_2$
- (ii)  $PS_2(f(t_1), f(t_2)) = H_2 PS_1(t_1, t_2)$  and  $QS_2(f(t_1), f(t_2)) = H_2 QS_1(t_1, t_2), \forall t_1, t_2 \in t_2$ . In these cases  $f$  is called  $(H_1, H_2)f$ -I-V soft intuitionistic morphism on  $\psi_1$  over  $\psi_2$ . When  $H_1 = H_2 = H$  then we say it is  $H$ - $f$ -I-V soft intuitionistic morphism on  $\psi_1$  over  $\psi_2$ .

**Definition 2.9.**

A co-week isomorphism from  $\psi_1$  to  $\psi_2$  is a map  $h : R_1 \rightarrow R_2$  which is bijective homomorphism that satisfies  $PS_1(t_1, t_2) = PS_2(h(t_1), h(t_2))$  and  $QS_1(t_1, t_2) = QS_2(h(t_1), h(t_2)), \forall t_1, t_2 \in R$ .  $R$  week isomorphism from  $\psi_1$  to  $\psi_2$  is a map  $h : R_1 \rightarrow R_2$  which is objective homomorphism that satisfies  $PR_1(t_1) = PR_2(h(t_1))$  and  $QR_1(t_1) = QR_2(h(t_1)), \forall t_1, t_2 \in R$ .

**THEOREM OF REGULAR I-V ATANASSOV SOFT INTUITIONISTIC FUZZY AND THEIR CHARACTERIZATION**

**Theorem 3.1.**

Cartesian product of two regular I-V Atanassov soft intuitionistic fuzzy graphs  $\psi_1$  and  $\psi_2$  is regular iff  $\psi_1$  is a week regular I-V intuitionistic fuzzy sub graph of  $\psi_2$  or vice versa.

**Proof.**

Let  $\psi_1$  and  $\psi_2$  be the two regular I-V Atanassov soft intuitionistic fuzzy graph then the Cartesian product of  $\psi_1$  and  $\psi_2$  is regular if the absolute grade of each arc  $e$  of  $\psi_1 \times \psi_2$  is equal and this is possible if  $d(e) = \inf\{d(e_i), d(e_j)\}$ , where  $e_i \in \psi_1$

Vijaya and Anitha

and  $e_j \in \psi_2$  for all  $i$  and  $j$  thus the condition is necessary for regularity of  $\psi_1 \times \psi_2$  is either of  $\psi_1$  or  $\psi_2$  be a weak regular sub graph of each other. Now, let  $\psi_1$  is weak regular sub graph of  $\psi_2$  then we know that each edge of  $\psi_1 \times \psi_2$  get I-V grade and non-grade as infimum of  $P_1$  and  $P_2$  and supremum of  $Q_1$  and  $Q_2$  thus, if  $\psi_1$  is weak then  $P_1$  and  $Q_1$  dominates all the arc of  $\psi_1 \times \psi_2$ . So all the arc receive same absolute grade which imply  $\psi_1 \times \psi_2$  is regular. Therefore the theorem.

**Theorem 3.2.**

Any I-V intuitionistic fuzzy path graph of length  $l$  is never an regular I-V Atanassov soft intuitionistic fuzzy graph for  $l > 1$ .

**Proof.**

Any I-V intuitionistic fuzzy path graph  $(R,S)$  has either all edges with the same absolute grade or some edges with different absolute grades. Thus, while all edges receive the same absolute grade, at least both end vertices of the path graph  $G$  receive a different absolute grade than in-vertices of the path graph, indicating that is not regular. Similarly, if certain edges have unique absolute grades, let  $d(e_1) \neq d(e_2)$  and both  $e_1$  and  $e_2$  are adjacent, and let  $u$  be the common vertex of  $e_1$  and  $e_2$   $d(u)$  is always bigger than other end vertices of  $e_1$  and  $e_2$ , implying that is not regular. Because the absolute grade of an edge becomes the absolute gradation of the vertices when  $l = 1$ , the graph is always regular. As a result, every I-V intuitionistic fuzzy path graph of length  $l$  is never a regular graph. For  $l > 1$ , I-V Atanassov soft intuitionistic fuzzy graph

**Theorem 3.3.**

Let  $\psi(R,S)$  be an strong I-V Atanassov soft intuitionistic fuzzy graph on  $\psi^*(t_2, E)$  Then  $PRU(t_1) = c_1$  and  $QRU(t_1) = c_2$ ; for all  $t_1 \in t_2$  if and only if the subsequent circumstances are equivalent. (i)  $\psi(R,S)$  is a  $(2,H)$ -regular I-V Atanassov soft intuitionistic fuzzy graph.

(ii)  $\psi(R,S)$  is a totally  $(2,H + c)$ -regular I-V Atanassov soft intuitionistic fuzzy graph where  $c = |c_1 - c_2|$ .

**Proof.**

Let  $PRU(t_1) = c_1$  and  $QRU(t_1) = c_2$  for all  $t_1 \in t_2$ .

Thus  $|PRU(t_1) - QRU(t_1)| = |c_1 - c_2| = c$  for all  $t_1 \in t_2$ .

Suppose that  $\psi : (R,S)$  is a  $(2,H)$ -regular I-V Atanassov soft intuitionistic fuzzy graph then  $d_2(u) = H$ , for all  $t_1 \in t_2$ .

Therefore,  $td_2(t_1) = d_2(t_1) + |PRU(t_1) - QRU(t_1)| \Rightarrow td_2(t_1) = H + c, \forall t_1 \in t_2$ .

Therefore,  $\psi : (R,S)$  is a totally  $(2,H + c)$ -regular I-V Atanassov soft intuitionistic fuzzy graph. Thus (i)  $\Rightarrow$  (ii) is proved.

Suppose,  $\psi(R,S)$  is a totally  $(2,H + c)$ -regular I-V Atanassov soft intuitionistic fuzzy graph therefore,

$td_2(t_1) = H + c, \forall t_1 \in t_2$

$\Rightarrow d_2(t_1) + |PRU(t_1) - QRU(t_1)| = H + c, \forall t_1 \in t_2 \Rightarrow$

$d_2(t_1) + |c_1 - c_2| = H + c, \forall t_1 \in t_2$

$\Rightarrow d_2(t_1) + c = H + c, \forall t_1 \in t_2$

$\Rightarrow d_2(t_1) = H, \forall t_1 \in t_2$ .

Therefore,  $\psi(R,S)$  is a  $(2,H)$ -regular I-V Atanassov soft intuitionistic fuzzy graph.

Therefore (i) and (ii) are equivalent. Conversely assume that (i) and (ii) are equivalent i.e., suppose  $\psi(R,S)$  is  $(2,H)$ -regular I-V Atanassov soft intuitionistic fuzzy graph and also a totally  $(2,H + c)$ -regular I-V Atanassov soft intuitionistic fuzzy graph where  $c = |c_1 - c_2|$ .

Thus,  $td_2(t_1) = H + c$  and  $d_2(t_1) = H, \forall t_1 \in t_2$

$\Rightarrow d_2(t_1) + |PRU(t_1) - QRU(t_1)| = H + c$

and

$d_2(t_1) = H, \forall t_1 \in V$

$\Rightarrow |PRU(t_1) - QRU(t_1)| = c = |c_1 - c_2|, \forall t_1 \in t_2$

$\Rightarrow PRU(t_1) = c_1$  and  $QRU(t_1) = c_2, \forall t_1 \in t_2$ .

Vijaya and Anitha

**Theorem 3.4.**

In the collection of all I-V Atanassov soft intuitionistic fuzzy graphs, the relation f -I-V intuitionistic fuzzy morphic is an equivalence relation.

**Proof.**

Let S be the set of all I-V Atanassov soft intuitionistic fuzzy graphs.

Now, define the relation  $\psi_1 \approx \psi_2$  when  $\psi_1$  is  $(H_1, H_2)$  f -I-V soft intuitionistic morphism on  $\psi_2$  where  $H_1, H_2$  are any non zero real numbers and

$\psi_1, \psi_2 \in S$ . Now for any identity morphism  $\psi_1$  over  $\psi_1$  is an one-one mapping and consequently  $0 \approx 0$  is reflexive.

Let  $\psi_1 \approx \psi_2$ , then there exists a  $(H_1, H_2)$ -I-V soft intuitionistic fuzzy morphism from  $\psi_1$  to  $\psi_2$  for some non zero  $H_1$  and  $H_2$ .

$$PR_2 (f (t_1)) = H_1 PR_1 t_1$$

$$\text{and } QR_2 (f (t_1)) = H_1 QR_1 t_1, \forall t_1 \in t_2$$

$$PS_2 (f (t_1), f (t_2)) = H_2 PS_1 (t_1, t_2)$$

$$\text{and } QS_2 (f (t_1), f (t_2)) = H_2 QS_1 (t_1, t_2), \forall u, t_2 \in t_2$$

Consider  $f^{-1} : \psi_1 \rightarrow \psi_2$ . Let  $x, y \in t_2$ . As  $f^{-1}$  is bijective,  $x = f (u), y = f (t_2)$ , for some  $u, v \in t_1$ .

$$\text{Now, } PR_1 (f^{-1} (x)) = PR_1 (f^{-1} (f (t_1))) = PR_1 (t_1) = 1 / H_1 PR_2 f (t_1) = 1 / H_1 PR_2 (x);$$

$$QR_1 (f^{-1} (x)) = QR_1 (f^{-1} (f (t_1))) = QR_1 (t_1) = 1 / H_1 QR_2 f (u) = 1 / H_1 QR_2 (x).$$

$$PS_1 (f^{-1} (x), f^{-1} (y)) = PS_1 (f^{-1} (f (t_1)),$$

$$f^{-1} (f (t_2))) = PS_1 (t_1, t_2) = 1 / H_2 PS_2 (f (t_1), f (t_2)) = 1 / H_2 PS_2 (x, y);$$

$$QS_1 (f^{-1} (x), f^{-1} (y)) = QS_1 (f^{-1} (f (t_1)), f^{-1} (f (t_2))) = QS_1 (t_1, t_2) = 1 / H_2 QS_2 (f (t_1), f (t_2)) = 1 / H_2 QS_2 (x, y).$$

Thus there exists  $1 / H_1, 1 / H_2 \in f$  -I-V soft intuitionistic morphism from  $\psi_2$  to  $\psi_1$ .

Therefore  $\psi_2 \approx \psi_1$  and therefore ' $\approx$ ' is symmetric.

Let  $\psi_1 \approx \psi_2$  and  $\psi_2 \approx \psi_3$ .

Thus there exist two I-V soft intuitionistic morphism say  $(H_1, H_2) - f$  and  $(H_2, H_3) - g$  such that  $f$  is I-V soft intuitionistic morphism from  $\psi_1$  to  $\psi_2$  and  $g$  is I-V soft intuitionistic morphism from  $\psi_2$  to  $\psi_3$  for non-zero  $H_1, H_2, H_3, H_4$ .

$$\text{So, } PR_3 (g(x)) = H_3 PR_2 (x)$$

and

$$QR_3 (g(x)) = H_3 QR_2 (x), \forall x \in t_2$$

and

$$PS_3 (g(x), g(y)) = H_4 PS_2 (x, y)$$

and

$$QS_3 (g(x), g(y)) = H_4 QS_2 (x, y), \forall (x, y) \in E_2.$$

Let  $h = g \circ f : \psi_1 \rightarrow \psi_3$ .

$$\text{Now, } PR_3 (h(t_1)) = PR_3 ((g \circ f)(t_1))$$

$$= PR_3 (g(f (t_1))) = H_3 PR_2 (f (t_1)) = H_3 H_1 PR_1 (t_1),$$

$$QR_3 (h(t_1)) = QR_3 ((g \circ f)(t_1)) = QR_3 (g(f (t_1))) = H_3 QR_2 (f (t_1)) = H_3 H_1 QR_1 (t_1),$$

$$PS_3 (h(t_1), h(t_2)) = PS_3 ((g \circ f)(t_1), (g \circ f)(t_2))$$

$$= PS_3 (g(f (t_1)), g(f (t_2))) = H_4 PS_2 (f (t_1),$$

$$f (t_2)) = H_4 H_2 PS_1 (t_1, t_2), QS_3 (h(t_1), h(t_2))$$

$$= QS_3 ((g \circ f)(t_1), (g \circ f)(t_2)) = QS_3 (g(f (t_1),$$

$$g(f (t_2))) = H_4 QS_2 (f (t_1), f (t_2)) = H_4 H_2 QS_1 (u, t_2).$$

Thus, there exists  $(H_3 H_1, H_4 H_2) h$ -I-V soft intuitionistic fuzzy morphism from  $\psi_1$  over  $\psi_3$ . Therefore,  $\psi_1 \approx \psi_3$  therefore, ' $\approx$ ' is transitive. So, the relation f -I-V soft intuitionistic fuzzy morphic is an equivalence relation in the collection of all I-V Atanassov soft intuitionistic fuzzy graphs.

**Theorem 3.4.**

Let  $\psi_1$  and  $\psi_2$  be two IVIFG's such that  $\psi_1$  is  $(H_1, H_2)$  I-V soft intuitionistic fuzzy morphic to  $\psi_2$  for approximately non-zero  $H_1$  and  $H_2$ . The copy of strong edge in  $\psi_1$  is strong edge in  $\psi_2$  if and only if  $H_1 = H_2$ .

**Vijaya and Anitha**

**Proof.**

Let  $(t_1, t_2)$  be strong edge in  $\psi_1$  such that  $(f(t_1), f(t_2))$  is also strong edge in  $\psi_2$ .

Now, as  $\psi_1 \approx \psi_2$   $H_2 P_{S_1}(t_1, t_2) = P_{S_2}(f(t_1), f(t_2))$   
 $= P_{R_2} f(t_1) \wedge P_{R_2} f(t_2) = H_1 \{P_{R_1}(t_1) \wedge P_{R_1}(t_2)\} = H_1 P_{S_1}(t_1, t_2), \forall t_1 \in t_2.$

Therefore,  $H_2 P_{S_1}(t_1, t_2) = H_1 P_{S_1}(t_1, t_2), \forall t_1 \in t_2, \dots \dots \dots (3.1)$

Similarly,  $H_2 Q_{S_1}(t_1, t_2) = Q_{S_2}(f(t_1), f(t_2)) = Q_{R_2} f(t_1) \wedge Q_{R_2} f(t_2) = H_1 \{Q_{R_1}(t_1) \wedge Q_{R_1}(t_2)\} = H_1 Q_{S_1}(t_1, t_2), \forall t_1 \in t_2.$

Therefore,  $H_2 Q_{S_1}(t_1, t_2) = H_1 Q_{S_1}(t_1, t_2), \forall t_1 \in t_2, \dots \dots \dots (3.2)$

Equations (3.1) and (3.2) holds if and only if  $H_1 = H_2$ .

**Theorem 3.5.**

If an IVASIFG  $\psi_1$  is coweak isomorphic to  $\psi_2$  and if  $\psi_1$  is regular then  $\psi_2$  is regular

**Proof.**

As IVASIFG  $\psi_1$  is coweak isomorphic to IVASIFG  $\psi_2$ , there exists a coweak isomorphism  $h : \psi_1 \rightarrow \psi_2$  which is bijective that gratifies  $P_{R_1}(t_1) \leq P_{R_2}(h(t_1))$  and  $Q_{R_1}(t_1) \geq Q_{R_2}(h(t_1))$ . It also satisfies,

$P_{S_1}(t_1, t_2) = P_{S_2}(h(t_1), h(t_2))$

And

$Q_{S_1}(t_1, t_2) = Q_{S_2}(h(t_1), h(t_2)), \forall t_1, t_2 \in T_1.$

As  $\psi_1$  is regular, for  $t_1 \in T$ ,

$\sum P_{S_U}(t_1, t_2) = \text{constant}$

and

$\sum Q_{S_U}(t_1, t_2) = \text{constant}.$

Now  $\sum P_{S_2}(h(t_1), h(t_2)) = \sum P_{S_U}(t_1, t_2) = \text{constant}$

and  $\sum Q_{S_2}(h(t_1), h(t_2)) = \sum Q_{S_U}(t_1, t_2) = \text{constant}$  Therefore  $\psi_2$  is regular.

**Theorem 3.6.**

Let  $\psi_1$  and  $\psi_2$  be two IVASIFG's. If  $\psi_1$  is weak isomorphic to  $\psi_2$  and if  $G_1$  is strong then  $\psi_2$  is strong.

**Proof.**

As an IVASIFG  $\psi_1$  be weak isomorphic with an IVASIFG  $G_2$ , there exists a weak isomorphism  $h : \psi_1 \rightarrow \psi_2$  which is bijective that gratifies

$P_{R_1}(t_1) = P_{R_2}(h(t_1))$

and

$Q_{R_1}(t_1) = Q_{R_2}(h(t_1)),$

$P_{S_1}(t_1, t_2) \leq P_{S_2}(h(t_1), h(t_2))$

and

$Q_{S_1}(t_1, t_2) \geq Q_{S_2}(h(t_1), h(t_2)), \forall t_1, t_2 \in t_1.$

As  $G_1$  is strong,

$P_{S_1}(t_1, t_2) = \inf P_{R_1}(t_1),$

$P_{R_1}(t_2)$  and  $Q_{S_1}(t_1, t_2) = \sup Q_{R_1}(t_1), Q_{R_1}(t_2).$

Now,  $P_{S_2}(h(t_1), h(t_2)) \leq P_{S_1}(t_1, t_2)$

$= \inf\{P_{R_1}(t_1), P_{R_1}(t_2)\}$

$= \inf\{P_{R_2}h(t_1), P_{R_2}h(t_2)\}.$

By definition,  $P_{S_2}(h(t_1), h(t_2)) \leq \inf\{P_{R_2}h(t_1), P_{R_2}h(t_2)\}.$

Therefore,  $P_{S_2}(h(t_1), h(t_2)) = \inf\{P_{R_2}h(t_1), P_{R_2}h(t_2)\}.$

Similarly,  $Q_{S_2}(h(t_1), h(t_2)) \geq Q_{S_1}(t_1, t_2)$

$= \sup\{Q_{R_1}(t_1), Q_{R_1}(t_2)\}$

$= \sup\{Q_{R_2}h(t_1), Q_{R_2}h(t_2)\}.$

And by definition,

$Q_{S_2}(h(t_1), h(t_2)) \geq \sup\{Q_{R_2}h(t_1), Q_{R_2}h(t_2)\}.$

Therefore,  $Q_{S_2}(h(t_1), h(t_2)) = \sup\{Q_{R_2}h(t_1), Q_{R_2}h(t_2)\}.$

Thus  $\psi_2$  is strong.

**Vijaya and Anitha**

## CONCLUSION

The regular I-V Atanassov soft intuitionistic fuzzy graph has several applications in the modeling of real-world systems where the quantity of knowledge inherited in the system fluctuates over time and has varying levels of precision and hesitation. Because most real-world operations are time-sensitive, symbolic models utilized in expert systems are more effective than classical ones. We presented the concept of a regular I-V Atanassov soft intuitionistic fuzzy graph and obtained various features over it in this work. We can extend this concept in the future to I-V bipolar regular fuzzy graphs, I-V regular hyper graphs, and other areas of graph theory.

### ABSTRACT

Analysis of feelings involves the analysis of natural language and the finding of emotions expressed by people. The idea behind sentimental analysis is to assess the polarity of the person's textual opinion. Social networks become a daily usage for the people that developed in this modern age. Billions of people were using Twitter in today's world and more and more increasing the users list. Every user needs privacy and protects their information also expect a safe communication and secure sharing in Twitter. However, it is really a challenging task to extract and select meaningful features from raw data's. We consider these stimulating task to propose an Artificial Bee Colony and Pigeon Inspired Optimization for Feature Selection and pack-author-date sentiment LDA (PADSLDA) for feature extraction. The proposed models outperformed the basic models because the additional parameters could affect the word generation process in a review according to assessment results. The main parameters used in the evaluations are sentiment analysis at document level, confusion and consistency of subjects. Finally, classification of tweet as positive, negative and neutral. The twitter classification process is handle by the machine learning classifier model as Decision tree, Navy Bias and Random Forest. The experiment is conducted by using STC dataset and proposed model performance is tested and verified by using different parametric metrics.

**Keywords:** Twitter data, machine learning, classifier, pack-author-date sentiment and optimization algorithm.

## INTRODUCTION

E-commerce and social media grow rapidly and contribute to opinion expressed and commented on all through different kinds of texts, including microblogs and on-line reviews. Existing online product reviews can assist new customers in deciding whether or not to buy their products and can help manufacturers explore new opportunities by examining user opinions [1-3]. It is therefore significant to analyse the reviews automatically to get opinions, topics and associations. The massive amounts of remarks posted on the web are however difficult to check. In order to overcome this issue, opinion mining (sentence analysis) can examine comment on the web automatically and class as positive or negative statements the huge number of reviews. Recently sentiment analysis has become one of the main areas in the processing of natural languages. The detection of sensations is currently widely used on websites which contain various goods. Analyzing user satisfaction from different internet services like email can also show the standing of emotions recognition. The views of various users can also be examined by way of opinion mining to raise awareness about the goods that gained positive views. There have been huge efforts to automate the detection of feelings and to test latent knowledge in text data. Modelling themes extracts from the documents the hidden topics. Thematic models such as LDA and PLSA were used to find themes from the texts effectively. PLSA is a probabilistic model that is capable of generating the data found in document matrix[4-6]. LDA is a model of probabilism, because it is expressed by probability and generative language because of the way documents are produced.

The aim is to find the best collection of hidden variables in topic modeling that can best describe the observed data. The word variable is visible, for example, and in the LDA the subject variable is hidden. The LDA model is based on the assumption that a document is a mix of topics where each topic is a distribution of probability over words and a word in a document is generated. The development and popularity of social networks is growing every day. To Share their product in social networking experiences. It's a difficult task to find a suitable product online. By providing suggestions, the recommendation system can help users. System Recommender creates a list of recommendations. Three system approaches are recommended, content based, hybrid and collaborative. The content-based method takes the material of an item and the user profile into account and the user preferences are based on the recommendation of items. The collaborative approach analyses user behaviour and preferences and identifies people's preferences. Collaborative techniques are well known to be generally more precise than content-based techniques. Different classifiers were used for classification accuracies in the classification domain and the frameworks were proposed by combining heterogeneous classifiers. However, the sentiment analysis is the process for extracting user experience from products purchased. Researchers in this field propose different approaches which classify reviews into positive, negative and neutral. The classification of feelings is done using a variety of words of polarity such as adjectives, verbs, adverbs, etc. [8]. In their work, the researchers used adjective as a single-focused polarity feature[9]. Researchers are also using forms of the adjective to achieve better results. In the field of opinion mining, researchers are working extensively on the evaluation of adverbs and verbs. For better results, researchers are taking a long list of hybrid approaches [14] [15] [16] [17] [18] [19] [20] [21] [22] [23] [24]. The latest approaches use different terms that endorse polarity; however, a crucial literature review has revealed that analysis of the impact for classification of sentiments of all types of adverbs is still an open research question.

## LITERATURE REVIEW

Liu et al. [10] have proposed a data driven view of machine learning techniques against security threats and its survey. Here, they discussed about the defensive techniques of machine learning and security threats against variety algorithms that include Support Vector Machine, DT, Naive Bayes, RF, Principal Component Analysis, and Logistic Regression and prevailing deep neural networks. Yang and Liu [11] have proposed a method based on a multi-objective discrete particle swarm optimization (PSO) for cost minimization – influence maximization in social networks. Maximum influence is expected to obtain by all companies with minimum cost or with acceptable cost. From this motivation, a model is developed and named as Influence-Maximization and Cost-Minimization (IM-CM) which helps in gathering real-world network characteristics better. For solving this proposed model, a multi-

### Kasthuri and Senthil

objective discrete PSO algorithm is used for IM-CM. Zhang et al. [12] have proposed a method for large-scale many-objective optimization using decision variable clustering based evolutionary procedure. Two types of decision variables divided by the decision variable clustering method and these are convergence related variables and diversity related variables. A convergence optimization strategy is used for two kinds of decision variables for optimizing and adopted diversity optimization strategy. The computational efficiency is improved further by developing a fast non-dominated sorting approach for the proposed algorithm. On a variety of large scale MaOPs conducted an empirical experiment for assessing the performance. Lakshmanaprabu et al. [13] have proposed a technique for classifying big data by effective features using social internet of things. A hierarchical framework is introduced for feature extraction in Social Internet of Things big data by using map reduce framework and a supervised classifier model is used. The unwanted data and noise is reduced by Gabor filter from the database. The big databases are reduced using Hadoop Map Reduce and also for mapping. Furthermore, Elephant Herd Optimization is used on filtered data for feature selection.

## PROPOSED METHODOLOGY

In this section, we discuss about the procedure of proposed methodology in twitter sentimental analysis, which is expressed in figure 1. Initially the experiment is conducted by using STC publically available dataset. In raw twitter sentimental data is pre-processes to remove some irrelevant content and provide useful data's. Then the proposed data is given to the extraction method, in this method we proposed the PADSLDA method. By this data extraction after we employed the optimization techniques as ABC-PIO scheme. Then we classify the twitter data by using different machine learning classifier as RF, DT and NB. The performance of the projected method is identified by using diverse parametric measure.

### Dataset Collection

Data collection and preprocessing are performed from the STC data set to enhance the collected data quality. The tweets had to go through the preprocessing stages before classification, since the language of Twitter has single attributes that are not relevant to the classification course, such as, hashtags usernames and links.

### Preprocessing

In this paper, preprocessing of tweet information is significant task. Substitute for negative references. Pre-processing is the main stage of the data mining process used for the conversion into text format of different data sources. After the data in the text is converted, the filter is used where the cue words are eliminated (connective words that connect semanticized relationships in text), the words are stopped (insignificant words used in English) and the words frequently used, which reduce the amount of the database. Stemming is carried out after filtration. Stemming is a method to reduce derived words. The tree may not necessarily be identical to the morphological root word. The tweets are made up of several negative notions. Negation generally plays a significant role in determining the tweet's feeling. Here, the "Won't", "Can't" process is transformed into "Not Will," "Cannot," and "Not" process. Revert to the original word form with repeated letters. In tweets, words with repeated letters, e.g. "Happpppyyy" are common and this is a way for people to rapid their feelings. Here, three characters replace a sequence of much than three alike characters. "happpppyy", for example, is swapped with "happy". The words like "happy" and "happpppyyy" are distinguished by using three characters. Numbers for removal. Generally speaking, numbers are useless when measuring feelings and are detached from tweets to refine tweets. Removal of corpus URL links. Most researchers believe that URLs contain little information on the tweet feeling. Here, short Twitter URLs will be extended and tokenized to the URLs. The URL corresponding to the tokens will then be deleted from tweets for tweeting. Stop words removal. The most common words in a language, like 'The', 'Is' and 'At,' are commonly referred to as stop words. In the opinion of most researchers, stop words play a negative role in the classification of feeling and are eliminated by researchers before selecting the feature..

**Kasthuri and Senthil**

**Feature Extraction**

This process is to extract the particular features to improve the accuracy of the classification model.

**The overall PADSLDA structure**

A model called PADSLDA is introduced in this subsection, which extends the DSLDA by the address. In DSLDA, date, feeling, and subtopic key roles, and key roles in PADSLDA are played by the author, date, feeling, and subtopics. The author who holds an opinion on something like an Amazon product or a film in an IMDB web site or a service in TripAdvisor is responsible for each document. In PADSLDA, reviews are inserted into the same category called a pack for a product with a score over 4 (positive feeling) or below 2 (negative feeling). Instead of negative and positive reviews, negative or positive packages are used. Each review has one author and one date, but each package has a connection to a number of authors and dates. It should be noted, however, that the various authors and dates are linked to each word. Each input text in the date sentiment LDA and author–date sentiment LDA shall be considered to be a single document or an online review. PADSLDA can summarize the process of creating a word in a document as follows: (a) from the per-pack sentiment distribution the proposed model chooses a sentiment label. (b) PADSLDA selects a theme from the package of topics that is subject to the sentiment label, author and date, or from the per-pack subtopic distribution depending on how word is affect by the subject matter or sub topic distribution, depending on the sentiment label and topic. (c) PADSLDA then draws a word out of the distribution of words per body conditioned by the topic or label of the subject, the author and the sentiment. In the Gibbs sample algorithm PADSLDA vary the number of dates and authors, and the date and author are selected from various sets of variables across Gibb's sample algorithm. Pack variable is used in PADSLDA rather than document or check. PADSLDA categorizes pack level opinions. Figure 2 shows the graphical model of PADSLDA as a plate notation. According to Figure 2,  $\theta_1$  is indicated as the probability of  $z$  given  $a, d, s,$  and  $r$ ; and  $r$  is indicated as the pack variable in PADSLDA and  $\theta_2$  is indicated as the probability of  $k$  given  $z, s,$  and  $r$  in PDASLDA; The generative model of PADSLDA is illustrated in Figure 3. According to Figure 2, the proposed model joint probability distributions can be factored as follows:

$$\text{Topic distribution: } P(z, w, s, d, a) = P(w/z, s, a) \times P(z/s, d, a, r) \times P(s / r) \tag{1}$$

$$\text{Subtopic distribution: } P(z, w, s, d, k, a) = P(w/s, k, a) \times P(p(k)/z, s, r) \times P(z) / s, d, a, r) \times P(s/r) \tag{2}$$

Where by integrating out  $\theta_1$ , we obtain:

$$P(z/s, d, a, r) = \left( \frac{\Gamma(|Z|) \times a_1}{\Gamma(a_1)^{|Z|}} \right)^{|R| \times |A| \times |S| \times |D|} \prod_r \prod_a \prod_d \prod_s \frac{\prod (N_{r,a,z,s,d} + a_1)}{z} \frac{1}{\Gamma(N_{r,a,s,d} + (|Z|) \times a_1)} \tag{3}$$

Where  $|R|$  the amount of packs and  $|D|$  is the amount of dates. The symbol  $N_{r,a,z,s,d}$  is the sum of words with topic  $z$  sentiment  $s$  date  $d$ , and author  $a$  in pack  $r$ , and  $N_{r, a, s, d}$  is the sum of words with sentiment  $s$ , date  $d$ , and author  $a$  in pack  $r$

**Optimization algorithm for feature selection**

The selection of features plays a crucial role in models of machine learning. Important data characteristics impact the model's accuracy and increase the required time for training. Feature selection is an important process for making better classification on twitter sentimental data.

**Algorithm of artificial bee colony**

It is a swarm based algorithm that is stirred by the very well defined seeking actions of honey bees. It incorporates the three important constituents specifically employed bees, onlooker bees and scout bees. The employed bees are related with the food sources in the closest area of the hive and it transmits the data regards the nectar aspect of using food sources to the onlooker bees, these bees are observing the employed bees dance interior to the hive to select one food source to make use of it depends on the data that are contributed by the employed bees. If the food sources of the employed bees are unused then it becomes the scout bees and searches for new food sources randomly. A sum of

**Kasthuri and Senthil**

food sources indicate the position of possible solutions of problems of optimization and the total nectar of food source indicates the aspect of the solution. The working approach of ABC algorithm is given in Figure 4.

**PIO algorithm for feature selection**

Recently, the PIO algorithm has demonstrated its efficacy in addressing many optimisation issues, for example air robot planning, 3D route planning, automatic landing system and PID controllers. In this paper, we adapt to the latest binary version of Pigeon Inspired Optimizer an IDS selection algorithm. Two PIO variants are suggested in this section. The first version of algorithm uses the sigmoid function to distinguish pigeon velocities, while the second version proposes to use the cosine sequence to determine the pigeon velocity in a new adapted binary version of the base PIO. On the other hand, each version has a different fitness feature to represent pigeons or solutions. Table 1 shows the process of mapping the PIO to optimize collection.

**Classification Using ML Algorithms**

The machine learning algorithms are the most common and descriptive methods for classification of the dataset. The proposed feature selection has analyzed with the three different classification machine learning algorithm such as Random forest (RF), Decisions tree (DT) and Navy Bias (NB).

**Random Forests**

An effective ensemble learning algorithm often used in classification tasks is Random Forests. It ranks on the basis of the results from numerous decision-making trees generated during training where each decision tree's mode of the targeted output is the forest output. Because of their low preference and broad variance, random forests appear to have an average of the many decision trees, trees are known to overfish data. Random forests produce random sample decision trees, reducing the variance of the global model to improve the efficiency and monitor the overfit. Features are displayed in classification trees in nodes of the trees where the tree has the most relevant characteristics and class marking in the leaves. Tiny impurity determines the importance of a function, as the less precision decreases by arbitrarily transferring the values of the feature, the less important the feature.

**Decision Tree**

In the DT classifier the inner nodes were characterized by features and edges left by the node as testing the weight of the data set. The leaves are categorized in the tree. This entire category of document starts from the tree root and moves effectively through its branches until a leaf node is reached. Learning in the decision tree is taken as a pre-emptive model by a decision tree classifier, mapping information from an item to conclusions on the expected value of that item. Many inputs can be identified in the decision tree by means of computer assets that are approved in the final time frame. It is simple to understand and to interpret the key advantages of the decision tree classification. Small data planning is essential for this classification. However, these definitions can construct complex trees which are not easily generalized.

**Naive Bayes**

The Bayesian Classification is a supervised technique of learning and a statistical classification technique. Assumes a probabilistic model, which enables one to evaluate in theory the uncertainty with respect to the model by calculating the probabilities of the effects. Diagnostic and predictive problems may be resolved. The title is taken from the Bayes Theorem by Thomas Bayes (1702-1761). Bayesian classification offers functional algorithms for learning and prior knowledge and combines observed data. Bayesian classification offers a valuable viewpoint for numerous learning algorithms to understand and evaluate. It calculates explicit hypothesis probabilities and is robust to ring in input data.

## RESULT AND DISCUSSION

In this section, the outcome for proposed implementation is given and explained in detail with experimentation results. The proposed model is tested by using a software tool as Python with 4GB RAM, 1TB hard disk and Intel i5 3.0 GHz are required for our implemented system.

### Evaluation Metrics

An evaluation metric is utilized to measure the usefulness of opinion mining systems and to explain the hypothetical and practical developments of these systems. It comprises of a metrics which trails the general unrevealed methodology of evaluation. Few of the measures that are selected for the purpose of evaluation are Recall, Precision, and the F-Measure. For better utilization of this proposed method for the efficient classification of reviews with mining, it needs the values of these measures to be calculated. By using these four basic values the measures of Precision, Recall, Accuracy and F-Measure are evaluated in this proposed approach. The illustrations of these evaluation measures are given in equations are as follows:

### Precision

The precision evaluates the number of reviews that are to be categorized as Positive (Negative or Neutral) is actually Positive (Negative or Neutral) through the equation (4):

$$P r e c i s i o n = \frac{T P}{(F P + T P)} \times 100 \quad (4)$$

### Recall

The recall specifies the numbers of reviews of Positives (Negatives or Neutrals) classes actually are categorized. The accurate classification percentage of Positives (Negatives or Neutrals) is specified using recall. It is also identical to Sensitivity, where the equation (5) presents the recall formula.

$$R e c a l l = \frac{T P}{(F N + T P)} \times 100 \quad (5)$$

### F-Measure

It integrates the precision and recall and it is deliberated as the harmonic mean of precision and recall, where the formula is given in Eq. (6):

$$F - m e a s u r e = \frac{2 T P}{(2 T P + F P + F N)} \times 100 \quad (6)$$

### Accuracy

Accuracy evaluates the weighted percentage of reviews Positive, Negative and Neutral which are categorized accurately, which is given in Eq. (7).

$$A c c u r a c y = \frac{T N + T P}{T P + T N + F N + F P} \times 100 \quad (7)$$

Where, true positive is denoted as  $TP$  and  $TN$  express true negative and then  $FP$  is expressed as false positive, and  $FN$  is expressed as false negative.

### Performance Analysis of Proposed

In this section, we analyzed the performance of the proposed model. The experiments is performed on STC data sets under different train and test conditions. The experiments carried out to classify the tweets polarity by using different three machine learning classifier as Random forest (RF), Decisions tree (DT) and Naïve Bayes (NB). The following Table 2 gives the validated results of with and without feature extraction as well as optimization

### Kasthuri and Senthil

techniques. In table 2 represent that the comparative analysis of different machine learning classifier performance. By this comparisons, we evaluated the results by using combination of PADSLDA-ABC-PIO with DT classifier achieved better performance than other classifier else. In PADSLDA-RF- ABC-PIO achieve the precision value of 85.98% and recall value of 84.75%. Also PADSLDA-NB- ABC-PIO scheme achieved the precision value of 81.48% and recall value of 79.10%. After that PADSLDA-DT- ABC-PIO achieved the precision value of 94.54% and recall value of 96.42%. In this comparisons conclude that the DT classifier achieved better performance than other models. The below table shows the comparison results of proposed method in terms of accuracy. In table 3 represent that the accuracy measurement of different combination classifier method. In PADSLDA-RF- ABC-PIO achieved the accuracy of 61.08% and PADSLDA-NB- ABC-PIO achieved 78.44%. Finally PADSLDA-DT- ABC-PIO achieved the accuracy of 99.12%. By this comparisons conclude that the PADSLDA-DT- ABC-PIO provide better classification accuracy than other combination models.

## CONCLUSION

In this study, we implemented the machine learning classifier model to classify the tweets efficiently with help of proposed different techniques. In primary we evaluate the STC dataset to preprocessing, then the data is given to feature extraction as pack-author-date sentiment LDA. A concept called pack is introduced for sentiment analysis at pack level. The projected models progress the evaluations outcomes compared with the baseline simulations. In next, the combination of two optimization algorithm is used to select the feature. Finally different machine learning classifier to classify the data. In these classifier model, DT classifier attained the better classification accuracy of 99.12% significantly.

### ABSTRACT

This process is orderly significant in many fields among them being image detection, Marking language identity, and Biomedical data analysis. Nevertheless, the greatest approaches for the greater classification accuracy and efficiency of the classification model are when considering equality to model's complexity and computational expenses. It is within this context that the present study investigates the influence of hyperparameter optimization on decision-making deep learning models for dataset categorization and the introduction of a systematic guide to boost model proficiency. Using a strong hyperparameter tuning algorithm on CNNs and LSTM networks, this research underscores that the algorithms produce improved performance on several datasets. Research data suggests that the systematic approach to hyperparameter tuning produces marked gains in accuracy of categorical variable classification and the cut in the computational burden.

**Keywords:** Data Classification, Hyperparameter-Tuned, Deep Learning Algorithm, Convolutional Neural Networks, Long Short-Term Memory.

Seethala Devi et al.,

## INTRODUCTION

As the amount of data increases dramatically in different areas, it is vital to classify data correctly in applications such as image detection, and text-based sentiment analysis [1]. Of the many sub-categories of machine learning, deep learning can deliver excellent results in classification problems, primarily because it can learn high-level features, as well as the structure of the data. Know architectures that are effective for Image data classification are Convolutional Neural Networks (CNNs) and for sequence data classification Long Short-Term Memory (LSTM) networks. However, the effectiveness of these models depends on the hyperparameters – the details related to a specific type of model and algorithmic process. It is indeed perhaps the most essential task for obtaining high accuracy in the hyperparameters' classification and generalization while limiting computation expenses.

### Problem Statement

Despite having a high classification accuracy, deep learning models can have their hyperparameters as a main determinant of their performance [2]. Suboptimal end solutions are realized with default identity or heuristic-selected hyperparameters that may be easily available or easily set. In the absence of guidelines on how to optimize the choices of these parameters, the models risk losing accuracy, taking longer time to train and using more resources. These problems restrain the use of deep learning solutions in real-world applications. Therefore, there is a clear need to develop an approach that suggests proper hyperparameters accurately, and with minimal computational resources to improve the model.

### Justification of the Study

This research aims at filling a known gap of hyperparameter tuning in data classification. In this tutorial, optimization techniques for selecting hyperparameters are discussed to increase the classification capabilities of deep learning models thus increasing their flexibility and performance on any given data set [3]. Specifically, the experiment focus on how several hyperparameters tuning methods such as grid search tuning, random search tuning and Bayesian optimization tuning to choose the best suitable techniques for Convolutional Neural Network (CNN) and Long Short-Term Memory (LSTM) architectures. By doing so this comparative study gives a roadmap of how practitioners can enhance the effectiveness and the precision of the classification models.

### Objectives

The objectives of this research are threefold:

- To create and foster an appropriate method of hyperparameters' tuning: for fine-tuning deep learning models with a particular focus on classification.
- For assessing and comparing the performance of CNN and LSTM models – default and tuned on benchmark datasets.
- For comparing the influence of various methods of hyperparameter tuning: In this comparison grid search, random search, and Bayesian optimization impact on classification accuracy and computational resources, the model's stability is to be measured.

### Scope of the Study

The study is conducted on two widely recognized datasets: CIFAR-10 a dataset for image classification and IMDB for text classification [4]. These datasets are of different data modality and data type, thus enabling sufficient analysis of the hyperparameter tuning process. The study only focuses on CNN, which has been demonstrated to excel in image tasks, and LSTM, which has had similar success with sequential data. However, the results may shed light on the RL going beyond these types of architectures to other families like transformers or generative models. Therefore, this research paper provides a comprehensive assessment of hyper-parameter tuning technique in deep learning classification models to provide structures to enhance accuracy and efficiency of data classification. As such, this paper will focus on an empirical comparison of the tuning methods to enhance better optimized data classification models in practical solutions.

Seethala Devi et al.,

## LITERATURE REVIEW

The fine-tuning of the hyperparameters of deep learning models is an area of present-day research focus because of the inherent benefits that results from the optimization process [5]. This section discusses some past works for hyperparameter tuning methods and the impacts on different deep learning configurations and structure using data classification tasks together with their corresponding performances.

### Hyperparameter Optimization in DL

The problem of hyperparameters playback is the most important aspect of fine-tuning deep learning models for higher accuracy and termination [6]. The Deep learning models, including CNN models for the image data and LSTMs for sequential data requirements the hyperparameters subsequently, including learning rate, batch size, networks depth, and the dropout rate. Therefore, the selection of appropriate hyperparameters makes a big difference all together and it can be quite a tricky business. In one progressing survey, Bengio et al. (2014) set up that the learning rates, optimizer setting, and parameter of regularization can make distinct impacts on model performance and convergence. They have identified that fine-tuned hyperparameters relevant to convolutional neural networks can bring the boost in image classification accuracy on average from 5% to 15%.

### The general approaches to choosing hyperparameters

The literature presents three major hyperparameter-tuning methods: A brief explanation of three optimization methods are the grid search, random search, and Bayesian optimization [7]. Every of them has specific characteristics that define the possibility and efficiency of the tuning for various types of deep learning.

#### Grid Search

The first tuning technique is the grid search where only a specific set of values for any specific hyperparameter is tried out. Although effective, grid search may easily become very wasteful of computational resources when dealing with models that have many hyperparameters, due to the exponential increase in the number of parameters to test. It observed that the use of grid search to optimise hyperparameters in a CNN model boosted the classification accuracy by as much as 3 percent; however, the exercise is computationally costly when applied to hyperparameter spaces of high dimensions.

#### Random Search

Random search was proposed, which randomly selecting the hyperparameters from the distribution, and it obtains far fewer trials compared to the grid search approach [8]. The experimental results indicated the advantages of random search over that of the grid search, in which random search yields the same or even better results with many fewer trials. For instance, it applied random search to find the hyperparameters of an LSTM for the text classification problem with an increase in accuracy by 4% than from grid search with 60% less trials.

#### Bayesian Optimization

So, the modern and efficient tuning technique is Bayesian optimization which is effective if the search space is high-dimensional. It constructs a probability model for the objective function and then choose the hyperparameter set which is 'likely' to produce better results. This approach was also determined to be better than grid and random search in the subsequent trials since it uses the outcomes of previous experiments [9]. To support the observation, in an empirical study showed how Bayesian optimization can drastically cut tuning time by 50 % and at the same time increase the models' performance by 5-10% across different datasets. BO also, has been implemented on CNN and LSTM and resulted in increased accuracy as well as, computational performance.

#### Hyperparameter Tuning for CNNs

CNNs are very common in image classification, object detection, and other possible visual processing tasks mainly because of its capacity to learn the spatial hierarchy [10]. The evidence found in the literature indicates that there is a

Seethala Devi *et al.*,

variation of CNN performance depending on certain architectural hyperparameters such as filter size, number of layers, and pooling. When tuned optimally a drop of 10% was obtained on the error rates while working on the ImageNet dataset. Furthermore, in the methods of automatic tuning, including those based on the use of Bayesian optimization, relatively high results have been achieved. For example, applied Bayesian optimisation for hyperparameter optimisation for a ResNet model for image classification and got a 6% improvement over CIFAR-10 in accuracy to untuned models. The study also pointed out that designing automation to tune the parameters could provide superior performance than conventional heuristic practices, particularly with techniques like dropout regularization.

### Hyperparameters optimization of the LSTMs

LSTMs while typically used in sequential dataset problems are very dependent on hyperparameters for example number of units in a cell, rate of learning and the size of the sequence [11]. Current studies show that optimization of these variables improves LSTM, especially in areas like language generation, and sentiment analysis. For instance, in one of our prior studies, we showed that adjusting the hidden layer size and the dropout rate enhanced the accuracy of text classification and surpassed 7% in sentiment analysis. Furthermore, it used Bayesian optimization techniques on LSTMs in time-series forecasting which led to a mean squared error decrease of 5 percent. This they mention can be attributed to the fact that the internal dependency generated by the sequential data makes LSTM amenable to Bayesian optimization thus enhancing the search for the optimal hyperparameters from their high dimensionality.

### Comparison between different hyper parameter tuning methods

Further, comparative research has shown the efficiency of other hyperparameter-tuning approaches. To date, they have made one of the most thorough investigations toward this direction and conclude that Bayesian optimization outperforms the other two approaches concerning the computational benefits added to performance enhancements [12]. The study also concluded that Bayesian optimization delivered the best accuracy on CNN and LSTM models and was up to 5% better than the grid search and random search, tried far less time. These studies also highlighted trade-offs: grid search is complete but requires lots of time; random search is fast but may not locate the best settings; Bayesian optimization is faster than grid and random search while utilizing prior knowledge to sort out the results.

### Summary And Research Gap

From the literature turn, hyperparameter tuning been highlighted as a critical step of enhancing the deep learning models particularly in data classification [13]. It has been noted that grid and random search methods have been extensively discussed, and new approaches indicate Bayesian optimization can provide better solutions and time complexity, especially for CNNs and LSTMs. However, although it has such potential, there is a relatively small amount of ongoing research that investigates and compares these tuning techniques on both image and sequential data classification problems. However, much of the information regarding the computational effectiveness and reliability of these tuning methods remains empirical and warrant further investigation and confirmation with other different sorts of empirical data and deep learning network architectures. This present study intends to fill these gaps by examining the efficiency of grid search, random search, and Bayesian optimization when used on CNN and LSTM models to classify the data. Consequently, this paper presents a comparison of these strategies with the hope of establishing the best tuning methods for improving the performance of models in real scale applications.

## METHODOLOGY

In this section, the methodology for assessing the effect of the hyperparameter tuning on deep learning models used for data classification is presented [14]. We explain the selected models, datasets, hyperparameters, methods of tuning, and metrics used when making the experiments. Fig 1 shows the flowchart on methodology for enhanced data classification model with hyperparameter tuning.

Seethala Devi et al.,

### Model Selection

Two commonly used deep learning architectures were selected for this study: CNN and LSTM networks which are used in the given context [15]. These models are particularly commonly used when coping with image and sequential data making them suitable for experiments on classification with various types of data.

### Convolutional Neural Network (CNN)

CNNs are employed frequently for image classification problems owing to its capability to take spatial and hierarchical features inside images. In this study, we test a CNN model with multiple layers of convolution and pooling and followed by multiple layers of fully connected layers for classification.

### Long Short-Term Memory (LSTM) network

LSTMs are best used with sequences as they strive to remember what has gone before with time steps hence perfect for text and temporal data classification. An LSTM, which is defined with multiple recurrent layers, is used, the dense layers are used for final predictions.

### Dataset Selection

Two benchmark datasets were selected for testing and evaluating the models [16]:

**CIFAR-10:** CIFAR-10 is a basic image recognition dataset with 10 classes (airplanes, cars, birds and etc) and includes 60,000 images total. The size of each image is 32 by 32 pixels. The whole data set consists of 50000 training images and 10000 test images.

**IMDB Reviews Dataset:** This dataset is composed of 50 000 movie reviews from IMDB, which is defined as positive or negative, and is perfect for binary classification of text. The obtained results are split 50/50 with 25,000 reviews used for the training and the other 25,000 for testing purposes.

### Other Adjustable Parameters and Methods

The most important hyperparameters were chosen because they have a direct influence on the model training and its job performance. Three tuning techniques were used to find optimal values for each hyperparameter [17]:

**Learning Rate:** That is, it fixes the amount by which each of these gradients is updated during the model training process. In addition, a lower learning rate means we might be taking too small a step to the bottom, whereas a high learning rate implies that we are likely to overshoot the minimum or get trapped into local minimum.

**Batch Size:** It means that the statistic parameters of the model are refreshed after a certain number of samples pass through them. Batch size has a relation to training time and volatility of the model.

**Dropout Rate :**A form of a regularization parameter that during training randomly fixes specific layer outputs to zero to reduce over fitting.

### Hyperparameter-Tuning Methods

To optimize these hyperparameters, three techniques were employed [18]:

**Grid Search:** The Grid search in machine learning ushers all the explored hyperparameters with respect to the established range exhaustively. In each case of the hyperparameters, potential values to be tested were predetermined, and every possible combination was run.

**Random Search:** Additional information can be obtained from the nature of the algorithms such as cross validation where random search simply chooses random values from the hyperparameter space. This technique is not as computationally intensive as the grid search and that it can cover more hyperparameters space.

Seethala Devi et al.,

### Bayesian Optimization

The Bayesian optimization model created in this approach builds a probabilistic model with iterative evaluations and selects the appropriate hyperparameters. This method is efficient in practice when mapping through complex hyperspaces and it is well suited to deep learning architectures and **Table 1** describes the model baseline and tuned performance.

### Experimental Design

The experimental process was divided into two main stages for each model on each dataset:

**Baseline Training with Default Hyperparameters:** First, training was performed on the CNN and LSTM models using the defaults parameters to capture the baseline accuracy.

**Hyperparameter Tuning:** All of them were hyper-parameter tuned individually with grid search, random search, and Bayesian optimization [19]. As shown in table 3, each of the tuning methods was implemented separately, using only the best set of hyperparameters for each tuning method as chosen from validation accuracy. To maintaining coherence of splits, each model was trained using the same splits of training and validation data across all the tuning approaches. Finally, after tuning, the performance of the models was tested on the test set to determine final values of the effectiveness measure.

### Evaluation Metrics

The following metrics were used to evaluate model performance:

**Accuracy:** Used to determine the ability of a model by comparing the number of samples predicted correctly to the total number of samples in each data set to give a general measure of the model's accuracy.

**F1-Score:** This is actually a smoothed mean between precision and recall, so it is even more useful when working with imbalanced classes [20]. Besides, the F1-score is most informative for evaluating the LSTM model and performance of the binary classification task of the IMDB dataset.

**Computational Time:** Ascertains the amount of time taken by each tuning method to perform, making it easy to compare the computational complexity of the three methods of grid search, random search as well as Bayesian optimization.

### Data Preprocessing

Data preprocessing was carried out to prepare the datasets for model input:

**For CIFAR-10:** Images were also scaled up to with a pixel range of between 0 and 1, and other methods used to increase model robustness include crop and flip.

**For IMDB Reviews:** For text data, tokenization was performed, and sequences were padded in a way to provide equal length. Besides that, most of the text contained only words up to the first 10 thousand of frequency list and

## RESULTS AND DISCUSSION

This section presents the results of the experiments conducted on the CNN and LSTM models for the CIFAR-10 and IMDB datasets, respectively, using three hyperparameter tuning methods: It compared three bases which include grid search, random search, and Bayesian optimization [21]. In this work we compare tuning methods with respect to accuracy, F1-score, and the time it takes for tuning. Furthermore, we analyze the implications arising from these results and compare performances of the models and datasets.

Seethala Devi et al.,

### Evaluation of the baseline model

As a first step, default parameter settings for the CNN and LSTM models were used to train both algorithms to identify benchmark performance [22].

CNN Model on CIFAR-10, Accuracy: 75.2%, F1-Score: 0.75, Training Time: ~1.5 hours.

LSTM Model on IMDB: Accuracy: 81.4%, F1-Score: 0.81, Training Time: ~1 hour.

These values can be considered as the initial assessment crucial for the evaluation of the impact of hyperparameters tuning for the model improvement.

### Effects of Optimizing Hyperparameters

The rest of this paper provides the experimental outcomes for each model regarding to grid search, random search, and Bayesian optimization performance on their corresponding dataset [23]. Lastly, performance of final model of each tuning method was validated on the test set.

#### CNN Model on CIFAR 10

**Grid Search:** Accuracy: 78.6%, F1-Score: 0.79, Computational Time: ~12 hours.

**Random Search:** Best Hyperparameters: Learning Rate = 0.002; Batch Size=32; Dropout Rate = 0.25, Accuracy: 80.1%, F1-Score: 0.80, Computational Time: ~5 hours.

**Bayesian Optimization:** Best Hyperparameters: These include Learning Rate = 0.0015, the Batch Size = 32 and, the Dropout Rate = 0.2, Accuracy: 82.5%, F1-Score: 0.82, Computational Time: ~3 hours.

#### Long Short-Term Memory Model on IMDB

**Grid Search:** Best Hyperparameters: Learning rate is 0.001, Batch size is 32, Dropout rate is 0.3 and Number of units in every layer are 128, Accuracy: 84.5%, F1-Score: 0.85, Computational Time: ~10 hours.

**Random Search:** Accuracy: 85.7%, F1-Score: 0.86, Computational Time: ~4 hours.

**Bayesian Optimization:** Best Hyperparameters: The learning rate was set as 0.0015, batch size as 32, the dropout rate was set to 0.2, number of units in the dense layer was 150, Accuracy: 87.8%, F1-Score: 0.88, Computational Time: ~3 hours.

### Computational Efficiency

**Grid Search:** Although grid search has provided considerable enhancements in accuracy, it was the most time-consuming procedure. Due to the truly random search over the configuration space, the training took almost 3-4 times more time compared to the previous experiments which resulted in 11-12 hours for the CNN model on CIFAR-10.

**Random Search:** Random search resulted in a more reasonable compromise between accuracy and time consumption in terms of computation. Thus, for both models, it achieved near to the optimum value of accuracy with lesser time than grid search in the approx. to the range of 60% less.

**Bayesian Optimization:** Unlike the other methods, Bayesian optimization was the most efficient in terms of computational cost; it took about 3 hours to achieve the tuning process of both models. Building the concept of previous experiments into the Bayesian optimization has eliminated unproductive calculations and directed estimates in the most viable areas in the hyperparameters space to get the highest accuracies in the shortest time.

### Trade-offs Between Accuracy and Computation

Although considerable enhancements over the baseline were obtained by means of grid search, the number of evaluations performed by this method by default results with extremely high time and computational complexity, which means it is not suitable for high-dimensional spaces or large numbers of hyperparameters. Random search while taking less time gave almost equivalent hyperparameter setting without the need for evaluating every setting given in the grid search. But the Bayesian optimization showed the best performance in terms of both, accuracy and less computational time.

Seethala Devi et al.,

### Findings

Therefore, the results from this study underscore the importance of performing structured hyperparameter tuning to improve upon the data classification problems [24]. The results showed the superiority of Bayesian optimization and fear that guided optimization methods are quite helpful for deep learning models where the data is large, or the input features are high-dimensional. This study also addresses the issue of potential losses incurred with regards to grid search in deep learning due to computational expense in the prospective of small increases in accuracy. Since both random search and Bayesian optimization took almost the necessary number of trials to reached near optimal hyperparameters, these methods are better suited for fine tuning complex models in real world scenarios and **Table 3** gives the training time comparison.

### Real-Life Application Connotations

From the practitioner's perspective, these findings imply that Bayesian optimization is an adequate solution for hyperparameters' tuning under limited computational budgets, but high accuracy is needed. The efficiency gains brought about by Bayesian optimization can be of significant usefulness in an actual time implementation or whenever a quick result is needed on huge data sets. Thirdly, this research also affirms the hypothesis that other similar studies have proposed that fine-tuning hyperparameters for the given dataset size and the architecture and design of the ML model can significantly improve the performance. For instance, sensitivity to batch size and learning rate were much higher for the CNN than for the LSTM where changes to dropout rate and number of units were more effective.

### Limitations and Future Work

Several limitations pertain to this study Thus, even though this study yielded useful findings, there are Limitations that must be taken into consideration. First, the hyperparameter tuning procedure was constrained with the presented values and ranges excluding some potentially beneficial configurations. Further, tuning has been performed only for CNN and LSTM models; expanding this crow's spring framework for other like transformer could be fruitful to investigate in future research [25].

More studies could investigate whether other forms of adaptive, self-adjusting hyperparameter optimization algorithms or a blend of the two approaches that present the best benefits of random search and Bayesian optimization exist [26]. Further, applying hyperparameter tuning by distributed computers may also prove useful in minimizing the computational time even more, thus feasible for larger dataset and complex model. Fig 2 to 4 contains these charts: plotting the comparison between the accuracy of CNN and LSTM models using four tuning methods (Baseline, Grid Search, Random Search, and Bayesian Optimization), plotting accuracy improvement as epochs in 20 epochs for each tuning method over a sample model (CNN), differentiating time taken in hours for tuning methods of model CNN and LSTM. **Fig 2** compares the accuracy of CNN and LSTM models across four tuning methods, **Fig 3** shows the model accuracy progresses over 20 epochs for each tuning method on a sample model (CNN), **Fig 4** contains the training time in hours for each tuning method, comparing CNN and LSTM models, **Table 4** is given the values of Accuracy Improvement Analysis by Tuning Method and **Table 5** is training time comparison by Tuning Method values.

## CONCLUSION

This study clearly illustrates that deep learning models tuned for hyperparameters are far more accurate in data classification than untuned models. Thus, the tuning method of Bayesian optimization dominated the set of tuning methods providing the highest gains, but at the same time demonstrating low time consumption. Further studies can be made to investigate how adaptive tuning methods are used in training where practitioners can change values of hyperparameters over time to enhance classification results. The research compared only CNN and LSTM models; further work could include transformers and more models. Moreover, a special emphasis on the F1-score and its sheer accuracy does not consider such aspects as time and space required for inference. Further work can also be made on understanding how the proposed Bayesian optimization-based tuning method can be combined with other

Seethala Devi et al.,

automated NAS approaches. When using transfer learning together with hyperparameter optimization, one might also achieve better results along specific domains to improve deeper learning contribution to classification.

## ABSTRACT

Sugarcane is an important crop worldwide and is often affected by diseases such as red rot, rust and smut caused by pathogens, which affect productivity. Traditional disease detection methods are often labor-intensive, time-consuming, and rely on expert knowledge, which is not easily accessible. Developments in image processing and DL have enabled the development of automated systems for detecting sugarcane diseases. This study proposed an integrated A deep learning architecture that integrates convolutional neural networks with recurrent neural networks and ensemble techniques to work on the exactness and strength of disease classification. Image pre-processing methods, including grayscale conversion, Gaussian median filtering, contrast enhancement, and histogram equalization, were applied to improve the quality of the input images. The model was prepared on a different dataset and accomplished superb execution in terms of accuracy, precision, recall, and F1 score, outperforming traditional methods. This study demonstrates the potential of combining deep learning and image processing to develop effective disease management tools, aid crop protection, and improve productivity.

## INTRODUCTION

Sugarcane, a crucial crop for sugar and biofuel, plays a significant economic role in Asia, Latin America, and Africa. However, diseases like red rot, rust, smut, and top shoot borer severely impact its yield and quality of crops are significantly impacted by diseases, making early detection of these issues crucial for effective management and minimizing losses. Traditional diagnosis methods, reliant on expert visual inspection, are time-consuming, error-prone, and unsuitable for large-scale fields, driving the need for automated, scalable solutions. Recent advances in image processing and DL, especially Convolutional Neural Networks (CNNs), have changed plant disease discovery Patel, *Set.al.*, (2024). These techniques extract disease-specific features like discoloration and lesions from images, outperforming traditional methods. Despite their success, challenges such as lighting variations, overlapping symptoms and inconsistent leaf textures can affect the accuracy of individual models. Ensemble learning, which combines multiple models, addresses these limitations by leveraging diverse strengths, improving prediction accuracy, and enhancing robustness. This study introduces an ensemble deep learning model for sugarcane disease detection, integrating CNNs, Recurrent Neural Networks (RNNs), and ensemble methods. The approach combines the strengths of individual models to capture diverse patterns in disease data. Image pre-processing techniques like grayscale conversion, Gaussian median filtering, contrast enhancement, and histogram equalization are employed to enhance image quality, highlight disease features, and reduce noise, enabling more effective pattern extraction by the models. The proposed system automates sugarcane disease diagnosis, reduces reliance on expert knowledge, and provides a scalable solution for early disease intervention Wani, *Z et.al.*, (2024). By integrating multiple deep learning models and advanced image processing, the ensemble approach demonstrates improved accuracy and reliability in detecting and classifying sugarcane diseases, supporting sustainable crop management.

## RELATED WORK

**Ali et al. (2022)** proposed a CNN-based approach to classify and predict sugarcane diseases like yellow leaf disease, smut, and rust. Their model achieved 95% classification accuracy, outperforming traditional ML algorithms such as SVM and RF. They utilized a large dataset of sugarcane leaf images and applied image augmentation techniques to improve model robustness. **Yin et al. (2023)** developed a multi-task deep learning model combining CNN with a transformer-based network for sugarcane disease detection. The model was prepared on a large dataset of images captured under different lighting conditions and angles. It demonstrated excellent generalization capabilities, achieving high accuracy even with limited training data. **Kumar et al. (2023)** explored the application of pretrained models like ResNet50 and InceptionV3 for sugarcane disease classification. They found that using transfer learning with a small dataset of sugarcane images resulted in faster convergence and better performance compared to training a model from scratch. The model was capable of classifying multiple diseases, including sugarcane leaf rust and downy. **Singh et al. (2023)** explored the use of hyper spectral imaging to detect early-stage infections in sugarcane plants. Their model analysed spectral bands that were sensitive to leaf chlorophyll content and moisture, revealing potential disease presence even before visible symptoms appeared. **Raj et al. (2023)** developed a mobile app that integrated an image processing-based disease detection system. The app uses the camera of a smartphone to capture leaf images and processes them in real-time using deep learning models deployed on the device's edge processor. This enables rapid disease identification, even in remote areas with limited internet connectivity. **Patel et al. (2022)** developed a hybrid model combining a support vector machine with a CNN. The CNN was used for feature extraction, while the SVM was employed to classify the disease. This approach achieved an accuracy of 96% for disease detection, outperforming individual models. **Ali, F., & Zafar, M. (2024)**: This study proposed a hybrid CNN model optimized for sugarcane disease classification. The model achieved superior performance by incorporating data augmentation techniques and fine-tuning on a specialized sugarcane leaf disease dataset, achieving an accuracy of 96%. It demonstrated the potential of deep learning for large-scale applications in real-world agricultural settings. **Kumar, A., & Gupta, P. (2024)** Using multispectral images developed a CNN-based model to differentiate between healthy and diseased sugarcane plants. The model demonstrated high accuracy in detecting diseases such as yellow leaf disease and bacterial wilt with 96% accuracy.

Umamaheswari and Kumaravel

## MATERIALS cAND METHODS

### Data Collection

In this work used Sugarcane Leaf Disease Dataset from Kaggle repository. The dataset includes high-resolution images of sugarcane leaves, which have been labeled with specific disease classifications. The images show different stages and severities of diseases that affect sugarcane, including:

- Rust Disease
- Mosaic Disease
- Bacterial Blight

### Disease Labels

Each image in the dataset is labeled according to the disease it represents, making it useful for supervised machine learning tasks. These labels help in classifying the type of disease based on visual patterns in the leaf images.

### Use in Deep Learning

Since the dataset includes images, it is particularly suited for DL applications like CNNs, which can learn to identify disease features such as texture, color variations, and lesions present on the leaves.

### Environmental Context

Some versions of the dataset may include additional data related to environmental conditions (e.g., temperature, humidity), which can help in improving the accuracy of disease predictions.

### Image Pre-processing

Pre-processing techniques, including grayscale conversion, contrast enhancement and noise filtering, are often used to prepare training images to improve features relevant to disease detection.

## IMAGE PREPROCESSING

Image pre-processing is crucial for enhancing input quality and improving the accuracy of sugarcane leaf disease detection models, particularly deep learning models like CNNs. Key techniques include:

### Gray scale Conversion

Converts color images to shades of gray, representing brightness levels from black to white.

- It Simplifies images by reducing color complexity, focusing on disease-relevant features, and lowering computational demands.

$$Gray = 0.299 \times R + 0.587 \times G + 0.114 \times B$$

- It achieved by averaging or weighted averaging the RGB pixel values.

### Gaussian Median Filtering

Combines Gaussian blur and median filtering to reduce noise while preserving edges Choi, Y *et.al.*, (2022).

- **Gaussian Blur:** Smooths images using a Gaussian-weighted average to reduce small intensity changes.
- **Median filtering:** Substitutes each pixel with the median value of its neighboring pixels, effectively eliminating salt and pepper noise.
- It Enhances image clarity by reducing noise and retaining disease-specific features like spots and lesions.

### Contrast Enhancement

Enhances image features by increasing the distinction between light and dark areas, aiding in detecting subtle disease symptoms.

### Umamaheswari and Kumaravel

- It Improves visibility of lesions, spots, and discoloration for better model feature learning.
  - *Histogram Stretching*: Expands pixel value range to maximize contrast.
  - *CLAHE*: Boosts contrast in local regions, highlighting fine details.

#### Histogram Equalization

Improves the overall contrast of the image by redistributing pixel intensities throughout the entire range.

- It reveals hidden details in low-contrast areas, improving visibility of disease symptoms in darker leaf regions.
- The Normalizes pixel intensities to span the full range (e.g., 0–255).

#### Adjusting Gamma Values

Gamma correction adjusts brightness and contrast to enhance low-contrast regions.

- It Highlights disease symptoms like rust or spots in dark or poorly lit areas.
- It Modifies pixel intensity using a gamma function:

$$I_{\text{new}} = I_{\text{old}}^{\gamma}$$

- $\gamma < 1$ : brighten the image.
- $\gamma > 1$ : darken the image.
- **Use Case**: Useful for revealing details in overly dark or bright regions.

#### Adjusting Color Tones

Enhances disease-relevant features in colored images by modifying color balance.

- It Highlights discolorations or spotting, aiding in disease detection.
  - *White Balance*: Normalizes color temperature for natural appearance.
  - *Channel Shifting*: Enhances specific channels (e.g., red for rust detection).
- It Useful for symptoms involving color changes like yellowing or browning.

#### SEGMENTATION

Segmentation plays a critical role in image processing for sugarcane leaf disease detection, as it isolates regions of interest (ROI) that exhibit disease symptoms, such as lesions, discoloration, or spots. This technique allows disease-related features to be distinguished from the background, improving the focus of subsequent analysis. By removing irrelevant parts of the image, segmentation enhances the effectiveness of disease prediction models. Effective segmentation is especially important when combined with DL methods like Convolutional Neural Networks, which rely on clear and accurate feature extraction for classification. Various segmentation techniques, including thresholding, edge detection, and region-growing methods, can be used depending on the nature of the image and disease symptoms. Singh, D., *et.al.*, (2023). Proper segmentation ensures that deep learning models can better identify and classify disease symptoms, leading to more accurate predictions and timely intervention in agricultural practices. Thresholding A simple and widely used segmentation technique for binary classification, dividing an image into two classes: foreground (interest) and background.

- Identifies regions with specific intensity levels, such as diseased areas on a sugarcane leaf.
- In binary thresholding, pixel values are compared to a set threshold, grouping pixels as one or the other forefront or foundation.

$$I(x, y) = \begin{cases} 255 & \text{if } I(x, y) > T \\ 0 & \text{if } I(x, y) \leq T \end{cases}$$

In thresholding, a Pixel value ( $x$ ) is compared to a threshold. If  $(x) > T$ , the pixel is classified as part of the foreground (diseased area); otherwise, it's considered background (healthy leaf).

### Umamaheswari and Kumaravel

- Global Thresholding: A uniform threshold is applied consistently throughout the entire image.
- Adaptive Thresholding: The threshold is modified according to the local characteristics of the image. (e.g., lighting).
- This threshold can be sensitive to noise, lighting changes, and changes in leaf texture. It works well with sharp contrast, but may struggle with complex backgrounds or overlapping symptoms.

#### RIO-based Intensity Adjustment (Region of Interest-based Intensity Adjustment)

##### ROI-based Intensity Adjustment

This technique focuses on adjusting intensity values within a specific Region of Interest (ROI) to improve segmentation accuracy, particularly for identifying disease symptoms on sugarcane leaves.

- It Enhances contrast in the diseased areas (e.g., discoloration, lesions) to make them more distinguishable from healthy regions.
- *ROI Identification*: Selects the ROI, either manually or automatically, based on patterns such as color or texture.
- *Intensity Adjustment*: Enhances or reduces intensity within the ROI to amplify disease symptoms, improving contrast with healthy areas.
- It highlights subtle disease symptoms for better detection during segmentation.
- Selecting the correct ROI can be difficult in complex images with overlapping symptoms or variable lighting.

#### Smoothing

Smoothing reduces high-frequency noise to enhance important features like disease symptoms while filtering out irrelevant details.

- The Minimizes noise and prevents small, irrelevant details from affecting segmentation, especially when detecting subtle disease symptoms.
- In Gaussian smoothing, a filter (kernel) is applied to each pixel, with surrounding pixels weighted based on their distance from the center pixel.

$$I_{\text{new}}(x, y) = \sum_{i=-k}^k \sum_{j=-k}^k I(x+i, y+j) \cdot G(i, j)$$

where  $G(i, j)$  represents the Gaussian kernel, and  $I(x, y)$  is the pixel value at position  $x, y$ .

#### Types of Smoothing Filters

Smoothing reduces noise and preserves relevant features by averaging pixel values.

- **Gaussian Filter**: Blurs the image while preserving edges.
- **Median Filter**: Each pixel's value is replaced by the median of its surrounding pixels, rendering this technique effective for removing salt-and-pepper noise
- **Advantages**: Removes small imperfections, enabling segmentation algorithms to focus on larger features like diseased areas.
- **Challenges**: Over-smoothing can blur important details, such as small disease spots, making them harder to detect.

#### Region Growing

A segmentation method that initiates with a seed pixel and progressively expands the region by incorporating adjacent pixels with similar properties (e.g., intensity, color). Shah, R *et.al.*, (2021).

- The Segments diseased regions from healthy areas by expanding a region based on predefined criteria.
  - *Seed Selection*: Selects one or more initial seed points in the suspected diseased region.
  - *Growing the Region*: Adds neighboring pixels to the region if they meet similarity criteria (e.g., intensity).

### Umamaheswari and Kumaravel

- *Stopping Criterion*: Stops when the region meets the similarity threshold or the entire diseased area is segmented.
- It Effective for segmenting areas with uniform texture or intensity, ideal for detecting localized disease symptoms.
- It Sensitive to seed point selection and can struggle with irregular or overlapping disease patterns.

## FEATURE EXTRACTION

### GLCM

Gray Level Co-occurrence Matrix is one of the most generally involved strategies for separating surface elements from pictures, particularly in image processing applications like disease detection. It focuses on analyzing the spatial relationship between pixels, helping to quantify patterns and textures that can be used to differentiate between healthy and diseased regions in images of crops like sugarcane leaves.

### GLRLM

The **Gray Level Run Length Matrix** is a statistical method used to describe the **texture** of an image based on the **runs** of pixels with the same intensity value. It is particularly useful for analysing **heterogeneous textures**, where regions of consistent intensity are followed by abrupt changes, which can be indicative of disease patterns in images of agricultural crops like sugarcane leaves

## PERFORMANCE ANALYSIS

### Sensitivity (True Positive Rate)

Sensitivity assesses the proportion of true positives (diseased leaves) that are accurately detected by the model. It reflects the ability of the model to detect diseased areas. High sensitivity indicates that the model is good at identifying disease when it is present, which is critical for early disease detection

$$\text{Sensitivity} = \frac{\text{True Positives (TP)}}{\text{True Positives (TP)} + \text{False Negatives (FN)}}$$

### Specificity (True Negative Rate)

Specificity quantifies the proportion of true negatives (healthy leaves) that the model accurately identifies. It assesses the model's ability to avoid false positives. High specificity ensures that the model is effective at ruling out healthy leaves and not misclassifying them as diseased Sahu, S *et.al.*, (2024).

$$\text{Specificity} = \frac{\text{True Negatives (TN)}}{\text{True Negatives (TN)} + \text{False Positives (FP)}}$$

### Accuracy

Precision is the total proportion of correct the ratio of predictions (which includes both true positives and true negatives) to the overall number of predictions made. Accuracy is a broad measure of model performance, but can be misleading if there is a class imbalance (e.g., more healthy leaves than diseased leaves). In this case, sensitivity and specificity can provide a clearer picture.

$$\text{Accuracy} = \frac{\text{True Positives (TP)} + \text{True Negatives (TN)}}{\text{Total number of samples}}$$

## Results

The entire results of the proposed work starting from image pre-processing to sugarcane disease prediction are detailed in this work. The dataset used in this research work consisted of images from Kaggle repository of Sugarcane Leaf disease dataset called Ensemble Model of Sugarcane Leaf Disease Segmentation using Image Processing with Deep Learning Techniques (SLDSDL). Raj, S. *et.al.*, (2023). The sugarcane disease dataset selected for

### Umamaheswari and Kumaravel

this study consisted of 15 images of the sugarcane. The proposed techniques were tested on these selected images using Python Jupiter tool for identifying diseases and is depicted in Figure 5.1

#### SLDSDL Image Pre-processing

The pre-processed images of SLDSDL are an efficient base for segmenting diseased objects from sugarcane images. The outputs from each pre-processing stage is given below

- **Grayscale conversion:** The preprocessing of the sugarcane image starts with conversion to grayscale. Python uses predefined functions that support different types of colormaps to colorize grayscale images. Li, W *et.al.*, (2024). First determine the minimum and maximum values of the source grayscale image and the defined colormap, then assign the minimum color value to the minimum grayscale value of the grayscale image, and assign the maximum color value to the maximum grayscale value of the grayscale image. Between the minimum and maximum values, all other colors in the colormap are linearly mapped to each grayscale value. Figure 5.2 shows the grayscale conversion of SLDSDL.
- **Gaussian median filtering:** Gaussian filter performs convolutions both in spatial and frequency domains and popularly known for blurring and reducing noise by smoothing the data. SLDSDL uses Gaussian followed by Median filter which helps remove impulsiveness. Kumar, V., *et.al.*, (2023). A median filter is a nonlinear filter used for signal smoothing. Figure 5.3 depicts the output of Gaussian followed by Median Filter on sugarcane Images.
- **Contrast enhancement:** Previous studies have evaluated the image quality of enhanced multiphase dynamic CT of the liver using different concentrations of contrast agents. Ali, F *et al.* (2022) The researchers demonstrated that higher concentrations of contrast agents can lead to better disease image enhancement. Figure 5.4 depicts SLDSDL Contrast enhance sugarcane Image.
- **Histogram equalization:** Histogram equalization is a method of processing images.. This processing results in a linear cumulative distribution function. Figure 5.5 shows the Histograms and Equalized Image output from SLDSDL.

#### SLDSDL Segmentation

Sugarcane Image Segmentation is detection of boundaries in an Image. Segmentation is a challenging task as the plant shows major modes of variation. Hence, SLDSDL pre-processes images prior to the image's segmentation which is utilized to acquire further indicative bits of knowledge Cheng, L., *et.al.*, (2022). Further processing after segmentation typically involves programmed estimation of organs, cell counting, or recreations in light of the removed limit data. SLDSDL follows thresholding as the first step of its segmentation followed by filtering and smoothing, before being identified with a region growing technique to segment required object parts.

- **SLDSDL Thresholding:** Otsu's method is a widely utilized global thresholding technique, renowned for its simplicity and effectiveness. Yin, L *et.al.*, (2023). Calculate the optimal threshold that separates two classes so that their inter-class variance is minimized, or equivalently, their inter-class variance is maximized. Figure 5.6 shows the input image and Otsu Thresholding Output.
- **Intensity Adjustment and Filtering:** After Otsu's thresholding the image's intensity is adjusted and a guided filter is applied. Guided Filter is used in SLDSDL as an edge-preserving and smoothing technique. Figure 5.7 depicts the Guided filter Output.
- **Region Growing:** The region growing technique employed in SLDSDL begins with the selection of an initial seed point. This approach is utilized because it evaluates the neighbouring pixels of the seed point to decide if they should be included in the growing region

#### SLDSDL Classification

Different imaging modalities are used to diagnose the soft layer of the plant depending on the nature of the disease. Each imaging modality plays an important role in the classification of sugarcane related diseases. The classification of a plant as either healthy or diseased is entirely based on its texture, which consists of patterns that may exhibit

### Umamaheswari and Kumaravel

regular or irregular frequencies. Kumar, R. et.al., (2023) In order to classify plants into their respective disease categories, it is important to accurately extract the region of interest (ROI) using segmentation, but since plant structures have the largest differences in intensity texture within and along their boundaries, this constitutes a major problem in segmentation and classification. Thus SLDSL's pre-processing and segmentation takes into account these features and prepares it for classification using Random Forest Algorithm. The algorithm can be applied to both classification and regression problems and was used by SLDSL for the classification problem of predicting liver abnormalities. Random forests split each node of the tree using the best subset of the randomly selected subset of predictor variables (segment features) at the node.

#### Algorithm steps for sugarcane preprocessing

Input: Selected Sugarcane Leaf images.

Output: Preprocessed Sugarcane Leaf images.

Step 1: Select image from database.

Step 2: Transform image or pre image of the particular subset of the co-domain of the function that map to the specify members.

Step 3: Finding boundaries of objects with in images.

$$\Delta f = \text{mag}(\Delta f) = [G_x^2 + G_y^2]^{1/2}$$

Step 4: To correct the detection of edges and boundaries of objects with in images by only centering circles on points in the center position of study plot.

$$P_y = \frac{e + d}{2d}$$

Step 5: The pixel values of the grayscale image were normalized to a range between 0 and 1 by dividing the possible intensity values (ranging from 0 to 255) as illustrated in the equation below

$$x_{ij} = \frac{\text{Image}_i}{255}$$

Step 6: To filter estimate of the inclination of the picture power using SOBEL image operator.  $G = \sqrt{G_x + G_y}$ , utilizing this data, we can likewise compute the inclination's heading

$$\theta = \text{atan}\left(\frac{G_x}{G_y}\right)$$

Step 7: Calculate the segmentation function from the sugarcane image.

Step 8: Assess the internal markers that represent the connected components of pixels related to the objects of interest.

Step 9: Measure the outside markers that are the associated parts of pixels related with the foundation of the mind picture.

Step 10: Update the division capability has least for inner and outer marker area.

Step 11: Measure the watershed change of the altered division capability.

Step 12: Preprocessed sugarcane images updated in a database. Figure 5.9 depicts the final output of SLDSL while Table 5.1 lists its comparative performance with other Classifiers in predicting diseased regions.

It is evident from Table 5.1 that SLDSL performs better than other classifier with 98.75% Sensitivity, 99.33 % Specificity, mainly due to its pre-processing and effective segmentation techniques.

## CONCLUSION

Preprocessing of the repository's sugarcane images becomes a necessary prior step to image processing and segmentation. Images may have labels or tags (film artifacts), such as the patient's name, age, and markings, or generate various types of noise. In complex image processing, it is necessary to smooth these images because the gray levels of the images overlap and make segmentation or feature extraction difficult. These artifacts also affect post-processing techniques and interpretation. Therefore, it is imperative to improve the image quality and make the

### Umamaheswari and Kumaravel

image suitable for further processing. Therefore, the main goal of pre-processing is to remove potential anomalies in the image Reddy, A., et.al., (2022). This study proposes a new sequential image pre-processing step for plant imaging modalities (e.g., scanning and photography) to improve the prediction or classification accuracy. The proposed technique, called SLDSL, will help improve the clarity and help avoid over-segmentation of diseased areas in sugarcane leaf images.

## ABSTRACT

Data mining (DM) is the process of examining datasets to display findings about the data they contain. Examining, cleaning, converting, and modeling data in order to find relevant information is the process. Semi-structured and structured data are both found in databases. The partially arranged data comes from a number of sources. An open power framework presentation stage is provided by the framework to allow for the breakdown of data from the full data bearer. The analysis is much more straightforward in accordance with this theory than other data mining techniques. Giving data with a larger and more comprehensive perspective is the main goal of the suggested study.

**Keywords:** The analysis is much more straightforward in accordance with this theory than other data mining techniques.

## INTRODUCTION

One of the most talked-about subjects among researchers these days is data mining. The data is used to refer to the vast number of datasets and is kept in cloud storage. The unstructured data in cloud storage datasets necessitates

**Chockalingam et al.,**

more thorough real-time analysis than traditional datasets [1]. The idea of cloud storage data aids in our comprehension of the abstraction and in-depth knowledge behind a number of hidden values. A technique made possible by technology, data mining allows for the acquisition of more precise, in-depth, and richer insights into the specifics of clients, partners, and companies, ultimately leading to a competitive edge. Organizations may monitor developing trends, make quick course corrections, identify new business possibilities, and make time-sensitive choices more quickly than ever before by analyzing a constant stream of real-time data [2].

**STRUCTURED DATA**

The data found in relational database systems is known as structured data. Because of its structure and organization, it may be controlled via SQL and its several IBM-developed variants, ADO.net, and ODBC in RDBMS systems. Simple and straightforward search engines may efficiently search for targeted content because of explicit semantics and structure [3].

**SEMI STRUCTURED DATA**

One type of organized data that lacks a structure for information display is semi-structured data, which can also support a rigid or formal structure. Since this semi-structured data is largely optional and includes labels or other markers to distinguish semantic elements and permit the pecking order of record fields within the data, it does not need a composition specification. It is crucial to use standard information mining methods or standard preparation dialects to convert semi-structured data to structured data [4].

**DATA MINING**

It is evident that several organizations are now using a significant amount of basic data that might be useful in a variety of domains, such as monitoring an article's activity, transmitting sensors, tracking data, and so on. Distributed storage is a term used to describe a severe data deluge. Information that respects the present state of data Comparable situations arise when an organization wants to examine its own data in order to analyze client complaints and rework services on a product [5]. This is similar to stockpiling executives and the measurable evaluation of data. As a result, producers would express their choices based on the analysis of extracted data or data that conveys a certain amount of value or weight [6]. AI, database frameworks, and insights can also be used to design data mining between irrelevant features of datasets. Networks were developed with data handling, capacity, and accessibility in a variety of logical domains. An assortment of distributed registering assets that are available via a local or wide area network and that look to an end user or program as a single, massive virtual figuring framework is called a matrix. In order to provide infrastructure-building, stage, and programming resources, it is possible that a few specific inventions and implementations will be anticipated for the cloud [7]. Distributed storage data, a collection of sophisticated data that includes both structured and unorganized data, is growing rapidly. Data from distributed storage is undoubtedly unique and has a direct impact on individual satisfaction. Utilizations of data can be traced in a variety of cloud PC frameworks, such as e-science and medical care frameworks, instructor critique, informal organizations, and procurement exchange divisions. Analyzing data to compile it and look for patterns is an important part of every evaluation. At the assessment setup stage, the systems for data analysis and orchestration should be used. By managing a steady stream of continuous data, associations can detect emerging patterns, make time-sensitive decisions more rapidly than ever before, move quickly, and seize new economic opportunities without hesitation. [8]. Finding meaning and uncovering hidden links in data mining can be accomplished using a variety of techniques, including requirements analysis. Three key prerequisites are necessary:

- Communicating computational resources is essentially the key to minimizing data transit. Data is entered into the computer system, processed, and then delivered to the next location in classic analysis situations. Flipkart sales data, for instance, might be taken out of the e-system, converted to a relational data type, and then put into an operational data store that is set up to provide reports. ETL (Extract, Transform, and Load) architectures of this kind grow less structured with each rise in data volume. Storing and processing data in the same location adds intelligence.
- Using current talents implies that new data or new data sources necessitate learning new abilities. Where analysis can and should be done is usually determined by the skill sets that are already in place. It is crucial to

### Chockalingam *et al.*,

be able to handle both types of processing, even though most firms have an increasing number of employees who can analyze data using either SQL or Map Reduce.

- Data security is a crucial component of many business operations. In essence, users of data warehouses are accustomed to a trustworthy set of management standards and security measures in addition to judgment-defined metrics, dimensions, and attributes. Open source analytic tools and unstructured data sources frequently fall short of these exacting procedures.

The core of data mining analytics is shaped by the process of transforming a large amount of unstructured, raw data that has been recovered from multiple sources into an information item that is useful for associations. Following data collection, we often have a variety of data sources with unique features. As we continue to create our data product, the most immediate step would be to homogenize these data sources. It depends on the kind of data, though. One of the most fundamental efforts in massive data analysis is quantifiable showing, which implies unsupervised and supervised portrayal or backslide problems. It is important to consider surveying several models with reasonable disaster estimations after the data has been cleaned and prepared for display. Once the model has been implemented, assistance evaluation and outcomes should be reported. In prudent displaying, a common mistake is to simply finish the model without ever assessing its execution. High-profile data privacy security is a difficult problem since unwanted individuals can simply breach the data. The primary focus of this suggested embedded security paradigm, in conjunction with the integrated data analytics approach, is data security. When creating the framework for the user's benefit, the following precautions are taken into consideration.

- Protecting the privacy of high-profile data.
- Using an integrated framework for data analytics to ensure data security.
- Increasing the level of authentication to guard against unauthorized users.
- Enabling privacy and security in the framework for data analysis.

#### The Research Objectives are

- **Confidentiality (data privacy):** Preserving confidentiality is the primary goal of this study. Encoding then hides the data set, the results of the data framework analysis, and the messages. Here, a USB key is used to create a unique key for encryption. By using the same special key, the information can be decrypted when it's needed. Data confidentiality is thus guaranteed.
- **Data Integrity:** Another crucial consideration when creating the framework is preserving the information's authenticity. By using a secure key to encrypt the database, the suggested approach safeguards the data. Only when the unique key is supplied can the same database be obtained. As a result, the stored information remains original.
- **Authentication:** Using a unique key for authentication protects the framework because safeguarding data from hackers is a top priority. This particular key cannot be changed by hand because it will be formed using the firmware key number of the USB device that was used, along with the password and generated keys. In the encryption and decryption processes, this key is utilized.

#### DEPENDENCY-ORIENTED DATA

In these situations, there might be links between data pieces, either explicit or implicit. For instance, a dataset has a collection of vertices, or data objects, that are linked together by a collection of edges, or relationships. Implicit dependencies, however, are present in time series. Two consecutive values obtained from a sensor, for instance, are probably related to each other. As a result, the time attribute subtly indicates a relationship between subsequent readings. Because of the complexity caused by pre-existing links between data elements, dependency-oriented data are generally more difficult to handle. To get answers that are contextually meaningful, the analytical process must explicitly incorporate these connections between data elements. In reality, the various data values may be implicitly connected to one another in terms of time, space, or explicit network relationship ties between the data pieces. Finding relationships between data items is the main goal of data mining, therefore knowing about preexisting dependencies significantly alters the process. The predicted relationships in the data and what can be deemed

**Chockalingam et al.,**

relevant from the standpoint of these expected relationships are thus altered by the presence of preexisting dependencies. There are various kinds of implicit and explicit dependencies that could exist:

- **Implicit dependencies:** These dependencies between data items are known to "typically" exist in that domain but are not expressly stated. For instance, a sensor's successive temperature readings are probably going to be very similar to one another. Therefore, it is quite rare and could be interesting for the data mining process if the temperature value recorded by a sensor at one moment differs greatly from that recorded at the following time instant. Multidimensional data sets, on the other hand, regard every data record as a separate entity.
- **Explicit dependencies:** This usually relates to network or graph data where relationships are explicitly specified via edges. In the context of other data types, graphs are very effective abstractions that are frequently employed as an intermediary representation to address data mining issues.

**RELATED WORK**

In 2020, Chris Clifton suggested the organization of semi-structured data, which is acknowledged as one of the main uncertain issues in the information industry and data mining paradigm, is surveyed in order to carry out this proposed task [16]. The computing grid functions thanks to new data processing systems that manage and distribute data to individual nodes, teach networked servers to operate in parallel, gather individual results, and then put them back together to create meaningful outcomes. It is quicker and more effective to process the data where it is stored rather than transferring it to a centralized system for analysis. R. Buse (2020) pointed out It will be in the form of computerized data that is not utilized by data mining because it lacks a data model [15]. [14]. According to LaValle S (2020), managing semi-structured data may represent the main data management potential, which leads to managing relational data. About 70% of the data gathered or kept in larger businesses is semi-structured, making it challenging to access, use, or recover. The majority of current technologies typically handle one text corpus or several corpora separately. [11] Found that these technologies might not provide a complete picture of what's going on in social media. To enable academics to concurrently study and correlate the subjects of several corpora, Topic Panorama was recently developed. In 2020, Barbierato E. observed with its high level of interaction, Topic Panorama helps users engage with matched topic graphs at various levels of granularity. Topic Panorama can see multiple corporate data at once; however it can only handle small-scale graphs. According to Millard (2019), cloud storage in just a few minutes, researchers can decode human DNA, forecast terrorist attack targets, identify the gene most likely to cause a particular disease, and, of course, identify Facebook advertising that you are most likely to interact with. Utilizing cloud storage data has strong commercial justifications. In 2019, N. Diakopoulos made the discovery as an example, Netflix used subscriber data to piece together the key components of its most recent blockbuster series, House of Cards, and it also used subscriber data to revive Arrested Development. Menzies, O.T. (2019) found the mining process was assessed using the hashing technique. Volume and velocity are satisfied by this strategy, and 7285 documents showed improved performance. These papers were splinting to 28% of test data and 72% of training data for evaluation. These two datasets had real sizes of 18,846 and 7285. This approach works with a variety of data types, including speech recordings, document scripts, and optical characters. Due to its consideration of fixed data size, the sparse hashing algorithm is not appropriate for velocity. Furthermore, it offers nothing concerning the accuracy of the data [9].

**PROBLEM IDENTIFICATION**

A significant amount of the existing framework only allows for the investigation of unstructured data; it does not address complex questions. The majority of the unstructured/semi-organized data originates from a variety of sources, including satellite imagery, sensor readings, email correspondence, virtual entertainment, web logs, review findings, sound, recordings, etc. As a result, our suggested open matrix rule-creation computation converts the data into completely sorted data. Before sorting, the data are organized and reduced to a level that is better at providing the approximate data that is needed [10] [23] [24] [25] [26] [27] [28] [29].

Chockalingam et al.,

## PROPOSED METHODOLOGY

The idea of data analysis for cloud storage Data provides analytical techniques that can be used to examine conventional datasets, such as software requirements and analytical architecture for investigating data from cloud storage [11]. One of the most crucial phases of the cloud storage data value chain is the open power system convention phase, where the major goal is to extract relevant information and offer recommendations and choices. Through the various phases of analysis in various areas, many kinds of potential and gravitational values can be generated [12].

### USER INTERACTION ISSUES

There can be user interaction issues as follows:

- **Mining various types of information in databases:** Users may have varying interests in various types of information. As a result, data mining must encompass a wide variety of knowledge finding tasks.
- **Interactive knowledge mining at various levels of abstraction:** The data mining procedure must be interactive in order to enable users to concentrate their search for patterns, submitting and modifying data mining requests in response to the results that are provided.
- **Incorporation of background knowledge:** Background knowledge can be used to represent the patterns found and to steer the discovery process. The found patterns can be expressed at several levels of abstraction and in succinct words using prior information.
- **Ad hoc data mining and data mining query languages:** Ad hoc data mining should be described using a data mining query language that is connected with a data warehouse query language and tailored for effective and adaptable data mining.
- **Results of data mining are presented and visualized:** After the patterns are identified, they must be represented visually and in high-level languages. These depictions ought to be simple to comprehend.
- **Managing incomplete or noisy data:** When mining for regularities in data, data cleaning techniques are necessary to manage incomplete objects and noise. The accuracy of the patterns found will be low if there are no data cleansing techniques in place.
- **Evaluation of the pattern:** The patterns found should be intriguing since they either lack novelty or reflect common knowledge.

### PERFORMANCE ISSUES

There can be performance-related issues as follows:

- **Efficiency and scalability of data mining algorithms:** Data mining algorithms need to be both efficient and scalable in order to successfully extract information from massive amounts of data stored in databases.
- **Parallel, distributed, and incremental mining algorithms:** The development of parallel and distributed data mining algorithms is driven by considerations including the growth of databases, the dispersion of data, and the complexity of data mining techniques. These algorithms separate the data into segments, which are then processed concurrently. The outcome of the partitions is then combined. Databases are updated via incremental algorithms without requiring new data mining.

### OPEN POWER SYSTEM CONVENTION PHASE

Specialized software tools and applications for text mining, data mining, forecasting, and data optimization are usually used for data mining. Open grid rule generation is used to manage all of these activities collectively, demonstrating highly integrated high performance mining functions. In order to identify which data is pertinent and may be examined to inform better business decisions, this allows an organization to evaluate extraordinarily enormous volumes of data that a company has gathered.

- The data set is created using a new template that imports both structured and semi-structured data from the database. As soon as the data is imported, it appears in the new data set template in its raw form. Data Analytic Tool Extension or datx.

### Chockalingam *et al.*,

- After being imported for mapping purposes, the data is loaded into the framework, which contains raw data. Therefore, it is taken in order to reduce the qualities.
- When the attributes list is assigned to the absolute form during the mapping process, the raw data is decreased. Because the database is where the mapped data is processed.
- Data is filtered according to threshold values, such as support and confidence level, in order to minimize data duplication and redundancy. Log files and data history are retrievable.

In addition to cloud storage data pretreatment augmentation, mapping and reduction, data filtering, and data parallelization techniques, a flexible and reconfigured grid may be a more efficient way to extract more significant information from the provided datasets. One of the most important phases of the big data value chain is the Wide-Open Power Convention, where the primary goal is to extract relevant information and offer recommendations and choices. The many phases of analysis in various fields might generate various kinds of potential and gravitational values. To analyze the data from the entire data container, the system comes with a rule generating mechanism. This idea states that compared to other data mining techniques, the analysis is far more absolute. The primary goal of the proposed study is to give an overview of data filtering and better and more meaningful perspective data. The data mining procedure using the open power system convention phase is depicted in figure 2 below. It displays the facts at a higher level with high efficiency since the procedure is more effective [17]. The user can access all of the raw data at any time once it has been cleared.

```

**Chockalingam et al.,**

Each attribute has a mean time that is specific to the user. Each attribute's beginning time may alter based on its likelihood, for example, if the mean time for that attribute changes, but it differs only slightly from the average time given for those attributes. In this scenario, each attribute's approximate time is determined by its beginning time and mean time [18]. The preliminary assessment of the investigative process based on its weight and vital type. The process shows the over-seed information delivered for reducing the rough data from the unstructured shape and turning it into the sorted out data with the capable course of action with the way toward sifting. Through this process, the data entered into the database and the crude data are removed from the data compartment [19,10,12,22]. In order to obtain a competitive edge, data mining is a technology-enabled approach that provides deeper, more accurate, and richer insights into partners, customers, and the company. In the current process, the data are examined using this crucial arrangement, and 55% of the separated data are required. Here, the analysis is conducted at a 95% confidence level, resulting in highly convincing and filtered information.

- The first step is to create the data set using a new template that will be used to import the structured and semi-structured data from the database. As soon as the data is imported, it appears in the new data set template in its raw form. Data Analytic Tool Extension or datx.
- After the raw data is imported for mapping purposes, the data is loaded into the framework. The goal of taking it is to reduce the characteristics.
- During the mapping process, the raw data is reduced because the mapped data is processed in the database, which assigns the attributes list into the absolute form.
- Data is filtered according to threshold values, which are the support and confidence level, in order to minimize data duplication and redundancy. Log files and data history are retrievable.

## RESULTS AND DISCUSSIONS

The data in the database is categorized up to the highest level using the open power system convention phase procedure. The information compartment's raw data is removed, and a manage is created to reduce the raw data's unstructured form and transform it into structured data using the mapping rule. The information is analyzed using such a simple configuration in the current technique, and the information that is broken down depends on 60%. Here, the examination was completed with remarkable efficiency and a 95% success rate.

### DATA TRANSFER

It should be guaranteed that the sensor data will not be transmitted over unprotected frameworks. For any data transfer, legitimacy and characterization must be guaranteed. Sincerity is protecting the data's credibility, whereas mystery is protecting sensitive information from an offending client. The often employed theories for safely trading data include cryptography and VPN techniques.

### DATA ACCESS

Data stored in an external group that contains previously identifiable information (or identifiers) poses a real risk to data security. Before long, identifiable information is delineated by individual and semi-identifiers. These traits have the ability to guide or specifically expose unique knowledge. This can be accomplished by safeguarding the data needed for analysis and mining as mentioned above.

### DATA STORAGE AND PROCESSING

Appropriate confirmation and endorsement should be obtained to guarantee system access. The system ought to be able to grant authorized users the ability to carry out analysis and mining tasks and gain access to the results of their work. Among other processes, role-based access control (RBAC) has gained widespread recognition due to its simplicity, adaptability in obtaining dynamic requirements, and support for both lucrative advantage and run of least advantage organization. The concept of information inspection of Systematic engineering and programming are required for the analysis of vast amounts of data, and data mining provides logical tools that can be connected to break down conventional datasets. One of the most fundamental stages of the massive information value chain is the

**Chockalingam et al.,**

open network lead age, where the main objective is to eliminate the important data and provide recommendations and options. Through the few stages of investigation in different domains, several kinds of conceivable and gravitational esteems can be formed.

**DATA MAPPING**

The process of assigning data that has been reduced to a level that the user may access whenever they need to is known as mapping. The dataset mapping procedure is depicted in the following figure.

**FILTERING DATA**

Figure 4 displays the filtered data, which is more definitive. The raw data was removed from the database in order to conduct this procedure. The generated open power system convention phase algorithm is contrasted with the Hadoop HDFS algorithm and the Data Mining KDD process in the graph above. It is evident that the suggested system has generated highly efficient information during the analysis process; the new algorithm differs greatly from the current one. The OPSC algorithm's time estimation for crime detection is displayed in the graph above by displaying the mean value for the attributes, whereas our method displays the more accurate approximation. The graph above uses the weights of the attributes to estimate the analysis process. Data mining is an approach made possible by technology that provides deeper, richer, and more precise insights into partners, customers, and the business environment. Clearing the raw data from the database is how this operation is carried out. After a data mapping procedure is completed, it is examined to make sure there is no data redundancy and that the amount of data has been decreased.

**CONCLUSION**

Data Mining has the potential to transform the way which shows sophisticated technologies to gain insight from their clinical and other data repositories and make informed decisions. This system was handled before by using many principles, but it does not give the clearance, OPSC algorithm gives. It is proved that this proposed system has produced more efficient result than comparing KDD and HDFS process. The data filtered is with high efficiency and there is no redundancy. The raw data can be also retrieved whenever the user needs, the data is more efficient upto 95% of approximate. This is the main reason for proper implementation of the data analytics methodology. One of the most crucial topics in the world of data analysis is exploratory data analytics. Despite being in the analytics field, the primary focus of this research project is the fundamental ideas of exploratory data analysis.

### ABSTRACT

Mining large datasets and discovering meaningful hidden patterns is not a new area but a lot of improvement is essential to overcome the cost and operational overheads, this paper finds a solution by splitting the large dataset finding the individual partition support count (IPSC) and then the partitioned dataset are merged to find the merged partitioned support count (MPSC) to reduce the burden of time and memory related issues. To find the IPSC and MPSC simple bit vector approach is utilized. The proposed algorithm is compared with the other existing algorithms to gauge its performance with respect to speed and the memory consumption.

**Keywords:** To find the IPSC and MPSC simple bit vector approach is utilized.

## INTRODUCTION

Retrieving a collection of items that frequently occur in the dataset and whose count is at least as high as the user-specified minimum support threshold value is known as mining frequent itemset. The support count, which should be higher than the user-provided threshold number, indicates how frequently objects are present in the transactional database. To extract the frequent itemset from the transactional database, a variety of methods and algorithms have been developed. In this field, the Apriori algorithm is a pioneering work that was developed by Srikanth Agarwal and his colleagues [1]. Based on the database being used, the new approach proved to be cost-effective. Other researchers have improved, modified, customized, and altered the Apriori algorithm, which has been called the pioneering work

### Manivasagan and Senthilkumaran

in the field. The next popular algorithm is FP-Growth which scans the entire database only twice unlike apriori but the entire database should fit in the memory of the system and consumes a lot of memory. The aforementioned methods, while well-known, nonetheless have several drawbacks. For example, the FP-Growth algorithm necessitates a large amount of memory space in order to maintain the full database, while Apriori constantly searches the database and generates numerous candidates for it [9] [10] [11] [12]. In order to get around these obstacles, the suggested method divides the whole database into individual processors and processes each partition independently, reducing the number of candidates and memory usage [13] [14] [15]. The results are then combined to identify recurring patterns. In order to produce frequent item sets from very big datasets, Zaki's parEclat [3] technique leverages the idea of parallel computing in conjunction with vertical data representation. An application of the Apriori method in parallel using map reduce is the Single Pass Counting SPC algorithm [4]. The algorithm functions effectively by addressing the shortcomings of the traditional Apriori algorithm [16] [17] [18]. Here, the support count of the candidates is parallelized, and the entire process is divided into two stages [19] [20] [21].

#### PROPOSED METHOD

The figure 1 showcased above is self-explanatory as the input raw data is fed initially, the details bifurcated into upper half and lower half, then the individual partition support count for both upper and lower are found. Next the partitioned data is merged to find the merged partition support count. Here the unpromising items are pruned and the process continues until the entire meaningful frequent patterns are discovered. The sample dataset used to discover the meaningful frequent patterns are shown in the table 1 and this dataset is partitioned into two portions one from top to the middle and the other from the bottom to the middle. The above shown dataset is bifurcated using the procedure Top Down Bottom Up as shown in the following table 2. The pseudo code to bifurcate the dataset is shown in the following figure 2 and the procedure Top Down Bottom Up is self-explanatory. The bifurcated data is assumed to be sorted and the distinct items present in the partitions P1 and P2 are found using the procedure Discover Distinct which is shown in the following figure 3 along with the individual count of the items. The transactional rows are iterated in a loop to acquire each row individually from the partitioned data. After determining the total number of items in the individual transactional row, each item is retrieved one at a time and checked against the distinct items DistArr[]. If the item is not found in DistArr[], it is placed there; if not, the item count is increased. During the first iteration in the loop, the transactional row 1 = {M1, M2, M3, M5, M6, M15} is fetched. Now the total number of items present in the row1 is computed and found to contain 6 elements. The inner loop is executed 6 times to discover the distinct elements. The first item retrieved is M1 and compared with the empty DistArr[], since the item "M1" is not present in the DistArr[], the first distinct element found is "M1" and stored in DistArr[].

**ITERATION 2:** "M2" not available in DistArr[ ], store "M2"

**ITERATION 3:** "M3" not available in DistArr[ ], store "M3"

**ITERATION 4:** "M5" not available in DistArr[ ], store "M5"

**ITERATION 5:** "M6" not available in DistArr[ ], store "M6"

**ITERATION 6:** "M15" not available in DistArr[ ], store "M15"

Inner loop closes

Outer loop iteration 2 commences,

Transactional row 2 in P1 = {M1, M3, M7} is initially fetched

The item count of the row2 is found to be 3 and the inner loop iterates three times as shown

**ITERATION 1:** "M1" available in DistArr[ ], increment count of M1

**ITERATION 2:** "M3" available in DistArr[ ], increment count of M3

**ITERATION 3:** "M7" not available in DistArr[ ], store "M7"

Inner loop ends

Similarly all the rows are fetched to discover the distinct elements and the resultant is shown in the table 3.

### Manivasagan and Senthilkumaran

Let us assume that the user defined support count is 4, the count which is less than 4 will be pruned and the final distinct element is shown in the following table 4. The elements M2, M4, M6, M9, M10, M11, M12, M13, M14, M15, M16 are pruned away and the remaining elements are shown in the table 4.

#### Property 1

*“If an element’s minimum support count is less than the user-specified minimum Support threshold value, it is deemed to be an infrequent element.”* The final dataset is shown in the table 5 after pruning the infrequent elements whose support count value is less than the user specified, Creating a bit vector table that corresponds to the database that has been pruned is the next step in the technique. The element in dataset will be indicated as “1” if it is present in the transactional row and “0” if it is not present. The distinct elements are confined into four elements {M1, M3, M5, M7} and these distinct values are marked for its present in a row with “1” and “0” if it is not present. The first element M1 is marked in partition P1 as shown in the following section, Here the element M1 is not present in the row 3 if partition P1 and it is represented by “0” whereas all other rows contains “1” as it is present. Next the elements are formed using some properties and definitions shown below,

#### Property 2

*“An element or item set might be infrequent in one partition but after merge that element or item set might be frequent.”*[7]  
 $\{(M1, M2), IPSC\} \neq \{(M1, M2), MPSC\}$

#### Property 3

*“It is possible for an infrequent candidate in one partition to be a frequent candidate in another, and vice versa for frequent candidates in different partitions.”*[8] This process is carried out in each and every level and then merged to get the overall item set with MPSC value. The procedure shown above is used to form the item sets with 2 element, 3 element and n elements. The first partition P1 is fed as an input which comprises of the following elements {M1, M3, M5, M7}

#### First iteration

Item M1 is fetched, and concatenated with the other elements to form {M1, M3}, {M1, M5}, {M1, M7}

#### Second iteration

Item M3 is fetched and concatenated with other elements to form {M3, M5}, {M3, M7}

#### Third iteration

Item M5 is fetched and concatenated with other elements to form {M5, M7} The IPSC is found using the bit table values formed in the individual partition shown in the figure 4.

M1 = 1 1 0 1 1  
 M3 = 1 1 0 1 1 &  
**M1, M3 = 1 1 0 1 1 → IPSC = 4**  
 M1 = 1 1 0 1 1  
 M5 = 1 0 1 1 1 &  
**M1, M5 = 1 0 0 1 1 → IPSC = 3**  
 M1 = 1 1 0 1 1  
 M7 = 0 1 0 1 1 &  
**M1, M7 = 0 1 0 1 1 → IPSC = 3**  
 M3 = 1 1 0 1 1  
 M5 = 1 0 1 1 1 &  
**M3, M5 = 1 0 0 1 1 → IPSC = 3**  
 M3 = 1 1 0 1 1  
 M7 = 0 1 0 1 1 &  
**M3, M7 = 0 1 0 1 1 → IPSC = 3**

### Manivasagan and Senthilkumaran

M5 = 1 0 1 1 1

M7 = 0 1 0 1 1 &

**M5, M7** = 0 0 0 1 1 → IPSC = 2

The three element candidate is found using simple AND operation as shown in the following operation,

M1, M3 = 1101101111

M5 = 1011111011&

**M1 M3 M5** = 1011101011 → IPSC = 7

M1, M5 = 1001101011

M7 = 0101100011&

**M1 M5 M7** = 1001101011 → IPSC = 4

M3, M5 = 1001101011

M7 = 0101100011&

**M3 M5 M7** = 1001101011 → IPSC = 4

M1 M3 M5 = 1011101011

M7 = 0101100011&

**M1 M3 M5 M7** = 0001100011 → IPSC = 4

The frequent pattern output formed with the user defined minimum support count value are found and they are {M1, M3, M5, M7, M1M3, M1M5, M1M7, M3M5, M3M7, M5M7, M1M3M5M7}

#### EXPERIMENTAL EVALUATION

The SPMF tool, which is based on the Java programming language, is used for coding, and large synthetic datasets [2] as well as benchmarked real datasets are utilized in tests to assess the performance of the proposed technique. For this experiment, six nodes are employed, and each system setup consists of an Intel Core I7 CPU, 8GB RAM, and a 1TB SDD drive. The benchmarked dataset used is shown in the table 8 The Experiments are carried out for the number of candidate generated during the process and the candidate produced are noted and compared with the state of the art existing algorithms as shown in the tables below, From the above tables it is quite obvious that the proposed SWAA algorithm out- performed the other three existing algorithms with respect to candidate generation and produced fewer candidates during the execution which reduces the runtime considerably. The runtime comparison for varying support value and for varying number of processors is shown in the following figures The above figure clearly indicates the effective and efficient performance of the proposed SWAA algorithm with respect to the speed of execution and out-performed the other algorithms by a good margin for varying user defined minimum support value as well as for varying number of nodes or processors. Similarly the memory usage is compared for the proposed SWAA with the existing algorithms and the results are showcased in the following figures and the result proved to be exemplary for the proposed SWAA algorithm.

#### CONCLUSION

The proposed SWAA algorithm is showcased in this paper and the important flaws that are prevalent in the existing algorithms are eradicated and from the experimental result, it is proved that the proposed algorithm produced fewer numbers of candidates due to the efficient pruning mechanism and this thereby reduces the runtime, memory consumption and increases the speed of the execution.

### ABSTRACT

The purpose of the paper is to demonstrate the relevance of fuzzy graph (f-graph) hypothetical concepts and the applications of dominations in fuzzy graphs to various real-world situations in the fields of science and design. The numerous applications in computer and communication, biomedicine, atomic material science and science, interpersonal organizations, natural sciences, and in other distinct fields make it a significant growth. Numerous people are associated in areas called interpersonal organizations. Regular fuzzy graphs, total degree fuzzy graphs, and absolutely regular fuzzy graphs are introduced in this study. Through numerous examples, regular fuzzy graphs and completely regular fuzzy graphs are contrasted. There is a given condition that is both required and sufficient for them to be equal. On a cycle, a description of regular fuzzy graphs is given. Some regular fuzzy graph features are researched and tested for completely regular fuzzy graphs.

**Keywords:** A vertex's degree, Total degree, entirely regular fuzzy graph; regular fuzzy graph.

### INTRODUCTION

The development of fuzzy sets by Lotfi A. Zadeh [1] in 1965 is one of the obvious scientific breakthroughs of the twentieth century. His goal was to develop a mathematical framework that could handle uncertainty and vulnerability. The standard approach for set theory and numbers is insufficient to handle the imprecise idea, so one should look to some alternative concepts. A fuzzy set is defined scientifically by assigning a value to every

### Anitha and Vijaya

imaginable human known to man, speaking to its appraisal of participation, which compares to the extent to which that individual is comparable or good with the idea spoken to by the fuzzy set. The benefit of replacing conventional sets with Zadeh's fluffy sets is that it improves precision and accuracy in theory and increases competence and framework similarity in applications. The difference between a set and a fuzzy set is that a set divides a general set into two subsets, namely individuals and non-individuals, whereas a fuzzy set assigns components of the all-inclusive set a series of participation esteems ranging from 0 to 1. Zadeh's fuzzy relations (1971) served as the foundation for Kaufman's fuzzy graph, which was published in 1973. The notion of fuzzy graphs was subsequently developed by Rosenfeld (1975) [2]. Fuzzy graphs have several uses in many fields of science and engineering, including broadcast communications, production, social networks, artificial reasoning, data hypotheses, neural systems, and organization, among others. Azriel Rosenfeld first proposed fuzzy graph theory in 1975. Although it is still relatively young, it has been growing quickly and has a wide range of uses. In this study, we introduce total degree, totally regular, and regular fuzzy graphs. Through a number of instances, we compare fuzzy graphs that are partially regular with those that are completely regular. We give a necessary and sufficient condition that must be met for them to be equal. We then give a description of regular fuzzy graphs with a cycle as the underlying crisp graph. Additionally, we investigate several regular fuzzy graph features to see if they apply to completely regular fuzzy graphs. Due to its broad range of applications in conventional combinatorial problems, arithmetic problems, computational problems, and other areas, graph theory has undergone a significant development during the last three decades. This is primarily due to the diversification of criteria that have been produced from the fundamental definition of dominance. With the help of some enthusiastic chess players in the 1850s, the concept of graph dominance found its origin. The question of determining the minimum number of sovereigns that can be placed on a chessboard to ensure that every square is either attacked by a sovereign or implicated by a sovereign was taken into consideration by chess enthusiasts in Europe. Cock and Hed present the control number [3]. The most frequently mentioned application of the domination theory in fuzzy graphs is a communication network. The challenge is to select the smallest possible configuration of locations for the transmitters to be placed such that each site in the system is connected by an immediate correspondence link to the site acting as a transmitter. Fuzzy graphs are being used in such large numbers on social networks like Facebook, Twitter, WhatsApp, and Research Gate.

## PRELIMINARIES

It is understood that graphs are associations or models. A graph is a useful tool for communicating data, including connections between items. Nodes represent the items, while arcs show relationships. We frequently have to plan a fuzzy network model whenever there is ambiguity or vagueness in the description of the items, their connections, or both.

### Definition: 2.1

Two functions,  $\beta: V \rightarrow [0, 1]$  and  $\Omega: E \rightarrow [0, 1]$  are put in a fuzzy graph, or f-graph,  $G(\beta, \Omega)$ . to the extent that  $\Omega(x, y) \leq \beta(x) \wedge \beta(y)$  For every  $x, y \in V$ .

### Definition: 2.2

Let  $G(\beta, \Omega)$  be an f-graph on  $V$  and  $V_1 \subseteq V$ . Describe  $\beta_1 = \beta(x) \forall x \in V_1$  &  $\Omega_1$  lying on the range  $E_1$  of 2 section subsets of  $V_1$  by  $\Omega_1(x, y) = \Omega(x, y) \forall x, y \in V_1$ . At that point  $(\beta_1, \Omega_1)$  is known as the fuzzy sub graph of  $G$  activated by  $V_1$  & is indicated by  $\langle V_1 \rangle$ .

### Definition: 2.3

The order  $m$  and size  $n$  of a f-graph  $G(\beta, \Omega)$  are considered to be  $m = \sum \beta(x)$  and  $n = \sum \Omega(x, y)$

### Definition: 2.4

Let  $G(\beta, \Omega)$  be a f-graph of  $V$  and  $S \subseteq V$ . At that point the fuzzy cardinality of  $S$  is characterized to be  $\sum \beta(V)$

Anitha and Vijaya

**Definition: 2.5**

Let us consider the fuzzy graph or a f-graph  $G(\beta, \Omega)$  on  $E$  and  $D \subseteq E$ . At that point the fuzzy edge cardinality of  $D$  is characterized to be  $\sum \Omega(e)$

**Definition: 2.6**

Consider a fuzzy graph  $G(\beta, \Omega)$ . Characterize the degree of a node  $v$  to be  $d(v) = \sum \Omega(u, v)$  The least degree of f-graph  $G$  is  $\delta(G) = \wedge \{d(v)/v \in V\}$  and greatest value degree of f-graph  $G$  is  $\Delta(G) = \vee \{d(v)/v \in V\}$ .

**Definition: 2.7**

An arc  $e = (v, w)$  of a f-graph is called an operative edge if  $\Omega(v, w) = \beta(v) \wedge \beta(w)$ .  $N(v) = \{w \in V / (v, w) = \beta(v) \wedge \beta(w)\}$  is known as the area of  $v$  and  $N[v] = N(v) \cup \{v\}$  is the bolted locality of  $v$ .

**Definition: 2.8**

Consider a fuzzy graph  $G(\beta, \Omega)$ .  $S \subseteq V$  is supposed to be governing set of  $G$  if envisioned for each  $v \in V - S \exists$  a factor  $u \in S$  with the end goal that  $\Omega(u, v) = \beta(u) \wedge \beta(v)$ . An overwhelming set  $S$  of  $G$  is known as the unimportant impressive arrangement of  $G$  if each node  $v \in S, S - \{v\}$  is definitely not a leading set. The least scalar cardinality of  $S$  is known as the supremacy number and it is specified by  $\gamma(G)$ .

**Definition: 2.9**

Let  $G(\beta, \Omega)$  be a f-graph.  $S \subseteq X$  is said to be edge supremacy set in f-graph  $G$  if for each or arc in  $X - S$  is adjacent to a least any one effective edge in  $S$ . The Lowest Fuzzy cardinality of an edge supremacy set  $G$  is known as the edge supremacy number of  $G$  and is directed by  $\gamma'(G)$ .

**Definition 2.10**

Uncertain graph  $G$  is a collection of functions with the formulas  $G^*(V, E)$ , where is a fuzzy subset of a nonempty set  $V$  and is a symmetric fuzzy relation on. When  $E \subseteq V \times V$ , the underlying crisp graph of  $G^*(V, E)$  is represented by  $G^*(V, E)$ . If  $(uv) = (u)(v)$  for every  $u, v$ , and  $V$ , where  $uv$  indicates the edge, then a fuzzy graph  $G$  is complete. If  $\phi(uv) = \beta(u) \wedge \beta(v)$  for every  $u, v$ , and  $V$ , where  $uv$  directs the edge, then graph  $G$  is complete.

**Definition: 2.11**

Let  $G=(V, E, \phi, \rho)$  be an Soft fuzzy graph. The order of  $G$ , denoted  $O(G)$ , is defined as  $O(G)=[O^-(G), O^+(G)]$ , where  $O^-(G) = \sum \phi - \Psi \in V(v); O^+(G) = \sum \phi + \Psi \in V(v)$ . Similarly, the size of  $G$ , denoted  $S(G)$ , is defined as  $S(G)=[S^-(G), S^+(G)]$ , where  $S^-(G) = \sum \rho - \Psi w \in E(vw); S^+(G) = \sum \rho + \Psi w \in E(vw)$ .

**Definition: 2.12**

An Soft fuzzy graph  $G=(V, E, \phi, \rho)$  is said to be a complete Soft fuzzy graph if  $\rho^-(vw) = \phi^-(v) \wedge \phi^-(w)$  and  $\rho^+(vw) = \phi^+(v) \wedge \phi^+(w)$ , for every  $v, w \in V$ .

**Definition: 2.13**

Let  $G=(V, E, \phi, \rho)$  be an Soft fuzzy graph. An edge  $e=vw$  is called effective if  $\rho^-(vw) = \phi^-(v) \wedge \phi^-(w)$  and  $\rho^+(vw) = \phi^+(v) \wedge \phi^+(w)$  for all  $vw \in E$ . it is denoted by  $\rho^e(vw)=[\rho^e^-(vw), \rho^e^+(vw)]$ . The effective degree of a vertex  $v$  in  $G$ , denoted by  $d^e(v)$ , is defined as  $d^e(v) = [\sum \rho^e - \Psi w \in E(vw), \sum \rho^e + \Psi w \in E(vw)]$ .

**Definition 2.14**

Let  $G:(\beta, \phi)$  be a fuzzy graph on  $G^*(V, E)$ . If  $dG(v)=k$  for all  $v \in V$ , (i.e) A regular fuzzy graph of degree  $k$  or a  $k$ -regular fuzzy graph is said to exist if each vertex has the same degree  $k$ . This is comparable to how regular graphs are defined in crisp graph theory.

Anitha and Vijaya

**Definition 2.15**

Let  $G:(\mathcal{B},\phi)$  be a fuzzy graph on  $G^*$ . The total degree of a vertex  $u \in V$  is defined by  $tdG(u) = \sum \phi(uv) + \mathcal{B}(u) = \sum \phi(uv) + \mathcal{B}(u) = dG(u) + \mathcal{B}(u)$ .  $G$  is referred to as a  $k$ -entirely regular fuzzy graph or an entirely regular fuzzy graph of total degree  $k$  if each vertex of  $G$  has the same total degree  $k$ .

**Definition: 2.16**

An example of a soft fuzzy graph is  $G = (V, E, \phi, \rho)$ . The neighbourhood degree of a vertex  $v$  is represented by the symbol  $d(v)$ , which is defined as the sum of the Soft grade values of the vertex's neighbourhood vertices.

**Definition: 2.17**

An example of a soft fuzzy graph is  $G = (V, E, \phi, \rho)$ . The closed neighbourhood degree of a vertex  $v$  is represented by the symbol  $d[v]$ , which is the sum of the Soft grade values of the vertex's neighbouring vertices, including the vertex's own Soft grade value.

**REGULAR FUZZY GRAPH THEOREM AND CHARACTERIZATION**

**Theorem 3.1:**

A fuzzy graph on  $G^*:(V, E)$  will be  $G:(\mathcal{B},\phi)$  If and only if the following statements are identical, then  $\mathcal{B}$  is a continuous function: (1). A typical fuzzy graph is  $G$ . (2). A completely regular fuzzy graph is  $G$ .

**Proof:**

Supposing that  $\mathcal{B}$  is a continuous function. Let  $\mathcal{B}(r) = c$ , a constant, for all  $r \in V$ . Assume that  $G$  is a  $m_1$  – regular fuzzy graph.

Then  $d(r) = m_1$ , for all  $r \in V$ .

So  $td(r) = d(r) + \mathcal{B}(r)$ , for all  $r \in V$ .

$\Rightarrow td(r) = m_1 + c$ , for all  $r \in V$ .

Hence  $G$  is a entirely regular fuzzy graph. Thus (1)  $\Rightarrow$  (2) is proved. Now, suppose that  $G$  is a  $m_2$  – entirely regular fuzzy graph.

Then  $td(r) = m_2$ , for all  $r \in V$ .

$\Rightarrow d(r) + \mathcal{B}(r) = m_2$ , for all  $r \in V$ .

$\Rightarrow d(r) + c = m_2$ , for all  $r \in V$ .

$\Rightarrow d(r) = m_2 - c$ , for all  $r \in V$ . So  $G$  is a regular fuzzy graph.

So, (2)  $\Rightarrow$  (1) is demonstrated. So, (1) and (2) are interchangeable. Alternatively, suppose that (1) and (2) are interchangeable.  $G$  is only completely regular if and only if it is regular. Assume  $\mathcal{B}$  is a variable function. For at least one pair of vertices,  $r, w \in V$ ,  $\mathcal{B}(r) \neq \mathcal{B}(w)$  Let  $G$  be a  $k$ -regular fuzzy graph. Then  $d(r) = d(w) = m$  So  $td(r) = d(r) + \mathcal{B}(r) = k + \mathcal{B}(r)$  and  $td(w) = d(w) + \mathcal{B}(w) = k + \mathcal{B}(w)$  Since  $\mathcal{B}(r) \neq \mathcal{B}(w)$ , we have  $td(r) \neq td(w)$ .

So  $G$  is not entirely regular which a contradiction to our assumption is. Now let  $G$  be a entirely regular fuzzy graph.

Then  $td(r) = td(w) \Rightarrow d(r) + \mathcal{B}(r) = d(w) + \mathcal{B}(w)$

$\Rightarrow d(r) - d(w) = \mathcal{B}(w) - \mathcal{B}(r) \neq 0$

$\Rightarrow d(r) \neq d(w)$ .

So  $G$  is not regular which a contradiction to our supposition is. Hence  $\mathcal{B}$  is a continuous function.

**Theorem 3.2**

If a fuzzy graph  $G$  is both regular and entirely regular, then  $\mathcal{B}$  is a continuous function.

**Proof:**

Let  $G$  be a  $m_1$  – regular and  $m_2$  – entirely regular fuzzy graph. So  $d(r) = m_1$ , for all  $r \in V$  and  $td(r) = m_2$ , for all  $r \in V$ .

Now  $td(r) = m_2$ , for all  $r \in V$ .

$\Rightarrow d(r) + \mathcal{B}(r) = m_2$ , for all  $r \in V$ .

Anitha and Vijaya

$\Rightarrow m_1 + \mathcal{B}(r) = m_2$ , for all  $r \in V$ .  
 $\Rightarrow \mathcal{B}(r) = m_2 - m_1$ , for all  $r \in V$ .  
 Hence  $\mathcal{B}$  is a continuous function.

**Theorem 3.3**

Let  $G:(\mathcal{B},\phi)$  be a fuzzy graph where  $G^*:(V,E)$  is an odd cycle. Then  $G$  is regular iff  $\phi$  is a continuous function.

**Proof**

If  $\phi$  is a continuous function, say  $\phi(rv)=c$ , for all  $rv \in E$ , then  $d(v)=2c$ , for every  $v \in V$ . So  $G$  is regular.  
 Conversely, suppose that  $G$  is a  $k$ -regular fuzzy graph. Let  $e_1, e_2, \dots, e_{2n+1}$  be the edges of  $G^*$  in that order.  
 Let  $\phi(e_1) = m_1$ . Since  $G$  is  $k$ -regular,  $\phi(e_2) = m - m_1, \phi(e_3) = m - (m - m_1) = m_1, \phi(e_4) = m - m_1$  and so on.  
 Therefore  $\phi(e_i) = m$ , if  $i$  is odd,  $0$ , if  $i$  is even.  
 Hence  $\phi(e_1) = \phi(e_{2n+1}) = m_1$ .  
 So if  $e_1$  and  $e_{2n+1}$  occurrence at a vertex  $r$ , then  $d(r) = k$ .  
 So  $d(e_1) + d(e_{2n+1}) = m \Rightarrow m_1 + m_1 = m$   
 $\Rightarrow 2m_1 = m \Rightarrow m_1 = m/2$   
 Hence  $m - m_1 = m/2$ . So  $\phi(e_i) = m/2$ , for all  $i$ .  
 Hence  $\phi$  is a continuous function.

**Theorem 3.4**

Let  $G:(\mathcal{B},\phi)$  be a fuzzy graph where  $G^*$  is an even cycle. Then  $G$  is regular iff either  $\phi$  is a continuous function or alternate edges have same grade values.

**Proof:**

$G$  is a typical fuzzy graph if either is a continuous function or the grade values on opposite edges are the same.  
 Assume, however, that  $G$  is a fuzzy graph with  $k$  regularities. The edges of the even cycle  $G^*$  should be in the following order:  $e_1, e_2, \dots, e_{2n}$ .  
 $\phi(e_i) = m$ , if  $i$  is odd  
 $0$ , if  $i$  is even  
 If  $m_1 = m - m_1$ , then  $\phi$  is a continuous function. If  $m_1 \neq m - m_1$ , then alternate edges have same grade values.

**Theorem 3.5:**

The size of a  $m$ -regular fuzzy graph  $G:(\mathcal{B},\phi)$  on  $G^*:(V, E)$  is  $pm/2$  where  $p = |V|$ .

**Proof:**

The size of  $G$  is  $S(G) = \sum \phi(rv)$ .  
 Since  $G$  is  $k$ -regular,  $d_G(v) = m$ , for all  $v \in V$ . We have  $\sum d_G(v) = 2 \sum \phi(rv) = 2 S(G)$ .  
 So  $2 S(G) = \sum d_G(v) = \sum m = pm$   
 Hence  $S(G) = pm/2$

**Theorem 3.6**

If  $G:(\mathcal{B},\phi)$  is a  $r$ -entirely regular fuzzy graph, then  $2S(G) + O(G) = pr$  where  $p = |V|$ .

**Proof:**

Since  $G$  is a  $r$ -entirely regular fuzzy graph,  
 $r = td(v) = d(v) + \mathcal{B}(v)$  for all  $v \in V$ .

$$\text{So } \sum_{v \in V} r = \sum_{v \in V} d_G(v) + \sum_{u \in V} \sigma(u)$$

$$\Rightarrow pr = 2S(G) + O(G)$$

**Anitha and Vijaya**

**Theorem 3.7**

An end vertex (a vertex of degree 1 in  $G^*$ ) cannot exist in a linked  $k$ -regular fuzzy network when  $m > 0$  with  $p \geq 3$ .

**Proof:**

Since  $m > 0$ ,  $dG(v) > 0$  for every  $v \in V$ . So each vertex is adjacent to at least one vertex. If possible, let  $r$  be an end vertex and let  $rv \in E$ . Then  $d(r) = m = \phi(rv)$ . Since  $G$  is associated and  $p \geq 3$ ,  $v$  is neighbouring to some other vertex  $w \neq r$ . Then  $d(v) \geq \phi(rv) + \phi(vw) > \phi(rv)$   
 So  $d(v) > k$ , which is a inconsistency. Hence  $G$  cannot have an end.

**Theorem: 3.8**

In any Soft fuzzy graph  $G=(V,E,\phi, \psi)$ , the sum of the degree is same as twice the sum of the Soft edge grade values. That is,  $\sum_{v \in V} (\Psi) = 2 \sum_{e \in E} (\Psi w)$

**Proof:**

Let  $G=(V,E,\phi, \psi)$  be a Soft fuzzy graph. Since each edge is incident with its two associated vertices, an edge contributes two to the sum of the degrees of the vertices.

$$d(v_1) = [1.1,1.3], d(v_2)=[1.3,1.1], d(v_3)=[0.8,1.2]$$

$$\sum_{v \in V} (v) = [3.2,3.6],$$

$$\sum_{vw \in E} (\psi w) = \{[0.3,0.7],[0.8,0.6],[0.5,0.5]\} = [1.6,1.8]$$

$$2 \sum_{vw \in E} (\psi w) = 2[1.6,1.8] = [3.2,3.6]$$

Therefore,  $\sum_{v \in V} (v) = 2 \sum_{vw \in E} (\psi w)$

**Theorem: 3.9**

Every Soft Fuzzy graph that is regular is also semi-regular.

**Proof**

Assume that  $G = (V, E, \phi, \psi)$  is a typical Soft fuzzy graph. Every vertex in  $G$  then has the same (open) neighbourhood degree. All vertices have the same Soft grade values since they all have the same neighbourhood degrees. The closed neighbourhood degree of the vertex results from adding the vertex's Soft grade to its matching neighbourhood degree. All closed neighbourhood degrees are identical, of course.  $G$  is a semi-regular Soft fuzzy graph as a result.  
 Let  $G = (V, E, \phi, \psi)$  be a Soft fuzzy graph, where  $V=\{V_1, V_2, V_3\}$ ,  $E=\{V_1V_2, V_1V_3, V_2V_3\}$  with  $\phi(V_1)=[0.5,0.3]$ ,  $\phi(V_2)=[0.5,0.3]$ ,  $\phi(V_3)=[0.5,0.3]$ ;  $\psi(V_1V_2)=[0.5,0.3]$ ,  $\psi(V_1V_3)=[0.5,0.3]$ ,  $\psi(V_2, V_3)=[0.5,0.3]$ .

**Anitha and Vijaya**

we have  $d(V_i)=[1.0,0.6]$ ;  $d_e(V_i)=[1.0,0.6]$ ;  $dN(V_i)=[1.0,0.6]$ ;  $dN[V_i]=[1.0,0.6]$  for all  $V_i \in V$ . Therefore, this Soft fuzzy graph is an [1.0,0.6]-regular  
 Thus, it is also a semi regular.

**Theorem: 3.10**

A semi-regular Soft fuzzy graph is a Soft fuzzy graph that is entirely complete.

**Proof:**

$d(V)$ 's are the same since  $G=(V,E,\phi, \rho)$  is a semi-regular Soft fuzzy graph. Since  $[V]$ s are equal only when all connections between vertices and all of their edges are functional. As a result, it follows that  $(V)$  is equivalent if and only if  $G$  is a whole Soft fuzzy graph. All semi-regular Soft fuzzy graphs are therefore whole Soft fuzzy graphs.

**Theorem: 3.11**

Semi-regular Soft fuzzy graphs are all semi-complete Soft fuzzy graphs.

**Proof:**

All of the vertices of  $G=(V,E,\phi, \rho)$  are connected to one another because it is a semi complete Soft fuzzy graph, and all of the edges are weak or ineffective. According to the definition of a vertex's closed neighbourhood degree,  $v$ , all vertices have the same closed neighbourhood degrees.  $G$  is a semi-regular Soft fuzzy graph because of this.

**Theorem: 3.12**

Regular Soft fuzzy graphs are not need to be completely constructed Soft fuzzy graphs.

**Proof:**

Consider a SFG,  $G=(V,E,\phi, \rho)$  is said to be a complete Soft fuzzy graph if  $\rho_-(vw) = \phi_-(v) \wedge \phi_-(w)$  and  $\rho_+(vw) = \phi_+(v) \wedge \phi_+(w)$ , for every  $v,w \in V$

We have  $d(V_1) = [0.5,0.6]$ ,  $d(V_2) = [0.5,0.8]$ ,  $d(V_3) = [0.4,0.6]$ .

A soft fuzzy graph If all of the vertices have the same neighbourhood degrees,  $G$  is considered to be a regular Soft fuzzy graph.

$d(V_1) \neq d(V_2)$  and  $d(V_3)$ . As a result, every Soft fuzzy graph that is complete need not be a typical Soft fuzzy graph.

**Theorem: 3.13**

Every regular Soft fuzzy graph does not have to be a complete Soft fuzzy graph.

**Proof:**

Let  $G = (V, E, \phi, \rho)$  be a regular Soft fuzzy graph, where  $V=\{V_1, V_2, V_3\}$ ,  $E=\{V_1V_2, V_1V_3, V_2V_3\}$  with  $\phi(V_1)=[0.5,0.5]$ ,  $\phi(V_2)=[0.6,0.6]$ ,  $\phi(V_3)=[0.5,0.6]$ ;  $\rho(V_1V_2)=[0.5,0.6]$ ,  $\rho(V_1V_3)=[0.5,0.6]$ ,  $\rho(V_2, V_3)=[0.5,0.6]$ .

**Anitha and Vijaya**

$d(V_1) = [0.5,1.1]$ ,  $d(V_2)=[0.5,1.1]$ ,  $d(V_3)=[0.5,1.1]$   $\phi^-(V_1) = 0.5$ ,  $\phi^-(V_2) = 0.5$  and  $\phi^-(V_3) = 0.5$  which contradicts to our solution  $\phi^+(V_1(0.5)) \wedge \phi^+(V_2(0.6)) = \phi^+(0.5)$

As a result, not every regular Soft fuzzy graph has to be a full graph.

**Theorem: 3.14**

Every regular Soft fuzzy graph contains several walks. Proof: Take into account a standard Soft fuzzy graph G.

**Proof:**

Consider a regular Soft fuzzy graph G

In G  $d(u) = (0.4,0.7)$ ,  $d(v) = (0.4,0.7)$ ,  $d(w) = (0.4,0.7)$ ,  $d(x) = (0.4,0.7)$ .

A walk in regular Soft fuzzy graph G is  $u(0.2,0.5) \phi(0.2,0.2) v(0.4,0.6) \phi(0.2,0.2) x(0.2,0.6) \phi(0.2,0.2) w(0.3,0.5) \phi(0.2,0.2)$ .

We represents a another fuzzy walk  $u(0.2,0.5) \phi(0.2,0.2) w(0.3,0.5) \phi(0.2,0.2) x(0.2,0.6) \phi(0.2,0.2) v(0.4,0.6) \phi(0.2,0.2)$ . Consequently, each walk in a regular Soft fuzzy graph is many.

**Theorem: 3.15**

In any Soft fuzzy graph  $G=(V,E,\phi, \phi)$ , the subsequent variations hold:  $O^-(G) \geq S^-(G)$  and  $O^+(G) \geq S^+(G)$

**Proof:**

Let  $G=(V,E,\phi, \phi)$  be an Soft fuzzy graph, where  $V=\{V_1, V_2, V_3\}$ ,  $E=\{V_1V_2, V_1V_3, V_2V_3\}$  with  $\phi(V_1) = [0.5,0.8]$ ,  $\phi(V_2)=[0.6,0.3]$ ,  $\phi(V_3)=[0.5,0.6]$ ;  $\phi_e(V_1V_2) = [0.3,0.5]$ ,  $\phi_e(V_1V_3)=[0.2,0.5]$ ,  $\phi_e(V_2V_3)=[0.7,0.3]$

**Anitha and Vijaya**

The order of  $G$ , represented  $O(G)$ , is well-defined as  $O(G) = [O^-(G), O^+(G)]$ , where  $O^-(G) = \sum \phi - \forall v \in V (v)$ ;  $O^+(G) = \sum \phi + \forall v \in V (v)$ .  $O^-(G) = [1.6]$ ,  $O^+(G) = [1.7]$ .  
 The size of  $G$ , represented  $S(G)$ , is well-defined as  $S(G) = [S^-(G), S^+(G)]$ , where  $S^-(G) = \sum \rho - \forall vw \in E (vw)$ ;  $S^+(G) = \sum \rho + \forall vw \in E (vw)$ .  $S^-(G) = [1.2]$ ,  $S^+(G) = [1.3]$   
 $[1.6] \geq [1.2]$  denotes that,  $O^-(G) \geq S^-(G)$   
 $[1.7] \geq [1.3]$  denotes that,  $O^+(G) \geq S^+(G)$

**Theorem: 3.16**

Every semi-regular Soft Fuzzy graph need not be a regular Soft Fuzzy graph.

Proof:

Let  $G = (V, E, \phi, \rho)$  be a Soft fuzzy graph, where  $V = \{V_1, V_2, V_3\}$ ,  $E = \{V_1V_2, V_1V_3, V_2V_3\}$  with  $\phi(V_1)=[0.6,0.6]$ ,  $\phi(V_2)=[0.4,0.4]$ ,  $\phi(V_3)=[0.9,0.9]$ ;  $\rho(V_1V_2)=[0.3,0.3]$ ,  $\rho(V_1V_3)=[0.3,0.3]$ ,  $\rho(V_2, V_3)=[0.5,0.5]$ .

we have  $dN(V_1)=[1.3,1.3]$ ;  $dN(V_2)=[1.5,1.5]$ ;  $dN(V_3)=[1.0,1.0]$ ;  $dN(V_i)=[1.9,1.9]$  for all  $V_i \in V$ . Consequently, this Soft fuzzy graph is an  $[1.9,1.9]$ -semi regular.  
 Conversely, it is not a regular

**Anitha and Vijaya**

## CONCLUSION

The article demonstrates the value of scientists' fuzzy graph hypothetical ideas in several fields of actual research. A particular outline is presented in order to expand on the concept of fuzzy graph theory. This document offers scientists and students a summary of the use of fuzzy graphs in several real-world disciplines, including computer science, biology, and geography. The fuzzy graph theory has been used to support the presentation of an informal community model. Fuzzy diagrams can also speak to media transmission or telecommunication network arrangements. A high client retention rate demonstrates the clients' security in the system. An individual cannot generally be a liar if they receive full participation credit in a unit-by-confirmation class. However, it's possible that the profile is fake if a person in the unit by acknowledgment classification receives the full participation value.

## ABSTRACT

This study proposes an innovative approach for enhancing the performance of Dynamic Source Routing (DSR) in Mobile Ad Hoc Networks (MANETs) through the incorporation of an improved Bacterial Foraging Optimization Algorithm (BFO). The conventional DSR protocol faces challenges in adapting to the dynamic nature of MANETs, leading to suboptimal routing decisions. To address this, our research introduces an Improved BFO that dynamically adjusts its parameters based on the network conditions. The improved algorithm aims to optimize the exploration and exploitation phases, resulting in more efficient route discovery and maintenance. Through extensive simulations and performance evaluations, the proposed DSR with the Improved BFO demonstrates superior adaptability, reduced latency, and enhanced overall network throughput compared to the traditional DSR protocol. This research contributes to the advancement of routing protocols in MANETs by integrating intelligent optimization techniques for improved real-time adaptability and robustness.

**Keywords:** To address this, our research introduces an Improved BFO that dynamically adjusts its parameters based on the network conditions.

## INTRODUCTION

Wireless Sensor Networks (WSNs) and Mobile Ad Hoc Networks (MANETs) represent two prominent types of wireless networks characterized by their absence of infrastructure. Comprising groups of wireless nodes, these networks establish connections without centralized management, fostering self-organized communication [1-2]. In

**Jahir Hussain and Ramalingam Sugumar**

this decentralized environment, nodes interact directly or indirectly through intermediary nodes. A pivotal focus within MANET research lies in routing, leading to the development of numerous routing protocols. These protocols fall into reactive, proactive, and hybrid categories based on path discovery approaches. Reactive routing, also known as on-demand routing, involves route discovery only when necessary [3]. Notably, Dynamic Source Routing (DSR) has proven effective for MANETs [4]. In the context of MANETs, traditional routing approaches prove deficient due to the impulsive modification in network topology. The constant variations in the network's structure necessitate substantial optimization efforts for determining the most efficient path among multiple alternatives. While conventional routing methods focus on identifying the shortest path between source and destination nodes, the inherent challenges of MANETs, such as dynamic topology and node mobility, demand a more comprehensive approach. Optimization in MANET node routing should consider variables such as wireless network quality, power consumption, fading, interference, propagation path loss, and security. Additionally, optimization efforts may address concerns related to latency, reliability, protection against intentional jamming, and failure recovery. The neglect of any of these critical factors could lead to a deterioration in the reliability and performance of the network [5-8]. The enhancement of the Dynamic Source Routing (DSR) protocol in Mobile Ad Hoc Networks (MANETs) is achieved through the utilization of the MET-MFO algorithm, as detailed in [9] [23] [24] [25] [26]. Although this method exhibits improved performance in various aspects, particularly in handling complex optimization issues like multimodal and high-dimensional scenarios. To overcome these deficiencies, the current study proposes a novel IBFO approach. This approach aims to address the specific challenges posed by difficult optimization problems, providing a more comprehensive and efficient solution for enhancing the overall performance of the DSR protocol in MANETs [27] [28] [29] [30] [31] [32].

**The contributions of this work are,**

- Examining DSR routing functionality on MANETs and optimizing it via the use of the BFO technique is the goal of this study.
- Choosing the step size for the BFO algorithm procedure by employing a non-linear adaptive adjustment technique. Avoiding local optima is aided by this.
- To assess how well the suggested IBFO-DSR performs in comparison to current techniques like DSR, ILFA-DSR and DSR-IMRP.

**RELATED WORKS**

The study in [10] delved into the influence of route request factors such as RREQ\_RETRIES and MAX\_RREQ\_TIMEOUT on the AODV protocol. Subsequently, an evaluation was conducted by comparing the standard performance of the AODV protocol with that of the Optimized Link State Routing (OLSR) protocols. The efficiency of MANET routing systems is impacted by various factors. In [11], mobility algorithms including RWM, SCM, FCM, and HWM, along with ten distinct pause time values, were employed to assess the efficacy of AODV, OLSR, and GRP protocols. TA-AOMDV (Topological Change Adaptive Ad hoc On-demand Multipath Distance Vector) emerges as a dynamic routing protocol, outlined in [12], poised to elevate Quality of Service (QoS) in the face of high-speed node mobility. This protocol introduces a novel path selection strategy, incorporating critical factors and the probability of connection stability between nodes. In tandem, a groundbreaking approach labeled the Maximum Throughput technique for Optimal Position (MTOPT) is unveiled by [13], leveraging the precise geographical coordinates of static users. This innovative method enriches the protocol's capabilities, promising an adaptive and resource-aware routing solution for ad hoc networks. A new technique for Dynamic Critical Node Identification (DCNI) is introduced in reference [14]. In [15], an innovative multi-objective periodic optimization method termed ES-NMPBFO, based on evolutionary states, is put forth. This approach integrates periodic Bacterial Foraging Optimization (BFO) to alleviate the high computational costs associated with the conventional BFO algorithm. Additionally, [16] introduces LPCBFO, an enhanced BFO algorithm that incorporates comprehensive swarm learning techniques. To overcome the limitations of the original BFO, [17] proposes an Improved BFO with features such as chaotic chemotaxis step length, Gaussian mutation, and chaotic local search, referred to as CCBFO.

### Jahir Hussain and Ramalingam Sugumar

To optimize resource utilization effectively, a novel approach leveraging the bacterial foraging optimization (BFO) algorithm was introduced [18]. This methodology, denoted as SBR\_E, intricately models the information exchange observed in bacterial foraging to construct a candidate set for Virtual Network Embedding (VNE) solutions.

## METHODOLOGY

The suggested work is thoroughly explained in this section. The shortest path is used by the original DSR routing system, however when network topology changes quickly, it is not guaranteed to remain stable or reliable. It does take node energy into account as well. Despite its high dimensionality and multimodal problems, the Moth Flame Optimization (MFO) approach might potentially identify a local optimum solution is used in current work to improve the DSR's performance [9] [20]. As a result, the DSR technique has been enhanced with the following features utilizing the suggested Improved Bacterial Foraging Algorithm (IBFO). This determines the optimal path for transferring a packet from source to destination inside the network, minimizing average end-to-end time, and transmission ratio, average utilization of energy, efficiency, and control overhead.

### Finding optimal route using Improved BFO

The following are the drawbacks of the standard BFO. The constant chemotactic step size makes it difficult to strike the ideal balance between exploration and exploitation. Chemotaxis is not as random as it may be due to the weak connections between bacteria. The two aforementioned disadvantages will cause the bacterial community to seek in a complicated multimodal solution set towards local convergence as opposed to global convergence. Additionally, the classic bacterial foraging algorithm lacks learning direction and has a sluggish convergence speed [16] [21]. An approach called Improved Bacterial Foraging Optimization (IBFO) is suggested in order to get around these problems. To change the step size, the non-linear adaptable modification method is applied. This aids in modifying the step size in accordance with the number of iterations and the bacterial nutrition gradient. The optimal path for transmitting data packets may be found using this proposed IBFO over the network with the least amount of energy and time. The route finding technique used the four BFO phases. The movement of bacteria is intricately influenced by the nutrient gradients at the nodes and the interactions between nodes. Bacteria select an optimal migration path by evaluating various routes based on the highest nutritional content and node-to-node communication capacity. In this process, each node in the network accurately pinpoints the location of each bacterium. This intricate interplay of nutrient gradients and bacterial interactions contributes to the bacteria's strategic movement within the network.

### Chemotaxis

The swim and tumble method is a part of the chemotactic stage. When node to node communication and a high nutritional gradient value are recognized, the bacteria switch between these two activities. The bacteria travels in the same direction when the nutritional gradient value is high. The bacteria begins to shift course when the nutritional value is low. The bacteria determines the other immediately linked node's nutritional value. The bacteria travels in the direction of the node with the highest nutritional value, which denotes the node's maximum remaining energy. The path with the highest residual energy nodes is chosen for packet delivery. As the bacteria approaches the  $q^{th}$  node, it detects the nutritional gradient value, which is represented by the following equation. The total nutritional values at the  $p^{th}$  node and the node to signaling between the  $p^{th}$  and  $q^{th}$  nodes make up this value.

$$N_g(p, q) = \frac{B(p)}{C} + B_{nn}(p, q)$$

where C is a network-size-dependent constant gradient factor. The search range is based on the step size. Inaccurate selection of the step size can lead the process to either become stuck at a local optimum or result in a failure. To determine the appropriate step size, we employed a non-linear adaptive adjustment method [22]. The adjustment of the step size is contingent on the maximum and current iteration counts, ensuring a dynamic and responsive adaptation throughout the optimization process. The node's present nutritional state provides the basis for this change.

$$S(q) = (S_{max} - S_{min} - k_1 - k_2) * \cos\left(\frac{i}{i_{max}} * \frac{\pi}{2}\right) + (S_{min} + k_2) + k_1 * \frac{\pi}{2} * \arctan\left(\frac{B}{B_{avg}}\right) - k_2 * \frac{\min(B, B_t)}{\max(B, B_t)}$$

### Jahir Hussain and Ramalingam Sugumar

The bacteria's average value and current fitness value are shown by the letters  $B$  and  $B_{avg}$  in the equation above. The preceding person's ideal fitness value is represented by the symbol  $B_i$ . The random numbers,  $k_1$  and  $k_2$ , can be changed in accordance with the nutritional value. Swarming Bacteria at any  $p^{th}$  node have the capacity to descend in the directions of its immediately connected nodes. The only directions in which bacteria may migrate along a branch that is connected to the node where they live are forward and backward. Bacteria can thus only be found at the terminal nodes of the branch and not along its length. Every bacterium is initially positioned at every network node, using the assumption that the entire amount of bacteria is equivalent to the total amount of network nodes. Since node-to-node transmission is crucial for determining movement direction during tumbling, it is highly significant. The behavior of the bacteria might be either repellent or attractant. When traveling to a nutrition gradient value, Swarms with high fitness values are produced by taking advantage of the attractant activity. The following equation may be used to illustrate how a bacteria at the  $p^{th}$  node communicates with the  $q^{th}$  node via node to node communication.

$$B_{nn}(p, q) = [d(p, q)_{att} \exp(-v(p, q)_{att} (\theta_p - \theta_q)^2)] - h(p, q)_{rep} \exp(-v(p, q)_{rep} (\theta_p - \theta_q)^2)]$$

The distance between point  $p$  and node  $q^{th}$  is represented by  $\theta_p - \theta_q$ ; the attractant's magnitude from point  $p$  to node  $q^{th}$  is represented by  $d(p, q)_{att}$ ; the attractant's diffusion rate from point  $p$  to node is represented by  $v(p, q)_{att}$ ; the repellent's magnitude from point  $p$  to node  $q^{th}$  is represented by  $h(p, q)_{rep}$ ; The representation of the repellent diffusion rate from point  $p$  to node is denoted as  $v(p, q)_{rep}$ .

#### Reproduction

Every chemotaxis step is followed by reproduction with the objective to maintain a consistent number of nodes in the network. This stage involves calculating each bacteria's health status, which is related to the nodes' fitness value. The computed fitness value is then split in half and sorted in ascending order. The microorganisms with bad health status are shown in the lower half. Therefore, it is eradicated and the higher half is procreated to keep the population healthy. The following formula is used to determine each bacterium's fitness or health  $B_{health}^p$ :

$$B_{health}^p = \sum_{q=1}^{N_{c+1}} B(p, q, r, s)$$

where the number of chemotactic steps is indicated by  $N_c$ .

#### Elimination and dispersal

Every stage of reproduction is followed by the elimination and dispersion process. Sick bacteria are removed and distributed at random to improve the bacteria's search accuracy. The node's elimination-dispersal probability may be expressed as,

$$P_{e_q} = P_{e_{min}} + \frac{i_{max} - i}{i_{max}} * (P_{e_{max}} - P_{e_{min}})$$

where  $i$  is the number of iterations and  $P_{e_q}$  denotes the likelihood of deleting the node.

## RESULTS AND DISCUSSION

We make use of the NRL sensim add on and the network simulator NS2. The experiment was set up as shown in Table 1.

#### Average End-to-End Delay

The average end-to-end latency represents the total time taken for a data packet to traverse from its origin to its designated destination node. This metric provides insights into the temporal delay encountered during the process of determining the optimal route between two locations. As the node count escalates under identical node speed and packet transmission rates, Figure 1 illustrates the diminishing average end-to-end latency across four different methods. The stability of the network's topology framework remains consistent at a constant rate throughout this evaluation.

**Jahir Hussain and Ramalingam Sugumar****Throughput**

Throughput is quantified as the ratio of the transmitted packet volume to the total number of packets. Figure. 2 shows the measured throughput in terms of different numbers of nodes. By sending the most packets possible, the IBFO performed better at higher nodes than previous algorithms and produced better results.

**Energy consumption**

The power used in node computations for routing and other choices is referred network as energy consumption. It is the amount of energy used per time unit to process the packets. When the number of nodes rises in any of these scenarios shown in Figure 3, an excessive quantity of energy is used. IBFO-DSR uses less energy than all the other nodes when compared to other methods. This is a result of the route discovery process's adaptive step size selection. The node's remaining energy or nutrition level determines the step size.

**CONCLUSION**

In conclusion, the application of the Improved Bacterial Foraging Optimization Algorithm to DSR in MANETs has proven to be a significant advancement in optimizing route discovery and maintenance. The integration of the Improved Bacterial Foraging Algorithm has demonstrated enhanced efficiency in adapting to the dynamic and often unpredictable nature of MANETs. The algorithm's ability to dynamically adjust routing parameters and adapt to changing network conditions contributes to improved packet delivery, reduced latency, and increased overall network performance. This research highlights the potential of leveraging nature-inspired optimization techniques, such as the Improved Bacterial Foraging Algorithm, to address the challenges inherent in MANETs, ultimately paving the way for more robust and adaptive routing protocols in mobile ad-hoc environments.

### ABSTRACT

Human Activity Recognition (HAR) is important for many applications such as health, smart homes and human computer interaction. This paper introduces a new metaheuristic technique associated with a hybrid Convolutional Neural Network (CNN) model for efficient human activity recognition and classification. Our proposed method integrates the advantages of metaheuristic optimization algorithms and deep learning, thereby improving classification accuracy as well as computational efficiency. The results show that the hybrid CNN architecture optimized by a metaheuristic algorithm surpasses conventional methods in terms of accuracy, speed and robustness on different data sets. This is a research paper in the field of HAR and can help in accelerating knowledge discovery on the topic as it enables similar techniques to produce real-time applications.

**Keywords:** Human Activity Recognition, Metaheuristic Optimization, Hybrid CNN, Classification, Deep Learning, Machine Learning, Smart Homes, Healthcare, Real-time Analysis.

## INTRODUCTION

HAR, being a line of research in demand due to its wide range of applications in areas such as healthcare, smart homes system and security up to human computer interfaces systems [1]. Automatically recognize and classify human activities, such as walking, running, sitting or standing using data from different types of sensors. The collected in ubiquitous environments for surveillance purposes required Integration risk%. Identifying and analyzing these acts are accurately crucial if human behavior can be monitored, as well intelligent systems are able to react in real-time. Historically, HAR systems used classical machine learning methods for classification tasks (Support Vector Machines SVMs, Random Forest RF and k-NN). And these methods seemingly required lots of manual feature engineering and were having difficulties dealing with the high dimensionality, noise present in sensor data [2]. However, the models above cannot well capture complex patterns and temporal dependencies in human activities, which resulted in relatively low effectiveness when applied to real-world applications [31] [32] [33] [34] [35] [36]. The more significantly one is the appearance of deep learning, and specifically Convolutional Neural Networks (CNNs), which have led a shift in the approaches to HAR from handcrafted feature generation to an end-to-end automatic extraction of real-time low/mid/high-level representing hierarchical features that are fed directly into different models. CNN has been effective for image and sensor-based HAR partly due to its strong capability in recognizing spatial patterns with more accuracy [3]. Due to their nature, CNNs are not well suited for modeling temporal dependencies that are so important when doing activity classification on sequential data i.e. human activities. To mitigate this issue, hybrid architectures that combine CNNs with Recurrent Neural Networks (RNN) or Long Short-Term Memory (LSTM) networks have been employed by researchers. These hybrids employ CNNs for the extraction of spatial features, and RNN/LSTMs networks to learn temporal dependencies leading towards higher classification accuracies. Although these models are powerful, hybrid ones typically demand a lot of hyperparameters settings such as layers depth & filter size and yet to full set unhem needs fine-tuning for better results [4]. Manual tuning can be extremely time-consuming and may not give us the best results in a non-trivial HAR task where we have many different classes within the same data set [37] [38] [39] [40] [41]. In recent years, metaheuristic optimization algorithms, including Genetic Algorithm (GA), Particle Swarm Optimization (PSO) and Ant Colony Optimization (ACO), have been developed successfully for solving a wide range of complex optimization problems in many areas [5]. They are especially good at traversing large search spaces and converging to near-optimal solutions with relatively few computational resources. This enables the metaheuristic algorithms can be applied on deep learning to highly automatize hyperparameter tuning as a result higher model performance and faster training [42] [43] [44]. In this study, a metaheuristic optimization algorithm is fused into the hybrid CNN for human activity classification and recognition. In our case, we use Particle Swarm Optimization (PSO) to tune the hyperparameters of a hybrid CNN model that shares convolutional layers for spatial characteristics extraction and Long Short-term Memory Layers LSTM architecture for temporal pattern recognition [6]. The overarching goal is to improve the sensitivity and specificity of HAR systems while availing an automated hyperparameter tuning approach that exploits both CNNs capabilities as well as those of LSTMs.

## METHODOLOGY

This section describes the methodology used to design and validate a metaheuristic-based hybrid Convolutional Neural Network (CNN) technique for Human Activity Recognition (HAR). The methodology consists of Data collection and preprocessing, Designing the hybrid CNN architecture i.e. ADANNET model Preparation for Particle Swarm Optimization (PSO) both wand Hyperparameter tuning through PSO algorithm followed by Training & evaluation process

**Mahesh and Vanjulavalli**

## MATERIAL AND METHODS

### Data Collection

For the development and assessment of the proposed HAR system, we used several publicly available benchmark datasets for human activity recognition which are well-known in HAR community [7]. The datasets used in this paper are as follows:

**UCI HAR Dataset:** This dataset contains the sensor data from accelerometers and gyroscopes of a smartphone worn by 30 subjects who perform six different activities including walking, walking-upstairs, walking-downstair, sitting, standing and laying.

**WISDM Dataset** – The Wireless Sensor Data Mining (WISDM) dataset includes accelerometer data from smartphones while users perform daily activities like walking, jogging, sitting, standing and going up/downstairs.

### Data Preprocessing

The raw sensor data in these datasets was processed such that it could be consistent prior to training the model.

**Normalization:** Sensor readings were scaled down to standard range (usually between 0 and 1), which avoided anomalies because of different scale on each sensor.

**Segmentation:** fixed-size windows (e.g. with a 50% overlap for continuous sensor data) Each window described what was happening at the time.

**Feature Extraction:** While deep learning models can learn features directly from raw data, we also explored the extraction of statistical descriptors (mean, standard deviation) along each window to improve model performance.

**Data Augmentation:** We used data augmentation techniques to alleviate class imbalance and increase the model's robustness. These included introducing noise and rotating or scaling the sensor data. Hybrid CNN Architecture Our proposed methodology includes a hybrid CNN architecture that was developed to capture spatial and temporal features from segmented sensor data. CNN for Spatial Feature Extraction The first component of the hybrid model is constructed using convolution layers that were employed to capture spatial features from the input sensor data [8].

**Convolution layers:** convolutional filters with optimized numbers, filter length, and stride to recognize local patterns, including movement characteristics of various activities using PSO. Activation function: ReLU activation function was employed for introducing non-linearity into the model to learn complex patterns.

**Pooling layer:** max pooling layers were used to reduce the spatial dimension to assist in decreasing the computational burden and decrease overfitting. LSTM for Temporal Pattern Recognition The hybrid model incorporated an LSTM layer after the convolution layers to learn the temporal patterns of the sequential data [9]. LSTM units: the optimal number of LSTM units, which correlates with the network memory capacities obtained using PSO. After the LSTM layer, it goes through 1 or multiple fully connected layers. These layers combine the learned features and feed them through for final classification. The last layer has a SoftMax activation function which gives probability scores for each class of activity.

### Metaheuristic Optimization

A population-based metaheuristic optimization algorithm inspired by the social behavior of birds flocking or fish schooling called as Particle Swarm Optimization [10] was used to tune the hyperparameters for our hybrid CNN architecture. PSO is an optimization algorithm that iteratively improves a population of candidate solutions (particles) by evaluating their performance on the fitness function, in our case – classification accuracy over valid dataset.

**Mahesh and Vanjulavalli**

**Initialization:** Each particle represents a unique combination of hyperparameters for the Hybrid CNN model, i.e., number of convolutional filters, filter sizes and the learning rates; Dropout rates & LSTM units.

**Fitness Evaluation:** The fitness was to be evaluated by training the hybrid CNN mode using appropriate hyperparameters of an individual particle and then measuring its classification accuracy on validation set.

**Update Rules:** The updated positions of the particles was based on their best known position and also neighbors. The best-so-far positions were to be included Sua moto. From one iteration to the next, they essentially told the swarm how it should move to find better solutions.

**Convergence:** The algorithm converged when the fitness values across iterations stopped changing (below a predefined threshold), implying an optimal or near-optimal set of hyperparameters treated as solution for optimization.

**Training and Evaluation**

After identification of optimal hyperparameters by the PSO algorithm, we trained a hybrid CNN model. This training process included [11]:

**Loss Function:** Categorical cross-entropy used as the loss function which is representation of how far predicted activity classes are from actual.

**Optimizer:** We use the Adam optimizer with PSO to control adaptive learning rate update during training.

**Regularization:** To avoid overfitting, dropout layers were introduced to the model that randomly drops units in a layer while training. It was also used to optimize the dropout rates

**Cross-Validation:** We used a 10-fold cross-validation scheme to guarantee robustness and generalization on our model. The complete data was split tenfold; nine loads were used for training and one job, moving into validation and ensuring that all cross-sectional points are covered.

**Evaluation Metrics**

The effectiveness of the proposed method was measured and compared to other existing approaches by Meansof metrics [12]:

**Precision:** Fraction of accurately classified activities from the whole set.

**Precision:**  $\text{True Positive} / (\text{True Positives} + \text{False Positives})$

**Sensitivity:** It is about Recall ( $\text{Recall} = \text{TP} / (\text{TP} + \text{FN})$ ).

**F1-Score:** F-measure or balanced f-score is the mixture of precision and recall.

**Computational Efficiency:** The authors also investigated the time needed to train a model and which computational resources were necessary using this method in order to analyze their practical feasibility.

The above-described methodology provides a well-defined process to create deep-learning-based HAR systems with the strength of metaheuristic optimization [13]. Since the proposed method combines PSO and a hybrid CNN architecture, an equilibrium between high classification accuracy and computation efficiency has been achieved that qualifies this approach for real-time applications [14]. Experimental results and detailed discussion on obtained findings are presented in subsequent sections.

**RESULTS**

In this section, the experimental results are explained to evaluate how well metaheuristic can enhance Convolutional Neural Network (CNN) model for Human Activity Recognition [15]. The goal of these experiments was to evaluate

**Mahesh and Vanjulavalli**

the results using a hybrid CNN architecture with PSO as optimizer, and hence they were applied on multiple benchmark datasets. The results provided below in the context of classification accuracies, precision-recall-F1scores and computational efficiency [16]. Furthermore, a comparison with other state-of-the-art HAR methods is included as well.

**Classification Accuracy**

The hybrid CNN model is optimized by PSO, and the variation of kernel size metaheuristic is evaluating on UCI HAR and WISDM dataset. Gradually, we obtained the classification accuracy on these datasets [17]: UCI HAR Dataset The average classification accuracy of the hybrid CNN model obtained 96.8 %. It is a significant improvement over the accuracies of traditional CNN models which are usually around 94.1% without optimization Average accuracy of 95.3% on the WISDM dataset – WISDM is a common activity recognition benchmark This shows that the model can be generalized very well across different datasets meaning it will perform at a high level even if your data is varied. This increase in accuracy is due to finding optimal hyperparameters by PSO which led this model be able to learn more productive features and patterns from data. We further evaluated the model performance by calculating precision, recall and F1-score of each activity class across our datasets. This is summarized in the below results for UCI HAR dataset [18].

**Precision:** The model had a precision of 96.4percent which means, most (but not all) patients who were predicted as positive by the model was indeed positive for pneumonia

**Average Recall:** 96.1% This means that the model can identify most of actual positives correctly and few as negative which is good for this specific problem since a positive or true label indicates further medical assessment by the specialist was necessary from an image picture.

**F1-Score** – The F1 score is 96.2% on average, showing a balance between precision and recall during our predictions. On the WISDM dataset we achieved an average precision of 95.0%, recall of 94.7% and F1-score is equal to 94.8%. This indicates the high stability of this method to accurately detect and classify human activities in multiple datasets.

**Computational Efficiency**

Besides the obvious reduction in computational time since hyperparameters are automatically optimized through PSO as one of the main benefits of this proposed approach [19]. They accomplished to reduce training time for the hybrid CNN model by about 30% than traditional manual tuning methods. Specifically:

**Training Time:** The PSO-optimized hybrid CNN trained in an average of 3 hours on UCI HAR dataset as compared to manually tuned CNN model (around 4.5 hrs.).

**Convergence Speed:** The PSO algorithm succeeded in quickly converging towards the best hyperparameters setting in less than 50 iterations which means that it can efficiently travel through the search space [20]. These enhancements in computational efficiency render the proposed method an excellent choice for real-time HAR applications, since quick deployment and response times are a necessity. We then compared the proposed method to other state-of-the-art HAR techniques, such as SVMs, RFs and RNN(LSTMs), typical CNN architectures to validate its better results. These findings are summarized in the table below [21]: The proposed hybrid CNN with PSO in Table is also the best performer of accuracy and smaller training time among all compared methods. This indicates that the hybrid approach is best suited for extracting both spatial and temporal characteristics, as well as using metaheuristic optimization to further enhance hyperparameter selection. Results show that the performance of HAR systems outperformed substantially with a new hybrid CNN approach guided by metaheuristic compared to typical methods [22]. The optimized hybrid model yields better classification accuracy and computational burden is reduced, which makes it viable for real-time applications. The comparison with some state-of-the-arts techniques further shows the better performance of our method not only in efficiency but also in accuracy [23].

**Mahesh and Vanjulavalli**

## DISCUSSION

Our study is sufficient to conclude the effectiveness of metaheuristic-driven CNN method for HAR. In this section we discuss the implications of these findings, advantages our approach has over previous work, potential weaknesses in addition to future research directions.

### Implications of the Study

In other words, this study demonstrates the effectiveness of integrating a metaheuristic optimization algorithm in fusion with an innovative hybrid CNN architecture for HAR [24]. The Results indicate that indeed this leads to significant improvements in terms of classification accuracy as well computational back passes the hybrid architecture uses CNNs as feature extractor along with Long Short-Term Memory (LSTM) networks to capture both the spatial and temporal patterns in sensor data, which is one of the key criteria to recognize and classify human activities reliably [25]. Additionally, results also indicate that using Particle Swarm Optimization (PSO) for hyperparameter tuning can be an effective approach to optimize the hybrid CNN model [26]. The primary benefit of PSO is that it can explore regions far from a given initial solution and find near-optimal solutions with relatively few function evaluations, which makes the practical automation of hyperparameter tuning possible (this frequently requires numerous runs) [27]. However, this automation helped not only the performance of the model but also speeded up significantly (it makes more than 30%-time difference) especially in a case using larger image. According to the authors, results of this study suggest that real-time HAR systems should consider such a method and open up an avenue for its application on areas where edge-based online human activity recognition is required (i.e., e-health monitoring, smart home scenarios or security) [28]. Improved accuracy and fast training time make the suggested approach ideal for deployment in real-world applications where meaningful responsiveness is important.

### Benefits of the Proposed Method

The new modular metaheuristic-based blueprint of hybrid CNN method is advantageous, compared to traditional HAR systems [29]. We show that: i) our proposed algorithm improves the accuracy of estimation compared to methods using a single CNN or classical machine learning algorithms, because it can use both spatial and temporal features on sensor data by combining with CNN and LSTM networks. Automated Hyperparameter Optimization: PSO automates the hyperparameters tuning which is done manually in deep learning models. This not only makes the process faster, but it also ensures that we tune our model to perform best.

**Computational Efficiency:** The hybridized model, when optimized to ensure the same level of accuracy as compared with a traditionally trained classifier, could be even more user for real-time applications on-the-go. This efficiency is vital in cases when computational resources are low, or model deployment must be rapid.

**Generalizability:** The proposed method showed good generalization ability of to various HAR tasks on different datasets. The degree of generalizability in doing so is crucial to designing HAR systems that could be used more widely across real-world environments.

### Potential Limitations

While the results look promising, there were limitations to the proposed approach.

**Complexity of the Model:** A hybrid CNN-LSTM architecture, which is more complex than traditional machine learning models. That complexity could be a challenge for environments with very limited computer capabilities (i.e. edge devices with low processing power). **Data Quality Dependency:** The performance of our approach is highly influenced by the quality and quantity of data set generated at sensor level. If the data is noisy, incomplete or imbalanced then the model will not perform as well. While data unwanted issues were dealt with stage of pre-processing and employing augmentation techniques, the robustness of model can be improved by using much better practices to handle such data problems.

**Mahesh and Vanjulavalli**

**Convergence of PSO:** Although PSO is a powerful method to tune the hyperparameters, it's still a stochastic process and may converge into bad solution in some cases especially when the search space becomes hugely or abnormally complex. One other thing that can influence the performance of this algorithm are parameters like swarm-size, and inertia weight.

**Future Research Directions**

Based on the findings of this study there are different avenues shown in first lines for further research [30]:  
**Investigation of Additional Metaheuristic Algorithms:** Since PSO was selected for use in this study because it is a simple and efficient algorithm, but the operation results available largely suggest that other candidate metaheuristics can be leveraged to tune hyperparameters. Some sort of comparison between these algorithms would make it easier to infer which one is proficient and non-proficient in optimizing deep learning models. **Simplification of the model:** As this architecture is relatively complex (the hybrid CNN-LSTM), future studies could focus on more light-weight models that retain high accuracies and requires lower computational cost. One could explore techniques like model pruning and quantization, or even venture a little bit deeper and use neural architecture search (NAS).

**Validation In the Real-World:** The proposed approach should be validated in real-world scenarios for testing its performance under practical conditions e.g. sensor placement, movement variations and user diversity (style heterogeneity). This would also show us a lot about the robustness of the model and how well it can be used in real-world applications.

**Addressing Noisy and Incomplete Data:** We look forward to improvements that will enhance the capability of this model in addressing noisy, incomplete or imbalanced datasets. Adversarial training, data imputation or robust loss functions might help for model to be more tolerant towards bad quality input data.

**Research direction:** Integration with Edge Computing. With the deployment of HAR systems in edge computing environments increasingly, research could explore how existing approaches integrate this method into devices at the edges which may have limited processing power and memory. This would include optimizing the model architecture and inference for resource scarce environments. In this discussion, the prominent novel attributes assisted hybrid CNN based technique to deal with HAR are underscored affirming for its high impact in accuracy and efficiency as compared to automated mechanisms. Despite some restrictions, the study suggests a variety of promising directions for future research to improve HAR system performance and usability. In solving the above-mentioned issues, the proposed method could revolutionize this domain leading to smarter more reactive and robust HUMAN activities recognition systems for a broad range of applications.

**COMPARISON STUDY**

Therefore, a comprehensive comparison is also developed between the proposed metaheuristic- based Hybrid Convolutional Neural Network (CNN) method with existing state-of-the-art Human Activity Recognition (HAR) approaches in this section. We compare across several dimensions, including classification accuracy, computational efficiency, robustness to data variability and ease of implementation. For these scenarios, the methods compared involve classic machine learning algorithms as well as deep-learning models and hybrid approaches. A important metric in the HAR models evaluation is its classification accuracy, which clearly reveals how well a model can perform to recognize and classify human activities. The proposed PSO-optimized hybrid CNN was benchmarked with the following approaches:

Support Vector Machines (SVM)

Random Forests (RF)

Recurrent Neural Networks (RNN)

- Standard CNN

- Hybrid CNN-LSTM: without Optimization

**Mahesh and Vanjulavalli**

**Analysis:** The proposed CNN-LSTM model integrated with PSO consistently outperformed other methods, obtaining the best accuracy on two datasets. The classification accuracy is low for SVM and RF compared to deep learning models as these conventional machine learning algorithms. CNN-LSTM hybrid performed well in the absence of optimization, but particle swarm 27 optimized CNN-LSTM is required to further expand its capabilities.

**Computational Efficiency Comparison**

Computational efficiency is equally important, especially in the case of real-time HAR tasks. They then measured the training time of their proposed model and compared it to other models in terms of convergence speed.

**Analysis:** The proposed method was computationally more efficient, taking 30% shorter time training compared to standard CNN and hybrid CNN-LSTM without tuning. Successful improvements suggested the proposed model is applicable for real operational procedures, and finally the state velocity method was optimized with PSO optimization. For the SVM and RF, which is a traditional method their low accuracies cause them for the need to be discard on situations that high precision required but faster training times are also one of their advantages. One of the most important requirements for a HAR system to work in reality is its robustness against data variation with noise, imbalanced class distributions and sensor position differences. These methods were assessed in terms of their ability to handle various data.

**SVM and Random Forest:** Both models demonstrated great sensitivity to noisy or imbalanced datasets as their accuracies fell drastically in such cases. They also needed heavy feature engineering to preserve accuracy.

**RNN:** RNR are usually great auto encoders that can capture temporal dependencies; however, they were prone to noise in the data and exhibited high variability performance across datasets.

**Standard CNN:** Better than traditional approaches but sensitive to data variability, especially important for temporal patterns.

**Hybrid CNN-LSTM (No PSO):** This model became more robust as it can encapsulate spatial and temporal features equally. On the other hand, it was still susceptible to overfitting on noisy data without optimization.

**Hybrid CNN-LSTM + PSO:** As the best model, it was robust under diverse circumstances. The PSO based optimization of hyperparameters also helped the model to be more robust towards different datasets and noise levels.

**Analysis:** Among the proposed models, the hybrid CNN-LSTM model with PSO exhibited higher robustness against data variability is well-suited for real-world deployment as external conditions can change drastically. Metaheuristic optimization in combination with CNN and LSTM led to a more robust solution against overfitting as well as enabled better generalization achieved on different datasets.

**Ease of Implementation**

Practical employment in industry and healthcare put HW requirement on the edge, thus deploying a HAR system must not be cumbersome. We compare the methods based on its difficulty to implement.

**SVM and Random Forests:** These methods are simple to implement as well which takes less computational resources. However, they tend to need a lot of work on feature engineering: as you will see next this can be time-consuming and needs some domain expertise.

**RNN:** Since RNNs are sequential and handle long-term dependencies, they take more time to implement. They're also more resource intensive.

**Standard CNN:** While CNNs are easy to code within modern deep learning frameworks, hyperparameter tuning can be difficult and time-consuming.

**Mahesh and Vanjulavalli**

**Hybrid CNN-LSTM (No PSO):** The hybrid nature of the model makes it more complex which leads to developing an architecture and hyperparameter tuning for both incorporated layers.

**Hybrid CNN-LSTM + PSO:** This proposed method adds some complexity as it incorporates PSO for optimization, but the automation of hyperparameter tuning does not also give that big room to manually tune something which facilitates easy access towards optimal performance without many iterations.

**Analysis:** Thus, the proposed hybrid CNN-LSTM model with PSO presumably robust in both complexity and simplicity. While more difficult to use than the default tuning methods, because PSO automates this process it will allow a broader range of practitioners with less machine learning expertise to easily tune their models.

**Summary**

In the experiment, several key aspects of HAR are considered as a benchmark dataset to compare our metaheuristic-based hybrid CNN technique for human activities recognition.

**Results- Accuracy:** The proposed approaches outperform other classification techniques on different datasets.

**Efficiency:** The model is computationally efficient resulting in reduced training time and faster convergence.

**Stability:** It is better able to resist change from different testing datasets or units of application.

**Ease of Implementation:** Although in theory an intricate function but the hyperparameter tuning is all automated thus streamlining its implementation. In summary, the approach put forth provides an impressive option for HAR by synergizing CNNs and LSTMs advantages with PSOs optimization potential to produce a supremely precise, effective system that is scalable in practice.

**CONCLUSION**

A new metaheuristic-driven mixed CNN based human activity recognition and classification framework is proposed in this paper, which provides significantly higher accuracy for classification as well reduces the computation time compared to existing methods. Its hybrid CNN architecture and metaheuristic optimization allow the automatic tuning of more complex model configurations, lending itself to real-time applications. Our future work will focus on improving the metaheuristic optimization process as well as incorporating other data modalities, to support a more robust HAR system.

### ABSTRACT

Let  $G_D(\sigma, \mu)$  be a fuzzy digraph (FDG) described on simple directed graph  $G_D(V, E)$  and let  $x$  and  $y$  be any two vertices of  $V$ . In this work, the strong edge in fuzzy digraph is initialized. We say that  $x$  dominates  $y$  if  $(x, y) \in \mu$  is a strong edge but  $y$  does not dominate  $x$ . The set  $D \subseteq V$  is a dominating set if for every  $y \in V - D$ , there exists  $x \in D$  such that  $x$  dominates  $y$ . The minimum number of cardinalities among all the dominating sets of a FDG  $G_D$  is known as the domination number of  $G_D$  as indicated by  $\gamma(G_D)$ . An introduction to the idea of domination in a fuzzy digraph by using strong arc, it is possible to characterize the domination number of a FDG, FDP, and FDC are discussed.

**Keywords:** Fuzzy digraph, Strong edge, Dominating set, Domination number.

**AMS Subject Classification:** 05C20, 05C72, 05C69

## INTRODUCTION

Ore [10] was initiated the concept of domination in 1962. In 1958 domination was formalized as a theoretical area in graph theory by Berge [1]. Conversely, Zadeh [14] presented a groundbreaking study in 1965 that developed the idea of a fuzzy set. In 1975, Rosenfeld [11] proposed fuzzy graphs and established and studied the idea of fuzzy relations on fuzzy sets. A compilation of significant advancements in fuzzy graph theory and applications were developed by Modersohn and Nair [8], while Modersohn and Chang-shy [6] established and some basic operations of fuzzy graphs. A. Somasundaram and S. Somasundaram [12] were first independently present the notion of domination in fuzzy graphs in 1998. Modersohn and Nair [7] were first established the idea of fuzzy directed graphs (digraph) on 1996. Kishore Kumar P.K and Lavanya.S [5] were discussed on fuzzy digraph on 2017. Bhutani,

### Mohamed Ismayil and Syed Asad Ahmed

K.R and Rosenfeld .A [2] introduced the concept of strong arcs in fuzzy graph.On 2021, Enrico Enriquez et.al [3] newly presented the idea of domination in FDG using adjacency.

The idea of domination set, domination number in fuzzy digraphs are initialized using strong arcs in this paper. The purpose of this work is to ease further developments on these ideas by generalizing the results of the smallest dominant set of a fuzzy digraph [15] [16].

## PRELIMINARIES

This section offers a revised description of the fuzzy digraph, presents some common working terminology, and provides some insightful commentary in the form of remarks and examples.

**Definition 2.1:** Let  $X$  be any set of the universe of discourse  $U$ . A fuzzy subset  $\sigma$  of  $X$  is a function from  $X$  into the closed interval  $[0,1]$ . Let  $\sigma$  be a fuzzy subset of a set  $S$  and  $\mu$  a fuzzy relation on  $S \times S$ . Then  $\mu$  is known as *fuzzy relation* on  $\sigma$  if  $\mu(x, y) \leq \sigma(x) \wedge \sigma(y)$  for all  $x, y \in S$ . Let  $\mu$  be a fuzzy relation on  $\sigma$ , where  $\sigma$  is a fuzzy subset of a set  $S$ . Then  $\mu$  is said to be *reflexive* if  $\mu(x, x) = \sigma(x)$  for all  $x \in S$ . Let  $\mu$  be a fuzzy relation on  $\sigma$ , where  $\sigma$  is a fuzzy subset of a set  $S$ . Then  $\mu$  is said to be *symmetric* if  $\mu(x, y) = \mu(y, x)$  for all  $x, y \in S$ . Let  $\mu$  be a fuzzy relation on  $\sigma$ , where  $\sigma$  is a fuzzy subset of a set  $S$ . Then  $\mu$  is said to be *transitive* if  $\mu^2 \subseteq \mu$ . i.e.  $\mu(x, z) \geq \sup_{y \in S} [\mu(x, y) \wedge \mu(y, z)] \quad \forall x, z \in S$ .

**Definition 2.2:** Let  $V$  be a non empty set. A *fuzzy graph* is a pair of function  $G: (\sigma, \mu)$  where  $\sigma: V \rightarrow [0, 1]$  &  $\mu: V \times V \rightarrow [0, 1]$  such that  $\mu(x, y) \leq \sigma(x) \wedge \sigma(y) \quad \forall u, v \in V$  is a unordered pair.

**Definition 2.3:** A *directed fuzzy graph or fuzzy digraph*  $G_D(\sigma, \mu)$  is defined on simple directed graph  $G(V, E)$  consist of a non empty finite set  $\sigma: V \rightarrow [0, 1]$  &  $\mu: E \subseteq V \times V \rightarrow [0, 1]$  such that  $\mu(x, y) \leq \sigma(x) \wedge \sigma(y) \quad \forall x, y \in V$  and  $V \times V$  is an ordered pairs of distinct vertices.

**Note:** In a digraph,  $\mu$  is not necessarily symmetric. i.e., If  $(x, y) \in E$  then  $x$  directed to  $y(y, x) \notin E$ . Since  $G_D$  is a simple directed graph. Hereafter  $G_D$  is a simple directed graph unless otherwise stated.

**Remark 2.1:** Let  $G_D(\sigma, \mu)$  be a fuzzy digraph of a digraph  $G(V, E)$ .

1.  $\mu(x, y)$  is a fuzzy edge directed from  $x$  to  $y$ .
2. If  $(x, y) \in E$  then  $\mu(x, y) \neq 0$  and if  $(x, y) \notin E$  then  $\mu(x, y) = 0$ .

**Example 2.1:** Let  $G_D = (\sigma, \mu)$  be a simple fuzzy digraph  $G(V, E)$  as shown in Figure 1. Because  $\mu(x, y) \leq \sigma(x) \wedge \sigma(y) \quad \forall x, y \in V$ , therefore Consequently,  $G_D$  is a simple fuzzy digraph.

**Definition 2.4:** For any two vertices  $u, v \in G_D$ ,  $N_{G_D}^+(u) = \{v \in V - \{u\} \mid (u, v) \in E\}$ ,  $N_{G_D}^-(u) = \{v \mid (v, u) \in E\}$ . The sets  $N_{G_D}^+(u)$  and  $N_{G_D}^-(u)$  and  $N_{G_D}(u) = N_{G_D}^+(u) \cup N_{G_D}^-(u)$  are called the *out-neighbourhood*, *in-neighbourhood* and *neighbourhood* of  $v$  respectively.

**Note:** Hereafter  $G_D$  stands for only non-symmetric simple fuzzy digraph.

### Domination in fuzzy digraph

In a fuzzy digraph  $G_D$ , a dominating set is defined in this section. Additionally, we describe the smallest dominating set of a FDG and provide a few insight ful findings.

**Definition 3.1:** An edge  $(x, y)$  of a FDG  $G_D(\sigma, \mu)$  is known as strong arc or strong edge if  $\mu_D(x, y) \geq \text{CONN}_{G-(x,y)}(x, y)$ . Otherwise it is a weak arc or weak edge.

**Example 3.1:** In Figure 1, All the edges are strong edges except  $(b, c)$  since  $\mu(b, c) \not\geq \text{CONN}_{G-(b,c)}(b, c)$ .

**Definition 3.2:** A fuzzy digraph  $G_D(\sigma, \mu)$  is claimed to be strong fuzzy digraph, if  $\mu(x, y) = \sigma(x) \wedge \sigma(y), \forall (x, y) \in E$ .

**Mohamed Ismayil and Syed Asad Ahmed**

**Definition 3.3:** If  $\sigma$  is a fuzzy subset of a set  $S$ , then for all  $x, y, (x, y)$  is called *effective edge* then  $\mu_D(x, y) = \sigma(x) \wedge \sigma(y)$  for all  $x, y \in S$ .

**Remark 3.1:** If  $G_D(\sigma, \mu)$  is a strong FDG, then all the edges are strong edges and also effective edges. Converse not true.

**Definition 3.4:** Let an edge  $(x, y)$  is a strong arc in a fuzzy digraph  $G_D(\sigma, \mu)$ , then the vertex  $x$  dominates  $y$  but  $y$  does not dominates  $x$ .

**Definition 3.5:** A set  $\sigma_1 \leq \sigma(D) \subseteq V$  is called domination set in a fuzzy digraph  $G_D(\sigma, \mu)$  if every vertex of  $V - \sigma \leq \sigma_1(D)$  is dominated by some vertex in  $\sigma(D)$ . A dominating set  $\sigma(D)$  of a fuzzy digraph  $G_D(\sigma, \mu)$  is called a minimal dominating set (MDS) if there is no proper subset of  $\sigma(D)$  is a dominating set. A dominating set  $\sigma(D)$  of a fuzzy digraph  $G_D$  is known as minimum dominating set (min DS) if all the dominating sets  $\sigma(D')$  such that  $|\sigma(D)| \leq |\sigma(D')|$ . If a MDS has a smallest cardinality, is known as domination number and it is termed as  $\gamma(G_D)$ . If a MDS has a greatest cardinality, is known as upper domination number and it is indicated by  $\Gamma(G_D)$ .

**Remark 3.2:** Let  $G_D = (\sigma, \mu)$  be a FDG of  $G = (V, E)$  and  $D \subseteq V$ .

1. If  $\sigma(D)$  is a dominating set of  $G_D$ , then  $D$  is a dominating set of  $G$ . It is not always the case that the converse is true.
2. The fuzzy cardinality of a smallest dominating set is called the domination number of  $G_D$  is known as  $\gamma(G_D)$ , i.e.,  $\gamma(G_D) = \min \sum_{x \in D} \sigma(x)$ . Where  $D$  is a dominating set of  $G$ .

**Note:** Let  $G_D$  serve as a FDG then  $N_s^-(a) = \emptyset, a \in D$  and  $N_s^+(a) = \emptyset, a \notin D$ .

**Example 3.2:**

Examine the fuzzy digraph given in fig 2,

1: There is only one path between  $v_1$  and  $v_2$ , then the edge  $(v_1, v_2)$  is a strong arc and its strength is 0.1. Then  $v_1$  dominates  $v_2$ , where as  $v_2$  does not dominates  $v_1$ .

2: There are two paths between  $v_2$  and  $v_3$ .

(i)  $P_1: v_2 \rightarrow v_3$ , the strength of  $P_1$  is 0.1, therefore  $\mu(V_2, V_3) = 0.1$

(ii)  $P_2: v_2 \rightarrow v_4 \rightarrow v_3$ , the strength of  $P_2$  is 0.3, therefore  $CONN_{G-(V_2, V_3)}(V_2, V_3) = 0.3$

Then the condition  $\mu(v_2, v_3) \geq CONN_{G-(V_2, V_3)}(v_2, v_3)$  is not satisfied. Then the edge  $(v_2, v_3)$  is a non strong arc, Hence  $v_2$  does not dominates  $v_3$ .

Similarly,  $v_2$  dominates  $v_4$ ,  $v_4$  dominates  $v_1$  and  $v_3$ .

$\therefore D_1 = \{V_1, V_4\}, D_2 = \{V_1, V_2, V_3\}$  are minimal dominating sets.

$\therefore \gamma(G_D) = 0.7, \Gamma(G_D) = 1.2$ .  $D_1$  is a smallest dominating set and  $D_2$  is minimal dominating set.

**Example 3.3:** Let  $G_{D'} = (\sigma_{D'}, \mu_{D'})$  and  $G_D = (\sigma_D, \mu_D)$  be a simple fuzzy digraphs, (See Figure 3). If

$$\sigma_D = \left\{ \frac{a}{0.5}, \frac{b}{0.6}, \frac{c}{0.7}, \frac{d}{0.8}, \frac{e}{0.9} \right\} = \sigma_{D'}$$

$$\mu_D = \left\{ \frac{ba}{0.5}, \frac{bc}{0.5}, \frac{bd}{0.4}, \frac{be}{0.5}, \frac{dc}{0.7}, \frac{de}{0.7}, \frac{ea}{0.6} \right\}, \mu_{D'} = \left\{ \frac{ab}{0.4}, \frac{bc}{0.5}, \frac{bd}{0.4}, \frac{be}{0.5}, \frac{dc}{0.7}, \frac{de}{0.7}, \frac{ea}{0.6} \right\}$$

Then  $\mu(x, y) = \sigma(x) \wedge \sigma(y) \forall x, y \in V$ . Therefore the set  $\{0.6\}$  is the MDS of  $G_D$  and the set  $\{0.5, 0.6\}, \{0.9, 0.6\}, \{0.9, 0.8, 0.5\}$  are MDS of  $G_{D'}$ . In addition,  $\gamma(G_D) = 0.6$  and  $\gamma(G_{D'}) = 1.1$ . (See Figure 3). Figure 3. The smallest dominating set of  $G_D$  is  $\{0.6\}$ , hence,  $\gamma(G_D) = 0.6$  as well as the smallest dominating set of  $G_{D'}$  is  $\{0.5, 0.6\}$ , hence,  $\gamma(G_{D'}) = 1.1$ . The following observation is evident from the definitions and observations.

**Remark 3.3:** Let  $G(V, E)$  be a simple digraph of a FDG  $G_D = (\sigma, \mu)$ . If  $D \subseteq V$ , then  $|\sigma(D)| \leq |D|$ .

**Proof.** Since  $0 \leq \sigma(x) \leq 1 \forall x \in D$ , it may be concluded that

$$|\sigma(D)| = \sum_{x \in D} \sigma(x) \leq \sum_{x \in D} 1 = \sum_{n=1}^{|D|} 1 = 1|D| = |D|.$$

For a fuzzy digraph, the MDS is characterized by the following result.

**Mohamed Ismayil and Syed Asad Ahmed**

**Theorem 3.1:** Let  $G_D = (\sigma, \mu)$  be a fuzzy digraph is defined on digraph  $G(V, E)$  and  $D \subseteq V$ . A dominating set  $D$  of  $G_D$  is a minimal iff, for every  $x \in D$ , also

- (i)  $N_S^+(\sigma(x)) \cap D = \emptyset$
- (ii)  $N_S^-(\sigma(y)) \cap D \subseteq D$  for some  $y \in V - D$ .

**Proof.** Let  $\sigma(x) \in D$ . If  $D$  is a MDS of  $G_D$ , then  $D - \{x\}$  is not a dominating set of  $G_D$ . Thus,  $\exists y \in V - [D - \{x\}]$  such that none of the elements in  $D - \{x\}$  dominate  $y$ .

Case 1. Let say  $y = x$ . In this case,  $N_S^+(x) \cap D = \emptyset$ , is that no element of  $D - \{x\}$  dominates  $x$ .

Case 2. Consider  $y \neq x$  Then,  $y \notin D$ . Because  $D$  is a smallest dominating set of  $G_D$ , hence it may be said that  $y$  is dominated by  $x \in D$ . consequently,  $N_S^-(y) \cap D = \{x\}$  for some  $y \in V - D$ .

On the other hand, suppose that  $D$  is dominating set and for each vertex  $x \in D$ , both conditions can hold in either case. Suppose  $D$  is not a MDS, then  $\exists$  a vertex  $x \in D$ ,  $D - \{x\}$  is a dominating set. Hence  $x$  is a strong neighbour to atleast one vertex in  $D - \{x\}$ , then condition (i) does not hold. If  $D - \{x\}$  is a dominating set then every vertex in  $V - D$  is a strong neighbour to atleast one vertex in  $D - \{x\}$ , then second condition does not hold which contradicts to our assumption that atleast any one of this condition holds. Hence  $D$  is a MDS.

**Domination Number of Some Unique Fuzzy Digraphs**

This segment presents the description of a few unique fuzzy digraphs  $G_D$ . Additionally, the overall results for the  $G_D$  domination number are provided.

**Definition 4.1:** An fuzzy dipath  $P_D$  is an series of strong arcs having the characteristic the beginning vertex of the subsequent arc in the series coincides with the end vertex of each arc.

**Remark 4.1:** Let  $P_D = (\sigma, \mu)$  be a fuzzy dipath  $P_n = (V, E)$  where  $n \geq 2$  is an integer. Then ,

- 1.  $\sigma_D = \{\sigma_D(x_i) : x_i \in V \forall i \in \{1, 2, \dots, n\}\}$ ;
  - 2.  $\mu_D = \{\mu_D(x_i, x_{i+1}) : (x_i, x_{i+1}) \in A \forall i \in \{1, 2, \dots, (n - 1)\}\}$ ;
  - 3. The vertices  $\sigma(x_1)$  and  $\sigma(x_n)$  belong to a nontrivial fuzzy dipath, and are its first and last vertex, respectively.
  - 4. If  $\sigma$  contains only two vertices then the path is trivial fuzzy dipath.
- $\gamma_{P_D}$  appears in the outcome that follows.

**Theorem 4.1:** Let  $P_D$  be a fuzzy dipath. Afterward, one of the subsequent conditions is met.

- 1.  $\gamma(P_D) = \sum_{k=1}^{\frac{n}{2}} \sigma(x_{2k-1})$ ;
  - 2.  $\gamma(P_D) = \min X$ , where
- $$X = \left\{ \sum_{k=1}^{\frac{n+1}{2}} \sigma(x_{2k-1}) + \sum_{k=\frac{n+3}{2}}^{n+1/2} \sigma(x_{2k-2}) : i \in \{0, 1, 2, \dots, (n - 1)/2\} \right\}.$$

**Proof.** Proof is obvious.

**Definition 4.2:** A fuzzy di cycle  $C_D$  is a dipath the point at which it has the identical vertex at both ends.

**Remark 4.2:** Let  $C_D = (\sigma, \mu)$  be a fuzzy dicycle  $C_n = (V, E)$ , where  $n \geq 3$ . Then,

- 1.  $\sigma = \{\sigma(x_i) : x_i \in V, \forall i \in \{1, 2, \dots, n\}\}$ ;
  - 2.  $\mu = \{\mu(x_i, x_{i+1}), \mu(x_n, x_1) : (x_i, x_{i+1}), (x_n, x_1) \in A, \forall i \in \{1, 2, \dots, (n - 1)\}\}$ ;
- $\gamma_{C_D}$  appears in the outcome that follows.

**Theorem 4.2:** Let  $C_D = (\sigma, \mu)$  be a fuzzy dicycle of a directed cycle  $C_n = (V, E)$  where  $n \geq 3$ . And hence one of the following requirements is satisfied:

- 1.  $\gamma(C_D) = \min \left\{ \sum_{k=1}^{\frac{n}{2}} \sigma(x_{2k-1}), \sum_{k=1}^{\frac{n}{2}} \sigma(x_{2k}) \right\}$ ;
- 2.  $\gamma(C_D) = \min(X \cup Y)$ , where

**Mohamed Ismayil and Syed Asad Ahmed**

$$X_{\lfloor \frac{n}{2} \rfloor} = \min \left\{ \begin{array}{l} \sigma(x_{i_1}) + \sigma(x_{i_2}) + \dots + \sigma(x_{i_{\lfloor \frac{n}{2} \rfloor}}), i_1 = 1, 2, 3, \dots, n - \left( \left\lfloor \frac{n}{2} \right\rfloor - 1 \right) \\ i_2 = 2, 3, \dots, n - \left( \left\lfloor \frac{n}{2} \right\rfloor - 2 \right) \\ i_3 = 3, 4, \dots, n - \left( \left\lfloor \frac{n}{2} \right\rfloor - 3 \right) \dots \\ i_{\lfloor \frac{n}{2} \rfloor} = \left\lfloor \frac{n}{2} \right\rfloor, \left\lfloor \frac{n}{2} \right\rfloor + 1, \dots, n \\ i_1 < i_2 < i_3, \dots < i_{\lfloor \frac{n}{2} \rfloor} \end{array} \right.$$

Hence  $\gamma(G_T)$  is a MDS of tournament fuzzy digraph  $\gamma(G_T) = X_i, i = 1, 2, 3, \dots, \lfloor \frac{n}{2} \rfloor$ .

**Observations 4.1:** For every complete fuzzy digraph  $G_D$ ,

1.  $\delta_d^+(G_D) < \gamma(G_D) \leq p(G_D) - \Delta_d^+(G_D)$
2.  $\sigma_0 \leq \gamma(P_\sigma) < \frac{p}{2} + 1$
3.  $\sigma_0 < \gamma(C_\sigma) < \frac{p}{2} + 1$

**Corollary 4.1:** For any fuzzy digraph  $G_D$  without isolated vertices,  $\gamma(G_D) \leq p(G_D)/2$ .

**Theorem 4.4:** Let  $G_D: (\sigma, \mu)$  be any fuzzy digraph and  $H_D: (\nu, \tau)$  be any fuzzy spanning digraph of  $G_D$ . Then  $\gamma_D(G_D) \leq \gamma_D(H_D)$ .

**Remark 4.3:** There is no relation between  $\gamma(G_D)$  and  $\Delta_d^+(G_D)$ .

**Example 4.1:**

In figure 5, the minimum domination number  $\gamma(G_D) = 1.1$  and maximum out-degree  $\Delta_D^+ = 1.2$ , then  $\Delta_D^+ \geq \gamma(G_D)$ . In figure 6, the minimum dominating number  $\gamma(G_D) = 1.0$  and maximum out-degree  $\Delta_D^+ = 0.9$  then  $\Delta_D^+ \leq \gamma(G_D)$ . Therefore there is no relation between  $\gamma(G_D)$  and  $\Delta_d^+(G_D)$ .

## CONCLUSION

The domination in fuzzy digraph and domination number of path, cycle and complete tournament digraph are obtained. Relations between strong degree and domination number are discussed.

### ABSTRACT

Medicine is one of the sciences where development of computer science enables a lot of improvements. Usage of computers in medicine increases the accuracy and speeds up processes of data analysis and setting the diagnoses. Nowadays, numerous computers aided diagnostic systems exist and machine learning algorithms have significant role in them. Faster and more accurate systems are necessary. Common machine learning task that is part of computer aided diagnostic systems and different medical data analytic software packages is classification. In order to obtain better classification accuracy, it is important to choose feature set and proper parameters for the classification model. Medical datasets often have large feature sets where many features are in correlation with others thus it is important to reduce the feature set. Most classifiers are designed so as to learn from the data itself using a training process, because complete expert knowledge to determine classifier parameters is impracticable. In this paper, in order to improve the accuracy of the classifier with proposed Feature Selection method. The proposed feature selection is used to select the most relevant features by removing the irrelevant and redundant features by means maximizing the feature-class relevancy. Differential evolution optimization is used to find the optimal subset obtained by the above feature-class relevancy methods. The performance of the proposed feature selection is evaluated with classifiers like Random Forest Classifier, Gradient Boosting Tree, Artificial Neural Network and Support Vector Machine.

## INTRODUCTION

Progress in computer science and technology development enables improvement in numerous fields and one of them is medicine. In medicine fast and accurate diagnosis can save a patient's life so it is crucial to have good computer aided diagnostic systems (CAD) that can help physicians. Usually, the most essential part of CAD systems is classification [1]. Classification is one of the machine learning tasks while machine learning algorithms are used to gather some knowledge from the set of given data, search for certain patterns and after that make their own decisions based on the learned facts. Nowadays, machine learning algorithms are widespread and studied since they are used in various fields such as medicine, bioinformatic, economy, agriculture, robotic, etc. Classification is a supervised learning task where the output is categorical, the class where certain instance belongs. Supervised learning is a process where the goal is to generate a decision model that will correctly classify unknown instances based on a model build on the training set where the classes of instances are known. Decision model search for patterns in training set data that will enable the classification of new unknown instances [2][3]. The classification of medical datasets is a challenging problem since it usually contains a lot of features and instances. Search for more accurate and faster classification methods in CAD systems is lead by the importance of early and precise diagnose for patient recovery. Each instance used in a classification task is represented by several features that can be numerical or categorical. The classification accuracy, besides classification method, highly depends on the chosen feature set which should enable to classification method to separate instances from different classes and to find similarities of instances that are in the same class. It is hard to determine which features will describe an instance in this way so the usual strategy while collecting data is to describe instances with as much as possible features and then decide which are important. Too many features can lead to the problem where the impact of the main differences and similarities in the decision model decrease since it will try to include all possible information [4]. This is why the feature selection problem attracts scientists and why it becomes one of the research topics. The goal of the feature selection methods is to determine the minimal subset of feature that provides the best classification. The feature selection problem is an exponential problem. For a set with the  $n$  features there are  $2^n$  subsets which means that exhaustive search is not possible (in reasonable time) even for rather small values of  $n$ . For solving problems like this, metaheuristics such as swarm intelligence and optimization algorithms can be used.

## IMPORTANCE OF FEATURE SELECTION

The accuracy of the classifier depends not only on the classification algorithm but also on the feature selection method used. Selection of irrelevant and inappropriate features may confuse the classifier and lead to incorrect results. The solution to this problem is Feature Selection i.e. feature selection is necessary in order to improve efficiency and accuracy of classifier. Feature selection selects subset of features from original set of features by removing the irrelevant and redundant features from the original dataset. It is also known as Attribute selection. Feature selection [5] reduces the dimensionality of the dataset, increases the learning accuracy and improves result comprehensibility. The two search algorithms 'forward selection' and 'backward Eliminations' are used to select and eliminate the appropriate feature. Feature selection is a three-step process namely search, evaluate and stop. Feature selection methods [6] are also classified as attribute evaluation algorithms and subset evaluation algorithms. In first method, features are ranked individually and then a weight is assigned to each feature according to each feature's degree of relevance to the target feature. The second approach in contrast, selects feature subsets and then ranks them based on certain evaluation criteria. Attribute evaluation methods do not measure correlation between feature are hence likely to yield subsets with redundant features. Subset evaluation methods are more efficient in removing redundant features. Different types of feature selection algorithms have been proposed. The feature selection techniques are broadly categorized into three types: Filter methods, Wrapper methods, and Embedded methods. Every feature selection algorithm uses any one of the three feature selection techniques. In this paper, we propose the optimal feature selection algorithm based on Differential Evolution and filter-based feature selection techniques for solving the feature selection problem in classification of medical datasets.

**Shanti and Karthick Babu****RELATED WORKS**

De Silva, Kushan, Daniel Jönsson, and Ryan T. Demmer [7] This work demonstrated the value of combining feature selection with machine learning to identify a wide range of predictors that could enhance prediabetes prediction and clinical decision-making. Feature selection algorithms were run on training data containing 156 preselected exposure variables. Four machine learning algorithms were applied on 46 exposure variables in original and resampled training datasets built using 4 resampling methods. Christo, VR Elgin, et al [8] m. In this work, both Feature and Instance selection are done using the wrapper approach, which uses co-operative co-evolution and random forest classifier. The reduced dataset is used to train a random forest classifier and this trained model helped in making clinical decisions. These decisions assist physicians as the second opinion for diagnosis and treatment. Wisconsin Diagnostic Breast Cancer (WDBC), Hepatitis, Pima Indian Diabetes (PID), Cleveland Heart Disease (CHD), Statlog Heart Disease (SHD), Vertebral Column, and Hepatocellular Carcinoma (HCC) datasets from the University of California Irvine (UCI) Machine Learning repository are used for experimentation. Gandhi, Kriti, et al [9] implemented functions of machine learning in health facilities in a particular system. Instead of directly performing treatment for the patient, if the disease is predicted beforehand using certain machine learning algorithms then the entire process of treatment can be made much more efficient. There are also some cases which occur when early diagnosis of a disease is not performed or carried out. de Lima, Márcio Dias, Juliana de Oliveira Roque e Lima, and Rommel M. Barbosa [10] aimed to present a new feature selection algorithm. In order to validate our study, we used eight benchmark data sets which are commonly used among researchers who developed machine learning methods for medical data classification. The experiment has shown that the performance of our proposed new feature selection method combined with twin-bounded support vector machine (FSTBSVM) is very efficient. Sahebi, Golnaz, et al [11] proposed a generalized wrapper-based feature selection, called GeFeS, which is based on a parallel new intelligent genetic algorithm (GA). The proposed GeFeS works properly under different numerical dataset dimensions and sizes, carefully tries to avoid overfitting and significantly enhances classification accuracy. To make the GA more accurate, robust and intelligent, proposed a new operator for features weighting, improved the mutation and crossover operators, and integrated nested cross-validation into the GA process to properly validate the learning model. The k-nearest neighbor (kNN) classifier is utilized to evaluate the goodness of selected features.

Muthulakshmi, I [12] presented an optimal feature selection based classification model for CKD. For feature selection purposes, particle swarm optimization (PSO) is employed and ant colony optimization (ACO) algorithm is used for the classification of medical data. A benchmark CKD is used to test the proposed model under several measures. Jain, Divya, and Vijendra Singh [13] In this research, a fast, novel adaptive classification system is presented for the diagnosis of chronic diseases. For this purpose, the proposed approach employs a hybrid approach comprising of PCA and ReliefF method with optimized Support Vector Machine classifier. To attain high classification accuracy, comprehensibility, and consistency, efficient parameter optimization approach is applied for the SVM classifier.

Xie, Jingui, et al. [14] This study focused on selecting critical features of demographic information, personal medical history and symptoms and improving the accuracy of syndrome classification. Feature selection methods and classification techniques were applied to mine data on TCM syndromes. Feature selection improved the performance of the classification models. Mezzatesta, Sabrina, et al. [15] Patients with End- Stage Kidney Disease (ESKD) have a unique cardiovascular risk. This study aimed at predicting, with a certain precision, death and cardiovascular diseases in dialysis patients. In particular, the authors obtained the best performances using the non-linear SVC with RBF kernel algorithm, optimizing it with GridSearch. The last is an algorithm useful to search the best combination of hyper-parameters (in the case, to find the best couple, in order to improve the accuracy of the algorithm. Álvarez, Josefa Díaz, et al [16] applied five feature selection algorithms to identify the set of relevant features from 18F-fluorodeoxyglucose positron emission tomography images of the main areas affected by PPA from patient records. On the other hand, we carried out classification and clustering algorithms before and after the feature selection process to contrast both results with those obtained in a previous work. We aimed to find the best classifier and the more relevant features from the WEKA tool to propose further a framework for automatic help on diagnosis.

### Shanti and Karthick Babu

Toğaçar, M., et al [17] used lung X-ray images that are available for the diagnosis of pneumonia. The convolutional neural network was employed as feature extractor, and some of existing convolutional neural network models that are AlexNet, VGG-16 and VGG-19 were utilized so as to realize this specific task. Then, the number of deep features was reduced from 1000 to 100 by using the minimum redundancy maximum relevance algorithm for each deep model. Cömert, Zafer, et al [18] In this paper, three filters and two wrappers feature selection methods and machine learning models, which are artificial neural network (ANN), k-nearest neighbor (kNN), decision tree (DT), and support vector machine (SVM), are evaluated on a high dimensional feature set obtained from an open-access CTU-UHB intrapartum CTG database. Raihan-Al-Masud, Md, and M. Rubaiyat Hossain Mondal [19] focused on the application of machine learning algorithms for predicting spinal abnormalities. As a data preprocessing step, univariate feature selection as a filter-based feature selection, and principal component analysis (PCA) as a feature extraction algorithm are considered. A number of machine learning approaches namely support vector machine (SVM), logistic regression (LR), bagging ensemble methods are considered for the diagnosis of spinal abnormality. Özyurt, Fatih [20] White blood cell (WBC) test is used to diagnose many diseases, particularly infections, ranging from allergies to leukemia. A physician needs clinical experience to detect and classify the amount of WBCs in human blood. WBCs are divided into four subclasses: eosinophils, lymphocytes, monocytes, and neutrophils. In the present study, pre-trained architectures, namely AlexNet, VGG-16, GoogleNet, and ResNet, were used as feature extractors. The features obtained from the last fully connected layers of these architectures were combined. Efficient features were selected using the minimum redundancy maximum relevance method. Finally, unlike classical convolutional neural network (CNN) architectures, the extreme learning Machine (ELM) classifier was used in the classification stage thanks to the efficient features obtained from CNN architectures. Li, Jian Ping, et al [21] proposed an efficient and accurate system to diagnosis heart disease and the system is based on machine learning techniques. The system is developed based on classification algorithms includes Support vector machine, Logistic regression, Artificial neural network, K-nearest neighbor, Naïve bays, and Decision tree while standard features selection algorithms have been used such as Relief, Minimal redundancy maximal relevance, Least absolute shrinkage selection operator and Local learning for removing irrelevant and redundant features.

#### PROPOSED OPTIMAL FEATURE SELECTION TECHNIQUE FOR MEDICAL DATASETS

In this proposed technique, the detailed description of the filter-based feature selection techniques and DF optimization algorithm are given. In this proposed approach, the best and worst solution are obtained by converting the real code into binary values string to speed up the process, for reducing the computation time.

##### Gain Ratio Feature Selection

The Gain Ratio [22] is the non-symmetrical measure that is presented to pay back on the bias of the Information Gain (IG). GR is given by Equation (1):

$$GR = \frac{\text{Information Gain}(IG)}{H(X)} \quad (1)$$

Information Gain (IG) is a symmetrical measure.

$$IG = H(Y) - H(Y|X) = H(X) - H(X|Y) \quad (2)$$

The information gained about Y after observing X is alike to the information gained about X after observing Y in the Equation (2). There, a weakness of the IG criterion is that it is biased in favor of features with more values even when they are not more informative. As in the above Equation (2) presents, when the variable Y has to be predicted, then regularize the IG by distributing the entropy of X, and vice versa. Owing to this normalization, the GR values constantly fall in the range [0, 1]. A value of GR = 1 specifies that the knowledge of X totally forecasts Y, and GR = 0 means that there is no relation between Y and X. In opposition to IG, the GR favor variables with lesser values.

##### Differential Evolution Optimization

Differential evolution (DE) is merely one of several approaches through evolutionary algorithm where in actuality the features are search and centred on ant colony. An easy and yet effective, DE give you the benefits usually requires like many optimization methods[23][24]. There are several actions from DE such; 1) ability to handle non-differentiable, nonlinear and value this is certainly multimodal, 2) parallelizability to cope with computation cost that

### Shanti and Karthick Babu

is intensive, 3) simplicity of good use, 4) good convergence properties. Like GA, DE employ factors which can be same of mutation, selection and crossover. The efficiency of DE depends on the handling of target vector and difference in order to acquire a task vector in exploring procedure. Every real-value this is certainly d-Dimensional, a population of NP members is provided. NP will be the population size and D will be the true range that is wide of to be fine-tuned. Among the members of two population like  $y_{s2}$  and  $y_{s3}$  added the vector of weight difference to the  $y_{s1}$  which is third member for creating a trial vector. This action is termed as mutation. A mutant vector is generating relating to for every target vector  $y_{(i,G)}, j = 1, 2, 3, \dots, M$  a mutant vector using the given equation:

$$w_{j,G+1} = y_{s1,H} + G(y_{s2,H} - y_{s2,H}) \quad (2)$$

Where  $s_1, s_2, s_3 \in \{1, 2, \dots, NP\}$  are integers that are chosen randomly, should be specific from 1 another plus unique through the operating index j. The control rate of Scaling factor F(0,1) that your particular population comprises. In order to improve the variety in connection with perturbed factor vectors, introduction of crossover is takes place. The trial vector:

$$v_{j,H+1} = (v_{1,j,H+1}, v_{2,j,H+1}, \dots, v_{E,j,H+1}) \quad (3)$$

Is from where;

$$v_{kj,H+1} = \begin{cases} w_{kj,H+1} & \text{if } \text{rand}(0,1) \leq d_s \\ y_{kj,H+1} & \text{otherwise} \end{cases} \quad (4)$$

Where the H is the current population and the trial vector  $k^{\text{th}}$  for the dimension of  $v_{(kj,H)}$ . The probability of crossover  $d_s(0,1)$  is a person described value that operates the portion in connection with parameter values which are often and that can be replicated through the mutant. Selection will be the stage to get the vector among the target vector as well as trial vector making use of the aim of generating an individual in terms of generation this is certainly next. Then your causing vector substitutes the vector with which it absolutely was compared [25] if the recently created vector leads to a lower objective function value (better fitness) as compared to population member that is predetermined. But, many factors from DE are instantly transformative without needed user to see by learning from your own error's strategy. In this work that is ongoing size of generation and population are adaptively identifying predicated on a total of features remained from relief-f. Hence, the buyer doesn't always have to initialize those factor values manually.

### Proposed Optimal Feature Selection Method

In this proposed OFS method, instead of using Crossover and Mutation operator of DF optimization, encoding of solution (converting real code to binary string) is introduced to consume the computation time for medical datasets during the classification of diseases. The following are stages involved in this proposed OFS method is given below:

#### Stage 1: Encoding of Solution

In this work, every individual solution in the population is represented as a binary string. The length of every individual solution (binary string) is equal to the number of distinct features available in the medical datasets. The binary code 1 of the solution represents the selection of features and binary code 0 of the solution represents the feature that was not selected. The solution  $S = [F_1, F_2, F_3, \dots, F_m]$  where m is the number of distinct features in datasets. Every position of the solution is binary values,  $F_q \in \{0,1\}$ ; For example, a solution defined as [1, 1, 0, 0, 1, 1, 0, 0, 0, 1] specifies that the features with index 1, 2, 5, 6 and 10 are selected while the others are not selected. The  $p^{\text{th}}$  solution of generation i is represented as  $S_p^{(i)}$ , and the  $q^{\text{th}}$  position of  $p^{\text{th}}$  solution of generation t is represented  $S_{p,q}^{(i)}$ .

#### Stage 2: Initial population

Set the initial population size of this work as 50. Randomly, we generate 50 solutions with random real values between 0 and 1. After this, the digitization process is applied to each position of individual solution for converting real values to binary values based on below equation:

$$S_{p,q}^{(i)} = \begin{cases} 1 & S_{p,q}^{(i)} > \text{rand} \\ 0 & \text{Otherwise} \end{cases}$$

Here rand is a uniformly distributed random number between 0 and 1.

### Shanti and Karthick Babu

#### Stage 3: Fitness function

Fitness function plays a vital role in the optimization problems. A fitness function computes a single positive integer to represent how good the solution is. The fitness of each individual solution in the population is calculated with the help of classifier error rate, which is formulated in below equations:

$$fitness(S_p^{(i)}) = ClassifierErrorRate(S_p^{(i)})$$

The classifier error rate (solution) is the testing error rate:

$$ClassifierErrorRate(S_p^{(i)}) = \frac{Number\ of\ misclassified\ records}{Total\ number\ of\ records} \times 100$$

#### Stage 4: Finding new solutions

The best and worst solutions in the generation  $t$  are used to generate the new solution. The best solution has the lowest fitness score (error rate) and worst solution has the highest fitness score (error rate) in the generation  $i$ . The best solution of iteration  $t$  is represented as  $S_{bt}^{(i)}$  and the worst solution of iteration ' $i$ ' is represented as  $S_{wt}^{(i)}$ . Considering the best and worst solutions of generation ' $i$ ', the  $q^{th}$  position of old solution  $S_{p,q}^{(i)}$  as formulated by the below equation:

$$S_{p,q}^{(i)} = S_{p,q}^{(i)} + A |S_{bt,q}^{(i)} - S_{p,q}^{(i)}| + B |S_{wt,q}^{(i)} - S_{p,q}^{(i)}|$$

Where  $A, B$  are two random numbers between 0 and 1. After this, the digitization process is applied to each position of new candidate solution at generation ' $i+1$ ' for converting real values to binary values based on the below equation:

$$S_{p,q}^{(i)} = \begin{cases} 1, & S_{p,q}^{(i+1)} > rand \\ 0, & \text{Otherwise} \end{cases}$$

Here  $rand$  is a uniformly distributed random number between 0 and 1.

#### Stage 5: Termination criteria

The proposed work is an iterative process. The termination criteria of the iterative process can be decided by the following factors:

- maximum number of iterations/generations ( $T_{max}$ )
- convergence rate of fitness score and
- maximum running time limit of iterative process. In this proposed work, the maximum number of iterations ( $T_{max}$ ) is used as the termination criterion.

#### Step by Step procedure for Proposed Optimal Feature Selection Method

Input: Medical Datasets (MD)

Output: Optimal Feature Subset (selected best features)

Step 1: Splitting of the Dataset into Training and Test ( $MD = MD_{tr} + MD_{ts}$ )

Step 2: Applying  $T = GR \leftarrow MD$

Step 3:  $m_f = |T|$

Step 4: Constructing Initial Population Table

Step 4.1: for each solution  $S_p, p=1$  to  $M$  do

Step 4.1.1: for each position  $q$  of solution  $S_p; q=1$  to  $m_f$  do

Step 4.1.2:  $S_{p,q} = rand(0,1)$

Step 4.1.3:  $S_{p,q} = Digitization(S_{p,q})$

Step 4.1.4: end

Step 4.2:  $S_p^{fitness} = computeFitness(S_p, C, f, MD_{tr}, MD_{ts})$

Step 4.3: end

Step 5:  $S_{bt} = findBestSolution()$

Step 6:  $S_{wt} = findWorstSolution()$

Step 7: Iterative Process

Step 7.1: for each iteration  $i=1$  to  $T_{max}$  do

### Shanti and Karthick Babu

Step 7.1.1: for each position  $q$  of solution  $S_p$   $p = 1$  to  $M$  do  
 Step 7.1.1.1: for each position  $q$  of solution  $S_p$ ;  $q = 1$  to  $m_f$  do  
 Step 7.1.1.2:  $A = rand(0,1)$ ;  $B = rand(0,1)$   
 Step 7.1.1.3:  $F_{p,q} = S_{p,q}^{(i)} + A |S_{bt,q}^{(i)} - S_{p,q}^{(i)}| + B |S_{wt,q}^{(i)} - S_{p,q}^{(i)}|$   
 Step 7.1.1.4:  $F_{p,q} = Digitization(F_{p,q})$   
 Step 7.1.1.5: end  
 Step 7.1.2:  $F_p^{fitness} = computeFitness(F_p, C, f, MD_{tr}, MD_{ts})$   
 Step 7.1.3: if  $F_p^{fitness} < S_p^{fitness}$  then  
 Step 7.1.3.1:  $S_p = F_p$   
 Step 7.1.4: end  
 Step 7.2: end  
 Step 7.3:  $S_{bt} = findBestSolution()$   
 Step 7.4:  $S_{wt} = findWorstSolution()$   
 Step 8: end  
 Step 9: Extracting the best optimal feature subset from the  $\Psi_{best}$   
 Step 10: for each position  $j$  of solution  $S_{bt}$   $j=1$  to  $m_f$  do  
 Step 10.1: if is Position Selected( $S_{bt,q}$ ) then  
 Step 10.1.1:  $OF_{bt} = OF_{bt} \cup T[q]$   
 Step 10.2: end  
 Step 11: end  
 Return  $OF_{bt}$

## RESULT AND DISCUSSION

The medical datasets like Heart Disease [26], Chronic Kidney Disease [27], and Hepatitis [28] are considered from the public UCI and Kaggle Repositories. The performance metrics like Accuracy (in %), and True Positive Rate (in %) are considered in this research work.

### Description of the Datasets

Table 1 depicts the number of features in the given Heart Disease, Kidney Disease and Hepatitis datasets.

### Number of Features obtained

Table 2 depicts the number of features obtained by Gain Ratio, Information Gain, Differential Evolution, Genetic Algorithm. From the table 2, it is clear that the proposed Optimal Feature Selection method generates least number of features than other existing feature selection techniques.

### Classification Accuracy (in %)

The performance analysis of the feature selection techniques like GR, IG, DE, GA, and Proposed OFSM are analysis with the classifiers like Random Forest, Gradient Boosting Tree, Artificial Neural Network and Support Vector Machine. Table 3 gives the Accuracy (in %) for the Heart disease (HD) dataset obtained by the various classifiers like RF, GBT, ANN, and SVM with Original dataset, GR, IG, DE, GA and Proposed OFSM. From the table 3, it is clear that the original HD dataset, GR processed HD dataset, DE processed HD dataset and proposed OFSM processed HD dataset with SVM classifiers gives increased accuracy than the other feature selection techniques with other classifiers. Table 4 gives the Accuracy (in %) for the Chronic Kidney disease dataset obtained by the various classifiers like RF, GBT, ANN, and SVM with Original dataset, GR, IG, DE, GA and Proposed OFSM. From the table 4, it is clear that the Original CKD dataset, GR, IG, DE, and GA processed CKD dataset with SVM classifiers gives improved accuracy than the other classifiers. Table 5 gives the Accuracy (in %) for the Hepatitis disease dataset obtained by the various classifiers like RF, GBT, ANN, and SVM with Original dataset, GR, IG, DE, GA and Proposed

### Shanti and Karthick Babu

OFSM. From the table 5, it is clear that the Original HP dataset, GR processed HP, DE Processed HP dataset and Proposed OFSM processed HP dataset with ANN gives improved accuracy, and IG processed HP, and GA processed HP dataset gives increased accuracy with RF classifier when it is compared with other classifiers. **True Positive Rate (in %)** Table 6 gives the True Positive Rate (in %) for the Heart disease (HD) dataset obtained by the various classifiers like RF, GBT, ANN, and SVM with Original dataset, GR, IG, DE, GA and Proposed OFSM. From the table 6, it is clear that the original HD dataset, GR, IG, GA, DE, and Proposed OFSM processed HD dataset with SVM classifiers gives more TPR rate than the other classifiers. Table 7 gives the True Positive Rate (in %) for the Chronic Kidney Disease (CKD) dataset obtained by the various classifiers like RF, GBT, ANN, and SVM with Original dataset, GR, IG, DE, GA and Proposed OFSM. From the table 7, it is clear that the original CKD dataset, GR, DE, and Proposed OFSM processed CKD dataset with SVM classifiers gives more TPR rate than the other classifiers. Table 8 gives the True Positive Rate (in %) for the Hepatitis Disease (HP) dataset obtained by the various classifiers like RF, GBT, ANN, and SVM with Original dataset, GR, IG, DE, GA and Proposed OFSM. From the table 8, it is clear that the original CKD dataset, GR, DE, GA and Proposed OFSM processed CKD dataset with ANN classifiers gives more TPR rate than the other classifiers.

## CONCLUSION

In medical diagnosis, it is very important to identify most significant risk factors related to disease. Relevant feature identification helps in the removal of unnecessary, redundant attributes from the disease dataset which, in turn, gives quick and better results. In this research work, an optimization-based feature selection with Filter approach is proposed to enhance the classification accuracy of the disease diagnosis. The combination of GR filter-based feature selection with DE optimization to find the most relevant features for the disease detection for various medical datasets like Heart Disease, Chronic Kidney Disease, and Hepatitis disease. From the result obtained, it is clear that the proposed OFSM with SVM classifiers performs better for HD dataset and CKD dataset, whereas proposed OFSM with ANN gives better result for Hepatitis dataset.

### ABSTRACT

Because of its scalable and dynamic features, cloud computing has gotten a lot of attention from the research community and IT management. Cloud computing allows businesses to outsource their IT infrastructure by providing on-demand access to a shared pool of computing resources. Cloud providers are constructing data centres to meet the ever-increasing demands of cloud consumers. As a result, these cloud data centres use a lot of energy and have the potential to squander a lot of it. Consolidation of Virtual Machines (VMs) aids in resource optimization and, as a result, lowers energy consumption in a cloud data centre. When it comes to VM consolidation, VM placement is crucial. A new revolution for providing pay-as-you-go virtual resources is cloud computing. When users' work needs are received, they are mapped to virtual resources operating on datacenter hosts. It is necessary to detect overloaded hosts in order to achieve workload consolidation. In order to avoid Service Level Agreement (SLA) violations, overloaded host detection is done for workload balancing, creating a list of overloaded hosts that will be helpful when placing virtual machines (VMs). By omitting the overloaded hosts when checking the under loaded host, computational costs are reduced. An optimization-based Host Detection methodology is proposed in this research study to analyse the host based on CPU, Bandwidth, and RAM utilizations in order to find overloaded and under loaded hosts.

**Keywords:** Cloud Computing, Virtual Machine, Host Detection, Overload, Underload, Energy Consumption, Service Level Agreement

**Devipriya et al.,**

## INTRODUCTION

A cutting-edge computer architecture called cloud computing enables users to pay-as-you-go rent resources over the Internet. Thus, service providers who do not wish to spend on infrastructure can just license resources from infrastructure providers and pay only for what they consume. A new generation of ecological and energy-efficient ICT may be built on the foundation of cloud technology, in addition to its great economic impact [1] [2]. By enabling the use of fewer physical servers with significantly higher per-server utilisation, virtualization technology in cloud data centres, on either hand, significantly reduces energy consumption. However, it also creates new management issues since a large pool of virtual machines should be managed and provisioned [3]. In reality, in a cloud computing context, energy efficient resource management means assigning a manner that dynamically allocates physical resources to virtualized resources which reduces data centre energy usage while maintaining SLA-based service quality. As a result, experts in this field have been working to create a management system that is effective and optimal and can satisfy these needs. A management solution that maximises energy efficiency in a cloud data centre by using dynamic VM consolidation as a technique of dynamic control [4] [5] [18] [19]. In general, the difficulty of dynamic VM consolidation can be broken down into four sub-problems. When a host is overloaded, live migration of one or more virtual machines from the overloaded host is necessary (host overloading detection); when a host is underloaded, all virtual machines must migrate from it before the host enters sleep mode (host under-loading detection) [20] [21]. (3) selecting the VMs to migrate from an overloaded host (VM selection); and (4) selecting the hosts to receive the migrated VMs (VM placement) [22] [23].

## RELATED WORKS

Mc Donnell, Nicola, Enda Howley, and Jim Duggan [6] A brand-new multi-agent framework called "Gossip Contracts" (GC) was put forth for the development of decentralised cooperation methods. GC was impacted by the Contract Net and Gossip technologies. The authors proposed a GC-based Dynamic Virtual Machine Consolidation (DVMC) method and contrasted it with two well-known methods that also use GC: eco Cloud, a distributed method, and Sercon, a centralised method. Yadav, Rahul, et al [7] VM selection from overloaded hosts is proposed using suggested adaptive heuristic techniques, such as least-medium-square regression and minimal utilisation prediction. These heuristic algorithms lower CDC energy consumption while requiring the least amount of SLA. The suggested VM selection strategy, in contrast to earlier methods, considers the types of running apps and their CPU usage at various points in time across the VMs. Ding, Weichao, et al [8] The framework that is being proposed involves four stages: residual available computing capacity for the host overload detection ; selection of suitable VMs for migration from overloaded hosts based on the required data transfer; host underload diagnosis on multi-criteria Z-score strategy; and allocation of the VMs chosen for migration from underloaded and overloaded hosts on a multi-criteria Z-score strategy. Xiao, Hui, Zhigang Hu, and Keqin Li [9] A new multi-objective VM consolidation strategy was developed based on various thresholds and an Ant Colony System (ACS). The suggested methodology determines the host load status using two CPU usage criteria; VM consolidation happens when the host is overloaded or underloaded. Consolidation uses ACS to select migrating VMs and destination hosts simultaneously, using various selection methods based on the host load status. Aslam, Anjum Mohd, and Mala Kalra [10] presented a VM selection method based on Artificial Neural Networks (ANN). It employed a back propagation learning strategy to train a feed forward neural network to choose a VM from an overloaded host. By learning from the training dataset, it optimises the VM selection problem and enhances the performance of the selection method. Hsieh, Sun-Yuan, et al [11] The suggested VM consolidation methodology assessed the current and planned resource utilisation through host overload (UP-POD) and host underload detection (UP-PUD). To accurately predict future resource use, a Gray-Markov-based model is employed. Li, Lianpeng, et al [12] based on the suggested Robust Simple Linear Regression prediction model, a Host Underloading / Overloading Detection algorithm and a novel VM placement process for SLA aware and energy-efficient consolidation of virtual machines in cloud data centres. Contrary to native linear regression, the proposed approaches modify the prediction and skew toward over-prediction by factoring in the error in the forecast Li, Zhihua, et al [13] A mixed optimization model for VM placement was created in order to determine

Devipriya et al.,

the best mapping between VMs and PMs in the search space. The optimization model is solved using an improved heuristic evolutionary method, resulting in the best VM placement scheme that is globally optimal. In order to consolidate virtual machines, the authors' Energy Efficient- Quality Aware Virtual Machine Consolidation (EQ-VMC) technique combines separate sub-algorithms for host overloading detection, VM selection, and under-loaded host detection. Moghaddam, Seyedhamid Mashhadi, et al [14] The best time to begin host migrations was predicted using various fine-tuned Machine Learning (ML) prediction models for particular VMs. Lexicographically assess migration time and host CPU usage before choosing which VMs to transfer in the second stage. Finally, a unique strategy based on the Best Fit Decreasing (BFD) algorithm was developed to select a destination host for the VMs being migrated.

## OPTIMIZED GRADIENT BOOSTING MACHINE CLASSIFIER BASED HOST DETECTION METHOD

### Artificial Bee Colony Optimization

The artificial bee colony algorithm is a population-based optimization method based on bee intelligence, which is divided into two types: foraging and reproduction (mating) behaviour [15]. Artificial bees scour the search space for viable ideas in a fair amount of time. In the subject of work scheduling, foraging behaviour is the most commonly utilised method. Employed bees are in charge of assigning jobs to resources and communicating with onlooker bees about food sources; onlooker bees are in charge of calculating fitness so that it may be used for further management of the entire assignment process; Bee scouts hunt for fresh search engines [16]. All bees go through a ruthless selection process. The bees remember the new position if the new amount of nectar is more than the old; otherwise, they recall the previous one. The procedure typically comes to an end at the maximum cycle number is reached.

### Gradient Boosting Decision Tree (GBDT)

In order to create a regression or classification model, gradient boosting, a potent ensemble machine learning method for regression and classification issues, combines a number of weak prediction models, often decision trees. According to gradient boosting, the GBDT algorithm extends and improves the classification and regression tree model. As opposed to the random forest algorithm, the GBDT learning process incrementally fits new models to produce a more precise assessment of the response variables. Decision trees are built iteratively by the GBDT algorithm. A decision tree is trained from the residuals of the preceding tree in each iteration. The output is provided by the accumulation of the classified results from each tree. Assume there are  $N$  training examples  $\{\{x_i, y_i\}\}_{i=1}^N$ , with the labels  $x_i$  and  $y_i$ , where  $x_i$  is a sample and  $y_i$  is the label for sample  $x_i$ . Let  $L(y, F(x))$  be a loss function and  $F(x)$  be a linear combination of distinct decision trees. For any sample  $x_i$ ,  $L(y_i, F(x_i))$  is the difference between  $F(x_i)$  and  $y_i$ , and  $F(x_i)$  is the classification (the  $i$ -th decision tree) of  $x_i$ . The objective of GBDT is to discover an ideal model  $F(x)$  such that  $L(y, F(x))$  is reduced for a given loss function, where  $i=1$ . To do this, the GBDT algorithm first creates an initial decision tree  $F_0(x)$ , after which  $m$  more trees are created repeatedly. The residuals, which are produced by the provided loss function  $L(y, F(x))$ , are reduced in each iteration by the addition of a new tree,  $h(x)$ . As a result, the following formula can be used to get the ideal model  $F^*(x)$  of GBDT:

$$F^*(x) = F_0(x) + v \sum_{t=1}^m \rho_t * h_t(x)$$

Where  $m$  is the number of iterations,  $v \{0 < v < 1\}$  is the shrinkage parameter controlling the GBDT's learning rate,  $h_t(x)$  stands for the tree trained in the  $t$ -th iteration, and  $\rho_t$  is the weight of  $h_t(x)$ . The following equation's negative gradients stand for the discrepancy between actual value and predicted value:

$$y'_i = - \left[ \frac{\partial L(y_i, F(x_i))}{\partial F(x_i)} \right] F(x) = F_{t-1}(x)$$

At each iteration in GBDT, the loss function is used to obtain residuals. The following step involves building a new decision tree called  $h_t(x)$  in accordance with the following:

$$\{\{x_i, y'_i\}\}_{i=1}^n$$

The following equations calculate the weight of this tree and update the identification model:

**Devipriya et al.,**

$$\rho_t = \arg \min_p \sum_{i=1}^n L(y_i, F_{t-1}(x) + p * h_t(x))$$

$$F_t(x) = F_{t-1}(x) + v * \rho_t * h_t(x)$$

The 0-1 loss function is used in the GBDT algorithm and is defined as follows:

$$L(y, F(x)) = \begin{cases} 1, & y \neq F(x) \\ 0, & y = F(x) \end{cases}$$

Only a few of the input variables often have a significant impact on the output of the model, and they are rarely equally relevant for the prediction performance.

### Proposed Optimized Gradient Boosting Classifier (OGBC) based Host Detection Method

Gradient Boosting Decision Tree is used in this proposed Host Detection method. VM placement plays an important part in the consolidation of the VMs. Users' job requirements are received and then mapped onto virtual resources operating on datacenter hosts. It is necessary to find the overloaded hosts in order to achieve workload consolidation. The goal of overloaded host detection is to balance workload. It involves compiling a list of overloaded hosts that will be useful when placing virtual machines (VMs) in order to avoid violating service level agreements (SLAs) and omitting overloaded hosts from consideration when determining whether a host is underloaded in order to save on computational costs. In this contribution, an optimization-based Host Detection technique is proposed to analyze the host based on the CPU, Bandwidth and RAM utilizations for detecting the overloaded and underloaded host. Artificial Bee Colony Optimization algorithm is used to update the negative gradients of the Gradient Boosting Decision Tree (GBDT) for classification of Host and it uses the power, CPU and Memory threshold for underloading and overloading host. In this proposed Optimization based Host Detection technique, a direction of the negative gradient in the GBDT is updated with respect to potential time, whenever the utilization of the power, CPU, Memory of the Hosts are greater than the prescribed threshold, then that tree will send to the overloaded state. If the utilization of the Power, CPU, and memory are less than the prescribed threshold then the hosts are underloaded. If it is equal, the host is normal for processing. To calculate the thresholds, then the Energy Consumed of the nodes during the particular time. So, the total energy consumption is the summation of each node energy consumed with the total number of nodes.

**Input:** Number of VMs and Hosts

**Output:** Host Classification (Underload or Overload)

**Step 1:** Calculation of host CPU and memory usage based on the number of VMs on the node and the number of jobs allocated to the VMs.

**Step 2:** The Hosts' power calculations are based on CPU and memory use. With a minimum and maximum power usage, the power consumption is normalized using the ABC technique.

**Step 3:** The power consumption of the node during the units of time divided by the energy consumption of the given host.

**Step 4:** Establishment of an Artificial Bee Colony Optimization for host categorization.

**Step 4.1:** Create a population of solutions that are generated at random by scout bees.

**Step 4.2:** Using the default function, assess the current population.

**Step 4.3:** Begin training the Gradient Boosting Decision Tree (GBDT) model, CART is preferred as a simple classifier with objective and loss function as softmax.

**Step 4.4:** The food position in the total population is randomly distributed during the training phase, as the fitness is randomly divided among decision trees.

**Step 4.5:** Evaluate the population's fitness function.

**Step 4.6:** Calculate the new solution using the onlooker bees, and assess the new source's suitability.

**Step 4.7:** Begin the ruthless selection process.

**Step 4.8:** Calculate the solution's probability value and normalize it into the interval.

**Step 4.9:** Onlooker bees use probability to come up with fresh solutions.

**Step 4.10:** Determine the new fitness level.

**Step 4.11:** Re-use the greedy selection method.

Devipriya et al.,

**Step 4.12:** If the probability of a solution is not approved, the scout bee will forsake the food source. The generator generates a new random value.

**Step 4.13:** Based on fitness, save the best solution and delete the prior number.

**Step 5:** Update the gradient direction by fitting the new decision model using ABC's ideal best solution.

**Step 6:** Develop a GBT model of regression tree which is used to classify hosts.

## RESULTS AND DISCUSSIONS

### Simulation Setup

Consideration is given to the data centre used in this study, which is also a part of Cloud Sim. There are two server models with 400 hosts each, 800 hosts total, and four different kinds of virtual machines in the data centre. The VM instances' CPU capacity is indicated in millions of instructions per second (MIPS). The two types of hosts and the VM types employed in this experiment are listed in the following tables. SLA violations (SLA-V) and Energy Consumption (EC in kWh) are regarded as performance measures. The performance of the proposed OGBC based host detection is analyzed with existing host detection techniques like Artificial Bee Colony (ABC), Local Regression (LR), Median Absolute Deviation (MAD) using the evaluation metrics like Energy Consumption (kWh) and Service Level Agreement (SLA) Violations (in %) with varying number of number of hosts and number of Virtual Machines (VMs).

### Result obtained at Number of VMs = 100 and Number of Hosts = 400

Table 2.1 depicts the EC (in kWh) of the Proposed OGBC Method, LR, MAD, ABC at host count=400 and VMs count=100. Figure 2.1 depicts the graphical representation of the EC (in kWh) of the Proposed OGBC Method, LR, MAD, ABC at host count=400 and VMs count= 100. From the figure and table 2.1, when compared to the current host identification methods, it is demonstrated that the proposed OGBC uses less energy. Table 2.2 depicts the SLAV (in %) of the Proposed OGBC Method, LR, MAD, ABC at host count=400 and VMs count= 100. Figure 2.2 gives the graphical representation of the SLAV (in %) of the Proposed OGBC, LR, MAD, ABC at host count=400 and VMs count= 100. From the figure and table 2.2, when compared to existing methods, it is evident that the suggested OGBC based detection method minimised the SLA violation.

### Result obtained at VMs count = 200 and host count = 400

Table 3.1 depicts the EC (in kWh) of the Proposed OGBC Method, LR, MAD, ABC at host count=400 and VMs count = 200. Figure 3.1 depicts the graphical representation of the EC (in kWh) of the Proposed OGBC Method, LR, MAD, ABC at the host count =400 and VMs count = 200. From the figure and table 3.1, when compared to the current host identification methods, it is demonstrated that the proposed OGBC uses less energy. Table 3.2 depicts the SLAV (in %) of the Proposed OGBC Method, LR, MAD, ABC at hosts count=400 and VMs count = 200. Figure 3.2 gives the graphical representation of the SLAV (in %) of the Proposed OGBC, LR, MAD, ABC at the hosts count=400 and VMs count = 200. From the figure and table 3.2, when OGBC-based detection is compared to existing methods, it is evident that the suggested method reduced SLAV.

### Result obtained at VMs count = 100 and Hosts count= 800

Table 4.1 depicts the EC (in kWh) of the Proposed OGBC Method, LR, MAD, ABC at the VMs count = 100 and Hosts count= 800. Figure 4.1 depicts the graphical representation of the EC (in kWh) of the Proposed OGBC Method, LR, MAD, ABC at the host count=800 and VMs count = 100. From the figure and table 4.1, When compared to the current host identification methods, it is demonstrated that the proposed OGBC uses less energy. Table 4.2 depicts the SLAV (in %) of the Proposed OGBC Method, LR, MAD, ABC at the hosts count=800 and VMs count = 100. Figure 4.2 gives the graphical representation of the SLAV (in %) of the Proposed OGBC, LR, MAD, ABC at the hosts count=800 and VMs count = 100. From the figure and table 4.2, when compared to existing methods, it is evident that the suggested OGBC based detection method minimised the SLAV.

Devipriya et al.,

**Result obtained at VMs count = 200 and Hosts count = 800**

Table 5.1 depicts the EC (in kWh) of the Proposed OGBC Method, LR, MAD, ABC at hosts count=800 and VMs count = 200. Figure 5.1 depicts the graphical representation of the EC (in kWh) of the Proposed OGBC Method, LR, MAD, ABC at the hosts count=800 and VMs count = 200. From the figure and table 5.1, when compared to the current host identification methods, it is demonstrated that the proposed OGBC uses less energy. Table 5.2 depicts the SLAV (in %) of the Proposed OGBC Method, LR, MAD, ABC at hosts count=800 and VMs count = 200. Figure 5.2 gives the graphical representation of the SLAV(in %)of the Proposed OGBC, LR, MAD, ABC at hosts count=800 and VMs count = 200. From the figure and table 5.2, when compared to existing methods, it is evident that the suggested OGBC-based detection method lowered the SLAV.

**CONCLUSION**

Cloud computing data centres are rapidly expanding to accommodate the enormous demand for high-performance computing (HPC), storage, and networking resources in corporate and scientific applications. Virtual machine (VM) consolidation entails moving virtual machines (VMs) to fewer physical servers in real time, allowing more servers to be turned off or operated in low-power mode, reducing energy consumption, operating costs, and CO<sub>2</sub> emissions. The Artificial Bee Colony Optimization approach was used in this study to improve the weak classifiers of GBDT for host classification. By multiplying the number of VMs and hosts, ABC calculated the memory, CPU, power threshold, and energy usage. Based on the findings, it is obvious that the proposed Optimized Gradient Boosting Classifier based Host identification methodology used less energy and reduced SLA violations as the number of hosts and virtual machines increased. The proposed method is compared to other optimization approaches such as ABC, Local Regression, and Median Absolute Deviation.

### ABSTRACT

A new method to discover maximal frequent items is proposed in this paper using top-down bottom up iteration and discarded elements in dense database to ease the computational cost and operational cost related to runtime and memory imprints. The proposed approach utilizes simple binary indexing for discarded elements in the transactional row and reducing the density of the dataset initially, and then simple mathematical computations are used to find the resultant maximal items by pruning the unwanted elements instantaneously. The proposed approach is compared with the other existing approaches to gauge its performance and from the experimental work; it is found that the proposed approach was miles ahead of the other state of the art algorithms.

**Keywords:** frequent itemsets, maximal frequent items, denser datasets, discarded elements, cutting edge algorithms

### INTRODUCTION

Numerous current algorithms generate frequent itemsets rapidly and effectively; nevertheless, their primary drawback is the quantity of items they generate. The bulk of frequently found items are meaningless, and there are too many of them. Maximal frequent itemset mining was introduced as a solution to this problem. Imagine, for example, a transaction database with six distinct items and a large number of items overall. The frequent itemsets are

### Senthilkumaran and Manivasagan

often displayed to consumers as their  $2^{6-1}$  subset by the great majority of frequent itemset mining algorithms. The algorithm's failure to finish in a reasonable amount of time (lower execution time) and the subsequent high memory footprints are almost certain due to the enormous volume of the resulting itemsets. To provide the necessary results for the user, most well-known frequent itemset mining algorithms would require  $2^6$  database projection operations to be completed. All that is known as a frequent itemset is one that appears in the transaction database at user-specified times [5]. The item's minimum support value is the number of times or occurrences that meet that criteria. If the minimal support is absent from an itemset's immediate supersets, the itemset is deemed closed. If the immediate supersets of an itemset are not common, the itemset is said to be maximally frequent.

#### Definition1

*"A closed itemset that is not technically included in any other closed itemset is called a maximal frequent itemset."*

#### Property 1

*"To retrieve every frequent itemset at any one moment, maximum itemsets are utilized. Typically, a maximal itemset is defined as a full representation of all frequent itemsets."*

#### Property 2

*"The maximum itemsets are often defined as a subset of closed itemset,.." [7]*

#### Property 3

*"The maximal frequent itemset has no superset that is frequent" [8]*

## PRELIMINARIES

Let  $E$  be an item set ( $E=\{1,\dots,N\}$ ). Let  $X$  be an itemset such that  $A1\subseteq E$ . If the cardinality of itemset  $A1$  is  $k$ , then  $A1$  is a  $k$ -itemset. Assume that database  $T$  is a multi-set of subsets of  $E$ , and that the support of itemsets  $A2$  in  $T$  such that  $A1\subseteq A2$  is represented by  $\text{support}(A1)$ . How frequently  $A1$  happens in the transaction database is described in this case by the itemset support. The set of all frequent itemsets is denoted by  $FI$ , and  $A1$  is considered a frequent itemset if  $\text{support}(A1) = \text{minSup}$ . A set of values is referred to as maximally frequent itemset  $MFI$  if it is frequent and none of its supersets are frequent [4]. The proposed algorithm is executed and then compared with the existing algorithms, GENMAX [1], MAFIA [2] and MAX-Eclat [3] algorithms and the runtime and memory consumptions are noted for a detailed comparison.

## PROPOSED APPROACH

The transactional database with dense elements is initially fetched and database is reduced using by representing only the discarded elements and it almost reduces the database size by 40%. The restructured database is represented in binary format and simple binary operations are carried out to discover the maximal frequent itemsets. The sample database is shown in the following table 1. Consider the transaction database shown in table 1. There are five different elements,  $E = \{M1, M2, M3, M4, M5\}$  and five transactions  $ID = \{1; 2; 3; 4; 5\}$  and the user defined minimum support is assumed to be 40%. The first procedure is finding the unique elements present in the sample database and the pseudo code is shown in the figure 2. When searching for unique elements, the process begins with a database scan. Next, every row in the transactional input database is fetched and every element is compared. If the element being compared is found in the  $DE[]$  array, it is ignored; if not, it is stored as a unique element.

## DISCARDED ELEMENT

The unique elements found by the procedure Unique Element is  $\{M1, M2, M3, M4, M5\}$  and the sample dataset is again scanned to find the discarded elements present in every transactional row and the pseudo code is shown below. The transactional rows present in the database  $DT$  is fetched and the set difference between the unique element "u" and the transaction row fetched is discovered, stored along the ID in the restructured output array as

### Senthilkumaran and Manivasagan

shown in the figure 4. The restructured database with discarded elements is shown in the following table 2 and this data is used to find the maximal frequent items. From the table the total number of elements is found to be 9 whereas the total number of elements in the actual input database is found to be 16. The first restructuring process reduced the database size by over 40%. The discarded elements are then marked with 0's and 1's depending upon its presence in the row. If an element is present, then it is marked as "1" else marked as "0" and the resultant binary representation is shown in the following figure 5. The level wise frequent items are found as shown in this section, First the 2 –itemset is discovered. {M1, M2}, {M1, M3}, {M1, M4}, {M1, M5}, {M2, M3}, {M2, M4}, {M2, M5}, {M3, M4}, {M3, M5}, {M4, M5} The binary values of these are fetched from the binary representation and using simple binary operation, it is declared as a maximal or min-maximal itemset. The value of M1 = 0 0 1 0 1 and the value of M2 = 0 0 0 1 1 and they are added to find the number of 0's like shown below, Here the number of zeroes is found to be 2 which is 40% and it is equal to the minimum support value given by the user and this item is considered for further examining. The next level of the tier is examined to prove whether the itemset is maximal, the third element M3 is added to {M1, M2} as shown Here the number of zeroes is found to be 40% which is equal to the user defined minimum support threshold value and it is considered for the next examination as shown below operation, Here the number of zero is found to be 20%, which is lesser than the user defined minimum support value so the 4-itemset {M1, M2, M3, M4} is not a maximal frequent but its immediate predecessor {M1, M2, M3} is a maximal frequent itemset. Similarly all the elements are examined and the maximal frequent itemsets are found. The pseudo code of the proposed algorithm is shown in the figure 6. The maximal frequent itemset found from the sample database is given in the following table 3.

## RESULTS AND DISCUSSIONS

With a 2.66GHz Intel Pentium I5 processor, 8GB RAM, and Windows 10 operating system, the proposed algorithm was implemented using the Java programming language. It is possible to obtain benchmark datasets from the UC Irvine Machine Learning Database Repository, including chess, mushroom, and connect4. The proposed algorithm is compared with other three algorithms with respect to the execution time and the comparison results are shown in the following section. The above table 5 displays the time taken to finish the execution of the proposed algorithm in conjunction with other cutting edge algorithms that are currently in use on the chess database. The comparison chart is shown in the following figure 8. From the above figures and tables it is quite evident that the proposed approach utilizes less time to execute when the minimum support value is varied and it completely out performed the other three algorithms by a good margin. The max-Eclat is the second best performed algorithm after the proposed algorithm.

## CONCLUSION

In order to find maximum frequent itemsets, a novel vertical data format combined with the binary representation [6] and discarded elements are used, along with some basic arithmetic manipulation described in this paper. In future, data compression can be used to reduce the size of the dataset, which will significantly reduce memory usage when working with denser datasets like Connect that have lengthy transactions. From the experimental results it is clear that the proposed approach utilized 25 – 30% less time to execute and 20 – 25% occupied less memory while discovering the maximal frequent items.

### ABSTRACT

The purpose of this research study is to compare different machine learning approaches used in breast cancer prediction by using mammography data. By making such strides, our research significantly advances ongoing attempts to enhance breast cancer prediction, enable earlier diagnosis, and perhaps save lives. With the potential to greatly enhance breast cancer diagnosis and prediction, machine learning techniques have become more important tools in predictive analysis. Through the exploration of various datasets, researchers want to employ various algorithms to predict the incidence of breast cancer, thus supporting the continuous endeavors to augment prediction precision and ameliorate patient consequences. The selected methodology entails a thorough analysis of datasets obtained from prior research, offering a solid basis for the thorough assessment of the precision and dependability of various machine learning algorithms. These methods make use of a wide range of information, such as minute data regarding the size and features of the tumor, to be extremely important in the early detection of breast cancer. With this information at their disposal, medical professionals may make better decisions and help those who are at risk of breast cancer receive timely interventions. In the field of breast cancer prediction, this comparison analysis is highly significant since it aims to determine the best strategy for improving the precision of early detection techniques.

**Keywords:** Random Forest(RF), Support Vector Machines (SVM), Gradient Boosting (GB) and Machine Learning (ML)

Ida Rose and MohanKumar

## INTRODUCTION

The initiation of machine learning techniques has marked a transformative era in breast cancer prediction, offering powerful tools for the analysis and interpretation of complex data. In the domain of supervised learning techniques, the linchpin for training models lies in labeled datasets, enabling the development of models capable of predicting breast cancer percentages on new and unseen data. Boosting algorithms within the realm of supervised learning have garnered attention for their efficacy in this context (Kurian and Jyothi, 2022). These algorithms excel in extracting features from datasets, using them to classify instances as either benign or malignant. However, the performance of these techniques can vary, necessitating a comprehensive comparison and evaluation to discern their effectiveness in breast cancer prediction (Kranjčić et al., 2019). Numerous researchers have undertaken the task of comparing machine learning techniques for breast cancer prophecy, delving into various facets such as demographic information, laboratory results, and mammographic data. A study was conducted to predict breast cancer, employing diverse machine-learning approaches (Rabiei et al., 2022). This comprehensive approach considered demographic, laboratory, and mammographic data, highlighting the multifaceted nature of breast cancer prediction. Another insightful comparative analysis was performed by Ebrahim et al., meticulously evaluating machine learning algorithms using a specific dataset and employing various performance evaluation measures to assess their effectiveness (Qorib et al., 2023). These measures offer crucial insights into the models' capacity to accurately classify instances of breast cancer, aiding in the identification of the most accurate and reliable machine learning technique. Furthermore, certain studies have showcased the dormant of machine learning algorithms in precisely predicting breast cancer based on diverse features and data inputs (Rabiei et al., 2022). Notably, techniques such as Random Forest (RF) have demonstrated higher performance compared to others, emphasizing their promise in enhancing breast cancer prediction and diagnosis (Naeem et al., 2021). The collective results from these studies underscore the considerable possibility of machine learning in improving the accuracy and reliability of breast cancer prediction. The imperative to compare the performance of different machine learning techniques for breast cancer prediction is paramount in discerning the most accurate and reliable methods. Another noteworthy study compared machine-learning techniques with existing risk prediction models, revealing that machine-learning techniques outperformed traditional models in personalized breast cancer risk prediction (Ming et al., 2019). These findings enhance the significant potential of machine learning techniques in advancing breast cancer prediction and diagnosis. Existing literary evidence indicates that in the domain of breast cancer risk prediction, machine learning techniques exhibit promise in providing personalized assessments (Ming et al., 2019). This burgeoning area of research holds great potential for refining and advancing personalized breast cancer prediction models, ultimately contributing to improved patient outcomes and more effective clinical interventions.

### Machine learning techniques

#### Decision Tree

A widely employed and well-regarded supervised learning technique for predicting breast cancer percentage is the utilization of decision trees. These decision trees are structured in a branchy format, where each internal node signifies a feature or attribute, each branch encapsulates a decision rule, and each leaf node denotes the outcome or class label (Kurian and Jyothi, 2022). The notable advantage of decision trees lies in their ease of interpretation, offering valuable insights into the underlying decision-making process. Their versatility is evident in their ability to handle both categorical and numerical data, making them highly adaptable for breast cancer prediction (Kranjčić et al., 2019). However, it's crucial to acknowledge that decision trees are not without their challenges. A notable limitation is their susceptibility to overfitting, a phenomenon wherein the model performs exceedingly well on the training data but struggles to generalize effectively to new, unseen data. Pruning can compromise the predictive accuracy of decision trees in real-world scenarios. To address this concern, regularization techniques, particularly pruning, can be employed to mitigate overfitting and enhance the overall performance of decision trees (Monirujjaman Khan et al., 2022). Pruning, as a regularization technique, involves selectively removing branches and nodes from the decision tree, simplifying its structure. This process prevents the model from

**Ida Rose and MohanKumar**

becoming overly complex and honing in too closely on the intricacies of the training data. By striking a balance between complexity and simplicity, pruning ensures that decision trees can more effectively generalize to new instances, ultimately bolstering their predictive capabilities in the background of breast cancer prediction. The judicious application of such techniques is crucial in optimizing decision tree models for accurate and reliable breast cancer percentage predictions. Decision trees, with proper regularization, continue to be a valuable asset in the realm of breast cancer prediction, offering interpretable insights while addressing challenges associated with overfitting.

**SVM**

Support Vector Machines (SVMs) stand out as a notable supervised learning technique applied to breast cancer prediction. The core principle of SVMs revolves around finding the prime hyperplane that effectively separates different classes by maximizing the margin between them. A study conducted by Hassan et al. delved into a comparative analysis of three prominent machine learning models for predicting breast cancer survival, with a specific focus on the utilization of support vector machines (Qorib et al., 2023). SVMs have demonstrated commendable performance across various classification tasks, showcasing their effectiveness in the monarchy of breast cancer prediction. Their versatility is particularly evident in handling high-dimensional data, and they exhibit efficacy in scenarios with limited sample sizes. The strength of SVMs lies in their ability to navigate complex datasets, making them a valuable asset in predicting survival outcomes associated with breast cancer. However, it is essential to acknowledge certain challenges associated with SVMs. Their computational expense, especially concerning large datasets, can pose a significant consideration. Additionally, achieving optimal performance may necessitate careful parameter tuning, as SVMs are sensitive to the selection of hyper parameters (Ming et al., 2019). Despite these considerations, the inherent capabilities of SVMs in handling intricate breast cancer prediction tasks, especially in the context of survival outcomes, underline their significance in the broader landscape of machine learning applications in healthcare. The study by Hassan et al. contributes valuable insights into the performance of SVMs in predicting breast cancer survival, emphasizing their adaptability to complex classification tasks and their potential impact on enhancing patient outcomes.

**Gradient boosting**

Gradient boosting has emerged as a highly effective machine-learning technique, particularly in breast cancer prediction. This approach involves combining multiple weak learners, often decision trees, to construct a robust and accurate predictive model. The iterative process of gradient boosting introduces new models to address instances misclassified by their predecessors (Akhtar et al., 2023). In a comprehensive comparative analysis evaluating various machine learning algorithms for breast cancer prediction, Gradient Boosting (GB) stood out as the top-performing algorithm, especially when using the Coimbra Breast Cancer dataset (Akhtar et al., 2023). This highlights the considerable potential of gradient boosting in achieving superior predictive accuracy in the circumstances of breast cancer (Wang et al., 2021). While gradient boosting is established as effective, its implementation can be intricate, requiring careful hyperparameter tuning to prevent overfitting (Kranjčić et al., 2019). Overfitting occurs when a model captures noise in the training data, compromising its generalizability to new, unseen data. To address this, practitioners must fine-tune hyperparameters like the hyperparameter, tree depth, and the number of boosting rounds. The learning rate determines the step size at each iteration, impacting convergence speed, and finding the right balance is crucial for optimal performance. Tree depth influences the complexity of individual decision trees within the ensemble, and striking a balance is vital to avoid underfitting or overfitting (Wang et al., 2021). The number of boosting rounds, representing sequential addition of weak learners, must be carefully chosen to prevent underfitting or overfitting, often determined through cross-validation techniques. Despite these challenges, gradient boosting remains a powerful tool for breast cancer prediction. Its effective implementation requires a nuanced understanding of hyperparameter tuning, ensuring accurate predictions and contributing to advancements in breast cancer diagnosis and treatment. In addition to gradient boosting, several studies have compared various machine learning algorithms for breast cancer prediction. Wu et al. focused on developing and validating classification models for breast cancer-related events (Wu et al., 2022). Chen et al. explored models using XGBoost, random forest, logistic regression, and K-nearest neighbor,

**Ida Rose and MohanKumar**

comprehensively assessing their performance in breast cancer prediction (Chen et al., 2023). Islam et al. compared classification accuracy, precision, sensitivity, and specificity of different machine learning algorithms on a newly collected dataset (Islam et al 2021). These studies contribute valuable insights, enhancing the collective knowledge on predicting breast cancer and refining methodologies for detection and prognosis (Kranjčić et al., 2019). Shifting to unsupervised machine learning techniques, clustering algorithms play a pivotal role in breast cancer prediction. K-means, hierarchical clustering, and DBSCAN are commonly employed algorithms (Ming et al., 2019). Each has advantages and disadvantages, and their selection depends on factors like computational efficiency and dataset characteristics. Recent research by Bansal et al. highlighted the effectiveness of the Support Vector Classifier (SVC) in breast cancer prediction, achieving high accuracy, precision, and F1 score (Zheng et al., 2023). Decision trees, shore-up vector machines, gradient boosting, and k-means offer unique strengths and weaknesses, emphasizing the need to choose the most suitable technique based on specific requirements (Islam et al., 2021). As breast cancer prediction evolves, ongoing research and comparative studies are crucial to determine the most effective techniques for specific contexts. Similarly, the choice of clustering algorithms requires careful consideration of dataset characteristics and analysis goals for optimal outcomes (Kurian and Jyothi et al., 2022). The proposed algorithm for breast cancer prediction leveraging various machine learning techniques and clustering algorithms emerges as a promising avenue. By integrating strengths from different approaches, this holistic method aims to contribute to advancements in early detection and personalized treatment strategies, further enhancing the field of breast cancer prediction.

**Proposed algorithm**

The proposed algorithm for accurate percentage prediction in breast cancer detection stands at the lead of cutting-edge applications of artificial intelligence (AI) and machine learning (ML) in the realm of medical diagnostics. Its foundation is rooted in comprehensive training on extensive datasets, encompassing images of breast tissue samples with known percentages of cancer cells. This meticulous training equips the algorithm with the capacity for pattern recognition, a fundamental aspect of machine learning, enabling it to identify and analyze intricate features within tissue samples. A key strength of the algorithm lies in its ability to scrutinize various characteristics of the tissue samples, including the shape, size, and arrangement of cells. This multifaceted analysis enables the algorithm to discern subtle patterns and nuances that may elude the human eye during traditional visual assessments. Going beyond conventional diagnostic methods, the algorithm provides a nuanced and comprehensive understanding of the composition of breast tissue samples. The core functionality of the algorithm revolves around comparing the identified features to the known percentages of cancer cells within the Practice data. This process allows the algorithm to establish correlations between specific patterns and varying degrees of cancer cell presence. Consequently, when faced with new, unseen samples, the algorithm can extrapolate from its learned patterns to make accurate predictions regarding the percentage of cancer cells present. What sets this algorithm apart is its capacity to introduce objectivity and standardization into breast cancer diagnosis. Relying on quantitative data and patterns rather than subjective visual assessments, the algorithm mitigates the potential for human bias. This objectivity not only enhances the accuracy of predictions but also contributes to a more standardized and consistent approach to breast cancer diagnosis, crucial for ensuring uniformity in medical practices. Moreover, the algorithm's efficiency is a notable advantage. It can analyze large numbers of samples in a fraction of the time it would take a human pathologist. This acceleration in the diagnostic process is particularly significant in the context of breast cancer, where timely detection and intervention can significantly impact treatment outcomes. The algorithm's ability to expedite the analysis of samples can lead to faster diagnoses and streamlined development of treatment plans, potentially improving patient outcomes and reducing anxiety in healthcare systems. In essence, the proposed algorithm represents a paradigm shift in breast cancer detection by seamlessly integrating AI and ML technologies. Its ability to learn, adapt, and make predictions based on complex patterns not only enhances diagnostic accuracy but also addresses the challenges associated with subjective assessments. As research and technology continue to advance, the integration of such algorithms into clinical practice holds immense promise for revolutionizing breast cancer diagnosis and treatment.

**Ida Rose and MohanKumar****Dataset selection and preprocessing**

The initial stage in predicting breast cancer percentage through machine learning techniques involves a meticulous process of dataset selection and preprocessing. These datasets typically encompass a variety of information, including demographic details, laboratory results, and mammographic data (Rabiei et al., 2022). Notable examples of datasets commonly used in these studies include the Coimbra Breast Cancer Database and the Wisconsin Breast Cancer Dataset (Monirujjaman Khan et al., 2022). Once the dataset is chosen, a critical step is the application of data cleaning and transformation techniques to ensure the quality and consistency of the data. This includes addressing missing values, eliminating outliers, and standardizing the data when necessary (Kranjčić et al., 2019). The significance of data preprocessing cannot be overstated, as it lays the foundation for machine learning algorithms to effectively learn from the data and subsequently make accurate predictions. Numerous studies have emphasized the importance of this preprocessing step in achieving robust and reliable results in breast cancer prediction (Delen et al., 2005).

Researchers have explored a spectrum of machine learning algorithms in the context of breast cancer prediction, including logistic regression, decision trees, artificial neural networks, and gradient boosting (Akhtar et al., 2023 and Delen et al., 2005). Comparative analyses across these algorithms have been conducted to discern their performance differences and identify the most suitable models for accurate predictions. Following data preprocessing, the next crucial step is feature selection and extraction. This process aims to identify the most pertinent features influencing breast cancer prediction and reduce the dimensionality of the dataset, thereby enhancing the efficiency and accuracy of machine learning models (Akhtar et al., 2023). Various feature selection methods, such as recursive feature elimination and least absolute shrinkage and selection operator (LASSO), have been employed in these studies (Qarib et al., 2023). Comparative analyses have also been undertaken to evaluate the performance of different feature selection and classification procedures (Taghizadeh et al., 2022). By strategically selecting the most informative features, machine learning models can effectively capture the underlying patterns and relationships within the data. This not only improves the efficiency of the models but also significantly contributes to the accuracy of predictions regarding breast cancer percentage (El\_Rahman et al., 2021). The integration of feature selection techniques ensures that machine learning models focus on the most relevant aspects of the data, avoiding noise and irrelevant information that might hinder predictive capabilities. In predicting breast cancer percentage through machine learning, each step, from dataset selection and preprocessing to the strategic application of diverse algorithms and feature selection methods, is meticulously designed to optimize the learning process. This comprehensive approach aims to enhance model efficiency and contribute to more accurate predictions in the critical domain of breast cancer diagnosis and prognosis.

**Experimental setup and methodology**

The landscape of machine learning models for breast cancer prediction is extensive, prompting numerous studies to compare their accomplishments and identify the most effective techniques. These comparative analyses serve as valuable tools for researchers and practitioners, allowing them to discern the strengths and weaknesses of various approaches to predicting breast cancer. By evaluating factors such as accuracy, precision, recall, and F1 score, as well as considering the specific requirements of the prediction task, researchers can gain insights into the optimal techniques for different scenarios (Naeem et al., 2021). For instance, a comparative study conducted by Kurian et al. in 2022 focused on evaluating the performance of different machine learning classifiers for the early prediction and diagnosis of breast cancer (Kurian and Jyothi., 2022). Similarly, a comparative analysis study in 2023 was conducted examining the performance of multiple machine learning algorithms in breast cancer prediction. These studies contribute to the evolving understanding of which techniques excel in specific contexts and assist in the selection of the most suitable models for breast cancer prediction. In the context of the proposed algorithm, its performance was rigorously validated by comparing its predictions with a dataset obtained from a previous study (Wu et al., 2022). This dataset comprises mammography images depicting both benign and malignant masses. To construct this dataset, 106 mass images were extracted from the INbreast dataset, 53 mass images from the MIAS dataset, and 2188 mass images from the DDSM dataset. All images were standardized to a size of 227\*227 pixels. Extensive testing and validation procedures were employed to assess the performance and accuracy of the

**Ida Rose and MohanKumar**

proposed algorithm. The implementation of the proposed algorithm was executed using the open-source programming language Python. This choice of technology not only reflects the accessibility and versatility of Python in the field of machine learning but also aligns with the collaborative nature of open-source development. Leveraging Python ensures that the algorithm can be easily shared, replicated, and extended by other researchers and practitioners in the scientific community. By validating the proposed algorithm against established datasets and employing Python for implementation, the research demonstrates a commitment to transparency, reproducibility, and collaboration within the scientific community. This approach not only showcases the algorithm's performance but also sets the stage for further refinement and exploration within the realm of breast cancer prediction through machine learning.

**Evaluation metrics for comparing machine learning techniques**

When comparing machine learning techniques for predicting breast cancer percentage, it is crucial to consider various evaluation metrics to gain a comprehensive understanding of their performance. Researchers in the field of breast cancer prediction consistently emphasize the importance of metrics such as accuracy, precision, recall, and F1 score to assess the effectiveness of different machine learning algorithms (Wang et al., 2021). Accuracy, a fundamental metric, measures the overall correctness of predictions made by the model. A higher accuracy score indicates that the model is making more correct predictions, providing a general overview of its performance across all classes (Rabiei et al., 2022). Precision, another critical metric, evaluates the proportion of correctly predicted positive cases out of all the predicted positive cases. It serves as an indicator of the model's ability to avoid false positives, which is particularly important in medical diagnoses where misclassification can have severe consequences (Ming et al., 2019). On the other hand, recall assesses the proportion of correctly predicted positive cases out of all the actual positive cases. This metric is crucial for evaluating the model's ability to identify all positive cases, emphasizing sensitivity in detecting instances of breast cancer (Kranjčić et al., 2019). F1 score, a harmonic mean of precision and recall, offers a balanced measure that considers both false positives and false negatives. It becomes particularly relevant in scenarios where achieving a balance between precision and recall is essential (Naeem et al., 2021). By employing these evaluation metrics, this work endeavors to compare different machine learning techniques and identify the most effective approach for predicting breast cancer percentage. Each metric provides unique insights into different aspects of model performance, enabling a nuanced evaluation that goes beyond a single measure. To further ensure the robustness of the evaluation process, cross-validation techniques are employed. Cross-validation involves splitting the dataset into multiple subsets, training the models on a combination of these subsets, and evaluating their performance on the remaining subset. This iterative approach helps guard against overfitting, ensuring that the models generalize well to unseen data. A study conducted by Mashudi et al. in 2021 exemplifies the application of cross-validation, comparing the performance of various machine learning techniques for breast cancer classification using 3-fold and 5-fold cross-validation. This approach not only provides a robust evaluation of the model's performance but also aids in selecting the best-performing technique by considering their consistency across different subsets of the data. The utilization of a range of evaluation metrics, including accuracy, precision, recall, and F1 score, along with cross-validation techniques, ensures a comprehensive and reliable assessment of machine learning techniques for breast cancer prediction. These measures collectively contribute to identifying the most effective models, fostering advancements in accurate and reliable breast cancer diagnostics.

**RESULTS AND ANALYSIS**

The interpretation of the results obtained from the comparison of machine learning techniques is crucial in understanding their implications for breast cancer prediction. The following table represents the accuracy, precision, recall, and F1 score of the decision tree, SVM, Gradient boosting, and the proposed algorithm. The following figure represents the accuracy, precision, recall, and F1 score of the decision tree, SVM, Gradient boosting, and the proposed algorithm. By comparing the results and considering the specific context and goals of

**Ida Rose and MohanKumar**

the prediction task, researchers can determine the technique that offers the highest performance and suitability for breast cancer prediction.

**Limitations and future directions**

Improving breast cancer prediction and diagnosis is a crucial endeavor, but it's equally important to acknowledge and address the limitations inherent in current studies to ensure the validity and generalizability of findings. One significant limitation highlighted in the current study is the reliance on specific datasets, which may not fully capture the diversity of breast cancer cases. Breast cancer is a complex and heterogeneous disease, exhibiting variability in factors such as tumor subtypes, genetic profiles, and patient demographics. Relying on limited datasets may result in biased models that might not generalize well to broader populations. To overcome this limitation, future research should prioritize the inclusion of more diverse and representative datasets, encompassing a wide range of breast cancer cases. This approach aims to mitigate biases and enhance the models' ability to generalize across different patient profiles and tumor characteristics. Moreover, the performance of machine learning algorithms can be influenced by the quality and quantity of the available data. Insufficient or imbalanced datasets may lead to biased model outcomes, affecting the reliability of predictions. Therefore, future research efforts should focus on the collection of high-quality, well-balanced datasets to ensure the robustness and generalizability of machine learning models for breast cancer prediction.

To enhance the external validity of the models and increase their applicability to diverse clinical scenarios, future research directions should also focus on validating the effectiveness of machine learning techniques across different populations and datasets. This approach ensures that the models are not only accurate but also adaptable to various contexts and patient groups. Looking ahead, there are several promising avenues for future research in breast cancer prediction using machine learning. First, exploring the integration of multiple machine learning models and algorithms holds the potential to improve the accuracy and robustness of predictions. Combining the strengths of various models may mitigate individual model weaknesses, leading to more reliable and accurate predictions. Additionally, investigating the impact of incorporating additional features, such as genetic data or lifestyle factors, could enhance the predictive power of machine learning models. The inclusion of diverse data sources could provide a more comprehensive understanding of the factors influencing breast cancer development and progression, resulting in more nuanced and accurate predictions. Furthermore, conducting longitudinal studies to assess the long-term performance and reliability of machine learning algorithms in predicting breast cancer is crucial. Understanding how these models perform over extended periods ensures their practical viability and relevance in clinical settings. Longitudinal studies also contribute to our understanding of how these models adapt to changes in patient conditions and disease progression over time. In conclusion, while machine learning techniques show great promise in breast cancer prediction, it is imperative to acknowledge and address current study limitations. Future research should prioritize diverse and representative datasets, consider the impact of data quality and quantity, and explore innovative approaches such as the integration of multiple models and the inclusion of additional features. These advancements will contribute to more robust, accurate, and applicable machine learning models for breast cancer prediction, ultimately benefiting clinical practice and patient outcomes.

**RESEARCH IMPLICATIONS**

These are some of the many research implications of this paper. Comprehensive training on large datasets, including pictures of breast tissue samples with known cancer cell percentages, is the basis of this approach. Through careful training, the algorithm gains the ability to recognize patterns, which is a key component of machine learning and allows it to recognize and examine complex features seen in tissue samples. The algorithm's capacity to closely examine the shape, size, and arrangement of the cells in the tissue samples is one of its main strengths. Comparing the detected attributes to the known percentages of cancer cells in the Practice data is the algorithm's primary method of operation. The program can create associations between particular patterns and different levels of cancer cell presence thanks to this approach. As a result, the system is able to extrapolate from its learnt patterns to

**Ida Rose and MohanKumar**

accurately forecast the percentage of cancer cells present in new, unknown data. With breast cancer, where prompt identification and therapy can have a major impact on treatment outcomes, this diagnostic process acceleration is especially important. The algorithm's capacity to accelerate sample processing can result in quicker diagnosis and more efficient treatment plan preparation, which could enhance patient outcomes and lessen stress in healthcare systems. By seamlessly fusing AI and ML technologies, the suggested method essentially represents a paradigm leap in breast cancer diagnosis. Its capacity for learning, adapting, and making predictions based on intricate patterns improves diagnostic precision while resolving issues with subjective evaluations. The application of such algorithms in clinical practice holds great promise for transforming breast cancer diagnosis and therapy as long as science and technology continue to progress. It is imperative to carry out longitudinal research to evaluate the long-term efficacy and dependability of machine learning algorithms in the prediction of breast cancer. The process can create associations between particular patterns and different levels of cancer cell presence thanks to this approach. This method is unique in that it can provide objectivity and standardization to the detection of breast cancer. By depending on numerical information and trends instead of arbitrary visual evaluations, the system reduces the possibility of bias from humans. This impartiality helps to ensure uniformity in medical procedures by improving prediction accuracy and promoting a more standardized and consistent approach to breast cancer diagnosis.

**CONCLUSION**

In conclusion, this study has made significant strides in comparing various machine learning techniques for predicting breast cancer percentages, yielding valuable insights into their strengths and limitations. The algorithm's capacity to carefully examine the shape, size, and arrangement of the cells in the tissue samples is one of its main strengths. The evaluation metrics employed, including accuracy, precision, recall, and F1 score, provided a comprehensive assessment of the performance of different models. The comparison of supervised learning techniques, particularly the use of decision trees, demonstrated promising results, showcasing its versatility in handling both categorical and numerical data. Conversely, unsupervised learning techniques, such as clustering algorithms, showed potential but raised challenges related to interpretability. The critical steps of dataset selection and preprocessing played a pivotal role in ensuring the quality and relevance of the data.

It can analyse a large number of samples in a fraction of the time that a pathologist who works with humans would need. With breast cancer, where prompt identification and therapy can have a major impact on treatment outcomes, this diagnostic process acceleration is especially important. The algorithm's capacity to accelerate sample processing can result in quicker diagnosis and more efficient treatment plan preparation, which could enhance patient outcomes and lessen stress in healthcare systems. By seamlessly fusing AI and ML technologies, the suggested method essentially represents a paradigm leap in breast cancer diagnosis. The robust experimental setup, including the meticulous use of cross-validation techniques, provided a reliable framework for evaluating the performance of the machine learning techniques. The results and analysis not only highlighted the strengths of each technique but also underscored their respective weaknesses, ultimately leading to the identification of the best-performing technique within the context of breast cancer prediction. However, it is imperative to acknowledge the limitations inherent in this study, including the reliance on a specific dataset and the potential for bias in the results. Looking ahead, future research should explore alternative machine-learning techniques and datasets to validate and extend the findings of this study. By diversifying the approaches and datasets, researchers can enhance the generalizability of the results and potentially improve the accuracy of breast cancer prediction models. In summary, this study significantly contributes to the growing body of knowledge on the application of machine learning in healthcare, particularly in the domain of breast cancer prediction. The insights gained from this research not only inform current practices but also pave the way for further advancements and innovations in leveraging machine learning for improved healthcare outcomes.

### ABSTRACT

This study presents a novel approach for predicting sugarcane diseases using image processing techniques integrated with a hybrid deep learning model, referred to as Hybrid Deep Learning for Sugarcane Disease Prediction (HDLSDP). The methodology involves capturing high-resolution images of sugarcane leaves affected by various diseases, followed by image processing steps such as enhancement, segmentation, and feature extraction to highlight key disease indicators. A hybrid deep learning model, combining a convolutional neural network (CNN) with a recurrent neural network (RNN), is then developed to leverage both spatial and temporal features from the image data. The HDLSDP model achieved over 98% accuracy in disease classification, outperforming traditional machine learning methods in both accuracy and robustness. These findings suggest that the HDLSDP model can be an effective tool for farmers and agricultural stakeholders to facilitate early detection and timely interventions, thereby promoting sustainable sugarcane production.

## INTRODUCTION

The Crop health is a cornerstone of agricultural productivity and global food security. Sugarcane, a vital crop for sugar and ethanol production, is especially vulnerable to diseases that can significantly diminish both yield and quality. Accurate and effective disease prediction is essential for timely intervention and sustainable agricultural practices. These studies explore image processing integration and DL technology to improve sugarcane disease detection prediction, providing innovative solutions to modern agricultural challenges. Deep learning has become a ground-breaking technology in the field of artificial intelligence. Offering unparalleled capabilities to analyze complex datasets. In agriculture, DL techniques like CNNs essential for disease diagnosis, pest detection, and crop monitoring. These models excel in extracting hierarchical features from images, enabling precise identification of subtle disease patterns. Compared to traditional diagnostic methods, DL approaches provide superior speed, accuracy, and scalability, making them ideal for sugarcane disease prediction. Image pre-processing forms the foundation of reliable disease prediction systems. It enhances the quality of input data through techniques such as noise reduction, contrast adjustment, resizing, and segmentation. These methods ensure the removal of irrelevant or distorted data, creating clearer inputs for the model. By isolating and emphasizing diseased regions, pre-processing ensures that deep learning models can focus on critical features. Moreover, advanced pre-processing techniques, such as data augmentation, improve the diversity of the training data set, thereby improving the robustness of the model.. This step not only boosts classification accuracy but also minimizes the impact of irrelevant visual elements, optimizing model performance. Pre-processing is particularly critical when dealing with complex agricultural images, where environmental factors like lighting and background variability can complicate disease detection Sugarcane is vulnerable to numerous diseases caused by pathogens such as fungi, bacteria and viruses. Notable diseases like red rot, smut, and mosaic virus exhibit visible symptoms, including stalk lesions, discoloration, and deformities. These diseases can spread rapidly under favourable conditions, leading to significant economic losses if not addressed promptly. Relying on traditional manual inspection methods for disease identification is labor-intensive and prone to errors. Consequently, there is an urgent need for automated, data-driven approaches to address these challenges effectively and ensure timely intervention for disease management. This study aims to leverage the synergy between image processing and deep learning to create a robust and efficient system for sugarcane disease prediction. By enabling early detection, such solutions can empower farmers to take proactive measures, reducing crop losses and enhancing productivity. Ultimately, this integration of technology and agriculture marks a step forward in achieving more sustainable farming practices.

## RELATED WORK

Babu and Srinivas (2023) propose a hybrid ML model to work on the exactness of sugarcane disease prediction. Their approach combines multiple ML algorithms, such as DT and SVM, with image processing techniques for better classification of disease symptoms in sugarcane leaves. The model aims to increase prediction accuracy by incorporating diverse learning mechanisms, which can handle variations in disease patterns across different environmental conditions. Patil and Deshmukh (2023) Investigate the application of Convolutional Neural Networks for detecting sugarcane diseases. specifically focusing on leveraging deep learning to enhance disease identification accuracy. Their study highlights the application of CNN architectures to classify disease symptoms in sugarcane leaves, offering improved performance over traditional image processing techniques Rubini and Kavitha (2024) propose a DL model for early detection of sugarcane diseases using DenseNet for feature extraction and SVM for classification. Their method efficiently identifies various diseases like bacterial blight and wilt by processing leaf images. The model's interpretability is enhanced through Local Interpretable Model-Agnostic Explanations (LIME), making it useful for farmers in disease management. Hasan and Alam (2024) proposed a deep learning based model to classify sugarcane diseases using leaf images. Their study used advanced CNNs to improve the accuracy of disease detection in sugarcane crops. By using deep learning techniques, their approach significantly improved the accuracy of disease classification, which is crucial for timely management of sugarcane diseases. Joshi and Kumar (2023) explored the use of deep learning techniques for identifying sugarcane diseases. Their research utilized advanced models, such as Convolutional Neural Networks (CNNs), to analyze images of

### Kumaravel and Umamaheswari

sugarcane leaves for disease classification. This work enhances the accuracy and efficiency of sugarcane disease detection, enabling timely interventions and improved crop management. Singh and Jain (2023) explored the use of hybrid ML models to predict sugarcane diseases. Their study combined multiple ML techniques to improve the accuracy of predictions, enabling early detection of diseases affecting sugarcane crops. This approach combined models such as DT and SVM with DL, demonstrating the benefits of hybrid models in improving disease classification and prediction. The study highlighted the potential of these models to reduce crop losses through timely intervention. Narayana and Govindarajan (2023) zeroed in on early discovery of sugarcane illnesses utilizing picture examination methods. His research highlighted the use of ML and DL models, including convolutional neural networks to classify sugarcane diseases from leaf images. The approach aims to improve crop management by identifying disease symptoms early, ultimately increasing yield and quality. Their research is part of the growing field of agricultural bioinformatics, which uses digital tools to optimize disease detection and management. Singh and Jain (2024) proposed a CNN-based sugarcane disease detection and classification system, demonstrating the effectiveness of deep learning in agricultural applications. This study is consistent with previous work, where CNNs achieved high accuracy in plant disease detection, such as 93.20% accuracy in sugarcane disease classification. Recent advances also include hybrid models that integrate CNNs with other techniques such as visual transformers, which have improved diagnostic accuracy for agricultural disease detection.

## MATERIALS AND METHODS

### Dataset Collection

Sugarcane Leaf Disease Dataset is designed to train machine learning models to detect and classify diseases in sugarcane crops, helping improve crop management and performance quality. The dataset contains high-resolution images of sugarcane leaves, categorized as healthy or diseased, to develop models that identify disease types based on visual features.

- **Healthy:** No visible disease.
- **Leaf Scald:** Bacterial infection causing scorched areas.
- **Yellow Leaf Syndrome:** Yellowing due to stress or disease.
- **Brown Rust:** Fungal infection with rust spots.
- **Red Rot:** Fungal disease affecting leaves and stalks.

Image pre-processing is a crucial step in preparing images for ML models, especially in tasks like sugarcane leaf disease prediction. It highlights key features in the images, reduces noise, and facilitates the ability of models, especially deep learning models like Convolutional Neural Networks, to identify patterns associated with diseases. Below are key preprocessing techniques commonly applied to sugarcane leaf disease datasets.

### Grayscale Conversion

Grayscale conversion simplifies images by removing color and focusing on texture and shape, converting the image into a single intensity channel using the average of RGB values. This helps models concentrate on key features for disease classification without requiring color information.

$$\text{Grayscale value} = 0.2989 \times R + 0.5870 \times G + 0.1140 \times B$$

### Contrast Enhancement

Contrast enhancement improves visibility by increasing the difference between light and dark areas in the image. This helps highlight subtle features like lesions or discoloration, making it easier for the model to distinguish between healthy and diseased areas.

$$I_{\text{new}} = \alpha(I - I_{\text{min}}) + I_{\text{min}}$$

### Kumaravel and Umamaheswari

Where:

$I$  is the original pixel value.

$I_{\min}$  is the minimum pixel value.

$\alpha$  is a contrast factor, greater than 1 for enhancement.

$I_{\text{new}}$  is the enhanced pixel value.

#### Histogram Equalization

Histogram equalization enhances contrast by redistributing pixel intensity values across the entire range, making features more distinguishable and improving detection of subtle disease symptoms.

$$I_{\text{new}} = T(I) = \frac{L-1}{N} \sum_{i=0}^I P(i)$$

#### Adjust Gamma Values

Gamma correction adjusts image brightness by applying a non-linear transformation, brightening or darkening regions to reveal hidden details and make disease symptoms more visible.

$$I_{\text{new}} = I^\gamma$$

#### Adjust Color Tones

Adjusting color tones modifies the image's color balance to emphasize disease-related features, such as yellowing or rust, helping the model detect and classify disease symptoms more effectively.

$$R_{\text{new}} = R + \Delta R, \quad G_{\text{new}} = G + \Delta G, \quad B_{\text{new}} = B + \Delta B$$

#### SEGMENTATION

Image segmentation is a crucial step in the preprocessing pipeline for sugarcane leaf disease prediction. The goal of segmentation is to identify and isolate regions of interest (ROI) in the image that correspond to specific features of the leaf, such as lesions, discoloration, or patterns that indicate disease. This helps machine learning models focus on relevant areas while ignoring irrelevant parts of the image. Below are key segmentation techniques commonly used for disease prediction in sugarcane leaves

##### Thresholding

Thresholding helps isolate disease-related areas, such as lesions or discoloration, by converting the image into a binary format, distinguishing diseased regions from healthy ones. It works by setting a specific intensity value (threshold) to classify pixels as "foreground" (disease) or "background" (healthy) based on their intensity. There are two types: global thresholding, which applies a single threshold to the entire image, and adaptive thresholding, where local thresholds are determined for different regions of the image. This technique effectively highlights disease-affected areas, making them easier to detect and classify in subsequent analysis.

##### ROI-Based Intensity Adjustment

ROI-based intensity adjustment highlights disease-related features by adjusting the intensity values of specific regions of interest (ROI). After isolating the diseased areas using segmentation techniques like thresholding, the pixel intensity in these regions is adjusted to enhance visibility, such as by increasing contrast or brightness. This method helps emphasize disease symptoms, making them more detectable by machine learning models for accurate classification.

### Kumaravel and Umamaheswari

#### Smoothing

Smoothing removes noise and reduces sharp edges in segmented images, helping to create cleaner boundaries between diseased and healthy areas. Filters like Gaussian or median filters are applied to blur the boundaries and smooth out rough regions. Gaussian smoothing reduces high-frequency noise, while median filtering removes salt-and-pepper noise. This process refines segmentation results, ensuring that disease features are more clearly defined and irrelevant regions are eliminated.

#### Region Growing

Region growing segments regions based on pixel similarity, starting from a seed point (typically a known diseased area) and growing outward. The algorithm iteratively adds neighbouring pixels that meet criteria such as color, texture, or intensity similarity. This technique is useful for identifying irregularly shaped disease areas, making it more effective for detecting complex lesions that do not follow simple geometric boundaries. It allows for more accurate detection of disease in regions that may be harder to isolate with traditional methods.

#### Experimental Result

Several studies have been published on various aspects of image processing, including filtering, segmentation, feature extraction, and classification. Filtering plays a crucial role in enhancing image quality, with median filters commonly used to reduce noise, such as salt-and-pepper or Poisson noise, thereby preparing the image for further analysis. Some approaches, like order statistics filters, combine median and mean filtering techniques to effectively remove noise, particularly in medical images. Anisotropic filters have also been explored to eliminate background noise while preserving image edges. Additionally, weighted median filters have been introduced to remove high-frequency components and salt-and-pepper noise. Image segmentation involves partitioning an image into regions based on specific features or characteristics, and for example, diseases in sugarcane images can be detected using histogram threshold segmentation. The histogram represents the image's intensity values, while threshold segmentation converts the image into a binary form for disease detection. Feature extraction techniques are employed to capture essential high-level features for classification tasks. Various techniques, such as GLCM are used to extract critical features like entropy, uniformity, energy, color, shape, intensity, and texture to improve performance. The proposed method predicts whether an image contains a disease with 95% accuracy. The architecture of this proposed approach is outlined. The proposed work predicts an image with disease or not-disease with 95% accuracy. The architecture of the proposed work is described in Figure 2

#### ALGORITHM STEPS FOR SUGARCANE DISEASE PREDICTION (HDLSDP)

**Input** : Select a query similar image.

**Output** : Prediction of disease and measure the performance with confusion matrix.

Step 1: Select appropriate sugarcane image.

Step 2: Transform image into gray scale image to reduce noise.

Step 3: Compute the distances

$$D_{ik}^2 = (x_k - v_i)^T (x_k - v_i), \quad 1 \leq i \leq c, 1 \leq k \leq N.$$

Step 4: Select the point in the group that has the smallest distance.

Step 5: Calculate the center of the pseudo group.

$$v_i^* = \frac{\sum_{j=1}^N x_j}{N_i}$$

Step 6: Select the nearest data point as the center of the cluster

$$D_{ik}^* = \sqrt{\left( (x_k - v_i^*)^T (x_k - v_i^*) \right)}$$

And

**Kumaravel and Umamaheswari**

$$x_i^* = \operatorname{argmin}_i (D_{ik}^{2*}); v_i^{(l)} = \min_i(x_i^*)$$

Until

$$\prod_{k=1}^n \max |v^{(l)} - v^{(l-1)}| \neq 0$$

Step 7: Ending Calculate the partition matrix

Step 8: Measure the mean difference of feature set and measure the prediction factor

Step 9: Predict the disease based on the prediction value.

If  $n > 0.25$  as denoted as Disease

Else denoted as No disease

Step 10: Measure Ratio of problem and estimation using following problem.

$$x^2 = \sum \frac{(\text{observed} - \text{expected})^2}{\text{Expected}}$$

Step 11: Measure sensitivity and specificity using confusion matrix.

Step 12: Find the sensitivity using the attributes of correctly identified true positives.

Step 13: Find specificity that probability of a negative test given that the patient has no disease.

Step 14: Measure and tabulated accuracy using sensitivity and specificity values.

$$\text{accuracy} = \frac{(\text{No. TP}) + (\text{No. TN})}{(\text{No. TP}) + (\text{No. TN}) + (\text{No. PF}) + (\text{No. FN})}$$

To simplify the calculation, the magnitude of the gradient is taken into account by the HDLSDP. It is calculated by the Equation (6.1).

$$|\nabla f| = |h_x * f| + |h_y * f| \tag{6.1}$$

basic derivative filters are  $h_x = [1 \ -1]$  and  $h_y = \begin{bmatrix} 1 \\ -1 \end{bmatrix}$ .

The center of the filter is located in the middle of two adjacent horizontal or vertical pixels (i.e., the grid). In order to use a pixel (rather than a grid) as the center, the filter is expanded to three pixels. Equation (6.2)

$$h_x = [-1 \ 0 \ 1] \text{ and } h_y = \begin{bmatrix} 1 \\ 0 \\ -1 \end{bmatrix}$$

A pathological sample image after the derivation of gradient magnitude would unambiguously exhibit a crystal clear image for feature segmentation in order to determine the location of disease (or) for color conversation Figure 3 is a black and white image. HDLSDP then computes Background Markers for cleaning up the image, where dark pixels belong to the background. HDLSDP also does not place the background markers to be too close to the edges of the objects. HDLSDP then uses these markings and superimposes on the original image. A clear image of sugarcane with edges for further processing is resulted. Figure 4 exhibits the HDLSDP image Segmentation resulted after using FCM Clustering. HDLSDP then generates features set using GLRLM and GLCM as described in earlier part of this work. Table 1 lists HDLSDP Difference table for GLRLM features set. In Table 2 of the GLRLM difference table, the values 0.0269, 0.0514, 0.0666, 0.0467, 0.0195, and 0.0251 indicate abnormal growth. The non-uniformity values range from 0.02 to 0.04, further highlighting irregularities. In Table 6.2, values exceeding 2 (such as 2.2307, 2.2412, 2.8861, 4.5497, and 2.9124) strongly suggest the presence of anomalous growth. Therefore, based on the data from Tables 1 and 2, it is clear that disease or anomalous growth can be identified. Data for a set of 20 selected images

### Kumaravel and Umamaheswari

are provided in the table. HDLSDP generates a hybrid feature set from the data in Tables 3 and 4, which is then used for disease detection through HDLSDP, as shown in Table 5.

## CONCLUSION

HDLSDP employs thorough pre-processing to enhance image quality by detecting and removing edges, resulting in a clearer representation of the object. It addresses the challenge of segmentation for disease identification by using clustering to segment sugarcane images and isolate the diseased area from the base image. Feature extraction in HDLSDP leverages GLCM and GLRLM features, forming the foundation for prediction. A hybrid feature set, created from the GLCM and GLRLM features, is utilized for sugarcane disease prediction, with segmentation and feature generation serving as critical components.

### ABSTRACT

Disease detection on plants is very much essential and critical for sustainable agriculture and economic growth. This work involves tremendous amount of manual work, an expertise to guide, and absolutely excessive technical processing time. Henceforth, image processing plays an essential role in the detection of popular plant diseases like bacterial and fungal spots and blight. Since the data samples are hugely available as well accurate and deep learning of features is required in identifying the disease. This paper presents a Region based Convolutional Neural Network (R-CNN) based model for plant leaf disease detection and classification. The proposed work is composed of two major steps. First, using selective search, it identifies a manageable number of bounding-box object region candidates (“region of interest” or “RoI”), then it extracts features from each region independently using Convolution network (CNN) for classification. Few specific plants are considered for experiment - tomato, potato and pepper bell. The input image is analyzed and categorized as either healthy or unhealthy. In case of unhealthy, the respective disease will be suggested with pest management solution. Accuracy of RCNN model is compared with CNN model, which obtains a significant and better results.

**Keywords:** Classification; Deep Learning; Disease Detection; Region based Convolutional Neural Network

**Poornima and Sripriya****INTRODUCTION**

Earlier, the diseases in plants are detected using image processing methods. To improve the classification and understanding the features in detail, huge samples are required. Later, deep networks used for processing the huge samples faster and helps to analyze the features in all aspects. Therefore, in this paper, diseased part of the plant is detected using Region based convolutional neural networks, considering fundamental categories of plant diseases in leaves, namely, *Alternaria Alternata*, Anthracnose, Bacterial Blight, *Cercospora* leaf spot and Healthy Leaves. Mostly these belong to fungal, viral or bacterial type of diseases. The main contribution of this research work are as follows:

- To apply and implement the RCNN algorithm to monitor the growth of the crop and detect the diseased part in the plant.
- To classify the plant disease type.
- To incorporate the global optimization strategy for enhancing the optimal solution.
- To modify the existing solution more efficiently to solve this problem.

Background study of this field and initial experiments using image processing are done earlier and also discussed in [1]. The proposed methodology with model architecture and object detection techniques are discussed in below sections with experimental results.

**BACKGROUND**

Research works in plant disease detection and identification of pest and determining the other external factors like soil, environment, climate, etc were popularly done by many researches of India and china. After a decade, many studies have shown and proven that CNN's work is better in many image processing techniques. The reason is that CNN's automatically extract features without using a feature extraction algorithm explicitly. Later on, with the technical enhancement on Deep Convolutional Neural Network, found to be more efficient in identifying the fine-grained disease severity. Transfer learning with VGGNet, Inception-v3 and ResNet50 architectures are effectively used to build a powerful classification network. Initially as referred in [2], Data Preprocessing includes scaling of arbitrary shaped images in both the model optimization and prediction on the rescaled images. Both the model optimization and prediction is performed on these rescaled images as in [2]. Finally, several random augmentations including random rotation, shearing, zooming, and flipping are applied to the training images. This is followed by building the neural network training Algorithm. Architecture of convolutional neural network begins with several convolutional layers and pooling layers, followed by fully connected layers. The fine-tuned VGG16 model in [2] achieves an accuracy of 90.4% on the test set, demonstrating that deep learning is the new promising technology for fully automatic plant disease severity classification.

Furthermore, authors of [3], defined a novel structure of a deep convolutional neural network based on the AlexNet model by removing partial full connected layers, adding pooling layers, introducing the GoogLeNet Inception structure into the proposed network model, and applying the NAG algorithm to optimize network parameters to accurately identify the leaf diseases. Using a dataset of 13,689 images of diseased leaves, the proposed model was trained to detect leaf diseases. The standard AlexNet model reduces the number of parameters greatly, which has a faster convergence rate, and the accuracy of the model with supplemented images is increased by 10.83% compared with the original set of diseased leaf images. The results indicated that CNN-based model can accurately identify the common types of leaf diseases with high accuracy, and provides a feasible solution for identification and recognition of leaf diseases [3]. Infected part in the plant can be detected with help of color, and other changing properties by using classification algorithm [4]. There are many methods in automated or computer vision for disease detection and classification but still there is lack in this research topic. All the disease cannot be identified using single method. From study of above classification techniques we come up with following solution. The RCNN method is used for predicting the class of a test example. SVM was found competitive with the best available machine learning algorithms in classifying high-dimensional data sets. Deep understanding of features are essential to identify their classification. A study is made from various articles [3-6] to explore the design of deep convolution networks.

**Poornima and Sripriya****DESIGN****Dataset**

The Plant Village dataset (PVD) is the only public dataset for plant disease detection to the best of our knowledge. The data set curators created an automated system using GoogleNet and AlexNet for disease detection, achieving an accuracy of 99.35%. In contrast, we curate real-life images of healthy and diseased plants to create a publicly available dataset.

- The dataset consists of about 20600 images of plant leaves collected under controlled environmental conditions.
- The plant images span the following species: Pepper bell, Potato, Tomato.
- The dataset contains a total of 38 **classes** of plant disease

The proposed approach is as a dataset is collected and pre-processing, Splitting is done in order to separate data for validation, training and testing. The noise is not filtered out in the pre-processing as all the filtering happens during feature extraction. Initially all the images are written in the matrix form with randomly initiated values. Then the filters are initiated with values accordingly to extract the features required for classification. Back propagation is then followed to adjust the weights in the image matrix. The image is then converted into 2D vector then passed through a fully connected layer to obtain the output. Then based on the output, pest management is done which suggests the appropriate pesticide along with the volume to be used is suggested. The volume is suggested based on how fast the disease is spreading and severity of the diseased leaves

**Data Augmentation and Pre- processing**

This includes Augmenting data set Images and listing the images in each class. Augmentation includes rotating, flipping the image so as to create a new version of the image. This is done when the Dataset size is Insufficient. Pre-processing Includes splitting and removing the noise from data.

**Sample output**

Train size( Tomato\_Bacterial\_spot ): 1701

Validation size( Tomato\_Bacterial\_spot ): 319

Test size( Tomato\_Bacterial\_spot ): 106

**DETECTION MODEL****CNN**

The images are resized into 150×150 for faster computations but without compromising the quality of the data. Model takes raw images as an input, so we used CNN's (Convolutional Neural Networks) to extract features, in the model would consist of two parts. The first part of the model (features extraction) consists of 4 Convolutional layers with Relu activation function, each followed by a Max Pooling layer. The second part after the flatten layer contains two dense layers and has 256 hidden units which makes the total number of network trainable parameters is 3,601,478. The last layer has Soft max as activation and 10 outputs representing the 10 classes. The Relu is an activation function that does the non-linear transformation to the input making it capable of learning and performing more complex tasks. The Input image of size 150×150 is fed into the first convolution layer which yields an image of size 74×74. The size of the image is reduced as some of the features are extracted. Then Max pooling is done to further extract the most important features. After the image is passed onto three more convolution layers each followed by a max pooling layer, the size of the image is reduced to 7×7. Then the image is flattened by converting the image into a 2D vector. Then image is passed through a dropout layer to avoid overfitting. The image is then passed onto two dense layers which then gives the result.

**R-CNN**

R-CNN stands for "Region-based Convolutional Neural Networks". The main idea is composed of two steps. First, using selective search, it identifies a manageable number of bounding-box object region candidates ("region of interest" or "RoI"). And then it extracts CNN features from each region independently for classification

How R-CNN works can be summarized as follows:

### Poornima and Sripriya

1. **Pre-train** a CNN network on image classification tasks; for example, VGG or ResNet trained on ImageNet dataset. The classification task involves N classes.
2. Propose category-independent regions of interest by selective search (~2k candidates per image). Those regions may contain target objects and they are of different sizes.
3. Region candidates are **warped** to have a fixed size as required by CNN.
4. Continue fine-tuning the CNN on warped proposal regions for K + 1 classes; Additional one class refers to the background (no object of interest). In the fine-tuning stage, we should use a much smaller learning rate and the mini-batch oversamples the positive cases because most proposed regions are just background.
5. Given every image region, one forward propagation through the CNN generates a feature vector. This feature vector is then consumed by a **binary SVM** trained for **each class** independently.
6. The positive samples are proposed regions with IoU (intersection over union) overlap threshold  $\geq 0.3$ , and negative samples are irrelevant others.
7. To reduce the localization errors, a regression model is trained to correct the predicted detection window on bounding box correction offset using CNN features.

#### FEATURE EXTRACTION

Various features color oriented, shape oriented are extracted which plays significant role in determining the affected region of the leaves. Various features like mean, standard deviation, variance and others are extracted in order to know the health of the leaf.

#### EXPERIMENT AND DISCUSSION

##### Training

Model undergoes a learning phase to better fit the data. 80% of the dataset is used for training. 15% of the data set is used for validation. 5% of the images are used for testing. Total number of epochs used is 105 and there are 43 steps in each epoch. In each layer, the features that are important for classification are extracted. This is done by using a filter whose values are randomly assigned initially. The weights are re-assigned based on the learning accuracy using back propagation. The proposed algorithm is made to run for each individual image. Given below figure shows the detected disease for input image from a particular disease dataset. The CNN model achieves an overall accuracy of 98.6%. The model is confined to tomatoes but it can be extended to other plants also.

##### RCNN

**Analysis:** Plant leaf infected with the alternaria alternate is loaded from database. Contrast enhancement and preprocessing of image is done in the second phase. In image segmentation column one of the cluster is loaded. As the above figure shows the disease classified as Alternaria Alternata. Also area of the affected region in percentage is also shown. To check the accuracy of the our proposed methodology the image is passed through five hundred iteration and every time different clusters is chosen by the algorithm and then accuracy is predicted.

##### Performance evaluation

Different quantitative metrics are used in this work to evaluate the performance of the framework for plant disease detection using a deep learning model. To measure the effectiveness of this system, the accuracy is calculated. In calculating the accuracy, the values for true positive (TP), true negative (TN), false positive (FP) and false negative (FN) for plant leaf disease detection are counted. The results obtained are given in table 5 using the formula.
