ABSTRACT

Entomophagy is an old tradition in the world, lots of edible insect species were recorded, however no any moth stage were reported as edible till date. *Antheraea assamensis* Helfer (Lepidoptera: Saturniidae), endemic to Assam and adjoining areas of North-Eastern, India is renowned principally for its silk yarn as well as for the nutritious pupae. In addition with the pupae the adult stage (moths) of *A. assama* are also taken as a delicious food item (after egg laying) by the ethnic people of Dhemaji according to their availability. Hence, the present work has been undertaken to evaluate the nutritional composition of *A. assama* moths. The female moths were procured from the muga rearers of Dhemaji and the macronutrient compositions were analyzed using Association of Official Analytical Chemists guidelines (AOAC, 1990). It was recorded that the moths contained appreciable levels of Crude protein (67.55%), Crude fat (14.44%), Crude fiber (9.73%), carbohydrate (8.04%) ash (4.8%), moisture (18.89%) and gross energy (414.56 kcal/gm). Hence, the muga moths may be an ideal alternative food source.

Keywords: *Antheraea assama*, adult stage, nutritional composition, alternate food source

INTRODUCTION

Sericigenous insects are the silk producing insects. In the midst of the five different commercial silkworm breeds, mulberry silkworm (*Bombyx mori*), tassar silkworm (*Antheraea mylitta* and *Antheraea pernyi*), muga silkworm (*Antheraea assama*) and eri silkworm (*Samia ricini*), muga silkworm is widely reared regularly for its highly demanded

**Mallika Gogoi and Jharna Chakravorty**

silk. Together with the silk as a byproduct of mugaculture the edible delicious pupae and the adults are obtained. The Saturniidae family have 1200 to 1500 species around the world and in India about 40 species of silk moth are reported [1,2]. Muga silkworm, *Antheraea assamensis* Helfer is widely distributed in the Brahmaputra valley, North Cachar Hills and Karbi anglong District of Assam [3], as well as in other North Eastern states like Arunachal Pradesh (Lohit District, Dibang Valley, Changlang and Papumpare Districts), Manipur (Tamenglong District), Meghalaya (East and West Garo Hills), Nagaland (Kohima, Wokha, Mokochung Districts) and South Tripura [3]. *Antheraea assama* is very precious due to its lustrous and costliest golden colored silk thread. This sericigenous insect completes its life cycle in 5 larval stages. The pupae of *Antheraea assama* were recorded as the rich source of nutrition [4]. Along with the delicious pupae the adults, are also taken as luscious food item by the ethnic people of Dhemaji. Since they are semi domesticated starting from the seed up to hatching completed in indoor and subsequently the newly hatched larvae are shifted onto the outdoor host plants. Throughout the process of rearing (including both the indoor and outdoor) lots of traditional knowledges are applied and usually in the initial stage after emerging the moths, the rearers tied up the female moth on a stick made up of thatch grass and allowed to mate with male moths[5]. Hence, after mating and egg laying the females remains in tied up condition, and are taken as delicious dishes after frying or roasting. However the consumption of edible insects depends on a variety of factors like their taste, palatability, availability, nutritional value and traditional belief system of the people [6]. Lots of research has been done on the nutritional contents of muga pupae but still there is no any report available on the nutritional contents of muga moth *Antheraea assama* [7, 8]. However data has been obtained on the adult stage of different edible insect but no any silkworm has been reported as edible till date. Hence, the present work has been undertaken and the proximate contents of edible muga silkworm moth were assessed, which may be a good supplement of nutrition.

MATERIALS AND METHOD

To record the uses of adult stage of muga silkworm as edible item extensive field surveys in five villages of Dhemaji district of Assam were conducted. The villages were Napam gaon, Deogharia, Gohaingaon, Luguti and Nahoroni. We have randomly selected the households and interviewed one individual per house. The surveys were carried out during May 2016-2019. The villagers were informed the objectives of this survey that only for academic purpose this information's were collected and then they convinced. We have interviewed a total of 100 respondents (30 female and 70 males). They were interviewed through a semi structured questionnaire includes the availability of the muga adult, mode of consumption, nutritional value and therapeutic value etc.

Sample preparation

After collection of the samples from the field they were brought to the laboratory and the wings were cut off and washed thoroughly with filtered water, blotted dry and oven dried ground to powder and stored in air tight container in deep freeze -20°C under vacuum for proximate component analysis. All the solvents and chemicals used in the study were of analytical grade and care was taken that the glassware were meticulously clean.

Estimations**Proximate estimation**

Methods and techniques adopted for the analysis are recommended by the AOAC (Association of Official Analytical Chemists, 1990). The parameters determined were Moisture, crude Protein, crude Lipid, crude Fiber, Ash and Carbohydrate.

A: Moisture

Sample was weighed oven dried at 40°C to 50°C and cooled in desiccators. The process of heating and cooling is repeated till a constant weight is achieved. Moisture content was calculated using the following formula:

$$\% \text{ of Moisture} = [\text{Initial weight} - \text{Final weight}] \times 100 / \text{weight of the sample}$$

B: Crude Protein: Crude protein content of the samples was estimated by Micro Kjeldhal method. The nitrogen content determined was multiplied by a factor of 6.25 to obtain the amount of crude protein. Nitrogen content was

Mallika Gogoi and Jharna Chakravorty

calculated using following formula :

$$\% \text{ of Nitrogen} = [14.01 \times (S - B) \times 0.1 \times 100] / [W \times 1000]$$

Where, S= 0.1N HCl required for titration of sample (ml)

B= 0.1N HCl required for titration of blank (ml)

W= weight of sample (g)

C: Crude Lipid: The lipid from the samples was extracted by solvent extraction in petroleum ether (boiling point 60°C to 80°C) using Soxhlet apparatus (Rivotek, Riviera Glass Pvt. Ltd., India). Percentage of crude lipid was calculated using following formula:

$$\% \text{ of Crude lipid} = [(W_1 - W_2) / W] \times 100 \text{ Where,}$$

W₁= weight of flask along with lipid extracted (g)

W₂= weight of empty flask (g)

W= weight of sample (g)

D: Ash: For ash estimation the sample was weighed in a crucible, followed by heating in a muffle furnace for about at a temperature 600°C and cooled and weighed. Ash was determined by using the following formula:

$$\% \text{ of Ash} = \text{Weight of the ash} \times 100 / \text{Weight of the sample.}$$

E: Crude Fiber: Defatted sample was digested with 0.255N Sulfuric acid (H₂SO₄) and 0.313 N Sodium hydroxide (NaOH), followed by drying overnight in hot air oven (80°C to 100°C) and ashing in muffle furnace (600°C). Percentage of crude fiber was calculated using following formula:

$$\% \text{ of Crude fiber} = [W_e - W_a] \times 100 / W$$

Where, W_e= weight of dried sample after overnight drying (g)

W_a= weight of ash (g)

W= weight of sample

F: Total Soluble Carbohydrates

The nitrogen free extract (NFE) or soluble carbohydrate % was calculated by subtracting moisture, ash, fat, protein and fiber percent of sample from 100 using following formula:

$$\% \text{ of NFE} = 100 - [\text{ash}\% + \text{ether extract or crude fat}\% + \text{crude protein}\% + \text{crude Fiber}\%]$$

RESULTS

Our study revealed that they contained appreciable levels of crude protein (67.55%), crude fat (14.44%), crude fiber (9.73%), carbohydrate or NFE (8.04%) ash (4.8%), moisture (18.89%), and gross energy (414.56 kcal/gm) respectively.

DISCUSSION

Since this adult stage is consumed and there is no data available on the edibility of moth stage therefore, it is quite necessary to analyze the nutritional contents of adult *Antheraea assama*. Zhou and Han reported the proximate content of muga pupae *Antheraea pernyi* as moisture 7.6%, crude protein 71.9%, crude fat 20.1% and ash 4.0% on dry matter basis [9]. The nutritional analysis of Muga pupae *Antheraea assamensis* (non deoiled) recorded to contain 7.8% moisture, 61.63% protein, 17% fat, 3.3% fiber and 4.56% ash [10] which is comparable with the proximate contents of the adult muga. As the North East India especially Assam is rich in natural resources and muga silkworm is one of such bio resources. Due to the suitable environmental condition it is widely available and cultured in Assam. Mugaculture is an essential part of assamese culture and tradition and muga cloths are traditional costumes of Assamese people. They reared the silkworm, spin the muga silk yarn and weave the cloths by themselves. Hence, it is a very noble idea of taking the waste products as delicious item. Along with the pupae the adults may also provide nutrition to the human being and as well as for other living being. It has been recorded from our study that the moths

Mallika Gogoi and Jharna Chakravorty

contain good quantity of protein, fat, fiber, ash and NFE. The analysis for micronutrient content is a need for the future and it will definitely show many more new findings. However, it may also contain some harmful components and hence further research is needed. Although the insects are consumed at various developmental stages including the eggs, larvae, pupae and adults [11] however the *Lepidopteran muga* adults are still not recorded for its edibility.

ACKNOWLEDGEMENT

Authors are grateful to the villagers for their assistance and sharing their precious information's throughout the research work.

ABSTRACT

The present study were investigated the systematic survey of Molluscan fauna in an around Coastal Area, Southern India between November 2023 to February 2024. Totally 33 Species of Molluscan Species were identified. Among the various faunal groups recorded from the Coastal area viz., Velankanni, Nagapattinam, Akkaripettai and Nagore, recorded from marine regions of India. A total of 33 species of molluscs were collected and identified. 25 species were gastropods while 8 were bivalves. Among them 25 Gastropoda and 8 Bivalvia were recorded. Totally 25 Gastropoda Species were collected during the study viz., (*Turritellacommunis*, *Canariummutabile*, *Tibia fusus*, *Murex pecten*, *Fusinus forceps*, *Rapanavenosa*, *Turbo mamaratus*, *Cypreatigris*, *Busycotopuscanaliculatus*, *Harphaarticularis*, *Semicassisbisulcata*, *Turvinellaalgalada*, *Laambis truncate*, *Xancuspyrum*, *Babylonia spirata*, *Ficusficus*, *Conus gradates*, *Chicoreusvirgineus*, *Babylonia japonica*, *Clavusbilinealus*, *Tonnadoliun*, *Phaliumglacum*, *Galeodearugose*, *Architectonicaperspectiva*, *Neveritajosephinia*) and 8 Bivalvia were recorded viz., (*Pectenmaximus*, *Anomia simplex*, *Cerastodermaedule*, *Tagelussubters*, *Pectenjacobaueus*, *Donexovariabile*, *Poradapestextilis*, *Argopectengibbus*). The distributions of molluscan fauna were influenced by various parameters such as salinity, temperature and water depth. Collected specimens were preserved in 90% formalin. The shells thus processed have been identified with the available guides,

Keywords: Molluscan fauna, Gastropoda, Bivalvia.

INTRODUCTION

Molluscs are among the most abundant of all animal. Among Marine taxa, Molluscs have achieved notable evolutionary divergence over the Phanerozoic and acquired a unique variety of morphologies (Scpkoski 1981[1],

**Vallipriyadharshini and Sumathi**

Russell Hunter 1983)[2]. In Particular; the evolution of a hard outer skeleton (Shell) has been associated with a great divergence of morphologies in group. White shell is useful of as an effective to the internal tissue(Stanley 1970,[3] 1988, Vermeij 1977[4], Raffalli 1982[5], Kardon 1988[6]).The whole body is covered by a single layer of epithelium, which, in parts not protected by the shell. The ventral side of the body in the Mollusca is characterised by the pronounced Development. The foot may become much modified in adaptation to various methods of life and of locomotion, in fact, it may entirely lose all resemblance to the primitive organ. The Molluscs are widely distributed in both time and space and have a rich and continuous fossil record since Cambrian time. They may be found on sea. There is scarcely and portion of the coast line of the world without Molluscan life. Except in regions of extreme cold. The Molluscs are of diversity from and size. Calcium Carbonate is a major component of Molluscs shells and is available in abundance in marine environments. But other components, particularly protein, are metabolically coastal to produce(Palmer 1983)[7]. Many Molluscs are considered keystone species and lor ecosystem engineers promoting nutrient recycling, soil generation and water filtration (Atkinson *et al* 2013[8]; Gomez-Chiarriet *al* 2015[9]; Schell *et al* 2017[10]; Sun *et al*; 2017[11],Powell *et al.*, 2008)[12]. Shell of molluscs, "chip" is always attraction of collection when one visits sea shore. Molluscs is the Second largest phylum of invertebrate animals. After Arthropoda Members are known as Molluscs. The group has enormous diversity, both in shape and size. Their ecology is also very diversity, for they have been able to live in nearly all kinds of habitat-from the depths of the ocean to some of the highest altitudes recorded for life. In Structure and functional adaptation, molluscs rank with the arthropods because some of the most unique invertebrate behaviour patterns are found among them. Most molluscan live in the sea.Molluscs are among the most ancient, widely diverse and ecological successful group of metazoans. The fossil record of molluscs can be tracked back to the earliest Cambrian period.(Ponder & Lindberg 2008)[13]. The shell has many evolutionary adaptations, such as heavy shells for withstanding stress and pressure, boring and burrowing shell for penetration, swimming shells for locomotion, and reduced shell for preventing encumbrance. Secretion of dorsal shell which in the beginning might have been in the form of layer of cuticle containing calcareous particles and would have served as a protective covering. It is believed, on the basis of biological studies made on molluscs, that all primitive univalves and bivalves had separate sexes, that there were no accessory sexual organs and that the ova and sperm were directly and freely discharged into the seawater. The shell-of ectodermic origin is produced by a group of cell located on the posterior side of larva. These cells field(Kniprath 1981).[14] The Shell is secreted by the mantle. Molluscan have a mantle. Molluscan have a mantle or mass of soft flesh that cover the body and encloses the internal organ.

STUDY AREA

The Present Study was carried out in The District of Nagapattinam lies on the shores of Bay of Bengal between latitude 10.7906°N and Longitude 79.8428°E and area of 1,379 square kilometres (539 sq mi). The District Capital, Nagapattinam lies on the Eastern coast.

Study Site

I have Selected 4 different stations for data collection they are

1. Nagapattinam Coastal Area
2. Akkarapettai Coastal Area
3. Nagore Coastal Area
4. Velankanni Coastal Area

Nagapattinam Coastal Area

Nagapattinam Beach is a famous beach in Tamil Nadu known for its Pristine Sand, Clear blue water and peaceful environment. Nagapattinam is one of the oldest port cities of chola empire. It was called as "Navalpattinam". A coastal district of Tamil Nadu on the eastern coast, Bey of Bengal, 326km, South of the state capital Chennai. The District capital Nagapattinam lies between Northern Latitude 10.7906 degrees and 79.8428 degrees Eastern Longitude.

**Vallipriyadharshini and Sumathi****Akkaraipettai Coastal Area**

Akkaraipettai is a fishing village located in Kelvelur Taluk Nagapattinam district in the State of Tamil Nadu, India. This is surrounded by the water, so called Akkaraipettai. A Majority of the people of Akkaraipettai are employed in sea-borne trading, fishing, Agriculture, Tourism and merchant navy. Coordinates 10.7429°N 79.8490°E.

Nagore Coastal Area

Nagore beach is very calm, small and natural beach. Good for rest and play. Located 6 km from Nagapattinam, Nagore Beach; a popular beach. Nagore beach in Nagapattinam is one of the leading businesses in the Tourist Attraction. Coordinates 10.82°N, 79.85° E.

Velankanni Coastal Area

Velankanni is one of the most visited Pilgrim centres in India. It is a town situated on the shores of Bay of Bengal. Velankanni is special Grade Town in Nagapattinam District in India state of Tamil Nadu. It lies on the coromandel coast of the Bay of Bengal, 12 km of Nagapattinam. Coordinates 10.40°N 79.49°E.

MATERIAL AND METHOD**Study Period**

The Survey and data collection on the population of molluscs from were conducted between November 2023 – February 2024.

Study Area

In order to understand the Molluscan diversity and enlist the Molluscan Population among the coastal wetlands the following Coastal Wetland the following Coastal wetlands (Area) Nagapattinam, Akkaraipettai, Nagore, and Velankanni.

Identification of Gastropods

Gastropods can be recognised by their large foot, tentacles, coiled shell and the presence of torsion, which is where the body is twisted round so that the anus, reproductive organs, mantle cavity, and gills all point forwards.

Identification of Bivalvia

Bivalvia have no head and they lack some usual molluscan organs, like the radula and the Odontophore. Have two hard, usually bowl-shaped, shells, enclosing the soft body.

Collection and preservation of Molluscan Form

Mollusc forms are generally found in the mudflats on the sea shore areas of and estuary the Mollusc have adapted to all habits. Although basically marine. Extensive surveys were conducted in the low total area of sea shore by walk and shells were collected. The collected animals and shells were brought to the laboratory, cleaned and preserved in 5-10% formalin later they were identified up to species level by using the identification of Apte (1998)[15]. Subtleties in the size, direction, number and type of ridges, knobs, folds, striations, crosshatching, spike height or compression, colour markings around the hip or crown. Length of siphon channel, shapes of opening and inner marking or ridges from the fore going discussion it is assembled that to study the different tropical community in order to understanding the dynamic of a habit.

OBSERVATION AND RESULT

The variation among 33 different Molluscan species were identified and also observed. Taxonomically classified and identified all Molluscan Species during Study Period. As Coastal Wetlands are especially important for some present Study has been undertaken to assess the biodiversity in of Molluscan. All the above studies have been carried out in

Vallipriyadharshini and Sumathi

the some selected Coastal Area of Some East Coast of India, Nagapattinam, Akkaraipettai, Nagore, Velankanni. Variations in Temperature, Chemical Properties of water are observed in sea Wetlands during the study period. Totally 33 different Species of Molluscan Shell species observed in Wetlands studies, the Molluscan was identified by Common Name, Scientific Name, Order, Family and Characters group and habitat. They are Eight Order viz, Caenogastropoda, Littorinimorpha, Neogastropoda, Trochida, Pectinida, Cardiidae, Venerida, Mesogastropoda and Twenty four Families viz, Turritellidae, Stombidae, Rostellariidae, Muricidae, Fasciolaridae, Turbinidae, Cypracidae, Pectinidae, Busyconidae, Anomidae, Cardiidae, Solecurtidae, Harpidae, Cassidae, Turbinellidae, Babalonidae, Fidae, Conidae, Donacidae, Drilliidae, Tonnidae, Veneridae, Architectonicidae, Naticidae. These Molluscan Species were Classified into Four Basis Foot, Mantle, Shell and Visceral mass. Among them 13 Species belong to Order Neogastropoda, 9 Species of Littorinimorpha, 4 Species of Pectinida, 3 Species of Cardiida, 1 Species to Caenogastropoda, Trochida, Veneridae, Mesogastropoda. All the Molluscan Species are Classified to the Taxonomic family which 3 Species Turbinidae, Pectinidae, Cassidae, 2 Species Muricidae, Turbinidae, Babyloniidae, 1 Species to Turritellidae, Stombidae, Rostellariidae, Fossicotarridae, Cypraeidae, Busyconidae, Anomidae, Cardiidae, Solecurtida, Harpidae, Fidae, Conidae, Donacidae, Drilliidae, Tonnidae, Veneridae, Architectonicidae, Naticidae. The present study on the Molluscan Population is due to some environment changes. After that resident and local resident Molluscan Species. Hence it is suggested in future research studies would provide valuable information and relationship between play a role the variation of Biodiversity

DISCUSSION

The Present study documented 33 Species of Molluscs among 25 Gastropoda Species, 8 Bivalvia Species, were identified from different habitat around Nagapattinam Coastal Area. Ecologically to this important group (Fabry *et al.*, 2008)[16]. With Their organism nested deeply with in Ediacaran Molluscan have a lively and fascinating evolutionary history. Recent Advantages in palaeontological, Phylogenetic Development and experimental approach have revealed some of mysteries revolving around the emergence of large phenotypic diversity encountered in modern and fossil species (Perry & Henry 2015)[17]. The higher diversity of gastro, Molluscs provide essential ecosystem services including habitat structure. For benthic organism, act as biological filter to purify polluted estuarine water are a good a for other organism. The conservation of Biological Diversity requires the Inclusion of biodiversity in Environmental Assessment, since recommended to devote more effort to repeated measurement is space and time than to a few sites on a short timescale (Costello *et al.*, 2004)[18]. Several Studies focused on the Molluscan fauna have been carried out in worldwide continental shelves. Algae or seagrass meadows, maerl and other hard substrate types tend to be richer in species than soft-bottom (Riera *et al.*, 2012)[19]; Urra *et al.*, 2013)[20]. Thus Molluscs have been used as community surrogates in these ecosystem because they are a group of animals with a wide ecological spectrum and which use a considerable portion of environmental resources due to their distribution and diversity, furthermore, they are important in food chains because they can be detritivores, herbivores, carnivores or omnivores (Levinton 1995)[21]. A number of studies have been conducted on various biological aspects Molluscs, along with Biodiversity and distribution patterns (Lowry *et al.*, 1974)[22]. The Mollusca diversity of Great Nicobar island (Arumugamet *et al.*, 2010)[23] and biodiversity of Barren island – Chandra and Rajan 2010)[24] were also studied recently. Among Various functions that shells may play, defence against predators is considered that most important from an evolutionary point of view (Vermeij, 1987)[25].

ABSTRACT

Macerated oil is prepared by infusing desired plant parts in a carrier or base oil of interest that could be either sunflower oil, sesame oil, olive oil or coconut oil for a specific period of time. This infusion is packed with enormous medicinal compounds that is being widely utilized in many pharmaceutical applications such as in aromatherapy, healing as they do not exhibit any toxic or side effects since, their preparation is devoid of chemicals and enriched only with natural compounds. It is also referred to as "Infused oil" and is known to possess numerous biological properties as a result of active compounds derived from plants. In the present study, Infused oil was prepared using dried plant leaf samples from *Mangifera indica* L. and *Piper betle* L. The carrier or base oil used in this preparation is Virgin Coconut oil. Infused oil was prepared by two methods – a) With heating (+H) and b) Without heating method (-H). The corresponding weight of infused oil was calculated. Physicochemical properties such as acid value, saponification value, ester value, free fatty acid value, insoluble impurities were evaluated and determined for the presence of fatty acid components in the oil by GC-MS analysis.

Keywords: Infused oil, Medicinal plants, Active compounds, Carrier oil, Physicochemical properties, GC-MS analysis.

INTRODUCTION

Bioactive compounds from plant sources encompass innumerable therapeutic properties and their functions vary with polarity i.e., From highly polar to highly non polar components each with a unique biological activity. These plant metabolites can be extracted through various techniques and one among these is maceration or also referred to as infusion. Infusion is the process wherein the powdered plant parts are kept immersed in the desirable solvent or carrier oil for a certain period of time allowing the complete extraction of phytocomponents into it and is suitable for delicate tissues like flowers, leaves and soon. [1]. Herbal oil thus prepared by infusion contains maximum number of beneficial compounds derived from plants along with the fatty acids in carrier oil thereby elevating the efficacy of oil for usage in wide therapeutic applications. Infused oil derived from plant source has been widely used since ancient times in treating inflammatory conditions [2] and are utilized in the form of medicines, perfumes, stabilizing agents, as disinfectants and so... [3]. They are also reported to play a vital role in pharmacological applications as antioxidants, in treating harsh skin conditions and hair fall, in healing wounds, reducing sprains and inflammation. The properties of herbal infused oil could also be further enhanced with the addition of ingredients like flavours, aromatic compounds and fragrances, gel/ ointment base depending upon the nature of usage. Assessment of oil quality is important in determining the purity, stability and suitability of oil for usage in various applications and can be evaluated based on their physicochemical properties [4,5]. Infused herbal oil can be prepared by means of either hot infusion method or cold infusion method i.e., with heat or without heat. However, the nature of carrier oil used, method of extraction and temperature employed also plays an important role in imparting the properties to the final product. In the current scenario, plant derived oils are gaining more attention and importance in the pharmaceutical industry since they are naturally derived, cost effective, safe and could have less or no negative impacts on our health. Virgin coconut oil contains fatty acids such as palmitic acid, myristic acid, linoleic acid, that have specific functional as well as medicinal properties [6]. They are also reported to contain high amount of phenolic compounds exhibiting antiproliferative activity, anticancer activity and also, used traditionally in treating hair and skin conditions [7]. The present study deals with preparation of infused oil from leaf samples of two medicinal plants *Mangifera indica* L. and *Piper betle* L. The dried and powdered plant leaf samples were infused in Virgin coconut oil as the carrier oil employing both the methods of, with heating (+H) and without heating (-H). Weight of infused oil obtained along with their physicochemical properties such as acid value, saponification value, ester value, free fatty acid value, insoluble impurities were evaluated. Bioactive components present in the oil samples were also determined by means of Gas Chromatography – Mass Spectrometric (GC-MS) analysis.

MATERIALS AND METHODS

Collection and authentication of Samples

Leaf samples of two medicinal plants *Mangifera indica* L. and *Piper betle* L. were collected from different localities and authenticated by Prof P. Jayaraman, Director, Plant Anatomy Research Centre (PARC), West Tambaram, Chennai. The collected samples were cleaned, dried, powdered and stored at 4°C until further use.

Preparation of Infused oil

Infused oil was prepared using the powdered leaf samples of *Mangifera indica* L. and *Piper betle* L. employing 2 methods.

With heating (+H)

About 5 grams of dried plant leaf samples were added individually to 50 ml of virgin coconut oil taken in a conical flask in the ratio of 1:10. The samples were heated on water bath at 60°C for about 30 minutes to allow complete infusion. It was then cooled and filtered. Infused oil thus obtained was stored in bottles at 4°C.

Leela and Anita R J Singh

Without heating (-H)

About 5 grams of dried plant leaf samples were added to 50 ml of virgin coconut oil taken in a glass bottle in the ratio of 1:10. It was covered and incubated for about a week at room temperature with frequent shaking to allow complete infusion. The oil was filtered and stored in bottles at 4^o C.

Determination of Weight (g) of Infused oil

Weight (g) of infused oil obtained by both the methods: With heating (+H) and Without heating (-H) was calculated using the formula:

Weight of Infused oil [g] = Weight of beaker + Oil [W₂] – Weight of Empty beaker [W₁]

Physicochemical Properties of Infused oil

Physicochemical properties of Infused oil such as Acid value, Saponification value, Ester value, Free Fatty acid (FFA) value and Insoluble impurities were determined [8-13].

Preparation of Fatty acid Methyl esters (FAME)

FAME preparation was carried out by means of Base catalyzed derivatization method. 2g oil sample was mixed with 16ml of 0.5M Methanolic KOH solution and heated at 50°C for 20 secs. 40 ml hexane was added and vortexed for 30 secs. It was allowed to settle and the top layer was collected. To that, about 16ml of 2N Methanolic HCL was added and vortexed. The solution was allowed to settle and the top layer collected was used for further GC-MS analysis [14].

GC-MS analysis

Gas Chromatography – Mass Spectrometry (GC-MS) analysis for the Fatty acid Methyl esters [FAME] of Infused oil from *Mangifera indica* L. and *Piper betle* L. was carried out using GC-MS Shimadzu QP2020 instrument with SH-RXi-5Sil MS Column and Helium as the flow gas. The conditions followed for GC-MS analysis was given - Column Oven Temperature: 50.0 °C, Injection Temperature: 250.00 °C, Pressure: 68.1 kPa, Total Flow: 16.2 mL/min, Column Flow: 1.20 mL/min, Linear Velocity: 39.7 cm/sec, Purge Flow: 3.0 mL/min, Split ratio: 10.0, Ion source temperature: 200.00 °C and Interface temperature: 250.00 °C. Oven Temperature Program was maintained as follows:

Rate	Temperature (°C)	Hold Time (min)
-	50.0	0.00
6.00	280.0	2.00

Spectrums of the components were compared with the database of spectrum of known components stored in the GC-MS NIST and WILEY library.

RESULTS AND DISCUSSION

Infused oil Preparation

Infused oil was prepared using the dried and powdered leaf samples of *Mangifera indica* L. and *Piper betle* L. with Virgin Coconut oil as base employing 2 methods: With heating (+H) and Without heating (-H). Weight (g) of Infused oil was calculated for about 50ml of oil sample. The weight of infused oil obtained was found to be higher in samples prepared with heating (+H) than samples prepared without heating (-H). Among the oil samples prepared by heating (+H) method, *Mangifera indica* L. showed higher yield with 45.793 g followed by *Piper betle* L. with 45.077 g [Figure 1].

Determination of Physicochemical properties of Infused oil

Physicochemical properties such as Acid value, Saponification value, Ester value, Free fatty acid value and Insoluble impurities were determined to understand the quality and efficacy of infused oil for therapeutic applications. Acid value is calculated as mg KOH / g oil and it indicates the quality of oil. Acid value was found to be higher in infused oil prepared without heating method (-H). Among the (-H) samples, *Piper betle* L. showed higher acid value with 5.049 mg KOH/g oil followed by *Mangifera indica* L. with 4.488 mg KOH/g oil while, samples prepared with heating

Leela and Anita R J Singh

method (+H) showed lower acid value with *Piper betle* L. having 2.244 mg KOH/g oil and *Mangifera indica* L. with 1.683 mg KOH/g oil [Figure 2]. Acid value determines the quality of oil wherein, higher acid value indicates deterioration of oil quality while, lower acid value indicates good quality of oil[15]. Saponification value is expressed as mg KOH/g oil and was found to be higher in oil prepared with heating method (+H) showing increased value in *Mangifera indica* L. with 424.022 mg KOH/g oil and *Piper betle* L. with 396.907 mg KOH/g oil while, oil prepared without heating method (-H) showed lower Saponification value for *Mangifera indica* L. with 337.067 mg KOH/g oil and *Piper betle* L. with 317.432 mg KOH/g oil [Figure 3]. Higher saponification value indicates short chain fatty acids with lower molecular weight that can be easily saponified and indicates good quality of oil while, low saponification value indicates long chain fatty acid with higher molecular weight that cannot be saponified [16]. Ester value is calculated as the difference between saponification value and acid value and is expressed as mg KOH/g oil. Ester value was found to be higher in infused oil prepared with heating method (+H) than the oil samples prepared without heating (-H). Among the oil samples prepared by heating (+H), *Mangifera indica* L. showed higher ester value of 422.339 mg KOH/g oil followed by *Piper betle* L. with 394.663 mg KOH/g oil [Figure 4]. Free fatty acid value was found to be lower in samples prepared with heating (+H) method compared to the samples prepared without (-H) heating. Among the (+H) samples, *Mangifera indica* L. showed Free Fatty acid value of 0.841 and *Piper betle* L. with 1.121 respectively [Figure 5]. Insoluble impurities were also found to be slightly lower in the (+H) samples compared to the (-H) samples. Among the (+H) samples, *Piper betle* L. showed 0.064 g while, *Mangifera indica* L. had 0.049 g insoluble impurities/ g oil [Figure 6]. Based on the yield obtained and its physicochemical properties, Infused oil prepared with heating method (+H) was selected and subjected to GC-MS analysis in order to determine the presence of bioactive components in the oil extracted from the plant samples.

GC-MS analysis

GC-MS analysis was carried out for the infused oil sample prepared using *Mangifera indica* L. and *Piper betle* L. Based on the physicochemical analysis, oil prepared by heating method (+H) was further subjected to Base catalyzed derivatization method and the fatty acid components in the infused oil were determined by means of GC-MS analysis. GC-MS Chromatogram of oil samples are given in Figures 7 and 8. *Mangifera indica* L. infused oil showed the presence of totally 21 compounds with corresponding retention time such as (1) Octanoic acid, Methyl ester [9.665]; (2) Cyclohexasiloxane, dodecamethyl- [13.857]; (3) Decanoic acid, Methyl ester [14.32]; (4) 1,3-Diphenyl-1-((Trimethylsilyl)oxy)-1(Z)-Heptene [17.467]; (5) Dodecanoic acid, Methyl ester [18.598]; (6) Tri-O-Trimethylsilyl, N-Pentafluoropropionyl derivative of Terbutaline [20.701]; (7) Tetradecanoic acid, Methyl ester [22.45]; (8) Phosphonous dibromide, [2,2,2-Trifluoro-1-(Trifluoromethyl)-1-[(Trimethylsilyl)oxy] Ethyl]- [23.497]; (9) Hexadecanoic acid, Methyl ester [25.938]; (10) (Z,Z)-Heptadeca-8,11-Dien-1-yl bromide [28.605]; (11) 9-Octadecenoic acid, Methyl ester [28.714]; (12) Octadecanoic acid, Methyl ester [29.119]; (13) Diisooctyl phthalate [34.753]; (14) 2,5-Dimethyl-1,3,5-Dithiazine [36.126]; (15) Methyl 3-Methyl-5-Oxy-2-Phenoxyhexanedithioate [38.742]; (16) 2-Fluoro-5-trifluoromethylbenzoic acid, propyl ester [38.88]; (17) N- {2- [2'- (5'' - Chloro - 1'' - Oxopentyl) - 4', 5'-Dimethoxyphenyl] Ethyl} Chloroethanamide [38.945]; (18) Ethyl 2-Cyano-2-(P-Methoxyphenyl)-3-Methylpentanoate [38.995]; (19) 4-Methyl-1H-Pyranolo [4,3-C] Pyridine [39.26]; (20) 14,19-Dioxoundecacyclo [9.9.0.0 (1,5). 0(2,12). 0(2,18). 0(3,7). 0(6,10). 0(8,12). 0(11,15). 0(13,17). 0(16,20)]icosane-4-syn, 9-syn-dica [40.055] and (21) 4-Methyl-1H-Pyranolo [4,3-C] Pyridine [40.207] [Figure 7]. *Piper betle* L. infused oil showed the presence of totally 19 compounds with corresponding retention time such as (1) Octanoic acid, Methyl ester [9.664]; (2) Cyclohexasiloxane, dodecamethyl- [13.859]; (3) Decanoic acid, Methyl ester [14.32]; (4) 1,3-Diphenyl-1-((Trimethylsilyl)oxy) -1(Z) -Heptene [17.467]; (5) Dodecanoic acid, Methyl ester [18.598]; (6) Tri-O-Trimethylsilyl, N-Pentafluoropropionyl derivative of Terbutaline [20.701]; (7) Tetradecanoic acid, Methyl ester [22.45]; (8) Hexadecanoic acid, Methyl ester [25.939]; (9) (Z,Z)-Heptadeca-8,11-Dien-1-yl Bromide [28.608]; (10) 9-Octadecenoic acid, Methyl ester [28.714]; (11) Octadecanoic acid, Methyl ester [29.12]; (12) 1,2-Benzenedicarboxylic acid, Dioctyl ester [34.753]; (13) 6,6-Dimethyl-9-Methylenebicyclo [3.3.1] Nonan -3-one [36.127]; (14) 1,4-Diphosphorin, 1,4-Dihydro-1-Phenyl-4-(Phenylmethyl)-, Cis- [39.02]; (15) Methyl 3-Methyl-5-Oxy-2-Phenoxyhexanedithioate [39.173 and 39.883]; (16) 1,8-Naphthalenediol, 1, 2, 3, 4, 4A, 5, 8, 8A-Octahydro - 4, 4, 8A-Trimethyl-6-(Phenylthio)-, (1. Alpha., 4A. Beta., 8. Alpha., 8A. Alpha.)- [39.599]; (17) Ethyl (1R*, 2S*, 11R*) - (+)-3,10-Dioxo-2,11-Epoxy cyclodecane-1-Carboxylate [39.705]; (18) Butanedioic acid, 2-Ethyl-2-(Phenylthio)-, 1-Ethyl ester [39.995]; (19) Benzamide, 2-Methyl-3,5-Dinitro- [40.185] [Figure 8].

Leela and Anita R J Singh

CONCLUSION

Plant based oil have enormous benefits that can be utilized for various therapeutic purposes. In this study, Infused oil prepared from the dried leaf samples of *Mangifera indica* L. and *Piper betle* L. were analyzed for their physicochemical properties and also determined for the presence of bioactive components by means of Gas Chromatography – Mass Spectrometry [GC-MS] analysis. Further studies can be carried out to explore the pharmacological importance of infused oil and their bio component based drugs in treating various diseases.

ACKNOWLEDGEMENT

ABSTRACT

Limonene is widely recognized as one of the most prevalent compounds in the essential oils derived from aromatic plants. Its presence as a monoterpene hydrocarbon in diverse plant genera can be attributed to its precursor role in the biosynthesis of other monoterpenes and its defensive capabilities against herbivores. The extensive investigation of limonene is attributed to its medicinal potential and its roles in the flavor and fragrance industries. This paper seeks to provide a comprehensive overview of the biosynthetic, ecological, and aromachological relevance of limonene, consolidating prominent insights from diverse studies into a brief review.

Keywords: Limonene, monoterpene, aromachology, bioconversion, biosynthesis

INTRODUCTION

Limonene, scientifically designated as 1,8-p-menthadiene or 1-methyl-4-(1-methylethenyl-cyclohexene), ranks among the most prevalent constituents of essential oils derived from aromatic plants. Its presence is widespread across various plant genera, which can be attributed to its role as a precursor for numerous monocyclic monoterpenoids. Many monoterpenes that feature the 1-*p*-menthene skeleton, including carveol, carvone, α -terpineol, pulegone, and 1,8-cineole, originate from limonene (Kjonaas and Croteau, (2003); Berteau et al.(2003). This compound exhibits optical

**Nissam Sainudeen et al.,**

activity and exists in two enantiomeric forms, namely R and S. The R-(+)-enantiomer, commonly referred to as d-limonene, predominates in the essential oils extracted from the peels of citrus species, while (+)-limonene is a cost-effective byproduct of orange processing (Arreola et al. (2005); Wang et al. (2008)). Furthermore, it is frequently found in certain species of *Lippia* and *Artemisia* (Gurgel do Vale et al., (2002); Sayyah et al., (2004). Conversely, Kokkini et al., (1996) reported that the l-limonene is primarily located within the essential oils of *Pinus*, such as those from pine needles, and *Mentha* species, including spearmint. Limonene is frequently added to many products to improve flavor and fragrance, including perfumes, drinks, soaps, detergents, and cleaning products. It also serves as a starting material for making other natural products like p-cymene. Taking into account the considerable amount of reports, its potential health benefits, and its use in cosmetics and household products, it's crucial to compile research on this important substance.

Biosynthesis of limonene in plants

Limonene is synthesized from geranyl pyrophosphate, following a pathway that includes a stable cationic intermediate, leading to the production of limonene along with other monoterpenes (Mann et al. (1994). The process of hydroxylation of limonene occurs at the C3 position via cytochrome P450, leading to the generation of (–)-trans-isopiperitenol, or alternatively, it can be hydroxylated at the C6 position to yield (–)-trans-carveol. Furthermore, carveol is subject to a dehydrogenation reaction that transforms it into the monoterpenoid carvon (Croteau et al. (1991). The transformation of carveol to carvone may be attributed to stability, with the formation of a conjugated cyclic ketone serving as the primary driving force for this reaction. This process may, among other factors, account for the relatively low concentrations of carveol found in many essential oils. Monoterpenoids that originate from limonene, including carvone and 1,8-cineole, are the predominant compounds in the essential oils extracted from *Mentha* and *Eucalyptus* species, respectively. The study by Kokkini et al. (1996) revealed that several *Mentha* species have essential oils with high carvone content, ranging from 50% to over 75% and limonene levels ranging from 3% to 20%. Elss et al. (2007) indicated that under acidic storage conditions, limonene-rich juices can convert some limonene into α -terpineol and carvone, depending on the oxygen levels. They also noted that a considerable amount of limonene comes from the essential oils of oven-dried *M. longifolia* leaves. Asekun et al. (2007) conducted a comparative analysis of the chemical compositions of essential oils from leaves treated in various ways, revealing that fresh leaves were predominantly rich in pulegone (35%), whereas the oils from oven-dried leaves were characterized by a higher concentration of limonene (40.8%). This finding supports the earlier research conducted by Lange et al. (2000), which indicated that limonene acts as a precursor in the biosynthesis of pulegone within the glandular trichomes of *Mentha* species.

Microbial conversion of limonene into oxygenated derivatives:

In recent days, there has been a notable increase in research focused on the biotechnological production of aroma molecules derived from monoterpenes like limonene as a result of the escalating demand for 'natural' fragrance materials in the flavor and fragrance markets (Chotani et al. 2000). The current focus is on employing microorganisms as biological vehicles for converting limonene and other monoterpenes into diverse oxygenated derivatives. This microbial biotransformation of monoterpenes is advantageous due to its ease of manipulation, the ability to operate under mild reaction conditions, high efficiency, and regio- and stereoselective outcomes (Houjin et al. 2006). The initial documentation of bioconversion can be traced to the 1960s, during which limonene underwent microbial conversion, resulting in the formation of several neutral and acidic compounds (Dhavalikar and Bhattacharya, (1966). Numerous studies have since emerged that explore the use of microbes for the bioconversion of limonene into a range of derivatives. *Pseudomonas incognita* and *P. gladioli* were among the pioneering bacterial species utilized in limonene metabolism studies. *P. incognita* has been found to metabolize limonene into dihydrocarvone, carvone, and carveol, while *P. gladioli* is known for converting limonene into α -terpineol and perillic acid (Cadwallader et al. (1989 and 1992). α -Terpineol is prevalent in natural sources and plays a significant role in the perfumery market. The research conducted by Duetz et al. (2001) indicates that soil microorganisms such as *Rhodococcus opacus* and *R. globerulus* have been utilized in bioconversion research. In contrast to the *Pseudomonas* assays, the *Rhodococcus* species demonstrated superior limonene metabolism, resulting in high yields of end products. In a chemostat culture where toluene served as the carbon and energy source, *R. opacus* exhibited both

**Nissam Sainudeen et al.,**

regioselectivity and stereospecificity in its conversion of limonene, exclusively hydroxylating the C6 carbon to produce enantiomerically pure (+)-trans-carveol with a yield of 97% and trace amounts of carvone. Conversely, *R. globerulus* displayed limited activity in a separate bioconversion, further oxidizing much of the generated trans-carveol into (+)-carvone. In addition, Hamada et al. (2003) indicated that the stereo- and regioselective hydroxylation of limonene has been successfully performed using the *Cyanobacterium*, *Synechococcus elongatus* PCC 7942. Following a six-hour incubation, the microorganism hydroxylated the allylic position (C6) of the endocyclic C=C double bonds of (S)-(-)-limonene, yielding cis- and trans-carveol at 11% and 9% yields, respectively. In contrast, under the same experimental conditions, (R)-(+)-limonene did not convert into its respective products, demonstrating a clear differentiation between the (S)- and (R)-stereoisomers of limonene. The promising bioconversion of limonene into various monoterpenes through the use of soil bacterial strains has stimulated additional research into the potential of other bacterial species. Subsequent studies have also highlighted biotechnological advancements, including the examination of plant gene expression within selected bacterial cells and Organisms such as *Escherichia coli* and *Saccharomyces cerevisiae* have been employed in modified bioconversion processes. According to Carter et al. (2003) and Haudenschield et al. (2000), the conversion of limonene to carvone and other derivatives using *E. coli* has proven to be less efficient in comparison to *Pseudomonas* species. Nonetheless, products like carvone have been successfully Furthermore, several fungal species have exhibited the ability to metabolize limonene into a range of derivatives. The first documented instance of successful bioconversion was reported by Kraidman et al. (1969) and Mukherjee et al. (1969) during the late 1960s, where a *Cladosporium* species referred to as T7 converted limonene into trans-limonene-1,2-diol. As stated by Mukherjee et al. (1973), the fungus *Cladosporium* can convert limonene into α -terpineol.

According to the findings of Mattison et al. (1971), the interaction of limonene with *P. italicum* and *P. digitatum* resulted in the production of trans-carveol (26%) as the predominant compound, along with (+)-carvone (6%) and various minor constituents. This discovery has generated significant interest in further exploring the metabolism of monoterpenes by *Penicillium* species. The research conducted by Tan and Day (1998) revealed that immobilized *P. digitatum*, when cultivated in submerged liquid cultures, effectively transformed (R)-(+)-limonene into (R)-(+)- α -terpineol. This transformation was similarly observed in studies examining the effects of organic co-solvents on the bioconversion of limonene to α -terpineol. Demyttenaere et al. (2001) demonstrated that the yield of α -terpineol can be effectively enhanced through the parallel application of sporulated surfaces and liquid cultures of *Penicillium* species. The findings of this assay revealed that *P. digitatum* produced the most compelling results, particularly in terms of its efficient recovery of α -terpineol. A subsequent experiment, in which the same microbe was allowed to metabolize a substrate for a period of 8 hours, resulted in an impressive recovery rate of up to 100% of α -terpineol. It was also established that the efficiency of substrate metabolism (specifically limonene) was influenced by the characteristics of the *P. digitatum* strain, the type of cosolvent used, and its concentration. Other fungal species evaluated in limonene bioconversion assays include *Aspergillus niger*, *A. cellulosa*, *Corynespora cassiicola*, and *Diplodia gossypina* (Abraham et al. (1986) Noma et al. (1992). The primary rationale for selecting limonene as the precursor for bioconversions has consistently been its abundant availability in its pure enantiomeric form and its cost-effectiveness.

Biosynthesis of natural products by using Limonene

The synthesis of natural products has consistently presented significant challenges, particularly concerning the starting materials, as many chemical compounds utilized may be toxic or potentially carcinogenic. For instance, the large-scale synthesis of p-cymene has traditionally relied on benzene combined with methyl and isopropyl halides in the presence of $AlCl_3$ as a Lewis acid catalyst, or alternatively, toluene with isopropyl alcohol. These reactions exhibit low selectivity, yielding both ortho and para isomers, necessitating additional separation processes. Increasingly stringent environmental regulations are limiting the use of these chemical compounds, highlighting the necessity for eco-friendly reagents in the synthesis of p-cymene. Limonene has emerged as a significant advancement in the search for safe, non-toxic starting materials for this natural product's synthesis. Its six-membered ring structure can be easily aromatized, making it a viable alternative to hazardous aromatic intermediates like benzene and toluene. This is supported by research conducted by Martín-Luengo and colleagues (2008), who utilized limonene as a precursor in the synthesis of p-cymene. The conversion was performed under solvent-free conditions using mesoporous silica-alumina supports and microwave irradiation, achieving a remarkable selectivity of 100% and high yields in a brief

**Nissam Sainudeen et al.,**

time frame. Specifically, a complete conversion of limonene to p-cymene was accomplished with Siral 40 (silica gel with a designated content of 40) in just 10 minutes. This illustrates a rapid and efficient conversion process suitable for p-cymene production. The high efficiency and selectivity present manufacturers with an attractive alternative to the traditional Friedel-Crafts alkylation methods involving benzene or toluene. p-Cymene is a crucial aromatic compound utilized in the synthesis of fine chemicals, which are essential for producing fragrances, flavoring agents, herbicides, pharmaceuticals, and p-cresol. Soung et al. (2000) have reported that limonene is effectively employed in the synthesis of natural products, particularly in the formation of β - and γ -thujaplicins. These compounds were first isolated from *Chamaecyparis taiwanensis* and *Thuja plicata*, where they were classified as naturally occurring monocyclic tropolones. Their importance as antibacterial and antifungal agents has led to increased interest in developing synthetic routes for their manufacture. The regioselective synthesis of β -thujaplicin and γ -thujaplicin from (R)-(+)-limonene involved several dienyl silyl ether intermediates, achieving yields of up to 18% and 22%, respectively, through 11 and 10 synthetic steps. The availability and affordability of (R)-(+)-limonene further reinforce its role as a key precursor for the synthesis of effective antimicrobial natural products.

Ecological aspects of limonene

Langenheim, (1994) indicated that limonene plays a significant ecological role in plants, functioning as an antifeedant within their defense mechanisms, exhibiting antifungal properties, and serving as an attractant for pollinators. In a study conducted by Sadof and Grant in 1997, the Scotch pine trees, *Pinus sylvestris* L., were examined for both resistant and susceptible cultivars in relation to the pine moth herbivore, *Dioryctria zimmermani* (Grote). The findings revealed that monoterpene levels varied considerably when the plants were under attack; notably, limonene was the only compound that consistently showed higher concentrations in the resistant cultivars. Furthermore, Cates and Redak, (1998) reported that the limonene acts as an oviposition deterrent for numerous herbivores and is toxic to various herbivore species. The study conducted by Flamini et al. in 2007 focused on the volatile emissions of different plant organs and pollen from *Citrus limon*, revealing interesting variations in the emission patterns of limonene. The research focused on different developmental stages of the plant, including young and mature leaves, buds, stamens, petals, pollen, and the pericarps of ripe and unripe fruits. Limonene was found to be the primary volatile compound in the gynaecium, epicarp, and young leaves, accounting for around 65% of the emissions in many samples. As the leaves matured, the limonene content decreased to 30.1%, which may be associated with the production of this defensive metabolite in the more vulnerable young leaves.

The buds showed a limonene emission of 38.9%, which rose to 44.3% as the flowers opened, suggesting that these variations could function as orientation cues for pollinators. Comparable findings were documented in the late 1980s when Armbruster et al. (1989) examined the ecological interaction between *Dalechampia magnoliifolia* and *D. spathula* (Euphorbiaceae) in relation to their pollinator, a male Euglossine bee. The morphology of the flowers, the size of the male bee, and the floral fragrances emitted from various parts of the flowers were recognized as significant elements influencing pollination biology. Notably, the flowers, particularly the pollen, were found to be abundant in limonene, which played a crucial role in attracting the pollinator. It is believed that limonene and other monoterpenes play a crucial role as allelopathic agents in hot and dry regions. Their high vapor density allows essential oils to penetrate the soil effectively, which can harm underground organisms, such as the roots of adjacent plants. Scrivanti et al. (2003) assessed the allelopathic properties of limonene and the essential oil from *Tagetes minuta*, which comprises 66.3% limonene, focusing on its impact on the roots of *Zea mays*. Both limonene and the crude essential oil demonstrated an inhibitory effect on the root growth of *Z. mays* seedlings. After a 96-hour exposure period, limonene reduced the root length to 13.56 cm, in contrast to the 15.09 cm observed in the untreated roots. The essential oil derived from *T. minuta* resulted in a further reduction, with root growth measuring only 6.21 cm compared to the untreated roots. It is evident that limonene, as a primary component, along with other monoterpenes present in the essential oil, significantly impacted this activity. This allelopathic characteristic indicates that plants releasing limonene from their root systems may effectively inhibit or completely prevent the growth of neighboring plants.

Nissam Sainudeen *et al.*,**The biological properties of limonene**

Limonene exhibits notable chemopreventive and chemotherapeutic characteristics, as demonstrated by numerous research studies investigating its medicinal capabilities. The widespread application of limonene in beverages, cosmetics, and various flavoring products has sparked interest in its antimicrobial, anticancer, toxicity, antiparasitic, and other beneficial properties.

Aromachological properties

Limonene, a compound found in essential oils, holds significant value and garners considerable interest among consumers due to its distinctive aroma. Consequently, numerous major fragrance companies are actively seeking highly purified limonene derived from the essential oils of specific fruits and flowers. This research focuses on the extraction process of essential oil from lime peel waste. Research conducted by Braddock and Cadwallader (1995) and Mazzaro (2000) has shown that D-limonene is a low-cost byproduct of the orange processing industry, typically costing between U.S. \$1 and \$2 per kilogram. This compound is regarded as an appropriate substrate due to its structural similarity to a variety of important and high-value flavor and medicinal compounds that are highly sought after in the market. The most common derivatives of limonene consist of oxygenated compounds such as alpha-terpeniol, perillyl alcohol, carveol, and carvone. According to Chubukov Victor *et al.* (2015), limonene is the predominant essential oil component in citrus fruit peels, characterized as a colorless liquid aliphatic hydrocarbon from the cyclic monoterpene category. D-limonene is commonly used as a flavoring and aromatic additive in a range of products such as soaps, detergents, cosmetics, pharmaceuticals, and food. Furthermore, it finds broad applications in the manufacturing of resins, acts as a wetting or dispersing agent, and is effective in pest control measures. Carvone, a common terpenoid, is sourced from over 70 different plant species. It comprises two enantiomers: R-(-)-carvone, which is recognized for its spearmint fragrance, and S-(+)-carvone, known for its caraway scent, as highlighted by Chubukov Victor *et al.* (2015).

According to Sarkic and Stappen (2018), carvone is a monoterpene predominantly found in the essential oils of spearmint, caraway, and dill. The R-(-) or L-carvone variant possesses a moderately strong, sweet minty fragrance. Presently, carvone is utilized in various pharmaceutical and cosmetic formulations. Additionally, carvone and other monoterpenes derived from plants are extensively employed in both traditional and contemporary food and beverage applications. Furthermore, carvone plays a crucial role in agriculture, particularly in crop protection and as an anti-sprouting agent for tuber storage. Duetz *et al.* (2003) identified carveol as a natural, monocyclic, unsaturated terpenoid that serves as a crucial constituent of the volatile oils found in spearmint and caraway. This compound exists in two enantiomeric forms: cis-(-)-carveol and trans-(+)-carveol. Characterized as a colorless liquid, carveol exhibits high solubility in oils while remaining insoluble in water. Its aroma and taste closely resemble those of spearmint and caraway oils, making it valuable as a fragrance and flavoring agent in both the cosmetics and food industries. Hassan *et al.* (2019) indicated that Perillyl alcohol, along with its precursors sourced from limonene, belongs to the category of cyclic monoterpenes that are produced via the mevalonate pathway in plants. The primary sources of Perillyl alcohol are the essential oils extracted from various plants, such as sage, lavender, peppermint, and lemongrass. Bailey *et al.* (2003) reported that the Perillic acid belongs to the category of organic compounds referred to as perillate or menthane monoterpenoids. Perillic acid is a water insoluble, hydrophobic and comparatively neutral compound. Perillic acid has a potent antimicrobial and antitumor activity.

CONCLUSION

Limonene, primarily recognized for its use as a fragrance, possesses a diverse range of potential applications as a bulk material. To facilitate the production of biomaterials, solvents, and fuels, a reliable and scalable source of limonene is essential. While microbial production has the potential to fulfill this requirement, it necessitates considerable engineering advancements. Currently, the yields achieved by various microbial systems must be enhanced by at least two orders of magnitude to achieve cost competitiveness with limonene derived from plants.

Nissam Sainudeen *et al.*,

This improvement would enable the extensive utilization of microorganisms for the production of limonene in new bulk applications, including solvents and biomaterials.

ABSTRACT

Solanum trilobatum, a widely used medicinal herb, is known for its antibacterial properties against various bacterial pathogens. This present study investigates the phytochemical constituents and antibacterial activities of solvent extracts (acetone, methanol, ethanol, and aqueous) from the leaves, roots, and fruits of *Solanum trilobatum*. The bioactive compounds were characterized using Fourier Transform Infrared (FT-IR) spectroscopy and Gas Chromatography-Mass Spectrometry (GC-MS). The plant materials of *Solanum trilobatum* were air-dried and subjected to Cold percolation extraction for 48 hours with intermittent shaking. The *Solanum trilobatum* extracts were filtered using Whatman No. 1 paper. The antibacterial activity was evaluated using the Disc diffusion method against four pathogenic bacteria: *Salmonella typhimurium* (ATCC 14028), *Pseudomonas aeruginosa* (ATCC 27853), *Escherichia coli* (ATCC 8739), and *Staphylococcus aureus* (ATCC 25923). The results revealed that methanol extracts exhibited the highest antibacterial activity among the solvents tested, with significant inhibition zones against all bacterial strains. *Staphylococcus aureus* was the most susceptible, while *Pseudomonas aeruginosa* showed the least susceptibility. GC-MS analysis identified 21 bioactive compounds in the methanol extract of the leaves, indicating its rich phytochemical profile. In conclusion, *Solanum trilobatum* extracts, particularly methanol, demonstrated potent antibacterial properties, suggesting its potential for developing novel antimicrobial agents. This study highlights the therapeutic

**Megala et al.,**

promise of *Solanum trilobatum* in combating bacterial infections and provides a foundation for further pharmacological exploration.

Keywords: *Solanum trilobatum*, Antibacterial activity, Fourier Transform Infrared (FT-IR) spectroscopy and Gas Chromatography-Mass Spectrometry (GC-MS).

INTRODUCTION

The world's growing population depends heavily on medicinal plants for the production of life-saving medications. The World Health Organization (WHO) estimates that up to 80% of people on the planet are primarily reliant on traditional medicinal herbs. Plant materials are the source of many contemporary medications, accounting for around 25% of prescription medications [1]. Additionally, plant sources are the source of the most valuable anti-cancer medications, such as vinblastine, vincristine, and paclitaxel, as well as the widely used painkiller aspirin [2]. In poor nations, where traditional medicine plays a significant role in healthcare, a significant reliance on plants exists [3]. Conventional medication use has unfavourable risks and adverse effects. India possesses a wealth of information regarding the use of plant-based medications for both therapeutic and preventative purposes. The subcontinent of India is ideal for growing a broad variety of aromatic and medicinal plants that may be utilized as raw materials for the agrochemical, pharmaceutical, fragrance, and cosmetic industries due to its diverse soil and climate. Many of these plants are harvested from their natural habitats, mostly for usage in domestic pharmaceutical companies. Several of these plants yield useful medications with significant export potential [4]. The indiscriminate use of commercial antimicrobial medications, which are often utilized in the treatment of infectious diseases, has led to the development of multiple drug resistance against numerous microbial illnesses in the modern world. Apart from this issue, antibiotics can also have negative consequences on the body, such as immunological suppression, hypersensitivity, and allergic responses. Given the rising prevalence of antibiotic resistance in bacteria of medical value and the ongoing demand for novel and potent therapeutic medicines, this circumstance compelled scientists to look for new antimicrobial compounds. Thus, the demand for innovative and potent therapeutic medicines to counteract the negative effects of chemicals remains continual. As a result, several antimicrobial medications derived from medicinal plants are required to treat infectious diseases [5]. *Solanum trilobatum* L. is an uncommon, thorny creeper belonging to the *Solanaceae* family. It is a perennial medicinal herb with bluish violet flowers that grows in some of the warmer portions of tropical and subtropical climates. This ethno-botanical plant, which the local tribes, peasants, and herbalists refer to as "Thuduvilai," is well-known for its special therapeutic qualities [6]. The leaves of *Solanum trilobatum* contain trace amounts of calcium, iron, phosphorus, carbohydrates, fat, and crude fiber. Different plant components have a unique therapeutic quality that has great promise. The plant's leaves and stems are prepared for use in herbal medicine to treat a variety of conditions, including leprosy, asthma, difficult parturition, halt blood vomiting, lower blood sugar, and bilious matter phlegmatic rheumatism. It was also discovered to possess antitumor, antioxidant, antifungal, and antibacterial qualities [7, 8]. The present research is aimed to identify the active ingredients in the extracts and assess the antibacterial activity of the medicinal plant *Solanum trilobatum*.

MATERIALS AND METHODS

Collection of Pathogenic Bacteria

The bacteria selected for the present research was collected from the American Type Culture Collection (ATCC) for an Antibacterial investigation. The pathogenic bacteria obtained are *Staphylococcus aureus* (ATCC25923), *Pseudomonas aeruginosa* (ATCC 27853), *Escherichia coli* (ATCC 8739) and *Salmonella typhimurium* (ATCC 14028). The collected bacterial isolates were maintained on Nutrient agar slants and stored at 4°C in a Refrigerator.

**Megala et al.,****Collection of Plant materials**

Adequate *Solanum trilobatum* L. plant material was gathered in and around the Cuddalore region of Tamil Nadu, India. Specimens were shaken off and quickly rinsed with tap water to remove any remaining soil or dust from the field. Plants were moved into the lab and put in paper bags. Leaves, roots, and fruits were among the healthy plant materials that were carefully cleaned with tap water and then shade-dried for a period of two weeks at room temperature. Subsequently, the fruits, roots, and leaves were ground into a powder using an Electric blender. Each powder was then separated from the plant fibers using a 315 mm-sized nylon screen. At last, the powders were gathered and kept apart in bottles with screw caps so they could be used later.

Preparation of Plant Extract**Solvent Extraction**

The antibacterial activity of fresh leaves, roots and fruits was assessed in the current investigation. The Cold percolation process was used to create plant extracts. For ten days, the fruits, roots, and leaves were allowed to air dry at room temperature. Weighing and powdering the completely dried plant materials was done. For 48 hours, the powdered leaves, roots, and fruits (5 gm each) were shaken intermittently at 300 rpm while soaking in 50 ml of various solvents, including acetone, methanol, ethanol, and aqueous. Subsequently, Whatman No. 1 (110mm) filter paper was used to filter the plant extracts, and the resulting filtrate was collected in separate clean beaker.

In vitro Antibacterial Assay

The Disc diffusion method was used to assess the Antibacterial activity of extracts from fruits, roots, and leaves. The Mueller Hinton agar was prepared and swabbed with sterilized cotton swabs that had been dipped in broth containing the Test bacterial cultures. The concentrations of the plant extract to be tested (50µg/ml, 100µg/ml, 150µg/ml, and 200µg/ml) were produced and then separately dipped in sterile discs. To guarantee that the sterile impregnated discs containing plant extracts made full contact with the agar surface, they were carefully put on the surface using sterile forceps. A 500 mg control disc of Meropenem was placed on the top of the Mueller Hinton agar. After that, each plate was incubated for 24 hours at 37 °C with the lid on, and the diameter of the zone of inhibition was measured and reported in millimeters [9].

Fourier Transmission Infrared (FTIR) Spectroscopic Analysis on Leaves of *Solanum trilobatum* L.**Analysis of active principle compounds in the *Solanum trilobatum***

The active principle of *Solanum trilobatum* L. was qualitatively analyzed using the Fourier Transmission Infrared (FTIR) technique [10].

Preparation of Potassium Bromide (KBr) discs

Thermo Nicolet, AVATAR 330 FT-IR system, Madison, WI 53711-4495 was used to record the FT-IR spectra (Thanjavur, Indian Institute of Food Processing Technology). A pure Potassium bromide salt was used to grind the sample of air-dried leaves in order to eliminate the scattering impact of the big crystals. After that, the powdered combination is compressed in a mechanical press to create a transparent pellet that the spectrometer's beam may pass through.

Infrared analysis

The analysis spectrum's frequency ranged from 4000 to 500 cm wave number, and the vibration spectrum was captured as a graphical representation. Bruker, a German company, manufactured the FTIR analysis equipment.

Determination of Phytochemical Contents using Gas Chromatography - Mass Spectrum (GC-MS) Analysis**Sample Collection and Processing**

A homogeneous powder was created by grinding fresh *Solanum trilobatum* leaves, which were subsequently dried at room temperature. For future usage, store in an airtight container. Using 50 milliliters of methanol and continuous shaking for 24 hours at room temperature, five grammes of powdered leaves were extracted. With the use of a

**Megala et al.,**

suction pump, the mixture was then twice filtered using Whatman No. 1 filter paper. The solvent was then gathered and put into bottles with screw caps.

Gas Chromatography- Mass Spectrum conditions

1. Capillary column 30m × 0.25 mm coated with 0.25 μ M film of HP-5.
2. Sample elution using 50: 1 helium was used as carrier gas at 1.0 ml min⁻¹.
3. Column temperature 100°C for 1 minutes increased 10°C min⁻¹ to 275°C min⁻¹ for 20 minutes.
4. Time taken for chromatography per sample in 40 mins.

Analysis of the Phytocomponents in *Solanum trilobatum* leaves using GC-MS technique

The filtrate was put into the GC-Column in a microliter volume. Subsequently, the material evaporates and is transported away by the helium carrier gas, causing it to be separated into distinct fractions. The mass spectra of every component was recorded when the sample fraction exiting the column was introduced into the mass detector. The unknown component's mass spectrum was compared to the known spectrum through the use of database dictionaries that were accessible at Annamalai University's central library.

Identification of Components

The National Institute of Standards and Technology (NIST) database was utilized to interpret the GC-MS results. The components kept in the NIST collection were compared to the spectrums of the unknown components. The compounds were then identified based on their structure, molecular weight, and molecular formula.

RESULTS

The outcome demonstrated that *Solanum trilobatum* extracts from its leaves, roots, and fruits had a noticeable antibacterial impact on *Staphylococcus aureus*. The outcome was shown in the Table-1. For acetone extract, the highest zone of inhibition is 13 mm in 200 μ l. For the methanol extract, the potential zone of inhibition is found at 200 μ l at a distance of 14 mm. The fruit extracts significantly reduced the growth of *Staphylococcus aureus*. In 200 μ l of acetone extract, the maximal zone of inhibition is found at 14 mm, while in 200 μ l of methanol extract, it was 13 mm. The extracts of *Solanum trilobatum* leaves, roots, and fruits demonstrate antibacterial activity against *Pseudomonas aeruginosa* (Table - 2). A considerable inhibition of 18 mm was noted in 200 μ l for the leaf methanol extract. The highest level of inhibition of the root extracts was measured in 200 μ l of ethanol extract (16 mm), and in 200 μ l of methanol extracts (14 mm). A promising inhibition of 12 mm was obtained in 200 μ l for fruit methanol extracts. The outcome demonstrated that *Solanum trilobatum* extracts from the leaves, roots, and fruits also have antibacterial activity against *Salmonella typhimurium*. The Table - 3 showed that the acetone extract of fruits displayed antibacterial activity (11 mm) in 200 μ l, but the ethanol extract of roots and the leaf extract shown antibacterial activity (12 mm and 11 mm, respectively) in 200 μ l. The outcome demonstrated that *Solanum trilobatum* extracts from its leaves, roots, and fruits had a noticeable antibacterial impact on *Escherichia coli*. For methanol extract, the greatest zone of inhibition (12 mm) is found in 200 μ l. In 200 μ l of ethanol extract, a moderate inhibition of the root extract (14 mm) was seen. Fruits were extracted with acetone, and the findings showed antibacterial activity (14 mm) in 200 μ l (Table - 4). The zone of inhibition for *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Salmonella typhimurium*, and *Escherichia coli* was 10 mm, 11 mm, 11 mm, and 10 mm for Meropenem, the positive control (Table - 5). In the current research work, the FTIR spectroscopic examination of the *Solanum trilobatum* Leaves sample revealed several peaks in the functional group area between 4000-650 cm⁻¹ (Figure - 1). However, the *Solanum trilobatum* methanol extract's Gas Chromatography Mass Spectrums (GC-MS) analysis revealed that the leaf sample included 21 distinct chemicals (Table – 6 and Figure - 2).

Megala et al.,

DISCUSSION

The emergence of microbial resistance and the prevalence of lethal opportunistic infections linked to AIDS, antineoplastic treatment, and transplants have made the quest for novel, effective antimicrobial medicines vital. Numerous antimicrobial agents have been identified via the use of ethnobotanical data, and many of these compounds have been extracted from therapeutic plants. The secondary metabolites found in plants are usually responsible for the positive therapeutic effects of plant materials. However, a mixture of the metabolites is typically responsible for its attribution rather than a single component. The idea that the mix of secondary products in a certain plant is taxonomically distinct is compatible with the fact that the therapeutic properties of plants are exclusive to a given plant species or group [11]. When selecting a plant for pharmacological investigation, a number of ethnobotanical approaches are typically used in the screening process. The search for novel antimicrobial agents has become necessary due to resistance to currently existing antibiotics [12]. Herbs and medicinal plants are favored sources of active molecules that are used as lead compounds in the production of a range of pharmaceutical products [13]. The *in vitro* antibacterial activity of *Solanum trilobatum* in this investigation demonstrated its inhibitory effect on the examined microorganisms. Significant inhibition of the bacteria was seen in all plant extracts. When the extracts were compared, the antibacterial activity of the leaf extracts was higher than that of the fruit and root extracts. When compared to other plant extracts, *Solanum trilobatum* fruit extracts were generally shown to have lower antibacterial activity. Methanol extracts of *Solanum trilobatum*, namely the leaves, roots, and fruits, had the most antibacterial activity when compared to acetone, ethanol, and aqueous extracts.

It was discovered that the solvent extracts had more antibacterial activity than the aqueous extracts. The solvent's superior polarity in dissolving both polar and non-polar plant components from *Solanum trilobatum* might be the cause. However, in contrast to the current investigation, Gopalakrishnan *et al.* [14] reported that while the *Solanum trilobatum* aqueous extract showed the greatest inhibitory efficacy against *Klebsiella pneumoniae*, *Staphylococcus aureus* was only modestly inhibited by the extract as a whole. The least amount of inhibitory action against *Escherichia coli* and *Pseudomonas aeruginosa* was displayed by aqueous, methanol, and ethanol extracts. Additionally, Hema and Sathya Savithri [15] assessed the antibacterial properties of *Solanum trilobatum* methanolic extract against *Escherichia coli* and *Bacillus cereus*. According to the research, *Solanum trilobatum* leaf extract had the highest activity against *Bacillus cereus*, with a measured zone of inhibition of 12 mm, and, with a measured zone of inhibition of 14 mm. The antibacterial potential of ethanol, acetone, and ethyl acetate extracts of *Solanum trilobatum* leaves, fruits, and flowers was reported by Kannabiran *et al.* [16] and Mihira *et al.* [17]. In line with previous findings, all plant extracts demonstrated antibacterial activity against both Gram-positive and Gram-negative organisms, even though *Pseudomonas aeruginosa* was found to be more susceptible than other test pathogens, such as *Staphylococcus aureus*, *Escherichia coli*, and *Salmonella typhimurium* [18, 19, 20]. However, *Solanum trilobatum*-mediated selenium nanoparticles demonstrated strong suppression against *Lactobacillus* sp., *Candida albicans*, and *Streptococcus* variants, according to Sarojini *et al.* [21] research.

Additionally, *Solanum trilobatum* was reported by Madhumitha *et al.* [22] to possess potent pharmacological effects, including antibacterial, antidiabetic, mosquito larvicidal, antioxidant, and anti-inflammatory qualities. The numerous peaks found in the functional group region of the *Solanum trilobatum* leaves sample underwent FTIR spectroscopic analysis in the current study, with the samples falling between 4000-650 cm⁻¹. The tuber and seed materials revealed that the peaks are involved in intermolecular hydrogen bonding N-H bond either primary, secondary, or tertiary amines, carbonyl group (>C=O), which may be either with the form of carbonyl acid or carbonyl group coupled with -C=C- group. These molecular stretches of active principles tested through FTIR spectroscopical analysis. A few peaks also correspond to the O-H group of alcohols. *Solanum trilobatum* Plant was examined using FTIR analysis, which was based on the skeletal shape of molecular stretches of active principles with aliphatic aldehyde, alkene, and ether groups [23]. The *Solanum trilobatum* Gas Chromatography Mass Spectrum (GC-MS) investigations showed that the leaf sample included 21 distinct chemicals. GC-MS study of *Gloriosa superba* seeds and tubers. Analysis was done on the colchicines, pentadecanoic acid, and hexadecanoic acid [24]. Gas Chromatography Mass Spectrometry (GC-

Megala et al.,

MS) investigation of bioactive chemicals found in ethanolic extract of *Solanum torvum* leaves was published by AzaguMadhavan[25]. According to the current investigation, the majority of the test pathogens are inhibited by the acetone, methanol, ethanol, and aqueous extracts. It is possible that some active ingredients in the extracts are what prevent these organisms from growing *in vitro*. The growth of the bacterial organisms may have been inhibited by these active principles acting alone or in combination. Tamil Nadu residents have long used these plants therapeutic properties to treat a wide range of illnesses, including infectious ones. Antimicrobial medicine use in the future is still unknown due to the rising problem of microorganism resistance. As a result, steps must be done to further research into the genetic causes of resistance and to carry out ongoing investigations aimed at creating novel medications, particularly those derived from synthetic or natural medicinal plants. The ultimate objective is to provide the patient with effective and suitable antibacterial medications. Overall, the current study found that *Solanum trilobatum* has made it possible to use plant extracts, which has produced scientific proof for the creation of antibacterial goods and the future treatment of bacterial illnesses.

CONCLUSIONS

The current study's findings unequivocally demonstrated the significance of *Solanum trilobatum* action against pathogenic bacteria that cause infectious diseases. The biologically active ingredients of the medicinal plant *Solanum trilobatum* have been shown to have an advantage in inhibiting pathogenic microorganisms in this note's early examination. Since the local people have long utilized *Solanum trilobatum* to treat certain ailments, further research is necessary to determine the plant's potential for usage in conjunction with other herbal remedies.

ABSTRACT

Mukia Maderaspatana L. is an important medicinal plant used as an herbal drug for cough and cold and is well integrated into South Indian food. The present study evaluated the phytochemical constituents, antimicrobial, antioxidant, and hepatoprotective properties of *Mukia Maderaspatana*. Qualitative analysis of the aqueous and ethanolic extracts revealed the presence of bioactive compounds such as saponins, flavonoids, alkaloids, and phenols, with ethanolic extract showing a higher concentration of phytochemicals. The antimicrobial activity was evaluated against five bacterial strains using the well diffusion method, where *Bacillus* exhibited the highest inhibition zone. The antioxidant activity of both extracts was measured using DPPH assays, indicating strong free radical scavenging abilities. GC-MS analysis identified the key compounds responsible for the plant's bioactivity. Auto dock simulations further revealed binding affinities of these compounds with liver cancer target proteins, suggesting potential anti-proliferative activity. The results support the traditional use of *M. maderaspatana* in treating various ailments, particularly liver-related diseases.

Keywords: *Mukia maderaspatana*, phytochemical screening, antimicrobial activity, antioxidant activity, anti-proliferative activity, GC-MS analysis.

INTRODUCTION

India possesses one of the world's most sophisticated indigenous medical systems, with a rich heritage dating back more than four millennia (Sazada Siddiqui et al., 2009). Despite the advances in modern medicine, communities in rural and remote areas continue to rely heavily on traditional medicinal practices. This reliance is often due to the high cost and limited availability of synthetic medicines, which may also be associated with contamination and side effects (Pandey et al.). Even in urban areas, many people still use medicinal plants to treat common ailments such as colds, coughs, fever, headaches, snake bites, skin conditions, and dental infections. *Mukia maderasapatana* (Linn.) also known as *Melothria maderasapatana* or *Cucumis maderasapatana*, is a member of the Cucurbitaceae family. This climbing or prostrate herb is widespread throughout India, growing in both wild and cultivated kitchen gardens. Traditionally used as a leafy vegetable in South India, the plant has been employed in treating a variety of ailments, including cough, cold, constipation, vertigo, burning sensations, dyspepsia, flatulence, and dental pain (Boobalan Raja et al., 2010). While the ethno-medicinal importance of *Mukia maderasapatana* is well-documented, there are few scientific studies available on its nutrient composition. Previous research has focused primarily on the antimicrobial properties of its aerial parts using different solvents such as chloroform, ethanol, hexane, ethyl acetate, and methanol. Given this gap, the present study seeks to explore the phytochemical profile of the plant in aqueous and ethanolic leaf extracts. Additionally, the study aims to evaluate its antibacterial activity against various bacterial strains, along with its antioxidant potential and hepatoprotective activity.

MATERIALS AND METHODS

Collection of plants

Mukia maderasapatana (Linn.) was obtained from its natural habitat in the Tiruchirappalli region, Tamil Nadu, India in December 2017. They were shade-dried, powdered, sieved, and stored prior to further use.

Extraction

20 g of the dried rhizome derived from the plant *Mukia Maderasapatana* was ground and changed into a coarse powder. The powder was put in a Soxhlet extractor harboring 500 mL of methanol and kept for 8 hours. This procedure was repeated three times. The extracts were concentrated within a rotary evaporator for 75 min (vacuum condition, 60°C) and then stored at 4 °C. The extracts of *Mukia Maderasapatana* were dissolved in Dimethyl sulphoxide (DMSO) for preparations of different concentrations and were tested for cytotoxicity.

Phytochemical analysis

The crude powdered plant samples were taken for preliminary phytochemical screening to identify the presence of secondary metabolites (alkaloids, flavonoids, saponins, tannins, carbohydrates, amino acids, steroids, glycosides, terpenoids) using standard established methods (Harbone, 1973).

Antimicrobial Activity Disc Diffusion Method:

In vitro antimicrobial was carried out by disc diffusion technique in whatman no;1 filter paper disc with 4mm diameter was impregnated with a known amount test samples of the disc were loaded each with 10µl of the extract by the first applying 5µl with the pipette allowed to evaporate than applying another 5µl than drying again. The positive control contained a standard antibiotic disc sterile disc used as a negative control. The impregnated disc along with the control (streptomycin) was kept at the center of agar plates, and seeded with test bacterial cultures. The discs were then placed individually using sterile forceps in appropriate grids which were marked on the undersurface of the plates Petri plates and kept for incubation at room temperature for 24 hours. After incubation plates were observed for zones of inhibition and recorded in millimeters.

Sharmila et al.,

Determination of Antioxidant Activity Using DPPH

The ability of *Mukia maderasapata* to scavenge 1, 1- diphenyl-2 picrylhydrazyl (DPPH) was measured by the reported method (Alothman et al., 2009). A mixture of absolute methanol and extract served as blank. Ascorbic acid was used as standard and different concentrations of the extract (50,100,150,200 and 250 µl) were marked as tests. Finally, the DPPH reagent was added to all the test tubes including blank. Then, the absorbance of all samples was read at 515nm.

Calculation

% Antioxidant activity = {(absorbance at blank) – (absorbance at test) / (absorbance at blank)} X 100.

MTT Assay

The anticancer activity of samples on MCF-7 was determined by the MTT assay (Mosmann, 1983). Cells (1×10^5 /well) were plated in 1ml of medium/well in 24-well plates (Costar Corning, Rochester, NY). After 48 hr incubation, the cells reached the confluence. Then, the cells were incubated in the presence of various concentrations of the samples in 0.1% DMSO for 48h at 37°C. After removal of the sample solution and washing with phosphate-buffered saline (pH 7.4), 200µl/well (5mg/ml) of 0.5% 3-(4, 5-dimethyl-2-thiazolyl)-2, 5-diphenyl--tetrazolium bromide cells (MTT) solution was added. After 4h incubation, 0.04M HCl/ isopropanol was added. Viable cells were determined by the absorbance at 570 nm. Measurements were performed and the concentration required for a 50% inhibition of viability (IC₅₀) was determined. The absorbance at 570 nm was measured with a UV- Spectrophotometer using wells with untreated cells as blanks. The effect of the samples on the proliferation of MCF-7 was expressed as the % cell viability, using the following formula:

% cell viability = OD value of treated cells / OD value of control cells × 100.

RESULT AND DISCUSSION

Phytochemical screening was conducted on various extracts of *Mukia Maderasapata* as a preliminary assessment. The ethanolic extract exhibited the highest diversity of phytochemicals, including carbohydrates, proteins, alkaloids, tannins, saponins, steroids, and glycosides, followed by the acetone extract. Additionally, the aqueous extract from both the stem and leaf showed the presence of flavonoids. However, alkaloids, saponins, phenols, and flavonoids were absent in the hexane and ethyl acetate fractions, though steroids and glycosides were identified in these extracts. Notably, the aqueous extracts from both the leaf and stem contained alkaloids and flavonoids. These findings suggest that the leaves of *M. maderasapata* contain significant amounts of tannins, alkaloids, and flavonoids compared to the stems. These phytoconstituents may serve as sources of pharmacologically active agents and natural antioxidants. The observed beneficial activities of *M. maderasapata* in traditional practices may be attributed to the presence of these phytochemicals, as demonstrated in various studies. For instance, flavonoids are known for their antibacterial, anti-inflammatory, anti-allergic, and antiviral properties (Alan and Miller, 1996). Many of these effects are linked to their roles as potent antioxidants, free radical scavengers, and metal chelators. Steroidal compounds are significant in pharmacology due to their association with sex hormones. Additionally, saponins have been reported to exhibit hypocholesterolemia and tumor-inhibiting activities in experimental models (Johns, 1996) and may enhance nutrient absorption during digestion. Alkaloids often possess pharmacological effects and are utilized in both medicinal and recreational contexts (Roger and Wink, 1998). Tannins and phenols, which together comprise the polyphenolic group, are recognized for their antioxidant, anticancer, and antimicrobial properties (Rice et al., 1996). The presence of tannins in *M. maderasapata* suggests potential applications in various industries, including food, pharmaceuticals, and leather (Nguji, 1988). Furthermore, glycosides have been reported to influence insulin secretion in vitro (Sumana and Suryawashi SA, 2001).

Antibacterial activity using well diffusion method

Notably, the inhibition zones for *Bacillus* varied with different concentrations of the extracts, suggesting a dose-dependent antibacterial effect. This variability highlights the strong antibacterial properties of the leaf extracts,

**Sharmila et al.,**

reinforcing the potential of *M. maderaspatana* as a source of natural antimicrobial agents. Among the different extracts tested, the ethanolic extract displayed the highest efficacy against all tested bacterial strains (*Bacillus* sp, *Pseudomonas aeruginosa*, *E. coli*, *Klebsiella*, and *Staphylococcus aureus*.) indicating its superior antibacterial activity. The findings of this study suggest that the ethanolic extracts of *M. Maderasapatana* possess a high phenolic content, which is likely responsible for their potent antibacterial properties. In aqueous extracts, the polarity of the solvent seems to play an important role in exhibiting potential antibacterial activity. The differential activity might be due to the presence of some oils, wax, rennin, or fatty acids in the plant material which may block the plant extract from entering the bacterial cell wall (Parekh et al., 2006). The results of the present study indicate that acetone and ethanol extract of *M. Maderasapatana* leaf and stem are high in phenolic content and so exhibit strong antibacterial activity. In addition, such results justify the traditional use of *M.maderasapatana* in various diseases. Furthermore, these results support the traditional use of *M. maderasapatana* in various medicinal applications, particularly in treating bacterial infections. The evidence provided herein underscores the need for further exploration of this plant's therapeutic potential, paving the way for its application in modern medicine.

GC-MS Analysis

GC-MS is a combined analytical technique used to determine and identify compounds present in a leaf sample of *Mukia maderasapatana*. The active principles with their retention time (RT), molecular formula, molecular weight (MW) and concentration (%) are presented in Table 6&7. five compounds were identified in ethanolic extract by GC-MS. The major components present in leaf of *Mukia maderasapatana* were[(2,3-Hexanediol, 3,4-dihydro-4-(1,3-Dioxolan-2-yl-dimethoxy-1(2h)-benzopyron-2-one, 4-(benzoylmethyl)-6-methyl-2h-1,4-benzoxazin-3-one, 1-(3,4-ditrimethylsiloxyphenyl)-2-Isopropylaminoethanol, 4A-methyl-1,2,3,4A,5,6,7,octahydro-2-naphthalenol, 2,3-hexanediol, 2,3,4,4-Tetrapropyl-1-(trimethylsilyl)-1-(trimethylsilyloxy)-1,3-diaza-2,4-diborobutane.))]. Seven compounds were identified in aqueous extract 1-(3,4-Ditrimethylsiloxyphenyl)-2-Isopropylaminoethanol, 2,3,4,4A-Tetrapropyl-1-(trimethylsilyl)-1-(trimethylsilyloxy)-1,3-diaza-2,4-diborobutane, Di-tert-butylester of phthalic acid, (ss)-or(RR)-2,3-hexanediol, 3,4-dihydro-4-(1,3-dioxolan-2-yl)-5,7-diamethoxy-1(2H)-benzopyran-2-one, 2,3-Bis (trimethylsiloxy)-2,3-Bis (4-methylphenyl)butane, 4-(Benzoylmethyl)-6-methyl-2H-1,4-benzoxazin-3-one. Phytochemical constituents which contribute to the medicinal activity of *mukia maderasapatana*.

Antioxidant activity

The results revealed that *Mukia maderasapatana* showed a significant effect on DPPH. The OD value shows the ethanolic and Aqueous extract were found in 517nm. The plants can be used as antioxidant because oxidative stress by the free radicals. The free radicals are neutralized by phenolic phytoconstituent possessing hydrogen donation in nature. The radical scavenging assays such as DPPH, hydrogen peroxide and hydroxyl radical proved the antioxidant activity by the *Mukia maderasapata*. (Wickramaratne MN et al 2016)

Anti proliferative activity by MTT assay

Anti-proliferative activity of ethanolic extract in *M.maderspatana* MCF-7 cells was determined by MTT assay as shown in (Table 7; Graph 1, Fig:5). Methanolic extract of *M.maderspatana* exhibited a suppressive effect on cell proliferation in dose dose-dependent manner. Cell proliferation was significantly ($p \leq 0.001$) decreased by viabilities of the rest of the treated groups. The IC₅₀ values were determined based on viability rates of cells that were treated with varying concentrations of the drug for 48h. The results obtained were in concordance with the anti-proliferative activity of ethanolic extracts of *Mukia madersapatna* against the MCF-7 cells where a 60% inhibition was observed at a concentration of 300 µg/mL.

CONCLUSION

The present study reveals that *Mukia maderaspatana* is an important medicinal plant. The preliminary phytochemical screening shows the presence of alkaloids, flavonoids, coumarin, glycosides, terpenoids, tannin, steroids, saponin, phenol, and anthraquinone in higher concentrations in ethanolic extract comparable to Aqueous

**Sharmila et al.,**

extract of *Mukia maderaspatana*. In exploring alternative therapies, particularly phytotherapy, both ethanolic and aqueous leaf extracts were prepared using an orbital shaker. Various properties of the extracts were analyzed, including phytochemical composition, anti-proliferative activity by MTT assay, antioxidant capacity through DPPH radical scavenging activity, and antibacterial activity against microorganisms like *Pseudomonas aeruginosa* and *E. coli* using the well diffusion method. Additional analyses GC-MS. indicated that both extracts contained a range of compounds identified through GC-MS. We can conclude that the Leaves of *Mukia maderaspatana* are a good source of antioxidants, which might cure diseases related to oxidative stress. GC-MS analysis detected many bioactive compounds from the ethanolic extract of *Mukia maderaspatana* possessing good pharmacological properties. Therefore, isolating, purifying, and characterizing particular bioactive chemicals from *Mukia maderaspatana* might help researchers better understand their distinct pharmacological active principles.

ACKNOWLEDGEMENT

I am thankful to the management of Bishop Heber College, DST FIST and UGC for providing me necessary facilities and assistance in carrying out this study in our College.

ABSTRACT

The present study focuses on the phytochemical screening and bioactive potential of *Millingtonia hortensis* L.f. leaves using four different solvents: petroleum ether, benzene, ethanol and water extracts. Of these, the ethanolic extract exhibited the presence of all tested phytochemical constituents, indicating its richness in bioactive compounds. Advanced analytical techniques, including UV-Vis spectroscopy, FTIR and GC-MS were employed to identify and characterize the functional groups and chemical compounds present in the ethanolic extract. The UV-Vis profile showed different peaks ranging from 200- 900nm with distinct peaks of varying absorption respectively. The FTIR spectrum revealed the existence of substances such as alkene, alkane, alcohol, amide, carboxylic acid, amino and fluoro compounds in the ethanolic flower extract. The GC-MS analysis of ethanolic flower extract yielded several peaks that indicated the presence of 101 phytochemical substances, of which 21 main components were identified. The antibacterial activity of the ethanolic extract was further assessed against three strains of bacteria: *Pseudomonas aeruginosa*, *Staphylococcus aureus*, and *Streptococcus pneumonia*. The results demonstrated dose-dependent antibacterial efficacy, with higher concentrations showing significant inhibition zones comparable to the standard antibiotic. These findings pave the way for further exploration of its therapeutic applications and the development of plant-based antibacterial agents.

Keywords: Bioactive compounds, antibacterial, UV-Vis, FTIR, GC-MS analysis.

**Parama Sakthi and Gomathy****INTRODUCTION**

In India, traditional medical practices make use of over 7300 plant species. Approximately 90% of the medicinal plants used in daily life are employed as herbal treatments. Man has utilized thousands of native plants to treat and cure illnesses since the beginning of time on every continent. Despite remarkable advancements in the field of allopathy, medicinal plants and their derivatives continue to be a key source of pharmaceuticals in both traditional and modern systems worldwide, with a significant role in therapeutic treatment [1]. The medicinal plants have the potential to be utilized in drug research and synthesis due to the existence of several active ingredients [2]. Now a days, traditional herbal remedies are becoming increasingly popular, both in developing and developed countries worldwide. The demand for Ayurvedic and traditional herbal medications has increased due to its lack of adverse effects and so modern people are increasingly relying on plant-based drugs [3]. *Millingtonia hortensis* L.f. is the only species in the genus *Millingtonia* and a member of the Bignoniaceae family. The English botanist Thomas Millington gave it the name *Millingtonia*, and the word *hortensis* means “grown in gardens”. It is also referred to as Tree Jasmine, Akash Neem, Neem Chameli, and Cork Tree [4]. *Millingtonia hortensis* Linn is a decorative tree that is planted as an avenue tree in parks and gardens. The tree is widely distributed over South Asia, including Thailand, Burma, India, and Southern China. The tree is easily recognized by its fragrant, highly scented blossoms, and it contains a lot of alkaloids, flavonoids, tannins, and essential oil [5]. It can reach a height of 18 to 25 meters. Its brittle timber is susceptible to storm damage. It is distinguished by its straight stem with few branches and corky bark. The tree blossoms at night throughout the winter months, and by dawn, fragrant blossoms blanket the ground [6]. It's a drought-resistant tree. This plant thrives in full sunlight and may grow in a variety of soil conditions, but likes a moist climate. The tree does not bloom in certain locations, such as Chennai. The plant reproduces through seeds and suckers, which are abundant [7]. Different portions of *M. hortensis* have been used for their medicinal qualities in traditional medicine. The leaves have been used as a cholagogue, a general tonic, an antipyretic, and a remedy for sinusitis [8]. According to reports, the stem bark possesses antimicrobial qualities and has been used to treat respiratory conditions [9]. Roots can heal tuberculosis and alleviate asthma. In Thailand, this flower is known as 'peep'. Flowers, particularly the buds, have been used in the treatment of asthma and as a lung tonic [7, 10]. Since *M. hortensis* L.f. contains a variety of phytochemical ingredients, pharmacological activity including antiproliferative, antimutagenic, antibacterial, antifungal, anticonvulsant, and antioxidant properties have been documented. Additionally, the leaves and flowers displayed larvicidal and antiasthmatic properties, respectively [6]. The present study aimed to identify bioactive compounds through spectral analyses, including phytochemical screening, UV-Vis spectroscopy, FTIR and GC-MS, along with antibacterial activity assays against selected bacterial strains. All analyses and antibacterial activity tests were exclusively performed using the ethanolic extract of the flower, with the objective of establishing standards for the standardization and potential therapeutic applications of this crude extract.

Plant Taxonomy

Kingdom	:	Plantae
Division	:	Magnoliophyta
Class	:	Magnoliopsida
Order	:	Lamiales
Family	:	Bignoniaceae
Genus	:	<i>Millingtonia</i>
Species	:	<i>hortensis</i>

MATERIALS AND METHODOLOGY**Collection of Plant Material**

The samples of *Millingtonia hortensis* L.f. flowers were collected in and around Thoothukudi district, Tamil Nadu, India (Figure 1). The flowers were then properly cleaned with running tap water to get rid of any remaining dirt and

**Parama Sakthi and Gomathy**

soil particles, and they were left to dry for ten days in the shade. The dried plant material is kept at room temperature (28° C) until the extraction procedure starts. Then, a heavy-duty blender was used to pulverize the dried plant material, which was then sealed in airtight glass container for laboratory analysis (Figure 2).

Preparation of Plant Extracts

The dried flower powder was subjected to solvent extraction using solvents of varying polarity: petroleum ether, benzene, ethanol and water. 10g of powder was first steeped in 50ml of petroleum ether in an airtight conical flask for two days. The flask was periodically subjected to shaking on an electric shaker and then it was filtered through Whatman no 1 filter paper and filtrate was collected into sterile air tight glass vials. The aforementioned techniques were replicated using benzene, ethanol and water [15].

Qualitative Phytochemical Analysis

Preliminary phytochemical analysis was performed on *Millingtonia hortensis* L.f. flower extract made with solvents of varying polarity using particular reagents for several classes of phytoconstituents, in accordance with the standard procedure [11,12]. Phytochemical screening was carried out to identify the major phytochemicals such as aromatic acids, phenols, flavonoids, alkaloids, terpenoids, steroids, coumarins, tannins, saponins, quinones, anthraquinones and catechins.

Characterization of Flower Extract**UV-Vis Spectroscopic analysis**

A UV-Visible Spectrophotometer (Jasco V650 Spectrophotometer) with a slit width of 2nm and a 1 cm cell at ambient temperature was used to perform a UV-Vis Spectrophotometric examination on the flower of *M. Hortensis* extracts. For proximate analysis, the extract was analysed under wavelengths ranging from ultraviolet (190nm) to near infrared (900nm). The ethanolic extract was centrifuged at 3000 rpm for 10 minutes in order to filter it through Whatman No. 1 filter paper for the UV-Vis Spectrophotometer analysis. Using the same solvent, the sample is diluted to the ratio of 1: 10 and the values are recorded.

FTIR Spectroscopic analysis

Fourier Transform Infrared (FTIR) was utilized to determine the extract's distinctive functional groups. Using the Thermo Scientific Nicolet is5, the IR spectrum was acquired. It provides details about the composition of a molecule found in the extract. A tiny amount of *Millingtonia hortensis* flower extract was combined with dried potassium bromide (KBr). After the material was well combined in a mortar, it was compressed for two minutes at a pressure of six bars to create KBr disc. The sample was scanned from 4000 to 400 cm⁻¹ and then the peak values of respected functional groups are noted.

GC-MS Analysis

The presence of active constituents and chemical composition of *Millingtonia hortensis* ethanolic extract was characterized by the use of Gas chromatography and Mass spectroscopy (GC-MS). The GC-MS analysis of *M. hortensis* L. extract was performed by using GCMS- 8040NX, GC-2030, AOC- 20i plus liquid auto samples. The column used was SH- Rxi- 5Sic MS of 30m× 0.25mm× 0.25µm size. The initial temperature range was 50°C with a hold time of 2 minutes. The temperature was further increased to 225°C at a rate of 5°C/minute with a hold time of 4 minutes. Finally, the temperature was raised to 310°C at a rate of 5°C/minute with a hold time of 5 minutes. The ion source of mass spectrophotometer was held at 230°C with an interface temperature at 280°C. Mass scan detection was performed in the range of 50mz to 800mz. The interpretation of chemical compound was achieved by using database stored in NIST library (National Institute of Standards and Technology).

Antibacterial Activity by Well Diffusion Method**Bacterial Pathogens**

The microorganisms of Gram-positive strains such as (*Streptococcus pneumonia* and *Staphylococcus aureus*) and Gram-negative strain (*Pseudomonas aeruginosa*) were used for the evaluation of antibacterial activity.

**Parama Sakthi and Gomathy****Reference Drug and Control**

As the standard reference for bacteria, ampicillin was selected. The test chemicals were soluble in solidified agar that had been coated with a solvent to serve as the controls.

Ethanollic Flower Extraction

20ml of ethanol was macerated with 4 grams of powdered leaf material in a 1:5 ratio for 24 hours at 50° C while being shaken at 130 rpm. After that, the extract was filtered through Whatman No. 1 filter paper. The filtrates were concentrated by employing an evaporator to remove the solvents at 40° C under decreased pressure (Figure 3).

Antibacterial Assay

All the three different bacterial strains were cultured on nutrient agar broth and incubated at 37° C for 18- 24 hours. Following that, a sterile swab was inserted into the produced bacterial suspension, evenly distributed throughout the entire surface area of Mueller-Hinton agar plates, and incubated for 15 minutes. The cultured plates were marked with wells (6mm in diameter). The wells were then injected with positive control (Ampicillin) along with ethanolic leaf extract (25, 50 and 100µg). Each plate was evaluated for the zone of inhibition (in mm) after 24 hours of incubation at 37° C.

RESULT AND DISCUSSION**Preliminary Phytochemical Screening**

In the current investigation, phytochemical screening was carried out utilizing solvents of increasing polarity in order of petroleum ether, benzene, ethanol and water in the flower of *Millingtonia hortensis*. Table 1 indicated both the presence and absence of different types of bioactive constituents such as carbohydrates, proteins, lipids, aromatic acids, phenols, flavonoids, alkaloids, terpenoids, steroids, coumarins, tannins, saponins, quinones, anthraquinones and catechins. Carbohydrates, proteins, lipids, aromatic acids, alkaloids, quinones, anthraquinones and catechins have been detected in petroleum ether (40- 60°C) extract whereas phenols, flavonoids, terpenoids, steroids, coumarins, tannins, saponins were not observed. Phenols, flavonoids, steroids, coumarins, quinones have been observed in benzene extract whereas, carbohydrates, proteins, lipids, aromatic acids, alkaloids, terpenoids, tannins, saponins, anthraquinones and catechins were not noted. Carbohydrates, proteins, lipids, phenols, flavonoids, alkaloids, terpenoids, tannins, saponins, anthraquinones were identified in water extract whereas aromatic acids, steroids, coumarins, quinones and catechins were absent in this extract. All the tested active constituents were present in ethanolic extract. Phenols and flavonoids which are considered as most important component were present in three extracts except petroleum ether. These results were mentioned in Table 1. Mahesh Kumar et al. (2014) and Chumbhalel et al. (2016) found similar results when total phenols, flavonoids, terpenoids, glycosides, and protein were present in chloroform and water extracts of *Millingtonia hortensis* [13, 14]. Similar findings reported by Karthiya et al., 2018 in different extracts (ethanol, chloroform, acetone and water) of *Millingtonia hortensis* L. and *Tecoma stans* L. flowers revealed the presence of saponins, glycosides, terpenoids, flavonoids, quinones and carbohydrates[15]. Janaki et al. (2017) conducted a preliminary phytochemical screening of petroleum ether, ethanol, methanol, chloroform, and aqueous extracts of *Millingtonia hortensis* L. leaves. All of the extracts from their investigation demonstrated the presence of flavonoids, alkaloids, cyanins, phenols, and coumarins [16]. A phytochemical examination of *M. hortensis* L. methanolic leaf extract revealed the presence of flavonoids, glycosides, phenolic compounds, alkaloids, terpenoids and saponins (Sivaraj et al., 2019)[17].

UV-VIS Analysis

The UV-Vis analysis was carried out to identify the phytoconstituents present in the ethanolic flower extract of *Millingtonia hortensis* L. f. The qualitative UV-Visprofile of the ethanolic extract of *M. hortensis* flower was taken at the wavelength of 200 to 900 nm. The spectrum exhibited a characteristic bell-shaped profile with a single distinct peak. The maximum absorbance (A_{max}) was observed at 390 nm, with an absorbance value of 0.889314, indicating the presence of a dominant chromophore absorbing in this region. Absorbance readings at different wavelengths (230

Parama Sakthi and Gomathy

nm, 286 nm, 390 nm, 444 nm, 566 nm, 734 nm, and 900 nm) showed varying values, were significantly lower and did not form distinct peaks, indicating the absence of additional chromophores in substantial concentrations. Table 2 displays the absorbance at these wavelengths and Figure 4 shows the absorption spectrum of *M. hortensis* extract in the wavelength region of 200- 900nm. The absorption peak at 390 nm is characteristic of compounds with strong light absorption in the near-UV region. This wavelength falls within the typical absorption range for flavonoids, phenolics, or other aromatic compounds, which are known for their $\pi \rightarrow \pi^*$ or $n \rightarrow \pi^*$ electronic transitions [18]. Two main absorption bands are frequently seen in flavonoids: Band I (300–400 nm), which is connected to the B-ring cinnamoyl system, and Band II (240–285 nm), which is connected to the A-ring benzoyl system. The prominent peak at 390 nm suggests the potential dominance of flavonoids or similar phenolic compounds in the *M. hortensis* ethanolic flower extract. Similar results have been observed in additional plant extracts with absorbance in the 380–400 nm region, attributable to these groups of phytochemicals [19].

FTIR Analysis

The IR spectral studies of ethanolic flower fractions of *Millingtonia hortensis* L.f. gave the following characteristic absorption peaks as shown in Figure 5 and Table 3 presents the observed wave numbers along with their corresponding stretching or bending vibrations and the functional groups they represent. These assignments were made based on comparisons with standard FTIR reference ranges and previous studies on plant-based compounds. The band at 3132.68 cm^{-1} is due to C-H and O-H stretch of alkene, alcohol and carboxylic acid. The band at 2361.92 cm^{-1} is assigned to the hydroxyl stretch of carboxylic acid. The bending mode of absorbed water is attributed to the band at 1633.44 cm^{-1} since plant extracts are known to have a high affinity for water. The band at 1400.28 cm^{-1} is due to C-H bend associated with alkane. It is tended to be amino and fluoro compounds by the C-N/F stretch at band 1075.43 cm^{-1} and finally the band observed at 669.16 cm^{-1} is associated with C=C bend of alkene [20, 21, 22].

GC-MS Analysis

The investigation revealed a total of 101 compounds from the ethanolic flower extract based on the peaks detected in the chromatogram. Among these, twenty-one compounds (phytochemical constituents) are selected which might represent most abundant constituents in the extract that could contribute the medicinal quality of the plant. The identification of the phytochemical compounds was confirmed based on the peak area, retention time and molecular formula. The active principles with their retention time (RT), molecular formula, molecular weight (MW) and peak area in percentage in the ethanol extract of *M. hortensis* L. flowers are presented in Table 4 and figure 6. The prevailing compounds in ethanol extract were 2- methylcyclohexanol (23.02%), 1'- hydroxy- 4, 3'- dimethylbicyclohexyl- 3,3'- dien- 2- one (21%), Eicosane (8.20%), Heneicosane (7.04%), 2H- Pyran- 2acetic acid, tetrahydro- 4hydroxy-6pentyl- (5.16%), Eicosane (4.63%), n- Hexadecanoic acid (3.56%), beta- sitosterol (3.19%), cyclobutanecarboxylic acid, decyl ester (2.55%), 2- Methoxymethyl-2methylpyridine-1- carboxyaldehyde (2.53%), Tetratetracontane (2.05%), 10E, 12Z octadecadienoic acid (1.91%). Previous studies showed that the GC-MS analysis of *Millingtonia hortensis* L. flower revealed the presence of 35 compounds. For instance, Aspidoseprmidin 17-ol, 1-acety-19,21-epoxy-15, 16-dimethoxy (R.T:27.90); 2-methyltetracosane (R.T:28.24); Alfaxalone (R.T:29.17); cis-13, 16-Docadienoic acid (R.T: 30.86); Olean-12-ene-3, 15, 16, 21, 22, 28-hexol (R.T: 33.14); Stigmasta-5, 22-dien-3-ol, acetate, (3 β) (R.T: 34.20); β -Sitosterol (R.T: 35.72); Stigmasta-5,24(28)-dien-3-ol, (3 β) (R.T:36.10); Betulin (R.T:37.86), were found along with other major components in the ethanol extract [23].

Antibacterial Activity

The antibacterial activity of an ethanolic extract of *Millingtonia hortensis* flowers against pathogens such as Gram-positive strains (*Streptococcus pneumonia* and *Staphylococcus aureus*) and Gram-negative strain (*Pseudomonas aeruginosa*). The diameter of the clear zone in petri plate cultures was used to objectively evaluate the antibacterial potency and sensitivity of crude extracts with varied degrees of concentration and compared to the standard antibiotic ampicillin (Table 5 and Figure 7). The antibacterial activity has increased with increasing concentrations of the extract. At a lower concentration of 20 μL , the extract produced inhibition zones of 5 mm for *Streptococcus* and *Staphylococcus*, but it did not show any activity against *Pseudomonas*. At 40 μL , the inhibition zones increased slightly to 5.5 mm for *Streptococcus*, 6 mm for *Staphylococcus*, and 5 mm for *Pseudomonas*. At the highest concentration of 60

**Parama Sakthi and Gomathy**

μL, the extract demonstrated the strongest activity, with zones of 6 mm for *Streptococcus*, 7 mm for *Staphylococcus*, and 6 mm for *Pseudomonas*. When compared to the standard antibiotic Ampicillin (25 μg), which produced inhibition zones of 6 mm, 6 mm, and 8 mm for *Streptococcus*, *Staphylococcus*, and *Pseudomonas* respectively, the extract was less effective at lower concentrations. However, at 60 μL, its activity against *Streptococcus* and *Pseudomonas* matched that of Ampicillin, and it was slightly more effective against *Staphylococcus*. These results suggest that the extract has promising antibacterial properties, especially at higher concentrations. It performed best against *Staphylococcus* and showed comparable activity to Ampicillin for the other two strains at 60 μL. Further research is needed to identify the active compounds in the extract, optimize its potency, and explore its use as a natural antibacterial agent. Prior research done by Sivaraj *et al.*, 2019 revealed that the antibacterial activity of *M. hortensis* leaf methanol extract was examined against both Gram-negative (*Escherichia coli*, *Proteus vulgaris*, *Shigella flexneri*) and Gram-positive (*Bacillus subtilis*, *Staphylococcus aureus*, and *Micrococcus luteus*)[17]. Previous research on the polar extracts of *Millingtonia hortensis* leaves has shown significant antimicrobial activity. The aqueous alcohol extract was tested against 20 bacterial strains and 2 yeast cultures. It showed strong activity, particularly against the Gram-negative bacteria *Escherichia coli* and *Salmonella typhimurium*, with a minimum inhibitory concentration (MIC) of 6.25 μg/ml. The results were comparable to standard antibiotics like gentamycin (for bacteria) and nystatin (for yeast) [24].

CONCLUSION

This study has given preliminary information to determine the chemical composition of *Millingtonia hortensis* L.f. using UV-Vis, FTIR and GC-MS. The phytochemical screening of *Millingtonia hortensis* flower extract using four different solvents revealed the presence of diverse bioactive compounds, including alkaloids, flavonoids, tannins, saponins, and phenolic compounds indicating the plant's rich phytochemical profile. In the present study, 21 out of 101 major chemical constituents are identified from ethanolic flower extract of *Millingtonia hortensis* by Gas Chromatogram-Mass Spectroscopy (GC-MS) analysis. The findings indicate that the ethanolic extract has promising antibacterial capabilities, particularly at higher concentrations. It was effective against *Staphylococcus* and equivalent to Ampicillin for the other two bacteria at 60 μL. The findings support the traditional medicinal use of this plant and highlight its potential as a source of natural antibacterial agents. Further research will include identifying and characterizing the individual bioactive chemicals responsible for the reported antibacterial activity, as well as testing their safety and efficacy in vivo. Therefore, it is suggested that this plant be used as a phytopharmaceutical.

ACKNOWLEDGMENT

The authors express their sincere gratitude to V. O. Chidambaram College, Thoothukudi, for providing the necessary facilities and resources to conduct this research.

ABSTRACT

A range of studies have explored the diversity and distribution of millipedes, including the yellow spotted millipede. Chen [1] and Patil [2] both identified new species in their respective studies in China and India, while Boccardo [3] and Bogyó[4] focused on the habitat and seasonal variations in millipede populations in Brazil and Hungary. These studies collectively contribute to our understanding of the yellow spotted millipede's ecological role and its potential as a bioindicator of environmental health. In India, particularly in the Western and Eastern Ghats, Patil [2] and Ramanathan [5] has revealed a rich diversity of species. Hence, the present study focus on the importance and application of the yellow millipede collected from various literature available in google scholar.

Keywords: These studies collectively contribute to our understanding of the yellow spotted millipede's ecological role and its potential as a bioindicator of environmental health.

INTRODUCTION

Millipedes, while generally harmless, can become a nuisance when they invade homes in large numbers, potentially contaminating food and causing respiratory problems for those with allergies. They are particularly attracted to damp areas, and their presence can be a sign of excess moisture in the home. To address infestations, it is recommended to wait for a few days for the problem to subside and then vacuum the remaining bodies, while also removing debris and sealing openings around the foundation. If problems persist, insecticides may be used. Insight Pest Solutions offers millipede extermination services to address these issues [6]. The yellow spotted millipede, a non-native species, has been introduced to various locations, including Arkansas, Louisiana, Oklahoma, Texas, India

**Vijaydharssani and Horne Iona Averal**

and Singapore [7, 8]. These millipedes are known to have arrived in non - native sites via potted plants and compost from greenhouses [7]. They are most commonly found in the order Polydesmida, which produces the brightest fluorescence under ultraviolet light [9]. Despite being a pest of potatoes in some areas, no pathogenic microorganisms have been found in these millipedes [10].

MILLIEPEDE IN A BIRDS EYE VIEW

The yellow spotted millipede, a member of the Chelodesmidae and Paradoxosomatidae families, has been found in canola cultivation in Brazil [11]. In Australia, the 'Ommatoiulus moreleti' millipede is a nuisance pest, with activity patterns influenced by climatic conditions [12]. Fossil evidence of millipedes, including the *Sinosomaluopingense*, has been found in the Middle Triassic Luoping biota of China [13]. In the Kalahari, millipedes exhibit unique behaviors and ecological adaptations, such as burrowing and surface activity after rainfall [14]. Research on the yellow spotted millipede in India is limited, with most studies focusing on other millipede species. Verma[15] identified various pests of pearl millet in India, but did not specifically mention the yellow spotted millipede. Ramanathan [5] and Alagesan [16] both conducted studies on millipede diversity and distribution in different regions of Tamil Nadu, but did not specifically mention the yellow spotted millipede. Gour[17] studied the diversity of millipedes in the Amravati region of Maharashtra, but also did not specifically mention the yellow spotted millipede. Therefore, there is a gap in the literature regarding the overall view of the yellow spotted millipede in India.

CLASSIFICATION OF MILLIEPEDE

The yellow spotted millipede, a member of the class Diplopoda, is a diverse and ecologically important group of arthropods [18]. It is found in various habitats, including Jamaican caves [19] and the Yintiaoling National Natural Reserve in Southwest China [1]. The species is not considered a pest in the cultivation of canola in Brazil [20].

TAXONOMIC POSITION

The millipede belongs to the kingdom Animalia, class diplopoda, order polydesmida and family Xystodesmidae. The Genus *Harpaphe* and Species: *Harpaphe haydeniana* [21].

RESEARCH IN INDIA

Research on millipedes in India, particularly in the Western and Eastern Ghats, has revealed a rich diversity of species [2, 5]. The presence of *Trigoniulus corallines* in both regions suggests a potential overlap in their habitats [2, 5]. Similarly, the Alagar Hills Reserve Forest in Tamil Nadu has been found to host a variety of millipede species, with mid-elevations being particularly rich in diversity [16]. However, specific information about the yellow spotted millipede in India is not provided in these studies, indicating a need for further research [22, 16, 23, 2] Fig - 1. The yellow-spotted millipede, *Harpaphe haydeniana*, is a common bug found in the moist forests along the Pacific coast [24]. These millipedes have long dark brown or black bodies with contrasting yellow spots down their sides and are known for having multiple body segments, each containing two pairs of legs [25]. Females usually consist of 31 pairs of legs while males have 30 [25]. The activity of these millipedes is influenced by environmental conditions, with a change in activity rhythm observed in late summer and autumn [12]. They play an important role as detritivores in the ecosystem [25].

DIVERSITY OF MILLIEPEDE IN INDIA

Research on millipede diversity in India has revealed a variety of species in different regions. In the Yelagiri hills of Tamil Nadu, 10 species were identified, with the genus *Arthrosphaera* being dominant [26]. Similarly, the Sirumalai Hills in Tamil Nadu were found to host 8 species, with differences in species composition across elevations [5]. The Alagar Hills Reserve Forest, also in Tamil Nadu, showed a peak in millipede diversity at mid-elevations, with specific species being more abundant at 450m [16]. In the Chandoli National Park in Western Maharashtra, a higher diversity of millipedes was found, influenced by less habitat disturbance and food availability [23]. These studies collectively highlight the rich and varied millipede diversity in India, with specific species being more prevalent in certain regions and elevations.

**Vijaydharssani and Horne Iona Averal****MILLIPEDE HABITAT AND PREVENTION STRATEGIES**

Yellow-spotted millipedes, which are harmless to humans, prefer damp and cooler environments and feed on organic debris. They can become an annoyance, especially if there is an invasion near your home. To prevent this, it is recommended to reduce moisture and seal potential entry points. Removing attractants, such as decaying plants and keeping the home clean can also help. In severe infestations, professional pest control services may be necessary [6].

MEDICINAL USES OF YELLOW SPOTTED MILLIPEDE

The yellow spotted millipede, a species found in India, is known for its medicinal uses. Sahu [28] and Mistry [26] both highlight the diverse medicinal applications of various plants and natural resources in India, suggesting that the millipede may also have medicinal properties. The Paite tribe of Manipur, as documented by Devi [29], uses a variety of plants for dermatological healthcare, indicating a potential use for the millipede in skin treatments. Similarly, Yuhlung [30] discusses the use of indigenous medicinal plants by the Maring tribe, Manipur suggesting that the millipede may have traditional medicinal uses in these communities. Further research is needed to explore the specific medicinal properties of the yellow spotted millipede.

ENVIRONMENTAL USES IN INDIA

A significant part of the forest ecosystem in India, plays a crucial role in the turnover of organic matter and the availability of minerals in its habitat [31]. However, its specific environmental uses in India, particularly in relation to pearl millet, are not explicitly discussed in the available literature. Further research is needed to explore the potential applications of the yellow spotted millipede in the context of pearl millet and other agricultural practices in India.

IMPACT OF POLLUTANT IN THIS SPECIES

The studies by Akkari, & Voigtlaender, [32] and Farfan [33] both highlight the ability of certain invertebrates, such as the midgefly and specific millipede species, to survive in polluted environments. This suggests that the yellow spotted millipede may also have a high tolerance for pollutants. However, the specific impact of pollutants on this species is not directly addressed in the available literature. Further research is needed to understand the potential effects of pollutants on the yellow spotted millipede.

MILLIPEDES AS A FOOD FOR TRIBALS IN INDIA

The use of the yellow spotted millipede by tribals in India is not directly addressed in the provided research papers. However, Enghoff [34] and Patil [2] provide valuable information on the nutritional value and diversity of millipedes, respectively. Lever [35] discussed that the irritant exudation from a centipede, has anti-parasitic effect, which may be relevant to the use of millipedes by tribals. Patil [36] highlights the use of wild animal parts, including millipedes, by tribals in Nandurbar district, Maharashtra, for medicinal purposes. This suggests that the yellow spotted millipede may have traditional medicinal uses among tribals in India.

CONCLUSION

The present study focusses on the review of the yellow spotted millipede *Harpaphe Haydeniana*. The diversity and the economic importance were discussed. In India, different species were identified and which showed a good diversity in Western and Eastern Ghats. From various literature it has been proved that tribes lived in India used the yellow spotted millipede as food as well as medicine. But research need to explore in this site to know the full pledged medicinal properties of this organisms. Hence it was concluded that further research is need to be conducted in yellow spotted millipede.

ABSTRACT

Fungi represent a critical component of diverse ecosystems, playing pivotal roles in nutrient cycling, symbiosis, and pathogenesis. Metagenomics, the study of genetic material recovered directly from environmental samples, has revolutionized fungal identification and taxonomy, providing an unprecedented ability to detect, classify, and study fungi without the need for cultivation. This review explores the current advances, challenges, and future perspectives in metagenomics-based fungal research. Metagenomics methodologies, including DNA extraction, amplification techniques, and sequencing technologies, which enable the comprehensive analysis of fungal communities across various environments such as soil, water, and clinical samples. Bioinformatics challenges related to fungal metagenomics, such as the lack of complete fungal reference databases and issues with taxonomic and functional annotation, are discussed in detail. Additionally, we highlight the complexity of fungal genomes, which includes large sizes, repetitive sequences, and horizontal gene transfer, complicating genomic analyses. Despite these challenges, the potential of metagenomics to address ecological and clinical questions is vast. This review also explores future directions, such as the integration of multi-omics approaches to provide deeper insights into fungal biology, the role of emerging sequencing technologies in improving genome resolution, and the expansion of reference databases. Furthermore, we discuss the growing applications of metagenomics in synthetic biology, where fungal enzymes and pathways offer promising industrial and therapeutic possibilities. Through these advancements, metagenomics is poised to significantly enhance our understanding of fungal diversity and its applications in various fields.

Keywords: Metagenomics, fungus, genomics, diversity, sequencing

INTRODUCTION

Metagenomics is a revolutionary field that has transformed our understanding of microbial communities[1]. By directly sequencing the genetic material extracted from environmental samples, metagenomics bypasses the limitations of traditional culturing methods, allowing us to explore the vast and largely uncultured microbial world. This approach has been particularly impactful in the study of fungi, a diverse kingdom of organisms that play crucial roles in ecosystems, human health, and industry[2]. Fungal identification has traditionally relied on morphological characteristics and laborious culturing techniques. However, these methods often fail to capture the full diversity of fungal communities, as many species are difficult to grow in the laboratory[3]. Metagenomics, with its culture-independent approach, offers a powerful alternative for unraveling fungal diversity. By targeting specific fungal genes, such as the internal transcribed spacer (ITS) region of ribosomal DNA, metagenomics can identify a wide range of fungal species, including those that are rare or unculturable[4]. The Internal Transcribed Spacer (ITS) region is the gold standard for fungal identification. Other markers, such as LSU and SSU rRNA genes, complement ITS for phylogenetic studies[5]. Figure 1 shows the different application of metagenomics in fungus research. This combination of metagenomics and targeted gene sequencing has opened up new avenues for fungal research, enabling us to explore fungal diversity in various environments[6]. Metagenomics has revealed the astonishing diversity of fungal communities in different habitats like soil, water, human microbiome etc[7]. By analyzing metagenomic data, researchers have discovered numerous new fungal species, expanding our knowledge of fungal taxonomy and evolution. Metagenomics has provided insights into the ecological functions of fungi, such as nutrient cycling, plant-microbe interactions, and bioremediation[8]. By studying the fungal communities associated with human diseases, metagenomics can aid in the diagnosis, treatment, and prevention of fungal infections. Metagenomics has revolutionized fungal identification, providing a powerful tool for exploring the hidden diversity of this important kingdom[9]. By applying metagenomic techniques deeper understanding of the fungal world and its impact on our planet and human health can be studied.

Metagenomic Analysis of Fungi

The accuracy of metagenomic studies begins with the collection of representative environmental samples. Common sources include soil, water, air, and host-associated environments. Proper sample preservation and extraction methods, such as bead-beating and enzymatic lysis, are essential to obtain high-quality fungal DNA[10]. Advancements in sequencing technologies have significantly impacted fungal metagenomics. Second-Generation Sequencing (SGS). Platforms like Illumina provide high-throughput sequencing with short reads, suitable for amplicon-based studies[11]. Third-Generation Sequencing (TGS) technologies like Oxford Nanopore and PacBio enable long-read sequencing, improving genome assembly and resolving complex fungal genomes[12]. List of sequencing technologies along with their applications and limitations have been shown in table 1. Bioinformatics pipelines are crucial for analyzing metagenomic data, providing the computational foundation to unravel the complexity of fungal communities from environmental samples. These pipelines involve multiple stages and specialized tools tailored to achieve specific goals in fungal metagenomics[13]. Taxonomic classification is essential to identify the composition of fungal communities at various taxonomic levels (phylum, genus, or species). QIIME2 (Quantitative Insights Into Microbial Ecology 2) is a widely used platform for processing and analyzing sequence data, QIIME2 integrates quality filtering, clustering, and taxonomic assignment. It supports fungal community analysis using Internal Transcribed Spacer (ITS) sequences, a popular fungal barcode[14]. MEGAN (MEtaGenome Analyzer) a versatile tool that visualizes metagenomic datasets and assigns taxonomic ranks by comparing sequences to databases such as NCBI or UNITE. MEGAN is particularly useful for exploring fungal diversity and phylogeny[15]. List of metagenomics tools used for taxonomic and functional analysis have been described in table 2. Functional annotation aims to predict the roles of fungal species in the ecosystem or host environment. FUNGuild is a powerful tool for guild-based classification of fungal functional groups, FUN Guild maps OTUs (Operational Taxonomic Units) or ASVs (Amplicon Sequence Variants) to ecological roles such as saprotrophs, pathogens, or symbionts[16]. PICRUSt (Phylogenetic Investigation of Communities by Reconstruction of Unobserved States) originally developed for bacteria, PICRUSt has been used for fungi analysis also. It predicts metabolic

**Ruchi Yadav**

pathways and gene functions based on reference databases and phylogenetic information[17]. Assembly and binning are critical for reconstructing fungal genomes and organizing them into discrete genomic bins for downstream analysis. MetaSPAdes is a metagenome-optimized genome assembler, MetaSPAdes is designed to handle fragmented fungal genomes, producing high-quality assemblies by stitching overlapping reads[18]. It is effective for recovering entire fungal genomes from complex datasets. MetaBAT tool is used for binning assembled sequences into genome bins based on sequence composition and co-abundance patterns. MetaBAT is useful for identifying specific fungal genomes from mixed community data, which is particularly challenging due to the complex and repetitive nature of fungal genomes[19].

Applications of Metagenomics in Fungal Research

Metagenomics has emerged as a powerful tool for investigating fungal diversity and function across various fields. This section outlines key applications of metagenomics in fungal research. Table 3 shows the various application of metagenomics in fungal research. Metagenomics has revolutionized the study of fungi by enabling comprehensive analysis of fungal communities, their functions, and their interactions with various environments. One of the primary applications is in fungal diversity and taxonomy, where high-throughput sequencing techniques, such as 16S and ITS rRNA sequencing, facilitate the identification and classification of fungal species across ecosystems, such as soil, water, and plant roots[20]. Another critical area is fungal pathogen detection, where metagenomic shotgun sequencing and DNA barcoding are used to identify fungal pathogens in clinical, agricultural, and environmental samples, such as detecting *Aspergillus* in respiratory infections[21]. In the field of fungal bioremediation, metagenomic tools help uncover fungal species capable of degrading pollutants, offering solutions for environmental cleanup. For example, specific fungal strains have been identified for the biodegradation of toxic compounds in polluted soils[22]. Similarly, fungal metabolite profiling utilizes metagenomics and metabolomics to explore secondary metabolites for drug discovery and industrial applications, leading to the identification of novel antimicrobials and anticancer compounds[23]. The role of fungi in human health is another emerging focus, with mycobiome studies revealing how fungal communities in the gut or on the skin influence autoimmune diseases and other health conditions. In agriculture and ecology, the study of fungal symbiosis and fungal ecology reveals how fungi interact with plants, animals, and microbial communities, aiding stress tolerance and nutrient cycling[24].

Finally, metagenomics contributes to fungal functional genomics and evolutionary studies, enabling the annotation of fungal genes involved in metabolism and pathogenesis and tracing the evolutionary history of fungi. These diverse applications demonstrate the transformative potential of metagenomics in advancing fungal research and addressing ecological, medical, and industrial challenges[25]. Table 4 summarizes the key roles of metagenomics analysis in the context of various fungal diseases. It includes a range of fungal diseases, such as invasive fungal infections (e.g., *Aspergillus*, *Candida*, *Pneumocystis*), chronic respiratory infections, and fungal microbiome studies in the human gut and environment. Metagenomics methods employed (primarily Metagenomic Next-Generation Sequencing - mNGS and 16S rRNA gene sequencing), and highlights the significant contributions of metagenomics in each case. These contributions include direct pathogen detection, improved diagnosis: Enhanced patient management, novel pathogen discovery, understanding fungal ecology [39]. Metagenomics has emerged as an indispensable tool for advancing fungal research across diverse fields. By providing a culture-independent approach to studying fungal communities, metagenomics has revolutionized our understanding of fungal diversity, ecology, and function. Metagenomics has revolutionized our understanding of fungal diversity in diverse ecosystems other application of metagenomics in fungal research has been enlisted below.

1. **Soil Microbiomes:** Numerous studies have employed metagenomics to characterize fungal communities in soils. These studies have elucidated the roles of fungi in crucial ecosystem processes such as nutrient cycling (carbon, nitrogen, phosphorus), decomposition, and soil health. For example, metagenomic analyses have revealed the presence of novel fungal taxa involved in the degradation of complex organic matter and the formation of soil aggregates[40].
2. **Marine Ecosystems:** Metagenomic investigations have expanded our knowledge of fungal diversity in marine environments, including oceans, estuaries, and coastal areas. These studies have uncovered unique fungal

**Ruchi Yadav**

species and lineages adapted to the marine environment, highlighting their potential roles in biogeochemical cycles and marine food webs[41].

3. **Clinical Mycology:** Metagenomics is transforming the field of clinical mycology by enabling the rapid and accurate identification of fungal pathogens, particularly those that are difficult to culture using traditional methods[42].
4. **Direct Pathogen Identification:** Techniques such as shotgun metagenomics allow for the direct identification of fungal pathogens from clinical samples (e.g., blood, tissue, respiratory fluids). This approach is particularly valuable for the diagnosis of rare or emerging fungal infections and for identifying mixed infections caused by multiple fungal species[43].
5. **Improved Disease Management:** Metagenomic data can provide insights into the virulence factors and drug resistance mechanisms of fungal pathogens, aiding in the development of more effective antifungal therapies[44].
6. **Bioremediation:** Metagenomic analyses can identify novel fungal species with the ability to degrade environmental pollutants, such as hydrocarbons, pesticides, and heavy metals. These fungi can be exploited for bioremediation strategies to clean up contaminated sites[45].
7. **Crop Protection:** Understanding the fungal communities associated with plants, including both beneficial and pathogenic fungi, has important implications for crop protection. Metagenomic studies can help identify beneficial fungi that can be used as biocontrol agents against plant diseases, enhance plant growth and development, and improve crop productivity[46].

Challenges in Metagenomics-Based Fungal Identification

Metagenomics technique faces several challenges, particularly in the areas of DNA extraction, amplification, bioinformatics, and genome complexity. Addressing these challenges is crucial for improving the accuracy and resolution of metagenomic fungal studies. Fungal DNA extraction from environmental samples, such as soil, plant roots, or clinical specimens, is often hindered by the presence of contaminants like bacterial DNA, humic substances, and other inhibitors[47]. These contaminants can interfere with the efficiency of DNA extraction, leading to biased representation of fungal communities. Additionally, the diversity of fungal species within a sample can complicate DNA amplification. Common DNA extraction methods are not always optimized for fungal cells, especially those with tough cell walls, such as *Chytridiomycota* and *Zygomycota*[48]. Furthermore, amplification biases introduced by primers, particularly in rRNA gene-based approaches, may skew the representation of fungal communities. To overcome these limitations, advancements in DNA extraction protocols tailored specifically for fungal biomass, as well as improved amplification strategies, are essential[49]. One of the most significant challenges is the lack of comprehensive fungal reference databases, which hampers accurate taxonomic and functional annotation. The current databases often suffer from incomplete or uneven representation of fungal species, particularly those from underexplored environments. This leads to misidentifications or failed annotations when analyzing complex fungal communities[50]. Additionally, the development of standardized pipelines for fungal metagenomic analysis is still in its infancy. Variability in data processing methods, such as read assembly, binning, and taxonomic assignment, results in inconsistencies and challenges in reproducibility across studies. Improved algorithms that are specifically designed to handle the unique aspects of fungal genomes, including their high diversity and low representation in public databases, are critical to advancing the field[51]. Fungal genomes exhibit considerable complexity, characterized by their large size, repetitive sequences, and the frequent occurrence of horizontal gene transfer (HGT). These features pose significant hurdles for accurate genome assembly and annotation. The repetitive nature of fungal genomes can complicate de novo assembly efforts, often leading to fragmented contigs and incomplete genome representations[52]. Furthermore, HGT between fungi and other organisms, including bacteria and plants, further complicates the interpretation of genomic data. This adds an additional layer of complexity in discerning evolutionary relationships and functional roles of fungal genes. To address these challenges, novel sequencing techniques, more refined assembly algorithms, and improved strategies for dealing with HGT are needed[53].

**Ruchi Yadav****Future Directions**

Despite the challenges, metagenomics holds great promise for advancing our understanding of fungal biology and ecology. Several emerging trends and technologies offer the potential to overcome current limitations and open new avenues for research[54]. One of the most exciting future directions in metagenomics is its integration with other omics approaches, such as transcriptomics, proteomics, and metabolomics. By combining metagenomic data with gene expression profiles, protein function analysis, and metabolite characterization, researchers can obtain a more comprehensive understanding of fungal biology[55]. This multi-omics approach will allow for a holistic view of fungal communities, their functional potential, and their interactions with the environment or host organisms. For example, integrating metagenomic data with transcriptomic and proteomic datasets can help elucidate the functional roles of specific fungal species within complex ecosystems[56]. Emerging sequencing technologies, such as single-cell sequencing and third-generation sequencing (TGS), hold great potential for resolving fungal genomes with greater accuracy and completeness[57]. Single-cell sequencing will allow for the analysis of individual fungal cells, which is especially useful in uncovering the diversity of rare or unculturable species within a sample[58]. TGS platforms, such as PacBio and Oxford Nanopore, offer long-read sequencing that can more effectively resolve complex, repetitive fungal genomes and improve genome assemblies. The development of these advanced sequencing technologies is expected to significantly enhance our ability to conduct in-depth fungal metagenomic studies[59]. Metagenomics has great potential in the field of synthetic biology, particularly in the discovery of novel fungal enzymes and metabolic pathways with industrial and therapeutic applications[60]. Fungi are known to produce a wide range of bioactive compounds, such as enzymes for bioremediation, antibiotics, and immunosuppressive drugs. Through metagenomic mining, novel fungal enzymes with unique properties can be identified, and synthetic biology approaches can be used to optimize their production. Additionally, metagenomics can aid in identifying new biosynthetic pathways for valuable bio-products, providing a sustainable source for industrial applications[61].

CONCLUSION

Metagenomics has revolutionized our understanding of fungal diversity, offering a powerful tool for the identification and characterization of fungi from complex environmental and clinical samples. By bypassing the need for culturing, metagenomic approaches enable the discovery of previously uncharacterized species and provide a more comprehensive picture of fungal communities. The integration of advanced sequencing technologies and bioinformatics tools has facilitated the analysis of vast amounts of genomic data, enhancing our ability to identify fungi at the species and strain levels. The significance of metagenomics in fungal research lies in its potential to uncover the intricate relationships between fungi and their environments, shedding light on their ecological roles and contributions to biodiversity. In the context of human health, metagenomic insights have profound implications, particularly in understanding the pathogenesis of fungal infections, their resistance mechanisms, and their impact on immunocompromised patients. Furthermore, it paves the way for the discovery of novel antifungal targets and the development of precision medicine strategies tailored to specific fungal pathogens. Future of fungal research through metagenomics holds tremendous promise. With the continued advancement of sequencing technologies, bioinformatics tools, and computational approaches, we can expect more precise, efficient, and cost-effective fungal identification. Future research will also focus on refining metagenomic workflows to better integrate multi-omics data, providing a more holistic view of fungal biology and interactions. These advancements will lead to deeper insights into the roles fungi play in both health and disease, fostering the development of innovative therapeutic strategies and environmental management practices.

ACKNOWLEDGEMENTS

I would like to acknowledge Amity Institute of biotechnology, Amity University Uttar Pradesh, Lucknow campus for providing us facilities to conducting this study.

Table 1 Metagenomics sequencing technologies along with its application and limitations.

S.No	Sequencing Technology	Read Length	Data Output	Applications	Advantages	Limitations
1	Illumina (SGS)	50-300 bp	High-throughput	Amplicon sequencing, whole-genome sequencing	High accuracy, cost-effective	Short reads, challenging for complex genomes
2	PacBio (TGS)	>10,000 bp	Moderate	Genome assembly, resolving repeats	Long reads, improved genome assembly	Higher error rate, expensive

Ruchi Yadav

3	Oxford Nanopore (TGS)	Up to 2 Mb	Moderate	Real-time sequencing, metagenome assembly	Portable, long reads, real-time analysis	High error rate, costly for large-scale studies
4	Ion Torrent (SGS)	200-600 bp	High-throughput	Targeted sequencing, small genome assembly	Fast turnaround, suitable for targeted studies	Limited by read length, sequencing errors
5	Sanger Sequencing	500-1000 bp	Low-throughput	Validation, single-gene studies	High accuracy, gold standard for validation	Labor-intensive, low throughput

Table 2 Bioinformatics tools used for taxonomic and functional analysis for metagenomics data

ABSTRACT

Green nanotechnology seeks to develop nanomaterials and products that are environmentally benign and safe for human health, while also addressing environmental challenges through innovative nanoproducts. The instability of residues from chemicals not produced by chemical synthesis necessitates the advancement of green chemistry in nanoparticle fabrication. The objective of this study was to synthesize and characterize cerium oxide nanoparticles (CeO₂NPs) from ethanol extracts of *Tamarindus indica* and evaluate their antibacterial efficacy against *Staphylococcus aureus* and other Gram-positive coagulase-positive cocci. The optical characteristics, crystallinity, dimensions, and morphology of the biosynthesized nanoparticles were evaluated using UV-Vis spectroscopy, FTIR (Fourier Transform Infrared Spectroscopy), and SEM (Scanning Electron Microscopy). The synthesis and characterization of cerium oxide nanoparticles (rare earth elements) were analyzed in an environmental study, which revealed that a more environmentally sustainable process could be identified even at the laboratory scale. This work concluded that cerium oxide nanoparticles may be produced utilizing extracts from ridge gourd shells. This method provides environmentally beneficial alternatives to more dangerous processes, while also fostering pollution avoidance through the synthesis of nanoparticles in their natural environments. The current research indicates that the produced cerium oxide nanoparticles may serve as an antioxidant activity and antibacterial agent against many pathogenic microorganisms.

Keywords: *Tamarindus indica*, Antibacterial activity, DPPH assay and Pathogenic organism.

Sakthivel *et al.*,

INTRODUCTION

The objective of the multidisciplinary field of nanotechnology is to create materials with enhanced atomic, molecular, and supramolecular properties. Abdelrahman, G.H *et al.*, 2019) assert that nanomaterials are employed in microelectronics, glucose detection, DNA and RNA analysis, heavy metal detection, disease diagnosis, and disease management. Metal nanoparticles can be synthesized using several physical, chemical, and biological methods. The synthesis of nanoparticles using bacteria, fungi, algae, yeast, and plants is referred to as the "biological method". The narrow size distribution of nanoparticles is a benefit of physical and chemical methods; nevertheless, the main disadvantages are high energy, time, and cost requirements, along with the usage of dangerous substances (Ain, Q.U *et al.*, 2023). Biological technologies provide numerous advantages over conventional methods, including high yields, low prices, absence of downstream processing, and environmental sustainability. Additionally, an alternative term for the biological processes is "green synthesis." Consequently, the synthesis of nanoparticles by plant extracts offers a simple, single-step reduction process suitable for large-scale production. Numerous research indicate that plant extracts exhibiting significant biological activity can be utilized to synthesize nanoparticles (Agarwal *et al.*, 2018).

Phytomining is the technique of utilizing plant extracts to convert metal ions into nanoparticles. Research on plant extracts for the synthesis of nanoparticles has been prevalent in recent years. Assert that plant extracts function as stabilizing, capping, and reducing agents. Plant-derived materials, such as leaves, stems, roots, shoots, flowers, bark, seeds, and there by products, have been successfully utilized for the creation of nanoparticles (Aly, S.H, *et al.*, 2023). Similarly, *Tamarindus indica*, a long-lived evergreen hardwood tree found in various countries/regions, such as Egypt, Africa (tropical region), and Asia (including India), is used for medicinal purposes. *Tamarindus indica* trees produce a large amount of green fruits. When green fruit fully ripens on the tree, it becomes a paste-like texture (brown/reddish brown color). And the fruit will become sweet and sour. Over time, every part of the tree has been used in the Ayurvedic medicinal system for its nutritional benefits. For example, tree pulp was employed as an ayurvedic element for both skin detoxification and body polishing (Anokwah, D *et al.*, 2022). Furthermore, Tamarind paste has antimicrobial characteristics, hence it was commonly used to treat wounds. According to a World Health Organization report, tamarind fruits contain the majority of necessary amino acids.

The importance of biomedical applications of CeO₂ has recently grown due to their ability to provide protection against radiation, toxicant-induced cellular damage, and various pathological conditions, including brain or heart ischemia, neurological disorders, and retinal neurodegeneration. CeO₂ exhibits low solubility in water, leading to challenges in biological applications. Multiple studies have demonstrated that nanomaterial polymer coatings improve stability, biocompatibility, and water solubility; for instance, dextran-coated nanoceria displays antioxidant properties (Bagevadi, Z.K *et al.*, 2019). Nanoceria is emitted into the atmosphere as a result of extensive utilization, raising significant concerns regarding human exposure, primarily through inhalation. The literature on the toxicity of CeO₂ presents inconsistent results. Doping cerium dioxide nanoparticles with various elements can alter their optical, electrical, structural, and biomedical properties (Baliyan, S *et al.*, 2022).

Hence, in the current study, we collected and extracted the rare earth cerium oxide nanoparticles from *Tamarindus indica* fruit shells were synthesized using a chemical method using methanol solvents, respectively. The samples were characterized through UV-spectroscopy, Fourier Transform Infrared Spectroscopy (FTIR), and SEM analysis. The antibacterial and antioxidant activities of the samples were also examined.

Experimental Section

Plant Material

Fruit shells of *Tamarindus indica* were procured from Thiruvkanager village, Tirupattur, Tirupattur District, Tamil Nadu, India, based on cost-effectiveness, accessibility, and medicinal properties. Shells of *Tamarindus indica* were

Sakthivel *et al.*,

locally sourced, meticulously cleaned with tap water and subsequently with distilled water to eliminate dust and extraneous elements, then cut into small fragments, air-dried, and ground into powder for subsequent application.

Extraction of Plant Material

The methanol extract of *Tamarindus indica* fruit shell was obtained by combining 10 g of fruit shell powder with 100 ml of deionised water in a 250 ml Erlenmeyer flask. The mixture was thereafter cooked on the hot plate at 60 °C for 20 minutes. The produced solution was first filtered via standard filter paper to remove undesirable components, followed by filtration with Whatman filter paper No. 1 (Bhadoriya, S.S *et al.*, 2011). Finally the prepared compound of extracts was denoted as TIFs. The filtered extract served as the reducing and stabilising agent in the creation of nanoparticles.

Synthesis of Cerium Oxide Nanoparticles

The first visual confirmation of the green synthesis of Cerium Oxide Nanoparticles utilising fruit shell extract came from observation. The shell extract was subjected to a Cerium ion solution, resulting in the formation of Cerium Oxide Nanoparticles. A 0.1M solution of Cerium (III) Nitrate Hexahydrate (CAS No: 10294-41-4) was acquired from Sigma-Aldrich, USA. Cerium Oxide Nanoparticles were synthesised by dissolving 25.2 grams of $(\text{Ce}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O})$ cerium in 50 ml of double-distilled water and swirling for 20 minutes. Simultaneously, an aqueous extract of fruit shell was prepared by incorporating 1 gram of shell powder into 50 ml of double-distilled water. This mixture was vigorously agitated using a magnetic stirrer for 30 minutes at 60 °C until completely dissolved, followed by filtration through Whatman No. 1 filter paper. Thereafter, the Cerium (III) Nitrate solution was incrementally introduced to the fruit shell extract hull solution and agitated vigorously for 6-8 hours at 60 °C. Initially, the reaction mixture appeared brown, subsequently changing to yellow, indicating the creation of cerium oxide nanoparticles (C. Godugu, A *et al.*, 2023). The yellow powder was ultimately acquired, signifying the presence of Cerium oxide nanoparticles was recommended in Figure 1.

Characterization of Cerium Oxide Nanoparticles

UV-Vis Spectrophotometer

A double beam UV-visible spectrophotometer was used to analyze the reduction of Cerium ions in Cerium oxide nanoparticles at various wavelengths between 300 and 700 nm. The Perkin Elmer Spectrophotometer, which has a resolution of 1 nm, was used to perform this research.

Fourier Transform Infrared Spectroscopy

FTIR was used to analyze the phytochemical components of fruit shell powder and the functional groups of artificially produced Cerium Oxide nanoparticles (SHIMADZU instrument). Using KBr pellets, the materials were ground, and their FTIR spectra were measured between 4000 and 400 cm^{-1} .

Scanning Electron Microscopy

The extracted powdered material was coated with gold ions using an ion coater set at 0.1 Torr pressure, 20 mA current, and 70 s coating time. SEM used a 15 kV accelerating voltage to visualize the subsurface structure. The Leica stereo scan-440 scanning electron microscope was used to evaluate the SEM measurements. The produced nanoparticles' size and shape are shaped in part by the SEM data.

Antibacterial activity by agar well diffusion method

The antibacterial efficacy of rare earth cerium oxide nanoparticles derived from methanol extracts of *Tamarindus indica* fruit shells was evaluated against pathogenic bacterial strains, specifically *Bacillus subtilis*, *Escherichia coli*, *Salmonella*, and *Staphylococcus aureus*. The bacterial cultures were cultivated in Mueller Hinton Agar (Himedia) (figure 2). Antibacterial activity was assessed using diffusion disc plates on agar, with approximately 0.1 mL of each bacterial culture spread across the agar plate surfaces. For the antibacterial assay, all bacterial strains were incubated in Mueller Hinton Broth (Himedia) for 24 hours at 37°C and subsequently plated on Mueller Hinton Agar (Himedia) for agar diffusion experiments. Paper discs (6 mm in diameter) were positioned on the agar medium to absorb

Sakthivel *et al.*,

cerium oxide nanoparticles from 100 μL of peel extracts of *Tamarindus indica* fruit shell. Inhibition diameters were assessed following incubation for 24 to 48 hours at 37°C . In this study, Gentamycin (100 $\mu\text{g/ml}$) served as the positive control, while DMSO was utilized as the negative control to assess the sensitivity of the bacterial culture (Breijyeh, Z *et al.*, 2020). Different amounts of methanol extracts, prepared identically, from selected samples are utilized to assess antibacterial activity.

Antioxidant Activity

The antioxidant efficacy of the extracts was assessed utilizing DPPH free radical scavenging techniques. A stock solution of 1 mg/mL of cerium oxide nanoparticles derived from *Tamarindus indica* fruit shell extract and ascorbic acid was prepared by dissolving in methanol. DPPH (Diphenyl-2-picryl hydrazyl radical) - 1 mM Three milliliters of 1 mM DPPH in methanol was combined with 100 microliters of peel extracts at concentrations of 20, 40, 60, 80, and 100 microliters (V. Kalyanaraman *et al.*, 2019). The DPPH solution in methanol served as a positive control (ascorbic acid), whereas methanol alone functioned as a blank. The solution was incubated for 30 minutes at ambient temperature, and the absorbance was recorded at 680 nm utilizing a UV-visible spectrophotometer. When DPPH interacts with the antioxidant in the sample, the color transitions from deep purple to pale yellow (Biswas, S.K *et al.*, 2016). Each assay was conducted in triplicate. The proportion of radical scavenging activity for each plant extract at various dilutions was determined using the subsequent equation:

$$\text{DPPH radical \% inhibition} = [(C(\text{OD}) - S(\text{OD})) / C(\text{OD})] \times 100$$

Here, optical density (OD) refers to the absorbance of a methanolic solution of DPPH, which serves as the control. S (OD) represents the absorbance of the test sample, which includes cerium oxide NPs from fruit shell extracts and ascorbic acid; together with DPPH. The ranges of IC_{50} values were also determined.

RESULTS AND DISCUSSION

UV-Visible spectroscopy analysis

The UV Vis Spectrophotometer is an effective instrument for assessing the optical properties of synthesised Cerium Oxide Nanoparticles. The UV spectrum of appropriate sample was analysed within the range of 200-1000 nm. The UV-Vis absorption spectrum indicates a surface plasmon resonance band centred at 302 nm, which is a characteristic peak for Cerium Oxide Nanoparticles (Figure 3). The process demonstrates the reduction of Cerium ions to form metallic rare earth nanoparticles within the reaction mixture. The SPR band was generated as a result of the excitation of free electrons in the Cerium Oxide Nanoparticles upon the absorption of visible light. A single peak was observed, indicating the formation of spherical-shaped nanoparticles. The broadened peak displayed indicates that poly-dispersed nanomaterials, synthesised using tamarind fruit shells, were reported by Ashraf *et al.* (2016). A comparable outcome was documented in the synthesis of Cerium Oxide Nanoparticles by Ben Ayed, A *et al.*, (2022).

Fourier Transform Infrared (FT-IR) Spectroscopic Analysis

FTIR Spectrum is used to determine the presence of organic molecules on the surface of Nanoparticles. In this present investigation, an FTIR measurement was used to identify phytochemical present in fruit shell extract responsible for reduction of rare earth cerium oxide nanoparticles.

The FT-IR analysis revealed the following absorption peaks: 3425 cm^{-1} , 2499 cm^{-1} , 2192 cm^{-1} , 1626 cm^{-1} , 1461 cm^{-1} , 1371 cm^{-1} , 1330 cm^{-1} , 1041 cm^{-1} , 811 cm^{-1} , 734 cm^{-1} , and 575 cm^{-1} . The O-H stretching of alcohol is represented by peaks at 3425 cm^{-1} . The band at 2499 cm^{-1} indicates the stretching of the H-C=O bond in aldehydes. The C=C stretching of the conjugated alkene is indicated by peaks at 2192 cm^{-1} and 1626 cm^{-1} . The presence of alkene C-H bending is indicated by a peak at 1461 cm^{-1} , along with an additional peak at 1371 cm^{-1} corresponding to the same bending mode. The presence of aromatic amine C-N stretching is evidenced by the band observed at 1330 cm^{-1} . The C-O stretching of aliphatic ether is indicated by a peak at 1041 cm^{-1} . Sharp bands observed at 811 and 734 cm^{-1} correspond to potent nitro compounds in the asymmetric stretch. The 825 cm^{-1} peak indicated the presence of vinyl bond tri-substituted alkenes, whereas the 575 cm^{-1} peak was associated with bromo alkanes, which were significant in

the synthesis of rare earth cerium oxide nanoparticles (Figure 4). The following results exhibit similarity to T. N. Ravishankar et al., 2015.

Scanning Electron Microscope (SEM) Analysis

The geomorphology of CeO₂ NPs was examined using SEM, revealing a spherical shape. The SEM image of CeO₂ NPs, exhibiting a spherical shape, resulted from the interaction of CeN₃O₉.6H₂O with the peel extract of *Tamarindus indica* over a duration of 6 hours, as illustrated in Figures-5. The typical SEM images of nanoceria clearly illustrate a significant presence of spherical shapes with a narrow size distribution. The low-resolution image confirms that the shapes were synthesised in substantial quantities, with individual nanoparticle sizes approximately 30 nm, exhibiting a uniform and spherical morphology. These results are consistent with earlier studies (Muruganantham Chelliah et al., 2012).

To identify the cerium oxide nanoparticles in methanol extracts of *Tamrandius indica* fruit shells, antibacterial activity was evaluated using the traditional agar well diffusion method (Table 1). The extracts were made at the identical amounts using 2% DMSO (dimethyl sulfoxide) as a negative control. The test microorganisms *Bacillus subtilis* and *Escherichia coli* were seeded into the proper Mueller-Hinton agar medium using the spread plate technique. The plate was then incubated at 37°C for 24 hours. The antibacterial activity was assessed by measuring the diameter of the inhibitory zone that developed around the well (Brindhadevi, K et al., 2023).

The prepared cerium oxide nanoparticles exhibit antibacterial activity against both gram-positive and gram-negative bacteria (figure 6). Four types of organisms were utilized in this study *Salmonella*, *Escherichia coli*, *Bacillus subtilis*, and *Staphylococcus aureus*. *Staphylococcus aureus* and *Bacillus subtilis* are classified as gram-positive bacteria, while *Salmonella* and *Escherichia coli* are identified as gram-negative bacteria for this experimental research work. (Manandhar, S et al., 2019).

Figure 7 illustrates that *Bacillus subtilis* exhibited a gradual rise in the zone of inhibition, beginning at 17 mm at 50 µg/ml and reaching a maximum of 25 mm at 100 µg/ml, in comparison to the positive control (15 mm). *Escherichia coli* exhibited comparable outcomes, with the inhibition zone expanding from 17 mm at 50 µg/ml to 25 mm at 100 µg/ml. This was similarly analogous to the activity of Gentamicin. *Salmonella* had a somewhat reduced escalation in the zone of inhibition, varying from 18 mm at 50 µg/ml to 21 mm at 100 µg/ml. *Staphylococcus aureus* exhibited a significant enhancement in antibacterial efficacy, with the zone of inhibition escalating from 17 mm at 50 µg/ml to 25 mm at 100 µg/ml, exceeding the positive control's 14 mm inhibition. The results demonstrate that the chemical exhibits dose-dependent antibacterial efficacy against all examined species, with increased concentrations leading to greater zones of inhibition (Asowata-Ayodele, A.M et al., 2016). DMSO served as a negative control for the inhibitory zone of the produced drug.

Antioxidant activity

Antioxidants protect cells from damage inflicted by free radicals. Antioxidants have been shown to inhibit or mitigate the oxidation of other compounds. By removing radical intermediates and undergoing self-oxidation, they possess the capability to halt chain reactions and avert oxidation processes. The body contains substances that can mitigate the damage inflicted by free radicals or inhibit their formation. Edible substances and therapeutic flora are abundant in natural antioxidants. These plant-derived nanomaterials, specifically nanoceria antioxidants such as carotenoids and polyphenols, exhibit diverse biological effects. To explore potential sources of antioxidants and encourage their application in functional foods, pharmaceuticals, and food additives, it is crucial to efficiently extract antioxidants from food and medicinal plants and assess them accurately (Agidew, A et al., 2023).

From the figure 8 showed the DPPH radical scavenging activity results indicated that the methanol cerium oxide nanoparticles derived from *Tamarindus indica* fruit shell extract exhibited IC₅₀ values of 20 µg and 42.5 µg for the control ascorbic acid and aqueous extract, respectively. The antioxidant activity of cerium oxide nanoparticles is illustrated in Fig 2. These extracts have demonstrated significant efficacy as DPPH radical scavengers. Blainski, A et

Sakthivel *et al.*,

al., 2013 employed the concentration of the sample and standard that achieved 50% inhibition of free radicals to calculate the IC₅₀ values. The antioxidant efficacy of *Tamarindus indica* extracts was assessed by the DPPH radical scavenging method. DPPH is a widely utilized free radical compound for assessing the scavenging activity of various samples of free radicals. The method provides advantages of speed, simplicity, and cost-effectiveness, while also delivering direct data on the overall antioxidant capacity of the test system (Camele, I *et al.*, 2019).

CONCLUSION

Recent literature demonstrates that synthetic nanoceria have emerged as a significant category of nanomaterials for many industrial and medical applications. The extract of *Tamarindus indica* fruit shell utilized for nanoceria synthesis is effective, economical, environmentally sustainable, and suitable for large-scale production. The UV-Vis spectrum displays a distinct absorption peak for cerium oxide nanoparticles at 302 nm. The FTIR analysis revealed absorption bands associated with the primary functional groups in the natural fruit shell extract. The substantial decrease in response time attained by the use of fruit shell extract is a pivotal outcome of the biosynthesis approach, unlike other nanoparticle manufacturing techniques that are now more rapid and reproducible. Scanning electron microscopy revealed that the produced nanoparticles are spherical and around 20–30 nm in diameter. Additionally, *in vitro* antibacterial efficacy against multidrug-resistant Gram-positive and Gram-negative isolates. It exhibited synergistic effects with conventional antibiotics, hence decreasing their minimum inhibitory concentrations (MICs). The DPPH assay demonstrated that cerium oxide nanoparticles exhibited free radical scavenging capacity, with IC₅₀ values of 20 µg for ascorbic acid and 42.5 µg for the aqueous extract, respectively. Recent research suggest that cerium oxide nanoparticles obtained from the fruit shell of *Tamarindus indica* may serve as potential therapeutic and environmental agents.

ABSTRACT

There is an incredible reservoir of ethnobotanical expertise in Korampallam village, in particular concerning the usage of medicinal vegetation in number onefitness care. The following findings were made clear. An ethnobotanical survey was made in the Korampallam village in Thoothukudi district, Tamil Nadu, India during the month of January 2020. Based on the literature review, about 14 categories of common ailments like Kidney Disease (KD), Skin disease (SD), Hair problem (HP), Stomach problem (SP), Respiratory disease (RD), Cold (C), Cough (CO), Diuretic (D), Tooth ache (TA), Head ache (HA), Fever (F), Body heat (BH), Insect Bite (IB) and Menstrual issues (MI) were selected for the present survey. Among 14 major disease categories, dermatological disorders were dominated followed by kidney disease with 451 use-reports, followed by skin disease and hair problem (302 and 242 use-reports, respectively). From the finding it was shown that hair problem was noted with the highest ICF value of 0.98 Highest RCF value of 2.84 was noted for *Azadirachta indica* which was followed by *Ocimumtenuiflorum* with 1.16 and *Cynodondactylon* with 1.14 RCF value. To treat cold and cough *Ocimum tenuiflorum* and *Justicaadhatoda* were greatly used. *Cynodondactylon* (75%) and *Azadirachta indica* (52%) showed highest FL for treating diuretic issues. Based on ROP value *Azadirachta indica* is widely used species with the RPL of 90%. Current research work suggests that priority research projects in this area should be planned for the pharmacological evaluation and conservation of medicinal plants in this field.

INTRODUCTION

People have persistently utilized therapeutic plants to bargain with themselves and combat maladies. In all memorable civilizations and on all landmasses, one uncovers strains of this utilize [1]. Ethnobotany offers with the coordinate pursuing of plant life with man. The term has regularly been considered synonymous with either financial botany or with conventional pharmaceutical [2]. The present study explained the plant differences of Kormapallam, Thoothukudi district, Tamil Nadu, India. The area has a rich variety of flowers with medicinal value and important economic benefits. These flowers are commonly used by the local population for various purposes. The goals of the display consider incorporate ethnobotanical study utilizing Google form and quantitative examination of therapeutic plants.

MATERIALS AND METHODS

Description of the study area

Korampallam village was the area selected for the present analysis. Korampallam is a panchayat village located in Tamil-Nadu state, India, in the Thoothukudi district. The Korampallam geographical coordinates are latitude 8.77° N and longitude 78.1° E

Medicinal Plants Survey

The medicinal plants study of the village includes the testing of knowledge about the usage of common medicinal plants. Based on the literature review, about 14 categories of common ailments like Kidney Disease (KD), Skin disease (SD), Hair problem (HP), Stomach problem (SP), Respiratory disease (RD), Cold (C), Cough (CO), Diuretic (D), Tooth ache (TA), Head ache (HA), Fever (F), Body heat (BH), Insect Bite (IB) and Menstrual issues (MI) were selected for the present survey. A questionnaire was prepared using Google forms to collect the ethnobotanical applications of the plants in the village. The link was then circulated among the residents of the chosen village.

Quantitative analysis of ethnobotanical data [3]

Informant consensus factor (ICF).

The Informant Consensus Factor (ICF) value reflects the level of agreement among informants on the use of medicinal plant species and assesses variations in their modes of utilization for reported diseases. A high ICF value, approaching 1, signifies that widely recognized plant species are commonly used by local communities, indicating their reliability and effectiveness in treating diseases.

$$ICF = \frac{Nur - Nt}{Nur - 1}$$

Where, "Nur" is the total number of use reports for each disease category, "Nt" indicates the number of species used in said category.

Use value (UV)

The Use Value (UV) measures the relative significance of plant species based on their various uses, reflecting their importance in traditional practices.

$$UV = \frac{\sum U}{N}$$

Where "UV" represents the use value of an individual species, "U" denotes the total number of recorded uses for that species, and "N" refers to the number of informants who reported its use.

Relative frequency of citation (RFC)

The Relative Frequency of Citation (RFC) represents the local significance of each species within a study area. It is calculated by dividing the number of informants who mention a species (FC) by the total number of informants in the survey (N).

Pauline Jenifer and Beulah Jerlin

$$RFC = \frac{FC}{N} (0 < RFC < 1)$$

Fidelity level (FL).

The **Fidelity Level (FL)** represents the percentage of informants who reported the use of a specific plant species for treating a particular ailment within a study area.

$$FL\% = \left(\frac{NP}{N} \right) * 100$$

Where "NP" represents the number of informants who reported using a specific plant species for a particular disease, and "N" is the total number of informants who cited the species for any disease. A higher **Fidelity Level (FL)** indicates a greater frequency and strong preference for using that plant species to treat a specific ailment among the informants in the study area.

Relative popularity level (RPL)

The Relative Popularity Level (RPL) is calculated as the ratio of the number of ailments treated by a specific plant species to the total number of informants citing any disease. The RPL value ranges from 0 to 1, where 1 indicates that the plant is widely recognized for treating major ailments, while 0 signifies no reported medicinal use for any ailment.

Rank order priority (ROP).

The Relative Optimal Popularity (ROP) is a correction factor used to appropriately rank plant species based on their Fidelity Level (FL) and Relative Popularity Level (RPL). It is calculated by multiplying the RPL and FL values, ensuring a more precise assessment of the plant's significance in traditional medicine.

$$ROP = FL \times RPL$$

RESULT AND DISCUSSION

Informant consensus factor (ICF):

To calculate ICF, the said illnesses had been first categorized into 14 unique ailment classes on the premise of the literature review. Among 14 major disease categories, from the finding it is shown that hair problem is noted with the highest ICF value of 0.98 which may be due to the water used in the area. This has been shown in Table 1. Similar findings have already been reported in the ethnobotanical survey of medicinal plants commonly used by Kani tribals in Tirunelveli hills of Western Ghats, India[4]. However, Indigenous and tribal people in Rangamati, Bangladesh [5] and medicinal plants used in Terai forest of western Nepal. This has also been defined greater range of species to deal with gastrointestinal illnesses as compared to dermatological ailments[6].

Relative frequency of citation (RFC) and use value (UV):

The RFC and UV indices are carried out to pick capacity plant species for similarly pharmacological examine and advice in drug development. The RFC of the stated species ranged from 0.1 to 2% (Table 2). Highest RCF value of 2.84 was noted for *Azadirachta indica* which is followed by *Ocimum tenuiflorum* with 1.16 and *Cynodon dactylon* with 1.14 RCF. The plant species with excessive RFC ought to be subjected to pharmacologic, phytochemical, and different organic research to assess and show their authenticity[7]. The use value (UV) index demonstrates the relative significance of plant species and households for a population. In the present investigation, the UV of the reported medicinal plant species varied from 0.01 to 0.2 as shown in Table 2. The highest UV was observed for *Azadirachta indica* with 0.20 followed by *Ocimum tenuiflorum* and *Cynodon dactylon* with the value of 0.08. These findings reveal the substantial use of above stated species with inside the remedy of diverse illnesses with the aid of using neighbourhood inhabitants/healers and the awareness of indigenous peoples, which makes such medicinal plants, the primary desire to deal with a disease[8].

Pauline Jenifer and Beulah Jerlin

Relative popularity level (RPL)

Our 123 informants referred to 48 plant species for 14 one-of-a-kind disorder categories. They are given in Table 2. *Azadirachta indica* is considered to be popular plant of that area due to their higher RPL value of 0.9 which is closely followed by *Acacia nilotica*, *Achyranthes aspera* and *Bryophyllum calycinum* with the RCF value of 0.6 each. These findings had been in regular with preceding research at the repute of medicinal plant life amongst Bedouins of Negev district[9] and medicinal plant survey in Palestinian area[10].

Rank order priority (ROP)

The Rank order priority (ROP) index is used to rank correctly the plant species with special FL values. The ROP values are therefore received are given in Table 2. Of the forty eight species, best 5 species attained ROP above 50. The ROP values mentioned for medicinal vegetation utilized by Bedouins network in Negev district and in Palestinian location had been similar to give findings[10].

Fidelity level (FL)

The constancy fee is an vital way to peer for which disease a selected species is greater effective. It suggests the informants' preference for every disease and the ability of the species associated with the ailments. The FL of plant species for precise sicknesses within the gift have a look at location is proven in Table 3. The medicinal plant life which can be extensively utilized by the human beings of the RCF have better FL values than the ones which can be much less popular. On the alternative hand, greater medicinal plant life which can be referred to as treatments of a unmarried aliment have a 100% FL than the ones which can be used as treatments for multiple kind of aliment[11].

CONCLUSION

There is a top notch reservoir of ethnobotanical information in Korampallam village, particularly concerning using medicinal flora in number one fitness care. It is well documented in the current findings that the *Azadirachta indica* plant is the most popular plant and traditional claim of that region which are now ready to be pharmacologically further investigated, which would lead to the discovery and development of natural drugs. Current research work suggests that priority research projects in this area should be planned for the pharmacological evaluation and conservation of medicinal plants in this field.

FUTURE SCOPE

The current study aided in the identification of regionally significant medicinal plant species that are used to cure various illnesses, contributing significantly to the region's ethnobotany. To identify active chemicals that can be employed for drug discovery, additional phytochemical and pharmacognostic analysis of these species will be performed.

Declaration

Acknowledgement

I wish to acknowledge the people of Korampallam village, Thoothukudi, Tamil Nadu, India for their constant support and help.

Conflict of Interest

We the authors of this paper declare no potential conflict of interest.

Author's Contribution

Dr. S. Beulah Jerlin – helped me in selecting this problem and helped me to visit the Korampallam village.

Ms. S. Pauline Jenifer – I carried out this project by visiting, collecting, analysis of data and documentation.

ABSTRACT

Marine crustaceans offer an abundant supply of biological compounds, giving rise to a diverse array of secondary metabolites with various functional properties. In recent times, marine bacteria have garnered significant attention from the biotechnology sector due to the plethora of bioactive compounds found within them. This research endeavors to investigate and assess the largely unexplored microbiome residing in the intestinal gut of crustaceans for potential biotechnological applications. This microbial consortium will provide more insight and can be harboured in the biotechnology industry for the development of new novel biological agents.

Keywords: Bioprospecting; Crustaceans; Phylogeny; MTT; Sequence and Metabolites

INTRODUCTION

The world oceans comprise a rich diversity of microbial life with current estimates reaching over a million different species. The vast metabolic diversity of marine microorganisms is underpinned by novel enzymatic functions. While marine microorganisms have already proven to be a rich source of biologically active (bioactive) compounds, recent large-scale surveys indicated the existence of thousands of other yet undescribed protein families that provide immeasurable health benefits. Furthermore, there is a growing fascination with marine life, given that products derived from marine organisms often exhibit greater efficacy compared to bioactive compounds sourced from terrestrial environments. This diverse and vast biodiversity fosters high hopes for marine organisms harboring exceptional biochemical attributes and functionally active compounds that hold promise for a wide range of applications. Crustaceans, like crabs, harbor a wealth of advantageous substances, and the gastrointestinal tracts of marine creatures host a multifaceted ecosystem containing distinct microorganisms, encompassing aerobic, facultative anaerobic, and obligate anaerobic bacteria. The gut plays a pivotal role in maintaining the well-being and fostering the growth of the host organism. Given the ongoing evolution of microbial pathogens towards antibiotic resistance, there is a pressing need for the creation of novel and potent antimicrobial compounds. The marine microbiome exhibits the capacity to generate anticancer compounds and secondary metabolites effective against infectious diseases. This study serves as an exploration and investigation into the capacity of marine organisms to serve as sources for the development of marine drugs. Remarkably, the symbiotic microbial communities also demonstrate their potential as reservoirs of bioactive compounds with pharmaceutical applications. Bacteria and fungi have been collected from the exteriors of marine plants and the internal tissues of invertebrates, with a growing focus, especially, on marine fungi.(Numata *et al.*, 1992; Cheng *et al.*, 1994; Kakeya *et al.*, 1995; Takahashi *et al.*, 1995).Meanwhile, oceans also feed millions of populations, simultaneously wastes are damped massively and consistently into the environment. Many scientists (Vicente, F. A *et al.*, 2022, Lanka, S., 2020, Hamed, I *et al.*, 2016) have reported on shells (chitin, chitosan) and marine food waste (hydroxyl compounds) conversion of waste into high-value commercial products. However, the scientific community has surpassed to concentrate on intestinal gut waste generated. All these factors have intended to take up this research on the bioprospecting of crustaceans and exploration microbiome of crustaceans' intestinal gut. The research untangled the new opportunities to a larger extent to acquire knowledge and work on a need of an hour.

MATERIALS AND METHODS

Study area, sample collection and preparation

Randomly crustaceans were accumulated freshly from the coast of the Bay of Bengal, Chennai. The collected crustaceans(crabs) were washed in clean water and crabs were kept in hot water for a few minutes to make their legs to be separated and killed, before dissection (Chandra, S *et al.*, 2018). Crabs were subjected to an abdominal incision using a sterile surgical blade, following which the intestine was carefully dissected and removed. About 15 different species of crustaceans (a variety of crabs) were taken for the study. Samples were prepared by removing the intestinal gut using a sterile surgical blade. Sterile deionized water was used to clean the dissected gut and 1g of the gut was taken for the research.

Microbiological Analysis and Isolation of Bacterial Colony

The optimum conditions required for the growth of gut bacterial flora were maintained using a marine nutrient agar medium. 0.1mL of prepared samples were added to petri plates using the spread plate technique and incubated at 37° C at room temperature for 24 hours. To replicate the conditions of marine water, an equivalent mixture of sterilized marine water and deionized water was incorporated into the medium to preserve the marine environment. Following a 24-hour incubation period, various bacterial colonies were distinguished by their morphology and color. These different colonies were picked and transferred on fresh plates containing the same media to obtain pure culture and incubated for 24 hours at 37°C. Purity was ensured by repeated streaking. Bacterial colonies of distinct appearance were sub-cultured and identified by 16s rRNA (Svanevik, C. Set al., 2017).

**Gomathi et al.,****Extraction of secondary metabolites**

The isolated bacterial strain was cultivated in 100 ml of nutrient broth for 24 hours at 37°C within a rotary shaker, marking the fermentation stage. Subsequently, the cultured broth was subjected to filtration using filter paper, and an equivalent volume of ethyl acetate was introduced into the filtrate. The mixture was separated by vigorous shaking and the separated upper layer was collected and dried. The dried layer was again dissolved with 1 ml of ethyl acetate and the secondary metabolites were extracted out. This extract (test material) is used for further bioassay tests.

Morphology and Biochemical Identification

To determine the identity of bacterial isolates at both the genus and species levels, standard conventional microbiological tests, including gram staining, catalase testing, oxidase testing, IMVIC testing, and sugar fermentation testing, were conducted.

Molecular identification – PCR

Universal primers, specifically designed to bind to the highly conserved region of the 16S rRNA gene, were chosen for this purpose. The reaction mixture contained sample 1µl, forward primer 1µl, reverse primer 1µl, DNase free water 7µl and master mix 10 µl to come to a total reaction mixture of 20 µl. The PCR was conducted in the Eppendorf thermocycler. PCR conditions were set at a total of 35 cycles, to denature at 94 °C, annealing at 58 °C, elongation at 72 °C and final elongation at 72 °C. The amplified 16S rRNA products were subjected to electrophoresis in a 1% agarose gel at 100 volts for a duration of 1 hour. To visualize the amplified bands under UV light, agarose gel was mixed with ethidium bromide (20 µl). About 10µl of DNA sample was mixed with 5µl of gel loading dye and poured into the stamp. The amplification products were captured in photographs under UV light.

Antagonistic activity of bacteria and fungi

Under the aseptic condition, the antagonistic character of fungi and bacteria was tested by the agar well diffusion method at two different concentrations (50µl and 100µl). *Bacillus subtilis* was used as the test organism and the inoculated plates were kept at 37°C for 24 hours. Subsequently, inhibition zone was measured to determine the potent organism and less effective test organisms were excluded. The selected isolates were grown in nutrient broth and incubated at 37°C for 24 hours. Ethyl acetate is added to the culture broth and distilled using a rotary evaporator resulting in a semisolid extract that contains the secondary metabolite. These secondary metabolites will be again utilized for antagonistic activity.

Free radical scavenging activity

The assay was performed by two methods using two different free radicals. The free radical used were 1,1-Diphenyl-2-picrylhydrazyl (DPPH) and ABTS (2,2-azino bis 3-ethyl benzthiazoline -6-sulphonic acid). In the DPPH method, the test material was mixed with 3ml of DPPH solution and kept in the dark for 30 minutes. The DPPH solution without a sample was used as control and methanol as blank. Absorbance was measured using a spectrophotometer at 515 nm. Antioxidance (%) = (Absorbance of control – Absorbance of sample)/(Absorbance of control) × 100

In the ABTS method, the ABTS solution without a sample was used as a control. PBS was used as blank. Absorbance at 734 nm was measured using a spectrophotometer.

Antioxidant ability (%) = (Absorbance of control – Absorbance of sample)/(Absorbance of control) × 100

Enzyme inhibition assay

An inhibition assay was carried out utilizing the DNS method. The complete assay mixture consisted of 200 µl of a 0.02 M sodium phosphate buffer, 1ml of amylase and extracts of concentration ranging from 20-100 µl were incubated at 37°C for 10 minutes. 200 µl of preincubated 1% starch solution was added to each tube and incubated at 37 °C for 15 minutes. The reaction was halted by introducing 400 µl of DNS reagent, followed by incubation in a water bath for 5 minutes. After cooling to room temperature, it was further diluted with 15 µl of distilled water, and the absorbance was subsequently measured at 540 nm. Inhibition ability (%) = (A540 of control – A540 of sample)/(A540 of control) × 100

Gomathi et al.,

Metabolite profiling using GC – MS

An Agilent 6890 gas chromatograph was equipped with a straight deactivated 2 mm direct injector liner and a 15m Alltech EC-5 column (250µ I.D., 0.25µ film thickness). Sample introduction utilized a split injection, with a split ratio set at 10:1. The oven temperature program was initiated at 350°C, held for 2 minutes, and then increased at a rate of 20°C per minute until it reached 300°C, where it was maintained for 5 minutes. The helium carrier gas was set to a constant flow mode at a rate of 2 ml/minute. For analysis, a JEOL GCmate II benchtop double-focusing magnetic sector mass spectrometer operated in electron ionization (EI) mode, utilizing TSS-2000 1 software. Low-resolution mass spectra were captured at a resolving power of 1000 (20% height definition), scanning the range from m/z 25 to m/z 700 at 0.3 seconds per scan with a 0.2-second inter-scan delay. High-resolution mass spectra were recorded at a resolving power of 5000 (20% height definition), scanning from m/z 65 to m/z 750 at 1 second per scan. The identification of the purified compound involved comparing their recorded spectra with the mass spectra data stored in the NIST library V 11 provided by the instrument's software.

Anticancer activity by MTT assay

SIHA cells (5,000 cells per well) were cultured in 100 mL of Dulbecco's Modified Eagle's Medium (DMEM) for 24 hours. Afterward, 100 mL of active extracts with concentrations of 5 µg/mL, 25 µg/mL, 125 µg/mL, and 625 µg/mL were added to the cell culture and incubated in a CO₂ incubator at 37°C for an additional 24 hours. Following the incubation, 100 µL of MTT (3-[4,5-dimethylthiazol-2-yl] 2,5-diphenyltetrazolium bromide) was introduced into each well and incubated for 4 hours at 37°C. Subsequently, the absorbance of formazan was measured at a wavelength of 595 nm. The percentage inhibition of SIHA cells was determined using the following formula:

Percentage Inhibition (%) = [(Absorbance of Control - Absorbance of Extract) / Absorbance of Control] × 100

Where:

- Absorbance of Control refers to the absorbance of cells without the extract.
- Absorbance of Extract is the absorbance of cells treated with the extract at various concentrations.

RESULTS AND DISCUSSION**Morphological Identification**

Exiguobacterium profundum (*E. profundum*), with GenBank Accession No. OR262688, is a bacterium belonging to the Gram-positive category. It is characterized as halotolerant, meaning it can withstand relatively high salt concentrations, and it is a facultative anaerobe, implying that it can thrive in both oxygen-rich and oxygen-depleted environments. *E. profundum* is moderately thermophilic, showing a preference for moderate temperatures. It does not form spores. This bacterium is a member of the *Exiguobacterium* genus and was originally isolated from marine crustaceans, specifically *Portunus pelagicus* (*P. pelagicus*) intestinal gut as represented in Fig. 1.

Biochemical identification

The biochemical characterization of secondary metabolite was performed using the standard procedure as given in Table 1. In terms of biochemical identification, *E. profundum* tested positive for various assays, including the citrate utilization test, urease test, triple sugar iron test, and sugar fermentation test. The biochemical test results also reveal the crucial role of (*E. profundum*) in industrial biotechnology. This bacterium is also salinity tolerant and can also be employed as a biosurfactant agent (Al-Ani et al., 2022).

Molecular identification – PCR

To extract genomic DNA, overnight cultures of the selected bacterial isolates were utilized, and a QIAGEN DNA isolation kit was employed. The extracted DNA was suspended in 100 µL of elution buffer (10 mM/L Tris-HCl, pH 8.5) and its concentration was quantified by measuring the optical density (OD) at 260 nm. PCR amplification was conducted using a 50 µL reaction mixture, which included 100 ng of template DNA, 20 µmol of 16S rRNA primers, 200 µM of deoxyribonucleotide triphosphates (dNTPs), 1.5 mM of MgCl₂, 1 unit of Taq DNA polymerase (MBI Fermentas), and 10 µL of 10x Taq polymerase buffer. The 16S rRNA primer sequences used were as follows:

Gomathi *et al.*,

- 27f: (5'-AGAGTTTGATCCTGGCTCAG-3')
- 1522r: (5'-AAGGAGGTGATCCANCCRCA-3')

The PCR process consisted of an initial denaturation at 95°C for 5 minutes, followed by 35 cycles of denaturation at 94°C for 45 seconds, annealing at 56°C for 45 seconds, extension at 72°C for 1 minute, and a final extension step at 72°C for 5 minutes. This PCR was performed using a thermocycler (iCycler; Bio-Rad Laboratories, CA).

The resulting PCR products were then analyzed by electrophoresis on a 1% agarose gel in 1x Tris-Borate-EDTA (TBE) buffer at 100 volts. Subsequently, the amplified DNA product was sequenced using an ABI PRISM 3730 Genetic Analyzer (Applied Biosystems), as depicted in Figure 2. The molecular profiling of *E. profundum* MKJCBT23 also unveils their importance in understanding the pathways associated with predicting the osmotic stress, differential temperature and their capability of degrading heavy metals present in marine water (Patel, V. K et al., 2018)

Phylogenetic analysis

The sequences of the 16S rRNA genes were compared to sequences available in GenBank, specifically Accession No. OR262688, using the BLASTN program (Altschule *et al.*, 1990). Subsequently, the sequences were aligned using CLUSTAL W software (Thompson *et al.*, 1994). Distances between sequences were computed utilizing Kimura's two-parameter correction (Kimura, 1980). To create phylogenetic trees, the neighbour-joining method was employed (Saitou and Nei, 1987). To assess the robustness of the tree, bootstrap analysis was conducted with 1000 replications. The MEGA4 package (Kumar *et al.*, 2007) was used for all analyses.

The evolutionary history was deduced through the application of the Neighbor-Joining method (Saitou and Nei, 1987). The optimal tree, with a sum of branch length equal to 0.00571483, is presented. The percentage of replicate trees in which the associated taxa clustered together during the bootstrap test (conducted with 1000 replicates) is indicated adjacent to the branches (Felsenstein, 1985). The tree has been scaled to represent branch lengths in the same units as the evolutionary distances used to construct the phylogenetic tree. These evolutionary distances were calculated using the Kimura 2-parameter method, (Kimura, 1980) and are expressed in the units of the number of base substitutions per site. The codon positions considered in this analysis encompassed 1st, 2nd, 3rd, and noncoding positions. Any positions containing alignment gaps and missing data were exclusively removed in pair wise sequence comparisons, adhering to the pairwise deletion option. The final dataset consisted of a total of 1461 positions. These phylogenetic analyses were carried out using MEGA4 (Tamura *et al.*, 2007). Based on the BLAST analysis conducted in the NCBI, RDB taxonomy analysis, and the resulting phylogenetic tree, it was clearly

**Gomathi et al.,**

established that the sample in question belongs to the actinomycetes group, with its taxonomic classification being *E. profundum*, as illustrated in Figure 3.

Microbiological Analysis and isolation of bacterial colony

Several colonies with distinct characteristics, such as creamy or white in color, were initially selected and purified from marine nutrient agar. During the preliminary antibacterial activity evaluation, among the 75 isolates tested, only five exhibited inhibitory zones, the extracts of the isolates from black crab 1, sea crab 1-1, and scar crab 1 showed good activity against indicator pathogen *Bacillus subtilis* (*B. subtilis*). The result also emphasizes their ability to sustain in hard environments due to high adaptable physiology (White III et al., 2019).

Antagonistic activity of bacteria and fungi

Among the five isolates, the isolate (sea crab strain 2) which has shown high antibacterial activity against *B. subtilis* shown in Table 2, was raised in broth culture for further assays. The experimental result suggests that intestinal bacteria with antibacterial properties might inhibit the growth of invading bacteria in the intestines of crustaceans. The strains have not shown any zone of inhibition for fungi against *Aspergillus niger* and *Aspergillus fumigates*. All the microorganisms were gifted by Apex Laboratory, Chennai. The earlier research explored the antibacterial properties of crustacean shells but not the gut bacterial extract. As reported (Laith A A., 2017), antibacterial activity was performed using hemolymph, whole crab extract, and shells. The experiment assessed revealed that *P. pelagicus* contains a rich source of antibacterial agents. The present study attempted to explore the antibacterial activity of intestinal gut bacterial flora in a variety of crabs among which *P. pelagicus* has produced a significant antagonistic activity. This may be the first study that utilized metabolite extracted from the gut. They can also be utilized in pharmaceutical industries as drug agents. This indicates that strains can be employed as potent antibacterial agents.

Free radical scavenging activity

The free radical scavenging activity was performed to analyze the scavenging property of the strain by two different methods such as ABTS and DPPH assay. It is the fundamental screening method to know the antioxidant capacity of the strain *P. pelagicus*, because antioxidant property reveals various potential such as anti-aging, antitumor, cell damage and antimutagenicity (N.C. Cook & S. Samman 1996). As shown in Table 3 and Figure 4. Free radical scavenging activity of strain against radical ABTS has produced maximum scavenging of about 83.57% at the concentration of 100 µg/µl. The free radical scavenging property of the strain was also analyzed by the DPPH method, where the strain has produced about 41.77% antioxidant ability at the concentration of 100 µg/µl as given in Table 4 and Figure 5. The results reveal that antioxidant ability increases with an increase in concentration. A significant difference in results is due to the type of free radicals, their binding affinity, type of bioactive compound present in the extract some of the bioactive compounds may react at a very low level and the antioxidant reactions are also a time-consuming process.

Enzyme inhibition assay

The alpha amylase inhibition assay has a crucial role in the management of diabetes and it also has several health benefits. This research might be a new approach to utilizing the gut bacterial flora of *P. pelagicus*. As in Table 5, the results show a concentration-dependent inhibition activity of 65.90% inhibition at the concentration of 100 µg/µl which is also evidenced in Figure 6. The experiment also confesses the benefits of intestinal gut bacteria, which can be employed in pharmaceutical industries.

Metabolite profiling using GC – MS

Seven major secondary metabolites confirmed the presence of carotenoids, esters, corticosterone and phenolic compounds at the retention time ranged from 15.13 to 19.87. Metabolite profiling of *Protunus pelagicus* confirmed the presence of fatty acids, stearic acid and esters as listed in table 6 and peak area with retention given in Figure 7.

Gomathi et al.,

Anticancer activity by MTT assay

The anticancer activity of marine bacterial isolate was tested against SIHA cells using an MTT assay. The absorbance of formazan was measured in an ELISA reader at 595 nm wavelength. The percentage inhibition of SIHA cells (viability) is given in Figure 8. Activity minimum inhibition of about 49 % viability at the concentration of 150 $\mu\text{g}/\mu\text{l}$. This confirms that the marine gut bacterial isolate can be utilized as an effective chemotherapeutic drug.

Conclusion

There are oceans of unexplored novel bioactive secondary metabolites present in marine crustaceans. Marine crustaceans are rich sources of protein and feed millions of populations. Meanwhile, the marine intestinal guts, shells, and scales are disposed of into the environment. In lieu of dumping as waste, these can be transformed into a value-added bioproduct. Among five varieties of crabs, the secondary metabolite isolated from *P. pelagicus* proved to be effective and robust antagonistic activity evidenced through free radical scavenging, which can be employed as a chemotherapeutic drug. The Bay of Bengal represents a promising reservoir of biologically active actinomycetes, which possess the capability to generate novel and potent secondary metabolites with antimicrobial properties. As depicted in Figure 9, the bioprospecting of these isolates has uncovered fresh possibilities and strategies, holding significant potential in various industries, including pharmaceuticals, nutritional supplements, cosmetics, agrichemicals, and enzymes. Each of these marine bioproducts carries substantial market value, offering exciting opportunities for commercial application.

ABSTRACT

This study explores the bio-efficacy and pesticidal potentials of various seaweed extracts, focusing on their impact against significant agricultural pests, including *Spodoptera litura*, *Dysdercus cingulatus*, and *Cnaphalocrocis medinalis*. Marine macroalgae, particularly red, brown, and green seaweeds, exhibit promising insecticidal, repellent, and growth-regulating properties due to their diverse bioactive compounds. Extracts from species such as *Gracilaria firma*, *Caulerpa scalpelliformis*, *Sargassum tenerrimum*, and *Ulva lactuca* were assessed for their pesticidal potential. Additionally, the role of abiotic factors in pest incidence and the behavioral impacts of Neem based biopesticide were investigated. Results demonstrate significant toxicity, growth inhibition, and behavioral alterations in target pests, indicating the potential of these seaweed-based biopesticides as eco-friendly alternatives for sustainable pest management. This study highlights the critical need for integrating marine-derived bioactive compounds into agricultural practices to reduce reliance on synthetic chemicals and enhance crop productivity.

Keywords: Marine algae, *Gracilaria salicornia*, Rice leaf folder (*Cnaphalocrocis medinalis*), Bio-efficacy and Seaweed extracts.

INTRODUCTION

Rice (*Oryza sativa* L.) is the main staple food for 2/3rd (almost two – third) of the world's population. Rice is rich in CHO (90%), starch (80-90%), protein (8%) and low in fat (2%) (Verma et al., 2011). Rice is prone to the attack of many insect pests, from sowing to harvest (Mandal and Mondal, 2018). Among those pests, Rice Leaf folder, *Cnaphalocrocis medinalis* (Guenée) (Lepidoptera: Pyralidae) is a major and destructive pest in rice ecosystem. They yield loss due to the infestation by rice leaf folder ranges between 5 and 25 per cent and it attacks the plant from tillering to booting stage (Kulgagod et al., 2011). Currently, the rice leaf folder population is predominantly controlled with chemical insecticides. However, repeated application of insecticides to control the pest population leads to insecticide resistance with resurging pest populations each year (Senthilnathan, 2011). Shyamrao and Raghuraman (2019) also stated that rice leaf folder turned to a major pest during the last two decades due to the indiscriminate use of nitrogenous fertilizers. Hence, switching over to eco-friendly insect pest management is considered to be a better alternative to insecticide usage. Among the different alternatives, seaweeds offer a non-toxic way to manage the pests (Hamed et al., 2018). Marine algae as renewable living resources are rich in biologically active metabolites and possess many insecticidal activities (Sahayaraj and Jeeva, 2012). *Gracilaria salicornia* is a red algal seaweed that occurs in the coastal area. This species was distinguished by its articulated branches and a characteristic yellow to orange color. In this context, our research was aimed at estimating the efficacy of a red algal seaweed *Gracilaria salicornia* (C. Agardh) for their insecticidal activity against the Rice Leaf folder (*Cnaphalocrocis medinalis*).

MATERIALS AND METHODS

Collection of seaweed

The seaweed belonging to the Rhodophyta, Red algae *G. Salicornia* were collected from the intertidal region and deep-sea regions of Mandapam, Ramanathapuram District, Tamil Nadu, Southeast coast of India by hand picking. Aqua Agri Processing Private Limited aided in the handpicking, dredging, and scuba diving. The collected seaweed sample was washed with seawater then transferred to the lab and washed with distilled water till the debris, related biota was eliminated. The sample was eventually shade – dried for three weeks and saved in air – tight bags (Kannan and Bharath Kumar, 2016). The collected seaweeds have been preserved and identified by Dr. P. Ananda Raman, Professor in Marine Biology and Centre for Advanced Studies in Marine Biology, Faculty of Marine Sciences, Annamalai University.

Mass culture of test insect

Rice cultivar (TN1) collected from Tamil Nadu Rice Research Station (TRRI-TNAU), Aaduthurai, Thanjavur district was used for the assessment of *Gracilaria Salicornia* against the rice leaf folder. TN1 seedlings were raised in cement pots for one month and maintained in cement pots covered with nylon mesh sleeves at temperature 26° to 28°C with a relative humidity of 80 per cent. Irrigation was done at regular intervals. The initial culture was established with the release of field collected larvae (Annamalainagar, Vallambadugai, Bhuvanagiri) into the potted rice plants in the greenhouse. The larvae were fed with leaves up to pupation. After pupation, emerged adults were collected and released into ovipositional cage (120 × 80 × 50 cm) containing rice plants. The culture was maintained with 12 females and 13 male moths inside the cages. Adult moths were provided with 10 per cent honey solution as food and allowed for laying eggs. After two days, the leaves containing eggs were clipped off from the plants and kept in the Petri plate with moist filter paper to keep the leaves fresh and maintain the moisture. The emerged larva was reared up to the third instar in rice plants grown inside the greenhouse and these larvae were used for experiments in Laboratory (Senthilnathan, 2005).

Priyanka et al.,

Preparation of seaweed

The red seaweed *G. salicornia* was tested on rice leaf folder *C. medinalis* in different formulations such as powder, aqueous solution and solvent extract. The dried plant materials were converted into a fine powder with the help of an electric blender. This fine powder was stored in a glass container and used for further experiments. A known concentration of powder formulation (2g,4g,6g,8g,10g) was topically applied on the test insect (Kannan and Bharath Kumar, 2016). For aqueous extract, 100g powdered seaweed was taken and mixed with 100ml water and kept overnight. This solution was filtered with fine muslin cloth and made up to different concentrations (1%,2%,3%,5%,10%) (Gunalan, 2019). Similarly for solvent extract, powdered *G. salicornia* was individually weighed as 1, 2, 3, 5 and 10g and mixed in 100ml solvent (acetone) separately and incubated for 12 hours at room temperature and filtered. The filtered extracts were stored in an amber color bottle at 4°C in a refrigerator and used for bioassay experiments (Kombiah and Sahayaraj, 2012).

Bioassay –No choice method:

TN1 variety of rice plants (5 cm) was treated with Tween 20 (1% - to remove wax layer) and were placed in a Petri plate @ five –leaf bits/dish and the leaves were dusted with seaweed powder at different concentrations, in case of aqueous/ solvent the leaf bits were dipped in different concentration and their effects were compared with a standard check (Neem leaf powder/ extract – 5%) and untreated control under Completely Randomized Design with three replications. Three hours pre – starved third instar larvae were released at the rate of 5 larva/ per Petri plate and allowed to feed on the treated rice leaves. After subsequent feeding, larvae were provided with untreated leaves for continuous observations. The insect mortality and IGR activity (during larval, pupal, and adult stages) data were recorded every 6 hours on the test insect till adult emergence. Observations were made on the growth of the test insect analyzed statistically.

RESULT AND DISCUSSION**Effect of *G. salicornia* extract on growth and development of *C. medinalis***

In this Investigation, the effect of different extracts of red algal sea weed extract on larvicidal and insect growth regulator activity on *C. medinalis* brought out the following findings. The observed larval mortality was observed from the initial period onwards i.e., six hours after treatment, T₅ (10%) of all the experiment expels 6.67 per cent mortality each wherein other treatments including standard check and untreated control exhibited no larval mortality. The influence of seaweed effect on the test insect gradually increased thereafter and at 12 and 18 hours of exposure, the highest mortality was observed in higher dosage T₅ @ 33.33 in acetone extract followed by powder with 26.67 then aqueous with 20 per cent wherein no casualty was recorded in the untreated control (T₇) without statistical significance in larval mortality between the treatments and controls. Eventually, the data ascertained after 24 hours of treatment revealed the larval mortality by all the treatments and standard checks wherein the range of mortality was within 13.33 to 46.67 in acetone extract was preferably higher than the powder and aqueous extract where higher concentration exerted 40 and 33.33 per cent. A similar trend of gradual increase in larval mortality in all the treatments was noticed at 36, 48, 60 and 72 hours after exposure. The larval mortality increased further in all the experiments as evidenced from the data obtained from 48 hours of the treatment shows increase in the level of mortality from the lower (1%) to higher concentration (10%) were acetone extracts exhibited more than 60 per cent of death rate on comparison with powder and aqueous. The mortality of the test insect reached its peak within 72 hours of the treatment where the maximum mortality was obtained from a 10 per cent concentration of acetone extract where it shows more than 70 per cent casualty other concentration of acetone extract also showed more than 50 per cent of death rate followed by this the maximum concentration (10g) of powder shows 66.67 per cent then aqueous extract (10%) shows 60 per cent which were comparatively higher compared to standard check where casualty maximum noticed in acetone extract (53.33%) whereas the other seaweed treatments have registered lesser mortality rate with significant difference between treatments and controls, wherein untreated control did not encounter any level of mortality.

**Priyanka et al.,**

Those survived larvae were transformed to pupa. The observation period extended up to the adult emergence where in the pre – pupal mortality was also noticed under the higher concentration prominently and vice – versa in a lower concentration. The pupation per centage was calculated based on the insect population that survived and the observation data denoted that the highest pupation rate occurs in the aqueous extract of seaweed with 93.37 per cent (1%) on other hand, least pupation rate occurred in powder form with 13.33 per cent (10g) and 100 per cent occurred in control in all the experiment as usual. The pupated insects were observed for adult emergence, meanwhile, the effect of seaweed greatly influenced the pupal stage and resulted in pupal malformation in due course of the observation period where a higher concentration (10%) of the all the bioassay significantly shows malformed pupae. Other pupae were emerged out a healthy adult and the data showed the least no of adult emerged @ 10 per cent of acetone extract and in powder form with 13.33 per cent where aqueous shows 26.67 per cent and the maximum no. of adults emerged out in control (100%) compared with other lower dosage and standard check. Adultmal formation was also noticed in higher dosages of 5, 10 per cent of a solvent extract with a significant difference which indicated a substantial difference between treatments with no mortality in the control. Among the three experiments of seaweed, solvent (acetone) extract expels the maximum efficacy on test insect compared with the powder and aqueous extract in all forms. The results also confirmed the presence of toxic principles in the selected red algal seaweeds which demonstrated larvicidal and growth regulator activity of *C. medinalis*.

These defined results from the above experiments are in close proximity to the the results observed by the other researchers around the globe and their views are disclosed as given below. Kalimuthu *et al.* (2014) demonstrated the bio-efficacy and potential of *Gracilaria firmain* different solvent extracts in combination with *Megacyclops formosanus* for controlling the larvae of *Aedes aegypti*. Mortality was observed from the 24 hours of the treatment where the first in star larvae showed casualty up to 48 per cent in methanol extract of *G. firma* treatment at 0.251 per cent dosage, wherein at 1 per cent of dosage exhibited 100 per cent mortality was registered. Moustafa *et al.* (2014) reported that the various solvent extracts of green algae *U. lactuca* tested on larval growth of *S. littoralis* reported that it expels higher mortality, highest inhibition of pupation and adult malformation. Out of these, acetone extract of seaweed reported more efficacy against *Culex pipens*. Investigations on the powder of red algal seaweeds against *Spodoptera litura* revealed that *Gracilaria corticata* exhibited cent per cent larval mortality followed by *Asparagopsis taxiformis* and *Liagora ceranoides* which reported more than 50 per cent mortality and recorded better insect growth regulator activity in *S. litura* test insect respectively (Dharanipriya *et al.*, 2019). Investigations on the pesticidal potential of several selected red algal seaweeds viz., *Gracilaria edulis*, *G. folifera*, *Grateloupia lithophila* and *Hypnea valentiae* methanol extracts against *S. litura* revealed that *G. edulis* recorded the maximum larval mortality and proved that the highest dosage of *G. edulis* exhibited desirable per centage of mortality and effect of insect growth regulatory activity (Gowthish and Kannan, 2019). The insecticidal properties of hexane, acetone and methanol extracts of *Gnidia kraussiana* Meisn roots and neem seed oil were tested against the eggs and larvae of different immature stages of *Callosobruchus maculatus*. The reports by Kosini *et al.* (2021) confirmed that acetone extracts were more effective against the immature stages of *C. maculatus*, as the extracts evoked stronger repellency and could be incorporated in integrated pest management programs for the control of *C. maculatus* in stored cowpea seeds. Furthermore, studies should be done with different kinds of solvents other than acetone under different increased concentrations.. In addition to this, it should be tested on the other leaf feeders to check their toxicity level and combination with neem oil, pungam oil, etc.

CONCLUSION

This study demonstrated the insecticidal potential of *Gracilaria salicornia*, a red algal seaweed, against the rice leaf folder, *Cnaphalocrocis medinalis*. Among the tested formulations, the acetone extract exhibited the highest efficacy, achieving significant larval mortality, pupal malformation, and inhibition of adult emergence, particularly at higher concentrations. The powder and aqueous formulations, while effective, were comparatively less potent. The findings confirm the presence of bioactive compounds in *G. salicornia* with larvicidal and insect growth regulatory properties. The study aligns with previous research on the pesticidal potential of algal extracts, reinforcing the suitability of

Priyanka et al.,

seaweed-based biopesticides as eco-friendly alternatives to chemical insecticides. However, to broaden the scope of applicability, further studies should evaluate the efficacy of *G. salicornia* in other solvent systems, higher concentrations, and combinations with neem or pungam oil. Additionally, testing its effects on other rice pests could help integrate this biopesticide into sustainable pest management programs. The use of *Gracilaria salicornia* as a natural pesticide represents a promising approach to reducing the reliance on synthetic chemicals, minimizing environmental impact, and combating issues like pesticide resistance and pest resurgence.

ACKNOWLEDGMENT

The authors are grateful to the Head Department of Entomology, Faculty of Agriculture, Annamalai University for the conduct of the experiments. We are gratefully acknowledging the services of Dr. P. Anantharaman, Associate professor, Centre for Marine Sciences, Annamalai University for identifying the seaweeds.

ABSTRACT

An ethnobotanical survey was conducted in the Marudhur Village, Karur District, Tamil Nadu, India during January 2021 to May 2022 and the informations were collected from traditional healers, vaithiyars and age old people through questionnaire method. The proper knowledge reframed with the guidance of taxonomists and ethno botanists. From the present survey 63 plant species belongs to 32 families and 56 species dicotyledons and 7 species monocotyledons. In the Fabaceae is containing 7 species and *Azadirachta indica* A. Juss. (Neem.) is more species was available. This study explored the traditional knowledge about medicinal plants and their therapeutic applications from ancestors to future generations as well as the advantageous to prepare novel drug.

Keywords: Ethno botany, questionnaire, traditional knowledge, Survey and therapeutic applications

Venkata Lakshmi *et al.*,

INTRODUCTION

Ethno botany is the study of plants and their practical uses through the traditional knowledge of local people (Saran raj, 2016). Since the ancient period plants have been used for curing several ailments of mankind and animals. Population rise, inadequate supply of drugs, the prohibitive cost of treatments, side effects of several synthetic medications and development of resistance to currently used drugs for infectious diseases have led to increased emphasis on the use of plant material as a source of medicines for a wide variety of human ailments. Among ancient civilization, India has been known to be rich repository of medicinal plants. About 8000 herbal remedies have been codified in Ayush system in India. Ayurveda, Unani, Siddha and Folk medicines are the major systems of indigenous medicines knowledge (Gopal Dixit, 2019). Among these systems, Ayurveda and Unani medicine are most developed and widely practiced in India. Medicinal plant plays an important role in supporting healthcare system in world. According to the World Health Organization 80% of the rural population in developing countries utilizes locally available medicinal plants for their primary healthcare needs (Saran raj, 2016). According to WHO, around 21000 plant species have the potential for being used as medicinal plants. About 90% of the country's medicinal plants are found in forest habitats. It may be noted that India is one amongst those nations which possess a historical track record of having made a significant global contribution by virtue of its traditional knowledge of the medicinal plants.

MATERIALS AND METHODS

The Marudhur village is located at Kulithalai Taluk of Karur District, Tamil Nadu, India lies between 10°52'2" N and 78°26'48" longitude. The survey was conducted during January 2021 to May 2022 and the ethno botanical data were collected through questionnaire method (Anantgobalsingh *et al.*, 2012). The information about medicinal plants was collected from traditional healers age old people, vaidhiyars. The data was framed with the knowledge of taxonomists and ethno botanist. According to the Flora of the presidency of Madras (Gamble, 1915) medicinal plants were arranged. Some of the highly valuable medicinal plants are kept secret from ancient period to now by the traditional healers. The collected voucher specimens were deposited in the PG & Research Department of Botany, Vivekanandha College of Arts & Sciences for Women (Autonomous), Tiruchengode, Namakkal District and Tamil Nadu.

RESULTS

The traditional information was accumulated by the local people has play an important role. In the present study, medicinal plant used by the people of Marudhur Village were collected and recorded. From this, we find out the 63 plant species are comes under 56 dicotyledons and 7 monocotyledons are recorded. The different plant habitnatures are categorized, this study mostly exhibited herbs (26), Shrubs (20) and trees (17). The different medicinal uses of various plant parts are recorded (Figure -1). This present survey we identified 63 plant species belongs to 32 families such as Fabaceae (7 species) is the highest followed by Lamiaceae and Solanaceae (5 species), Euphorbiaceae (4 species), Moraceae (3 species), Acanthaceae, Annonaceae, Cucurbitaceae, Lythraceae, Myrtaceae, Phyllanthaceae, Rubiaceae, Rutaceae, Sapotaceae (2 species) and remaining families were single plant species present like Acoraceae, Amaranthaceae, Anacardiaceae, Arecaceae, Asphodelaceae, Asteraceae, Boraginaceae, Caricaceae, Cyperaceae, Malvaceae, Meliaceae, Musaceae, Oleaceae, Poaceae, Rhamnaceae, Sapindaceae, Simaroubaceae (Figure - 2) and as well as the study exposed many plant leaves and stems are used to cure the various diseases like fever, asthma, cough, cold, diarrhoea, rheumatism, ulcers, skin diseases, etc., (Figure-3). In the study area *Azadirachta indica* A. Juss. (Neem.) is highest population and *Adhatoda vasica* Nees. is least concern (Table 1 & Plate 1).

DISCUSSION

In this present study, we found that 63 medicinal plants belonging to 32 families were identified in the study area. In Worldwide many herbal medicines are prepared from different parts of the plants and they are cured many diseases through pharmacological analysis. Different plant species are used in the treatment such as anti - diabetic, hypertension, gastrointestinal diseases, respiratory diseases and haemorrhoids. Similarly, Natarajan *et al.*, (2012) documented that 80 medical plants belonging 41 families, 74 genera found in the Kalrayan hills, Tamil Nadu and Thangaraj Francis Xavier *et al.*, (2015) recorded 86 medicinal plants categorized under 46 families, 76 genera of Malayali tribes in Eastern Ghats, Tamil Nadu. Since they are also used in other parts of the world for treating comparable diseases, they can be considered as pharmacologically effective. Documentation of wild edible and medicinal plants from ethno botanical approach is important for enhancing understanding of indigenous knowledge systems. Therefore, this type of work may assist ethno botanical studies and also pharmaceutical leads to the formation of new drugs.

CONCLUSION

The traditional medicine is made up of different herbal formulations to cure many diseases and disorders. Due to the over consumption of medicinal plants, lack of population in certain area. So, there is urgent need for the scientific awareness about the importance of medicinal plants conservation and sustainable utilization of natural resources. Such ethno botanical studies enable the transfer of knowledge on plant-based treatments to be followed by the future generations.

ABSTRACT

An increasing number of children are being diagnosed with autism spectrum disorder (ASD), a neuro developmental condition that impairs a child's ability to connect and communicate with others and their surroundings. Since there is no known cure for the condition, treatments often focus on speech and behavioral therapies to enhance the ASD-specific social, behavioral, and communication symptoms. Common comorbidities like digestive issues are regarded to not only be another sign of ASD but also to actively influence how the disorder manifests in social and behavioural symptoms. In order to treat gastrointestinal and behavioural problems, the majority of people with ASD adopt nutritional therapies, both with and without therapeutic supervision. This study aimed to investigate the behavioral problems seen in children with autism and discuss the potential nutritional interventions in reducing these problems. For pertinent studies, the databases Web of Science and PubMed were examined. The search was conducted using combinations of the terms "autism," "autistic," "nutritional intervention," and "behavior problem." Human studies examining the connection between nutritional intervention and behavioral issues in autism were included in the analysis. 27 studies were found in the initial search, 14 of which fully met the requirements for inclusion. By these investigations, we were able to ascertain the link between a child's diet and behavioural issues associated with autism and enhance their functionality. Published studies on the relationship of gastrointestinal and behavioural problems with gut microbiota in autism are very limited and contradictory. The fact that the results of the studies are not consistent with each other may be explained by the differences in the age of participants, geographical region, sample size.

Keywords: Nutrition, Intervention, Autism, behavioral problem

**Umera Begam and Sasikala Hephzibah**

INTRODUCTION

Autism is a neurobehavioral and cognitive condition that is characterized by repetitive behaviors, restricted imagination, impaired sociability, and communication. One of the most severe childhood diseases, autism affects almost one child in every 500. A spectrum of problematic behaviors are present in autism, which is a complex condition. Nevertheless, Desorgher et al. (2000) characterize autism as a neuro- gastro- immunological problem stemming from an immuno- genetic mistake during foetal development rather than a psychiatric condition. The most prevalent of these atypical behaviors include unusual eating patterns, irregular sleeping patterns, temper tantrums, and hostility towards oneself and others (Dominick et.al., 2007). Communication, social interaction, and behaviour are all impacted by the complex neurodevelopmental disease known as autism spectrum disorder (ASD). Although there is no known treatment for ASD, early intervention can help manage symptoms and enhance results. One sort of intervention that has been researched in the management of behaviours in children with ASD is nutritional intervention. We are aware that eating foods high in nutrients can help the body eliminate pollutants, build a strong immune system, control hunger, and avoid obesity. Eating disorders frequently have an impact on children with autism spectrum disorders (ASDs). Their propensity for nutrient-poor, high-energy foods can affect their metabolism, which can cause an accumulation of reactive radicals and a decline in both their mental and physical health. According to a recent report by the Indian Journal of Pediatrics published in 2021, the prevalence of autism spectrum disorder (ASD) in India is estimated to be around 1-2% among children aged 2-9 years. This suggests that there may be around 1.6 million children with ASD in India. This would make India the most populated nation in the world in terms of autistic patients, making recent advancements in autism research more pertinent to India. There are many different ways to treat autism, including medication, behaviour therapy, physical therapy, occupational therapy, and a number of complementary therapies. In many nations, particularly India, nutrition therapy for autistic children has not received the attention it deserves.

A series of metabolic and nutritional problems that autistic people experience have an impact on their health and behaviour. Williams et al. (2000) noted that children with autism usually experience substantial feeding challenges and have a very limited menu of food options. According to Lowe (2010), autistic children tend to decline more meals and limit their diets to fewer types of food than typical kids. All autistic children suffer from gastrointestinal issues, dietary intolerances, or nutritional deficits that are not properly treated. Many autistic children may also suffer from a subclinical nutritional insufficiency, which can lead to irritability, lack of focus, sadness, anxiety, disturbed sleep, or appetite loss (Strickland 2009). Those with autism spectrum disorders may have difficulty digesting casein, a protein found in milk and wheat, and gluten. Children with Autism Spectrum Disorder (ASD) have elevated amounts of certain peptides in their urine, which may indicate inadequate peptide breakdown. Peptides may disturb biochemical and neuroregulatory processes in the brain, disrupting brain functions, due to inadequate breakdown and excessive absorption. Some hypothesis that children with ASD have "leaky guts," or small holes in their intestinal tract, which may be caused by an overgrowth of yeast that produces toxic substances. Toxic metabolites from the gastro intestinal tract seep into the blood stream and contribute to behavioural and medical issues in people with autism, including confusion, hyperactivity, stomach issues, and fatigue. The basis of autism treatment is dietary intervention. The first step in enhancing the health and wellbeing of autistic children is to make thoughtful exclusions and additions to food choices. Some foods high in healing elements are advantageous when added to children's diets, while certain dietary substances are known to be hazardous and should be avoided (Matthews 2010). The aim of nutrition therapy for autism is to maximise the child's brain function so that the response to other treatments is improved and to support the child's body and brain structure to function at their best. In this review of the literature, we'll look at the research on nutritional therapies for children with ASD and how they affect behaviour.

1. Gluten-Free, Casein-Free (GFCF) Diet: Diet GFCF (Gluten-Free, Casein-Free) One of the nutritional therapies for ASD that has been most extensively researched is the GFCF diet. It entails removing from the child's diet everything containing casein, a protein included in dairy products, and gluten, a protein present in wheat,

**Umera Begam and Sasikala Hephzibah**

barley, and rye. Several studies have demonstrated that the GFCF diet can result in behavioural changes, such as decreased hyperactivity, increased concentration, and decreased irritability.

2. **Vitamin and Mineral supplementation:** Supplemental vitamin and mineral intake The impact of vitamin and mineral supplements on the behaviour of kids with ASD has also been studied. According to several studies, children with ASD are more likely to have nutritional deficiencies, and behaviour can be improved by taking vitamins and minerals supplements. In one study, for instance, it was discovered that children who received a multivitamin and mineral supplement exhibited improvements in communication and socialization skills.
3. **Omega-3 Fatty Acids:** Omega-3 fatty acids are necessary lipids that are extremely important for the growth and operation of the brain. According to several research, giving children with ASD omega-3 supplements may help them behave better. One study, for instance, discovered that youngsters who took omega-3 supplements had improvements in hyperactivity, stereotypy, and communication.
4. **Probiotics:** Live bacteria and yeasts known as probiotics are good to human health. The gut-brain axis, or connection between the gut and the brain, is thought to include them. Probiotics have been studied as a possible dietary intervention for kids with ASD. According to one study, kids who took a probiotic supplement displayed improved behaviour, including less irritation and hyperactivity.

RATIONALE

A developmental disorder known as autism spectrum disorder (ASD) is marked by deficiencies in social communication, impaired social engagement, and repetitive and stereotyped activities. In addition to behavioural problems, children with ASD are more likely to experience gastrointestinal difficulties, food preferences, and nutritional deficits. The rationale for nutritional interventions in managing behaviors of children with ASD is based on the following:

1. **Nutritional deficits:** Due to their restricted diets and picky eating habits, children with ASD are more prone to suffer nutritional deficiencies. These inadequacies may exacerbate their behavioural issues, further isolating them from society and lowering their quality of life. Dietary supplements and other nutritional interventions can assist to address these deficiencies and enhance general health.
2. **Food sensitivity:** ASD children may have food sensitivities, which can lead to behavioural problems. Their behavioural problems can be improved by identifying and removing certain trigger foods from their diet.
3. **Digestive problems:** Children with ASD are more prone to have digestive problems include constipation, diarrhoea, and pain in the abdomen. An increase in irritation and behavioural issues can result from these symptoms. Interventions in nutrition can help reduce these symptoms and enhance general health.
4. **Imbalances in neurotransmitters:** According to research, children with ASD may experience unbalances in dopamine and serotonin, which may be a factor in their behavioural symptoms. Specialized diets and nutritional supplements can help balance these neurotransmitters and reduce behavioural problems.
5. **The gut-brain axis:** There is mounting proof that the gut microbiota affects how the brain and behaviour are developed and regulated. The gut health of children with ASD can be improved by nutritional therapies, such as probiotics and prebiotics, which may also help with behavioural symptoms. Overall, addressing nutritional deficiencies, removing trigger foods, relieving gastrointestinal symptoms, balancing neurotransmitters, and improving gut health are the justifications for nutritional interventions in regulating behaviours in children with ASD. There is evidence that suggests nutritional therapies may be a helpful complement to behavioural and pharmaceutical interventions in controlling the symptoms of ASD, though the study is still in its early stages.

INTERNATIONAL STATUS

A topic of attention around the world is the use of nutritional therapies in controlling the behavior of kids with autism spectrum disorder (ASD). Guidelines for their use have been released by a number of international organisations that have acknowledged the potential advantages of dietary therapies in treating ASD symptoms.

**Umera Begam and Sasikala Hephzibah**

The American Academy of Pediatrics (AAP) advises that gastrointestinal symptoms and nutritional inadequacies in children with ASD be assessed, and that suitable therapies be used to address these problems. The AAP also acknowledges the potential advantages of specific dietary therapies, including omega-3 fatty acid supplementation, in enhancing behaviour and cognitive function in kids with ASD. Guidelines for the identification and treatment of gastrointestinal issues in children with ASD have been released by the European Society for Paediatric Gastroenterology Hepatology and Nutrition (ESPGHAN). In order to treat gastrointestinal issues in kids with ASD, the recommendations suggest using a gluten- and casein-free diet. The World Health Organization (WHO) understands how critical it is to meet the nutritional requirements of kids with developmental disorders, including ASD. The WHO advises providing children with ASD with a nutritious diet that is both balanced and varied.

Children with ASD in Australia can get support for nutrition-related interventions, such as nutritional assessments and supplements, under the National Disability Insurance System (NDIS). In conclusion, the potential advantages of dietary therapies in controlling the behaviors of children with ASD are acknowledged on a global scale. Many organizations have released guidelines and recommendations in favour of the use of these therapies in the treatment of ASD symptoms. To completely comprehend the usefulness of nutritional therapies in treating ASD symptoms and to create evidence-based recommendations for their application, more study is necessary.

NATIONAL

In India, there is a growing area of research on nutritional therapies for treating ASD-related disorders in kids (ASD). Other pertinent studies include:

1. Srinivasan et al. (2018) did a study to look at how a gluten-free and casein-free diet affected the behavior and cognitive function of Indian children with ASD. According to the study, the children's behavior, attention, and communication all improved after they changed their diet.
2. In a second study, Tandel et al. (2019) examined the impact of an omega-3 fatty acid, vitamin, and mineral supplement on the behavior of ASD-afflicted children in India. According to the study, children's behavior and social skills significantly improved as a result of taking the supplement.
3. An investigation of the incidence of nutritional deficits in Indian children with ASD was conducted by Krishnaswamy et al. (2018). According to the study, vitamin D, vitamin B12, and iron deficits were common among children in India with ASD.
4. Children with ASD exhibited different levels of gut bacteria than children who were typically developing, which may explain their gastrointestinal symptoms and behavioural issues, according to a 2018 Indian study by Marwaha et al. According to the study, probiotic therapies may be helpful in treating these symptoms. According to these studies, specific diets and nutritional supplements may be useful in regulating the behaviors of Indian children with ASD. To completely comprehend the efficacy and safety of these therapies, as well as to create evidence-based recommendations for their application in the Indian setting, more research is nonetheless required.

METHODS

We originally searched PubMed and Web of Science for papers between the years 2000 and 2020 using the medical subject heading (MeSH) phrases terms "autism," "autistic," "nutritional intervention," and "behaviour problem". As there wasn't enough information, we added another 20 years to the total, bringing it up to 1980. This search turned up 69 papers, all of which were in English. We used the population's inclusion criteria, which included being under 18, all human research, and having free full-text papers available. It produced 30 papers, including surveys, case-control studies, literature reviews, and meta-analyses. With the identical search terms on Google Scholar, we received 200 results; but, after applying all the inclusion criteria outlined above, we only received 11 items that were significant to us. 27 studies were found in the initial search, 14 of which fully met the requirements for inclusion. By these investigations, we were able to ascertain the link between a child's diet and behavioural issues associated with autism and enhance their functionality.

**Umera Begam and Sasikala Hephzibah**

REVIEW OF LITERATURE

Gluten-Free, Casein-Free (GFCF) Diet

An increasing number of studies is looking into how well a gluten-free, casein-free (GFCF) diet controls behavior in kids with autism spectrum disorder (ASD). These are some important conclusions from recent research:

1. The GFCF diet may be helpful in lowering ASD-related symptoms, particularly in the areas of communication, socializing, and repetitive behaviors, according to a systematic review and meta-analysis of 27 research (Mazzone et al., 2018).
2. In a randomized controlled experiment with 72 ASD children, those who adhered to the GFCF diet for six months had significant behavioural and physiological benefits when compared to those who followed a conventional diet (Elder et al., 2006).
3. A comprehensive analysis of 15 research on the application of dietary treatments, such as the GFCF diet, in children with ASD was carried out in one article that was published in 2015 in the Journal of Autism and Developmental Disorders. The GFCF diet is one of the most popular dietary therapies for ASD, but the study revealed that there is little evidence to support its use in controlling ASD-related behaviors.
4. A GFCF diet was linked to enhancements in socializing, cognitive function, and behavior in certain kids with ASD, according to a 2013 study that appeared in the Journal of Child Neurology. 30% of the 387 ASD participants in the research followed a GFCF diet. In comparison to individuals who did not follow the regimen, the researchers discovered that those who did so significantly improved their conduct, socializing, and cognitive function. The fact that the study was not a randomized controlled trial and depended on parental reports of dietary consumption and behavioral changes, however, placed limitations on it.
5. 98 children with ASD, a more recent randomized controlled experiment compared the GFCF diet to a control diet. The results were published in 2019 in the Journal of Autism and Developmental Disorders. Between the two groups, there were no discernible differences in behaviour, cognition, or socialization, according to the study. The study was, however, constrained by its small sample size and brief intervention period. In the past 20 years, there has been a marked increase in research on diet and nutrition in autistic and ASD children, with a focus on studies of hyperactivity and attention. In 2016 and 2013, respectively, Catassi et al. and Cruchet et al. conducted two separate investigations on nonceliac gluten sensitivity-based, gluten-free diet trials on autistic and ASD children. The gluten-free diet kind of test, which was initially carried out in the 1980s and lately rediscovered, theorized a possible increase in peptide creation due to inadequate and inappropriate digestion of meals containing gluten and casein. These peptides may pass the blood-brain barrier due to the "leaky gut" characteristic prevalent in autism and ASD, altering the endogenous opiate neurotransmission systems. By getting rid of these 'toxins,' the kids are better able to control their behaviour and emotions. When Robertson et al. compared the original research on intestinal permeation conducted by Lau et al., they did not discover any alterations in intestinal permeability as claimed by the later. There is still more evidence to support these impacts, despite the prevalence of testing various food regimens on young children and all this research. Overall, there is conflicting and inconclusive information supporting the GFCF diet's ability to control the behaviors of children with ASD. While some research has indicated that the GFCF diet might help certain kids with ASD, other research has revealed no appreciable effects. To fully comprehend the possible advantages and restrictions of the GFCF diet in the control of ASD-related behaviors, more study is required.

Vitamin and Mineral supplementation

Although vitamins and dietary supplements have been proposed as potential treatments for autism spectrum disorder (ASD) symptoms, there is scant scientific support for their efficacy. Below is a quick summary of several recent studies that are pertinent to this subject. 18 randomised controlled studies exploring the use of different vitamins and supplements in kids with ASD were examined in a 2019 systematic review article published in the Journal of Autism and Developmental Disorders. While some supplements, such omega-3 fatty acids, showed promise in alleviating some ASD symptoms, the study found that there was inadequate data to recommend the use of the majority of other supplements. Vitamin D is one dietary supplement that has undergone substantial research. A systematic analysis from 2020 indicated that children with ASD frequently have low levels of vitamin D, and that

**Umera Begam and Sasikala Hephzibah**

vitamin D treatment might help with ASD symptoms, particularly social communication. The analysis found that additional studies are necessary to fully comprehend the possible advantages and recommended vitamin D dosage for kids with ASD. Melatonin, a hormone that controls sleep-wake cycles, is another supplement that has been researched. A 2017 meta-analysis indicated that melatonin supplementation may enhance sleep quality and lessen insomnia in kids with ASD. This finding was published in the Journal of Clinical Medicine. The study did point out that further investigation is required to establish the ideal dosage and long-term security of melatonin use in this population. Probiotics, vitamin B6, and folic acid are some other dietary supplements that have been researched in relation to ASD. To ascertain their possible advantages and dangers, additional research is required because there is little proof on their efficacy. Children with autism and ASD require vitamin and mineral supplements since they are thought to be very beneficial. For countless biochemical enzymatic reactions in our bodies, several of these vitamins and minerals function as co-enzymes and neurotransmitters. In a three-month, randomised control trial, Adams et al. discovered that deficiencies in vitamins and minerals can affect metabolic function. In addition to improving biotin, oxidative stress, glutathione, methylation, adenosine triphosphate (ATP), the reduced form of nicotinamide adenine dinucleotide phosphate (NADPH), and sulphate, the study found that the supplements also reduced hyperactivity, tantrums, and general language reception with fewer side effects. Studies by Buie et al., Horvath et al., and Ashwood et al. demonstrated that a ParentScore on the Parent Global Impression-Revised (PGI-R) significantly increased. A child's PGI-R score, which takes into account many variables including pain and hunger that can be evaluated, is a sign of psychosocial impairment in children with special needs. It assesses the efficacy of all therapies provided to autistic children and has good sensitivity, specificity, consistency, reliability, and validity. These studies' shortcomings included their limited sample size and need for in-depth investigation. Overall, there is little and conflicting data supporting the use of vitamins and nutritional supplements to treat ASD symptoms. While some dietary supplements might be able to improve some elements of ASD, additional research is required to fully appreciate their potential advantages and disadvantages. Before beginning any supplement regimen for a child with ASD, it is crucial to speak with a healthcare practitioner as with any other treatment strategy.

Omega-3 Fatty Acids

Due to their involvement in brain development and function, omega-3 fatty acids have been investigated as a potential treatment for autism spectrum disorder (ASD). Below is a quick summary of several recent studies that are pertinent to this subject. The use of omega-3 fatty acid supplements in kids with ASD was the subject of 12 randomised controlled trials, which were examined in a 2019 systematic review and meta-analysis published in the journal Molecular Autism. According to the study, giving children with ASD omega-3 fatty acid supplements was linked to a considerable improvement in their communication, stereotypy, and hyperactivity. The study did point out that further investigation is required to establish the ideal omega-3 fatty acid supplementation regimen, duration, and timing for this population. Another 2014 study that appeared in the Journal of Child Neurology looked at how omega-3 fatty acid supplementation affected the behaviour and cognitive of kids with ASD. 57 children with ASD were enrolled in the trial, and 31 of them received omega-3 fatty acid supplements while the remaining 26 received a placebo. In comparison to individuals who received a placebo, the study discovered that those who received omega-3 fatty acid supplements significantly improved their social interaction and hyperactivity. In a 2017 randomised controlled experiment, the benefits of omega-3 fatty acid supplementation on parent-reported problem behaviours in kids with ASD were investigated. The results were published in the Journal of Child Psychology and Psychiatry. 57 children with ASD were enrolled in the trial, and 29 of them received omega-3 fatty acid supplements while the other 28 received a placebo. In comparison to individuals who received the placebo, the study discovered that those who received the omega-3 fatty acid supplements significantly reduced their levels of hyperactivity, irritability, and stereotypy. Overall, the data point to omega-3 fatty acid supplementation as a potentially effective therapy strategy for addressing several ASD-related symptoms, including hyperactivity, stereotypy, and communication. The ideal supplementation dosage and duration as well as the long-term efficacy and safety of this method, however, still require further study. It's crucial to speak with a medical practitioner before beginning an omega-3 fatty acid supplementation programme for a child with ASD, as it is with any therapeutic strategy.

**Umera Begam and Sasikala Hephzibah****Probiotics**

Based on their ability to affect the gut-brain axis and the microbiome, probiotics—live bacteria thought to have health benefits—have been investigated as a potential treatment for autism spectrum disorder (ASD). Below is a quick summary of several recent studies that are pertinent to this subject. A 2017 comprehensive review and meta-analysis of 10 randomized controlled trials looking into the use of probiotics in children with ASD was published in the journal *Frontiers in Psychiatry*. According to the study, probiotic supplementation was linked to appreciable gains in social interaction and conduct in kids with ASD. The study did point out that more investigation is required to establish the best probiotic strains, doses, and administration times for this population. Another 2016 study that appeared in the *Journal of Clinical Psychopharmacology* looked at how *Bifidobacterium longum*, a particular probiotic strain, affected the behaviour and cognitive of young ASD patients. 44 children with ASD participated in the trial, and 22 of them received *B. longum* while the other 22 received a placebo. In comparison to those who received the placebo, individuals who received *B. longum* shown appreciable gains in social conduct and communication, according to the study. In a 2019 randomized controlled trial, the benefits of a probiotic and prebiotic combo supplement on behavior and gastrointestinal symptoms in kids with ASD were investigated. The results were published in the journal *Nutrients*. 75 kids with ASD were enrolled in the trial, and 38 of them received the supplement while the other 37 received a placebo. Comparing those who received the supplement to those who received a placebo, the study indicated that those receiving the supplement significantly improved their social interaction and gastrointestinal problems. Overall, the data points to probiotic supplementation as a potential therapy strategy for controlling various ASD-related symptoms, particularly social behaviour and communication. The best strains, doses, and length of supplementation, as well as the long-term efficacy and safety of this strategy, still require further study. Before beginning probiotic supplementation for a child with ASD, it is crucial to speak with a healthcare practitioner as with any other therapy strategy.

DISCUSSION

As a potential treatment for controlling the behaviours of autistic children, nutritional intervention is receiving more and more attention. A growing amount of research has recently examined the connection between diet and behaviour in autistic kids. This review tries to compile the body of knowledge on dietary management of autistic children's behaviour. According to a number of studies, kids with autism may require special dietary needs, such as those related to vitamin, mineral, and other nutrient shortages. For instance, research by Adams et al. (2011) indicated that children with autism had lower levels of calcium, selenium, and the vitamins C, D, and E than children who were typically developing. Deficits like these could be a factor in issues with aggression, hyperactivity, and self-harming behaviour. Studies have looked into the use of dietary supplements, such as probiotics and omega-3 fatty acids, as a nutritional intervention for controlling behaviour in autistic kids. According to a review by Mazahery et al. (2019), omega-3 fatty acid supplementation may help children with autism who exhibit hyperactivity and inattention. To find the ideal amount and duration of omega-3 supplementation, more research is required because the evidence is not consistent across different trials. Probiotics, live bacteria that have been shown to have health advantages when taken, have also been investigated as a potential treatment for autism-related behavioural issues in young children. In children with autism, probiotic supplementation improved gastrointestinal symptoms and decreased irritability, according to a randomized controlled experiment by Pärtty et al. (2015). The usefulness of probiotics for controlling behaviours in this population, however, requires further study. Dietary therapies, such as the gluten-free, casein-free (GFCF) diet, have also been researched as prospective interventions for controlling behaviours in autistic kids in addition to supplements. Casein, a protein included in milk and dairy products, and gluten, a protein present in wheat, barley, and rye, are both prohibited on the GFCF diet. According to some research, the GFCF diet may help children with autism who exhibit traits including irritability, hyperactivity, and social withdrawal. To establish the efficacy and safety of this dietary intervention, more study is required because the evidence is not consistent across all studies. Overall, the body of research points to dietary intervention as a potentially effective strategy for controlling behaviours in autistic kids. However, further investigation is required to establish the best dietary and

**Umera Begam and Sasikala Hephzibah**

nutritional supplement interventions, dosages, and durations, as well as the possible dangers and advantages of such interventions.

CONCLUSION

The research on nutritional treatments for behaviour management in kids with autism spectrum disorder (ASD) indicates that dietary treatments and supplements may be effective. According to a number of studies, children with ASD may have particular nutritional requirements and deficits that might lead to behavioural issues. While there is some evidence that supplements like probiotics and omega-3 fatty acids may benefit specific behaviours, further research is required to establish the ideal supplement dosages and duration. Also investigated as a potential therapeutic, the gluten-free, casein-free (GFCF) diet has shown promise in improving several behaviors in ASD youngsters. To ascertain its efficacy and safety, more research is required because the evidence is not uniform across various investigations. Overall, future research into nutritional therapies for controlling behaviors in children with ASD is promising. Therefore, it is crucial to move slowly and carefully with the advantages and disadvantages of any dietary intervention. To better understand the underlying mechanisms by which dietary interventions may affect behaviour in kids with ASD and to determine the most efficient and secure approaches to enhance their health and wellbeing, more research is required.

ABSTRACT

The purpose of this study is to review the impact of Wildlife trafficking and poaching on tiger population in India. a comprehensive review has been conducted here to know illegal trafficking and poaching of tiger scenario in India. This review has revealed that widespread poaching and trafficking threaten tiger population of India. as the demands for different body parts of Tiger is increasing across different nations, the rate of illegal tiger trafficking or poaching is also increased in this country. Despite conservation efforts, illegal activities persist. Effective legislation, community engagement, and economic development are essential. Collaborative data sharing can identify high-risk areas, enabling targeted interventions to protect tigers from imminent threats.

Keywords: Wildlife traffic, Tiger poaching, Tiger conservation, Wildlife protection, Tiger Population

INTRODUCTION

“Poaching” and “illegal wildlife trafficking” are significant dangers to biodiversity, particularly when it comes to endangered species. Tigers are known as iconic creatures, and this species’ body parts are highly valued in both

**Kaji Mainuddin et al.,**

domestic and foreign criminal markets. Despite having several rules and strict enforcement, trafficking or poaching is at its highest in India, which is the largest tiger conservation unit in the world[1]. Habitat loss has become one of the biggest threats to the survival of wild tigers in India. According to a recent report, India ranked at the 4th position for wildlife crime across the world. It is now known that an even greater threat is being posed by the trade of tiger bones that are intended for use in Oriental medicine outside of India[2]. Manufacturers of traditional medicines from the Far East are now focussing on India for their supply of tiger bones after destroying their own sources. However, since India is home to the world's biggest population of wild tigers, illegal tiger poaching and trafficking pose serious dangers to biodiversity. Because of the strong demand for tiger body parts in both domestic and foreign markets, poaching rates have increased despite strict regulations and conservation efforts. Tigers are the main target of this illicit traffic, which is worth between \$19 and \$26 billion a year, because their bones, skins, and other body parts are used in luxury products and traditional medicine[3]. Additionally, the issue is made worse by habitat loss, which makes conservation efforts more difficult. The severity of this problem is highlighted by the startling fact that wildlife crime in India ranks fourth globally. By taking all these aspects into consideration, this current review has focused on the impact of Wildlife trafficking and poaching on tiger population in India.

Tiger conservation in India

India has the world's largest tiger conservation unit, yet despite the country's tough rules and enforcement, poaching is at an all-time high. The goal of India's tiger conservation is to preserve the biggest number of wild tigers in the world, which are a representation of the country's abundant biodiversity. In 1973, the Indian government started Project Tiger, a historic program that created protected areas and attempted to stop habitat degradation and poaching[4]. According to the most recent census, the number of tigers has expanded dramatically as a result of this effort, from about 1,800 in the early 1970s to over 2,900 by 2018[5]. However, "the Sundarbans National Park (SNP)" is the largest "tiger reserve", "national park", and "bio-sphere reserve" in west Bengal, India[6]. However, with its forthcoming functions, the Sundarbans Tiger Reserve has encountered a variety of situations. The clash between humans and tigers has been an issue, according to the roving tigers. It has been estimated that hundreds of native people have been mercilessly murdered by Sundarbans tigers over the previous forty years[7]. Tigers in the Sundarbans region hunt people. It has not yet been determined how many tigers are present on the reserve using a sophisticated method. The state equal direction-finding panel, led by the chief minister, and the reserve, in particular the Tiger Conservation Foundation, have been expected to include the tiger preservation strategy as constituents. Despite these advancements, problems still exist. Three major risks still exist, including illegal wildlife trafficking, habitat fragmentation, and human-animal conflict. Although protected sites like Jim Corbett, Ranthambore, and the Sundarbans are important habitats, surrounding communities and development activities frequently put strain on them.

Purpose of wildlife trafficking

Wildlife trafficking refers to the unlawful possession, transportation, taking, or trading of animals or their derivatives in violation of national, international, and regional laws[8]. In addition to violating animal rights, wildlife trafficking is a growing global issue that poses a harm to the environment, society, and economy. It has a negative impact on people's well-being and supports an illicit economy. Based on the previous relevant cases and literature, it has been noted that there are many purposes for wildlife trafficking and poaching across the world. For instance, it has been noted that Wildlife products are frequently valued as luxury goods in many nations. For example, it is seen as a prestige symbol to possess jewellery, carvings, or artwork made from rhino horn or ivory[9]. Some wildlife items are used for bribes (in other criminal organisations) or gift-giving in addition to their personal value. Wildlife that has been trafficked, usually birds and reptiles, are also frequently used in the exotic pet trade. In this context, some specific animal parts such as tiger bones or teeth, pangolin scales and rhino horns are used in different traditional medicine making. According to a report by the World Health Organisation (WHO), 88% of member states recognise the practice of traditional medicine[10]. Traditional medicine is a more important healthcare resource in China, India, and a number of African nations. In 2020, it was predicted that traditional medicine in China was worth over \$40 billion USD[11]. Unfortunately, overharvesting and poaching are causing populations of several animal products used in traditional medicine to decline below sustainable levels. Moreover, hunting or poaching wild animals for

**Kaji Mainuddin et al.,**

food has also been a necessary and common practice for thousands of years[12]. Therefore, reviewing the relevant literature, it has become clear that there are a range of reasons behind the illegal hunting, trafficking or poaching of different wildlife animals. In this context, as per recent reports and research, every part of a tiger's body has a market value[13]. Their bones are utilised in traditional medicines and also these parts are boiled down in terms of making tiger bone glue, or steeped in wine. On the other hand, their skins are also used for clothing or rugs. Furthermore, their teeth and claws are used to make amulets and trinkets; their meat is eaten and even their whiskers are highly valued in black markets.

Poaching and trafficking threats to Tiger in India

The illegal trafficking of endangered species or wildlife animals' commercially valuable body parts has a sophisticated global network. In nations with abundant biodiversity, such as India, such practices are extremely concerning since they undermine conservation efforts¹. According to current reports, the population size of wild tigers has decreased worldwide by half in the past 20 years¹⁴. They are excessive susceptible to poaching because of the rise in demand for body parts; because of this reason, between 2000 and 2018, different law enforcement organisations confiscated 2,359 tiger parts worldwide[1]. Most of the bones, flesh, and other components are generally found in the northern and eastern states that border each other. In this context, the intensity of seizures has been found to be very high in the states of Tamil Nadu, Karnataka, Assam and Maharashtra[15]. Four trade routes, including the Nepal-Bhutan border, the Assam border, the Mumbai port and the Brahmaputra, have been highlighted for the export of the seized parts of Tiger across India. However, this is in line with India's five tiger protection blocks, and the Western Ghats region has a high seizure rate, which has not yet been identified. On the contrary, another literature has argued that the Indo-Chinese border is the main illegal trade route for tiger body parts is across[16]. India has the most tiger seizures globally and is a major tiger habitat[17]. The extensive employment of contemporary firearms in the late 1800s marked the beginning of the Indian tigers' predicament. Even with stringent laws such as the Wildlife Protection Act 1972 and its 2006 tiger amendment, poaching still happens in India. During 1994 and 2003, it was reported by "the Environmental Investigation Agency (EIA)" that more than 684 cases of tiger poaching and seizure occurred in India.

Apart from that, India lost almost 1,110 tigers between 1994 and 2016¹. Another report has also indicated that around 369 tiger seizures took place in India between 2000 and 2018, which is more than any other tiger range country[18]. On the other hand, a recent study has shown that between January 2000 and June 2022, more than 2,205 poaching instances occurred in 50 nations and territories worldwide, resulting in the confiscation of 3,377 tigers. In the past 22 years, 893 (26% of all tigers) have been seized in India, which has the most seizure incidents (759; 34% of all tigers)[19]. These reports indicate that there has been a significant growth in Wildlife trafficking over recent years. However, it has been noted that Tribes have a great deal of experience in handling and moving animals, and many of their hamlets are located inside reservations. Another study has indicted that in India, during the COVID-19 lockdowns, tiger poaching reached a height of 151%[20]. Studies examining the effects of tiger poaching on the ecosystem and the individuals involved have not been conducted. Poachers use this since it can be difficult to police tough laws in a scheduled tribal hamlet. The extent of tiger poaching and the beginnings of trade channels are not well understood in the Indian context. The India-China-Nepal trafficking route and the severity of seizures in states bordering China and Nepal are the main topics of the majority of the literature on tiger trading and poaching[1]. Additionally, they predict a commerce route with China as the main customer that passes through Ladakh, Tibet, Laos, and Bhutan. Studies mostly concentrated on identifying and enhancing tiger habitats and populations, with little attention paid to domestic demand or the origin of the trade route. However, a recent study has indicated that there is a greater demand for skin, claws, bones, and teeth, with local markets favouring the teeth and nails of tigers. Previous studies have indicated that the skin, fat, claws, teeth, meat, genitals, and even bones of Tiger are poached for the purpose of traditional medicines[21]. In addition to that, other body parts, such as whiskers, eyeballs, and tails, are also used in making different types of medicine. In this context, China has been found as the main consumer of such tiger trafficking activities in India as there are high.

**Kaji Mainuddin et al.,****Impact of Wildlife trafficking and poaching on tiger population in India**

Tiger populations in India have been severely harmed by wildlife trafficking and poaching, which poses a serious threat to their survival. India has the highest tiger population in the world, but illegal hunting brought on by the market for luxury products and traditional medicine is making matters worse. Tigers are at the heart of India's wildlife crime epidemic, which is estimated to be worth between \$19 and \$26 billion a year[22]. On the other hand, "Panna Tiger Reserve", in Central India lost all its tigers in 2009 due to huge rage of wildlife trafficking or poaching practices. This loss of entire populations in reserves like Panna, where all tigers were exterminated by 2009, is an example of how poaching has caused sharp drops in tiger populations. Over 2,300 tiger parts were confiscated by law enforcement worldwide between 2000 and 2018, underscoring the scope of the trafficking network[23]. The problem is made worse by habitat loss brought on by agriculture and urbanization, which increases tigers' susceptibility to poaching. The tiger population in India, which is home to the greatest number of wild tigers worldwide, is severely impacted by wildlife trafficking and poaching. Despite strict regulations and conservation efforts like Project Tiger, the illicit trade remains a serious concern because of the demand for tiger body parts in luxury goods and traditional medicine. According to studies, poaching rates have dramatically increased, particularly during the COVID-19 outbreak[24]. The issue is made more difficult by habitat loss, as growing human activity encroaches on tiger habitats, increasing conflict between humans and wildlife. Over the course of the last century, India's tiger population is thought to have declined substantially, with illegal poaching playing a major role. The general trend is still alarming, even though certain areas, like the Sundarbans, are showing signs of recovery.

Enforcement measures are complicated by the intricacy of trafficking networks, which frequently operate internationally[25]. The survival of tigers in India is still uncertain unless swift and concerted action is taken, combining habitat preservation, community involvement, and legal measures. Resolving these problems is essential for preserving biodiversity and ecological balance in the area as well as for the survival of this iconic species. However, Royal Bengal Tiger is one of the identify and significant marks of India but this species is at high threat to habitat loss. For instance, a recent news report has indicated that the combined threats of poaching, trafficking, habitat loss, global warming and urbanization has caused India to lose 97% of its Bengal Tiger population in the last century[26]. On the contrary, another report argues that the number of tigers in the Sundarbans shows a rise in the next census as there is no significant threat of saturation. Apart from that, there is also no threat to sufficient prey base in the 4,200 sq km area around the mangrove forest[27]. According to this report, the number of tigers was 88 in 2018 in Sundarbans which went up to 101 in 2022[27]. However, as poachers frequently take advantage of enforcement weaknesses, the rise of organised crime in wildlife trafficking makes conservation efforts more difficult. Poaching rates increased despite tougher regulations and government programs like Project Tiger, particularly during the COVID-19 pandemic[28]. The stability of India's tiger populations is in jeopardy due to the combination of these causes, which makes immediate and concerted conservation measures necessary to successfully battle poaching and trafficking.

Legal Initiatives to minimizing Tiger Poaching or trafficking occurrences in India

Under "the Wildlife (Protection) Act of 1972", it is illegal to trade in more than 1800 species of wild animals, plants, and their derivatives[29]. This law aims to prohibits the illegal capturing, killing, buying and selling of animals across the country. After the "Wildlife Protection Act" was put into effect in 1972 and cases were documented in the 1980s, the handling and trafficking of tiger parts was outlawed in India. Due to their healthy tiger populations, southern Indian states have the highest number of tiger smuggling instances. The network of illegal trafficking expanded to cover Madhya Pradesh, Andhra Pradesh, Uttar Pradesh, Bihar, Maharashtra, Karnataka, and Bengal. For example, according to a recent report, two poachers were arrested by the wildlife wing of the forest department" as they were wanted to hunt a Royal Bengal Tiger in "Similipal Tiger Reserve" in 2021[30]. As per the Indian law, this case was non-bailable and due to this reason, they are still in the judicial custody. Apart from that the Project Tiger government program that focusses on habitat preservation and anti-poaching tactics. Numerous tiger reserves have been established as a result, and patrolling efforts have risen. In order to dismantle transnational trafficking networks, the government works with non-governmental organisations (NGOs) and foreign agencies like the Environmental Investigation Agency (EIA)[31]. Moreover, specialised anti-poaching units, awareness campaigns,

**Kaji Mainuddin et al.,**

and community engagement initiatives that motivate locals to take part in conservation initiatives are examples of state-specific strategies. Successful arrests in recent years demonstrate the value of community involvement and coordinated police enforcement. There are still issues, though, such as corruption and a lack of funding for law enforcement. The protection of India's tiger population depends on continued monitoring, increased public awareness, and improved collaboration between stakeholders for these programs to be successful.

Current initiatives to stop tiger trafficking or poaching in India

Given the importance of preserving its declining tiger population, India has started a number of recent steps to fight tiger trafficking and poaching. The Government of India as well as different State Governments have already taken some initiatives to reduce the risks of illegal poaching or trafficking of wildlife animals. The Wildlife Protection Act of 1972, which forbids the shooting and sale of tigers and their parts, is a crucial element. Poachers now face harsher punishments thanks to recent legislation that highlight the government's dedication to strict legal measures[32]. The "Environmental Investigation agency's" (EIA's) Tiger Campaign promotes the breakdown of transnational criminal networks engaged in illicit commerce in order to aid in the rehabilitation of wild tiger populations[31]. Thus, this agency is presenting for better legislation along with the protection of tigers' habitat. In addition to that, this initiative also exposes the role of tiger farming in stimulating demand and thus poaching of wildlife species can be reduced. Apart from that, the "Project Tiger" started in 1973, is one of the most significant programs the Indian government has undertaken to conserve tigers. a thorough conservation effort that seeks to lessen threats to the existence of tigers and preserve their habitats nationwide. This particular initiative has expanded to include more than 50 tiger reserves nationwide³³. In addition to protecting habitat, this program improves anti-poaching patrols by using drones and video traps to track tiger movements and identify poaching activity. In order to guarantee on-the-ground enforcement, the Indian government has also deployed Tiger Protection Force units in a number of reserves. As a result of the effort, India's tiger population has grown by more than 500%[34]. However, the forest department of India, specifically West Bengal is working on several initiatives such as anti-trafficking, and anti-poaching activities. In addition to that the Indian forest department has also focused on strict policies to ensure barring entry of wood collectors, fishermen, honey collectors, as well as other villagers living in these contiguous. Apart from that, these initiatives heavily rely on partnerships with international agencies like the "Environmental Investigation Agency (EIA)" and "non-governmental organizations (NGOs)". Dismantling transnational criminal networks engaged in wildlife trafficking is the goal of the EIA's Tiger Campaign. In order to deter poaching, this partnership encourages intelligence sharing, improved training for law enforcement personnel, and community awareness campaigns. Additionally, Campaigns to raise public awareness are also essential for altering attitudes regarding tiger conservation. The goal of social media, educational initiatives, and community workshops is to draw attention to the significance of tigers' protection and the negative effects of trafficking. On the other hand, local communities are empowered to take an active role in tiger protection through programs like Community-Based protection. These initiatives seek to lessen the local population's dependency on poaching by offering alternate sources of income and raising awareness of the tigers' ecological significance.

CONCLUSION

In the end of the entire review, it can be concluded that widespread poaching and wildlife trafficking, which are motivated by the demand for tiger body parts both domestically and internationally, pose a serious danger to India's tiger population. Illegal operations continue despite strict regulations and substantial conservation efforts, compromising the efficacy of established restrictions. To counter these risks, strong legislative frameworks, increased enforcement, and community involvement are crucial. Project Tiger and other initiatives have showed potential, but in order to address the underlying causes of poaching, more work must be done to priorities local economic development and education. Based on the findings of this overall review, it has become clear that tiger population is in danger because of high rates of illegal poaching and trafficking across the country. Due to this reason, it is essential to take effective and strict legal initiatives to reduce the risks of tiger and overall wildlife trafficking. In this context, in terms of identifying high-risk locations and create focused solutions, researchers and conservationists must work

Kaji Mainuddin et al.,

together to share data. Similar to the terrible outcomes of Sariska and Panna, numerous tiger reserves may suffer grave consequences if prompt and concerted action is not taken. To secure the survival of this iconic animal, protecting India's tigers necessitates a multipronged strategy that incorporates community engagement, rigorous enforcement, and sustainable development. However, in order to share and analyse data, this calls for the cooperation of numerous scholars from around the nation. Finding high-risk poaching locations can only aid in lowering the illicit trade by raising awareness of these locations. This can further help identify the justifications for the tiger poaching by the locals as well as tribal people. The economic and educational standing of the local poachers might be addressed to manage the situation. A portion of the substantial sums of public funds that India spends on tiger conservation needs to be redirected to mitigate this pressing problem. Moreover, it can be suggested that authorities need to take extra precautions to shield tigers from illegal trafficking and poaching. If it does not, many tiger reserves of India can resemble Sarika and Panna, where several tigers were slaughtered.

ABSTRACT

Synthetic dyes persist in the environment due to their recalcitrant nature and hence have to undergo efficient treatment before being released in the environment. This study aimed at isolating and characterizing potential triphenylmethane dye degrading bacteria from soil sample contaminated with textile effluent. Primary screening was done by plate assay containing bromocresol purple. Isolates showing prominent zone of clearance were selected for secondary screening by broth assay in mineral salt medium (MSM). Optimization of parameters such as dye concentration, temperature and pH for dye decolorization was done. Maximum decolorization of 75.24% was observed at 37°C and pH 8 after 72 hours of incubation. Decolorization efficiency of the immobilized cells was investigated further by immobilizing the isolate in calcium alginate beads. Based on the preliminary characterization, 16S rRNA sequencing and phylogenetic analysis the isolate was identified as *Nesterenkonia* sp., a halo-alkaliphilic bacteria. Phytotoxicity studies on the germination of the seeds of *Vigna radiata* indicated that dye degradation metabolites obtained do not have any inhibitory effect.

Keywords: Triphenylmethane dye, Bromocresol purple, Decolourisation, *Nesterenkonia* sp., Immobilization, Phytotoxicity.

INTRODUCTION

Synthetic dyes have a wide range of applications in industries and clinical setups. These dyes are favoured over natural dyes for properties such as steadfast colour, easy availability and economic feasibility[1]. However, the application of synthetic dyes is also accompanied by environmental issues due to their recalcitrant nature. Synthetic dyes are synthetic aromatic organic coloring agents that are soluble in water, where the basic structure is mostly comprised of carcinogenic compounds like benzidine and other aromatic compounds[2, 3]. Application of the dyes in various industries leads to the entry of dyes into the environment through wastewater. Dyes tend to remain in the environment due to their recalcitrant nature and are resistant to degradation by factors like light, water and oxidising agents [4, 5]. Most of the wastewater treatments for dye removal are physicochemical treatments, which are less effective owing to the complex molecular structure of synthetic dyes, waste produced and the cost [6, 7]. Biological methods have also been adopted for dye containing wastewater treatment and have been found to be advantageous due to the cost, decreased production of sludge and production of products compatible with the environment [8, 9]. Biological processes degrade the complex compounds by mineralising organic contaminants without producing any toxic components [10]. The present study was carried out to screen and isolate triphenylmethane dye degrading efficient strain of bacteria from industrial wastewater.

MATERIALS AND METHODS

The soil sample was collected from effluent contaminated site in the vicinity of local textile industry in Yelahanka, Bengaluru Karnataka, India. After collection, the soil sample was serially diluted and stored at 4°C. Bromocresol purple (BCP) was procured from Himedia India. Stock solutions of BCP of one mgmL⁻¹ concentration were prepared by dissolving in cold sterile distilled water, autoclaved and stored in a brown bottle at room temperature for further use. Modified mineral salt medium (MSM) was prepared as per Ayed *et al.*, (2010) [11]. MSM was prepared by the addition of the following components (gL⁻¹): NaCl (1), CaCl₂·2H₂O (0.1), MgSO₄·7H₂O (0.5), KH₂PO₄ (0.1) and Na₂HPO₄ (1). Nutrient broth and nutrient agar were used for culture maintenance.

Primary screening and characterization of the dye decolorizing bacteria

Isolation of the dye degrading organism was carried out using spread plate technique for the serially diluted soil samples by plate assay method [12]. The isolates were grown in nutrient agar containing BCP dye. The plates were incubated at 37°C for 24-48 hours and were then observed for colonies showing zone of clearance indicating the dye decolorization. They were then picked and further purified by streaking. The selected isolate was further subjected for preliminary identification tests including Gram staining, biochemical test and colony characterization. Biochemical tests and Gram staining procedures were performed [13].

Secondary screening

Secondary screening by broth assay in MS medium containing BCP dye was initially done using smaller volume of the samples. The isolated bacterial strain was allowed to grow in 25 mL MSM broth by using BCP as the sole source of carbon and nitrogen. Uninoculated MS broth incorporated with the dye was used as the control. All the sets were run in six replicates. After incubation the culture was centrifuged at 10,000 rpm for 10 minutes and the bacterial cells were pelleted down, and a clear supernatant was obtained. The absorbance of the clear supernatant was measured by monitoring the absorbance at the maximum absorption wavelength (λ_{max}) at 580nm for BCP using an UV-Visible Spectrophotometer (UV-1700PharmaSpec).

Decolourization (%) was calculated using the following formula [14]:

$$\text{Decolourization (\%)} = \frac{(\text{Initial OD} - \text{Final OD})}{\text{Initial OD}} \times 100$$

Gowri Subramanian *et al.*,

Optimization of temperature and pH for dye decolorization

For optimization of dye concentration, two concentrations were selected. In the first experimental setup the optimization study of dye concentration was done by adding 500 μL of dye in 50 ml of MSM (0.05%). In the second setup the concentration of dye was reduced to 0.025% by adding 250 μL in 50ml MSM. The decolourization assay was carried out at three different temperatures i.e. 30°C, 37°C, and 40°C under shaking conditions to evaluate the optimum dye decolorizing activity of the isolate 1. This assay was performed in 6 replicates. The flasks were incubated for 120 hrs and thereafter checked for decolourization by measuring the absorbance at 580nm in UV- vis spectrophotometer. The decolourization assay was carried out at pH 7, 7.5, 8 and 8.5 under shaking conditions to determine the optimum pH for decolourization of the isolate 1. This assay was performed in 6 replicates. The flasks were incubated for 72 hrs and thereafter checked for decolourization by measuring the absorbance at 580nm in UV- Vis spectrophotometer.

Immobilisation of the isolate and screening of the efficiency for dye decolorization

Immobilization of the dye degrading bacterial isolate was carried out in 2% sodium alginate [15]. The bacterial cell pellet was mixed with 10 mL of sodium alginate which was later suspended in chilled 0.1M calcium chloride solution. Uniform sized beads with the entrapped bacterial isolate were used at the rate of 15 per culture flask containing solutions of pellet and supernatant obtained after centrifugation. They were incubated at 37°C in the shaker incubator for 72 hrs. Control was kept with 15 sodium alginate beads without the bacteria to rule out the possibility of bead matrix efficiency in degrading the dye by adsorption process. After incubation, absorbance was measured using UV visible spectrophotometer at 580nm. The result obtained was then compared with plate and broth assays. The inoculum in the nutrient broth was centrifuged at 6000 rpm for 12 mins. The pellet was resuspended in the phosphate buffer and sonication was done for 20 minutes at 37°C to obtain lysate. The supernatant and the lysate were subjected to fractionation by ammonium sulphate precipitation by stirring on ice. Ammonium Sulphate precipitation was done separately for the cell free extract 1 (extracellular) and 2 (intracellular) obtained after centrifugation of the assay broth. Precipitation was achieved at 80% ammonium sulphate fraction. It was seen that the extracellular supernatant showed higher and faster precipitation than the intracellular supernatants. The precipitate was obtained after centrifuging at 10,000 rpm for 20 minutes at 4°C. The precipitated proteins in the pellet were resuspended in 50mM phosphate buffer (pH 7). The resuspended ammonium sulphate precipitates were desalted by dialysis. Boiling of dialysis membrane (MWCO- 10KD) for 20 minutes in sterile distilled water was carried out to activate the membrane. It was then placed in sterile distilled water and refrigerated until further use. Dialysis was done against 50mM phosphate buffer (pH- 7) for overnight. Then the dialyzed samples – lysate and supernatant were transferred into sterile vial for SDS- PAGE. The molecular weight of the samples obtained after the ammonium sulphate precipitation was determined by SDS – PAGE.

Phytotoxicity studies

The phytotoxic effect of the dye before and after decolorization by microorganism was assessed by using *Vigna radiata* [16]. Twenty seeds each in petri plate placed on the sterile circular filter paper were observed for germination and growth. The experimental set up consisted of seeds treated with dye (1mgmL⁻¹) and seeds treated with degraded sample of dye. Control consisted of seeds allowed to germinate in presence of water. The length of plumule and radicle was recorded after 48 hours and 72 hours respectively and the percentage of germination was recorded.

Antibiotic sensitivity of the isolate to antibiotics

Disc diffusion method was followed to test the sensitivity of the isolate to the antibiotics [17]. The zone of inhibition was measured around each disc. The antibiotic discs used were of ampicillin (10 μg) and penicillin (10 μg).

Statistical analysis

The decolourisation experiments in this study were conducted in six replicates. The findings were reported as mean and standard deviation. Bar graph was plotted along with standard error.

Gowri Subramanian *et al.*,**Molecular identification of the isolate and its phylogenetic analysis**

A16S rRNA sequencing was done for the identification of the isolate. The 16S rRNA sequencing was done by Credora Life Sciences. The nucleotide sequence obtained from the 16S rRNA sequencing was analysed through NCBI BLAST by aligning the homologous sequences. 16S rRNA gene sequence of Isolate1 was submitted in Barcode Biosciences under the reference number 0309_011. The BLAST analysis of the sequence was done.

RESULTS AND DISCUSSION**Primary screening of dye degrading bacteria from the soil sample**

Nutrient agar plates containing bromocresol purple dye showed very few CFU indicating the toxic effect of the textile effluent on the microbial population in the selected soil sample. Several isolates didn't show zones of clearance. Isolate 1 from 10^{-4} dilution showing a zone was selected for secondary screening in mineral salt medium.

Secondary screening

No growth of the isolate was observed on the nutrient agar medium containing a dye concentration of 0.1% and 0.05% indicating that the concentration of the dye was inhibiting the growth of the bacteria. However, at a lower concentration of 0.025% in MSM the bacteria showed better tolerance. Therefore, this concentration was used for further experimental procedures.

Decolorization (%) of BCP by the isolate 1 at different temperatures

The decolourisation ability of the isolate 1 was studied at different temperatures namely, 30°C, 37°C, and 40°C in MSM (pH 7). The decolourization percentage was calculated from the decolourisation percentage formula. The values were confirmed using the standard graph (Fig. 1) and similar values were obtained. Isolate 1 showed maximum decolourisation ($54.52 \pm 8.64\%$) at 30°C when incubated for 120 hours followed by 37°C (51.56 ± 3.42) and 40°C ($49.06 \pm 1.65\%$) as shown in table 1. As illustrated in the figure 2 there is a decrease in the ability of the IS 1 to degrade the dye with the increase in the temperature. It was observed that *Nesterenkonia lacusekhoensis* EMLA3 degraded methyl red at the temperature range of 30°C - 35°C. No changes were seen at 15° C and 50° C [18]. In a Similar study by Prabhakar *et al.*, where reactive violet 1 dye was degraded by *Nesterenkonia* strain at the optimum temperature range of 25° C to 35° C [19]. The microbial growth and the enzyme activity are influenced by the incubation temperature [20]. It was observed that the optimal temperature for the growth of *Nesterenkonia lacusekhoensis* sp. isolated from Antarctica was 25°C – 33.5 °C [21]. The degradation of the dye increases with the increase in the temperature to a particular limit [22]. But at high temperatures, inactivation of enzymes takes place resulting in decrease in the dye degrading ability of the strain [23].

Decolorization (%) of BCP by the isolate 1 at different pH

pH is a significant parameter in wastewater treatment especially in case of biological wastewater treatments [7]. The decolourisation percentage of the dye was calculated after 72 hrs of incubation at pH 7, 7.5, 8, 8.5. As illustrated in table 2, maximum degradation ($75.24 \pm 2.27\%$) was observed at pH of 8.0 followed by pH 7.0, 7.5 and 8.5 when incubated for 72hrs. The figure 3 indicates that the isolate has maximum decolourisation potential at an alkaline pH. A study by Bhattacharya *et al.*, (2017) regarding the removal of azo dye methyl red by *Nesterenkonia lacusekhoensis* showed that optimum pH range required for decolourization was 8-11.5 [18]. Reduction in the pH of the media was also observed after the dye degradation. There were no changes when the pH was adjusted to pH 13. In a similar study by Prabhakar *et al.*, (2019) it was observed that with the increase in pH from 8, there was an increase in the decolourization of reactive violet 1 dye by *Nesterenkonia* strain [19]. It was observed that the optimal pH for the growth of *Nesterenkonia lacusekhoensis* sp. nov., isolated from Antarctica was 8.6 [21].

Preliminary identification of isolate 1

The Gram staining and microscopic observation showed isolate 1 as a Gram-positive short rod. Several Gram-positive rods have been shown to possess dye degrading property [18]. The results of IMViC test showed that the

Gowri Subramanian *et al.*,

isolate gave positive result for only citrate test indicating that the isolate can use citrate as a source of carbon. Negative results were observed for urease test and gelatin hydrolysis test. The isolate when tested for starch hydrolysis showed a positive result as a clear zone was seen around the growth which indicates the production of amylase. It is found that amylase is produced by *Nesterenkonia* sp.. A study on a halophilic bacterium *Nesterenkonia* sp demonstrated the presence of a stable alpha amylase [24]. Similar results were obtained in a study by Li *et al.*, (2008) on *Nesterenkonia halophila* [25]. The isolate gave positive results for catalase test characterised by the appearance of bubbles due to the breakdown of hydrogen peroxide into oxygen and water. Similar results were found by Collins *et al* where *Nesterenkonia lacusekhoensis* tested positive for catalase test [21]. Li *et al.*, (2008) described. The characteristics of *Nesterenkonia alba* which showed catalase positive [25]. A study on *Nesterenkonia natranophila* also showed similar results [26].

Screening of the dye decolorization by the immobilized isolate

The highest decolorization percentage of around 61% was seen in the sample treated with the immobilized beads made from the supernatant as mentioned in table 3 and figure 4. Immobilised amylase enzyme showed maximum decolorisation of azo dyes at pH 8 [27]. In another study, laccase produced by *Bacillus subtilis* was immobilised on chitosan beads for the degradation of indigo carmine and malachite green. The results showed that immobilised laccase was able to decolorise 95.24% indigo carmine and 90% malachite green [28]. Immobilised *Pseudomonas guariconensis* in calcium alginate beads has increased decolorisation ability when compared to free cells [29].

Spectral analysis of the decolorized dye products

Shift in the peak from the visible range to UV range was observed during the spectral analysis of the decolorized sample indicating the degradation of the BCP dye into metabolites. As is evident from Figure 5, the absorption maxima (λ_{max}) of BCP were determined using UV-Visible Spectrophotometer (UV-1700 PharmaSpec) in the UV and visible range (400 – 700 nm). The dye gave a purple shade when dissolved in water. The maximum absorbance was detected by the peak in UV-Visible spectrum at 580nm. A shift in the peak to the range of 200nm-300nm was observed confirming the degradation of the dye.

Partial purification and determination of molecular weight of the dye decolorizing enzyme

Based on the bands formed on the SDS-PAGE as shown in Figure 6, the molecular weight of the enzyme was estimated by comparing with the protein marker. The molecular weight of the enzyme depicted as the prominent band was estimated to be of approximately 40 KDa. Correlating the molecular weight of the band obtained to the enzyme molecular weight reported by Bharagava *et al* it can be assumed that the degrading enzyme could be lignin peroxidase with a molecular weight of ~ 40-45 KDa [30].

Evaluation of toxicity of the degraded dye sample on plants

The treated dye samples were further assessed to study their toxic effect on plants (*Vigna radiata*). Phytotoxicity studies help in examining the detrimental effects of dye containing effluents on the plants. In this study the phytotoxicity of dye before and after degradation was assessed on *Vigna radiata* and the results were tabulated (Table 4). Phytotoxicity studies help in examining the detrimental effects of dye containing effluents on the plants. In this study the phytotoxicity of the dye before and after degradation was assessed on *Vigna radiata*. Germination of seeds was observed in seeds treated with dye decolorized metabolite sample as well as non-decolorized dye. After day 3, inhibition in the germination of the seeds treated with the dye was observed whereas the radicle of the seeds grown in metabolites extracted after decolorisation showed significant growth as shown in Figures 7, 8 and 9. The germination percentage was the highest in seeds treated with decolorized dye metabolites as illustrated in the Table 4. The phytotoxicity results indicated that the metabolites produced on microbial degradation of dyes are non-toxic to the plant growth. Earlier study conducted by Parshetti *et al.*, (2006) showed that germination of *Triticum aestivum* was more when treated with degradation product of malachite green as compared to the non-degraded dye [31]. Similarly other study done by Ayed *et al* (2011) revealed that degradation products are less toxic on the growth of *Sorghum bicolor* and *Triticum aestivum* [32].

Gowri Subramanian *et al.*,

Evaluation of antibiotic sensitivity of the isolate

The increasing antibiotic resistance of microbes is an emerging threat to public health. Wastewater system harbours a diverse community of microorganisms some of which are antibiotic resistant bacteria and are also source of antibiotic-resistant genes [33]. Hence it is important to determine antibiotic sensitivity of the microorganism before its application in waste water treatment. The isolate obtained was tested for sensitivity to antibiotics against ampicillin and penicillin. Clear zones of inhibition were observed suggesting that the antibiotics used inhibited the growth of isolate 1. The zone of inhibition was found to be 50.9mm for ampicillin and 45.9mm for penicillin respectively. This rules out the antibiotic resistance of the isolate and hence there is no threat of its application in any wastewater treatment.

Molecular identification of the isolate and its phylogenetic analysis:

16S rRNA gene sequence of Isolate 1 was submitted to Credora Lifesciences for analysis. The BLAST analysis of the sequence was done. The BLAST sequence exhibited 100% similarity with *Nesterenkonia* sp. MK818807.1. Through phylogenetic analysis, isolate 1 was identified as *Nesterenkonia* sp. strain ADL055 (Figure 11).

Isolate-1: *Nesterenkonia* sp.

Application of microorganisms for the bioremediation of synthetic dyes has been found to be great value to the environment as the method is eco-friendly and cost effective. In this study bacterial isolate *Nesterenkonia* sp. from effluent contaminated soil showed great potential in the decolourisation of bromocresol purple. The results from this study indicate that maximum decolourisation of bromocresol purple was obtained at alkaline pH 8 at 37°C. Further, phytotoxicity studies on the germination of *Vigna radiata* showed that the degraded dye metabolites had no inhibitory effects on the germination of seeds. Antibiotic sensitivity experiments revealed that the isolate was inhibited by antibiotics. Hence any risk of bacterial antibiotic resistance that could pose a threat in handling the isolate is ruled out. Moreover, there are no reports about its pathogenicity. Immobilization of cells and enzymes can be efficient tools in dye decolourisation. Immobilization experiments showed that higher decolourisation percentage was observed in sample treated with immobilised beads prepared from supernatant. Further work can be done in purifying the enzymes secreted by *Nesterenkonia* sp. degrading bromocresol purple and immobilising the same to achieve greater results. *Nesterenkonia* has a great potential for its application in industries for the treatment of dye effluents since it is a halophilic bacterium that can tolerate a high salt concentration usually present in textile effluents.

ACKNOWLEDGEMENT

We appreciate Credora Lifesciences, Bengaluru, Karnataka, India for the help received in identification and phylogenetic analysis of the isolate.

ABSTRACT

An important commercial crop in Manipur, the pineapple (*Ananas comosus*) generates significant farm income and economic stability. The Manipur Organic Mission Agency (MOMA) has undertaken a number of projects to improve pineapple output through the establishment of efficient marketing infrastructure and the promotion of scientific growing techniques. The purpose of this study was to evaluate the growers' knowledge and determine the elements that affect them. By using a proportionate random sampling study design, a sample of 300 respondents was chosen from three districts in Manipur. The results show that the majority of respondents had a medium level of knowledge, with high and low knowledge groups follows. Each respondent possessed extensive knowledge about various techniques, including propagating plants using suckers, choosing soil and locations with moderate slopes, spacing plants in a single row system (75 x 30 cm), utilizing rainfed irrigation, manually pulling weeds to prevent pests and diseases, harvesting plants at a mature but green stage for the neighborhood market, cleaning for post-harvest handling, identifying plants according to size, shape, maturity, and disease-free status, packing using bamboo baskets and jute sacks, and applying conventional storage techniques.

Keywords: Knowledge, Organic, Pineapple, Manipur.

**Nongmaithem Gyaneshor Singh et al.,**

INTRODUCTION

Ananas comosus, or pineapple, is one of the most significant commercial crops in the world (Hossain, 2015). It is also one of the most popular fruits consumed worldwide because of its unique flavor and fragrances (Maia et al., 2020). With a share of almost 8% of the world's pineapple production, India comes in sixth place globally (Priyanka Roy & Souvik Ghosh, 2022). The pineapple became known as the Manipur state fruit on the 12th of June 2009 (E Pao, 2009). It is grown in almost every district of the state. Pineapples are the primary source of income for many farmers (Das et al., 2019). It is known as a cash crop in Manipur. In terms of business, growing pineapples has become a major income source for many farmers. Pineapple's growth in Manipur has the potential to become a major industry that creates a lot of jobs and income. Kew and Queen Pineapples are the main types grown in Manipur. In the state, pineapples are significant fruit crops that are produced in large quantities for eight months out of the year (Rabina et al., 2021). 30% to 40% slopes are ideal for cultivation due to steeper slopes might cause excessive soil erosion in the wet season and insufficient moisture retention in the winter. Because of its susceptibility to hilly terrain, the Queen variety is mainly grown in the districts of Thoubal and Imphal East (T. Chanu, 2014). In Manipur's hill regions, where pineapple farming is a significant source of income, financial service providers operating under the Manipur Organic Mission Agency (MOMA) along with other related agencies have been supporting pineapple farming communities.

To support and promote pineapple production, MOMA's intervention initiatives have provided farmers with necessary farming supplies and marketing platforms in partnership with partner business agencies. The Department of Horticulture and Soil Conservation, Manipur, reached a remarkable accomplishment in July 2022 when they shipped 20 metric tons (MT) of fresh, ripe, organic pineapples to Dubai for the first time. The Manipur government's Directorate of Horticulture and Soil Conservation noted the achievement in a survey that was conducted in 2022 (Imphal Free Press, 2022). Manipur's actual pineapple production averages 21.56 tonnes per hectare, a figure that is less than the estimated yield of 40–50 tonnes per hectare. A lack of adoption of contemporary farming techniques, such as high-density planting, efficient fertilizer management, skilled weed control, and sustainable farming practices-particularly in hilly terrain with suitable soil conservation measures is the cause of this gap. Marketing pineapples effectively is one of the biggest problems Manipur's pineapple growers confront. Regarding the newest advances in pineapple growing, many farmers are ignorant. This can be resolved by putting in place a strong extension program that informs farmers about the newest techniques for growing pineapples and promotes their adoption. According to Roy et al. (2013), farmers will find it easier to adopt new farming technology if they are introduced through an intense extension system and regularly scheduled training programs. The purpose of this study is to determine how much knowledge pineapple growers in the state of Manipur have about scientific cultivation practices.

METHODOLOGY

The state of Manipur was selected for this investigation due to its well-known status as one of India's primary pineapple-growing regions. The investigation was conducted in three districts that had a high density of pineapple growers. A proportionate random sample technique was used to select 300 respondents in total. A pre-tested organized schedule and in-person interviews were used to acquire data. The ICAR Research Complex for NEH Region Manipur Center, Lamplalpat, Imphal, proposed pineapple cultivation procedures, and this was the study's main focus. The respondents' knowledge was divided into three categories using cumulative frequency methods: low, medium, and high. Frequency and percentage were utilized to examine the knowledge levels.

RESULTS AND DISCUSSION

The data regarding the practices-wise knowledge of recommended technologies in pineapple cultivation are present in Table 1.

**Nongmaithem Gyaneshor Singh et al.,****Improved variety**

It is divided into two different pineapple varieties, Queen and Kew, compared to the suggested enhanced varieties. The findings indicate that respondents had a very high level of knowledge about these types. The majority of participants are acquainted with both the Queen and Kew types. Compared to the Queen variety, which has an awareness rate of 97.7%, the Kew variety has a slightly higher rate of 98.7%. Despite the fact that both types are well-known, this little variation suggests that pineapple growers in the area might prefer the Kew variety more. 98.2% of respondents, on average, are aware of both suggested variations. This indicates that growers in Manipur's have efficiently received information about enhanced pineapple cultivars, leading to nearly universal

Method of Propagation

The data provided shows the following about the different ways pineapple is propagated, such as Ratoons, Suckers, Slips, and Crown: Since all responders (100%) are aware of the Suckers approach, it is the most well-known and probably the one that farmers employ the most frequently. The Ratoons (83.0%) and Slips (87.7%) approaches are similarly well-known, however not as widely accepted as Suckers, according to a sizable portion of respondents. Only 3.3% of respondents, in contrast, were aware of the Crown technique, indicating that producers in the area either do not support it or do not see it as extensively marketed. The average awareness of all approaches is 68.5%, which suggests that respondents have a typically moderate understanding of the various dissemination strategies.

Treatment of Sucker

The investigation indicates that respondents understood very little about Panchagavya (8.7%) and Amritpani (4.0%) treatments. This suggests that growers of pineapples in the area are not well-informed about or using these treatments. The average awareness rate for these sucking treatments is 6.35%, indicating that respondents generally know very little about these particular techniques. Results show a critical knowledge gap about sucker treatments and emphasize the need for better agricultural extension and related educational programs.

Selection of Suitable Soil/Site

The fact that all respondents (100%) agree that moderate slopes are best for growing pineapples shows that producers fully comprehend and accept this site selection criterion. The majority of respondents (94.3%) had knowledge that hill areas are appropriate for pineapple farming, indicating that this information is widely disseminated and acknowledged. In contrast to mild slopes and hills, plain sites can also be appropriate, as indicated by the knowledge of just over half of the respondents (57.7%), indicating a lack of agreement or information regarding this fact. The average awareness rate for all site selection criteria is 84.0%, suggesting that although specific site characteristics, such as hills and moderate slopes, are well known, there are general gaps in thorough understanding of various site types. The information presented here emphasizes the need to improve our knowledge of the general suitability of sites for pineapple production.

Land preparation

In regarding land preparation methods for pineapple growing, almost all respondents (99.3%) have knowledge of the trenches method, which suggests that growers are aware of this technique and probably use it frequently. A sizable portion of respondents (66.0%) are also aware of the raised beds method, which suggests that although growers are aware of this approach, a sizable portion may not be familiar with it. The average awareness percentage of land preparation procedures among the respondents is 82.65%, indicating an average level of knowledge. This analysis shows that while there is a high level of awareness about some approaches, there is a need to increase knowledge about all suggested practices to guarantee that all pineapple growers are well-informed and capable of using these strategies.

Times of Planting

Almost all respondents (97.7%) understood that April to May is the best season to plant when it comes to pineapple production, indicating that growers are aware of this recommendation and frequently follow it. Significantly more respondents (75.0%) are aware that the months of June through August are ideal for planting, suggesting that this

**Nongmaithem Gyaneshor Singh et al.,**

time range may not be as well-known or extensively advertised by extension services. There is a moderate overall level of knowledge regarding the optimal planting periods, as seen by the average awareness percentage of 86.35% for planting times. Although most people are aware of the April–May planting season, it can still be successful to cultivate if the benefits and recommended practices for this time of year are emphasized.

Spacing

All respondents (100%) are aware of the Single row system (75×75 cm) when it comes to spacing techniques for growing pineapples, suggesting it is the most well-known and probably the most frequently employed technique among producers. A moderate level of awareness regarding the Double row system ($60 \times 90 \times 60$ cm) is shown by the fact that less than half of the respondents (46.3%) are familiar with it. The High-density planting ($35 \times 75 \times 35$ cm) approach is the least known among growers, since only 25.0% of the respondents are aware of it. A moderate overall understanding of the various spacing approaches is shown in the average awareness percentage of 57.1% for all spacing methods. According to this data, even though everyone is familiar with the single-row approach, more needs to be learned about other efficient spacing techniques. Raising knowledge of these techniques may aid in increasing planting density and yield optimization.

Fertilisers

A significant portion of respondents (87.3%) aware of Farmyard Manure (F.Y.M.) when it came to the usage of different fertilizers for pineapple cultivation, suggesting that it is a well-known and frequently utilized fertilizer among pineapple growers. The fact that a sizable percentage (73.7%) are familiar with urea suggests that it is also widely utilized and understood. A considerable amount of familiarity with Single Super Phosphate (S.S.P.) is indicated by the fact that just over half of the respondents (53.3%) are aware of it. Only one-third of respondents (33.3%) were aware of the use of muriate of potash (M.O.P.), and only 26.7% of respondents were aware of micronutrients. These two topics have the lowest levels of awareness. This suggests that there remains much to learn about the significance and practical uses of micronutrients. The average knowledge percentage for all types of fertilizers is 54.86%, suggesting that respondents have a moderate level of general comprehension. This information highlights the necessity of focused instructional programs to increase pineapple growers' understanding of fertilizer use, which could increase fertilizer efficiency and increase crop yields.

Irrigation

It is evident that depending on rainfall is a widely known technique and probably a standard practice for pineapple growers in the area, as all respondents (100%) are aware of the rainfed irrigation method. It is evident that growers have a moderate level of awareness and potential use of sprinkler irrigation, as more than half of the respondents (56.0%) are familiar with it. With regard to surface and sub-irrigation techniques, slightly more than half (50.7%) have some awareness of them, indicating a reasonable level of understanding. More formal or systematic irrigation techniques are likely less common, as seen by the fact that fewer than half (43.7%) of respondents are aware of the general irrigated method (possibly implying methods other than rainfed, sprinkler, or sub-irrigation). The average awareness percentage of all irrigation techniques is 62.6%, indicating that respondents had a reasonable level of knowledge about different irrigation systems overall. According to this investigation, pineapple growers should become more knowledgeable about alternative efficient irrigation techniques in order to improve water management and possibly boost crop output, even though rainfed irrigation is widely known.

Weeding and hoeing operations

Almost all respondents (98.0%) were aware of the guideline of carrying out weeding and hoeing operations four times, which suggests an extensive amount of knowledge and probably widespread adoption of this frequency among growers. Significantly more (73.3%) are aware of the advice to carry out these procedures twice, indicating moderate familiarity with this less common practice. About weeding and hoeing activities, the average awareness percentage is 58.65%, indicating a moderate level of general understanding regarding the appropriate frequency. In order to maximize cultivation practices and enhance crop results, it is imperative that pineapple growers get ongoing and focused education regarding the optimal frequency of weeding and hoeing.

**Nongmaithem Gyaneshor Singh et al.,****Weed Control**

The fact that every respondent (100%) knows about the hand-weeding technique suggests that pineapple growers are generally aware of it and probably use it frequently. The mechanical weeding method is known to slightly more than half of the respondents (50.7%), indicating an average degree of familiarity and possibly limited utilization among producers. A comparable percentage of participants (54.3%) acknowledge their familiarity with the chemical weeding technique, implying that although it is fairly well-known, its application may be less extensive than that of hand weeding. The average awareness rating for all weed management techniques is 68.33%, indicating that respondents generally know a moderate to high amount about different weed control strategies.

Pest and disease management

With regard to various methods of controlling pests and diseases, all respondents (100%) know how important it is to use good planting materials in order to prevent rot diseases, suggesting that producers might be experienced in this activity. A reasonable level of awareness of this preventive practice is indicated by the fact that about half of the respondents (52.3%) are aware of how important proper drainage is in preventing various rot diseases. There is a notable lack of awareness about Mealy bug wilt and the recommended methods for managing it, as just 9.0% of respondents were aware of them. Furthermore, not a single responder (46.6%) understood that defoliation sprays or treatments may be used to manage rot diseases, indicating a complete lack of awareness or application of this chemical control strategy. Because adopting healthy planting materials is widely known to be important, the average awareness percentage for all pest and disease management approaches is 51.8%, showing a generally reasonable degree of knowledge.

Harvesting

That every respondent (100%) knows about the practice of collecting mature but still green pineapples for the local market suggests that growers are certainly familiar with and frequently use this technique. Regarding harvesting pineapples at 75–80% maturity for distant markets, about half of the respondents (51.0%) are aware of this practice, indicating a modest level of knowledge and maybe limited implementation among growers. There is a notable knowledge gap for this particular harvesting technique, as just 9.3% of respondents are aware that pineapples can be harvested for embankment when they are between 1/2 and 3/4 yellow. The average awareness percentage of all harvesting activities is 53.43%, indicating that respondents have a moderate understanding of the suggested harvesting methods overall.

Yield

Regarding the expected yield of pineapple, a considerable segment of participants (63.3%) knows about the expected production range of 50-80 tonnes per hectare. This suggests that growers possess a moderate degree of awareness regarding the output potential of pineapple under ideal circumstances. Even though the amount of awareness is moderate, it can still be raised. The main goal of education should be to guide growers on the elements - such as appropriate cultivation techniques, disease and insect control, and sufficient fertilization-that can contribute to reaching the ideal yield range of 50–80 tonnes per hectare.

Aftercare of Ratoon Crop

Desuckering is a well-known and probably commonly used aftercare technique for ratoon crops, as indicated by the large majority of respondents (84.3%) who were aware of it. The practice of fertilization and earthing up after desuckering is, however, only 34.3% known to the respondents, indicating a substantial knowledge gap with this particular aftercare procedure. A usually modest degree of knowledge is reflected in the average awareness percentage of 59.3% for ratoon crop aftercare practices among the respondents.

Post-harvest management

Cleaning harvested pineapples is one of the post-harvest management activities that all respondents (100%) are aware of, indicating that growers likely engage in this commonly known and practiced post-harvest activity. The pre-cooling method, which helps preserve pineapple quality and improve its shelf life, is well-known to a sizable

**Nongmaithem Gyaneshor Singh et al.,**

majority (76.7%) of respondents. Furthermore, the majority of participants (93.3%) indicated that they are aware of the post-harvest drying of pineapples, indicating that drying is a common procedure that lowers moisture content and guards against spoiling. An overall high level of knowledge regarding appropriate post-harvest activities is shown in the average awareness percentage of 90.0% for all post-harvest management practices among respondents.

Grading

All responders (100%) are aware of the standards for grading pineapples, which include size, shape, maturity, and lack of diseases or flaws. This suggests that grading is a commonly understood concept and probably a common practice among producers. This information emphasizes how crucial it is to provide ongoing training to pineapple growers so they can reliably use efficient grading techniques and raise the produce's quality and market value.

Packaging and Transport

The majority of respondents (100%) know that growers generally follow and are generally aware of the suggested packing techniques, which include utilizing jute sacks, bamboo baskets, crates lined with paddy straw, and other materials. It is also suggested that these transport strategies are also widely understood and used because all respondents (100%) are aware of the suggested modes of transportation, which include head load, cartload, trucks, and tractors. An overall high degree of knowledge regarding these post-harvest practices is seen in the average awareness percentage of 100% for packaging and transport techniques among respondents.

Storage

All of the respondents (100%) are aware of common storage techniques shows that producers generally accept and are familiar with this essential technique. A sizable majority (83.0%) are aware of cold storage techniques, indicating a high degree of awareness of this innovative method that can increase pineapple shelf life. About 17.3% of respondents, however, were aware of the use of ethereal treatment for uniform ripening, indicating a notable lack of knowledge about this particular post-harvest technique that can improve the uniformity and quality of ripening. The average awareness rating for all storage procedures is 66.76%, indicating that respondents generally know a moderate to high amount about efficient storage techniques.

Processing

Slightly more than half of the respondents (61.0%) are aware of methods like producing syrup, juice, and jam regarding the recommended processing processes for pineapples, demonstrating a moderate level of knowledge among the growers regarding these value-added approaches. Growing pineapples for syrup, juice, and jam offers growers a great opportunity to teach them about the benefits, as 39.0% of respondents were unaware of these processing methods. This can boost profitability, cut waste, and help them diversify their product line. The findings emphasize how crucial it is to provide ongoing training and assistance to pineapple growers so they may become knowledgeable about different efficient processing techniques, which will allow them to increase the value of their produce and boost overall profitability. From table 2 inferred that a significant proportion of pineapple growers surveyed (67.7%) demonstrated a medium overall knowledge level, suggesting a reasonable understanding of relevant agricultural practices and techniques. A considerable number of respondents (20.3%) reported a high overall knowledge level, indicating potential gaps in understanding key aspects of pineapple cultivation and management. A smaller yet noteworthy segment (12.0%) exhibited a low overall knowledge level, indicating a strong grasp of agricultural knowledge and potentially advanced skills in pineapple cultivation. Efforts should focus on enhancing the overall knowledge level of pineapple growers, particularly among those demonstrating low or medium levels of knowledge. Collaboration with agricultural experts, research institutions, and experienced farmers can provide valuable insights and support in disseminating best practices and advanced techniques to improve overall knowledge levels among pineapple growers.

Nongmaithem Gyaneshor Singh *et al.*,

CONCLUSION

From the findings, it can be concluded that the majority of respondents had a medium level of knowledge followed by high and low knowledge groups. While awareness remains high in certain areas, there are notable knowledge gaps in others. In order to maximize production and boost profitability, growers of pineapples must be adequately informed about all facets of cultivation, post-harvest handling, and value addition.

ABSTRACT

The beginning of a new training schedule or significant increases in workout volume are frequently linked to the development of hamstring strain. Hamstring tightness is commonly correlated with good health. Young adults (18-25 years old) enrolled in college often report having tight hamstrings. This study suggests that the neuro dynamic sliders approach and bowen therapy are the two ways to increase hamstring flexibility. According to this study, either the bowen treatment or neurodynamic sliders are more effective at increasing hamstring flexibility. Experimental study was done. A total of 60 college students with asymptomatic hamstring tightness have been selected according to the criteria for inclusion and exclusion. They have been split into two groups, The bowen technique group (n = 30) and a neurodynamic sliders group (n = 30). Both the intervention were given for three weeks, three sessions per week in alternating days. Passive straight leg raise (PSLR) and the active knee extension test (AKE) was used to evaluate the subjects. Goniometer is used to measure ROM. According to the statistical analysis, The paired and unpaired t test were used to analyse the values. The pre and post test values were analysed by using PSLR and AKE in both groups. The mean value of bowen technique group was found to be more significant than the neurodynamic sliders technique with p value is <0.0001 The result suggests that bowen technique shows a significant improvement in increasing hamstring flexibility and ROM than neurodynamic sliders.

Keywords: Hamstring muscle, range of motion, muscle tightness, college students, muscle stretching Exercise.

INTRODUCTION

There is a traditional term for the fatty and muscular region behind the knee, called the "ham." The term "hamstrings" refers to the tendons that feel like strings on either side of the back of the knee. The hamstring's medial group consists of the semitendinosus and semimembranosus muscles, while the lateral group is made up of the long and short heads of the biceps femoris, which together create this two-joint muscle structure. The short head is the only portion of the biceps femoris muscle that does not extend the hip and knee joints.[1] Most people who have tight hamstrings are in good health.[2] More women (45%) than men (27.50%) experience hamstring tightness. Exercise causes the release of endorphins, or "feel-good hormones," which reduce dysmenorrhea symptoms.[3] To treat hamstring tightness, There have been several methods employed in the past, including spray, muscular energy technique (MET), soft tissue mobilization technique, and stretching exercise.[4] For athletes with ITB tightness, IASTM and FR methods greatly increase the advantages of exercise.[5] Flexibility can be impacted by how tight certain soft tissue components, joint capsules, muscles, and fascia are about one another.[6] One of the main reasons why healthcare workers become unwell is because of work-related musculoskeletal disorders (WRMSDs); similarly, Asymptomatic hamstring tightness is a common issue among college students, often resulting from prolonged sitting, poor posture, or a lack of regular stretching. Despite the absence of pain or noticeable discomfort, this tightness can impact flexibility and muscle function over time. Given the numerous studies conducted on hamstring tightness, it is essential to concentrate on a patient-reported outcome.[7] In addition to its primary effect on the person experiencing hamstring muscle stiffness, which may or may not cause pain, it can limit functional activities and quality of work performed by the workers. Although hamstring injuries have no single known cause, a number of variables, such as age, ethnicity, poor running form, insufficient flexibility, muscle weakness, and an imbalance in muscular strength, may be involved.[8] Information from college students who started their courses online is provided by a survey. These late-night internet activities lead to sleep disturbances, prolonged exposure to smartphones and computers, and late-night sleep. Individuals with an evening mentality are more likely to experience mental health issues they also tend to maintain sedentary lifestyles, which can cause weakness and tightness in their muscles.[9] The onset of neuromusculo skeletal disorders and limited range of movement. The connective tissue that envelops muscles is called myofascial tissue. It helps transmit force, gives the muscles structural support, and permits flexibility and mobility of the muscles throughout the body.

When it is injured, inflamed, or inactive, it can diminish strength and endurance and limit ROM.[6] Although the absolute lengths of the hamstring muscles varied by gender, these variations did not correspond to variations in the proportions of femur length.[10] The paraspinal and hamstring muscles exhibited a moderate to strong connection, and the SWE modulus of all the muscles rose significantly after submaximal hamstring contractions.[11] In a range of motion (ROM), the hamstring muscles are used to control human mobility such as sprinting, jumping, forward bending while seated or standing, and various postural control exercises.[12,13] For postural balance, hamstring muscle flexibility is essential, full maintenance of the extent of mobility in the knee and hips, injury prevention, and optimal musculoskeletal function, especially in the field of rehabilitation.[14] People won't be able to carry out basic daily tasks that call for bending at the knee or extending at the hips without sufficient hamstring flexibility.[15] Among the most widely recognised reasons for injury to the hamstring appears to be inadequate flexibility inside the posterior thigh compartment.[16] The tibial, sciatic and common fibular nerves altered neurodynamics may be the cause of reduced flexibility in the hamstrings, as shown by the passive straight leg raise test (PSLR) restricted range.[17] It's possible that changes in the neurodynamics of the posterior lower extremities could impact resting muscle length and change how someone experiences pain or stretch. The flexibility of the hamstring muscles in the back of the leg, thigh, buttock, and spinal canal may be affected by the mechanosensitivity of the brain regions. Because of hamstring tension and the accompanying risk of strain injury, protective muscle activation of the hamstring muscles may be responsible for neural mechanosensitivity.[18] The hamstring muscle group was outstripped and innervated by self-stretching, which was combined with neurodynamic sliders. The only treatment used was Bowen to increase hamstring extensibility. In this research, we evaluate the impacts of the Bowen technique and neurodynamic sliders to promote flexibility in hamstring muscle tightness.

Surendhar Mohan *et al.*,

MATERIALS AND METHODS

According to inclusion criteria, the study participants were selected from the physiotherapy OPD at the private multi-speciality hospital, Chennai, Tamil Nadu, India. Participants who were college students without symptoms of hamstring tightness, both genders aged between 18 and 25, subjects with a positive Supine SLR test, active 20–50 degree reduction of knee extension while the hip is 90 degrees flexed, and dominant right lower limb were included. Individuals experiencing both neurological and low back discomfort, individuals who have experienced a lower extremity injury within the last three months, any fracture or surgery performed on the knee, hip, pelvis, or back, hamstring injuries, hypermobility of the lower limb joint, and muscle imbalance of the lower limb were excluded in this study. The study used a sample of 60 college students with asymptomatic hamstring tightness. It was an experimental study conducted among college students with asymptomatic hamstring tightness. The study used a random allocation technique to divide the groups with a convenient sample. Materials required for this study was universal double-arm goniometer. The total duration of this study was three weeks. These treatments were administered to both groups three times a week on different days. Subjects from both the bowen technique group and the neurodynamic sliders group participated in the pre-test evaluation and The outcome of the investigation were then assessed using the active knee extension test (AKE) and the passive straight leg raise (PSLR). A universal goniometer is used for ROM measurement. The official approval from the Institutional Scientific Review Board with the ISRB number(01/029/2023/ISRB/SR/SCPT).

bowen technique group (30)

On the plinth, The patient is lying down on their back. Lift the leg to a 90-degree angle; the therapist should grip the ankle while performing the initial exercise with the same hand's elbow. Place a couple of fingers below the sit bone and make a first move[19]with the biceps femoris at the middle of the semitendinosus and semimembranosus muscles. Make a lateral slack, press in, and perform a medial move on the midline of the hamstring muscles, a few inches below the sit bone. The second move is to place your thumb behind in the popliteal fossa. The therapist should next hold your ankle and move it erratically. Then, give your foot a firm tap to activate your hamstrings. Apply pressure over the hamstring muscle and the thumb should hooked onto the lateral edge.[20] The muscle begins to contract, plop, or react in some other way when we start to place our thumb down in a medial direction. The fingers should move from the left side of the body toward the right side. On alternate days, three sessions per week, the intervention was administered, and each session took 20 minutes.

neurodynamic sliders group (30)

The "Seated Straight Leg Slider" (SSLS), was executed by participants. To perform this sliding technique, participants had to seated in slump position (both lumbar and thoracic flexion), which they were required to keep up during the workout. In this seated straight leg sliders, the movements were alternated between knee flexion and ankle plantar flexion, which resulted in a decrease in neural tension followed by knee extension and ankle dorsiflexion, which resulted in an increase in neural tension, combined with cervical extension, which resulted in a decrease in neural tension.[21]

outcome measures

At baseline, an assessment was carried out (before starting treatment) and Using the active knee extension test (AKE) and passive straight leg raise (PSLR), three weeks into the study period. The active knee extension test (AKE) measures the length of the hamstrings and looks for potential hamstring contractures. It is also known as the 90-90 hamstring test. The knees are extended until they are parallel to the ground, and the opposing arm is elevated until the hip forms a 90-degree angle. Any extension less than 20 degrees is seen as hamstring tightness, while a 20-degree lag is considered normal from full extension. The AKE test is used to measure hamstring length, detect hamstring stiffness, and determine whether hamstring contracture may be present. A basic physical examination method for individuals experiencing lower back pain and discomfort is the Lasague test, also referred to as the straight leg lift test or the passive straight leg raise (PSLR). Participants with normal hamstring flexibility can achieve 80° or more in that test, while those with tight hamstrings can only reach less than 80°.

RESULTS

The PSLR and AKE tests indicate a significant reduction in hamstring tightness post-examination, suggesting improved flexibility or muscle relaxation compared to prior measurements. This decrease in tightness could imply effective treatment or alleviation of muscle strain. These results indicate improved hamstring flexibility and mobility. The decrease in tightness suggests increased muscle length and reduced stiffness after the intervention.

Table-1 Compares the Bowen technique group's pre- and post-test values in PSLR, The pre-test's mean(41.9), SD(6.09). In contrast, $t=22.707$, the post- test mean(44.6), SD(6.1). the P-value is less than 0.0001, the results are considered highly significant. However, compares the Neurodynamic sliders group's pre- and post-test values. The pre-test's mean(39.2), SD(6.16). On the other hand, $t=14.252$ and the post-test mean(40.9) and SD(6.25), respectively. the P-value is less than 0.0001, it means that the results are very statistically significant.

Table-2 Compares the post-test results for the Neurodynamic sliders group and the Bowen technique group in PSLR. The results show that the mean value for the Neurodynamic sliders group(40.9), SD(6.25), $t=2.318$, whereas the mean value for the Bowen technique group(44.6), SD(6.11). When the P-value = 0.0002, the results are considered to be statistically significant.

Table-3 The Bowen technique group's pre- and post-test values in AKE. The Post-test mean value(39.2), SD(5.08), and $t=25.938$. The pre-test mean(36.6), SD(5.06). the P-value is less than 0.0001, the findings are very statistically significant. However, compares the Neurodynamic sliders group's pre- and post-test values. The pre-test's mean(34.4), SD(4.22). In contrast, $t=13.857$, the post-test mean(35.6), SD(4.26). Very statistically significant outcomes are shown by P-values less than 0.0001.

Table-4 Post-test results for the Neurodynamic sliders group and the Bowen technique group in AKE. The mean value for the Neurodynamic sliders group(35.6), SD(4.26). $t=2.974$, whereas the mean value for the Bowen technique group(39.2), SD(5.08). p value=0.0043. The results are considered statistically significant. This shows that, when compared to the neurodynamic sliding technique, the bowen technique yields more functional benefits.

DISCUSSION

Experimental comparison of the Bowen's effects and neurodynamic sliding techniques on flexibility in asymptomatic college students with tight hamstrings is the aim of the current study. In this study, 60 subjects with asymptomatic hamstring tightness were selected, and PSLR and AKE tests were used as outcome measures to mark pre-test values. Values of before and after the treatment were tabulated. The goniometer is the material required to determine ROM. According to a study by Michelle Marr that examined hamstring flexibility over time as a result of the approach, although the superficial pressure used during the procedure invalidates changes caused by tissue slide due to stress or tissue plastic deformation, there is no bearing weight, warming up, stretching, or joint loading associated with it.[15] This research's findings show the significance of the Bowen technique and neurodynamic sliders on promoting flexibility in hamstring tightness in asymptomatic college students in terms of flexibility and the extent of movement. The hamstring flexibility and ROM have been evaluated using AKE and PSLR tests. A statistically significant difference between the groups was revealed by the current investigation's results ($p<0.001$) and a difference that is statistically significant was found for both approaches in terms of improving hamstring flexibility for between-group analysis; the p value for the Bowen technique group is equal to 0.0002, which is considered statistically significant. Given that the p value for the neurodynamic sliders group is 0.0043, it is considered statistically significant. Roel de Ridder, et al. In individuals with decreased flexibility, This was the initial investigation to examine the effects of a neurodynamic intervention plan that lasted 6 weeks at home on the flexibility of the hamstrings in comparison to a static stretch.[21] All patient's hamstring flexibility increased significantly as a result of both therapies, surpassing the MDC of 3.18° , but with a significantly greater gain in flexibility of the hamstrings (12.6° versus 9.3°), our outcomes significantly demonstrated what could be beneficial of employing neurodynamic sliders superior to the conventional

**Surendhar Mohan et al.,**

approach, supporting the hypothesis of our study.[22]The sciatic nerve can be linearly extended using neurodynamic sliders.[23]which might avoid or alter these adhesions, resulting in a decline in the mechano sensitivity of neurons and an increase in the visco elasticity of neurological tissue, which would promote hamstring mobility.[24]Small lesions in the hamstring muscle might progressively reduce stretch tolerance, particularly during explosive eccentric loading at the end range. If left untreated, this may increase the risk of strain injuries in the hamstring. Malliaropoulos et al. (2004) continued to follow eighty Greek athletes who had been diagnosed with second-degree hamstring injuries. In rehabilitation, sliders may offer the best solution since they primarily increase the mobility and mechanical function of the nerve within the mechanical interaction with minimal neural pressure.[25]The effects of bowen therapy on hamstring tightness are investigated in this study in asymptomatic college students, and significant improvement has been achieved in terms of hamstring flexibility.[18]The AKE test was used as a hamstring flexibility measuring technique.[25] Thus, our research determined that when applied alternately for three sessions, the bowen technique and the neurodynamic sliding technique both have similar efficacy in improving the range of motion and flexibility. To help individuals with hamstring tightness, both methods can be utilized therapeutically to improve flexibility and ROM.According to our research, We determine that both the neurodynamic sliding technique and the Bowen techniqueimprove flexibility of hamstring muscle and ROM. The study found significant improvements in hamstring flexibility and functional outcomes following the Bowen technique intervention, particularly in asymptomatic college students. Future research can be conducted over longer time periods. A similar study could be expanded with a large number of sample. The bowen and neurodynamic sliding procedures can also be used to operate with other muscles. These results align with current research supporting the bowen method's benefits. The technique shows potential for enhancing functional outcomes and hamstring flexibility. However, To validate these results and evaluate long-term impacts, more investigation and long-term monitoring are required.

Abbreviation

range of motion (ROM),passive straight leg raise(PSLR), active knee extension test (AKE)

ACKNOWLEDGEMENT

I sincerely appreciate the assistanceand guidance.I gained information from a variety of people during this research, as their influence has been instrumental in shaping my understanding and foundation in this field. I want to convey my heartfelt gratitude to the department for providing the resources and environment necessary for my growth. We are especially grateful to the volunteers who took part in this study.Without their time, effort, and cooperation, this project would not have been possible. Their contribution was vital in bringing the study to fruition. I truly appreciate the collective efforts that made this research a success.

Table 1: Comparison between the pre-test and post-test values of bowen technique group and neurodynamic sliders

PSLR (ROM)		MEAN	SD	T-VALUE	P –VALUE
BOWEN TECHNIQUE GROUP	PRE-TEST	41.9	6.09	22.707	< 0.0001
	POST-TEST	44.6	6.11		
NEURODYNAMIC SLIDERS GROUP	PRE-TEST	39.2	6.16	14.252	
	POST-TEST	40.9	6.25		

Compares the pre and post-test values of bowen technique group, The mean value of the pre-test is 41.9 and the SD value is 6.09, Where as the post-test mean value is 44.6,SD value is 6.1, $t = 22.707$. As a result, the findings are considered extremely statistically significant when the p-value is <0.0001 and Compares the pre and post-test values of neurodynamic sliders group, The mean value of the pre-test is 39.2 and the SD value is 6.16, Where as the post-test mean value is 40.9,SD value is 6.25, $t = 14.252$. As a result, the findings are considered extremely statistically significant when the p-value is <0.0001.

Table 2: Comparison between the post-test values of bowen technique group and neurodynamic sliders group in PSLR.

PSLR (ROM)		MEAN	SD	T-VALUE	P-VALUE
BOWEN TECHNIQUE GROUP	POST- TEST	44.6	6.11	2.318	p = 0.0002
NEURODYNAMIC SLIDERSGROUP	POST- TEST	40.9	6.25		

Compares the post-test values of the bowen technique group and neurodynamic sliders group, revealing that the mean value of the bowen technique group was 44.6 and SD value is 6.11, whereas the neurodynamic sliders group mean value was 40.9 and SD value is 6.25, $t = 2.318$. As a result, the findings are considered statistically significant when the p-value is equal to 0.0002.

Table 3: Comparison between pre-test and post-test values of bowen technique group and neurodynamic sliders group in AKE.

AKE (ROM)		MEAN	SD	T -VALUE	P -VALUE
BOWEN TECHNIQUE GROUP	PRE-TEST	36.6	5.06	25.938	< 0.0001
	POST-TEST	39.2	5.08		
NEURODYNAMIC SLIDERS GROUP	PRE-TEST	34.4	4.22	13.857	
	POST-TEST	35.6	4.26		

Surendhar Mohan et al.,

Compares the pre and post-test values of bowen technique group. The mean value of the pre-test is 36.6 and the SD value is 5.06, Whereas the post-test mean value is 39.2, SD value is 5.08. $t = 25.938$. As a result, the findings are considered extremely statistically significant when the p-value is <0.0001 and Compares the pre and post-test values of neurodynamic sliders group. The mean value of the pre-test is 34.4 and the SD value is 4.22, Whereas the post-test mean value is 35.6, SD value is 4.26, $t = 13.857$. As a result, the findings are considered extremely statistically significant when the p-value is <0.0001 .

Table 4: Comparison between the post-test values of bowen technique group and neurodynamic sliders group in AKE.

AKE (ROM)		MEAN	SD	T-VALUE	P-VALUE
BOWEN TECHNIQUE GROUP	POST-TEST	39.2	5.08	2.974	P = 0.0043
NEURODYNAMIC SLIDERSGROUP	POST-TEST	35.6	4.26		

Compares the post-test values of the bowen technique group and neurodynamic sliders group, revealing that the mean value of the bowen technique group was 39.2 and SD value is 5.08, whereas the neurodynamic sliders group mean value was 35.6 and SD value is 4.26, $t = 2.974$. As a result, the findings are considered statistically significant when the p-value is equal to 0.0043.

ABSTRACT

The expansion of wireless networks, driven by 5G, IoT, and forthcoming 6G technology, brings an increased need for energy-efficient solutions to mitigate high power demands, environmental strain, and operational costs. This study systematically addresses these challenges, focusing on cutting-edge energy-saving strategies for wireless communication. We reviewed recent literature from key databases including Google Scholar, IEEE Xplore, SCIE, and Scopus, narrowing down relevant studies from 2018 to 2024. Our keyword selection included "Energy Efficiency," "5G Networks," "Machine Learning in Wireless Networks," and "Energy Harvesting in IoT," with rigorous inclusion criteria prioritizing research on power optimization, resource allocation, and adaptive network control. Using a comparative approach, we analyzed a range of techniques, such as machine-learning-enhanced resource allocation, energy harvesting, and adaptive modulation schemes, illustrating findings through flowcharts, tables, and performance graphs. Our results reveal that the proposed Energy-Aware Resource Allocation Algorithm (EARAA), which leverages machine learning to predict network traffic, achieved up to 40% energy savings, boosted throughput by 35%, and lowered latency by 30% over conventional methods. These improvements underscore the suitability of EARAA for applications in high-demand networks like IoT and urban infrastructure. This review provides a fresh perspective by focusing on predictive, machine-learning-based approaches to resource allocation, an area often overlooked in past studies that primarily explored static or isolated techniques. Furthermore, we discuss practical deployment challenges and outline future directions, including field testing and model enhancements. By presenting a detailed comparison of energy-saving strategies, this study offers essential insights and a clear pathway toward more sustainable network management solutions.

Keywords: Energy Efficiency, Wireless Networks, Machine Learning in Wireless Communications, Energy Harvesting, Resource Allocation, 5G and Beyond.

INTRODUCTION

The landscape of wireless communication has rapidly evolved with the development of 5G networks, IoT applications, and the emerging framework for 6G technologies. These advancements have redefined connectivity standards, supporting a broad spectrum of applications in sectors such as smart cities, autonomous systems, and industrial automation. However, the increased demand for constant connectivity and high-speed data transmission has significantly impacted energy consumption. Maintaining efficiency in network operations while minimizing energy usage has, therefore, become an urgent priority to sustain this growth. Current research has contributed valuable insights into energy optimization for wireless networks. For example, [1] developed a regression-based model to enhance energy efficiency in wireless sensor networks by dynamically adjusting power levels based on network load. Although effective, this model focuses on sensor networks and may struggle to accommodate the complexity of more diverse and high-demand applications. [2] took a step further by implementing machine learning to optimize energy usage in NOMA (Non-Orthogonal Multiple Access) systems, focusing on downlink efficiency. However, their approach, while promising, is specific to NOMA environments and lacks scalability across broader network types. Furthermore, [3] explored energy reductions through resource allocation using free-space optics in dense network setups, but this approach does not fully address the need for resource adaptability to manage diverse and dynamic traffic patterns. A significant gap remains in designing a flexible, energy-optimizing strategy that adjusts dynamically to real-time network conditions. The evolving landscape of heterogeneous networks requires adaptable solutions that can provide scalable, real-time resource allocation based on traffic forecasts. The present study addresses these issues by introducing a holistic, predictive approach to energy management.

Research Contributions

This paper introduces the Energy-Aware Resource Allocation Algorithm (EARAA), which integrates machine learning to predict network traffic and adjusts resource allocation accordingly. This approach builds on prior work by offering a flexible, real-time optimization solution that improves energy efficiency across a variety of network conditions. Through simulations, the EARAA method demonstrated up to 40% energy savings, a 35% throughput gain, and a 30% latency reduction over conventional static methods.

Research Gaps

While existing methods offer valuable insights into energy efficiency, most solutions focus on isolated optimizations, lacking a comprehensive, predictive framework. Many studies either address specific network types or employ fixed resource allocation that does not accommodate real-time traffic changes. This limited adaptability fails to address the energy demands of increasingly complex, large-scale, and heterogeneous networks.

Research Questions

This study explores the following research questions:

- How can machine learning models effectively predict network traffic to optimize energy usage in real-time across diverse network types?
- What impact does predictive, adaptive resource allocation have on energy consumption, latency, and throughput in large-scale wireless networks?
- How does the proposed EARAA approach compare to conventional energy optimization methods in terms of efficiency and scalability?

LITERATURE REVIEW

Significant research has been conducted on reducing the energy consumption of wireless networks. Researchers have developed various techniques, including adaptive power control, energy harvesting systems, and machine learning-based solutions. Below, we review key contributions in this area. [1] developed a regression model to enhance energy

**Soumya Roy and Gouranga Bag**

efficiency in WSNs, focusing on energy harvesting based on network load. While promising, this approach is less adaptable for networks with varying traffic demands. [2] applied machine learning to optimize energy in NOMA systems, focusing on downlink energy efficiency. However, its scope is limited to NOMA, reducing its general applicability. [3] used free-space optics to improve energy efficiency in urban networks; however, its application is limited in low-density or rural settings. [5] introduced a coot-based energy management model for WSNs; however, this model is best suited for small-scale networks and not easily transferable to larger systems, such as those used in IoT or 5G. [6] tested wireless power transfer relays, effective in non-cooperative networks but limited in more interconnected, cooperative networks. [7] investigated delay-phase precoding for MIMO in THz frequencies, achieving energy gains but only effective in specific MIMO configurations. [7] explored energy harvesting specifically for 6G networks, demonstrating sustainable energy use in high-density networks but lacking scalability for varied or complex network environments. [8] used machine learning for resource allocation in mobile edge computing, enhancing energy efficiency but at a high computational cost, limiting broader scalability. [9] applied deep learning for fault-tolerant routing in WSNs, tailored to handle network faults but not easily adaptable for high-capacity 5G or IoT networks. [9] developed a fault-tolerant protocol for WSNs, emphasizing reliability, but lacking adaptability for high-traffic network environments. [10] implemented the PTS method for reducing PAPR, which achieves energy savings but is constrained to certain waveform types. [11] utilized multi-hop routing to reduce energy consumption in underwater networks, although its methods struggle to address the dynamic needs of terrestrial network traffic. [14] designed self-organizing ad-hoc networks with machine learning, improving autonomy but lacking the energy metrics required for large-scale applications. [15] investigated battery-less WSN sensors using solar energy, which enhances energy sustainability but relies on solar conditions, limiting wider application. [16] implemented adaptive modulation in dense IoT networks, but may not handle high-speed networks that require rapid modulation changes. [18] evaluated machine learning algorithms for 5G, achieving energy gains but requiring further adjustments to manage high computational demands. [19] employed machine learning for energy harvesting in IoT networks, yet the solution's suitability for larger networks remains untested. [21] studied power control techniques for 5G, but they require frequent recalibration, making real-time application challenging. [23] used AI to optimize IoT network energy use, but the solution has yet to be tested across diverse network configurations. [23]

Studied resource allocation in cognitive radio networks, effective under fixed conditions but limited in dynamic settings. [24] examined dynamic spectrum allocation within 5G networks, though its scope is restricted to fixed network conditions, limiting its flexibility for more varied network types. Dynamic Spectrum and Adaptive Protocols. [24] examined resource allocation for 5G, yielding some energy savings but not fully scalable for 6G or IoT applications. [25] explored power management for drones, suitable for constrained setups but not applicable to larger network configurations. [26] studied energy harvesting for mobile networks, effective but limited for large IoT systems that need varied energy sources. [27] developed an AI-based resource management system for 5G, achieving energy efficiency, but computationally demanding, challenging its scalability. [29] addressed sustainable communication in 6G, providing a forward-looking framework but lacking immediate applications for current networks. [30] researched resource allocation in satellite-terrestrial networks, suitable for integrated systems but lacking adaptability for terrestrial-only networks. [31] proposed adaptive routing to save energy but focused on low-power settings, limiting the approach's utility in more demanding network scenarios. [32] examined routing in WSNs, focusing narrowly on low-power networks, limiting insights for larger, mixed-infrastructure networks. [33] explored adaptive modulation for IoT, improving efficiency for low-density scenarios, but untested for mixed, high-traffic environments. Challenges in Energy-Efficient Protocols. [34] developed a power-saving protocol for high-speed 5G but lacks adaptability for slower, high-density environments. [35] presented a fault-tolerant protocol enhancing network reliability but with limited application in highly variable traffic settings.

METHODOLOGY

The methodology outlines the steps taken to design and evaluate the proposed Energy-Aware Resource Allocation Algorithm (EARAA), detailing the materials used, data sources, criteria for study selection, and the algorithm's development. This section emphasizes a systematic approach to ensuring the reliability and relevance of data used.

Database Selection and Keyword Search

The following academic databases were consulted to review prior studies and establish a foundational understanding of energy-efficient networking methods: IEEE Xplore, ScienceDirect, SpringerLink, and Google Scholar. These sources were selected for their extensive, peer-reviewed publications in wireless communication technologies.

1. Keywords Used: Searches included combinations of terms such as "energy-efficient wireless networks," "machine learning in wireless networks," "5G resource allocation," "IoT energy management," and "spectrum management for network efficiency."

2. Year Range: We focused on articles published between 2018 and 2024 to incorporate the most recent advancements in 5G, IoT, and AI-based solutions for network efficiency.

Inclusion and Exclusion Criteria

A set of criteria was applied to select relevant studies, ensuring the inclusion of high-quality and pertinent research. This filtered out articles lacking substantial experimental data or rigorous methodology.

Parameters for Concept Development

The development of the EARAA algorithm centered on optimizing power consumption and network efficiency under variable loads. Several performance metrics were identified as essential to achieving the study's goals, as shown in Table 2.

Required Materials

Hardware Requirements

- High-Performance Computer: To conduct simulation, equipped with:
 - Processor: Intel Core i7 or higher
 - Memory: 16GB RAM minimum
 - Storage: SSD with 500GB for high-speed data processing
 - Router/Modem: Optional if physical network testing is needed.
- IoT Devices: Devices with network connectivity for optional real-world validation, such as:
 - Raspberry Pi or Arduino modules with communication capabilities
 - Power monitoring sensors

Software Requirements

- MATLAB/Simulink: Main software environment for network simulations and EARAA development.
- NS-3 Network Simulator: Used to emulate real-world network environments and assess algorithm performance.
- Python Libraries:
 - TensorFlow or PyTorch for deep learning-based traffic prediction.
 - NumPy for data handling and numerical analysis.

Proposed Algorithm: Energy-Aware Resource Allocation Algorithm (EARAA)

The flowchart in Figure 1 illustrates the logical progression of the EARAA algorithm, from traffic prediction through power adjustment, resource allocation, and performance evaluation.

The EARAA algorithm leverages machine learning to manage resources efficiently by predicting network traffic demand and adjusting power levels accordingly. The following steps outline its core functions:

**Soumya Roy and Gouranga Bag**

1. **Traffic Prediction:** The algorithm begins with predicting upcoming network traffic levels based on past usage patterns. For this, a machine-learning model, specifically the Long Short-Term Memory (LSTM) network, is utilized due to its effectiveness in handling time-series data. Regular updates to the model with recent data allow for accurate, real-time predictions that adapt to dynamic network conditions.
2. **Power Adjustment:** Using the traffic forecasts, the algorithm dynamically adjusts power levels across the network. For periods of high anticipated traffic, power is increased to ensure smooth data flow and prevent potential bottlenecks. Conversely, during expected low-traffic periods, power is decreased to save energy while maintaining baseline connectivity.
3. **Resource Allocation:** The algorithm then allocates essential network resources—like bandwidth, processing power, and other necessary computational resources—based on the predicted demands. This step includes dynamically adjusting spectrum usage to maximize bandwidth efficiency, thereby helping reduce network latency and maintain steady connectivity under varying loads.
4. **Performance Evaluation:** Finally, the algorithm assesses its performance by measuring key metrics such as latency, throughput, and energy usage. By continuously monitoring these metrics, the algorithm can make fine adjustments to ensure optimal energy use without compromising on performance quality.

RESULTS AND DISCUSSION

The results below reflect the simulation outputs of the EARAA algorithm, evaluated under varying load conditions and benchmarked against conventional resource allocation methods. The performance metrics include power consumption, energy efficiency, network throughput, and latency.

Simulation Setup

The MATLAB/Simulink platform was used to conduct simulations over a 10,000-second timeframe, covering a range of network loads. The network model included 5G base stations, Wi-Fi nodes, and IoT devices to simulate real-world, heterogeneous traffic scenarios.

Performance Metrics

The key performance metrics used to assess the EARAA algorithm include: Power Consumption (W) to measure the average network power usage across varying traffic loads. Energy Efficiency (J/bit) to indicate energy required per bit transmitted, allowing for cross-scenario comparison. Network Throughput (Mbps) provides average data transmission rate achieved under each load condition. Latency (ms) to show delay experienced by packets, monitored as an indicator of algorithm responsiveness.

RESULTS

Table 3, Table 4, Table 5, Graph 1 and Graph 2 illustrate the EARAA algorithm's impact on power consumption, energy efficiency, and network performance.

DISCUSSION

The results indicate that the EARAA algorithm provides consistent power savings across all load scenarios, as seen in Table 3 and Graph 1. By dynamically adjusting power levels based on anticipated traffic, the algorithm achieves up to a 30% reduction in energy use for high-traffic situations compared to baseline approaches. As shown in Table 4 and Graph 2, EARAA significantly improves energy efficiency metrics. The energy-per-bit ratio decreased by nearly 40%, demonstrating the algorithm's effectiveness in resource allocation. This improvement is crucial for applications such as IoT and 5G, where energy efficiency impacts both operational costs and environmental sustainability. The algorithm's resource allocation features notably increased network throughput by 35% and reduced latency by 30%, supporting a smoother and faster user experience. This performance boost is critical for high-demand scenarios like

**Soumya Roy and Gouranga Bag**

real-time IoT applications or streaming services, where low latency and high throughput are essential. These findings confirm that EARAA's energy-saving approach is highly beneficial for real-world applications, especially within smart cities, industrial IoT systems, and other environments with dense device deployments. The ability to reduce power costs while maintaining network quality has significant potential for widespread adoption.

CONCLUSION

This paper presents the Energy-Aware Resource Allocation Algorithm (EARAA), designed to address critical energy efficiency demands in modern wireless networks, particularly across 5G, IoT, and potential 6G systems. By utilizing machine learning for predictive traffic analysis, EARAA adjusts power levels and allocates resources in real-time, leading to optimized performance while significantly lowering energy consumption. Through simulations, EARAA has shown substantial improvements across key metrics, including power conservation, network latency, and data throughput, compared to conventional methods. This study enriches the current body of knowledge by combining machine-learning-based traffic forecasting with real-time resource management, offering a comprehensive approach to reducing energy consumption in communication networks. Distinguishing it from prior studies that often focused on singular methods like dynamic spectrum management or energy harvesting, EARAA integrates these approaches into a unified, adaptive framework. By demonstrating up to 40% in energy savings and enhancing throughput by 35%, EARAA contributes a versatile, practical tool for sustainable network management—filling a gap in the research on adaptive, machine-learning-based network resource allocation. While EARAA provides valuable advancements, certain limitations remain. The algorithm was tested in controlled simulations that, while detailed, cannot fully emulate real-world conditions, which often include diverse hardware and environmental variations. Additionally, EARAA's use of machine learning for predictive adjustments introduces a level of computational demand that may not be ideal for lower-power IoT devices. Future studies could explore more lightweight models or decentralized approaches to increase suitability for such resource-limited environments. There is also room to further develop energy-efficient solutions specifically for low-power networks, which would allow EARAA to expand its applicability across even more constrained settings. These results open up various paths for further investigation. Testing EARAA in real-world deployments within 5G and IoT networks would yield deeper insights into its scalability and effectiveness. The integration of EARAA with edge computing and small cell infrastructures would also enable more localized, energy-conscious resource management, with potential benefits across smart cities, industrial IoT applications, and green networking. Additionally, adapting EARAA for multi-access edge computing (MEC) could meet the needs of highly heterogeneous networks, creating a flexible, efficient power management system. Compared to existing approaches, EARAA is a novel blend of predictive traffic analysis with adaptable, real-time resource management, addressing an underexplored area in energy-efficient network design. This work provides a bridge between data-driven forecasting and active resource allocation, areas that have rarely been combined in prior studies. By delivering empirical evidence of power savings and network performance improvements, EARAA offers a promising framework for advancing sustainable, high-performance network solutions in the evolving field of wireless communications.

Table.1: Inclusion and Exclusion Criteria

Criteria	Inclusion	Exclusion
Study Focus	Energy efficiency, resource allocation	Topics outside wireless networking
Publication Type	Peer-reviewed journals, conference papers	Non-peer-reviewed articles
Content Quality	Quantitative analysis, experimental data	Lacks quantitative results or experimental data
Technological Scope	5G, IoT, AI-driven resource allocation	Focus on outdated technologies (e.g., 3G)
Language	English	Non-English
Metrics Reported	Power consumption, latency, throughput	Lacks data on energy or performance metrics

Soumya Roy and Gouranga Bag

Table.2: Key Parameters for Concept Development

Parameter	Description
Power Consumption	Measures network power use across varying loads (in Watts)
Energy Efficiency	Calculated as energy consumed per bit of data (Joules per bit)
Network Throughput	Assesses average data rate (in Mbps)
Latency	Measures packet delay across different load conditions (in ms)

Table.3: Power Consumption Under Different Traffic Loads

Network Technology	Low Load (W)	Medium Load (W)	High Load (W)
4G	1.3	2.9	5.2
5G	1	2.4	4.5
IoT Devices	0.5	1.3	2.2
Wi-Fi	1.2	2.7	5.3
NB-IoT	0.4	1	1.6

Table.4: Network Performance Metrics Comparison

Metric	Baseline Approach	EARAA Method
Power Consumption (W)	4.2	3
Energy Efficiency (J/bit)	3.5	2.1
Network Throughput (Mbps)	150	210
Latency (ms)	48	28

Table.5: Resource Allocation Strategies and Impact on Performance

Allocation Strategy	Energy Savings (%)	Latency Reduction (%)	Throughput Increase (%)
Dynamic Spectrum Management	25%	20%	18%
Energy Harvesting	30%	15%	10%
ML-based Resource Allocation	35%	25%	30%
Adaptive Modulation	28%	18%	25%
Power-Aware Routing	32%	22%	20%
EARAA	40%	30%	35%

ABSTRACT

Jyotish is one of the *Vedanga*. *Ayurved* is an ancient system of medicine of India. Roots of both sciences are connected to *Vedas*. *Ayurved* focuses on physical, mental, social, spiritual wellbeing of a person while *Jyotish* provides insights into planets and their effects on one's mind and body. *Jyotish* predicts the possible future outcomes regarding behaviour, mental and physical health status of individual. *Ayurved* believes in prevention of possible diseases and *Chikitsa* (treatment) of patients and besides this, *Jyotish* also provides solutions to improve mental and physical health status through various methods. Through this article, an approach has been made to understand how these sciences - *Jyotish* and *Ayurved* have many similarities between them, are interconnected and can be integrated to gain wellbeing of an individual.

Keywords: *Veda, Jyotish, Ayurved, Prakriti, Daivavyapashraya Chikitsa, Tithi*

INTRODUCTION

According to ancient Indian scholars, *Vedas* form the foundation of Indian culture and are closely connected with the Indian system of medicine. Four *Vedas* existed i.e. *Rigveda*, *Yajurveda*, *Samaveda* and *Atharvaveda*. [1] The word *Veda* is derived from the *Sanskrit* word 'Vid'. [2] Which means Knowledge. [3] *Vedas* are the sacred texts which contain recitation of hymns, performance of rituals, code of social conduct, chanting of songs, and are source of culture, beliefs and customs. *Vedas* have six *Anga*(parts) i.e. *Shiksha*, *Kalpa*, *Vyakarana*, *Nirukta*, *Chhanda* and *Jyotish*. [4] *Jyotish* is said to be the Eye of *Vedapurusha*. [5] Just like one cannot work properly without an eye, same way one cannot achieve

Bhumi Lad and Akshar Ashok Kulkarni

proper knowledge of *Veda* without *Jyotish*. *Jyotish* is an ancient science which is endowed with knowledge of movement and positions of *Graha*(Planets) and *Nakshatra*(Constellations).[6] In ancient times, *Jyotish Shastra* primarily served to calculate time, to predict eclipses, to determine auspicious moments for rituals, ceremonies, and offerings. However, in modern times, *Jyotish* has also proven to be valuable in medical area for early detection of possible diseases and treatment purposes. *Jyotish Shashtra* believes that the situation of planets affects the individual's mental status and also affects the physical health.[7]It also helps to predict the possible future outcomes and events in person's life. *Jyotish Shastra* offers the solutions which can be used as preventive measures and curative measures for wellbeing.[8] *Ayurved* represents the ancient Indian tradition of medical science.[9]It is believed to be *Upaveda* derived from the *Atharvaveda*,[10]thus tracing its origins back to the *Vedic* tradition. *Ayurved* is a science of life. *Ayurved* teaches a way to live prosperous life without ailments. *Ayurved* provides the social and behavioural conduct.[11]*Ayurved* also teaches to have desirable life, enough wealth to live comfortable life and to wish for salvation(healthy life without diseases).[12]The goal of *Ayurved* is to prevent potential illnesses and alleviate the suffering of individuals through treatment.[13]*Ayurved* emphasizes the importance of preventing future health issues by promptly identifying symptoms through careful observation of symptoms. Ancient Indian scholars advised treating diseases promptly to prevent their further spread. Therefore, both *Jyotish* and *Ayurved* prioritize the holistic well-being of individuals, encompassing both mental and physical health, and even spiritual wellness. These two disciplines share intertwined similarities. Objectives of this article are to explore intertwined aspects and the interrelation between *Jyotish* and *Ayurved*.

MATERIALS AND METHOD

Jyotish is sixth *Vedanga*. [14] *Jyotish* is mentioned in *Rigveda*, *Yajurveda* and *Atharvaveda*. [15]Some people say *Ayurved* is the fifth *Veda*. [16]It is *Upaveda* of *Atharvaveda*. *Jyotish* and *Ayurved* share numerous similarities, aiming to alleviate mental, physical, and spiritual distress in individuals. The word 'Jyotish' is mentioned In *Charaka Samhita Chakrapani Teeka*, *Ashtanga Samgraha* and *Ahstanga Hridaya*. In *Upakalpiniya Adhyaya*, *Sutrasthana* of *Charaka Samhita Acharya Chakrapani* referenced *Jyotish* regarding the timing for medication intake. [17]He advised that individuals undergoing for *Vamana* and *Virechana* procedures should seek blessings from *Brahmanas* at the appropriate *Nakshatra*, *Tithi*, *Karana*, *Muhurta* and take medicine for procedure. For those undergoing *Shodhana Kriya*, it is recommended to take medicine during auspicious *Nakshatra* such as *Pushya*, *Hasta*, *Jyeshtha*, *Rohini*, *Shravana*, *Ashvini* etc. It is advised against taking medicines during other *Nakshatras*. [18]In *Dutadivignaniya Adhyaya*, *Shareera Sthana* of *AshtangaSamgraha*, *Vaidyas* are advised to consider 108 favourable indicators while leaving their residence and entering a patient's home. Among them one of the factors is *Jyotish*. [19] In *Dinacharya Adhyaya SutraSthana* of *Ashtanga Hridaya*, same has been told to note the factors while going to visit the patient's home and *Jyotish* is one of them. [20]

Observations

- In *SutraSthana* of *CharakaSamhita*, glimpse of *Jyotish* is seen. The pursuit of *Ayurvedic* knowledge arose from the necessity to alleviate illnesses. [21] According to *Charaka Samhita*, *Acharya Bharadwaja* sought the wisdom of *Ayurved* from Lord *Indra* during a time of widespread ailments among the people. Thus, the acquisition of *Ayurvedic* knowledge was driven for the welfare of society. [22] Similarly, in *Jyotish*, knowledge was pursued for the betterment of people's well-being. [23]
- In *Jyotish*, the study revolves around *Graha* (planets) – *Nakshatra* (Constellations) and their movements. [24]*Jyotish* identifies nine *Graha*(planets). For instance, *Surya* (Sun) transitions towards the *Uttara Disha* (North direction) during *Uttarayana*. [25] Auspicious ceremonies are preferred during *Uttarayana*, while *Dakshinayana* is avoided for sacred activities. Likewise, in *Ayurved*, *Samskaras* are recommended mainly to be conducted during *Uttarayana*. *Charakaacharya* mentioned that universal *Vayu* maintains the movement of *Surya*, *Chandra* and *Nakshatra*. [26]
- *Acharya Charaka* gave three types of treatment in *SutraSthana* of *CharakaSamhita*. 1. *Daivaavyapashraya Chikitsa* 2. *SatvavajayaChikitsa* 3. *YuktivyapashrayaChikitsa*. In *DaivaavyapashrayaChikitsa*(treatment), they included *Mantra*(Incantations), *Aushadhi*(Talisman), *Mani*(Gems), *MangalBali*(Auspicious offering), *Upahara*(Gifts),

Bhumi Lad and Akshar Ashok Kulkarni

Homa(Oblations), Niyama(Observance of scriptural rules), Prayaschita(Atonement), Upavasa(Fasting), Japa(Prayer) etc. [27] In Jyotish, the solutions given are recitation of Hymns (MantraUccharan), Japa, Homa, Manidharana, Archana(prayers) of God.[28]

- In Vimana Sthana of Charaka Samhita, Acharya mentioned certain time and day for performing procedure. Jyotish has five Angas(parts) i.e. Tithi, Nakshatra, Vara, Karana and Yoga.[29] In Jyotish, Kala(time) is counted by these factors. In ancient time, Jyotish was used for obtaining information about Dina(day), Saptaha(week), Paksha(fortnight), Masa(month), Ayana (group of 3 seasons), Ritu(season), Samvatsara(year). An auspicious day or time is selected to perform certain sacred rituals and events with the help of Jyotish. Acharya Charaka mentioned specific Nakshatra, Tithi, Muhurta and Karana for Shishyopanayana Vidhi in Vimana Sthana.[30] Acharya Charaka mentioned in Vimana Sthana, that due to abnormality of Nakshatra, Graha (Planets), Chandra(moon), Surya(sun) etc Rutuvikara (seasonal abnormalities) are created means abnormal signs of seasons are seen.[31]
- Ayurved has a concept of Prakriti(constitution). Prakriti is decided at the time of birth. Prakriti indicates particular behaviour and habits of a person. Jyotish also indicates mental and physical status of a person based on the time of birth and day. It anticipates certain exploits depends on their birth charts. In Ayurved, Prakriti is explained by Acharyas. Sharirika and Manasika Prakriti are explained. Vata, Pitta and Kapha Prakriti and their combinations are SharirikaPrakriti.[32] In Jyotish, Graha(planets) also have their Prakriti(nature).Surya-PittaPrakriti, Chandra-VataKapha Prakriti, Mangala-Pitta Prakriti, Budha-KaphaVataPrakriti, Guru-KaphaPrakriti, Shukra-KaphaVataPrakriti, Shani-Vata Prakriti, RahuKetu-VataPrakriti.[33] Planets have their characteristics according to their nature just like persons have their behaviour and habits according to their Prakriti.
- Shareera Sthana of Charaka Samhita has mentioned specifically that Pushya Nakshatra should be selected for Pumshavanakarma.[34]Particular time is mentioned for entering of Sutikagara i.e. KalyanaKarana, Maitre Muhurta and sacred Nakshatra.[35] Namakarana Samskara is mentioned by Acharya Charaka in JatisutriyaAdhyaya. Acharya told to name the child by Its Nakshatrika Name (in which Nakshatra child is born, named accordingly).[36]Ayurved gave the Loka-Purusha Samya Siddhanta, which means whatever is in body, same exists in universe.[37]
- AcharyaSushruta explained that there are three Dosha in our body i.e. Vata, Pitta, Kapha. Similarly, the universe is run by Anila (Air), Surya (Sun) and Soma (Moon).[38] If these Dosha remain in normal state, then body works well but if they are imbalanced, they create disturbance in body. Similarly, in Jyotish if the Graha(planets) are in their Swagruha (own place), they appear normal but if they are in NichaSthana (Inferior state, not in normal position) they cause disturbance in individual's mental and physical state. Moon affects the mind of the person and behaviour.[39]
- Ayurved gave three mental faculty. i.e. Satva, Raja and Tama.[40] In Jyotish, Planets also have their Guna. Surya-Satvik, Chandra-Satvik, Mangala-Tamas, Budha-Rajas, Guru-Satvik, Shukra-Rajas, Shani-Tamas. [41]SatvaGuna is Superior in virtue. Raja is needed to run body and universe and Tamas is believed to be inferior in virtue.
- In IndriyaSthana of CharakaSamhita, Jyotish is mentioned. If a person sees destruction of Surya, Chandra and Nakshatra in his dream, it is said to be inauspicious.[42]
- In ChikitsaSthana, AcharyaCharaka mentioned the person to enter the Kutifor the KutipravesikaRasayana procedure in UttarayanaKala, ShuklaPaksha and ideal Tithi, Nakshatra, Muhurta and Karana.[43]Acharyas told to collect the medicine in best Muhurtaafter praying to God and well wishes from the Brahmanas.[44] AcharyaCharaka told to have Amalaki fruits in ShuklaPurnimaTithi of Posha orMagha or Falguna month after chanting of GayatriMantra for one year. PurnimaTithi is auspicious and believed best for work to be done.[45]
- In SiddhiSthana of CharakaSamhita, Acharya told to give AsthapanaBasti in auspicious day and Nakshatra. AcharyaHarita said to treat the disease in KrishnaPaksha because strength of disease is increased in that time. And its best time to eliminate the diseases.[46]AcharyaCharaka told to triturate the drug in PushyaNakshatra because it enhances the attributes of drug.
- In KashyapaSamhita, Acharya told to do MarutiIshti (Oblation) if there abnormal teeth in child.[47] There also AcharyaKashyapa said that pupil should not study during full moon, new moon and Ashtami.[48]
- AcharyaSushruta gave a concept of ShatakriyaKala (Six stages of disease manifestation). So, we can understand from the earlier stages how symptoms will be shown in future if left untreated.[49] In JyotishShashtra, from the positions of planets, future outcomes can be predicted.

Bhumi Lad and Akshar Ashok Kulkarni

- In *AshtangaHridaya*, Acharya Vagbhata told to wake up early in *BrahmaMuhurta* daily.[50] Acharya Vagbhata mentioned *Daivavyapashraya Chikitsa* in *JvaraChikitsa* chapter, treatment mentioned in *Atharva Veda*. [51]
- Acharya Sushruta mentioned to bath a child influenced by *Skandagraha* disease with water chanted with *GayatriMantra*. [52] Offering should be done on *Shashthi Tithi* for the child who is suffering from *Naigameshagraha*. [53]

DISCUSSION

Both disciplines of *Ayurved* and *Jyotish* have aim to treat the issue regarding health and take necessary measures to prevent the possible future illness. *Ayurved* also told that to gain a proper and deep understanding of the concept, one must study other books too. Both *Jyotish* and *Ayurved* have similar concepts on *Prakriti*, *Sharirika* and *Manasika Dosha* and *Guna*, similarities between the body and the universe (*Loka-Purush Samya Siddhanta*). *Jyotish* provides solutions in form of prayers, *Mantra* recitations, wearing gems, offerings gifts to gods, *Homa*, fasting, riddance of anger-greed-jealousy, which are also called *Daivavyapashraya Chikitsa* in *Ayurved*, one of the *Chikitsa* mentioned by Acharya Charaka. In fact, Acharya Charaka mentioned *Daivavyapashraya Chikitsa* first. In *Varnasvariya Adhyaya* in *Charaka Samhita* *Indriya Sthana*, Chakrapani mentioned about *Samudrika Shahstra* that is *Jyotish*. [54] Acharya Sushruta told about organs and their *Devta* (God). From that we can understand that the effects of *Graha* occurs on mind and organs, and by taking preventive and curative steps, the health and psychological issues can be prevented. [55] Both sciences understand the importance of *Kala* (time). In *Jyotish*, the *Nakshatra*, *Graha*, *Tithi* moves at a particular time and they have their specific effects on person's body and mind. Solutions are also given to perform at specific time, too. Same way *Ayurved* also have the concept of *Shatakriya Kala*, which shows the significance of time. Time is precious in medical field for physician forearly diagnosis and early treatment in which if the physician does not diagnose the disease earlier by symptoms, then it will be difficult to treat it on later stages. [56]

Some medicines mentioned to give on early stages of diseases and some to be given after some time. Concept of *Ausadha Kala* is there i.e. medicines are given to different times according to the need of diseases. [57] In today's modern era, everyone asks for proof before believing in the concept. The scepticism faced by both *Jyotish* and *Ayurved* in today's time. There are challenges of integrating these ancient practices with today's contemporary medical science. There are so many potentials areas for further research and exploration in the integration of both *Ayurved* and *Jyotish* like in today's fast era, everyone wants the speedy result but these both science requires time and patience. The persons in dire need in search of relief come and agree to these sciences. There also research done in field of *Ayurved* to identify the possible causative factors of *Vandhyatva*. [58] The physician believed to be *Yuktigna* (intelligent enough to plan the treatment in less time with less medicines and solutions), using that he can plan a treatment combined of these both sciences to treat a disease for fast recovery. *Ayurved* has *Satvavajaya Chikitsa* which means having control on mind to not indulge in unnecessary and harmful factors or things. Peace of mind can be gained by following *Ashtanga Yoga* i.e. *Yama*, *Niyama*, *Asana* etc which is on spiritual level. *Jyotish* also believes in *Mantra* chanting and doing prayers to god which are spiritual. Considerations should be made to combine both spiritual or astrological guidance with medical advice.

CONCLUSION

Jyotish and *Ayurved* both believe in spirituality. *Ayurved* has *Daiva Vyapashraya Chikitsa* for the *Karmaja Vikara* and *Jyotish* also gives solutions similar to that. The integration of *Jyotish* and *Ayurved* offers a framework for enhancing health. Early diagnosis and early treatment can be achieved by combining both sciences. Through insights and practical, one can achieve a more balanced state of physical, mental wellbeing and spiritual level. Synergy between two ancient sciences underscores the holistic philosophy that true wellness arises from harmony between the cosmos and the individual. This shows how astrological principles can enhance *Ayurved* practices, offering a unique perspective.

ABSTRACT

Plectranthus barbatus Andrews contains several bioactive components, making it a chemically diversified plant that is a treasure trove for obtaining terpenes and other phytochemicals. The chief phytochemicals obtained from *P. barbatus* are labdane diterpenes, followed by phenolic compounds, Essential Oils (EOs), tannins, flavonoids, and saponins. Owing to its vast phytochemical diversity, *P. barbatus* is used for several herbal preparations. The major products are the forskolin containing weight loss capsules and powders of its roots. Therefore, the plant is widely used in several organic anti-obesity product preparations. A reliable identification marker is needed to combat intentional and accidental adulteration in the industries. The highly conserved quadripartite plastome is a promising tool for DNA barcoding, but the conventional markers such as *rbcL* and *matK* are not 100% accurate for all the lineages. This review aims to compile various phytochemicals isolated from this plant, to highlight the need to develop advanced plastome molecular markers for barcoding of *P. barbatus* Andrews, and to stimulate the use of a novel approach that is complemented with DNA barcoding, i.e. the use of non-invasive biophoton emission signature for its ability to check the adulteration in its herbal products.

Keywords: Anti-obesity, Barcoding, Biophoton, Phytochemistry, Plastome, *Plectranthus barbatus*

INTRODUCTION

Housing more than 7000 species, Lamiaceae is the largest of 26 families of Lamiales and the 6th biggest family of angiosperms in terms of species number [1]. *Plectranthus* L'Hér., also known as the genus of 'spurflower plants', is a multifaceted complex genus of Lamiaceae, which includes widely used horticultural and medicinal plants. *Plectranthus* belongs to Tribe Ocimeae, Subtribe Plectranthinae, and includes about 300 plant species distributed over East and Central Africa (>200 species), Arabian Peninsula, Indian Subcontinent to SC China (>22 species) and Australia (>40 species) [2]. It also grows in some parts of Brazil, Pakistan, and Sri Lanka [3]. One such pharmaceutically vital member of this genus is *Plectranthus barbatus* Andrews, which is commonly referred to as 'Dala Garmar' in Gujarati, 'Pattharchur' in Hindi, 'Maimnul' in Marathi, and also several botanical synonyms such as *Plectranthus forskohlii* Briq., *Coleus forskohlii* auct., *Coleus barbatus* (Andr.) Benth. [4]. Taxonomically, the "*Plectranthus*–*Coleus* complex" has long been a subject of debate among botanists. At present, the genera *Plectranthus* and *Coleus* are combined by Japanese botanists into the single genus *Plectranthus* [5], which is also supported by a molecular study carried out by Paton and colleagues in 2018 [6]. *Plectranthus barbatus* Andrews is a perennial herb, scattered across the tropical and sub-tropical zones of the Indian subcontinent and is cultivated commercially by local farmers of Gujarat for its roots ('Garmar' in Gujarati) which are traditionally used in preparation of pickles [7]. In Gujarat, it is cultivated mainly in the Saurashtra regions of Veraval, Khambhadiya, and Madhapar [7]. *P. barbatus* Andrews is a commonly used therapeutic plant species in India (both Ethno and Ayurvedic treatments), East and Central Africa, Federative Republic of Brazil, and the People's Republic of China. It is used to treat various ailments like dysentery [8], Nausea [9], liver fatigue, general respiratory ailments [10], cardiac disorders [11], ringworms and certain brain disorders like epileptic fits (Seizures which causes body to jerk and shake) [12]. The ancient Indian medicinal text book 'Ayurveda' describes the use of a plant named "Pashanabhedhi" and "Balakah" (Sanskrit names), as a remedy to treat various ailments like cardiovascular disorders, pulmonary, kidney, and certain neurological diseases. In the latter years, one of several plants linked to the above-mentioned plant was *Coleus amboinicus* Lour [3]. As a result, *Coleus amboinicus* Lour and its taxonomic relatives were included in the studies for the exploration of novel pharmacologically active compounds. Among such taxonomic relatives was *Coleus forskohlii* Briq., presently known as *Plectranthus barbatus* Andrews [3].

The root extract of *P. barbatus* Andrews in methanol exhibited hypotensive activity [3]. In the latter years, chromatography studies on silica gel of methanolic extract of this plant led to the discovery of numerous labdane diterpenes as major active phytochemicals including the main constituent Forskolin (formerly known as 'Coleonol') and a more recently characterized abietane diterpene i.e., Plectrabarbene [13]. Originally named 'coleonol', Forskolin was discovered by Forskal (1774), a Finnish botanist. Since then, as other diterpenoids and iso-coleonols have been isolated, the compound is now renamed as 'forskolin', after its discoverer Forskal [14]. The main pharmacological activities of *P. barbatus* Andrews are attributed to a single compound, the diterpene 'Forskolin'. It is the primary component of the roots, which is known to activate the enzyme class of Adenylate Cyclases (ACs), which converts ATP to cyclic AMP (cAMP), a secondary messenger in the G-Protein Coupled Receptor (GPCR) signaling pathway [10]. Forskolin-induced cAMP is known to stimulate lipolysis, which has been experimentally concluded in the case of Obese Men [15] and mildly overweight women [16]. However, some experimental evidence suggests that additional phytochemicals, such as volatile oils and other diterpenoids of the roots, may influence the absorption and activity of forskolin [17]. This review aims to highlight the phytochemical importance of this plant, especially the anti-obesity compound Forskolin, and to stimulate research for finding novel plastome barcodes for its authentic identification and industrial exploration.

PHYTOCHEMISTRY OF PLECTRANTHUS BARBATUS

Phytochemical studies have targeted to discover novel compounds with potential pharmaceutical applications. A total of 109 compounds found in various parts of *P. barbatus* Andrews, categorized into 7 groups and 6 major classes, are listed in Table 1 [3,5,13,19-55]. The primary components are the 69 Diterpenoids, 25 Phenolic compounds, 12 Major EOs, tannins, flavonoids, and saponins. The 69 diterpenoids have been sub-classified into 5 groups: Abietane diterpenoids (26); 8,13-Epoxy labd-14-en-11-one diterpenoids (27); 8,13-Epoxy labd-14-en-11-one diterpene

Mohitgiri A. Goswami *et al.*,

glycosides(5);8,13-Epoxy-labd-diterpenoids with some deviations(6) and miscellaneous labdane diterpenoids(see Table 1). Terpenes aid in protecting the plant against biotic and abiotic stresses and attracting pollinators [18]. From **Table 1** we can infer that almost all the phytochemicals of *P. barbatus* Andrews growing in India are obtained from its roots. Whereas, in Brazil, most diterpenoids were isolated from the leaves and stems, and from the leaves East Africa (Kenya). Phytochemicals are abundant in leaves, roots, and whole plant extracts from China. In Italy, a total of 128 EOs have been identified through GC-MS analysis of different plant parts, out of which 12 EOs that make up 98.68% (quantitatively) of the total 128 EOs are listed in Table 1 [19]. The whole plant extract of *P. barbatus* in Italy is rich in essential oils with the highest proportion in roots, followed by leaves and stem [19]. Tannins, Saponins, and Flavonoids have been identified in the leaves from Nyamira County, Kenya (see Table 1) [20]. Therapeutic actions of medicinal plants are determined mainly by their secondary metabolites. The 22-carbon lipolytic plantditerpene forskolin stimulates all isoforms of mammalian adenylate cyclases (ACs) except the membrane-bound $G\alpha_s$ -activated enzyme AC9[56].As summarized in **Table 2**, several clinical trials (8-12 weeks long for humans and 16 weeks long for mice) have been conducted in the past to check the efficacy of *P. barbatus* root extracts in reducing weight [15, 16, 57-61]. None of the studies reported any major side effects, but several participants reported mild diarrhoea which was not considered as clinically significant [57]. The Crypts of Lieberkühn cells near the base of intestinal villi, secrete ions (Na^+ , K^+ and Cl^-) in the intestine, through their series of transporter channels.

It is an intrinsic mechanism of our body to generate an osmotic potential gradient across the epithelium that leads to the endosmosis of H_2O into the small intestine; and in turn, maintain its physiological functioning [57]. Cystic Fibrosis Trans membrane Conductance Regulator (CFTR) channel of ABC (ATP-binding cassette) super family of transporters is located at the luminal face of the crypt epithelium and consists of 5 domains out of which 2 are trans membrane protein domains that functions as a cAMP-dependent Cl^- channel [62, 63].This channel is commonly found at 2 major sites, epithelial membrane lining the lumen of digestive system, and the respiratory system i.e. Tracheo-bronchial tree. When the plantis consumed, forskolin increases intra-cellular concentrations of cAMP within the crypt cells and activates the CFTR channel that transports Cl^- anions across the epithelium, into the digestive lumen. The formation of $NaCl$ salt in the small intestine, created as a collective result of the charge-concentration gradient generated by the accumulation of Cl^- anions in the crypt and its stimulation of the passive diffusion of positively charged Na^+ ions into the lumen, presumably across the Occluding junctions/Tight Junctions[57].When $NaCl$ is secreted into the crypt, the lumen experiences a negative osmotic gradient, which results in endosmosis of H_2O into the digestive lumen. Theoretically, this could result in soft stool and diarrhea observed during the clinical trials[57]. Most of the clinical trials are of very short duration (56 to 84 days long). Further trials are needed to find out the long-term effects of forskolin consumption in humans and to establish the root as a safe and effective weight loss and other personalized supplements and medicines. For compounds other than Forskolin, no clinical trials could be identified for the plant.

Hydrolysable Tannins (HTs), with a carbohydrate core, are plant polyphenols commonly found in a wide range of plants, including the leaves of *P. barbatus*. They are composed of a central core of carbohydrates (typically Dextrorotatory(D)-glucose) that is esterified with phenols, like Gallic acid (GA) and Ellagic acid (EA). HTs have been shown to have antioxidant activities on copper and iron-mediated formation of free-radicals [64, 65], as well as inhibitory effects on gastric Proton- K^+ -ATPase pump[66]. This suggests that the leaf extract of *P. barbatus* can be used for potential Treatment of Diarrhoea. However, their effects on CFTR Cl^- channels of the digestive tract have remained unknown so far [67].So, the Forskolin of the root and HTs of the leaf of *P. barbatus* are antagonistic in their function. Thus, a combination of root and leaf extract of *P. barbatus* Andrews can be administered to mitigate the mild diarrhea experienced during the clinical trials of forskolin, while maintaining its lipolytic efficacy. Recent studies show that roots are also abundant in phenolic compounds, the chief constituent being flavonoids. Rosmarinic acid was the dominant phenolic compound in almost all ethanolic root extracts but it is not so in water extract [54]. Rosmarinic acid incorporated intonutritional dietary supplements or other drugs can be used to treat digestive ailments. Water extracts of *P. barbatus* root were found to exhibit the lowest antioxidant capacity as compared to 40%, 60%, and 80% ethanolic extracts[54]. Kulbat-Warycha and colleagues (2022) reported that the 80% ethanol solution was the most efficient solvent for flavonoid extraction, whereas 40% and 60% ethanolic extracts are most suitable for

Mohitgiri A. Goswami *et al.*,

the isolation of the total polyphenol pool from its roots [54]. Phenols from the plant roots such as EA and GA, can inhibit seed germination, plant development, and fungal growth [68, 55]. Thus, phenolic compounds may serve as a defence mechanism for the plant against soil fungal parasites and other growth competitors. A fascinating question arises from the above observations that is why does *P. barbatus* produce forskolin? One theory suggests that the purpose is protection against soil pathogens as it is highly susceptible to root rot/wilt infection by numerous strains of pathogenic fungi, the major one being *Fusarium chlamydosporum* [69]. The fact that a large number of pathogens use the same basic strategy for infection by escalating cAMP levels in host cells to manipulate the cell environment, increase virulence gene expression, and manipulate host immunity [70] suggests that cAMP manipulation is crucial for pathogenicity. Forskolin is believed to be the tit-for-tat counterattack against the pathogens by the plant. This statement is based on the fact that forskolin is produced and stored only in the specialized oil bodies present in the periphery of the root i.e., the cork cells [71]; its nature to activate ACs; as well as some AC independent functions like inhibition of GLUT (Glucose transporters), competitive inhibitory of effects of the myco-metabolite 'Cytochalasin B' [72]. The oil bodies in the cork cells are the first cells that come in contact with any pathogen/mycelium. The oil containing forskolin might be working like a 'trojan horse' that when absorbed by the pathogen for nutrition, wreaks havoc at the cAMP levels and its related responses of the pathogen from within its own cells. This suggests that *P. barbatus* produces forskolin as a line of defence against root pathogens. However, every rose has its thorns, forskolin is not effective against all pathogens. Fungal pathogens like *Ustilago maydis* without cAMP and its effect or enzyme Protein Kinase A (PKA) show constitutive filamentous growth, which is reversed by exogenous cAMP exposure or gain-of-function mutation in the regulatory subunit of PKA [73].

On the contrary, in *Magnaporthe grisea*, intracellular cAMP levels regulate the recognition of the plant surface and stimulate pathogenic developments. Moreover, the addition of cAMP analogs like 8-bromo cAMP and N6-monobutyryl cAMP to vegetative hyphae and conidia possibly retarded vegetative growth and as a result, induced appressorium formation [74]. Increased cAMP can be helpful against *U. maydis* but could produce higher infection of *M. grisea*. The reason why *P. barbatus* suffers significant root damage by *Fusarium chlamydosporum* is possibly because increased cAMP levels due to forskolin might aid in its pathogeny-related developments. Extensive research is required to determine the effects of forskolin on different pathogens, thus opening the possibility of using Forskolin as an anti-fungal, anti-microbial agent against all plant and human pathogens that cannot survive/develop in high cAMP environments. *Plectranthus barbatus* Andrews is widely used in the industries for the preparation of several herbal products. The major herbal products are the forskolin-rich weight-loss capsules and powder prepared from its roots. On account of its diverse medicinal applications, and to ensure the best quality of its supply, especially in the times of rampant adulteration and substitution in the markets of India, there is a dire need for personalized identification strategies for *P. barbatus*. Srivastava *et al.* (2002) reported that the Forskolin content of *P. barbatus* from south India (Andhra Pradesh) is higher than that of North India (Uttar Pradesh) [75]. On the other hand, protein content was higher in Uttar Pradesh counterparts compared to South India. Tannin content didn't show much variation in both regions, however, starch content correlated with forskolin concentration in the root powder [75]. It is evident from the above report that the biochemical profile is highly dynamic, it changes with the geographical region in which the plant develops and can give misleading results during specimen identification. Therefore, the situation presses for the development of efficient plastome DNA markers for this plant. Linking biochemical and plastome variation data in *P. barbatus* from different geographical regions can help in screening the plants with higher forskolin content while simultaneously exposing adulteration.

AUTHENTICATION AND BARCODING OF *PLECTRANTHUS BARBATUS*

Despite almost 270 years of taxonomic efforts since Carolus Linnaeus coined the term "Taxonomy", the characterization and precise cognition of plant species remains a substantial challenge to this day. The endosymbiotic genesis of chloroplast and mitochondria is now universally accepted, owing to genomic similarity evidence that is stronger than ever. Studies by Falcón *et al.* (2010) linked 16S rRNA and *rbcL* genes (ribulose 1,5-bisphosphate carboxylase/oxygenase) which suggests that chloroplast resulted from endosymbiosis of a nitrogen-fixing unicellular cyanobacteria [76]. Four decades ago, we viewed the evolution of mitochondria and chloroplast like two sides of the same coin. However, recent pieces of evidence argue that the host cell that incorporated the α-

Mohitgiri A. Goswami *et al.*,

proteobacteria was prokaryotic and not a eukaryotic cell[77]. This raises the possibility that endosymbiosis might've been crucial for eukaryogenesis. This points towards the highly malleable nature of organelle genomics. Even though the origin of chloroplast is still a point of debate, the credibility of plastome for specimen identification and phylogenetic analysis is well established among evolutionary biologists. Thus, the plastome is widely used in DNA barcoding and phylogenetic studies of plants. Adulteration can be unintentional due to a lack of skilled taxonomists for accurate identification, phenotypic plasticity due to changing environmental conditions, or intentional adulteration to maximize profits. Since *Plectranthus barbatus* Andrews is an economically important plant, owing to its huge arsenal of secondary metabolites as shown in Table 1, plastome comparative studies along with barcoding will prove to be very useful for its precise recognition and exposing adulteration in its commercially available products. "DNA barcoding" is a 21-year-old term coined by Prof. Paul David Neil Hebert, a Canadian biologist in 2003. It is defined as a technique for recognizing organisms by using single/multiple DNA sequence(s) from specific regions of nuclear genome, chloroplast genome (plastome) or mitochondrial genome (MG) termed "DNA barcodes", to make taxonomic studies swifter and more accurate, enhance adulteration analyses, and to get better resolved phylogenetic trees. While for most fauna, the accepted barcode sequence is the Cytochrome Oxidase complex (complex IV of ETC) gene of the MG, it is a ubiquitous and relatively precise system for animal DNA barcoding. Since the efficiency of individual DNA barcodes varies widely throughout taxa, there are very few comprehensive single DNA barcodes for plants to this day. The British botanist Peter M. Hollingsworth and colleagues from "Plant Working Group" of Consortium for the Barcode of Life (CBOL) initiative compared performance of 7 genes of plastome from 550 species and proposed a combination of portions of two coding regions from the plastome as core barcodes for plants—*rbcL* + *matK*[78], to be augmented with additional family/genus specific genes like *ndhF*, *rpl16*, *psbA*, *clpP*, as well as other regions of DNA such as Inverted Repeat (IR) region as required. The International community of CBOL accepted their recommendation, but with an additional clause that development of new barcode markers should be carried out to expand the existing knowledge of plastome barcoding[79].

As summarized in Table 3, it is clear that the traditional barcode genes are not equally competent across the plant kingdom and concatenated protein-coding gene sequences from plastomes show higher resolution than unaided single-locus barcode genes. It is evident that combination of multiple barcodes provides a better discriminatory power, but in some cases the efficiency of multiple-locus barcode is lower than single locus genes as shown by de Vere [84]. Therefore, instead of single or multiple genes, several researchers supported the use of the whole plastome as a 'Super Barcode'[86-91]. Single-locus barcodes lack adequate variations while the whole plastome super-barcode currently can be resource intensive. Some other issues with super barcodes that need to be solved, i.e., intraspecific sampling remains inconsistent, and discrimination is not rapid and may be too complicated for laboratories that lack the necessary knowledge and experience. There must be a 'golden mean' which can concurrently solve the limitations of both traditional barcoding and super-barcoding. To work out this current challenge, the authors support the concept of using specific 'Pro-barcode' which involve the use of all the protein-coding genes together (Concatenated protein-coding sequences) as a barcode, since any organism is ultimately the resultant of its expressed proteins. Pro-barcode refers to an intermediate of single-locus and super-barcode. Pro-barcode is of apposite length so as not to compromise between variability, efficacy, and plausibility. Pro-barcode can be used to improve the resolution of phylogenetic trees, including the *Plectranthus barbatus* Andrews housing family Lamiaceae. Rapid evolutionary radiations could account for the higher degree of diversity in different lineages as they are ubiquitous across all forms of life. Besides barcoding, plastomes can also be used to gain more insights into the evolution, speciation, and adaptation of a lineage using recent radiations as models. A phylogenetic tree for different plant lineages that is accurate and well-resolved is needed to understand the complete history of plants. However, determining phylogenetic relationships by considering recent radiations has been difficult because no traditional phylogenetic DNA markers are able to provide enough information and clarity for all lineages. Because of low mutation rates, high copy number, and uniparental inheritance, plastome DNA could significantly improve the resolution of phylogenetic trees in plant groups resulting from recent radiations as shown in 23 species of the *Rhodiola* genus, a recent rapidly diverging group of Crassulaceae family on the Qinghai-Tibetan Plateau [92]. Since no individual barcode can resolve all lineages, Pro – barcodes could be the answer to further refine the phylogenetic trees and possibly differentiate between recently diverged closely related species as reported by Jiang *et al* for 3

Mohitgiri A. Goswami *et al.*,

cultivated varieties of *Scutellaria baicalensis* Georgi [93] and also by Bhatt and Thaker for 82 species of Poaceae Grasses from Kutch desert, Gujarat [80]. The plastome of *P. barbatus* from Portugal is 157,467 bp long and has 133 genes, including 87 CDS sequences [94]. Since *P. barbatus* Andrews can be easily adulterated by *P. neochilus* Schltr and *P. grandis* (Cramer) R. Willemse [95] because of similarity in leaf morphology, it is necessary to develop barcodes for accurate authentication of the former plant. Several phylogenetic and barcoding analyses of *P. barbatus* plastome have been performed using whole chloroplast genome [96-97], *rbcL* and *matK* [98], *rps16*, *trnL-F* and *trnS-G* [6]. However, no comparative barcoding studies of Indian *P. barbatus* with other Lamiaceae plants using the Pro-barcode have been reported so far.

A STEP BEYOND BARCODING

A different aspect that also needs to be addressed is the adulteration in herbal products beyond the species/variety level. Ayurveda, a text on conventional Hindu medicine, states that for a plant's optimal therapeutic efficiency, specific plant tissues should be harvested at particular times of the year [99]. If the tissue of the same plant is harvested at the wrong time of the year (generally earlier than usual to maximize profits), its potency will not be up to the mark, and DNA barcoding will fail to catch this type of adulteration, responsible for compromising the quality standard of the herbal product. Therefore, DNA barcoding needs to be complemented with other tools and techniques so that it can be more accurately adopted for quality control purposes of Ayurvedic and other herbal products on the market [100]. Such a technique should be able to identify the metabolomic profile of the sample in real-time and preferably in a non-invasive manner. One such technique is to study the Biophoton or Ultra-weak Photon Emission.

BIOPHOTON: POTENTIAL DARK HORSE OF SPECIMEN IDENTIFICATION

Plastome barcoding for effective identification of adulteration in industries is just one-half of a two-part problem. The other half of the problem is the effective selection of plant parts in a specific physiological phase for maximum yield of desired phytochemicals, as the phytochemical profile of any plant is time-dependent and highly dynamic with different developmental stages of the plant, and the time of the year when the plant is studied. This part of the problem cannot be solved with barcoding and phytochemical testing of every batch can be uneconomical. Therefore, for the selection of perfectly suitable plant material, there should be a relatively simple, rapid, and cost-effective technique to predict the potency of plant material. One option is to perform the Biophoton emission analysis of the sample. Many metabolically active biological systems e.g., algae, fungi, plants, animals, and several microorganisms, show ultra-weak photons emission in the visible wavelength spectrum (380 to 700 nm), even after being devoid of light for many hours [101] and these emitted photons are termed as 'Biophotons' (Bio- γ). The Bio- γ radiating due to intrinsic metabolism of an organism are termed as 'Spontaneous emission'. Besides this, a different type of luminescence is observed when the sample is subjected to an external light source, termed 'Delayed Luminescence' (DL). It is different from bioluminescence as the source of these Bio- γ is believed to be various enzymatic activities of the cells, respiratory chain in mitochondria, or the generation of various Reactive Oxygen Species (ROS) during metabolic activities of the cells [102]. DL is measured between the 2 – 200 second gap after the sample has been subjected to external light (background illumination). These Bio- γ are detected using PIAS Hamamatsu (Photo Image Acquisition System, Hamamatsu, Japan). DL is generally represented as a time-dependent 'Ln(Counts/Sec)' graph of negative slope. The delayed Bio- γ emission count differs for every species and it is also dynamic with the physiological phases (age) of plants belonging to the same species [101]. The Bio- γ emission count patterns for different parts of *Plectranthus barbatus* Andrews have not yet been standardized. The Bio- γ emission signature of *P. barbatus* Andrews can be used to non-invasively predict the physiological maturity stage of the plant material for cost-effective screening of the material that is rich in phytochemicals of interest, which will ultimately result in more potent herbal products.

Mohitgiri A. Goswami *et al.*,

CONCLUSIONS

Plectranthus barbatus Andrews is a phytochemical-rich plant that is widely used in the industry for the preparation of various weight loss products, owing to the diterpene forskolin present in its roots. Other terpenes, phenolic compounds, tannins, and EOs make this plant industrially very important and prone to adulteration. In this review, we highlight the need of comparative analysis and plastome DNA barcoding study to provide a reliable way for quality control and removal of other morphologically similar plants, which will ultimately help to control all types of adulteration. Besides quality control, the Bio- γ DL signature analysis can also aid in rapid and hassle-free identification of the physiological maturity stage of the desired plant material. In the future, we hope to see a synchronized unification of Plastome DNA barcoding and Bio- γ analysis, which will help in the production of more potent herbal products with a higher amount of the desired phytochemicals from *P. barbatus* Andrews and several other Lamiaceae plants.

Table 1. Various Phytochemicals found in *P barbatus* Andrews. *WP – Whole Plant

Sr. No.	Plant Part	Name of Compound	Geographical Location of <i>P. barbatus</i>	References
Chemical Class 1: Abietane diterpenoids				
1	Leaf	(+)-Allylroyleanone (Plectranthone J)	East Africa – Kenya	[21]
2	Leaf	Coleon S	China	[22,5]
3	Leaf	Coleon O	East Africa - Kenya	[23]
4	Leaf	Coleon T	China	[22,5]
5	Leaf	Plectrin	East Africa - Kenya	[21, 23]
6	Leaf	Barbatusin	Brazil	[24, 25]
7	Leaf	3 β -Hydroxy-3-deoxybarbatusin	Brazil	[24]
8	Leaf	Cyclobutatusin	Brazil	[24, 26]
9	Leaf	7 β -Acetyl-12-deacetoxycyclobutatusin	Brazil	[25]

Mohitgiri A. Goswami et al.,

10	Leaf	(16R)-Coleon E	East Africa - Kenya	[21, 25]
11	Leaf	Coleon F	East Africa - Kenya	[21]
12	Leaf	(16R)-Plectrinon A	Brazil, East Africa - Kenya	[21]
13	Leaf	Plectrinon B	East Africa - Kenya	[21]
14	Root	14-Deoxycoleon U	China	[28]
15	WP	Coleon C	China	[29, 5]
16	Stem	6,7-Secoabietane diterpene I	Brazil	[30]
17	Stem	6,7-Secoabietane diterpene II	Brazil	[30]
18	Stem	Cariocal	Brazil	[31]
19	Root	Abietatriene (dehydroabietane)	India	[32]
20	Root	Demethylcryptojaponol (11-hydroxysugiol)	China	[28]
21	Stem	Ferruginol	Brazil	[33]
22	WP	Sugiol	China	[5]
23	Stem	20-Deoxocarnosol	Brazil	[34]
24	Stem	6 β -Hydroxycarnosol	Brazil	[35]
25	Stem	Barbatusol	Brazil	[33]
26	Stem, Leaf	Plectrabarbene	Saudi Arabia	[13]
Chemical Class 2: 8,13-Epoxyabd-14-en-11-one-diterpenoids				
27	Root	Forskolin	India, China	[3]
28	Root	9-Deoxyforskolin	India	[3]
29	Root	1,9-Dideoxyforskolin	India	[3]
30	Root	1,9 Dideoxy-7-deacetylforskolin	India	[3]
31	Root	Deacetyl-1-deoxyforskolin	India	[36]
32	WP	6-Acetyl-1-deoxyforskolin	China	[37]
33	WP	6-Acetyl-1,9-dideoxyforskolin	China	[37]
34	Root, WP	Forskolin A	China	[38]
35	Root, WP	Forskolin B	China	[38]
36	WP	Forskolin C	India, China	[38, 39, 48]
37	Root	1,9-Dideoxycoleonol B	India	[40]
38	Root, WP	Forskolin D	India, China	[38]

Table 1. cont.

39	Root, WP	Forskolin E	China	[38]
40	Root, WP	Forskolin F	India, China	[38]
41	Root, WP	Forskolin G	China	[41, 42]
42	Root, WP	Forskolin H	China	[42]
43	Root, WP	Forskolin I	China	[42, 43]
44	Root	Forskolin J	China	[43]
45	Root, WP	Forskolin K	China	[5]

Mohitgiri A. Goswami et al.,

46	Root	Forskolin L	India, China	[36]
47	Root	Coleosol	India	[44, 45]
48	Root	1-Acetoxy coleosol	India	[40]
49	Root	Coleol	India	[46, 5]
50	Root	11-Oxomanoyloxide (8,13-epoxy-labd-14-en-11-one)	India	[5]
51	Root	Coleonol E	India	[47, 5]
52	Root	Coleonol F	India	[47, 5]
53	Root	Deoxycoleonol	India	[39, 48, 5]
Chemical Class 3: 8,13-Epoxy-labd-diterpenoids with some deviations				
54	WP	3-Hydroxyforskolin	China	[49, 5]
55	WP	3-Hydroxyisoforskolin	China	[49, 5]
56	Root	13-Epi-9-deoxycoleonol	India	[50]
57	Root	Coleonol C	India	[39, 48, 5]
58	Root	Coleonone (8,13-epoxy-labd-14-en-12-one)	India	[46, 5]
59	Root	Manoyl oxide (8,13-epoxy-labd-14-ene)	India	[5]
Chemical Class 4: 8,13-Epoxy-labd-14-en-11-one-diterpene glycosides				
60	WP	Forskoditerpenoside A	China	[51]
61	WP	Forskoditerpenoside B	China	[51]
62	WP	Forskoditerpenoside C	China	[52]
63	WP	Forskoditerpenoside D	China	[52]
64	WP	Forskoditerpenoside E	China	[52]
Miscellaneous labdane diterpenoids				
65	Root	13-Epi-sclareol	India	[53]
66	WP	Forskoditerpene A	China	[52]
67	WP	12-Hydroxy-8,13E-labdadien-15-oic acid	China	[37]
68	WP	Coleolic acid (11-ol,13-Me,8(9),13(14)Z-labdadien-15-oic acid)	China	[5]
69	WP	Coleonic acid (11-one,13-Me,8(9),13(14)Z-labdadien-15-oic acid)	China	[5]
Chemical Class 5: Phenolic Compounds				
70	Root	Quinic Acid	Poland	[54]
71	Root	Protocatechuic Acid	Poland	
72	Root	4-Hydroxybenzoic acid	Poland	
73	Root	Protocatechuic aldehyde	Poland	

Table 1. cont.

74	Root	Gentisic acid	Poland	[54]
75	Root	4-Hydroxybenzoic acid O-hexoside	Poland	
76	Root	Vanillic acid	Poland	
77	Root	Hydroxygallic acid	Poland	
78	Root	Syringic acid	Poland	
79	Root	p-Coumaric acid	Poland	
80	Root	Ferulic acid	Poland	
81	Root	2-Hydroxybenzoic acid	Poland	
82	Root	Ellagic acid	Poland	
83	Root	Caffeic Acid	Poland	
84	Root	Rosmarinic acid	Poland	
85	Leaf	Gallic Acid	Brazil	[55]

Mohitgiri A. Goswami et al.,

86	Leaf	Boldine	Brazil	
87	Leaf	Rutin	Brazil	
88	Leaf	Quercitrin	Brazil	
89	Leaf	Quercetin	Brazil	
90	Leaf	Isoquercitrin	Brazil	
91	Leaf	Kaempferol	Brazil	
92	Leaf	Luteolin	Brazil	
93	Leaf	Ellagic acid	Brazil	
94	Leaf	Caffeic Acid	Brazil	
	Chemical Class 6: Major Essential Oils (EOs)			
95	WP	β -caryophyllene	Italy	[19]
96	Root	β - phellandrene		
97	Root	β -gurjunene		
98	Root	Humulene		
99	Stem	β -linalool		
100	Stem	α -copaene		
101	Stem	β -caryophyllene		
102	Stem	δ -cadinene		
103	Leaf	Anethol		
104	Leaf	β -caryophyllene		
105	Leaf	D germacrene		
106	Leaf	1-octen-3-ol		
	Other Phytochemicals			
107	Leaf	Tannins and Hydrolysable Tannins (HTs)	Kenya	[20]
108	Leaf	Flavonoids		
109	Leaf	Saponins		

Table 2. Humans and Mice Clinical trials to establish the lipolytic potential of forskolin from *P. barbatus* root

Sr No.	Dose of Forskolin	Test Subjects	Study Period	Results	Side Effects	References
1	25 mg	1 Male, 13 Females	12 weeks	Significant decline in body weight, body fat %, BMI	No major side effects	[58]
2	50 mg	Overweight women (6)	8 weeks	Significant decline in body weight and fat %	No major side effects	[59]
3	50 mg	Overweight women (30)	12 weeks	No weight loss but Prevented weight gain	No major side effects	[16]
4	50 mg	Overweight men (30)	12 weeks	Significant decline in body fat % and fat mass	No major side effects	[15]
5	100 mg	Normal Healthy volunteers (15)	8 weeks	Decline in BMI, fat %, and body weight as compared to week 0	No major side effects	[60]
6	50 mg	60 (Men + women)	12 weeks	Significant decline in body weight	No major side effects	[57]
7	0 mg (control), 2 mg/kg and 4 mg/kg	3 groups, 8-11 male mice per group	16 weeks	Mild Reduction in fat cell diameter and improved glucose metabolism	No major side effects	[61]

Mohitgiri A. Goswami *et al.*,

Table 3. Level of Species Discrimination from various barcoding studies

ABSTRACT

Hypertension remains a leading cause of cardiovascular diseases worldwide, with effective management being crucial to reduce morbidity and mortality. Traditional oral antihypertensive medications often have delayed onset of action, making them less effective in urgent situations such as hypertensive crises. Sublingual drug delivery systems present a promising alternative by enabling rapid absorption, leading to quicker therapeutic effects. The application of Quality by Design (QbD) principles in the development of sublingual antihypertensive tablets is key to ensuring high-quality, consistent products. QbD emphasizes the identification and control of Critical Quality Attributes (CQAs) such as disintegration time, dissolution rate, and bioavailability. It also involves the careful selection of Critical Material Attributes (CMAs) and Critical Process Parameters (CPPs) that directly influence these properties. By utilizing tools like Design of Experiments (DoE), QbD facilitates the optimization of formulation and manufacturing processes to achieve robust drug products. Advanced technologies such as Process Analytical Technology (PAT) and continuous manufacturing techniques offer further opportunities to improve quality control throughout production. Integrating QbD principles into the development of sublingual antihypertensive tablets holds significant potential for improving hypertension management. This approach ensures rapid drug onset, enhanced bioavailability, and improved patient compliance. By addressing both clinical needs and regulatory expectations, QbD-based sublingual formulations can lead to better therapeutic outcomes and greater patient satisfaction, offering a promising solution for the future of hypertension care.

Ishan Dubey et al.,

Keywords: Hypertension, Sublingual Drug Delivery, Quality by Design (QbD), Antihypertensive Tablets, Critical Quality Attributes (CQAs), Design of Experiments (DoE)

INTRODUCTION

Hypertension, often referred to as the "silent killer," is a leading cause of cardiovascular morbidity and mortality worldwide. Affecting over 1.4 billion adults globally, it significantly increases the risk of heart attacks, strokes, kidney failure, and other severe complications. Despite advances in medical therapies, the control rates for hypertension remain suboptimal, with less than half of those diagnosed achieving target blood pressure levels. This alarming scenario highlights the pressing need for innovative therapeutic strategies to manage this condition effectively [1-3]. Hypertensive crises, characterized by sudden and severe elevations in blood pressure, can lead to life-threatening complications if not managed promptly. In such scenarios, rapid drug action is critical to preventing end-organ damage. Conventional oral medications may not provide the required immediacy due to delays in absorption and onset of action. This underscores the necessity for advanced drug delivery systems that can deliver therapeutic effects swiftly and effectively during emergencies [4]. Sublingual drug delivery offers a promising alternative for the management of hypertensive crises [5]. By bypassing the gastrointestinal tract and first-pass metabolism, sublingual tablets enable rapid absorption directly into the systemic circulation, ensuring a faster onset of action. Moreover, their ease of administration enhances patient compliance, especially among populations with swallowing difficulties or in emergency settings. Sublingual formulations provide a dual advantage: improved therapeutic outcomes and better patient adherence [6-11]. Incorporating Quality by Design (QbD) principles in pharmaceutical development has revolutionized the industry by ensuring product quality and performance through systematic and science-based approaches. QbD emphasizes the identification of critical quality attributes (CQAs) and critical process parameters (CPPs) to optimize formulations and manufacturing processes. Applying QbD to sublingual antihypertensive tablets can facilitate the development of robust, high-quality products that meet the therapeutic demands of hypertensive emergencies, thereby bridging the gap between innovation and regulatory compliance [12].

Hypertension and Current Treatment Strategies

Pathophysiology of Hypertension

Hypertension, or high blood pressure, arises from a complex interplay of genetic, environmental, and lifestyle factors. It is characterized by sustained elevation of arterial blood pressure due to increased systemic vascular resistance and/or cardiac output. Key mechanisms contributing to hypertension include [13-17]

- Renin-Angiotensin-Aldosterone System (RAAS) Dysregulation: Overactivation of RAAS leads to vasoconstriction, sodium retention, and increased blood volume.
- Sympathetic Nervous System (SNS) Overactivity: Heightened SNS activity promotes vasoconstriction and cardiac output, further elevating blood pressure.
- Endothelial Dysfunction: Impaired production of vasodilators like nitric oxide (NO) and increased release of vasoconstrictors exacerbate vascular resistance.
- Structural Changes in Blood Vessels: Chronic hypertension leads to vascular remodeling, reducing elasticity and perpetuating high blood pressure

Challenges in Existing Drug Delivery Methods

Current antihypertensive therapies face several limitations in their delivery [18-22]

1. **Delayed Onset of Action:** Oral drugs undergo first-pass metabolism, reducing bioavailability and delaying therapeutic effects.
2. **Poor Patient Compliance:** Complex dosing schedules and side effects contribute to non-adherence, undermining treatment efficacy.
3. **Limited Effectiveness in Hypertensive Crises:** Conventional formulations lack the rapid action required for emergency situations.

Ishan Dubey et al.,

4. **Stability Issues:** Some antihypertensive agents are sensitive to environmental factors, affecting their efficacy.
5. **Inconsistent Absorption:** Variability in gastrointestinal conditions and food interactions impact drug absorption.

Sublingual Drug Delivery System

The sublingual drug delivery system utilizes the highly vascularized mucosa beneath the tongue for direct absorption of drugs into the systemic circulation. This mechanism bypasses the gastrointestinal tract and first-pass metabolism in the liver, resulting in a faster onset of action compared to conventional oral formulations [23-25]. The thin mucosal barrier and extensive capillary networks under the tongue facilitate efficient drug diffusion into the bloodstream. Sublingual delivery offers several advantages, including rapid therapeutic effects, improved bioavailability, ease of administration without the need for water, and enhanced patient compliance. These attributes make sublingual delivery particularly suitable for managing acute conditions such as hypertensive crises [26]. Developing effective sublingual formulations requires attention to key factors such as drug permeability, solubility, and stability. Drugs intended for sublingual absorption must possess adequate lipophilicity and molecular size to diffuse through the mucosal membrane efficiently. High solubility is critical to ensure rapid dissolution in saliva, while pH compatibility with physiological saliva (6.0–7.0) enhances drug stability and reduces the risk of irritation. Additionally, rapid disintegration of sublingual tablets, ideally within seconds to minutes, is vital for prompt drug action. Stability under environmental conditions, such as humidity and temperature, and palatability through taste masking, are also crucial considerations for patient acceptance and product efficacy [27-33]. Sublingual tablets are increasingly recognized as a promising option for antihypertensive therapy, particularly in emergencies. Drugs such as nifedipine and captopril have been formulated into sublingual tablets to provide rapid relief during hypertensive crises. For instance, nifedipine's calcium channel-blocking properties and captopril's RAAS-inhibiting effects make them effective choices for sublingual delivery. Additionally, nitroglycerin sublingual tablets, although primarily used for angina, exemplify the potential of sublingual formulations for cardiovascular drugs. By ensuring swift absorption and immediate action, sublingual tablets address critical gaps in current antihypertensive treatments, offering a practical and efficient approach for acute blood pressure management. Further advancements, guided by Quality by Design (QbD) principles, promise to optimize these formulations, ensuring enhanced therapeutic outcomes and better patient care [34-36].

Quality by Design (QbD) in Pharmaceutical Development

Quality by Design (QbD) is a systematic, science-driven approach that emphasizes product and process understanding to ensure pharmaceutical quality. QbD principles involve identifying the critical quality attributes (CQAs) of a drug product and establishing a design space through a thorough understanding of the formulation and manufacturing processes. Central to QbD are tools like risk assessment, design of experiments (DoE), and process analytical technology (PAT), which help in identifying and controlling the critical material attributes (CMAs) and critical process parameters (CPPs). Risk assessment techniques, such as failure mode and effects analysis (FMEA), prioritize potential risks in the development process, while DoE enables robust optimization by evaluating multiple variables simultaneously [37]. The integration of QbD into pharmaceutical development offers numerous benefits. By promoting a deeper understanding of product and process parameters, QbD facilitates the design of robust, high-quality formulations that meet patient needs. It reduces variability in production, enhances product consistency, and minimizes the risk of batch failures. Moreover, the proactive nature of QbD allows for more efficient troubleshooting and continuous improvement throughout a product's lifecycle. These advantages not only enhance the therapeutic performance of drug products but also lead to cost savings and streamlined development timelines [38-39]. Regulatory perspectives on QbD further highlight its importance in the pharmaceutical industry. International guidelines, such as ICH Q8 (Pharmaceutical Development), Q9 (Quality Risk Management), and Q10 (Pharmaceutical Quality System), emphasize the implementation of QbD principles to ensure product quality and regulatory compliance. ICH Q8 focuses on the systematic development of formulations using QbD, while Q9 provides a framework for risk management throughout the drug's lifecycle. ICH Q10 outlines the quality systems required for continual improvement in manufacturing and development processes. Regulatory agencies encourage

Ishan Dubey *et al.*,

QbD to foster innovation, enhance patient safety, and improve manufacturing reliability [40-43]. By embedding QbD into pharmaceutical research, companies can create innovative, patient-centric drug products with higher efficiency and reliability. The application of QbD in sublingual antihypertensive tablet development ensures the creation of formulations that address both clinical needs and regulatory expectations, paving the way for improved therapeutic outcomes and patient care. Figure 01 Represent quality by design approach for Pharmaceutical Product[44].

Implementation of QbD in Sublingual Antihypertensive Tablets

The application of Quality by Design (QbD) principles in the development of sublingual antihypertensive tablets is crucial to ensuring high-quality, effective, and robust formulations. The process begins with the identification of Critical Quality Attributes (CQAs), which are the key physical, chemical, or biological properties that must be controlled to ensure the drug product's safety, efficacy, and quality. For sublingual antihypertensive tablets, CQAs include disintegration time, dissolution rate, bioavailability, stability, and sensory qualities such as taste. These attributes are critical because they directly influence the drug's onset of action, release profile, and overall effectiveness in managing blood pressure. Disintegration time, for example, must be rapid to ensure quick absorption, while the dissolution rate determines how fast the drug enters the bloodstream, which is essential for acute conditions like hypertensive crises [45-46]. Once CQAs are defined, the next step involves selecting Critical Material Attributes (CMAs) and Critical Process Parameters (CPPs). CMAs refer to the raw material properties that affect the final product's quality. In the case of sublingual antihypertensive tablets, CMAs include the particle size of the active pharmaceutical ingredient (API), the solubility of the drug, and the moisture content of excipients. The excipient selection is particularly important as it impacts disintegration time, stability, and the bioavailability of the drug. Similarly, CPPs are the variables in the manufacturing process that need to be controlled to ensure the CQAs are met. For sublingual tablets, CPPs such as compression force, granulation method, and drying parameters must be optimized to achieve the desired tablet hardness, dissolution, and stability. Figure 02 represent risk assessment Matrix for Sublingual tablet [47-50]. Design of Experiments (DoE) is an essential tool in QbD to systematically optimize the formulation and manufacturing process. DoE allows for the efficient evaluation of multiple formulation variables simultaneously, helping identify the most effective combination of excipients, tablet hardness, and disintegration conditions that will achieve the desired drug release and bioavailability. For instance, in the development of sublingual antihypertensive tablets, DoE can help determine the optimal disintegrant concentration and compression force that will ensure rapid dissolution and effective drug delivery. This approach reduces variability, enhances the reproducibility of the formulation, and accelerates the optimization process [51-53]

Challenges and Future Directions

The implementation of Quality by Design (QbD) in pharmaceutical development, particularly for sublingual antihypertensive tablets, presents several technical and regulatory challenges. One of the key technical challenges is the complexity of defining and controlling Critical Quality Attributes (CQAs) such as dissolution rate and bioavailability. Achieving rapid disintegration and dissolution for sublingual formulations requires a detailed understanding of material properties, manufacturing processes, and the interactions between the drug and excipients. Additionally, optimizing these parameters through the use of Design of Experiments (DoE) can be resource-intensive, requiring sophisticated equipment and expertise to ensure the reliability and consistency of results. From a regulatory perspective, while QbD is increasingly recognized and encouraged, its implementation can be difficult due to the evolving nature of guidelines and the need for close collaboration between pharmaceutical companies and regulatory bodies. The transition from traditional batch testing to a more comprehensive, real-time monitoring system, using tools like Process Analytical Technology (PAT), also poses challenges in terms of cost and regulatory acceptance [54]. Emerging trends in sublingual drug delivery and QbD applications point to significant advancements in the field. The development of new excipients, such as fast-dissolving agents and bio-enhancers, is improving the speed and efficiency of sublingual drug release. Furthermore, innovations in nanoformulations and solid dispersion technologies are enhancing drug solubility and absorption, especially for poorly soluble antihypertensive agents. In the context of QbD, the use of advanced modeling and simulation tools is gaining traction, enabling more precise prediction and control over the formulation and manufacturing processes. Additionally, the integration of real-time monitoring through PAT and continuous manufacturing techniques is

**Ishan Dubey et al.,**

becoming more feasible, providing the ability to control quality attributes throughout the production cycle, ensuring consistency and reducing risks associated with batch-to-batch variation [55]. Looking ahead, the future of antihypertensive sublingual formulations holds great promise, driven by the evolving landscape of QbD and innovative drug delivery technologies. The need for rapid, effective, and patient-friendly treatments for hypertensive emergencies will continue to propel the development of sublingual formulations. There is potential for personalized medicine, where formulations can be tailored to individual patients based on their specific needs, genetic profiles, or response to treatment. Advances in nanotechnology, 3D printing, and biocompatible polymers could further enhance the efficacy and patient compliance of sublingual antihypertensive tablets. Moreover, as regulatory bodies continue to embrace QbD, the approval processes may become more streamlined, providing faster access to market for innovative sublingual therapies. In conclusion, while challenges remain, the future of sublingual antihypertensive formulations, guided by QbD principles, promises to deliver more efficient, patient-centric solutions for managing hypertension [56].

CONCLUSION

Combining sublingual drug delivery with Quality by Design (QbD) principles represents a significant advancement in pharmaceutical development, particularly for antihypertensive therapy. By leveraging QbD, the development of sublingual formulations can be optimized to ensure that critical quality attributes, such as rapid disintegration, dissolution, and bioavailability, are consistently met. This approach allows for the creation of robust, high-quality formulations that not only meet regulatory standards but also enhance the therapeutic performance of antihypertensive drugs. The use of QbD tools like Design of Experiments (DoE) and risk assessment ensures that the formulation and manufacturing processes are thoroughly understood and controlled, leading to improved consistency and reduced variability. The impact on hypertension management and patient care is profound. Sublingual antihypertensive tablets, when developed using QbD, offer the advantage of rapid onset of action, which is crucial in emergency situations such as hypertensive crises. The ease of administration, coupled with improved bioavailability and faster drug absorption, enhances patient compliance and satisfaction. Furthermore, the ability to design personalized, patient-centric formulations opens up new avenues for more targeted and effective hypertension treatments. In conclusion, the integration of sublingual drug delivery with QbD principles has the potential to revolutionize hypertension management, ensuring that patients receive safer, more efficient, and faster-acting treatments, ultimately improving their quality of life and clinical outcomes.

ABSTRACT

Flexibility is a very important physiological component of physical fitness required for our daily activity or for athletic events. If there is reduction in flexibility then it can cause inefficiency at workplace and can be a risk factor for the various conditions like muscle strain during sports, lower back pain, knee pain etc. Tightness of muscle can affect activities of daily living (ADL) of an individual. There are many methods available to measure the muscular tightness, one of the methods for identifying the flexibility of the muscle of lower limb muscle is by performing the sit and reach test. By using this test, it can be identified if the muscle tightness is present and also post treatment improvement in flexibility can be noted. To improve flexibility stretching can be useful, methods like static stretching, dynamic stretching etc. can be given also manual techniques like active release technique (ART), positional release technique can be useful. So, aim of this study is to compare immediate effect of Dynamic Stretching and ART To study and compare the effect of active release technique and sit and reach on subjects with calf and hamstring tightness. The subjects fulfilling selection criteria were selected between the age of 18-30 years, then they were randomly divided in to either of two groups (Dynamic Stretching or ART). Before giving the intervention analysis of flexibility by sit and reach test was done. The intervention was given for both hamstrings and calf muscles in the form of active release technique or the dynamic stretching. Then post evaluation for Calf and Hamstring tightness by sit and reach test was done. The statistical analysis shows that there is a significant improvement (P value <0.05) in flexibility when analysis is done within group using paired t - test in both the groups. But there was no significant difference between both the interventions when analysed using unpaired t test. This study concludes that individual receiving

Arya Nandalal Dadhaniya *et al.*,

dynamic stretching and active release techniques both techniques is equal effectiveness on calf and hamstring tightness in sit and reach test.

Keywords: Dynamic stretching, Active Release technique, Sit and Reach test, Flexibility.

INTRODUCTION

Flexibility is a very important physiological component of physical fitness required for our daily activity or for athletic events. [1] If there is reduction in flexibility then it can cause inefficiency at workplace and can be a risk factor for the various conditions like muscle strain during sports, lower back pain, knee pain etc. [2] The ability of an individual to move smoothly depends on his flexibility, an attribute that enhances both safety and optimal physical activities. [3] There are various causes for limitation in flexibility like sex, joint type, extensibility of tendons and ligaments, and muscle relaxation ability. [3] Hamstring tightness is reportedly associated with a posterior rotation of the pelvis in standing. [3] A posterior rotation of the pelvis tends to flatten the lumbar spine, which may increase the risk of low back pain. [3] Gastrocnemius tightness results in a significant increase in knee flexion at initial contact and mid-stance. Continuity and development of flexibility is ensured by stretching exercises. Numerous stretching techniques have been developed, reported and applied by physical therapists, coaches and athletic trainers for improving ROM as well as for warm-up purposes. [4] Dynamic stretching (DS) – Low-intensity active stretching, using repeated, short-duration, end-range active muscle contractions of the muscle opposite the shortened muscle are a form of self-stretching exercise [4] Active release technique (ART) is a manual therapy for treating soft tissue problems in muscles, joints, and connective tissue. [5] Active Release Technique is based on the theory of cumulative trauma disorder (CTD). CTD is a soft tissue injury that results from acute injury, repetitive injury, or a constant pressure/tension injury. [6] The active release technique (ART) is a treatment method used for soft tissue injuries of muscles and myofascial that cause mechanical dysfunction, which can lead to pain and muscle weakness. [4] Long duration sitting is a contributory factor for developing tightness. [7] Flexibility dysfunction is a widespread problem faced by common people as well as sportspersons, especially in case of hamstring group of muscles. A tight gastrocnemius (with increased compensatory pronation) also predisposes patients to plantar fasciitis. The need of the study is to identify the effective technique to reduce the tightness of the muscle. [7]

METHODS

This study was conducted in and around Rajkot city, ethical permission was taken from departmental ethical committee. Total 30 subjects were selected who would fulfil the criteria of selection. Criteria for selection were [8]: inclusion criteria – Individuals between 18-30 years age, Male and Female both, Calf and hamstring both muscles tightness should be present. Exclusion criteria - History of previous lower limb injury or pain from past one year, history of fracture or surgery of back, pelvis, hip, knee or ankle from past one-year, inflammatory condition that could affect motion, Spinal deformity or any neurological condition. After proper explanation about the purpose and procedure of the study, individuals who participate in this study were requested to sign a written consent form. The selection of participants was done by convenient sampling and then randomly divided into either of the two groups by odd and even number into either Group – A DS and Group – B ART. After proper explanation about the purpose and procedure of the study, individuals who participate in this study were requested to sign a written consent form. A pre-participation evaluation form consisting of basic assessment chart was filled which included name, age, gender, occupation, address, and Range Of Motion (ROM) and sit and reach test. For Group – A: Dynamic Stretching exercises were given for both hamstring and calf muscles 15 repetitions were given. For Hamstrings muscle (Figure 1): The subject contracted the hip flexors with knee extended and flexed the hip joint so that the leg swung forwards to the anterior aspect of his body i.e. front kick through the active ROM of the hip joint. For calf muscle (Figure 2) – Step forward with one leg and keep back heel flat on the ground while knee was flexed. Contraction of quadriceps and tibialis anterior muscles to extend back knee. At the same time, move forward to the point of mild stretch on the back

calf muscle and then immediately release i.e., forward lunge. [9] For Group B – ART: For ART Subjects lie supine on the plinth and gentle tension is applied to the hamstring muscle along the entire length (longitudinal length) while stretching the leg in different positions to better work the muscle, then palpate the taut band. Then individual was asked to perform movement for 15 times. [10] For calf muscle subject was in prone lying position with the knee flexed to 90 degree and the ankle maintained in plantarflexion. Therapist applied deep manual pressure on the trigger point and while sustaining it the subject actively extended the knee as well as dorsiflexed the ankle 15 repetitions were performed (Figure 3). [11] Following intervention post data for V sit and Reach test was taken and statistical analysis was done.

RESULTS

The result of current study analysis was done by Statistical Package for the Social Sciences (SPSS). Data of test are of interval/ratio type, and normality was followed according to Shapiro-willk test. So parametric test was applied. Intra-group comparison was done by applying Paired t- Test and inter group comparison between both the group was done by Unpaired t- Test. Analysis shows that there is a significant improvement in flexibility when analysis is done within group using paired t- test in both the groups (Table-1&2). This suggests that there both the techniques are helpful for improving flexibility. When comparison is done between the effectiveness of two techniques, it has been identified that there is no significant difference between them (Table-3). This suggests that both techniques can improve the flexibility equally

DISCUSSION

The purpose of this study was to find the effective treatment for improving flexibility by assessing through sit and reach test performance between DS and ART. According to the analysis both group shows improvement in flexibility. But when compared between two groups both shows equal improvement when flexibility is evaluated by Sit and Reach test performance. The effects of DS component for increase in ROM post intervention can one possible effect of an elevated muscle temperature resulting from dynamic stretching is a decrease in muscle viscosity. [12] It is reported that passive stiffness decreased following dynamic stretching, also it has been proposed that an increase in temperature may decrease the viscous resistance of muscles and by consequence enhance tissue extensibility. [12] One of the research article also found that DS caused a sustained reduction in passive stiffness of the hamstrings and increase in knee ROM, as well as a less lasting increase in passive torque at the onset of pain. As increased passive stiffness of the hamstrings and decreased knee ROM are both risk factors for hamstring injury during sports. [13] Another study done by Kaushik on immediate effect of active release technique (ART) versus muscle energy technique (MET) on hamstring tightness in sewing machine operators. concluded that Active Release Technique (ART) is more effective than Muscle Energy Technique (MET) in reducing hamstring tightness immediately. [14] Another study done by Jain NM, Zore L, Kumar A. on comparison of active release technique and positional release therapy for gastrosoleus trigger point release in recreational runners, concluded that there was a significant increase in the ankle dorsiflexion range of motion following ART, but PRT shows better improvement by reducing pain. [11] Both of these articles support our findings that ART can improve flexibility, the possible mechanism by which ART improves pain could be because of breaking the cross-fibre adhesions which restricts the smooth movement of tissues by adhering to adjacent tissues. [11]

CONCLUSION

This study concludes that individual receiving dynamic stretching and active release techniques both techniques is similar effectiveness on calf and hamstring tightness in sit and reach test. Hence any technique can be useful for improving flexibility in clinical practices.

ABSTRACT

Stomach cancer mortality continues to account for a substantial proportion of the total number of cancer-related deaths. The majority of those with advanced cancer suffer from cancer anorexia-cachexia syndrome, which includes weight loss, a loss of appetite, exhaustion, and weakness. Undernutrition is frequently observed in stomach cancer patients. Nutrition should be a significant and mandatory aspect of complex treatment in cachectic individuals with stomach cancer. Nutritional support should be provided to patients before, during and after surgery. Maintaining proper nutritional intake while undergoing active treatment might be difficult for cancer patients. Poor nutrition is exacerbated by nausea, anorexia, and alterations in smell and taste. Thus, adequate nutrition before, during and after cancer treatment can help patients to improve survival rate, prevent the onset of malnutrition and enhance morbidity. Here, we report a case of gastric cancer in a 36-year-old male who came with complaints of vomiting for the last forty days within half an hour of eating food which is bilious in nature and contains food particles. He was a known case of T2DM and HTN for seven years and was on regular medications.

Keywords: Gastric Cancer, Malnutrition, Nutritional Support

INTRODUCTION

Stomach cancer, also known as gastric cancer, arises from the lining of the stomach and is often associated with various risk factors including *Helicobacter pylori* infection, dietary habits (e.g., high salt intake, consumption of smoked foods), smoking, and genetic predisposition. It is a significant health concern globally, particularly in East Asia, with symptoms often including indigestion, stomach pain, nausea, and weight loss [1]. Hyperglycemia, or high blood sugar levels, is a condition commonly seen in cancer patients. This can be due to various factors such as the stress response to cancer, side effects of cancer treatments like chemotherapy or steroids, and underlying conditions such as diabetes. Uncontrolled hyperglycemia in cancer patients can complicate treatment, affect the patient's prognosis, and diminish quality of life [2]. Nutrition plays a critical role in the management of both gastric cancer and hyperglycemia. For gastric cancer patients, maintaining adequate nutrition can be challenging due to symptoms like nausea, vomiting, and early satiety. Proper nutritional support is essential to maintain body weight, strength, and immune function, which are crucial for tolerating cancer treatments [3]. In the context of hyperglycemia, nutritional strategies become even more complex. Managing blood glucose levels through diet involves balancing carbohydrate intake, monitoring glycemic indices of foods, and ensuring adequate nutrient intake to support overall health and cancer treatment efficacy. Key aspects include Dietary Modifications such as incorporating low glycemic index foods, spreading carbohydrate intake throughout the day, and avoiding sugary and high-carbohydrate foods; Monitoring and Adjustment like regular monitoring of blood glucose levels to tailor dietary recommendations and adjustments in response to fluctuations and Multidisciplinary Approach like collaboration between oncologists, dietitians, endocrinologists, and other healthcare professionals to create a comprehensive care plan that addresses both cancer treatment and glucose management [4].

CASE REPORT

A 36-year-old male came with complaints of vomiting for the last forty days within half an hour of eating food which is bilious in nature and contains food particles. He was a known case of T2DM and HTN for seven years and was on regular medications. On the third day of hospital admission the patient underwent USG, Endoscopy and Biopsy which revealed a tumor of three centimeters in fundus region of the stomach, requiring partial Gastrectomy followed by Chemotherapy. Nutritional assessment was done using GLIM Criteria, Phenotypic [Figure 1], [Figure 2] and Etiologic criteria [Figure 3], [Figure 4] were assessed. Nutritionally diagnosed to be moderately malnourished, with anemia and hyperglycemia, as evidenced by weak handgrip strength, anorexia, early satiated and suboptimal food and nutrient intake and blood sugar levels. Medical Nutrition Therapy initiated with energy and protein recommendations set at 30 kcal/kg/IBW and 1.2g/kg/IBW based on ESPEN 2021 dietary guidelines during cancer [5]. Oral Diet initiated on POD 4 and progressed in consistency from liquid to normal based on tolerance. Oral Nutrition Supplement meeting 35% of estimated requirement was provided and tapered according to improvement in oral intake.

DISCUSSION

It is advisable for cancer patients to be screened regularly for risk of malnutrition. Adequate nutrition before, during and after cancer treatment can help patients to improve survival rate, prevent the onset of malnutrition and enhance morbidity. In this case at the time of discharge the phenotypic status improved to normal as evidenced by improvement in Handgrip Strength and the etiologic status improved to normal food intake as evidenced by improvement in nutrient intake. Thus, appropriate assessment of nutritional status using the GLIM Criteria, coupled with timely nutritional intervention, counseling and monitoring improved patient outcome as evidenced through improved nutritional parameters, glycemic control and length of hospital stay. Several studies support the recommendation that cancer patients should be regularly screened for malnutrition to improve their outcomes. Research by Arends et al. (2017) highlights that nutritional support is essential before, during, and after cancer treatment to enhance survival rates and prevent malnutrition [6]. Similarly, a study by Cederholm et al. (2019) confirms that assessing nutritional status using the Global Leadership Initiative on Malnutrition (GLIM) criteria,

**Soma Basu and Hemamalini**

which includes parameters such as Handgrip Strength and nutrient intake, is effective in identifying malnutrition and guiding interventions [7]. A comprehensive review by Laviano et al. (2018) indicates that timely nutritional interventions and counseling significantly improve nutritional parameters, glycemic control, and reduce hospital stay length [8]. These findings correlate well with the case discussed, where the patient's phenotypic and etiologic statuses improved to normal, demonstrating the effectiveness of early and ongoing nutritional assessment and intervention.

CONCLUSION

Individualized Nutritional Support with continuous monitoring and counseling resulted in significant improvement in nutritional status, as evidenced by an improved Malnutrition Universal Screening Tool (MUST) score and enhanced Handgrip Strength (HGS). The tailored dietary interventions were meticulously designed to meet the specific nutritional deficiencies of the patient. Regular evaluations and adaptive modifications based on ongoing assessments facilitated timely and effective interventions. This comprehensive support system not only optimized physiological health markers but also positively influenced the patient's overall well-being and functional capacity.

ABSTRACT

This study presents a comparative analysis of curd derived from cow, goat, and buffalo milk, focusing on Ayurvedic perspectives regarding nutritional composition and therapeutic potential. Using established Ayurvedic principles, including Rasa (taste), Virya (potency), and Vipaka (post-digestive effect), the nutritional profiles of curd from different animal sources were evaluated. Additionally, therapeutic properties such as Grahi (constipative), Dhatusarata (tissue nourishing), and JatharagniBalapravritti (enhancement of digestive fire) were assessed. Results revealed distinct variations in nutritional composition and therapeutic attributes among cow, goat, and buffalo curd. Cow curd exhibited predominance in Sattvic properties, while buffalo curd demonstrated Rajasic characteristics. Furthermore, goat curd displayed a balance of Sattvic and Rajasic qualities. The study underscores the importance of considering animal source variability in curd production for optimizing its therapeutic potential according to Ayurvedic principles.

Keywords: Curd, Cow, Goat, Buffalo, Ayurveda, Nutritional Composition, Therapeutic Potential, Rasa, Virya, Vipaka, Grahi, Dhatusarata, JatharagniBalapravritti, Sattvic, Rajasic.

Bharat Patil *et al.*,

INTRODUCTION

According to Ayurveda, balance of Dosha, Agni, Dhatu and Mala is called as Health. There are three pillars to maintain this equilibrium, Aahara, Nidra and Bramhacharya. Now a day, Aahara and Vihara of people is not in a proper direction. People are adopting western food culture leaving the traditional food pattern. The consumption of Dadhi without following the rules of Ayurved has also increased nowadays. Regarding this, different methods of consumption that have been seen in consumption of Dadhi. This result in increased occurrence of diseases. The consumption of curd, a staple in many cultures worldwide. In the realm of Ayurveda, an ancient system of medicine originating from the Indian subcontinent, curd holds a significant place due to its perceived therapeutic properties. This research endeavours to conduct a literary comparative analysis focusing on the nutritional composition and therapeutic potential of curd derived from three distinct sources: cow, goat, and buffalo milk. By delving into Ayurvedic perspectives, this study aims to elucidate the unique attributes of each type of curd, exploring their respective roles in promoting health and well-being according to traditional wisdom. Through this comparative lens, we seek to contribute to in detail knowledge of the nutritional and medicinal aspects of curd consumption, offering insights that may inform dietary practices and healthcare strategies in both traditional and contemporary contexts.

Literature Review

Ayurvedic Perspectives on Curd

Ayurveda, an ancient system of medicine originating in India, classifies Aahar depend on their effects on the body's doshas. Each type of curd is believed to possess unique properties that influence its therapeutic uses:

Cow Curd (GoDadhi)

- **Qualities (Gunas):** Cooling, heavy, and unctuous.
- **Dosha Impact:** Primarily pacifies vatadosha but can increase kapha and pitta doshas if consumed excessively.
- **Therapeutic Uses:** Recommended for digestive issues, malnutrition, and strengthening the body. It is also believed to promote mental stability and improve complexion.

Goat Curd (AjaDadhi)

- **Qualities (Gunas):** Light, cooling, and astringent.
- **Dosha Impact:** Balances all three doshas but is especially beneficial for pitta and kapha imbalances.
- **Therapeutic Uses:** Known for its digestive benefits, it is less likely to cause congestion compared to cow curd. It is also recommended for patients with respiratory conditions and weak digestive systems.

Buffalo Curd (MahishaDadhi):

- **Qualities (Gunas):** Heavy, cooling, and sweet.
- **Dosha Impact:** Increases kaphadosha and can pacify pitta dosha while having a neutral effect on vatadosha.
- **Therapeutic Uses:** Valued for its nourishing and strength-giving properties. It is often recommended for those needing weight gain, increased muscle mass, and strength. However, it may be contraindicated in conditions where kapha is already aggravated.

Nutritional Composition

Modern scientific analysis complements Ayurvedic knowledge by detailing the macronutrient and micronutrient content of curd:

Cow Curd:

- **Protein:** High-quality proteins with all essential amino acids.
- **Fat:** Lower fat content compared to buffalo curd.
- **Carbohydrates:** Contains lactose, beneficial for gut health due to probiotic content.
- **Vitamins and Minerals:** Rich in calcium, vitamin B12, and riboflavin.

**Goat Curd**

- **Protein:** Easily digestible proteins, suitable for lactose-intolerant individuals.
- **Fat:** Medium-chain fatty acids that are metabolized differently and beneficial for heart health.
- **Carbohydrates:** Lower lactose content, reducing the risk of lactose intolerance symptoms.
- **Vitamins and Minerals:** High in calcium, potassium, and vitamin A.

Buffalo Curd

- **Protein:** Higher protein content compared to cow and goat curd.
- **Fat:** Higher fat content, leading to a creamier texture and more calories.
- **Carbohydrates:** Similar lactose content to cow curd.
- **Vitamins and Minerals:** Rich in calcium, magnesium, and phosphorus.

Therapeutic Potential

The therapeutic potential of curd, as discussed in Ayurvedic texts, is supported by modern research:

Digestive Health

- Probiotic content in curd enhances gut flora, aiding in digestion and preventing gastrointestinal infections.
- Curd's cooling properties help in managing hyperacidity and gastritis.

Nutritional Benefits

- A rich source of essential nutrients, curd helps in maintaining bone health due to its high calcium content.
- The protein in curd is crucial for muscle repair and growth.

Immunomodulatory Effects

- Regular consumption of curd can boost the immune system due to its probiotic content.
- It also helps in reducing inflammation and may have potential benefits in managing autoimmune diseases.

Weight Management

Depending on the type of curd, it can aid in weight gain (buffalo curd) or weight management (goat curd).

Aim

To conduct a comprehensive comparative analysis of cow, goat, and buffalo curd through the lens of Ayurvedic principles, examining their nutritional compositions and therapeutic potentials.

Objectives

- 1) To analyze the nutritional composition of cow, goat, and buffalo curd
- 2) To explore the Ayurvedic properties and classifications of cow, goat, and buffalo curd
- 3) To evaluate the therapeutic potential of cow, goat, and buffalo curd:
- 4) To compare the suitability of cow, goat, and buffalo curd for different health conditions and dietary needs

MATERIAL AND METHODS**Materials****Primary Sources:**

- Classical Ayurvedic texts such as CharakaSamhita, SushrutaSamhita, and AshtangaHridaya for qualitative data on the properties and therapeutic uses of cow, goat, and buffalo curd.

Modern Scientific Literature

- Peer-reviewed journal articles, books, and research reports on the nutritional composition and health benefits of cow, goat, and buffalo curd.

**Bharat Patil et al.,**

○ Databases such as PubMed, Google Scholar, and JSTOR for sourcing relevant scientific literature.

Methods

Literature Review

Ayurvedic Literature Review

- Systematic examination of classical Ayurvedic texts to extract information on the properties (gunas), dosha impacts, and therapeutic uses of cow, goat, and buffalo curd.
- Cross-referencing multiple texts to ensure comprehensive coverage and accuracy of Ayurvedic perspectives.

Modern Scientific Literature Review:

- Systematic review of scientific literature on the nutritional composition and health benefits of cow, goat, and buffalo curd.
- Using keywords such as "nutritional composition of cow curd," "therapeutic potential of goat curd," and "health benefits of buffalo curd" to search databases.
- Summarizing findings to provide a modern scientific context to the Ayurvedic properties.

Comparative Analysis

Ayurvedic Comparison:

- Comparison of the Ayurvedic properties of cow, goat, and buffalo curd based on textual evidence.
- Identifying similarities and differences in dosha impacts and therapeutic uses.

Nutritional and Therapeutic Comparison

- Comparative analysis of the nutritional profiles of cow, goat, and buffalo curd.
- Correlating the nutritional data with Ayurvedic properties and therapeutic potentials.

Data Synthesis

- Integrating findings from both Ayurvedic texts and modern scientific literature to provide a holistic understanding of the nutritional composition and therapeutic potential of cow, goat, and buffalo curd.
- Summarizing the results in a comparative framework to highlight key differences and similarities.

Validation

- Peer review of findings by experts in Ayurveda and nutrition science to ensure accuracy and relevance.
- Incorporating feedback and making necessary adjustments to the analysis and interpretation of data.

DISCUSSION

Ayurvedic Perspectives on Curd

The analysis of Ayurvedic texts reveals that cow, goat, and buffalo curd possess distinct properties and therapeutic potentials. Ayurveda classifies foods based on their effects on the body's doshas, Ras, Veerya, Vipaka.

Comparative Analysis

The comparative analysis highlights key differences and similarities in the nutritional composition and therapeutic potentials of cow, goat, and buffalo curd:

Cow vs. Goat Curd

- Cow curd is more suitable for general health and digestive issues, while goat curd is better for those with lactose intolerance and specific respiratory conditions.

**Cow vs. Buffalo Curd**

- Cow curd has lower fat content, making it suitable for a broader population, while buffalo curd is ideal for those needing additional calories and strength.

Goat vs. Buffalo Curd:

- Goat curd is lighter and more easily digestible, while buffalo curd provides higher energy and nourishment, suitable for specific therapeutic needs.

CONCLUSION

The study "Literary Comparative Analysis of Cow, Goat, and Buffalo Curd: Ayurvedic Perspectives on Nutritional Composition and Therapeutic Potential" offers a comprehensive evaluation of the nutritional and therapeutic attributes of cow, goat, and buffalo curd through both Ayurvedic and modern scientific lenses. The findings highlight the unique qualities and health benefits of each type of curd, making them suitable for various health conditions and dietary preferences.

Cow Curd:

- **Ayurvedic Perspective:** Recognized for its cooling and nourishing properties, cow curd is ideal for digestive health, addressing malnutrition, and enhancing mental stability.
- **Nutritional Composition:** Rich in high-quality proteins, calcium, and essential vitamins, it supports bone health and overall wellness. Its lower fat content makes it a versatile choice for the general population.

Goat Curd

- **Ayurvedic Perspective:** Known for its light and easily digestible nature, goat curd balances all three doshas and is particularly beneficial for those with respiratory issues and weak digestion.
- **Nutritional Composition:** High in easily digestible proteins, medium-chain fatty acids, and essential minerals, it is suitable for lactose-intolerant individuals and those with specific dietary needs.

Buffalo Curd:

- **Ayurvedic Perspective:** Valued for its heavy and nourishing properties, buffalo curd is recommended for individuals needing weight gain, increased muscle mass, and overall strength.
- **Nutritional Composition:** With a higher protein and fat content, it provides significant caloric and nutritional value, though it may not be suitable for those managing weight or with kapha imbalances.

The integration of Ayurvedic knowledge with modern nutritional science underscores the therapeutic potential of curd as a functional food. Each type of curd offers distinct benefits, making them appropriate for different health conditions and dietary preferences. Future research should focus on identifying specific bioactive compounds in curd that contribute to its therapeutic effects, further bridging traditional Ayurvedic practices and contemporary health science. This holistic understanding can enhance dietary recommendations and promote the use of curd in therapeutic diets globally.

ABSTRACT

Mobility is accessibility—the ability to go from one location to another in a secure, safe, economical, and convenient manner. Commuters should have arrived at their destination within a set amount of time. Transportation is meaningless without mobility. On a trip, one should have a variety of high-quality transportation options. One should have transportation options for their trip, as well as quality of it. To improve one's mobility should be the aim of any transportation. [1] The aim of this research paper is to check the feasibility of the BRTS route in Lucknow. The study has been done on the selected route to assess its feasibility based on factors like: Population served, Passenger per hour per direction (PPHPD) and availability of right of way (ROW), feeder service, user satisfaction, ridership, and landuse pattern. Inferences are drawn from analyzing the survey data to find out the gap and formulate the final proposal.

Keywords: Bus Rapid Transit System, Passenger demand, Right of Way, Passenger per hour per direction, Ridership, Feeder service.

INTRODUCTION

According to a UN estimate from 2014, almost 54 % of the world's population lives in urban areas. This figure is expected to rise to 66 % by 2050. The workforce frequently uses public transport for commuting, which increases the chance for traffic congestion. Congestion in public transportation systems has become a point of concern in many

90715

**Shagufta Irshad et al.,**

parts such as New Delhi, Mumbai, and others, and it must be handled on an urgent note. Insufficient parking spaces, lack of pedestrian facilities, last mile connectivity, feeder services, encroachment on road, lack of traffic signals are the main issues which affect BRTS. The Platform level boarding, Bus way alignment, Intersection treatments and Off-board fare collection are important considerations for the effective implementation of BRTS. BRTS is a dedicated Right of Way (ROW) on a major arterial road. BRTS delivers comfortable, fast and cost-effective services and carries a large number of passengers along it. BRTS is a public transportation system that prioritizes its customers and is of the highest quality, capacity, and speed.

Literature Study

The BRT Standard is an evaluation tool for BRT routes based on international best practices. BRTS Ranking is done on BRT Standard and have been scored, verified by The BRT Standard Technical Committee by Institute for Transportation & Development Policy. The BRT Standard Technical Committee evaluates BRT Corridor on the five parameters i.e. BRT Basics (38 points), service planning (19 points), infrastructure (13 points), stations (10 points), communication (5 points) and access & integration (15 points). [2] Based on these parameters, BRT standard ranking will be done and is defined in three class Gold (above 85 points), Silver (70-84.9 points) and Bronze (55-69.9 points). [2] For case study, BRT corridor (routes) of three cities i.e., Surat, Ahmedabad and Pimpri Chinchwad has been taken for analysis and also done the comparative analysis of it on the basis of BRT Standard. The corridors which are selected for the following cities

- a) Ahmedabad BRTS (Janmarg Ltd.): Narol – Naroda, [3]
- b) Surat BRTS: Udhna Darwaja – Sachin Gidc [4] and
- c) Rainbow BRTS (Pimpri Chinchwad): Sangvi Phata– Kiwale.[5]

As per the BRTS ranking, Ahmedabad (2013) scores silver: 72 points, Surat (2014) scores bronze: 58 points and Pimpri Chinchwad (2016) is below the BRT ranking and scores only: 43 points. [6] Ahmedabad BRTS scores the highest points because of the high-quality customer-oriented services, infrastructural services, easy and affordable trips, ITS technology, modal share of buses is high i.e. 12%. [7] Surat BRTS scores second highest points because it provides quality customer-oriented services, easy and affordable trips, ITS technology, Surat's BRT is not so successful as compared to Ahmedabad's as Surat shares modal bus share which is only 1 %, ridership is increasing [8] due to quality services and its BRT coming into recognition, people are majorly dependent on three-wheeler public transport. [9] Pimpri Chinchwad BRTS scores the lowest points because there is no provision for ITS technology (proposed), provides ticketing system and shares only 2 % of the modal bus service. [10] The BRT of Pimpri Chinchwad is not successful as compared to Ahmedabad and Surat. Pimpri-Chinchwad is developing, so there is a scope for BRT in the future.

Study Area And Analysis of Study Area**Introduction**

Lucknow is the capital of Uttar Pradesh, is the largest state of India in terms of population. Lucknow is situated at the heart of Uttar Pradesh and is surrounded by Barabanki on east side, Raebareilly on south side, Unnao on west side and Hardoi and Sitapur on north side. Lucknow district is divided into five sub districts i.e., Bakshi ka talab, Malihabad, Mohanlalganj, Sadar and Sarojani nagar. It consists of eight Nagar Panchayat, one Cantonment Board and one Municipal Corporation. Population of Lucknow as per census 2011 is 2,817,105 and as per United Nations, World population prospects 2022 is 3,854,224. Modal share in Lucknow for year 2010-Private vehicle 80%, Intermediate public transport 16%, Public transport 4% whereas for 2031 that is projected for Private vehicle 64%, Intermediate public transport 6% and Public transport 30 %. Therefore, the share for public transport will increase from 4% to 30%, resulting in high ridership for BRTS in the future. [11] Study area lies within Lucknow Municipal Corporation boundary having an area of 348 Ha.

Analysis of study area

The Lucknow city has fulfilled all the basic requirements to run a BRTS stated herewith

Shagufta Irshad et al.,

Population- Population of Lucknow as per census 2011 is 2.8 million and as per United Nations, World population prospects 2022 is 3.8 million

Passenger demand in PPHPD

Passenger demand in PPHPD (Passenger per hour per direction) has been analysed at various junctions. The junctions selected for ground survey includes:

- Bithauli Crossing – BC: 6560 pphpd
- Engineering College Chauraha – ECC: 6120 pphpd
- Kanchana Bihari Marg – KBM: 6179 pphpd
- Scetor-25, Indira Nagar – SIN: 6232 pphpd
- Munshipulia – MU: 6708 pphpd
- Polytechnic Chauraha – PC: 7015 pphpd

Three surveys were conducted from jan 2022 to mar 2022 for analysis:

- 1.Reconnaissance Survey & Landuse Analysis
- 2.Origin-Destination Survey
- 3.Traffic Volume Count

Inference of Reconnaissance Survey & Landuse Analysis

Reconnaissance survey is done for Landuse analysis along BRT Corridor. A buffer of 500 metres on both sides has been taken as a study area for the analysis of the BRT Corridor. [Map 1] Commercial areas are identified along the BRT corridor, which is 10.53% of the study area. Commercial activities attract a greater number of people for job opportunities as it also attracts commuters for their needs. Public/semipublic areas comprises 10.53% of the study area. IET College and polytechnic attracts educational trips. Major Trips originate from Residential areas (64%) such as Kalyanpur, Indira nagar, Vikas nagar, Khurram nagar, Aziz nagar, Ishwarpuri, Bhagwatipuram, Aliganj etc which consist of 63.99% of study area. Recreational areas include Swarn Jayanti Smriti Vihar Park along a corridor that results in recreational trips. Transportation consists of 7.66% of study area which also include railway track along a Bithauli crossing. The Industrial area consists of HAL which is 1.48% of the study area.

Analysis of Origin-Destination Survey

Origin-destination (O-D) surveys provide a detailed analysis of trip patterns and travel choices of a city's commuters, origin and destination of various vehicles, user satisfaction while travelling and feeder services. For origin-destination survey, 200 commuters have been taken for analysis in which the maximum number of trips is for work, followed by education, recreation, shopping, and lastly, health. The mode of travel used for these trips are 2-wheeler which is 52% of total sample taken, followed by 4 wheeler which is 24%, then auto which is 20% and lastly bus which is 4% of total sample taken as shown in Figure 1

Inference of OD Survey

Maximum number of trips are generated in the study area due to (fig 2)

- **Educational Trip** shares second major of all trips generated. The reason is several educational and research institutes are situated along the study BRTS route e.g. Integral University, Engineering college, Polytechnic & IIM
- **Work Trip** shares the major proportions of all trip generated especially towards Gomtinagar, Polytechnic, Indira nagar, Nishatganj, Hazratganj, Charbagh, Bithauli, BKT, Madiyaon etc.
- **Health Trip** – Availability of various hospital on ring road such as Jagrani hospital, Regency Multispeciality hospital etc
- **Shopping Trip** – At Bhoothnath market, Wednesday (weekly market), Tedhi pulia, Kapoorthala market etc. Commercial development along ring road

Inference of Traffic Volume Count (TVC) survey

Traffic Volume Count survey (TVC) has been done to analyze Level of Service (LOS) of the road, traffic congestion, carrying capacity, Volume capacity Ratio, to determine peak hour, average daily traffic (ADT) and ridership scenario.

Private vehicles i.e., 2 & 4 wheelers are the most prevalent mode of transportation in this corridor, followed by public transportation. The Average speed at the junctions is 32 km/h. The Volume capacity ratio is more than 1 and the Level of Service is D, which results in severe congestion at junctions in peak hours. As a result, BRTS can be used to shift the mode from private vehicles to public transportation, particularly BRTS. A dedicated bus lane on the BRTS would reduce traffic and provide a more friendly environment. The majority of people commute by 2-Wheeler, then 4-Wheeler, and lastly by auto. Bus usage is really low as the frequency of buses is 15-20 minutes. The maximum Traffic flow in PCU/Hr is 1968 at Polytechnic. The average vehicular composition of study area is 2-Wheeler which is 54% & 4-Wheeler which is 27%. Auto which is 12% and Bus & HCV is 1%. Cycle which is 3% of study area as shown in figure 3. The shift from private vehicles to public transportation is much needed because it will reduce the hazardous impact on the environment while also making the trip more affordable.

Regional and Intra City Connectivity

Existing bus routes are identified to know the best suited route for BRTS as shown in Map 1 [12] Existing metro routes are identified in order to provide feeder services through BRTS as shown in Map 2 [13] The main aim of BRTS is to complement MRTS rather than to compete with it because they both have different characteristics. Identified corridor length for different corridor are as follows: Corridor 1 (Dubagga station to Bithauli Crossing)– 12 Km, Corridor 2 (Bithauli crossing to Polytechnic chauraha) – 12 Km, Corridor 3 (Polytechnic chauraha to Transport Nagar) – 25 Km, Corridor 4 (Cantonment to Shaheed path)– 7 Km, Corridor 5 (Mahanagar to Shaheed path)– 12 Km, Corridor 6 (Engineering College to Medical College)– 7 Km, Corridor 7 (Vasantkunj to Telibagh)– 16 Km. Seven corridors have been identified in which corridor 2 from Bithauli crossing to Polytechnic chauraha is finalised for study area.

Availability of ROW

Availability of ROW on different junction of Study Area are as follows: Bithauli Crossing – 30 m, Engineering College Chauraha – 45 m, Kanchana Bihari Marg – 35 m, Sector -25, Indira Nagar – 35 m, Munshpulia – 40 m and Polytechnic Chauraha – 40 m as shown in Map 1. Passenger demand is above 6000 person per hour per direction. Study area fulfils all the three requirements which are required to run a BRTS, therefore BRTS is feasible in Lucknow city.

Based on survey and analysis factors affecting the BRT Route

Factors which affect the BRT Corridor are: feeder system [14], user satisfaction [15], ridership and land use (TOD). [16] It has been analysed that Feeder services are lacking in some inner parts of the corridor, so people use their private vehicles to commute, compared to other modes of transportation, buses have a low ridership. As per the table, various modes have been taken for survey, in which time taken by different modes and money spent on the trip from Polytechnic chauraha to Bithauli Crossing has been analysed. IPT – Changing 2 autos to reach from origin to destination results in delay to reach to their final destination. 2 and 4-wheeler modes of transportation are convenient, but not as affordable as public transportation. The Bus is affordable, but the time taken by this mode is longer and the frequency of buses is also low. The best option for any trip is BRTS, as it takes less time due to dedicated lane as compared to other public transport and is affordable too.

Proposal

There are five essential features that define BRTS in the study area. It includes: Dedicated Right of Way, Busway alignment, Platform level boarding, Off-board fare collection and Intersection treatments. These five essential aspect result in a faster trip for commuters and make traveling on transit more efficient and convenient therefore it is necessary to get the basics right. As per BRT Guidelines for Indian Cities IRC, 2017, average spacing between stations should be between 300 to 800 m is optimal for commuters. [17] Therefore, proposing 800 m distance between two stations of BRTS. As total length of corridor is 12 km, it consists of 15 stations. The slope of the ramp should be convenient for all commuters especially for the differently abled users. Commuters can purchase tickets in the fare collection area, which also has information displays about the system. At least 1.1 m by 1.5 m should be available for the ticket booth. [17] The boarding area serves as a waiting area for buses as well as circulation space for commuters arriving or departing the station.

Shagufta Irshad *et al.*,

Availability of ROW on different junction of Study Area are as follows: Bithauli Crossing – 30 m, Engineering College Chauraha – 45 m, Kanchana Bihari Marg – 35 m, Sector -25, Indira Nagar – 35 m, Munshpulia – 40 m and Polytechnic Chauraha – 40 m A sensitive Local Area Plan (LAP) may provide incentives for TOD redevelopment. More Value Capture from development along transportation corridors is made possible by TOD. Along transit corridors, FSI could be increased.

CONCLUSION

Through primary survey it has been observed that Lucknow fulfils the basic requirements of BRTS. Therefore, BRTS is feasible in Lucknow City. As this corridor majorly covers residential areas, therefore, maximum trips originate from residential areas. Trips for all sections of society should be affordable and accessible, then only ridership will increase.

ACKNOWLEDGEMENT

I would like to thank my Institute: Faculty of Architecture & Planning, AKTU, Lucknow which helped me tremendously during the research and analysis that went into this project.

ABSTRACT

This study focused on microplastic contamination and looked at seasonal changes in the water quality in Kukkarahalli and Dalvoy Lakes in Mysuru. Water samples were tested for microplastics, dissolved oxygen, conductivity, turbidity, pH, and nutrition levels. The findings indicated Dalvoy Lake had higher pollution and lower water quality than Kukkarahalli Lake, although seasonal variations did not affect sediment characteristics or water quality. Kukkarahalli Lake had a higher pH of 8.58 and a lower conductivity of 593.75. In the case of sediments, both lakes show a pH of less than 6.5, with higher conductivity in Kukkarahalli Lake. The microplastic content was 164 particles/m³ in Kukkarahalli and 212 particles/m³ in Dalvoy lake showing more polymers presence in Dalvoy lake. The findings highlight the importance of improved pollution control techniques and regular water quality monitoring to address water pollution and conservation.

Keywords: Water quality, Kukkarahalli Lake, Dalvoy Lake, Pollutants, Microplastic

INTRODUCTION

Life depends on water, which is crucial for ecosystems and human civilization. Water quality impacts industries, agriculture, the environment, and public health. To ensure that the water is pure and suitable for human consumption, a water quality examination is required [1]. Water's qualities are assessed by a scientific method to determine its condition and suitability for various applications. Water quality parameter analysis is extremely

**Ashashree and Raju**

important since it affects the economy, public health, and the environment in a variety of ways. Water quality parameter analysis encompasses a broad variety of physical, chemical, and biological characteristics[2]. The physical attributes include things like temperature, turbidity, colour, and odour. The solubility of gases and biological activity in water is influenced by temperature. The amount of suspended particles in water is explained by its turbidity, but colour and odor might reveal the presence of organic or inorganic material pollution[3]. Examples of biological parameters include microbiological pollutants like *E. Coli* and coliforms, which may indicate fecal contamination and the potential presence of harmful organisms, and algal biomass, which may indicate nutrient pollution and the potential for hazardous algal blooms. Conductivity, pH, heavy metals, nutrients including phosphate and nitrogen, dissolved oxygen (DO), chemical oxygen demand (COD), and biochemical oxygen demand (BOD) are the final chemical parameters. The pH scale indicates how acidic or alkaline the water is, which is crucial for chemical reactions and aquatic life[4, 5]. Water quality analysis ensures safe drinking water. Pathogens, heavy metals, and chemicals can cause severe and mild medical conditions like malignancies, neurological abnormalities, and gastrointestinal illnesses. Frequent monitoring promotes public health and assists in the prevention of water-borne diseases[6,7]. According to the Central Pollution Control Board of India's standards for water quality monitoring, the metrics to be picked are primarily determined by how water is used in society[8]. The imbalanced entry and outflow of water may produce cultural eutrophication in these lakes. Excreta from humans and agricultural wastes, which are rich in fertilizers comprising nitrogen, phosphorous, and potassium phosphorus as the main factor restricting the growth of algae and eutrophication in lakes introduce nutrients into the water[9, 10]. The potentially toxic elements (PTEs), and polycyclic aromatic hydrocarbons (PAHs) are causing widespread contamination of aquatic environments. Sediments are the primary sink of PTEs in aquatic ecosystems, but their concentrations are not well characterized on a wide scale. Microplastics may absorb larger amounts of some elements than soil particles, making them a transport channel for pollutants. Microplastics have a large surface area and physicochemical properties similar to suspended particles with high concentrations of Fe and Mn oxides[11-13]. Heavy metal pollution in water sediments poses ecological and health hazards. However, there is currently a shortage of information about microplastic pollution. This study examines the link between microplastics and PTEs in sediments and water to enhance understanding of water and sediment quality. The purpose of this study is to provide comprehensive and continuing data on the water quality indicators specific to Dalvoy Lake and Kukkarahalli Lake.

MATERIALS AND METHODS

Study Area

Mysuru, 140 km from the City of Gardens, has a lot of large and small bodies of water. Kukkarahalli Lake, Lingambudi Lake, Devanoor Lake, Dalvoy Lake, and Karanji Lake are a few of the larger lakes[14, 15, 18]. The two lakes studied in this paper are shown in Figure 1. Kukkarahalli Lake, located at approximately 12.312° N and 76.628° E, has a catchment area of approximately 414 hectares and a lake area of approximately 58 hectares. The lake's water levels fluctuate with the seasons, reaching their highest points during the monsoon season and their lowest points during the dry season. The lake includes a variety of ducks, cormorants, egrets, herons, and pelicans and is home to approximately 180 known bird species[16, 17]. Dalvoy Lake is located on the outskirts of Mysore, to the southwest. Compared to Kukkarahalli Lake, it is located in a more rural location surrounded by small towns and agricultural areas. The lake has an area of around 215 acres. It is located at around 12.277° N and 76.637° E. The primary sources of water for Dalvoy Lake are rainfall, surface runoff, and input from nearby streams and agricultural areas. It was previously part of an irrigation system [14,17, 18].

Sampling

The two lakes under research, Kukkarahalli and Dalvoy, were sampled both upstream and downstream of each. Surface water and sediment samples were collected in triplicate from each site during the rainy (May-October) and dry (November-April) seasons. Specifically, between 10:00 a.m. and 12:00 p.m., two liters of bulk surface water samples were collected three times at each station, from 0-20 cm deep and 5-25 cm from the lake. The water samples were stored at 4 °C in plastic bottles until further testing. To collect sediment samples, the top 2 cm of silt from a 15

**Ashashree and Raju**

cm by 15 cm quadrant at each site was removed with a stainless-steel trowel. To prevent contamination until further testing, approximately 2 kg of silt was collected and stored in aluminum foil.

Sample preparation

Samples were collected from many places at the surface and subsurface levels during various seasons (pre-monsoon, monsoon, and post-monsoon) using pre-cleaned polyethylene bottles and conventional techniques. The samples were kept in iceboxes and delivered to the lab within 24 hours for analysis. Physicochemical parameters were measured, including pH (using a digital pH meter), dissolved oxygen (DO) using the Winkler method, conductivity (using a conductivity meter), turbidity (via a Nephelometric Turbidity Meter), temperature (using a mercury thermometer), and nutrient levels (nitrates and phosphates) using spectrophotometry. Microplastic samples were collected concurrently, filtered via bulk sampling, and density-separated using a saturated sodium chloride (NaCl) solution. A stereomicroscope was used to identify the microplastics, which were then tested for polymer identification using Fourier Transform Infrared Spectroscopy. The ANOVA test was used to examine seasonal fluctuations and associations between water quality and microplastic contamination. All statistical analyses were performed using software such as SPSS, with strong quality control measures in place, such as equipment sterilization and triple measurements to ensure accuracy.

RESULTS AND DISCUSSION**Physico-chemical characteristics of water**

pH, Conductivity, Total Suspended Solids (TSS), Total Dissolved Solids (TDS), Hardness as CaCO_3 , Total Alkalinity as CaCO_3 , Dissolved Oxygen, Biological Oxygen Demand (BOD), and Total Coliform comparison was shown in fig 2 and table 1.

pH

The Two-Way ANOVA results show a significant pH difference between the lakes ($F=15.280$, $p=0.001$). Specifically, Kukkarahalli Lake has a higher pH than Dalvoi Lake. However, there is no significant interaction between lake and season ($F=0.715$, $p=0.398$), indicating that seasonal fluctuations have no substantial effect on pH levels in either lake, as tabulated in Table 1.

Conductivity

For conductivity, the Two-Way ANOVA reveals a very significant difference between the lakes ($F=403.545$, $p=0.001$), with Dalvoi Lake having significantly greater conductivity levels than Kukkarahalli Lake. Furthermore, the interaction between the lake and the season is significant ($F=21.818$, $p=0.001$), demonstrating that the effect of the season on conductivity varies between lakes.

Total Suspended Solids (TSS)

The TSS results show a significant difference between the lakes ($F = 11.733$, $p = 0.001$), with Dalvoi Lake having higher TSS levels than Kukkarahalli. There is no significant interaction effect between lake and season ($F=0.733$, $p=0.396$), indicating that seasonal fluctuations have no significant impact on TSS levels across lakes.

3.1.4. Total Dissolved Solids (TDS)

The Two-Way ANOVA results show a significant difference in TDS between the lakes ($F=343.171$, $p=0.001$), with Dalvoi Lake having substantially greater TDS than Kukkarahalli Lake. The interaction of the lake and season is also significant ($F=18.537$, $p=0.001$), indicating that seasonal fluctuations affect TDS differently in the two lakes.

Hardness as CaCO_3

Water hardness varies significantly between the lakes ($F=182.323$, $p=0.001$), with Dalvoi Lake having higher hardness than Kukkarahalli Lake. Furthermore, there is a significant interaction effect between the lake and the season ($F=11.914$, $p=0.001$), demonstrating that the effect of the season on hardness varies between lakes.

**Ashashree and Raju****Total Alkalinity as CaCO_3**

The Two-Way ANOVA results reveal a significant difference in total alkalinity between the lakes ($F=99.091$, $p=0.001$), with Dalvoi Lake having a higher alkalinity. There is also a significant interaction between lake and season ($F=5.256$, $p=0.023$), indicating that seasonal fluctuations alter alkalinity in distinct ways in the two lakes.

Chlorides

For chlorides, the ANOVA shows a significant difference between the lakes ($F=182.548$, $p=0.001$), with Dalvoi Lake having greater chloride contents. The interaction impact between lake and season is also significant ($F=13.868$, $p=0.001$), indicating that seasonal fluctuations affect chloride levels differentially in lakes.

Dissolved Oxygen

Dissolved oxygen levels varied significantly between the lakes ($F=191.814$, $p=0.001$), with Dalvoi Lake having lower levels of dissolved oxygen than Kukkarahalli Lake. There is no significant interaction between lake and season ($F=0.290$, $p=0.593$), implying that seasonal fluctuations have no significant effect on dissolved oxygen levels in the two lakes.

Biological Oxygen Demand (BOD)

The two-way ANOVA results show a significant difference in BOD levels between the lakes ($F=180.255$, $p=0.001$), with Dalvoi Lake having higher BOD values than Kukkarahalli Lake. There is no significant interaction impact between lake and season ($F=0.236$, $p=0.630$), showing that seasonal fluctuations do not significantly affect BOD levels in lakes.

Total Coliform

The results for total coliforms demonstrate a significant difference between the lakes ($F=99.697$, $p=0.001$), with Dalvoi Lake having higher coliform counts. The interaction between the lake and season is not significant ($F=2.633$, $p=0.112$), indicating that seasonal fluctuations have no substantial effect on coliform levels in the two lakes.

Physico-chemical characteristics of sediments

pH, Conductivity, Total Nitrogen, Total Phosphate, Moisture Holding Capacity, Porosity, and Organic Carbon of lakes comparison shown in fig 3 and table 2.

pH

The Two-Way ANOVA results indicate a significant variation in sediment pH between the lakes ($F=3.912$, $p=0.050$). Dalvoi Lake has a somewhat higher pH than Kukkarahalli Lake. However, the interaction between lake and season is not significant ($F=0.707$, $p=0.405$), implying that seasonal variations have no meaningful effect on sediment pH in either lake.

Conductivity

Sediment conductivity varies significantly between the lakes ($F=3398.96$, $p=0.001$), with Kukkarahalli Lake having far higher conductivity than Dalvoi Lake. The interaction between lake and season is near to significance ($F=3.940$, $p=0.053$), indicating that, while the overall difference is substantial, the effect of seasonal fluctuations on conductivity is not visible.

Total Nitrogen

The findings indicate a significant difference in total nitrogen levels between the lakes ($F=1869.1$, $p=0.001$), with Kukkarahalli Lake having much higher levels of total nitrogen than Dalvoi Lake. There is no significant interaction effect between lake and season ($F=0.001$, $p=0.980$), indicating that seasonal variations have no substantial impact on total nitrogen levels in either lake's sediments.

**Ashashree and Raju****Total Phosphate**

Similarly, Kukkarahalli Lake has significantly higher total phosphate levels than Dalvoi Lake ($F = 1738.186$, $p < 0.001$). The interaction between lake and season is not significant ($F=0.097$, $p=0.760$), implying that seasonal variations have little effect on total phosphate levels in sediments.

Most Water Holding Capacity

There is a substantial difference in sediments' maximum water holding capacity between the lakes ($F=748.921$, $p=0.001$), with Dalvoi Lake having a larger capacity than Kukkarahalli Lake. Seasonal fluctuations have no significant effect on this metric ($F=0.054$, $p=0.817$), implying that both lakes' water-holding capacity remains constant throughout the year.

Porosity

The Two-Way ANOVA revealed a significant difference in sediment porosity between the lakes ($F=493.94$, $p=0.001$), with Dalvoi Lake having higher porosity than Kukkarahalli Lake. There is no significant interaction effect between lake and season ($F=0.057$, $p=0.812$), indicating that seasonal fluctuations do not significantly alter sediment porosity.

Organic Carbon

There is a substantial difference in organic carbon content between the lakes ($F=73.692$, $p=0.001$), with Kukkarahalli Lake having more organic carbon than Dalvoi Lake. The interaction between lake and season is not significant ($F=1.460$, $p=0.233$), implying that seasonal variations have no meaningful effect on organic carbon levels in sediments. Dalvoi Lake shows significantly higher conductivity, Total Dissolved Solids (TDS), hardness, alkalinity, chlorides, Biological Oxygen Demand (BOD), and total coliforms. These indicators reflect more severe pollution or higher environmental stress. From the results above, the mentioned parameters are significantly higher than the required specification and that of Kukkarahalli Lake. Commonly used indicators of the ionic content of water, conductivity, and TDS are frequently linked to the presence of dissolved salts and minerals. A range of synthetic polymers are released into the aquatic environment when larger plastic waste breaks down into microplastics. These polymers can absorb and leach chemical additives, heavy metals, and other contaminants into the water. Since some plastics, especially polyvinyl chloride (PVC), release chloride ions when they break down, the presence of chlorides in water can also be connected to microplastic contamination. Kukkarahalli Lake has higher sediment levels of pH, conductivity, total nitrogen, total phosphate, and organic carbon. Microplastics might alter the pH of sediments by interfering with several chemicals and contaminants. Dalvoi Lake sediments have higher water-holding capacity and porosity compared to Kukkarahalli Lake. Microplastics are ubiquitous in Dalvoi Lake sediments, which reason for increased porosity and capacity to store water when compared to Kukkarahalli Lake sediments. As microplastics are small in size and are in diverse shapes they affect the structure of sediments, altering their physical characteristics including porosity and water-retention capacity. According to studies, when microplastics are present the natural packing of mineral particles in sediments is disturbed, which results in a more loosely packed sediment structure with increased pore space¹⁹. Enhanced porosity becomes vital as it improves water flow through the sediment and has a direct impact on nutrient cycling and pollutant transport. The water-holding capacity of sediments is increased as microplastics can absorb the water immediately, particularly those with hydrophilic qualities or rough surfaces [20].

Microplastic content

According to statistics from the initial analysis of the microplastics, there were 164 particles/m³ in Kukkarahalli Lake and 212 particles/m³ in Dalvoi Lake. A graphical depiction of the abundance of various polymers is shown in Table 3. Fibers are the most prevalent form of microplastic found, followed by pieces. The high content of polymers detected in Dalvoi Lake means more pollution by polymers will enhance the low quality of water.

Ashashree and Raju

CONCLUSIONS

The current study conducted a thorough assessment of the lake's water quality that further revealed the major influence of microplastics and pollution indicators, such as conductivity, total dissolved solids (TDS), hardness, alkalinity, chlorides, BOD, and total coliforms on the water quality of the two lakes. As per the data. The higher pH of 8.58 and 8.07 in Kukkrhalli Lake and Dalvoi Lake respectively is unsuitable for drinking. The conductivity is higher in the case of Dalvoi Lake of 1102.25 compared with Kukkrhalli Lake's conductivity of 595.25. The hardness and TDS of both lakes are lesser than the permissible limit when compared between the lake and the higher in Dalvoi lake. The sediment pH was less than 6.5 indicating the acidic nature of the sediments—the high polymer content results in decreased water quality in both lakes. Between Kukkrhalli and Dalvoi Lake the Dalvoi lake is contaminated with microplastics. The study's findings helped to conclude that strict pollution control measures and routine monitoring are necessary to ensure the sustainability of water resources.

ABSTRACT

The present study is aimed to find out the scanning electron microscopic changes in the fat body of the adult male *Sphaerodema rusticum* treated with the median lethal concentration (LC₅₀, 14 ppm) of chromium for 48h. The present results revealed that characteristics SEM changes in the fat body of treated insect than control insect such as shrunken ruffled membrane with small pinocytotic pits. The disorganized cytoplasmic in origination indicates the occurrence of less amount of storage substance may probably be utilized for the insects to avoid the stress during the chromium intoxication.

Keywords: *Sphaerodema rusticum*, Fat body, SEM changes, Chromium, Ultra structure.

INTRODUCTION

Scanning electron microscopic study was used to surface observation and characterization of tissues. The scanning electron microscope (SEM) is an engineering instrument that has been shown to a useful investigative tool in surface modification. Scanning electron microscopy is an important tool in many morphology studies, that SEM shows

**Babitha et al.,**

surface structure (Song, Y *et al.*, 2013; Liu, C. 2008). The scanning and transmission electron microscopy (SEM and TEM, respective) are used to great effect to study their morphology and internal anatomy (Yan-Ru Zhang, 2020). However, during preparation of insect samples for electron microscopy (EM), the objectivity and authenticity of the observation site may be affected (Chen, X.F and Hu,M,Y, 2001).In general, SEM sample preparation of insects requires cleaning, tissue fixation, dehydration, metathesis, drying and sputter-coating (Zhou, W *et al.*, 2006).SEM studies were performed to probe the mechanism of action of the local isolates as compared to commercial and reference strains (Tanvi Sharma *et al.*, 2017). The assessment of pollution impact on aquatic ecosystems is usually based on both physical and chemical analysis of water quality and biomonitoring of living organisms. How were, the emphasis in evaluation of the environment pollution of surface water has been recently shifted to monitoring of bioindicator species (Rochfort *et al.*, 2000; Wright, J.F., 2000).The heavy use of chemicals has already caused grave damage to health and ecosystems (Ambika *et al.*, 2012). Among traditional used bio-indices, a majority are founded on taxonomic differentiation of aquatic invertebrates or multispecies assemblages' sensitivity in response to human-induced stressors (Kefford, B.J *et al.*, 2011). Also morphological (Lenat, D.R, 1993) or behavioural (Johnson, R.K *et al.*, 1993; Marques, M.J, 2003) changes in comprehensively studied species that are caused by modifications of environment quality may turn out to be as exploitable as traditional biotic indices (Tszyd el, M *et al.*, 2015). The using of individual taxons as one-species universal bioindicators is gaining more and more attention in assessment of aquatic pollution (Tszydel, Met *et al.*, 2015). Morphological abnormalities of bioindicator species offer another useful tool for pollution assessment, reflecting metal exposure conditions via element concentration in organism tissues (Vuori, K.M and Kukkonen, J, 1996). The fat body is the main storage and intermediary metabolism organ of insects and is responsible for the synthesis and supply of haemolymph substances. It consists of a mass of cells located underneath the epidermis and, in some insects, that the fat body also surrounds the digestive and reproductive organs reviewed by (Haunerland & Shirk 1995 and Roma *et al.*, 2010).

Fat body cells, known as trophocytes, are clustered together by a thin basal lamina that expands into the haemocoel and forms amorphous lobes or ribbons that increase the organ surface area, which in turn enhance the exchange of substances between the organ and the haemolymph (Martins & Pimenta 2008, Arrese & Soulages 2010). Insect fat body is considered as tissue equivalent to that of the liver in vertebrates (Sobotnik *et al.*, 2016; Liu *et al.*, 2009;Gullan&Cransto, 2014). It is also responsible for many activities such as amino acid, nitrogen, lipid and carbohydrate metabolism and protein sythesis (Liu *et al.*, 2009; Arrese & Soulages, 2010; Li *et al.*, 2019). The fat body is divided into two regions in many insects. These are peripheral (PF) fat body located below the integument and perivisceral (PV) fat body, observed around the digestive tract (Resh & Carde, 2003; Lipovsek & Novbak, 2016). It is very important to know the structure and contents of trophocytes in these insects throughout their development (TugbaZulfikaroglu *et al.*, 2023). Although trophocytes of have been determined in the species of *Blattodea* orders (Park *et al.*, 2013; Makki *et al.*, 2014). The fat body, which also expresses a number of malespecific proteins in addition to takeout, is a candidate for mediating the observed behavioural effect (Fujii S, and Amrein H. 2002). The fat body is a major secretory tissue in both larvae and adults. It secretes factors into the hemolymph, the fly's circulatory system (Lazareva AA, *et al.*, 2007). This revolution in preparing pesticides from plants has reduced the environmental problems; avoid the hazardous effects from chemical pesticides and save the whole universe from the pesticide pollution. The high biotic potential of insect makes the reproductive process a subject of importance in applied entomology. In recent years the dynamic aspects of insect reproduction has received more attention (Adiyodi and Adiyodi, 1974). Hence, the present study was undertaken to find out the morphology of Scanning microscopic changes in the fat body with special references to male reproductive process in the test insect, *Sphaerodemarasticum* when intoxicated with chromium.

MATERIALS AND METHODS

The insects collected from the local ponds and steams were maintained in plastic through at the laboratory temperature of $28 \pm 5^{\circ}\text{C}$ with a relative humidity of 80 ± 5 percent. The insects daily fed with mosquito larvae, pieces of earthworm and aquatic plants. The insects were survived well on these feeds. The troughs were cleaned properly

**Babitha et al.,**

on every alternative day by changing the water. The nymphal instars hatched out from the egg were transferred to another plastic trough and thus, a continuous culture was maintained.

Scanning electron microscopic study

The mortality was recorded for *Sphaerodemarusticum* at 48 hours of exposure of the chromium of various concentrations. The calculated LC 50 value was chromium for 48h. After the exposure period, the fat body of control and treated insects were dissected out and the fat body tissues were fixed in 2.5 Glutaraldehyde in 0.1 phosphate buffer at pH 7.4 for 24 h, then the samples were washed in 0.1 m phosphate buffer and dehydrated in removal of water, the tissues were mounted on metal stubs using conductive tape, coated with a thin layer of conductive material is deposited only for non-conducting samples and they were examined with Scanning electron microscope (JEOL-JSM-IT 200).

RESULT AND DISCUSSION

There are numerous studies on the structure, composition and function of fat body in insect species (TugbaZulfikaroglu *et al.*, 2023). Under SEM and light microscopy, trophocytes were observed to constitute the main cell population. Trophocyte inclusions represent fat, protein and sugar reserves used by insects to meet their energy demands during reproduction and diapause, to provide energy for the developing embryo and to provide energy for prolonged periods of light (Arrese & Soulages, 2010). Trophocytes are the basic cells in the fat body and store lipids, proteins and glycogens (Arrese & Soulages, 2010; Azeezet *et al.*, 2014; Lipovsek & Novak, 2016). The fat body of the control insect was found to be the occurrence of trophocyte with web like ruffled membrane had several pinocytotic pits and secretory granules. The cytoplasm of the trophocytes seems to be flattened sheet around the nuclei, which could be seen as prominent bulges near the centre of the cells. In some locations, these protuberances to be occurred in sub-peripheral regions, while the outer margin of the membrane was appeared as rope like structure (Figure 1 and 2). The invagination resembled like pinocytotic pits was seen inside. Minute blebs associated with cytoplasmic invagination were also seen along the margin of the membrane. Penetration of macrophages and phagocytosis on such trophocytes were visible. The apices of secretory cell seem to be revealed the smooth secretory granules beneath the apical plasma membrane. The trophocytes of treated insects showed remarkable changes in the scanning electron micrograph such as shrunken ruffled membrane with very small pinocytotic pits. The protuberances near the centre of the cells were found to be shrunken (Figure 3 and 4). The outer margin of the rope like structure is disintegrated. Minute blebs associated with cytoplasmic invaginations were found to be disorganized, indicates the less amount of storage substance probably be utilized for the insects to avoid then stress due to heavy metal chromium intoxication. In the present study, it has been observed that characteristic SEM changes in the treated insects than the control insects such as shrunken ruffled membrane with small pinocytotic pits. These changes may be attributed due to treatment with median lethal concentration of chromium on *Sphaerodemarusticum*.

These results are in consistent with the works of ultra-structural study on *Ranaesculenta* during starvation. Similar results were observed by Sumathi (2005) and Lousia (2010) for *Gryllotalpa Africana* and *O. varicornis* treated with the pesticide endosulfan and the zoopesticide, pygidial secretion, respectively. The secretory epithelial cell was covered with very thick rope like structure with basement membrane consists of less amount of secretion by these affected cells, when insects are intoxicated with the heavy metal chromium. Several SEM changes have been observed in the fat body of *Sphaerodemarusticum* when exposed to chromium for 48h. The following SEM changes were observed in the treated insects like shrunken tubule with thick myoepithelial cells, the rope like structure of the plasma membrane, which was observed to be highly pycnotic and disintegrated cubical epithelial cells. The muscular layer was also found to be thickened and highly pycnotic. The pinocytotic vesicles pits were found to be disintegrated with less organized microvilli. Underlying the multiple metabolic functions associated with the fat body, the structural pleomorphism of this major insect organ has received limited attention (reviewed in Haunerland & Shirk, 1995). Generally studies show that trophocytes contain an irregular-shaped nucleus with dense chromatin and cytoplasm with various vesicular structures, mitochondria, GER and Golgi body (Paes-de-Oliveira & Cruz-Landim, 2003; Roma

Babitha et al.,

et al., 2010). These SEM changes perhaps attributed to interaction with the chromium. In the present study, the heavy metal intoxication led to disturbance in the specific mode of secretion by these pseudostratified epithelial cells than the control insects. In treated insects, it has further been revealed that the secretory vesicle and granules with more vacuoles and pits were not observed in the control insects, suggested that the mechanism of secretion may become impaired in the treated insects. These changes might be disturbed the reproductive physiology of *Odontopusvaricornis*, similar results have been also reported by (Verma and Raji, 2000) and (Sumathi, 2002) exposed to dichlorvos and endosulfan for *Oreochromismossambicu*; *Gryllotalpa Africana*, respectively. (Jayakumar, 1988) has observed the same changes in the *O. varicornis* treated with dimethoate. Similarly, (Balakrishnan, 1990) has noticed several SEM changes in *Pherosphuslissoderus* treated with dimethoate, which are similar to the results of other workers namely (Nirmaladevi, 1990) for *Catacanthus incarnates* exposed to phosphomidon. (Rajathi, 2004) exposed to heavy metal mercury for *Sphaerodemarusticum*, (Rameshkumar, 2004) for *Laccotrephesruber* exposed to heavy metal zinc, *Odontopusvaricornis* with pygidial secretion (Lousia et al., 2010), and (Shoba, 2011) exposed to phytopesticidenimbecide for *Sphaerodemarusticum*, (Vivekananthan et al., 2011) *Mylabrisindica* for phytopesticide and *Odontopusvaricornis* exposed to phytopesticidenimbecidide (Ramesh kumar et al., 2014). In the present study, it has been observed that characteristic SEM changes in the treated insects comparatively more than control insects such as shrunken ruffled membrane with small pinocytotic pits. These changes might be disturbed the reproductive physiology of heavy metal chromium on the test insect, *Sphaerodemarusticum* that the control insect.

CONCLUSION

The median lethal concentration of heavy metal chromium caused remarkable changes in the fat body of *Sphaerodemarusticum* when it exceeds required concentration of chromium for regular biological functions. It reduces the potentiality of reproduction. It reveals that, the chromium is considered as an effective heavy metal, eco-friendly for sustainable in the aquatic environment.

ABSTRACT

Exopolysaccharides (EPSs) like Xanthan gum, produced by microorganisms like *Xanthomonas* species represent an industrially untapped market. These microorganisms can produce and excrete EPS in simple but costly production conditions. In the present study, xanthan production was investigated utilizing a local isolate of the *Xanthomonas* species in an effort to minimize the expense of the carbon source and maximize the overall yield of xanthan gum. Potential xanthan gum producers include isolates displaying yellow colonies, gram-negative rods, and mucoidal characteristics calcium Carbonate enriched media. These requirements were satisfied by two isolates obtained from diseased tomato leaves and lemon fruit. Bacterial isolates from diseased plant leaves and fruits were defined as *Xanthomonas* spp. based on their morphological and biochemical characteristics. The molecular analysis of the xanthan gum producing isolate (LI) revealed that it was *Xanthomonas oryzae*. An attempt was made to synthesize xanthan gum from cheaper carbon sources such as agro-industrial wastes (molasses, bagasse, and orange peels). Production conditions of xanthan gum and their relative viscosity by these bacterial isolates were optimized using yeast dextrose calcium carbonate medium containing agroindustrial carbon sources and various temperatures and rotations. The highest level of xanthan gum (62.5 g/l) with a relative viscosity of 1.05 was produced at 30 °C, pH 8.0, and 150 rpm using orange peels as a carbon source in an orbital shaker. Chilled isopropanol was used to recover the xanthan gum. FTIR spectral studies were also confirmed the successful recovery of Xanthan gum by detecting the chemical groups.

INTRODUCTION

Biopolymers are polysaccharides formed by microorganisms, specifically yeasts, molds, and bacteria. Because these complex chain polysaccharides can form gels or viscous solutions in aqueous conditions, they are also known as gums. The importance and potential applications of gum use in industry are demonstrated by the widespread use of xanthan gum as a suspension-thickening and stabilizing agent, particularly in the food, cosmetic, pharmaceutical, and petrochemical sectors [1,2]. Xanthan's primary structure consists of repeating pentasaccharide units with a (1→4)-linked β -D-glucopyranosyl backbone, alternating D-glucosyl units, and terminal D-mannosyl units with pyruvic acid moiety and acetyl group substitutions[3]. The polymer's excellent structural and rheological characteristics render it suitable for use as a gelling and stabilizing agent across various industries [4]. Water - soluble hetero-exopolysaccharide xanthan is generated by the gram-negative bacterium *Xanthomonas campestris* [5]. *Xanthomonas campestris* is a plant pathogen responsible for causing diseases like bacterial leaf blight, black rot of crucifers, citrus canker disease, and others, which harm crops [4]. Xanthan, the microbial polysaccharide approved by the FDA and widely accepted commercially, is projected to grow from USD 0.62 billion in 2023 to USD 0.82 billion by 2030, exhibiting a compound annual growth rate of 4.73% during the forecast period (2023-2030). It's crucial to find a local strain of *Xanthomonas* species and enhance fermentation conditions for producing xanthan gum. FTIR analysis is vital for identifying chemical groups present in xanthan gum [4]. In the present study, we aimed to identify the most effective *Xanthomonas* species strain from nearby foliage and fruits such as lemons, and assess its ability to generate xanthan gum.

MATERIALS AND METHODS

Microorganisms and Media

Xanthomonas species was isolated from different leaves and fruits. Samples like mango, pepper, tomato and lemon showing black rot symptoms with varying lesion shapes were collected from fields. After collection stored at 4°C for further analysis. Symptomatic plant samples were washed, dried, and excised. The excised tissues underwent surface sterilization with 1% sodium hypochlorite followed by rinsing with sterile distilled water and 70% ethanol. Teased tissue segments were incubated on nutrient agar plates at 25-30°C for 3-5 days for further analysis. Samples were streaked onto nutrient agar plates and incubated at 28-30°C for 48 hours. Yellow-pigmented colonies were chosen for subsequent characterization. The suspected bacterial colonies were selected and streaked onto the surface of complex solid media such as YDC (Yeast Dextrose Calcium Carbonate) and YPGA (Yeast Peptone Glucose Agar) plates for 48 hours at 30°C, followed by storage at 4°C. Every 14 days, the culture is transferred to fresh medium to maintain strain viability. To assess culture viability, YDC agar slants are incubated at 25°C for 3 days. Selective isolates were subjected to morphological, and biochemical characterization for the preliminary characterization of isolates [4,6,7].

Inoculum and culture condition

The inoculums required for xanthan gum production were prepared by inoculating 10 ml of sterile yeast dextrose calcium carbonate broth with the culture of isolates. The tubes were incubated at room temperature for 24h [8].

Xanthan gum production

Experiments were carried out in 500 ml Erlenmeyer flasks with 100 ml of medium containing sterile Glucose broth (containing g/mL Glucose 6g, Yeast Extract 0.6g, H_2PO_4 0.4g, $MgSO_4 \cdot 7H_2O$ 0.02g) incubated in a rotatory shaking incubator at 28 to 30°C, 150 rpm under shaking condition for 10 days. In the gum production process, 10 ml of inoculum was combined with 90 ml of production medium in 500 ml Erlenmeyer flask. The flasks were placed on an orbital rotary shaker for fermentation. After 10 days, samples were collected and boiled in water bath at 10 to 15 min for cell lysis followed by centrifugation at 8000 rpm for 10 min for cell debris removal. The remaining supernatant was utilized for xanthan gum isolation. Three volumes of chilled isopropanol were added to the supernatant, causing

**Mansi Mulani et al.,**

the xanthan gum to precipitate and settle down. The precipitated gum was then dried in an oven at 50-60°C until a constant weight was achieved[9].

Relative viscosity measurement

In a Rheoviscometer 1% KCl and 0.1% (W/V) gum solution were used to measure viscosity [10].

Optimization studies for Xanthan gum and Biomass production

The optimization studies involve the maximum xanthan gum and biomass production using various agro-industrial wastes as carbon sources, different pH and temperature conditions.

Effect of carbon sources

The optimization studies for xanthan gum production involved various carbon sources such as orange peels, molasses, and bagasse. Isolates were incubated at 30°C for 10 days in sterile glucose broth supplemented with different carbon sources while maintaining other conditions constant [3,11,12].

Effect of pH

pH optimization experiments were conducted using sterile glucose broth with pH levels ranging from 6 to 9. Isolates were incubated at room temperature for 10 days. Thus, the effect of different pH on production of xanthan gum and biomass were determined by maintaining other conditions constant [13].

Effect of Temperature

Temperature optimization trials involved incubating isolates in sterile glucose broth at temperatures of 25°C, 30°C, 35°C, and 40°C for 10 days each by keeping other conditions constant [14].

FTIR analysis

The Nicolet iS10 FT-IR spectrometer was utilized to analyze the functional groups of polymers, while the Rheolab QC Bohlin rheometer was employed for assessing the rheological characteristics [4,15,16].

16s rRNA gene sequencing

After isolating DNA from a culture, the scientist observed a singular band of high-molecular-weight DNA on a 1.0% Agarose Gel. Following PCR amplification, they obtained a distinct single amplicon band, which underwent purification to eliminate impurities. Using the primer 1492R and a BDT v3.1 Cycle sequencing kit on an ABI 3730xl Genetic Analyzer, the purified PCR amplicon was sequenced. The resulting gene sequence underwent comparison with sequences in the NCBI GenBank database via BLAST, with the top ten matches selected based on their maximum identity scores and aligned using multiple alignment software programs.

RESULTS

Sample collection from infected plant parts

A significant commercial product, Xanthan gum is a microbial exopolysaccharide (EPS) generated by *Xanthomonas* sp. responsible for a number of plant diseases, including bacterial leaf, citrus canker disease and black rot of crucifers, which can harm crops. In order to isolate *Xanthomonas* spp. black rot diseased infected fruits and leaves grown in Kansali village, Surat, South Gujarat were collected and used for isolation of promising Xanthan producing bacterial isolates. Various infected plant parts were collected such as pepper leaf, Mango leaf, tomato fruit, lemon fruit to isolate expected *Xanthomonas* sp.

Isolation and purification of *Xanthomonas* species

Colonies of *Xanthomonas* can range from yellow to yellow-orange. This typical growth was obtained from infected tomato fruit and lemon fruit named as TI and LI. Selective media play crucial role by providing an environment that

**Mansi Mulani et al.,**

favors growth of specific microorganisms while inhibiting the growth of others. The yellow pigmented and mucoidal characteristics showing colonies were observed on YDCA (Yeast Dextrose Calcium Carbonate Agar) plate Fig. 1a. *Xanthomonas* species can also grow on YPGA (Yeast Extract Peptone Glycerol Agar) may produce creamy, opaque and slightly mucoid colonies in texture. Similar results produced shown in Fig. 1b. Thus, the growth of bacterial strains from genera that produce xanthan was permitted by both selective mediums.

Identification of causal organisms:**Morphology and Biochemical characterization**

The isolates obtained on selective media were further subjected to gram's reaction and morphological characteristic studies. Colonial characteristics were recorded from YDC agar plate. The colonies were yellow, round, convex with smooth textures. Both isolates were gram negative, short rods. Results of biochemical tests were recorded in table 1. Lemon isolate (LI) and tomato isolate (TI) were showing positive test for Indole, MR, VP, Citrate, H₂S production, Catalase, Urea, KOH, Ammonia and starch hydrolysis test. Whereas, negative biochemical test for gelatin, Urea and Indole for tomato isolate.

16s rRNA gene sequencing:

16s rRNA sequencing, which allows for the comparison of genetic sequences to known data bases to infer taxonomic relationships. In this study, we employ 16s rRNA sequencing to identify the unknown organism isolated from Lemon fruit (LI). Experimentation method includes DNA isolation followed by 16s rRNA gene amplification using PCR Fig. 2(A). Our data analysis revealed a 92.93% sequence match with *Xanthomonas oryzae* strain YNCX Fig. 2(B). Furthermore, phenotypic characterization of the unknown organisms demonstrated its ability to produce Xanthan gum, a polysaccharide with various industrial applications. Xanthan gum production is a hallmark trait of many *Xanthomonas* species, including *X. oryzae*.

Xanthan gum production and its recovery

The isolate was inoculated in sterile glucose broth incubated at room temperature under shaking condition for 10 days. Intensity of broth color was increased and changed to the bright yellow, which was primary indication of xanthan gum for fermentation. In order to recover xanthan gum, centrifugation and precipitation was done by ice cold Isopropanol (IPA) followed by drying at 45 °C in oven for 2-3 hours. The dry weight of product was recorded. Precipitates of xanthan gum was obtained from Lemon isolate (LI) and absent in Tomato isolate (TI). Fig. 3a and 3b depicted the xanthan gum precipitation and recovery respectively. Tomato isolate was further subjected to optimization study.

Optimization of Xanthan gum and cell biomass production**Effect of carbon sources**

Xanthan gum has been successfully produced from orange peels extracts, bagasse and molasses using lemon isolate. Fig. 4a suggest the maximum yield of xanthan gum (112.8 g/L) with the orange peel as carbon sources. One more observation was that cell dry weight was also higher in orange peels (17.66 g/L) containing media which suggest favorable carbon source for greater growth of organisms. Different concentration of orange peels (3%, 5%, 7% and 10%) were used. The maximum yield of xanthan gum (60.61 g/L) was attained in 10% concentration of orange peels (Fig. 4b). The fermentation using *Xanthomonas* species and orange peels as the carbon source was best combination for maximum xanthan production.

Effect of pH, Temperature and Rotation

To observe the effect of pH, media were adjusted to different pH, was 6.0 to 9.0. The study revealed that as pH increased from 6 to 8 the xanthan gum production also increased and decreased beyond pH 8. Thus, the optimum pH for xanthan production was 8 and maximum yield was found to be 61.3 g/L. The optimum pH for biomass production is 8 and maximum production is 6.6 g/L (Fig. 5a). The effect of temperature on xanthan production was studied for temperature ranges from 28°C, 30°C, 35°C, 37°C, 55°C. It was found that as temperature increased from 25°C to 30°C, the production of biomass and xanthan gum also increased but further increase in temperature lead to

**Mansi Mulani et al.,**

reduction in production of both biomass as well as xanthan gum. It is clear that the optimum temperature for biomass and xanthan gum production was 30°C and maximum production of biomass was found to be 6.45 g/L and the maximum xanthan gum production was 61.5 g/L (Fig. 5b). The effect of rotation on xanthan production was studied in the range of 110 rpm to 150 rpm. It was found that as rotation increased from 110 rpm to 150 rpm, the production of biomass and xanthan gum also increased. The optimum spindle speed for biomass and xanthan gum production was 150 rpm inferred from Fig. 5c. The maximum production of biomass was found to be 7.2 g/L and xanthan gum production was 62.5 g/L. Table 2 represents overall idea on effect of different parameters such as pH, Temperature, and carbon sources on xanthan gum, cell dry weight and relative viscosity.

Effects of Temperature and Rotation on Viscosity

The relationship between temperature and viscosity as well as rotation and viscosity could be established by plotting the appropriate curves using experimental data obtained. The higher the spindle speed (shear rate) the lower the viscosities of xanthan gum can be inferred from Fig. 6a and this behavior is typical of non-Newtonian fluids. There was also a variation of viscosity as a result of increasing temperature. Xanthan gum viscosity increased as temperature increased from the range of 20 °C to 37 °C but decreased at 55 °C can be inferred from Fig. 6b.

FTIR analysis

The FTIR spectrum was used for detection of different functional groups of xanthan gum such as hydroxyl, carboxyl, carbonyl, and acetal groups. The x-axis represents wavelength (cm⁻¹). FTIR spectrum of the commercial xanthan gum contains peaks typically appear in the regions associated with OH stretching vibrations (around 3000-3500 cm⁻¹), C-H stretching vibrations (around 2800-3000 cm⁻¹), and carbonyl (C=O) stretching vibration (around 1600-1800 cm⁻¹). Similar peaks observed in our study where gum produced from LI isolate of lemon plant contained i.e. carboxyl (2974 cm⁻¹), carbonyl (1640 cm⁻¹), acetal (1162 cm⁻¹), and hydroxyl groups (3358 cm⁻¹) as depicted in Table 3 and Fig. 7. These are very important groups formed during the production of xanthan gum from glucose. Xanthan gum with high acetal content was easily soluble in water, which was due to high hydrophilic properties of the produced xanthan.

DISCUSSION

A significant commercial product, Xanthan gum is a microbial exopolysaccharide (EPS) generated by *Xanthomonas campestris*. Plant pathogen *X. campestris* is responsible for a number of plant diseases, including bacterial leaf, citrus canker disease and black rot of crucifers, which can harm crops[4]. The isolation revealed the presence of yellow colonies, indicative of *Xanthomonas* species, prompting further confirmation. Two colonies, Gram-negative traits short rod and displayed a mucoid, convex form with a yellow pigmentation [17,18]. Cellular growth was assessed using a culture medium containing yeast, dextrose, and calcium carbonate (YDC) as it is suitable for this particular phytopathogenic bacteria [18-20]. The isolates obtained from selective media were subjected to Gram staining and colony-based morphological assessment, revealing gram-negative short rod-shaped cells with colonies exhibiting yellow, round, convex morphology and smooth textures on YDC agar plates. Many such literature studies gave rise to an idea to achieve the selective growth of xanthan producers on YDC agar. *Xanthomonas* species typically grow well on YDC agar as carbonates present in YDC agar enhance the growth of *Xanthomonas* by providing additional carbon source. It may produce small, circular, yellowish colonies with slightly raised edges. Similar results produced in our study as shown in Fig. 1a. *Xanthomonas* species can also grow on YPG agar and may produce creamy, opaque and slightly mucoid colonies in texture. Similar results produced shown in Fig. 1b. Both lemon isolate (LI) and tomato isolate (TI) demonstrated positive results in various biochemical tests indicative of Xanthan gum-producing microorganisms, such as Indole, MR, VP, Citrate, H₂S production, Catalase activity, Urea utilization, KOH string assay, Ammonia production, and starch hydrolysis. Results of morphological and biochemical studies aligning with findings reported in previous investigation by Naik *et al.* (2018) [6]. Furthermore, phenotypic characterization of the unknown organisms demonstrated its ability to produce Xanthan gum, a polysaccharide with various industrial applications. Xanthan gum production is a hallmark trait of many *Xanthomonas* species, including *X. oryzae*. Kim *et al.*, 2009 did mutational analysis of gum gene cluster required for xanthan biosynthesis in *X.*

**Mansi Mulani et al.,**

*oryzae*pv *oryzae* [21]. He found many ORFs consist of gumM, gumB gene with significant homology with the expected protein product of the gum gene cluster of *X. campestris*pv. *campestris*. This suggests the positive lead of xanthan gum production by *X. oryzae*. Various agro-wastes have been explored as economical substrates for xanthan gum production due to their abundance, low cost, and potential to serve as carbon source. Comparing the result of our study with Olanipekun *et al.*(2018), where *Xanthomonas campestris* yielded 8 mg/mL xanthan gum, our lemon isolate (*Xanthomonas oryzae*) showed a notably higher yield, suggesting its superior effectiveness in xanthan gum production³. This underscores the potential of orange peel as a promising carbon source, emphasizing the need for further optimization studies to enhance xanthan gum production. Such exploration aligns with the rising interest in eco-friendly and cost-effective industrial processes, emphasizing the importance of sustainable carbon sources. The influence of temperature on Xanthan gum production has been widely studied. The temperatures employed for Xanthangum production ranges from 28 °C to 55 °C[22]. Several studies on the synthesis of Xanthan, such as those by Gumus *et al.*, 2010; Kerdsup *et al.*, 2011, Psomas *et al.*, 2007, and Silva *et al.*, 2009, have shown that *Xanthomonas oryzae* flourishes best at neutral pH [13,14,23,24]. Because xanthan contains acid groups, during Xanthan formation the pH drops from neutral to values near to 5. These findings are supported by studies conducted by Borges *et al.* 2008 and Esgalhado *et al.* 1995[22,25].The viscosity and dissolution of xanthan gum is dependent on the temperature. The viscosity of the xanthan gum solution decreases by increasing temperature. With the increase of xanthan gum concentration, the viscosity increases with statistical significance as projected. Rottova *et al.*, 2009 and Khusherova *et al.*, 2024 have reported that viscosity has no correlation with the pH value because the viscosity values were not influenced by pH value [8,15]. The Xanthan gum generated in this investigation had an FT-IR spectra that matched the emission band pattern from the previous studies reported by Nayan *et al.*, 2019; Sinha *et al.*, 2012;Khusherova *et al.*, 2024 suggested the successful synthesis of xanthan gum[15,26,27].

CONCLUSION

Xanthomonas species can be isolated from the diseased lemon fruits had the potential to synthesize xanthan gum. *Xanthomonas oryzae* was discovered to be effective xanthan gum producer, producing 112.8 g/L xanthan gum for using orange peels as carbon source at 10% concentration after 10 days of incubation. This study focused on the optimization of xanthan gum production using various environmental and nutritional parameters. Incubation time of 10 days at 30°C temperature with pH 8 were observed to be optimal environmental conditions and orange peels was found to be optimal agro-waste for maximum production of xanthan gum. Using agro-waste in production of xanthan has high demand ensures a low-cost alternative with high productivity. Further, purification procedure is needed to obtain food grade xanthan.

ABSTRACT

The present study aims to explore the identification of taxa *Cleome* species by anatomical characteristics. The following species were selected to provide taxonomical evidence i.e *Cleome aspera* J. Koing ex DC., *C. felina* L. F., *C. viscosa* L., *C. gynandra* L. and *C. rutidosperma* DC. The anatomical observation on these plant materials has been made from different parts such as epidermis, trichomes, leaves, petiole, leaf venation, stem and root. The overall study showed significant anatomical variations from the sections of stem, root and petiole, whereas broader anatomical variations were identified from foliar abaxial epidermis and venation and areole characters of lamina. It was clear that certain structural characteristics such as epidermis and venation and areole were of significant importance in separation of these *Cleome* species. In this study, characters such as epidermal cells wall shape, number of epidermal cells, venation pattern and trichomes demonstrated a strong influence on the taxonomic identification of *Cleome* species.

Keywords: taxonomical evidence, *Cleome* species, anatomical observation, taxonomic identification.

INTRODUCTION

One of the oldest scientific fields, dating back thousands of years is plant taxonomy. It predates even the significant contributions made by Greek and Roman scholars such as Theophrastus, Pliny the Elder, and Dioscorides. The major navigations, the printing press, the establishment of botanical gardens, and the adoption of drying techniques to preserve plant specimens all contributed to the advancement of botanical taxonomy in the fifteenth and sixteenth centuries. Subsequent major steps in the history of plant taxonomy include the formulation of the principle of subordination of characters, the emergence of evolutionary theory, and the adoption of the dichotomous nomenclature binomial naming system (with Linnaeus playing a major role) and other universal rules for plant naming. These developments occurred concurrently with the growing body of morpho-anatomical data. Plant taxonomists have been looking for more accurate methods to comprehend the relationships between genera and families over the past fifty years. (Taia, 2005). More recently, the Hennig-initiated cladistics theory and the swift advancements in DNA technologies have made it possible to infer phylogenies and suggest real, genealogy-based classifications that are faithful to nature. Plant systematics, which aims to clarify plant variety, phylogeny, and evolution, has always been based on the comparative study of plant structure, morphology, and anatomy. Since the nineteenth century, anatomical data have been employed extensively as a taxonomic tool. Understanding the links between taxa at higher classification levels can be greatly aided by studying anatomy. As to Jones and Luchsinger 1987, several plant families possess numerous anatomical features that hold significant significance for their application at both the generic and sub-generic levels. In the exciting second part of the 20th century, new techniques and methodologies substantially aided systematics and structural research. (Endress *et al*, 2000). Using characteristics of anatomy, Auguste Mathiew, one of the first taxonomists, described the forest plants in *Florae Forestiere*. Later, in his seminal work "Systematische Anatomic der Dicotyledonen," another taxonomist named Solereder addressed the systematic significance of anatomical features in dicotyledons. Anatomical evidence is consistently helpful in many ways. For example, the taxonomic technique can be effectively applied to identify biological specimens that have been broken up into smaller pieces. (ii) When morphologies are not used to identify herbarium materials early on, studying anatomical demonstrations can be helpful. (iii) Anatomical information has shown to be extremely helpful in identifying linkages and evolutionary patterns across taxa at higher taxonomic levels and above the species level.

When figuring out the relationships between various genera, species, families, orders, and other taxonomic groupings, they are quite helpful. The evolutionary relationships have also been clarified in large part by the anatomical features. With eight species in the family Capparidaceae, Linnaeus (1753) initially described the genus *Cleome* L. Since then, numerous researchers (DE Candolle 1824, Bentham and Hooker 1862, Boissier 1867, Oliver 1868, Hooker 1875, Hedge and Lamond 1970, Jafri 1973) have studied this genus under the Capparidaceae family. *Cleome* and other related genera were previously included under the family Capparidaceae by floristic authors such as Hooker and Thomson (1872) and Cooke (1903). More recently, however, all of these taxa have been taxonomically split and placed into a different family, the Cleomaceae. Prior to DNA research (APG II system) revealing that the principal members of Cleomaceae are more closely related to Brassicaceae than Capparidaceae, many workers had treated this genus inside the family Capparidaceae (Stevens, 2001). With 180–200 species of herbaceous annual or perennial plants and shrubs that are extensively dispersed in tropical and subtropical regions, *Cleome* is the biggest genus in the Cleomaceae family. Approximately 150 species of *Cleome* have been identified in tropical locations, which are home to the majority of its variety (Raghavan, 1993). The genus *Cleome* was selected for the present anatomical character elucidation based on earlier descriptions, some unique morphological and floral characters in *Cleome* species may not be support to proper identification in all seasons. Such issues have been arising in particular characters such as leaf morphology, stem pubescence and glandular appearance, similar floral patterns and capsule type of fruits. In light of these facts the present study has explored based on anatomical aspects. The following species were selected to provide taxonomical evidence i.e *Cleome aspera* J. Koing ex DC., *C. felaina* L. F., *C. viscosa* L., *C. gynandra* L. and *C. rutidosperma* DC. The anatomical observation on these plant materials have been made from different parts such as epidermis, trichomes, leaves, petiole, leaf venation, stem and root. The taxonomic identification catalogue has prepared in order that the investigation on anatomical difference.

Sathishkumar *et al.*,

MATERIALS AND METHODS

Collection of plant materials

Fresh plant specimens of *Cleome* species such as *C. aspera*, *C. monophylla*, *C. felina*, *C. viscosa*, *C. gynandra* and *C. rutidosperma* were collected from in and around the campus of N. G. M College in Pollachi. The collected plant materials were washed for removal of dirt and dust particles. Then the specimens were undergone for fixing process.

Preparation of FAA₅₀

The fixative solution made of formalin, acetic acid and ethyl alcohol (50%) were mixed in the ratio of 5 cc, 5 cc and 90 cc per 100 cc were added and stored accordingly (Toji Thomas, 2004).

Fixing process

Samples from the healthy parts *viz.* leaves, stem, petiole and roots were fixed in FAA₅₀ solution immediately after collection. After 24 hours, the fixed materials were stored in 50% ethanol for further studies.

Sectioning and slide preparation

Thin free hand sections of petiole, stem and root of selected plants were taken using razor blade and dehydrated with ethanol series (25%, 50%, 75%, 95% and absolute). The dehydrated sections were stained with 10% safranin and 0.1% fast green (Toji Thomas, 2004). The sections were placed on a clean slide and mounted in 50% glycerin and observe under the light microscope.

Epidermal studies

Healthy leaves of selected plants were collected and dipped in distilled water for 90 minutes to prevent them from drying. 3-4 leaves of each plant were kept in test tubes containing 30% of nitric acid and 70% of lactic acid in the ratio of 1:1. Then the test tubes were warmed using water bath till the leaves become transparent. Then the leaves were washed with distilled water for 2-3 times. The adaxial or abaxial surfaces of the leaf epidermis were separated very carefully, using pointed needle and hair brush. The separated epidermis portions were isolated and treated with a drop of lactic acid, to clear the surface and put on slide with coverslip. (Fazal *et al.*, 2018) The features of epidermal peels including the epidermal cell shape and stomatal types were observed. Stomatal index was calculated using the formula:

$$\text{Stomata Index (I)} = S / E + S \times 100$$

Where, S = Number of stomata and E = Number of ordinary epidermal cells plus the subsidiary cells in the same unit area (Metcalf, 1979).

Foliar vasculature study

Entire fresh leaves were submitted to 10 % sodium hydroxide solution and 20 % sodium hypochlorite solution in 2:1 ratio and stand for 2-3 days for transparency. The treated samples were stained with 0.01 % basic fuchsin stain for 24 hours using hot air oven at 60 °C. Then the stained leaf specimens were mounted in glycerin for microscopic evaluation (Valdne'a, 2014). The structural venation types were identification according to Hickey (1973).

Preparation of 0.01% of basic fuchsin

For 10 ml of stain, 0.001 gram of basic fuchsin was dissolved in 10 ml of 50% ethyl alcohol. The stain was in pinkish purple in color.

RESULT AND DISCUSSIONS

The anatomical studies on the stem, root, petiole and leaf blade of *Cleome* species i. e *Cleome aspera*, *C. felina*, *C. gynandra*, *C. rutidosperma* and *C. viscosa* shows that their own unique features. These studies were gave additional support for taxonomic identification. Their qualitative and quantitative anatomical features were under consideration in this study. These characteristic features of a species were compared with each other to develop a taxonomic key.

Stem anatomy

The stem of concerned plants were show a wide range of variations in following character; shape, trichomes, cortex organisation and medullary rays. The outline shape of the section was commonly in circular except *C. viscosa* and *C. rutidosperma* which were in wavy and angular respectively this was admit with the work of Okonwu (2017) on the anatomy of *C. rutidosperma*. The trichomes were present in all studied plant of *Cleome*. Glandular trichomes were present in *C. gynandra* and *C. viscosa*, while the nonglandular trichomes were occur in *C. aspera*, *C. felina* and *C. rutidosperma* (Fig. 1). In *C. rutidosperma* the nonglandular trichomes were spaciouly distributed which was agreed with Okonwu (2017). The cortex region was contains a different layers of cells as mentioned in Table 1. The cortex of *C. felina* and *C. viscosa* were made up of triple layers of cells. The results of *C. gynandra* and *C. viscosa* were accordance with Wael (2016). The interfascicular region was commonly incorporated by sclerenchymatous cells. According to Wael (2016) the interfascicular region of *C. viscosa* was homogeneous which was owed here also.

Root anatomy

The transverse section of roots were show a different characters based on the species as mentioned in the Table 2. It is considered all plant roots had secondary growth (Fig. 2). The major part of the root was reserved by xylem elements. There were ray parenchyma cells between these xylem elements. The layers number of these cells was minimum 3 in *C. aspera* and *C. rutidosperma* and maximum 15 in *C. felina*. In *C. gynandra* and *C. viscosa* he xylem reys were indistinguishable. The xylem elements were embedded mostly in sclerenchymatous or parenchymatous conjunctive tissue as mentioned in table 2. Due to the secondary thickening the pith was replaced by xylem elements. So mostly the pith was absent except *C. rutidosperma*. The cortical regions of *C. aspera* and *C. felina* showed that the intracellular starch grains are present. In *C. felina*, primary phloem elements also present in the cortical region.

Petiole anatomy

The petiole of the examined species of *Cleome* showed some variations in following characters, trichomes, hypodermis, bundle sheath and the number of lateral bundles as mentioned in Table 3. They were commonly had adaxial prominence with a deep furrow. The transverse section of petioles (Fig. 3) shows the prescence of trichomes in *C. felina*, *C. gynandra* and *C. viscosa*. In these *C. felina* had exceptionaly multicellular non glandular trichomes with small projection which was aid to identification. The hypodermis was commonly made up of chlorchymatous and collenchymatous cells as in Table 3. The chlorchymatous cells reserved part of hypodermis in all concerned plants. The vascular bundles were conjoint, collateral and open. They were embedded in parenchymatousgroud tissue. According to the classification of Hare (1942-1943) these are comes under the 'U' shaped petiole based on the petiole structure. The sclerenchymatous cells were surrounded the vascular bundle as a bundle sheath in *C. aspera* and *C. viscosa*. The vascular bundle which was possess straight below the furrow was considered as main bundle and other adjacent bundles were considered as lateral bundles. Here the number of the lateral bundles was minimum 2 in *C. aspera* and maximum 6 in *C. gynandra* and *C. viscosa*. Morvillez (1919), Watari (1934), Hare (1942-1943) and Howard (1962) were proposed different classification through their work based on different phenomina.

Epidermal study

The analysis of epidermal peelings from the lower surface of the leaves were manifested a wide range of contrasting characters in studied plants. These characters were found in the following phenomenon, anticlinal wall shape in frontal view, trichomes, length of the trichomes and stomatal index. The pavement cells were commonly undulate or wavy in *C. gynandra*, *C. rutidosperma* and *C. viscosa*. The non-glandular and glandular trichomes were distributed as

Sathishkumar *et al.*,

mentioned in table 4 which had a similarity with stem. The length of those trichomes was varied from 0.5 mm to 4 mm (Table 4 & Fig. 4). *C. rutidosperma* and *C. viscosa* had very short glandular and non-glandular trichomes respectively. *C. gynandra* contains lengthy glandular trichomes were about upto 4 mm in height. According to many eminent authors from Metcalfe and Chalk (1979) and Watson (1963) to Attar *et al* (2019) had proven that stomatal structure and distribution has a strong implication on the taxonomic identification. Here all considered plants have anamocytic type of stomata. The distribution ratio of stomata was understood by calculating the stomatal index. In this work the stomatal index was minimum 13.6 in *Cleome rutidosperma* and maximum 33.79 in *Cleome felina*. The stomatal index and stomatal type of *C. gynandra* and *C. viscosa* were concealed with the anatomical work of Wael (2016). Whereas this results, was accordance with the work of Aleykutty and Inamdar (1978) on the ontogeny and structural study of stomata and trichomes of some capparidaceae members.

Foliar vasculature

The wide variation of venation in the studied species of *Cleome* was identified their venation pattern, marginal venation, areolation shape, areolation development and veinlets (Table 5 & Fig. 5). The result revealed that the commonest venation pattern in this study is the eucamptodromous in the species of *C. gynandra*, *C. rutidosperma* and *C. viscosa* whereas the *C. aspera* and *C. felina* were exceptionally identified as reticulodromous and cladodromous respectively. For the marginal venation also entirely different in *C. aspera* and *C. felina* (looped marginal venation) while other species were observed as fimbriate type of marginal venation. This is clearly help to differentiate for the identification of *C. aspera* and *C. felina* with use of venation evidence. Followed by the areolation shape is irregular in *C. gynandra* and *C. rutidosperma* whereas the other three species are identified as polygonal type of areolation shape (Figure 5). Also the similarities and differentiation of areolation development and veinlets are given in table 5. The major similarity among the species is the presence of eucamptodromous venation pattern. Recording the differentiation of leaf venation it is observed areolation shape, areolation development and veinlets. The particularly wide variation in leaf venation patterns of angiosperms has been classified by, for example, Ettingshausen von (1861), Melville (1976) and Hickey (1979). In the following, the widely used system of Hickey (1979) and its terminology is adopted. Whereas Ettingshausen von (1861) only considered leaf venation, the scheme of Hickey (1979) also uses other elements of leaf architecture in the classification process, such as leaf shape or the structure of the leaf margin.

CONCLUSION

Overall, the investigation revealed notable anatomical differences in the stem, root, and petiole sections, while more extensive anatomical differences were found in the foliar abaxial epidermis, venation, and areole characteristics of the lamina. It became evident that specific anatomical features, like the epidermis, venation, and areole, were crucial in helping to distinguish between various *Cleome* species. Characters including trichomes, venation pattern, number of epidermal cells, and wall shape of epidermal cells had a considerable influence on the taxonomic identification of *Cleome* species in this study. Ultimately, the study has demonstrated the value of using anatomical data to identify links between different taxa within a species. It is highly helpful in figuring out how different species relate to one another, and anatomical traits were crucial in clarifying evolutionary relationships.

ACKNOWLEDGEMENT

The authors are thankful to the management, Principal and Head of the Department of Nallamuthu Gounder Mahalingam College, Pollachi, Tamilnadu, India for providing laboratory facilities to carry out the research work.

ABSTRACT

The study conducted in Majathal Wildlife Sanctuary observed 82 bird species from 11 orders and 37 families, assessing their migratory status and seasonal distribution. During study 55 resident, 13 summer visitor, 7 winter visitor, 5 residents with altitudinal movement and 2 residents with local movement were observed. Seasonal variations in species abundance and diversity were noted, with spring hosting the highest Shannon diversity index and winter the lowest due to harsh conditions. Migration patterns were observed, with certain species arriving in winter from higher elevations experiencing snowfall. Some lowland species visited sanctuary during late spring and summer. This research offers significant insights into the avian ecology and seasonal dynamics of the sanctuary.

Keywords: Migratory status, Himalaya, Seasonal distribution, Bird diversity.

INTRODUCTION

Himalayas, a hotspot of global biodiversity and a repository of unique faunal and floral wealth [1], mark the southern boundary of the Palearctic in South Asia. Here, the transition from Palearctic temperate forests to the subtropical and tropical forests of Indomalaya fosters a diverse and abundant collection of plant and animal species [2]. The variations in elevation, rainfall patterns, and soil compositions, along with the elevated snow line, contributes to the presence of diverse biodiversity [3]. The vulnerable Himalayan landscapes face significant risks from natural hazards, intensifying concerns regarding the impacts of climate change [4-6]. These include landslides, floods, droughts and concerns about human health, biodiversity and agriculture [7]. Prins and Namgail[8] conducted

Navneet Kaur et al.,

a detailed study on bird migration across the Himalayas and assessed the impact of global change. Birds, being mobile creatures, are adapted to find environments that cater to their needs throughout different seasons [9-10]. This migration of birds involves regular and seasonal movement of populations from one geographic location to another [11]. In Himalayas or peninsular mountains, migration varies from short, local movements of just a few kilometres to extensive trans-Himalayan journeys covering several thousand kilometres [12]. Altitudinal migration involves birds moving horizontally and vertically across mountains. Some birds migrate from lowlands to Himalayan slopes in summer and return to lowlands in winter. Identification of impacts and timing of limiting factors for migratory birds is difficult due to the interconnectedness of their conditions throughout yearly cycle [13]. Understanding the arrival and breeding dates of birds is crucial for analysing the patterns in breeding timing amid climate change [14-16].

During both summer and winter seasons, the sanctuary is visited by birds known as summer and winter visitor, respectively. These birds are predominantly found during specific times of the year due to temperature and climatic variations. If they find favourable food sources in a particular area, they tend to stay there; otherwise, they migrate to more suitable areas. The studies on bird migratory status and seasonal variation [17-21] in Himachal Pradesh were conducted by various researchers. Pong Dam, key wetland in the area, attracting a considerable number of migratory birds from the plains of India and countries in Central Asia [22-23]. Likewise, Gobind reservoir stands out as a significant sanctuary within Himachal Pradesh due to its role in providing habitat for a diverse range of migratory bird species. There is scarce information regarding the diversity, migratory status and seasonal distribution of birds in the Majathal Wildlife Sanctuary. This study is the primary endeavour to document migratory patterns of birds in the sanctuary.

MATERIALS AND METHODS

Study area

The Majathal Wildlife Sanctuary is situated on the border of Solan and Shimla districts in Himachal Pradesh and present within latitude 31°15'00" N - 31°18'45" N and longitude 76°56'45" E - 77°02'18" E (Fig. 1). The altitude range of the sanctuary lies between 575 meters to 1975 meters above sea level and total area spanning over 30.86 sq. km [24]. The sanctuary exhibits cold winter and hot summer with temperature range from 1°C to 40°C. the rainfall varies from 17 mm in April to 348 mm in August. The flora of sanctuary includes Ban Oak Forest, Chir Pine forest, Deodar trees on higher elevations of the Chandi beat. Among the fauna present are Leopard (*Panthera pardus*), Black Bear (*Ursus thibetanus*), Himalayan Goral (*Naemorhedus goral*) and Barking deer (*Muntiacus muntjac*).

METHODOLOGY

The current study focuses on investigating the migratory status and abundance of the birds of Majathal Wildlife Sanctuary in different seasons throughout the year. The study was conducted from February, 2023 to January, 2024. The survey period was divided into four seasons based on climatic conditions. These four seasons were namely, Summer (May, June and July), Monsoon/Autumn (August, September and October) Winter (November, December and January) and Spring (February, March and April). The migratory status of birds was based on sighting in different seasons namely, Winter visitor (WV), Summer visitor (SV), Residential (R), Residential with Local Movement (R/LM) and Residential with Altitudinal Movement (R/AM). The birds survey involves either line transect and point counts [25-26] depending on the different habitats in the sanctuary. Bird identification followed the methods outlined [27-28] with nomenclature based on the guidelines provided by Manakadan and Pittie [29]. The diversity indices were used to calculate the species abundance and evenness present in the sanctuary. The data analyses performed by using PAST software. The following statistical diversity indices were used in the study:

Simpson's Index of Diversity (1-D)

$$= 1 - \sum n_i (n_i - 1) / N (N - 1)$$

Where, n_i = the total number of individuals of a particular species

Navneet Kaur *et al.*,

N = the total number of individuals of all species

Shannon Diversity Index H'

$$H' = -\sum p_i \ln p_i$$

Where, H' : Shannon Diversity Index

p_i : Relative abundance of each species = n_i/N

n_i : Number of individuals within a species

N: Total number of individuals in the sample

Species Evenness Index (E)

$$E_H = e^{H'/S}$$

Where, E_H = evenness index from Shannon diversity index

e = constant, that is base of natural logarithm

H = Shannon diversity index

S = Total number of species in a community

RESULTS AND DISCUSSION

The present study focuses on migratory status and seasonal distribution of various bird species found in Majathal wildlife sanctuary. The 82 species belonging to 11 orders and 37 families were observed in sanctuary (Table 2) and their migratory status were assessed. Analysis of conservation status revealed that one species falls under Vulnerable (VU), one species under Near Threatened (NT) and rest 80 species under Least Concern (LC) category. During study 55 resident, 13 summer visitor, 7 winter visitor, 5 residents with altitudinal movement and 2 residents with local movement were observed (Fig. 2a). During summer, monsoon/autumn, winter, and spring, the observed number of species were 62, 51, 42, and 66, respectively. Likewise, the number of individuals observed during these seasons were 382, 378, 282, and 456, respectively (Table 1). The highest number of species and individuals were found in spring season and lowest in winter season. The diversity indices provide measures of abundance and species evenness within each season. Simpson's index of diversity and Shannon diversity index both measure species diversity, with higher values indicating greater diversity. The Shannon index typically ranges between 1.5 and 3.5, with rarely going above 4.5. Values exceeding 3.0 suggest a stable habitat, while those below 1.0 signify an unbalanced ecosystem [30].

The species evenness index measures the uniformity of individuals among the species present, with values closer to 1 indicating more even distribution. The Shannon diversity index, ranging between 3 and 4, indicated that the overall diversity within the sanctuary was found to be good. During the spring season, the highest number of individuals was observed, coinciding with the highest Shannon diversity index value of 3.819 (Fig.2b). During spring, biodiversity reaches its peak due to several factors. Many species migrate from lower elevations as temperatures rise in those regions. Additionally, in the spring season, the blooming of numerous plant species provides nectar to birds and insects, leading to the flourishing of insectivorous and nectarivores bird populations. During early spring, the sighting of winter visitor birds was recorded, while in late spring, the appearance of summer visitors correlated with the observation of high Shannon index values. Monsoon/Autumn shows slightly lower diversity indices compared to Summer and Spring, but still maintains considerable biodiversity. The lowest Shannon diversity index was observed in the winter season, primarily due to harsh climatic conditions and limited food availability, resulting in fewer species being present. However, certain species, such as winter visitors, are found during this season as birds migrate to the sanctuary from higher elevations experiencing snowfall. The fire fronted serin (*Serinus pusillus*), wallcreeper (*Trichoderma muraria*), pink browed rose finch (*Caprodacus rodchroa*), white tailed nuthatch (*Sitta himalayaensis*), white capped bunting (*Emberizastewartii*), altai accentor (*Prunella himalayana*) and rock bunting (*Emberizacia*) was observed in the sanctuary during the winter season, as they migrate to the sanctuary from colder, higher regions. These birds typically remain in the sanctuary until mid-spring, around March, before returning to their higher elevation habitats. During the summer season, the Asian flycatcher and verditer flycatcher thrive

Navneet Kaur et al.,

abundantly due to the rich diversity and high numbers of insects. Some species found in low elevational areas or plains such as Eurasian collared dove (*Streptopeliadecaecto*), Oriental magpie robin (*Copsychussaularis*), Red vented Bulbul (*Pycnonotuscafer*), Indain robin (*Copsychusfulicatus*), White wagtail (*Motacilla alba*), Purple sunbird (*Cinnyris asiaticus*), Common myna (*Acridotheres tristis*), White throated fantail (*Rhipidura albicollis*) and Ashy prinia (*Prinia socialis*) come to the sanctuary during late spring and summer. The wallcreeper (*Trichoderma muraria*), prefers rocky surfaces, breeds within the sanctuary between December and February as noted by Saniga [31] in the Western Carpathians. In Tamhini, located in the northern Western Ghats, the study noted a high diversity of birds during the spring [32]. Similarly, a study conducted at Palampur Agricultural University showcased significant diversity, particularly from January to February [33].

CONCLUSION

The current work on the Diversity and Migratory status of birds in Majathal Wildlife Sanctuary has revealed that the overall bird diversity in the sanctuary is nearly good. Migratory patterns of birds changes in response to various climatic changes. The sanctuary hosts migratory species that inhabit the area during different seasons. Therefore, it's crucial to maintain undisturbed habitat and preserve the vegetation. Continuous monitoring of these resident and migratory birds is necessary to ensure their habitat conservation is effectively carried out.

ACKNOWLEDGEMENTS

The authors are thankful to the Himachal State Forest department for their permission to conduct field survey and required logistic support. The authors would like to express their gratitude to the University Grants Commission (UGC) for the financial support provided during this study. Additionally, thankful to the Chairperson of the Department of Biosciences at Himachal Pradesh University, Shimla, for their support in conducting the research.

Authors' contributions: Both the authors contributed equally.

Conflict of interest: Authors declare no conflict of interest.

ABSTRACT

Lumbar spondylosis, a common degenerative condition of the spine, is frequently observed in occupations involving prolonged driving, such as truck driving. This observational case series study aims to explore anatomical changes in lumbar vertebrae (Kati Kasheruka) among 30 truck drivers, with a focus on understanding their correlation with Kati Graha (lumbar spondylosis). Radiographic analysis was conducted to assess structural changes including osteophyte formation, disc space narrowing, and osteopenia at multiple levels of the lumbar spine, particularly L4-L5 and L5-S1. Participants were evaluated based on demographic characteristics, occupational history, and specific radiographic findings related to lumbar spondylosis. This study revealed a high prevalence of osteophytes and disc space reduction at the L4-L5 and L5-S1 levels among truck drivers, indicating significant degenerative changes in the lumbar spine. These findings underscore the impact of occupational demands, such as prolonged sitting and vibration exposure, on spinal health. This study provides compelling evidence linking occupational factors associated with truck driving to anatomical changes indicative of lumbar spondylosis. The observed degenerative alterations highlight the need for targeted interventions aimed at reducing risk factors and promoting spinal health among individuals engaged in professions characterized by prolonged driving. Future research should further explore preventive strategies and ergonomic interventions to mitigate the impact of occupational hazards on spinal health in high-risk populations.

Keywords: Lumbar spondylosis, Kati Kasheruka, Kati Graha, lumbar spondylosis

Riya Joy et al.,

INTRODUCTION

Ayurveda is the science of life which describes advantage and disadvantage, happiness and sorrow, good and bad, living being with proportions [1]. In Ayurveda, there is description of the whole-body including bones, muscles, organs etc [2]. Kati means waist, it is one of the anatomical terms used in Ayurveda [3], and Kasheruka means Merudanda (spinal column) [4]. The word Kati Graha originated from union of two words, Kati and Graha. The part of body which is covered with cloth[5]. Graha means to hold, it originated from dhatu GrahaUpadane which gives support. Kati Graha a condition which is characterized by Shoola & Sthabda due to vitiated Vata alone or along with Kapha which gets lodged in the Kati Pradesh. It is also called as Trika Graha and Prishta Graha [6]. Kati Graha explained as one of the Lakshana of Vata Vyadhi but, Bhavaprakasha & Gada Nighra explained separate diseases in Ayurveda classical text and Acharya Charaka while explaining 80 types of Vatajananatmajavikaras, he gives the description about Prustagraha. Kati Graha has mentioned indirectly in that [7] According to Shabdakalpdruma - Kati is the waist region where the dress is worn. [8]In Samhitas, Shroni or Kati is mentioned as a region rather than an organ. While numbering the Siraas, acharya Vagbhata has explained 32 Siras, among the 136 Siras present in the Antaradhi, are located in Shroni. Thus, to infer that Shroni is a region in the Antharadhi.[9'10] Kati is also mentioned as the seat for Vata dosha. Apana vata is mainly present in the Kati pradesha. [11] The intervertebral discs connect the upper and lower surfaces of the adjacent vertebral bodies, and extend from the axis vertebra to the sacrum.[12] Lumbar spondylosis can be described as all degenerative conditions affecting the discs, vertebral bodies. Spondylosis may be applied non-specifically to any and all degenerative conditions affecting the discs, vertebral bodies, or associated joints of the lumbar spine.[13] Chakrapani comments on this quoting that the height of Kati is not mentioned since another Sandhi is present between the heights of Uru (thigh) & Antharadhi (thorax & abdomen).[14] Acharya Sushruta says, the Pramana of Kati in males are 18 angulas in vistara (dimension) which is equal to the vistara of Urahpradesha of females.[15] Kati is also mentioned as the base for Vata dosha. Apana vata is mainly present in the Kati pradesha [16]. Radiating nerve pain caused by a prolapsed disc can also cause bowel and bladder incontinence[17]. Disc herniation's may be result from general wear and tear, such as constant sitting or bending, driving, or a sedentary lifestyle[18]. People over the age of 40 are at the highest risk of developing symptoms of lumbar spondylosis[19]. Upper limitation – could be taken as Nabhi, Lower limitation-could be taken as the Medhra & Mushka[20]. In Most of Samhitas it is mentioned that Kati as the sthana for VataDosha[21].

Acharya Sushruta has mentioned kati is the moolasthan for Medovaha srotas[22]. Kati is the region which is affected in many disorders such as, Katigraha in kshataksheenaand vaatajapradara, Katishula in Vaatodara, Vaatajarsha, Vaatajashula, Kati dourbalya in Darvikaravishavega, Katibhanga in 7th Vishavega. Similarly Kati shool also observed in like Gridhrasi and Grahani etc.[23-28] Back ache found in around 175.8 million days of limited motion each year in the United States. On some known time, 2.4 million Americans are difficult to move because of low back pain, along with 1.2 million on a constant basis. In the year of 2005, lower back ache, position as the number one reason of difficult to move in persons under the period of forty.[29] In the year of 1990, 400,000 industrial low back traumas lead to difficult to movement in the United States[30]. The effects of heavy physical activity are controversial, as is a purported relation to disk degeneration[31]. Professional drivers have been found to be at high risk for developing lumbar spondylosis due to prolonged sitting and vehicle vibration. As study has shown that whole body vibration to be factors which increase both the possibility and severity of spondylosis[32]. In addition to normal working hours, truck drivers may work overtime. This might lead to a long working week exceeding, in practice, the official working week[33]. Approximately 76% of computer professionals from India reported musculoskeletal discomfort in various epidemiological studies [34]. Lower back pain is also very common among workers whose work encompasses activities that involving long hours of sitting, standing and bending[35]. In the year 2005, lower back pain, position as the number one reason of difficult to move in persons under the period of forty[36]. Emphasize the energetic and reparative traits of the intervertebral disc, responding to variations in prolonged sitting, improper position, etc and influencing vertebral kinematics but a strong association remains between the presence of Osteophytes and others like disc space reduction, Osteopenia, spine deformities etc, even though isolated instances of one without the other occurs, in the absence of over symptoms. Thus, research

**Riya Joy et al.,**

substantiation setup in modern medicine bears out the classical Nidana to be causing initial degeneration[37]. Some conditions related to kati region is given below.

Kati Shula

The occurrence of pain in the lumbar region of the axial spine, specifically at sites of degenerative changes, is anticipated due to the presence of nociceptive pain generators in various anatomical structures, including the facet joints, intervertebral discs, sacroiliac joints, nerve root dura, and myofascial components within the axial spine[38].

Kati Sthambhata

The exacerbation and increase of Vata in its own site (Ashraya) negatively impacts Kapha and reduces its fluid component (Dravamsha). From a modern medical perspective, disc degeneration is associated with specific risk factors. Retrospective studies have identified Body Mass Index (BMI), back trauma, daily spine loading activities (such as twisting, lifting, bending, and sustained non-neutral postures), and whole-body vibration (e.g., vehicle driving) as contributors to the likelihood and severity of spondylosis[39].

Pada Harsha

defines as tingling sensation of the legs. As per the Chakrapani Teeka that due to the Prabhava of Vata the symptom may be formed/ arise. Whereas according to the Acharya Sushruta it is affected due to vitiated Vata and Kapha⁴⁰. As per Acharya Vaghbhatta opinion that the Vyana Vayu along with Kapha obstructs the lumen of the Sira and causes Pada Harsha. By dilatation of Sira this will get calmed[41].

Pada Shupthi

defines as numbness of the legs. In Charaka Samhita, Pada Shupthi has been mentioned as a symptom of Snayu Gata Vata whereas Sushruta Acharya has stated it as a condition of Rakta Avrita Vata. Acharya Vaghbhatta hold the view that vitiated Vyana Vayu produces Pada Shupthi⁴². In modern medical terms, compressive radiculopathy can lead to paresthesia, which manifests as hypoesthesia (reduced sensation) or hyperesthesia (increased sensitivity) in specific areas.

Pada Dhaurbhalya

At the chronic stage, due to pain cause the Pada Dhaurbhalya. As per Acharya Vaghbhatta mentioned aggravated Vyana Vayu as the one among the cause of Pada Dhaurbhalya[43].

Stinging pain

It is a symptom commonly seen in the condition in which the intervertebral disc degeneration in specifically lower back region or degenerative disk disease it is may be due to any nerve root pinch[44].

Burning Pain

It is a symptom commonly seen in low back pain in conditions when irritation of nerve root in the lower region of spine due to arthritis of spine's facet joints. Patient often explain that burning pain that can run through the gluteal muscle, to thigh, calf, and foot[45]. Due to excessive standing or sitting condition kinetic pressure comes on the Low back region[46]. The repetitive movements of flexion, Extension, Rotation, Lateral Flexion, either alone or in combination, that are often associated with resistance are the biomechanical movements that shows the highest prevalence of low back pain[47].

AIM AND OBJECTIVES

- Investigate the impact of driving on the lower back (Kati Kasheruka) of truck drivers, focusing on how it contributes to lumbar spondylosis.
- Analyze the connection between anatomical changes observed in lumbar spondylosis and related back ailments described in Ayurvedic texts.

**Riya Joy et al.,**

- Conduct a comparative review of Kati Kashheruka (lumbar vertebrae) and Kati Graha (lower back conditions) in Ayurveda and modern science.

MATERIALS AND METHODS

- An observational study observes participants without manipulating any variables.

STUDY DESIGN

Selection: Thirty diagnosed cases of Kati Graha (lumbar spondylosis) were recruited from the Outpatient Department of Parul Ayurved Hospital.

Study Approach: A two-pronged approach was adopted for this research:

1. **Conceptual Study:** This involved a comprehensive literature review. Relevant resources were gathered from:
 - Ayurvedic texts
 - Previous research works on the topic
 - Modern medical textbooks
 - National and international medical journals
 - Online resources (carefully selected and evaluated)
2. **Clinical Study:** The details of the clinical study design was be outlined in the following section.

INCLUSION CRITERIA

- Diagnosed Lumbar Spondylosis: Participants must have a confirmed clinical diagnosis of lumbar spondylosis.
- Age Range: The age range targeted was 40-50 years old.
- Driving Experience: Drivers needed to have a minimum of 10 years of experience behind the wheel.
- Work Schedule: Participants' typical daily driving hours should fall within the range of 6 to 8 hours.

EXCLUSION CRITERIA

- Surgical history of lumbar region.
- Accidental history of lumbar region with fracture of lumbar vertebrae.
- Inter vertebral disc prolapsed of lumbar vertebra
- Other vehicle drivers

DURATION- 90 days

CRITERIA FOR ASSESSMENT

This study incorporated both subjective and objective parameters to assess the participants' condition:

A. Subjective Parameters

These parameters rely on self-reported experiences of the participants:

- Kati Shula: Pain in the lower back
- Kati Sthambhata: Stiffness in the lower back
- Pada Shupthi: Numbness in the legs
- Pada Harsha: Radiating pain in the legs
- Pada Daurbalya: Weakness in the legs
- Range of Movement: Assessed flexibility of the lumbar spine
- SLR Test (Straight Leg Raise): Evaluates hamstring tightness and potential nerve impingement
- Lasègue's Test: Another test for nerve impingement in the lower back

**Riya Joy et al.,****B. Objective Parameters:****These parameters involve quantifiable measurements:**

X-Ray (LS-Spine) AP & Lateral Views: Images of the lumbar spine from front-to-back (AP) and side (Lateral) views to assess structural changes

Assessment Criteria

The assessment compared the subjective symptoms reported by the participants with the objective findings from the X-Ray examinations. This combined approach aimed to create a comprehensive picture of the participants' condition.

Statistical Design

Since this is an observational study, the data collected was analyzed using descriptive statistics. This involve summarizing the data using measures like frequency tables, means, and medians to understand the characteristics of the participants' symptoms and X-Ray findings.

OBSERVATIONS AND RESULTS**According to addiction**

26 (86.7%) subjects were addicted to Smoke. 25 (83.33%) were addicted to tobacco chewing followed by 22 (73.33 %) were addicted to Tea/ coffee. 20 (66.66 %) were addicted to alcohol.

Observations on Lakshana**DISCUSSION**

- Discussion on Addictions: The study found a high prevalence of smoking (86.7%) and tobacco use (83.3%) among the truck drivers with Kati Graha (lumbar spondylosis). Existing research suggests nicotine in cigarettes may be a culprit, potentially causing disc herniation through coughing or by harming disc health through impaired blood flow and nutrient deficiencies. While tea/coffee consumption (73.3%) wasn't directly linked to Kati Graha, it might contribute to dehydration, another potential risk factor. Dehydration due to the drivers' work schedules could hinder nutrient exchange in the spine, further promoting disc problems.
- Discussion on Range of movement: Repetitive biomechanical movements such as flexion, extension, rotation, and lateral flexion, either individually or in combination, particularly when performed against resistance, exhibit the highest prevalence of lumbar spondylosis.
- Discussion on radiological study: In radiography, the lumbar AP view reveals the morphology, alignment, and symmetry of the spinal column, including the spinous and transverse processes, pedicles, facets, and lamina. Lumbarization of S1 and sacralization of L5 are also evident. The lateral view highlights osteophytes, disc space reduction, osteopenia, and vertebral slippage. The oblique view provides a clear visualization of the facet joints and pars interarticularis. The intervertebral disc exhibits dynamic and reparative properties, responding to variations such as prolonged sitting, improper posture, and excess weight, which influence vertebral kinematics. There is a strong correlation between the presence of osteophytes and other conditions like disc space reduction, osteopenia, and spinal deformities, although isolated occurrences of these conditions without accompanying symptoms do exist. Modern medical research supports classical Nidana (causative factors) as contributors to initial degeneration.
- Discussion on Examination: The examination of the back is completed by evaluating straight leg raising (SLR), muscle strength, sensation, and reflex activity in the legs. Pain and limitation during SLR are indicative of a prolapsed intervertebral disc, particularly when there is irritation or compression of a sciatic nerve root. Tight hamstring muscles can produce similar symptoms; however, if severe pain occurs, it is advisable to lower the leg just below the SLR limit and observe if gentle passive dorsiflexion of the foot reproduces the pain. If uncertainty remains, dorsiflexion of the foot at the SLR limit should be performed. This maneuver further stretches the sciatic nerve, increasing pain, without affecting the hamstrings. This is known as Lasegue's Test.

Riya Joy et al.,

CONCLUSION

Lumbar spondylosis, with its clinical manifestations, pathogenesis, and complications, can be effectively correlated with Kati Graha as described in Gada Nighraha. In this study, the majority of subjects were between 46-50 years old, with 16-20 years of work experience and an average of 8 hours of daily activity. The findings revealed significant disc space reduction primarily at L4-L5, followed by L5-S1. Structural changes, such as osteophyte formation and osteopenia, were predominantly observed at L4, L5, and S1. This study conclusively demonstrates that truck drivers are particularly susceptible to structural changes in these vertebrae. Comprehensive efforts were made to thoroughly review the literature and correlate the anatomical changes associated with lumbar spondylosis with the conditions described in Ayurvedic classics. This study highlights the occupational risks and underscores the importance of preventive measures and early intervention for individuals in similar professions.

ABSTRACT

A series containing ten 2-benzylidene-1-tosylhydrazines were synthesized by Fly-ash fly-ash: H_3PO_4 aided condensation of 1-tosylhydrazine and substituted benzaldehydes under microwave irradiation. These 2-benzylidene-1-tosylhydrazines compounds were characterized by physical constants, UV-Visible, FT-IR, 1H & ^{13}C -NMR spectral

Manikandan et al.,

data. The group frequencies of infrared $\nu(\text{cm}^{-1})$ of $\text{C}=\text{N}$, $\nu\text{SO}_2(\text{sym})$, $\nu\text{SO}_2(\text{asym})$, $\nu\text{N-H}$, NMR chemical shifts (δ , ppm) of N-H , C-H , CH_3 and $\text{C}=\text{N}$ of these hydrazine derivatives were correlated with Hammett sigma constants, Swain-Lupton's F and R parameters using single and multi-regression analyses.

Keywords: 2-Benzylidene-1-tosylhydrazines, Fly-ash: H_3PO_4 , IR and NMR Spectra, Correlation analysis, Swain-Lupton parameter

INTRODUCTION

Now-a-days hydrazine are considered to be various and good pharmaceutical applications in the chemistry and biological chemistry field[1, 2]. The hydrazine derivatives exhibit a wide-ranging interesting pharmaceutical derivatives and are also used for important intermediates in organic synthesis[3]. Because, the growing requisite for environmentally responsible means of preparing a wide diversity of chemical products demanded by society drives the quest for synthetic efficiency. For the condition of the environment, in order to minimize the utility of underdone resources and waste production, a chemical reaction should proceed with high levels of step and low cost is important[4, 5]. For the present world wanted, an ideal chemical synthesis takes place in quantitative yield, with complete control of chemo-, regio- and stereo selectivity, without by products. The synthesized hydrazine derivatives have some biological activities notably trypanocidal potency on the parasite study[6]. Hydrazine derivatives behave as polydentate ligands, depend upon the naturally occupied groups present in the hydrazine unit. And also hydrazine their complexing properties may use for the drugs based on presenting transition metals. Some glycosyl phenylhydrazones and oximes were made and respectively, proving the existence of aldehydes in molecules[7, 8]. Sulphur hydrazides exhibit a great interest owing to their importance in synthesis a variety of valuable heterocyclic compounds which have pharmaceutical activities and chemotherapeutic value[9-12] against cognitive disorder because the existence of sulphur atom. In this perspective, the high synthetic potential of unsaturated systems has made possible for the wide-spread variety of cyclic building blocks[13]. Hydrazine derivatives are also used as analytical reagents, a polymer coating of ink, pigments and fluorescent materials[14]. Many greener catalysts were used for the efficient synthesis of hydrazine compounds by using SOCl_2 -Ethanol as catalyst was used[15, 16]. Rajarajan et al., studied the linear regression analyses on the substituted (*E*)-1-benzylidene-2-(4-bromophenyl)hydrazines and (*E*)-1-benzylidene-2-(4-chlorophenyl)hydrazines[17, 18]. Manikandan et al. have investigated the regression analyses on the (*E*)-*N*-(1-(substituted phenyl)ethylidene) benzo hydrazides, (*E*)-1-Benzylidene-2-(diphenylmethylene) hydrazines and (*E*)-2-(1-phenylethylidene)-1-tosylhydrazines[19,20]. In this contemporary study is mainly focused to correlated the spectral data of hydrazines with Hammett sigma constants employing statistical-regression analysis. From the statistical work results the probability of the substituent effects of substituents were predicted.

EXPERIMENTAL

General Procedure for preparation of aryl hydrazides [16, 21]

Appropriate stoichiometric quantities of 1-tosylhydrazine (100mmol) and *meta* and *para* substituted benzaldehydes (100mmol) and 0.5 g of fly-ash: H_3PO_4 nano-catalyst were microwaves in a Microwave Oven (**Scheme1**) at 120°C by means of 30s interval time (Ragotech, RG 31L Scientific Microwave Oven, 230 V A/C, 50 Hz, 2450 Hz, 1200 rpm (beam reflector)). After the treatment of the reaction mixture, it gave 95 % of the respective hydrazines. The spectroscopic data of synthesized 2-benzylidene-1-tosylhydrazines are utilized for the examination of purity and are given in Table 1.

RESULTS AND DISCUSSION

In the contemporary work, the spectral-linearity of made 2-benzylidene-1-tosylhydrazines has been studied by assessing the substituent effects. The perceived spectral data for the benzohydrazides, UV $\lambda_{\text{max}}(\text{nm})$, infrared $\nu\text{C}=\text{N}$,

Manikandan et al.,

$\nu\text{SO}_2(\text{sym})$, $\nu\text{SO}_2(\text{asym})$, $\nu\text{N-H}$, the chemical shifts $\delta(\text{ppm})$ of N-H, C-H, CH_3 and C=N were correlated with various sigma constants [22-26].

UV spectral study

The measured UV absorption maxima (λ_{max} nm) values of the made 2-benzylidene-1-tosylhydrazines were recorded and presented in above. Regressions of these data against Hammett sigma constants, F and R parameters [22-26]. The statistical form of Hammett equation applied for the statistical evaluation is shown in equation (1).

$$\lambda = \rho\sigma + \lambda_0 \quad \dots(1)$$

where λ_0 is the maximum absorption for the parent member of the series. From the Table 2, it is evident that the UV absorption maxima (λ_{max} nm) values of except 3- NO_2 substituent of substituted 2-benzylidene-1-tosylhydrazine compounds with Hammett sigma constant σ_1 (0.906) and F (0.966) parameter give satisfactory correlations. The substituent constants σ , σ^+ , σ_R and R factors fails in correlations ($r < 0.900$). This is endorsed by the polar and resonance possession of substituents not obey the Hammett equation and the corresponding conjugative structure as displayed in Figure 1. Except σ_R , all constants gave positive ρ values. This designates the casual substituent effect operated in 2-benzylidene-1-tosylhydrazine compounds. Approximate number of mono-regressions failed and they show satisfactory correlation through multi-linear regressions with Swain-Lupton's [27] and the observed correlation equations are shown in (2) and (3).

$$\lambda_{\text{max}} (\text{nm}) = 271.98(\pm 5.7900) + 31.3610(\pm 11.6241)\sigma_1 - 18.2898(\pm 12.6158)\sigma_R \quad \dots(2)$$

($R = 0.973$, $n = 10$, $P > 95\%$)

$$\lambda_{\text{max}} (\text{nm}) = 275.06(\pm 6.2881) + 29.1058(\pm 12.3494)F - 0.5868(\pm 7.2660)R \quad \dots(3)$$

($R = 0.966$, $n = 10$, $P > 95\%$)

IR spectral study

The consigned infrared frequencies (cm^{-1}) of $\nu\text{C=N}$, $\nu\text{SO}_2(\text{sym})$, $\nu\text{SO}_2(\text{asym})$, $\nu\text{N-H}$ of substituted 2-benzylidene-1-tosylhydrazines are exist in Table 1. The measured infrared frequencies were utilized for regression analysis [22-26] and the mathematical form of Hammett equation was shown in (4).

$$\nu = \rho\sigma + \nu_0 \quad \dots(4)$$

where ν_0 is the frequency for the parent member of the series.

IR Spectral Correlation of $\nu\text{C=N}$ (cm^{-1})

From the Table 2, it is evident that the IR frequencies of $\nu\text{C=N}$ (cm^{-1}) all substituted 2-benzylidene-1-tosylhydrazine compounds with Hammett sigma constant σ (0.906) give satisfactory correlations. Except 4-F substituent of substituted 2-benzylidene-1-tosylhydrazine compounds with σ_1 ($r = 0.906$) give satisfactory correlations. However, IR $\nu\text{C=N}$ (cm^{-1}) frequencies 2-benzylidene-1-tosylhydrazine compounds fails in correlation against σ^+ , σ_R and F and R parameters ($r < 0.900$). This is happened by feeble polar, resonance and field effects substituents and the corresponding conjugative structure as displayed in Figure 1. Here negative ρ values obtained in all statistical operations and reversal of substituent effect takes place.

IR Spectral Correlation of $\nu\text{SO}_2(\text{sym})$ (cm^{-1})

From the Table 2, it is evident that the IR $\nu\text{SO}_2(\text{sym})$ (cm^{-1}) frequencies of made 2-benzylidene-1-tosylhydrazine compounds were fail in single statistical regressions along with negative ρ values. Reason for this is already stated above along with the conjugative structure as displayed in Figure 1. This inferred that the reversal effect of substituents operated in all compounds.

IR Spectral Correlation of $\nu\text{SO}_2(\text{asym})$ (cm^{-1})

From the Table 2, a satisfactory correlation coefficient was perceived for the IR $\nu\text{SO}_2(\text{asym})$ (cm^{-1}) frequency values of except 3-OH and 4-OH substituents of substituted 2-benzylidene-1-tosylhydrazines σ ($r = 0.902$) and σ^+ ($r = 0.901$). The same was failed in the constants σ_1 , σ_R , F and R factors ($r < 0.900$). Here, the regression exists positive ρ values except σ^+ and R parameter. Reasons stated earlier for failed regressions and the conjugative structure was displayed in Figure 1.

Manikandan *et al.*,**IR Spectral Correlation of $\nu\text{N-H}(\text{cm}^{-1})$**

From the Table 2, it is evident that the IR $\nu\text{N-H}(\text{cm}^{-1})$ frequency values of except 2-Cl substituent of substituted 2-benzylidene-1-tosylhydrazine compounds created agreeable correlation co-efficient for Hammett sigma σ_R ($r=0.902$) constant. However, the IR frequency $\nu\text{N-H}(\text{cm}^{-1})$ values of 2-benzylidene-1-tosylhydrazines compounds with Hammett σ , σ^+ , σ_I , F and R constraints were fails in regression ($r < 0.900$). Reasons stated earlier and the conjugative structure as displayed in Figure1 leads to fails in the regressions. Here negative ρ values exists for σ and σ_R parameter and it inferred the reversal of correlations in substituted 2-benzylidene-1-tosylhydrazines compounds. While looking the multi-regression analysis with Swain-Lupton's [27] parameters, there is a satisfactory correlations were observed and are shown in the equations (5) to (12).

$$\nu\text{C=N}(\text{cm}^{-1}) = 1573.62(\pm 22.5709) - 87.9954(\pm 45.3134)\sigma_I - 44.6426(\pm 49.1790)\sigma_R \quad \dots(5)$$

($R = 0.965$, $n = 10$, $P > 95\%$)

$$\nu\text{C=N}(\text{cm}^{-1}) = 1574.07(\pm 26.4610) - 66.2770(\pm 51.9674)F - 1.6081(\pm 30.5760)R \quad \dots(6)$$

($R = 0.946$, $n = 10$, $P > 90\%$)

$$\nu\text{SO}_2(\text{sym})(\text{cm}^{-1}) = 1164.82(\pm 7.5644) - 13.1606(\pm 15.1864)\sigma_I + 2.1043(\pm 16.4819)\sigma_R \quad \dots(7)$$

($R = 0.938$, $n = 10$, $P > 90\%$)

$$\nu\text{SO}_2(\text{sym})(\text{cm}^{-1}) = 1164.82(\pm 7.7253) - 6.3071(\pm 15.1720)F - 0.5667(\pm 8.9267)R \quad \dots(8)$$

($R = 0.915$, $n = 10$, $P > 90\%$)

$$\nu\text{SO}_2(\text{Asym})(\text{cm}^{-1}) = 1327.31(\pm 16.4202) + 30.6133(\pm 32.9651)\sigma_I - 1.4158(\pm 35.7774)\sigma_R \quad \dots(9)$$

($R = 0.933$, $n = 10$, $P > 90\%$)

$$\nu\text{SO}_2(\text{Asym})(\text{cm}^{-1}) = 1319.33(\pm 14.7134) + 34.8353(\pm 28.8961)F - 18.7761(\pm 17.0018)R \quad \dots(10)$$

($R = 0.952$, $n = 10$, $P > 95\%$)

$$\nu\text{N-H}(\text{cm}^{-1}) = 3210.7(\pm 30.6054) - 28.7828(\pm 61.4433)\sigma_I + 48.1146(\pm 66.6849)\sigma_R \quad \dots(11)$$

($R = 0.989$, $n = 10$, $P > 95\%$)

$$\nu\text{N-H}(\text{cm}^{-1}) = 3194.5160(\pm 31.3145) - 11.1116(\pm 61.4992)F - 5.4632(\pm 36.1842)R \quad \dots(12)$$

($R = 0.909$, $n = 10$, $P > 90\%$)

NMR spectral study

In nuclear magnetic resonance spectra, the proton and the ^{13}C chemical shifts (δ , ppm) depends on the electronic environment of the nuclei concerned. The allocated chemical shifts (δ , ppm) have been subjected to single regression analysis with reactivity parameters [22-26] through Hammett equations as in (13)

$$\delta = \rho\sigma + \delta_0 \quad \dots(13)$$

where δ_0 is the δ chemical shifts (δ , ppm) for the parent member of the series.

 ^1H NMR Spectral Correlation **^1H NMR Spectral Correlations of N-H (ppm)**

From the Table 2, the assigned N-H chemical shifts (δ ppm) values of except parent, 2- NO_2 and 3- NO_2 substituents of substituted 2-benzylidene-1-tosylhydrazines compounds exhibits satisfactory linear regression for σ_I ($r=0.904$). Except parent and 3- NO_2 substituent of substituted 2-benzylidene-1-tosylhydrazines produced acceptable regression co-efficient for F ($r=0.904$) parameter. However, the N-H chemical shifts (δ ppm) ^1H NMR values of 2-benzylidene-1-tosylhydrazines compounds with σ , σ^+ , σ_R and R factors fails in regressions ($r < 0.900$). Failed regression analysis is due to the reasons mentioned in earlier and the conjugative structure as displayed in Figure 1. Regressions exhibits positive ρ values except σ_R and R parameter. It inferred that the normal substituent consequence-effect operates maneuvers in 2-benzylidene-1-tosylhydrazines compounds.

 ^1H NMR Spectral Correlations of C-H (ppm)

From the Table 2, the assigned C-H chemical shifts (δ ppm) values of except 3-OH, 4-OH and 4- CH_3 substituents of substituted 2-benzylidene-1-tosylhydrazines compounds exhibits casual regression co-efficient σ constant ($r=0.936$). Similarly, except 4-OH and 4- CH_3 substituents of substituted 2-benzylidene-1-tosylhydrazines compounds exhibits casual regression co-efficient constant σ^+ ($r=0.910$). The σ_I constants produced acceptable regression co-efficient

Manikandan et al.,

($r=0.920$) except 2-Cl, 4-F and 4-CH₃ substituents. Except 3-OH and 4-OH substituents of substituted 2-benzylidene-1-tosylhydrazines compounds exhibits regression co-efficient for σ_R ($r=0.903$) constants. However, the ¹H NMR –C-H chemical shifts (δ , ppm) values 2-benzylidene-1-tosylhydrazines compounds with F and R factors were failed in regression ($r < 0.900$). The pathetic F and R factors and conjugative structure in Figure1 were leads to fails in regressions. Majority regressions exhibits positive ρ values except R parameter.

¹H NMR Spectral Correlations of -CH₃ (ppm)

From the Table 2, the assigned –CH₃ chemical shifts (δ ppm) values of except 4-F and 4-OH substituents of substituted 2-benzylidene-1-tosylhydrazines exhibits acceptable regression coefficient for σ_R ($r=0.903$) constant. Except parent and 4-OH substituents of substituted 2-benzylidene-1-tosylhydrazines exhibits reasonable regression co-efficient for F ($r=0.909$) parameter. Except 4-OH substituent of substituted 2-benzylidene-1-tosylhydrazines exposed casual regression co-efficient for R ($r=0.910$) parameter. However, the ¹H NMR –CH₃ chemical shifts (δ ppm) of 2-benzylidene-1-tosylhydrazines compounds failed for σ , σ^+ and σ_I ($r < 0.900$) constants. Failed regression is associated with the reasons stated already and the conjugative structure as displayed in Figure1. Selective regressions exposed positive ρ values except σ , σ^+ and σ_R constants. It designates that the casual substituent effects operated in substituted 2-benzylidene-1-tosylhydrazines compounds. While looking the multi-regression analysis with Swain-Lupton's parameters [27], there is a satisfactory correlations are observed as in the following equations (14) to (19).

$$\delta N-H(\text{ppm}) = 9.5696(\pm 0.1518) + 0.4069(\pm 0.3048)\sigma_I - 0.2452(\pm 0.3308)\sigma_R \quad \dots(14)$$

($R = 0.947$, $n = 10$, $P > 90\%$)

$$\delta N-H(\text{ppm}) = 9.5986(\pm 0.1538) + 0.3657(\pm 0.3022)F - 0.0624(\pm 0.1778)R \quad \dots(15)$$

($R = 0.942$, $n = 10$, $P > 90\%$)

$$\delta C-H(\text{ppm}) = 8.3668(\pm 0.2341) + 0.3380(\pm 0.4700)\sigma_I + 0.4607(\pm 0.5101)\sigma_R \quad \dots(16)$$

($R = 0.942$, $n = 10$, $P > 90\%$)

$$\delta C-H(\text{ppm}) = 8.2629(\pm 0.2460) + 0.3375(\pm 0.4832)F - 0.0596(\pm 0.2843)R \quad \dots(17)$$

($R = 0.926$, $n = 10$, $P > 90\%$)

$$\delta CH_3(\text{ppm}) = 2.3971(\pm 0.0380) + 0.0026(\pm 0.0764)\sigma_I - 0.0069(\pm 0.0829)\sigma_R \quad \dots(18)$$

($R = 0.903$, $n = 10$, $P > 90\%$)

$$\delta CH_3(\text{ppm}) = 2.3969(\pm 0.0161) + 0.0161(\pm 0.0727)F + 0.0128(\pm 0.0427)R \quad \dots(19)$$

($R = 0.945$, $n = 10$, $P > 90\%$)

¹³C NMR Spectral Correlation

¹³C NMR Spectral Correlations of C=N (ppm)

From the Table 2, the assigned C=N chemical shifts (δ ppm) of substituted 2-benzylidene-1-tosylhydrazines failed in regression ($r < 0.900$) for sigma constants, F and R factors. The reason for failed regression was stated already along with the conjugative structure d displayed in Figure1. Entire regressions produced positive ρ values except σ_R . Here the normal effect of substituents circulates in 2-benzylidene-1-tosylhydrazines.

¹³C NMR Spectral Correlations of CH₃ (ppm)

From the Table 2, the assigned –CH₃ chemical shifts (δ , ppm) values of 2-benzylidene-1-tosylhydrazines were fails in regression ($r < 0.900$) sigma constants, F and R parameter. A feeble I, R and F factors and the conjugative structure illustrated in Figure1 were sleeps for finding the regression co-efficients. Except resonance component, all regression produced negative ρ values and it referred to reversed substituent effects in whole 2-benzylidene-1-tosylhydrazines compounds. The multi regression investigations with Swain-Lupton's parameters [27] formed agreeable correlation co-efficients with the following equations (20) to (23).

$$\delta C=N(\text{ppm}) = 127.65(\pm 0.1616) + 0.3999(\pm 0.3246)\sigma_I - 0.2571(\pm 0.3522)\sigma_R \quad \dots(20)$$

($R = 0.945$, $n = 10$, $P > 90\%$)

$$\delta C=N(\text{ppm}) = 127.73(\pm 0.1693) + 0.2891(\pm 0.3326)F - 0.0065(\pm 0.1957)R \quad \dots(21)$$

($R = 0.931$, $n = 10$, $P > 90\%$)

$$\delta CH_3(\text{ppm}) = 21.5927(\pm 0.0641) - 0.1551(\pm 0.1288)\sigma_I + 0.0515(\pm 0.1398)\sigma_R \quad \dots(22)$$

($r = 0.914$, $n = 10$, $P > 90\%$)

Manikandan et al.,

$$\delta\text{CH}_3 \text{ (ppm)} = 21.5749(\pm 0.0661) - 0.0920(\pm 0.1298)F + 0.0398(\pm 0.0763)R \quad \dots(23)$$

(R = 0.920, n = 10, P > 90%)

CONCLUSION

A series of ten numbers of substituted 2-benzylidene-1-tosylhydrazines were made through the green condensation of 1-tosylhydrazine and *meta* and *para* substituted benzaldehydes. The purities of these substituted 2-benzylidene-1-tosylhydrazines analyzed from their physical constants, spectral data reported in the literature. The UV, FT-IR, NMR spectral data of these 2-benzylidene-1-tosylhydrazines were utilized for regression analysis against Hammett sigma constants, F and R factors. Many single regression and multi-regressions produced agreeable correlation coefficients.

ACKNOWLEDGEMENT

The authors thank Indian Institute of Science Education and Research, Thiruvananthapuram for recording NMR spectra of all compounds.

ABSTRACT

The multi frequency GPS satellite data obtained at Bhopal (23.2° N, 77.4° E & MLAT 14.2° N) India were analysed to study the vertical total electron content (VTEC) changes during the strong geomagnetic storms occurred on March 23-24, 2023 (Dst = -163 nT) and April 23-24, 2023 (Dst = -213 nT) i.e. ascending phase of 25th solar cycle. Positive and negative deviation with VTEC has been observed for both strong geomagnetic storms. A positive deviation on(+38%) in VTEC was observed at 0415 UT on March 24, 2023, while it is minimum (-76%) at 1533 UT on March 24, 2023. Similarly, positive deviation of +28% in VTEC was observed at 0300 UT on April 24, 2023, whereas it is minimum (-74%) was observed at 1705 UT on April 24, 2023. We compared the IRI 2020 TEC with the observed VTEC and found that it is well aligned with the storm occurred on March 24, 2023, while it is suppressed with the GPS-VTEC for April 21-25, 2023 during the main phase of storm. Generally, IRI TEC has been underestimate with GPS VTEC during the different phases of the occurred strong geomagnetic storms. The results are compared with the earlier observations and possible mechanism is also discussed.

INTRODUCTION

It is well known that the ionosphere is a non-uniform and anisotropic atmospheric layer that ranges between 80 and 1500 km from the Earth's surface. This layer contains gases from the ionized plasma by changing its state owing to the solar radiation. The ions and electrons are formed as pairs owing to ionization. Free and mobile electrons affect electromagnetic signals depending on their frequency. Ionospheric variation is influenced by space weather events, such as solar winds, solar flares, and geomagnetic storms. Disturbed space weather conditions trigger unexpected irregular changes in the magnetosphere-ionosphere-thermosphere system. Geomagnetic storms are extreme space weather events that have considerable impacts on the ionosphere and power transmission systems. Geomagnetic storms are large disturbances in the geomagnetic field that last from several hours to days. This produces a global disturbance in the Earth's magnetic field, which usually occurs owing to abnormal conditions in the interplanetary magnetic field (IMF) and solar wind plasma emissions caused by various solar phenomena. Furthermore, the magnitude of these geomagnetic effects largely depends on the configuration and strength of potentially geoeffective solar/interplanetary features. The storms are characterized by enhanced magnetospheric and ionospheric current systems (Gonzalez et al., 1994; Lühr et al., 2017). However, several current systems contribute to different ground magnetic field disturbances (or geomagnetic storms) at different latitudes. Therefore, storms at low, mid, and high latitudes are usually represented by indices such as disturbance storm-time (Dst), Kp, and AE, respectively (Love & Gannon, 2009). Storms at low latitudes arise mainly from enhanced solar wind-magnetosphere coupling and ionosphere-ring current coupling due to solar storms (Daglis, 1997; Ebihara et al., 2005). Due to geomagnetic disturbances such as geomagnetic storm sudden impulse (SI) or sudden commencements (SSCs), the magnetospheric electric field is transferred to the magnetic equator from auroral latitudes through mid-latitudes (Gillies et al., 2012; Shinbori et al., 2014; Haridas et al., 2024), and the distribution of ionospheric plasma is affected by perturbations in the field. Throughout the day, the prompt penetration electric field is eastward and amplifies the dynamo electric field. This dynamo electric field enhances the vertical $E \times B$ plasma drift by lifting the plasma to higher altitudes (Rastogi and Klobuchar 1990, Chakraborty et al., 2015). During the day, the prompt penetration electric field (PPEF) is eastward, and at night, westward (Huang et al., 2005; Sastri et al., 1997; Sastri et al., 1992). Among severe storm periods, strong eastward PPEF and super fountains are built up due to the cause of fast neutral wind, which may shift the crest of the equatorial ionization anomaly (EIA) up to $\pm 30^\circ$ latitudes (Balan et al., 2011).

The impact of geomagnetic storms is accidental in various aspects, such as the dayside compression of the magnetosphere (Borovsky & Denton, 2016; Cattell et al., 2017), increase of magnetospheric currents (Ganushkina et al., 2017; Stepanova et al., 2019), depletion and enhancement of trapped particles in the radiation belts (Moya et al., 2017; Tuner et al., 2015; Turner et al., 2019), intensification of precipitation in the auroral regions (Longden et al., 2008), qualifications in the dynamics and properties of the ionosphere, and geomagnetically induced currents on the Earth's surface (Shi et al., 2008). The TEC response to the geomagnetic storm has been reported for the station near the crest of equatorial anomaly by several authors (Bagiya et al., 2009; Dashora et al., 2007; Manju et al., 2009; Sreeja et al., 2009; Jain et al., 2010; Trivedi et al., 2011 and references therein) using GPS and ionosonde data. The TEC response to the geomagnetic storm of May 15, 2005, at Udaipur, (24.73° N, 73.73° E and GMLAT 16.12° N) India, was studied by Dashora et al. (2009), and they found that the large enhancement in vertical TEC is attributable to the prompt penetration of electric fields. The geomagnetic storm that occurred in Rajkot, (22.29° N, 70.74° E and GMLAT 13.99° N) India, was studied by Bagiya et al. (2009) at the August 24, 2005 station using GPS TEC and found that the enhancement in VTEC is attributable to prompt penetration of electric fields during the storm day, and suppression in VTEC on the subsequent recovery day is due to disturbance dynamo electric fields and thermospheric composition changes. The storm of May 15, 2005, and August 24, 2005, for Bhopal using GPS TEC data was studied by Jain et al., 2010, and it was found that the under-shielding and over-shielding conditions and peak-like structure in the EIA region were the reasons for the prompt penetration of the electric field, which was observed for both storms. Trivedi et al., (2011) studied the 21 storms of 2005-2007, for Bhopal using GPS TEC data. They also found that the suppression in VTEC was observed on August 25, 2005, which was mainly due to the thermospheric composition changes and possibly due to the disturbance dynamo electric fields. The equatorial and low-latitude ionospheres

**Amita Pal et al.,**

exhibit remarkable behaviors, which have been a subject of immense interest for the ionospheric community, including equatorial ionization anomaly (EIA), equatorial electrojet (EEJ), equatorial spread-F (ESF), etc. (Chkraborty et al., 2015). Recently, the storm-induced responses of ionospheric total electron content (TEC) over the Indian region and Atlantic-Pacific Ocean sectors were studied by Simi et al. (2021) and Akala et al. (2011), respectively. They assumed that PPEFs triggered ionospheric irregularities during the main phase of storms. Positive (negative) ionospheric storms are defined as the increase (decrease) in ionospheric metrics such as peak electron density (N_{\max}), electron density (N_e), and TEC from their respective quiet-time values caused by geomagnetic storms. The magnitude and characteristics (whether positive or negative) of ionospheric storms depend on the latitude (Shreedevi & Choudhary, 2017), local time (Maruyama et al., 2004), and phases of geomagnetic storms (Pedatella et al., 2009; Haridas et al., 2024). The International Reference Ionosphere (IRI) is an empirical model based on data from the worldwide network of ionosonde stations, incoherent scatter radars (at Jicamarca Arecibo, Millstone Hill, Malvern, and St. Santin) and has been widely accepted as a reliable ionospheric model (Sahu et al., 2021) used by the scientific community. Several studies have been conducted comparing IRI-TEC and GPS-VTEC over different regions, and the IRI model has been steadily improved from IRI-78 to IRI-2016 (Rawer et al., 1978; Bilitza, 1986, 1990, 2001; Bilitza and Reinisch, 2008; Bilitza et al., 2014) and now IRI-2016 (Bilitza et al., 2017), and the latest is IRI-2020 (Bilitza et al., 2022).

Sahu et. al. (2021) compared GPS-VTEC with IRI-TEC for quiet days during the study period of May 2016 to August 2017 and observed that IRI-TEC consistently underestimated GPS-TEC across all months during the study period. Furthermore, He et. al. (2023) evaluated the ionospheric response over China using TEC data from the IRI-2020 model and the GNSS-GIM model. Yang et al. (2023) conducted a statistical analysis of latitude-dependent variations over mainland China using TEC data and the IRI-2020 model. Mridula et al., (2024), the ionospheric response over the equatorial region India was compared and analysed using TEC data from the IRI-2020 and TIE-GCM models, revealing that IRI-TEC underestimated the observed GPS-TEC. Recently, Jain et al. al. (2024) Compared the IRI-2020 model and the GPS-VTEC model for super-intense geomagnetic storms occurred on 10-11 May, 2024 at Bhopal. The procedure of monitoring the ionosphere with the Global Positioning System (GPS) is currently widely used. GPS is an effective tool to investigate ionospheric structure owing to its continuous operation and the large number of worldwide receivers, mainly during magnetically disturbed periods when dynamics and energy dissipation processes in the magnetosphere–thermosphere–ionosphere system become extremely complex (Liu et al., 2002, Trivedi et al., 2011). In the last three decades, many authors have studied several individual measurements of TEC variation with local time, season, and solar activity. Since the past few decades many authors using different techniques observed and reported the ionospheric response to geomagnetic storms at low and equatorial latitudes in the Indian longitude (Dabas et al., 1989; Dabas et al., 2006; Dashora and Pandey, 2007; Sreeja et al., 2009; Trivedi et al., 2011 and references therein). Chakraborty et. al. (2015) examined the impact of geomagnetic storms on the low-latitude ionosphere of the Indian equatorial region. They found that there was a significant increase in VTEC of up to 150% and a decrease of up to 72% throughout the storms of April 24 and July 15, 2012. Electron dynamic effects, such as PPEF and DDEF, as well as mechanical effects, such as storm-induced equatorward neutral wind and thermospheric composition changes, were observed. The electrodynamic effect of geomagnetic storms around the region is more effective than that at lower latitudes, and this was further confirmed by using the O/N₂ ratio and VTEC map, which was constructed from International GNSS Service (IGS) data.

Jain et. al., (2024) observed at Bhopal (23.2° N, 77.4° E & MLAT 14.2° N) for super-intense geomagnetic storms that occurred on May 10 to 11, 2024 (Sym-H: -518 nT) were studied using the (VTEC). It was observed that the super-intense geomagnetic storm produced positive and negative influences on the VTEC. They observed a +61 % deviation in VTEC at ~ 0500 UT on May 12, 2024, whereas (-68.5%) deviation in VTEC was observed at ~ 2045 UT on May 11, 2024. The increase in VTEC (+24% to 50%) during the main phase of the storm was attributed to the prompt penetration of electric fields (PPEFs), and the suppression of VTEC during the recovery phase of the storm was attributed to the changes in the thermospheric composition and ionospheric disturbance dynamo electric fields (DDEF). They also compared IRI-2020 TEC with the observed VTEC and found that the IRI-TEC model accurately estimated the suppression in TEC on May 11 and 12, but could not reflect the wave-like structure observed in VTEC on May 12, 2024. In this study, an attempt was made to study the effect of two geomagnetic storms that occurred on

Amita Pal et al.,

March 23, 2023 and April 23, 2023, that is, the rising phase of 25th solar cycle. The investigation aims to study the effect of storms on the low-latitude ionosphere, with the aid of GPS-based TEC measurement from an Equatorial Ionization Anomaly (EIA) Bhopal (23.2° N, 77.4° E & MLAT 14.2° N) station.

DATA AND METHOD OF ANALYSIS

To study the ionospheric variability and irregularities over a station near the crest of the equatorial ionization anomaly, a multi-frequency GPS receiver was installed at the Upper Atmospheric Laboratory of the Institute for Excellence in Higher Education (IEHE) in Bhopal (23.2° N, 77.4° E & MLAT 14.2° N) in April 2016. with the collaboration of the Space Physics Laboratory, VSSC Thiruvananthapuram, under its In-SWIM science program. The receiver tracks signals from the GPS, GLONASS, GALILEO, SBAS, COMPASS, and QZSS constellations of GNSS satellite systems. Each satellite is identified by a unique sequence of number called Pseudo Random Number (PRN). The multi frequency GPS receiver can track GPS signals at L1 (1575.42 MHz), L2 (1227.60 MHz), and L5 (1176.45 MHz) frequencies. The receiver generates and outputs 50-Hz phase and amplitude samples for all visible satellites and frequency bands. The TEC data are recorded every minute for all satellites tracked by the receiver. Amplitude and phase scintillation data along with satellite PRN, azimuthal angle, and elevation angle are also recorded simultaneously. We used TEC data for March 21-25, 2023 and April 21-25, 2023, recorded by a GPS receiver, and their responses to two geomagnetic storms are presented in this paper. The total electron content (TEC) is defined as the line integral of electron density on a given ray path. This slant TEC (STEC or simply TEC) corresponds to the total number of free electrons along a cylindrical path with a 1 m² cross-sectional area. The unit of TEC is equal to TECU, where 1 TECU is equal to 10¹⁶ electrons/m². When TEC is calculated on a vertical path in the local zenith direction, it is called the vertical total electron content (VTEC). STEC is converted to VTEC by assuming the penetration point of the satellite ray path with the ionospheric thin shell at a height of 350 km from the Earth's surface as follows:

$$VTEC = \cos \chi \cdot STEC$$

where χ is the angle of incidence at an altitude of 350 km of the GPS ray path from the satellite to the ground receiver, and $\cos \chi$, an oblique factor:

$$\cos \chi = \sqrt{1 - \left(\frac{R_E \cos \theta_e}{R_E + H_{iono}} \right)^2} \quad \dots\dots (1)$$

where R_E , is the radius of the earth; θ_e , the elevation angle of the satellite; and H_{iono} , the height of ionospheric penetration point (IPP) usually assumed to be 350-400 km. It follows that an IPP height of 350 km for the Indian region can be suitably used for vertical TEC calculation (Jain et. al., 2024, and references therein). To remove multipath errors, the data were filtered for elevation angles less than 30°. In order to study the effect of two geomagnetic storms on low-latitude TEC during the data of Interplanetary magnetic field (IMF Bz), Proton density (Np), Speed velocity (Vp), have been obtained from internet through (<http://omniweb.gsfc.nasa.gov/from/dx1.html>) and Sym-H, dsym-H/dt data for March and April 2023 were collected from the website of the World Data Center (WDC) for Geomagnetism, Kyoto. The response of the ionosphere to geomagnetic disturbance is most conveniently described in terms of Δ TEC (the percentage deviation of TEC) from the quiet time value (Jain et. al., 2024, and references therein).

$$\Delta TEC\% = \left[\frac{TEC_{disturb} - TEC_{quiet}}{TEC_{quiet}} \right] \times 100\% \quad \dots\dots (2)$$

Where $TEC_{disturb}$ = TEC on disturb day, TEC_{quiet} = TEC on quiet day

We restricted our analysis to over five days from the day of the main phase onset (MPO) and to four days subsequent to the MPO of the storm. In this paper, we present an analysis of TEC behavior and percentage deviation of TEC with respect to the average quiet day TEC of the month). We followed the Classification of geomagnetic storms characterised by Sugiura and Chapman 1960, and grouped as Extreme ($Dst_{min} < -350$ nT), Severe (-250 nT $\geq Dst_{min} \geq -350$ nT), Strong ($-100 \geq Dst_{min} \geq -250$ nT), and Moderate ($-50 \geq Dst_{min} \geq -100$ nT) and weak ($-30 \geq Dst \geq -50$).

IRI-2020 data set was download from <https://kauai.ccmc.gsfc.nasa.gov/instantrun/iri/> with default parameters for geographic latitude 23.2° N, 77.4° E (Bhopal) from March 21-25, 2023 & April 21-25, 2023. As this data set is of 1-hour interval, we also used the 1-hour average of VTEC for a better comparison with IRI-TEC (Jain et. al., 2024).

Amita Pal et al.,

RESULTS AND DISCUSSION

Geomagnetic condition

To study the impact of strong geomagnetic storms on the ionosphere, we selected two cases of storms that occurred on March 23, 2023 ($Dst_{min} = -163$ nT) and April 23, 2023 ($Dst_{min} = -213$ nT). The details of geomagnetic parameter variations during these storms are described in the following subsections.

Storm on March 23, 2023

The effect of strong geomagnetic storm occurred on March 23, 2023 is shown in Figure-1 (a-f) for the period March 21-25, 2023. The solar wind (proton) speed (V_p), proton density (N_p), IMF Bz, and Dst are shown in Figure-1 (a-d). The Vertical total electron content (VTEC) and percentage deviation of VTEC are given in Figure 1 (e-f), respectively. It is observed in Fig. 1(a) that the solar wind speed (V_p) was almost constant until 1100 UT on March 21, 2023, and then started increasing gradually, after which small amplitude fluctuations were observed from March 21, 2023 at 1700 UT to March 23, 2023, at 2350 UT, then it again started decreasing gradually and reached its minimum value of 412 km/s at 1600 UT on March 24, 2023. Subsequently, it again started increasing gradually and reached a maximum value of 586 km/s at 2000 UT on March 25, 2023. Fig. 1(b) illustrates two peaks (~ 30 cm⁻³) in solar wind density, around 1400 UT on March 23, 2023 and around 0800 UT on March 24, 2023 during main phase and recovery phase of the storm respectively. As shown in Fig. 1(c), After 0600 UT on March 21, 2023, the IMF Bz fluctuated with a small amplitude in the northward and southward directions and then turned southward at 0805 UT on March 23, 2023. IMF Bz remains in southward direction for approx. eight hours and then turned northward again and reached a normal value at ~ 0900 hrs UT on March 24, 2023. The rapid decline in IMF-Bz triggered the main phase of geomagnetic disturbance. The rapid decrease (increase) in IMF-Bz and the ensuing under-shielding (over-shielding) condition resulted in an eastward (westward) PPEF during the daytime and westward (eastward) at night. This phenomenon generates upward (downward) and downward (upward) vertical plasma movements in the equatorial ionosphere and low-latitude regions, respectively (Jain et al., 2024 and references therein).

From Fig. 1(d), it can be observed that the main phase onset (MPO) occurred at ~ 0800 UT on March 23, 2023. Dst reached its minimum value of -163 nT at 0315 UT on the subsequent day (March 24, 2023). It recovered its normal value of ~ 2000 UT on March 25, 2023. During this strong geomagnetic storm, variations in VTEC and $dVTEC$ are shown in Fig. 1(e) and Fig 1(f), respectively. On March 23, 2023, at 2030 UT approx. -50% deviation in VTEC was observed during the main phase of the storm. This may be due to the northward turning of IMF-Bz ~ 1600 UT and there by penetration of the westward electric field in the region. On March 24, 2023 $\sim +38$ % deviation in VTEC was observed during the recovery phase of the storm (~ 0500 UT). This may be attributed to the ionospheric disturbance dynamo effect in the region. After 0500 UT on March 24, 2023, the whole-day TECU was suppressed during the recovery phase and -75 % deviation in VTEC was observed at ~ 1500 UT. This may be attributed to thermospheric neutral composition changes in this region due to the Joule heating effect at auroral latitudes, which generates long-lived electric field disturbances at mid and low latitudes. The VTEC declined, from the normal peak of ~ 120 TECU, (~ 1000 UT) on March 21, 2023 to 50 TECU ($\Delta = -70$ TECU) at ~ 1000 UT on March 23, 2023 at Bhopal in Fig. 1(e).

This suppression is similar to the observations reported by several researchers for the equatorial and EIA region (Bagia et al., 2009; Chakaraborty et al., 2015; Choudhary et al., 2024; Jain et al., 2010; Shreedevi and Choudhary, 2017; Jain et al., 2024). Recently Rajana et al., 2023 conducted study for two stations KLEF (16.44° N, 80.62° E, GMLAT, 8.03° N) and HYDE (17.42° N, 78.55° E, GMLAT, 9.15° N) and concluded that $dVTEC$ declines in the range of 50-60 TECU, while for the low-latitude station IISC (13.02° N, 77.57° E, GMLAT, 4.86° N) it showed a $dVTEC$ of around 20 TECU for the same storm occurrence on March 22-23, 2023. These reductions in TEC indicate a significant negative ionospheric storm effect. Our results are similar and support the result reported by Rajana et al. (2024). Global Ultraviolet Imager (GUVI) onboard the Thermospheric-Ionosphere-Mesosphere Energetics and Dynamics (TIMED) satellite observes the column-integrated oxygen to molecular nitrogen ratio (O/N₂) (<https://guvitimed.jhuapl.edu/>). The daytime O/N₂ measurements were assimilated in the research to elucidate the response of ionospheric F-layer electron density variations. Fig. 2 presents the TIMED/GUVI images from March 22, 2023, to March 25, 2023, depicting the map of the

**Amita Pal et al.,**

[O/N₂] ratio, with values denoted by different colors. The approximate location of the receiver is indicated by the red arrow. As illustrated in Fig. 2, it is observed that on March 22, 23, and 24, 2023, no color is visible in the region of interest, potentially due to inadequate data recording. However, on March 25, 2023, a suppression in the region (~0.8-0.9) is clearly discernible in green. The suppression in VTEC from March 23, 2023, to March 25, 2023, is attributed to thermospheric neutral composition changes induced by the Joule heating effect at auroral latitudes, which generates long-lived electric field disturbances at mid and low latitudes.

Storm on April 23, 2023

An extremely active solar region emitted a halo Coronal Mass Ejection (CME) that reached Earth's vicinity, subsequently causing a severe geomagnetic storm on April 23-24. The effect of this geomagnetic storm is shown in Figure-3 for the period April 21-25, 2023. The solar wind (proton) speed (V_p), proton density (N_p), Dst, and IMF Bz are shown in Figure-3 (a-d). The vertical total electron content (VTEC) and percentage deviation of VTEC are given in Figure 1 (e-f), respectively. Figure 3(a) illustrates that the solar wind speed (V_p) reached its minimum value of 372 km/s at 0213UT on April 21, 2023. The value remained approximately constant from April 21, 2023 until 1805 UT on April 23, 2023. Subsequently, the solar wind speed began to increase gradually, reaching its maximum value of 711km/s at 2108 UT. Thereafter, it decreased gradually, and the solar wind speed stabilized at 524 km/s during the recovery phase of the storm. Fig. 3(b) illustrates the solar wind proton density. Its minimum value was 2.2 cm^{-3} at 0200 UT on April 21, 2023, after which it began to increase gradually, reaching 7.9 cm^{-3} at 1400 UT on April 21, 2023, before gradually decreasing. Subsequently, it remained constant from April 21, 2023 at 1600 UT to April 23, 2023 at 0800 UT. Following this period, distinct peaks were observed in the solar wind density. The first peak was recorded on April 23, 2023, with a value of 18.9 cm^{-3} at 2000 UT, while the second was observed on April 24, 2023, with a value of 14.1 cm^{-3} at 2400 UT. These two peaks occurred during the main phase of the storm. Variations in IMF Bz are depicted in Fig 3(c). On April 23, 2023, it exhibited initial fluctuations, moving southward before transitioning northward. Subsequently, it shifted slightly southward, reaching a value of -21 nT at 2000 UT, before turning strongly northward with a value of 12.1 nT at 2305 UT on April 23, 2023. Following this, it again shifted slightly southward, then northward, before experiencing a sudden southward drop. It reached its lowest value of approximately -32.4 nT at approximately 0305 UT on April 24, 2023, and attained its highest value of 22.5 nT at 1710 UT on April 24, 2023. It subsequently turned southward again and returned to its normal value on April 25, 2023.

The value of Dst remained approximately constant from April 21, 2023, at 0100 UT to April 23, 2023, at 0908 UT. The Dst value began to decline gradually from approximately 1600 UT on April 23, 2023, subsequently reaching a value of -163 nT at 2210 UT on April 23, 2023. Following a slight increase, it gradually decreased to the minimum Dst value of -213 nT at approximately 0605 UT on April 24, 2023. Subsequently, the recovery phase commenced, and the Dst value returned to its normal level on April 25, 2023, as illustrated in Fig. 3(d).

The variation in VTEC and percentage deviation in VTEC (d VTEC) are shown in Fig 3(e) and Fig 3(f) respectively. The VTEC peaks occur during April 21-23, 2023 at 1000 UT (~110 TECU) was slightly suppressed on April 24, 2023 (1000UT) on the storm day Fig 1(e). In addition, +28% deviation in VTEC was observed at ~ 0300 UT, which may be attributed to the prompt penetration of the electric field, aligning with the rapid decrease in IMF-Bz (-32.4 nT). Afterwards it drops again and the whole day VTEC was suppressed on April 24, 2023. This may be attributed to the thermospheric neutral composition changes and supported by the reduction in O/N₂ ratio in this region (refer Fig. 4). Our results for storm occurred on April 23, 2023 are agrees with the result reported by Rajana et al., 2024 for multiple stations, which falls in EIA region, Figure 4 shows the TIMED/GUVI images from April 22, 2023, to April 25, 2023, which shows the map of the [O/N₂] ratio, whose values are marked by different colors. The approx. location of the receiver is indicated by the red arrow. Suppression in the [O/N₂] ratio (0.7–0.8) is clearly visible on the day of the storm of April 23, 2023, as compared to April 22, 2023 (~0.8–0.9) and April 24, 2023 (~0.9–1.0). A similar suppression in the [O/N₂] ratio was found on April 25, 2023 (~0.7–0.8). Comparable findings were documented by Bagia et al. (2009) and Tiwari et al. (2011) regarding the geomagnetic storm that occurred in August. Using GPS-VTEC. Their research noted an increase in the O/N₂ ratio on August 24 and a decrease on August 25, based on TIMED/GUVI images. Recently, similar results were reported by Jain et al. (2024) for May 10-11, 2024 severe geomagnetic storm. The electron loss at the F2 peak was influenced by recombination/attachment with N₂; as N₂ density decreased

**Amita Pal et al.,**

(increased), electron density increased (decreased), resulting in a positive (negative) storm effect. Suppression in VTEC from April 23, 2023 to April 25, 2023, is attributed to thermospheric neutral composition changes by joule heating effect at auroral latitudes that generates long lived electric field disturbances at mid and low latitudes

Comparison with IRI-2020

We compare the observed GPS-VTEC with the TEC obtained from the IRI-2020 model for the March 23-24, 2023 and April 23-24, 2023 geomagnetic storms, and our results are presented in Fig. 5 and 6 respectively. In these figures, GPS-VTEC is depicted in blue, while IRI-TEC is represented in magenta. As illustrated in Fig. 5, the IRI-TEC exhibited close agreement with observed GPS-VTEC during the initial and main phases of the storm occurred on March 23. On March 21, 22, 24, and 25, 2023 IRI-TEC underestimated the observed GPS-VTEC values by approximately 38, 39, 40, and 20 TECU, respectively. Fig. 6 clearly indicate that the IRI-TEC underestimated GPS-VTEC during the all phases of the storm occurred on April 23, 2023.

CONCLUSION

In the present study, we investigated the ionospheric response to two strong geomagnetic storms that occurred during the ascending phase of 25th solar cycle on March 23-24, 2023 and April 23-24, 2023 over Bhopal and near the crest of the equatorial anomaly region. Prompt penetration electric fields (PPEFs) originating from under-shielding and over-shielding conditions demonstrated enhancement and suppression in vertical total electron content (VTEC) during the recovery phase for both storms. The suppression in VTEC during the recovery phase of the storm is attributed to the combined effect of thermospheric composition changes in this region, which is consistent with observations reported by several researchers for the equatorial and equatorial ionization anomaly (EIA) region (Bagia et al., 2009; Chakraborty et al., 2015; Choudhary et al., 2024; Jain et al., 2010; Shreedevi and Choudhary, 2017; Rajana et al., 2024). We also evaluated the performance of IRI-2020 for these strong geomagnetic storms. The results are summarized as follows:

- The March 23-24, 2023 and April 23-24, 2023 strong geomagnetic storms produced both positive and negative impacts on the VTEC at Bhopal.
- -76% deviation in VTEC during the main phase of the storm may attributed to the westward PPEFs and thermospheric neutral composition changes at 1533 UT on March 23, 2023 at Bhopal.
- A positive impact with a +38% deviation in VTEC was observed at approximately 0415 UT on March 24, 2023, which may be attributed to the presence of ionospheric disturbance dynamo effect in the region.
- A positive impact with a +28% deviation in VTEC was observed at approximately 0300 UT on April 24, 2023, attributed to PPEFs, whereas a negative impact of approximately -74% deviation in VTEC was observed at 1705 UT on April 24, 2023, and can be attributed to thermospheric neutral composition changes.
- Both the storms occurred on March 23-24, 2023 and April 23-24, 2023, shows positive deviations in the local morning hours while negative deviations were evident in the evening hours.
- IRI-TEC aligned well with GPS-VTEC during the storms occurred on March 23, 2023. However, it underestimates GPS-VTEC on the remaining days of both storms.

ACKNOWLEDGEMENT

The authors are thankful to SPL VSSC Thiruvananthapuram for installing the GPS receiver at Bhopal. Solar wind speed (Vp), Solar wind density (Np), Disturb storm time (Dst) index and Interplanetary magnetic field (IMF-Bz), data are downloaded from (<http://omniweb.gsfc.nasa.gov/from/dx1.html>). The Authors are thankful to reviewers for their specific suggestions.

ABSTRACT

In the phase of urban growth and industrialization, groundwater resource is utmost natural resource used widely in various region from rural to semi-urban and urban area for irrigation and drinking purpose. In Aundha Nagnath tehsil, majority of area covered by rural settlements; hence, quality of groundwater is meticulously accompanying with health of this rural inhabitants. Therefore, detailed hydrochemical investigation has been carried out along with its suitability for drinking and irrigation uses. On the basis of geomorphology, geology, LULC etc., a total one hundred and twenty (120) representative water samples were collected from study region during pre-monsoon (PRM) and post-monsoon (POM) periods of year 2023. The major ions including cations and anions were analyzed by standard procedures of American Public Health Association (APHA). Analytical results of groundwater samples were compared with standard guidelines given by World Health Organization (WHO, 2017) for drinking use. It is observed that water quality parameters like pH, magnesium (Mg), sodium (Na), calcium (Ca), sulphate (SO_4), chloride (Cl) are within allowable limit, excepts a few parameters like electrical conductivity (EC), total hardness (TH), total dissolved solids (TDS), potassium (K), nitrate (NO_3) and bicarbonate (HCO_3) exceed the permissible limit (PL) of the WHO from PRM and POM seasons. The groundwater quality is mainly influenced by both anthropogenic and geogenic inputs. Water Quality Index (WQI) has been used to examined groundwater quality of drinking purpose and results signify that more than half of the area shows poor water quality for drinking in PRM and POM. The United States Soil Laboratory Staff's (USSL's) proposed a method for identification of groundwater quality for irrigation suitability and both PRM and POM results from present study depicts that low sodium and moderate to high salinity hazards.

Keywords: Groundwater, Hydrochemistry, Basaltic terrain, Irrigation, WQI, GIS

Vaishnavi Raut et al.,

INTRODUCTION

One of the basic and vital resource for living things in the world is groundwater. It is routine for drinking, agricultural, industrial and domestic purpose worldwide (Wagh et al. 2016). Major reserves of freshwater on the earth are occur as groundwater, which has been contributory approximate 100-times more water than numerous freshwater bodies like ponds, streams and lakes (Kumar et al. 2005). Now a days groundwater is a main growing reserve for consumption for all living being. Moreover, groundwater occurred in subsurface region which is stored in the rock openings. The annually usable surface water and subsurface water resources of India are predictable as 396 km³ and 690 km³ per year respectively (Dhingra et al. 2021). The groundwater moves through aquifer material, ionic constituents are dissolved in groundwater as of the minerals and rocks with which the water has reacted, either precipitating or dissolving (Zhou et al. 2000). In central India, particularly in Maharashtra Deccan volcanic provinces aquifers are the important source of subsurface water (Pawar et al, 2008). The groundwater travels through pore spaces and follow an easiest path within rocks material and it responds to mineral that dissolve from the rocks during the course of migration (Amadi et al. 2012; Boateng et al. 2016). Geogenic factors like lithology of any region plays a dynamic role to regulates geochemistry of groundwater and it signify the rock domain impact on water quality (Wagh et al. 2020). In India, rise in the groundwater demand owed to fast rising inhabitants, faster step of industrial expansion and development (Yisa and Tijani, 2010). The groundwater appropriateness for irrigation and drinking is significantly based on the concentration of major ions existing in the groundwater (Wagh et al. 2016). The groundwater deterioration is due to fast rising expansion and industrialization universally and due to overexploitation (Wagh et al. 2019a). Understanding groundwater chemistry is the critical fundament for mechanism analysis and quality evolution (Gaikwad et al. 2019; 2020b, Yunhui Zhang et al. 2021).

The study area is very significant in groundwater quality point of view and it needs to understand the geochemistry of groundwater for any further involvements if desirable. The worsening of groundwater is due to fast growing expansion and industrial development in the world (Gaikwad et al. 2020a). Hydrochemical investigation of water quality parameters like pH, EC, TDS, TH, HCO₃, major anions like Cl, NO₃, SO₄ and major cations like K, Ca, Na and Mg are essential for better understanding of overall superiority of groundwater from the study region. WQI has been assigned by Horton (1965) to regulate the excellence for drinking water in an index scale. It helpful for classification of drinking water excellence in an easiest way on scale of excellent to poor and its convenient for users in a particular area for good management of water resources. Many investigators have used this method from different locations worldwide for better classification of water quality which helps to end user easily. (Sethy et al., 2017; Trikoilidou et al., 2017; Alhadithi, 2018; Wagh et al., 2019b; Kadam et al., 2019a). The groundwater has been increasingly advanced as a backbone of India's drinking and agricultural water safety with its excellence and its contribution practically 62% in agriculture, 50% in urban water supply and 85% in rural water supply (CGWB, 2022). Based on SAR (Sodium Adsorption Ratio) and EC (Electrical Conductivity) values of the groundwater, proposed a diagram to ascertained the aptness of waters for agricultural persistence by USSLS's. USSSL diagram is the representation of water eminence for irrigation suitability by different classes of sodium and salinity hazard. Hence, the present research has been performed in the Aundha Nagnath region to study the hydrochemical evaluation through WQI and GIS with the main objectives of 1) to study the hydrochemical evaluation of major ions from pre- and post-monsoon seasons, 2) to ascertain the geological or anthropogenic influences through WQI and USSSL techniques, 3) to demarcate the polluted groundwater zones with the help of GIS tools.

Study area and geology

The Aundha (Nagnath) tehsil is located 19° 40' to 19° 71' N latitude and 76° 86' to 77° 24' E longitude and covered under Survey of India (SOI) toposheet numbers 56A/11, 12; 56A/14, 15, 16 and 56E/2, 3, 4 on the 1:50,000 scale (Fig.1). It is a part of Hingoli district and covers an area of approximately 813.17 km². Sidheshwar dam is one of the water reservoirs which is constructed on Purna river. The river Godavari, Purna, Asna, Kayadhu are the main river basin which is associated to drainage network of dendritic to sub dendritic in the study region (Sahu et al. 2020). Physiographically terrain exhibits the elevated mountain of Ajanta hill ranges with Hingoli Plateau of moderate to low

**Vaishnavi Raut et al.,**

towards south slope and elevation ranges from 561m to 304m above mean sea level (AMSL). Climatic conditions are dry except during southwest monsoon and annual precipitation of approximately 750 to 900 mm (GSDA, 2001). The range temperature is varying from 12.7 °C to 42°C in winter and summer seasons; however, hot and dry summers are more extreme than winters (CGWB, 2013). Soils of the study area derived from the parental rock Deccan basalt. The area under investigation is a part of the Deccan Trap with diverse lithology is a part of Deccan Trap Super group (Table 1). The litho units in the area include Deccan Trap Super group of Upper Cretaceous to Palaeocene age and inland river valley of alluvial sediments of quaternary age. The three main geological formations from the study region are Buldhana, Chikhli and Ajanta. The younger formation is Buldhana followed by Chikhli and Ajanta. It is consisting of three 'aa' flows in study area region. These lava flows are light grey, sparsely to moderately porphyritic with ropy surface. The Chikhli formation is comprising of one mixed flow with large aerial extent and is a rhythmically layered sequence of compound 'pahoe' and 'aa' units, while; Ajanta formation Comprises of three lava flows from study region are of mixed nature. These are rhythmically layered sequence of 'pahoe' and 'aa' flows where the upper part is vesicular and basal part with pipes and amygdules. The alluvium in the study area is of Quaternary age with dark to grey clay, silt, sand and gravel in nature (Fig. 1), (Table 1).

MATERIAL AND METHODS

In this study, a total number of 120 representative water samples were collected from pre-monsoon (PRM) and post-monsoon (POM) seasons (May 2023 and December 2023) from bore well (BW), dug well (DW), hand pump (HP) and surface water (SW) from the different locations with considering settlement, drainage pattern, geomorphology, geology etc. Out of 60 samples, 29 samples are from DW, 19 samples of BW, 11 samples of HP and 1 sample is SW i.e., Shiddheshwar Dam (Fig.1). Prior to water sample collection, one litre pre-sterile plastic bottles of poly-ethylene material were used. The sample bottles were labelled and sealed properly and brought to the laboratory for further analysis of physicochemical parameters. The physico-chemical analysis was carried out with standard analytical protocols of American Public Health Association (APHA, 2016). The location coordinates were recorded by Garmin eTrex 10 GPS for preparation of sampling location map. The parameters such as pH, EC and TDS were measured in field by Aquaread AP-700 and Multi-Parameter PCS Tester 35. Further, titrimetric method was used to calculate TH, Ca^{2+} , Cl^- and HCO_3^- . SO_4^{2-} and NO_3^- concentration was analysed on spectrophotometer (Shimadzu UV-1800). Na^+ and K^+ were determined using Systronics 108 flame photometer. For analytical precision, charge balance error (CBE) is considered and found within $\pm 10\%$. WQI method is used to expressed the water quality as excellent, good, poor, very poor and unfit for drinking based on its numerical values. Also, spatial distribution maps were prepared for better understanding of poor water quality zones using Arc GIS 10.8 v software. USSL is well design diagram used for irrigation suitability based on SAR and EC values.

RESULTS AND DISCUSSION

Hydrochemical investigation

Generally, the pH, EC, TH and TDS are both anthropogenically and lithologically affected in the various study area. The Ca^{2+} , Mg^{2+} , Na^+ and K^+ cations are dominated through geogenic (basalt) and agricultural sources; while, the Cl^- , SO_4^{2-} and NO_3^- ions derived mainly from uses of chemical fertilizers, pesticides and man-made activities (Wagh et al. 2019a, Farid et al. 2023). pH is on scale, EC in $\mu\text{S}/\text{cm}$ and remaining all parameters are in mg/l (PL: Permissible Limit, DL : Desirable Limit) Hydrochemical analysis of both PRM and POM seasons illustrated in table 2, reveals that pH values varying from 6.35-8.5 in PRM and 5.9-8.3 in POM with an average value of 7.64 and 6.9 respectively. According to WHO2017 drinking standards majority of samples from both the monsoon are below PL. pH of groundwater shows acidic to alkaline in nature is owed to basaltic terrain (Pawar et al. 2008). EC values vary from 313-2370 (PRM) and 365-1729 (POM) with its average values of 847.13 and 790. The TDS shows below PL with mean values of 600.25 and 561.83 in PRM and POM seasons. From the result of TH, it specifies that water is hard for drinking use and may owed to Ca and Mg rich natural factors like basaltic rocks contributing in geochemistry (Wagh et al. 2019a, Deshpande, 1998). Cationic trend is in ascending order of $\text{Ca} > \text{Na} > \text{Mg} > \text{K}$ (PRM) and $\text{Mg} > \text{Na} > \text{Ca} > \text{K}$ (POM)

Vaishnavi Raut et al.,

with majority of samples is below permitted limit except a few of K samples and signifying those high values of Ca and Mg are due to basalt terrain reveals the geogenic inputs from olivine, plagioclase, biotite etc minerals bearing lithology (Pawar et al. 2008). The tendency of anions is in increasing trend of $\text{HCO}_3^- > \text{Cl}^- > \text{SO}_4^{2-} > \text{NO}_3^-$ in PRM and POM. This tendency evidently signifying contribution of anthropogenic contamination of Cl^- , SO_4^{2-} and NO_3^- in groundwater (Wagh et al. 2016, 2020; Gaikwad et al. 2020b; Patil et al. 2024). As compared to WHO limits, geochemistry of major ions specifies that overall groundwater quality from study area is moderately suitable for drinking purpose. According to Davies and DeWiest classification (1966)(table 3), 45% (PRM) and 46.67% (POM) samples falls in desirable for drinking category. The remaining 46.66% (PRM) and 53.33% (POM) samples and 8.34% (PRM) and 5% (POM) samples are permissible for drinking which is generally freshwater and useful for irrigation (freshwater to brackish water) respectively. Aquifer bodies with long dwell times, weathering parent rock components, salts from the soil and wastewater, all contribute to the groundwater elevated dissolved solids levels (Subramani et al. 2010; Nematollahi et al. 2016). In this area the main contributor of TDS concentration is weather basalts (Dimple et al. 2023). The classification based of EC values (Dar et al. 2011), permissible class represented 91.66% (PRM) and 96.66% (POM) samples and 8.34% and 3.34% from PRM and POM seasons, characterised as not-permissible class and these samples are influenced by salinity and human activities leads to more concentration. No one sample from study region shows hazardous class (table 4). Sawyer and Mc Carty classification (1967) is represented in table 5, which specifies that groundwater hardness based on different classes, 8.34% and 0% of samples from pre- and post-monsoon season shows soft water category; while, 43.33% (PRM) and 1.67% (POM) samples indicating moderately high class with range of 75-150 mg/l. It observed that 41.66% and 6.67% (PRM) and 41.67% and 56.66% (POM) samples fall under hard to very-hard water types respectively which is owed to presence of alkaline earth elements in the study area (Pawar et al. 2008).

Computation of Water Quality Index (WQI)

WQI is used widely to ascertain the water quality for beneficial use in any study region. The WQI has computed by considering various water quality variables like pH, EC, TDS, TH, cations (Ca, Mg, Na, K) and anions (Cl^- , NO_3^- , SO_4^{2-} , HCO_3^-). The WHO drinking water specification is used for computation of WQI. The weightage is assigned to each water quality variable by considering apparent hazard to water eminence. The assigned weights on degree of 1 to 5 scale by considering the relative importance in drinking and health risk potential (Table 6). Relative weights (Rwi) to water quality parameters are illustrated in table 6. Subsequent equation is used to calculate WQI;

$$\text{Rwi} = \text{Awi} / \sum \text{Aw} \quad \text{qi} = (\text{ci} / \text{si}) * 100 \quad \text{Sli} = \text{Rwi} * \text{qi} \quad \text{WQI} = \sum \text{Sli}$$

where, Rwi = relative weight, Awi are assigned weight of i^{th} parameters, qi = quality rating for i^{th} parameter, ci = content of i^{th} chemical parameter of water sample (mg/l), si = desirable standards for i^{th} parameter set by the WHO, Sli = sub-index of i^{th} parameter and WQI = Water Quality Index. Based on these stated methods, WQI for the groundwater of Aundha (Nagnath) tehsil has been calculated and values are represented in table 7. It is classified into five different classes, viz., class first indicate excellent type of water having class range of 0-50; class with range in between 50–100 represent as good water quality; value with 100–200 fall under poor category; very poor class of water type ranges from 200-300 and WQI values >300 signify as not fit for drinking (table 7). Its value range among 80.59-193.3 (PRM) and 72.06-301.61 (POM); although, overall water quality according to average values of area is poor in both PRM and POM (table 7) (Fig. 2). Table of categorization of water quality depicts that 11 and 18.34% samples and 16 and 26.67% samples fall under good water category in PRM and POM respectively. This area having a very few dense urbanization and industrialization, although; it is observed that 81.66% (PRM) and 71.66% samples (POM) characterize as poor water quality, which owed to the continued exhaustive consumption and agriculture may affects human health (Wagh et al. 2018, Howladar, 2018). Only 1.67% sample is unfit for drinking from POM (table 7). In general, overall water eminence from study region s exaggerate owed to water-rock contact and low hydraulic gradient (Varol and Davraz, 2015; Kumar and Mourya, 2023). Furthermore, water quality from POM has been undesirably pretentious from renewing water due to its soakings the salinities from domestic waste and agricultural field. Figure 2 is the well illustration for good type of water from numerous sampling locations in PRM and POM;

**Vaishnavi Raut et al.,**

whereas, more samples from poor type (PRM and POM) and one sample (POM)(sample number 18) come under unfit type, clearly represent in WQI spatial distribution maps and it represents that overall water quality for drinking purpose is poor (Fig. 2).

The United States Soil Laboratory Staff's (USSLS's, 1954)

Based on SAR and EC values of the ground water, a diagram has been proposed to ascertain the aptness of waters for persistence irrigation also known as USSL plot (Fig. 3). In this plot, the EC values are represented on log scale plot against SAR on the arithmetic scale is plotted. This diagram is divided into different classes such as a slow (C1), medium (C2), high (C3) and very high (C4) for EC (C= salinity hazards) and low (S1), medium (S2), high (S3) and very high (S4) for SAR (S= sodium hazards). Where, C and S with 1-4 values indicates different classes of agricultural suitability of groundwater. US Salinity Laboratory hazard diagram (USSL's) is created by associating sodium adsorption ratio (SAR) and electrical conductivity (EC). In this study it specifies that twenty-five (25) i.e. 41.67% groundwater samples of the study region fall in the category of C2–S1 groups (low sodium and medium salinity hazard), thirty-four (34) i.e. 56.66% samples are come under C3–S1 indicates that low sodium and high salinity hazard; while, only 1 sample (sample number 21) fall under C4–S1 i.e. 1.67% sample signify very high salinity and low sodium hazard (PRM). Moreover, in POM, 31 samples (51.66%) and 29 samples (48.34%) fall in C2–S1 and C3–S1 classes which indicating medium-high salinity and low sodium hazard (Fig. 3). High to very high sodium hazard represents excess usage of chemical fertilizers and pesticides (Wagh et al. 2018, Ahadi et al. 2019).

CONCLUSION

The hydrochemical evaluation coupled with WQI and GIS approach is summaries with succeeding conclusion; cation abundance is in ascending order of $\text{Ca} > \text{Na} > \text{Mg} > \text{K}$ (PRM) and $\text{Mg} > \text{Na} > \text{Ca} > \text{K}$ (POM) and anionic tendency trend of $\text{HCO}_3 > \text{Cl} > \text{SO}_4 > \text{NO}_3$ in both PRM and POM. As from hydrochemical analysis result, water quality is acidic to slightly alkaline. Majority of parameters are within WHO limits; except, EC, TH, TDS, K, NO_3 and HCO_3 from both PRM and POM. Also, it specifies that overall groundwater quality is moderately desirable for drinking purpose after comparison with WHO drinking water guidelines. WQI specifies that only a few samples (18.34% and 26.67%) having good water quality; while, 81.66% and 71.66% samples showing poor water quality in PRM and POM seasons. Spatial variation map has been prepared and it indicates that only 1 sample (sample number 18) from POM shows unfit class for drinking. USSL salinity diagram represent that, 41.67% groundwater samples of the study region fall in the low sodium and medium salinity hazard, 56.66% samples are come under low sodium and high salinity hazard; while, only 1 (one) sample 1.67% (sample number 21) signify very high salinity and low sodium hazard in PRM. Furthermore, in POM, 51.66% and 48.34% samples fall in classes which indicating medium-high salinity and low sodium hazard. Nut shell, the overall water quality for drinking and agriculture is moderately suitable. Though, it is suggested that, in future water quality improvement methods are required with considering the natural as well as anthropogenic inputs. The results of this work will useful as baseline data to local administrative authorities and new researchers in hydrochemistry to develop a sustainable groundwater management strategy in the study area.

ACKNOWLEDGEMENT

The first author Vaishnavi Raut is grateful to Mahatma Jyotiba Phule Research Fellowship – 2021 (Mahajyoti) for pursuing Ph.D. in Environmental Science (Outward No. MAHAJYOTI/Nag./fellowship/2021-22/1042(377)). Also, thankful to DST FIST (Level II) FIST Project No: SR/FST/ES-II/2020/85 for providing financial assistance to procure water analysis kit instrument (Aquaread AP-700). Also, authors indebted to university administration and school director for providing necessary facilities to perform the work.

ABSTRACT

As the use of wireless devices continues to rise, the incidence of cyber-attacks has similarly escalated, making cyber security a global priority. Intrusion Detection Systems (IDS) play a pivotal role in safeguarding cyberspace by identifying malicious activities on the internet. While embedding machine learning (ML) algorithms into IDS has enhanced detection efficiency, there remains a need for more effective approaches for real-time monitoring and detection. In this context, we introduce Spiking Neural Networks (SNN) to detect temporal malicious attacks such as DDoS, brute force attacks, and SQL injection. Our approach also includes the classification of normal and malicious behavior, providing a robust solution for dynamic and real-time intrusion detection.

Keywords: Intrusion Detection System (IDS), Spiking Neural Networks (SNNs), temporal encoding, Spike-Timing-Dependent Plasticity (STDP), Winner-Take-All (WTA)

INTRODUCTION

In this era of wireless communication, the usage of the internet has grown to such an extent that people now depend on it for everything from basic grocery payments to high-level financial transactions. However, as internet dependency increases, the prevalence of cyber-attacks has also risen. Miscreants conduct cyber-attacks in various ways, such as password cracking, phishing, SQL injection, DDos, buffer overflow attacks, and IP spoofing. To address this growing threat, Intrusion Detection Systems (IDS) were introduced to detect and control such intrusions. Over time, different machine learning algorithms, such as Support Vector Machines (SVM), K-Nearest Neighbour (KNN), and Naïve Bayes, have been employed to improve the efficiency of IDS. These algorithms achieved accuracy rates of 97.77%, 93.33%, and 95.55%, respectively, in detecting intrusions [5]. However, when it comes to real-time prediction, IDS requires a more efficient approach than classical machine learning algorithms, which can be achieved through Spiking Neural Networks (SNNs). As SNNs are event-based processing systems, they can monitor and generate spikes in response to intrusions, enabling real-time prediction [9]. Additionally, SNNs are noise-tolerant and energy-efficient, making them ideal for modern IDS applications. This document will explore how SNNs are used in IDS to efficiently predict and detect intrusions.

LITERATURE SURVEY

IDS using SVM and Decision tree

The SVM classification system involves preprocessing the data by mapping symbolic features to numeric values and implementing scaling to address the varying resolutions and ranges in the data. The attribute data are scaled to fall within the range [-1, 1]. Attack names are then mapped to one of two classes: 0 for Normal and 1 for Attack. Features are ranked according to the score assigned by the Information Gain Ratio (IGR) measure. The k-means classifier is subsequently used to compute the detection rate (accuracy) for each subset of features. Initially, the set of features SS contains only the top-ranked feature. After each iteration, a new feature is added to the list SS based on the rank assigned by the IGR measure, one by one, as long as the accuracy of the selected subset does not decrease. When the accuracy drops, indicating potential model overfitting, the algorithm is stopped [1].

IDS using Navie Bayes

The researcher utilized the naïve Bayes classifier available in the WEKA (Waikato Environment for Knowledge Analysis) software. For testing, they employed both the full training set and a 10-fold cross-validation method. In 10-fold cross-validation, the dataset is randomly divided into 10 equal-sized, non-overlapping subsets. Each subset takes a turn as the test set, while the other nine subsets are used to train the classifier. The classifier's accuracy is then evaluated using the test set. This procedure is repeated 10 times to ensure that each subset acts as the test set exactly once. The overall accuracy is calculated as the average of the results across all iterations. This approach achieved a detection rate of 95%. [2].

IDS Using kNN

In this approach, once a training dataset representing normal system behavior is prepared, the k-Nearest Neighbors (kNN) method can be utilized for anomaly detection. The test audit data is analyzed to extract the sequence of system calls for each new process. These sequences are then converted into vectors using the same weighting technique as in the training phase. The similarity between the vector of the new process and each vector in the training dataset is computed using a specified formula. If the similarity score of any training process is exactly 1, indicating a perfect match in system call frequencies between the new and training processes, the new process is classified as normal immediately. If no perfect match exists, the similarity scores are ranked, and the k-nearest neighbors are identified. The average similarity score of these neighbors (i.e., the k closest matches) is then calculated. A predefined threshold is applied: the new process is classified as normal only if its average similarity score exceeds the threshold[3]. Here's a comparison of Intrusion Detection Systems (IDS) using SVM, KNN, and Naïve Bayes presented in a table format for clarity, which clearly shows that these ML algorithms are not enough efficient for real

Eswin Pria Angel et al.,

time performance and sensitivity to noise and it can be overcome by the proposed Intrusion detection system using SNN

PROPOSED METHODOLOGY

In this proposed methodology, we outline the design and operation of an Intrusion Detection System (IDS) using Spiking Neural Networks (SNNs), leveraging temporal encoding and Spike-Timing-Dependent Plasticity (STDP) learning [7] to analyze and classify network behavior. This approach enables the system to detect anomalous activity, such as password cracking attempts, by identifying deviations in temporal patterns of network traffic. The system begins at the input layer, where network traffic patterns, x_i , observed at time t_i , are processed using a temporal encoding function f_{encode} to generate spike trains $S(t)$ at specific spike times t_s . The temporal encoding process maps inter-event timing information $\Delta t = t_{i+1} - t_i$ into spikes, effectively capturing the temporal dynamics of the network traffic. Normal network behavior, characterized by steady and predictable activity, results in sparse spike generation, where the spike rate $\lambda_s(t)$ remains minimal, indicating the absence of anomalies. Conversely, intrusive behavior, such as repeated login attempts, generates spikes with higher frequency $\lambda_s(t) \gg \lambda_s^{\text{normal}}$ or shorter latencies $t_s \rightarrow 0$, reflecting abnormal activity. To ensure precision, synaptic thresholds θ_{syn} are defined to regulate spike generation, suppressing spikes when $\Delta t > \theta_{\text{syn}}$ and reducing noise. This approach ensures an efficient and precise mapping of network events into spike trains, distinguishing between normal and anomalous patterns in the network.

Spike-Timing-Dependent Plasticity (STDP) in the Hidden Layer

The encoded spike trains $S(t)$ generated by the input layer are transmitted to the hidden layer, where the Spiking Neural Network (SNN) employs **Spike-Timing-Dependent Plasticity (STDP)** as the learning mechanism [6] [7]. The STDP rule adjusts the synaptic weights w_{ij} between neurons dynamically, based on the relative timing of presynaptic and postsynaptic spikes. The change in synaptic weight, Δw_{ij} , is determined by the STDP update function

$$\Delta w_{ij} = \eta \cdot \exp(-|t_j - t_i| / \tau_{\text{STDP}})$$

Where Δw_{ij} change in synaptic weight between neuron i (presynaptic) and neuron j (postsynaptic), η is the Learning rate of SNN, t_j and t_i Spike times of the presynaptic and postsynaptic neurons, respectively, τ_{STDP} is time constant defining the sensitivity window for STDP.

For typical network traffic, the timing between spikes aligns with expected temporal patterns, causing synaptic weights w_{ij} to converge towards stable values. ie

$$\Delta w_{ij} \rightarrow 0, \text{ if } |t_j - t_i| > \tau_{\text{STDP}}$$

And for unusual network behavior, such as irregular timing or burst-like activity, the synaptic weights undergo significant adjustments. ie

$$\Delta w_{ij} \gg 0, \text{ for } |t_j - t_i| \ll \tau_{\text{STDP}}$$

This learning process autonomously identifies temporal correlations in network traffic.

Output Layer and Classification Using Winner-Take-All (WTA)

The output layer aggregates the spike patterns processed by the hidden layer and classifies network behavior as either normal or anomalous using the Winner-Take-All (WTA) mechanism [8]. This classification relies on the density, pathways, or timing of spikes received from the hidden layer. Each output neuron N_c corresponds to a specific class c , such as "normal" or "anomalous." The spike count C_c for each neuron is defined as

$$C_c = \sum_{k=1}^n S_k(t)$$

Where C_c is Spike count for class c , $S_k(t)$ is Spike activity from hidden layer neuron k at time t and n is total number of neurons in the hidden layer projecting to N_c . In the WTA mechanism, neurons in the output layer compete based on their spiking activity. The "winning" neuron is determined as

$$c_{\text{win}} = \arg \max_c C_c$$

Where c_{win} is the class of the neuron with the highest spike count. And finally the decision is based on the winning neuron.

Eswin Pria Angel et al.,

Behavior=Normal, $\left\{ \begin{array}{l} \text{if } C_{win} = \text{"normal"} \\ \text{Anomalous, if } C_{win} = \text{"anomalous"} \end{array} \right.$

Normal behavior is characterized by predictable and sparse spike patterns, leading to a lower C_c value for the neuron associated with the "anomalous" class. ie. $C_{normal} \gg C_{anomalous}$ and anomalous behavior is characterized by dense or irregular spike distributions, resulting in a higher C_c for the "anomalous" neuron, ie. $C_{anomalous} \gg C_{normal}$. The WTA mechanism ensures biologically plausible decision-making by suppressing the activity of all non-winning neurons [8] [10]. This competitive process highlights the most significant response to the observed spike patterns, enabling the efficient and accurate classification of network behavior.

Algorithm:

1. **Input Layer (Temporal Encoding):**
 - 1.1. Capture network traffic x_i at timestamps t_i .
 - 1.2. Encode x_i into spike trains $S(t)$ using temporal encoding.
 - 1.3. Apply synaptic limits to filter noise.
2. **Hidden Layer (STDP Learning):**
 - 2.1. Receive $S(t)$ from the input layer.
 - 2.2. Update synaptic weights using the STDP rule:
 $\Delta w_{ij} = \eta \cdot \exp\left(\frac{-(|t_j - t_i| - \tau_{STPL})}{\tau_{STPL}}\right) \cdot \tau_{STPL}$
 - 2.3. Strengthen pathways for normal patterns; adjust for anomalies.
3. **Output Layer (Classification):**
 - 3.1. Aggregate spikes from the hidden layer.
 - 3.2. Apply Winner-Take-All (WTA) mechanism:
 - Neuron with the highest spike count classifies traffic as "normal" or "anomalous."
4. **Decision:**
 - 4.1. Flag and log anomalous behavior.
 - 4.2. Adapt the system by updating weights based on new traffic patterns.
5. **Repeat:**
 Continuously process new traffic data for real-time detection.

RESULT

The classification system effectively differentiates between normal and anomalous network traffic by leveraging spike-timing-dependent plasticity (STDP) in the hidden layer and the Winner-Take-All (WTA) mechanism in the output layer. As shown in the spike activity plot, normal traffic is characterized by sparse and predictable spike patterns, while anomalous traffic generates dense and irregular spike patterns, reflecting deviations from typical network behavior (fig 1). The **WTA decision** process accurately classifies the observed network traffic into two categories: "normal" and "anomalous." The spike counts for the "anomalous" class were consistently higher, indicating the system's ability to highlight deviations in traffic patterns. The output classification was determined by the neuron with the highest spike count, confirming the system's effectiveness in distinguishing between these two behaviors (fig 2). To further assess the system's performance, the Receiver Operating Characteristic (ROC) curve was utilized to evaluate the trade-off between the True Positive Rate (TPR) and False Positive Rate (FPR). The ROC curve demonstrated the system's robust ability to detect anomalous traffic while minimizing false alarms. The Area Under the Curve (AUC) metric was calculated, yielding a value close to 1, signifying that the system achieves high accuracy in distinguishing between normal and anomalous behavior (fig 3). These results confirm that the system can

Eswin Pria Angel et al.,

autonomously detect network anomalies based on temporal patterns of spikes, providing an efficient, biologically inspired approach to network traffic classification.

CONCLUSION

In conclusion, this IDS leverages the unique properties of SNNs to bridge the gap between biological inspiration and practical applications in network security. By capturing temporal dynamics and adapting synaptic weights to learn network behaviors, it ensures robust and efficient detection of intrusions, enhancing the security of modern digital systems. Future work could involve fine-tuning the temporal encoding granularity, calibrating STDP parameters, and integrating advanced classification methods to further improve accuracy and efficiency.

Table 1 comparison of Intrusion Detection Systems (IDS) using SVM, KNN, and Naïve Bayes

Aspect	Support Vector Machine (SVM)	K-Nearest Neighbor (KNN)	Naïve Bayes
Approach	Supervised learning with a hyperplane to separate classes	Instance-based learning using distance metrics	Probabilistic classification using Bayes' theorem
Accuracy	High (e.g., 97.77%)	Moderate to high (e.g., 93.33%)	High (e.g., 95.55%)
Complexity	Computationally expensive, especially during training	Computationally expensive during classification	Low computational complexity
Handling High Dimensions	Effective with kernel methods	Can handle, but performance decreases with many dimensions	Performs poorly with too many dimensions
Scalability	Limited scalability for very large datasets	Struggles with large datasets due to storage and computation	High scalability due to its simplicity

Eswin Pria Angel et al.,

Sensitivity to Noise	Sensitive to noise, especially in overlapping class boundaries	Sensitive to noise, as it directly impacts nearest neighbors	Less sensitive due to probabilistic nature
Real-Time Performance	Moderate, as it requires significant training but fast inference	Poor, due to the need to calculate distances for classification	Good, due to its low computation requirements

ABSTRACT

This review explores the antidepressant potential of various phytoconstituents, highlighting their mechanisms of action and therapeutic benefits. Natural compounds such as quercetin, harmine, ginsenosides, linalool, resveratrol, essential oils (lavender and bergamot), and tannic acid have demonstrated significant promise in regulating mood and reducing symptoms of depression and anxiety. These phytoconstituents act through diverse pathways, including modulation of neurotransmitters like serotonin, regulation of the hypothalamic-pituitary-adrenal (HPA) axis, and neuroprotection. While the evidence suggests these compounds may serve as effective natural alternatives or complements to conventional antidepressant treatments, further clinical research is necessary to confirm their efficacy and safety. This review emphasizes the growing importance of phytoconstituents in mental health management and their potential role in developing novel, plant-based antidepressant therapies. Antidepressant screening models are critical for discovering and developing new depression-specific treatment medicines. This review provides a thorough overview of current methodology, which include in vivo and vitro models such as forced swim test, tail suspension test, cell-based and receptor binding assays, high-throughput screening (HTS) technologies, and in silico computational approaches. Furthermore, machine learning (ML) and artificial intelligence (AI), have emerged as effective tools for predicting medication efficacy, pharmacokinetics, and probable side effects. Future directions, including biomarker identification, computational models, and personalized approaches, aim to improve the predictability and efficiency of antidepressant discovery.

Vivek T. Kumbhar *et al.*,

Keywords: Antidepressant screening, cell-based assays, receptor binding assays, behaviour test, high-throughput screening, in silico screening, artificial intelligence, Phytoconstituents.

INTRODUCTION

Depression is a life-threatening condition that affects hundreds of millions. It can happen at any age, from early childhood to late life. Depression can lead to a loss of hope, ambition, and even the desire to live, causing significant societal costs.[1] Despite breakthroughs in depression treatment with SSRIs and SNRIs, there are still unmet clinical needs regarding efficacy and side effects. These demands include efficacy in treatment-resistant patients, improved onset, and reduced side effects such as emesis or sexual dysfunction. Several combination medicines and novel targets have been developed to address these demands and potentially improve outcomes in multiple areas. The aims and approaches used vary greatly.[2] Antidepressant screening models are pivotal in the ongoing quest to identify effective treatments for Major Depressive Disorder (MDD), which is the leading source of disability worldwide. The intricate nature of depression presents significant challenges in drug development, necessitating diverse methodologies to ensure that new compound candidates are assessed accurately for their efficacy and safety.[3] The importance of employing both in vivo and in vitro models cannot be overstated, as these models help to elucidate the complex neurobiology underlying depression and guide the selection of appropriate therapeutic agents.[4] Experimental animal models are critical for understanding pathophysiology and developing new treatments for depression. An ideal animal model should have face, concept, and predictive validity. It is difficult to create a comparable model using mice that mimics all of the depressive signs that humans experience. Aside from the traditional stress-induced depression models, the researchers are creating and testing novel models involving neuro-inflammation, genetic and epigenetic dysregulation, and optogenetic techniques.[6] This review provides a comprehensive overview of current methodologies used for screening antidepressants, focusing on in vitro, in vivo, and ex vivo models, and highlighting Phytoconstituents for Antidepressant.

Phytoconstituents for Antidepressant

1. **Flavonoids:** Quercetin, a flavonoid present in fruits and vegetables, has received interest due to its potential antidepressant qualities. As a powerful antioxidant and anti-inflammatory, quercetin may work by altering important neurotransmitters involved in mood regulation, such as serotonin and dopamine. These neurotransmitters play an important role in maintaining mental balance, and changes in their levels are frequently associated with depressive illnesses. According to research, quercetin may help alleviate depression symptoms by modulating certain neurochemical pathways, making it a viable natural compound for the treatment of mood disorders. [6,7]
2. **Alkaloids:** Harmine, an alkaloid produced from the ayahuasca plant, has demonstrated promise antidepressant activity due to its ability to block monoamine oxidase (MAO) enzymes. MAO enzymes break down vital neurotransmitters like serotonin, dopamine, and norepinephrine, which are essential for mood regulation and emotional well-being. By blocking these enzymes, harmine may help maintain higher levels of these neurotransmitters, potentially leading to better mood and fewer depressed symptoms. This method shows that harmine may act as a natural antidepressant, particularly in cases of serotonin deficit.[8]
3. **Saponins:** Ginsenosides, the active chemicals present in ginseng, have been shown to have antidepressant properties by altering the hypothalamic-pituitary-adrenal (HPA) axis, which regulates the body's stress response. HPA axis dysregulation is frequently associated with persistent stress, anxiety, and depression. Ginsenosides influence this mechanism, allowing them to modulate cortisol levels and lower stress, potentially alleviating depression symptoms. Ginsenosides' potential to influence the HPA axis suggests that they may play a therapeutic function in the management of stress-related mood disorders, making ginseng a valuable natural medication for mental health support.[9]

**Vivek T. Kumbhar et al.,**

4. **Terpenoids:** Linalool, a terpenoid often found in lavender, is known for its relaxing and anxiolytic characteristics, making it a good candidate for antidepressant treatment. Linalool has been proven in studies to have a favorable effect on the central nervous system by lowering anxiety and stress, both of which are linked to depression. Its calming effects on the brain may improve mood and reduce depression symptoms by encouraging relaxation and lowering mental stress. Linalool's natural anxiolytic effects have drawn interest as a potential therapeutic alternative for treating depression and anxiety-related diseases. [10,11,12]
5. **Polyphenols:** Resveratrol, a polyphenolic molecule found in grapes and red wine, has received interest due to its potential antidepressant properties. According to research, resveratrol may increase the production of serotonin, a neurotransmitter important for mood regulation, resulting in better emotional well-being. It also has neuroprotective qualities, which protect neurons from injury and promote general brain health. These combined results show that resveratrol may play an important role in reducing depressed symptoms, making it a viable natural compound for mental health support and mood disorder management.[13,14]
6. **Essential oils:** Linalool, found in lavender oil, and bergamot oil are essential oils known for their depressive properties, notably in aromatherapy. These oils have been demonstrated to have soothing effects on the central nervous system, which can greatly alleviate feelings of anxiety and sadness. The soothing perfume of lavender and the energizing scent of bergamot combine to improve mood, induce relaxation, and reduce stress. Research suggests that inhalation or topical use of these essential oils can be helpful supplementary therapy for treating depression and anxiety.[15]
7. **Tannins:** Tannic acid, a kind of tannin found in abundance in tea leaves, has been studied for its possible antidepressant properties due to its capacity to control the body's stress response. Tannic acid, by altering stress-related hormones and neurochemical pathways, may help alleviate the physiological and psychological effects of stress, both of which are associated to depressive disorders. According to research, drinking tannin-rich liquids like tea may improve mood and contribute to mental health. These qualities make tannic acid a viable natural chemical for further investigation in the treatment of depression and stress-related disorders.[16,17]

In Vivo Models

Rodent Models

Rodents are the most commonly utilized species for antidepressant testing due to their short lifetime, genetic resemblance to humans, and simplicity of manipulation. Several rat behavioral assays have been validated as predictive models for antidepressant efficacy.

Forced Swim Test (FST):[18]

The forced swim test is a mouse behavioral test used to evaluate antidepressant medicines, the efficacy of novel substances, and experimental manipulations aiming at producing or preventing depressive-like states. Mice are placed in an impenetrable clear tank filled with water, and their escape-related movement behavior is recorded. The forced swim test is simple to perform consistently and requires little specialist equipment. The successful administration of the forced swim test necessitates strict adherence to certain procedural parameters and the minimizing of unnecessary stress on the mice.

Materials: The water tanks, Thermometer, Timer, Dividers, White noise generator, Drying paper and heat lamp.

Behavioral Procedures

To conduct the Forced Swim Test (FST), ensure counterbalancing of treatment groups and rotate mice across different tanks to avoid bias. Set up the camera close to the tanks for high-resolution video, and fill the tanks with tap water at 23-25°C, adjusting temperature if necessary. Use white noise if needed to mask external sounds. Acclimate mice in the testing room if necessary. Begin video recording, gently place mice in the tanks, and ensure the procedure minimizes disruptions. Test each mouse for six minutes, with special care taken to avoid startling them. Monitor behavior and intervene if a mouse appears distressed. After testing, remove the mice, dry them, and return them to their home cages. For analysis, measure the time each mouse is mobile during the last four minutes of the test.

**Vivek T. Kumbhar et al.,**

Subtract mobility time from 240 seconds to calculate immobility time. To prevent bias, cover the stopwatch display except for milliseconds. New observers should undergo training to ensure consistent behavioral scoring, with inter-observer reliability tests conducted before analyzing experimental data.

Behavioral Analysis

In the Forced Swim Test (FST), the last four minutes of the six-minute test are typically analyzed to avoid the initial burst of activity that could obscure treatment effects. Mobility is measured by recording active movements, while immobility is calculated as the time when the mouse shows no movement except to stay balanced in the water. Subtle movements like floating or momentum-driven drifting are excluded from mobility scoring. Video analysis is done via PC using stopwatch software, with controls for ensuring consistency and avoiding bias. Observers are trained extensively, scoring alongside experienced analysts to achieve high inter-observer reliability. Differences in mobility across mouse strains, sexes, or new genetic models require re-testing for consistency. The lab maintains an internal standard for comparison and training purposes.

Tail Suspension Test (TST):[19]

The tail-suspension test is a mouse behavioral test useful in the screening of potential antidepressant drugs, and assessing of other manipulations that are expected to affect depression related behaviors. Mice are suspended by their tails with tape, in such a position that it cannot escape or hold on to nearby surfaces. During this test, typically six minutes in duration, the resulting escape-oriented behaviors are quantified. The tail-suspension test is a valuable tool in drug discovery for high-throughput screening of prospective antidepressant compounds.

Materials

Suspension Box, Tape, Timer, White noise generator, cleaning supplies, Climb stoppers (optional: dependent upon strain used).

Behavioral Procedures

Ensure proper counterbalancing in the Tail Suspension Test (TST) by rotating mouse positions and representing all treatment groups equally in each session. Position the camera close for optimal resolution. Prepare and mark tape fragments before the session. If using a white noise generator, start it before introducing the mice to the testing room, keeping the noise level consistent for all animals. Acclimate the mice if needed. For strains prone to tail climbing, use Climb stoppers. Apply tape to the ends of the tails, leaving 2-3 mm uncovered, and prevent tangling by sticking the middle portion to the inner walls of the cage. Begin recording before suspending the mice in a counterbalanced order, ensuring the camera view is unobstructed. After the session (usually six minutes), return the mice to their homecage and carefully remove the tape. Clean the apparatus after each session.

Behavior Analysis

In the Tail Suspension Test (TST), the entire six-minute session is analyzed, as mice tend to show immobility earlier compared to the Forced Swim Test (FST). The analysis focuses on measuring mobility time, with overt escape behaviors like reaching for the walls and strong body movements counted as mobility. Subtle movements, such as front leg movements without hind leg involvement or pendulum-like swings, are excluded. In the lab, video recordings are uploaded for analysis, and mobility is tracked using on-screen stopwatch software. To minimize bias, the total elapsed mobility time is hidden, showing only the milliseconds to prevent the observer from forming pre-emptive judgments. Multiple mice on screen should be covered to avoid distractions during analysis. New observers undergo rigorous training to ensure inter observer reliability before analyzing actual experimental data. Observers first watch experienced analysts, then score together until they gain confidence. A high level of consistency is required between observers, with archived training data serving as a reference. Additionally, differences in mobility between strains, sexes, and new genetic models require re-assessment of reliability to account for behavioral variability.

**Vivek T. Kumbhar et al.,****Chronic Mild Stress (CMS) Model**

The chronic mild stress (CMS) model of depression is frequently used as a model. In this model, rats or mice are persistently exposed to a steady bombardment of unpredictable micro-stressors, resulting in a slew of behavioral alterations, including decreased reaction to rewards, which is a behavioral correlate of the clinical core symptom of depression, anhedonia. The canonical form of the paradigm measures reward sensitivity by frequent testing in which the animal is provided access to a highly desired sweet solution, or a choice between a sweet solution and plain water.[20]

Materials

Standard laboratory animals, stressors such as cage tilt, food and water restriction, changes in light/dark cycles, crowding, and noise are all necessary. Standard housing and enrichment tools are also utilized to keep animals under controlled settings, as well as specialized equipment for behavioral testing, such as sucrose preference tests or forced swim tests.

Procedure

The behavioral approach is subjecting mice to a series of random mild stresses over the course of many weeks. These stressors are introduced at random, preventing the animals from adjusting to or anticipating the stress. Food and water restriction, changed lighting conditions, social isolation, and exposure to unfamiliar or stressful surroundings are all common stressors. The idea is to replicate the persistent and unpredictable type of stress found in human depression.

Behavioral Analysis

During the behavioral study, numerous tests are used to examine the animals' responses to persistent stress. The sucrose preference test is used to assess anhedonia, in which decreased sugar consumption implies a loss of pleasure, a core sign of depression. Other tests, such as the forced swim test and the tail suspension test, assess immobility time, which suggests despair-like behavior. The results of these behavioral assessments are compared between stressed and control groups to determine the effects of persistent mild stress.[21]

Non-Rodent Models

While rats predominate in antidepressant screening, non-rodent models like zebrafish (*Danio rerio*) are gaining popularity due to their genetic closeness to humans, transparency throughout early development, and simplicity of genetic modification. Although zebrafish models provide advantages in drug screening by allowing for high-throughput in vivo testing, their translational utility in simulating complex human emotional states is debatable.

Zebrafish model[22]

Zebrafish (*Danio rerio*) are increasingly being used as a novel and successful model organism for research into major depressive disorders (MDD). Given their genetic and physiological similarities to humans, as well as the benefits of transparent embryos, quick development, and ease of pharmacological treatment, zebrafish have emerged as an important tool for investigating the underlying causes of depression. The authors examine the many behavioral assays and stress paradigms utilized in zebrafish investigations, emphasizing their importance in studying depressive-like behaviors and determining the efficacy of antidepressant treatments. This study highlights the utility of zebrafish as a model system for bridging the gap between molecular biology and behavioral neuroscience in the context of MDD.

Materials

Zebrafish (*Danio rerio*) are utilized as model organisms because of their genetic closeness with humans, transparent embryos, and quick development. The study makes use of specifically designed tanks for behavioral experiments, as

**Vivek T. Kumbhar et al.,**

well as video capturing technology to analyze fish behavior. Zebrafish responses can also be evaluated using pharmacological treatments such as antidepressants and stress-inducing chemicals.

Procedure

To simulate conditions associated with depression, the researchers subjected zebrafish to a variety of stress paradigms, including social isolation, exposure to novel surroundings, and light/dark tests. Behavioral techniques such as the innovative tank diving test, which places zebrafish in a new setting and analyzes their vertical swimming patterns, were employed to assess stress and anxiety-like behavior. To assess the impact of chronic stressor exposure on behavior and physiology, antidepressant medications were administered concurrently.

Evaluation

The major evaluation criteria included alterations in zebrafish behavior, notably increased immobility, changed swimming patterns, and decreased exploration, all of which indicate depressive-like states. Antidepressant effects were tested by reversing these actions. Furthermore, molecular assays such as gene expression profiling were used to monitor changes in stress-related pathways.

In Vitro Models

In vitro models offer the advantage of being cost-effective, high-throughput, and less ethically contentious than *in vivo* studies. These models involve cellular assays, receptor-binding studies, and genetic manipulation to explore antidepressant activity at the molecular and cellular level.

Cell-Based Assays[22,23]**Materials**

Cell-based assays often use neuronal or neuroblastoma cell lines (e.g., SH-SY5Y or PC12), freshly cultured neurons, or iPSC neurons. Culture conditions, growth nutrients, and supplements such as fetal bovine serum (FBS) or neurotrophic factors are required to sustain cell viability. Test chemicals (possible antidepressants) and reagents for evaluating cellular responses, such as MTT (viability) or antibodies for signaling pathways such as CREB or BDNF, are also utilized.

Procedure

Cells are grown in multi-well plates under ideal circumstances. After achieving the desired confluency, the test chemicals are added at varied quantities. The cellular response is assessed after a treatment time (which can last anywhere from hours to days depending on the test). Cell viability tests, such as MTT or lactate dehydrogenase (LDH) release assays, as well as signaling pathway activation assays (e.g., CREB or BDNF levels) using Western blotting or ELISA, are common.

Evaluation

Potential antidepressants' effects are assessed using changes in cell survival, neurite outgrowth, and the activation of neuroprotective and neuroplasticity pathways. Positive outcomes are often characterized by enhanced cell survival, neurite length, or overexpression of proteins linked with antidepressant effects (for example, BDNF, CREB). The data is statistically examined to establish the efficacy and therapeutic potential of the test substances.

Receptor Binding Assays[24,25]**Materials**

Receptor binding experiments often use brain tissue or cell membranes that express specific receptors (for example, serotonin 5-HT, dopamine D2, or adrenergic receptors). Radiolabeled ligands, such as [³H]-serotonin or [³H]-ketanserin, are often employed to measure receptor-ligand interactions. Buffer solutions, test chemicals (possible antidepressants), and a scintillation counter for measuring radioactivity are all essential components.

**Vivek T. Kumbhar et al.,****Procedure**

Membrane preparations containing target receptors are treated with radio labeled ligands and increasing quantities of test chemicals. The test chemicals compete against the radio ligand for receptor binding. Following incubation, the free ligand is removed from the bound fraction via filtration or centrifugation. The bound radio ligand is subsequently quantified with a scintillation counter, which provides information about the test compound's binding affinity.

Evaluation

The assay analyzes the test compound's capacity to displace the radio labeled ligand from the receptor. Data is evaluated to determine the compound's binding affinity (which is commonly represented as IC₅₀ or K_i values). A lower IC₅₀ implies better binding affinity, implying a stronger contact with the receptor. The efficacy of the test substance in modifying receptor function can help determine its potential as an antidepressant.

High-Throughput Screening (HTS)**Materials**

HTS necessitates sophisticated automated systems capable of processing vast amounts of data. Microtiter plates (typically in 384- or [1]536-well formats), test compounds from huge chemical libraries, biological response detection reagents (e.g., fluorescent or luminous markers), and liquid handling robotic systems are all important ingredients. Plate readers and other assay detection systems are used to monitor cellular or molecular responses.

Procedure

HTS begins with the preparation of microtiter plates, often in 384- or 1536-well configurations, containing cells or biochemical targets related to antidepressant effect, such as neurotransmitter transporters, receptors, or enzymes like monoamine oxidase. Automated robotic equipment then distributes small amounts of test chemicals from enormous chemical libraries into each well. These substances are evaluated for their capacity to influence the target's activity. Following incubation, detection reagents such as fluorescent, luminescent, or colorimetric markers are added to determine the assay's biological response. The entire procedure is intended for high-speed, high-volume data collection, allowing thousands of chemicals to be evaluated concurrently. Following the test, the plates are examined using detection tools such as automatic plate readers, which record signals proportional to the activity of each component. The obtained data is processed and statistically analyzed to find active chemicals (hits) that exhibit considerable activity when compared to controls. These hits are chosen based on parameters such as the Z'-factor, which assesses assay quality, and then prioritized for secondary validation. Promising compounds with antidepressant efficacy are tested further in more specialized and complicated assays, such as secondary screens and *in vivo* models, to confirm their therapeutic potential.

Evaluation

HTS generates large datasets where the effects of each compound are analyzed for their ability to induce or inhibit specific biological responses. Hits are identified based on statistical thresholds (e.g., Z'-factor) that indicate significant activity. These hits are further evaluated for their potential as antidepressants by comparing their activity to known reference compounds. Hits with favorable activity profiles are advanced to secondary validation assays.

Computational Approaches

Computational approaches to antidepressant development use computer-based tools and algorithms to forecast new drug candidates' efficacy, safety, and mechanisms of action. Molecular docking, virtual screening, and quantitative structure-activity relationship (QSAR) modeling are all used to mimic how chemicals interact with biological targets such neurotransmitter receptors and enzymes. These methods, which use databases of known compounds and targets, enable researchers to quickly screen huge chemical libraries, select interesting candidates, and estimate pharmacokinetics and toxicity profiles. Computational techniques considerably speed up the drug discovery process,

**Vivek T. Kumbhar et al.,**

lowering the requirement for early-stage experimental testing and directing compound selection for future development. [26,27]

In Silico Screening: [28,29]**Material**

In silico screening makes use of computational software and databases. Chemical libraries (molecular structure databases like as PubChem or ZINC), target protein structures (for example, from the Protein Data Bank), and molecular modeling tools such as molecular docking software (AutoDock, Schrödinger, etc.) and virtual screening platforms are also important resources. Advanced algorithms and machine learning models are also used to forecast drug-target interactions and pharmacokinetics.

Procedure

In silico screening begins by identifying molecular targets involved in depression, such as serotonin transporters or monoamine oxidase. The 3D structures of these targets are determined, and test compounds from virtual chemical libraries are tested against them using molecular docking techniques. The docking software models how well each molecule fits into the target's active site, assigning binding affinity ratings based on molecular interactions (e.g., hydrogen bonding, hydrophobic interactions). Virtual screening algorithms can quickly sift through thousands of chemicals and predict their effectiveness in binding to the target. Once prospective drugs with positive docking scores have been found, additional computer analyses are performed to evaluate their pharmacokinetic features (absorption, distribution, metabolism, excretion, and toxicity, or ADMET). Machine learning models can also anticipate adverse effects, efficacy, and off-target interactions. Selected compounds with significant target interactions and favorable ADMET profiles are identified as candidates for further *in vitro* and *in vivo* validation, expediting the drug development process and lowering the time and cost of experimental screening.

Machine Learning and Artificial Intelligence (AI) [30,31,32]**Material**

Machine learning (ML) and artificial intelligence (AI) models require large datasets that include information about chemical structures, drug-target interactions, pharmacokinetics, and clinical outcomes. Curated databases such as ChEMBL, DrugBank, or PubChem contain information on bioactive chemicals, their characteristics, and mechanisms. ML frameworks such as Python-based libraries (e.g., TensorFlow, Scikit-learn) and AI tools (e.g., deep learning neural networks) are used to train models for therapeutic efficacy and side effects.

Procedure

Data preparation is the initial step in drug discovery using machine learning and artificial intelligence. Chemical, biological, and pharmacological data are collected and cleaned to assure accuracy. Using this information, algorithms are trained to spot patterns linked with antidepressant efficacy or toxicity. Supervised learning techniques use labeled datasets to educate algorithms to anticipate outcomes such as receptor binding affinity, whereas unsupervised learning can help find novel drug-target interactions that lack established labels. Deep learning methods, such as convolutional neural networks (CNNs), are used to assess complicated chemical characteristics and predict bioactivity using structural properties. AI also aids in product selection by predicting pharmacokinetics, toxicity, and off-target effects. Once trained, the algorithm can evaluate novel chemical compounds and score their antidepressant potential using previously acquired patterns. Furthermore, AI systems can examine genetic data to find biomarkers connected to depression, allowing for more tailored therapy recommendations. The process speeds up drug discovery by focusing on the most promising candidates for experimental validation, optimizing resources, and shortening time to market.

Vivek T. Kumbhar *et al.*,

Challenges and Future Directions

Despite major advances in antidepressant screening methods, some problems remain. One key concern is the complexity and variety of depression, which can lead to variations in drug reactions between individuals. Current models may not adequately represent the disorder's complex character, reducing their predictive value. Furthermore, many standard in vitro and in vivo experiments do not effectively imitate the human brain's environment, which might lead to incorrect results.³³ Future research should focus on establishing more comprehensive models that account for genetic, epigenetic, and environmental factors that influence depression. Organ-on-a-chip technologies and patient-derived iPSC models can improve the utility of screening tests. Furthermore, combining AI and machine learning with developing omics technologies (genomics, proteomics, and metabolomics) will allow for a more personalized approach to antidepressant development, aiding in the identification of biomarkers for treatment response and optimizing medication selection. Finally, addressing present obstacles and developing antidepressant medicines will require a multidisciplinary strategy that incorporates computational approaches and experimental validation. [34,41,42]

Advances in Humanized Models

Humanized models provide a big step forward in the research of depression and the development of effective medicines. These models strive to closely imitate human physiology and pathology, resulting in more relevant data than standard animal models. Recent advances in humanized models include the use of human induced pluripotent stem cells (iPSCs), which may differentiate into a variety of cell types, including neurons, allowing researchers to examine depression causes at the cellular level. These models enable the investigation of genetic variants and their effects on medication response, opening the door for personalized treatment.²³ Another interesting option is the creation of organ-on-a-chip technologies that mimic the human brain's microenvironment. These systems can reproduce the blood-brain barrier and neural networks, allowing researchers to study drug delivery, pharmacokinetics, and toxicological effects in a controlled environment.[24] Furthermore, advances in 3D bioprinting allow for the production of complex tissue structures that better mimic the architecture of human brain tissue. These models improve our understanding of neurodevelopment, synaptic connection, and the impact of antidepressants on neuroplasticity. Overall, incorporating these humanized models into antidepressant research opens up new paths for drug discovery, increasing the likelihood of developing successful depression treatments. [35,36]

Biomarkers and Omics Technologies

Biomarkers and omics technologies are critical to enhancing our understanding of depression and discovering new antidepressants. Biomarkers, which are observable indications of biological processes, disease states, or pharmacological reactions, can assist identify people who are at risk of depression, predict treatment outcomes, and track therapeutic efficacy. The integration of genomes, proteomics, metabolomics, and transcriptomics enables researchers to identify molecular markers related with depression and antidepressant response, allowing for more tailored therapy approaches. Omics technologies allow for extensive profiling of biological materials, showing complex relationships between genes, proteins, and metabolites involved in depression. For example, genomics can discover genetic polymorphisms associated with depression, but proteomics can reveal changes in protein expression levels in response to treatment. Metabolomics provides insights into metabolic pathways that are changed in depressive illnesses, which might help identify therapeutic targets. Together, these technologies improve the ability to identify novel biomarkers, streamline drug development procedures, and develop targeted therapy tactics, ultimately leading to more effective depression treatments. [37,38,39,40]

CONCLUSION

In conclusion, different phytoconstituents obtained from natural sources show promise antidepressant properties, providing a supplementary strategy to addressing depression and anxiety. Flavonoids (quercetin), alkaloids

**Vivek T. Kumbhar et al.,**

(harmine), saponins (ginsenosides), terpenoids (linalool), polyphenols (resveratrol), essential oils (lavender and bergamot), and tannins (tannic acid) have all been shown to modulate key neurochemical pathways, reduce stress, and promote overall mental health. While these plant-based elements have significant therapeutic promise due to processes such as serotonin augmentation, HPA axis control, and neuroprotection, more research is needed in clinical settings to fully understand their efficacy, safety, and mechanisms of action. Nonetheless, these phytoconstituents represent a viable option for developing natural alternatives or adjuncts to traditional antidepressant therapy.

Antidepressant screening models have advanced dramatically, employing a diverse set of techniques to speed drug development and improve therapeutic effects. Traditional *in vitro* and *in vivo* techniques, such as cell-based and receptor-binding tests, forced swim test, tail suspension test, offer important insights into the molecular and cellular effects of prospective antidepressants. High-throughput screening (HTS) technologies have made it easier to identify interesting compounds, while *in silico* methodologies and computational tools provide a cost-effective and quick way to forecast medication efficacy and safety. Machine learning (ML) and artificial intelligence (AI) have changed the sector by allowing the analysis of huge datasets, optimizing chemical selection, and improving customized medicine approaches. As antidepressant research progresses, the integration of these various techniques promises to result in more effective and focused medicines that address the intricacies of depression at multiple physiological levels. By merging classic experimental procedures with cutting-edge computational technologies, researchers are better able to address drug discovery hurdles, thereby enhancing patient outcomes and quality of life.

ABSTRACT

Varmam treatment is part of *Siddha* medicine, an ancient healing practice that stimulates key energy centres called "*varmam* points." This therapy attempts to improve prana flow and restore equilibrium, particularly in musculoskeletal diseases. Combining *varmam* therapy with herbal therapies provides a comprehensive approach to wellness. The study was designed to observe the quality of life (QOL) of patients with *Ceganavaatham* which may be correlated with Cervical spondylosis (CS) under *varmam* treatment. 20 subjects were followed for 30days and their quality of life is assessed with Neck Disability index questionnaire and Short Form-36 health survey questionnaire. SPSS was used to perform statistical analysis with Wilcoxon Signed rank test. A probability value of <0.05 was considered as statistical significance. The Statistical analysis of SF-36 scores and NDI scores before and after *varmam* treatment with Wilcoxon signed-rank test also showed statistical significance results (P<0.001). The results of this study demonstrated that *Varmam* treatment gives significant improvement in the quality of life in subjects with *Ceganavaatham* (Cervical spondylosis)

Keywords: VARMAM, SIDDHA, CEGANA VAATHAM, CERVICAL SPONDYLOSIS, QUALITY OF LIFE

INTRODUCTION

Based on the literature evidences, the Siddha system of medicine focuses on maintaining a balance of 3 humors and 7 constituents of the body. Diseases are believed to arise when there is an imbalance in these humors and constituents. They are classified into various types, such as *Vaathadiseases*, *Pithadiseases*, and *Kaba diseases*, based on the specific imbalance observed.[1] *CeganaVaatham* is categorized as a *Vaatha* disease and shares symptoms similar to cervical spondylosis, including pain below the neck to the inguinal level, radiating pain in the hands, body heaviness, giddiness, burning sensation in the eyes, numbness, and tingling sensations throughout the body.[2] In *Siddha* medicine, treatment includes various internal medicine, external medicine each of 32 types, and it also possess a unique therapy known as *Varmam* therapy. *Varmam* therapy focuses on manipulating specific points known as *Varmam* points, which are believed to be crucial for the flow of vital energy in the body.[3] This therapy is particularly employed for musculoskeletal disorders, addressing issues with bones, nerves, and muscles.[4] Neck discomfort is a significant issue in modern life, though not the most common musculoskeletal disorder. The age-standardized prevalence of neck pain is 3551.1 per 100,000 population, with an incidence of 806.6 per 100,000.[5] Cervical spondylosis (CS) is an age-related degenerative condition affecting the cervical spine, typically at levels C5-C6 and C6-C7. It causes pain, tingling, numbness, and weakness in the upper extremities, leading to disability. Factors contributing to CS include aging, occupational stress, neck injuries, and genetic predisposition.[6] *Varmam* therapy is widely used in the management of *Vaatha* type of pain related conditions among the *Siddha* system of medicine. The quality of life in *CeganaVaatham* patients is affected by the pain interrupting their normal day to day activities like reading, sleeping, personal care, work etc. By reducing the pain their quality of life may improve. Thus, an attempt was made to study the Quality of Life (QOL) in *CeganaVaatham* patients using Short Form-36 health survey questionnaire (SF-36) and Neck disability index (NDI).

MATERIAL AND METHODS

Sample and subjects

An observational study was conducted to analyze the impact of *Varmam* treatment on the quality of life of patients diagnosed with Cervical Spondylosis (*CeganaVaatham*). The study, conducted between February and June 2023 at *Varmamaruthuvam* OPD, AyothidossPandithar Hospital, National Institute of Siddha in Chennai, aimed to evaluate changes using the Short Form-36 Health Survey Questionnaire and Neck Disability Index (NDI) over a 30-day period. The inclusion criteria comprised individuals of all genders aged between 30 to 60 years, diagnosed with Cervical Spondylosis exhibiting symptoms such as neck pain radiating to the arms, numbness, and neck stiffness. Patients had to provide informed consent and be undergoing *Varmam* treatment. Exclusion criteria included patients with a history of cervical spine fracture, Pott's disease, spinal stenosis, or Ankylosing spondylitis. Out of 54 screened patients, 20 met the inclusion and exclusion criteria and consented to participate. The study received ethical clearance from the Institutional Ethical Committee of the National Institute of Siddha (NIS/23/IEC/2022/MP/11) and was registered in the Clinical Trials Registry of India (CTRI/2023/02/049697). All participants provided informed consent. This research aims to contribute to understanding how *Varmam* treatment may improve the quality of life and reduce disability in Cervical Spondylosis patients.

Clinical evaluation

The clinical evaluation process for patients with *CeganaVaatham* involves gathering detailed sociodemographic and clinical data, along with utilizing specific assessment tools to gauge their quality of life.

Data Collection

Comprehensive information is gathered, including age, gender, height, weight, BMI, education, occupation, income, socio-economic status, marital status, personal habits, and dietary patterns. A detailed clinical history is also obtained, covering comorbidities, traumatic events, and other medical backgrounds.

Sasikumar et al.,

Assessment Tools

Neck Disability Index (NDI): NDI aims to assess the impact of neck pain on day-to-day activities through 10 items. Each domain is rated from 0 to 5, reflecting varying degrees of severity. The total score, which ranges up to 50, indicates the level of disability, with higher scores indicating greater impairment.[7] Short-Form 36 Health Survey (SF-36): This survey measures various dimensions of health-related quality of life. It consists of 36 items in 8 groups, covering aspects like vitality, physical functioning, physical and emotional well-being, social functioning, general health perception, bodily pain and mental health. Scores for each scale range from 0 to 100 where higher scores indicate the better health and lower scores indicate more limitations.[8] This structured approach allows healthcare providers to comprehensively assess the impact of *Ceganavaatham* on patients' lives, integrating objective measurements with patient-reported outcomes to guide effective treatment and management strategies.

Data analysis

Data collected from patients with *Ceganavaatham* were meticulously organized in Microsoft Excel, with variables allocated to columns and patient records to rows. Statistical analysis was conducted using SPSS, which included the Wilcoxon Signed Rank test to evaluate changes over time or between related groups. Descriptive statistics such as frequency distributions and cross-tabulations summarized categorical variables, while visual aids like bar diagrams and pie charts depicted variable distributions. Mean and Standard Deviation summarized quantitative data, and percentages summarized qualitative variables. A significance level of <0.05 was considered as statistical significance. This systematic approach ensures comprehensive analysis and clear presentation of data, facilitating informed decision-making in treatment strategies for *Ceganavaatham* patients.

Standard operating procedure for Varmam therapy for Ceganavaaatham patients

Varmam therapy was done under the supervision of the Guide and monitored by the Head of the Department. The therapy was given for about 4 sittings (weekly once in 1 month) after monitoring the vitals and eligibility of the patient.

RESULTS

Based on the sociodemographic data of patients with *Ceganavaatham*, subjects were predominantly male (65%), married (65%) and in the age range of 41-50 (50%) with normal BMI (60%). Most of the patients were skilled and semi-skilled workers with high school qualifications. In case of socio-economic status majority comes under Upper lower IV (60%). The NDI scores before treatment were recorded as among 20 patients, 2 patients scored between (24-34 points) with severe disability in daily activities and other 18 scored (34 – 50 points) with complete disability in daily activities due to pain. After 30 days in treatment in Varma Maruthuvam OPD, among 20 patients 2 patients scored (15 – 24 points) with mild disability, 17 patients scored (24- 34 points) with moderate disability in activities and 1 patient scored (35 – 50 points) with severe disability in performing their day-to-day activities because of pain. (Table- 2 & 3) The SF-36 Health survey questionnaire assess the patients with 8 domains and their observations were found to be as follows. In vitality domain, the average value before treatment was found to be 39% and was increased to 52.25% after the treatment with the maximum score of 65% having good amount of energy in performing their activities. In physical functioning, the average value before treatment was found to be 33.75% and was increased to 72.5% after the treatment with maximum score of 85% like better changes in walking, carrying things, stepping stairs. In bodily pain, the average value before treatment was found to be 19.75% and was increased to 47.6% after the treatment with maximum score of 67% as reduction in pain and its interruption in activities. In General health, the average value before treatment was found to be 13.5% and was increased to 51.35% after the treatment with maximum score of 70% as improvement in overall health perspective. In physical role functioning and emotional role functioning, the average value after treatment was found to be 50% and 51.62% as accomplishment of their usual work and relieving from depression and anxiety. In Social role functioning, the average value before treatment was found to be 21.25% and was increased to 52.5% after the treatment with maximum score of 62.5% like visiting family, friends, neighbors or groups. In mental health, the average value before treatment was found to be 36.2% and was increased to 67.8% after the treatment with the maximum score of 80% as

Sasikumar et al.,

feeling calm and peaceful, not being downhearted and nervous person.(Table- 4 & 5)

DISCUSSION

This article examines the socio-demographic data, clinical presentations and quality of life (QoL) aspects of patients diagnosed with *CeganaVaatham* (Cervical spondylosis) over a six-month study period. The current studies showed that the prevalence of neck pain is equally distributed in genders and women are mostly affected.[9] In this study those who predominantly participated were male (65%) and married (65%). Most cases come under the age category between 41-50 years (50%) in relation with age standard prevalence of neck pain in recent studies.[10] Most of the patients were skilled and semi-skilled workers (65%) with high school qualifications. There is a high prevalence of neck pain in persons who has long working hours (>8 hours). In case of socio- economic status majority comes under Upper lower IV (60%). A meta-analysis on Socioeconomic status and occurrence of chronic pain revealed that there is an association between lower SES and incidence of chronic pain.[11] Various case reports and prospective observational case series on *Varmam* therapy shows promising results in pain management. [12,13] This observational study focused on how the pain reduction by *Varmam* therapy in Cervical spondylosis patients had impact in improving their quality of life. Data from NDI scale showed most patient scored 4 and 5 in each domains representing severe and worst pain at the moment, difficulty in handling weights, undertaking personal care, reading, developed headache with sleep disturbances. The patients also faced difficulty in driving, unable to concentrate on work and recreation. After *varmam* treatment the most patients showed good improvement in Sleeping, personal care, reduction in pain intensity and headache. Moderate improvement in reading, concentration, work and recreation. Mild improvement in lifting weights and driving. Data from SF36 showed good improvement comparing before and after *varmam* treatment as good amount of energy in performing their activities like walking, carrying things, stepping stairs due to reduction in pain.

Mental health of the patients showed good results in Social and emotional role as relieving from depression, visiting family and friends. The analysis of SF-36 and NDI scores before and after treatment revealed significant findings using the Wilcoxon signed-rank test. When discussing *Varmam* therapy for cervical spondylosis, it's important to delve into its underlying principles and how they may relate to the condition. One potential benefit of *Varmam* therapy for cervical spondylosis lies in its holistic approach to healing. Rather than simply treating the symptoms, *Varmam* therapy aims to maintain the vital energy balance. Proponents suggest that by stimulating specific *varmam* associated with the cervical region, circulation can be improved, energy blockages can be cleared, and the body's innate healing mechanisms can be activated. Moreover, *Varmam* therapy often incorporates various techniques such as massage, pressure, and manipulation, which can help alleviate muscle tension and promote relaxation. For individuals with cervical spondylosis, these techniques may provide relief from the discomfort associated with muscle spasms and stiffness in the neck and shoulders. However, it's essential to approach *Varmam* therapy for cervical spondylosis with caution and under the guidance of a qualified practitioner. While many people report positive experiences with alternative therapies like *Varmam*, scientific evidence supporting its effectiveness specifically for cervical spondylosis is limited. Therefore, it's crucial to integrate *Varmam* therapy into a comprehensive treatment plan that may include conventional medical interventions such as physical therapy, medication, and lifestyle modifications.

CONCLUSION

In conclusion, while *Varmam* therapy offers a unique approach to addressing cervical spondylosis, further research is required to get a comprehensive understanding of its efficacy and mechanisms of action. Nevertheless, for individuals seeking alternative or complementary therapies, exploring *Varmam* therapy under the guidance of a knowledgeable practitioner may offer potential benefits in managing symptoms and improving overall well-being.

ABSTRACT

Ascorbic acid also known as Vitamin C, is one of the most important and protective micronutrients. It is naturally present in some foods, added to others, and available as a dietary supplement. Humans, unlike most animals, are unable to synthesize vitamin C endogenously, so it is an essential dietary component. It mainly involves collagen, carnitine, and neurotransmitter bio synthesis. It also helps to maintain the shape and structure of the skin, bones, and connective tissue, It is the most potent water-soluble vitamin. vitamin C is also known as a good antioxidant which is responsible for protecting against viral infection and allergic reaction. Vitamin C protects cells from damage caused by free radicals, which are molecules produced when the body breaks down food or is exposed to pollution, tobacco smoke, and radiation. Vitamin C is effective in several human health benefits such as colds, scurvy, asthma, obesity, cardiovascular disease, diabetes, sepsis, atherosclerosis, etc. Research shows that people who took ≥ 700 mg/day of supplemental vitamin C had a 25% lower risk of coronary heart disease incidence than those who took no supplemental vitamin C. The exact role of vitamin c in the perspective of human health and disease is yet a mystery.

Keywords: Vitamin c;Anemia;Obesity;Cancer;Covid-19

**Luxita Sharma and Dhananjay Sharma**

INTRODUCTION

Vitamin c essential nutrient which is important for our body so we need to add vitamin c which found in our diet because vitamin c is important for our body from toxic substances which is also known as oxidant. it is essential enzymes that make collagen, hormones, carnitine, genes (Bozonet and Carr, 2019). Vitamin c refers to collection of water soluble substance for example L-ascorbic acid, ascorbic acid, ascorbate. vitamin c help in making chemical and these chemical for help in our blood vessel make functioning and tissue building and growth and maintenance (Gordon et al., 2020). In past, we recommended the intake of micronutrient based on prevention of disease secondary to deficiency. In globally may people do not have enough micronutrient in body. many expert suggest that taking high intake of vitamin c good for our growth and maintenance of overall body health (Comunian et al., 2022). A crucial phyto nutrient in vitamin c one of the most important water soluble antioxidant which are present in some vegetable and fruits. vitamin c food contain a good amount of antioxidant which is help to fight against the free radical and suppresses the oxidation of LDL as a person suffering from atherosclerosis. previous researches show that vitamin c reduce the risk of chronic illness such as heart disease, cancer infection disease etc (Kongkachuicha et al., 2019). If you take a good amount of vitamin c it will help to enhance the level of antioxidant as well as fight against inflammation. Some clinical studies suggested that intake of vitamin c is stop because during pregnancy it became fatal growth, premature delivery and neonate death. vitamin c help to reduce the risk of rupture of the membrane and suggested 100mg for reduce the risk of urinary infection during pregnancy (Brown & Wright, 2020). Vitamin c covered across the placenta and maternal plasma level are decrease and daily intake of vitamin c need for lactation mother is around 60-85mg per day (Mousa et al., 2019). Increase the intake of vitamin c rich food such as citrus fruits and vegetable, raw broccoli, pepper, kiwi etc suggested that 400mg per day require for increase the plasma level of vitamin c at least 200 mg (Brown & Wright, 2020). Vitamin c is a water soluble vitamin c which is easily absorbed by our body but our body is unable to synthesized by own itself. the term vitamin c essential micronutrient protect our body from scurvy disease and it is introduced by Albert Szentgyorgyi in 1930s and help to prevent from damage to cell and many other benefit for our body are uses for energy and build up new things (Comunian et al., 2022). The purpose of this review paper to discuss about how vitamin c effect on different disease such as cardiovascular disease, obesity, anemia, covid-19 etc and their different dosage against particular disease.

HEALTH BENEFITS OF ASCORBIC ACID

Vitamin c and scurvy

Scurvy disease is very fatal disease and this disease describe in previous time. In 16th and 18th century James Lind who was famous physician he suggest that drink lemon juice for prevention from scurvy (Kazmierczak-Barańska et al., 2020). Human need 100 to 200mg of vitamin c from a daily diet and it reduce the risk of vitamin c deficiency and we need to treat if the scurvy is untreated because it is very harmful disease. We must take 10mg per day to avoid from scurvy (Mousavi, et al., 2019). Vitamin c prevent from scurvy and mostly research show different doses of vitamin c in scurvy. We need 40-220mg of vitamin c everyday this range given the diversity of guidelines (Carr & Lykkesfeldt, 2021). Lack of vitamin c in diet as a result illness because pneumonia and scurvy are linked with each other. Many people believe that vitamin c may affect a person refers to respiratory infection. In pre-diabetes and metabolic syndrome patient. Vitamin deficiency line with respiratory infection for example pneumonia. This disease is very fatal and cause many number of death in scurvy cases. Healthy manner intake of vitamin c is 200mg/day is enough and fight against the infectious disease (Rowe & Carr, 2020). International guidelines for daily intake of vitamin c are insufficient. it has already shown that 10mg of vitamin c in a daily basis is sufficient (Khalife et al., 2019). The treatment against scurvy is vitamin c supplementation. there are different dosages and treatment has been successful. treatment of abnormal eating pattern and it require long term nutritional counseling and therapy are also necessary (Kothari et al., 2020). Supplementation of oral vitamin c has very rapidly effect against scurvy taking 300 mg of vitamin c twice in a day is currently recommended and it continue at least our health and serum level show that

**Luxita Sharma and Dhananjay Sharma**

our body has replenished its store(Roy-Lavallee et al., 2020).Vitamin c recommended is 0.25mg/dl for scurvy.its measure correctly in urine and serum. high dose around 1g are used for scurvy treatment(Essien et al., 2022).After taking vitamin c patient feel immediate improvement and oral symptoms improved within 6 days but ecchymes and bones abnormalities take some weak to recover and may be it take 2-3 month(Kothari et al., 2020)

Vitamin c and Cancer

Many people are suffering from cancer and he is became a first and second cause of death in the world and day by day cancer patient is increasing both physically, economically and developing, omit cancer drug became important need(Chen et al., 2022).Cameron and Pauling conducted some trials in which they treated 10g per day for next 10days result its very beneficial and after mayo clinic performed two randomised double blind clinic trial in which patient with advance cancer around 10g per day but both study have no benefit from high dose of vitamin c therapy(Yue & Rao, 2020).Several study suggested that venous administration of high intake of vitamin c is effective in cancer patient. Due to provident impact which promote apoptic death cancer cell in tumours periphery stimulating angiogenesis and spread. Some study show low millimetre doses range of pharmacological vitamin c eliminate tumours in vitro and decrease the risk of cancer formation in vivo. In reality there are several routines through which vitamin c influence cancer progression(Mussa et al., 2022).It is still unknown that how this nutrient particularly after more than 50year of study on function .In 1970s Ewan Cameron expanded on McCormick idea he proposed that vitamin inhibited the hyaluronidase which is help to reduce damage tissue and cell growth of cancer(Roa, et al., 2020).Study found those who have higher plasma level of vitamin c or consume vitamin c is reduce the risk of cancer .vitamin c intake is good indicator of taking fruits and vegetable many function of vitamin c in our body in various anticancer mechanism. Taking large dose of vitamin c than typical dietary intake and many physician recommended lager dose of vitamin c for prevention of cancer patient (Carr & Lykkesfeldt,2021) there are many study show that milimolarintake of pharmacological vitamin c successful to kill cancer cells as well as tumour development some cancer because sensitive against vitamin c and normal cell continue to became resistance(Carr & Cook, 2018). In 1950,vitamin c use for cancer treatment was initially explain the role of collagen synthesis to hypothesis that ascorbate replenishment is help in protect a normal cell. again metastatis as well as cancer development of supplementation of vitamin c is help improve our immune system(Codini, 2020)

In 1969, cancer cell was mentined ,large amount of vitamin c might be prooxidant effect on cancer cell .yun said formation of h2o2 is the main cause of destroying the cancer cell and produce very less antioxidant enzymes such as catalase, superoxide dimustase and glutathione peroxidase as compared to any other normal cell(Carità et al., 2020). Many author are fear to recommended the dose of vitamin c for treatment because of antioxidant property and it's accumulate in tumour and some another think different they think high dose of vitamin c supplementation not interfere with any therapy and it will be increase. Clinical study show there is no between effectiveness of chemotherapy medicine and antioxidant drug(Codini, 2020).Study show that the ability of vitamin c to kill many types of cancer cell and some study show that combination of high dose of vitamin c with conventional and anti drug increase cytotoxicity in many cancer cell(Bedhiafi et al.,2022).large dose of vitamin c cause cytotoxicity in our body which is may be harmful. Many researcher show that high intake of vitamin c cause ROS buildup as a result immunogenic cell death. Some reacher investigator that the high intake of vitamin c and ICT with combination(Fan et al., 2023). Few studies claim that high dose of vitamin c help to reduce the risk of pancreatic cancer and some other types of cancer (Visser &Das, 2018). Fewstudy show that vitamin c can kill cancer patient, in cancer patient common to have low plasma concentration of ascorbate then healthy person and vitamin c deficiency can relate with increased the cancer risk, cancer cell are high in oxidative stress than a normal cells (Ngo et al., 2019). Cancer patient found that have lower plasma level of vitamin c as compared to healthy person .Some study claim that high dose of vitamin c is not helpful for cancer patient. Vitamin c important for our well-functioning of immune and epithelial barrier cell. In many people are suffering from infection because of low intake of vitamin c (Doseděl et al., 2021).In pre-clinical studies we clearly show that vitamin c is very important role in our normal immune functionally and manufacture of immune cells for ex- natural killer cells and T-lymphocytes which are fight against cancer cell in infection (Van Gorkom et al., 2019). In 1970; s Linus Pauling already develop a strategy to use intravenous vitamin c in cancer patient, this method treat many patient in advance cancer. Patient recommended high dose of vitamin c. (Magri, et

**Luxita Sharma and Dhananjay Sharma**

al., 2020). In recent result there is no evidence both human and animal, studies claim that there is no clear evidence of antioxidant reduce the risk of cancer (Ngo et al., 2019). Many cancer patient found that have lower plasma level of vitamin c as compared to healthy person. Some study claim that high dose of vitamin c is not prevent from cancer (Van Gorkom et al., 2019). Many researchers show that large dose of vitamin c can boost our immune system during winter. vitamin c supplement is very beneficial remedy to prevent from infection (Cerullo et al., 2020). During winter taking of vitamin c help to reduce the risk of tiredness and boost our immune system.

Vitamin c and Covid-19

Corona virus disease 2019(covid) main caused is SARS-COV2 corona virus. In world more than 100 million people are infected (Milani et al., 2021). Vitamin c is mostly used for treatment of respiratory infection. Vitamin c first used by early 1930s and 1970s after Linus Pauling found that it can treat common cold but many evidence unable to show the benefit for to treat respiratory infection (Hemilä & Chalker, 2013). In many study show that vitamin reduced the vasopressor, mortality and organ damage of sepsis patient (Rawat et al., 2021). High dose of vitamin c is very effective against sepsis and septic shock (Bae & Kim, 2020). Intake of vitamin c everyday help you to get over a flu but doesn't effective for who are involve in intense physical activity for example long distance race, skin. vitamin c supplement take once and show any benefit. people are very interested in wheather or not vitamin c for used to treatment of covid-19 because of may be have antiviral effect (Simonson, 2020). Vitamin c and some othere medicine such as corticosteroid as well as thiamine help to stop organs from getting worse and reduce the risk of sepsis and septic shock (Feyaerts, 2020). Vitamin c contain antioxidant, antithrombotic and anti inflammatory function and at reduce swelling, prevent from blood clotting as well as immune system (Pedrosa, 2022). Vitamin c is used in very widely in the world because of its safe, effective and inexpensive treatment. it boost our immune system function such as enhance the level of phagocytes, lymphocytes and improve T lymphocyte too (Hemilä & Chalker, 2013). No evidence yet that except vitamin c no can increase our immune system or help to protect from any types of virus. if a person follow healthy diet everyday it can be provided a strong immune system that can fight against any types of viral attack (Hemilä & Chalker, 2013). Globally confirmed that covid-19 pandemic which is caused by SARS-COV-2 infection. no effective treatment found yet for prevention of covid-19. some numerous research study show that large dose of vitamin c help in treatment of lung injury due to various type of inflammatory illness and lower the death rate and improve condition of oxygen support experience covid-19 patient (Gao, 2021). Vitamin c contain antioxidant, anti-inflammatory, immune-modulating are characteristics are processed for vitamin c. Important role of vitamin c in down regulation of cytokines for endothelium protection from oxidative damage during covid -19 if tested for effective and safe for many clinical trials (Rs et al., 2022). Function of vitamin c in covid-19 and pneumonia is the first mandolin randomization research. In data revealed that circulating level of vitamin c are not linked to covid-19 infection or pneumonia (Hui et al., 2022). Some study show that vitamin c, prophylaxis and progress. some few study claim use of vitamin c treat covid-19 (Rs et al., 2022).

Vitamin c and anemia

Vitamin c production of haemoglobin for fast recovery of anemia. orange contain good sources of nutrient especially in vitamin c and bioflavonoid. which role in important for stop the bleeding, increase the physical and mental decline. Vitamin c help to boost absorbic ferroin iron (Novelia et al., 2020). Anaemia it can happen when enough blood is not in your body. haemoglobin stimulate in blood to carry oxygen in the cell. some common symptom are difficult in breathing, headache, irregular heartbeat, pain on chest (Bhadra and Deb, 2020). A previous study found that relation between vitamin c and haemoglobin and later auther claim that there was no linked between iron and vitamin c. orange is block their iron absorption as well as haemoglobin level. its hoped that anemia will be decrease (Novelia et al., 2020). Some food in anemia patient must be added in our diet such as red meat, fish, egg, darkgreen vegetable, to fu, and all type of citrus fruits. are also rich in vitamin c which are help to treat anemia as soon as possible (Bhadra and Deb, 2020). Recommended dose of vitamin c is high because of its absorption of iron and this is very effective method for pregnant women anemia. intake of iron tablets everyday and vitamin c rich food, green vegetable everyday and anemia pregnant mother must be avoided drinking coffee or tea when she is not have enough vitamin c in her body and 50mg of vitamin c give in everybody (Gusmaliza, 2022). Vitamin c show that proper iron apsrption is gastroint estional tract and extra iron preparation are often found. vitamin c contain high

Luxita Sharma and Dhananjay Sharma

amount of antioxidant(Wiciński et al., 2020) Vitamin c is vital component and our body require for the creating red blood cells. It inhibit the growth of hemosiderin which is very difficult to movement for iron realeasing when its needed. vitamin c eaten in our diet give acidic atmosphere the reduction of ferric acid into ferrous iron which is absorbed by own small intestine is very easy(Elba et al.,2021) Vitamin c improve non-heme iron absorption and the mechanism behind this effect is not yet known(Gupta et al., 2020).This study was investigated that show a good amount of iron and vitamin c intake help in iron development especially in older patient.those patient which are consume below then 50% of RDA cause the high of developing anemia(Rahfiludin et al., 2021).Vitamin c ability to absorption of iron was not used since and meet combined with food who content iron in same meal(Wiciński et al., 2020).Iron deficient patient should learn about which food contain a good amount of iron. Some sources are red meat, raisin ,dates, to fu and green leafy vegetable.vitamin c help in iron absorption(Turner et al., 2022).Vitamin c contain plant boost our bioavailability suggested that 250mg of vitamin c dosage for enhance the gastro intestinal absorption of iron and also increase the speed of erythropoiesis as a result it easy to digest by bone marrow(Wiciński et al., 2020). High dose of vitamin c around 10mg per day. They are found very few side effects.there are found in only few side effects. There are linked between high intake of vitamin c and theseside effect not clearly seen yet and explain 10mg per day in adult(Juneja et al., 2022)

Vitamin c and Obesity

In globally the obesity patient is more than triple more than triple in adult in the 1970,s increase both in children and adolescent(Blühe et al.,2020).Vitamin c deficiency is mostly found in obese people because antioxidant reduce the oxidative stress. Vitamin c prevent from free radical and lastely Johnston discovered the negative relation between plasma content as waist circumference and BMI(Lapik et al., 2020).Vitamin c very negative effect when a person body weight higher multiple epidemiological relation between plasma ascorbate concentration and body weight .mostly global recommended for adult for vitamin c intake increasing cases of obese in all over world (Carr et al., 2022). Advantage of vitamin c, multifunctional molecule oxidative stress protected by vitamin or relieving inflammation and some other health beneficial need special attention(Marks et al.,2021) Levine pharmacokinetic study used to require concentration the potential intake of vitamin c for higher body weight to reach vitamin c status as compared to individual ingestivity of a good amount of vitamin c(Carr et al., 2022).Vitamin c fruits are found they have antiobesity properly which can reduce our body weight and adipocyte number reasearcher show that some infant who formula fed and bottle fed are the risk of vitamin c deficiency and obesity too.vitamin c deficiency can be reversible if vegetable and fruits are available and consume everyday(Marks et al.,2021).

CONCLUSION

To put it simply, studies looking at how much vitamin c affect our health, disease and mortality. In this review paper we discussed about vitamin c for different disease but my own opinion is that make it hard to say that vitamin c is really effective for all disease. many cases vitamin c is not protect our body against some disease such as corona and covid-19 are not proven yet that is effective or not. Otherwise vitamin c is also beneficial against anemia, scurvy and obesity etc. Vitamin c is one of the important and necessary vitamin for our maintaince of all over body. numerous physiological process for human body and vitamin c dose depend on the basis of patient need for example if a person intake of alcohol and smoking on the daily basis so he need some extra vitamin c as compared to normal person intake. In future generation we all want to know that vitamin c effect clearly proven against covid-19 and cancer

ABSTRACT

The study aims to evaluate and compare remaining dentin thickness (RDT) after retreatment and time required for GP removal using two different retreatment file systems. 40 single rooted, non-carious, single canal permanent teeth were selected. The teeth were decoronated to obtain a standard length of 16 mm. Endodontic treatment was performed and obturation was done using single cone technique. Specimens were stored in saline at 37°C for 1 week. A CBCT scan was obtained in which Remaining Dentin Thickness (RDT) was measured for each sample at 3, 6 and 9 mm from the apex. The specimens were randomly divided into 2 groups (n=20) based on the retreatment file system used Group 1 – Style Italiano files and Group 2 – Neo-Endo files. Then while retreatment procedure was being performed the time required to remove the Gutta percha (GP) was measured using a stopwatch. After removal of GP, a CBCT scan was performed to measure the RDT post retreatment procedure. The data obtained were tabulated and evaluated using the Statistical Package for the Social Sciences (SPSS) software program. The results indicate that in terms of dentin removed there was statistically significant difference between the two groups at level 3 mm and 6 mm, whereas at level 9 mm, there was no statistically significant difference between the two groups. Also, statistically significant difference was found between the two groups in terms of time required for GP removal. The study concluded that in terms of Remaining Dentin Thickness, Style Italiano files preserved more dentin than Neo Endo group. Whereas, the time required for Gutta Percha removal was lesser in Neo Endo group.

INTRODUCTION

Root canal treatment, although generally successful, may sometimes fail to achieve the intended result.[1] Failures can occur even with the most careful procedures and adherence to best practices. [2] The primary causes of these failures are the continued presence of bacteria in the complex root canal system, often due to improper cleaning or filling, procedural errors, or the absence of an appropriate fluid-tight seal, allowing microorganisms to survive in dentinal tubules, apical ramifications, and accessory or secondary canals. [3] Modern techniques for removing root filling materials include the use of hand or rotary nickel-titanium (NiTi) instruments, sometimes with heat, solvents, or ultrasonic tools. Specialized rotary instruments designed specifically for retreatment, such as Neo-Endo and Style Italiano retreatment files, are now available. In non-surgical retreatments, maintaining the remaining dentin thickness is critical to avoid complications like excessive dentin removal or perforation. [4] Orthograde retreatment involves the removal of existing filling material, followed by debridement and then obturation. In addition to removal of the old filling material, it is of great significance for the operator to conserve the remaining tooth structure to improve the long-term success of the treated tooth.[5] Neo-Endo retreatment files (Orikam Healthcare, India) feature advanced heat treatment and micro grinding manufacturing techniques to reduce the engagement zone. These files possess controlled memory along with a parallelogram cross-section, and a positive cutting tip which help to prevent ledge formation and file breakage during retreatment.[6] Style Italiano retreatment files (Style Italiano, Italy) are designed to remove gutta-percha in a minimally invasive manner and utilize heat treatment technology and is a set of five files. Style Italiano retreatment files have lesser taper to ensure a better outcome and to reduce further complications like stripping, zipping of the apex and alteration of the original anatomy. Cone-beam computed tomography (CBCT) is frequently used in endodontics and is more effective than traditional radiographs for detecting periapical pathologies and root resorption. It is also superior for assessing root canal morphology and guiding endodontic surgery. [7] With the aim of preserving the remaining dentin thickness, this study aimed to evaluate the RDT using two different retreatment instruments through CBCT and the time taken by these systems for removal of gutta percha.

MATERIALS AND METHODS

Sample Preparation

For this study, forty freshly extracted single-rooted permanent teeth were chosen. Teeth that exhibited additional canals, fractures, significant canal curvature, or signs of internal and external resorption, as identified through radiographic evaluation, were excluded. The selected teeth were carefully cleaned to remove any tissue remnants and debris using a scaler, disinfected in 5.25% sodium hypochlorite for one hour, and then stored in saline for later use. The teeth were then decoronated using a diamond disk, and the length of each tooth was standardized to 16 mm.

Root Canal Preparation

After creating an access cavity in each tooth with a high-speed handpiece and a No. 2 round bur (Mani) with air-water spray, a #10 stainless steel K-file (Mani) was inserted into the root canal, and the working length was measured using RVG. The root canals were shaped using Hero Gold rotary files (Micro Mega, France) with the crown-down technique, up to size #30 and a 0.06 taper. Canal irrigation was carried out with 3% sodium hypochlorite, saline, and 17% ethylenediaminetetra acetic acid (EDTA). The canals were dried using paper points and filled with gutta-percha points of the appropriate size and taper, along with AH Plus resin-based sealer (Dentsply De Trey, Konstanz,

**Mukund V Singh et al.,**

Germany). Cavit G was placed to temporarily seal the teeth, which were then stored at 37°C and 100% humidity for one week to allow the sealer to fully set. Following this, the samples underwent pre-operative CBCT scan.

CBCT Scanning and Evaluation

The samples were placed on a wax mold to maintain consistent positioning. The remaining dentin thickness was calculated by measuring the shortest distance from the edge of the uninstrumented samples to the root margin. These measurements were then compared with those obtained from the scans of the instrumented samples at 3 mm, 6 mm, and 9 mm from the apex. The average dentin removed at these levels for both groups was calculated using the formula: $\text{MD1} - \text{MD2}$, where MD1 is calculated as $m1 + d1/2$ and MD2 as $m2 + d2/2$. In this formula, m1 and d1 represent the shortest distances from the mesial and distal edges of the root to the corresponding edges of the filled canal, while m2 and d2 represent the shortest distances from the mesial and distal edges of the root to the corresponding edges of the canal after gutta-percha retrieval.

Retreatment Procedure

Twenty samples of teeth were randomly assigned to each of the two experimental groups. Group 1 – Neo-Endo retreatment files: Gutta-percha removal from the coronal third of the root canal was done using the N1 file (30/09), from the middle third using the N2 file (25/08), and from the apical third with the N3 file (20/07).

Group 2 – Style Italiano retreatment files

Gutta percha was removed from the coronal third of root canal using Bull-Y file (25/07), from the middle third using Skinn-Y (24/04), and from the apical third using Shap-Y1 (20/05) All rotary files were used according to the manufacturer's instructions. Irrigation was performed using 3% sodium hypochlorite. When there was no visible gutta percha residue left on the instrument, retreatment was deemed to be complete. To evaluate the effectiveness of the retreatment preparation, digital radiographs were taken to check for any traces of the obturating material or sealer left in the canals. The time taken for the gutta-percha removal process was recorded using a stopwatch, and the amount of remaining gutta-percha was assessed using conventional radiographs. Post the gutta-percha removal, the root canal irrigation was done for three minutes with 3mL of 17% EDTA followed by saline rinse, and then dried with absorbent paper points.

Statistical Analysis

Statistical analysis was done using descriptive statistics. Paired t-test was employed to compare the pre and post mean RDT of all samples in both groups. Unpaired t-test was applied to compare mean RDT in both groups. One way ANOVA was used to compare the means of both the study groups. An independent t-test was performed to evaluate the time taken by each group to retrieve gutta percha. Statistical software namely SPSS version 21 was used to analyze the data. p-value of less than 0.05 was considered to be statistically significant.

RESULTS

At level 3 mm and 6 mm, there was statistically significant difference between the two groups. At level 9 mm, there was no statistically significant difference between the two groups. Table 2 and Figure 2 represents the mean and standard deviation for the time taken for gutta percha retrieval using the two file systems Neo Endo and Style Italiano. Statistically significant difference is found between these two groups.

DISCUSSION

There are several factors that can contribute to endodontic failure, including incomplete cleaning, incomplete obturation, and missed canals which may result in retreatment. [8] Endodontic retreatment is largely replacing endodontic surgery as the preferred approach for resolving persistent periapical infections since it is less invasive.[9] Numerous studies have been conducted in the past to compare the efficacy of various file systems in removing

**Mukund V Singh et al.,**

obturator material. [10] These studies followed specific protocols, such as the use of chemical solvents to remove gutta-percha, and two-dimensional digital radiography to confirm the complete elimination of the filling material. [11] The study did not use solvents, as previous research has indicated that their use can lead to inaccurate results by leaving significant amounts of endodontic material and sealer on the canal walls during retreatment procedures. [12] Furthermore, the use of solvents can aggravate periapical tissues, making it harder to accurately determine the retrieval time, as noted in previous studies. [13] Various techniques, including conventional radiographs, microcomputed CT, CBCT, and longitudinal sectioning, are recommended for assessing remaining obturator material during endodontic retreatment. [14,15] In this study, CBCT was employed to evaluate the complete removal of the filling material. The time for gutta-percha retrieval was recorded using a stopwatch. Rotary instruments are typically favored over hand instruments in retreatment procedures as they generate friction that softens the gutta-percha, making it easier to remove. Additionally, rotary instruments help reduce operator fatigue, shorten working time, and preserve the canal's shape. [16] The study identified a statistically significant difference in remaining dentin thickness between the Neo-Endo and Style Italiano retreatment groups, which can be attributed to two factors: the taper variation between the instruments and the heat treatment of the Neo-Endo files, whereas only the Bull-Y (25/07) and Shap-Y1 (20/05) files from Style Italiano were heat-treated. The heat treatment of Neo-Endo retreatment files enhances their flexibility. Additionally, the smaller taper of Style Italiano files helps preserve dentin and reduces the risk of canal transportation. Further research is needed to include a variety of retreatment file systems, posterior teeth, curved canals, and more advanced imaging techniques like micro-CT to support and expand upon these findings.

CONCLUSION

Within the limitations of the study, we can conclude that in terms of time required for gutta percha removal, the Style Italiano retreatment files took longer time but preserved more dentin than the Neo-Endo retreatment files which took lesser time for gutta percha removal and resulted in lesser remaining dentin thickness compared to the Style Italiano retreatment files group.

ABSTRACT

Image tampering, a critical issue in the digital age, poses significant challenges to the authenticity and integrity of visual data. This comprehensive survey explores various image tampering localization techniques, tracing their evolution from traditional methods to advanced deep learning approaches. This paper categorizes these techniques into four main groups: block-based, keypoint-based, deep learning-based, and hybrid methods. Each category is meticulously examined, highlighting key methodologies, their advantages, and limitations. Furthermore, this survey analyzes the trends in the field, emphasizing the shift towards more sophisticated and robust deep learning frameworks that offer improved accuracy and reliability. Additionally, the survey addresses the challenges faced by current techniques, such as the need for large annotated datasets and the high computational costs. Finally, we propose future research directions, advocating for the integration of multi-modal data, the development of real-time tampering detection systems, and the exploration of unsupervised learning techniques to enhance the efficacy and applicability of image tampering localization methods. This survey aims to provide a comprehensive reference for researchers and practitioners, facilitating further advancements in the domain of image forensics.

Keywords: Image tampering, Deep learning, Restoration, SIFT, SURF.

INTRODUCTION

Digital pictures are ubiquitous in our everyday lives, serving as key carriers of information transfer. As image processing technology has advanced, several picture editing tools have made it easy to produce realistically altered images [1][2][3]. A cascade of unfavourable outcomes is inevitable whenever altered photos are used for malevolent objectives, including fabricating certifications or spreading rumours [4][5][6]. Consequently, identifying manipulated photos is crucial for preventing their exploitation. Forensic techniques to identify altered photos and pinpoint their exact locations have proliferated in recent years [7][8]. A shift from using hand-crafted features to deep learning approaches has been seen in the technical paradigms of these methods [9]. These days, forensic techniques based on deep learning outperform their more traditional counterparts [10]. The use of efficient network topologies, including fully convolutional networks, U-Net, faster R-CNN, mask R-CNN, and ViT, is one possible explanation. Also, forensics relies heavily on a mix of deep learning and domain expertise [11][12]. In order to detect any changes done after capture, image tampering localization seeks to locate and identify changed areas within a picture [13]. When faced with the variety and complexity of manipulation techniques, traditional methods that depend on heuristic and statistical approaches often fail [14][15]. There has been a lot of development in the area since the introduction of machine learning and, more newly, deep learning; new approaches provide better detection accuracy and resilience [16][17]. This review summarises the current status of the art in localising image manipulation [18],[19]. In this survey classifies the current methods according to their underlying architecture: block-based, keypoint-based, deep learning-based, and hybrid approaches [20][21]. There is an in-depth analysis of each grouping, with a focus on the fundamental ideas, advantages, and disadvantages of each. The goal of this study is analysing these approaches to find out what's happening now and where the research in this important field is heading [22]. Additionally, we tackle the typical issues encountered by existing tampering localization methods, including the need of big, annotated datasets, significant computing loads, and the capacity for processing in real-time [23][24]. In this work lays the groundwork for future study by highlighting these obstacles; the propose investigating unsupervised learning methods, improving algorithm efficiency and effectiveness, and integrating multi-modal data [25]. The paper is organized as follows. In Section 2, Background of the study was discussed. An existing methods image restoration and tampering localization methods are discussed in section 3. Section 4 shows the Discussion and Finally section 5 gives the conclusion of this paper.

Background study

Akhtar, N. et al. [1] the field of digital video forensics was very new, and the validity of digital footage as evidence in legal proceedings was uncertain because of the possibility of manipulation (forgery). Any number of video editing programmes, including Adobe's, GNU Gimp, Premier, and Vegas, were easily accessible for use in such endeavours. The research issues that guided this effort were addressed in this study, which included a thorough assessment of methods for detecting digital video forgeries. Bhalerao, S. et al. [2] since the advent of digital communication, the safety of multimedia communications has risen to the forefront of people's minds. Consequently, this study suggests a delicate and safe method of picture watermarking for the purpose of detecting image tampering. A SHA-1 hashing algorithm-based block-based watermarking method was suggested. Cao, G. et al. [3] to test how well state-of-the-art image tampering localization methods protect against intrusion, the author provide an adversarial assault approach. Following a formal formulation of the attack on tampering localizers, unified attack architecture was used to demonstrate two adversarial example techniques of attack. In both white-box and black-box situations, these authors suggested assaults considerably lower the accuracy of state-of-the-art tampering localizers. Diallo, B. et al. [4] the author present a deep learning architecture that can reliably identify cameras and detect instances of manipulation in images. It encompasses all the usual picture alterations that users employ while sharing photographs. By manipulating the compression quality factor, the author evaluate these authors system and demonstrate that it outperforms methods found in the literature on a global scale. Guo, K. et al. [5] the author provide a new method for localising instances of picture manipulation that makes use of co-attention feature fusion and a two-branch improved transformer encoder. The author uses the feature improvement module to make the network representation stronger, and the author use the coordinate attention-based fusion module to integrate the features from different scales. Hao,

**Karpagadeepa and Sumathi**

J. et al. [6] to simulate global context and all pairwise interactions between patches at various sizes, the author introduce TransForensics, which employs dense self-attention encoders. This study was ground breaking because it applies transformer self-attention techniques to the problem of identifying and localising altered areas. Jena, R. et al. [7] the author presented a privacy-preserving system for encrypted JPEG picture tamper detection in this study. Combining two JPEG photos of varying quality was likely to result in forgery detection, according to these authors research. One of the initial minima in the energy graph was the featured image's quality. When the JPEG quality remains constant, however, the likelihood of detecting forgeries was minimal. Joshi, V., & Jain, S. [8] Digital movies may be efficiently feature extracted using the suggested approach, which was both robust and compact. These characteristics were retrieved from digital video clips that portray a video segment with both spatial and temporal information. The suggested method can identify and pinpoint the edited area in a digital video. Laouamer, L., & Tayan, O. [9] an effective spatial-domain non-blind watermarking method was presented in this work, and its tamper-localization accuracy and image-recovery quality were shown to be exceptional. These authors robust watermarking system incorporates linear interpolation to improve performance during watermark picture extraction; this improvement allows these authors approach to provide complete detection and recovery capabilities, which was a noteworthy contribution/novelty of this study. Li, D. et al. [10] the author provide a new approach to localising image fraud using a two-stage edge-aware regional message passing control mechanism. In particular, making preparations to make maximum use of the edge information was the first stage.

Second, an edge-aware dynamic graph was constructed to reduce the strength of the message flowing between the genuine and forged areas, led by the learnable edges. In order to address the issue of misjudgement in IFL, these authors work presents a novel research approach. Rao, Y., & Ni, J. [12] these authors research proposes a self-supervised domain adaptation network (ComNet) for JPEG-resistant picture fraud localization. The network combines a backbone network with a compression approximation network. The author do away with data augmentation using genuine JPEG compressed pictures and instead use ComNet, trained with self-supervised learning, to approximate the JPEG compression procedure, and produce JPEG-agent images. Saju, G., & Sreenimol, K. R. [13] to attain high levels of authenticity and integrity, these authors algorithm has been suggested. If someone tampers with a digital document picture, these authors method can find it and pinpoint where. Misdiagnosis could result from even a little amount of manipulation, such as a thin line. Insurers may lose a lot of money if this kind of manipulation occurs. This condition was well-suited to the discrete wavelet transform approach. The tuple-nature of the hash function allows it to pinpoint the precise location of the tampering. Salim, M. et al. [14] the author presented a method in this research that uses a visual cryptography watermarking system to identify and pinpoint picture forgeries. To ensure this method was effective and resilient, it was tested on the SIPI dataset and the CASIA V 1.0 dataset. The digitally altered photos in these datasets were subjected to a number of well-known assaults, such as compression, noise (both Gaussian and Speckle), sharpening, median filtering, scaling, rotation, and salt & pepper. Shaik, A. et al. [15] the author provide a method for perceptual picture hashing that makes use of ring partition and CSLBP. After the picture was transformed into a standard image, CSLBP was used to extract ring-based statistical information. These characteristics were fixed and do not change with rotation.

Since the ring partition has no effect on picture rotation, this was achieved. In comparison to previous methods, the findings demonstrate that the suggested hashing algorithm was more resilient and discriminative, and it can withstand geometric manipulations (such as rotation) applied to pictures. Shaik, A. et al. [16] these authors' research presents a method for picture hashing that utilises LWT and DCT. Tampering localization was one area where the suggested approach excels above the blind geometric correction method. After conducting the experiment on a big database, the results showed that the technique suggested for dealing with CPOs was effective. Additionally, pinpointing tampering zones and good discriminative ability would be great. Wang, M. et al. [19] a wavelet-based Compression Representation Learning Network (CRL-Net) was used to guide a JPEG Compression-Aware Image Forgery Localization Network (CA-IFL), which was proposed in this research. The compression representations obtained by CRL-Net using its contrastive learning technique were quite similar to those of JPEG compression. Using the learned representations as a foundation, the author describes the CA-IFL, which can adaptably deal with fake pictures compressed using different JPEG quality factors. Yarlagadda, S. et al. [21] these authors suggested technique

**Karpagadeepa and Sumathi**

for detecting and localising satellite images forgeries was detailed in this publication. An autoencoder may be trained to acquire a compact representation of image patches derived from perfect satellite photos, which was the reasoning behind the suggested approach. A feature extractor for picture patches may thereafter be used with this autoencoder. Ying, Q. et al. [22] an innovative generative technique for picture self-recovery, Imuge+ was introduced in this study. It was impervious to image tampering. The author take the original photos and make them immune to tampering so that the author can pinpoint where the assaults occurred and restore the original material in the affected regions. The author use an INN architecture to build the invertible function for image immunisation and improve speed. Zhang, W. et al. [23] these authors research presented a new multi-scale fusion approach that uses PRNU to identify digital picture forgeries, such as copy-move and splicing. Instead of estimating PRNU correlations on overlapped patches like current sliding window-based algorithms do, the suggested algorithm directly segments the test image into irregular, nonoverlapping blocks of multiple scales and calculates correlations on nonoverlapped segmentation patches. Zhang, X. et al. [24] here the author introduce EditGuard, the first effort at designing a deep adaptable watermarking method. Decoding correct copyright information and tampered regions, as well as integrating invisible localization and copyright watermarks, makes it a trustworthy tool for creative production and legal forensic investigation, adding credibility to photos. Zhu, H. et al. [25] through the exploration of pictures' general inherent properties, the author provide a new method for localising instances of image manipulation. The ConvNeXt encoder will extract characteristics that indicate hierarchical manipulation. Zhuang, P. et al. [26] the author provides ReLoc, a restoration-assisted framework, to make tampered localization more resistant to post-processing. Two modules make up the ReLoc framework: one for restoring images and another for localising instances of manipulation. In order to retrieve evidence of manipulation from warped photos, the author uses the image restoration module.

Existing methodology

Figure 1 is describe the overview of this paper and it is combined with deep learning based methods and block and keypoint based method using CNN, SIFT and SURF algorithms.

Image Tampering Detection algorithms

Convolutional Neural Networks: CNNs' capacity to learn intricate patterns and attributes from data allows them to identify and localise manipulated areas with high accuracy. Convolutional neural networks (CNNs) are able to detect minor signs of manipulation because they collect hierarchical characteristics, starting with low-level edges and textures and progressing to high-level semantic data. Demerits of this algorithm is To get decent results from CNNs, you need a lot of labelled training data. It could be difficult and time-consuming to collect and mark such data in order to identify manipulation. Not all applications may be able to handle the computational expense of training convolutional neural networks (CNNs). Generative Adversarial Networks: In order to detect small differences caused by manipulation, GANs may learn complicated, high-dimensional distributions of actual pictures. Demerits of this algorithm is essential to carefully balance the generator and discriminator networks while training a GAN, and the networks themselves are infamously tough to train. It is important to fine-tune training to avoid instability and ensure convergence.

SIFT

SIFT characteristics are great for identifying manipulations that affect scale, rotation, and lighting since they are resistant to these changes. In order to help localise manipulated areas, SIFT finds unique and repeatable keypoints and descriptors across many pictures. Demerits of this algorithm is It may not be feasible to use SIFT for real-time applications or big datasets due to the computationally demanding procedures involved, such as keypoint identification, descriptor calculation, and matching.

SURF

With its quicker architecture compared to its predecessor SIFT, SURF is more suited for real-time applications and efficient processing of huge datasets. Reliable recognition of keypoints and descriptors is assured using SURF features, which are resilient to picture noise. The accuracy of tamper detection, particularly in cases involving

**Karpagadeepa and Sumathi**

sophisticated picture alterations, may be affected by the fact that SURF, in comparison to SIFT, may not yield as unique features in some instances. Similar to SIFT, SURF is mainly designed to identify simple geometric changes like scaling, rotation, and translation. It could have trouble detecting more complicated forms of manipulation, such as content modification or sophisticated counterfeiting.

Convolutional Neural Networks

Because of their hierarchical feature extraction capabilities, Convolutional Neural Networks (CNNs) identify complicated patterns suggestive of tampering, such as structural abnormalities and texture inconsistencies, and picture tampering categorization is one area where CNNs really shine. By employing convolutional layers to capture local visual cues and pooling layers to minimise dimensionality while maintaining critical information, CNNs can successfully discern between tampered and real photos. Convolutional neural networks (CNNs) improve end-to-end to learn discriminative features and decision boundaries, guaranteeing excellent accuracy in classification tasks. CNNs are trained via supervised learning on labelled datasets. Despite the computational costs and possible interpretability issues, convolutional neural networks (CNNs) continue to play a crucial role in forensic analysis. They can identify different types of image manipulation by not only categorising manipulated areas but also localising them within pictures

Generative Adversarial Networks

A novel architecture called a Generative Adversarial Network (GAN) uses a competitive game between two neural networks, the discriminator and the generator, to improve the production of realistic data. Image tampering is an area where GANs really shine. These networks can generate fake but convincing pictures by manipulating the original, and then they use a discriminator to tell the difference between the two. This method uses adversarial training to fine-tune detection sensitivity, making GANs very good at identifying small tampering artefacts like colour or texture irregularities. Reliable tampering detection findings need careful tuning and robust data preparation since GANs encounters problems such training instability, mode collapse, and high computing costs. Notwithstanding these obstacles, GANs have great promise as instruments for sophisticated forensic analysis and systems for detecting manipulation due to their capacity to produce and distinguish realistic pictures.

DISCUSSION

Thanks to advancements in deep learning that provide more accurate and resilient localization of picture manipulation. While keypoint and block-based approaches have provided a solid foundation, they now confront obstacles including high computing costs and diminished efficacy in low-texture areas. Although they need massive computer resources and massively annotated datasets, deep learning methods have utterly transformed the industry. Combining deep learning techniques into hybrid methods has great potential for achieving a happy medium between promptness and accuracy. Challenges in dataset availability, processing costs, generalizability, and resistance to adversarial assaults continue, while current trends emphasise the development of real-time detection systems and increasingly advanced neural network designs. To improve the effectiveness and practicality of image tampering localization methods, future studies should inspect ways to fit in multi-modal data, enhance models for real-time processing, investigate unsupervised learning as a means to lessen reliance on labelled data, and strengthen models against adversarial manipulations.

CONCLUSION

In order to guarantee the genuineness and validity of digital visual data, the area of image tampering localization is vital and ever-evolving. With this all-encompassing review, have followed the development of localization techniques from their earliest iterations to modern deep learning and hybrid techniques. Although there are still issues with processing needs and data requirements, deep learning has brought exceptional resilience and accuracy, building on top of older approaches. Advancements in the discipline are seen in the growing trend of real-time

Karpagadeepa and Sumathi

detection and the creation of complex neural network structures. Big annotated datasets are necessary, but lot of obstacles to overcome, such as high computing costs, problems with generalizability, and exposure to adversarial assaults. A multi-pronged strategy including optimisation for real-time applications, research of unsupervised learning approaches, integration of multi-modal data, and enhancement. In order to ensure that digital images can be trusted in an increasingly digital environment, researchers should concentrate on these future paths to improve image tampering localization techniques.

ABSTRACT

The skin permeation therapy is the sustained and controlled drug delivery whose goal is to spread the drug via the skin at a specific and regulated rate and time. More prevalent disorders in the world today is hypertension. Although it is not a disease and of itself, it is a substantial risk element to cardiovascular morbidity and death. This article gives the efforts made to make and administer transdermal patches as a means of increasing the bioavailability of antihypertensive medications. The first transdermal antihypertensive medication created was clonidine. Many transdermal patches for hypertension are now being launched to the pharmaceutical market. For the manufacture of transdermal patches, solvent evaporation or solvent casting processes were used in the majority of documented methods in the literature. Polymer, plasticizer, and Atenolol administered by transdermal patch allows drug molecules to enter the bloodstream directly, circumventing the harsh gastrointestinal environment and first-pass metabolism that are frequently associated with oral delivery. Transdermal patches having atenolol were created utilizing the solvent evaporation method. Various proportions of Methacrylic acid copolymer (RL type), Ethylcellulose resin, and PVP were combined.

Keywords: Hypertension, Percutaneous absorption, Controlled release, Adhesion, Matrix film.

Harsha H. Tarare et al.,

INTRODUCTION

Drug administration through the skin has drawn more attention as a means of both systemic and topical drug delivery, as well as local therapeutic effects on skin. Compared to many other ways of drug incorporation, the skin offers a number of important advantages for drug delivery, such as the ability to prevent issues with pH and emptying rate effects, gastric irritation, and hepatic first-pass metabolism, which increases the drug's bioavailability, lower the risk of systemic side effects by minimizing serum level correlated to oral therapy, provide a localized pharmaceutical distribution place of application, enable rapid therapy termination by removing the device or formulation, and reduce fluctuations in plasma levels.(1) When it comes to the long-term management and prevention of long term conditions like hypertension, the TTS (Transdermal Therapeutic System) is especially clinically significant. Age-related increases in heart disease mortality are significant. (2) One of the primary factors that contributes to heart disease as well as the age-adjusted death rates from hypertension and heart disease in recent years have been going up 57 percent of cases are directly caused by hypertension. Fatalities from stroke and 24% of cases of coronary heart disease pass away in India. Combining Indian health data Studies reveal that 25% of people have hypertension. 10% of subjects were rural, 10% urban. Even though TDDS is a good option for treating long-term conditions including hypertension, the high expense of patches for hypertension rather than traditional goods (3)

History

The FDA approved, At 1979 motion sickness transdermal patches and it contained Scopolamine. In 1981, nitroglycerine was approved as the second patch. There is a wide range of transdermal application patches on the market. (4)

Advantages

1. This procedure is easy to use and just needs to be applied once a week. Such a basic dosage schedule can help patients follow their medication regimens.
2. Since transdermal distribution prevents side effect on the stomach and gastric area drug that disturb the digestive system is favourable for this mode of administration. Avoid gastrointestinal incompatibility.
3. Medication which degrades the stomach's acids and enzymes could potentially be a useful target. (5)
4. A consistent and long-lasting activity allows for the use of a medication with a brief biological half-life and a limited window for treatment. (6)

Disadvantages

1. The potential for localized irritation when the product is applied.
2. The medicine, bonding agent in the patch making may induce erythema, irritation, and local edema.
3. Could result in allergic responses.
4. 500 Da or less weight is necessary.(7)

STRUCTURE OF SKIN

Epidermis

The thickness of the multilayered epidermis varies from 0.9 mm on the grips and undersides of the feet to 0.05 mm on the eyelids, depending on the size and quantity of epidermal cell layers. Corneum stratum. This is the skin's outermost layer. When completely hydrated, it swells to several times its dry thickness of around 10 mm. It contains 10 to 25 layers of corneocytes, which are dead, keratinized cells. Although it is flexible, it is not very porous. The main obstacle to drug penetration is the horny layer. The keratinized cells in this model serve as protein "bricks" encased in lipid "mortar." The fats are organized lipid portion, including cholesterol and polar free fatty acids, to preserve a bilayer structure. Keratinized layer is covered by viable epidermis, which ranges in thickness from 0.05 mm on the eyelids to 0.9 mm on the palms. Consists of many membranes that go inward, including the stratum lucidum, granular layer, spinus layer, and the stratum basal. The epidermis at the basal layer is continuously renewed by cell mitosis, which makes up for the loss of dead horny cells from the skin's surface.

Harsha H. Tarare et al.,

Dermis

This is a layer that is 3 to 5 mm thick and is composed of a connective tissue matrix that includes nerves, lymph vessels, and blood vessels. The skin's blood supply plays a crucial regulatory function in anatomy temperature. The majority of molecules that penetrate the skin barrier find a sink state in capillaries, which extend to within 0.2 mm of the skin's surface.

Hypodermis

The true skin and cutaneous layer are supported by the hypodermis, or subcutaneous fat tissue. It acts as a place to store fat. This layer offers nutritional assistance, mechanical protection, and aids in temperature regulation. It transports the main blood vessels, nerves, and maybe sensory pressure organs to the skin. For drug to be penetrate transdermally, it must go by all three of these layers and reach the systemic circulation; for topical drug administration, just the stratum corneum must pass through before the drug is retained in membrane of skin.(8)

PERMEATION THROUGH SKIN

The most popular route for medication molecules to enter the body is the paracellular route. This mechanism keeps API in lipid moiety and close to the keratin (which makes it easier for lipid-soluble drugs to do so than proteins).

The transappendgeal route creates a continuous conduit for drug penetration, although it is readily impeded by the existence of sweat ducts and hair follicles.(9)

TRANSDERMAL PATCHES

Recent advancements have broadened its application to include the delivery of stimulants for Hyperactivity disorder, hormonal contraceptives, and even antidepressants. The FDA declared in 2005 that it was looking into reports of fatalities and other severe side effects associated with opiate overdose in patients taking Duragesic, a transdermal patch containing fentanyl, for pain relief. Later, in June 2005, the Duragesic product label was revised to include safety information. Transdermal medication patches with metallic backings have the potential to cause burns during MRI scans, according to a 2009 public health advice issued by the FDA. It is recommended that patients take off any medication patches before having an MRI and replace them with fresh ones when the scan is finished.(10)

Selection of percutaneous therapeutic agent

PERCUTANEOUS ABSORPTION

The movement of chemicals from the outer surface of the skin to blood stream.

- substance's entry into a certain layer is known as penetration.
- Permeation: the infiltration of one layer into another, which differs from the initial layer in terms of both structure and function.
- Absorption: system that facilitates a material enters the bloodstream.

Diffusion's first law is Fick's first law of diffusion helps to explain the passive-diffusion process of percutaneous absorption, which is how most medications are absorbed.

$$dQ/dt = JT = P.A.DC$$

JT = flux total transported through a unit area of skin per unit time in steady state ($\mu\text{g/hr}$)

A = area of the skin

P = the effective permeability coefficient

ΔC = drug concentration gradient through skin (12).

Epidermal Diffusion

Diffusion through the horny layer is influenced passively by physical variables. The percutaneous absorption to systematic circulation is a more complex process, consisting of two phases: epidermal diffusion and dermal clearance. Effective blood flow, interstitial fluid movements, lymphatic flow, and maybe other elements like interaction with skin components are necessary for percutaneous absorption. (13)

Harsha H. Tarare *et al.*,

FACTORS AFFECTING TRANSDERMAL DRUG DELIVERY

Physicochemical properties of penetrant molecule

Partition coefficient

Drugs that are soluble in water and fats are fastely absorbed to skin. Drugs with high lipophilicity and an intermediate partition coefficient ($\log K$ 1 to 3) can be administered using the intercellular route. For more hydrophilic compounds, the transcellular pathway most likely predominates. And unionized drug can be asily administered.

Molecular size

Molecular weigth 100- 500 dalton are taken.

Melting point / solubility

lipophilic molecules encorporates the skin quickly than more hydrophilic ones. When exposed to normal temperature and pressure, large melting point drug have comparatively limited water solubility.(14)

Physico-chemical Drug delivery parameters

Release characteristics

The drug's solubility in the vehicle indicates the release rate. The drug's intersurface partition coefficient in between the skin tissue and the delivery mechanism.

Composition of drug delivery:

The drug delivery system influences the stratum corneum's permeability through hydration, mixing with skin lipids, or other sorption-promoting actions with drug elution rate. Similar to salicylic acid, methyl salicylate exhibits more lipophilicity than its parent acid and produces a greater percutaneous absorption when administered to the skin from fatty carriers.

Transdermal permeation enhancement

Organic solvents -

Because partial leaching process of the epidermal liquids caused by these agents, the absorption of oil-soluble medicines is enhanced, improving the skin's conditions for wetting as well as for epidermal and follicular penetration. such as cyclohexane, acetone, ethyl ether, benzene, and chloroform. Dimethyl sulphoxide has been demonstrated to have a permeation-promoting effect on a range of medicines, including antibiotics, quaternary ammonium compounds, hormones, dyes, iodine, and local anesthetics.

Surface active agent

The action of surfactants is thought to be responsible for improving skin wetting, lowering surface tension, and facilitating penetration. For example, sodium dioctyl sulfo- and sodium lauryl sulphate(15)

TDDS Componentes

Polymer matrix

The polymers employed in TDDS should be chemically and biocompatible with both the drug and other system elements like PSAs and penetration enhancers. They should also be of safe status and distribute a medicine consistently and effectively for the duration of the product's stated shelf life.(16)

- a. **Natural polymer:** chitosan, natural rubber, cellulose derivatives, zein, gelatin, shellac, and waxes.
- b. **Synthetic elastomers** : Butylrubber, nitrile, acrylonitrile, neoprene, silicon rubber, polybutadiene, hydrin rubber, and polyisobutylene
- c. **Synthetic polymers** : ethylene, propylene, polyvinyl alcohol, polyvinyl chloride, polyacrylate, polyamide, polyurea, polyvinyl pyrrolidone, and polymethyl-methacrylate.(17)

**Harsha H. Tarare et al.,****Drug**

Drugs having a limited therapeutic window, high first pass metabolism, or short half lives . appropriate combination of physicochemical and biological qualities should not be ionic, have a low molecular weight (less than 500 Daltons), have a low melting point (less than 200°C), and be sufficiently soluble in oil and water (log P in the range of 1-3). day). selegiline for depression, Metadate disorder, rivastigmine for Parkinson's and Alzheimer's dementia, and rotigotine for Parkinson's disease have recently been licensed as TDDS.(24).

Permeation enhancers

Are pharmacological substances that raise stratum corneum permeability in order to reach higher therapeutic concentrations of the medication candidate. Proteins and lipids, which are structural elements of the stratum corneum, are interacting with penetration enhancers. They affect the stratum corneum's protein and lipid packing, which chemically modifies the barrier's activities and increases permeability. Dimethyl sulfoxide, ethanol, fatty acids and esters, pyrrolidones, etc. are a few permeation enhancers .(25)

Pressure sensitive adhesive (Self Adhesive)

A PSA is material supports the preservation of close contact between the skin's surface and the transdermal system. It should be aggressively and persistently sticky, adhere using just finger pressure exerted, and exert a strong holding power. It should also be able to be removed from the soft area.(26) polyacrylates, and polyisobutylene.. The selection process for drug-in-adhesive matrix systems will be based on how quickly the drug and penetration enhancer diffuse through the glue. PSA should ideally not change medication release and be compatible with biology and physicochemistry.(27)

Release liner

The patch is stored with a protective liner covering it .Before applying a patch to the skin, release liner must removed and disposed of since it comes into close contact with the transdermal system and should be both chemically and physically inert. such as polyethylene or polyvinyl chloride, and a release coating layer, consisting of silicon or Teflon, make up the release liner.

Backing laminate

Possessing a low speed of steam movement for increasing skin moisturizer and, thus, increased drug permeability on the skin .Compatibility is must with the transdermal system, as it will be used during application. Having a superior yield capacity and being non-irritating Polyethylene film, polyester film, polyolefin film, and aluminum vapor coated layer are a few types of laminate backings.

TYPE OF TRANSDERMAL PATCHES**Single layer drug-in-adhesive patches**

A reservoir for drug dispersion is made of a one membrane of sticky polymer. After the deposition into and adhering to the single polymer layer medication is released from the backing laminate layer that supports the drug reservoir . example is methylphenidate is the transdermal product Day-trana

Multilayer drug-in-adhesive patches

The two layers of multilayer transdermal patches are an adhesive layer with active ingredient layer and regulated drug release over time. This patches contains a fixed substrate laminate and a transient protective layer. Hormone therapy, medications that promote quitting smoking, and painkillers are all delivered via multilayer patches. (28)

Matrix system

The active ingredient storage modified for disperse the medication via single or two membrane percutaneous patch onto an adhesive polymer. This drug polymer matrix is deposited in sealing layer by solvent casting or melting the

Harsha H. Tarare *et al.*,

sticky polymeric components there are several commercial version of these transdermal patches available the climara transdermal patch for ex. Has 100 microgram of estradiol for a single application day.(29)

Transdermal vapor patches

Are made of one adhesive polymer layer along a steam expoler feature that allows vapor to be released. There are several vapor dermal patches on the market, each with a distinct purpose. Nicoderm CQ, for instance, are transdermal patches that release essential oils and include nicotine vapor that can aid in quitting smoking.

Example

1. Clonidine. Catapres-TTS High blood pressure
2. Selegiline Emsam Depression

Transdermal microreservoir patches

Combine a pharmacological reservoir with matrix dispersion. The drug is halted in water hydrophilic polymer solution to construct the reservoir. The drug suspension is then uniformly dispersed on a lipophilic polymer. High pressure is applied during dispersion, forming thousands of minute, unleachable spheres in the process. The drug level in the plasma is kept constant by the drug release profile, which adheres to a zero order rate of kinetic drug release .(30)

TRANSDERMAL PATCHES FORMULATION OF DIFFERENT ANTIHYPERTENSIVE DRUGS :

Atenolol

Atenolol, chemically known as 4-(2-hydroxyl-3-isopropyl aminopropoxy) phenylacetamide, is for treatment of hypertension , chest pain ,failure of heart , and myocardial infarction. It is a selective antagonist of the β_1 -receptor. Atenolol is a good option for TDDS administration because to its physicochemical characteristics, which include its low molecular weight (266.336), acceptable elimination half-life (6-7 hours), and modest water solubility. Based on assessment trials, the polymeric film comprising the medication, ethylene glycol, PVP, and Eudragit RL 100 was chosen for transdermal delivery(36). PEG-400 forsoftening agent in the mercury product process used to create the polymeric films. In the investigation, two distinct penetration enhancers—urea and dimethyl sulphoxide (DMSO)—were used. A variety of criteria were used to assess the dried polymeric film, such as thickness homogeneity, drug content, in vitro drug release from films, and in vitro drug skin penetration.Using a mercury substrate and a solvent evaporation process, the transdermal patch was created. Atenolol was added to a polymer solution that had been produced in ten millilitres of ethanol. During patch casting, the plasticizer and permeability enhancer were introduced. Glass rings set on a mercury surface were filled with the solution, and they were left to dry in the air for a whole day. From semi-dried patches, circular patches with a diameter of 2 cm (3.14 cm²) were cut and put in vacuum desiccators.(31)

Metoprolol

One API to recover mild to moderate essential hypertension is metoprolol tartrate. It functions by inhibiting beta1 adrenoreceptors and is nearly entirely absorbed (95%) upon oral administration; however, due to significant presystemic metabolism (40–60%), the systemic bioavailability varies greatly. After two to three hours, peak plasma concentrations are reached. Due to the medication's four-hour plasma half-life, regular dosage is required to keep the medicine at therapeutic blood levels throughout the duration of a patient's treatment. As a result, MT is a perfect choice for transdermal medication administration.(38) In a fabricated stainless steel apparatus, polymeric films were cast onto aluminum foil to prepare TDDSs. The device was made out of a 14 x 14 x 2 cm wooden block that could be screwed onto to hold a 9 x 9 x 1 cm stainless steel plate with a 4 cm diameter cylindrical cup. Before the device was screwed together to cast the films, a thick layer of aluminium foil was sandwiched between the steel plate and the wooden block. Mixing Methacrylic acid copolymer and polyvinyl alcohol in a mixture of DCM and IPA (80:20 v/v) along with 10% (w/w) of metoprolol tartrate, 5% (w/w) of plasticizer DBP, and 5% (w/w) of penetration enhancer (\pm) menthol (based on total polymer weight) were used to create the polymeric solution (10% w/v).The solvent was

**Harsha H. Tarare et al.,**

allowed to evaporate at room temperature (32°C and 45% relative humidity) for 24 hours after the solution added onto the aluminum foil that had been placed to base of the cylindrical cup of the apparatus mentioned above. Following drying, the films, along with the aluminium paper which covers that functioned as the backing film, were divided into patches measuring 6.74 cm² in area using a circular metallic die with an internal diameter of 2.93 cm. Next, the backing film was protected with a sticky tape with a flange left around the edge for simple adhering. Lastly, a release liner made of thin aluminum foil was applied to the opposite side; this could be quickly removed before the patch was applied to the skin. After that, the TDDSs were kept for seven days at room temperature in sealed containers before being used.

RESULT

The polymers displayed λ_{max} different from that of the medication, indicating that they did not interfere with the UV spectrophotometric technique utilized for the study. The maximum quantity of medicine released in 48 hours, $95.04 \pm 2.7\%$, came from the formulation M-4 that carried PVA and Eudragit RL-100 in an 8:2 ratio. The formulation M-4 containing Eudragit RL-100 and PVA in an 8:2 ratio had the largest cumulative quantity of medication released in 48 hours, at $95.04 \pm 2.7\%$. Formulation M-4 once again had more medication penetration rate, measuring 909. Following additional research, formulation M-4 was chosen as the optimal formulation and put to use. Based on the rise in drug release and permeation with an increase in Eudragit RL 100 quantity in formulations M-1 to M-4, the results indicate that Eudragit RL 100, a freely permeable polymer, has a significant impact on drug release and permeation.(32)

PROPRANOLOL

Arrhythmias of the heart, hypertension, and angina pectoris are all treated with propranolol hydrochloride. Given that it has a short terminal elimination half-life of three to five hours and that frequent dosage is required to maintain the therapeutic blood level for an prolonged time of treatment, it is the medication of choice for sustained release formulations. The medication has a limited bioavailability (15–23%) when taken orally because of hepatic first pass metabolism and its low molecular weight (295.81) further suggests that transdermal administration is the most appropriate method of administration. By employing a glass mold and the solvent evaporation process, propranolol percutaneous patch were created using three polymers in two distinct combinations and proportions, such as Ethylcellulose with Polyvinyl pyrrolidone and Ethylcellulose resin with HPMC K4M. The backing layer was created by adding 4% w/v PVA solution to distilled water, then drying in an oven at 60°C for six hours. Each polymeric combination's added in chloroform. As a plasticizer, dibutyl phthalate (30% w/w) of the polymer composition was applied. To achieve a homogenous dispersion, propranolol hydrochloride was added at a concentration of 21% w/w of biopolymer and agitated using a mechanical stirrer. Each mould's makes Polyvinyl Alcohol film was filled with a 2 ml dispersion. A funnel was placed above the mold to regulate the rate of evaporation. The mold was then dried in a thermal dryer at six hours at 40 °C, and the dry material was kept in desiccators for later use. Finally, the degree of propranolol spreads from the transdermal patches indicated that the films with a higher PVP F6 (6:1) proportion were appropriate for once-daily drug delivery, and the films with a higher EC proportion were appropriate for a prolonged regimen of sustained drug delivery through transdermal route for a duration of more than 48 hours.(33)

LABETOLOL

These days, the primary and most commonly prescribed medication for the long-term management of hypertension is labetalol (mol weight: 364.9). After being taken orally, labetalol is quickly absorbed from the digestive system; nevertheless, due to its substantial first pass metabolism, its oral bioavailability is still only 25%. The majority of biotransformation of this drug occurs in the liver, with the metabolites being eliminated in the urine along with very little levels of the original drug. The principal metabolites of labetalol do not have any appreciable effect – inhibiting consequences. Because of its short plasma half life (three to five hours) and inadequate bioavailability, long-term oral betametalol treatment for hypertension typically leads in unsatisfactory patient complaints. Eudragit E PO: Plasdone (Series A) & Eudragit RL 100: Plasdone S 630 (Series B) were used in varying ratios to make the transdermal patches

**Harsha H. Tarare et al.,**

having matrix containing Labetalol hydrochloride. To achieve a total weight of 800 mg, the polymers were raised in various ratios and dissolved in ethanol. To create a homogeneous solution, labetalol hydrochloride was gradually added to the polymer solution and carefully mixed. A 5% w/w addition of basil oil was applied as a penetration enhancer, and 20% di-n-butyl-phthalate was utilized as a plasticizer. The drug polymeric solution was applied to the mercury surface, which had an internal diameter of 6 cm. The surface was then dried at 24 hr. at $32 \pm 2^\circ\text{C}$ and $45 \pm 5\%$ relative humidity. The films were sliced into a 6.74 cm² patch after a day, and a backing membrane made of laminated aluminum foil was adhered to. Transdermal films were stored in a desiccator until further used.

RESULT

Greater release and greater permeation were seen in patches containing Plasdene S 630 and EPO compared to patches containing Plasdene S 630 and Eudragit RL 100 together. Preliminary investigations also showed that the medication was evenly dispersed across the film and that it did not interact with the carriers that were utilized to create matrices. Whereas patches with increasing Concentrations of Eudragit EPO demonstrated an anomalous transport, patches containing higher Concentrations of Plasdene S 630 demonstrated a release mechanism toward Fickian first order diffusion release mechanism. (34)

CARVEDILOL

The most often recommended medication for the long-term management of hypertension is carvedilol. Carvedilol is quickly absorbed through GI area (81%) after oral administration; however, due to considerable first-pass hepatic metabolism by cytochrome P450, the oral bioavailability is still low (e.g., 23%). The half-life of carvedilol is six hours. Create distinct matrix patches using varying ratios of lipophobic and lipophilic polymer combinations, such as (a) polyvinylpyrrolidone (PVP) and ethyl cellulose (EC), and (b) carvedilol- containing ERL 100 and ERS 100; In order to manufacture transdermal patches of matrix containing carvedilol, several ratios of ethyl cellulose: polyvinylpyrrolidone were used. The biopolymers mixed in chloroform after being raised in weight to 400 mg in various ratios. To create a homogeneous solution, carvedilol (2.5% wt/wt) was gradually added to the polymer solution and well mixed. As a plasticizer, di-n-butyl-phthalate was used. The drug polymeric solution was applied to the 25 cm² mercury surface and allowed to air dry at ambient temperature in a dust-free atmosphere. The films were sliced into a 5 cm² piece and covered with a polypropylene film backing membrane after 24 hours. Before being used again, the percutaneous patch put in drying chamber. (35).

CONCLUSION

The percutaneous absorption device is used for topically administer medications by skin at a previously selected place for systemic effects. Antihypertensive medication delivered transdermally can offer the ideal dosage to treat the illness with the fewest possible negative effects. This analysis of many high blood pressure medications revealed that using this delivery method enhances both patient compliance and bioavailability. This may also result in the long-term management of hypertension being treated with healthcare at a cost that is economical. The primary constraint is that the medication must have particular physical and chemical characteristics that allow it to pass through the skin; as a result, not all antihypertensive medications may be administered in this way. The market for transdermal medication delivery is expanding, and during the coming years, there is a chance that this industry may develop even more.

ABSTRACT

Phytochemical studies on *Himantocladium plumula* (Nees) M. Fleisch., a moss of the Neckeraceae family were conducted with respect to qualitative analysis in addition to FTIR spectroscopic studies to identify functional groups and compounds. Plant samples were collected from Kallar adjoining the Ponmudi peak, dried, powdered and solvent extracts were prepared using Soxhlet apparatus in petroleum ether, hexane, chloroform, ethyl acetate, acetone, methanol and water. Qualitative analysis showed the presence of an array of phytochemicals. FTIR analysis indicated the occurrence of complex compounds with different chemical bonding activity and the occurrence of organic compounds as well as inorganic ions. The nature of substances identified strongly indicates the functionalities of this species concerning stress resistance and bioactive potentiality.

Keywords: *Himantocladium plumula*, Neckeraceae, qualitative analysis, FTIR spectroscopy, phytochemicals

INTRODUCTION

The world of plants involves several unique groups of which bryophytes stand out with regard to their amphibious nature and predominantly gametophytic terrestrial habits. This collection of distinct plant life comprises members that colonise and inhabit substrata bearing harsh and extreme conditions which is not supportive of any other life

**Jerry C. Jacson and Remya Krishnan**

forms except perhaps the Lichens. Ecologically they are found to be an important link in the process of succession modifying rocky substrata enabling rock weathering creating soil surfaces conducive to sustaining higher plant forms. Preferring moist shady climes, they are found to have species exhibiting desiccation resistance indicating the existence of diverse members. For a long time, the phytochemistry of bryophytes has been neglected due to their small size and the challenges associated with collecting large, pure samples. Identifying them, even under a microscope, is exceedingly difficult. Moreover, they have been deemed nutritionally useless to humans[1]. In recent years the focus of research in bryophytes has shifted to aspects that have not been explored till now including molecular, pharmacognosic, ethnobotanical and phytochemical realms. Traditionally the attention of investigators hinged on higher plant forms and the few who ventured into bryophyte research focused on taxonomic studies resulting in several unexplored areas that requires intensive study. The available literature indicates that several species of commonly occurring bryophytes of the forests of Kerala have not been investigated and the existing research indicates the potential of this group with regard to secondary metabolites and bioactive potential[2]. This work focusses on the qualitative characterisation as well as FTIR analysis of the moss *Himantocladium plumula* (Nees) M. Fleisch. A search on the available literature on the phytochemistry of *H. plumula* reveals the absence of studies in this regard and based on literature available on bryophytes in general the possibility of identifying molecules with bioactive potential that can be applied in a variety of therapeutic domains. *Himantocladium plumula* is a member of the Neckeraceae family in the main category of the simple or leafy mosses (Bryopsida)[3]. This moss is found growing predominantly on rocks lining flowing streams and rivers under the shade of riparian canopies of arboreal foliage and are seen to extend into the bark of trees and onto lianas as well as woody creepers and climbers growing on or adjacent to such rocks. This species is found to adjust more favourably to conditions of desiccation stress when compared to other bryophyte species, this and other characteristics can be understood more precisely with investigations into the molecular and chemical nature of the plant. An effort is made in this work to identify the presence of secondary metabolites as well as to identify the functional groups through FTIR analysis which can be used to identify molecules of importance.

MATERIALS AND METHODS

The work involved initial characterisation of secondary metabolites through qualitative analysis and this was followed by determination of the molecular nature through FTIR techniques.

Collection and Preparation of the Plant Sample

Samples of the bryophyte under study were gathered from the Kallar region, nestled at the base of the Ponmudi peak in the Thiruvananthapuram district of Kerala State, India. *Himantocladium plumula* (Nees) M. Fleisch. exhibits synoicous reproduction, with elongated stems reaching 5 cm to 7 cm and arranged in a frondose manner, featuring octastichous leaf arrangement, particularly at the base. The leaves are characterized by rugose or somewhat complanate texture with regular shallow lunate undulations[4]. Branching displays a heterotrichous pattern reminiscent of asexual propagation through prostrate runner formation. Among Neckeraceae species, *H. plumula* stands out due to its synoicous nature. The specimens were delicately removed from their natural habitat and carefully placed in paper bags, ensuring the entirety of the plant body was collected. After obtaining a sufficient quantity, the material underwent a thorough washing in running water to eliminate all traces of soil and debris. Subsequently, the material was shade-dried for 15 days in preparation for extraction, followed by pulverization using a mortar and pestle.

Soxhlet extraction

Extraction was done using a Soxhlet apparatus, 50 grams of the powdered plant material was loaded into the apparatus and it was subject to boiling using solvents selected based on the polarity index. The sequence of solvents used from non-polar to polar were Petroleum ether, hexane, chloroform, ethyl acetate, acetone, methanol and water.

**Jerry C. Jacson and Remya Krishnan**

The solvent extracts were collected in 30 ml glass vials and water extracts were stored in refrigerators at 3°C to prevent decomposition and for further studies.

Qualitative Analysis

Each of the solvent extracts was subjected to qualitative tests for various organic molecules, conducted using standard protocols [5-7]. Phenol is assessed using the Lead Acetate Test, while Tannin presence is determined through the Ferric Chloride Test. Flavonoids are detected using the Ferric Chloride Test, Saponins are identified via the Foam Test. Terpenoids are examined using the Liebermann-Burchard Test, Alkaloids with Wagner's Reagent. Glycosides are evaluated using the Kellar-Killani Test, Steroids are detected through the Liebermann-Burchard Test, Quinones presence is determined by the HCL Method, the test for Coumarin involves treating the substance with alcoholic KOH or NaOH, with the presence of a dark yellow color indicating its presence [8].

FTIR Analysis

Dried and powdered plant samples were used for FTIR (Fourier Transform Infrared Spectroscopy) with 2 grams of plant material used. FTIR spectroscopy can be performed on minute quantities of plant material and is a vibrational spectroscopic technique providing data on absorbance by atoms when exposed to medium infrared radiation. The data is expressed as wave number (cm^{-1}) and not wave length providing a direct indicator of the energy level of atoms. This data can be used to identify the nature of chemical bonds with which the atoms are involved and the functional groups in which they are involved leading to molecular Identification (9). Result of FTIR analysis was obtained as graphical data and compared to data bases to identify the functional groups present.

RESULTS AND DISCUSSION

Qualitative Analysis

The various phytochemical components were extracted in a series of non polar to polar solvents by hot continuous Soxhlet extraction. Characterisation of the extracts by qualitative methods could detect the presence of secondary metabolites in *Himantocladium plumula* shown in the table 1. The *H. plumula* extract is rich in alkaloids, terpenoids, and glycosides across all solvent extracts, with additional presence of saponins in the water extract and steroids in the hexane extract. Tannins were not detected in any of the extracts. Petroleum Ether extract didn't show the presence of any of the tested secondary metabolites. Hexane extract showed the presence of alkaloids, steroids, and glycosides. In Chloroform extract alkaloids, terpenoids, and glycosides were detected. Ethyl acetate extract exhibited the presence of terpenoids, alkaloids, and glycosides. Similar to the ethyl acetate extract, acetone extract: contained terpenoids, alkaloids, and glycosides. In methanol extract alkaloids, terpenoids, and glycosides were present. Water extract showed the presence of saponins, alkaloids, and glycosides. Saponins, present in methanol and water extracts, indicate the presence of triterpenoid and steroid saponins[10]. Tannins are known to be extracted in solvents with high polarity indices, such as methanol and water. Additionally, studies have shown that hot water is particularly effective for tannin extraction[11]. Terpenoids, found in polar solvents like ethyl acetate, acetone, methanol and water, suggest the presence of volatile terpenoids with significant bioactive potential. These volatile terpenoids also contribute to the desiccation-resistant properties of Bryophytes [12]. Alkaloids are extracted in various solvents based on their polarity, with different alkaloids showing solubility in different solvents. Steroids are primarily detected in solvents with lower polarity indices such as petroleum ether, hexane, and chloroform, indicating the presence of non-polar steroids such as brassinosteroids, bufadienolides, cardenolides, and vertebrate-type steroids [13]. Glycosides are detected in both polar and non-polar solvents, suggesting the presence of various groups of glycosides with potential bioactive functions, consistent with their abundant presence in many plants.

FTIR Analysis

FTIR spectroscopy, or Fourier Transform Infrared Spectroscopy, is an analytical technique utilized to identify and analyze the chemical composition of substances. It operates by measuring the interaction between the sample and

**Jerry C. Jacson and Remya Krishnan**

infrared radiation. When exposed to infrared radiation, molecules within the sample undergo characteristic vibrations corresponding to their chemical bonds. By examining the absorption of infrared light across various wavelengths, FTIR spectroscopy yields comprehensive insights into the functional groups, molecular structure, and composition of diverse materials. These materials encompass organic and inorganic compounds, polymers, proteins, and pharmaceuticals. The FT-IR characteristic absorption bands and their assignments reveals the Finger print band features of *Himantocladium plumula* (Figure1, Table2). The presence of 11 absorption bands here denotes the presence of complex molecules. The absorption bands 3275.37 cm^{-1} and 2918.75 cm^{-1} indicate single bond regions and 3275.37 cm^{-1} is an indicator of hydrogen bonding confirming the presence of hydrate, hydroxyl, ammonium or amino. The band 2918.75 cm^{-1} indicates long chain linear aliphatic compounds. The band 1629.35 cm^{-1} informs double bonds or aromatic compounds with C-H bending vibration indicated by the band 829.55 cm^{-1} [14].The functional groups identified and assignments are provided in the table 2 below,

CONCLUSION

Himantocladium plumula (Nees) M. Fleisch. is a moss of the Neck eraceae family with no data or studies reflecting its phtochemistry including any literature on the metabolite types or specific compound identification. The qualitative and FTIR analysis studies have revealed a wealth of data providing insights into the presence of substances with potential bioactive functions which can be revealed through further investigations. Qualitative studies have provided information on the presence of saponins, tannins, terpenoids, alkaloids, steroids and glycosides. The occurrence of saponins and terpenoids in polar extracts indicates the presence of triterpenoid saponins, steroid saponins and volatile terpenoids. The FTIR spectroscopy data indicates the presence of complex compounds involving both organic substances and inorganic ions. The data from this study indicates the presence of distinctive physiological characteristics related to stress like especially desiccation resistance and bioactive potentiality providing scope for further investigation.

ABSTRACT

The Quality Management System (QMS) is essential for achieving effective regulatory compliance in the pharmaceutical industry, particularly in light of increasing scrutiny from the FDA. QMS provides a structured framework that ensures adherence to regulatory requirements by establishing standardized procedures and processes. It addresses critical issues such as quality failures and insufficient corrective actions, thus mitigating risks associated with regulatory inspections. By promoting a culture of continuous improvement, QMS enhances overall product quality and fosters customer satisfaction. It facilitates compliance with dynamic regulatory environments, ensuring that organizations remain prepared for inspections and audits. Furthermore, QMS optimizes operational efficiency by streamlining processes, reducing costs, and enhancing yield. This article examines the integral role of QMS in maintaining regulatory compliance and outlines its key modules for effective implementation. Ultimately, a robust QMS not only minimizes the likelihood of receiving 483s and warning letters but also contributes to the long-term success of pharmaceutical organizations.

INTRODUCTION

Pharmaceutical enrollment dossiers are crucial documents that applicants submit to regulatory bodies for evaluation before releasing their goods for sale [1]. It contains the information acquired from every study in an exact format called the Common Technical Document (CTD) format, which is kept up to date by the ICH [2]. Both novel and generic medications have significantly increased worldwide as a result of the pharmaceutical industry's globalization. Quality, safety, competitiveness, and the future of the pharmaceutical sector and Drug creation are all significantly impacted by these global shifts [3]. Experts have also been actively involved in the global effort to prevent the proliferation of subpar medications and the spread of counterfeit medications [4]. Pharmaceutical Producers are currently concentrating on efficient dossier management given the regulatory result determines how these marketing approvals turned out [1,5]. Effective planning, formatting, and compilation are necessary to gain market acceptance beforehand, which may ultimately result in increased earnings and prices. The number of The Office of Generic Drugs (OGD) is reviewing registration applications has significantly increased concurrently [6,7]. Several tactics have been developed by the Food and Drug Administration (FDA), the US pharmaceutical regulator, to expedite the review of Marketing Authorization Applications (MAA). QbR-QOS, or question-based review-quality overall summary, was one such tactic [8]. For the Chemistry Manufacturing and Controls (CMC) evaluation of an application, the QbR has two functions [8]. Initially, it offers a guide to the reviewer in determining the degree of risk involved in the product's design and manufacture as well as whether the product is of high quality [9,10]. Second, it makes the reasoning that reviewers use in their CMC reviews transparent to sponsors. When it comes to finding the flaws that are directly related to important problems with product quality, QbR is crucial because fixing these problems results in a better product when it is approved [8,11]. The focus of this article will be on how to stop FDA 483s, warning letters, import alerts, scientific misconduct, and regulatory noncompliance.

QMS combining ISO and GMP

As previously said in a few recent guidelines, authorities generally have a clear preference for Quality Management Systems (QMS) e.g. in ICH Q7a, Section 2.11 "Each manufacturer should establish, document, and implement an effective system for managing quality that involves the active participation of management and appropriate manufacturing personnel" In conclusion, ISO 9002 already mentioned in the introduction: It is stressed that the technical (product) stated requirements and the quality system requirements outlined in this International Standard are complimentary, not interchangeable. The API makers have access to a 1997 CEFIC/APIIC guidance on the integration of the GMP requirements with the QMS criteria [13].

Present Pharma Framework

FDA 483s, warning letters, Notice of Violations, and import alerts have resulted from a spike in regulatory non-compliance (Violations) at a number of drug plants during the 2013–2014 period [14]. Despite the fact that laws, regulations, and guidance have been in place for a long time in the pharmaceutical industry, the numerous FDA 483s, warning letters, and import alerts demonstrate that businesses are facing non-compliances and implementation issues. In order to guarantee that the public has access to safe and effective medications as soon as possible, authorities are actively involved in the pharmaceutical industry and have implemented stringent regulations. Nevertheless, they have observed a number of businesses disregard these rules, which has resulted in the denial of product approval or the closure of a facility [15]. USFDA inspectors found that drug ingredients that had failed quality testing were retested, circumventing regulatory processes and deliberate manipulations, perhaps in an effort to reverse the positive results. The experts advise businesses to put quality and regulatory compliance first because these are core values shared by all governments across the globe.

Regulatory non-compliance in the modern era

The USFDA has discovered the retesting of medication ingredients that had failed quality testing, as well as procedural errors, a lack of educated staff, and a failure to monitor and document quality-related activities, all in an

**Deepika and Koushik**

apparent attempt to produce positive results [16,17] The fact that businesses submit inadequate FDA 483 responses to inspectional observations, which only provide one side of the story and omit crucial data, is another problem. This occurs when regulators identify noteworthy findings during inspections. Instead of identifying the issue, businesses turn to temporary solutions. Ultimately, the regulatory authorities may issue warning letters, refuse to approve a product, or shut down the plant [14].

FDA-Reported common violations

FDA has taken action against a number of companies for regulatory non compliances, including notices of violations (Table 2), import alerts, and 483 notifications. The outcome of an FDA inspection can vary from no necessary actions to the facility being shut down entirely and the company facing administrative, civil, or criminal charges. The U.S. pharmaceutical regulator even stated that it could refuse to approve any new applications or supplements until the required corrective actions are taken and approved in accordance with the rules.

The FDA's Present Approach to Successful Regulatory Compliance

The FDA's strategy for regulatory compliance prioritizes high-risk products, focusing on prevention and early intervention. It uses advanced technology, including data analytics and real-world evidence, to improve monitoring and decision-making. Through global collaboration with regulatory bodies and industry, the FDA enhances standards and inspection capabilities. A hybrid model of on-site and remote inspections is used to ensure flexibility, while robust quality practices and continuous improvement are emphasized. Transparent communication, education, and guidance support public and industry understanding, and enforcement actions like warnings and recalls ensure compliance. Finally, the FDA supports innovation with fast-tracking and flexible regulatory frameworks for essential treatments.

- Unannounced, unexpected inspections;
- Additional inspectors; new inspectors;
- Tough regulatory measures for non- compliances
- Enforcing businesses to conduct ongoing evaluations of their Quality Management System (QMS) in order to minimize quality issues, process nonconformances (PNC), material nonconformances (MNC), rectify cGMP violations, and implement Corrective Action Procedures (CAPA) when mistakes are made.

Regulatory Non- Compliance in India

Nearly 80% of the active pharmaceutical ingredients (API) needed by the US are imported, as are about 40% of the finished drugs. India continues to be a location of great importance to the US health regulator because it has the most FDA-approved drug manufacturing facilities (more than 150 formulation facilities) and is the second-largest pharmaceutical supplier to the US market in terms of volume of generic drugs. Indian pharmaceutical companies hold 13 percent of the generic market in the United States. The Centre for Monitoring of the Indian Economy (CMIE) estimates that between 2008 and 2013, India's exports of generic drugs to the US market grew by 27% a year. Indian companies are especially vulnerable to the heightened regulatory scrutiny because of their greater market share. Additionally, the FDA takes action against the biggest pharmaceutical companies for violating various US regulations, which can result in import alerts, unannounced inspections and other repercussions.

India's USFDA Checks

A Quality Management System (QMS) includes policies, standards, and procedures that guide a company in meeting legal and operational requirements. Experts recommend that QMS should emphasize sustainability, as this focus promotes systematic thinking, transparency, and accountability. This approach is expected to help reduce quality issues over time [19]. QMS[20]is essential for regulatory compliance in drug production, coordinating activities to direct and control continuous improvement in effectiveness and efficiency [21] QMS begins by identifying customer prerequisites as key contributions as well as involves monitoring customer satisfaction to ensure these needs are met effectively [22]. Early QMS focused on product outcomes, but later shifted to teamwork and early problem detection through continuous improvement. Customer satisfaction now evolves with technology, market complexity, and competition, requiring QMS to be in a state of continual improvement. An effective QMS boosts business

**Deepika and Koushik**

performance, helping organizations achieve their purposes and aims [20]. Software for automated QMS provides a systematic approach for reporting, evaluating, and managing quality issues, including discrepancies and non-conformances. It helps manufacturers ensure effective monitoring and decision-making for quality control [23]. Effective internal audits and continuous improvement are essential for regulatory compliance, especially in a competitive, tech-driven market. Automating QMS enhances product quality, efficiency, and customer value by streamlining processes and ensuring safe, effective drug production [24]

METHODOLOGY

This research adopts a qualitative approach to explore the role of Quality Management Systems (QMS) in regulatory compliance, focusing on data from FDA inspections, recalls, warning letters, injunctions, and seizures. A literature review will establish theoretical frameworks by analyzing peer-reviewed articles, industry standards, and regulatory guidelines, identifying gaps in current research. Data collection will involve retrieving quantitative metrics such as inspection frequency, recalls, and enforcement actions from the FDA's dashboard, alongside qualitative insights from warning letters and injunctions to understand regulatory challenges. A purposive sampling technique will select cases demonstrating significant QMS-regulatory interactions. Statistical methods will quantify the relationship between QMS implementation and compliance outcomes, while thematic analysis of qualitative data will uncover contextual patterns. Case studies of organizations with effective QMS implementations will provide real-world examples of best practices and challenges. Triangulation will enhance reliability and validity by cross-verifying data from FDA databases, literature, and interviews. Ethical considerations include informed consent, data confidentiality, and adherence to institutional guidelines to ensure research integrity. This comprehensive methodology aims to provide a systematic and credible analysis of QMS in achieving regulatory compliance.

RESULTS

From 2019 to 2024, the issuance of warning letters, injunctions, seizures, and product recalls highlights significant fluctuations in regulatory activities across industries. Warning letters peaked at 15,103 in 2019 but dropped dramatically to 2,504 by 2021 before surging to 17,351 in 2022 and stabilizing around 13,307 in 2024. This variability indicates changing enforcement priorities or external factors influencing regulatory actions. Similarly, injunctions peaked at 8 in 2019 and 2020 but declined steadily to 4 by 2024. Seizures showed a sharp drop from 2 in 2019 and 2021 to zero from 2020 onward, reflecting a shift in enforcement strategies or the effectiveness of compliance efforts. Product recalls also exhibited notable trends, with initial declines from 7,894 in 2019 to 5,309 in 2021, followed by a resurgence to 6,524 in 2024. These changes suggest an evolving regulatory landscape, influenced by shifting priorities, industry compliance, and safety measures. Sector-wise, medical devices accounted for the highest number of recalls at 15,718, driven by rapid technological advancements and stringent regulations. Food and cosmetics followed with 9,405 recalls, primarily due to contamination and labelling issues. Pharmaceuticals saw 7,339 recalls, highlighting the critical need for strict quality controls, while biologics, with 3,678 recalls, reflected their inherent complexity and risks. Veterinary products experienced 1,331 recalls, underlining their importance in animal health, whereas tobacco products had only two, possibly indicating effective oversight or lower inherent risks. These figures underscore the vital role of regulatory oversight in ensuring consumer safety across diverse sectors, reflecting both challenges and achievements in maintaining public health and trust.

DISCUSSION**Case Studies on Quality Failures**

Product: Drugs

Company Name: Med Office Saglik Endustri Anonim Sirketi

October 23, 2024

**Deepika and Koushik**

Warning Letter 320-25-07 According to 21 CFR 211.100(a), your company did not create sufficient written production and process control procedures that would have ensured that the pharmaceutical products you produce had the identity, strength, quality, and purity that they claimed or were represented to have. Additionally, your company's quality control unit did not examine and approve those procedures, including any modifications. This letter describes problems with your equipment qualification, cleaning protocols, and manufacturing process validation. The FDA has found issues with your systems' sufficiency. Provide a thorough plan that addresses these issues: 1) design, validate, and monitor processes with vigilance over variation; 2) a timeline for finishing PPQ for each marketed drug; 3) process performance protocol(s) and equipment qualification procedures; and 4) your validation program to ensure state of control throughout the lifecycle, including PPQ and monitoring intra-batch and inter-batch variation. Additionally, improve your cleaning validation program by addressing worst-case scenarios for drugs with higher toxicities, potencies, lower solubility, and hard-to-clean characteristics. Assign swabbing locations, hold times, and areas that are challenging to clean. Describe the procedures in your change management system for new products or equipment as well. Summarize the most recent SOPs for equipment, processes, and product cleaning validation.

CONCLUSION

The issues at your facility are not limited to the violations listed in this letter. To stop recurrence, you must look into and fix any infractions right away. Regulatory action, such as seizure, injunction, or rejection of new drug applications, may follow noncompliance. On October 4, 2024, the FDA put your company on Import Alert 66-40 and threatened to deny admission of articles that were tampered with. Within 15 working days, kindly reply in writing outlining the necessary remedial measures and completion dates.

Product: Drugs

Company Name: MMC Healthcare Ltd.

Warning Letter 320-24-62

September 24, 2024

According to 21 CFR 211.22(a), your company did not set up a sufficient quality control unit wherein all components, drug product containers, closures, in-process materials, packaging materials, labelling, and drug products could be approved or rejected. Investigators discovered backdated signatures, additional data, and pages that were modified in your process validation reports during the inspection, and managers acknowledged their involvement. Your explanation of inadvertent backdating is insufficient since it does not include a thorough analysis of the problem or comprehensive corrective actions (CAPAs) for documentation procedures. Data integrity is essential to every CGMP procedure. To make sure your Quality Unit (QU) has the right power, resources, and supervision to maintain product quality, you must present a remediation plan. Along with an impartial evaluation of your documentation procedures and a thorough CAPA plan to guarantee proper record-keeping, this also entails assessing batch records, investigations, and QU duties.

CONCLUSION

The FDA has put your company on Import Alert 66-40 and may not approve new applications until all problems have been resolved. Under the FD&C Act, your items may continue to be denied entry into the United States if infractions are not corrected. You have fifteen working days to reply in writing, outlining the corrective measures you took to avoid a recurrence. Provide justifications and a completion timeline if corrective activities cannot be finished in this time frame. This letter is an opportunity to show compliance and address the shortcomings. [28]

Product Type: Drugs

Company Name: Diamond Chemical Co., Inc.

September 6, 2024

A sufficient documented testing procedure to evaluate the stability characteristics of drug products was not established or followed by your company (21 CFR 211.166 (a)).

**Deepika and Koushik**

For hand sanitizer goods, your company failed to set up a sufficient continuous stability testing program to guarantee that the products meet quality, purity, strength, and identification requirements for the course of their shelf life. Your response, which cites continuous testing during the pandemic and the absence of evaporation in bottles filled with ethanol, is inadequate because it omits testing evidence showing that the products' chemical and microbiological characteristics stay within specification. Your pledge to stop producing FDA-regulated goods is respected, but you must give the FDA advance notice if you plan to start producing drugs again. Because of the infractions found, you should hire a trained consultant to assess your operations, help you comply with CGMP regulations, and do a thorough system audit. Correcting errors and making sure CGMP is followed are still the responsibilities of your top management.

CONCLUSION

To stop recurrence, you are in charge of looking into and dealing with any infractions at your establishment. If remedial measures are not implemented promptly, there may be legal or regulatory repercussions, including seizure and injunction. Your ability to receive export certificates or federal contracts may also be impacted by unresolved breaches. Until infractions are completely resolved, the FDA may refuse to approve further applications. Within 15 working days, kindly reply in writing with plans and corrective steps. Give justifications and a completion timetable if you are unable to finish them by this deadline. [29]

Impact of QMS

All issues, including deviations, non-conformances, and complaints, should be managed by a change control system that tracks changes throughout the product lifecycle, providing detailed information on the history, rationale, and differences between current and proposed changes. A deviation report initiates an investigation, where cross-functional teams from departments like QC, Production, Process Engineering, and QA work under the oversight of the QA department head to identify the root cause. The CAPA owner then categorizes corrective actions into audits, documentation changes, or training, and preventive measures are implemented to avoid recurrence. Once the effectiveness of the corrective actions is confirmed, the CAPA is closed if deemed satisfactory. The CAPA system is reviewed regularly during the monthly Quality Review Meeting (QRM) to assess its effectiveness and discuss key quality indicators for continuous improvement [22,32,33].

CONCLUSION

In conclusion, a robust Quality Management System (QMS) is essential for regulatory compliance in the pharmaceutical industry. QMS provides a structured framework for companies to ensure product quality, adherence to regulatory standards, and mitigation of risks related to non-compliance. Implementing QMS effectively can reduce the likelihood of receiving FDA warnings and import alerts, supporting both operational efficiency and long-term organizational success. The study highlights that continuous improvement, strong leadership, and a culture focused on compliance are critical to achieving sustainable success.

ACKNOWLEDGEMENT

I express my gratitude to the Chalapathi institute of pharmaceutical sciences for the support as well as Mr. Koushik Yetukuri for his guidance and help in seeing article through to completion.

ABSTRACT

Agri tourism, the fusion of agricultural and tourism, has emerged as a promising strategy for promoting sustainable farming practices with simultaneous contribution to rural development and environmental conservation. It refers to the practice of opening agricultural operations to visitors, allowing them to engaging in farming activities, experiencing rural life and connecting with the source of their food. Sustainable farming on the other hand, encompasses agricultural practices that prioritize environmental stewardship, economic viability and social equity. This paper explores the dynamic relationship between Agri - tourism and sustainable farming, shedding light on their mutual benefits, challenges and the potential they hold for reshaping rural land scape worldwide through case study analysis of Agri tourism in India.

Keywords: Sustainability, Agri – Tourism, sustainable farming, Doubling farmers income.

INTRODUCTION

Agricultural tourism refers to the opening of agricultural enterprises to tourists, the participation of tourists in agriculture, experiencing rural life and establishing a bond with food. Permaculture includes agriculture, which is important for environmental protection, economic sustainability and social well-being. In a world grappling with the needs of a resilient food system, rural revitalization and natural resources, the interplay between these two seemingly contradictory elements is vital. Agricultural tourism provides additional income to farmers, reducing their dependence on traditional agriculture. This economic diversification can improve the financial stability of agriculture, making it more resilient to economic changes. Visitors to agritourism destinations can understand permaculture practices. This course raises awareness of the importance of the environment, local agriculture and

**Varanasi Rahul et al.,**

health. Agritourism can help preserve rural culture and cultural heritage as visitors learn about the unique traditions, food, and lifestyle of communities. Permaculture practices such as organic growth and integrated management are often promoted in agritourism areas. This contact promotes the use of environmentally friendly technologies and helps protect soil, water and biodiversity. It is important to fight to balance the economy and control the reality of agriculture. Too much commercialization can lead to changes in rural life, which can lead visitors away from real farming. Creating a suitable system for agriculture, including hospitality and business ideas, can be a valuable resource for farmers. Cooperation with local governments and tourism organizations is required. If not managed properly, the influx of tourists can impact the environment. Strategies to reduce the ecological footprint of agritourism operations are important. This article provides case studies from different regions that demonstrate that successful agritourism is a useful first step towards permaculture practices

LITERATURE REVIEW

Agricultural tourism, Agriculture with tourism A multi-faceted concept that integrates, it is gaining widespread attention as the promotion of permaculture practices (Ammirato. ;2014). This literature review presents key findings from relevant studies and sheds light on the relationship between agriculture and permaculture (Barbieri; Mshenga. ;2008). Many studies have demonstrated the potential of agriculture in diversifying farmers' income and increasing the economic importance of rural areas. Income from tourist activities such as farm tours, self-collection and on-site sales increases farm income and reduces dependence on agriculture (Nickerson N.P.; Black R.J.; McCool;2001). Environmental sustainability is the foundation of permaculture. Agritourism provides a platform for promoting environmentally friendly agricultural practices such as organic farming, reducing pesticide use and soil conservation. This exhibition encourages visitors to appreciate responsible agriculture (Chang J.; Gerrish S.; Wang). Agricultural tourism can play an important role in preserving agricultural biodiversity. Agritourism provides a better understanding of the importance of biodiversity in agriculture, encouraging farmers to adopt practices that support community health (Campbell J.M.; Kubickova M.;2020). Soil health and water conservation are important aspects of permaculture. Data show that agricultural practices often include sustainability of soil and water management, reducing tillage, cover crops, and promoting efficient water use (Das B.R.; Rainey;2010). Community participation is critical to the success of agritourism businesses. Research shows that involving local people in agricultural production strengthens relationships and strengthens culture (Valdivia C.; Barbieri;2014). Agritourism can increase food security by encouraging local food production and consumption. Research shows that tourists who love local products can boost local businesses and support small farmers. Climate change poses serious challenges to agriculture (Wilson J.; Thilmany D.; Watson P;2014). Agritourism is a platform to promote agricultural adaptation to climate change, including drought-resistant crops and adaptation strategies. Agritourism often provides opportunities for women's participation and empowerment (Tew C.; Barbieri C). Research shows that women play an important role in farming and agriculture, contributing to family income and decision-making processes. Agritourism diversifies income, increases economic activity and supports rural development. It is also an educational tool to raise awareness of permaculture practices among visitors (Yang L.;2012). Agritourism contributes to environmental sustainability by promoting biodiversity conservation, responsible land and water management, and climate protection. Community engagement, including women's participation, can strengthen rural relationships and strengthen local communities (Iancu T.;2020). Additionally, agritourism increases food security by encouraging local food production and consumption, ultimately supporting the local economy. However, it is important to be aware of the challenges presented by agritourism, including balancing business with managing the reality of agriculture, managing the impact on the business environment, and investing in infrastructure and business investments (Sharpley R ;2007). Despite these challenges, the literature supports the idea that agriculture is a good strategy for promoting culture while benefiting rural communities and the environment (Yang L;2012).

**Varanasi Rahul et al.,****Case Studies****Sustainable Agri Tourism in Maharashtra**

Maharashtra is a major state in Western India where new models of agritourism are emerging, aiming to promote cultural practices while offering rural experience to audiences. Rural Odyssey, an agritourism project known for its commitment to sustainability, economic sustainability and community engagement, is a major research project. At the heart of Country Odyssey is its commitment to permaculture practices. The project is located on a farm where visitors can witness first-hand the use of good environmental strategies such as organic farming, pesticide use and water management. One of Rural Odyssey's main goals is to diversify the income of local farmers. By opening their farms to visitors, local farmers can reduce their dependence on traditional agriculture and create additional resources. Rural Odyssey offers visitors a variety of experiences including farm tours, farm work and interaction with the local community. These experiences provide visitors with a hands-on experience while encouraging an appreciation of rural life and agriculture. A key feature of Country Odyssey is its commitment to community engagement. The program actively involves the local community in every aspect of the farm, from leading tours to preparing meals for guests. This approach improves community relations and empowers local residents. This project attaches great importance to the protection of biodiversity. Visitors can explore the farm's many animal and plant species, and courses demonstrate the role of biodiversity in permaculture. Rural Odyssey includes environmental sustainability measures such as rainwater harvesting, composting and waste reduction. These practices both reduce the ecological orientation of the project and become an educational tool for visitors. Rural Odyssey has had a positive impact on the local economy. It created employment for local people, increased farmers' income and contributed to the growth of the local economy. Like many agritourism ventures, Rural Odyssey faces the challenge of balancing business with the reality of managing and managing the environmental impact of the business. However, its commitment to sustainability and community engagement is key to its success. Rural Odyssey is a shining example of entrepreneurship in the Indian state of Maharashtra. By combining environmentally friendly agriculture with social participation and public awareness, it provides ample income to farmers as well as supporting urban development and environmental protection. This research demonstrates model agriculture's potential to support permaculture practices while supporting local businesses and strengthening Indian communities.

Sustainable Agri-Tourism in Odisha

Odisha is a state in eastern India and is home to Chilika Lake, Asia's largest lake and a place of biodiversity. This case study examines Chilika Fresh, an innovative agricultural program in Odisha that not only promotes groundwater production but also enhances the tourism experience of tourists. Chilika Fresh is based on the principles of the aquaculture industry. The program focuses on sustainable agriculture, emphasizes responsible management, reduces pesticide use and reduces environmental impact. One of Chilika Fresh's main goals is to distribute revenue to local fishermen and aquaculture farmers. By integrating agritourism into their activities, they obtain a stable source of income beyond fishing. Chilika Fresh offers visitors a variety of activities such as boat tours, fishing experiences and shrimp farm visits. These experiences not only teach visitors about healthy aquaculture, but also allow them to experience coastal life. The program actively engages the local community in its work. Fishermen and their families are involved as leaders and owners, improving and sustaining their livelihoods through meaningful participation. Chilika Lake is famous for its diverse ecosystem. The program's training and tours emphasize the importance of biodiversity conservation in the context of aquaculture and wetland conservation. Chilika Fresh incorporates environmental practices including water quality management and recycling. These practices are consistent with the project's commitment to minimizing environmental impact. The project had a positive impact on the regional economy. It creates jobs, increases local income and supports local economic growth. Chilika Fresh faces many challenges, such as managing the balance between water resources and tourism, as well as solving environmental problems associated with the increasing number of visitors. Despite these difficulties, it has become a successful model for the integration of the aquaculture sector with agriculture. Chilika Fresh's case study shows how agritourism plays an important role in supporting healthy aquaculture while encouraging visitors to travel. Promoting responsible management, community participation and biodiversity conservation, the program not only diversifies fishermen's income but also supports the protection of important coastal ecosystems.

**Varanasi Rahul et al.,****Agri - Tourism Kerala**

Odisha is one of the eastern Indian states that is home to Chilika Lake, Asia's largest lake and a diverse cultural centre. This case study examines Chilika Fresh, an innovative agricultural program in Odisha that not only promotes groundwater production but also enhances the tourism experience of tourists. Chilika Fresh is based on the principles of the aquaculture industry. The program focuses on sustainable agriculture in terms of managing resources, reducing pesticide use and reducing environmental impact. By integrating agritourism into their activities, they obtain a stable source of income beyond fishing. Chilika Fresh offers visitors a variety of activities such as boat tours, fishing experiences and visits to the shrimp farm. These experiences not only teach visitors about healthy aquaculture, but also allow them to experience coastal life. The program actively engages the local community in its work. Fishermen and their families are involved as leaders and owners, improving and sustaining their livelihoods through meaningful participation. Chilika Lake is famous for its diverse ecosystem. The program's training and tours emphasize the importance of biodiversity conservation in the context of aquaculture and wetland conservation. Chilika Fresh incorporates environmental practices including water quality management and recycling. These practices are consistent with the project's commitment to minimizing environmental impact. The project had a positive impact on the regional economy. It creates jobs, increases local income and supports local economic growth. Chilika Fresh faces many challenges, such as managing the balance between water resources and tourism, as well as solving environmental problems associated with the increasing number of visitors. Despite these difficulties, it has become a successful model for the integration of sustainable agriculture with agriculture. Chilika Fresh's case study shows how agritourism plays an important role in supporting healthy aquaculture while encouraging visitors to travel. By emphasizing responsible management, involving local communities and promoting biodiversity conservation, the program not only diversifies fishermen's income but also contributes to the protection of important coastal areas.

CONCLUSION

Agritourism is a wonderful and evolving concept that promotes culture while encouraging remote development. The city, environmental protection and tourist education are very good. This research in agriculture and permaculture reveals numerous benefits, challenges and opportunities. In this concluding section, we present the key findings and insights from the case study and literature review, highlighting the synergies between agritourism and permaculture. One of the most successful aspects of agriculture is the ability of farmers to diversify their income sources and reduce dependence on agriculture. This funding gap can support rural communities, strengthen local businesses and contribute to overall rural development. Case studies such as 'Rural Odyssey' in Maharashtra and 'Spice Village Farm' in Kerala exemplify how the agritourism industry can bring significant economic benefits to rural areas. Permaculture practices are at the heart of agritourism and this partnership provides a strong platform for the dissemination of environmentally friendly technologies. From organic farming to responsible resource management, agritourism services often engage guests in discussions about permaculture. This course develops knowledge of food production and nutrition. "Chilika Fresh", which promotes groundwater production in Odisha, is a good example. Community participation is critical to the success of agritourism businesses. Collaborating with local people as guides, hosts and participants not only enhances their sense of ownership but also helps preserve heritage and culture. "Chilika Fresh" actively engages with the community in its work to support fishermen and their families. Agritourism plays an important role in promoting on-farm biodiversity conservation. Visitors can learn firsthand the importance of managing various ecosystems and the knowledge that often translates into sustainable agriculture. Rural Odyssey demonstrates the positive impact of agritourism on biodiversity conservation. Rapid climate change causes serious problems in agriculture. Agritourism helps farmers become stronger against climate change by promoting climate-smart practices and adaptation strategies. This dimension is especially evident in Chilika Fresh, which has introduced aquaculture to adapt to climate change. Agritourism initiatives often challenge gender roles in agricultural communities by providing opportunities for women's participation and empowerment. Women are involved in all areas of agriculture, contributing to family income and decision-making processes. In summary, the combination of case studies and literature review demonstrates the synergy between agritourism and permaculture.

Varanasi Rahul et al.,

Agritourism diversifies income, strengthens rural communities and promotes environmental stewardship. This way visitors get a good idea of permaculture and immerse themselves in a real rural experience. Stakeholders, including farmers, policy makers and tourism officials, need to work together to realize this partnership. Addressing issues such as precisely measuring work and managing environmental impacts remains important. Additionally, continuous research, innovation and knowledge sharing are important to expand the boundaries of agriculture and make it more profitable for permaculture, urban growth and education for visitors. Going forward, the integration of agritourism and permaculture holds great promise not only in India but also globally. It advocates planning for shared economic success, environmental protection and community strengthening, the path to a better and stronger agriculture in the future. Agritourism and permaculture journeys are a continuation of farmers, communities and visitors' commitment to responsibility and change.

ABSTRACT

The open disposal of biodegradable waste may not appear immediately harmful, yet it presents significant long-term environmental risks. Such practices can lead to nuisances, including foul odors and the spread of infectious materials by vectors like flies and birds. Historically, dumping sites for organic waste have attracted scavenger birds, and with ongoing urbanization, waste generation has increased considerably. This study examines the relationship between humans and birds near an open solid waste dumping site in Arambagh Municipality, West Bengal, India, adjacent to the Darakeswar River (22.8765° N, 87.7910° E). The predominant bird species observed include the house crow (53%), common myna (20%), and pied myna (19%), with fewer eastern great egrets and jungle babblers. Bird populations fluctuate throughout the day, with over 46% foraging in the early morning and about 40% in the afternoon. Additionally, a local survey reveals significant shortcomings in solid waste management practices. Some residents report skin diseases, underscoring the public health risks posed due to pathogens spread by birds and other vectors. There is an urgent need to implement alternative waste management strategies to mitigate these risks.

Keywords: Avian, open-dumping, biodegradable, nuisances, solid waste

INTRODUCTION

Throughout global activities, humans have intentionally and unintentionally changed the biosphere. The vital factors impacting the current environment are the predictable food waste generated by humans and consumed by animal species, particularly birds, from garbage dumps. Solid waste generation is mostly an urban issue, but it is even worse as urbanization is increasing faster. The production rate of daily waste is not expected to diminish in the coming decades, as the degree of concern about this issue is minimal. As the reports reveal, just before the century out, the trash produced each day would be more than 11 million tons, up from the current global average of 3 MT per day. The start of this century is expected to mark the peak of garbage production [1-5]. It's anticipated that this excessive waste production will worsen ecosystem changes and create biodiversity shifts. It is interesting to note that the recycling rate of some countries has increased from 2% to over 90% in 20 years after banning direct land filling of waste in 2005. China, Japan, Malaysia, and Thailand, have also implemented laws to manage waste [6-8]. This presents an opportunity to transition from simple waste management to energy production through waste recovery and recycling programs. Birds play a vital part in ecosystems by dispersing seeds, controlling pests, and pollinating flowers. In addition to helping with nutrient exchange, migratory birds are hunted for food and recreation in several regions of the world. [9,10]. Birds first appeared around 165-150 million years ago whereas the appearance of modern human dates back nearly 200,000 years, but synthetic plastic was only invented in 1907, with mass production starting in the 1950s [11,12]. By 2050, global plastic production had exceeded yearly 800MT, with 79% of it ending up in the environment, including 1,610Lac tons of packaging waste alone.

Plastic is now recognized as a significant feature of the anthropogenic because of its connection to human action. Artificial waste that resembles natural food can have a detrimental impact on wildlife. The intestines of pet birds for example have been reported to trap rubber, which may be fatal if it obstructs food passage [13-15]. There is evidence that wild birds also eat rubber bands; in fact, rubber bands were discovered in the digestive systems of 26% of dead cranes. In West Sussex, ducks were rescued after consuming red balloons, thinking they were worms. This problem was caused by rubber bands used for bundling mail being washed away during rainstorms and ending up in the lake, where they were misguided to be food by birds [16-18]. The Swachh Bharat Mission, initiated in 2014, aims to provide sanitation facilities, including toilets, and implement scientific waste collection, processing, and disposal methods for every household. However, about 30% of the Indian population resides in urban areas[19,20]. India belongs to the list of top ten countries in creating MSW (municipal solid waste) over 65 million tons of garbage annually, with over 62 million tons being MSW (organic waste, recyclables such as paper, plastic, wood, glass, etc.). The collection of municipal waste in India is not up to the mark and of that, only 22-28% is processed and treated. The rest is disposed of in dump yards. It is reported that by 2030, 165 million tonnes waste will be generated, and this number will increase to 436 million tonnes by 2050. To manage solid waste properly with this growing amount of waste, the efficiency of waste collection in India needs to improve. Currently, collection of waste varies from 70 to 90% in major metropolitan areas, but is less than 50% in many smaller towns [21,22]. This study focuses on the existence of common birds at an open waste dumping site on the bank of the Darakeswar River in Arambagh. Additionally, the study includes the opinions of local residents regarding the problems associated with waste dumping and the presence of birds and other pests. The study will emphasize the conflicts between birds and humans as open dumping sites can attract avifauna while also causing disturbances to humans.

MATERIALS AND METHODS

Study Area

Our study area is the only open disposal site situated within the jurisdiction of Arambagh Municipality, Hoogly (22°53'19.0" N, 87°46'39.7" E), West Bengal, India, beside the Darakeswar River (Shown in Figure 1 and 2).

Sauvik Bose *et al.*,**field survey and collection of data**

Field visits were conducted from 7:00 am to 9:00 am, 12:00 pm to 2:00 pm, and 5:00 pm to 6:00 pm every other day from May to July 2023. Additionally, face-to-face interviews with local people were done to guess the link between solid waste and birds. Furthermore, in-person interviews with community members were conducted to evaluate the effects of solid waste management and bird-related concerns.

Mathematical Tool

The Shannon diversity index (H) is used to evaluate species diversity in a community, evaluating the evenness and abundance of the species present.

$$\text{Shannon Index (H)} = -\sum_{i=1}^S P_i \ln P_i$$

where S is the total number of species and P_i is the percentage of individuals in the i th species out of all individuals.

RESULTS AND DISCUSSION

On and near the dumping ground, five species were found. Their distinguishing characteristics are documented in Table 1. House crow were the most commonly found birds at the dump site while Jungle babbler was only a few in number. We observe that bird occurrences fluctuate throughout the day. 46% of the birds typically appear in the early morning to collect food, while around 40% are noted in the afternoon. However, the number decreases (14%) noticeably as the sun sets in the west. Distribution of the occurrence of birds (%) and Shannon diversity index is presented in Table 2. The Simpson's index (D) indicates good diversity at approximately 0.36, while the Shannon entropy of 1.22 suggests a higher level of entropy in the occurrences of birds, as shown. From field survey it was noted that some wastes attract birds for feeding (Table 3). Interaction was initiated with individuals residing near the dumpsite during our survey. The information gathered is cited in Table 4. Figure 3 shows the relation among humans, birds, and other vectors carrying pathogens encircling open solid waste dumping. Open dumping has a positive impact on the diversity of birds, as seen in field results, but it also poses a threat to human health and living.

CONCLUSIONS

The two possible functions of birds in the dumping sites could be, one is the roles of scavengers to eat up the organic (mostly fleshy) wastes which are very prone to grow microbes; the second one might be consumption of some vermin and other macro populations growing at the dumping grounds. Though we did not observe scavengers, the first purpose is not pertinent to this field, but the second one is quite relevant. Since the dwellers do not have a remarkable issue related to any of the vector-borne diseases. It is conceivable that the birds at open dumping sites help to control the growth of macro and micro-organisms. However, these birds and other vectors can also spread infections, which is a significant issue in tropical countries. To prevent this, it is important to implement alternative waste management methods, as open dumping has numerous negative effects on our environment and also human health. Currently, our country has introduced various systems to disinfect, recycle, and reuse MSW in different areas. However, the question remains: while dumping yards undoubtedly support avian populations, they are also sources of pathogenic infections. If the country can successfully process a large proportion of MSW in the coming decades, some avian species might disappear from our surroundings. In this conflict, preventing the spread of infections should be the top priority. One potential solution to attract birds is to place feeders or feeding bowls on windowsills.

ACKNOWLEDGMENTS

We appreciate all of the assistance that JIS University has given us. We also thank the residents around the dumping area for participation in the survey and the Arambagh Municipality for their assistance as and when needed.

Table 1: Identifying Characteristics of Birds

Common Name	Scientific name	Identification
House crow	<i>Corvus splendens</i>	Glossy black, the neck and breast are a lighter grey in colour. The wings, tail and also legs are black.
Common myna	<i>Acridotheres tristis</i>	Brown body and Black hooded head. The bare yellow patch behind the eye. The bill and legs both are bright yellow
Pied Myna	<i>Gracupica contra</i>	Yellowish bill, an orange base and black upper parts, white belly and white rump.
Eastern great egret	<i>Ardea alba modesta</i>	White in color. Yellowish-orange bills, and the legs black.
Jungle babbler	<i>Turdoides striata</i>	plain-looking babbler with a compact built and conspicuous pale eye

Table 2: Occurrences of birds on the dumping ground and diversity index

Name	Population	Simpson's index	Shannon Entropy
<i>Corvus splendens</i> (House Crow)	53%	0.36	1.22
<i>Acridotheres tristis</i> (Common myna)	20%		
<i>Gracupica contra</i> (Pied Myna)	19%		
<i>Ardea alba modesta</i> (Eastern great egret)	5%		
<i>Turdoides striata</i> (Jungle babbler)	3%		

Table 3: Types of waste

General wastes (non-attracting)	Wastes attracting the birds
Paper, wood, plastics, glass, metals, medicine strips, stones, ceramics, leathers and so on.	Kitchen waste, grass, fruits- seeds and peels, husks, grains, rodents, dead animal parts etc

Table 4: Information from face to face interview

Parameters	Information
Sex Ratio	Male: 80% and Female: 20%
Age Group	10yrs-15yrs: 20% 15yrs-25yrs: 10% 26yrs-59yrs: 50% 60yrs+: 10%
Occupation	Government employee: 10% Private employee: Nil Business/Entrepreneur: 10% Student: 40% Housewife: 10% Retired: Nil Other: 30%
Duration of staying at that place	Greater than 10yrs

Sauvik Bose *et al.*,

Whether knowing MSW	Yes: 10%, No: 90%
Mode of disposal of daily household wastes	Gather the waste in a bucket and throw that waste in the dumpsite.
Distance from the dumping site	Around 400m
Nuisance because of open dumping	During the monsoon and rainy days, bad smell comes from the dump site.
Whether the local authority responsible enough to manage solid wastes	Yes: 70%, No: 30%
Health issues	Sometimes skin irritations and skin diseases occur to the family members beside no other big disease occurred as of now.
Whether birds are one of the major factors in increasing trouble	Yes: 85%, No: 15%

ABSTRACT

Sericulture, an agro-based industry, employs many women and elderly people, with their skilled and unskilled labours. Silkworm rearing is very sensitive and delicate work especially during later instar where the rural women are suitable for the work. It is impossible to sustain their ongoing daily needs solely through agriculture. Data on the rearing performance of Daba eco-race Tirvoltine DTV-1, DTV-2, and DTV-3 Tasar silkworms in the villages of Baroghutu and Harangara in Khatra Block were gathered and analyzed for the following years: 2014–15, 2015–16, 2016–17, and 2017–18. The post hoc analysis reveals that both DTV-I and DTV-II differ significantly from DTV-III ($p < 0.0.1$) in case of the total number of groups cultivated them. Significant differences between various sericulture-related parameters in Baroghutu and Harangara villages were observed. The net income (NI) of farmers in Harangara village was markedly higher than that of farmers in Baroghutu village, as evidenced by an F-value of 7.762 ($p < 0.01$). The purpose of self-help groups are to prevent economic marginalization, empower one another,

**Pragati Patra et al.,**

and confront common social and economic challenges. Because of this, "Tasar" culture can support year-round, sustainable economic growth. Therefore, it is possible to view sericulture as a crucial tool for the empowerment of rural women to raise the standard of living for their entire family, the village, and bioresource management. Here, appropriate administration and a variety of self-help groups can be crucial to the empowerment of rural women.

Keywords: Baroghutu; eco-race, empower, Harangara, rural, Sericulture, Tasar silk worms, women

INTRODUCTION

Sericulture or silk farming is a promising agricultural business that has the ability to boost the farming community's economic standing and also generating foreign revenue [1]. It is positioned as a means of improving farming communities' economic standing. Farmers can diversify their income sources by engaging in sericulture, potentially lowering their reliance on single crops and enhancing overall financial stability. Sericulture allows those with little skills or resources to participate in meaningful economic activities. This inclusion of less-skilled and underprivileged members of society has the potential to result in more equitable development. More than 58 countries of the world practicing sericulture but only in India where all four varieties of silk are cultured [2]. On global scale Asian countries contributes 95% of the total silk production and contributes a leading role in sericulture industry. [3] According to International Sericultural Commission (2021), India and China are major silk production countries subsequently followed by countries like Japan, Brazil, Uzbekistan and Republic of Korea [5]. Sericulture, a labour-intensive industry, currently employs about one million people in China's silk sector. In India, around 7.9 million people were connected directly with silk industry, whereas 20,000 weaving families were engaged with sericulture industry in Thailand [4]. More than 1.5 lakh rural tribal people in the Indian states of Bihar, Andhra Pradesh, Jharkhand, Uttar Pradesh, Chhattisgarh, Maharashtra, West Bengal and Orissa heavily dependents on this agro-based cottage industry. This industry's relevance extends beyond economic contributions, as it is critical to the livelihoods and cultural legacy of these regions. Sericulture provides various benefits to these rural communities, including job creation, skill development, income diversification, female empowerment, and the preservation of traditional practices. Silkworm rearing involves several stages, from mulberry cultivation to silk processing, allowing a variety of chances for individuals to participate in various sectors of the industry. Sericulture is also compatible with the cultural and traditional fabric of these states, and is frequently incorporated into local customs, festivals, and rituals.

This intimate relationship highlights its importance in conserving and fostering cultural history, making it more than just a business but also a symbol of identity [6]. As per silk production estimates of total raw silk production of 30,348 MT, 70.10% of silk production comes from mulberry while non-mulberry silk production measured for 10.77%, 18.57%, and 0.56%, respectively silk in the year of 2016-17 [7,8, 9]. Host plant of tropical tasar (*Antheraea mylitta*) is mainly Asan (*Terminalia tomentosa*) and Arjuna (*Terminalia arjuna*) forests of central and north-eastern India, which is found commonly in the states of Bihar, Jharkhand, Chhattisgarh and Andhra Pradesh. Maharashtra, Telangana, Odisha and West Bengal, provides sustainable livelihood to rural tribal communities [7]. Jharkhand is the largest tasar silk producer state in terms of quantity of India with production reaching 2217 MT in 2017-18 subsequently followed by Chhattisgarh, Odisha, and Bihar follow, while West Bengal produces 35 MT of raw tasar silk and ranks fifth among other states [7]. Purulia, Bankura, and Midnapore, which are considered tribal dominated areas of West Bengal state, contribute significantly to the production of tasar silk [5]. Women workers contribute one-third of the global labour force and give nearly two-thirds of total working hours, yet their contribution to crucial productive work-share remains unnoticed [10]. In India approximately 12.7 crore women work as women labour, with majority of them working in unorganized sectors. They are employed particularly as marginal and casual agricultural jobs, where the gender wage disparity is prominent [11]. Women in India are also engaged in agro-based home chores, where they often serve as unpaid family labour and hence go unnoticed.

**Pragati Patra et al.,**

Sericulture is one of such field where majority of the work is done only by the women. Thus, they can play a very significant role in the activities spectrum as well as in decision-making in household business [10]. Women's contributions to sericulture have been neglected throughout history. They can play a significant role in various stages of the sericulture industry, from rearing silk-producing worms through processing and weaving silk [12]. The caring nature of a woman depicts very significantly by the way they take care of creating an appropriate habitat for the silkworms, assuring proper feeding, and safeguarding them from infections. This delicate and detailed activity necessitates precise care, patience, and attention to detail, all of which women have constantly displayed. In addition women played an important role in delicately unravelling the silk threads from the cocoons once the silkworms have made cocoons. Women have long been noted for their ability to perform this intricate chore with ease, passing down information and techniques from generation to generation.

AIMS AND OBJECTIVES

The paper makes a modest effort to present a picture of Bankura District's female workers in the sericulture industry and account for the predominance of female workers in sericulture farms in West Bengal. Comparative studies of the possibilities, cost effectiveness, and man-day generation by rearing of different silkworm varieties were also conducted. This paper will also attempt to shed some light on the role of self help groups (SHG's) for encouraging women to join in sericulture practices and also diagnosing how sericulture might help to improve the socioeconomic status of underprivileged tribal families

Present status of sericulture in Bankura district

Bankura district has a long history of sericulture. Bankura district contributes main silk production zone of West Bengal. The district's sericulture industry mainly divided into mulberry and tasar sectors. Tasar silk is mostly reared by tribal people in the district's southern and western regions. The majority of the blocks of this district are engaged with tasar cultivation, with only a small (276.50 acre) portion to mulberry silk cultivation. The majority of the Barjora, Bishnupur, Patrasayer, Kotulpur, Onda, Simlapal, Saltora, and Taldangra blocks exhibit mulberry sericulture, although there is no post cocoon activity. 14 of the district's 22 blocks are involved in tasar sericulture. Only 5 blocks are participating in post-cocoon activity (Table 1) [13]. Tribal people of this district have a long-standing custom of raising tasar silkworms in natural forests. Tasar silkworm rearing in natural forest flora like Arjun (*T. arjuna*), Asan (*T. tomentosa*), Sal (*Shorea robusta*), and Sidha (*Lagerstroemia parviflora*), is a traditional activity among the tribal people since time immemorial as a part of their tribal culture. Grainage units have been established in different blocks in order to preserve and offer high-quality, disease-free layings (dfls) to the rearers at a reduced cost. Since 1980, the district's Tasar host plantation (Arjun) has also grown significantly. Arjun has covered the hillocks and fallow ground that were the most unproductive desolate wastelands, giving the poor tribal people a means of subsistence and making it one of their main sources of revenue. Now a days by the use of more advanced technology, a continual improvement in and maintenance of the quality of disease-free layings (dfl) were observed. Tasar silk production covered 6972 acres of plantation space in 2017–18 and 13.36 MT of raw silk was produced [14]. Six out of the 14 tasar-farming blocks in Bankura account for 84.8 % of the region's total tasar cocoon production. The remaining 8 blocks account for only 15.2 % of the total production for the whole of the district. Maximum tasar silk production occurred from block Ranibandh (47.3%) taken after by Khatra (18.1%), Raipur (8.3%), and Hirbandh blocks (6.4%) [13]. Post cocoon activities were conducted in Bishnupur, Sonamkuh, Patrasayer (Banbirsingha), Khatra (Harangara) and Joypur blocks of this district. In 2014–15, PRADAN started work on the cultivation of tasar in West Bengal through the MKSP-NTFP programme of Mahila Kisan Soaktikaran Parishiyojana (PRADAN). The first year PRADAN worked with 480 families. By 2017–18, PRADAN had 2,066 tassel-based families engaged in the activities of Binpur-2, Ranibandh and Jhargram blocks in West Bengal. The concept of tasar based activities in group being a great initiative to bring villagers and stakeholders under the umbrella of a livelihoods group named Tasar Vikas Samiti (TVS) (Figure 1 & Figure 2).

MATERIALS AND METHODS

Study area

Two villages (Baroghutu and Harangara of Ranibandh Block which is about 90 k.m. from Durgapur and about 45 k.m. from Bankura) of Bankura district in West Bengal were chosen as the study area. Bankura district lies between 22°38' and 23° 38' N and 86° 36' and 87° 46' E (Figure 3 & Figure 4). Bankura can rightly be described as an intermediate zone with unique geo-climatic characteristics, lying between the plains of Bengal in the east and the plains of Chhota Nagpur in the west. A large part of the district is under forest cover of Arjun (*T. arjuna*), Asan (*T. tomentosa*), Sal (*S. robusta*) and Sidha (*L. parviflora*) and is inhabited by castes (>32%) and Scheduled Tribes (>10%). Agricultural productivity is weakened by low rainfall, dry weather and undulating terrain compared to other regions of the neighbouring municipalities. Monoculture is common in the region, where rice is the most popular crop. Due to the unfavourable climate and monoculture farming model, most farmers are tied to some secondary source of income. Being the tasar silk belt, thousands of farmers in that region opt for tasar silkworm rearing as a secondary source of income. Cultivation of trivoltine (TV) tasar silkworm *Antheraea mylitta* D. occurs in different areas of the region dominated by Arjun plant (*T. arjuna*).

Data Collection

Repeat visits were made in two selected villages where silkworm host plant cultivation, silkworm rearing and post cocoon activity were observed during the year 2015-16, 2016-17 and 2017-18 season. We purposefully selected these settlements because we knew there were several SHGs operating there, many of which were dependent on the forest for their raw supplies. According to the ease of accessibility and the presence of members at the time of the survey, the SHG members were chosen using a convenience sampling method. The necessary information was gathered in accordance with a schedule that was structured to compile each piece of information on the numerous ways SHGs work, engage in activities, and express opinions, among other things (Figure 5). The analysis involved a sample of 125 individuals from various SHG groups. Responses from local residents, government officials, sericulture farmers, winders, weavers and traders are recorded and analysed. Current reproductive practices and the production process are also critically examined.

Statistical analysis

Data processing and statistical analysis were thoroughly conducted using SPSS (Statistical Package for Social Science), a statistical software package. Analysis of variance (ANOVA) were conducted using continuous variables while chi-square test were conducted using categorical variable data. When the F value indicated statistically significant results ($p < 0.05$), to identify differences between pairs of means, Dunnett's post hoc test was conducted. Statistical significance was set at $p < 0.01$. Karl Pearson's bivariate correlation analysis was used to explore the relationships between the studied parameters. A rain cloud plot was generated using JASP 0.18.3.0, and an alluvial plot was created to demonstrate significant associations between categorical variables.

Missing value analysis

Neglecting the issue of missing data can lead to reduced statistical power of the models, biased parameter estimates, and erroneous conclusions about the studied phenomenon [15,16]. Expectation maximization (EM) method was applied to determine the missing data and imputed the data in this study. [17].

RESULTS AND DISCUSSION

In Bankura district, there are patches of forests where tasar host plants are naturally grown. In these areas, there are a large number of tribal people who depend on the forest for their livelihood and social well-being. Tribal communities of this region contribute to the growth and development of the tasar industry with their roots in tasar tradition and culture from ancient times. In these tribal dominated villages, Tasar plantation starts in 1981 and up to 2003 many barren lands were converted for tasar culture. Women were previously excluded from silkworm rearing.

Pragati Patra et al.,

Traditionally, only tribal male members (including children) engaged in rearing silkworms in the forest. Women's involvement in the rearing of silkworms has proven necessary to overcome a major impediment to women's equal participation in sustaining livelihoods and to revive a sector in decline. Tribal women of Ranibandh block were more actively participated in tasar culture than other villages. Most of the villagers of these block were engaged with Tasar rearing and Disease free egg production and few were only engaged with rearing. In this paper, we have compiled and analyzed the data regarding the rearing performance of Daba eco-race Tirvoltine DTV-1, DTV-2, DTV-3 for the year 2014-15, 2015-16, 2016-17 and 2017-18 silkworm seed. Tasar silkworm rearing performance of Baroghutu and Harangara villages of Bankura District were collected and examined (Figure 6). Tasar silkworm rearing performance of Baroghutu and Harangara villages of Khatra Block during the years 2015 – 16, 2016 – 17 and 2017 – 18 of Daba eco-race of Tirvoltine (DTV) was collected, compiled and presented Table respectively. In Baroghutu Village, they select DTV-I type of crop but in Harengara they reared DTV-III type of crop and number of female member engaged in rearing in these villages' ranges between 23-36 members. Good quality cocoon of DTV-I type found in 2015-16 is 96295 but in next two years cocoon production decreases but DTV-III type cocoon production increases from 91520 in 2014-15 to 195840 in 2017-19 in Harengara. So a total of 21.32% increase of income through cocoon selling occur from 2015-16 to 2017-18 in Harengara but total earning decreases in Baroghutu village by rearing in DTV-I race. Highest number of Dfl/ cocoon yield was harvested in Harengara (1:104) and in Baroghutu it is 1:60. Duration of DTV-I type of crop rearing takes time 41-42 days whereas in Harengara DTV-III type of crop rearing takes 60 days.

In these study areas In 2014 to 2018 only 03 women groups were engaged with Daba eco-race Tirvoltine DTV-1 rearing and post cocoon rearing while interest of rearing were more in DTV-III rearing and 2014-15 only 12 groups were engaged with this type of rearing but it increases up to 17 groups and total man-day produced 9009 days where as in DTV-1 culture man-day produced ranges between 802- 2242 days in four consecutive years. DTV-I type Dfls were reared 2000number in 2014-15 and it increases upto 3000 in 2017-18. But in 2014-15 a total of 18450 number of DTV-III type of Dfls were reared which increases upto 28910 in 2017-18. The number of DTV-I type cocoon produced in 2014-15 was 45984 which increases upto 137684 in 2017-18. Similarly production of DTV-III type cocoon increases every year and in 2017-18 a total of 550200 numbers of cocoons produced in these areas. Similar types of observation were reported in Ghar Ghoda tribal block of Raigarh district of India [18]. So for the past two decades, the members have earned their income by Tasar rearing and reeling on an individual basis in these villages. But now, working in a group setting, these tribal women are able to earn their income in a better manner reducing the seasonal and forced migrations. There is a significant difference between the number of groups ($F=190.029$, $p < .001$) cultivated various species indicating a large variation attributed to the differences between the groups (Figure 7a). The ANOVA also shows significant differences (Figure 7b) between the CDG and species ($F=19.489$, $p < 0.01$). The between-groups sum of squares is 237.400, with a mean square of 118.700, while the within-groups sum of squares is 54.816, with a mean square of 6.091. This indicates that the variation between the groups is significantly greater than the variation within the groups. The post hoc analysis using Dunnett t-tests compares each group against the control group, DTV-III. The post hoc analysis reveals that both DTV-I and DTV-II differ significantly from DTV-III ($p < 0.01$) in case of the total number of groups cultivated them. For the CDG variable, only DTV-I differs significantly from DTV-III ($p < 0.01$), while the difference between DTV-II and DTV-III is not statistically significant.

Significant differences between various sericulture-related parameters in Baroghutu and Harangara Villages were illustrates in Figure 8. The net income (NI) of farmers in Harangara village was markedly higher than that of farmers in Baroghutu village, as evidenced by an F-value of 7.762 ($p < 0.01$). Additionally, the study highlights substantial differences in the number of cocoons (NC) ($F = 18.976$; $p < 0.01$) and the number of DFLs reared (NDR) ($F = 145.223$; $p < 0.01$) between the two villages. Furthermore, a significant year-on-year difference in the cost per man-day (CPM) was observed ($F = 4.987$; $p < 0.05$). Figure 9 elaborates significant association between the categorical variables. For Dfl by species, the distribution shows a significant difference ($\chi^2 = 8.914$, $p < 0.05$). DTV I and II primarily have ≤ 10000 dfls, whereas DTV III has > 10000 dfls. For Group by species, the chi-square test indicates a highly significant difference ($\chi^2 = 12.000$, $p < 0.01$). DTV I and II are mostly found in ≤ 10 groups, while DTV III is in > 10 groups. For Dfl by village, there is a significant difference ($\chi^2 = 8.400$, $p \leq 0.004$). Baroghutu predominantly has ≤ 10000 dfls, while Harangara has > 10000 dfls. For CPD by village, the distribution shows a significant difference ($\chi^2 = 6$, $p \leq 0.05$).

Pragati Patra et al.,

Baroghutu has mostly normal CPD, whereas Harangara has a mix of low and normal CPD, with no high CPD. These results indicate distinct patterns in dfI rearing, group sizes, and cost per man-day between different species and villages, suggesting non-random distributions. The correlation matrix (Figure 10) provides insights into the relationships among variables. Each cell shows Pearson's correlation coefficient (r) and its corresponding p -value, indicating the strength and significance of associations. For instance, NDR is strongly negatively correlated with CDG ($r = -0.822$, $p < 0.001$), suggesting a robust inverse relationship. NC exhibits a strong positive correlation with both NDR ($r = 0.863$, $p < 0.001$) and TC ($r = 0.865$, $p < 0.001$), highlighting significant positive associations. Conversely, CD shows a weak negative correlation with NDR ($r = -0.468$, $p = 0.125$), which is not statistically significant at the typical alpha level of 0.05. These findings provide a nuanced understanding of how these variables interrelate in the dataset. Research shows that microfinance for the poor is easier, more efficient and less expensive if it is organized into self-help groups. Self-help groups are small, non-profit organizations of people from similar socio-economic backgrounds who share a common need or interest. They work together to solve social and economic issues by providing self-help, mutual empowerment and preventing economic marginalization.

CONCLUSION

In many countries of the world employment opportunities of rural women were restricted to low-skilled jobs. Sometimes women were exposed to unsafe working conditions. Now a day's women's participation in the labour force has increased a little bit despite many challenges. Women can play a vital role in natural resources management as well as restoration and preservation of the natural and man-made environment. Women have good understanding of the environment because rural women are mostly responsible for domestic and household management so they interact more with the environment. Agro based industry like sericulture has the potential to increase the job opportunities for rural people. It also empowering women and many women can take part in these activities and get benefit from it. Recently group-based approaches to poverty alleviation have become increasingly popular, particularly in the area of microfinance for the poor. Sericulture can help rural women under the umbrella of self help group can overcome various obstacles. Government and non government organization should come forward to access credit, education, and vocational training, thus increasing empowerment opportunities for rural people. Thus, it is possible to state that the sericulture sector has both potential and obstacles. For the development of the silk industry in this area, we require a well-thought-out plan with sensible policies for sericulture. So that many women in this area can take part in the plan and get benefit from it, It also helps to eradicate poverty of this region and ultimately lead to the district's overall upliftment.

Ethical approval (for researches involving animals or humans)

No Tasar cocoons were captured or killed or subjected to any experimental treatment during the study period.

ACKNOWLEDGEMENTS

We want to acknowledge Principal, Bankura Sammilani College, Bankura for his kind help and support for conducting the research work. We also want to acknowledge the help received from the people of Baroghutu and Harangara tribal village belonging to Bankura district of West Bengal, India during data collection.

ABSTRACT

This study compares two models in Data Envelopment Analysis (DEA) namely;Charnes, Cooper, and Rhodes (CCR) model and Banker, Charnes, and Cooper (BCC) model, with an emphasis on how the district hospitals in Madhya Pradesh, India, can use them. In operations research, decision-making units (DMUs) are evaluated for effectiveness using DEA, a non-parametric technique. While BCC model permits variable returns to scale (VRS), CCR model is predicated on constant returns to scale (CRS). In order to determine efficiency scores and benchmark performance, this study uses both models to assess the operational efficiency of district hospitals. We used data from a subset of Madhya Pradesh district hospitals for the 2019–2023 fiscal year. The number of beds, doctors, and health personnel (such as nurses, lab technicians, etc.) were among the input factors. The number of deliveries, maternal deaths, and infant deaths were among the output variables. The outcomes show that there are notable variations in the efficiency scores between the two models, underscoring the significance of scale efficiency in assessing hospital performance. The present study examines the consequences of these variations and offers suggestions to hospital administration and policymakers to enhance resource distribution and operational efficacy.

Keywords: Efficiency, Data Envelopment Analysis, CCR Model, BCC Model, District Hospital.

INTRODUCTION

A potent non-parametric technique called data envelope analysis (DEA) is used to assess the effectiveness of decision-making units (DMUs) that transform many inputs into multiple outputs. Since its introduction by Charnes, Cooper, and Rhodes in 1978 which assumes constant returns to scale (CRS) [1], DEA has gained widespread recognition as a useful instrument in performance evaluation and operations research. DEA compares the weighted outputs to weighted inputs ratio to determine the relative efficiency of DMUs. In contrast to conventional techniques, which call for predetermined functional forms and weights, DEA builds an efficiency frontier through linear programming. The best-performing units are represented by this frontier, which serves as a baseline for other units. A unit having an efficiency score of 1 is considered totally efficient. The efficiency value ranges from 0 to 1. Variable returns to scale (VRS) are supported by a particular formulation of Data Envelopment Analysis (DEA) known as the BCC model, named for its authors, Banker, Charnes, and Cooper [2]. Evaluating and comprehending the operational efficiency of the DEA CCR and BCC models in connection to Madhya Pradesh's district hospitals is the main goal of this comparison. Our goal is to distinguish between hospitals that are running efficiently and those that are not by calculating and comparing the efficiency ratings using both models. Comprehending the distinctions between the efficiency measurements of the CCR and BCC models—specifically, the assumptions of constant versus variable returns to scale—is essential for accurate evaluation. The study also aims to identify benchmark hospitals that establish the benchmark for efficient operations, offering guidance for underperforming hospitals. The study's conclusions will guide the best use of resources and point out areas where input-output ratios might be improved. The results will be used to inform the formulation of policy recommendations that will increase hospital efficiency by implementing techniques like process optimization and resource reallocation. In the end, the objective is to improve Madhya Pradesh's healthcare system by encouraging resource efficiency, guaranteeing improved patient care, and establishing the framework for DEA applications and healthcare efficiency research in the future.

ROLE AND IMPORTANCE OF DISTRICT HOSPITALS

In order to guarantee accessibility for the vast majority of the people, district hospitals are positioned strategically in each district headquarters. Within the district, these hospitals serve both rural and urban communities' medical requirements. District hospitals' bed capacities fluctuate based on the district's population and healthcare needs.

The district hospital is a crucial component of the health care delivery system in the three-tiered hierarchical level of public health care. It serves as a supplementary level of healthcare, offering the residents of the district complete preventive, promotional, and curative medical services. Public hospitals and health centres like the community health centre (CHC), primary health centre (PHC), and sub-centre (SC) are connected to each district hospital. District hospitals are required by the Indian Public Health Standards (IPHS) to:

1. offer the community complete secondary health care, including expert and referral services;
2. attain and keep a satisfactory level of care quality; and
3. Increase the responsiveness and sensitivity of services to the requirements of the local population as well as the hospitals and centres that send patients to them. In India, there are 810 district hospitals that offer vital services to the populace. Numerous health indicators have been taken into account in this study, such as the number of beds, the number of physicians, nurses, and paramedical personnel, the availability of diagnostic and medical specialties, and the rate of bed occupancy, among others. A comprehensive assessment approach was required to achieve the goals and objectives that guided the identification of the indicators. Under the structural and output domains, indicators were extensively categorized, and the best and worst performing district hospitals for each indicator were determined.

METHODOLOGY

DEA, a non-parametric method based on linear programming, evaluates the relative efficiency of homogeneous sets of DMUs utilizing various inputs to produce multiple outputs. It does not assume an explicit functional form but relies on basic assumptions about the underlying technology, allowing the construction of the production possibility

Manish Sharma et al.,

set from observed data. By calculating scores that range from 0 to 1, which indicate their efficiency inside a linear programming approach, the DEA methodology allows to benchmark the best practice decision-making unit (DMU) [15]. Efficiency is defined as the ratio of input to output. But according to Sinuany-Stern et al. [16], the DEA frequently deals with a unit that has many inputs and multiple outputs. This study compares the efficiency scores of Madhya Pradesh's district hospitals using data envelopment analysis using the CCR and BCC models. DEA is a technique created by Charnes et al. [1] (also known as the CCR Model) that measures the technical efficiency of DMUs based on the efficiency frontier. If a DMU's efficiency rating is less than 1, it is regarded as relatively inefficient. The Charnes, Cooper and Rhodes (CCR) and Banker, Charnes and Cooper (BCC) [2] models are the two fundamental models in the DEA approach. Although the BCC model relies on the premise that there is a variable return to the scale, the CCR model is predicated on the idea that there is a constant return to the scale.

DEA-CCR Model

The DEA CCR Model is defined as follow:

The efficiency of each DMU_o, Z_o, can be found by solving the LPP below.

$$Z_o = \max \sum_s v_s y_{so} \quad (1)$$

Constraints

$$\sum_k w_k x_{ko} = 1$$

$$\sum_s v_s y_s - \sum_k w_k x_{ko} \leq 0$$

$$v_s, w_k \geq 0$$

The dual of equation (1) can be used to find this sort of DMU. 2 defines the duality of (1).

$$\min e_o \quad (2)$$

Constraints

$$\sum_p \rho_p x_{kp} - e_o x_{ko} \leq 0$$

$$\sum_p \rho_p y_{sp} - y_{so} \geq 0$$

$$\rho_p \geq 0$$

When $e = 1$, $q = 1$, and $q \neq 0$, the efficient value 1 is given by equation (2). Where m DMUs best DMU₁, DMU₂,...DMU_m. All DMUs with $p = 1, 2, \dots, m$ require n inputs (x_{kp}) for $k = 1, 2, \dots, n$ and produce t outputs (y_{sp}) for $s = 1, 2, \dots, t$. Assume the variables are the output weight v_s ($s = 1, 2, \dots, t$) and the input weight w_k ($k = 1, 2, \dots, n$).

DEA-BCC Model

The healthcare industry frequently experiences a fluctuating return on scale as a result of fierce rivalry, governmental regulations, and budgetary constraints. This study also uses the input-oriented DEA-BCC model. This model is defined as follow:

$$\text{Min } e_o - \varepsilon (\sum_{r=1}^s s_r^+ + \sum_{i=1}^m s_i^-) \text{ Subject to}$$

$$\sum_{j=1}^n \lambda_j x_{ij} + s_i^- = e_o x_{i0} \quad i = 1, 2, \dots, m$$

$$\sum_{j=1}^n \lambda_j y_{rj} - s_r^+ = y_{r0} \quad r = 1, 2, \dots, s$$

$$\sum_{j=1}^n \lambda_j = 1 \quad j = 1, 2, \dots, n$$

$$\lambda_j \geq 0, s_r^+ \geq 0, s_i^- \geq 0$$

Where x_{ij} is the inputs and y_{rj} the outputs for DMU j ; e_o is the efficiency value, ε is an infinitesimal non-Archimedean constant, λ_i are the weightings and s_i^- and s_r^+ are the inputs and outputs slacks respectively.

DEA CCR & BCC Models Frontier Analysis

The CCR Model has a limitation that the benchmarking DMUs may not always do the same activities as an inefficient DMU. To address this issue, researchers have used performance-based clustering algorithms to group similar DMUs. The assumption of constant return to scale (CRS), which may or may not be true in different situations, is the

**Manish Sharma et al.,**

limitation of CCR models. To address this issue, researchers modified the original DEA model by adding variable return to scale (VRS). The fundamental VRS model is the BCC model.

DATA SOURCES

The yearly reports and bulletins issued by the Department of Public Health and Family Welfare, Madhya Pradesh provided the data used in this study. In order to choose the input and output variables for the data collection process, research on the healthcare department conducted between 2019 and 2023 was reviewed.

Input-Output Variables

The model's input and outcome variables were chosen by looking through the research done on MP district hospitals between 2019 and 2023. Three inputs and three outputs variables were selected in light of this analysis. Table I displays the data on the chosen input and output variables. The 51 district hospitals of Madhya Pradesh made up the study's sample. For the years 2019 through 2023, the data for this study came from the Public Health and Family Welfare Department's Annual Statistical Reports, HMIS Health Bulletin, National Health Mission, NITI Ayog District hospital Reports, MPMC, and Directorate of Public health.

DEA CCR and DEA BCC Results Comparison

Efficiency study was conducted on the sample data using the general basic DEA-BCC and DEA-CCR techniques. An overview of the findings is provided in Tables II. DEA-BCC and DEA-CCR methods were used to compute the District Hospitals' efficiency scores at this point. In 2019-20, when comparing the two models, the DEA-CCR model showed that there was more room for resource reduction among the inefficient hospitals and that fewer hospitals were classified as efficient. On the other hand, the DEA-BCC model identified a higher proportion of hospitals as efficient, indicating a more permissive evaluation of efficiency in the context of fluctuating returns to scale. While DMU6, DMU9, DMU19, DMU24, DMU37, and DMU50 were recognized as effective by both models, DMU1, DMU2, DMU4, DMU17, DMU20, DMU22, and DMU44 were also highlighted as efficient by the DEA-BCC model. Overall, the DEA-BCC model gave a more flexible evaluation that took into account various operating scales, but the DEA CCR model's assumption of constant returns to scale provided a stricter measure of efficiency. Overall, between 2019–20 and 2020–21, both models showed notable shifts in the Madhya Pradesh district hospitals' efficiency landscape. While DMU6 witnessed a deterioration and lost its efficient reputation, DMU23 stood out with considerable advances in both models. Compared to the DEA-BCC model, which revealed a large drop in DMU38 but indicated fewer institutions with deteriorating efficiency, the DEA-CCR model found a greater decline in efficiency across more hospitals. In 2021-22, In general, the DEA-CCR model demonstrated a more stringent evaluation, designating a smaller number of hospitals as efficient in contrast to the DEA-BCC model, which acknowledged a wider spectrum of hospitals as efficient. Notable efficiency increases were noted by both models for DMU25, DMU22, and DMU51 also shown noteworthy gains.

On the other hand, in both models, DMU1 continued to be a consistently ineffective hospital. In contrast to the DEA-CCR model, which saw more significant efficiency losses, especially in DMU44, the DEA-BCC model reported a higher number of efficient hospitals and a less severe fall in efficiency scores. Different viewpoints on hospital performance were offered by the DEA-CCR and DEA-BCC models in the evaluation of hospital efficiency for 2022–2023. Only 7 out of 51 hospitals met the DEA-CCR model's efficiency requirements; considerable gains were observed in hospitals like DMU9, DMU16, DMU19, DMU33, DMU37 and DMU44, whose efficiency scores increased. DMU23 and DMU25, on the other hand, suffered severe declines in efficiency, which caused them to be reclassified as inefficient. In this model, DMU31 demonstrated the biggest efficiency gain. At contrast, improvements were observed at DMUS like as DMU19, DMU31, DMU33, and DMU46. The DEA-BCC model found 16 efficient hospitals, including DMU1, DMU2, DMU4, and others. Both models emphasized the difficulties hospitals encounter in sustaining or increasing efficiency, notwithstanding variations in the rankings of particular hospitals. Different patterns are evident when comparing hospital efficiency using the DEA-CCR and DEA-BCC models from 2019 to 2023. DMU50 is the hospital with the most efficiency according to the DEA-CCR Model, while DMU1 is the hospital with the lowest efficiency among the group of inefficient hospitals. Remarkably, the only district hospitals that

Manish Sharma et al.,

continued to operate efficiently throughout that time were those in DMU9 and DMU37. In addition, DMU50 had the lowest volatility in efficiency scores, whereas DMU31 had the most. By comparison, DMU16 had the greatest average efficiency value within the group of inefficient hospitals, while DMU29 registered the lowest, according to the DEA-BCC Model. DMU1, DMU2, DMU4, DMU9, DMU17, DMU20, DMU22, DMU24, DMU37, DMU44, and DMU50 are the eleven district hospitals that consistently displayed effectiveness from 2019 to 2023 during the same period. Depending on the assessment model applied, this analysis reveals notable variations in the hospitals' levels of stability and efficiency.

CONCLUSION

In this study, the DEA CCR and BCC approaches, are applied to MP's district hospitals to measure their efficiency levels. It was found that DEA-CCR and DEA-BCC data, the two approaches yielded identical efficiency scores. Using the average efficiency score, 02 district hospitals and 13 district hospitals were determined to be efficient under both DEA-CCR and DEA-BCC, respectively. Furthermore, it was discovered that the DEA-BCC model's average efficiency score was higher than the DEA-CCR model's average efficiency score. According to this study, the most effective district hospitals are located in DMU9, DMU22, DMU37, and DMU50. In DEA-CCR Model, referencing hospitals for other hospitals with better outputs are designated from districts such as DMU1, DMU3, and DMU29, which provide subpar healthcare with fewer inputs. The relative effectiveness of these hospitals is shown by the efficiency ratings in the DEA models. In DEA-BCC Model, the based on average efficiency, the district hospitals in DMU1, DMU2, DMU4, DMU9, DMU17, DMU20, DMU22, DMU24, DMU37, DMU44, and DMU50 have effective health systems.

ABSTRACT

The prevailing strong editing tools and Artificial Intelligence (AI) has paved the way for increase in image tampering, which is the manipulation of digital photos to deceive or alter their content. Politics, advertising, journalism and social media make has utilized the tampering for diffusing fake information and impact public opinion. Convolutional Neural Network (CNN), Error Level Analysis (ELA), Residual Network 50 version 2 (ResNet50v2) and You Only Look Once version 5 small (YOLOv5s) are the Deep Learning (DL) algorithms incorporated in this survey. These methods avail in the identification of image forgery. By analyzing the irregularities and patterns, CNN detect the instances of manipulation and spot their precise locations in image. Deep residual learning in ResNet50v2 permits the accurate feature extraction, to be exerted on image forgery detection. When considering the modification signs in images, ELA assist by focusing on differences in compression levels. In order to locate the real-time manipulation instances, the method YOLOv5s is exploited. The subsequent content emphasizes the methods for detecting the forged images from the actual images.

INTRODUCTION

Image tampering, picture manipulation, or photo editing refers to the practice of altering the image to achieve certain effect, which distorts the original intent[1-3]. Evolution of social platform, online information sites, and visual storytelling, picture editing has become very trendy in digital era[4]. Although the techniques for altering images are present, the advent of robust digital technology has made manipulation easier and spotting harder, which has implications for artistic, commercial, and editorial purposes[5-7]. Picture editing is simple like adjusting the colors, cropping, correcting the pictures and difficult with components added or removed, backdrop changes, or even complete scene building. The intricacy and actuality of image alteration has evolved with digital technologies throughout time[8-10]. For the typical human, this makes difficult to distinguish the real from fake images[11]. Image editing has a wide range of applications[12]. Image editing is often used in media to improve the looks and communicate a message, magnify certain aspects for commercial reasons. Deep fakes are movies or photos made with advanced Artificial Intelligence (AI) that seem to be authentic but has not accurately reflected the actual people in their surroundings. These conditions raise ethical concerns, specifically with privacy, defamation, and the transmission of deceptive information[13-16]. On the negative side, picture editing is used to fabricate evidence, mislead people or harm people's reputations[17][18]. Images manipulated in political campaigns on social media confuse people, change their minds, or even cause societal upheaval[19]. This kind of modification makes tools for detecting and stopping picture hacking increasingly important. Image manipulation has consequences that extend beyond ordinary human deception. It renders the visual information susceptible[20-23]. Pictures depicting the previous happenings are been viewed in this manner. Whenever the photos and videos are progressively manipulated, it becomes more difficult to discern between fact and fantasy[24-26]. Aside from the duties of individuals who develop and disseminate digital material, there are serious worries regarding the effect of visual media on public opinion[27]. Moreover, it's difficult to identify the persons altering images by the progression in AI and Machine Learning (ML)[28]. With algorithms in place, more advanced techniques—such as producing fake photos that resemble real ones—are deployed. This makes it more important than having an accurate, automated method of detecting changed photos[29-31]. The easiest way to prevent from manipulating images is to use tools and software that check digital photos for faults, changes, or inconsistencies. However, these strategies are always developing to accommodate new ways of doing things[32].

LITERATURE REVIEW

Ahmad, M., et al (2022) presented a new methodology for detecting and localizing photo tampering. The recommended model consisted of three steps: feature extraction, tamper detection, and localization. Several features that included "Scale-based Adaptive Speeded Up Robust Features (SA-SURF)," "Discrete Wavelet Transform (DWT) based Patched Local Vector Pattern (LVP) features," and others were retrieved from the used input digital pictures. This generated feature strain was used to train the "optimized Convolutional Neural Network (CNN)" in tamper detection. Since the Improved Sea-lion Customized Fire Fly (ISCFF) model had historically played a crucial role in determining the occurrence of tampering, it was used to refine its weighting variables. Asaad, A., et AL (2017) introduced a topological method for forensic image modification detection. Topological Data Analysis (TDA) postulated that some image features were associated with persistent homological invariants and this method expanded on assumption. Pixels that consistently displayed texture descriptors using Local Binary pattern (LBP) coding were the picture attributes of interest. A series of simple complexes with progressively larger distance thresholds was designed using the selected pixels as vertices and found the corresponding non-growing homology invariants that measured the number of connected components. This tamper detection method supported the design's persistent homology that was sensitive to image degradation in calculating the sequence termination speed. A huge collection of passport photos was used to test the method, and showed that the persistent homology sequence had morphing attack differentiating feature. Roy, A., et al (2024) showcased a compact **Multi-Resolution U-Net**(Multi ResUnet) design with the Similarity-based Positional Attention Module (SPAM) attention module for Copy-Move Forgery Detection (CMFD). This attention module found patches where the fabricated used similarity

**Prince Joy and Jayanthi**

measure across the feature patches. In addition, lightweight network had helped resource-efficient training in making the model suitable for real-time use. Doan, T. N. C., et al (2021) used Joint Photographic Experts Group(JPEG) format to introduce a new approach for natural picture modification identification. The image fraud detection technique explained a natural image obtained by a digital camera. Two fingerprints defined the Falsified identification in that parametric model. After demonstrating their theoretical usefulness, the Generalized Likelihood Ratio Tests (GLRT) was deemed adequate for practical application. Image forgeries such as re-sampling, median filtering, and Gaussian filters were discussed in this study. Testing the suggested method with actual and virtual photos demonstrated its usefulness. Chakraborty, S., et al (2024) guaranteed a dual-branch CNN for photo authenticity. The outcomes are improved by neural networks and photo pre-processing. Image Error Level Analysis (ELA) data was fed as an input to one network node and evaluated. These 30 stage analysis-specific high-pass filters generated noise residuals and simultaneously sent to another network branch. This strategy beat the several earlier methods. Despite its small size and low parameter count, the model needed minimal time and computer resources to achieve this precision. The prescribed algorithm was able to differentiate real and edited photographs, but the specification of existed modification had been limited. Dong, L., et al (2024) suggested a robust network system to identify and localize text picture forgeries. Enhanced forgery traces and multistage attention-based localization were used in this framework. Deep module was utilized to augment the forging traces from many domains, decreased picture backdrop distraction and aided localization. Multistage Attention module combined high-level semantics with low-level details to create **Enhanced Semantics-based Network(Es-NET)**. Even carefully manipulated areas were revealed by joint restoration and multistage forgery feature learning. A big dataset with several tampering techniques and distortions were constructed to test the system under real-world distortion situations.

González Fernández, E., et al (2018) exposed a unique approach to identify digital picture tampering via the use of Color Filter Array (CFA) artifacts, which arise from differences in the distribution of collected and interpolated pixels respectively. The experimental results show that the suggested method detected several types of modifications, including copy-move, resizing, rotation, filtering, and colorization. This method had identified altered areas by first determining the pixel-specific interpolation probability and then applied the **Discrete Cosine Transform(DCT)** to discrete blocks of the probability map. For each block, the highest frequency coefficient was used to determine tampering status in the examined area. Rhee, K.H (2022) presented the Ground Truth (GT) as a game-changing approach to creating images that identified the copy-moved patches in fake photos. The above method applied 'Image classification' and 'Semantic segmentation' for Copy-Move forging pictures, generated the best-fit GT image of test fake picture. Several fake patches in Copy-Move, such as Rotate, Scale, and Blur, were discovered while testing in the net model training data set. The proposed GT image made use of CNN architecture to improve semantic segmentation and picture categorization, Copy-Move matching detection accuracy and F1 Score. Cut-Paste, In painting, and Forgery feature extraction are just a few of the image forensic applications that have been improved by using picture classification and semantic segmentation in this study. Kim, C., et al., (2021) demonstrated a fragile, productive Absolute Moment Block Truncation Coding (AMBTC)-based self-embedding watermarking approach. Block units' recovery bits (LSB2 and LSB3) and **Least Significant Bit(LSB)** were concealed using the Optimal Pixel Adjustment Process (OPAP) technique. The correctness of the block authentication was assured by including a checksum. Checksum replaced binary bits for authentication since they were imprecise. Li, H., et al (2017) provided a system that used tampering possibility maps to boost forgery localization efficiency. The suggested system has used two existing forensic methods—the copy-move forgery detector and the statistical feature based detector—to generate tampering possibility maps, which were further improved. This investigation on possibility map attributes and comparison of fusion strategies led to propose a simple but effective method for integrating the altering possible maps into the final localization findings.

Existing Methods**Convolutional Neural Network (CNN)**

Using the first few layers of CNN, important visual components including textures, forms, and edges are automatically identified by feature extraction. In order to differentiate real and altered areas in photos, the collected features are later identified by CNN. This model learns to distinguish the real and altered pictures by training a

**Prince Joy and Jayanthi**

dataset which contains both image types. The network's parameters are fine-tuned using loss function and back propagation methods to minimize mistakes in forgery identification. To train a CNN in classifying photos, the first step is to assign labels for each image. This allows the CNN to distinguish between real and modified regions in images by learning patterns and characteristics from the training data. After training, the CNN's ability to correctly recognize there cent-imported photos serves as a powerful tool for detecting picture frauds.

Error Level Analysis (ELA)

In order to function, ELA algorithms examine the picture compression settings. Using a comparison of compression levels across several picture components, ELA can detect manipulated regions. Images saved in lossy formats, such as JPEG, benefit greatly from this method. On editing a JPEG picture, save it again in the same format and few pictures are lost in each time. Taking advantage of this vulnerability, ELA examines the degree to which the original and resaved images differ before saving the image at a pre-set compression rate. The error levels of modified areas vary after creating the ELA of a picture, in contrast to the practically identical error levels of unmodified sections.

Residual Network 50 version 2 (ResNet 50 v2)

The ResNet50v2 architecture is shown in Figure 3. The first step is batch normalization, later activation function and updating the weights follow. Following that, the ReLU activation functions and batch normalization are executed. Next, the weights underwent optimization following the activation function. Utilizing pre-activation of weight layers rather than post-activation is the primary distinction from ResNet50v2 design. In order to establish the identity link between input and output, ResNet50v2 is designed to eliminate nonlinearity. The activation function and batch normalization are both executed by the second version of the ResNet module prior to weight multiplication.

You Only Look Once version 5 small (YOLOv5s)

YOLO uses CNN to extract characteristics from the whole picture and direct regression to calculate the target's coordinate values and classification probability. YOLO methods use regression to identify targets. Candidates' box positions need not be predicted. Using a single CNN for end-to-end model training, object identification is made faster than real-time detection. YOLO's fundamental notion is regressing target suggestion box location coordinates and categorization probability. To separate the recognized object from backdrop, each regression target is constructed using the whole picture's pixels. This avoids background misrepresentation. YOLOv5s has the shortest feature map width and network depth of the four models. This model detects quickest and best. The code controls the depth and breadth of the other three models using this basis. Due to its modest network depth and breadth, YOLOv5s reduces deployment costs and makes the network lightweight.

DISCUSSION

This survey has utilized 32 articles of image tampering. The algorithms like CNN, ELA, ResNet50v2 and YOLOv5s are used in the case of detecting tampered images. Of those, the First method CNN identifies spatial correlations and hierarchical patterns in accurately portraying intricate visual details but leads to vulnerability in image forgery. These techniques implement image forgery detection to automatically learn and identify patterns of manipulation, enhancing accuracy in spotting forged images. Although the analysis identifies tampering, ELA has difficulty detecting in high-quality photos and subtle changes. Despite spotting such manipulations, ELA in image tampering detection draws attention to compression anomalies by highlighting regions with abnormally high error levels. Although ResNet50v2 provides steady Deep Learning (DL) training and feature extraction, it is computationally intensive and fits maximum to small datasets. When it comes to detecting picture manipulation, ResNet50v2 uses deep residual networks to extract complicated characteristics and spot little changes. YOLOv5 offers fast, accurate real-time object detection and flexibility for custom datasets, but is quite resource-intensive and struggle with bounding box precision in complex scenes. This survey is used for recognizing forged images. Thus, the real image is characterized from the fake ones. With its real-time speed and effective resource utilization, YOLOv5s in image tampering detection efficiently finds and detects modified areas in photos. Using methods such as CNN, ELA,

Prince Joy and Jayanthi

YOLOv5 and ResNet50v2, picture forgers alter digital images to fabricate information. Several people use it to spread false information, commit fraud, or alter evidence, which raises ethical and legal questions. Reduce its harmful effects by raising public awareness and enacting stringent controls.

CONCLUSION

In this survey, 32 articles are undertaken, which detects and alters the image forging with the flowing algorithms. In order to identify pixel-level anomalies or compression artifacts, CNNs are used in image manipulation detection to obtain features and detect minute inconsistencies. As the preceding method enables automatic and trustworthy analysis, they are vital for detecting changed photographs in complex datasets. On looking for evidence of manipulation in images, ELA helps to find instances when the compression levels are inconsistent throughout the picture. This analysis grabs attention to the places with noticeable artifacts. Using its deep residual learning architecture, ResNet50v2 extracts the detailed characteristics from altered photos, making useful for image tampering detection. The available lucid design allows detecting the patterns of image variance. For the real-time localization of altered areas, picture tampering detection has used YOLOv5s, a lightweight variant of YOLOv5. Due its speed and efficiency, finding the modification zones in large datasets or in real-time applications is a breeze with this strategy.

Table 1: Comparison of various algorithms used in Image Tampering

Reference	Methodology	Datasets Used	Evaluation Metrics	Performance Keys
Pun et al (2015)	Matching features and adaptive over-segmentation	Not explicitly mentioned (requires details)	Likely True Positive Rate (TPR), False Positive Rate (FPR), etc.	Reliable in detecting fabricated regions in a wide range of attack situations
Sarreshtedari, S., et al (2015)	Method for self-recovery and protection using source-channel coding	Likely includes publicly available tampering datasets	PSNR, SSIM	Efficient self-recovery and tampering localization
Teerakanok, S., et al (2015)	JPEG quantization and re-interpolation processes for detection enhancement	Likely standard JPEG datasets	TPR, FPR, precision	Enhanced detection accuracy in JPEG-tampered images
Warbhe et al. (2016)	Scaling-resilient forensic approaches for detecting copy-paste manipulation	Likely includes small custom or public datasets	Accuracy, robustness against scaling transformations	Effective detection of copy-paste tampering, robust against scaling effects
Rajput et al. (2020)	Self-recovery using multiple median watermarking	Custom or public tampered image datasets	PSNR, SSIM, tampering detection rate	Improved tamper recovery using watermarking techniques
Sarkar et al. (2020)	Framework for massive-scale tamper detection and repair	Not explicitly mentioned (requires verification)	PSNR, tampering detection rate	Effective in detecting large-scale tampering and restoring tampered images
Vega et al. (2020)	Detection by estimating interpolation patterns	Likely includes standard datasets	Precision, recall, F1-score	Accurate detection of tampered regions by analyzing interpolation artifacts
Su et al. (2021)		Likely custom or standard watermark datasets	Detection accuracy, tampering localization accuracy	Achieves efficient tampering detection and localization via fragile watermarking
Qazi et al. (2022)	DL-based system for forgery detection	Likely includes standard forgery datasets	Likely accuracy, precision, recall	Achieved high accuracy in forgery detection with DL

Role of *Ocimum basilicum* in the Management of Diabetes and Cardiovascular Diseases - A Systematic Review

ABSTRACT

Ocimumbasilicum (basil) is investigated in this systematic review as a means of managing diabetes and cardiovascular diseases. The foremost purpose is to assess the influence of basil on the major metabolic parameters, such as blood glucose, lipid profile, and cardiovascular markers. Furthermore, the current review also analyses the possible therapeutic effects of basil in metabolic disorders through mechanisms like the effect on carbohydrate metabolism, antioxidant activity, and anti-inflammatory activity. In accordance with PRISMA, a systematic search was carried out in PubMed and Google Scholar for RCTs published between 2000 and 2023. The *Ocimumbasilicum* interventions for both diabetes and cardiovascular diseases were considered in human and animal research. From a total of 1070 articles, the features of 20 RCTs including sample, intervention details, control groups, and results were selected as per the set criteria. Additional references were also included to give more general information. All the 20 RCTs reviewed established that basil lowers blood glucose and enhances insulin sensitivity in diabetic models. The lipid profiles were also significantly altered for the better, with observed reductions in total cholesterol, LDL cholesterol and triglycerides, well-controlled blood pressure, and improved cardiac function. *Ocimumbasilicum* can be used in the complementary therapy of diabetes and cardiovascular diseases due to the suppression of hepatic glucose output, stimulation of lipid utilization, and cardiovascular shield. Nevertheless, further research, primarily in the form of large-scale trials, is needed to confirm its clinical efficacy given the wide study design and dosing variation.

Keywords: LDL cholesterol and triglycerides, well-controlled blood pressure

INTRODUCTION

Diabetes and cardiovascular diseases (CVDs) are leading causes of morbidity and mortality, worldwide. In 2021, 537 million adults worldwide had diabetes, and the number is set to rise dramatically in the coming decades, according to the International Diabetes Federation (IDF). Because of shared risk factors, such as obesity, hypertension, and dyslipidemia, diabetes and cardiovascular complications often coexist. Typically, management strategies are pharmacological, lifestyle, and in some cases surgical. But, as with most medications, long-term use is often accompanied by adverse side effects, prompting the search for safer, natural alternatives to be used in conjunction with standard treatments. *Ocimumbasilicum*, commonly known as basil is one promising natural remedy that has been used in traditional medicine over the centuries. Phytochemicals such as flavonoids, eugenol, and rosmarinic acid (essential oils) are the most contributing phytochemicals in Basil that specifically help in maintaining health. The herb is believed to have anti-inflammatory, antioxidant, hypoglycemic, and cardioprotective properties and may be a therapeutic agent for diabetes and cardiovascular diseases.

Pathophysiology of Diabetes and Cardiovascular Diseases

Chronic hyperglycemia defined as diabetes is due to defects in insulin secretion, insulin action, or both. Type 1 diabetes (T1D) is the autoimmune destruction of pancreatic beta cells and type 2 diabetes (T2D) is associated with insulin resistance. Nephropathy, retinopathy, neuropathy, and an increased risk of cardiovascular events, such as myocardial infarction and stroke, are long-term complications of uncontrolled diabetes. CVDs are a group of diseases that affect the heart and blood vessels (coronary artery disease, hypertension, heart failure). Hyperglycaemia and insulin resistance enhance the underlying pathophysiology often characterized by endothelial dysfunction, inflammation, and oxidative stress. In diabetic patients, dyslipidemia, i.e. elevated levels of low-density lipoprotein (LDL) cholesterol and triglycerides, and low levels of high-density lipoprotein (HDL) cholesterol, further increases cardiovascular risk.

Therapeutic Role of *Ocimumbasilicum*

Ocimumbasilicum phytochemical composition is responsible for its therapeutic effects on metabolic and cardiovascular health. For example, eugenol has been shown to present antihyperglycemic properties by increasing insulin sensitivity and decreasing hepatic glucose production. In addition, rosmarinic acid and other polyphenols in basil are potent antioxidants which fight free radicals and lower oxidative stress that are associated in the pathogenesis of both diabetes and CVDs. Basil's anti-inflammatory properties can help fight the chronic inflammation that accompanies these diseases, according to research. Basil may help reduce inflammation-induced damage to tissues including the vascular endothelium through the modulation of pro-inflammatory cytokines, such as interleukin-6 (IL-6) and tumor necrosis factor-alpha (TNF- α).

Objective of the Review

The clinical and experimental evidence supporting the use of *Ocimumbasilicum* for managing diabetes and cardiovascular diseases is the aim of this systematic review. The review analyzes 20 RCTs that examine the herb's effects on glycemic control, lipid metabolism, inflammation, and cardiovascular markers to establish a base for the possible integration of basil into therapeutic regimens for metabolic health.

MATERIALS AND METHODS

Study Design and Search Strategy

The review was performed according to the PRISMA guidelines. PubMed, Google Scholar, and other databases were searched for studies published between 2000 and 2023. Search terms were "*Ocimumbasilicum*" AND "diabetes" AND "cardiovascular diseases" AND "randomized controlled trials." Only RCTs with *Ocimumbasilicum* as an intervention in human and animal models were included. The search was to find studies that measured outcomes such as glycemic control, lipid profiles, inflammation, and cardiovascular health markers.

Debasrita Banerjee and Luxita Sharma

Inclusion and Exclusion Criteria

- **Inclusion Criteria**
 - RCTs with interventions using *Ocimumbasilicum* for diabetes and cardiovascular outcomes.
 - Studies published in English between 2000 and 2023.
 - Trials involving both human and animal subjects.
 - Full-text availability for data extraction and analysis.
- **Exclusion Criteria**
 - *In vitro* studies, observational studies, reviews, and case reports.
 - Studies without appropriate control groups or lacking sufficient details on interventions and outcomes.
 - Articles published in non-peer-reviewed journals.

RESULTS

The beginning database search picked out an aggregate of 1070 articles, 482 in PubMed, 545 in Google Scholar, and 43 records from other sources. A total of 886 (total duplicates 325) were found after removing the duplicated articles, and after reading the title and abstracts, they were further decreased to 188 full-text articles. These 188 studies went for full-text analysis, which resulted in the exclusion of 168 studies and generated a final 20 articles included for systemic analysis, as depicted in the flowchart presented in Figure 3.

Data Extraction

Data were extracted from a standardized form that included study characteristics (author, year, country), population details (number of subjects, type of subjects), intervention details (type, dose, duration), outcome measures (blood glucose levels, lipid profile, inflammatory markers) and findings. A comprehensive summary table (Table 1) was created using the extracted data.

Quality Assessment

The Cochrane Risk of Bias tool was used to assess the quality of each included study. Random sequence generation, allocation concealment, blinding of participants and personnel, incomplete outcome data, and selective reporting were considered as factors. These domains were rated as low, unclear, or high risk of bias in studies.

Statistical Analysis

In studies measuring quantitative outcomes, mean differences in blood glucose levels, lipid profile changes, etc. were extracted. Because of the heterogeneity in study designs, interventions, and outcome measures, meta-analysis was not performed.

Key Findings from the RCTs

Ocimumbasilicum in the management of diabetes and cardiovascular diseases. Taken together, the studies show that there are significant improvements in glycemic control, lipid metabolism, cardiovascular function, and inflammatory status in a variety of animal models and human subjects.

1. **Glycemic Control:** Basil was found to significantly reduce blood glucose in several trials. For example: Ezeani et al. (2017) found that basil extract lowered the rats' diabetes-related fasting blood glucose levels by 35% and Patil et al. (2016) noted a 30% drop in glucose levels in the rats after giving them basil leaf extract. Basil also showed promise in human trials, as researchers noted some reduction in fasting blood glucose levels, by up to 28 percent, in diabetic patients (200 patients) when basil was tested as part of a triple formula treated with ginger, cinnamon, and guggul. It is assumed that any of the above-mentioned compounds including eugenol as well as caffeic acid contribute to these effects of cinnamon by increasing insulin sensitivity as well as inhibiting the production of hepatic glucose.
2. **Lipid Metabolism:** Most of the studies showed that *Ocimumbasilicum* is able to improve lipid profiles. Looking at diabetic rats, Khare & Upadhyay (2017) found 28% reduction in LDL cholesterol levels as well as a 20%

**Debasrita Banerjee and Luxita Sharma**

increase in cardiac function. Like Behbahani et al. (2017), basil extract supplementation reduced total cholesterol by 25% and triglycerides by 22% in rabbits. Possibly through the presence of ursolic acid and its flavonoids promoting lipid metabolism – reducing cholesterol absorption.

3. **Cardiovascular Health:** In addition, these trials also show improvements in cardiovascular markers. In diabetic rats, basil oil treatment resulted in a 25 percent increase in ejection fraction as well as improved cardiac function. The antioxidant properties of basil which reduce oxidative stress and lipid peroxidation are responsible for the bulk of the cardioprotective effects, which we observed. The presence of rosmarinic acid and linalool, which enhance endothelial function and promote nitric oxide release, further supports these benefits.
4. **Anti-inflammatory and Antioxidant Effects:** Hussain & Majeed (2018) reports a 32% reduction in C reactive protein (CRP) levels and Fernandes & Almeida (2011) a 28% reduction in interleukin 6 (IL-6) levels. They are likely due to basil's bioactive compounds known to inhibit pro-inflammatory cytokines and decrease the enzymes involved in oxidative stress. The trials also showed the herb's potent antioxidant effects as it reduced malondialdehyde (MDA) levels by 31%, and reactive oxygen species (ROS) by 30%.

Outcome Markers for the Included Studies**Description**

The distribution of outcome indicators among the reviewed studies is shown in this chart. Of the 20 RCTs, 15 studies documented improvements in glycemic control and were the most commonly evaluated measure. Twelve studies showed reductions in cholesterol and triglyceride levels, a key outcome in lipid metabolism. Eight studies reported reductions in cardiovascular markers (ejection fraction, blood pressure) and nine anti-inflammatory effects based on CRP and IL-6 levels. Seven studies also tracked changes in oxidative stress markers (MDA and ROS) to measure antioxidant effects. Basil's broad therapeutic potential in metabolic and cardiovascular health is reflected in the chart.

Country-wise Number of Studies

The geographic distribution of the 20 included RCTs is shown in this figure. Six studies were from India and focused on traditional medicine applications of basil in the management of diabetes and cardiovascular diseases. The emphasis of the three studies conducted in the United States was on the herb's integration into complementary and alternative medicine. Two studies each were also from the United Kingdom, Brazil, and Iran, showing the worldwide interest in basil's therapeutic properties. Other countries included in the studies are Egypt, China, and South Africa, with one study each that shows the widespread acceptance and use of basil in other countries.

Year-wise Distribution of the Included Studies**Description**

The temporal distribution of studies included in the present review is presented in this graph. The number of studies increased gradually from 2005 to 2016, with a peak in 2015 to 2018 when eight studies were published. The trend indicates that there has been growing scientific interest in the therapeutical potential of *Ocimum basilicum* for diabetes and cardiovascular management. Nevertheless, studies decreased slightly from 2019 to 2023, possibly because of new research priorities or the effects of global events, such as the global COVID-19 pandemic. An ongoing interest is indicated by the year-wise distribution but these need further large-scale trials to establish more robust evidence.

DISCUSSION**Antidiabetic Effects**

Ezeani et al. (2017), studied in animal models, reported that basil extracts reduce blood glucose levels by 35% and Patil et al. (2016) reported a 30% reduction in blood glucose levels in animal models. The attributions for these effects are to compounds such as eugenol and caffeic acid, which enhance insulin sensitivity and suppress hepatic glucose production. Research by Kumari & Ravishankar (2010) showed that basil supplementation, could reduce Fasting Blood Glucose by 28%, and plays an adjunctive role as a therapy in diabetes management. Basil also has supportive

**Debasrita Banerjee and Luxita Sharma**

studies that indicate its glycemic benefits are due to inhibition of α -glucosidase and α -amylase enzymes that slow carbohydrate digestion and reduce postprandial glucose spikes (Upadhyay, 2017; Benavente-Garcia et al., 2016).

Cardioprotective Properties

Cardiovascular benefits were reported by the experiment of Khare & Upadhyay (2017) showing a 28 percent reduction in LDL cholesterol and a 20 percent improvement in cardiac function. Modulating cytokine levels has been demonstrated for flavonoids in basil to exert anti-inflammatory effects. However, studies by Khare & Upadhyay (2017) and Dinda & Maulik (2014) showed that basil supplementation had significant cardioprotective properties, such as a 28% lowering of the levels of LDL cholesterol and 210 – 25 % improvement in cardiac function. Basil flavonoids and other bioactive compounds are shown to reduce oxidative stress and inflammation, important factors in the pathogenesis of cardiovascular diseases. These benefits are contributed to by rosmarinic acid and ursolic acid inhibit lipid peroxidation and improve endothelial function. It is essential for the prevention of atherosclerosis and other complications of the cardiovascular system. These findings are echoed in other studies that show how basil might be able to reduce blood pressure by releasing nitric oxide, which relaxes blood vessels lowering resistance to its blood flow (Aggarwal & Prasad, 2018). Basil's anti-inflammatory action can also help reduce chronic inflammation in vascular tissues, a common problem in diabetic and heart patients (Ganaie et al., 2020).

Anti-inflammatory and Antioxidant Activities

The therapeutic effects of *Ocimum basilicum* depend significantly on its anti-inflammatory and antioxidant properties. According to studies by Fernandes & Almeida (2011) and Hussain & Majeed (2018), basil extract reduced inflammatory markers such as CRP and IL-6 by 32% and 28%, respectively, in subjects. Flavonoids and polyphenols mediate these effects by decreasing pro-inflammatory cytokines and decreasing the production of oxidative damage. The antioxidant properties of basil found from supportive research suggest that it can help in reducing levels of Reactive Oxygen Species (ROS) and malondialdehyde (MDA), and therefore save cells from oxidative stress linked to both diabetes and cardiovascular diseases (Ahmad et al., 2017; Pant et al., 2021). Basil can consequently be used regularly to help manage inflammation and protect vascular tissue from damage.

Mechanisms of Action in Diabetes and Cardiovascular Disease Management

Basil phytochemicals (eugenol, rosmarinic acid, and linalool) have multiple mechanisms of action to manage diabetes and cardiovascular diseases. Insulin sensitivity has been improved, hepatic glucose production reduced, and glucose uptake in muscle cells increased by eugenol. This is consistent with Patil et al. (2016), who found that diabetic models are reduced by 30% in blood glucose. Other chemicals such linalool and rosmarinic acid, in turn, contribute to cardiovascular health by decreasing the amount of lipid peroxidation, preventing platelet aggregation, and promoting vasodilation via nitric oxide pathways (Vafaei et al., 2018). Basil is a potent natural agent for comprehensive metabolic and cardiovascular management due to the combined effects of these compounds.

Comparative Effectiveness with Conventional Treatments

However, basil has many advantages, and it is important to compare its effects with conventional antidiabetic and cardiovascular drugs. Basil differs from synthetic drugs such as statins and metformin, wherein the former can cause side effects like muscle pain, and muscle spasms while the latter causes gastrointestinal side effects. But it may be less potent than pharmaceutical options, and so is more likely to be used as a complementary therapy than as a stand-alone treatment. The promising results from studies such as Kumari & Ravishankar (2010) in which basil has been used together with conventional treatments yield improved overall therapeutic results.

CONCLUSION

The results of 20 RCTs provide evidence for the use of *Ocimum basilicum* as an adjunct therapy for diabetes and cardiovascular diseases. Improvements in glycemic control, lipid profiles, and oxidative stress markers support the

**Debasrita Banerjee and Luxita Sharma**

herb's antidiabetic effects, cardioprotective properties, and anti-inflammatory activities. Still, additional study is required to those dosages as standardized, and confirm these benefits in larger, more diverse populations.

Table 1: Summary of RCTs Evaluating *Ocimum basilicum* for Diabetes and Cardiovascular Management

Study	Subjects (Exp/Control)	Intervention (Dose & Duration)	Outcome Measures	Key Findings
Ezeani et al. (2017)	60 rats (30/30)	Basil extract (100-400 mg/kg, 28 days)	Blood glucose, lipid profile	Fasting blood glucose reduced by 35% in high-dose group; total cholesterol decreased by 30%.
Khare & Upadhyay	50 rats (25/25)	Basil oil (0.5 ml/kg, 8 weeks)	Cardiac function, lipid profile	LDL cholesterol reduced by 28%, cardiac function improved

Debasrita Banerjee and Luxita Sharma

(2017)				by 20% (ejection fraction).
Malapermal et al. (2017)	40 rats (20/20)	Basil extract + silver nanoparticles (10 mg/kg)	Blood glucose, antimicrobial activity	Blood glucose lowered by 40%; microbial colony count reduced by 60%.
Behbahani et al. (2017)	30 rabbits (15/15)	Basil extract (200 mg/kg, 6 weeks)	Cholesterol levels, atherosclerosis	Total cholesterol reduced by 25%, triglycerides decreased by 22%.
Patil et al. (2016)	60 rats (30/30)	Basil leaf extract (150 mg/kg, 12 weeks)	Glycemic control, oxidative stress	Blood glucose decreased by 30%; malondialdehyde (MDA) levels reduced by 35%.
Hussain & Majeed (2018)	70 rats (35/35)	Basil extract (100 mg/kg, 10 weeks)	Inflammation, lipid profile	C-reactive protein (CRP) levels reduced by 32%; HDL cholesterol increased by 15%.
Fernandes & Almeida (2011)	80 patients (40/40)	Basil oil capsules (250 mg, 12 weeks)	Blood glucose, lipid profile	Fasting glucose decreased by 18%; HDL cholesterol increased by 12%.
Kumari et al. (2013)	100 patients (50/50)	Basil-based Ayurvedic formulation	Blood glucose, inflammation	Postprandial glucose decreased by 22%; IL-6 levels reduced by 28%.
Chopra et al. (2004)	60 patients (30/30)	Basil-derived formulation for arthritis	Inflammation, blood glucose	Blood glucose levels decreased by 20%; joint inflammation markers reduced by 25%.
Huang et al. (2005)	50 mice (25/25)	Basil containing oleanolic acid	Glycemic control, hepatic enzymes	Blood glucose decreased by 40%; alanine aminotransferase (ALT) reduced by 33%.
Eliza et al. (2009)	80 rats (40/40)	Basil extract (oral, 150 mg/kg)	Blood glucose, lipid peroxidation	Glucose levels dropped by 34%; lipid peroxidation markers reduced by 31%.
Dinda & Maulik (2014)	70 rats (35/35)	Basil oil (dietary supplement, 0.3 ml/kg)	Cardiac function, oxidative stress	Ejection fraction improved by 25%; reactive oxygen species reduced by 30%.
Kelm et al. (2000)	45 rats (23/22)	Basil phenolic compounds (diet, 6 weeks)	Inflammation, lipid profile	TNF- α levels reduced by 30%; LDL cholesterol decreased by 18%.
Mandal & Mandal (2014)	90 rats (45/45)	Basil extract (150 mg/kg)	Glycemic control, lipid profile	Blood glucose reduced by 36%; triglycerides lowered by 24%.
Kanuri & Weber (2013)	40 mice (20/20)	Basil leaves (5% diet supplementation)	Blood glucose, insulin sensitivity	Glucose levels decreased by 38%; insulin sensitivity improved by 30%.
Nagassapa & Matsuura (2015)	60 rats (30/30)	Basil-derived eugenol (0.2 ml/kg)	Blood glucose, lipid profile	Blood glucose levels decreased by 32%; total cholesterol reduced by 20%.
Kumari & Ravishankar (2010)	100 patients (50/50)	Basil leaves (500 mg, 8 weeks)	Glycemic control, inflammation	Fasting blood glucose decreased by 28%; CRP levels reduced by 25%.
Prakash & Gupta (2005)	30 patients (15/15)	Basil supplement (oral, 250 mg/day)	Blood glucose, lipid profile	Blood glucose levels dropped by 20%; LDL levels reduced by 18%.
Sasidharan et	40 rats (20/20)	Basil extract (oral, 0.5	Blood glucose,	Blood glucose decreased by

Debasrita Banerjee and Luxita Sharma

al. (2008)		ml/kg)	oxidative stress	26%; antioxidant levels increased by 30%.
Kothari & More (2011)	40 rabbits (20/20)	Basil oil (oral, 0.4 ml/kg)	Cardiac function, lipid profile	Ejection fraction improved by 20%; triglycerides lowered by 22%.

Table 2: Nutritional Composition of Basil Leaves (per 100g)

Nutrient	Amount per 100g	Reference
Energy	22 kcal	USDA FoodData Central
Carbohydrates	2.7 g	USDA FoodData Central
Dietary Fiber	1.6 g	USDA FoodData Central
Protein	3.2 g	USDA FoodData Central
Total Fat	0.6 g	USDA FoodData Central

ABSTRACT

This study aimed to determine the clinical efficacy of Vasambu Patru external therapy in reducing pain in patients diagnosed with Azhal Keelvaayu or Osteoarthritis. A group of ten patients was selected to participate in the study, and they were administered the trial therapy over fifteen days. The participants were selected based on the inclusion and exclusion criteria of the study. The pain level was assessed using the Visual Analogue Scale before and after treatment. The average values of the Visual Analogue Scale were evaluated to be 6.6 before the administration of the trial therapy and 2.6 after the therapy, indicating a significant reduction in pain. This study indicates a pressing need to increase awareness and understanding of Siddha external therapy. Patients with knee osteoarthritis have been found to benefit from Vasambu patru potentially. So, the study may be undertaken with the same trial therapy in a large number of samples and it may throw new light on the treatment of Azhal Keelvaayu.

Keywords: Vasambu, patru (poultice), External therapy, Osteoarthritis, Acorus calamus, Siddha

Adlin Reshma *et al.*,

INTRODUCTION

osteoarthritis, commonly called as Azhal Keelvaayu, is the most prevalent form of arthritis and a chronic degenerative joint disease. In addition to developing new bone and reshaping the joint's contour, this condition is marked by the localized loss of articular hyaline cartilage. Osteoarthritis is one of the most prevalent chronic arthritic disorders and is the leading cause of pain and disability in many nations worldwide. The World Health Organization (also known as the WHO) estimates that in the world, 18.% of women and 9.6% of men over 60 have symptomatic osteoarthritis[1]. Between 2000 and 2020, knee OA was very common worldwide, which could put a strain on the world healthcare system. OA is more common in women than in men. Over 15 million persons in India suffer from osteoarthritis, the most common type of arthritis. It is one of the top five most common diseases in India[2]. South India is the place of origin of the old indigenous medical system known as Siddha medicine. In Siddha literature, thirty-two distinct treatment processes are used as external remedies. One of the 32 external therapies that have been traditionally used for alleviating problems including arthritis, sprains of the muscles, swellings, abscesses, and other related conditions is PATRU. It involves covering the affected area with a soft, moist poultice consisting of a semi-solid paste prepared by grinding plant fragments or unprocessed raw medications. As per Siddha literature,

Vasambu patru plays a vital role in treating Azhal keelvaayu[5]. Hence, the study evaluated **Vasambu Patru's** efficacy in managing OA knee symptoms.

IEC approval: The IEC (Institutional Ethical Committee), Government Siddha Medical College, Chennai –600106 reviewed and approved the study protocol and informed consent. IEC NO:GSMC-CH-1243/ME-II/040/2023

CTRI No: This trial was also registered in the Clinical Trial Registry of India (CTRI), CTRI NO: CTRI/2023/08/056965.

MATERIALS AND METHODS

The pilot study was conducted at Government Siddha Medical College, Chennai.

CTRI approval

This trial was also registered in the Clinical Trial Registry of India (CTRI), CTRI NO: CTRI/2023/08/056965. This study was initiated only after CTRI REGISTRATION.

MATERIALS AND METHODS

The pilot study was conducted at Government Siddha Medical College, Chennai.

CTRI approval

This trial was also registered in the Clinical Trial Registry of India (CTRI), CTRI NO: CTRI/2023/08/056965. This study was initiated only after CTRI REGISTRATION.

Patient consent

Informed consent was obtained from all individual participants included in the study. The study was conducted by the Declaration of Helsinki, and the protocol was approved by the IEC (Institutional Ethical Committee), Government Siddha Medical College, Chennai –600106 (Approval No. IEC NO: GSMC-CH-1243/ME-II/040/2023). They reviewed and approved the study protocol and informed consent. All participants were assured of the confidentiality of their personal information, and participation was entirely voluntary with the option to withdraw from the study at any time.

**Adlin Reshma et al.,****Enrolling of patients**

Patients who matched the criteria for enrolment were allowed to participate or take part in the study. The study's objectives, potential outcomes, and trial medication were disclosed to the participants who were recruited for the research. Trial therapy was carried out for fifteen days. Data from baseline assessments as well as pre- and post-assessments were gathered. Records were kept of the analytical statistics and outcomes.

INTERVENTION - Vasambu patru

STUDY DESIGN - Pilot study

STUDY PERIOD - 15 days

STUDY DURATION - 3 months

SAMPLE SIZE - 10 patients

STUDY PLACE - Arignar Anna Government Hospital of Indian Medicine, Government Siddha Medical College (GSMC), Chennai 106.

Sampling technique

The data was collected by consecutive sampling among persons accompanying patients attending the OPD at Arignar Anna Government Hospital of Indian Medicine, Chennai.

Eligibility criteria

There were 10 patients included in this study, and subjects were enrolled based on inclusion and exclusion criteria.

Inclusion criteria

Age limit - 31 to 70 years, all genders, Pain, and swelling in the joint, Early morning stiffness (less than 15 mins), Reduced range of motion in the knee joint

Exclusion criteria

Rheumatoid arthritis (RA), Psoriatic arthropathy, Gouty Arthritis, Septic arthritis, Fracture, and Any other serious systemic illness will be excluded clinically or based on available medical reports. All collected data were entered into MS EXCEL SOFTWARE using different columns as variables and rows as patients, SPSS software was used to perform the statistical analysis. A probability value of <0.05 was considered as indicated as statistically significant.

RESULTS

10 patients presented with complaints of OA-knee were included in the study and were given the trial therapy. The baseline data was collected along with demographic details of the patients. Results were observed to the following criteria.

1. GENDER
2. AGE DISTRIBUTION
3. OCCUPATION
4. BMI
5. VISUAL PAIN ANALOG SCALE
6. STATISTICAL ANALYSIS

Demographic profile**Gender**

In the study, 70% of the participants were females and the remaining 30% were males

Age distribution

30% of participants were distributed in 41-50, 40% were in 51-60%, 20% were distributed in the 61-70 age group, while only 10% fell within the 31-40 age group.

**Adlin Reshma et al.,****Occupation**

Out of 10 patients, 40% of the participants were Home Makers, 30% were Teachers and 30% were private employees like security guards and hotel servants.

Body mass index

30% of the participants had normal BMI 30% were Over Weight and the remaining 40% were Obese.

Visual pain analogue scale

Among 10 patients, 2 cases (20%) were on a pain scale of 4, 1 case (10%) was on a pain scale of 5, 6 cases (60%) were on a pain scale of 6, and 1 case (10%) was on pain scale 7 before treatment. Out of 10 patients, 1 case (10%) was in pain scale 2, 3 cases (30%) were in pain scale 3, 3 cases (30%) were in pain scale 4, and 3 cases (30%) were in pain scale 5 respectively after treatment.

Statistical analysis

Before treatment Min, Max, and mean values (4, 7, 5.6) after treatment the above values (2, 5, 3.8) are reduced and the p-value is **0.004**. Since the p-value is less than 0.05 it is statistically significant, that shows the VASAMBU PATRU is acting against the OSTEOARTHRITIS – KNEE.

DISCUSSION

Patru is one of the 32 external therapies practised in ancient Siddha treatment and it is placed second in the series of external therapies. Patru, a semisolid paste is obtained from plant extracts or by grinding crude raw drugs and applied as a thick paste over the affected region. Before initiating the study, the protocol along with informed consent was designed and submitted to INSTITUTIONAL ETHICAL COMMITTEE and after approval from members of the IEC, the trial was registered in the CLINICAL TRIAL REGISTRY OF INDIA. After the arrival of CTRI number CTRI/2023/08/056965, the trial was started. The trial therapy of Vasambu Patru has been evaluated by administering it to 10 patients externally for 15 days. Vasambu Patru has been chosen for the trial under the rationale that the literature review of the Siddha classical book recommends the use of a semi-solid poultice of powdered vasambu and kaachukatti for treating joint pain. The anti-inflammatory and analgesic actions of Vasambu and kaachukatti have been proved in previous studies and the review of Siddha literature suggests the same. Hence, based on the above-mentioned references and the research works it justifies the beneficial treatment of Azhal Keel Vaayu (OA-knee). The following data were collected during enrolment:

Distribution of cases by gender

Among 10 patients of Azhal keel Vaayu, 7 patients (70%) were females and 3 cases (30%) were males (Table 1.1). According to the World Health Organization (WHO), 9.6% of men and 18% of women aged over 60 years have symptomatic osteoarthritis worldwide^[1]. This study shows women are more prone to OA than men.

Distribution of cases by age

Among 10 patients, 30% of participants were distributed in 41-50, 40% were in 51-60%, 20% were in the 61-70 age group, while only 10% fell within the 31-40 age group (Figure 1.1). The global prevalence of knee OA was 16.0% in individuals aged 15 and over and 22.9% in individuals aged 40 and over. Similarly, there are around 654.1 million individuals i.e. 40 years and above, with knee OA in 2020 worldwide^[2]. This study shows that above 40-year-olds are more prone to OA-knee.

Distribution of cases by occupation

Out of 10 patients, 40% of the participants were Home Makers, 30% were Teachers and 30% were private employees i.e. conductors, security, and hotel servants. Occupation takes a major part of our day. One of the most common occupational risk factors for OA knee is a heavy physical workload. Other risk factors like frequent exposure to

Adlin Reshma et al.,

oppressive biomechanical stresses such as bending of the knee joint, kneeling or squatting, prolonged standing greater than 2hrs/day, regular stair climbing, heavy weight lifting greater than 10 kg, jumping, and vibration. Occupation is one of the major risk factors for OA^[3]. This study reveals the significant occupation-related risk factor for OA (Figure 1.2).

Distribution of cases by BMI

In this study, 30% of the participants had normal BMI 30% were Over Weight and the remaining 40% were Obese. Coggon et al reported that subjects with a Body Mass Index of more than 30kg/m² were 6.8 times more likely to develop knee Osteoarthritis than the subjects who were under normal weight. The impact of body mass index (BMI) on the incidence of knee OA was assessed in a recent meta-analysis, including both cohort and case-control studies by Jiang et al. Obesity is the highest alterable risk factor for OA. Obesity contributes to the incidence and progression of OA, with the strongest relationship being at the knee. Weight reduction improves both symptoms of Osteoarthritis and can reduce disease progression.^[6] The current evidence points to obesity-related Osteoarthritis as both their problem of excessive weight loading in the knee joint and hormonal and cytokine dysregulation (Figure 1.3).

Changes in visual pain analogue scale

From the VPA Scale,

1. 4 cases (40%) changed from moderate to mild level
2. 1 case (10%) changed from severe to moderate level
3. 5 cases remained at a moderate level.

According to Figures 1.4 & 1.5, Before treatment Min, Max, and mean values (4, 7, 5.6) after treatment the above values (2, 5, 3.8) are reduced and the p-value is **0.004**. Since the p-value is less than 0.05 it is statistically significant, which shows the VASAMBU PATRU is acting against the OSTEOARTHRITIS – KNEE.

Statistical analysis

The p-value <0.05 for the Visual Pain Analog Scale, thus it is statistically significant. All collected data were entered into MS EXCEL SOFTWARE using different columns as variables and rows as patients, SPSS software was used to perform the statistical analysis. A probability value of <0.05 was considered as indicated as statistically significant.

From this study, it is evident that the trial external therapy showed good results in treating AZHAL KEEL VAAAYU (OSTEOARTHRITIS – KNEE) by reducing pain significantly. Based on changes in the Visual Analogue Scale, out of 10 cases, 4 cases (40%) changed from moderate to mild level, 1 case (10%) changed from severe to moderate level, and 5 cases remained at a moderate level. The clinical study's findings show that the trial therapy was clinically beneficial for treating osteoarthritis in the knee. This study's objective was to present baseline data that demonstrate Vasambu Patru's clinical efficacy in treating OA knees with external treatment. Notable amelioration was observed in a limited cohort of individuals who received Vasambu Patru. There was no adverse reaction noted while receiving therapy. Therefore, I conclude that this study of the clinical evaluation of Vasambu patru (semi-solid poultice) in the treatment of osteoarthritis – Knee has a major role in symptom reduction for patients with Azhal Keel Vaayu. So, the study may be undertaken with the same therapy in a large number of cases and it may throw new light on the treatment of Azhal Keel Vaayu.

ABSTRACT

The present study evaluates the antimicrobial activity of various soaps against the pathogens found on the exterior of skin surface like *Pseudomonas aeruginosa*, *Staphylococcus aureus* and *Escherichia coli* using Agar Well Diffusion Method. Every human skin and mucous membranes are habitat to a variety of microbiota from the instant moment of birth until death. A vast variety of microflora is found on human skin that gives birth to skin infections, also enter our internal organs and damage them under unfavorable conditions. In the context of this antimicrobial activity of different soaps was studied on such micro-organisms that can prevent these infections. While determining the results it revealed that all soaps contain antimicrobial activity and kill microbes to large extent. The acquired results demonstrated that the test organisms were sensitive to soap samples at various concentrations. All soaps showed better and similar Zone of Inhibition against these pathogens. Highest efficiency to kill microbes was shown by Melashine and Dettol for *P. aeruginosa* whereas Twinkle followed by Melashine were most effective against both *Staphylococcus aureus* and *Escherichia coli*.

Keywords: Antibacterial activity, Antiseptic and herbal soaps, Skin flora pathogens, S. Aureus, E. Coli, P. Aeruginosa.

Shrikant Yadav et al.,

INTRODUCTION

The skin of every individual has a normal micro flora, or surface microorganisms. (Prescott & Associates, 2008).(1) The adult human body is made up of 10¹⁴ cells, of which 10% make up the body proper and 90% are made up of microflora.(2) The protective layer of body (skin) and mucous membranes are residence to a variety of microbiota from the instant moment of birth until death. Different species occupy different bodily sites at different times over an individual's life, indicating that the normal microbial flora is very stable. The steady populations of bacteria that make up the typical adult flora are frequently the result of some organized process or succession, in which the normal flora in humans normally develops after birth.(3) The skin, being the most exposed area of the body, is susceptible to foreign particles that can cause a variety of skin-related illnesses.(4) Skin infections are caused by gram negative and gram positive bacteria that are placed on the skin layer by the environment. Example of these bacteria includes *Staphylococcus aureus*, *B. subtilis*, *P.aeruginosa* and *E coli*. (5) Therefore, to protect the skin from a variety of ailments, it is necessary to maintain appropriate hygiene and cleanliness for the body's most exposed areas and to stop microorganisms from spreading throughout the environment.(4) The first line of protection against germs, pathogens that can prompt flu, colds, skin infections, even deadly communicable diseases is cleaning your hands and body, especially using soaps(6) Proper washing of hands with soap and water has been the "gold standard" for abolishing the majority of resident and transient bacteria from the hands (Foddai et al., 2016). (7)Among the substances with antimicrobial activity against bacteria, particularly those on the skin are soaps. Many authors have given alternative definitions of soap. Some have defined it as cleansing agent that is created in the form of granules, bars, flakes, or liquid by reacting salts of potassium or sodium with different fatty acids that are naturally occurring (salt of non-volatile fatty acids).(8) Soaps are made up of oils, fats (vegetable or animal origin), and salts. Soaps are typically salts generated by saponification of alkaline material with free fatty acids in fat and oil. (9)Even though the main ingredients of soap include fat, oil and detergents (added to boost the antibacterial properties of soap).(10) These soap qualities include protecting against skin conditions (such as rashes, eczema, and scabies), leaving the skin feeling soft and rich in lather management of skin infections (like ring worm) safeguarding the skin's smoothness and even tone.(11)Good components that may destroy bacteria without harming bodily tissues should be present in the soap.(12) As antimicrobial compounds are included in antiseptic soaps, they help stop the spread of infection by these bacteria. However, excessive soap use can cause antimicrobial resistance and increase person's susceptibility to allergies as well as skin rashes.(13)

MATERIALS AND METHODS

Study Design and Settings

This study was conducted from April to June 2024 at School of Life Sciences Microbiology Lab Starex University Gurugram.

Sample Collection

Different types of soap samples, which people often utilize, was purchased from standard pharmaceutical shops from Manesar (Gurugram).

Every soap's contents and expiration date was recorded. The list of soap includes Margo, Twinkle, Dettol, Savlon , Medimix, Melashine.

Test Organism

The bacterial cultures employed in this investigation include, *Staphylococcus aureus* (ATCC 25923) [14], *Pseudomonas aeruginosa* (ATCC 27853)[15] and *Escherichia coli* (ATCC 25922). [16]

Preparation and dilution of soap sample extract

A sterilized, sharp knife was used to remove soap off one side. 100mg, 250mg and 500mg of every sample of soap was measured and dissolved in 1ml of sterile distilled water individually in different sterile test tubes.

Shrikant Yadav *et al.*,**Media preparation**

The media and peptone was obtained in the commercially organized powered (dehydrated) form and was arranged according to the manufacturer's information. Specified amount of each powered media was reconstituted in individual quantity of distilled water in a conical flask and mixed appropriately by shaking. The flask was then stopped and sterilized by autoclaving at 121°C and 15 psi for 15 minutes. After cooling to 45°C in a water bath, the autoclaved medium was dispensed into Petri dishes that had already been sterilized and left to harden. While the reconstituted peptone water was poured into test tubes.

Inoculum Preparation

After cooling, the ATCC strain of *S.aureus*, *P.aeruginosa* and *E.coli* was inoculated in peptone and incubated at 37°C for 24 hours. Sample was taken from incubated peptone and lawn sample on prepared MHA plates with the help of swab stick. An overnight culture in peptone was kept set for antimicrobial activity. The Agar well diffusion method was used to test the antibacterial activity of soaps.

Agar well Diffusion method

The experiment was conducted using the agar well diffusion technique. The prepared molten agar was permitted to solidify for 20 minutes, 6mm cup borers was used to bore five (5) holes in the media plates at specific intervals, and samples of soap in various quantities was added and labeled after being inserted into the drilled holes. The plate was left to stand at room temperature for a minimum of half an hour in order to ensure adequate diffusion, following that, each soaps was incubated for 24 hours at 37°C. After incubation, the consequent diameter of the zone of inhibition was determined and reported.

RESULTS AND DISCUSSIONS

The study's findings showed that the majority of soaps exhibit antimicrobial action, although to differing degrees, as demonstrated by the isolate's growth pattern being inhibited. Every antimicrobial soap provides a distinct zone of inhibition at a different dose for a particular bacterium, according to a comparison of the soaps' efficiency using the well agar diffusion technique. Microorganisms found in normal human skin can be classified as resident and transitory flora.[17] Microbes differ in their nutritional supplies and stage of susceptibility to antimicrobial agents. The impact of soap on the skin's microflora remains relatively underexplored. No soap contains a universally suitable ingredient that meets the needs of all skin types. Individual skin responses vary from soap to soap since the skin is the primary location where soap exposure is highlighted in this case. [18] In most cases, soaps are used to clean and remove dust and bacteria from the skin's surface. The selection of soap varies from people to people but it should not have an effect on the sensitive skin and it should be helpful against infection causing microbes present on skin.[19]

The current study was conducted in order to ascertain the antibacterial effectiveness of soaps such as Savlon, dettol, Margo, Medimix, Twinkle, Melashine against skin microfloras important microorganisms which is *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *E.Coli*. Antimicrobial activities of all the six soaps against selected bacterial strains (*S.aureus*, *P.aeruginosa* and *E.coli*) was recorded in the form of inhibition zone and measured in millimeters. The antibacterial activity of various soaps was tested against *Staphylococcus aureus*, *Pseudomonas aeruginosa*, and *Escherichia coli* using the zone of inhibition method. The results indicated that all soaps showed increased antibacterial activity with higher concentrations. Among the soaps, Melashine demonstrated the highest efficacy across all three bacterial species, with the largest zone of inhibition recorded at 500 mg concentration. For *Staphylococcus aureus*, Melashine achieved a zone of 21 mm, followed by Twinkle at 24 mm, while Dettol showed the least activity with a 12 mm zone. Against *Pseudomonas aeruginosa*, Melashine again had the highest zone of 20 mm at 500 mg, with Dettol close behind at 18 mm, and Margo being the least effective. For *Escherichia coli*, the inhibition zones were generally smaller, with Melashine showing the highest activity of 18 mm at 100 mg, while other soaps like Margo and Medimix exhibited minimal activity with zones around 10-11 mm. Across all tests, the positive control antibiotics, including Linezolid, Ciprofloxacin, and Azithromycin, showed significantly larger zones of inhibition compared to the soaps, confirming their superior antibacterial effectiveness. Negative controls showed no inhibition, validating the results. These

**Shrikant Yadav et al.,**

findings highlight the variability in soap efficacy against different bacteria and the critical role of antibiotics in combating bacterial infections. When we compare our study with G.B.Patel Science and S.T.S.K.V.S Commerce College, the results revealed that among the antiseptic soaps highest efficacy was performed by Dettol and Lifebuoy Plus soaps against Gram positive isolates but in Gram negative isolates Dettol and Savlon had maximum bactericidal activity.(19) One more study from Mehta Science College showed that comparative study between non medicated and medicated soaps, it was observed that medicated soaps showed the highest inhibition against *Staphylococcus aureus* in comparison to non medicated soaps.(21) The indicated soap in this study contains some active antimicrobial agents like chloroxylenol. These substances work by denaturing everything, which interferes with microbial metabolism and disrupts cell activity. These based on a number of factors such as the contact time, the inherent properties of the organisms, concentration of individual formulation and skin sensitivity.[19] The experimental data findings show that the majority of the antiseptic soap has antimicrobial activity, thought to varying degrees as showed by the inhibition of growth outline of the isolates. This study clearly demonstrated that the Gram-positive bacterium *Staphylococcus aureus* was inhibited by all the soaps tested, in contrast to the Gram-negative bacteria. According to the work, some resistance developed once the agent was applied repeatedly. Therefore, washing hands before eating, after a patient examination, and before surgery is standard practice to eliminate some potentially hazardous temporary flora and decrease a number of resident flora that could lead to infection chances.(20)

CONCLUSION

The most important aim of this study was to determine the antimicrobial activity of 6 various soaps Dettol, Savlon, Margo, Medimix, Twinkle, Melashine. The result shows that all soaps give different zones of inhibition at different concentrations. Soaps are common cleaning products used to clean and eliminate germs. Soaps break down the proteins and membranes of microorganisms. The zone of inhibition varied significantly across all soap types used in the study. Hence Dettol followed by savlon among other soaps commonly utilized to prevent skin diseases and transmission of skin pathogens when utilized in hand washing. However, prolonged utilize of these soaps could potentially result in microbial resistance and skin allergies. Active germicidal chemicals are present in antiseptic and medicinal soaps; it eliminates infections; however extended use should be avoided. As herbal soaps like Margo, Medimix and other soap like Twinkle and Melashine revealed similar or more antibacterial properties similar to those of medicated or antiseptic soaps, some extra elements make them more effective and better in our day-to-day lives/component which is beneficial for our skin in other aspects like gentleness, softness and glowing skin. The soap is an everyday need, however, it should contain effective active ingredients or plant-derived extracts it should be capable of killing bacteria without causing harm to body tissues, even with regular use.

ABSTRACT

Urinary Tract Infection (UTI) in general can be termed as the symptomatic presence of microbial pathogens in the urinary tract. It is found to be one of the most common and frequent bacterial infections. These infections can vary in severity from mild cystitis or inflammation of the bladder, to severe cases of uroseptic shock. It is found in all age groups and sexes. The incidence of UTI is more common in female than male. UTI can be classified into Complicated UTI and Uncomplicated UTI, and depending upon the cause it can also be distinguished into Community acquired and Hospital acquired. Few examples of common causative agent are *Escherichia coli*, *Klebsiella pneumoniae*, *Staphylococcus aureus*, *Enterobacter spp*, *Proteus mirabilis*, *Enterococcus faecalis* and some *Candida spp*. The economic burden of these diseases could rise significantly due to high recurrence rates and rising antibiotic resistance in Uropathogens. Based on specific risk factors, a focused history is used to diagnose UTI and relevant investigations are conducted. UTI is a serious health problem if untreated, early diagnosis and treatment with antibiotic is mainly recommended. This study aims to estimate the prevalence rate of UTI among adults of western UP between the age group of 20-70.

Keywords: Symptomatic, Uropathogens, Complicated UTI, Uncomplicated UTI

INTRODUCTION

Urinary Tract Infection (UTI) is an infection of the urinary system. It is a bacterial infection which affects different parts of the urinary tract (**Demelie *et al.*, 2012**). The urinary tract consists of the kidneys, ureters, urinary bladder and urethra. Bacterial invasion of the urinary system is typically the source of infection. It is diagnosed when there is an overgrowth of bacteria in the urinary tract (**Czajkowski *et al.*, 2021**). UTI has the potential to induce sepsis, a condition that poses a risk to life; however, the majority of infections exhibit less severity. It is also found to be one of the most common bacterial infections and affects around 150 million people worldwide each year. Most people experience UTI at least once in their lifetime (**Mlugu *et al.*, 2023**). UTI affects both male and female, but females are more commonly affected (**Flores-Mireles *et al.*, 2015**). Women are more prone to UTI because of their anatomy as they have shorter urethral length and due to the presence of vaginal cavity (**Tan *et al.*, 2016**). UTI can be classified mainly into Lower or Upper UTI or Complicated or Uncomplicated UTI (**Sheerin *et al.*, 2011**). Complicated UTI (CUTI) can be defined as those associated with urinary tract abnormalities that increase susceptibility to infection, whereas, Uncomplicated UTI (UUTI) are those which affects healthy patients in the absence of neurological abnormalities (**Klein *et al.*, 2020**). It can also occur in two forms such as symptomatic and asymptomatic infection. Symptomatic bacteriuria are those which shows symptoms, whereas, Asymptomatic bacteriuria are those which occurs without showing symptoms. These infections arise due to the development and expansion of microorganisms within the urinary tract (**Mandokhail *et al.*, 2015**). Symptomatic UTI's are further classified into upper and lower infections (cystitis) and (pyelonephritis) (**Hooton *et al.*, 2012**). Upper UTI impact the kidneys and ureters, as seen in the case of pyelonephritis, whereas lower UTI's affect the urethra and bladder (**Kaur *et al.*, 2021**). Numerous risk factors are correlated with cystitis, such as the female gender, sexual activity, diabetes, vaginal infections, a history of UTI, obesity and genetic predisposition (**Foxman *et al.*, 2014**). UTI can also be community acquired or hospital acquired according to the source of infection. Urinary Tract Infections (UTI's) can be attributed to a variety of microorganisms like Gram-positive and Gram-negative bacteria as well as certain fungi. Uropathogenic *Escherichia coli* (UPEC) stand out as the predominant causative agent for both uncomplicated and complicated UTI's (**Kline *et al.*, 2011**). The other common causative agents are *Klebsiella pneumoniae*, *Staphylococcus aureus*, *Staphylococcus saprophyticus*, *Enterococcus faecalis*, group B *Streptococcus*, *Proteus mirabilis*, *Pseudomonas aeruginosa*, *Staphylococcus aureus* and *Candida species*. (**Levison *et al.*, 2013**)

MATERIALS AND METHODS

This study was carried out at the Department of Paramedical Sciences, Subharti Medical College, Swami Vivekanand Subharti University, in association with Central Laboratory of Chhatrapati Shivaji Subharti Hospital, Meerut.

Sample Collection and processing

Antibiotic Susceptibility Testing (AST)

Antibiotic Susceptibility Testing of all the organisms were done by VITEK-2

Inoculums preparation

- Two scratch-free VITEK unsensitized (polystyrene) tubes were taken. The first tube is usually marked for ID and the second tube is for AST.
- At least 3 ml of sterile saline must be transferred into the unsensitized tube using a saline dispenser aseptically.
- Using sterile cotton swabs or sterile loops, a homogenous organism suspension was prepared by transferring several isolated colonies from the plates to the saline tube. The bacterial strain was rubbed to the internal surface of tube.
- Swab stick moistened with saline in tube was again rubbed to make a smooth paste. The bacterial suspension was uniformly mixed with saline in tube.
- Mix well using pipette with only sterile tips.
- The suspension was adjusted to the McFarland recommended for GP (0.50-0.63 McFarland) ID and AST.

Angela Laldinpuii Renthlei *et al.*,

RESULTS AND DISCUSSION

A total of 231 urine samples were collected from the clinically suspected patients of UTI. Data of all the patients were taken during the study period of six months. Out of the total urine samples collected, clinically significant pathogens were grown in 87 samples comprising 37.67% of overall culture positivity among urine samples. The distributions of positive and negative specimen are shown in the table and figure given below.

Distribution of Causative organisms

Out of total 87 urine culture positive samples, bacteria were isolated from 63(72%) and Fungi were isolated from 24(28%). The numbers of bacterial and fungal growth are shown in the table given below.

Distribution of Gram-Positive, Gram-negative and Candida species

Out of total 87 isolates grown on culture from urine specimen, most of the isolates were bacteria, out of which Gram positive bacteria (GPB) isolates were found to be 16 (18%) ,Gram negative bacteria (GNB) were found to be 47 (54%) and *Candida* species were found to be 24 (28%). The distribution of GPB, GNB and *Candida* species are shown in the table and figure given below.

Distribution of bacteria on the basis of positive samples

Out of total 87 isolates grown on culture from urine specimen, 63 isolates were found to be bacteria. Gram-positive bacteria were found to be 16 in number and Gram-negative were found to be 47 in number. *Enterococcus faecium* were found in 7 isolates, *Acinetobacter baumannii* in 4 isolates, *Enterococcus avium* in 1 isolate, *Escherichia coli* in 23 isolates, *Enterococcus faecalis* in 4 isolates, , *Enterococcus gallinarum* in 3 isolates, *Klebsiella pneumoniae* in 13 isolates, *Pseudomonas aeruginosa* in 5 isolates, *Myroides* in 1 isolate, *Proteus mirabilis* in 1 isolate and *Staphylococcus hominis* in 1 isolate. *E.coli* was found to be the commonest causative agent of UTI.

Distribution on the basis of gender

Out of 87 positive sample, female with positive samples were found to be 47(54%) in number while male were found to be 40 (46%) in number. Female were found to be more affected by UTI than male. The distribution is shown in the table and figure given below

Age-wise distribution of UTI patients

Maximum numbers of isolates were seen in age groups of 40-50 years, followed by 50-60 years. Minimum numbers of isolates were seen in age group of 20-30 years, as shown in the table and figure given below.

Antibiotic Susceptibility Pattern of bacterial isolates

Out of the 63 positive bacteria samples, it was found that the pathogens were mostly sensitive to Nitrofurantoin and mostly resistant to Ciprofloxacin as shown in the table given below.

Anti-fungal susceptibility pattern of *Candida* isolates

Out of the 24 positive samples, it was found that *Candida* species were mostly resistant to Fluconazole, and intermediate to Fluconazole. They were mostly sensitive to VORI, Amp-B, and FLC as shown in the table given below. Urinary tract infection is one of the commonest infections of the urinary tract caused by microorganisms. It affects people of all age and all sexes around the world. It is one of the leading microbial infections in the world.

A total of 231 urine culture samples received during the study period were analyzed. The urine culture positivity rate in our study was found to be among 87 cases i.e 37.67%. A study conducted by **Odoki *et al* 2019** also shows similar positivity rate of 32.2%, a study conducted by **Kabugo *et al* 2016** also shows similar positivity rate of 38%. Whereas, a study conducted by **Tibyangye *et al* 2015** shows significantly lower rate 22.33%. There may be variation in urine culture positivity rate due to many factors such as disruption of micro flora of patients or sample contamination.

Angela Laldinpuii Renthlei *et al.*,

This present study shows that Gram-negative bacteria made up 54% of the isolates. Similar study with a higher positivity rate of 85.20% gram-negative bacteria was shown by **Serretielloet al 2019**. Our present study shows *E.coli* as the most prevalent bacterial uropathogen with 23 (36%) out of 63 positive samples. A study conducted by **Rajendran et al 2017** also shows *E.coli* as the most prevalent with a similar positivity rate of 35.5%. In species wise distribution of bacterial isolates our study showed that *E.coli* (36%) was the most frequent isolate followed by *Klebsiella pneumoniae* (21%), *Enterococcus faecium* (11%), *Pseudomonas aeruginosa* (8%), *Acinetobacter baumannii* (6%), *Enterococcus faecalis* (6%), *Enterococcus gallinarum* (5%), *Proteus mirabilis* (2%), *Myroides spp* (2%), *Staphylococcus hominis* (2%) and *Enterococcus avium* (1%). Slightly similar results has been shown in a study done by **Mancuso et al 2023** where *E.coli* was the most common bacterial isolate followed by *Klebsiella pneumoniae*, *Enterococcus spp.*, *Pseudomonas aeruginosa*, *Proteus mirabilis* and *Staphylococcus spp.* A study done by **Badiger et al** also shows similar findings where *E.coli* was the most frequent isolate followed by *Klebsiella pneumoniae* and *Enterococcus spp.* This study shows that *Candida spp.* is one of the most common fungi which can cause UTI. In the present study it was shown that 24 out of 87 positive isolates were *Candida spp.* A study done by **Komala et al 2013** also shows that *Candida spp.* are the most common fungal isolates. In the present study, women (54%) were found to be more prone to UTI than men (46%), which is similar to a study conducted by **Hooton et al 2012**. A study conducted by **Pardeshi et al 2018** also shows that growth in women 66.78% were found to be more than male 33.22%. A study done by **Mlugu et al 2023** also found a higher prevalence rate of UTI in women than men ($p=0.05$). UTI usually occurs more in female due to their anatomy as they have shorter urethra which is close to the perineum, than men.

In this current study it was shown that Urinary Tract Infection positivity rate was seen mostly between the ages of 40-60 years. According to recent studies done by **Rodriguez-Manas et al 2020** the elderly have an increased risk of contracting UTI in comparison to younger people. The resistance pattern of bacteria and fungi is ever changing and varies in different geographical areas. In this study it was found that bacterial isolates were mostly sensitive to Nitrofurantoin, **Badiger et al 2021** study also shows that bacterial isolates were sensitive to Nitrofurantoin. On the contrary a study done by **Mlugu et al 2023** displays moderate resistance rate of Nitrofurantoin (37%). According to study done by **Johansen et al 2011** it shows much higher resistance rate of Nitrofurantoin. The bacterial isolates in this study shows high resistance rate of 78% for Ciprofloxacin, whereas a study done by **Mlugu et al 2023** shows moderate resistance rate of 37%. A study done in Tanzania shows that Ciprofloxacin was the drug of choice for UTI. Regarding antifungal susceptibility our study shows that most of the isolates showed higher level of sensitivity towards Voriconazole (91%), Amphotericin-B (91%) and Flucytosine (91%). Similar study by **Yashavanth et al 2013** shows that *Candida* isolated showed sensitivity towards Amphotericin-B (91%), Flucytosine (82%). Comparatively higher resistance in our study was seen in Fluconazole (12%). **Fan et al 2023** study also showed a high resistance rate of 16.5% for Fluconazole.

CONCLUSION

A total of 231 urine samples were received in the Microbiology Laboratory, the culture positivity rate was 37.67%. Out of 231 urine samples, bacteria were isolated from 63 urine samples and fungi from 24 urine samples. Out of 87 positive urine samples, Gram-positive bacteria were found to be 16; Gram-negative bacteria were found to be 47 and *Candida* species 24 in number. There was a female predominance, with 47 (54%) females and 40 (46%) males. Most of the isolates were found from people between the age of 40-60 years. Gram-negative bacteria were found to be the most pathogenic. *Escherichia coli* were found to be the main causative agents of UTI. Urinary Tract infection is one of the main leading microbial infections affecting people of all age groups and genders all around the world. In this study it was found that Gram-negative bacteria were the most common bacteria causing UTI out of which *Escherichia coli* was found to be the most common and important causative agent of UTI and *Candida* species were found to be one of the most common fungal growth causing UTI. Women were found to be more prone and affected by UTI than men. The infection mostly occurs in older people in comparison to younger people. The AST patterns of bacteria were found to be most resistant to Ciprofloxacin and most sensitive to Nitrofurantoin. The AST patterns of fungi were found to be most resistant to Fluconazole and most sensitive to Voriconazole, Amphotericin-B and Flucytosine.

Angela Laldinpuui Renthlei et al.,

The increasing prevalence of UTI in India emphasizes the need for prior knowledge of causative agents of UTI and their antibiotic and anti-fungal susceptibility patterns as it is expected to improve the development of treatment, management and outcome. Antibiotics are mainly given for the treatment, such as Nitrofurantoin, Tetracycline, Fosfomycin etc. Although antibiotics are given for treatment some pathogens can become resistant to various antibiotics and can prevent the activity of the antibiotics. Recent studies shows that consumption of cranberry can help get rid of burning sensation or vaginitis caused by UTI and it could be one of the major important candidates to treat UTI. Preventive measures have to be taken to reduce the various risk factors. It can be mainly prevented by following a clean and hygienic lifestyle like drinking plenty amount of water, avoiding sexual intercourse with different multiple partners. If infected with UTI early treatment should be given to prevent further serious infections.

ABSTRACT

India is rich medicinal plant heritage is being documented through an ethnobotanical study in Paruthivillai, Kanyakumari district, TamilNadu. Ethnobotanical data were gathered via interviews and semi-structured questionnaires from elderly traditional medicinal practitioners and local faith healers. A total of 62 plant species, representing 26 families, were documented, including 29 herbaceous species, 13 shrubs, 12 trees, and 8 climbing species. Plant species of Euphorbiaceae, Solanaceae, Fabaceae (6) is predominantly used, followed by Amaranthaceae (4), Malvaceae, Apocynaceae (3), Acanthaceae, Cucurbitaceae (2), Aeraceae, Rutaceae, Ashphodelaceae, Annonaceae, Meliaceae, Basellaceae (1) each etc., The traditional herbal healers quite frequently use leaves (36) followed by root (3), whole plant (8), fruit (10), flower (5), seed, and stem (2). The most common methods of drug preparation and application are the paste form (19), juice (25), decoction (11), powder (6), and gel (1). The diseases include skin diseases (9), asthma (7), fever, diabetes, dysentery (6), cough (4), jaundice, diarrhea (3), hair diseases, cold, anemia, chicken pox, rheumatism, (2), piles, kidney stone, scabies, arthritic, insect bite, hypertension, liver diseases, smallpox, ulcer (1) each. The indigenous community prefers these plants as home remedies against fever, rheumatism, headache, constipation, etc., simultaneously, effective measures should be taken to protect and preserve these significant plant species for future generations. I conclude traditional knowledge of medicinal plants is a valuable resource that deserves preservation and integration into modern healthcare.

Keywords: Traditional medicine, Paruthivilai, Medicinal uses.

INTRODUCTION

The plant parts used for the arrangement from asserting drug. Sum plants were found again used for those arrangements about cures (Kumar et al. 2019). Individuals living in emerging nations depend actually on customary medication for essential medical services (Singh 2002). India possesses an extraordinary wealth of plant resources, with a vast and varied flora that is among the most extensive in the world. It is assessed that north of 18,000 types of higher plants happen in various phytogeographical/biological locales of the country, in which around 33% are restoratively and monetarily significant species are recorded (Revathi et al. 2013). Plant drugs are generally utilized by the human populace either as people cures or straightforwardly from the systematized restorative frameworks for current homegrown arrangements. Native home-grown treatment is a piece of the way of life and a dominating method of treatment in most non-industrial nations. The traditional herbal remedies in question have proven to be remarkably effective and are both socially accepted and economically feasible, making them a valuable option. 33% of present-day drug arrangements have plant beginnings (Padal et al. 2021). Restorative plants are presently more engaged than at any other time since they have endless advantages to society for sure to humanity, particularly in the line of medication (Hussain et al. 2011). There is a pressing need to document these plant species before this valuable knowledge is lost forever, succumbing to the risk of extinction and cultural obsolescence. Furthermore, this study contributes to the conservation of these medicinal plants and provides foundational data for future phytochemical and pharmacological investigations (Gritto et al. 2015). Ethnobotany is drawing in experts from assorted scholastic foundations and interests. Ethnobotany might assume a significant part in getting manageable supplies, and it can likewise be useful in the quest for new restorative recipes that could be utilized to treat sicknesses for which no standard treatment has been accounted. Phytochemical research and ethnobotanical studies can unlock the medicinal potential of plant species by harnessing their chemical diversity (Kumar et al. 2022). In regards to medicinal utilization from claiming plant species, it varies around those communities, while a couple of plant needs the same use (Sukumaran et al. 2014). To document the indigenous uses of plants in healthcare among the local people of Paruthivillai in the Kanyakumari district. To document the botanical name, families, local names, habits, useful parts, diseases, and modes of use for each medicinal plant species.

STUDY AREA

Paruthivillai village located Under Nagercoil town has been chosen as the study area

MATERIALS AND METHODS

During the survey, a through approach was taken to ensure that no location was overlooked, as every area was considered potentially valuable for collecting plant species. Plant specimen were collected from their natural habitats during various seasons and at different reproductive stages. As part of the floristic documentation of the paruthivillai region, interviews were conducted with local people, traditional medicine men, and experts to gather information on the utilization value of plant species (Jain 1991). During each field trip and survey, efforts were made to collect both wild and cultivated plant species in their flowering, fruiting, and mature stages. Immediately after collection, specimens were numbered, labeled, and stored in polythene bags. Eac specimen was then identified and critically examined with the aid of written floras to ensure accurate classification (Gamble and Fisher, 1915-1935).

RESULT AND DISCUSSION

A total of 62 plant species from 26 families were indetified in the present study. Of these 29 were herbs, 13 were shrubs, 12 were trees and 8 were climbers. Plant species of Euphorbiaceae, Solanaceae, and Fabaceae (6) are predominantly used, followed by Amaranthaceae (4), Malvaceae, Apocynaceae (3), Acanthaceae, Cucurbitaceae (2), Asteraceae, Rutaceae, Ashphodelaceae, Annonaceae, Meliaceae, Basellaceae (1) each, etc., Traditional herbal healers quite frequently use leaves (39) followed by root (6), whole plant (5), fruit (12), flower (6), seed (2), stem (3), and bark

**Santhiya and Mahesh**

(1). The most common methods of drug preparation and application are the paste form (19), juice (25), decoction (10), powder (7), and gel (1). The diseases include skin diseases (9), asthma (7), fever, diabetes, dysentery (6), cough (4), jaundice, diarrhea (3), hair diseases, cold, anemia, chicken pox, rheumatism, (2), piles, kidney stone, scabies, arthritic, insect bite, hypertension, liver diseases, smallpox, ulcer (1) each. The plant species in question possess medicinal properties capable of treating over 22 ailments. Interestingly, the number of plant species used to treat various across different regions. Moreover, it has been observed that a single plant species can be used to treat a single condition. This discovery contradicts existing research in the field. A total of 62 plant species have been identified in Kanyakumari district (Santhiya et al. 2021); 59 species (Kumaresubitha and Kolar, 2021); 44 plant species (Sheeja and Lohidas, 2020); 30 plants (Kingston et al. 2009); 25 plant species (Kingston et al. 2007); A total of 82 plant species (Loganathan and Selvam, 2018); A total of 35 angiosperm species, (Kannan and Jeeva, 2008); 55 plantspecies (Jhoncy et al. 2011); 54 plantspecies (Kensa et al. 2018); 106 plant species (Divya et al. 2013); 81 plant species (Vizhi and Lohidas, 2020); 48 medicinal plants (Pradeesh et al. 2020); 89 plant species (Jeeva and Femila, 2012); 138 plant species (Sukumaran et al. 2020); 29 plant species (Divya and Sukesh, 2023); 70 plantspecies (Prakash et al. 2024) are reported.

CONCLUSION

This study examines the medicinal value of plants in Paruthivillai village, Nagercoil Town Municipality. Taxonomically a total of 62 plant species belonging to 26 families were recorded. Of these 29 were herbs, 13 were shrubs, 12 were trees and 8 were climbers. Plant species of Euphorbiaceae, Solanaceae, Fabaceae (6) is predominantly used, followed by Amaranthaceae (4), Malvaceae, Apocynaceae (3), Acanthaceae, Cucurbitaceae (2), Aeraceae, Rutaceae, Ashphodelaceae, Annonaceae, Meliaceae, Basellaceae (1) each etc., The traditional herbal healers quite frequently use leaves (36) followed by root (3), whole plant (8), fruit (10), flower (5), seed, and stem (2). The most common methods of drug preparation and application are the paste form (19), juice (25), decoction (11), powder (6), and gel (1). The diseases include skin diseases (9), asthma (7), fever, diabetes, dysentery (6), cough (4), jaundice, diarrhea (3), hair diseases, cold, anemia, chicken pox, rheumatism, (2), piles, kidney stone, scabies, arthritic, insect bite, hypertension, liver diseases, smallpox, ulcer (1) each. Traditional knowledge of medicinal plants is a valuable treasure trove of natural remedies that have been passed down through generations, offering a sustainable and holistic approach to healthcare that warrants preservation, promotion, and integration into modern medicine to ensure a healthier future for all. Feel free to modify it to fit your specific needs or let me know if you'd like me to suggest any changes.

AGKNOWLEGEMENT

We thank the stipend Department of Collegiate Education, Government of Tamil Nadu has granted by you during her studies was very much helpful to carried out her research studies.

ABSTRACT

Epilepsy, known as *Apasmara* in Ayurveda, is a chronic neurological disorder characterized by recurrent seizures. This case study explores the therapeutic potential of *PanchgavyaGhrita*, a traditional Ayurvedic formulation, described in *Charak Samhita* in the management of *Apasmara*. The *PanchgavyaGhrita*, composed of five articles derived from cow, namely *Dugdha*(milk), *Dadhi*(curd), *Ghrita*(ghee), *Mutra* (urine), and *Shakrit*(dung), is renowned for its neuroprotective and anticonvulsant properties. This study is limited to one case of epilepsy who was treated with *PanchgavyaGhrita* over specific period. A 14-year-old male patient, with a history of frequent seizures since the age of five years was evaluated clinically by *Ayurveda* and advised to use *PanchgavyaGhrita* along with diet and lifestyle modifications. This application was not oral but specifically through *Matra basti* and *Nasya* with regular monitoring for seizure frequency, duration and intensity. The patients showed high levels of clinical response in seizure reduction as well as improved cognitive and motor skills. Neuro protective effect of *PanchgavyaGhrita*, due to its special and unique content seems to protect neuronal membrane stabilization thus improving synaptic transmission. The present case study serves an effort to showcase the immense potential of *PanchgavyaGhrita* in epilepsy along with appropriate adjuvant treatment which not only proves a new dimension for better management but keeps our traditional wisdom intact using modern therapeutic tools. More extensive studies are required to verify these results and identify the mechanisms involved.

Keywords: *Apasmara*, *PanchgavyaGhrita*, *Matra basti*, *Nasya*, Seizures.

INTRODUCTION

Smritapragamam prahurapasmaram [1] Epilepsy, known as *Apasmara* in *Ayurveda*, is a neurological disorder characterized by recurrent seizures. According to *Ayurvedic* texts, Due to mental causes such as *Chinta* (Anxiety) and *Shoka* (grief), the *Prakupita Vatadi doshas* (aggravated Vata and other doshas), residing in the *Manovahisrotas* of *Hridaya*, destroy the *Smaranshakti* (memory) and give rise to the disease of *Apasmara*. *Tamah pravesah*, *Samrambho* (Irritation), and loss of memory due to the aggravation of *doshas*. This severe disease is known as *Apasmara* [2]. *Smriti* is another name for the knowledge of past events, and the condition of its disassociation with above mentioned symptoms is termed as *Apasmara* [3]. *Apasmara* (epilepsy) is also a mental disorder, similar to *Unmada* (insanity), where no visible pathological changes are observed in the brain. From the perspective of the destruction of knowledge, it is like *Unmada*. However, in *Unmada*, there is a distortion of intellect, making it difficult for the patient to grasp the reality of what they see or hear. An insane person talks, but their speech is incoherent. Similarly, they eat but often do not have the proper sense of taste. The patient of *Apasmara* suddenly loses consciousness and cannot perform any action. In this way, there is a distortion of intellect in *Unmada*, whereas there is a complete destruction of perception (*sangya*) in *Apasmara*. The seizure in *Apasmara* is temporary and lasts for a short period, with the timing of the seizure often being predictable. This is not the case in *Unmada*, where the episodes are not temporary but rather have a more permanent nature [4]. This disease *Apasmara* occurs due to mental causes such as *Kama*, *Krodha*, *Bhaya*, *Lobha*, *Moha*, *Harsha*, *Shoka*, *Chinta*, *Udweaga*, as well as physical causes like head injury, meningitis, cerebral hemorrhage, and brain tumors. It arises when there is a deficiency of *Sattva Guna* and an increase in *Rajas* and *Tamas Gunas*. It is more commonly found in individuals with naturally weak minds. The aggravated *doshas* due to the aforementioned causes settle in the brain, sensory centers of the brain, and the nervous system, leading to the manifestation of *Apasmara* [5].

There are four types of *Apasmara* [6]

1. *Vataj*,
2. *Pittaj*,
3. *Kaphaj*,
4. *Sannipataj*

Nidanapanchaka of *Apasmara*

1. *Nidana*- The person whose *Vata* and other *doshas* wander in abnormal paths and move to the upper parts of the body, and the *doshas* have increased from their normal state, who consume *Ahita* and *Ashuchi Bhojana* (impure food); in such men, due to the increase of *Rajoguna* and *Tamoguna*, when *Sattvaguna* becomes weak and the *Hridaya* (heart) is surrounded by *Vata* and other *doshas*, and when the *Mana* becomes *Dushita* due to *Chinta*, *Kama*, *Bhaya*, *Krodha*, *Shoka*, *Udweaga*, etc., then the disease *Apasmara* occurs [7].
2. *Purvaroop*- *Hridkampa* (Palpitation of heart) and *Shunyata* (a feeling of emptiness in the heart), *Sweda pravritti* (sweating), *Chinta*, impairment of the functions of the *Mana* (mind) and *Indriyas*, and *Nidranasha* are the *Purvaroop* (prodromal symptoms) of *Apasmara* [8].
3. *Roopa*- The *Roopa* / *Lakshana* (symptoms) of four types of *Apasmara* are:
 - a. *Vataj Apasmara*- In this condition, the patient's body trembles, they clench their teeth, *Phen vaman* (dry froth comes out of their mouth), they take deep breaths, and see *Parush* (coarse), *Arun* (blackish red), and black forms.
 - b. *Pittaj Apasmara*- In this condition, yellow-colored *Phen* (froth) comes out of the patient's mouth, and the patient's body parts, face, and eyes turn yellow. When an episode occurs, the patient sees yellow or red forms. This patient experiences excessive thirst, a higher body temperature, perceives everything around them as if it is on fire.

Chitranjan Sharma and Vijay Bhagat

- c. *KaphajApasmara*- In this condition, white-colored froth comes out of the patient's mouth, and the patient's body parts, face, and eyes turn white. During an episode, the body becomes cold to the touch, the patient experiences *Hrishtaangata* (goosebumps), and a *Guruta*(sense of heaviness in body). During the episode, the patient sees everything in a white color, loses consciousness, and regains it after a long time.
- d. *SannipatajApasmara*- When the symptoms of *Vata*, *Pitta*, and *Kapha* are all observed together, are indicative to *Tridoshaja* (*Sannipataja*) type of *Apasmara*. This *Sannipataja Apasmara*is incurable. Moreover, if a man's *Dhatus* such as *Rasa*, *Rakta*, and others have become depleted, and this disease has become chronic, that *Apasmara*is also considered incurable.
- e. *Upshaya*- *Upshaya*of *Apasmararoga* depends on which *Dosha* is in domination. The diet and drugs which are opposite in nature to the predominant *Dosha*, prove to be *Upashaya*- beneficial for the cure of the disease.
- f. *Samprapti-Prakupita dosha* by *Visham Cheshta* will locate to the *Hridaya* and *Indriya* where *Rajas* and *Tamas* are already in *Prakupita*form. Once there, influenced by *Kama*, *Krodha*, *Bhaya*, *Lobha*, *Moha*, *Harsha*, *Shoka*, *Chinta*, *Udwega*etc., they suddenly attack the *Hridaya*and *Indriya* again, causing the person to lose his/her memory⁹.
- g. *Ayurved* provides multilevel treatment approach in such case that give relief in the complaints and provides the easiness in day-to-day work. In this case, *Apasmaraw*as diagnosed as the patient had symptoms like *BibhatsaCheshta*, *Smriti Naasha*, *Angamarda*, *Moha*, *Shirah Shula*, *Moorcha*. To describe the whole course of the treatment that was provided to the patient and thus get direction to treat such cases is the main aim of this Article.

Case Report

Chief Complaints

- Recurrent episodes of loss of consciousness, stiffening of the body and jerking of limbs (since 10 years)
- Sudden onset of strange smells.
- Drowsiness and Headache.
- Difficulty in recalling events before or after seizures.

Past History

- K/C/O: High grade fever in the age of 05yr.
- H/O: The patient had high fever for 3 days which caused him to have seizures.

Present Illness

- A 14-year-old male patient came in OPD with complaints of recurrent episodes of loss of consciousness, stiffening of the body and jerking of limbs, with Sudden onset of strange smells, Drowsiness and Headache. He also experienced difficulty in recalling events before or after seizures.
- In the age of 05 yr, he suffered from high grade fever for approximately 3 days and during this, he got seizures due to which he became unconscious and he regained consciousness after 12 hours., as per history given.
- From 2015, the patient undergone the treatment regimen that included AEDs (Anti-epileptic drugs), along with Multivitamins and some brain tonics.
- By 2020, despite taking this treatment continuously, he still had seizures twice a month, and an EEG test of the brain was performed in which changes in the pattern of brain waves was detected.
- Then the doctor has changed some medicines and continued the treatment.

Personal History

- Diet: Vegetarian, *Ruksha* (food have dry property/low fat diet), *Katuahara* (Spicy food), *Pishtanna* (Fine Flour-Fast Food)
- Appetite: Low
- Sleep: Disturbed due to headache
- Bowel: Irregular -occasional constipation

Chitrnanjan Sharma and Vijay Bhagat

- Micturition: Abnormal
- Addiction: No specific addiction
- Blood Group: B+ve

Examination

General Examination

- The general condition of the patient was fair.
- No pallor seen.
- Pulse-78/min
- BP: 130/90 mm of hg
- CVS: S1, S2 Normal
- Ht: 150cm
- Weight: 42Kg
- RS: Auscultation of the lungs reveals clear breath sounds in both the anterior and posterior regions.
- P/A: The abdomen is soft and non-tender on palpation.

Clinical Examination

EEG -in sleeping condition, in which changes in the pattern of brain detected.

Ashtavidha Pariksha

- Nadi (Pulse)- Vata Pitta
- Mala (Bowel habits)- Irregular
- Mutra (Urine)- NAD
- Jihva (Tongue)- Mild coated
- Shabda (Voice of patient)- NAD
- Sparsha (Touch)- Sama shitoshna
- Drik (Eye & Vision)- NAD
- Akriti (samhanan)- Madhyama (Medium)

Investigation

SampratiGhataka

Agni: Jatharagni, Rasagni

Srotas: Manovahsrotas

Dosha: Tridosha (Vata, Pitta, Kapha), Rajas, Tamas

Dushya: Ras, Rakta, Manas

Samutthana: Vata Pittakara Ahar

Vyaktasthana: Gyanendriya, Karmendriya

Diagnosis

The patient was already diagnosed with Epilepsy in 2014 which is compared with *Apasmara* in *Ayurved* on the basis of the symptoms, described by the patient at the time of consultation.

Treatment Plan

Upon considering the seriousness of this illness, it is essential to assess the condition of the disease and the patient and validate the effectiveness of a well-established medication like '*PanchagavyaGhrita*' through clinical trial. According to the line of the treatment of *Apasmara*, *PrabodhanoftheHridaya*, *Srotas*, and *Manas*, *Avrit* by these *PrakupitaVata* and other *doshas*, the physician should initially treat the patient with *Tikshna Vaman*, *Nasya*, etc. procedures[10]. As per the symptoms it is understood that the *Vata dosha* is vitiated in patient so, to counter act it, the *basti* therapy was planned.

Purva Karma

Chitrnanjan Sharma and Vijay Bhagat

Pradhana Karma

Pratimarsha Nasya-

Shiva Kshara Pachana Churna- 10 gms- after ½ hr. of meal- twice a day.

Dietary Regimen

- Provide *Laghu Ahara* (a light, easily digestible diet) such as *Peyaa* (rice gruel), boiled vegetables, and moong dal soup.
- Avoid foods that aggravate Vata, such as dry, cold, and raw foods.

Lifestyle Recommendations:

- Encourage the patient to follow a Proper *Dincharya* and sleep schedule.
- Meditation, *Pranayama* and gentle yogic exercise for mental relaxation and peaceful surroundings.

Follow-Up

To Monitor the patient's response to the treatment. Follow up after 15 Days. Patient came for follow up on Date 11/03/2024- In this duration no any episode of *Apasmara* occurred in patient. He feels relief in Headache and Drowsiness also. He feels fresh and more focused. So, we continue only the *Nasya* of *Panchagavya Ghrita* for next 15 days. After 15 days patient came for follow up on Date 25/03/2024- In this duration no any episode of *Apasmara* occurred in patient. He got complete relief in Headache and Drowsiness also. He feels fresh and more focused. No onset of strange smells.

Observation

A comparison between the results of EEG - in sleeping condition conducted after treatment, in which no changes in the pattern of brain detected. So, we Continue the *Nasya Karma* for next 2 months.

DISCUSSION

In the present case, the patient reported a reduction of 60% in signs and symptoms within first 15 days treatment. As per the chronic condition of the patient and the recommendation in the classics for treating *Apasmara*, the *Panchgavya Ghrita* was incorporated into the treatment plan with appropriate modifications. There was significant improvement in the episodes of *Apasmara*, seizures and headache with reduced severity of the all symptoms.

Shodhana Chikitsa

Snehana: As a part of the initial treatment protocol, *Snehana Karma* was administered before *Basti Karma*.

Swedana

After *Snehana*, *Swedana* is done to dissolve the *Prakupita Doshas*. So *Avgahana Swedana* was performed by considering the *Aayu* and *Bala* of patient.

Basti Karma

Basti is considered as *Ardhachikitsa*. In this case as *Apasmara* has the good amount of involvement of *Vata Dosh*, *Basti* produced a significant result. By applying *Matra Basti*, the timing in the interval between seizures took a significant change and symptoms like headache and drowsiness etc, got completely cured.

Pratimarsha Nasya

Nose is considered as the gateway towards the head. By applying *Nasya*, the patient gets significant relief in symptoms like headache etc in the first week itself. That really helps the patient to come to follow up. And by relieving other symptoms, the focus easily shifts into main disease and the *Nasya Karma* helps in bringing back the *Smaranashakti* (memory).

Chitrnanjan Sharma and Vijay Bhagat

CONCLUSION

In above said case, the patient showed more than expectation improvement through the combined treatment of *Panchakarma* therapy *Basti* and *Nasya*. Despite the usual oral use of *PanchgavyaGhrita* the incorporation of *Basti* and *Pratimarsha Nasya* of *PanchgavyaGhrita* proved highly beneficial. As patient has History of *Vata* dominant *Apasmara* the treatment resulted in Headache, Drowsiness and mainly in seizures leading to improvement in *Smaranshakti*(memory)and a better-quality life. This case highlights the efficacy of a well-adapted and holistic approach to treating *Apasmara*.

ABSTRACT

Tuberculosis (TB) is an infectious disease that most often affects the lungs and is caused by a type of bacteria *Mycobacterium tuberculosis*. Infected people spread TB through the air when they cough, sneeze, or spit. An estimated 10.6 million people effected with tuberculosis and 1.3 million people died from TB in 2023 as per WHO reports. India has incidence rate of 192 cases per 100,000 of population and in 2023, India accounted for 2.5million TB cases registered. Although there was treatment for TB like first line and second line drugs but the usage is for prolonged time and it is not assured that it can completely kill the tuberculosis bacteria. Due to that the new novel drug treatment was introduced that is called as BPaLM therapy. It stands for Bedaquiline, Pretomanid, Linezolid and Moxifloxacin. This combination therapy is part of newer treatments being developed to address multidrug resistant TB (MDR-TB) and extensively drug-resistant TB (XDR-TB). It has been a promising alternative due to shorter treatment durations and improved outcomes. The drugs were chosen because they target different critical bacterial functions such as energy production, protein synthesis, cell wall synthesis, and DNA replication-providing a strong and multi-prolonged attack on *Mycobacterium tuberculosis*. This new treatment duration is very short that is 6Months as compared to older therapy of 18-24 months. The CDSCO in India approved this therapy on 6th October 2024.

Keywords: Tuberculosis, MDR-TB, BPaLM, Bedaquiline, Pretomanid, Linezolid, Moxifloxacin, ATP Synthase, Peptidyl transferase, DNA topoisomerase & DNA Gyrase.

Purna Nagasree *et al.*,

INTRODUCTION

Tuberculosis (TB) is caused by a type of bacteria known as *Mycobacterium tuberculosis* which is responsible for the infectious disease, it generally affects the lungs. People who are infected with cough, sneeze, or spit, it spreads through the air [1]. tuberculosis can be avoided or treated. It is estimated that TB bacteria has infected 25% of the world's population [2]. Approximately 5–10 percent of TB infected individuals will eventually experience symptoms and develop TB disease. The disease cannot be transmitted by those who are infected. Antibiotics are usually used to treat tuberculosis, which can be fatal without treatment [1]. The Bacille Calmette-Guerin (BCG) vaccine is given to babies and young children in some countries to prevent tuberculosis. The vaccine does not prevent TB other than lungs [2]. A sum of 1.3 million individuals died from TB in 2022 (167000 individuals with HIV). After COVID-19, TB is the leading infectious disease that kills more people worldwide than HIV and AIDS [3]. TB affects people of all ages and nationalities.

Tuberculosis status in India

Tuberculosis is one of India's major public health issues. India has the largest tuberculosis epidemic in the world, according to WHO estimates. In 2020, India will account for 26% of all incident TB cases worldwide [2]. The incidence rate in India is 192 cases per 100,000 people. India was responsible for 34% of all TB deaths among HIV-positive and HIV-negative individuals and 38% of all deaths worldwide among HIV-negative individuals. Furthermore, many research studies have investigated the effects and consequences of TDR-TB, particularly in India, where social and economic development is still in progress [3]. In India, tuberculosis is responsible for the death of every third AIDS patient. In 2020, India accounted for 24% of the global gap between the estimated incidence of TB and the number of people newly diagnosed with TB and reported. The ministry reiterated their commitment to eliminating tuberculosis in the country by 2025. On December 30, 2019, the Union Government changed the name of the Revised National Tuberculosis Control Program (RNTCP) to National Tuberculosis Elimination Program (NTEP). This was performed as part of its efforts to eradicate tuberculosis [4].

Treatment of TB with novel drugs in different nations:

A brief overview of countries with BPALM or related regimens, along with timelines, are as follows:

- i. South Africa (2018): One of the first nations to use Pretomanid -based regimens in clinical trials to combat XDR-TB was South Africa. After the WHO approved BPALM, it became easier to access.
- ii. India (2021): To address its significant drug-resistant TB, India has participated in BPAL and BPALM regimen research and clinical trials. India's Central Drugs Standard Control Organization granted Pretomanid approval. The World Health Organization (WHO) approved pretomanid-containing regimens in 2019, leading the WHO to roll out these regimens more broadly across several countries actively involved in TB research and treatment. As more nations adopt these more recent regimens in response to their requirements for public health and regulatory approval, access continues to rise [4].
- iii. United States (2019): The treatment of extensively drug-resistant tuberculosis (XDR-TB) with Pretomanid, Bedaquiline, and Linezolid received approval from the Food and Drug Administration (FDA). MDR-TB and XDR-TB are both treated with this regimen. In the United States, clinical trials have performed for BPALM, including Moxifloxacin, but BPAL was the first significant step [5].
- iv. France (2019): By the WHO recommendation in 2019, the use of Pretomanid-containing regimens was approved in France through the European Medicines Agency (EMA). For MDR-TB patients, French healthcare authorities have participated in clinical trials and special access programs, and BPALM has been included in these trials for cases of drug-resistant TB [5].
- v. United Kingdom (2021): UK's National Health Service (NHS) and Public Health England began using Pretomanid-containing regimens to treat MDR-TB in 2021. Pretomanid and the BPALM regimen have been approved, but their rollout has been limited, with MDR-TB and XDR-TB cases serving as the primary focus [4].

Purna Nagasree et al.,

- vi. Russia (2020): BPALM regimen was part of national programs to combat drug-resistant TB in Russia, which had one of the highest rates of MDR-TB and XDR-TB in Europe. Early use of the regimen was prompted by Russia's participation in the WHO-coordinated clinical trials and its need for effective MDR-TB treatments [5].

Types of Tuberculosis

- i) **Pulmonary Tuberculosis:** Common symptoms of pulmonary tuberculosis include a cough and abnormal chest radiographs. They might spread disease among people and causes most cases registered for Pulmonary TB [6].
- ii) **Extrapulmonary Tuberculosis:** This affects the lungs and causes extrapulmonary tuberculosis, which affects the pleura, lymph nodes, brain, kidneys, and bones and joints. TB can affect any part of the body. Most of the time, people with extrapulmonary TB disease don't get sick unless they have a disease of the lungs in addition to other diseases of the lungs or laryngeal disease, an extrapulmonary condition or an extrapulmonary disease with an open abscess or lesion that has a high concentration of organisms, especially if the drainage fluid from the abscess or lesion is aerosolized or if it drains a lot. Both pulmonary and extrapulmonary TB are frequently present in HIV-positive individuals [5].
- iii) **Miliary TB disease:** Miliary TB disease is a rare but serious condition caused by tubercle bacilli spreading to all parts of the body, where they grow and cause disease in multiple locations. Miliary refers to the appearance of millet seeds dispersed throughout the lung on a radiograph. It can affect anyone, but infants and children younger than 5 years old and people with immune problems are more likely to be affected. Military tuberculosis can be found in a single organ (such as the brain), multiple organs, or the entire body. If left untreated, it is fatal [4][5]. Meningeal involvement may occur in up to 25% of military TB patients [6].
- iv) **TB Meningitis:** The tuberculosis causes the Meningitis of the brain and the spinal cord. Imaging studies frequently reveal it at the base of the brain. Meningitis patients frequently have miliary TB disease and chest radiograph abnormalities that are consistent with previous or current TB disease [4].
- v) **Drug-Resistant TB diseases:** Drug-Resistant TB disease is affected by *Mycobacterium tuberculosis* organic entities that are impervious to the medications ordinarily used to treat the sickness [3]. Drug-resistant tuberculosis is as infectious as drug-susceptible tuberculosis and is transmitted in the same manner. However, prolonged periods of infectiousness or a lack of recognition of drug resistance may facilitate increased transmission and the development of drug resistance [4]. TB is caused by a *Mycobacterium tuberculosis* strains that are *in vitro* resistant to rifampicin and isoniazid is MDR (multidrug-resistant) TB. TB brought about by types of *M tuberculosis* that are safe *in vitro* to isoniazid, rifampicin and something like one injectable specialist (i.e., amikacin, kanamycin or capreomycin) and any of the fluoroquinolones [6].
 - a) **Mono-resistant TB:** This is a type of TB caused by strains of *M. tuberculosis* that are resistant to just one first-line anti-TB drug.
 - b) **Poly-resistant TB:** TB caused by strains of *M. tuberculosis* that are resistant to more than one first-line drug, but not isoniazid and rifampicin together
 - c) **Multidrug resistance TB (MDR-TB):** It is a form of TB that is resistant to either one of the most powerful first line drugs such as either isoniazid or rifampicin.
 - d) **Extensively drug-resistant TB (XDR-TB):** It is most rare and severe case where all effective drugs to treat *mycobacterial tuberculosis* is resistant

vi). Drug-susceptible Tuberculosis: DS-TB is a case where a person is infected with TB bacteria that are to all first line anti-TB drugs. It means that all of the first line TB drugs will be effective as long as they are taken properly and regularly. This type of TB has the best prognosis and the shortest treatment duration. Patients diagnosed with TB are considered to be DS-TB the case, till such time they are detected with resistance to any anti-TB drugs.

Treatment of TB

Treatment of MDR-TB is difficult due to the majority of weak and toxic second-line TB medications. The majority of these drugs were developed decades ago but are rarely utilized due to their adverse effects. MDR-TB treatment typically takes 18–24 months due to the second-line drugs' weak sterilizing properties [4]. Cure rates range from 60 to 80 percent in the most effective treatment programs that aggressively manage side effects and address socio-economic barriers [5]. However, the cure rate for MDR-TB is significantly lower worldwide. The World Health

90975

Purna Nagasree et al.,

Organization said in 2013 that only 48% of MDR-TB patients were cured. Even lower is the global cure rate for XDR-TB: according to WHO 2013 Only 20% are cured, and 44% died [6]. The primary first-line anti-TB medications are isoniazid, rifampicin, pyrazinamide, ethambutol, and streptomycin. Anti-TB medications have traditionally been classified as first-line and second-line medications [7]. We use the WHO system for this review, which divides the drugs into five groups based on efficacy, use experience, safety, and drug class. The safety profile and efficacy of drugs in the same group are not always the same, and they do not always belong to the same drug class [8]. The below table 1&2 describes about the classes of anti-tubercular drugs based on Minimum inhibitory concentration (MIC), efficacy, drug class and their experience of use.

TREATMENT OF TB THROUGH MDR TB & XDR TB

The BPaLM regimen combines four drugs with distinct but complementary mechanisms of action to target energy production, cell wall integrity, protein synthesis, and DNA replication of *Mycobacterium tuberculosis*. It is highly effective in treating drug-resistant tuberculosis. These mechanisms are complement to one another as following: The depletion of energy caused by Bedaquiline makes it more difficult for the bacteria to resist the effects of the other drugs. By making the bacterial cells more permeable, Pretomanid makes it easier for Linezolid and Moxifloxacin to enter and function more effectively [9]. Linezolid and moxifloxacin impair the bacterium's ability to repair the damage brought on by energy loss and cell wall disruption by interfering with fundamental processes like protein synthesis and DNA replication.

Bedaquiline (B)

Starving a Bacteria, Bedaquiline targets the ATP synthase enzyme in TB bacteria, this ATP synthase is responsible for energy production through the generation of ATP. Without energy, the bacteria cannot survive, especially in actively replicating states [9]. Bedaquiline inhibits bacteria by reducing their energy, which leaves them more susceptible to the effects of other medications that target essential functions including DNA replication, protein synthesis, and cell wall formation [8][10].

Pretomanid(Pa)

Disrupting the Cell Wall and Killing Dormant Bacteria, Pretomanid disrupts mycolic acid synthesis, which is essential for building and maintaining the thick and waxy cell wall that protects TB bacteria. It also generates reactive nitrogen species under low-oxygen (anaerobic) conditions, effectively killing dormant TB bacteria [9]. As Pretomanid disrupts the cell wall, the bacteria are exposed and more vulnerable to the energy depleting effects of Bedaquiline as well as the impacts of Linezolid and Moxifloxacin on DNA and protein activities. Additionally, Pretomanid ensures complete bacterial death by killing dormant or slow-growing bacteria that other medication.

Linezolid(L)

Inhibition of Protein Synthesis, Linezolid binds to the 50S ribosomal subunit, blocking bacterial protein synthesis. Without functional proteins, the bacteria cannot maintain essential cellular processes or reproduce [10]. The combination of the other medications increases the effectiveness of linezolid's suppression of protein synthesis. Pretomanid's rupture of the cell wall increases Linezolid's capacity to enter bacterial cells, while Bedaquiline's energy depletion makes it more difficult for the bacteria to adapt or survive [11]. Linezolid inhibits the bacterial repair of the damage caused by the other medications by inhibiting the synthesis of proteins.

Moxifloxacin (M)

Preventing DNA Replication as Moxifloxacin is a fluoroquinolone that targets DNA gyrase and topoisomerase IV, enzymes necessary for DNA replication and repair [8]. This prevents the bacteria from copying their DNA, effectively inhibiting their reproduction and ability to fix any DNA damage. Bedaquiline which deprives the bacteria of energy and Linezolid which inhibits protein synthesis work in tandem with Moxifloxacin's capacity to inhibit DNA replication. When combined these processes stop the bacteria from growing or repairing themselves which results in the death of the organism [9][10].

Purna Nagasree et al.,

The Benefits of novel combination BP aLM

- i) The bacteria have a much lower chance of developing resistance if they target multiple pathways including energy, the cell wall, protein, and DNA. The other drugs target distinct essential systems so even if the bacteria were to adapt to one they would not be effective [11].
- ii) Dormant TB bacteria which are typically more difficult to eradicate with standard antibiotics are particularly well-suited to Pretomanid's effectiveness. This guarantees that the treatment works on all bacterial populations not just those that are actively reproducing [10].
- iii) In contrast to older TB regimens which can take anywhere from 18 to 24 months the potent combination enables a shorter treatment duration of typically 6 months.
- iv) The BP aLM regimen treatment acts effectively by developing and lethargic microorganisms are destroyed there is no chance for the microscopic organisms to continue and reactivate later [11].

BEDAQUILINE

Mechanism of action

Bedaquiline is an anti-mycobacterial diarylquinoline that inhibits *M. tuberculosis* energy-generating enzyme, ATP (adenosine 5'-triphosphate) synthase, by binding to subunits of the enzyme [10][11]. From bacteria to mammals, the F₁F_o ATP synthase (M.W. 600 kDa for the monomer) is highly conserved. The ATP synthase contains a reactant F₁ segment, a fringe tail or stator, and the layer installed, F_o district. F_o has a proton turbine made up of a ring of c-subunits—eight in mammals, ten in yeast, 14 in the chloroplast, and a variety of stoichiometries in bacteria—and an a-subunit that serves as the conduits for proton entry and exit. The proton flow provides the energy for the phosphorylation of ADP in the active site of F₁, and the c-ring, which is connected to the central stalk of F₁, rotates driven by the movement of protons down the potential gradient from the cell's cytosol to the mitochondrial matrix [12]. By binding to F_o of the ATP synthase Bedaquiline inhibits *Mycobacterium tuberculosis* ATP synthesis. According to biochemical and x-ray crystallographic studies, BDQ binds to the *Mycobacterium phlei* 23 c-ring. While BDQ is a potent inhibitor of the mycobacterial ATP synthase, studies have shown that it has little effect on the human enzyme. The studies decided to independently examine the effect of BDQ on the mitochondrial ATP synthase because of the high rate of death following the administration of Sirturo. The studies present biochemical evidence that BDQ inhibits mitochondrial ATP synthase in yeast and humans. The mammalian enzyme's highly conserved BDQ binding site on yeast mitochondrial F_o is identified by cryo-EM [13]. A model of the binding pose is then created using simulations of molecular dynamics. These findings suggest that BDQ's inhibition of the human ATP synthase may be a factor in the high mortality rate following administration, and it is likely that BDQ derivatives can be more selective toward the mycobacterial enzyme. The human ATP synthase is inhibited by Bedaquiline [12].

One or more BDQ molecules can bind to the c-ring's membrane-exposed ion-binding sites and approach the ATP synthase, depending on the concentration of BDQ. Whether BDQ would likewise bind to the a-subunit or bind some place at or inside the a/c-ring point of interaction can't be decided with sureness with a presently accessible information. However, the fact that no drug-resistant a-subunit mutants have yet been identified contrasts with resistant mutants with c-subunit-exclusive mutations and suggests that this is not a possibility. Therefore, Phe69 alters its conformation as the drug approaches the c-ring to prevent steric clashes and provides BDQ with a hydrophobic platform. BDQ itself has the ability to alter its conformation and, as a result, aids in the development of numerous distinct molecular interactions, such as the ionic intermolecular H-bond between the DMA group and Glu65. Similar to the ion-coordinating glutamate-arginine interaction in the adjacent stator subunit a, this interaction is strictly conserved and essential to function [12]. As a result, when a c-subunit crosses the rotor-stator interface, the Glu65-DMA conformation appears to mimic a transition state during the ion translocation process, allowing BDQ to capture this crucial state in the F_o-motor mechanism. The bulky BDQ molecule would be energetically highly unfavourable to bind or pass this barrier because of the tight and partially hydrophilic rotor-stator region found in bacterial ATP synthases effectively preventing c-ring rotation and consequently an ion exchange in F_o. The complete halt of coupled ATP synthesis that follows has a significant effect on the general bioenergetic metabolism [13][14]. Tuberculosis and ultimately kills mycobacterial survival. According to this proposed mechanism, biochemical data

Purna Nagasree *et al.*,

support the conclusion that binding just one BDQ molecule to each ATP synthase is sufficient to completely prevent ATP synthesis [14].

Uses

Bedaquiline is used with three other medications to treat multi drug-resistant tuberculosis this treats only bacterial infections[12][13].

Side effects

Nausea, joint pains, headaches, and chest pain, liver dysfunction, and increased risk of death, coughing up blood, chest pain, fast/irregular heartbeat, severe dizziness fainting [14].

LINEZOLID

Chemical Formula: C₁₆H₂₀FN₃O₄

Mechanism of action

Linezolid inhibits bacterial protein translation by binding to a site on the 50S subunit of 23S ribosomal RNA and preventing the formation of a functional 70S initiation complex, which is necessary for bacterial reproduction, thus inhibiting bacterial division. At first, it was thought that linezolid worked by binding to the 23S rRNA of the 50S ribosomal subunit, close to the peptidyl transferase centre (PTC) of the would-be ribosome, before the 70S initiation complex was formed. The antibiotic would inhibit the ability of the 50S ribosomal subunit to bind to the 30S subunit upon binding to the subunit. This would prevent the 70S initiation complex, which is made up of the 50S and 30S subunits obstruct the early stages of protein synthesis. In contrast to other antibiotics that inhibit the elongation phase of protein synthesis, this proposed mechanism of action is unique [15]. However, subsequent research and crystallography analyses suggested that the more likely binding site for linezolid to the ribosome's PTC. Additionally, when alanine is the ultimate amino acid in the nascent chain, it was discovered that linezolid binds more effectively to the A site of the ribosome. This is because the alanine residue would fit into a hydrophobic pocket in the structure of the linezolid, allowing it to bind to the ribosome and prevent the PTC from interfering with the formation of the peptide bond between the A and E sites of the tRNA depicts the reported mechanisms of linezolid resistance in mycobacteria [16]. The tRNA loss-of-function mutations are not depicted, due to a lack of information regarding the proposed mechanism associated with these mutations, the tRNA loss-of-function mutations are not depicted. a) Ribosomal changes (mutations in either the L3 ribosomal protein or the 23S rRNA) that change the rRNA's conformation at the linezolid binding site and prevent it from binding to the peptidyl transferase centre (PTC) b) Mutations that result in the overexpression of efflux pumps that remove linezolid molecules from within cells [17]. c) The mutation in FadD32 that affects how mycolic acid is made. The increased hydrophobicity of the mycobacterial cell wall and decreased intake of linezolid, a drug that is hydrophilic, could result from this mutation's increased production of mycolic acids. The linezolid's decreased activity is indicated by red crosses.

Mutations in a 23S ribosomal RNA (rrl)

The 23S ribosomal RNA is a crucial part of the ribosome and makes up a significant portion of the 50S ribosomal subunit. It is one of the most frequently targeted binding sites for ribosome-targeting antibiotics like chloramphenicol and forms the PTC. It is centered around DomainV of the rRNA. As a result, linezolid-resistant mycobacteria also frequently exhibit 23S rRNA mutations. Linezolid resistance-conferring mutations in the 23S rRNA have been found to be mostly concentrated in its two domains, Domain V and Domain VI. Mutations in the rrl gene, which encodes the 23S rRNA, have been observed in numerous clinical isolates, particularly g2814t, which has been reported in numerous locations as far apart as India, South Africa, and Russia. Since this domain forms the PTC of the ribosome, a site where linezolid binds, mutations in Domain V should be expected to have an effect on linezolid resistance. However, the mechanism by which linezolid resistance is conferred on mycobacteria by mutations in Domain VI is poorly understood. Mutations may alter the interactions between the domain and the L6 ribosomal protein, an important protein close to the PTC's binding site, as one possible mechanism [15][17]. In addition, cross-linkages between the helices of Domain VI, the L6 protein, and Domain V are essential for preserving the ribosome's

Purna Nagasree *et al.*,

secondary structure. As a result, linezolid resistance may be conferred by mutations in Domain VI altering the structure of the rRNA. To better comprehend the connection between linezolid resistance and these ribosomal structures, additional research is required [15][16].

Uses

Linezolid is used to treat various infections such as including pneumonia and infections of the skin [16].

Side effects

Decreased platelets, white blood cell counts, headache, haemoglobin levels, diarrhoea, elevated pancreatic enzymes, elevated liver function tests, and neuropathy [15][17].

PRETOMANID:

Chemical formula: C₁₄H₁₂F₃N₃O₅

Mechanism of action

Pretomanid is a prodrug that is metabolically activated by a nitroreductase enzyme known as Ddn. This causes Pretomanid to produce the number of active metabolites that are responsible for its other therapeutic effects, particularly its ability to increase nitric oxide levels. Pretomanid is activated by the nitroreductase enzyme, which requires the reduced cofactor F420 and is dependent on deazaflavin. The enzyme glucose-6-phosphate dehydrogenase is used to reduce F420[18]. The metabolites, which include a des-nitro derivative, are created when the imidazole ring of the Pretomanid is reduced at the C-3 position. It has been reported that bactericidal activity against anaerobes is associated with a shorter duration of antibiotic treatment because the formation of this derivative results in increased levels of nitric oxide, which in turn causes bactericidal activities under anaerobic conditions through its action as a bacterial respiratory poison [19]. Pretomanid is a Nitroimidazooxazine medication that prevents mycolic acid from being made by preventing the production of bacterial cell walls, it kills *M. tuberculosis* that is actively reproducing, allowing for increased drug penetration into the bacterial cell[20]. Pretomanid is a prodrug that is metabolized to highly reactive nitro compounds like nitric oxide by the bacterial reductase enzyme deazaflavin-dependent Nitroreductase (Ddn) and reduced the form of cofactor F420. Pretomanid has demonstrated high anti-TB activity compared to other anti-TB drugs, with a minimum inhibitory concentration (MIC) ranging from 0.06 to 1 mcg/ml [19][20]. Through its inhibition of bacterial cell wall mycolic acid biosynthesis, Pretomanid has an aerobic bactericidal effect [21]. This enables the treatment of active tuberculosis infection by killing *Mycobacterium tuberculosis* bacteria that are actively reproducing. The molecular mechanism of a fore mentioned bactericidal effects is currently poorly understood, but it may involve effects on various genes that affect the cell wall, such as the *fas1* and *fas2* operons and the *efpA* and *iniBAC* operons. Theoperational genes are one or more set of potential targets. The above target relations' clinical effects are currently unknown [22].

Uses

To treat lung tuberculosis (TB) that is extensively drug resistant (XDR) or which cannot be tolerated or do not respond to treatment for multidrug-resistant (MDR)-TB, Pretomanid is used in a combination regimen with Bedaquiline and linezolid. Pretomanid stops tuberculosis from growing in the body [25].

Side effects

Difficult respiration problems with nerves, numbness, burning, or prickly feeling in arms, hands, legs, or feet swelling a face, lips, tongue, or throat. tremors, weakness, problems with balance, altered vision, shortness of breath, cough with mucus or blood, chest pain that gets worse when you breathe or cough, and nerve problems [23][24].

MOXIFLOXACIN

Mechanism of action

Moxifloxacin is an antibiotic that kills bacteria. By restricting DNA gyrase (topoisomerase II) and topoisomerase IV, essential bacterial catalysts involved in the replication, interpretation, fixation, and recombination of

Purna Nagasree *et al.*,

deoxyribonucleic acid, it impairs bacterial strength [26]. The Moxifloxacin binds the DNA gyrase and Topoisomerase very tightly. However, it restricts DNA gyrase in particular in gram-negative bacteria and *Streptococcus pneumoniae* and it inhibits ligase activity which cause cleavage of the DNA and damages DNA stands which results in incapable to repair the DNA stands thereafter inhibits DNA replication and causes cell death. Antibacterial fluoroquinolone Similar to other quinolones, moxifloxacin prevents bacterial cell DNA and RNA synthesis and inhibits DNA gyrase. Moxifloxacin has broad antimicrobial activity and is bactericidal. It differs slightly from earlier veterinary fluoroquinolones in terms of its chemical structure (eight methoxy substitutions). Compared to the veterinary fluoroquinolones (enrofloxacin, orbifloxacin, and marbofloxacin), this newer generation of drugs, like moxifloxacin, is more effective against gram-positive bacteria and anaerobes [27]. Pradofloxacin is a medication for animals that has been approved and has a similar spectrum. In some cases, pradofloxacin may be used in place of moxifloxacin in animals [28]. The development of a regimen that includes several bactericidal agents that the infecting organism is susceptible to is essential for the successful treatment of MDR-TB [29]. The lack of agents that are not only highly bactericidal but also nontoxic makes it difficult to achieve this goal. This is especially true given the extended duration of MDR treatment up to 24 months where toxicity can make it difficult for some patients to complete it. Treatment response can be slow due to the lower bactericidal activity and higher toxicity of many second-line agents like Linezolid, Prothionamide, and Cycloserine. This also explains why prolonged treatment is required. Patients who stop a portion of their treatment regimen due to exhaustion or toxicity run the risk of developing additional resistance [30]. There is a risk that patients will fall into a vicious cycle of failing regimens and increasing resistance, eventually leading to complete resistance, if the treatment they receive is not optimal. A lot of this issue is exacerbated by the shortfall of compelling medication vulnerability testing in some high-trouble nations, and that implies that managing a routine uncontrolled by powerlessness testing risks further opposition enhancement with diminishing choices for treatment [32]. The below given fig. 5 gives information about moxifloxacin mechanism of action.

Uses

A wide range of bacterial infections can be treated with moxifloxacin. Quinolone antibiotics are a class of drugs. These shows action by inhibiting the growth of bacteria. This antibiotic only treats infections caused by bacteria [31][32].

Side effects

Nausea, vomiting, dizziness, headache, weakness, or difficulty in falling sleep unusual bleeding and bruising, symptoms of a new infection such as a fever and sore throat that lasts for longer period, problems with the kidneys such as a change in the amount of urine, and problems with the liver such as nausea and vomiting that won't stop, unusual tiredness, stomach/abdominal pain, yellowing of the eyes and skin, and dark urine [33].

The Summary of newer anti-TB drugs

Bedaquiline, Pretomanid, Linezolid, and Moxifloxacin (BPALM) is a treatment for tuberculosis (TB) that has proven to be safer, more effective, and more rapid than previous treatments. The drugs in the BPALM regimen treat TB in various ways:

- i) Pretomanid: It eradicates TB-causing bacteria that are both dormant and actively reproducing [29].
- ii) Bedaquiline: Targets an enzyme's c-ring and s-subunit, which prevent ATP synthesis and disrupt the network of amino acid interactions.[31].
- iii) Linezolid: Inhibit MAO-A, which in turn may raise serotonin levels.
- iv) Moxifloxacin: An antibiotic that eliminates infection-causing bacteria. When it comes to treating patients with MDR or DR-TB, the BPALM regimen has demonstrated promising results in clinical trials [32]. If a patient exhibits a delayed treatment response within the first eight weeks, the regimen can be extended [33]. The below table 3 describe about the drugs and dose of BPALM regimen. These doses are not suitable for the children who are lesser than 14 years because it causes many major complication such as mutations, gene replication and there are no proper clinical studies conducted on Pretomanid so that there was another 9 months course duration for children that is oral regimen consists of Bedaquiline (which is used for 6 months), in combination with

Purna Nagasree *et al.*,

levofloxacin or moxifloxacin, ethionamide, ethambutol, isoniazid (high dose) and also pyrazinamide and clofazimine[34][35]. Table 4 gives information about drug structures, their mechanism and also side effects.

Advantages of using BPaLM regimen

A combination of drugs like moxifloxacin, linezolid, Bedaquiline, and Pretomanid are used because they:

- i) TB treatment time can be cut down with combination therapy.
- ii) The likelihood of the disease recurrence can be reduced with combination therapy.
- iii) Drug resistance can be slowed down with combination therapy.
- iv) Combination regimens have demonstrated greater bactericidal activity than first-line regimens in animal models [35].

Disadvantages of BPaLM regimen

- i) Bedaquiline, Pretomanid, and Linezolid (BPaL) as a combination drug therapy for tuberculosis (TB) may have drawbacks, including: Negative effects on Peripheral neuropathy, optic neuritis, myelosuppression, hepatotoxicity, and pancreatitis.
- ii) Linezolid causes toxicity when taken in large quantities, linezolid can cause optic neuropathy, peripheral neuropathy, and bone marrow toxicity.
- iii) Bedaquiline causes prolongation of QT wave- QT prolongation brought on by Bedaquiline may alter cardiac rhythm.
- iv) Pretomanid causes musculoskeletal pain, headaches, nausea, acne, and vomiting, Pretomanid can harm the liver, eyes, and reproductive system [34][35].

Rationale behind BPaLM regiment

- i) A robust and multi-pronged attack on *Mycobacterium tuberculosis* was provided by these drugs, which were chosen because they target various critical bacterial functions like energy production, protein synthesis, cell wall synthesis, and DNA replication. The chances of the bacteria surviving and developing resistance are significantly reduced by employing this multi-target strategy.
- ii) MDR and XDR TB, which are resistant to standard first-line treatments, have all been shown to be effective with each of these medications. Particularly Bedaquiline and Pretomanid have become crucial in combating these resistant strains of tuberculosis.
- iii) Drug-resistant forms of traditional TB treatment frequently necessitate lengthy treatment regimens, lasting anywhere from 18 to 24 months. Patient adherence and outcomes are enhanced by the BPaLM regimen's shorter treatment duration of typically 6 months.
- iv) When choosing these drugs, safety and tolerability are also taken into consideration. Patients infected with strains that are resistant to isoniazid and rifampicin known as multidrug-resistant (MDR) TB are practically incurable by standard first-line treatment. While some medications, such as Linezolid may carry risks of toxicity (such as bone marrow suppression or neuropathy) MDR-TB patients are virtually incurable. MDR-TB strains that are resistant to fluoroquinolones and second-line injectable drugs are referred to as extensively drug-resistant (XDR) TB and there were approximately 4,50,000 new cases and 1,70,000 members deaths in 2012[36].

CONCLUSION

The BPaLM regimen consisting of Bedaquiline, Pretomanid, Linezolid, Moxifloxacin represents a significant breakthrough in the treatment of multi drug resistant tuberculosis. The BPaLM regimen is a crucial addition to the global fight against MDR-TB with its novel mechanism of action it reduces treatment duration (6months). This combination of drugs improves its efficacy and also stops the chance of reoccurrence. Normally to treat TB it used to take 18 months treatment by using nearly more than 14000 pills overall by using some of the first line and second line drugs but after this BPaLM regimen it can treat within 6months by using less than 750 pills. Over all this treatment helps the patient to a certain extent and provides a greater relief from treatment of Tuberculosis. As the global health

Purna Nagasree et al.,

community continues to work towards ending the TB epidemic, the BPaLM regimen will undoubtedly play a vital role in achieving this goal.

Table 3: BPaLM regimen

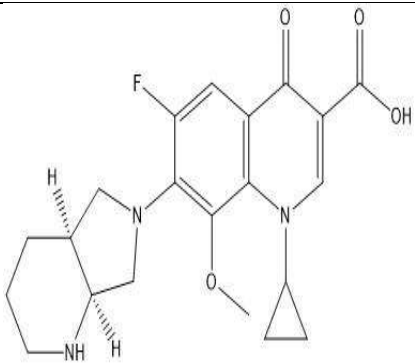

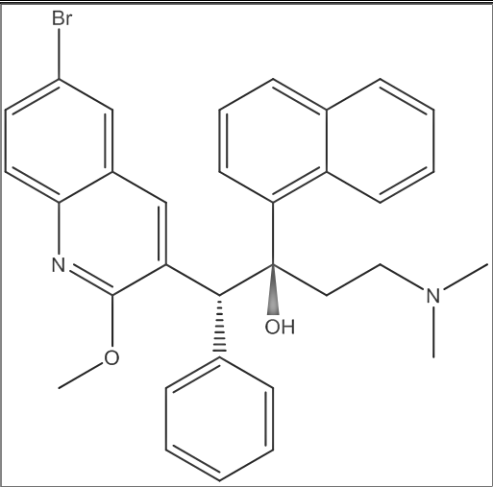

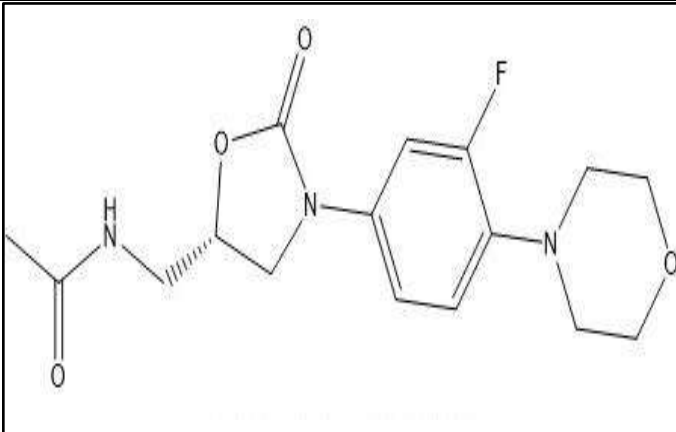

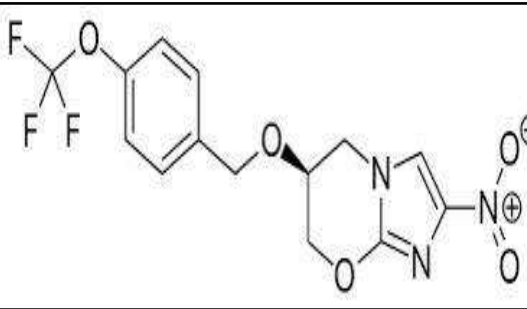

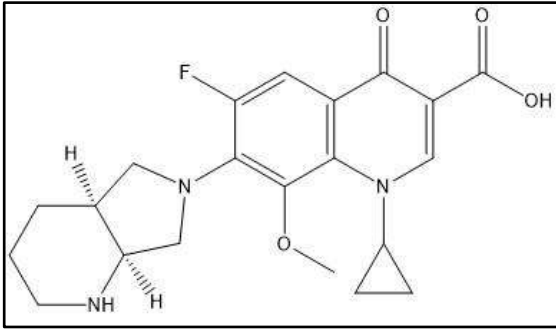

DRUG	DOSE
1)Bedaquiline (100 mg tablet)	400 mg once daily for 2 weeks, then 200 mg 3 times per week afterwards OR 200 mg daily for 8 weeks, then 100 mg daily
2)Pretomanid (200 mg tablet)	200 mg once daily
3)Linezolid (600 mg tablet)	600 mg once daily
4)Moxifloxacin (400 mg tablet)	400 mg once daily

Table 4: BPaLM drugs mechanism and side effects

Name	Structure	MOA	Side Effects
Bedaquiline (B)		It inhibits ATP synthase enzyme, that interrupts energy production and causes cell death	Joint pains, headaches, chest pain, chest pain, liver dysfunction, coughing up blood.
Pretomanid (Pa)		It disrupts mycobacterial cell wall synthesis and generates nitrogen species and leads to bacterial death	Numbness, burning, or prickly feeling in arms, hands, legs, or feet, tremors, weakness, altered vision, shortness of breath
Linezolid (L)		It inhibits bacterial protein synthesis by binding to 50S ribosomal subunits	Decreased platelets, white blood cell counts, headache, haemoglobin levels, diarrhoea, elevated pancreatic and liver functions

Purna Nagasree *et al.*,

Moxifloxacin (M)		It inhibits Topoisomerase ii & Topoisomerase iv enzymes which are essential for DNA replication	Nausea, vomiting, dizziness, headache, weakness, difficulty in falling sleep unusual bleeding and bruising, yellowing of the eyes and skin, and dark urine.
		<p>Fig.1: Bedaquiline CLogP: 7.2505 Mol.Wt.: 555.504 g/mol Chemical Formula: C₃₂H₃₁BrN₂O₂</p> <p>Fig.2: Linezolid CLogP: 0.168099 Mol. Wt: 337.346 g/mol Chemical Formula: C₁₆H₂₀FN₃O₄</p>

ABSTRACT

The early and accurate diagnosis of kidney diseases is crucial for effective treatment and improved patient outcomes. Automated analysis of urine samples has emerged as a reliable, cost-effective, and non-invasive diagnostic approach. This study explores the integration of advanced technologies, including image processing, machine learning, and biochemical assays, to enhance the precision and efficiency of kidney disease diagnosis. By analyzing key parameters such as protein levels, glucose, pH, specific gravity, and microscopic elements like red blood cells, white blood cells, and casts, the system provides comprehensive insights into renal health. The proposed automated system minimizes human error, reduces processing time, and enables real-time monitoring, making it a valuable tool for clinical laboratories. Results demonstrate a significant correlation between automated findings and clinical outcomes, supporting the system's potential for widespread adoption in early kidney disease detection and management.

Keywords: Automated Urine Analysis, Kidney Disease Diagnosis, Non-Invasive Diagnostics, Urinalysis Automation, Renal Health Monitoring

Vishant Pal *et al.*,

INTRODUCTION

Early medical diagnoses were grounded in what ancient physicians could observe visually and aurally, often incorporating the examination of human specimens. The ancient Greek medical tradition linked all diseases to imbalances in bodily fluids known as humors. By the late medieval era, uroscopy had become a common practice among physicians for diagnostic purposes[1,2]. Acute kidney injury (AKI) is a common condition observed in hospitalized and critically ill patients, characterized by a sudden decline in renal excretory function, often associated with other underlying illnesses[3]. The causes of AKI are typically categorized as prerenal, intrinsic renal, or postrenal. The microscopic examination of urine in AKI reveals a range of findings depending on the underlying etiology. Prerenal AKI often presents with a bland urinary sediment containing minimal hyaline casts, while intrinsic renal AKI may show muddy brown casts, coarse granular casts, epithelial cell casts, and renal tubular epithelial cells (RTEC). Additionally, findings such as hematuria, red cell fragments, red cell casts, and white cell casts can indicate glomerular involvement[4-5]. Chronic kidney disease (CKD) affects approximately 8% to 16% of the global population and often goes unrecognized by both patients and healthcare providers[6-9]. It is defined by a glomerular filtration rate (GFR) below 60 mL/min/1.73 m², albuminuria of 30 mg or more per 24 hours, or persistent markers of kidney damage—such as hematuria or structural abnormalities like polycystic or dysplastic kidneys—for a duration exceeding three months[10]. CKD is notably more prevalent in low- and middle-income countries compared to high-income nations [11].

MATERIAL AND METHODS

The study was conducted using a total of 98 urine samples collected from individuals meeting the inclusion criteria. The samples were sourced from JITM Skills Private Limited, Pathology laboratory, Noida. Ensuring a representative mix of patients with and without kidney disease.

Sample Collection and Preparation

Urine samples were collected in sterile containers following standard protocols to minimize contamination. Each sample was labeled with a unique identity and stored at 4°C, until analysis. Prior to processing, the samples were brought to room temperature and gently mixed.

RESULT

The automated analysis of urine samples for kidney disease diagnosis involved the measurement and evaluation of several key parameters. These included ketones, bilirubin, glucose, pH, protein, and blood, with the results providing valuable insights into the diagnostic process.

Glucose

Urinary glucose levels are commonly used to assess conditions such as diabetes mellitus or impaired glucose tolerance. Automated analysis of glucose concentrations in the 98 urine samples revealed the following distribution of results:

- **Normal (Negative):** 89 samples
- **Trace:** 6 samples
- **Positive:** 3 samples

The majority of the samples (89 out of 98) exhibited normal (negative) glucose levels, indicating no significant abnormality related to glucose excretion. A smaller proportion showed trace (6 samples) or positive (3 samples) glucose levels, which could suggest potential issues such as diabetes-related kidney complications in the affected individuals.

**Vishant Pal et al.,****Trace Glucose Levels (6 samples)**

Six samples exhibited trace amounts of glucose, suggesting a mild elevation in glucose excretion. This could indicate early signs of metabolic disturbances, warranting further monitoring or clinical investigation.

Positive Glucose Levels (3 samples)

Three samples displayed elevated glucose levels, indicative of potential diabetes-related kidney complications. These findings emphasize the need for further assessment of renal function and possible intervention in individuals with underlying metabolic disorders. The majority of urine samples (89 out of 98) displayed glucose levels within the normal range, suggesting no significant abnormalities related to diabetes mellitus or impaired glucose tolerance. However, a smaller subset of samples demonstrated trace and positive glucose levels, which may indicate potential underlying health concerns.

Ketones

Ketones are metabolic byproducts that can serve as indicators of conditions such as diabetic ketoacidosis or starvation. Automated analysis of urine samples revealed the following distribution of ketone levels:

- **Normal (Negative):** 97 samples
- **Elevated:** 1 sample

The majority of the samples (97 out of 98) showed normal (negative) ketone levels, suggesting no significant metabolic disturbances. However, one sample exhibited elevated ketone levels, which may point to a potential metabolic abnormality requiring further investigation. This finding emphasizes the importance of monitoring ketone levels as part of a comprehensive approach to diagnosing kidney-related metabolic conditions.

Bilirubin

Bilirubin in urine may indicate liver disease or hemolytic disorders. Automated analysis of 98 urine samples for kidney disease diagnosis revealed the following distribution of bilirubin levels:

- **Normal (Negative):** 96 samples
- **Positive Bilirubin:** 2 samples

The majority of the samples (96 out of 98) did not show detectable bilirubin, suggesting no significant bilirubinuria. However, two samples tested positive for bilirubin, which could be indicative of underlying liver-related abnormalities or hemolysis affecting the urinary system. These findings highlight the importance of bilirubin monitoring in the context of kidney disease diagnosis, particularly for detecting potential hepatic or hematological issues. The automated analysis effectively identified bilirubin levels, aiding in the differential diagnosis of kidney diseases linked to systemic abnormalities. These findings underscore the capability of automated urine analysis in detecting and quantifying critical biomarkers associated with kidney disease. By integrating advanced technologies such as biochemical assays and image processing algorithms, the system enabled a rapid, objective assessment, ultimately improving diagnostic accuracy and efficiency in clinical settings.

pH

Urine pH is a critical parameter for assessing acid-base balance and renal function. Automated analysis of pH values in the 98 urine samples revealed the following results:

- **pH 5.5:** 2 samples
- **pH 6.0:** 13 samples
- **pH 7.0:** 1 sample
- **pH 7.5:** 1 sample
- **Normal pH (within range):** 81 samples

The majority of the samples (81 out of 98) exhibited normal pH levels, typically ranging from 5.0 to 7.5, indicating a balanced acidity/alkalinity in the urine. A small number of samples exhibited pH values outside this range, suggesting potential deviations in renal function:

**Vishant Pal et al.,**

- Two samples with a pH of 5.5 indicated increased acidity, which could suggest renal tubular dysfunction or other metabolic disturbances.
- Thirteen samples with a pH of 6.0 were slightly below the normal range, potentially reflecting early signs of renal imbalance or dietary influences.
- One sample with a pH of 7.0 was within the upper limit of the normal range, while another sample with a pH of 7.5 was at the upper end, indicating mild alkalinity. The analysis of urine pH levels revealed variability, with a small subset of samples displaying abnormal acidity or alkalinity. This highlights the significance of comprehensive urine analysis in evaluating renal function and maintaining acid-base balance. Further investigation of cases with abnormal pH, in conjunction with other clinical parameters, may offer valuable insights into underlying metabolic disorders or renal dysfunction. Automated urine analysis proves to be an effective screening tool for identifying subtle imbalances in the urinary tract, supporting early detection and timely management of kidney-related conditions.

Protein

Proteinuria, defined as the presence of excess protein in the urine, is a key indicator of kidney disease. Automated analysis of protein levels in the 98 urine samples yielded the following results:

- **Normal (Negative):** 92 samples
- **Trace Proteinuria:** 3 samples
- **Positive Proteinuria:** 3 samples

The majority of the samples (92 out of 98) exhibited normal protein levels, indicating no significant proteinuria and suggesting intact glomerular filtration in these cases. These findings underscore the importance of protein quantification in diagnosing renal abnormalities, as deviations from normal levels may indicate underlying glomerular damage or other renal dysfunctions.

Protein levels in the urine were within the normal range in the majority of samples, indicating an absence of significant proteinuria or renal dysfunction.

- **Trace Proteinuria (3 samples):** Trace amounts of protein were detected in three samples, indicating a mild elevation that may require further evaluation or ongoing monitoring.
- **Positive Proteinuria (3 samples):** Elevated protein levels were identified in three samples, consistent with proteinuria, a hallmark of kidney disease. These findings suggest the presence of underlying renal pathology in these individuals.

Blood

The presence of blood in urine (hematuria) is a significant finding that can indicate various conditions, including urinary tract infections or kidney stones. Automated analysis of urine samples detected blood cells in the sediment, contributing to the identification of underlying kidney pathologies.

The analysis of 98 urine samples for kidney disease diagnosis revealed the following distribution:

- **Normal (Negative):** 90 samples
- **Trace Hematuria:** 2 samples
- **Positive Hematuria:** 6 samples

The majority of samples (90 out of 98) demonstrated no detectable blood, indicating the absence of hematuria in these cases. However, two samples showed trace amounts of blood, suggesting mild hematuria that may warrant further investigation. Six samples exhibited positive hematuria, pointing to potential underlying renal or urinary tract abnormalities.

These findings emphasize the role of automated urine analysis in detecting hematuria and its significance in diagnosing kidney-related conditions.

Blood was absent in the majority of urine samples, indicating no significant hematuria or evidence of renal bleeding.

- **Trace Hematuria (2 samples):** Trace amounts of blood were detected in two samples, indicating a minor presence that may require additional evaluation.

**Vishant Pal et al.,**

- **Positive Hematuria (6 samples):** Six samples showed elevated levels of blood in the urine, consistent with hematuria. This finding suggests the possibility of underlying kidney pathology or other conditions impacting the urinary tract.

DISCUSSION

Automated urine analysis proves to be an efficient and reliable method for evaluating biomarkers related to kidney disease and systemic conditions.

Glucose

Most samples (89/98) were normal, with trace (6) and positive (3) levels indicating potential diabetes or metabolic disorders. Early detection of glycosuria can aid in identifying diabetic complications.

Ketones

Only one sample showed elevated ketones, highlighting a low prevalence of metabolic disturbances such as ketoacidosis or starvation.

Bilirubin

Positive bilirubin in 2 samples suggests potential liver or hemolytic abnormalities, reinforcing its importance in systemic evaluations.

pH

While 81 samples showed normal pH, deviations (e.g., acidic or alkaline values) in a few cases suggest possible renal tubular dysfunction or metabolic imbalances.

Protein

Proteinuria was absent in 92 samples, with trace (3) and positive (3) levels indicating potential glomerular damage or early renal pathology.

Blood

Hematuria was detected in 8 samples (2 trace, 6 positive), pointing to possible infections, stones, or glomerulonephritis. These findings demonstrate the utility of automated urine analysis in early disease detection and monitoring. By enabling rapid, objective assessments, it supports timely interventions and improves diagnostic accuracy in clinical practice. Future studies should validate these findings over larger populations and integrate additional biomarkers for enhanced diagnostic capabilities.

Conflict of Interest

The authors declare no conflict of interest. The study was conducted independently, without any financial or commercial influence that could affect the research outcomes. All data analysis, interpretation, and reporting were carried out with the sole objective of advancing scientific knowledge and improving clinical diagnostics.

ABSTRACT

In this paper, I present new type of N-cld sets within NI-cld, NI-open sets, along with various properties associated with them.

Keywords: NI-cld, NI-open, $N\hat{g}$ -cld, NI-int, NI-cl.

INTRODUCTION

Topology is a division of Mathematics, primarily aimed at clarifying and exploring the notions of continuity within the Mathematics. Introduced [5] the weakly open sets, which they defined via approximations and boundary regions of a subset from a universe U utilizing an equivalence relation, alongside definitions for nano closed sets, nano interior, and nano closure. Similarly, S. Jafari and T. Noiri [4], introduced the another generalization of closed sets. Furthermore, introduced [3] on nano semi-generalized closed sets.

PRELIMINARIES

Throughout this paper U constitute nano topological spaces (NTPS) on which no separation axioms are assumed except in any other case mentioned.

Definition 2.1.[5]

Let U be a non-empty finite set of objects called the universe and R be an equivalence relation on U . The pair (U, R) is said to be the approximation space. Let $X \subseteq U$.

Amala Priya

1. The lower approximation of X w.r.t R , $L_R(X) = \cup\{R(X): R(X) \subseteq X, x \in U\}$ where $R(X)$ denotes the equivalence class determined by $x \in U$.
2. The upper approximation of X w.r.t R , $U_R(X) = \cup\{R(X): R(X) \cap X \neq \Phi, x \in U\}$.
3. The boundary region of X w.r.t R , $Br(X) = U_R(X) - L_R(X)$.

Definition 2.2. [5]

Let U be the universe, R be an equivalence relation on U and $\tau_R(X) = \{\Phi, L_R(X), U_R(X), Br(X), U\}$ where $X \subseteq U$. Then $U_R(X)$ satisfies the following axioms:

1. Φ and $U \in \tau_R(X)$.
2. The union of the elements of any sub-collection of $\tau_R(X)$ is in $\tau_R(X)$.
3. The intersection of the elements of any finite subcollection of $\tau_R(X)$ is in $\tau_R(X)$.

Then $(U, \tau_R(X))$ is called the nano topological space (NTPS).

Definition 2.3

Let $K \subseteq U$. Then K is called

- (i) NSO [3] if $K \subseteq Ncl(Nint(K))$.
- (ii) NPO [2] if $K \subseteq Nint(Ncl(K))$.
- (iii) NRO [6] if $K = Nint(Ncl(K))$.
- (iv) NSPO [3] if $K \subseteq Ncl(Nint(Ncl(K)))$.
- (v) $N\alpha O$ [1] if $K \subseteq Nint(Ncl(Nint(K)))$.

Definition 2.4

Let $K \subseteq U$. Then K is called

1. Ng-cld [7] if $Ncl(K) \subseteq M$ where $K \subseteq M$ and M is NO.
2. Ngp-cld [6] if $Npcl(K) \subseteq M$ where $K \subseteq M$ and M is NO.
3. Ngsp-cld [3] if $Nspcl(K) \subseteq M$ where $K \subseteq M$ and M is NO.
4. $Ng\alpha$ -cld [5] if $N\alpha cl(K) \subseteq M$ where $K \subseteq M$ and M is NO.
5. $N\hat{g}$ -cld [6] if $Ncl(K) \subseteq M$ where $K \subseteq M$ and M is NSO.
6. N^*g -cld [7] if $Ncl(K) \subseteq M$ where $K \subseteq M$ and M is $N\omega O$.
7. Nsg-cld [4] if $Nscl(K) \subseteq M$ where $K \subseteq M$ and M is NSO.
8. Ngs-cld [7] if $Nscl(K) \subseteq M$ where $K \subseteq M$ and M is NO.
9. $N\alpha g$ -cld [4] if $N\alpha cl(K) \subseteq M$ where $K \subseteq M$ and M is $N\alpha O$.

NEW TYPE OF NI-cld sets

Definition 3.1

Let K be NI-closed (NI-cld) if $Nsgcl(K) \subseteq M$ where $K \subseteq M$ and M is $N\hat{g}O$.

Proposition 3.2

Each N-cld \Rightarrow NI-cld.

Proof

Let K be a N-cld and $K \subseteq U$. Let $K \subseteq M$ and M is every $N\hat{g}O$. Then K is N-cld, $Ncl(K) = K$. Since each N-cld is NS-cld, $Nsgcl(K) \subseteq Ncl(K) = K \subseteq M$. Therefore $Nsgcl(K) \subseteq V$ and K is NI-cld.

Remark 3.3

The reverse of the above proposition doesn't necessarily hold.

Amala Priya

Example 3.4

Consider $\mathbb{U} = \{n_1, n_2, n_3, n_4\}$; $\mathbb{U}/R = \{\{n_1\}, \{n_3\}, \{n_2, n_4\}\}$ and $X = \{n_1, n_2\}$. We have $\tau_R(X) = \{\Phi, \{n_1\}, \{n_2, n_4\}, \{n_1, n_2, n_4\}, \mathbb{U}\}$. Here $\{n_1\}$ is NI-cld, $\{n_1\}$ isn't N-cld.

Proposition 3.5

Each NR-cld \Rightarrow NI-cld.

Proof

Let K be a NR-cld and $K \subseteq \mathbb{U}$. Let $K \subseteq M$ and M is $N\hat{g}O$. Then K is NR-cld, we have $Nrcl(K) = K$. Since each NR-cld is N-cld, $Ncl(K) \subseteq Nrcl(K)$. Since each N-cld is NS-cld, $Nsgcl(K) \subseteq Ncl(K)$. We have $Nsgcl(K) \subseteq Nrcl(K) = K \subseteq M$. Therefore $Nsgcl(K) \subseteq M$ and K is NI-cld.

Remark 3.6

The reverse of the above proposition doesn't necessarily hold.

Example 3.7

Consider $\mathbb{U} = \{n_1, n_2, n_3, n_4\}$; $\mathbb{U}/R = \{\{n_1\}, \{n_3\}, \{n_2, n_4\}\}$ and $X = \{n_1, n_2\}$. We have $\tau_R(X) = \{\Phi, \{n_1\}, \{n_2, n_4\}, \{n_1, n_2, n_4\}, \mathbb{U}\}$. Here $\{n_2, n_4\}$ is NI-cld, $\{n_2, n_4\}$ isn't NR-cld.

Proposition 3.8

Each N^*g -cld \Rightarrow NI-cld.

Proof

Let K be a N^*g -cld and $K \subseteq \mathbb{U}$. Let $K \subseteq M$ and M is $N\hat{g}O$. Since K is N^*g -cld, $Ncl(K) \subseteq M$. Also since each N-cld is NS-cld, $Nsgcl(K) \subseteq Ncl(K) \subseteq M$. Therefore $Nsgcl(K) \subseteq M$ and K is NI-cld.

Remark 3.9

The reverse of the above proposition doesn't necessarily hold.

Example 3.10

Consider $\mathbb{U} = \{n_1, n_2, n_3, n_4\}$; $\mathbb{U}/R = \{\{n_1\}, \{n_3\}, \{n_2, n_4\}\}$ and $X = \{n_1, n_2\}$. We have $\tau_R(X) = \{\Phi, \{n_1\}, \{n_2, n_4\}, \{n_1, n_2, n_4\}, \mathbb{U}\}$. Here $\{n_2, n_4\}$ is NI-cld, $\{n_2, n_4\}$ isn't N^*g -cld.

Proposition 3.11

Each NI-cld \Rightarrow Ngsp-cld.

Proof

Let K be a NI-cld and $K \subseteq \mathbb{U}$. Let $K \subseteq M$ and M is N-open. Since each NS-cld is NSP-cld and K is NI-cld. Therefore $Nspcl(K) \subseteq Nsgcl(K) \subseteq M$. Therefore $Nspcl(K) \subseteq M$ and K is Ngsp-cld.

Remark 3.12

The reverse of the above proposition doesn't necessarily hold.

Example 3.13

Consider $\mathbb{U} = \{n_1, n_2, n_3, n_4\}$; $\mathbb{U}/R = \{\{n_2\}, \{n_3\}, \{n_1, n_4\}\}$ and $X = \{n_1, n_2\}$. We have $\tau_R(X) = \{\Phi, \{n_2\}, \{n_1, n_4\}, \{n_1, n_2, n_4\}, \mathbb{U}\}$. Here $\{n_1, n_2\}$ is Ngsp-cld $\{n_1, n_2\}$ isn't NI-cld.

Proposition 3.14

Each NI-cld \Rightarrow Nsg-cld.

Amala Priya

Proof

Let K be a NI-cld and $K \subseteq U$. Let $K \subseteq M$ and M is N-open. Since each Nano open is $N\hat{g}O$ and K is NI-cld, $Nsgcl(K) \subseteq M$. Therefore K is Nsg-cld.

Remark 3.15

The reverse of the above proposition doesn't necessarily hold.

Example 3.16

Consider $U = \{a_1, b_1, c_1, d_1\}$; $U/R = \{\{b_1\}, \{c_1\}, \{a_1, d_1\}\}$ and $X = \{a_1, b_1\}$. We have $\tau_R(X) = \{\Phi, \{b_1\}, \{a_1, d_1\}, \{a_1, b_1, d_1\}, U\}$. Here $\{d_1\}$ is Nsg-cld, $\{d_1\}$ isn't NI-cld.

Remark 3.17

The reverse of the above proposition doesn't necessarily hold.

Example 3.18

Consider $U = \{n_1, n_2, n_3, n_4\}$; $U/R = \{\{n_1\}, \{n_3\}, \{n_2, n_4\}\}$ and $X = \{n_1, n_2\}$. We have $\tau_R(X) = \{\Phi, \{n_1\}, \{n_2, n_4\}, \{n_1, n_2, n_4\}, U\}$. Here $\{n_2, n_3\}$ is Ng-cld, $\{n_2, n_3\}$ isn't NI-cld.

Example 3.19

Here the above Example 3.18, $\{n_2, n_4\}$ is NI-cld but not Ng-cld.

Remark 3.20

The reverse of the above proposition doesn't necessarily hold.

Example 3.21

Consider $U = \{a_1, b_1, c_1, d_1\}$; $U/R = \{\{a_1\}, \{b_1\}, \{c_1, d_1\}\}$ and $X = \{a_1, c_1\}$. We have $\tau_R(X) = \{\Phi, \{a_1\}, \{c_1, d_1\}, \{a_1, c_1, d_1\}, U\}$. Here $\{d_1\}$ is Ngp-cld, $\{d_1\}$ isn't NI-cld.

Example 3.22

In Example 3.21, Here $K = \{c_1, d_1\}$ is NI-cld, K isn't Ngp cld.

Remark 3.23

NI-cld and Nsg-cld are independent.

Example 3.24

Consider $U = \{a_1, b_1, c_1, d_1\}$; $U/R = \{\{a_1\}, \{d_1\}, \{b_1, c_1\}\}$. Let $X = \{a_1, c_1\}$. We have $\tau_R(X) = \{\Phi, \{a_1\}, \{b_1, c_1\}, \{a_1, b_1, c_1\}, U\}$. Here $\{a_1, b_1\}$ is Nsg-cld, $\{a_1, b_1\}$ isn't NI-cld and $\{b_1, c_1\}$ is NI-cld, $\{b_1, c_1\}$ is not Nsg-cld.

Remark 3.25

We obtain the following diagram

Amala Priya

SOME PROPERTIES OF NI-CLD SETS

Theorem 4.1

If $K \subseteq U$ is NI-cld such that $K \subseteq L \subseteq \text{Nscl}(K)$. Show that L is also NI-cld.

Proof

Let V be $\hat{N}\hat{g}O$ in U such that $L \subseteq M$. Then $K \subseteq M$. Since K is NI-cld, $\text{Nscl}(K) \subseteq M$. We have, $\text{Nscl}(L) \subseteq \text{Nscl}(\text{Nscl}(K)) = \text{Nscl}(K) \subseteq M$. Then $\text{Nscl}(L) \subseteq M$ and L is NI-cld.

Theorem 4.2

If K is $\hat{N}\hat{g}O$ and NI-cld, then K is NS-cld.

Proof

Let $K \subseteq K$ where K is $\hat{N}\hat{g}O$ and NI-cld. Then $\text{Nscl}(K) \subseteq K$ and $K \subseteq \text{Nscl}(K)$. Therefore $K = \text{Nscl}(K)$ and K is NS-cld.

Theorem 4.3

If K and L are NI-cld in U , prove that $K \cup L$ is NI-cld.

Proof

Consider K and L be each two NI-cld in U s.t $K \subseteq M$ and $L \subseteq M$ where M is $\hat{N}\hat{g}O$ in U . Therefore $K \cup L \subseteq M$. Then K and L are NI-cld, $\text{Nscl}(K) \subseteq M$ and $\text{Nscl}(L) \subseteq M$. We have $\text{Nscl}(K) \cup \text{Nscl}(L) \subseteq M$. Then $\text{Nscl}(K \cup L) \subseteq M$ and $K \cup L$ is NI-cld.

Theorem 4.4

If K and L are NI-cld in U , show that $K \cap L$ is NI-cld.

Proof

Consider K and L be each two NI-cld in U s.t $K \subseteq M$ and $L \subseteq M$ where M is $\hat{N}\hat{g}O$ in U . Therefore $K \cap L \subseteq M$. Then K and L are NI-cld, $\text{Nscl}(K) \subseteq M$ and $\text{Nscl}(L) \subseteq M$. Therefore $\text{Nscl}(K) \cap \text{Nscl}(L) \subseteq V$. Then $\text{Nscl}(K \cap L) \subseteq V$ and $K \cap L$ is NI-cld.

Theorem 4.5

For all $x \in U$, either $\{x\}$ is $\hat{N}\hat{g}$ -cld or $\{x\}^c$ is NI-cld.

Proof

If $\{x\}$ is not $\hat{N}\hat{g}$ -cld. Then $\{x\}^c$ isn't $\hat{N}\hat{g}O$. Then only $\hat{N}\hat{g}O$ containing $\{x\}^c$ is the space U itself. Then $\text{Nscl}(\{x\}^c) \subseteq U$ and so $\{x\}^c$ is NI-cld.

Amala Priya

Theorem 4.6

If a subset K of \mathbb{U} is NI-cld iff $\text{Nscl}(K) - K$ contains no non-empty $\text{N}\hat{g}$ -cld.

Proof

Let K be a NI-cld . Let F be a non-empty $\text{N}\hat{g}$ -cld subset of $\text{Nscl}(K) - K$. We have $F \subseteq \text{Nscl}(K) - K$. Then $F \subseteq \text{Nscl}(K) - (\mathbb{U} - F)$. Since $\mathbb{U} - F$ is $\text{N}\hat{g}\text{O}$ and K is NI-cld , $\text{Nscl}(K) \subseteq \mathbb{U} - F$. Then $\text{Nscl}(K) \subseteq F^c$ and $F \subseteq [\text{Nscl}(K)]^c$, $F \subseteq \text{Nscl}(K) \cap [\text{Nscl}(K)]^c = \Phi$. Which is a contradiction. Then $\text{Nscl}(K) - K$ does not contain any non-empty $\text{N}\hat{g}$ -cld.

ABSTRACT

Triage is done in emergency rooms, disasters and wars, to prioritize care to save maximum number of lives. It helps to identify the urgent needs among patients. Triage knowledge among nurses is important for supervision in emergency department. 1) To assess the pre-test and post-test level of knowledge regarding triage among 4th Year B.Sc. Nursing students. 2) To evaluate the effect of Structured Teaching Programme regarding triage among 4th Year B.Sc. Nursing students. 3) To determine the association between pre-test knowledge scores regarding triage with the selected demographic variables. The research approach and design adopted for this study is quantitative pre-experimental one group pre-test post-test design. The study was conducted at CPMS College of Nursing, PEWS Group of Institutions, Guwahati, Assam among 4th Year B.Sc. Nursing students. 60 nos (Sixty) of 4th Year B.Sc. Nursing students were selected by using non-probability purposive sampling technique. The tools used in the study were demographic pro form a and Self -Structured knowledge questionnaires regarding triage (Total no. of items were 30) were used to assess the knowledge regarding triage. Descriptive and Inferential statistics were used to analyse the data. Results revealed that pre-test mean with standard deviation was 15.23±4.09 and post-test mean with standard deviation was 22.95±2.45 using paired 't' test ($t=15.07$ at $p<0.001$). The result suggests that Structured Teaching Programme was effective in improving the knowledge of students regarding triage. Moreover, it indicates a significant correlation between pre-test knowledge scores and clinical exposure to accident and emergency ward during postings.

Keywords: effect, structured teaching programme, knowledge, triage, 4th Year B.Sc. Nursing students.

**Smita Limbu and Yumnam Chanu Superior**

INTRODUCTION

Triage is the process of sorting people based on their need for immediate medical treatment as compared to their chance of benefiting from such care. Triage is done in emergency rooms, disasters, and wars, when limited medical resources must be allocated to maximize the number of survivors. An accurate triage decision helps the patients to receive the emergency care in the most appropriate time. [1] Triage is putting the patient in the right place at the right time to receive the right level of care and the allocation of appropriate resources to meet the patient's medical needs'. This place of the hospital allows for assignment of the care taker to suitable assessment and treatment place. [2] Triage knowledge among nurses is one of the key elements of supervision in emergency department, if it is not carried out at standard level; the outcomes of clinical care of patients and efficiency of emergency departments get compromised. As emergency departments are struggling to cope with overcrowding there is a critical need for a valid, reliable triage acuity rating system in order to sort these incoming patients more rapidly and accurately.[3] The World Health Organization believes that nurses and midwives are frontline workers under stable conditions but more so during situations of emergencies in Hospital settings. In order to contribute to saving lives and promoting health under such difficult conditions, they need to have the adequate knowledge. Hence, the nursing staff must show the ability for critical thinking in demonstrating best standard. [4]

Objectives of the study

1. To assess the pre-test and post-test level of knowledge regarding triage among 4th Year B.Sc. Nursing students
2. To evaluate the effect of Structured Teaching Programme regarding triage among 4th Year B.Sc. Nursing students.
3. To determine the association between pre-test knowledge scores regarding triage with the selected demographic variables.

MATERIALS AND METHODS

A pre-experimental one-group pre-test post-test design was used for the study to accomplish the objectives. 60nos(Sixty) 4th Year B.Sc. Nursing students studying in CPMS College of Nursing, PEWS Group of Institutions participated in the study from 27th January – 2nd February 2024. Formal permission for data collection was taken from the concerned authority of CPMS College of Nursing, PEWS Group of Institutions, Guwahati, Assam before the data collection procedure. Informed consent was taken from the participants and confidentiality was maintained. Pre-test was conducted on the first day by using knowledge questionnaires to assess the knowledge regarding triage among 4th Year B.Sc. Nursing students. Structured Teaching Programmeregarding triage was administered for 45 minutes using pamphlet, chart, handout, power-point presentation and whiteboard. Post test was conducted on the 7th day by using the same knowledge questionnaires. Descriptive and Inferential statistics were used to analyse the data. The frequency and percentage was calculated to assess the knowledge of students.

RESULTS

Section A

Frequency and percentage distribution of demographic variables.

The sample of the study consists of 60 students of 4th Year B.Sc. Nursing of CPMS College of Nursing, PEWS Group of Institutions. Non- probability purposive sampling technique was used. In this section, data collected were analyzed by using descriptive statistics and presented in terms of frequency and percentage distribution. The following are presented in Table 1. The table 1 shows the frequency and percentage distribution of demographic variables of 4th Year B.Sc. Nursing students of selected nursing college. Data analysis shows that out of 60 students, 42(70%) were of the age of 23 years & above and 18(30%) were of the age of 21-22 years. 57 (95%) of the participants were females and 3(5%) were males. 54 students (90%) had exposure to accident and emergency ward during clinical posting and 6

students (10%) had no exposure to accident and emergency ward during clinical posting. 53 students (88%) had previous training on triage and 7 students (12%) had no previous training on triage.

Section B

Description of knowledge of students regarding triage.

This section represents the findings in frequency and percentage distribution related to the pre- test and post-test level of knowledge regarding triage among 4thYear B.Sc. Nursing students. The level of knowledge of 4th Year B.Sc. Nursing students regarding triage was assessed using Self-Structured knowledge questionnaire. Based on the score obtained, the students were arbitrarily categorized as adequate, moderately adequate and inadequate knowledge. The frequency and percentage distribution of pre-test and post-test knowledge are presented on Table 2. **TABLE 2.** depicts the frequency and percentage distribution of level of knowledge score regarding triage among 4th Year B.Sc. Nursing students. Results revealed that in pre-test, majority of the participants i.e., 43 (71.7%) had moderately adequate knowledge, 11 (18.3%) had adequate knowledge and 6(10%) had inadequate knowledge. However, in post-test, majority of the participants i.e., 50 (83.3%) had adequate knowledge and 10(16.7%) had moderately adequate knowledge.

Section C

Effect of Structured Teaching Programme on knowledge regarding triage among 4thYear B.Sc. nursing students

The pre-test and post-test knowledge score obtained by the 4th Year B.Sc. Nursing students regarding triage were tabulated in terms of mean, standard deviation, mean difference and paired *t* value.

S*=Significant at $p<0.001$

NS = Non significant

Table 3 shows that the pre-test mean knowledge score among 4th Year B.Sc. Nursing students was 15.23 ± 4.09 and post-test mean knowledge score was 22.95 ± 2.45 . The calculated '*t*' test value of $t=15.07$ was found to be statistically significant at $p<0.001$ level.

Section D

Association between pre-test knowledge regarding triage with selected demographic variables among 4th Year B.Sc. Nursing students.

This section represents the association of the pre-test level of knowledge regarding triage among 4thYear B.Sc. Nursing students with their selected demographic variables. Chi square was computed to find the significant association between pre-test knowledge regarding triage among 4th Year B.Sc. Nursing students with their selected demographic variables. The data is presented in Table 4.

S*** - Significant at $p<0.001$

NS – Non significant

The table 4 shows that the association of knowledge score regarding emergency triage was significant ($\chi^2=1.25$, $p=0.002$) with the demographic variable exposure to accident and emergency ward during clinical posting at $p<0.001$ level of significance among 4th Year B.Sc. Nursing students and the other demographic variables did not show statistically significant association with pre-test level of knowledge regarding triage among 4th Year B.Sc. Nursing students with their selected demographic variables. Therefore, there is association between the pre-test knowledge regarding triage and exposure to accident and emergency ward during clinical posting.

DISCUSSION

The present study was designed to assess the knowledge regarding triage. The research design adopted for the study was One Group Pre-test Post-test design. Non probability purposive sampling technique was used to select 60 students for the study. The data were analysed statistically and discussed based on the objectives.

**Smita Limbu and Yumnam Chanu Superior**

The first objective of the study was to assess the level of knowledge regarding triage among 4th Year B.Sc. Nursing students.

The finding of the present study reveals that in the pre-test, 43(71.7%) i.e., majority of the students had moderately adequate knowledge, 11(18.3%) had adequate knowledge and 6(10%) had inadequate knowledge on triage whereas in the post-test after the Structured Teaching Programme, 50(83.3%) had adequate knowledge and 10(16.7%) had moderately adequate knowledge. The present study is supported by a study of **Khan S, Fatima B(2024)** to assess the knowledge regarding emergency triage among student nurses in selected institutions, Jalandhar. The finding shows that the mean knowledge was 20.16 (± 3.62). As per level of knowledge more than half of the student nurses i.e. 54 (54%) were having average knowledge regarding emergency triage. [5]

The second objective was to assess the effect of Structured Teaching Programme on knowledge regarding triage among 4th Year B.Sc Nursing students.

The pre-test mean score of knowledge among 4th Year B.Sc. Nursing students was 15.23 \pm 4.09 and the post-test mean score of knowledge was 22.95 \pm 2.45. The mean difference score was 7.72. The calculated paired 't' test value of t = 15.07 was found to be statistically significant at p < 0.001 level. This clearly infers that administration of Structured Teaching Programme on knowledge regarding triage was effective in increasing the level of knowledge among 4th Year B.Sc. Nursing students. The present study is supported by a study done by **Supriya R, Gondhuli G, Swastika D (2021)** to assess the effectiveness of structured teaching programme on knowledge and skill regarding management of patients admitted in hospital triage setting among the staff nurses at Era Hospital Lucknow. In the pre-test, among 30 staff nurses, 5(16.66%) were having poor level of knowledge, 22(73.33%) were having average level of knowledge and 3(10%) were good level of knowledge. In the post-test, among 30 staff nurses, 2(6.66%) were having poor level of knowledge, 8(26.66%) were having average level of knowledge and 20(66.66%) were good level of knowledge. [6]

The third objective of the study was to determine the association between pre-test knowledge regarding triage with the selected demographic variables.

The demographic variable exposure to accident and emergency ward during clinical posting ($\chi^2 = 1.25$, $p = 0.002$) has shown statistically significant association with pre-test level of knowledge regarding triage among 4th Year B.Sc. Nursing students at p < 0.001 level and the other demographic variables has not shown statistically significant association with pre-test level of knowledge regarding triage among 4th Year B.Sc. Nursing students. The present study is supported by a study of **Arora A, Thomte H, Swati, Johnson TA, Singh C, Parashar D et al.** to assess the effectiveness of structured teaching program on knowledge regarding triage among the nursing students of selected schools of Greater Noida. According to the study's findings, the majority of pre-test respondents had inadequate knowledge (78.46%), moderate knowledge (20%), good knowledge (1.54%), and very good knowledge (0%). As opposed to this, in the post-test, the maximum percentage of respondents who knew about triage was 38.46%, 32.31% knew it very well, 24.62% knew it averagely and 4.62% knew it poorly. Additionally, it is discovered that, at the p < 0.05 level of significance, there is a significant correlation between nursing students' knowledge scores and a few socio demographic variables, such as whether they have attended disaster management seminars or workshops, are posted in an emergency ward, and are actively involved in managing disaster situations. [7]

CONCLUSION

The present study was conducted to assess the effect of Structured Teaching programme on knowledge regarding triage among 4th Year B.Sc. Nursing students of selected Nursing college of Guwahati, Assam. The findings of the study revealed that the total post-test knowledge score is significantly higher than pre-test as evidenced by t = 15.07 which indicated that STP is effective. It also reveals that there was a significant association between exposure to accident and emergency ward during clinical posting and the pre-test knowledge score regarding triage among 4th Year B.Sc. Nursing students.

ABSTRACT

Anemia is a significant health concern among women aged 15–49 in the northeastern region of India, a region characterized by its unique cultural and geographical features. To assess trends and identify key socio-economic, demographic, and dietary determinants of anemia prevalence among women of reproductive age in Northeast India, using data from NFHS-4 and NFHS-5. This cross-sectional study used NFHS data to assess anemia in women aged 15–49. Bivariate logistic regression calculated crude odds ratios (COR) for each predictor. Multivariate logistic regression, with adjusted odds ratios (AOR) and 95% confidence intervals (CI), controlled for confounders. Statistical significance was set at $p < 0.05$. Women's residence, childbirth, education, wealth, ethnicity, and marital status have a significant impact on the prevalence of anemia. Contradictory findings have been observed among women who never consume fish, vegetables, and aerated drinks. Young (adolescent) and non-pregnant women are found to be most vulnerable, which is a serious concern as it may affect the growth and development of the future generation. Enhancement of women's nutritional education and empowerment may contribute to a great extent to reduce the problem of anemia.

Keywords: Anemia, reproductive-age, women, socio-economic, demographic, diet, logistic regression, Northeast-India

INTRODUCTION

Anemia is a warning sign of serious illness, and iron deficiency is considered to be the most common anemia and nutritional disorder worldwide[1]. In the era of advanced science and technology, more than a quarter of the world's population is suffering from anemia, and about half of this burden is caused due to deficiency of iron[2]. Although iron deficiency anemia rarely causes death, it has a considerable negative influence on human health and affects a major portion of the population in undeveloped nations, especially women from low and middle-income nations[1,2]. Around 2 billion people worldwide suffer from nutritional anemia, with iron deficiency identified as the primary cause[3]. The prevalence of anemia among non-pregnant women aged 15–49 years has changed a little between 2000 and 2019, from 31% to 30% while the prevalence decreased from 41% to 36% among pregnant women aged 15–49 years [4]. Nutritional deficiency affects individuals all over the world, particularly in developing countries than in developed countries, and females are more likely to be anemic than males where the socio-economic status of people dominates anemia level [4,5]. The National Family Health Survey (2015–2016) found that 53% of women in India were anemic, indicating the country's ongoing high anemia rate [6] In India, the issue of iron deficiency anemia continues to be a serious problem, with more than 15 states having a high prevalence of anemia (>55%), primarily in socially disadvantaged groups, between 2019 and 2021. Most Indian states (eastern, northeastern, and central) have experienced that reproductive women are more susceptible to anemia due to low nutritional intake. Anemia affects northern women more than southern women, and the southern states of India are in much better position than the other states [7]. The high prevalence of anemia among women in India, particularly in the North-East region, is a significant health problem that affects maternal mortality rates[8]. In northeast India, the prevalence of anemia varies within the region and within the states along with their changing socio-economic characteristics, and women are adversely affected by anemia over time [8]. About 40% of women had anemia, which is a significant frequency among women in the northeastern region of India [9]. Additionally, the prevalence of anemia among pregnant women in a rural farming population in Northeast India is almost 90%, which is higher than the national average of 65-70% [10]. As the prior research has not yet provided a clear explanation of the factors that increase the prevalence of anemia in North-East Indian reproductive women [8,9,10,19]. Therefore, with the sharp rise of anemia noticed in the northeastern region of India, this study aimed to assess the trend and identify the significant determinants responsible for the prevalence of anemia with respect to socio-economic, demographic, and dietary factors, including all women of reproductive age in Northeast India, by using NFHS-4 and NFHS-5.

MATERIALS AND METHODS:

Data Source

The present study utilizes the data on anemia from the two rounds of the National Family Health Survey (NFHS), which were carried out by the Ministry of Health and Family Welfare of the Government of India, with the International Institute for Population Science acting as the nodal organization.¹² It uses secondary data from NFHS-4 (2015–2016) and NFHS-5 (2019–2021) on anemia among women in the northeastern states (Arunachal Pradesh, Assam, Manipur, Meghalaya, Mizoram, Nagaland, Tripura, and Sikkim) of India, with a sample size of 100435 in NFHS-5 and 96352 in NFHS-4 who are between the ages of 15 and 49.

Variable Measurement

The dependent variable is classified dichotomously as 'anemic' and 'non-anemic'. The socio-economic factors include place of residence, educational level, religion, ethnicity, wealth status, children ever born, and pregnancy status of women. Demographic factors include the age and marital status of women. Among dietary factors, the frequency of diet intake for various types of nutritional foods, such as pulses or beans, fruits, eggs, vegetables, fish, fried foods, chicken or meat, as well as the consumption of milk or curd and aerated beverages, has been included in the analysis.

Data Analysis

Data were entered and analyzed using SPSS Version 26 for Windows. Descriptive statistics are presented as percentages, where appropriate. The odds ratio (OR) is computed to determine the association between outcome and

**Sabrina Sultana Rahman and Ruma Talukdar**

predictor variables. Bivariate logistic regression analysis is initially conducted to examine the individual association between each predictor variable and anemia among women aged 15–49. This is followed by multivariate logistic regression analysis to identify trends in anemia while controlling for potential confounding variables. Findings from both NFHS surveys are presented as crude odds ratios (COR) and adjusted odds ratios (AOR) with 95% confidence intervals (CI). The AOR measures the strength of statistical associations, with a p-value <0.05 indicating statistical significance.

RESULTS

Trends of anemia

The trend of anemia among northeastern women has significantly increased from 38.7% in NFHS-4 to 50.1% in NFHS-5. This cross-sectional study has shown an overall increment of 11.4% (Fig. 1). With respect to different respondents' characteristics, the trend of anemia has shown different variations. Anemia has increased among women in all age groups. Age groups 15–19 and 40–44 have witnessed the highest (15.90%) and the lowest (9.10%) rates, respectively. Increment of anemia in women is slightly more in rural areas (10.90%) as compared to urban areas (10.50%), while a huge difference in increment is seen among non-pregnant anemic women (11.8%) and pregnant anemic women (3.90%). Among uneducated women, the trend of anemia has risen from 44.5% in 2015–16 to 53.9% in 2019–21. In all marital statuses—never in union, married, widowed, divorced, or separated women, the level of anemia showed an increase of above 10%. Anemia has risen by 9.20% among women who belong to the poorest wealth index. Muslim women are found to be more anemic, with an increase of 17.50%, followed by Hindu women at 17.30%. Although both in NFHS-4 and NFHS-5 the highest percentage of anemia is seen among women who don't know their ethnicity (51.0% in 2015-16 and 65.7% in 2019-21), but increment is seen more among those who belong to caste (17.70%). Also, an equal increment of 9% is seen among women with three, four or more child. As per the diet pattern, a high increment in anemia is seen among northeastern women who daily consume fried foods (15.90%) and aerated drinks (12.70%). Women's daily consumption of milk or curd has increased by the least amount, 9.20%. An equal increment of 14.80% is seen among women who never consume chicken or meat and who occasionally eat vegetables. Similarly, a 12.90% rise has been observed in women who never eat fruits and eggs. Daily consumption of fish (15.80%) and pluses or beans (13.10%) by women has witnessed substantial growth in anemia, causing inconsistent results (Table 1).

Factors associated with anemia among women

Bivariate Analysis: In NFHS-5, women's age, place of residence, education level, religion, wealth index, marital status, pregnancy status, consumption of milk or curd, fruits, fish, chicken or meat and aerated drinks are found to be significantly associated with anemia at $P < 0.05$, whereas in NFHS-4, women's place of residence, education level, religion, wealth index, children ever born, pregnancy status, marital status, and consumption of fruits are found to be significantly associated with anemia at $P < 0.05$ (Table 2). Multivariable Analysis: After adjusting for confounders, in NFHS-5, mostly women's age, place of residence, religion, ethnicity, wealth index, marital status, and pregnancy status remain significantly associated with anemia at $p < 0.05$, whereas in NFHS-4, women's place of residence, religion, ethnicity, number of children born, wealth index, and pregnancy status remain significantly associated with anemia at $p < 0.05$. In NFHS-5, anemia is more common among women from rural areas as compared to urban areas; the risk of anemia among rural women is 1.23 times higher (AOR=1.23, 95%CI=1.19-1.28), whereas the risk of anemia among pregnant women is found to be lower than that of non-pregnant women (AOR=0.71, 95%CI=0.66-0.76). Women aged 20-24 years (AOR=0.85), 25-29 years (AOR=0.77), 30-34 years (AOR=0.71), 35-39 years (AOR=0.71), 40-44 years (AOR=0.69) and 45-49 years (AOR=0.67) are less susceptible to anemia than women aged 15-19 years. Muslim women (AOR=0.69), Christian women (AOR=0.55) and women belonging to other religions (AOR=0.57) are less likely to be anemic than Hindu women. Women with secondary education have 0.91 times (AOR=0.91, 95%CI=0.87-0.95) and those with higher education have 0.87 times (AOR=0.87, 95%CI=0.82-0.92) have lower odds of being anemic when compared to those with no education. Similarly, women having only two children (AOR=1.12, 95%CI=1.05-1.19) and four or more children (AOR=1.21, 95%CI=1.13-1.29) are more likely to be affected by anemia than women without

**Sabrina Sultana Rahman and Ruma Talukdar**

children. When compared with women who are never in union, married women are 1.08 times (AOR=1.08, 95%CI=1.02-1.15) and women who are widowed/divorced/separated are 1.18 times (AOR=1.18, 95%CI=1.09-1.29) more likely to suffer from anemia. Women belonging to tribe (AOR=0.83) have less likelihood of being anemic, while those women belonging to no caste/tribe (AOR=1.09) and those who do not know their ethnicity (AOR=1.39) are more susceptible to anemia when compared with caste. The chance of having anemia are less among poorer women (AOR=0.87), middle-class women (AOR=0.81), richer women (AOR=0.80) and richest women (AOR=0.80) in comparison to the poorest women. As per dietary pattern when compared with never consumption of food, women who consume fried foods daily (AOR=1.11), green leafy vegetables occasionally (AOR=1.42), fish weekly (AOR=1.24) are more susceptible to anemia while the risk of anemia is low among those who consume chicken or meat daily (AOR=0.79) and weekly (AOR=0.87), milk or curd daily (AOR=0.88). Contrasting results have been found where fruit consumption has no significant impact on the occurrence of anemia.

Consumption of aerated drinks weekly (AOR=0.93) and daily (AOR=0.93), occasional consumption of pulses or beans (AOR=0.85) and eggs (AOR=0.89) are found to be less anemic. When compared to NFHS-5, in NFHS-4, similar high prevalence of anemia is seen among women belonging to rural areas, Hindu religion, poorest wealth index, and non-pregnant women. While low prevalence of anemia is seen among women who have never in union. Additionally, women's education, consumption of fruits and aerated drinks showed similar result as in NFHS-5. In NFHS-4, changes are seen among women aged 25–29 years (AOR=0.91), 30–34 years (AOR=0.86), 35–39 years (AOR=0.86), 40–44 years (AOR=0.89) and 45–49 years (AOR=0.82) who are found to be less susceptible to anemia than women aged 15–19 years. While women aged 20–24 showed insignificant result. All women having one child (AOR=1.09), two child (AOR=1.14), three child (AOR=1.11) and four or more child (AOR=1.16) are more prone to experience anemia. Similarly, all women belonging to tribe (AOR=1.05), no caste/tribe (AOR=1.09), and those who do not know their ethnicity (AOR=1.33) are more susceptible to anemia. When compared with never consumption of foods, women who weekly (AOR=0.85) and occasionally (AOR=0.78) consume pulses or beans, daily consume green leafy vegetables (AOR=0.77), occasionally consume fish (AOR=0.89) are less likely to be affected by anemia. Although consumption of milk or curd daily (AOR=0.95) have lower likelihood of anemia but consuming it weekly (AOR=1.07) increases the chances of developing anemia. Moreover, consumption of eggs, chicken or meat, and fried food showed a negligible impact on the prevalence of anemia in NFHS-4 (Table 2). Abbreviation: AOR, Adjusted Odds Ratio; COR, Crude Odds Ratio; *Statistically significant ($p < 0.05$)

DISCUSSION

Anemia is a significant health concern among reproductive women in Northeast India.⁹ Therefore, the aim of this study is to determine the trend of anemia prevalence and the influence of a wide range of socio-economic, demographic, and dietary factors on the prevalence of anemia in reproductive-age women in northeast India. Among the various socio-economic factors that are explored in this study, few are found to have direct association, whereas others illustrate an inverse relationship. Two in every five women had anemia, and the prevalence of anemia was high among women residing in rural areas, having no education, and belonging to low-income families, which is similar to the findings of the present study [9]. Studies have revealed similar findings in national contexts as well [3, 7, 14, 20]. Highly educated women are more aware of anemia and take the necessary steps to prevent it by consuming foods high in iron and taking iron supplements. Rural women experience more suffering as a result of their lower purchasing ability to meet their basic needs. Hindu women in the northeast have the maximum risk of being anemic, while Christian women continue to be in a privileged position [3]. According to this study, pregnant women have lower level of anemia than non-pregnant women, which might occur as a result of pregnant women receiving additional care, iron-rich foods, and supplements. While, previous study carried out in northeast India revealed high prevalence of anemia among pregnant women [8]. In India, pregnant women experience anemia more severely than non-pregnant women do, but it is also evident that non-pregnant women aged less than 25 years are mostly affected by anemia [3]. In northeastern India, women belonging to Scheduled Castes and Scheduled Tribes are seen to be primarily affected by anemia [9]. While women who don't know their ethnicity have high prevalence

**Sabrina Sultana Rahman and Ruma Talukdar**

of anemia, according to the current study. Insufficient healthy food consumption increases the prevalence of anemia among tribal populations in north-eastern India [11,19,21]. Additionally, this study discovered that anemia is more common in women who have had two or more children. Sharif *et al* [7]. found similar results in a cross-sectional study conducted in India. The reason might be that repetitive pregnancy reduces Hb in blood and increases the risk of anemia significantly. Among the demographic factors, the present study found that young (adolescent) women aged 15-19 are more likely to suffer from anemia. Contrary to this, a previous study done in northeast India inferred that women aged 35–49 are more likely to develop anemia [9]. Anemia is also seen to be adversely affected by women's marital status in our study. As reported by Barman [18] the EAG states of India showed similar results where widowed and no longer living-together women are more likely to suffer from anemia, followed by married and other women. This might be due to improper diet, which is causing nutritional deficiencies in their loneliness. The third most significant factor in the current study is dietary consumption. Daily consumption of milk or curd and chicken or meat decreases the risk of anemia. This study is comparable to the prior one.¹⁵ Blood hemoglobin level is significantly correlated with intake of milk and yogurt [13]. Dietary pattern with high intakes of fried foods significantly increases the risk of anemia. This contradicts a previous study conducted in northeast India, where the consumption of fried foods showed no significant connection [9]. Never consumption of aerated beverages increases the risk of anemia, which contradicts the outcome that consumption of fizzy drinks leads to anemia [16]. A similar conflicting outcome with respect to dietary intake of vegetables and fish is seen in our study, where women who never consume green leafy vegetables and fish are found to be less anemic. Vegetarian diets are associated with a higher risk of developing iron-deficiency anemia, and daily consumption of fish is associated with lower odds of being anemic among Indian women [15]. Anemia is more likely to occur in northeastern women who never consume eggs and pulses or beans. Daily consumption of eggs and pulses or beans are found to be significantly associated with a lower risk of anemia among women in India.[15,17] In our study consumption of fruits is found to be statistically insignificant with anemia. Although fruits are rich source of iron, which improves our hemoglobin levels but studies conducted in India have found that consumption of fruits by women has no statistically significant impact on anemia status.[15]

CONCLUSION AND RECOMMENDATION

With the aid of present study, we could comprehend better relationship between socioeconomic, demographic, and dietary factors and the prevalence of anemia in women in northeast India. Multivariable analysis reveals that young (adolescent) women, rural residents, Hindu religion, uneducated, higher-order births, poor wealth index, non-pregnant women, women who don't know their ethnicity, widowed, divorced, or separated women, along with inadequate dietary intake, are among the major determining factors behind the high prevalence of anemia. There have been some conflicting findings, where women who never consume vegetables, fish are found to be less anemic, and those who never consume aerated drinks are found to be more anemic. Awareness regarding the cause and spread of anemia must be created, and economic health facilities must be imposed. Additionally, nutrition education program must be promoted to focus on the development of healthy eating habits and the consumption of iron-rich foods. Diversity in the region leads to the need for more in-depth research among the women of northeastern states individually to better understand and combat the problem of the high prevalence of anemia among women aged 15–49 across the northeast region.

ABSTRACT

The present study develops a predictive model for the rice crop production of India based on yield and area under irrigation using Threshold Auto Regression (TAR). The objective of this paper has been on finding nonlinear patterns and thresholds existing within rice production data to understand the volatility in production. By using data of India rice production from the period 1950-2022, TAR model with R-squared value of 0.9937, very high value of predictability and depicts more than 99% variation in rice production data. These error metrics also give testimony to the reliability of this model. The RMSE stands at 2.41, MAE is 1.62, and MAPE is 2.67%. These error metrics point towards slight deviation between the values predicted and the actual results, giving evidence of the fact that the TAR model surely captures the underlying pattern in data. This research will therefore provide a normative-based tool for all stakeholders to forecast potential changes in rice production and thus inform food security planning.

Keywords: Rice production, Threshold Auto Regression (TAR), Predictive modelling, Agricultural forecasting, India

INTRODUCTION

For millions of people around the world, especially in India, the largest rice-producing country, rice production is among the most important lifelines and outlets for food security. The large agricultural landscape itself and the

**Kesavulu Poola et al.,**

variability of the climate conditions are indeed hard to predict when it comes to rice yield. Yield per hectare and area irrigated have been identified as crucial variables determining productivity in rice production (Ansarifar et al., 2021a). The yield is represented as the production efficiency per unit area, while the area under irrigation represents the investment in resources for production. However, the total production often goes hand-in-hand with these parameters in a non-linear, dynamic way, thus posing the need for advanced predictive models that can capture such complexity (Lan & Dinh, n.d.). In this work, we employ an advanced econometric technique peculiarly suited for data with threshold effects and regime shifts—namely, the Threshold Auto Regression (TAR) model to analyze and forecast rice production based on these critical parameters. Our analysis employs historical data from 1950 to 2022 to cover over half a century and permit a longer-run examination of trends and volatility in rice production. From the descriptive statistics, considerable variation in rice output over the years is revealed with high standard deviations and noticeable skewness, which requires accurate predictions for agricultural planning purposes (Satpathi et al., 2023). Correlation analysis in figures 5 and 6 shows a very high positive association between rice production, yield, and irrigation, which is why those parameters were chosen for the TAR model. Model validation against error metrics such as R-squared, RMSE, and MAPE confirms the model as reliable in explaining over 99% variance in rice production (Broms et al., 2023). This would enable policymakers and other stakeholders to derive valuable insight into policy considerations by providing a strong framework for forecasting production and identification of imperatives of targeted strategies toward stabilization with environmentally and economically changing conditions. Our study provides a detailed and evidence-based tool that is supportive of sustainable agriculture and strengthens food security planning in India (Ansarifar et al., 2021b).

LITERATURE REVIEW

Rice yield forecasting is important for the reason of providing food security and the need for rational use of resources. Various statistical methods have been attempted in rice yield forecasting with varying degrees of accuracy and usability (Kern et al., 2018). Regression models, especially the multiple linear regression (MLR), have been one of the most widely used tools that allow one to establish relations between climatic variables, such as rainfall or temperature, and crop yields. The research has shown that such models work perfectly for locations where weather conditions have good predictability and, therefore, the data of past values can become a relatively good basis for forecasting (Masrur Ahmed et al., 2022). MLR often fails to deal with nonlinear relationships and interactions between two or more influencing factors. Another very powerful tool applied in the process of forecasting rice production has been time series analysis, which particularly gives good results for areas where seasonal trends are quite strong. Others include ARIMA and SARIMA, especially in picking the natural seasonal oscillations in rice output. It involves the analysis of past data to predict yields yet unrecorded; hence these are very applicable in areas whose agricultural cycles repeatable and reliable. Moreover, studies combined time series models with climatic factors such as temperature and rainfall (Mishra et al., 2020). This is usually more accurate because past trends can be offset by environmental conditions to produce a better estimate. The accuracy of such models deteriorates in fluctuating or rapidly shifting climates (Felkner et al., 2009). The flexibility of such models to adapt to stationary or non-stationary patterns and to provide more solutions in forecasting is much augmented. For example, it was shown in Indonesia that the combination of fuzzy logic with Markov Chains was an improvement for the forecast, especially in regions with varying weather conditions, however unpredicted (Montesinos-Lopez et al., 2021). Recently, the application of machine learning techniques such as Random Forest (RF), Random Trees (RT), Naïve Bayes (NB), and Artificial Neural Networks (ANN) is considered as the new frontier in rice production forecasting (Prakash Jorvekar et al., 2024a). The models are particularly powerful since they enable the processing of large datasets while simultaneously learning complex relationships and adapting to non-linear interactions among multiple variables. Recent studies have demonstrated how machine learning models, mainly RF and RT, significantly outperform traditional methods in terms of achieving higher prediction accuracies (Kim et al., 2023). For example, it will be proved that a machine learning model can make up to 100% predictions regarding the yields of rice using climatic and environmental data. These are new promising ways of developing methodologies in rice forecasting, but they require considerable

amounts of data as well as considerable computing resources. This is critical for sparse or irregular regions with limited data (Dharmaraja et al., 2020).

METHODOLOGY

The study employs a Threshold Auto Regression (TAR) model to analyze the non-linear relationships between rice production, yield (Rahman et al., 2021), and area under irrigation in India. Historical data from 1950 to 2022 is used to identify yield thresholds, segment the dataset, and estimate regime-specific parameters.

The Threshold Auto Regression (TAR) model segments data into distinct regimes based on a threshold variable, applying different linear regression equations to each regime. Below is a step-by-step derivation and parameter estimation process for a TAR model (Prakash Jorvekar et al., 2024a).

$$y_t = \begin{cases} \alpha_1 + \beta_1 X_t + \gamma_1 Z_t + \varepsilon_t, & \text{if } X_t \leq \tau \\ \alpha_2 + \beta_2 X_t + \gamma_2 Z_t + \varepsilon_t, & \text{if } X_t > \tau \end{cases} \quad (1)$$

Here, y_t is Dependent Variable, X_t is Predictor 1, Z_t is Predictor 2, ε_t is Residual, τ is Threshold Value and α, β, γ are constants

Then the OLS estimates of the both regression line for Regime 1 & 2 are

For Regime 1: for $X_t \leq \tau$, β_1 and γ_1 are

The regression Equation of regime 1 is,

$$\alpha_1 + \beta_1 X_t + \gamma_1 Z_t + \varepsilon_t, \text{ if } X_t \leq \tau \quad (2)$$

the OLS estimates of the equation become

$$\begin{bmatrix} \sum X_{t1}^2 & \sum X_{t1}Z_{t1} \\ \sum X_{t1}Z_{t1} & \sum Z_{t1}^2 \end{bmatrix} \begin{bmatrix} \beta_1 \\ \gamma_1 \end{bmatrix} = \begin{bmatrix} \sum X_{t1}Y_{t1} \\ \sum Z_{t1}Y_{t1} \end{bmatrix}$$

For Regime 2: for $X_t > \tau$, β_2 and γ_2 are

The regression Equation of regime 2 is,

$$\alpha_2 + \beta_2 X_t + \gamma_2 Z_t + \varepsilon_t, \text{ if } X_t > \tau \quad (3)$$

the OLS estimates of the equation become,

$$\begin{bmatrix} \sum X_{t2}^2 & \sum X_{t2}Z_{t2} \\ \sum X_{t2}Z_{t2} & \sum Z_{t2}^2 \end{bmatrix} \begin{bmatrix} \beta_2 \\ \gamma_2 \end{bmatrix} = \begin{bmatrix} \sum X_{t2}Y_{t2} \\ \sum Z_{t2}Y_{t2} \end{bmatrix}$$

The developed rice production model was evaluated in terms of predictive performance using the metrics RMSE, MAE, MAPE, and sMAPE. While RMSE focuses on larger errors and is considered to be a measure of the model's precision, MAE provides the average absolute error, an easy and easy accuracy measure. MAPE conveys error in percentage form of actual values; one of its advantages is the possibility of cross-scale comparisons, but requires considering both actual and predicted values symmetrically to avoid the imbalance in its evaluation. Therefore, these metrics evaluate the model's accuracy and reliability holistically (Lee et al., n.d.).

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (Y_t - \hat{Y}_t)^2} \quad (4)$$

$$MAE = \frac{1}{n} \sum_{i=1}^n |Y_t - \hat{Y}_t| \quad (5)$$

$$MAPE = \frac{1}{n} \sum_{i=1}^n \left| \frac{Y_t - \hat{Y}_t}{Y_t} \right| * 100 \quad (6)$$

$$sMAPE = \frac{1}{n} \sum_{i=1}^n \left| \frac{Y_t - \hat{Y}_t}{\frac{|Y_t| + |\hat{Y}_t|}{2}} \right| * 100 \quad (7)$$

RESULTS AND DISCUSSIONS

Data sources on rice production, yield, and area under irrigation for this paper are pulled from World Bank's WDI over the history spanning 1950 to 2022. Descriptive statistics for rice production, yield, and area under irrigation give an idea about the distribution of data in the dataset, the central tendencies of the data, and the variability in the data (Prakash Jorvekar et al., 2024b). The mean of production, yield, and area under irrigation is 65.85 million tonnes,

Kesavulu Poola *et al.*,

1605.59 kg/hectare, and 43.91 million hectares, respectively, which have been the typical levels of all these attributes during the years that have been used for analysis. With standard deviations of 30.69 for production, 635.56 for yield, and 7.05 for area under irrigation, the spread around the mean is huge, while the fluctuation in production and yield is more prominent, which indicate there are other influencing factors than these variables, such as climate and technology, influence these numbers. The skewness values for production, yield, and area under irrigation are 0.33, 0.53, and 0.26, respectively, indicating the data are mildly positively skewed and have a tendency to have values above the mean value. For all three, production with 1.99, yield at 2.55, and area under irrigation with 2.05, the kurtosis values are just barely above 2, which is positive for all of them. The correlation analysis shows a strong positive relationship between production and yield (correlation coefficient = 0.98), as well as between yield and area under irrigation (correlation coefficient = 0.76). This high correlation suggests that increases in yield and irrigation area are closely tied to higher rice production, making these variables essential for forecasting. The model stratifies the data on the basis of two yield thresholds: one yields less than or equal to 2391 kg/hectare and the other where it exceeded above this level. The model computes different regression equations for each regime, which then allows having unique intercept for the relevant coefficients of each variable within these regimes. This segmentation makes the TAR model very effective for agricultural application, as it adapts to changes in productivity caused by such factors as variations in climate or resource constraints.

Regression Equation for Yield \leq 2391 (61 Observations)

If the yield is up to 2391 kg/hectare, the regression equation is as follows:

$$\text{Production} = -23.56163 + (0.043978 \times \text{Yield}) + (0.419996 \times \text{Area under irrigation})$$

The intercept of -23.56163, theoretically means that, at zero yield and irrigation, production would be negative. This is of course, only hypothetical. The yield coefficient is 0.043978, indicating that every 1 kg/hectare increase in yield increases production by 0.044 million tonnes while an additional million hectares under irrigation expands production by 0.42 million tonnes. Both predictors are statistically significant at the 0.01 level ($p < 0.01$), indicating a strong influence on production

Regression Equation for Yield $>$ 2391 (10 Observations)

In this regime where the yield is more than 2391 kg/hectare the regression equation is as follows:

$$\text{Production} = -84.25757 + (0.003411 \times \text{Yield}) + (4.167946 \times \text{Area under irrigation})$$

The intercept of -84.25757 suggests that, at higher yield levels, the dynamics of production shift. The yield coefficient being 0.003411 implies an insignificant impact wherein an increase in yield by 1 kg/hectare results in an addition of only 0.0034 million tonnes to production. However, the irrigation coefficient at 4.167946 exemplifies a significant impact wherein each million hectares irrigated increases production by 4.17 million tonnes and, thus, establishes an indispensable role of irrigation during high-yield conditions. And while the yield coefficient is not statistically significant ($p = 0.2056$), irrigation remains highly significant ($p < 0.01$).

Residuals Plot

A residual plot of the Threshold Auto Regression (TAR) model would now become an important diagnostic tool since it helps to discover observed and predicted values of rice production as being different from each other (Setiya *et al.*, 2024). Ideally, residuals should be randomly scattered around zero with no visible patterns that indicate the underlying data structures are appropriately captured by the models. The residuals in this analysis seem to be evenly spread around the zero line with no peculiar trends, which is evidence that TAR has effectively decomposed the non-linear and threshold effects of yield and irrigation area on rice production, leaving only random error (Kastens *et al.*, 2005). This randomness offers scope for the assumptions of homoscedasticity—that is, constant variance—and independence with no autocorrelation—in the residuals (Paudel *et al.*, 2021). These two are crucial requirements for a model to have validity. The fact that there is no systematic pattern or clustering in the residuals also supports the idea that the TAR model captures all the significant relationships between variables, resulting in no major predictive bias. If patterns in the residual plot take the form of a funnel shape or wave-like formation, then funnel or wave-like shapes would depict some forms of heteroscedasticity or autocorrelation pointing to model inadequacy. But this perfectly regular, patternless residual distribution around zero in this case reinforces that the TAR model is well

**Kesavulu Poola et al.,**

suited to capture the nuances of the rice production, including these thresholds, and thus validate its use as a reliable tool to forecast within this agricultural context. RMSE of 2.41 reflects the average value of error the model makes in predicting rice production values. Lower is the RMSE, the better fit is. This is a very good metric because greater errors incur more and one realizes how close the predictions are to the actual value on average. The MAE, at 1.62, brings a less complicated measure of mean prediction error without the magnification of large deviations whereby there is averaging of absolute differences between predicted and actual values of production. MAPE stands at 2.67%, meaning that this model predicts the values of production, on average, with almost an error of about 2.67% from the actual value, which is a minor error and goes to signify the high predictive accuracy. Further support to the strength of the model is provided by the level of 2.65% in sMAPE, thus giving a balanced measure of accuracy that reduces bias from the outliers. The Theil Inequality Coefficient was at 0.0166, which came close to the value of zero, thus pointing to almost perfect levels of forecasting accuracy. Taken together, these metrics confirm that the TAR model correctly extracts the main patterns from rice production data, producing reliable predictions that can actually be relied upon to provide planning and decision-making confidence in agriculture. The low error values found across all these metrics therefore emphasize the accuracy of the model and consolidate its utility in forecasting rice production under differing conditions of yield and irrigation.

Normality test

The histogram displays a right-skewed distribution of residuals, suggesting a tendency for the model to over predict rather than under predict. The mean (-1.92e-14) and median (0.42) are close to zero, indicating the model's overall accuracy. However, the standard deviation (2.43) and kurtosis (11.34) reveal significant variability and heavy tails in the residuals. The Jarque-Bera test statistic (267.64) with a p-value of 0.000000 confirms non-normality, violating a key assumption of many models. To improve the model, consider transformations, alternative models, outlier analysis, and further diagnostic checks. From the plot in the graph provided, no statistically significant process changes during the time span of 2016-2022 is shown, since the plot lies within the 5% significance limits. However, a gradual upward trend from the CUSUM plot might indicate an increasing variability of the process or a slight shift in the mean. For better understanding, probable causes like natural variation, minor changes in the processes, and issues associated with data quality may be analyzed. Monitor the process further, tighten the control limits as needed, and take corrective actions if any specific causes are identified

CONCLUSION

The fitted TAR model captured the non-linear dynamics and threshold effects involved among rice production, yield, and area under irrigation; that is, it had a very high R-squared value of 0.9937, that explained more than 99% of the variation in production. The developed statistics of performance, with a RMSE of 2.41, MAE of 1.62, and MAPE of 2.67%, establish the reliability of the model and its ability to predict the outcome of the crop. This study emphasizes the crucial function that irrigation plays in stabilizing production at higher yield levels besides highlighting thresholds where the effect of yield reveals signs of a downward trend. In this context, the TAR model turns out to be one of the best alternate forecasting models that capture all the non-linear relationships and threshold effects. This makes it highly suited for complex agricultural predictions

FUTURE SCOPE OF RESEARCH

Future research should extend this work by taking climatic conditions, technological advancement, and market dynamics into the model to enhance predictive power. Some of the more advanced models that one could use for testing, such as machine learning algorithms like Random Forest or Neural Networks, may improve the model's accuracy and flexibility further. Regional analysis could also make provision for regional-level insights into the dynamics of production, so targeted interventions can be taken in these regions. Residual non-normality can also be addressed or even hybrid modelling techniques might open doors to further improvement of the framework for wider application in agricultural forecasting.

ABSTRACT

This study presents a non-linear epidemic mathematical model that takes into account the impact of vaccination and treatment on the spread of Influenza. The model was thoroughly analyzed to gain insights into the dynamics of the disease. The paper explores the stability of the disease-free equilibrium, both at a local and global level. Additionally, the model calculates the basic reproduction number, R_0 . The model is applied to the influenza cases in India from 2010 to 2023. We are currently utilizing the normalized forward sensitivity index method to analyze the sensitivity of the parameters in relation to R_0 . An analysis is conducted on the influence of vaccination and treatment rates on populations that have been infected. The optimal control approach focuses on continuously vaccinating individuals who are still susceptible and aims to enhance the treatment for those who are infected. The combination of treatment and vaccine strategies has shown promising results, leading to a significant decrease in the prevalence of disease within the desired timeframe.

INTRODUCTION

Mathematical modeling is a crucial method for understanding the spread and management of many infectious illnesses. Mathematical models consider various crucial factors such as vaccination, transmission, recovery, and other elements that influence the progression of a disease [2],[3],[4] and [5]. Optimal control theory, a branch of mathematics, was developed to ascertain the most effective approach for regulating dynamic systems. The aim of utilizing optimum control theory is to compute the efficacy of various policies and control systems, along with their associated expenses [6],[7] and [8]. Vaccination is a widely employed method of disease control. Based on calculations, implementing a vaccination program would prevent approximately 2-3 million deaths each year. Recently, vaccination and other preventative techniques such as treatment, isolation, screening, and quarantine have been employed to diminish the transmission of infectious diseases [9]. Srivastav et.al. [10] examined epidemic models that include vaccination and the latent stage. Srivastav et.al. [11] constructed an optimal control model that integrates the disease transmission rate and treatment rate. Asymptomatic individuals who are affected with the disease remain contagious and facilitate the transmission of the disease from one person to another [12]. A decrease in immune function might heighten an individual's vulnerability to a range of diseases resulting from asymptomatic infections. Prior to undergoing medical testing, the absence of symptoms in the patient may remain undetected. Consequently, certain individuals may endure extended durations without manifesting any symptoms, perhaps leading to their demise [13]. Multiple studies indicate that approximately one-third of infections are asymptomatic infections [14] and [15]. Stilianakis et al. [16] developed a model that incorporates the asymptomatic compartment into a SARS epidemic model. This model was used to assess the impact of treatment and chemotherapy regimens on the transmission of the disease. The influenza virus primarily targets the nasal passages, throat, bronchial tubes, and, in rare cases, the lungs. The symptoms of infection, which have a normal duration of one week, encompass fever, myalgia, headache, pharyngitis, coughing, and prostration. Influenza is highly contagious and easily transmitted by direct exposure to respiratory droplets expelled by an infected individual through coughing and sneezing. The ailment impacts the respiratory system, specifically the lungs, throat, or nose. It often originates as an epidemic that rapidly disseminates from urban areas to rural areas and from one region to another. The duration of an outbreak in a certain region normally spans 4-6 weeks before it diminishes. Owing to its high transmissibility, influenza has the potential to rapidly induce a widespread outbreak of sickness among a substantial population. The swine flu pandemic emerged in 2009, originating in Mexico and rapidly spreading to other parts of the world due to its highly contagious nature and the swift transportation of infected individuals across nations via air travel. This virus seems to be a hybrid of four distinct strains. There are four endemic strains of the influenza A virus: variation H1N1, which primarily infects people, a strain that infects birds, and two strains that infect pigs (swine). The World Health Organization [1] declared the flu as a pandemic on August 10, 2010. A novel SVL I_aI_s TRD epidemiological model has been constructed by integrating three distinct categories, namely asymptomatic, treatment, and deceased, into the existing SVEIR model [10] for the transmission of the influenza virus. The basic reproductive number is computed, followed by an assessment of the stability of the disease-free equilibrium. The model is calibrated using data from India and a sensitivity analysis is conducted. In addition, we expanded our model to incorporate an optimal control model problem with two control functions: vaccination and treatment controls, in order to reduce both the number of infected individuals and the number of fatalities.

MODEL FORMATION

This work presents the development of the SVL I_aI_s TRD epidemiological model, which incorporates vaccination and therapy, to illustrate the transmission dynamics of Influenza in India. The population $N(t)$ at time t is partitioned into 8 distinct compartments, referred to as susceptible ($S(t)$), vaccinated ($V(t)$), exposed ($L(t)$), asymptomatic infected ($I_a(t)$), symptomatic infected ($I_s(t)$), recovered ($R(t)$), and deceased ($D(t)$). Therefore $N(t) = S(t) + V(t) + L(t) + I_a(t) + I_s(t) + T(t) + R(t) + D(t)$. It is assumed that all individuals have an equal probability of becoming infected if they come into contact with diseased persons. This assumption is based on the belief that the overall population is both homogeneous and uniformly dispersed. The population of individuals who are infected can be categorized into two distinct groups: symptomatic infected individuals ($I(t)$), who exhibit symptoms of the disease,

Venkatesh et al.,

and asymptomatic infected individuals ($A(t)$), who do not display any symptoms of the disease. The infectivity of $A(t)$ seems to be lower than that of $I(t)$.

The susceptible population ($S(t)$) refers to those who are currently susceptible to illness but do not currently have an infection. The population is determined by the rate of recruitment or birth (Π) and is reduced by the natural mortality rate (δ). An individual who is vulnerable to the virus and comes into touch with an infected individual at a rate β will become part of the exposed population. The decline occurs due to a low vaccination rate η , resulting in only a small number of susceptible individuals receiving immunizations. Thus

$$\frac{dS}{dt} = \Pi - \beta S(\zeta I_a + \phi I_s) - (\eta + \delta)S$$

The vaccinated population ($V(t)$) refers to the subset of the vulnerable population who have received vaccination. The population undergoes growth at a pace determined by the vaccination rate η and experiences decline due to the natural death rate δ . This population may see a resurgence of the disease because of the vaccine's inefficacy, leading to a drop in population at a rate of ψ . So

$$\frac{dV}{dt} = \eta S - \beta \phi V(\zeta I_a + \phi I_s) - (\gamma_v + \delta)V$$

The exposed population ($L(t)$) refers to individuals who have been exposed to the virus but have not yet become infectious. Once the individuals who have been exposed to the virus become sick, a fraction (α) of those who do not show any symptoms associated to the virus migrate to group A at a rate of σ , while the remaining fraction ($1 - \alpha$) of individuals who do exhibit virus-related symptoms move to group I. The population undergoes a decline at a rate of σ . The population grows as susceptible individuals become exposed to the virus and vaccinated persons become infected due to the ineffectiveness of the vaccination. This population decreases due to the natural mortality rate δ . Therefore

$$\frac{dL}{dt} = \beta S(\zeta I_s + \zeta I_a) + \beta \phi V(\zeta I_a + \phi I_s) - (\sigma + \delta)L$$

The asymptomatic population ($I_a(t)$) is considered to be infected while not displaying symptoms. The production of these people occurs at a rate of $\alpha\sigma$ relative to the exposed population and diminishes at a rate of δ . As a result of some individuals in this group naturally recovering without treatment due to their immune system, while others develop disease symptoms and migrate to I_s , the population shrinks at rates θ and γ_a . So that

$$\frac{dI_a}{dt} = \alpha\sigma L - (\theta + \gamma_a + \delta)I_a$$

The symptomatic population ($I_s(t)$) refers to those who have been infected and are displaying signs of the disease. The individuals are produced at a rate of $(1 - \alpha)\sigma$ from the exposed population and decrease at a rate of δ . As a result of a serious disease, a portion of these folks succumbed while others were admitted to the hospital for improved medical care. Therefore, this population decreases at the rates κ and δ_s . Thus

$$\frac{dI_s}{dt} = (1 - \alpha)\sigma L + \theta I_s - (\kappa + \delta_s + \delta)I_s$$

The Treatment population ($T(t)$) refers to those who are hospitalized as a result of their sickness. The population increases at a rate of κ and decreases at a rate of δ . Due to variations in treatment effectiveness and the severity of sickness, the population experiences declines at rates γ_t and δ_t , resulting in some persons recovering and others succumbing to their illness. Hence

$$\frac{dT}{dt} = \kappa I_s - (\gamma_t + \delta_t + \delta)T$$

The Recovered population ($R(t)$) refers to those who have successfully overcome a sickness. The population grows at rates γ_a and γ_t , and decreases at a rate δ . Hence

Venkatesh et al.,

$$\frac{dR}{dt} = \gamma_a I_a + \gamma_t T - \delta R$$

The Deceased population ($D(t)$) refers to those who have succumbed to a serious infection. This population increases at the rates δ_a and δ_t . Thus

$$\frac{dD}{dt} = \delta_s I_s + \delta_t T$$

The proposed model is given by following system of non – linear differential equations

$$\frac{dS}{dt} = \Pi - \beta S(\zeta I_a + \varrho I_s) - (\eta + \delta)S$$

$$\frac{dV}{dt} = \eta S - \beta \phi V(\zeta I_a + \varrho I_s) - (\gamma_v + \delta)V$$

$$\frac{dL}{dt} = \beta S(\zeta I_a + \varrho I_s) + \beta \phi V(\zeta I_a + \varrho I_s) - (\sigma + \delta)L$$

$$\frac{dI_a}{dt} = \alpha \sigma L - (\theta + \gamma_a + \delta)I_a \quad 1$$

$$\frac{dI_s}{dt} = (1 - \alpha)\sigma L + \theta I_a - (\kappa + \delta_s + \delta)I_s$$

$$\frac{dT}{dt} = \kappa I_s - (\gamma_t + \delta_t + \delta)T$$

$$\frac{dR}{dt} = \gamma_v V + \gamma_a I_a + \gamma_t T - \delta R$$

$$\frac{dD}{dt} = \delta_s I_s + \delta_t T$$

with the primary conditions $S(0) \geq 0, V(0) \geq 0, L(0) \geq 0, I_a(0) \geq 0, I_s(0) \geq 0, T(0) \geq 0, R(0) \geq 0$, and $D(0) \geq 0$. The model is graphically represented in Fig.1 and the model parameters is described in Table 1

SVLI_aI_sTRD MODEL ANALYSIS

Positivity and boundedness

Theorem 1 The solutions $(S, V, L, I_a, I_s, T, R, D)$ of the system (1) are non-negative for any $t > 0$, assuming non-negative fundamental conditions. Moreover $\lim_{t \rightarrow \infty} \sup N \leq \frac{\Lambda}{\mu}$

Proof. Let $T = \sup \{t > 0 : (S, V, L, I_a, I_s, T, R, D > 0)\}$. Then $T > 0$. From the first equation of system (1), we get

$$\frac{dS}{dt} = \Pi - \beta S(\zeta I_a + \varrho I_s) - (\eta + \delta)S \geq \Pi - \chi(t)S$$

where $\chi(t) = \beta(\zeta I_a + \varrho I_s) + (\eta + \delta)$

Then $\frac{dS}{dt} + \chi(t)S \geq \Pi$

$$\frac{d}{dt} \left[S(t) \exp \left(\int_0^t \chi(u) du \right) \right] = \Pi \left[\exp \left(\int_0^t \chi(u) du \right) \right]$$

$$\Rightarrow S(t) \exp \left(\int_0^t \chi(u) du \right) = S(0) + \int_0^t \Lambda \exp \left(\int_0^y \chi(v) dv \right) dy$$

So that

$$S(T) = S(0) \exp \left(- \int_0^T \chi(u) du \right) + \int_0^T \Lambda \exp \left(\int_0^y \chi(v) dv \right) dy \times \exp \left(- \int_0^T \chi(u) du \right) > 0$$

$$\Rightarrow S(T) > 0$$

Similarly we can prove that $V(t) > 0, L(t) > 0, I_a(t) > 0, I_s(t) > 0, T(t) > 0, R(t) > 0$ and $D(t) > 0 \forall t > 0$

As a result, for any $t > 0$, all model solutions with non-negative primary conditions remain non negative.

Theorem 2. For the system (1) with primary conditions in \mathbf{R}_+^8 , the region Ω is positively invariant

Proof.

By adding all the equations of system (1), we get

$$\frac{dN}{dt} = \Pi - \delta N$$

Which leads to $\lim_{t \rightarrow \infty} \sup N \leq \frac{\Pi}{\delta}$

Then we get $N \leq \frac{\Pi}{\delta}$

Therefore $N(t) \rightarrow \frac{\Pi}{\delta}$ as $t \rightarrow \infty$

If $N > \frac{\Pi}{\delta}$, then $\frac{dN}{dt} < 0$

From the first and second equations of (1), we get

$$\lim_{t \rightarrow \infty} \sup S \leq \frac{\Pi}{(\eta + \delta)} \text{ and } \lim_{t \rightarrow \infty} \sup V \leq \frac{\Pi \eta}{\delta(\eta + \delta)}$$

Therefore, the region of attraction for the system (1) is given by

$$\Omega = \left\{ (S, V, L, I_a, I_s, T, R, D) \in \mathbf{R}_+^8 : 0 \leq \left(S + V + L + I_s + I_a + T + R + D \leq \frac{\Pi}{\delta}, S \leq \frac{\Pi}{(\eta + \delta)}, V \leq \frac{\Pi \eta}{(\gamma_v + \delta)(\eta + \delta)} \right) \right\}$$

The given set is considered a positive invariant set as it encompasses all solutions of system (1) with initial conditions within Ω for every time $t > 0$.

Basic reproduction number

The illness free equilibrium corresponds to the point E_0 at which infection disappears (i.e., $L = I_a = I_s = T = 0$) from the population is $E_0 = \left(\frac{\Pi}{(\eta + \delta)}, \frac{\Pi \eta}{(\gamma_v + \delta)(\eta + \delta)}, 0, 0, 0, 0, 0 \right)$.

Here, using the Next-generation technique described in [23] and [24], we derive the corresponding basic reproduction number for the system (1).

Let $y = (L, I_a, I_s, T)^T$. Then the system (1) can be written as $\frac{dy}{dt} = F(y) - V(y)$

where

$$F(y) = \begin{bmatrix} \beta S(\zeta I_a + \varrho I_s) + \beta \phi V(\zeta I_a + \varrho I_s) \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \text{ and } V(y) = \begin{bmatrix} (\sigma + \delta)L \\ -\alpha \sigma L + (\theta + \gamma_a + \delta)I_a \\ -(1 - \alpha)\sigma L - \theta I_a + (\kappa + \delta_s + \delta)I_s \\ -\kappa I_s + (\gamma_t + \delta_t + \delta)T \end{bmatrix}$$

$$\text{We can get } F = \begin{pmatrix} 0 & \frac{\beta \Pi \zeta (\delta + \eta \phi)}{(\gamma_v + \delta)(\eta + \delta)} & \frac{\beta \Pi \varrho (\delta + \eta \phi)}{(\gamma_v + \delta)(\eta + \delta)} \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \text{ and } V = \begin{pmatrix} (\sigma + \delta) & 0 & 0 \\ -\alpha \sigma & (\theta + \gamma_a + \delta) & 0 \\ -(1 - \alpha)\sigma & -\theta & (\kappa + \delta_s + \delta) \end{pmatrix}$$

$$\text{Then } V^{-1} = \begin{pmatrix} \frac{1}{(\sigma + \delta)} & 0 & 0 \\ \frac{\alpha \sigma}{(\sigma + \delta)(\theta + \gamma_a + \delta)} & \frac{1}{(\theta + \gamma_a + \delta)} & 0 \\ \frac{\alpha \sigma (\sigma + \delta) + (1 - \alpha)\sigma(\theta + \gamma_a + \delta)}{(\sigma + \delta)(\theta + \gamma_a + \delta)(\kappa + \delta_s + \delta)} & \frac{\theta}{(\theta + \gamma_a + \delta)(\kappa + \delta_s + \delta)} & \frac{1}{(\kappa + \delta_s + \delta)} \end{pmatrix}$$

Since the largest eigen value of the matrix FV^{-1} is the reproduction number (R_0), the basic reproduction number is

$$R_0 = \frac{(\delta + \eta\phi)\beta\Pi [\zeta\alpha\sigma(\kappa + \delta_s + \delta) + \varrho(\alpha\sigma\theta + (1 - \alpha)\sigma(\theta + \gamma_a + \delta))]}{(\eta + \delta)(\gamma_v + \delta)(\theta + \gamma_a + \delta)(\kappa + \delta_s + \delta)(\sigma + \delta)}$$

Local and global stability of disease free equilibrium

Theorem 3: The disease free equilibrium $E_0 = \left(\frac{\Pi}{(\eta + \delta)}, \frac{\Pi\eta}{(\gamma_v + \delta)(\eta + \delta)}, 0, 0, 0, 0\right)$ of the system (1) exhibited local asymptotic stability when the value of $R_0 < 1$.

Proof

The Jacobian matrix corresponding to the system (1) at disease free equilibrium point E_0 is

$$J(E_0) = \begin{pmatrix} -(\eta + \delta) & 0 & 0 & -\beta\zeta & -\beta\varrho & 0 & 0 \\ 0 & -(\gamma_v + \delta) & 0 & \beta\phi\zeta & \beta\phi\varrho & 0 & 0 \\ 0 & 0 & -(\sigma + \delta) & \beta\zeta(1 + \phi) & \beta\varrho(1 + \phi) & 0 & 0 \\ 0 & 0 & \alpha\sigma & -(\theta + \gamma_a + \delta) & 0 & 0 & 0 \\ 0 & 0 & (1 - \alpha)\sigma & \theta & -(\kappa + \delta_s + \delta) & 0 & 0 \\ 0 & 0 & 0 & \gamma_a & \kappa & -(\gamma_t + \delta_t + \delta) & 0 \\ 0 & 0 & 0 & 0 & 0 & \gamma_t & -\delta \end{pmatrix}$$

The characteristic equation is

$$(\lambda + (\eta + \delta))(\lambda + (\gamma_v + \delta))(\lambda + \delta)(\lambda + (\gamma_t + \delta_t + \delta)) \begin{vmatrix} -(\sigma + \delta) & \beta\zeta(1 + \phi) & \beta\varrho(1 + \phi) \\ \alpha\sigma & -(\theta + \gamma_a + \delta) & 0 \\ (1 - \alpha)\sigma & \theta & -(\kappa + \delta_s + \delta) \end{vmatrix} = 0$$

Here $-\delta$, $-(\eta + \delta)$, $-(\gamma_v + \delta)$ and $-(\gamma_t + \delta_t + \delta)$ are the four eigen values of $J(E_0)$ and the remaining three eigen values are obtained from the cubic equation $(\lambda^3 + a_1\lambda^2 + a_2\lambda + a_3) = 0$

Where $a_1 = (\sigma + \delta) + (\theta + \gamma_a + \delta) + (\kappa + \delta_s + \delta)$

$$a_2 = (\sigma + \delta)(\theta + \gamma_a + \delta) + ((\sigma + \delta) + (\theta + \gamma_a + \delta))(\kappa + \delta_s + \delta) - \beta(1 + \phi)(\zeta\alpha\sigma + \varrho(1 - \alpha)\sigma)a_3 = \frac{(\sigma + \delta)(\theta + \gamma_a + \delta)(\kappa + \delta_s + \delta)}{(\delta + \eta\phi)\Pi} [(\delta + \eta\phi)\Pi - (1 + \phi)(\eta + \delta)(\gamma_v + \delta) + (1 + \phi)(\eta + \delta)(\gamma_v + \delta)(1 - R_0)]$$

Using Liénard-Chipart test the disease free equilibrium point E_0 is locally asymptotically stable if $a_1, a_2, a_3 > 0$ and $a_1a_2 > a_3$

Clearly $a_1 > 0$, $a_2 > 0$ and $a_3 > 0$ if $R_0 < 1$

It is easily to verify that $a_1a_2 > a_3$ for $R_0 < 1$

Hence the disease free equilibrium point E_0 was locally asymptotically stable if $R_0 < 1$.

Theorem4: The disease free equilibrium $E_0 = \left(\frac{\Pi}{(\eta + \delta)}, \frac{\Pi\eta}{(\gamma_v + \delta)(\eta + \delta)}, 0\right)$ of system (1) exhibited global asymptotic stability when the value of $R_0 < 1$.

Proof .

The system (1) can be written in this form:

$$\frac{dX}{dt} = P(X, Y), \frac{dY}{dt} = Q(X, Y) \text{ and } G(X, 0) = 0 \quad (*)$$

where $X = (S, V, R) \in \mathbb{R}_+^3$, $Y = (E, I_a, I_s, T) \in \mathbb{R}_+^4$ representing the number of uninfected and infected populations respectively. Then the disease free equilibrium is denoted by $E_0 = \left(\frac{\Pi}{(\eta + \delta)}, \frac{\Pi\eta}{(\gamma_v + \delta)(\eta + \delta)}, 0\right)$

For E_0 is global asymptotically stable, the following two conditions (H_1) and (H_2) must be satisfied.

(H_1): $\frac{dX}{dt} = P(X_0, 0)$, X_0 is globally asymptotic stable.

(H_2): $Q(X, Y) = BY - \widehat{Q}(X, Y)$, $\widehat{Q}(X, Y) \geq 0$, here $B = D_Y Q(X_0, 0)$ is M matrix.

Venkatesh et al.,

The system (1) can be rewritten as $P(X, 0) = \begin{pmatrix} \Pi - (\eta + \delta)S \\ \eta S - (\gamma_v + \delta)V \\ -\delta R \end{pmatrix}$
 $S(t) = \frac{\Pi}{(\eta + \delta)} - \frac{s(0)}{(\eta + \delta)} e^{-(\eta + \delta)t}$ and $V(t) = \frac{\Pi\eta}{(\gamma_v + \delta)(\eta + \delta)} - \frac{v(0)}{(\gamma_v + \delta)(\eta + \delta)} e^{-(\eta + \delta)t}$ and $R(t) = e^{-\delta t}$
 As $t \rightarrow \infty$, $X_0 = \left(\frac{\Pi}{(\eta + \delta)}, \frac{\Pi\eta}{(\gamma_v + \delta)(\eta + \delta)}, 0 \right)$ is global asymptotically stable for $\frac{dX}{dt} = P(X_0, 0)$.

Hence the first condition (H_1) is verified.

Band $\hat{Q}(X, Y)$ expressed as

$$B = \begin{pmatrix} -(\sigma + \delta) & \beta\zeta(1 + \phi) & \beta\varrho(1 + \phi) & 0 \\ \alpha\sigma & -(\theta + \gamma_a + \delta) & 0 & 0 \\ (1 - \alpha)\sigma & \theta & -(\kappa + \delta_s + \delta) & 0 \\ 0 & \gamma_a & \kappa & -(\gamma_t + \delta_t + \delta) \end{pmatrix} \text{ and } \hat{Q}(X, Y) = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

Hence B is an M matrix. Thus the two conditions are verified.

Therefore disease-free equilibrium E_0 of system (1) was globally asymptotic stable if $R_0 < 1$.

Numerical Simulation

Model fitting

The suggested model was applied to the cumulative confirmed instances of influenza and cumulative influenza-related mortality in India [25] throughout the time span from 2010 to 2023. The parameters β and θ are computed by minimizing the sum of squared error technique using the lsqnonlin function in MATLAB. The given data is represented by blue circles in Fig.2, whereas the model solution is represented by a red circle.

Sensitivity Analysis

The sensitivity analysis played a vital role in determining the impact of various parameters on the transmission of influenza. This technique is particularly valuable for detecting variations in the R_0 value in relation to other factors. We do sensitivity analysis to evaluate the influence of factors on the model. The normalized forward sensitivity index for the significant parameter p in R_0 was determined using the normalized forward sensitivity method [25] as $\Gamma_p^{R_0} = \frac{\partial R_0}{\partial p} \frac{p}{R_0}$.

Fig. 3 presented the sensitivity indices of R_0 in relation to different parameters. Indices with greater magnitude exhibit more sensitivity to variations in R_0 . When the sensitivity index is positive, the value of R_0 grows as the value of p increases. Similarly, when the sensitivity index is negative, a rise in p leads to a drop in R_0 . Our sensitivity analysis indicates that the parameters $\Pi, \zeta, \varrho, \sigma, \phi, \theta$ and β positively affect R_0 , while the parameters $\eta, \kappa, \gamma_v, \gamma_a, \delta_s$ and δ negatively affect R_0 . The parameters ϱ, β , and ϕ have a greater impact on the transmission of influenza, while the parameters η, κ, γ_v and γ_a are more successful in reducing the influenza. The vaccination rate and treatment rate are utilized to assess the prevalence of the influenza-infected population. Based on the observations from Fig. 4a and Fig. 4b, it can be inferred that an increase in the vaccination rate (η) and treatment rate (κ) leads to a decrease in the spread of influenza.

Optimal control

Optimal control for the $SVLI_a I_s TRD$ model

The system (1) is expanded in this part to include optimal control issue by integrating two distinct control factors, u_1 and u_2 . Vaccines are administered to this specific group of individuals with the purpose of enhancing their immune system's ability to recognize the disease and eliminate any related microorganisms they may encounter in the future. u_1 refers to vaccine control, which mandates that all individuals who are vulnerable to influenza must receive a vaccination in order to minimize the continued transmission of the virus. In order to mitigate the severity of diseases and halt the transmission of infections, enhanced medical care is provided to specific subsets of the affected

Venkatesh et al.,

population. The variable u_2 indicates the control group for patients infected with influenza who are receiving treatment. Considering all above assumptions, the optimal control model is formulated as follows:

$$\frac{dS}{dt} = \Pi - \beta S(\zeta I_a + \varrho I_s) - (u_1 + \delta)S$$

$$\frac{dV}{dt} = u_1 S - \beta \phi V(\zeta I_a + \varrho I_s) - (\gamma_v + \delta)V$$

$$\frac{dL}{dt} = \beta S(\zeta I_a + \varrho I_s) + \beta \phi V(\zeta I_a + \varrho I_s) - (\sigma + \delta)L$$

$$\frac{dI_a}{dt} = \alpha \sigma L - (\theta + \gamma_a + \delta)I_a \quad (2)$$

$$\frac{dI_s}{dt} = (1 - \alpha)\sigma L + \theta I_a - (\kappa + u_2 + \delta_s + \delta)I_s$$

$$\frac{dT}{dt} = (\kappa + u_2)I_s - (\gamma_t + \delta_t + \delta)T$$

$$\frac{dR}{dt} = \gamma_v V + \gamma_a I_a + \gamma_t T - \delta R$$

$$\frac{dD}{dt} = \delta_s I_s + \delta_t T$$

Where objective functional for fixed time t_f is

$$J = \int_0^{t_f} (C_1 I_a + C_2 I_s + C_3 T) + \left(\left(\frac{C_4}{2} \right) u_1^2 + \left(\frac{C_5}{2} \right) u_2^2 \right) dt \quad (3)$$

Where C_1, C_2, C_3, C_4 and C_5 are nonnegative weight constants.

Our main objective is to find the control variables u_1^* and u_2^* such that

$$J(u_1^*, u_2^*) = \min_{u_1, u_2 \in U} J(u_1, u_2) \quad (4)$$

where $U = \{u_1, u_2 : \text{measurable and } 0 \leq u_1, u_2 \leq 1\}$ and $t \in [0, t_f]$.

The Hamiltonian function (H) are defined as

$$H = (C_1 I_a + C_2 I_s + C_3 T) + \left(\left(\frac{C_4}{2} \right) u_1^2 + \left(\frac{C_5}{2} \right) u_2^2 \right) + \lambda_1 \frac{dS}{dt} + \lambda_2 \frac{dV}{dt} + \lambda_3 \frac{dL}{dt} + \lambda_4 \frac{dI_a}{dt} + \lambda_5 \frac{dI_s}{dt} + \lambda_6 \frac{dT}{dt} + \lambda_7 \frac{dR}{dt} + \lambda_8 \frac{dD}{dt}$$

where $\lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5, \lambda_6, \lambda_7$ and λ_8 are the adjoint variables.

Theorem.5

If $(S^*, V^*, L^*, I_a^*, I_s^*, T^*, R^*, D^*)$ is the solution of the system (2) associated to the optimal controls u_1^*, u_2^* and $u_3^* \in U$, then there exist an adjoint functions $\lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5, \lambda_6, \lambda_7$ and λ_8 satisfying the equation

$$\frac{d\lambda_1}{dt} = \frac{\partial H}{\partial S} = (\lambda_1 - \lambda_3) \beta (\zeta I_a + \varrho I_s) \frac{1}{N} + (\lambda_1 - \lambda_2) (u_1) + \lambda_1 \delta$$

$$\frac{d\lambda_2}{dt} = \frac{\partial H}{\partial V} = (\lambda_2 - \lambda_3) \beta \phi (\zeta I_a + \varrho I_s) \frac{1}{N} + (\lambda_2 - \lambda_7) \gamma_v + \lambda_2 \delta$$

$$\frac{d\lambda_3}{dt} = \frac{\partial H}{\partial L} = (\lambda_3 - \lambda_5) \sigma + (\lambda_5 - \lambda_4) \sigma \alpha + \lambda_3 \delta$$

$$\frac{d\lambda_4}{dt} = \frac{\partial H}{\partial I_a} = -C_1 + (\lambda_1 - \lambda_3) \beta \zeta \frac{S}{N} + (\lambda_2 - \lambda_3) \beta \phi \zeta \frac{V}{N} + (\lambda_4 - \lambda_7) \gamma_a + (\lambda_4 - \lambda_5) \theta + \lambda_4 \delta$$

$$\frac{d\lambda_5}{dt} = \frac{\partial H}{\partial I_s} = -C_2 + (\lambda_1 - \lambda_3) \beta \varrho \frac{S}{N} + (\lambda_2 - \lambda_3) \beta \phi \varrho \frac{V}{N} + (\lambda_5 - \lambda_6) (\kappa + u_2) + (\lambda_5 - \lambda_7) \delta_s + \lambda_5 \delta$$

$$\frac{d\lambda_6}{dt} = \frac{\partial H}{\partial T} = -C_3 + (\lambda_6 - \lambda_7) \gamma_t + (\lambda_6 - \lambda_8) \delta_t + \lambda_6 \delta$$

$$\frac{d\lambda_7}{dt} = \frac{\partial H}{\partial R} = \lambda_7 \delta$$

$$\frac{d\lambda_8}{dt} = \frac{\partial H}{\partial D} = 0$$

with the transversality conditions at time t_f ,

Venkatesh et al.,

$\lambda_S(t_f) = 0, \lambda_V(t_f) = 0, \lambda_{I_a}(t_f) = 0, \lambda_{I_s}(t_f) = 0, \lambda_T(t_f) = 0, \lambda_R(t_f) = 0$ and $\lambda_D(t_f) = 0$

Furthermore, for $t \in [0, t_f]$, the optimal controls u_1^*, u_2^* and u_3^* are determined by

$$u_1^* = \min \left\{ 1, \max \left(0, \frac{(\lambda_1 - \lambda_2)S}{C_4} \right) \right\} \text{ and } u_2^* = \min \left\{ 1, \max \left(0, \frac{(\lambda_5 - \lambda_6)I_s}{C_5} \right) \right\}$$

Proof

The Hamiltonian function for the optimal control system(2) is

$$\begin{aligned} H = & (C_1 I_a + C_2 I_s + C_3 T) + \left(\frac{C_4}{2} \right) u_1^2 + \left(\frac{C_5}{2} \right) u_2^2 + \lambda_1 (\Pi - \beta S (\zeta I_a + \rho I_s) - (u_1 + \delta) S) + \lambda_2 (u_1 S \\ & - \beta \phi V (\zeta I_a + \rho I_s) - (\gamma_v + \delta) V) + \lambda_3 (\beta S (\zeta I_a + \rho I_s) + \beta \phi V (\zeta I_a + \rho I_s) - (\sigma + \delta) L) + \lambda_4 (\alpha \sigma L \\ & - (\theta + \gamma_a + \delta) I_a) + \lambda_5 ((1 - \alpha) \sigma L + \theta I_a - (\kappa + \delta_s + u_2 + \delta) I_s) + \lambda_6 (\kappa I_s - (\gamma_t + \delta_t + \delta) T) \\ & + \lambda_7 (\gamma_v V + \gamma_a I_a + \gamma_t T - \delta R) + \lambda_8 (\delta_s I_s + \delta_t T) \end{aligned}$$

Through Pontryagin's maximal principle [27], there exists a co-state variable that satisfy the canonical expressions as follows,

$$\frac{d\lambda_1}{dt} = -\frac{\partial H}{\partial S}, \lambda_S(t_f) = 0$$

$$\frac{d\lambda_2}{dt} = -\frac{\partial H}{\partial V}, \lambda_V(t_f) = 0$$

$$\frac{d\lambda_3}{dt} = -\frac{\partial H}{\partial L}, \lambda_L(t_f) = 0$$

$$\frac{d\lambda_4}{dt} = -\frac{\partial H}{\partial I_a}, \lambda_{I_a}(t_f) = 0$$

$$\frac{d\lambda_5}{dt} = -\frac{\partial H}{\partial I_s}, \lambda_{I_s}(t_f) = 0$$

$$\frac{d\lambda_6}{dt} = -\frac{\partial H}{\partial T}, \lambda_T(t_f) = 0$$

$$\frac{d\lambda_7}{dt} = -\frac{\partial H}{\partial R}, \lambda_R(t_f) = 0$$

$$\frac{d\lambda_8}{dt} = -\frac{\partial H}{\partial D}, \lambda_D(t_f) = 0$$

Now using the optimal condition $\frac{\partial H}{\partial u_1} = 0, \frac{\partial H}{\partial u_2} = 0$ and $\frac{\partial H}{\partial u_3} = 0$, we get

$$\frac{\partial H}{\partial u_1} = -\lambda_1 S + \lambda_2 S + C_4 u_1 = 0 \Rightarrow u_1^* = \frac{(\lambda_1 - \lambda_2)S}{C_4}$$

$$\frac{\partial H}{\partial u_2} = -\lambda_5 I_s + \lambda_6 I_s + C_5 u_2 = 0 \Rightarrow u_2^* = \frac{(\lambda_5 - \lambda_6)I_s}{C_5}$$

Optimal control simulation for the $SVLI_a I_s TRD$ model

The characteristics of Table 1 were utilized to develop an optimal control model in MATLAB. The weight constants utilized for the optimal control issue are as follows: $C_1 = 1, C_2 = 1, C_3 = 1, C_4 = 100, C_5 = 100$. The optimality system was solved iteratively using forward and backward difference approximations [28] within the time interval of $[0, 30]$. Figure 5 depicts the differences in groups that are vulnerable, immunized, symptomatic and asymptomatic infected, treated, recovered, and deceased, both with and without control measures. This diagram illustrates that the implementation of controls leads to an increase in the populations of those who are infected but exhibit no symptoms, those who are infected and display symptoms, and those who are receiving treatment. Conversely, the populations of individuals who are vulnerable to infection, those who have been vaccinated, and those who have recovered from the infection fall. Figure 6 displays the most favorable control profile for u_1 and u_2 . Figure 7 illustrates that when the weight constants grow, the cost of control also increases, leading to a decrease in the number of control options. The simulation findings demonstrate the efficacy of appropriate control measures in reducing the number of illnesses.

Venkatesh et al.,

CONCLUSION

An epidemiological model for influenza A (H1N1) is developed and analyzed using vaccination and treatment methods. The immunization is only administered to individuals who are susceptible to the disease, and its effectiveness is not guaranteed. The model's solution is proven to be positive and bounded, and the fundamental reproduction number is calculated. An analysis is conducted on the stability of the disease-free equilibrium, both at a local and global level. Our analysis indicates that higher rates of vaccination and treatment lead to a decrease in the number of individuals who are infected, ultimately leading to the complete elimination of the disease. In addition, the proposed model encompasses the optimal control problem by integrating two types of controls: u_1 , which represents the vaccination of susceptible individuals, and u_2 , which enhances the treatment for sick individuals, resulting in their rapid recovery and transition to the recovered class. The numerical simulation findings demonstrate that the integration of vaccination and treatment strategies is highly efficient in reducing the overall number of infections.

ABSTRACT

Herbal cosmetics have become very popular recently because they are safe for the skin, natural, and environmentally friendly. These products improve skin health and appearance by utilising the medicinal qualities of plants instead of artificial chemicals. With an emphasis on their biological activities, cosmetic applications, and evidence-based advantages, this review aims to examine a variety of herbs with cosmetic uses. In the context of their active ingredients, advantages, and formulations in skincare, haircare, and other cosmetic products, about 56 plants from various research articles are examined in this review.

Keywords: Herbal Cosmetics, Natural Products, Herbal Products, Eco-friendly beauty

INTRODUCTION

Herbal cosmetics have become increasingly popular as consumers seek safer and more sustainable alternatives to synthetic beauty products. These cosmetics are formulated using natural plant-based ingredients known for their therapeutic and cosmetic properties. The global shift toward herbal products is largely driven by concerns over the potentially harmful effects of chemicals and synthetic substances in conventional cosmetics, as well as a growing preference for products that align with eco-friendly and wellness-oriented lifestyles [1]. Herbal cosmetics not only promise safety and minimal side effects but also claim to offer numerous skin benefits, including anti-ageing, anti-inflammatory, and moisturizing effects, making them a viable alternative to chemical-laden beauty products. Herbal ingredients such as aloe vera, turmeric, and green tea have been used in traditional medicine for centuries due to their proven therapeutic effects on the skin. Aloe vera, for example, is widely recognized for its soothing, moisturizing, and healing properties, especially in the treatment of sunburns and dry skin [2]. Similarly, turmeric,

**Priyadharshana**

with its antioxidant and anti-inflammatory properties, has become a key ingredient in skincare formulations aimed at treating acne and promoting even skin tone [3]. Green tea, rich in polyphenols, is a well-documented antioxidant that helps fight oxidative stress and reduce the visible signs of ageing, making it a popular inclusion in anti-ageing and rejuvenating skincare products [4]. Despite the growing demand for herbal cosmetics, several challenges remain in the industry. These include the standardization of herbal ingredients, ensuring product safety, and addressing the risk of allergic reactions to certain plant-based substances. Furthermore, there is a need for more scientific research to validate the efficacy of these products and provide concrete evidence of their long-term benefits [5]. Nevertheless, the herbal cosmetics market continues to expand, driven by consumer demand for natural, sustainable, and health-conscious beauty solutions. The development of new formulations and innovations in herbal product extraction techniques holds great potential for the future of this industry. This review aims to explore the scientific evidence behind herbal cosmetic ingredients, their efficacy, and the environmental benefits of using plant-based alternatives in the beauty industry. By analysing current trends and challenges, this review article provides a comprehensive overview of the plants that are commonly used in herbal cosmetics in India.

METHODOLOGY

The review method for this article involves a systematic approach that includes comprehensive literature searches, data extraction, and critical analysis of scientific studies. Research is conducted using reputable databases such as PubMed, Science Direct, and Google Scholar, focusing on peer-reviewed articles that discuss the chemical composition, therapeutic properties, and efficacy of herbal ingredients used in cosmetic formulations [6]. The review typically includes studies on popular plant-based ingredients like aloe vera, turmeric, and neem, examining their antioxidant, anti-inflammatory, and antimicrobial effects. [7] Articles are selected based on criteria such as relevance to the topic, publication date, and clinical or consumer efficacy findings, providing an in-depth understanding of the benefits, safety, and sustainability of herbal cosmetics compared to traditional chemical-based products. The results of the current review are presented in Table

Key Benefits of Herbal Cosmetics

- Synthetic chemicals are more likely to cause allergies or skin irritation than natural, plant-based ingredients.
- Skin and hair are nourished and protected by the vitamins, minerals, and antioxidants found in herbal products.
- Since herbal cosmetics use natural, renewable resources, they are usually more environmentally friendly.
- Moisturising, anti-inflammatory, antimicrobial, and anti-ageing qualities are multifaceted benefits that many herbs provide.

RESULTS AND DISCUSSIONS

A thorough examination of plants that are commonly used in India as herbal cosmetics in this review found a wide range of plants with various bioactive compounds that support their anti-ageing, skincare, and haircare qualities. *Aloe vera*, tulsi (*Ocimum sanctum*), neem (*Azadirachta indica*), *Hibiscus rosa-sinensis*, saffron (*Crocus sativus*), and turmeric (*Curcuma longa*) are among the plants that have long been prized in traditional medicine for their medicinal and aesthetic properties. The plants that are mostly used for cosmetic purposes are members of different plant families, and their parts - leaves, flowers, seeds, roots, and stems are used to make a variety of cosmetic products, including face masks, oils, creams, and lotions. The plants reviewed in this study have a variety of active substances, such as flavonoids, alkaloids, saponins, essential oils, and antioxidants, which help to hydrate, cleanse, and revitalise the skin and hair. For example, the essential oils of rose (*Rosa damascena*) aid in preserving skin elasticity and moisturising the skin, while the phenolic compounds in turmeric and tulsi have anti-inflammatory and antioxidant qualities. The plants identified in this study are not only integral to the Ayurvedic system but also have a growing presence in the global beauty market due to their natural, effective, and less harmful alternatives to synthetic cosmetics (Rani et al., 2019). The wide range of plants used, including well-known ones like Neem and Aloe vera, as

**Priyadharshana**

well as lesser-known species such as *Bacopa monnieri* and *Bhringraj*, reflects the diversity of therapeutic uses found in traditional cosmetic practices. Due to their natural, safe, and effective substitutes for synthetic cosmetics, the plants in this study are not only integral to the Ayurvedic system but are also becoming more and more popular in the global beauty market in recent days [64]. The bioactive substances such as antioxidants, vitamins, and minerals found in these plant species have been scientifically proven to promote skin regeneration, increase suppleness, and guard against environmental damage [65]. As an example, Neem's antibacterial qualities are well-known for treating acne and promoting skin healing, while *Aloe vera* can hydrate and calm irritated skin is well-established [66]. Many of these plants, such as turmeric and saffron, are also well-known for their anti-ageing qualities, which makes them useful components of skin-brightening and anti-wrinkle products [67]. In addition to lowering oxidative stress, the antioxidant qualities of turmeric and tulsi also promote the synthesis of collagen, which improves the suppleness and smoothness of the skin [68]. Furthermore, the hair care advantages of fenugreek and hibiscus highlight the plants' versatility in herbal cosmetics. While fenugreek is high in proteins that nourish hair follicles, hibiscus's flavonoids and amino acids help to strengthen hair and prevent premature greying of hair [69].

Challenges in Herbal Cosmetics

- Variations in the quality of raw materials and the absence of standardised production techniques might impact the consistency of the final herbal product.
- Since herbal components don't contain artificial preservatives, their shelf lives are frequently lower.[70].

Future Prospects

Emerging technologies, such as nanotechnology and green chemistry, offer opportunities to enhance the stability and efficacy of herbal cosmetics. Additionally, consumer education on the benefits and limitations of herbal products can foster trust and drive adoption.

CONCLUSION

In conclusion, the plants reviewed in this study present substantial potential for use in herbal cosmetics, offering a range of therapeutic benefits for skin and hair care. These plants provide natural, eco-friendly alternatives to synthetic chemicals, aligning with the growing consumer preference for organic and holistic beauty products. However, to fully unlock the potential of these plants, further scientific studies, including clinical trials and pharmacological research, are necessary to validate their cosmetic claims and ensure their safety for long-term use. With further exploration and integration into the beauty industry, these plants contribute to a more sustainable and health-conscious approach to skincare and hair care. In future the herbal cosmetics will represent a promising segment in the beauty and personal care industry.

Table – 1: Common plant species used as Herbal cosmetics

Sl.No	Botanical Name of the Plant	Common Name	Parts Used	Uses	References
1	<i>Acacia concinna</i>	Shikakai	Pods	Natural hair cleanser; promotes hair growth; and prevents dandruff.	[8]
2	<i>Aloe vera</i>	Aloe	Leaves	Moisturizes and soothes skin; treats sunburn; acts as a natural conditioner for hair.	[9]
3	<i>Azadirachta indica</i>	Neem	Leaves	Treats acne; and has antibacterial and antifungal properties.	[10]
4	<i>Bacopa monnieri</i>	Brahmi	Whole plant	Promotes hair growth; strengthens hair roots; and improves scalp health.	[11]
5	<i>Beta vulgaris</i>	Beetroot	Root	Brightens skin; natural blush; improves skin hydration; natural red pigment and it provides hydration and nourishment to dry lips.	[12]
6	<i>Calendula officinalis</i>	Calendula	Flowers	Soothes irritated skin; heals minor cuts.	[13]
7	<i>Camellia sinensis</i>	Green Tea	Leaves	Antioxidant, anti-ageing, protects skin against UV radiation and reduces skin inflammation.	[14]
8	<i>Carica papaya</i>	Papaya	Fruit	Exfoliates skin; brightens complexion.	[15]
9	<i>Chrysopogon zizanioides</i>	Vetiver	Roots	Cools and soothes skin; treats acne; used as perfume.	[16]
10	<i>Cicer arietinum</i>	Gram Flour	Seeds	Natural cleanser; used in face packs.	[17]

Priyadharshana

11	<i>Citrus limon</i>	Lemon	Fruit	Treats acne; lightens pigmentation.	[18]
12	<i>Citrus sinensis</i>	Orange	Peel	Natural exfoliant; brightens skin.	[19]
13	<i>Cocos nucifera</i>	Coconut	Oil from kernel	Moisturizes skin; nourishes hair; used in massage oils.	[20]
14	<i>Coriandrum sativum</i>	Coriander	Seeds	Treats blemishes; balances skin tone.	[21]
15	<i>Crocus sativus</i>	Saffron	Stigmas	Enhances skin complexion; reduces pigmentation; used in face packs.	[22]

ABSTRACT

The current research focuses on a major dykes located in the Ranipet district, which exhibits WSW-ENE trending dykes that intruded the hornblende-biotite gneiss, with gabbroic diorite and granite gneiss. The dolerite in this area exhibits a typical dolerite composition with significant alteration such as chloritization and sericitization. From a mineralogical perspective, the rock contains plagioclase laths, anhedral to euhedral clinopyroxene with basal cleavage, and quartz minerals. Opaque minerals such as ilmenite and magnetite crystals are interspersed among the major minerals and display altered boundaries. Texturally, the rock exhibits a sub-ophitic and intermediate gabbroic (granular) texture. The TAS diagram illustrates that the dykes are situated within the basalt, basalt andesitic, and rhyolitic fields (highly sericitized dolerite). The host and other associated rocks fall within the sub-alkaline field. The bivariate analysis of the dolerite under study reveals a positive relationship with SiO₂, CaO, Na₂O, K₂O, and P₂O₅, while displaying a negative correlation with TiO₂, Fe₂O, and Al₂O₃. Both the AFM and Jensen plots indicate that the dolerite samples are located in the tholeiitic field with Fe enrichment and a High Fe tholeiitic character respectively. The primitive mantle diagram demonstrates the depletion of Nb, P, and Ti, suggesting potential crustal interaction during the emplacement process. The Chondrite normalized plot for the dolerite exhibits an enrichment of LREE and a slight depletion of HREEs, indicating an OIB character. Tectonically, the dolerites were emplaced in continental and alkaline arc OIB settings with E-MORB affinity. The dolerites are derived from garnet lherzolite/garnet peridotite field indicating a deep mantle source.

Keywords: Dolerite, Mafic dyke, Ranipet, Petrogenesis, Geochemistry.

INTRODUCTION

Peninsular mafic dykes in India reveal the subcontinent's tectonic evolution, and intrusions provide a window through which to observe mantle evolution (Tarney, 1992; Hall and Hughes 1993). The dimensions and orientations of the mafic dyke intrusions in the Indian subcontinent vary (Naqvi, 2005; Srivastava and Gautam, 2008). In peninsular India, mafic dykes, particularly dolerite intrusions, are large-scale formations exposed in stabilized cratons and terrains (Dash et al., 2013; Pivarunas et al., 2019; Srivastava et al., 2019, 2021). In the northern portion of the Southern Granulite Terrain (SGT), the dolerite dykes are extensively exposed and pertain to discrete crustal-scale shear zones (Collins et al., 2014; Pandit et al., 2016). The mafic dyke is exposed to basement rocks such as hornblende biotite gneiss, charnockite gneiss, granitic gneiss, and diorite intrusion as part of the southern granite terrain in the northern granulite terrain. In the northern parts of the Archean to Proterozoic crustal blocks of the SGT, a number of mafic dyke intrusions are observable. According to Radhakrishna and Joseph (1998), the dolerite dykes in the Tamil Nadu regions of Tiruvannamalai and Dharmapuri have Fe-rich tholeiitic compositions with enrichment in large-ion lithophile elements (LILE) and light rare-earth elements (LREE), along with depletion of Nb and Ta. The geochemical characteristics align with the derivation from a source of enriched lithospheric mantle, potentially impacted by previous Archean crustal building events. This mafic dyke exposure in Tamil Nadu's northern Ranipet district is most likely the southern edge of the Cuddapah basin dykes. The dykes in the northern part of Tamil Nadu were emplaced during the Proterozoic period adjacent to the Cuddapah basins within the peninsular gneissic complex from multi-episode injections, probably single to various magma sources with crustal interactions (Drury, 1984; Murthy et al., 1987; Sankar et al., 2015). The Cuddapah mafic dykes adjacent to the Dharwar eastern margin recognized that the dyke swarm was older than 2082 Ma and was emplaced around the Cuddapah basin (Kumar et al., 2015). The dykes in this study area fall at the margin of the Fermor line or orthopyroxene isograd (Fermor, 1936; Drury et al., 1984). The orthopyroxene isograd cannot host the dolerite dykes in this region, but occasionally exposed charnockitic enclaves were identified in this region. The western and southern borders of the Cuddapah Basin open up onto the eastern edge of the Dharwar Craton dykes. Chittoor and Anantapur are affected by the dolerite intrusion with an OIB nature that is present in the southern edge of the Cuddapah Basin (Ramamohana Rao et al., 1986). Mafic to ultramafic dolerite intrusion with a tholeiitic to highly dolerite composition is made possible by the OIB created by the rifting activity (Bas, 1971). The current study outlines how the current study area connects to adjacent dolerite intrusions in the southern margin of the Cuddapah Basin and the eastern margin of the Dharwar craton. It also discusses the nature of the intrusion, mineralogical character, geochemical nature, and tectonic settings of dolerite intrusion in the Ranipet district.

Geological setting

The mafic dykes, particularly the dolerite dykes, in Peninsular India have been extensively studied (Ernst and Srivastava, 2008; Pati et al., 2008; Pratheesh et al., 2011; Dash et al., 2013; Radhakrishna et al., 2013; Pivarunas et al., 2019; Kumar et al., 2020; Srivastava et al., 2008, 2021, 2022; Ramachandran et al., 2023a, b; Datta et al., 2023; Ashutosh et al., 2024). In Tamil Nadu, the northernmost intrusion within the Southern Granulite Terrain (SGT) comprises dolerites in the Ranipet area. These dolerite dykes extend into the Chittoor district of Andhra Pradesh, spreading along an east-west orientation through Archean–Proterozoic rocks. Predominantly dolerites, these intrusions occasionally include gabbroic dykes. The Ranipet dolerite dykes and the Chittoor dolerite dykes share the same orientation, with more extensive exposure in Chittoor compared to Ranipet. The southern tip of the Cuddapah Basin also extends into the Chittoor district, characterized by the peninsular gneissic complex and granitic plutons. The paleo-tectonic environment of Anantapur–Chittoor basic dykes was studied by Ramamohana Rao et al. (1986), indicating formation in Oceanic Island Basalt (OIB) settings linked to hotspots. The Chittoor dykes, in contrast, are associated with subduction-related processes, evidenced by their low TiO₂ content and Nb/La ratio of ~0.40 (Sankar et al., 2014). Situated south of the Cuddapah basin sedimentation (Halls, 1982; Drury, 1984), the Chittoor dykes indicate that the mafic intrusion in Ranipet might predate the Cuddapah basin sedimentation and could originate from the same source as the Chittoor dolerite dykes. Additionally, the dolerite dykes in this region are likely in contact with the eastern Dharwar craton dykes.

Rameshkumar *et al.*,**Field Relationship**

The dolerites in the study area exhibit east-west trending intrusions emplaced within hornblende biotite gneissic rock (Fig. 2). These dolerites, located in the Ranipet district, are characterized by their dark green to greenish-black color. In hand specimens, the dolerites display massive, fine to medium grains, with finer textures observed at the chilled margins and medium to coarser grains towards the center of the dykes. The color of the dolerites is typically greenish-grey. The dykes present a linear and sometimes crooked contact with the host rock. The hornblende biotite gneiss contains amphibolite xenoliths aligned parallel to the gneissic foliation of the host rock. The dykes exhibit numerous fractures and joints with varying orientations. The hornblende biotite gneissic host rock is leucocratic, predominantly comprising feldspar and quartz, with hornblende and biotite minerals also present. The host rock is intruded by pegmatite and quartz veins, which show evidence of deformation displacements. These vein intrusions occurred prior to the emplacement of the dolerite dykes in the region. The pegmatite intrusions are noted for their medium to coarse grains in some locations, attributed to intermediate cooling rates within the hornblende biotite gneiss. The alignment of hornblende and biotite minerals in the host rock is almost perpendicular to the dolerite dykes, which crosscut the gneissic foliation. Additionally, granitic gneiss and gabbroic diorite rocks are identified as part of the intrusive suite within the peninsular gneissic complex. The structural and compositional characteristics of these rocks provide insights into the geological history and tectonic processes that have shaped this region. The east-west orientation of the dolerite dykes suggests a significant tectonic influence, possibly related to regional stress fields during their emplacement. The presence of amphibolite xenoliths and the varied grain sizes within the host rock indicate a complex cooling history, while the fractures and joints reflect subsequent tectonic activities. Moreover, the relationship between the dolerite dykes and the hornblende biotite gneissic host rock reveals important information about the timing and sequence of geological events. The pre-existing pegmatite and quartz veins suggest multiple phases of intrusion and deformation, highlighting the dynamic geological environment of the region. The alignment of hornblende and biotite minerals perpendicular to the dykes indicates the relative ages of the intrusions and the orientation of the stress fields during their emplacement. This geological setting, with its diverse rock types and structural features, provides a valuable context for understanding the tectonic evolution of the Southern Granulite Terrain and its relationship with adjacent geological units like the Cuddapah Basin and the eastern Dharwar craton.

Petrography

A total of 61 fresh rock chips from medium and coarse-grained dolerite are collected. These samples are specifically taken from the center of dykes for detailed textural analysis. The samples are then sent to Continental Instruments in Lucknow for thin section production. Once the thin sections are prepared, the next phase involves studying the petrographic characteristics using a Leica DM2700 P petrological microscope at the Department of Geology, Periyar University, India. This microscope is equipped with the Leica Application Suite, which aids in analysing the mineral composition and texture of the dolerite samples. The photomicrographs of Fig 3a) show the subophitic texture of dolerite rock exhibit plagioclase laths and pyroxene and opaque minerals. b) –c) Photomicrograph showing medium grain plagioclase and pyroxene mineral shows subophitic and intersertal texture with granophyric intergrowth. d-g and i) Photomicrograph of the XPL sections shows dolerite mineralogy, where a sub-ophitic is present in the rock. h) shows microcrystalline groundmass with microphenocryst of plagioclases, sample collected from the chilled margin of the dyke. j)–l) Photomicrograph shows quartz and feldspar as essential, and biotite and hornblende present as accessory minerals in the hornblende biotite gneiss. A few opaque minerals were present in the rock with mafic minerals.

Analytical Techniques**Whole-rock geochemistry**

The samples were ground to a size of 63 μ using steel and agate mortars. Subsequently, 17 pulverized samples were dispatched to Activation Laboratory Limited in Canada for Lithogeochemistry and Whole Rock Analysis. The samples were examined under the package code 4Litho (WRA+ICP), requiring 5g of the pulverized sample to meet the criteria of 95% passing through 105 microns (μ m). The fusion process, which involves lithium metaborate/tetraborate fusion, is carried out by a robotic system at Actlabs. Following fusion, the resulting molten

Rameshkumar *et al.*,

bead is swiftly digested in a dilute nitric acid solution to ensure complete dissolution of the entire sample. This aggressive fusion technique is crucial for the solubilisation of major oxides such as SiO_2 , refractory minerals (e.g., zircon, sphene, monazite, chromite, and gahnite), REE, and other high field strength elements. Although high sulphide-bearing rocks may necessitate different treatment, they can still be effectively analyzed. The analysis is conducted using ICP-OES and ICP-MS. In samples with exceptionally high Ba concentrations (> 5%), Eu determinations are considered semi-quantitative. Major oxides and selected trace elements (4B) are analyzed on an ICP instrument. Calibration is carried out using 14 meticulously prepared USGS and CANMET-certified reference materials.

Whole-rock geochemistry

The geochemical composition of the dolerite, hornblende biotite gneiss, granitic gneiss, and amphibolite rocks is presented in Table 2. The dolerite contains 51.57-55.95% SiO_2 and 4.66-8.79% MgO. The CIPW norm calculated for total iron (Fe_2O_3^T) for all samples indicates quartz normative (Table 2). Additionally, quartz normative tholeiites for dolerite dykes have been identified in certain areas of Chittoor, Anantapur, and Mahbubnagar districts (Sarma, 1991; Reddy 1991). The mafic index character of the dolerite dyke was determined using the Harker binary diagram based on MgO vs Major elements (Fig 6) and Trace (Fig 7) plots. The bivariate plot of MgO vs SiO_2 shows a negative correlation as MgO increases with decreasing SiO_2 . Similarly, the bivariate plot of MgO vs Al_2O_3 , Na_2O , and TiO_2 also shows a negative correlation, while the plot of CaO , P_2O_5 , and FeO^T vs MgO shows a positive correlation. The positive correlation of CaO vs MgO suggests clinopyroxene fractionation during crystallization. The Mg\# ($100\text{Mg}/(\text{Mg}+\text{Fe}^T)$) ranges from 34.60 to 56.97, indicating mafic characteristics. The total alkali versus SiO_2 (TAS) diagram (Fig 4) shows that the dolerite dykes fall within the basalt and basalt andesitic field. The AFM ($\text{A}=\text{Na}_2\text{O}+\text{K}_2\text{O}$; $\text{F}=\text{Fe}_2\text{O}_3^T$; $\text{M}=\text{MgO}$) plot of Irvine and Baragar (1971) diagram (Fig 8a) shows that dolerite, amphibolite, and gabbroic diorite rocks fall within the tholeiite series field, with dolerites exhibiting a prominent iron-enrichment trend. The triangular cation plot by Jensen (1976) illustrates the distribution of dolerite and amphibolite samples in the high-Fe tholeiite basalt field, along with one sample in the komatiite basalt field. In contrast, the bivariate classification diagram developed by Miyashiro (1974) (SiO_2 vs FeO/MgO) displays the positioning of dolerite samples in the calc-alkaline series, with one sample in the tholeiite series.

The amphibolite sample was also positioned within the tholeiite series. Due to the elevated SiO_2 content and high FeO/MgO ratio, the granitic gneiss samples are located within the tholeiite series field (Miyashiro, 1974). The Nb/Y vs Zr/TiO_2 binary diagram, as proposed by Winchester & Floyd (1977), indicates that the dolerite samples fall within the subalkaline basalt and andesitic/basalt field. Specific trace elements are utilized to track the fractionation process of magma. By plotting trace and REE elements against MgO, the genetic nature of the dolerite dykes can be distinguished. In Figure 7, trace elements are plotted against MgO, revealing a positive correlation for Cr, Ba, Ni, Mg, Sr, Rb, and $\text{K}_2\text{O}/\text{Na}_2\text{O}$, while Y, Ce, La, Zr, and A/CNK ratio exhibit a slightly negative correlation. The positive and negative correlations of elements with MgO are indicative of compatible elements that align with compatible and incompatible elements. In the bivariate plot against MgO, compatible elements display a positive correlation, whereas incompatible elements exhibit a negative correlation as the magma undergoes fractional crystallization from the parent magma. The trace element compatibility diagram for Ranipet dolerite dykes, based on the Primitive Mantle normalization method (Fig 9, Sun & McDonough, 1989), reveals positive enrichment of Ba, K, Pb, Sr, Nd, and negative anomalies of Nb, P, Zr, and Ti. The depletion of Ti in gabbroic diorite and hornblende biotite gneiss indicates an incompatible nature that cannot coexist with the minerals in the rock. Additionally, Th and U show a slight depletion pattern in all samples except one from the Venkatapuram area, where they exhibit slightly high spikes, suggesting a higher concentration compared to the other dolerite dykes. The low Th, U, and Sr content in the present study suggests that the dolerites evolved in an oceanic environment, with some dolerites exposed in continental settings. Furthermore, the granitic gneiss in the diagram shows a high positive enrichment of Th. Eu shows no or little anomaly in all dolerite samples. All studied dolerite dyke samples, other associated rock samples, OIB, E-MORB, and N-MORB samples (from Sun and McDonough, 1989) were normalized to Chondrite REE (Fig 9 below) for comparison, revealing sharply fractionated LREE enrichment pattern relative to HREE, with MREE showing a slightly inclined pattern, and one dolerite sample exhibiting a flat MREE pattern. Additionally, HREE (Tb-

**Rameshkumar et al.,**

Lu) shows steep depletion with no appreciable or little anomaly of Eu, behaving like OIB. The low ratio of Nb/La (~0.03-0.40) and low levels of TiO₂ suggest an intrusion related to subduction. Nevertheless, the enrichment of LREEs and the depletion pattern of HREEs are characteristic of OIB, with the exception of one sample that exhibits behavior consistent with E-MORB, contradicting the typical OIB signature.

Tectonic Settings

The dolerite intrusions in the Ranipet district of Tamil Nadu and the southern border of Andhra Pradesh are part of the peninsular gneissic complex (PGC), which also includes hornblende biotite gneiss. Proterozoic dykes from the Cuddapah basin are found near the study area. Various tectonic setting diagrams were utilized to illustrate the emplacement settings of the dolerite dykes. In the ternary tectonic diagram by Pearce et al. (1977) using major oxides MgO-Fe₂O₃-T-Al₂O₃, dolerite samples and one amphibolite sample are categorized into Ocean Island and continental settings, while the host rock HBG falls under orogenic settings. The Zr-3*Y-Ti/100 ternary diagram (Fig 10b) by Pearce and Cann (1973) shows that all dolerite samples are located in the Within Plate Basalt region, except for one sample which falls under the MORB field. OIB and CONB (Within Plate Continental Basalt) are collectively referred to as WPB, characterized by tholeiitic and alkali basalt (Ramamohana Rao et al., 1986). The Zr-Ti plot (Pearce, 1982) illustrates the distribution of dolerites (Fig 11a) within the Island Arc Basalt and Within-Plate lavas field. The binary plot (Fig 11b) Ti vs V (Shervais, 1982) indicates that the dolerite samples fall within the Oceanic Flood Basalt (OFB) field with a Ti/V ratio ranging from 20-50. Another bivariate discrimination diagram (Fig 11c) Zr vs Zr/Y (Pearce and Norry, 1979) shows that most dolerite samples are located outside the field of Within-Plate Basalt (WPB), with one sample falling inside the WPB region. The Nb/Yb vs Th/Yb ratio discrimination diagram (Fig 11d, Pearce, 2008) reveals that dolerite samples align closely with the E-MORB array and trend from E-MORB to OIB. All tectonic discrimination diagrams indicate that the majority of dolerite samples cluster tightly, with the exception of one sample. The tectonic discrimination diagrams for dolerite dykes suggest an affinity with MORB and within-plate basalt, displaying OIB characteristics. However, the chemical variations in the basaltic magma of different environments are influenced by crustal interaction and partial melting of magma.

Petrogenesis

The La vs La/Sm plot (Figure 12a) demonstrates the fractional melting and partial melting trends during the evolution of the analyzed samples from the Ranipet dolerite. These trends indicate varying degrees of partial melting and fractional crystallization in the magma source. Meanwhile, the Sm vs Sm/Yb ratio plot (Zhao and Zhou, 2007) reveals that most samples are situated within the Garnet Peridotite field, with only one sample plotting close to the Spinel peridotite source, corresponding to a melting curve ranging from 5 to 10 degrees of partial melting (Figure 12b). Samples with high Sm/Yb ratios plotting in the Garnet Peridotite field indicate that they may have originated from a deep mantle source, where garnet is present as a residual phase. The elevated Sm/Yb ratios suggest that these rocks originate from a deep mantle source. Additionally, the La_(PM) vs La/Yb_(PM) plot (Figure 12c) shows that the dolerite samples predominantly fall within 3 to 5 % of melting curve in the Garnet lherzolite field, with the exception of one sample that plots within the Spinel lherzolite field. This distribution further supports the inference of a deep mantle origin, with varying degrees of partial melting and source characteristics influencing the geochemical signatures of the Ranipet dolerite samples. The La/Sm vs Sm/Yb plot (figure 12d, after Aldanmaz et al., 2000) shows that the samples plot in the spinel-garnet-lherzolite field within 1 to 5 % of melting curve. Here, the intermediate Sm/Yb ratios, indicating the presence of both spinel and garnet, suggesting a transitional depth for the dolerite samples.

CONCLUSION

The present study outlines the mineralogical, geochemical, tectonic conditions and petrogenesis for dolerite in the Ranipet district of Tamil Nadu. The present research identifies several factors, such as the doleritic composition of the collected dyke samples, the predominant presence of lath-shaped plagioclase and clinopyroxene in these rocks, and the minor amounts of opaque minerals. Additionally, the granophyric intergrowth is observed in the interstices of

**Rameshkumar et al.,**

plagioclase minerals. The collected dolerite rock exhibits subophitic textures, while a few dykes display gabbroic texture with relict doleritic intergrowth. Geochemically, the dolerite rocks demonstrate quartz normative tholeiites with Fe enrichment. The TAS plot for dolerites indicates a basaltic-to-basaltic andesitic composition. Furthermore, the compatible elements exhibit a positive correlation with MgO. The primitive normalized diagram reveals positive enrichment of Ba, K, Pb, Sr, and Nd, as well as negative anomalies of Nb, P, Zr, and Ti. Eu shows no or little anomaly. The chondrite normalized diagram plot illustrates the enrichment of LREE and depletion of HREE pattern for dolerites relative to Ocean Island Basalt. The tectonic settings for the current dolerite samples indicate Island Arc Basalt, WPB character, suggesting that the dolerites were likely emplaced in the island arc and WPB settings with OIB and E-MORB affinity during fractionation of partial melting of magma. The petrogenesis plots suggest that the samples derived from the deep mantle source of garnet lherzolite field, where garnet remains as a residual phase.

ABSTRACT

This study presents an innovative approach to distinguishing between cats and dogs in video footage through deep learning, specifically using Convolutional Neural Networks (CNNs). By integrating both RGB and thermal imaging, our method leverages distinct data sources to enhance classification accuracy. Thermal imaging detects heat patterns, while RGB imaging captures visible attributes, providing a more comprehensive basis for animal identification. To address challenges such as fur interference, cages, and other occlusions, a two-stage framework is developed. Initially, a robust preprocessing pipeline minimizes obstructions and optimizes the quality of RGB and thermal images. Extensive experimentation on diverse datasets demonstrates the effectiveness of our approach in improving classification accuracy across various environmental conditions.

Keywords: Convolutional Neural Networks, RGB imaging, Thermal imaging, Animal classification, Deep learning.

INTRODUCTION

Identifying animals in video recordings poses significant challenges, particularly in dynamic environments where fur, enclosures, and other obstructions hinder visual recognition. Conventional methods often struggle with such complexities, leading to decreased classification accuracy. To enhance reliability in distinguishing between cats and

**Chinnaraju and Prabavathy**

dogs, this research employs deep learning techniques, particularly CNNs, in combination with RGB and thermal imaging. Our proposed dual-modality system integrates RGB and thermal imaging to capture both visible features and heat signatures, ensuring a more accurate identification process. This fusion of imaging techniques mitigates common visual disruptions and enhances classification performance. Additionally, a two-stage preprocessing pipeline is designed to address occlusions and variable environmental factors, refining input quality for analysis.

The contributions of this research are threefold:

1. Introduction of a dual-modality approach to improve classification accuracy.
2. Development of a robust preprocessing pipeline to enhance image quality by reducing occlusions.
3. Comprehensive evaluation using a diverse dataset, demonstrating the superiority of our method over existing techniques.

This paper is structured as follows: Section 2 reviews related literature on deep learning in animal classification. Section 3 details the proposed methodology, including dual-modality integration and preprocessing steps. Section 4 presents experimental results and comparisons with existing methods. Section 5 discusses key findings, implications, and future research directions.

LITERATURE SURVEY

Existing research highlights the potential of integrating thermal and RGB imaging for improved animal classification. However, many studies fail to adequately address the impact of occlusions such as fur and cages. This study aims to bridge this gap by implementing a robust preprocessing strategy that minimizes obstructions and enhances classification accuracy under diverse environmental conditions. Recent advancements in deep learning and computer vision have significantly improved image and video classification capabilities. CNNs, in particular, have demonstrated remarkable performance in tasks such as object detection, image segmentation, and video analysis. Traditional animal classification methods have relied primarily on RGB imaging, but these approaches often struggle in low-light settings and with occlusions. Thermal imaging, which detects heat signatures, provides a complementary solution by overcoming lighting variations and penetrating obstacles like fur. Previous studies have explored thermal imaging for animal detection. For instance, Smith et al. (2019) demonstrated that thermal imaging could reliably detect wildlife in low-visibility environments. Similarly, Jones and Adams (2020) integrated RGB and thermal imaging to enhance livestock monitoring accuracy. However, these studies did not fully address occlusion challenges. Our research extends these findings by implementing a preprocessing pipeline that effectively mitigates obstructions and improves classification performance.

PROPOSED METHODOLOGY FOR THERMAL AND RGB ANIMAL CLASSIFICATION WITH OBSTACLE REMOVAL**Data Preprocessing**

The first step in the process is **data preprocessing**, which ensures that raw data is cleaned, structured, and optimized for further processing. This step includes multiple sub-processes:

Data Collection

- Video recordings of **cats and dogs** were obtained from various sources, including:
 - **Veterinary clinics** (capturing medical imaging and real-world pet behavior).
 - **Thermal imaging databases** (for high-quality heat signature data).
 - **Wildlife monitoring systems** (for analyzing how animals behave in natural and controlled environments).
- The dataset contains **a variety of conditions**, such as different backgrounds, lighting conditions, and occlusions (e.g., fur, cages, shadows).

**Chinnaraju and Prabavathy****Frame Extraction and Synchronization**

- Video footage was split into individual **image frames** for analysis.
- Each frame was tagged to identify **key anatomical features** (eyes, ears, tail, etc.).
- RGB and thermal frames were **synchronized** using **feature-based alignment techniques** to ensure that both modalities corresponded to the same time points in the video.

Data Normalization and Standardization

- **Thermal images were normalized** to a consistent temperature scale, ensuring that heat variations between different animals were accounted for.
- **RGB images were resized** and adjusted for brightness and contrast to create a **uniform dataset**.

Obstacle Removal and Image Enhancement

Since animal images may have **visual obstructions** (fur, cages, background clutter), an advanced **preprocessing pipeline** was developed to **eliminate distractions and enhance image quality**.

Obstacle Detection Using Edge Detection

- The **Canny Edge Detector** was applied to identify sharp intensity changes in the image, which helped in detecting **obstructing elements like fur and cage bars**.
- Detected edges were analyzed to determine **which areas should be removed or corrected** in subsequent processing steps.

Morphological Processing for Refinement

- **Dilation and erosion** techniques were applied to **smooth edges** and remove small artifacts that could interfere with classification.
- These operations improved the visibility of animal features while suppressing background noise.

Occlusion Removal Using Inpainting

- **Navier-Stokes inpainting techniques** were applied to **reconstruct occluded parts** of the image.
- This method **fills in missing or obstructed areas** by predicting pixel values based on the surrounding pixels, restoring hidden features like eyes and facial contours.

Image Enhancement

- **Histogram Equalization** was used to adjust the contrast of both RGB and thermal images, making features more distinct.
- **Gaussian Smoothing** was applied to reduce noise and produce cleaner input images for classification.
- The enhanced images provided **sharper details**, leading to improved feature extraction and classification accuracy.

Feature Extraction and Analysis

Once the images were **preprocessed**, the next step involved **extracting meaningful features** from RGB and thermal images. Feature Detection Using Histogram of Oriented Gradients (HOG)

- The **HOG algorithm** was used to extract **structural and texture-based features** from images.
- Features such as **edges, contours, and gradients** helped in differentiating between cats and dogs.

Thermal Signature Analysis

- **Temperature-based features** were extracted from thermal images.
- High-temperature regions (e.g., nose, eyes, ears) were **analyzed to identify key traits** unique to each species.

**Chinnaraju and Prabavathy****Thermal Profile Generation**

- A **temperature distribution map** was generated for each animal.
- This profile allowed the model to **distinguish between similar-looking animals based on heat signatures**, which are less affected by fur or lighting conditions.

Multi-Modal Feature Fusion

- Features extracted from **both RGB and thermal images were combined** into a unified feature set.
- This **hybrid feature representation** improved classification robustness, as it incorporated both visual (RGB) and temperature-based (thermal) characteristics.

Robust CNN-Based Classification

The extracted features were then fed into a **Convolutional Neural Network (CNN)** to classify animals as either **cats or dogs**.

CNN Model Training

- The CNN was trained using the **combined RGB and thermal feature sets**.
- Training involved **backpropagation and optimization** to minimize classification errors.

Architecture Optimization

- The CNN was designed to **handle the complexity of multi-modal inputs** (RGB and thermal).
- It contained multiple layers, including:
 - **Convolutional layers** for feature extraction.
 - **Pooling layers** for dimensionality reduction.
 - **Fully connected layers** for final classification.

Handling Occlusions and Variations

- The CNN was trained to **recognize animals even in the presence of partial occlusions**.
- Various **augmentation techniques** (rotation, flipping, brightness adjustments) were used to make the model more robust.

Performance Metrics and Model Evaluation

- The CNN was evaluated based on:
 - **Accuracy** (How often it correctly classifies cats and dogs).
 - **Precision & Recall** (How well it identifies each class).
 - **F1-Score** (A balance between precision and recall).
 - **Inference Time** (The speed of classification).

The TRACOR model was compared with standard CNN and VGG16 models, demonstrating superior classification performance.

CONCLUSION

The TRACOR framework significantly enhances animal classification, particularly in distinguishing between cats and dogs under diverse environmental conditions. By integrating RGB and thermal imaging with advanced preprocessing techniques, TRACOR outperforms conventional models in terms of accuracy and robustness. This study underscores the potential of deep learning and multi-modal imaging for improved animal detection and monitoring. Future research will focus on refining the model and exploring its applicability to broader classification tasks.

ABSTRACT

Benign prostatic hyperplasia (BPH) refers to the non-malignant growth or hyperplasia of prostate tissue and is a common cause of lower urinary tract symptoms (LUTS) in older men. This condition may be correlated to vata ashthila in Ayurvedic reference. Conventional therapies have limitations in efficacy and side effects. This case report highlights the use of Punarnavadi Yoga Basti (medicated enema) from Ayurveda in managing an 80-year-old male patient with BPH. Following an 8-day course of Anuvāsana and Niruha Basti, there was a notable improvement in urinary flow, a reduction in prostate size from 26 cc to 20 cc, and a decrease in post-void residual volume from 65 mL to 20 mL. The patient experienced significant symptomatic relief with no recurrence of symptoms for a month. There were no adverse effects, demonstrating the therapeutic potential of Punarnavadi Yoga Basti in BPH management.

Keywords: BPH, Punarnavadi Yoga Basti, Vata Ashthila, niruha basti, anuvāsana basti, post voidal.

INTRODUCTION

Benign prostatic hyperplasia (BPH) refers to the non-malignant growth or hyperplasia of prostate tissue and is a common cause of lower urinary tract symptoms (LUTS) in older men[1]. This condition may be correlated to vata

91068

**Kashyap K. Patel et al.,**

ashthila in Ayurvedic reference [2]. Conventional therapies have limitations in efficacy and side effects. This case report highlights the use of Punarnavadi Yoga Basti[3]. Medicine management and how ayurveda can help Analysis of Medicare charges from the authors' institution, as well as local retail costs of medication, demonstrated a wide range in costs of commonly used BPH treatments. Interventions for BPH reached cost equivalence with combination medical therapy within 6 months to 8 years. A myriad of options for managing men with symptomatic BPH exist. It is prudent not only to consider surgeon preference and patient-specific factors when selecting a treatment but also to understand the economic impact different BPH therapies confer. A significant global trend is emerging: the elderly population is growing rapidly, and in most countries, the oldest age groups are expanding the fastest. With this demographic shift, the incidence of BPH and the number of men seeking treatment for the condition are steadily increasing. BPH is often considered a progressive disease. Management has shifted from surgical interventions to medical therapies for patients with mild to moderate symptoms, due to advancements in pharmacological treatments. In Ayurveda, the bladder (Basti) is considered the site of various urinary disorders, such as Mootraghata, Prameha, Shukradosha, Mootradosha, and others [4]. Among the twelve types of Mootraghata [5], where urine retention is a key feature, Vatassthila (or Mootrashthila) is correlated with BPH, as both conditions involve similar pathologies—urinary obstruction. In Vatassthila, the obstruction is caused by a stony nodule (Ashthilavat Granthi), whereas in BPH, it is due to an enlarged prostate. Ayurvedic understanding attributes the condition to a vitiation of a type of Vata (Apana Vata), which becomes localized between the bladder and the rectum (guda). This leads to the formation of a hard, stone-like mass that obstructs the passage of stool, urine, and gas, causing bladder distension and discomfort in the bladder region.

PATIENT INFORMATION

80-year-old male, presented with complaints of dribbling micturition, burning micturition, and a weak urinary stream, which had persisted for the previous four to five months. He had a history of hypertension and was on antihypertensive medication (Tab Nebicard 5 mg once daily in the morning). A digital rectal examination (DRE) revealed an enlarged prostate. The patient visited the outpatient department (OPD) on July 19, 2024, where an International Prostate Symptom Score (IPSS) assessment was performed which showed score of 24. After receiving a detailed explanation of the treatment procedure, the patient was admitted to the hospital for further management.

CLINICAL FINDING

Inspection

The external urethral meatus appeared normal upon inspection, with no visible deformities such as hypospadias. The foreskin was normal and fully retractable. According to the patient's report, he experienced dribbling and a weak urinary stream.

Palpation

No strictures were detected in the penile urethra upon palpation.

Per Rectal Examination

A per rectal examination along with bimanual palpation, confirmed enlargement of the medial lobe of the prostate, presenting as a soft, uniform swelling palpable on examination. The median ridge was not detectable during the examination. A digital rectal examination (DRE) revealed an enlarged prostate. Pre-treatment investigations included IPSS scoring which was 24, ultrasonography, and blood and urine tests. Prostate size was 26 cc, with a post-void residual volume of 65 mL and a prostate-specific antigen (PSA) level of 0.67 ng/mL.

MATERIALS AND METHODS

Basti Therapy

- Punarnavadi Kashaya Yoga Basti

**Kashyap K. Patel et al.,****Shamana (Palliative Therapy):**

- Chandraprabhavati [7]
- Gokshuradi Guggulu [8]

Pathya-Apathya (Diet and Lifestyle Recommendations):

- **Diet:** The patient was advised to follow a diet that pacifies Vata and Pitta doshas. This includes avoiding spicy, oily, and heavy foods. Emphasis was placed on the consumption of fresh fruits, vegetables, and whole grains.
- **Punarnavadi Kashaya Yoga Basti**

RESULTS AND DISCUSSION

Benign Prostatic Hyperplasia (BPH) is a common condition in aging males, characterized by the non-cancerous enlargement of the prostate gland. In Ayurveda, BPH is correlated with "Ashthila," a condition mentioned in Susruta Samhita under Mutraghata, where there is an obstruction in the urinary pathway. The primary aim of this case study was to explore the effectiveness of Ayurvedic management, particularly the Punarnavadi Yoga Basti, in the treatment of BPH. Due to the combined effect of Punarnavadi Yoga Basti (Niruha and Anuvasana), there was a significant decrease in the size of the prostate, along with a reduction in post-void residual urine. The patient, who followed the Basti schedule, also showed significant improvement in the IPSS scoring. Symptoms like nocturia and hesitancy, which are particularly bothersome in cases of BPH, were considerably reduced, providing the patient with notable relief. The procedure was conducted over a duration of 8 days, with supportive medication. This not only alleviated the symptoms but also provided the patient with long-lasting relief for up to 2 months.

EFFICACY OF PUNARNAVADI YOGA BASTI

Basti therapy, particularly Punarnavadi Yoga Basti, has shown promising results in the management of BPH. The therapy, which involved a combination of Anuvasana Basti (oil-based enema) and Niruha Basti (decoction-based enema), was administered over a period of 8 days. The formulation of Punarnavadi Kashaya, used in Niruha Basti, contains ingredients like Punarnava (*Boerhavia diffusa*), Gokshura (*Tribulus terrestris*), and Shatapushpa (*Anethum sowa*), which are known for their anti-inflammatory, diuretic, and urinary tract supportive properties. These ingredients work synergistically to reduce prostate size, alleviate inflammation, and improve urinary flow. The Punarnavadi compound is predominantly composed of Pitta-shamaka Rasa, Tridosahara Guna, Tridosahara Veerya, and Pitta-shamaka Vipaka. This unique combination makes it an effective Tridosahara remedy, primarily targeting the Pitta Dosha. In the context of chronic renal failure, where Pitta is the dominant factor in the Tridosha pathology, it can be proposed that Punarnavadi works by controlling both Pitta and Vata, followed by stabilizing the remaining Doshas. This action prevents further aggravation of the disease, thereby slowing its progression. The Tikta Rasa present in Punarnavadi is beneficial as it promotes Niraamata (freedom from toxins) and enhances Jatharagni (digestive fire), both of which are crucial in managing renal failure where Agni Mandya (weakened digestion) is often a concern. Additionally, Tikta Rasa and Rooksha Guna (dry quality) help in drying up Ama (toxins), producing a clearer Rasa Dhatu (nutritive fluid), and clearing the Srotas (channels), which improves circulation and aids in nourishing the Dhatus (tissues). Tikta Rasa is particularly valuable in diseases affecting Rakta Dhatu (blood), and since Rakta is one of the first Dhatus impacted in renal failure, this makes the compound even more suitable for treatment [9].

Punarnavadi Kashaya is a herbal decoction that includes Punarnava (*Boerhavia diffusa*) as a key ingredient, known for its diuretic, anti-inflammatory, and rejuvenating properties. In BPH, it helps by:

1. **Reducing Inflammation and Prostate Swelling:** Punarnava and other herbs in the Kashaya help reduce inflammation and swelling of the prostate, easing urethral compression and improving urine flow.
2. **Improving Urinary Function:** The diuretic action of Punarnava helps reduce fluid retention and improve bladder function, which can reduce urinary frequency and nocturia.

**Kashyap K. Patel et al.,**

3. **Basti Therapy (Medicated Enema):** Basti is a well-known Panchakarma procedure for detoxifying and balancing Vata dosha, which plays a role in urinary disorders. Administering Punarnavadi Kashaya through Basti helps deliver the herbal medicine directly to the colon, which is connected to urinary and reproductive systems. This aids in clearing blockages, promoting smooth urine flow, and reducing bladder irritability, thus relieving nocturia and frequency. By targeting both the obstructive pathology and the underlying Vata imbalance, Punarnavadi Kashaya Yoga Basti offers a holistic and effective approach to managing BPH symptoms like nocturia and urinary frequency.

PROBABLE MODE OF ACTION

Effects on BPH and Urinary Problems

1. Punarnava (*Boerhavia diffusa*) - Its active component β sitosterol reduces prostate size by inhibiting cell proliferation, while flavonoids and triterpenoids reduce inflammation in the prostate. The increased urine output helps alleviate urinary retention [10].
2. Gokshur (*Tribulus terrestris*) - The saponins reduce prostate inflammation, and β -sitosterol prevents further enlargement of the prostate. Its alkaloids relax bladder muscles, improving urinary flow [11].
3. Yava Kshar (Alkaline preparation of *Hordeum vulgare*) - Yava Kshar's lithotriptic and alkalinizing effects prevent urinary stones and maintain healthy pH levels, reducing complications in BPH patients.
4. Shatpushpa (*Anethum sowa* or *Foeniculum vulgare*)- Shatpushpa contains bioactive compounds like flavonoids and essential oils (carvone, limonene) that exhibit significant anti-inflammatory properties. These may help reduce the inflammatory processes in the prostate tissue, potentially alleviating the symptoms associated with BPH [12]. The improvement in clinical symptoms and the reduction in prostate size from 26 cc to 20 cc post-treatment highlight the therapeutic efficacy of Punarnavadi Yoga Basti. The significant decrease in post-void residual (PVR) urine volume from 65 mL to 20 mL further emphasizes the treatment's effectiveness in improving bladder emptying and reducing the frequency of micturition. The slight increase in PSA levels from 0.67 ng/mL to 1.1 ng/mL, though still within the normal range, suggests a positive response to the therapy without raising concerns about malignancy.

CONCLUSION

This case study demonstrates the potential of Punarnavadi Yoga Basti as an effective and safe alternative to conventional therapies in the management of Benign Prostatic Hyperplasia. The treatment not only resulted in significant symptomatic relief but also in the reduction of prostate size and improvement in urinary flow parameters. The Ayurvedic approach offers a holistic management option that emphasizes the balance of doshas and the use of natural therapies to restore health, making it a valuable consideration in the treatment of BPH. After 2 months, the patient was consulted again, and the IPSS scores were measured. The patient continued to experience relief from both obstructive and irritative symptoms. The IPSS score remained promising even after 2 months. The patient had not taken any medication for the past 1 month.

PATIENT CONSENT

The patient provided informed consent for the publication of this case report and any accompanying images. These materials are available for verification by the journal's editor if required.

ABSTRACT

This paper presents the development and implementation of a real-time face recognition-based attendance system using OpenCV. The system leverages the Haar Cascade Classifier for face detection and the Local Binary Patterns Histogram (LBPH) algorithm for face recognition. Designed to streamline the attendance process in educational settings, the system automates attendance logging through live video feeds. It achieves high detection and recognition accuracy, operating efficiently in real-time. A user-friendly graphical interface allows instructors to easily manage attendance sessions, offering features such as subject selection and automated updates. While the system is sensitive to factors like lighting, face orientation, and occlusions, it has been successfully tested in classroom environments, with positive feedback from users. This project demonstrates considerable potential for reducing manual attendance efforts and serves as a foundation for future advancements in automated recognition systems across various applications.

Keywords: Face recognition, LBPH, Haar Cascade, OpenCV, attendance monitoring, real-time system, machine learning.

INTRODUCTION

In today's fast-paced world, automation is becoming increasingly prevalent across multiple industries, including education. Educational institutions, particularly schools and universities, manage a large number of students, which makes the task of tracking attendance cumbersome and time-consuming. Traditional methods of attendance, such as manual roll calls or paper-based systems, are not only inefficient but also susceptible to errors and manipulation. These systems require considerable human intervention, and they may cause delays in tracking and analyzing student attendance data. Face recognition technology offers a promising solution to this problem by providing a reliable, secure, and automated method for verifying identity and tracking attendance. This paper presents the development and implementation of a face recognition-based attendance system using OpenCV. Our system automatically captures and recognizes faces from video streams, logs the attendance of students in real-time, and stores the data in a structured format.

The primary motivations behind this project are to:

1. Reduce the administrative burden of manual attendance-taking processes.
2. Improve the accuracy and efficiency of attendance monitoring.
3. Develop an easily deployable solution for institutions that is user-friendly and cost-effective.
4. Ensure scalability and robustness for handling real-time recognition with a large number of users. The real-time attendance system was designed to process live video streams, detect student faces, and mark attendance automatically in a database. This provides educational institutions with a more efficient, less intrusive method for keeping track of attendance while also reducing human errors and eliminating proxy attendance.

LITERATURE REVIEW

Face recognition is a widely researched field in computer vision, and several techniques have been proposed for identifying and verifying individuals based on their facial features. The development of robust algorithms has enabled its use in various domains such as surveillance, authentication, and automation.

Face Detection

Face detection is the first and most critical step in any face recognition system. The Viola-Jones object detection framework, developed by Paul Viola and Michael Jones (2001), is one of the most popular and widely used face detection methods. It utilizes Haar-like features to quickly and efficiently detect faces in an image or video stream. This technique applies a series of classifiers, trained through AdaBoost, to identify regions of an image that contain a face. It has been implemented successfully in real-time face detection applications due to its speed and accuracy.

Face Recognition

For face recognition, multiple algorithms exist, each with its advantages and trade-offs. Early methods such as Eigenfaces and Fisherfaces used Principal Component Analysis (PCA) and Linear Discriminant Analysis (LDA), respectively, to reduce the dimensionality of face images and identify distinguishing features. More recent approaches have leveraged Local Binary Patterns (LBP), which capture the local structure of an image by comparing the intensities of neighboring pixels. The Local Binary Patterns Histogram (LBPH) technique extends LBP by creating histograms that represent the frequency of patterns within a face image. LBPH has gained popularity because it is robust to changes in lighting, and it performs well even with low-resolution images. Unlike deep learning-based methods, LBPH does not require large datasets and high computational power, making it ideal for real-time systems on lower-end hardware.

Attendance Monitoring Systems

Automated attendance systems have been researched extensively in recent years, with some systems employing biometric authentication methods such as fingerprint scanning and iris recognition. However, these methods require

**Krishnamoorthy and Anubhav Lal**

direct contact or specialized equipment, which can be costly or invasive for large-scale deployment. Face recognition offers a non-intrusive and scalable alternative, with the potential to streamline attendance monitoring in classrooms, offices, and public venues. Previous studies have demonstrated that face recognition systems are well-suited for real-time applications, particularly in settings where speed and accuracy are critical.

METHODOLOGY

The proposed system consists of three main components: face detection, face recognition, and attendance logging. The system is implemented using Python and OpenCV, with additional libraries such as Pandas for data handling and Tkinter for the graphical user interface (GUI).

System Architecture

The face recognition system follows a structured workflow, divided into the following stages:

1. **Face Detection:** Captures live video frames and detects faces using the Haar Cascade Classifier.
2. **Face Recognition:** Identifies the detected faces by comparing them with the training dataset using the LBPH algorithm.
3. **Attendance Logging:** Marks the identified students as present in the attendance log, which is stored in a CSV format.

Face Detection

Face detection is performed using OpenCV's pre-trained Haar Cascade Classifier, which is optimized for frontal face detection. The system captures frames from a video feed and converts them to grayscale to reduce computational complexity. The detected faces are then cropped and resized for recognition.

```
import cv2
```

```
# Load the pre-trained Haar Cascade Classifier
```

```
face_cascade = cv2.CascadeClassifier('haarcascade_frontalface_default.xml') # Convert the frame to grayscale
```

```
gray_frame = cv2.cvtColor(frame, cv2.COLOR_BGR2GRAY) # Detect faces in the frame
```

```
faces = face_cascade.detectMultiScale(gray_frame, scaleFactor=1.3, minNeighbors=5)
```

Face Recognition

The LBPH face recognizer was chosen for this system due to its simplicity, speed, and robustness. LBPH works by dividing the image into small grids and calculating the binary patterns for each pixel based on its neighboring pixel values. The histogram of these patterns is used to recognize faces.

The recognizer is trained using a dataset of student images, each labeled with a unique ID. During real-time execution, the detected faces are compared with the trained data to identify the student.

```
import cv2
```

```
# Initialize the LBPH face recognizer
```

```
recognizer = cv2.face.LBPHFaceRecognizer_create() # Train the recognizer with training images and labels  
recognizer.train(training_images, labels)
```

```
# Predict the identity of the detected face
```

```
student_id, confidence = recognizer.predict(cropped_face)
```

Attendance Logging and Data Storage

Once a face is successfully recognized, the system logs the student's attendance into a CSV file using the Pandas library. The file can later be accessed for reports and analysis.

```
import pandas as p
```

**Krishnamoorthy and Anubhav Lal**

```
# Load existing attendance records attendance_df = pd.read_csv('attendance.csv') # Mark the recognized student as present
attendance_df.loc[student_id, 'attendance'] += 1 # Save the updated attendance record
attendance_df.to_csv('attendance.csv', index=False)
```

Graphical User Interface (GUI)

A user-friendly interface was created using Tkinter to facilitate ease of use for instructors. The GUI allows users to start a new attendance session, select subjects, and view attendance records.

Results

The proposed face recognition system was tested in a controlled environment using a dataset consisting of 500+ facial images, divided into a training set and a test set. The system was evaluated based on multiple criteria, including detection accuracy, recognition accuracy, processing speed, and usability. Below is a detailed analysis of the results obtained during the testing and implementation phase.

Face Detection Accuracy

The Haar Cascade Classifier, a well-known algorithm for object detection, was used for detecting faces in real-time video streams. Its performance was evaluated under different environmental conditions, including variations in lighting, background clutter, and face orientation.

- **Lighting Variations:** The classifier performed reliably in well-lit conditions with an average detection accuracy of **92%**. In environments with dim lighting or inconsistent light sources, the accuracy dropped slightly to **85%**. This was expected, as Haar Cascade relies heavily on pixel intensity contrasts, which become less pronounced in poor lighting.
- **Face Orientation:** The system demonstrated consistent performance when detecting frontal faces, achieving an accuracy rate of **90%**. However, in cases where the subject's face was turned sideways or partially occluded (e.g., by a hand or mask), the detection rate dropped to around **75%**. While Haar Cascades are optimized for frontal face detection, they struggle with rotated or occluded faces.
- **Real-time Detection:** The system was able to process **30 frames per second (FPS)** on a standard laptop (Intel i5 processor, 8GB RAM). This ensured smooth real-time detection without significant latency. The detection speed was sufficient for classrooms or other scenarios involving multiple subjects moving in and out of the camera's view.

Face Recognition Accuracy

The LBPH (Local Binary Patterns Histograms) face recognizer was chosen for its robustness in real-time face recognition tasks. LBPH was trained on a dataset of over 500 images representing approximately 50 unique individuals. These images were captured in varied conditions, ensuring that the recognizer was exposed to different lighting, angles, and facial expressions.

- **Recognition Rate:** The system achieved an average recognition accuracy of **85%**. This value represents the percentage of correctly identified faces out of the total number of faces processed. The model performed better with images captured in controlled environments (i.e., consistent lighting, minimal background noise) compared to real-world, unstructured environments.
- **Confidence Level:** The LBPH algorithm provides a confidence score for each prediction. During testing, the average confidence level for correct predictions was around **75%**, indicating reliable identification. For incorrect predictions, confidence levels were often below **40%**, providing a clear threshold for identifying potentially misclassified faces.
- **Impact of Dataset Size:** The size and diversity of the training dataset played a critical role in recognition performance. The system was initially trained with 300 images and showed **78%** recognition accuracy. After expanding the dataset to 500+ images, including varied expressions and lighting conditions, the recognition

**Krishnamoorthy and Anubhav Lal**

accuracy improved to **85%**. This suggests that increasing the dataset further with more varied training data could lead to even higher recognition accuracy.

- **Performance with Occlusions:** The system's recognition accuracy dropped significantly in cases where faces were partially occluded by objects such as masks, glasses, or hats. In such cases, the recognition accuracy was around **65%**. This is a known limitation of the LBPH algorithm, which focuses on local pixel patterns and struggles with missing facial features.

Processing Speed and System Efficiency

The system's efficiency was measured in terms of its real-time performance during both detection and recognition tasks.

- **Processing Speed:** On average, the system took **0.04 seconds** to detect and recognize a face in a given frame. This allowed the system to process live video feeds at approximately **25 frames per second (FPS)**, which is suitable for most real-time applications. The speed was sufficient to handle classroom environments with multiple students entering and leaving the camera's field of view.
- **Memory and CPU Usage:** The system was tested on a machine with an **Intel i5 processor and 8GB of RAM**. The memory footprint was minimal, and CPU usage remained below **40%** during continuous face detection and recognition tasks. This makes the system feasible for deployment on standard laptops or desktops, without the need for high-end hardware.

Attendance Logging and Data Integrity

The real-time attendance system was tested in simulated classroom settings. The system successfully logged attendance for up to **50 students per session** without any performance bottlenecks.

- **Data Accuracy:** The attendance log, stored in a CSV format, was dynamically updated every time a student was recognized. After conducting multiple tests with different session durations, the system maintained an **error-free attendance log**, with no duplicate or missing entries. The data integrity was ensured through proper handling of exceptions, such as instances where the same student entered and exited the frame multiple times within a short period.
- **Session Management:** The graphical user interface (GUI), developed using Tkinter, allowed users to start, pause, and stop attendance sessions seamlessly. During testing, the GUI proved to be responsive, with minimal delay in updating the attendance log. Instructors were able to manage sessions with ease, even in the presence of multiple students moving around in the camera's field of view.

User Experience and Usability

- **GUI Usability:** A key aspect of the project was the development of a simple yet functional interface that instructors could use without extensive training. The GUI provided features such as subject selection, real-time attendance monitoring, and session control. User feedback during testing was overwhelmingly positive, with instructors noting the ease of operation and the system's ability to reduce the time spent on manual attendance-taking.
- **User Satisfaction:** A feedback survey conducted among the test users (instructors and students) revealed a **90% satisfaction rate**. Users appreciated the non-intrusive nature of face recognition, the accuracy of attendance logging, and the real-time feedback provided by the system. Some suggestions for improvement included the integration of additional features, such as support for multiple cameras and the ability to view historical attendance data within the GUI.

Limitations

Despite the system's success, certain limitations were noted during testing:

1. **Lighting Dependency:** As with most computer vision systems, the performance of the face detection and recognition modules was dependent on lighting conditions. The system's accuracy decreased under poor lighting or when strong shadows were present.

**Krishnamoorthy and Anubhav Lal**

2. **Face Orientation:** The Haar Cascade Classifier performed well with frontal faces but had difficulty detecting side profiles or tilted faces. This occasionally led to missed detections, particularly when students were not directly facing the camera.
3. **Occlusions:** While the system performed well with unoccluded faces, recognition accuracy dropped significantly when students wore masks, hats, or glasses. This limitation could be addressed by
4. incorporating more advanced face recognition algorithms such as deep learning models (e.g., CNNs) that are better suited for handling occlusions.
5. **Scalability:** The current implementation was tested with up to 50 students, and while performance was satisfactory, larger class sizes might require further optimization, especially in terms of recognition accuracy and system responsiveness.

CONCLUSION

The face recognition-based attendance system developed in this project has proven to be an effective and efficient solution for automating attendance tracking in classroom settings. By utilizing OpenCV's Haar Cascade for face detection and LBPH for face recognition, the system achieved a high level of accuracy, with an average face detection rate of 90% and a face recognition accuracy of 85%. The system's ability to operate in real-time, processing live video streams at 25 FPS, ensures seamless performance even in dynamic environments where multiple students move in and out of the camera's field of view. A key achievement of this system is its user-friendly interface, which allows instructors to manage attendance sessions effortlessly. The integration of features like real-time monitoring, subject selection, and automated attendance logging has significantly reduced the time and effort required for manual attendance. User feedback further reinforced the system's utility, with a 90% satisfaction rate highlighting its ease of use and accuracy. However, the system's performance does have certain limitations. It is sensitive to environmental conditions such as lighting and face orientation, with recognition accuracy dropping when faces are partially occluded or poorly lit. Additionally, scalability could become a concern when applied to larger class sizes, although current tests with up to 50 students have shown no significant performance issues. In conclusion, the system demonstrates significant potential for adoption in educational institutions, streamlining attendance processes and improving accuracy. Future improvements, such as incorporating more advanced face recognition algorithms to handle occlusions and varying facial orientations, could further enhance its robustness. Additionally, optimizing the system for larger-scale deployments and diverse environments will make it even more versatile and practical for real-world applications. Overall, this project has successfully met its objectives and offers a solid foundation for further development and refinement.

ABSTRACT

In chemical research, the green approach is the process of creating safer chemicals and procedures that lessen the harm that chemicals cause to the environment and human health. The element of color has the power to completely alter life itself. It's the first characteristic that people see, and it often influences fabric selection first. Ancient literature frequently mentions the significance of color in textiles, a fact that has been acknowledged for thousands of years. Natural dyes always acts as a green material extracted from the natural resources and because of their non-toxic, biodegradable, and environmentally beneficial qualities, natural dyes have always preserved the environment and made it more eco-friendly. The general use of colors extends beyond the shading of material filaments; they are also employed in the preparation of food, medications, handicrafts, leather, ink, and herbal dye. Processing textiles involves several steps, including extraction, purification, printing, and maintaining color strength and fastness. Many contemporary and sophisticated techniques, such as microwave assisted, padding method, and ultrasonic radiation, are now used for textile dyeing. Additionally, there are several dye extraction processes that are currently in use, including solvent extraction, aqueous extraction, enzymatic extraction and fermentation extraction using microwave or ultrasonic energy, supercritical fluid extraction, and alkaline or acid extraction, among others. Depending on the factors that must be balanced throughout the extraction process, each of the aforementioned extraction methods have pros and cons. The significance of natural dyes and their various uses are presented in an orderly fashion by this study.

Keywords: Natural dyes, Natural sources, Textiles, Fastness, Extraction, Eco-friendly nature.

**Naveen Kumar and Shyam Vir Singh**

INTRODUCTION

In recent times, natural dyes have garnered considerable interest owing to their sustainable qualities and eco-friendliness. The purpose of this literature study is to investigate how natural dyes can help the textile and dyeing industry become more ecologically friendly.

An historical view on natural dye

Historical records from ancient civilizations such as the Indus Valley and ancient Egypt attest to the long history of using natural dyes (Robinson, 1969). These colors come from minerals, plants, and even animals. The historical viewpoint highlights the long-standing custom of utilizing natural dyes, which is currently seeing resurgence, as shown by Carter (2010), Melo (2009), and Yusuf et al. (2017). Natural dyes provide an interesting historical perspective that highlights the colorants' ongoing significance in human culture and civilization. For thousands of years, natural dyes have been integral to the development of economies, communities, and forms of creative expression. We explore the historical development of natural dyes in this section (Crowfoot et al., 2006; Frose et al., 2019). Numerous natural dyes have historical and cultural significance (Vandiver, 1987). For millennia, several nations have employed them for cultural customs, traditional attire, and creative expression. Utilizing and conserving these colors can support the preservation of cultural legacy.

Classification of natural dyes

Generally natural dyes can be classified on the bases of its chemical composition, sources and methods of application (Tanaya et al., 2024) which are as follows (Figure 1):

The availability of natural dye resources

Sources of natural dyes may not always be readily available and may vary depending on regional, climatic, and soil conditions. The dependability of natural dye sources may be impacted, and supply chain issues may arise (Guha, 2019; Saxena and Raja, 2014). Natural dyes are often more environmentally friendly and have more biodegradability. Because they are derived from plants or animals without being chemically processed, they are non-toxic, non-allergic, and non-carcinogenic (Pruthi, et al., 2008). According to Singh and Parmer (1998) and Khan et al. (2005), natural dyes are multi-component extracts with unknown quantities from which the structure of just the primary component is known. Plants, animals, and minerals are the primary sources of natural dyes (Rose et al., 2005; Bansal and Sood, 2006; Phukan et al., 2005). Natural dyes are colorants made from plants, minerals, and animals that can be used to dye a variety of materials, including leather, food, medicine, and textiles. The ancient people used this dyeing method before the passage of thousands of years (Geelani et al., 2015).

Status of Natural Dyes and Dye-Yielding Plants in India

The practice of natural dyeing has long been credited to Indians traditionally. Textiles such as wool, cotton, silk, medications, cosmetics, and more are colored using natural dyes (Rastogi et al., 2000; Saxena, 1997; Ibrahim et al., 2010). They are also used to color a variety of food goods because of their non-toxic properties. More than 450 plants in India have the ability to produce dyes (Siva, 2007). Some of these plants have medical benefit in addition to their ability to yield dye. Despite the vastness of the plant resource base, not much has been used up to this point. It has not achieved the same level of commercial success as synthetic dyes due to a lack of exact scientific expertise on the extraction and coloring process. The usage of natural dyes has decreased over generations despite the long history of using indigenous knowledge systems, primarily because of a lack of documentation. Furthermore, databases pertaining to dye-yielding plants and their products are devoid of much information.

Current Applications and Trends in Natural Dyeing

These days, there are a plethora of contemporary methods (Jang, 2017; Shahid, 2013) and technologies (Jothi, 2008; Batchold, et al., 2003; Frose, et al., 2019; Shenai, 1977; Samanta, 2020) for dyeing textiles and extracting natural dyes, such as the ultrasonic method (Liu, et al., 2009; Rahman, et al., 2013; Shirsath, et al., 2012; Sheikh, et al., 2016;

Shivakumar, et al., 2009; Shivakumar and Rao, 2001), microwave assisted method, and ultrasonic method. The increased price of carmine cochineal and the expanding global demand drove an astonishing 181.0% annual growth in natural dye exports between January and September 2010. The most recent data on the performance of the input production process—which includes paprika, marigold, annatto, and turmeric—for natural dyes production is presented in this paper. It offers details on the typical yield of these commodities, farm-gate prices, an analysis of the worldwide dye industry, and the evolution of Peruvian imports and exports of natural colors. We are currently seeing a phase of increase in the market for natural dyes, which has fluctuated over the years much like the fashion trend. Today's industrial sectors that are most eager to use natural dyes are those that deal with intimate apparel, children's clothing, and interior design—fields where a greater emphasis is placed on naturalness and where allergy issues are more prevalent. Natural dyes have a variety of uses (Samanta and Agarwal, 2009) and one example of how to color textiles is shown in Figure 2.

Natural dyes' advantages for the environment

Biodegradability

Natural dyes are non-toxic and biodegradable because they come from renewable sources like plants and insects (Adrosko, 2012; Dawson, 2009; Saxena and Raja, 2014). This trait lessens the harm that dye disposal causes to the environment. Diminution of Chemical Contamination: Natural colors are usually made without the use of dangerous chemicals, which lessens pollution and harm to aquatic environments. This is in contrast to synthetic dyes, which frequently contain harmful compounds.

Biodiversity conservation

Plants and insects that produce dyes can be cultivated to increase biodiversity and safeguard endangered species. Maintaining these sources can help keep ecosystems intact (Merdan et al., 2017; Mongkholrattanasit et al., 2015).

Natural dye benefits

Because of their many benefits, natural dyes are a great option for a variety of applications, particularly when it comes to encouraging sustainable and environmentally responsible behaviors. Natural colors provide the following main benefits:

Non-toxic nature of natural dyes

In general, natural dyes are harmless for the environment and human health, and they are not harmful (Ahsan, 2009; Dawson, 2000). They lessen the possibility of air and water pollution because they don't produce any hazardous chemicals or volatile organic compounds (VOCs) during manufacture or use. Biodegradability: Natural dyes decompose organically with time, producing very little waste. Because of their biodegradability, natural color-dyed textiles and goods are guaranteed to have a lower potential to cause long-term environmental issues.

Vibrant Color Scheme

Natural dyes come in a wide variety of distinctive colors. In contrast to the frequently homogeneous and artificial colors, colors derived from natural sources frequently have an earthy, organic character. Artists, designers, and customers who value individuality and authenticity will find this distinctiveness appealing.

Advantages for Health

Certain natural colors, especially those made from medicinal plants, can have extra health advantages. Turmeric-based colors, for instance, might have antioxidant and anti-inflammatory qualities. Customer Inquiry: Products colored with natural colors are in greater demand as people grow more environmentally concerned. Businesses that sell natural-dye products can tap into this market and demonstrate their dedication to sustainability.

**Naveen Kumar and Shyam Vir Singh****Reduced Waste**

Fruit peels and leaves, for example, can be used to make some natural dyes from waste materials or agricultural by-products. This circular economy is encouraged and overall waste is decreased through the repurposing of waste items.

Controlling standards and quality

Given the unpredictability of natural sources, maintaining quality control and uniformity in the manufacturing of natural dyes can be difficult. It takes close observation and tweaking to make sure that every batch of natural dye yields uniform colors.

Skill and Education Gaps

The information and abilities needed to work with natural colors are not as widely available as those needed to work with synthetic dyes (Mayusoh, 2015). There can be a dearth of skilled artisans and dyers who know how to use natural colors efficiently. Despite these difficulties, many of these restrictions are intended to be overcome by ongoing research and advancements in color modification techniques, sustainable practices, and natural dye manufacturing. The growing need for sustainable and environmentally friendly products means that resolving these issues is crucial to maximizing the potential of natural dyes across a range of industries.

Investigation of natural dyes using earlier studies

Previous studies on natural dyes have looked into a variety of topics, including their chemistry, uses, and effects on the environment (Al-MojnumShamim, et al., 2019). An outline of several important topics of natural dye research is provided below:

Enhancement and Color Modification

In order to produce desired hues, researchers have looked for ways to change the molecular structures of natural dyes or blend multiple sources to increase their color spectrum. The use of mordants—substances that fix dyes to textiles—to improve colorfastness and intensity of color has been studied.

Procedures and Techniques for Dyeing

Studies on dyeing methods and procedures have been carried out, such as dyeing at various pH levels, temperatures, and dye concentrations using natural dyes (Adeel et al., 2020; Adeel et al., 2019; Al-MojnumShamim et al., 2019; Ahsan et al., 2020; Broadbent et al., 2001; Mahmud-Ali et al., 2012; Mayusoh, 2015; Singh and Purohit, 2012; Saxena et al., 1997; Wangatia, et al., 2015). Numerous aspects, including fabric type, pre- and post-dyeing processes, have been studied in relation to the quality and longevity of colored materials.

Aspects of sustainability and the environment

Natural and synthetic dyes have been examined for ecological footprint in environmental impact studies. These studies frequently emphasize how natural colors are more environmentally friendly because they degrade more easily and produce less chemical pollution. The potential of natural dyes to support sustainable agriculture, biodiversity conservation, and the preservation of traditional knowledge has been the subject of numerous studies.

Industrial applications

Research has looked into the viability of using natural dyes in textile, cosmetic, food, and pharmaceutical industries (Akilandeswari and Pradeep, 2016; Das, 2013; Vankar, 2016). Scholars have investigated the obstacles and prospects associated with increasing the production of natural dyes for commercial use.

**Naveen Kumar and Shyam Vir Singh****Customer and Market Preferences**

Consumer preferences for natural dye-dyed products have been studied in market research, especially when considering sustainable and eco-friendly product options. Research has looked into the market potential and economic sustainability of producing natural dyes.

Policy and Regulatory Aspects

Studies have looked into the laws and regulations pertaining to natural dyes, such as those governing product certifications, quality standards, and labelling specifications.

Cooperation between Communities and Artists

Research on partnerships with local communities and artists engaged in traditional dyeing techniques has been conducted with the goal of advancing sustainable lifestyles and the preservation of cultural heritage. Together, these study fields advance our knowledge of natural dyes, their potential uses, and how they support environmental responsibility and sustainability across a range of businesses. You can use the body of information already established in this area as you continue your investigation into the role natural dyes play in fostering an environmentally friendly atmosphere.

New Developments in Research and Innovation

Natural dyes and their uses in a variety of industries were the subject of numerous ongoing research projects and inventions. You should be able to get a sense of the trends and directions in natural dye research and invention up to that point from the information presented here, which might not include the most recent advancements. To ensure you have the most recent information, it is best to check the most recent sources. The following are some areas of recent advancements and study pertaining to natural dyes:

Teaching and Preserving Knowledge

Efforts have been made, especially from indigenous people, to record and conserve traditional knowledge about natural dyes. The goal of these initiatives is to maintain the use of conventional dying techniques. In order to promote the use of natural dyes in industries ranging from textiles to renewable energy, researchers and practitioners are constantly looking for new and creative ways to overcome obstacles.

Applications of Dyeing in Medicine and Healthcare

The use of natural colors in medical fabrics and wound dressings has been studied. Certain natural dyes are appropriate for these kinds of applications because of their antibacterial, antimicrobial, and anti-inflammatory qualities (Aino et al., 2018; Ibrahim et al., 2013; Kasiri and Safapour, 2014; Selvam et al., 2015; Venil et al., 2013; Vigneswaran et al., 2004).

Dyeing in the Food Industry

As natural substitutes for artificial food coloring, natural dyes have grown in favor in the food business (Batchold, et al., 2006). The goal of ongoing research is to create natural food dyes that are safe, stable, and compliant with regulations.

Sustainable Textiles and Fashion

Natural dyes are becoming more and more popular in the fashion industry as a way to make eco-friendly and sustainable clothes. Research addresses the incorporation of natural dyes into sustainable fashion supply chains (Dweck, 2002).

Applications connected to photovoltaics and UV protection

The use of natural dyes in dye-sensitized solar cells (DSSCs) has drawn attention (Al-Alwani, et al., 2015; Hao, et al., 2006). In addition to being a more environmentally friendly option to conventional silicon-based solar cells, these cells also help shield dyed fabrics from UV radiation that could cause lightening or fading (Chattopadhyay, et al.,

**Naveen Kumar and Shyam Vir Singh**

2013; Grifoni, et al., 2009; Ibrahim, et al., 2013; Katarzyna, et al., 2008; Sarkar, 2004; Sun and Tang, 2011). These cells harvest solar energy using natural dyes.

Role of Natural Dyes in Nanotechnology

Advances in nanotechnology have resulted in the creation of materials at the nanoscale that has the ability to improve the characteristics of natural dyes. Natural dyes' color permanence, UV resistance, and other qualities can be enhanced by nanoparticles and nanostructures.

Optimization and Extraction

Many studies conducted in the present day have improved the effectiveness of natural dye extraction techniques using a variety of plant materials, fungi, and marine organisms (Adeel, et al., 2020; Adeel, et al., 2019; Al-MojnumShamim, et al., 2019; Batchold, et al., 2006; Borges, et al., 2012; Jiang, et al., 2019; Rahman, et al., 2013; Singh and Purohit, 2012; Wang, 2013). This includes creating brand-new extraction methods and maximizing color production by using enzymes. The extraction of dyes from a variety of natural sources, such as plants, insects, and minerals, has been the subject of numerous investigations. Researchers have developed and optimized extraction procedures to increase dye production and quality. Spectroscopy and chromatography are two characterization techniques that have been used to detect and analyse the chemical components that give natural dyes their colors. A general schematic extraction process for extracting natural using various extraction methods (Ghorab, et al., 2023) are as follows (Figure 3):

Assessment of Color Fastness

The fastness characteristics of various textiles determine their durability (Prabhu and Bhute, 2012; Mahmud-Ali, et al., 2012; Adeel, et al., 2020; Adeel, et al., 2019; Singh and Purohit, 2012). Using a Sasmira launder-O-meter, the color fastness of colored fabric samples to washing was evaluated in compliance with IS: 764-1984 techniques, which are based on IS-3 wash fastness method. A grey scale was used to assess the wash fastness grade in compliance with ISO-05-A02 (loss of shade depth) and ISO-105-AO3 (extent of staining). A computer-aided color measurement system linked to the relevant software and Macbeth 2020 was used to measure the staining and loss of color depth in order to cross-check the results. Using a manually operated crock meter and a grey scale in compliance with ISO-105-AO3 (staining extent), color fastness to rubbing (dry and wet) 12 was assessed in compliance with IS: 766-1984. To evaluate color fastness to light exposure, the IS: 2454-1984 approach was used. The sample and the eight blue wool standards (BS1006: BOI: 1978) were exposed to UV radiation in a Shirley MBTF Microsal fade-O-meter. A 500 watt Philips mercury bulb tungsten filament lamp that simulated daylight was part of the apparatus. The fading of each sample was assessed against the blue wool standards (1–8). The test specimen was sandwiched between two nearby pieces of textile fabric and stitched all the way around to create a composite specimen. In compliance with IS 971-1983, its color fastness to sweat was assessed. For half an hour at room temperature, each sample was submerged separately in an MLR 1:50 acidic/alkaline test solution. The sample was then loaded between the perspirometer, two glass plates weighing 4.5 kg (10 lbs). The apparatus was kept in the oven for four hours at $37\pm 2^{\circ}\text{C}$. At the end of this period, the specimen was removed and left to dry in the air at a temperature of no more than 60°C . The test samples were scored using grey scales according to color and staining changes. The rating of the samples for fastness to light and washing was done as follows:

Rating for the light fastness:

- 8 - Outstanding
- 7 - Excellent
- 6 - Very good
- 5 - Good
- 4 - Fairly good
- 3 - Fair
- 2 - Poor
- 1 - Very poor

**Naveen Kumar and Shyam Vir Singh****Rating for the washing fastness:**

- 5 - Excellent
- 4 - Good
- 3 - Fair
- 2 - Poor
- 1 - Very poor

Rating for staining:

- 5 - Negligible or no staining
- 4 - Slightly stained
- 3 - Noticeably stained
- 2 - Considerably stained
- 1 - Heavily stained

Lighting fastness and fading

Compared to synthetic dyes, natural dyes are typically less lightfast—that is, less likely to fade when exposed to light. This means that products dyed with natural dyes may fade more quickly when exposed to sunshine or other environmental influences. For fabrics and items meant for outdoor use, this is a serious problem.

Wash Fastness

Another thing to consider with natural dyes is how washable they are. Natural dyed fabrics might not hold their color well after several washings, which could restrict their use in clothing and other textiles that need to be laundered frequently.

Rubbing Fastness

Similar to the fastness mentioned above, rubbing fastness is significant for textile textiles that were measured using a grey scale and a manually controlled crock meter. The textiles' longevity is also impacted by this feature.

Perspiration Fastness

Under this fastness conditions, the textile sample was then positioned between two glass plates of the perspirometer with a force of 4.5 kg (10 lbs) (Singh and Purohit, 2012). The apparatus was kept in the oven for four hours at $37 \pm 2^\circ\text{C}$.

Mordants and Mordanting methods

A color fixative that helps to quickly bring out color is called a mordant. Mordants can be chemical, such as metallic salts, or botanical, such as plant extracts (Banna et al., 2019; Mahmud-Ali et al., 2012; Prabhu and Bhute, 2012; Wangatia et al., 2015; Singh and Purohit, 2012). The color produced by the dye is directly influenced by the mordant; hence, if two different acids or mordants are employed with the same dye, various colors will result. Compared to darker tones, lighter hues require less mordanting. Mordanting requires extreme caution since the color will fade if the mordant is not allowed to fully penetrate the fiber's shaft. The yarn or cloth needs to be mordanted right away after scouring for optimal results. Before the mordants are mixed with the yarns, they must be thoroughly dissolved and the yarns must be free of all grease and soap. There are many mordanting processes responsible to alter fastness and color shades of fabrics employed. Three main techniques for mordanting are typically employed: pre-mordanting (Anderson, 1971), simultaneous mordanting, also known as meta-mordanting, post-mordanting, etc. We can classify mordants as follows (Figure 4.):

Features of the dyed fabrics' colors

The determination of several characteristics for colored fabrics, such as lightness (L^*), redness-greenness value (a^*), yellowness-blueness value (b^*), chromaticity (c^*), and hue saturation (h^*), was done using CIEL^aa^b* values (Choudhary, 2015).

**Naveen Kumar and Shyam Vir Singh****Determination of surface colour strength (K/S value)**

By measuring the surface reflectance of the samples using a computer-aided Macbeth 2020 plus reflectance spectrophotometer and applying the Kubelka-Munk equation (Choudhary, 2015) with the aid of pertinent software, the K/S value of the undyed and dyed wool fabrics was ascertained:

$$K/S = (1 - R_{\lambda\max})^2 / 2R_{\lambda\max}$$

Where K represents the absorption coefficient, S the scattering coefficient, and $R_{\lambda\max}$ is the sample's surface reflectance value at a specific wavelength, or the point at which a given dye/color component absorbs the most.

Natural dye chemistry with textiles including mordant

In general, the chemistry of dyeing (Saxena and Raja, 2014; Samanta, 2020) describes how different fabrics are dyed based on the nature of the dye constituent and how it bonds with the functional groups in the fabric to form a complex that gives the fabric its color. However, if mordanting is used to change the color of the fabric to a different shade, three conditions must be met: pre-mordanting, meta-mordanting, and post-mordanting. In this case, if we follow the pre-mordanting condition, mordant (metallic or natural) will react first with fabrics and form a metallic complex with it after that dyeing process will occur in the presence of dye component which was isolated from the dye bearing plant or other natural resources, give the another complex of fabrics-mordant-dye component. For instance, if wool were a cloth, quercetin was a dye ingredient, and mordant was a metal; the reactive scheme might look something like this (Figure 5):

CONCLUSION

An investigation under present study concluded that natural dyes are sustainable, non-toxic, and beneficial resources with little impact on the environment. Because of this, and because of certain contemporary methods as well, the scientific community is becoming interested in using natural dyes in a range of established and emerging application fields. The people who work with natural dyes to color textile fabrics and preserve their sustainable qualities may find this paper useful. The information produced by these investigations could lay the groundwork for the natural dye industry to produce natural dyes on a commercial scale and use bioresources sustainably. From the different approaches, it can also be inferred that natural dyes can be employed to color fabrics on a modest scale, which could inspire young people and women in rural areas to launch a cottage business. Modern textile designers can easily use these lovely tones into today's color schemes, as they can easily satiate their artistic and creative cravings and help to create a more sustainable and environmentally friendly world, the study also makes suggestions for future research and useful tactics to promote the industry-wide use of natural dyes.

ABSTRACT

Patients with coronary artery diseases suffers from symptoms like chest pain, breathlessness, fatigue, which may have an effect on their functional status and vo2 max. Physiotherapy intervention is one of the core components of cardiac rehabilitation, which can play a major role in improving functional status. Since there isn't a protocol for this, tailor- made exercise training protocol was given for these patients. A pilot randomized research was conducted to validate this protocol. The conventional group was advised to walk for minimum 30-40 minutes per day. The interventional group was taught 30-40 minutes of tailor-made exercise training once along with walking and provided a home exercise programme. Home diary was maintained to check adherence for both groups. Both groups were instructed to follow protocol for 5days/week for 3 months. Paired T-test showed significant improvement($P<0.05$) in the six-minute walk test duration, recovery period and maximum oxygen consumption in interventional group. Unpaired T-test showed significant improvement($P<0.05$) between the groups. There is an effect of symptoms limited exercise training to improve functional status and maximum oxygen consumption in patients with non-operated stable coronary artery disease.

Keywords: Exercise training, Coronary artery disease, Functional status, Maximum oxygen consumption

INTRODUCTION

Coronary Artery Disease (CAD) is the most common type of heart disease, which is characterized by the presence of atherosclerosis in the epicardial coronary arteries [1-3]. Atherosclerotic plaques, the hallmark of atherosclerosis, progressively narrow the coronary artery lumen and impair ante grade myocardial blood flow [4-6]. The reduction in coronary artery flow may be symptomatic or asymptomatic, may occur with exertion or at rest, and may culminate in a myocardial infarction, depending on obstruction severity and the rapidity of its development [7,8]. Every year, an estimation of 17.7 million people died which is 31% of all global deaths are from having coronary artery disease. India is experiencing an escalating epidemic of CAD [9,10]. The contribution of CAD to total deaths and disease burden in India has almost doubled since 1990. Overall, CVD contributed to 28% of the total deaths in India in 2016, compared to 15% in 1990. [11] Cardiac Rehabilitation (CR) is a comprehensive treatment process that is centered on providing supervised aerobic exercise training, along with delivering ancillary services (e.g., nutrition counseling, smoking cessation, psychosocial support) for cardiovascular disease (CVD) patients. [12,13] Cardiac rehabilitation is used for cardiovascular diseases, it further divides into pre and post-operative rehabilitation. [14] Prescribing safe and progressive exercise programs in CR is critical to improving functional capacity, which is a key prognostic indicator for CVD patients. [15] Physiotherapy management is key component of cardiac rehabilitation, which helps to reduce dyspnea level, to improve endurance, to improve functional status and thus by improving overall quality of life. [16] Patients are suffering from symptoms like chest pain, breathlessness, fatigue, etc., which can have an overall negative effect on their functional status and quality of life. Many patients do not choose or are unwilling to undergo a surgical procedure due to the cost of surgery, their fear of surgery, and other factors, so they are treated only with medications. With regular exercise training patients may have improvement in functional status and maximum oxygen consumption. There are studies that show aerobic exercise can improve the functional status of patients, but there is no protocol-based exercise training to improve functional status and maximum oxygen consumption for patients with non-operated stable coronary artery disease. Since there isn't a protocol for this, we have a specially tailor-made exercise training for these patients. We conducted a pilot randomized research to validate this protocol. The protocol will be used to a larger population once it has been shown to be effective. Our objective of the study was to evaluate effect of symptoms limited exercise training on functional status in patients with non-operated stable coronary artery disease.

MATERIALS AND METHODS

This interventional pilot study was commenced after approval of institutional ethical committee and clinical trial registration.

The inclusion criteria were

- 1) Age group 40 to 70 years both men and women
- 2) Patients who were screened and diagnosed with stable coronary artery disease by interventional cardiologist
- 3) Severe stable coronary artery disease (>70% Blockage) who refused for CABG/PCI
- 4) Moderate stable coronary artery disease (>50-70% Blockage) who does not require PCI
- 5) Mild stable coronary artery disease (<50% Blockage).

The exclusion criteria were

- 1) Patients who were diagnosed with rheumatic heart disease.
- 2) Patients who were diagnosed with unstable coronary artery disease and required surgery.
- 3) Patients who were diagnosed for any associated pulmonary disease.
- 4) Patients who were suffering from any neurological conditions that affects upper limb movements and gait.
- 5) Patients with any lower limb musculoskeletal deformity affecting mobility.
- 6) Patients who were suffering from psychiatric disorders.

**Brijesh Acharya and Harihara Prakash****Sample size**

According to the literature, the standard deviation (SD) of the quality of life of CAD patients ranged from 12 to 18.^{17,18} Assuming a standard deviation of 15 and an 11-point difference as clinically important, a sample size of 30 per group will be required to attain 80% power while allowing for 5% type I error. Assuming a 20% loss to follow-up, the sample size inflated to 38 per group. The total sample size was 76. As this was pilot study 8-10% of total sample size was considered. Hence in this study, 20 patients were enrolled for pilot study.

Sampling method

Computerized randomization

Outcome measures

- 1) Six-minute walk test to evaluate functional status of patients[19].
- 2) Maximum oxygen consumption to evaluate myocardial oxygen demand [Equation: - Mean Peak $\text{VO}_2(\text{ml/kg/min}) = 4.948 + 0.023 * \text{Mean 6 MWD (meters)}$] [19]

METHODOLOGY

Patients who met the inclusion and exclusion criteria were recruited for the study. A total of 32 patients were screened for eligibility. Eight individuals did not match the inclusion requirements, three had lung disease, and one was denied participation. Twenty patients were randomly divided into two groups. Baseline data and outcome measures were evaluated following participation. The control group was told to walk for 30 minutes five days a week for three months. The interventional group received 30-40 minutes of symptoms-limited customised exercise intervention along with walking 5 days a week for three months. Once enrolled in the interventional group, all patients were provided a tailored exercise intervention. They were given a home exercise programme. They were asked to keep a home diary for reminders and follow-up purposes. Reminders were given by telephonic conversation every two weeks. Following a three-months follow-up, patients in both groups were assessed using outcome measures. Symptoms-limited exercise intervention was given to interventional group according to FITT protocol mentioned in table 1 to 3.

RESULTS

Paired T-test was used for within group analysis and unpaired T-test was used for between group analysis. Table 4 showed total of 10 (5 Male, 5 Female) patients with mean age (58.4 ± 6.43) in control group and 10 (6 Male, 4 Female) patients with mean age (51.1 ± 4.17) in interventional group were enrolled for the study. All patients had completed their course of exercise training for 3 months in both the groups respectively. Both groups have similar characteristics at baseline with respect to the severity of coronary artery disease. Table 5 showed there was no significant improvement in control group for vo_2 max, 6MWT recovery timings, 6MWT distance ($p > 0.05$). Table 6 showed there was significant improvement in interventional group for vo_2 max, 6MWT recovery timings, 6MWT distance ($p < 0.05$). Table 7 showed intergroup comparison, there was no significant improvement in control group for vo_2 max, 6MWT recovery timings, 6MWT distance ($p > 0.05$).

DISCUSSION

Cardiac rehabilitation has become a well-established treatment modality in patients with heart disease. The present study focused on effect of symptoms limited exercise training on functional status and maximum oxygen consumption in patients with non-operated coronary artery disease. Both qualities bear on important issues that are related to the goal of cardiac rehabilitation, namely restoration of normal daily functioning. This study showed

Brijesh Acharya and Harihara Prakash

significant improvement in interventional group in all the parameters, which suggest tailor made symptoms limited exercise intervention was effective. Meka N, Katragadda S, Cherian B, et al. did study on endurance exercise and resistance training in cardiovascular disease, which suggests overall improvement on functional status.[21] Lavie CJ, Thomas RJ, Squires RW, et al. did study on exercise training and cardiac rehabilitation in primary and secondary prevention of coronary heart disease, they concluded that Regular exercise training have a role in reducing CHD risk in both primary and secondary prevention.[22] In control group we could not found significant difference, but we achieved clinical significance within group. Though Kelley GA, Kelley KS. Efficacy of aerobic exercise on coronary heart disease risk factors, they concluded that aerobic exercise can reduce selected risk factors of CHD.[23] Present study concluded that there is positive effect of symptoms limited exercise training to improve functional status and maximum oxygen consumption in patients with non-operated stable coronary artery disease.

LIMITATIONS

One of the limitations of this study was the inability to give exercise training to patients in center-based cardiac rehabilitation due to barriers such as transportation, economical aspect and far distances of center to rural areas and reaching the center five times per week for twelve weeks. It can be an interest of consideration for future studies.

ABSTRACT

For thousands of farmers, the weekly markets have been a source of income. However, it has been noted that farmers who have long participated directly in these weekly marketplaces are not experiencing major social or economic growth. This study aims to comprehend the significance of weekly markets in the lives of thousands of farmers who depend on them as their primary source of income. The socioeconomic effects of rural weekly markets on farmers' lifestyles are examined in this research. In the weekly market, farmers' average monthly revenue and financial standing are rising with time. Farmers have greater opportunities to engage with other vendors and consumers through the market. They are now more involved in market-related activities, supporting one another when things go tough, and they are getting greater moral support from others, such as vendors and buyers.

Keywords: Farmers Weekly Market, Rural Market, Socio economic conditions

INTRODUCTION

Following independence, rural India operated like a self-sufficient village economy until 1960. There was close proximity between the producers and the customers. Agri inputs and output services dominated the rural market with the advent of the green revolution in 1960, with the exception of a few products from distant areas. (Das, 2018) The most distinctive way for the people of each nation-state to come together and exchange and maintain their cultural, social, political, and economic facets is through village "Haats," or markets. Haats are ill-defined structures

**Vinuchakravarthi et al.,**

that offer venues for local craftspeople and artists to exhibit their work in addition to selling their products, which may only be accessible in certain areas (Deogam, 2023). Haats is defined as a "public assembly of commodity buyers and sellers, meeting at a designated or customary location at regular intervals." The majority of these periodic markets only take place once every week. Haats serve as both physical marketplaces for the sale of agricultural surplus and retail locations for the purchase of everyday necessities and farmingsupplies. In India's rural areas, there are roughly 42,000 haats. One haat typically serves 20 to 50 towns, has over 300 stores, and receives over 4,500 visits (Chatterjee, 2023). In order to promote and maintain the pace of rural economic growth, agricultural marketing infrastructure is essential. Just as important to improved agricultural performance as farming itself is marketing. The decision to create a marketable agricultural product is the first step in the agribusiness process, which includes all pre- and post-harvest activities such as grading, value addition, packaging, processing, and shipping. Farm produce gains value from these activities (Jeyaramya, 2022). Weekly village markets are a frequent sight in Tamil Nadu, dating back to the emperor era. Some of the most well-known ones to this day include Ponmalaisanthai in Trichy, Anthiyursanthai in Erode, Pochampallisanthai in Dharmapuri, and Pallavaramsanthai in Chennai. Tamil Nadu's weekly market has a lengthy history. Because it provides jobs, revenue, and status for its members, it plays a crucial role in the development of farmers, coolies, and the impoverished (Kumaresan and Manivannan, 2019).

Significance of Haats

Various Channels of Selling to Farmers

The impact of farmers' markets: Over time, individual farms tend to specialize in producing particular categories of agricultural goods, which they then sell at such markets. Because those farms make good use of their comparative advantages—such as their close proximity to markets, infrastructure, favorable environmental conditions, etc.—their financial situation is better. Farmers' markets have a big influence on pricing because they establish prices in a traditional way—based on supply and demand. Farmers' markets offer better costs than wholesale, which makes them more likely to choose to sell their goods directly to consumers. It is significant to highlight that while transportation costs associated with farmers' market sales are somewhat lower for producers than for trading groups, they still require some transportation, therefore producers do not own the entire difference in these prices (Tošović-Stevanović et al., 2020).

RESEARCH AREA

The district of Kanchipuram is located on Tamil Nadu's northeast coast. The district is bordered to the east by the Bay of Bengal, to the west by the districts of Vellore and Thiruvannamalai, to the north by the districts of Thiruvallur and Chennai, and to the south by the district of Villuppuram. It is located between latitudes 11° 00' and 12° 00' and longitudes 77° 28' and 78° 50'. The district is 4, 43, 210 hectares in total size, with 57 kilometers of shoreline. Pre-monsoon rainfall is consistent throughout the district, while it is heavier toward the shore than in the interior. There will be a hardship situation if the monsoon is unsuccessful. The two main contributors, the Northeast and Southwest monsoons, are 54% and 36%, respectively. A typical monsoon brings 1200 mm of rain to the District. With 47% of the population working in agriculture, it is the most common occupation. While other crops including groundnuts, sugarcane, cereals and millets, and pulses are also grown, paddy is the main crop. The primary soil resources found in the Kanchipuram District include Clay Loam, Red Sandy Loam, and Saline Coastal Alluvium. The Palar River, tanks, and wells are the primary irrigation sources (Kalpana et al., 2019). Five Prospective villages were identified in all the taluks of the district. In 5 villages 50 prospective entrepreneurs from each village were identified and these entrepreneurs were selected based on simple random sampling technique. Based on collected data 20 incomplete responses were eliminated and 230 responses were finalized.

Specific objectives

- To identify the nature of entrepreneurship practice in selected rural villages in Kanchipuram District.
- To find out the socio and economic condition of the Stall owners under study.
- To identify the impact of Gender and economic condition from the weekly Santhai

**Vinuchakravarthi et al.,**

- To identify the recognizing weekly santhai as source of income across Gender

Data analysis

Responses obtained from the returned questionnaires were separately coded and entered on the computer terminal for use in computer tabulations. SPSS (Statistical Package for Social Sciences) was used to show relationships between various variables. Tests of significance in independent sample were calculated using specific SPSS to check the emotional intelligence of the students.

Tools for Analysis

In this study, some related tools of statistics have been used for the purpose of analysis. Percentage, F-Test, T-Test and are used. The uses of all these techniques have been made as per the requirement of the analysis.

RESULTS AND DISCUSSIONS

Out of total 230 respondents, 74.3 per cent of the respondents are males and the remaining is coming under the category of females. Majority of respondents are male. 40.4 per cent of the respondents are in the age group of 31-40 years, 25.2 per cent of respondents are fall under the age group of 41-50 years and the least percentage of respondents are in the age group of above 60 years. It is observed that most of the respondents (40.4 per cent) are in the age group of 31-40. Out of total (230) respondents, 82 per cent of respondents are living in Kanchipuram taluk and only 2.6 per cent of respondents located in uttiramalur taluk. It is found that most of the respondents are living in Kanchipuram taluk. Of total respondents, 46.5 per cent of respondents are having Tiled house, 41.7 per cent of respondents having concrete house and 5.2 per cent of respondents having Thatched house. Out of 230 respondents, 64.8 per cent of the respondents not having any loan, rest of them having loan for developing their life. 59.9 per cent of respondents facing the major problem which is Poor lighting, 15.2 per cent of respondent's choice is insufficient water and bathroom facility, and least number of respondents problem is traffic issue.

Relationship between Gender and Sources of Income

Null Hypothesis (Ho): There is no significant between the Sources of income and gender. T test has been applied at 5 per cent level of significance to examine the hypothesis and the computed results are presented in the following table. It is stated from the above table that among the two categories of gender, female respondents are having maximum level of mean score towards Sources of income. It is noted from the T test analysis that the null hypothesis is accepted. Hence, It is found that there is no significant between the sources of income and gender of selected respondents in the study area. Reboul from his research the findings theoretically emphasize the gendered earmarking of debt and credit, since the meanings and applications of debt and credit differ for men and women. They also support the gendered dimension of behaviour, since caste, poverty, and familial ties significantly influence women's behaviour while having little effect on men. Finally, these findings raise concerns about the explicit targeting of women by microcredit schemes, which is likely to intensify the role that women play in managing scarcity and deepen the link between debt and poverty for women. (Reboul et al., 2021)

Gender and Weekly income

In order to find the relationship between the gender of the respondents and Weekly income, the following hypotheses are formulated.

Null Hypothesis (Ho): There is no significant between the weekly income and Gender of selected respondents in the study area. T test has been applied at 5 per cent level of significance to examine the hypothesis and the computed results are presented in the following table. It is stated from the above table that among the two categories of gender, male respondents are having maximum level of mean score towards weekly of income. It is noted from the T test analysis that the null hypothesis is accepted. Hence, It is found that there is no significant between the weekly income and gender of selected respondents in the study area. Devaki research indicates the majority of farm women

**Vinuchakravarthi et al.,**

had low levels of yearly income, had animals, were exposed to the media, were motivated by economic factors, and interacted with locals and cosmopolitans. They had a high degree of extension agency contact and a medium level of social activity. (Devaki et al., 2015)

Relationship between Gender and Adequate Transport facility

Null Hypothesis (Ho): There is no significant between the Adequate Transport facility and gender. T test has been applied at 5 per cent level of significance to examine the hypothesis and the computed results are presented in the following table. It is stated from the above table that among the two categories of gender, female respondents are having maximum level of mean score towards adequate transport facility. It is noted from the T test analysis that the null hypothesis is rejected. Hence, It is found that there is a significant between the adequate transport facility and gender of selected respondents in the study area. According to the Elakiya Study, when it comes to gender analysis, vans were used by more than half (55.88%) of the male agripreneurs for transportation, followed by two-wheelers (41.18%) and lorries (2.94%). When it came to female agripreneurs, vans were used by more than half (56.86%) of them, followed by two-wheelers (40.20%) and lorries (2.94%). The agripreneurs' business, the customers, and the quantity of output all influence the manner of transportation. For transportation, the majority of agribusiness owners utilized two-wheelers because they were limited to the local area and the quantity of products they collected was smaller. Products relating to coir, coconut flakes, and bio inputs were delivered by truck. The people that sold to contractors and distributors set up the transportation and split the expense. This could be the cause of the aforementioned. (Elakkiya and Asokhan, 2021)

Gender and various challenges

In order to find the relationship between the gender of the respondents and various challenges, the following hypotheses are formulated.

Null Hypothesis (Ho)

There is no significant between the various challenges and Gender of selected respondents in the study area. T test has been applied at 5 per cent level of significance to examine the hypothesis and the computed results are presented in the following table. It is stated from the above table that among the two categories of gender, male respondents are having maximum level of mean score towards weekly of income. It is noted from the T test analysis that the null hypothesis is accepted. Hence, It is found that there is no significant between the various challenges and gender of selected respondents in the study area. According to the Kumerasan study, the weekly market is typically held in the village center, on public roadsides, or in places of worship, but it lacks a formal structure and organization. Many conflicts arise between vendors and customers as well as between the market's contractors during operating hours. Various regional names for the village weekly market include Haats, Shandy, Santhai, Bazaar, and rural markets. There are, however, between 21000 and 47000 markets in the nation. Weekly village markets are a frequent sight in Tamil Nadu, dating back to the emperor era. (Kumaresan and Manivannan, 2019)

CONCLUSION

From the study it is found that weekly santhai plays a significant role in improving the financial status of the farmers and it is important medium in developing sustainably and improve rural economy. The farmers typically attend the market on a seasonal basis because their livelihoods depend on the availability of seasonal fruits, vegetables, and other agricultural products. Their financial situation is getting better even if they are unable to use the earnings to buy additional assets. Like everyone else, the farmers are interacting socially with other market goers, exchanging knowledge and offering encouragement. Through market activities, the weekly markets continue to provide a means of subsistence and a forum for social interaction between market participants.

ABSTRACT

Transfer learning is a powerful technique to utilize an already existing pre-trained deep learning model which was previously trained for some exclusively different task than the problem in question. This research focus on the concept of transfer learning where a previously trained convolutional neural network based model was fine tuned to perform classification of breast cancer mammograms. A modified mini DDSM dataset was used. The images were pre-processed and a random split has been performed on images for training and testing purpose. The cross entropy loss criterion was used to check performance of the model. Stochastic Gradient Descent algorithm was also used for fitting the proposed model with 0.001 learning rate. A decay LR scheduler was used after each 7th epoch to revise the learning rate by 0.1 factor. The contribution of this paper can be summarized in two parts. First, the ResNet50 was implemented by with generalized weights (IMAGENET1K_V1) and with only three layers unfreeze and further fine-tuned for the target problem. Second, the model after fine tuning classifying breast cancer mammograms with 90.94% average training accuracy and 95.19% average validation accuracy in 25 epoch training for finding malignancy. By training the model up to 50 epochs the proposed model achieve 96.79% average training accuracy and 99.93% average validation accuracy. Due to the high accuracy achieved by the model on a small dataset by limited training epochs, the proposed model can be used to detect malignancy in breast mammograms.

Keywords: Breast Cancer, Classification, Mammograms, Transfer Learning, Deep Learning, Fine Tuning

INTRODUCTION

Breast cancer detection is considered as a leading research area because breast cancer is the second leading cause of mortality worldwide [1]. Screening mammography is a renowned and promising tool to detect malignancies in the breast cancer. This can be helpful in early detection of breast cancer and to reduce mortality rate [2]. Breast cancer detection using digital mammography is an image classification problem in the area of computer vision. This problem can be solved by using object detection and object recognition algorithms of computer vision. Innovations and advancements in the field of deep learning are working as a fuel in the area biomedical image processing. Breast cancer detection with substantial accuracy at the early stage of the disease is most important. Research indicate that digital mammography based breast cancer detection systems showing average 86.9% and 88.93% sensitivity and specificity respectively [3] and need further improvement. Research suggests that deep learning based breast cancer detection algorithms showing promising results [4-11]. A vast amount of data is required for training of deep learning models. Being an emerging field, not much official biomedical digital image datasets and benchmarking datasets are available for deep learning researchers. To solve the scarcity of data a comparatively new sub field of deep learning called transfer learning is used these days. Transfer learning is a promising deep learning method which is used to train deep neural network when large training dataset is not available. In this method, a deep learning model is first trained on an existing pre-trained model, initialize its weights for recognizing primitive features such as edges, lines, corners and texture. Further this same model is fine tuned for another task. Classification of breast mammograms is a challenging research problem of image classification area because the Region of Interest (ROI) which include lesion and masses (approximately 100 x 100 pixels) are located in a very small portion of the whole image of breast mammogram (approximately 4000 x 3000 pixels) [18]. Due to this reason in most of the researches whole mammograms are pre-processed (clipped and annotated) to focus on ROI only [8, 12-16,19-22]. This clipping approach has limitation to have intervention of radiographers to mark ROI region in whole mammograms. In the present study we have used whole mammography images and transfer learning for classification of mammograms to detect malignancy which need no human intervention.

MATERIAL AND METHODS

Dataset

A modified mini DDSM [17] dataset has been used to perform this experimentation. MiniDDSM is a lightweight thumbnail image dataset having three classes Normal, Benign and Malignant. Each class has lossless JPEG images with MLO and CC views of left and right breast of each case. The present experiment emphasizes on classification of tumours so we have discarded the normal cases from the dataset. The dataset is pre-processed and augmented using various transformation functions. Images are randomly cropped and resized to 224 pixel size, the available images are horizontally flipped and normalized. The complete dataset has been divided into 70:30 train-test split for further experimentation.

Hardware and Software

We used Google Colab for Google Computer Engine backend (GPU) with Python 3 provided with 12.7GB RAM, 15.0GB GPU RAM and 78.2GB Disk Storage, for the training, validation and testing process. TorchVision0.16.0 is used to perform the experimentation

Proposed Method

In the present work we have proposed a transfer learning based breast tumour classification system. Transfer learning addresses the performance degradation issue of deep learning models due to lack of data for proper training. We used PyTorch version 2.1.0 to design our classification model. This is a five stage detection system. The five stages include pre-processing of images, segmentation, feature extraction, feature selection and classification.

Garima Charan and Jyoti Lakhani

Deep Network Architecture

The deep networks imitate human brain and composed of multiple layers of neurons. In deep networks the starting layers are convolution layers. These convolution layers are used to extract important features from the images. These are followed by pooling layers to perform subsampling of the feature maps identified by the convolution layers. The last layers of deep networks are fully connected layers which perform classification of images on the basis of sampled feature maps. The deep learning models imitate the human brain. It is composed of multiple layers. Starting layers are convolution layers which are used for feature extraction. The following few pooling layers performs subsampling of the feature maps. The final layers called fully connected layers perform classification. In the present work we have used transfer learning in which an already existing pre-trained deep neural network is used to solve the problem concern by performing changes in the layers and adjusting the parameters of few layers while keeping other layers frozen. In this experiment we have used ResNet50 pre-trained model to perform breast cancer detection and classification. The architecture of the ResNet50 is given in Table 1. We keep top layers freeze and layer 4, fully connected layer and average pool layer have remain unfrozen. To make the model adapt to our case, we switched the previous output to one output with a sigmoid activation function since our case is a binary classification. Several trials were applied to establish the suitable parameters for fine-tuning, compiling, and fitting the models. The images were pre-processed and a random split has been performed on images for training and testing purpose. The cross entropy loss criterion was used to check performance of the model. Stochastic Gradient Descent algorithm was also used for fitting the proposed model with 0.001 learning rate. A decay LR scheduler was used after each 7th epoch to revise the learning rate by 0.1 factor. Table1 shows the final and optimal parameters. The weights of the final model used for transfer learning are given in Table2. The fine tuning and fitting parameters used for in our work is given in Table 3.

RESULTS AND DISCUSSION

In this section, we have presented a comparative performance analysis for breast cancer detection. The proposed deep network was initially trained and validated for 25 epochs. At each epoch during the training phase the accuracy of the model is identified and after 25 epochs the best model state showing highest accuracy during the training was selected. The validation steps are performed for this best model. This model show average 20.65% training loss and 90.94% training accuracy with minimum training loss 7.53% and maximum accuracy 97.74% respectively. The model shows average 11.57% validation loss and 95.19% average validation accuracy. At the best end, the model shows 1.25% validation loss and 99.89% validation accuracy. Further, the model was trained for 50 epochs. The model shows 10.03% and 1.77% average loss in training and validation respectively. A significant 96.79% and 99.93% accuracy was seen during training and validation phase. Figure 1 showing the performance of the proposed model for 25 and 50 epochs of training and validation. The training and validation loss observed during 25 epoch and 50 epoch execution is shown in Figure 2. Figure 3 is showing training and validation accuracy seen during the 25 epoch and 50 epoch execution respectively. In this figure a trend line is also plotted. The coefficient of determination (R^2) for 25 epochs to 50 epoch execution is 1 for both validation loss and prediction accuracy which indicates that the model is perfectly predicting the outcomes. The R^2 is a number between 0 and 1 that measures how well a statistical model predicts an outcome. There are several other methods also available to evaluate the results of classification process. In the present paper we have used accuracy, sensitivity, and specificity and confusion matrix. The confusion matrix was created on the basis of the results of the proposed model. From this confusion matrix we have calculated accuracy, sensitivity and specificity by using True Positive (TP), False Positive (FP), True Negative (TN) and False Negative (FN). True Positive (TP) is the total number of correctly identified benign and malignant breast tumour. False Positive (FP) is the total number of breast tumour identified as malignant but are benign. True Negative (TN) is the total number of cases correctly identified as benign. False Negative (FN) is the total number of images identified as benign but is malignant.

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \% \text{ (Equation 1)}$$

$$\text{Sensitivity} = \frac{TP}{FN+TP} \% \text{ (Equation 2)}$$

Garima Charan and Jyoti Lakhani

$$\text{Specificity} = \frac{TN}{FP+TN} \% \text{ (Equation 3)}$$

The confusion matrix of the model is given in Figure 4. The values of TP =1318, FP =2, FN=2 and TN=2347 are identified using this confusion matrix. The sensitivity(99.84%) and specificity(99.91%) are identified using equation 2 and equation 3 respectively.

CONCLUSION

A breast cancer prediction detection model using deep neural network has been proposed. Transfer learning has been used in which a pre-trained ResNet50 model was used to identify parameters of the model. ResNet50 was modified by unfrozen last three layers, fine tuning and fitting parameters was done for the targeted problem. We collected benign and malignant tumour images from miniDDSM dataset. These images were pre-processed and augmented such that we managed to reach 99.93% breast cancer detection accuracy, 99.84% sensitivity and 99.91% specificity. The performance of the model can be improved further by using other efficient pre-trained model and by using other pre-processing techniques for images, which is one of our future research directions.

ABSTRACT

The purpose of the study was to determine the mediating effect of marital adjustment and social support on the relationship between partner abuse and general health among Sikkimese married women. Utilizing the quantitative method via sequential mediation, data were obtained from 400 Sikkimese married women within the age group of 18-40 years as early adults and 41-60 years as middle adults from the rural and urban areas of Sikkim. For the sequential mediation, the present study employed a partial least square method. To find out the prediction of GHQ Positively phrased items (GHQPP) and GHQ Negatively phrased items (GHQNP) from partner abuse, marital adjustment, and social support were considered as mediators with/without demographic variables. The only possible path for the sequential mediation was Partner abuse -> Marital adjustment -> Social support -> GHQPP/GHQNP. Results revealed a significant effect on the prediction of GHQPP from Partner abuse with Marital adjustment and social support as mediators with/without demographic variables. In addition, results also revealed a significant effect on the prediction of GHQNP from Partner Abuse with Marital Adjustment and Social Support as mediators with/ without demographic variables.

Keywords: Marital Adjustment, Social Support, Partnerabuse, General Health

INTRODUCTION

Marriage is a significant life event that occupies a remarkable place in the lives of many women and men (Berscheid & Regan, 2005). Marriage has been identified to be one of the most powerful predictors of happiness and well-being.

**Lalfamkima Varte *et al.*,**

Besides, Argyle and Furnham (1983) explained that "Marriage is the most important form of social support for most people, greater than friends or other emotional and marital support and companionship". According to the study by Brigoli & Sandoval (2023), there are important correlations between married couples' well-being and leading satisfying lives, as well as between married couples' well-being and marital satisfaction. Marital adjustment is defined as the mental condition in which spouses have an overall feeling of happiness and satisfaction with their marriage and with each other (Sinha & Mukerjee, 1990). As a result, it calls for a satisfying relationship between spouses that is characterized by reciprocal concern, care, understanding, and acceptance. It entails being able to effectively negotiate and cope with the different transitions, obligations, and duties that come with being married. Marital adjustment is a continuing process that requires communication, flexibility, and collaborative effort from both parties. Each marriage is unique, and success is defined differently by different people and it's important to remember that every marriage is different, and the meaning of marital success may differ from couple to couple. What works for one marriage might not work for the next (Bentler & Newcomb, 1978; Glenn & Uecker, 2010). Marital adjustment is a process that arises in the course of a couple's relationship because it is essential for the development of behavioural norms, personality traits, and relational models (Aminjafari, *et al.*, 2012). Cobb (1976) defined social support as "the feeling of belonging to a network of communication and mutual responsibility, as well as the knowledge that one is respected and cherished by loved ones". Social support can be distinguished by its sources like friends, family, teachers, romantic partners, relatives, neighbours, co-workers, organizations, etc. Each support an individual receives from any source is beneficial for well-being and for promoting positive feelings (Chu, *et al.*, 2010). Prezza & Pacilli (2002) found that married men perceive more support for a certain person than married women, proving that marriage benefits men. On the other hand, women are better able to rebuild their support system after a marriage ends due to separation or the death of one partner. Likewise, the concept of the mediating role of social support and marital adjustment in marriage describes how certain variables, such as individuals' well-being, communication and emotional well-being, intimacy and conflict, cohesiveness and marriage satisfaction, and quality of the marriage, can affect the relationship between the various factors (Nihayah *et al.*, 2023; Tönbul & Malkoç, 2023).

As a "bridge" between different relationship variables, marital adjustment and social support can affect how couples handle opportunities and obstacles, which in turn shapes the nature and course of their relationship (Caldwell & Bloom, 1982; Mert, 2018). Muslima & Herawati (2018) in their study revealed that social support and marital adjustment affect an individual's marriage quality. It was also reported that social support had a significant positive relationship with marital adjustment, moreover, marital adjustment was positively correlated with marital quality. Sometimes, there comes a situation where everyone experiences ups and downs in their marriage. Spouses are happier, healthier, and live longer in secure, happy relationships. However, other foundations of well-being are compromised when the partnership fails (Karney & Bradbury, 2020). One of the common marital problems faced by married women in India is intimate partner violence, also known as partner violence/abuse from their partners (Bhat & Ullman, 2014; Ahmed-Ghosh, 2004; Nadda *et al.*, 2018). Partner abuse is one kind of domestic violence. Partner abuse refers to the battering that occurs in a relationship between a couple who is married and living together. Research has suggested that the forms of partner abuse that occur are not the same for all couples but it is experienced differently by each individual (Dobash & Dobash, 1979; Indu *et al.*, 2021). There are many different forms of partner abuse and a person may be subjected to one or more than one form of violence. It includes physical violence, sexual violence, psychological abuse, emotional abuse, and many more (Kahol, 2003; Ahuja, 2009; Aminjafari *et al.*, 2012; Devi, 2005). Moreover, the physical, mental, and emotional well-being of an individual is directly impacted by partner abuse, which means that there is a close correlation between general health and relationship abuse. An individual's overall health is harmed in several ways when they experience abuse from their relationship (Svavarsdóttir, & Orlygsdóttir, 2009). The term "general health" refers to an individual's total well-being, which includes physical, mental, and emotional elements. It is a multidimensional term involving a variety of aspects that contribute to an individual's overall health state. It is essential to remember that the overall health and well-being of an individual vary from person to person and are interconnected. It can be impacted by various combinations of genetic influences, lifestyle choices, socioeconomic considerations, and the general social and

physical environment. Therefore, maintaining and developing overall health necessitates a multifaceted approach that covers all areas of well-being (Huppert & So, 2013; Ruggeri *et al.*, 2020).

Objectives of the study

- 1.To determine the role of marital adjustment and social support in the prediction of GHQ positively phrased items (GHQPP) from partner abuse among the samples.
