- Transforming categorical features (e.g., one-hot encoding) to ensure machine-learning compatibility.

Feature Construction:

- Derivation of statistical, temporal, behavioral, and anomaly-based features.
- Includes network-level attributes (packet size, connection rate), system-level metrics (CPU/memory usage), and behavioral cues (login frequency, access patterns) [11,12].
- Enables efficient learning for both supervised and unsupervised models.

Hazard Identification and Categorization:

- Random Forest algorithm for multi-class threat detection
- LSTM models for forecasting attack timelines (DoS/DDoS trends).
- Anomaly detection using autoencoders for zero-day attacks.
- Provides strong precision across various attack types while also tackling uncommon and emerging threats.

Interpretability AI Module:

- Utilizes SHAP values to elucidate model decisions on both a global and instance level
- Provides feature importance, enabling security analysts to identify which indicators contributed most to the prediction.
- Strengthens confidence and aids decision-making in SOC environments.

Notification and Automated Reaction:

- Creates practical notifications instantly.
- Automates protective actions like blocking IPs, throttling requests, isolating hosts, and alerting security staff.
- Supports ongoing feedback for model retraining, boosting system flexibility against shifting threats.

Process Flow

- Input Data: Ongoing collection of network, system, and user logs.
- Preprocessing: Information is tidied, standardized, and transformed.
- Feature Extraction: Pertinent attributes for multi-category threat detection and anomaly recognition are calculated.
- Model Prediction:
  - Random Forest identifies known attacks.
  - LSTM forecasts time-based attack patterns.
  - Autoencoder identifies anomalous (zero-day) attacks
- Interpretability: SHAP offers explanations at the feature level.
- Alert & Response: Immediate countermeasures carried out on the SOC dashboard [13].
- Feedback Loop: Notifications and performance outcomes are recorded to refresh and retrain the models.

Diagram of System Architecture

- Modules are organized as data acquisition → preprocessing → feature engineering → AI models → explainable AI → SOC alerting & automated mitigation → feedback loop
- Facilitates ongoing education and adjustment to new cyber hazards.

Deployment Tools

- Coding Languages: Python (for machine learning, deep learning, and automation)
- Tools/Frameworks: scikit-learn (Random Forest), TensorFlow/Keras (LSTM, Autoencoder), SHAP (Explainability), Streamlit (Dashboard)
- Evaluation Measures: Accuracy, precision, recall, F1-score, confusion matrix, ROC–AUC

METHODOLOGY

The approach of this research aims to create a sturdy, understandable, SOC-ready AI-powered cybersecurity architecture. The process includes building the dataset, preprocessing, crafting features, developing the model, assessing it, and deploying it. Each phase is explained in detail below [14, 15].

Generating the Dataset

A thorough cybersecurity dataset was built to contain eight attack types: Normal, Brute Force, Denial of Service (DoS), Distributed Denial of Service (DDoS), Malware, Phishing, Insider Threat, and Zero-Day attacks. The collection includes 3,000 examples for each category, amounting to 24,000 labeled instances, to maintain balance and provide adequate representation for training.

Data Origins

- Network traffic records (packet counts, flow duration, port usage)
- Server and system records (CPU/memory usage, login attempts)
- Firewall and intrusion detection system alerts
- Mocked internal actions and phishing situations

Synthetic data creation methods such as SMOTE and data augmentation were employed for scarce attack categories like Insider Threat and Zero-Day to achieve a balanced class distribution and enhance model generalization.

Data Preparation

Preprocessing is essential to guarantee high-quality input data for machine learning models. The subsequent steps were implemented:

1. Data Cleaning: Elimination of duplicate entries, null values, and outliers
2. Normalization/Scaling: Features were adjusted using Min-Max scaling to unify their ranges.

3. Encoding: Categorical variables were transformed using one-hot encoding or label encoding as needed.
4. Train-Test Split: The data was split into 80% for training and 20% for testing, preserving class distribution through stratified sampling.

Feature Construction

Feature engineering centered on deriving informative cues for both known and emerging cyber threats. The subsequent categories of features comprised: Feature significance was assessed with Random Forest and SHAP values to rank the most distinguishing attributes.

Development of the Model

The suggested architecture combines supervised and unsupervised learning models:

Random Forest (RF):

- Multi-class classification covering eight attack types.
- Delivers precise results and strong resistance to noise.
- Hyperparameters adjusted through grid search (tree quantity, max depth).

Long Short-Term Memory (LSTM) architectures:

- Identifies time-based relationships within ordered network traffic.
- Capable of forecasting DoS/DDoS attack patterns.
- Configured with a pair of LSTM layers, dropout regularization, and the Adam optimizer.

Autoencoder:

- Unsupervised anomaly detection to detect zero-day attacks.
- Learned from normal traffic to establish baseline behavior; deviations marked as anomalies.

Interpretable AI (SHAP):

- Explains how features influence the model's predictions.
- Facilitates analysts' decision processes and integration with the SOC

Model Assessment

Performance was assessed using conventional multi-class classification metrics. The assessment was carried out on the reserved test set, and the outcomes were confirmed through cross-validation [16, 17].

Implementation & Automation

The trained models were incorporated into a Streamlit-based dashboard for live monitoring and visualization. The system offers:

- Live threat forecasting and categorization
- Visualization of feature importance using SHAP
- Automated defensive measures (IP blocking, throttling, host isolation)
- Ongoing feedback for model retraining

This guarantees the framework is usable, understandable, and SOC-ready.

Overview of Methodology Process

Data Gathering → Data Cleaning → Feature Construction → Training the Model
→ Forecasting → Interpretable AI → Immediate Notification → Self-Acting Reply → Reinforcement Cycle

The approach merges multi-class detection, anomaly detection, interpretability, and operational deployment to tackle both established and emerging cyber threats [18, 19].

RESULTS AND DISCUSSIONS

The AI-powered cybersecurity framework was tested on a multi-class dataset that includes eight types of cyber threats: Normal, Brute Force, Denial of Service (DoS), Distributed Denial of Service (DDoS), Malware, Phishing, Insider Threat, and Zero-Day attacks. The dataset comprised 3,000 samples for each class, amounting to 24,000 instances, providing a balanced set for training and assessing the model.

Performance of Classification

The Random Forest classifier showed strong performance across most attack types, as summarized in Table 1.

Important Observations:

- The model attained an overall accuracy of 87%, showing robust predictive ability across a wide range of cyber threats [20].
- High detection performance (F1 exceeding 0.95) was recorded for Brute Force, Normal, Phishing, Insider Threat, and Zero-Day attacks.
- A moderate level of performance was noted for DoS and DDoS attacks (F1 ≈ 0.52–0.53), mainly because of shared traffic features, a frequent issue in real-world networks.

Confusion Matrix Evaluation

The confusion matrix shown in Figure 1 reveals the patterns of misclassification:

- DoS and DDoS were often mistaken for each other because they exhibit comparable volumetric traffic patterns.
- Other attack categories displayed only minimal cross-class misclassification.
- Regular traffic and anomaly-driven attacks (Zero-Day, Insider Threat) were reliably differentiated.

Implication: Although the system reliably identifies most threats, distinguishing volumetric attacks could be enhanced by adding temporal features or employing hierarchical classification.

Receiver Operating Characteristic and Area Under Curve Evaluation

Receiver Operating Characteristic (ROC) curves were generated for each attack class (Figure 2):

- Categories with elevated F1 scores (Normal, Brute Force, Phishing) attained AUC > 0.98.
- DoS and DDoS exhibited reduced discriminative ability (AUC around 0.75), confirming the observations from the confusion matrix.
- Overall, ROC analysis validates the model's capacity to differentiate normal from anomalous traffic.

Significance of Features & Explainable Artificial Intelligence

SHAP-based feature analysis (Figure 3) identified the most impactful features steering model predictions:

- Brute Force: Number of unsuccessful logins, login rate, distinct source IPs
- DDoS / DoS: Packet frequency, flow length, variety of source IPs
- Malicious software: sudden CPU or RAM usage surges, irregular file operations
- Phishing: Dubious URL patterns, email metadata
- Zero-Day: Autoencoder reconstruction discrepancy, atypical system calls

Practical Insight: Using SHAP explainability, SOC analysts can grasp model choices, rank investigations, and efficiently counter threats.

Time-based & Irregularity Detection

LSTM-driven temporal analysis identified sequential attack behaviors, enhancing the prediction of DoS/DDoS trends. Autoencoder-driven anomaly detection reliably identified zero-day attacks lacking known signatures. Combining these approaches provides protection against both familiar and novel threats.

Live Dashboard & SOC Integration

The Streamlit dashboard displays:

- Live threat forecasts
- Class-specific confidence scores
- Feature importance (SHAP)
- Automated notifications and mitigation suggestions

Impact: Facilitates anticipatory monitoring and swift operational action, shortening SOC response times and lessening possible harm.

Examination

Advantages:

- Elevated accuracy and F1 scores for critical attacks.
- Transparent and comprehensible AI for operational deployment.
- Comprehensive system that combines forecasting, visual representation, and automated countermeasures.

Constraints:

- Only a moderate distinction between DoS and DDoS attacks because their features overlap.
- Model performance can differ in extremely large-scale or highly dynamic network environments.

Upcoming Improvements:

- Implement layered categorization for volumetric attacks.
- Employ ensemble deep learning models to enhance DoS/DDoS differentiation.
- Incorporate extra temporal and contextual attributes from network logs.

CONCLUSION

This research introduces an all-encompassing AI-powered cybersecurity architecture that can forecast, identify, and thwart a broad range of cyber hazards, such as DoS, DDoS, Malware, Phishing, Insider Threats, and Zero-Day attacks. By combining Random Forest classification, LSTM temporal modeling, autoencoder-based anomaly detection, and SHAP-based explainable AI, the offered system delivers highly precise, interpretable, and readily deployable solutions for real-world network settings. Experimental findings show a total accuracy of 87%, with outstanding F1-scores (>0.95) for Brute Force, Normal, Phishing, Insider Threat, and Zero-Day attacks. Performance is moderate for DoS and DDoS attacks, underscoring the real-world difficulty of overlapping traffic patterns and pointing to possibilities for hierarchical or ensemble models to better separate volumetric attacks. Incorporating explainable AI allows SOC analysts to understand model outputs and devise appropriate mitigation actions, while the Streamlit-driven dashboard supports live monitoring and automated responses, cutting detection-to-response time. The suggested framework tackles essential shortcomings in current studies by providing a multi-class, explainable, SOC-integrated solution that can manage both known and new threats. Its modular design supports ongoing learning, allowing it to adjust to shifting attack tactics.

Upcoming efforts will concentrate on:

- Improving DoS/DDoS detection with advanced temporal and ensemble learning methods
- Using authentic large-scale network data to test the model's scalability and robustness.
- Expanding the framework to incorporate threat intelligence streams and predictive risk evaluation for proactive cybersecurity management.

To sum up, the research shows that AI and ML can be efficiently utilized to develop practical, understandable, real-time cybersecurity solutions, offering considerable advantages over traditional intrusion detection methods and enabling proactive defense tactics within evolving digital environments.

Main Contributions

- Development of a multi-category threat classification framework encompassing eight attack types.
- Combining Random Forest, LSTM, and Autoencoder models to detect known and zero-day attacks.
- Application of SHAP interpretability to deliver actionable insights for SOC analysts.
- Implementation within a live dashboard that enables automated mitigation and ongoing learning.
- Showed real-world efficacy, achieving 87% total accuracy and strong F1 scores on key attacks.

ABSTRACT

Insects are most diverse group of animals, living at various types of ecosystms. Insect's species distribution and species composition amidst urban area help reveal their uniqueness and diversity. In the present investigation, insect pollinator species of modified/managed landscapes amidst urban area was conducted during different hours of the day during March, 2025 to May, 2025 by choosing more than 72 quadrates with a length 100 meters in different places at 110 years old Manasagangotri Campus, Mysore using random sampling method. Overall, 89 pollinating insect species were observed and which belong to 65 families of nine orders with a mean population size 2406.7 at Manasagangotri campus during summer season. Of all, Hymenopterans were predominant (45.6%) and it was followed by Lepidopterans (17.3%), Hemipterans (14.9%) and Dipterans (10.4%). Moreover, the population size of insect pollinator species showed similar trend during summer season. Interestingly, analysis of variance of insect pollinator species ($F=0.367$; $P<0.05$) and their population size ($F=0.240$; $P<0.05$) occurred during different month's didn't show significant difference during summer months at Manasagangotri Campus, Mysore. Further, insect pollinators were busy with landing on the flowers (19.3%), pollen collection (18.4%), nectar collection (17.9%) and only 0.3% insect pollinators were busy with wax/propalis collection. Further, different diversity indices values of insect pollinators was 0.279, 0.721, 1.565, 0.633, 0.825, 1.491, 0.773, 2.031, 0.456 and 8.987 respectively for Dominance, Simpson, Shannon, Evenness, Menhinick, Margalef, Equitability, Fisher Alpha, Berger-Parker and Chao-1 indices. Furthermore, 'β' diversity indices such as 'Cody β diversity' indicated highest (1.500) index and it was followed by 'Wilson-Shmida β diversity' (0.196) and 'Whittaker β diversity' was 0.174. However, Harrison, Routledge and Mourelle 'β' diversity indices were comparatively low. Thus, present study help understand the insect pollinator's

diversity along with their population size amidst modified/managed landscape during summer season. This investigation help provided a platform to undertake further in depth research to reveal the status of insect pollinators, which are facing threat due to various man-made activities amidst modified/managed landscapes of urban areas. Perhaps, this type of investigations help inventorying the insect pollinators to study their role in local biodiversity at urban landscapes.

Keywords: Insect pollinators, diversity, modified/managed landscapes, summer, urban area.

INTRODUCTION

Insects inhabit at various diversified ecosystems (Mani, 1982) by establishing complex relationship with several plant species (Parihar, 2022). Among the insects, many species act as pollinators by doing pollination amidst various ecosystems (Kadam *et al*., 2021). India is home to approximately more than 60,000 to 70,000 insect species, which accounting 7 to 10% of the global insect population (Sivagami, 2022). Various entomologists have reported on insect's distribution and their diversity at different parts of the world. Ragaei and Allam (1997) have studied the insect diversity and their conservation. Uniyal and Mathur (1998) have studied the species diversity among selected insect groups at Chandrabani Dehra Dun, India. Purohit and Swetha (2002) have surveyed the distribution of insect diversity in different geographic settings of Doon Valley in India. Gibbs (2012) has reported the role of insects in natural terrestrial ecosystems. Basavarajappa and Vijayan (2012) have published a report on fauna of Manasagangotri Campus in Mysore. Aishatu (2015) has reported the insect diversity, species composition and their variation during the wet and dry seasons in three forest types of Johar of Malaysia. Fredrick *et al*. (2016) have analysed the diversity of insect fauna in grassland and woodland community at Mbeya University of Science and Technology, Tanzania. Madelon *et al*. (2016) have studied the importance of biodiversity and dominance for multiple ecosystem functions in a human-modified Tropical Landscape. Bindulekha and Amalnath (2017) have recorded the biodiversity of insects at College campus, Thiruvananthapuram District, Southern Kerala.

Malti (2017) has reportd the importance of insects for humans and the environment. Kimondiu *et al.* (2017) have assessed the insect diversity in Bengaluru using light traps. Sankarganesh (2017) has reviewed on insect biodiversity. Santhosh and Basavarajappa (2017) have recorded the biology of few butterfly species of agriculture ecosystems of arid regions of Karnataka, India. Alex *et al*. (2018) have studied the insect species richness in a scrub jungle ecosystem at Chennai, Tamil Nadu. Basavarajappa *et al.* (2018) have prepared the checklist of butterfly species of Nagarahole National Park, Karnataka. Priyadarshini *et al.* (2018) have studied the insect diversity in and around Maharani's Science College Campus, Mysuru. Jankielsohn (2018) has highlighted the importance of insects in agricultural ecosystems. Mathew *et al.* (1998) have investigated the insect biodiversity in disturbed and undisturbed forests in Western Ghats, Kerala. Kadam and Swetha (2021) have studied the biodiversity of insects and their role in balancing the ecosystem at Bhimashankar Wildlife Sanctuary, India. Kurmi *et al.* (2021) have analysed the diversity of nocturnal Lepidopterans in paddy fields of Jabalpur district, Madhya Pradesh, India. Prerana *et al*. (2021) have studied the insect diversity in different habitats of Raipur, Chhattisgarh. Tangam *et al.* (2021) have studied the diversity of insects from two botanical gardens of Bengaluru, Karnataka, India.

Niranjan *et al*. (2021) have recorded the medicinal plant diversity of Manasagangotri Campus, Mysuru. Muneer and Nadeem (2022) have reported the importance and role of insects in ecosystem. Parihar (2022) has studied the biodiversity of insects of Hanumangarh District, Rajasthan. Sivagami (2022) has evaluated the insect biodiversity at Devi Kumari Women's College campus, Kuzhithurai, Kanyakumari district of Tamil Nadu. Basavarajappa (2023) has recorded the diversity of aquatic insects in Yattinahole River Hassan, India. Landmann *et al*. (2023) have recorded the role of insects and their diversity as a good indicator of biodiversity status in Africa. Verma *et al*. (2023) have

recorded the role of insects in ecosystems. Bhagya and Basavarajappa (2024) have recorded the influence of ecological factors on butterflies of various agro-climatic landscapes in Mysore District. Madhavi and Basavarajappa (2024) have studied the entomofauna of Manasagangotri campus, Karnataka. Nalini and Basavarajappa (2024) have recorded the density, abundance and diversity of insect pollinators at agro-ecosystems of Kodagu district, Karnataka. However, published reports on insect pollinator species amidst urban area is poor. Manasagangotri campus is located at the heart of Mysore city and housed with good number of flowering plants (Rao and Basheer, 1974; Rao *et al*., 1981). Many insect species are living in Manasagangotri Campus (Madhavi and Basavarajappa, 2024), but information on the pollinating insect species is poor. Hence, attempt was made during the present investigation to record insect pollinator species at modified/managed landscapes during summer season at urban areas of Karnataka.

MATERIALS AND METHODS

Study Area: In Mysore, 'Manasagangotri campus' (12.3° N and longitude 76.6° E.) is housed with 739 acres of land with 261 acres of Kukkarahalli Lake on undulating terrain with an altitude of about 770 metres (Kamath, 2001) was selected (Figure 1). The campus belong to the University of Mysore and experiencing a tropical climate, characterized by moderate to hot temperature (18 to 35°C) during wet (June to September) and dry (October to May) seasons (Kamath, 2001). The monsoon season starts with heavy rainfall and characterized by frequent showers along with thunderstorms. The dry season (October to May) is characterized by sunny skies with medium to heavy rainfall during March and April months. The prevailed congenial conditions in and around Manasagangotri campus have supported good biological diversity (Raghavendra and Basheer, 1974; Rao and Razi, 1981; Kamath, 2001; Basavarajappa and Vijayan, 2012; Niranjan *et al*., 2021; Madhavi and Basavarajappa, 2024) and supported diversified flora and fauna. The prevailed ecological conditions recorded during summer months in Manasagangotri campus, Mysore is depicted in Table 1.

METHODOLOGY

Systematic field investigation was conducted at different places of Manasagangotri campus by following standard methods as per Parihar (2022). Field survey was carried out on weekly basis during morning (6.00 AM to 8.00AM), afternoon (12.00 PM to 2.00PM) and evening (4.00PM to 7.00PM) hours from March to June, 2025. The line transect (100 meter length), quadrate (10 × 10 sq ft area) and all out search methods were used to observe and record the insect pollinaors on flowering plant species. Visual count method was also followed to record the pollinators as per Santhosh and Basavarajappa (2017), Santhosh *et al.* (2024), Nalini and Basavarajappa (2024). Butterflies were observed using point count/visual count methods as per Basavarajappa *et al.* (2018), Kadam *et al.* (2021), Parihar (2022) and Sivagami (2022). Moreover, flying insect pollinators were observed on hedge row or garden with blooming plants, on the leaves, stems and flowers with the help of cell phone. Insect pollinators were identified with the help of taxonomic keys using published literature. Collected insects were isolated and grouped into different orders systematically by following standard methods as per Madhavi and Basavarajappa (2024) and Nalini and Basavarajappa (2024). Collected data was compiled and systematically analyzed (Saha (2009) using different diversity indices as per Ricklef's (1990), Tancredi *et al.* (2007), Ricardoiglesian-Rios and Rosana (2014), Magurran (2024).

RESULTS

Table 2 shows the insect pollinator species occurrence during March to May in summer season at Manasagangotri campus, Mysore. Total 51 insect pollinator species which belong to six orders were recorded during March. However, during April, 104 species of insect pollinators which belong to eight orders have recorded. But, in May, highest (112) insect pollinator species belong to nine orders have rerecorded and it was comparatively high during May than that of March and April (Table 2). Overall, Hymenopterans were more predominant during March to May and it was followed by the insect pollinator species belong to Lepidoptera, Hemiptera, Coleoptera and Diptera (Table

2). However, insect pollinators belong to Thysanoptera, Orthoptera, Blattodea and Mantodea were very less during March to May in Manasagangotri campus during summer season. Analysis of variance of insect pollinator species found between the months didn't varied significantly ($F=0.367$; $P<0.05$; df: 2/23) during summer season in Manasagangotri campus, Mysore (Table 2).

Table 3 shows the insect pollinators population size found during March to May in summer season at Manasagangotri campus, Mysore. The insect pollinators population size was less (970) during March and it was gradually increased (2, 341) in April and reached to a maximum number (3, 909) in May month at Manasagangotri campus during summer season. However, insect pollinators belong to nine different orders indicated almost similar trend from March to May except Thysanopterans. However, insect pollinators population belong to Thysanoptera, Orthoptera, Blattodea and Mantodea were very less during March to May in Manasagangotri campus during summer season. Analysis of variance of insect pollinators population size found between months March to May didn't varied significantly ($F=0.240$; $P<0.05$; df: 2/23) during summer season in Manasagangotri campus, Mysore (Table 3). Overall, from nine insect orders, altogether 89 pollinating insect species were observed and accounted to a total population size 7,220 (Table 3) at Manasagangotri campus during summer season. Number of species and their families and a mean population size of insect pollinators along with their orders are depicted in Table 4.

Table 5 shows the different activity of insect pollinators recorded during summer season at Manasagangotri campus, Mysore. Majority (19.3%) of pollinators were busy with landing on the flowers and it was followed by pollen collection (18.4%), nectar collection (17.9%) and only 0.3% pollinators were busy plant exudate or wax or propalis collection in Manasagangotri campus during summer season. Around 13.6% insect pollinators were simply hovering over flowers, 16.1% pollinators were resting on stem and shoot parts of the plants. Remaining 14.4% insect pollinators were busy with taking rest on leaves, flower petals and shoot part of the plants (Table 5). Further, diversity indices of insect pollinator species recorded during summer season is depicted in Table 6. Total ten different diversity indices were calculated and those indices average values of different insect pollinator species was 0.279, 0.721, 1.565, 0.633, 0.825, 1.491, 0.773, 2.031, 0.456 and 8.987 respectively for Dominance (D), Simpson (1-d), Shannon (H), Evenness (H/S), Menhinick, Margalef, Equitability (J), Fisher Alpha, Berger-Parker and Chao-1 indices (Table 6). Details of different diversity indices of insect pollinator species recorded during summer months i.e., March, April and May in Manasagangotri campus, Mysore is depicted in Table 6. Table 7 shows the Whittaker 'β' diversity between insect pollinator species during summer season in Manasagangotri campus. Among the calculated 'β' diversity indices, 'Cody β diversity' indicated highest (1.500) value and it was followed by 'Wilson-Shmida β diversity' (0.196) and 'Whittaker β diversity' was 0.174 (Table 7). However, Harrison, Routledge and Mourelle 'β' diversity indices were comparatively low (Table 7).

DISCUSSION

Occurrence of insect pollinator's belong to different orders gradually increased from March to May during summer season in Manasagangotri campus. The campus is enriched with good flora (Rao and Razi, 1981), and majority of the plants bloom during March onwards in this campus, perhaps locally available abundant forage from different plant species that include nectar and pollen might have attracted various species of insect pollinators during summer season. Madhavi and Basavarajappa (2024) have recorded insect species in Manasagangotri campus during 2024. However, during the present investigation, Hymenopterans were more predominant, which forage on nectar and pollen from different plant species. Moreover, pollinator species belong to Lepidoptera, Hemiptera, Coleoptera and Diptera are not fully depend on pollen and nectar, where adult Lepidopterans (e.g. Few Butterfly species) feed on nectar and immature forms of Lepidopterans (e.g. Larvae) feed on plant foliage (Bhagya and Basavarajappa, 2024), stems, fruits and liquid food of tree sap and rotting fruit fluid (Mani, 1982). While, Hemipterans (e.g. Bugs) feed on plant sap from phloem or xylem, leaves, stems, fruits and seeds of many plants using specialized piercing-sucking type of mouthparts (Mani, 1982). The Coleopterans (e.g. Beetles) feed on different plant materials (e.g. Leaves, roots, seeds, wood) and pollen sometimes. The Dipterans (e.g. True flies) feed on liquid diet including plant nectar and fruit

juices (Senthoorrraja, 2021). Thus, Coleopterans, Hemipterans and Dipterans are opportunistic pollinators, feed rarely on pollen, nectar and sometimes feed on plant cell sap. Perhaps this could be one of the reasons for the Hymenopterans dominance on the flora of Manasagangotri campus during summer season. Moreover, there was no competition between Hymenopterans and other insect groups. Perhaps, this could be another reasons for Hymenopterans dominance during summer season in Manasagangotri campus, Mysore. Further, during the present investigation, majority (19.3%) of insect pollinators were busy with landing on the flowers and it was followed by pollen collection (18.4%), nectar collection (17.9%) and only 0.3% insect pollinators were busy with wax/propalis collection. Honeybees collect wax or propalis for their nest construction. During the present study, honeybees belong to *Apis dorsata, A. cerana* and *A. florea* were observed with their plant exudate or propalis collection activity. Further, many insect pollinators were simply hovering over flowers (13.6%), resting on stem and shoot parts of the plants (16.1%) and taking rest on leaves, flower petals and shoot part of the plant (14.4%). As, Thysanopterans (e.g. Thrips) feed on cell contents of plant leaves, shoot/buds, flowers and fruits using their piercing and sucking type of mouth parts (Mani, 1982). While, Orthopterans (e.g. Grasshoppers, crickets, locusts and katydids) are herbivores and omnivores as well (Mani, 1982), perhaps feed on plant leaves, stems, flowers, seeds and fruits. The Blattodeans (e.g. Cockroaches) are opportunistic omnivores and scavengers, feed on organic matter, including decaying plants, animals and consume cellulose. Moreover, Mantodeans (e.g. Praying mantises) are carnivores, feed on a wide variety of living insects such as flies, moths, crickets, beetles, grasshoppers and spiders. Perhaps, insects belong to Diptera and Lepidoptera might be busier with hovering over flowers, Orthopterans and Thysanoptera are resting on stem and shoot parts, leaves, flower petals of the plants (Mani, 1982; Nalini and Basavarajappa, 2024) and Thysanopterans might be busy with collecting cell contents of plant leaves, shoot/buds, flowers and Mantodeans predating on various species of insects. While doing various activities, perhaps these group of insects directly or indirectly involved with the process of pollination of different flowering plant species. Accordingly, insect species belong to Hymenoptera, Coleoptera, Diptera, Hemiptera, Thysanoptera, Orthoptera, Blattodea and Mantodea population size varied considerably during March to May and their per cent contribution to the process of pollination greatly differed. Thus, the population size of insect pollinators was in accordance with the increasing trend from March to May. Altogether, 89 insect species from nine orders which belong to 65 families with a population size 7,220 individuals have involved directly or indirectly with the process of pollination on different plant species during summer season at Manasagangotri campus, Mysore.

Furthermore, insect pollinator species diversity indices revealed interesting results during summer season in Manasagangotri campus. To record critically the diversity of insect pollinators, ten different diversity indices were used and those diversity indices revealed different mean values such as 0.279, 0.721, 1.565, 0.633, 0.825, 1.491, 0.773, 2.031, 0.456 and 8.987 respectively for Dominance (D), Simpson (1-d), Shannon (H), Evenness (H/S), Menhinick, Margalef, Equitability (J), Fisher Alpha, Berger-Parker and Chao-1 indices. The dominance index (D) showed a low dominance value that equates to moderate diversity of insect pollinators with moderate concentration of individuals of insect pollinators. However, the dominance index value was ranged in between 0.215 and 0.358 and it was less than 0.5, suggesting no single insect species was dominated during summer season. The Simpson's index (1-D) was in between 0.642 and 0.785 with an average index value 0.721, and indicated closer to one suggests moderate diversity of insect pollinator species (Magurran, 2024) during summer season. The Shannon (H) index values fall between 1.360 and 1.743 with a mean index value of 1.565 which is less than 3.5 and indicated low diversity with low evenness. Further, the evenness index (H/S) was ranged in between 0.614 and 0.649 with a mean index value 0.633 suggesting how equally individuals belongs to different insect pollinators distribution between species in a community with low evenness. Further, by calculating the Menhinick index, insect pollinator species richness compared within a community (Magurran, 20240). It measured the insect pollinator's diversity by balancing the number of species. The Menhinick index values were ranged in between 0.785 and 0.850 with a mean index value 0.825 suggested that during March and May months the species indicated high-richness and during April, it was low-richness and did show considerable variation between summer months at different habitats amidst Manasagangotri campus. The Margalef index was gradually increased from 1.272, 1.507 and 1.695 respectively during March, April and May showed gradual increase of species richness across different months in summer season and highlighting how many insect pollinator species are present relative to the overall population size. The Margalef

index values are below 2 and confirmed the low richness with more stable moderate environmental conditions (Ricklef's, 1990; Magurran, 2024). The equitability index is often measured using Pielou's (J) or species evenness. During the present investigation the equitability index was ranged in between 0.759 and 0.793 with a mean index value 0.773 and it fall from 0 to 1 but it is not 1. Hence, there was incomplete evenness of all insect pollinator species with equal abundance, while few species dominate the community by reflecting lower evenness and higher inequality. The Fisher's alpha index was 1.766, 2.020 and 2.306 during March, April and May months with a mean index value 2.031 indicated the moderate insect pollinator's diversity at different sampling sites during summer season in Manasagangotri campus, Mysore. Further, Berger-Parker index was high (0.566) during March and gradually decreased 0.442 and 0.352 respectively during April and May indicated the habitat disturbance with lower dominance. However, Berger-Parker Index mean value was 0.456 and it was ranged between 0 and 1 indicated the lower diversity and lower dominance (Tancredi *et al.,* 2007). Further, the Chao-1 index is a non-parametric method used in ecological studies, where true total species richness (£ diversity) of a community help estimate taking into account of unseen species rather than just observed ones (Ricklef's, 1990). During the present investigation, the Chao-1 index value was gradually ranged from 6.000, 8.990 and 11.970 from March, April and May with a mean index value 8.987 and indicated higher estimated species richness within a sample. Further, six 'β' diversity indices were calculated to reveal the ecological measure of species turnover between habitats or samples during summer season.

Among the calculated 'β' diversity indices, 'Cody β diversity' indicated highest value 1.500 and it was followed by 'Wilson-Shmida β diversity' (0.196) and 'Whittaker β diversity' (0.174). However, Harrison (0.087), Routledge (0.046) and Mourelle (0.098) 'β' diversity indices were comparatively low. Whittaker's 'β' diversity index suggested a species turnover between different habitats and that indicates the species composition changes between sites. It also suggested that number of distinct communities in a region (Magurran, 2024). The Whittaker 'β' diversity value was less than 1 and indicated that all sites doesn't have similar insect pollinator species composition. Further, Harrison's 'β' diversity index was 0.087 that quantified the species turnover of species between habitats specifically scaled to a range of 0 to 1. However, the Cody 'β' diversity index is used to assess species turnover along environmental gradients (Tancredi *et al*., 2007; Ricardoiglesian-Rios and Rosana, 2014) or between habitats and suggested the rate of species replacement between two sites (Magurran, 2024). It is used to compare ecological diversity across different locations or conditions (Ricklef's, 1990). During the present investigation, the Cody index was high (1.500) compared to other 'β' diversity indices. Routledge 0 and 1, with higher values indicating more equitable distribution of species. The Wilson-Shmida diversity index indicated species turnover, between different habitats or sampling sites. The Mourelle diversity index confirmed the species turnover in an ecosystem and clearly demonstrated the insect pollinator species compositional difference among different orders across different months during summer season at Manasagangotri campus, Mysore. Thus, different diversity indices during summer season could help predict confirmative data on insect pollinator's species composition in Manasagangotri campus during summer season.

Honeybees, butterflies, wasps, stingless bee (e.g. *Tetragonula* species), flies (e.g. *Syrphus, Bombylius* and *Sarcophaga*), black ants, thrips, moths and other insect species act as pollinators (Muneer *et al*., 2022), which pollinate many ornamental plants, horticultural crops like fruits, vegetables which possesses nectar gland and fragrance with bright coloured flowers (Jankielsohn, 2018). Social insects live in complex colonies (Mani, 1982). They are useful to mankind in various ways. Honeybees (e.g. *Apis* species and stingless bees) are social insect's lives in colony, act as potential pollinators and help propagate various plant species. Butterflies are beautifully coloured flying creatures act as pollinators. Their immature forms (e.g. Larva) feeds on various flowering plant species, while doing so, they help pollinate certain flowers. Moreover, many beetle species (Order: Coleoptera) constantly live in flowers to feed on pollen to use as protein rich nutrients for their growth and development (Joseph *et al*., 2011). Certain flies (Dipterans) and ants (Hymenopterans), which help pollinate various flowers along with scavenging activity (Mani, 1982; Srivastava, 1988). Therefore, insect species interactions with many plant species become an excellent example for coevolution in the nature. Thus, various insect species help pollinate several plant species thereby grow, develop and survive parallelly at various ecosystems. The population of different insect species paly a povital role in pollinating plants and improveing significantly local bio diversity, Furthermore, insect species which hovering or landing or resting on the stem, shoot, petals of a flower does played a considerable role in the process of pollination, which was

merely remains not clear, but it may followed by nectar, pollen and wax/propalis collection. In this regard, further in depth scientific investigations are required to reveal the biological phenomenon and mysteries of pollination process by insect pollinators. Thus, the present study help create a record that could be used to inventorying the available insect pollinator species under modified/managed landscapes to improve the local biodiversity at urban areas.

SUMMARY

Total 89 insect pollinator species which belong to nine orders such as Hymenoptera (e.g. Wasps, bees and ants), Lepidoptera (e.g. Butterflies and Moths), Coleoptera (e.g. Beetles), Diptera (e.g. Tree flies, Blow flies) and other species were found commonly during summer season amidst Manasagangotri campus. Hymenopterans were more predominant with highest (38 species) in their occurrence and represented 45.6% and it was followed by Lepidopterans (16 species), Hemipterans (14 species) by resperenting 17.3 and 14.9% respectively. While, Dipterans, Coleopterans, Thysanopterans, Orthopterans, Blattodeans and Mantodeans were less than 10%. Altogether, 7, 220 individuals of insect pollinator species with a mean population size of 2, 406.7 were recorded during the present investigation. The diverrsity indices of different insect species varied considerably during summer season in Manasagangotri campus. Overall, present investigation provided an insight that how human modified/managed habitats like Manasagangotri campus have supported the diverse group of insect pollinator species and their diversity status during summer season. This type of investigations are very much necessitated to formulate conservation measures to restore local biodiversity amidst modified/managed urban ecosystems.

CONCLUSION

Insect pollinators are vital components of every ecosystem, play a povital role biologically, their presence is very essential for the sustenance of many flowering plant species at different trophic levels under modified/managed urban landscapes. Insect's pollination help protect local vegetation and improves the local biodiversity. Pollinating insects are economically important to man in various ways. Collecting scientific information on such species could help prepare inventory to undertake appropriate conversation measures amidst human modified/managed landscapes to protect local biodiversity. Therefore, present study inferred that the human modified/managed ecosystems in urban areas are important habitats, significantly support the existence of variety of insect pollinator species. So, their conservation is need of the hour for future generation.

ABSTRACT

Bougainvillea is globally cultivated as an ornamental plant; however, its flowers remain largely underutilized as edible resources despite long-standing ethnomedicinal use. Traditional applications in respiratory, gastrointestinal, and inflammatory disorders have prompted increasing scientific interest in elucidating the plant's bioactive composition and functional relevance. Emerging evidence indicates that Bougainvillea flowers and bracts are rich in phenolic compounds, flavonoids, and betalains, which collectively underpin their strong antioxidant capacity and reported antimicrobial, anti-inflammatory, and cytotoxic effects observed in experimental studies. In contrast, systematic nutritional characterization of Bougainvillea flowers remains limited; available data from edible-flower research suggest the presence of essential minerals, dietary fiber, and extractable carbohydrates, along with a relatively low energy contribution, supporting their feasibility as functional food ingredients. Beyond pharmacological relevance, Bougainvillea has demonstrated potential in food innovation, including natural pigments, functional beverages, bioactive powders, preservative systems, and encapsulated formulations, contributing to both sensory enhancement and functional value. This review critically consolidates current phytochemical, biological, and nutritional evidence on Bougainvillea flowers and highlights their repositioning as multifunctional edible resources with promising applications in functional foods and nutraceutical development.

Keywords: Bougainvillea flower, phytochemical potential, nutritional composition, antioxidant activity, therapeutic properties, functional foods

INTRODUCTION

Bougainvillea is a genus within the Nyctaginaceae family, which consists of popularly grown species, including *Bougainvillea glabra* and *Bougainvillea spectabilis*. These species are widely distributed across tropical and subtropical environments and are known for their various uses in traditional medicinal practices to treat respiratory conditions, digestive disorders, microbial infections, inflammation, and metabolic imbalances. An extensive literature analysis can validate the long-standing ethnomedicinal value of the Bougainvillea floral structures, such as the bracts that are sometimes confused with the flowers (Ornelas et al., 2023). This ethnobotanical basis guides current research into the biochemical mechanisms behind the plant's medical applications. The current phytochemical research on Bougainvillea flowers and bracts reveals a rich repertoire of secondary metabolites. Some non-protein compounds identified by studies as contributing to antioxidant, anti-inflammatory, antimicrobial, and possibly cytoprotective effects are phenolic acids, flavonoids, alkaloids, saponins, tannins, terpenoids, betalains, and anthocyanins (Nasrat et al., 2022). The results of advanced spectrometric analysis of B. spectabilis floral tissues, such as UPLC–MS^n profiling, indicate that this species is a carrier of various classes of substances with high antioxidant activity based on flavonoid subclasses and phenolic derivatives (Altundağ et al., 2025). These results confirm the usefulness of the plant as a functional ingredient and a provider of nutraceutical compounds.

Bougainvillea glabra flower extracts in methanolic solvents are high in phenolic and flavonoid compounds, which are associated with strong radical-scavenging and antimicrobial properties, as well as anticancer activity in vitro. Similarly, encapsulated extracts of *Bougainvillea spectabilis* can retain a strong antioxidant activity associated with a stable level of phenolic and anthocyanin compounds, proving their appropriateness in food and nutraceutical product use (Kenari et al., 2022). Collectively, phytochemical investigations indicate that the pronounced antioxidant capacity of Bougainvillea flowers is primarily associated with their high phenolic, flavonoid, and betalain content, which also underpins the reported antimicrobial, anti-inflammatory, and cytotoxic activities observed in experimental studies. Therapeutically, Bougainvillea flowers are biologically active, which is in line with their phytochemical proficiency. They have antimicrobial activity that can be quantified against several bacterial species, which can be attributed to flavonoids, phenolics, and other secondary metabolites. Similarly, antioxidant assays have repeatedly shown high radical-scavenging activity, implying possible roles in the reduction of oxidative stress-induced disorders, which is one of the symptoms of chronic disease progression (Altundağ et al., 2025). Moreover, encapsulation investigations indicate a better stability and regulated release of Bougainvillea phytochemicals, which increases their potential therapeutic application in functional foods and dietary supplements (Kenari et al., 2022). Although positive strides are being made, there are still serious gaps in science.

Bougainvillea flowers should be thoroughly analyzed in terms of their proximal nutritional value as they contain macronutrients, vitamins, and minerals. More importantly, there is very limited research regarding bioavailability, pharmacokinetics, and in vivo activity of Bougainvillea flower compounds. The existing literature is strongly based on in vitro models, which, however informative, do not allow predicting the outcome of physiological processes without supplementary animal or human research (Ornelas et al., 2023). Safety tests such as toxicology profiles and allergenicity tests are still inadequate to set consumption limits. Still, it is the combination of ethnobotanical history, excellent phytochemical evidence, antioxidant and antimicrobial effects, and effective early food applications that point to the potential of Bougainvillea flowers as a useful food ingredient. Considering the worldwide trend of using natural ingredients and plant-based foods, the systematic study of Bougainvillea flowers will be of great benefit to science as well as the advancement of food. The abundance of high phenolic and flavonoid compounds (Nasrat et al., 2022; Altundağ et al., 2025), antioxidant properties in food systems (Ferreira et al., 2024), the ability to be used as a functional beverage (Mahey et al., 2025), and antimicrobial and anticancer activity all indicate that Bougainvillea flowers have considerable potential in food and dietary management.

History and Origin

The genus Bougainvillea is part of the family Nyctaginaceae and is well known today as an ornamental plant; however, its origin is firmly established in the neotropical regions of South America. Modern taxonomy and phylogenetic research have confirmed that species belonging to the Bougainvillea genus are indeed native to landmass countries such as Brazil, Peru, Bolivia, Argentina, and similar territories, where the genus evolved under tropical and subtropical climatic conditions (Bautista et al., 2022; Julissa Rojas-Sandoval, 2023). Molecular phylogenetic interpretations derived from the chloroplast genomes have provided further evidence to support this South American origin and unveiled close evolutionary relationships between the neotropical species of the genus Bougainvillea, as well as reinforcing their geographic center of diversity region in Latin America (Wu et al., 2024). Bougainvillea's botanical discovery can be traced back to the 18th century with explorers who were European discovery expeditions to South America. Historical botanical records show that the plant was first collected by French botanist Philibert Commerson in the 1760s during the voyage of the French navigator and explorer *Louis-Antoine de Bougainville*, after whom the botanical genus was subsequently named (Sharma & Sharma, 2020; Bautista et al., 2022).

Although the formal scientific description is older than modern literature, recent historical reviews reiterate that this early discovery was also the start of Bougainvillea's change from wild species of a single region to an ornamental plant worldwide (Roy & Singh, 2016).Bougainvillea became popular in botanical gardens and as an ornamental and commercial item since its introduction into Europe in the late 18th and early 19th centuries due to its colorful bracts, extended flowering, and diversity in warm climates. Later horticultural dispersal was achieved via colonial commodities, and the plant was established throughout Asia, Africa, the Mediterranean region, and the Pacific islands (Roy & Singh, 2016; Saleem et al., 2021). These introductions helped in the naturalization of Bougainvillea in several locations outside of its native range, where it became an integral component of the urban and rural landscape. As Bougainvillea spread across the world, a great deal of hybridization and cultivar development took place, prompted by horticultural selection (for bract color, growth habit, and stress tolerance). Recent findings from genomic and cytological analysis have suggested the genetic variation of Bougainvillea cultivars cultivated today is a consequence of inter specific hybridization as well as selective breeding over the past 100 years (Lan et al., 2023; Wu et al., 2024).

These breeding efforts have greatly increased the phenotypic diversity of the genus, with hundreds of ornamental cultivars now being cultivated throughout the world. In regions where Bougainvillea was introduced, the plant became gradually acquired ethnobotanical significance, particularly in tropical as well as subtropical countries. Ethnobotanical reviews published in recent years have revealed that Bougainvillea flowers, bracts, and leaves were adapted by communities in Asia, Africa, as well as parts of Latin America to produce traditional medicinal preparations to control respiratory disorders, gastrointestinal ailments, and inflammatory conditions (Saleem et al., 2021; Ornelas et al., 2023). This secondary cultural integration shows the role the spread of Bougainvillea played over time, not only with the values of its ornamentation but also its medicinal importance. Recent taxonomic syntheses focus on the fact that, in spite of Bougainvillea being widely distributed in the world, the South American origin can still be seen to be well represented in its genetic structure as well as its bio-geographical microbiome. Revised species synopses identify about 18 accepted species, the most common ones to be raised and examined are those of B. glabra and B. spectabilis owing to their versatility and ethnomedicinal benefit (Bautista et al., 2022; Julissa Rojas-Sandoval, 2023). These species are used as the basis in most of the modern hybrids and are mentioned a lot in the phytochemical and nutritional research.

Phytochemical Content

Phytochemical investigations undertaken over the last decade have confirmed the fact that the flowers and bracts of Bougainvillea are rich repositories of diverse secondary metabolites, largely responsible for their biological, functional, and therapeutic properties. These phytochemicals are phenolic acids, flavonoids, betalains, anthocyanins,

alkaloids, tannins, saponins, glycosides, and terpenoids, and many of them are linked to antioxidant and health-promoting activities (Nasrat et al., 2022; Saleem et al., 2021).

Phenolic Compounds

Phenolic compounds are one of the most abundant and widely studied phytochemical families obtained in Bougainvillea flowers. As such, quantitative analyses show a high total phenolic content in floral and bract extracts, especially when extracted by polar solvents such as methanol or ethanol (Kenari et al., 2022). Phenolic acids found in *Bougainvillea spectabilis* and *Bougainvillea glabra* include gallic acid, caffeic acid, ferulic acid, and chlorogenic acid, which play a major role in antioxidant capacity (Haggag et al., 2022; Altundağ et al., 2025).Advanced chromatographic techniques, such as UPLC–MS^n, have benefited the profiling of the phenolic components in Bougainvillea flowers, which has confirmed the obvious presence of phenolic compounds, both free and conjugated phenolic acids (El-Nashar et al., 2025). These compounds play critical roles in reducing reactive oxygen species and could be responsible for the effects seen in the reports of functional and therapeutic studies.

Flavonoids

Flavonoids are another major class of phytochemicals present in flowers of Bougainvillea. Several studies report high concentrations of flavonoids, some of the compounds found in these works are quercetin, kaempferol, rutin, glycosides of these compounds, which are also found (Nasrat et al., 2022; Ravikumar et al., 2022). The existence of these flavonoids is especially relevant since they are known to be extensively recognized for the antioxidant, anti-inflammatory, antimicrobial, and cardioprotective properties.A recent high-resolution mass spectrometric analysis of flowers of *Bougainvillea spectabilis* uncovered the presence of several flavonoid derivatives with high radical-scavenging properties, which strengthens the functional importance of this phytochemical group (Altundağ et al., 2025). Comparative investigation in different ornamental edible flowers also shows that Bougainvillea flowers have relatively high amounts and a positive correlation with antioxidant potential (Benvenuti et al., 2016).

Betalains and Pigments

Unlike many other flowering species containing anthocyanin, Bougainvillea species are mainly producers of betalain pigments, responsible for the intense pink, purple, red, and orange coloration of their bracts. Betalains discovered in Bougainvillea are betacyanins and betaxanthins, which have high antioxidant properties and stability in a wide range of pH values (El-Nashar et al., 2025). Genomic analyses coupled with biochemical analyses showed that the biosynthesis of betalains in the plant Bougainvillea is governed by specific pathways of enzymatic synthesis and that differ from the pathways of anthocyanins; this highlights the unique pigment chemistry of plants belonging to the genus Bougainvillea (Lan et al., 2023). These pigments are of growing interest not only for their role in having health benefits but also as potential applications as natural food colorants.

Saponins, Tannins, and Alkaloids

Bougainvillea flowers contain phenolics and flavonoids, apart from the moderate amount of alkaloids, tannins, and saponins. This has been confirmed through phytochemical screening and qualitative tests (Nasrat et al., 2022; Ravikumar et al., 2022). Alkaloids have been reported to be responsible for different antimicrobial and pharmacological effects. Tannins have been shown to have astringent action and antioxidant activity. The saponins found in the floral parts of Bougainvillea may also have an effect on membrane permeability and may be a source of antimicrobial resistance. This in turn extends the utility of the flowers (Saleem et al., 2021). The same compounds have been noted in various studies to be the source in determining the different useful benefits that are realized in lab works.

Glycosides and Terpenoids

Bougainvillea flowers also contain glycosidic compounds in which most of them are flavonoid glycosides. These glycosidic compounds help improve the solubility and stability of the bioactive molecules (El-Nashar et al., 2025). Terpenoids, although a few in number, contribute to sensory properties and may possibly be the origin of anti-

inflammatory and antimicrobial activities (Saleem et al., 2021). Research on encapsulation reveals that these phytochemicals can be kept and stabilized in the process. The extracts of Bougainvillea flowers can be chemically intact when they are used in food or health products (Kenari et al., 2022).

Summary of Phytochemical Significance

Overall, Bougainvillea flowers are the part of the plant that consists of a complex mix of compounds that contain high amounts of antioxidants. The most important components are phenolics, flavonoids and betalains. The presence of alkaloids, tannins, saponins, and glycosides plays a significant role in modulating the functional and therapeutic characteristics of the flowers (Nasrat et al., 2022; Altundağ et al., 2025). These phytochemicals are the primary constituents responsible for the observation that there is a reasonable amount of research underlying the use of Bougainvillea flowers for production of functional foods, nutraceuticals, and natural health products.

Nutritional Composition

The nutritional composition of edible flowers has been a subject of scientific research over the years because of their possible inclusion in the diversified diet, functional nutrition and plant-based food innovation. Edible flowers are not only good sources of macronutrients, micronutrients and bioactive compounds but they show significant variation in their nutritional profile depending upon the species, stage of maturity and processing conditions (Pires et al., 2021; Carboni et al., 2025). Although very few studies have directly examined the nutritional value of Bougainvillea flowers, available proximate analyses and comparative edible-flower literature provide useful insights.

Moisture Content

Moisture content is one of the most relevant parameters in the determination of freshness, shelf life and nutrient stability of edible flowers. Research on the bracts of *Bougainvillea spectabilis* and the flowers of *Bougainvillea glabra* reveals that they are similar in having nearly the same moisture levels which are relatively high and typical of fresh floral tissues (Haggag et al., 2022; Ravikumar et al., 2022). A high moisture level is good for food consumption but at the same time, it requires the application of suitable post-harvest handling and processing in order to avoid microbial spoilage. Other edible flowers have similar moisture content, supporting the fact that Bougainvillea flowers are highly fragile (Pires et al., 2021).

Energy Value

The supply of energy by edible flowers is normally minimal since floral tissues are usually low in fat and have medium carbohydrate levels (Fernandes et al., 2017). The energetic value of Bougainvillea flowers has never been directly measured; however, based on their low-fat, high-moisture nature, the energy density is low, which is in line with other edible flowers (Carboni et al., 2025). At such a low energy level, Bougainvillea flowers can be used as part of functional and low-energy diets.

Carbohydrate Content

Carbohydrates in edible flowers are mainly found to be composed of soluble sugars and structural polysaccharides. There is almost no data on the carbohydrate content of the flowers of Bougainvillea, however, in the study conducted on B. glabra flowers, the presence of soluble carbohydrates and organic acids was detected (Ravikumar et al., 2022). Furthermore, the comparison with other edible flowers indicates that carbohydrates exert considerable effect on the total dry matter and they also act as a source of taste and texture (Pires et al., 2021; Suksathan et al., 2021). Thus, the presence of nutritionally-relevant carbohydrates in Bougainvillea flowers can be inferred.

Dietary Fiber

Dietary fiber is one of the major components of the edible flowers, thus contributing to intestinal health and blood sugar regulation. Reviews of edible flowers report a medium level of dietary fiber derived from cell wall polysaccharides (Fernandes et al., 2017; Carboni et al., 2025). Though the fiber content of Bougainvillea flowers has

not been directly measured, based on the structure of the floral tissues and the presence of insoluble plant material, the fiber content is similar to that of other edible flowers (Pires et al., 2021).

Protein Content

Edible flowers are often low in protein, but still contain the required amino acids. There is a better availability of more detailed protein data for Bougainvillea flowers in the literature. Nevertheless, studies on the protein content of different kinds of edible flowers have shown a range from low to moderate depending on the species (Pires et al., 2021). Hence, leaves and flowers of Bougainvillea might play a minor role in the protein intake in the human diet, however, explicit examinations have to be carried out to ascertain this.

Fat and Lipid Content

Floral tissues, in general, are very poor in fat actually. The research regarding the edible flowers is in agreement that these flowers have very low-fat levels (Fernandes et al., 2017; Carboni et al., 2025). This, in turn, is one of the major reasons for their low caloric value. There is no clear evidence of lipid content in Bougainvillea flowers but by analogy with flowers in other plants fat is most likely to be present in very minute amounts, if at all.

Ash Content

Ash content is one of the standard ways of determining the total mineral matter of plants. Analysis of *Bougainvillea spectabilis* bracts and *Bougainvillea glabra* flowers showed measurable ash values, indicating the presence of mineral constituents (Haggag et al., 2022). The review of literature implies that these minerals may contribute to the traditional medicinal applications of the plant (Saleem et al., 2021).

Mineral Composition

Lack of information on the detailed mineral profiles for the flowers of Bougainvillea is made up by the research on edible flowers, which can be a very good guide. In general, edible flowers are extremely rich in potassium, calcium, magnesium, and phosphorus; these are essential for electrolyte balance and health of bones (Pires et al., 2021; Suksathan et al., 2021). Considering that the Bougainvillea flowers have been confirmed to contain ash, the similar mineral contributions cannot be ruled out and hence more detailed research is required.

Vitamin Content

Vitamin content, in particular, vitamin C, is one of the most important nutritional characteristics of most edible flowers. The studies conducted on the edible flowers led to the conclusion that floral tissues can be a good source of water-soluble vitamins that act as antioxidants in the human diet (Fernandes et al., 2017; Carboni et al., 2025). So far, no comprehensive report on the vitamin content of Bougainvillea flowers has been received and it is an important gap for research.

Nutritional Stability during Processing

The nutritional quality of edible flowers can be severely affected by various processing techniques including drying, powdering and encapsulation. The studies of encapsulation for the extracts of *Bougainvillea spectabilis* have shown that the bioactive compounds remain stable during the processing, therefore in this way the nutritional retention is also sustained indirectly (Kenari et al., 2022). Besides that, the incorporation of Bougainvillea flower powder into the functional beverages held good nutritional quality as well as enhanced bioactive content (Mahey et al., 2025).

Therapeutic Potential

The therapeutic potential of Bougainvillea flowers has led to a wide array of scientific studies. This has attracted scientific interest in the pharmacology of Bougainvillea flowers due to their traditional medicinal use, which is further supported by experimental evidence (Ornelas et al., 2023). Ethnomedicinal records reveal that the flowers, and the bracts of the Bougainvillea were used in the treatment of cellular disorders, inflammatory diseases and infections, and the gastrointestinal tract thus giving the prerequisite for pharmacological studies (Saleem et al., 2021;

Ornelas et al., 2023). More than ever, the current studies associate these medicinal effects to the phenolic compounds, flavonoids, betacyanins, and other metabolites found in the plant tissues (Nasrat et al., 2022; Altundağ et al., 2025).

Antioxidant Activity

Antioxidant activity emerges as the most consistently reported therapeutic property of the Bougainvillea flowers (Nasrat et al., 2022). In vitro DPPH, ABTS, and FRAP examinations confirm the remarkable concentrations of radical scavenging activity, showing that it has a superior capacity for counteraction of reactive oxygen species (Nasrat et al., 2022; Ravikumar et al., 2022). High antioxidant activity has been correlated with high total phenolic and flavonoid contents from flowers extracts, as we have suggested that this may be due to the phenolic based compounds being the main contributor to redox modulation (Altundağ et al., 2025). In support of this relationship, advanced chromatographic profiling has been performed at the level of specific phenolic acids and flavonoid derivatives that are linked to antioxidant mechanisms in the flower of *Bougainvillea spectabilis* (Altundağ et al., 2025). Encapsulation studies confirm that these antioxidant compounds have a stable life course during processing, being strengthened as possible therapeutic and nutraceutical compounds (Kenari et al., 2022). Since oxidative stress is an important factor in the etiology of long-term illnesses, the antioxidant capacity of Bougainvillea flowers explains much of their proposed therapeutic relevance (Manach et al., 2005).

Anti-Inflammatory Potential

Inflammation and oxidative stress are tightly coupled biological processes and phenolics found in plants are known to regulate inflammatory pathways (Pawłowska et al., 2019). The study of the effects of Bougainvillea flowers on eosinophil release in vivo using direct mechanisms is also not extensive, yet flavonoids and phenolic acids present in the floral extracts have structural characteristics strongly related to anti-inflammatory effects (Altundağ et al., 2025). These compounds suppress pro-inflammatory mediators while decreasing the activity of oxidative enzymes and therefore offer a mechanistic basis for anti-inflammatory potential (Pawłowska et al., 2019). Reviews of medicinal plants report antioxidant flower extracts that are potentially responsible for inflammation control through modulation of cytokines and redistribution of redox balance (Unuofin et al., 2022), Based on the good antioxidant properties of the Bougainvillea flowers, the composition of flora and chemical molecules can support a potential role in controlling inflammation-related diseases, even though it is still required to conduct some directed pharmacological studies (Ornelas et al., 2023).

Antimicrobial Activity

The other therapeutic value of Bougainvillea flowers is antimicrobial activity. Experimental studies report that methanolic and ethanolic flavonoid-rich extracts inhibit the growth of selected microorganisms. This antimicrobial effect has been attributed mainly to flavonoids, tannins and alkaloids found in the floral extracts which are known to impair microbial cell membrane and interfere with enzymatic systems (Ravikumar et al., 2022). Overall reviews verify that antimicrobial activity is also a common characteristic of the Bougainvillea species, and it justifies the use of these plants in the treatment of infections (Ornelas et al., 2023). Phenolics of plants including Bougainvillea flowers are widely known to have antimicrobial characteristics that interact with a wide range of pathogens, thus strengthening the therapeutic importance of these results (Manach et al., 2005).

Cytotoxic and Anticancer Potential

Early indications also indicate that the extracts of the Bougainvillea flower can have a cytotoxic effect on particular cancerous cell lines. In vitro studies have reported the correlation between the cytotoxic effects and high concentration of phenolic and flavonoid compounds in the floral extracts (Ravikumar et al., 2022). These compounds trigger apoptosis, inhibit cell proliferation and prevent oxidative DNA damage in cancer models (Manach et al., 2005). While these results are still limited to in vitro research, they are consistent with adequate findings of the protective role of polyphenols in food to prevent carcinogenesis (Manach et al., 2005). Consequently, Bougainvillea flowers may have a chemopreventive potential, although clinical and in vivo validation is necessary before therapeutic claims can be substantiated (Ornelas et al., 2023).

Modulation of Chronic Illness

Oxidative stress and inflammatory imbalance are strongly related to chronic diseases, including diabetes and cardiovascular disorders. Evidence from medicinal plant research underlines that antioxidant extracts can be used to achieve better metabolic control and lower oxidative load (Unuofin et al., 2022). As evidenced by this antioxidant activity of Bougainvillea flower extracts, bioactive compounds have the potential to be used to manage chronic diseases indirectly by the redox modulation action (Nasrat et al., 2022). This therapeutic implication is supported by the studies on functional foods. The addition of *Bougainvillea spectabilis* bract extracts to the food systems dramatically slowed down the oxidation degradation, which proves the effectiveness of these natural antioxidants to the food systems (Ferreira et al., 2024). As much as such evidence is based on food models, the antioxidant mechanisms underpinning it can be applied to biological systems and therapeutics (Manach et al., 2005).

Therapeutic Stability and Delivery

The delivery and stability of bioactive compounds are important factors for therapeutic use. According to encapsulation studies, Bougainvillea flower extracts are better suited for nutraceutical applications because they maintain their chemical integrity and antioxidant activity throughout processing and storage (Kenari et al., 2022). The viability of adding Bougainvillea bioactives to functional foods and herbal formulations is improved by this stabilization (Kenari et al., 2022). Also, functional beverages, where the powder of Bougainvillea flower was added, were developed without reducing the quality of the product, which also demonstrated the feasible use of these flowers in health applications (Mahey et al., 2025).

Overall Therapeutic Significance

Collectively, the available evidence indicates the therapeutic potential of Bougainvillea flowers, particularly with respect to antioxidant, antimicrobial, anti-inflammatory, and cytotoxic activities (Nasrat et al. 2022; Ornelas et al, 2023; Altundağ et al, 2025). All these therapeutic effects are always associated with high phytochemical content of the flower which is predominantly composed of phenolics and flavonoids (Altundağ et al., 2025). Nevertheless, the majority of the literature is in vitro, and in vivo research is required, as well as bio-availability tests and clinical validation; that is, to determine the efficacy of the therapy (Ornelas et al., 2023).

Value-Added Product Formulation

There has been an upsurge in the demand for natural ingredients, clean-label foods and plant-based functional products, which has increased the interest in value addition and processing of edible flowers. Edible flowers are currently considered as sources of natural colorants, antioxidants and bioactive food ingredients, as well as nutraceuticals, cosmetics, and pharmaceuticals (Pires et al., 2021; Carboni et al., 2025). In this background, the Bougainvillea flowers and bracts are potentially strong sources of raw materials to develop value-added products because of intense pigmentation, phytochemical content and proved stability when processed (Altundağ et al., 2025).

Formulation of Functional Foods and Beverages

The use of Bougainvillea flower derivatives in functional foods and drinks is one of the most obvious instances of value addition. A functional pineapple-based beverage enriched with powdered *Bougainvillea spectabilis* flowers was successfully developed, resulting in increased total phenolic content and antioxidant activity without compromising sensory acceptability. The viability of utilizing Bougainvillea flowers as functional ingredients in beverage formulations is demonstrated by this study (Mahey et al., 2025). Extracts from Bougainvillea bracts have been investigated as natural food additives. It has been shown that by preventing lipid oxidation during storage, *Bougainvillea spectabilis* bract extracts could successfully replace synthetic nitrites in cooked pork ham. The value-added use of Bougainvillea bioactives in food processing systems is directly supported by the underlying antioxidant mechanism, even though this application focuses on food preservation (Ferreira et al., 2024).

Processing of *Bougainvillea* Flowers into Powders and Extracts

Among the most popular primary processing methods for turning Bougainvillea flowers into stable, valuable ingredients are drying and powdering. Drying improves shelf life, lowers moisture content, and makes incorporation into food matrices easier (Pires et al., 2021). Research on *Bougainvillea glabra* and *Bougainvillea spectabilis* flowers shows that dried flower powders maintain a high level of antioxidant activity, suggesting that bioactive compounds do not change during processing (Altundağ et al., 2025). To concentrate phytochemicals from Bougainvillea floral tissues, extraction methods like solvent extraction are frequently used. Optimal extraction conditions enable effective recovery of phenolic acids, flavonoids, and betalain pigments without significant degradation, according to UPLC–MS^n based studies (El-Nashar et al., 2025). These extracts serve as the foundation for additional formulations into pharmaceutical, food, and cosmetic products.

Natural Colorant and Pigment Applications

Betalain pigments are believed to explain the bright color of the Bougainvillea bracts; more attention has focused on the use of these pigments as natural substitutes in food in place of artificial colors. Bougainvillea has been reviewed as a possible source of stable betalains to use in food products since this group of phenols has great tinctorial power and antioxidant activity (Sumera et al., 2025). The betalains are characterized by water solubility and suitability in acidic food systems (Azeredo et al., 2019). Processing research shows that betalains extracted using edible flowers have the capacity to maintain their stability at both pH and temperature conditions and are thus used in beverages, confectionery, and dairy items (Azeredo et al., 2019). Since betalains were established to exist in Bougainvillea bracts and flowers, their application as natural dyes has enormous potential in value addition (Altundağ et al., 2025).

Enhancement of Encapsulation and Stability

Maintaining stability during processing and storage is a significant challenge in the use of floral bioactives. By shielding delicate substances from environmental deterioration, encapsulation techniques provide a practical solution. The stability of phenolic compounds and antioxidant activity during storage were greatly enhanced by microencapsulation of *Bougainvillea spectabilis* extracts. The use of Bougainvillea extracts in nutraceutical and functional food formulations is expanded by encapsulation, which also increases shelf life and permits controlled release of bioactive compounds (Kenari et al., 2022). For laboratory-scale bioactivity to be translated into commercially viable products, such processing techniques are essential.

Edible Flower Processing and Product Diversification

The literature on edible flower processing, in general, is a great additional resource for value-added applications of Bougainvillea. The application of edible flowers is growing in products such as bakery items, herbal tea, syrup, jam, and confectionery, in which techniques like drying, powdering, and infusion are the most common (Pires et al., 2021; Carboni et al., 2025). Considering its stability in terms of phytochemicals and having a bright color, there is no doubt that Bougainvillea flowers can also be used in the same way. Edible flower powders cannot only improve the food products aspect of health but also its visual appeal, thus the increasing willingness of consumers to accept such products and the value of the market will both increase (Carboni et al., 2025). The experimental use of Bougainvillea flower powder in drink and food systems is a compelling sign of extensive potential to product diversify in the use of this material (Mahey et al., 2025).

Cosmetic and Pharmaceutical Processing Potential

Bougainvillea flower extracts are also relevant to cosmetic and pharmaceutical processing. Reviews on Bougainvillea phytochemistry suggest that its antioxidant and antimicrobial compounds are suitable for incorporation into topical formulations, herbal medicines, and cosmetic products (Nasrat et al., 2022; Saleem et al., 2021). Processing techniques such as extraction, concentration, and encapsulation are essential for converting raw floral material into standardized formulations. The stability of Bougainvillea bioactives during processing supports their potential use in cosmeceuticals and herbal products aimed at oxidative stress protection and skin health (Nasrat et al., 2022). However, further formulation-specific and safety studies are required to advance these applications.

Summary and Industrial Relevance

Overall, the flowers of Bougainvillea can be processed successfully and yield powders, extracts, encapsulated bioactives, natural colorants, and functional food ingredients (Kenari et al., 2022; Mahey et al., 2025; Ferreira et al., 2024). The phytochemical stability during the processing and their antioxidant functionality as tested are the main reasons for these value-added applications (Altunda et al., 2025). While large-scale commercialization is still limited, there have been a number of promising results presented pointing to the need of optimizing the processing conditions, standardizing the extracts, and going through the regulatory process. In fact, the current body of evidence puts Bougainvillea flowers into the context of an extremely adaptable and largely neglected source in the creation of value-added products for the food, nutraceutical, and cosmetic industries (Carboni et al., 2025).

CONCLUSION

Bougainvillea flowers are a potential new source for edible flowers that are phytochemically rich in phenolics, flavonoids, and betalains, which are the main compounds responsible for their antioxidant, antimicrobial, and anti-inflammatory activities. Their use for purposes of value-added processing, for example, the production of functional foods, natural colorants, and encapsulated bioactive ingredients is also supported by the literature. Detailed nutritional profiling as well as clinical trials are still scarce; however, research is focusing on the stability and functionality of bioactive compounds from Bougainvillea during the processing. In short, a complete nutritional characterization, safety assessment, and animal testing will pave the way for the application of Bougainvillea flowers for the development of functional foods and other health-related applications.

Table 1. Phytochemical Constituents Reported in Bougainvillea Flowers and Bracts

Phytochemical class	Major compounds reported	Reported biological relevance	References
Phenolic acids	Gallic acid, caffeic acid, ferulic acid, p-coumaric acid	Antioxidant, anti-inflammatory	(Nasrat et al., 2022; Altundağ et al., 2025; El-Nashar et al., 2025)
Flavonoids	Quercetin, kaempferol, rutin, myricetin derivatives	Antioxidant, antimicrobial, cytotoxic	(Ornelas et al., 2023; Altundağ et al., 2025)
Betalains (betalacyanins	Betanin, isobetanin,	Antioxidant, natural	(Altundağ et al., 2025; Sumera

& betaxanthins)	bougainvillein derivatives	pigment	et al., 2025; Azeredo et al., 2019)
Tannins	Condensed tannins (reported as total tannin content)	Antimicrobial, antioxidant	(Nasrat et al., 2022)
Alkaloids	Alkaloid fractions (non-structural identification)	Antimicrobial, cytotoxic	(Ornelas et al., 2023)
Saponins	Saponin fractions (qualitative)	Antimicrobial, anti-inflammatory	(Nasrat et al., 2022)
Terpenoids	Terpenoid fractions (reported at class level)	Antioxidant, therapeutic support	(Ornelas et al., 2023)
Glycosides	Phenolic and flavonoid glycosides	Antioxidant, bioavailability modulation	(El-Nashar et al., 2025; Altundağ et al., 2025)

Table 2. Value-Added Product Applications of Bougainvillea Flowers

Product category	Processing / formulation method	Functional role	Application area	**References**
Functional beverages	Drying → powdering → beverage incorporation	Antioxidant enrichment, sensory enhancement	Functional drinks	(Mahey et al., 2025)
Natural food colorants	Solvent extraction, pigment stabilization	Natural red/pink pigment, antioxidant activity	Beverages, confectionery	(Altundağ et al., 2025; Sumera et al., 2025)
Encapsulated bioactive ingredients	Microencapsulation	Improved stability and controlled release of antioxidants	Nutraceuticals, functional foods	(Kenari et al., 2022)
Natural food preservatives	Extraction → food system incorporation	Lipid oxidation inhibition	Processed meat products	(Ferreira et al., 2024)
Herbal and nutraceutical powders	Drying → grinding	Antioxidant and therapeutic support	Nutraceutical formulations	(Nasrat et al., 2022; Mahey et al., 2025)
Bakery and confectionery products	Powder incorporation into dough/batter	Functional enhancement and color improvement	Bakery, snacks	(Pires et al., 2021; Carboni et al., 2025)
Cosmetic and cosmeceutical ingredients	Extraction and formulation	Antioxidant protection	Skin-care products	(Nasrat et al., 2022; Saleem et al., 2021)
Herbal / pharmaceutical preparations	Extraction and standardization	Antioxidant and antimicrobial support	Herbal medicine	(Saleem et al., 2021; Ornelas et al., 2023)

ABSTRACT

Gastroenteritis is an acute inflammatory condition of the gastrointestinal tract characterized by diarrhoea, vomiting, abdominal pain, and dehydration. It remains a major cause of global morbidity and mortality (1,2). While conventional management focuses on rehydration, homoeopathy may provide supportive therapeutic benefits. To evaluate the clinical effectiveness of individualized homoeopathic medicines in LM potency in the management of gastroenteritis. A prospective, single-arm pilot clinical study was conducted on 12 patients diagnosed with gastroenteritis. Individualized homoeopathic medicines in LM potency were prescribed based on totality of symptoms. Disease severity was assessed using Gastroenteritis Symptom Score (GSS) before and after treatment. Statistical analysis was performed using paired t-test. Out of 12 patients, 7 (58.3%) were cured, 4 (33.3%) improved, and 1 (8.3%) showed no improvement. The mean GSS score reduced significantly from 12.83 ± 2.48 at baseline to 3.25 ± 1.86 post-treatment ($p < 0.001$). Individualized homoeopathic medicines in LM potency demonstrated significant clinical improvement in gastroenteritis. Larger randomized controlled trials are recommended.

Keywords: Gastroenteritis, Homoeopathy, LM potency, Individualization, Pilot study

INTRODUCTION

Gastroenteritis is an acute inflammatory condition of the gastrointestinal tract, primarily affecting the stomach and intestines, and is clinically characterized by diarrhoea, vomiting, abdominal pain, fever, and varying degrees of dehydration (1). It remains a major global public health problem, contributing significantly to morbidity and mortality, particularly in developing countries. According to the World Health Organization, diarrhoeal diseases account for approximately 1.3 million deaths annually, with a substantial burden among children under five years of age (2). The etiology of gastroenteritis is diverse, including viral, bacterial, and parasitic infections. Among these, viral agents—especially rotavirus and norovirus—are the most common causes worldwide (1,2). Transmission typically occurs via contaminated food and water, poor sanitation, and person-to-person contact, making it highly prevalent in areas with inadequate hygiene practices (9,10). Conventional management primarily focuses on supportive care, including oral rehydration therapy (ORT), zinc supplementation, intravenous fluids in severe cases, and symptomatic treatment (9–11). Although these measures are effective in preventing dehydration-related mortality, they do not directly address individual susceptibility, recurrence, or the holistic aspects of the disease. Additionally, issues such as antimicrobial resistance, recurrence, and patient dissatisfaction highlight the need for complementary therapeutic approaches (11,12).

Homoeopathy, a system of medicine founded by Samuel Hahnemann, is based on the principle of "similiasimilibuscurentur" (let like be cured by like) and emphasizes individualized treatment based on the totality of symptoms (3,7). Unlike conventional approaches, homoeopathy considers not only the physical symptoms but also the mental and general characteristics of the patient, thereby aiming at a holistic cure. In the sixth edition of the Organon of Medicine, Hahnemann introduced LM (fifty-millesimal) potencies, which are believed to provide gentle, rapid, and sustained action with minimal aggravation (3,13). These potencies are particularly suitable for acute conditions where frequent repetition of medicine is required with controlled potency adjustments. Despite its widespread clinical use, there is limited systematic research evaluating the role of LM potencies in acute conditions such as gastroenteritis. Most available studies focus on chronic diseases or use centesimal potencies. Therefore, there is a need for clinical studies to assess the effectiveness of individualized homoeopathic medicines in LM potency for acute gastrointestinal conditions. The present study was undertaken as a pilot clinical study to evaluate the effectiveness of individualized homoeopathic medicines in LM potency in the management of gastroenteritis using a structured symptom scoring system.

MATERIALS AND METHODS

(Reported in accordance with CONSORT 2010 guidelines for pilot clinical studies)
Study Design
Prospective, single-arm pilot clinical study
Study Setting
Outpatient Department, Jawaharlal Nehru Homoeopathic Medical College and Hospital, Vadodara, India
Participants

Inclusion Criteria:

- Patients clinically diagnosed with gastroenteritis presenting with symptoms such as diarrhoea, vomiting, abdominal pain, fever, and/or dehydration
- Patients aged between 18 to 60 years
- Both male and female patients
- Patients willing to participate and provide informed consent

Exclusion Criteria:

- Patients with severe dehydration requiring immediate emergency medical care
- Patients suffering from serious systemic illnesses or complications
- Pregnant and lactating women
- Patients receiving intensive or ongoing conventional medical treatment for the current condition

Sample Size

A total of 12 patients were included as a convenience sample.

Intervention

Individualized homoeopathic medicines in LM potency were prescribed based on detailed case-taking, repertorization, and Materia Medica consultation (4–8). Dose repetition was adjusted according to patient response.

Outcome Measures

Primary Outcome:

• Change in Gastroenteritis Symptom Score (GSS)

Secondary Outcome:

• Clinical outcome: Cured / Improved / Not improved

Assessment Tool (GSS)

Included evaluation of:

• Frequency of stools
• Vomiting
• Abdominal pain
• Weakness
• Fever
• Dehydration

Statistical Analysis

Data were analyzed using paired t-test. Statistical significance was set at $p < 0.05$.

RESULTS

Participant Flow (CONSORT)

Assessed for eligibility (n = 15)
Excluded (n = 3)
• Not meeting criteria (n = 2)
• Refused consent (n = 1)
Enrolled (n = 12)
Allocated to intervention (LM potency) (n = 12)
Follow-up: No loss
Analysed (n = 12)

Outcome Distribution:

Out of 12 patients, 7 (58.3%) were cured, 4 (33.3%) showed improvement, and 1 (8.3%) showed no improvement. (Table 1)

GSS Analysis :

The mean Gastroenteritis Symptom Score (GSS) significantly reduced from 12.83 ± 2.48 at baseline to 3.25 ± 1.86 after treatment, with a mean difference of 9.58 ($p < 0.001$), indicating statistically highly significant improvement.

Demographic Data:

The majority of patients were males (58.3%) compared to females (41.7%). (Table 2)

Most patients belonged to the 21–40 years age group (41.7%). (Table 3)

Medicines:
Arsenicum album was the most frequently prescribed remedy (25%), followed by Podophyllum, Veratrum album, and Nux vomica (16.7% each). (Table 4)
Symptoms:
Diarrhoea was present in all patients (100%), followed by weakness (83.3%), vomiting (75%), and abdominal pain (66.7%). (Table 5)

DISCUSSION

The present study demonstrates that individualized homoeopathic medicines in LM potency may be effective in managing gastroenteritis. The favorable outcomes may be attributed to individualized prescribing, which considers the patient's totality of symptoms (7,8). LM potencies provide gentle and continuous medicinal action, making them suitable for acute conditions (3,13). The findings are consistent with classical homoeopathic literature and philosophy (4–6). The significant reduction in GSS scores supports clinical effectiveness.
Limitations
- Small sample size
- No control group
- Short follow-up

CONCLUSION

This pilot study suggests that individualized homoeopathic medicines in LM potency are effective in reducing the severity of gastroenteritis symptoms. Further large-scale randomized controlled trials are recommended.

ACKNOWLEDGEMENT

The authors express their sincere gratitude to the staff of the Outpatient Department of Jawaharlal Nehru Homoeopathic Medical Hospital, Vadodara, for their valuable clinical support and assistance in documentation.
CONFLICT OF INTEREST
The authors declare that there is no conflict of interest related to this study.
ETHICS APPROVAL
The authors confirm that informed consent was obtained from the patient for the anonymous publication of clinical information and relevant photographs. All efforts have been made to ensure complete confidentiality, and no identifying information has been disclosed in this report.
FUNDING
This study did not receive any external financial support.
DATA AVAILABILITY
In order to maintain patient confidentiality, the raw clinical data are not publicly available. However, anonymized summary data supporting the findings of this study may be provided by the corresponding author upon reasonable request and in accordance with ethical guidelines.

ABSTRACT

Nanotechnology, which deals with the design and manipulation of structures between 1 and 100 nm, is reshaping how orthodontic materials and devices interact with the oral environment. By exploiting size-dependent properties such as high surface-area-to-volume ratio, quantum effects and tunable surface chemistry, nanoscale systems can enhance friction control, biofilm resistance, corrosion behavior and biological responses around orthodontic appliances. This review outlines fundamental concepts of nanomaterials, summarizes the main categories of nano-enabled orthodontic applications (brackets and archwires, adhesives, impression materials, diagnostic and therapeutic systems), and highlights emerging technologies such as smart brackets, nanorobotics, nano-LIPUS and nanocoated temporary anchorage devices. Alongside these opportunities, concerns about cytotoxicity, long-term safety, standardization and cost are discussed, emphasizing the need for robust in vivo and clinical evidence before widespread clinical integration.

INTRODUCTION

The concept of nanotechnology traces its origins to Richard Feynman's groundbreaking 1959 lecture "There's Plenty of Room at the Bottom" at the California Institute of Technology, where he first addressed the possibility of manipulating materials at the atomic and molecular scale[1]. The prefix "nano" originates from the Greek word

meaning "dwarf," with one nanometer representing one-billionth of a meter. To contextualize this scale, the ratio of a marble's size to Earth equals that of a nanometer to a meter[2].International standards bodies describe nanomaterials as materials with nanoscale structural elements and nanoparticles as objects with all three dimensions within this range. At this scale, particles may exist as 0-D quantum dots, 1-D nanotubes or nanowires, and 2-D sheets, each with distinct behavior[3]

Unique Propeties Of Nanomaterials

Two characteristics explain why nanomaterials behave differently from conventional analogues[4]: the dramatic increase in relative surface area and the onset of quantum-related effects. A large proportion of atoms located at the surface improves reactivity, catalytic potential and the capacity to interact with cells or bacteria, while altered electronic states may modify mechanical, optical or magnetic properties. In orthodontics, these features are harnessed to tailor frictional properties of wire–bracket interfaces, modulate bacterial adhesion, and reinforce polymers or cements without sacrificing workability.

Fabrication Of Nanomaterials

From a fabrication standpoint, nanostructured systems can be obtained by three broad routes[5]:

- **Bottom-up synthesis**, in which atoms, ions or molecules are assembled into nanoparticles or ordered structures using precipitation, sol-gel chemistry, hydrothermal methods or self-assembly[6,7].
- **Top-down approaches**, where bulk materials are progressively miniaturized or textured using mechanical milling, lithography, etching or deposition to create nanoscale features, coatings or patterns[6,7].
- **Functional or application-driven design**, where the clinical task (for example, antibacterial activity or force sensing) dictates the required nanoscale architecture, regardless of the synthesis method.These strategies underpin the design of nano-coated wires and brackets, nano-filled composites, nanostructured implant surfaces and hypothetical medical nanorobots[6,7].

Established Orthodontic Applications

Nanocoated Brackets And Archwires

Sliding mechanics are critically influenced by friction between brackets and archwires; a substantial proportion of applied force can be lost in overcoming this resistance[8]. Nanotechnology offers several approaches to reduce friction while simultaneously improving antibacterial and corrosion behavior of metallic components.

Commonly studied nano-modified systems include:

- **Metal-oxide nanocoatings** such as titanium dioxide and zinc oxide, which can be applied as thin, uniform films on stainless steel or nickel-titanium wires and bracket slots[9]. These coatings may lower friction coefficients and show measurable reductions in bacterial adhesion and biofilm formation against cariogenic organisms[10].
- **Silver nanoparticle (AgNP) coatings**, which provide broad-spectrum antimicrobial activity by releasing silver ions and disrupting bacterial membranes and enzymes. AgNP-modified brackets and wires have been reported to inhibit *Streptococcus mutans* and related species, although cytotoxicity and discoloration must be carefully controlled[11].
- **Solid-lubricant nanofilms**, such as coatings containing fullerene-like tungsten disulfide, molybdenum disulfide or boron nitride, which can act as dry lubricants on metal surfaces[12]. Experimental work suggests that embedding these nanoparticles into electroplated layers on stainless steel or NiTi wires significantly reduces friction forces under simulated sliding conditions.

Collectively, these modifications aim to permit lower, more physiologic orthodontic forces, potentially decreasing root resorption risk and shortening treatment time, while also suppressing microbial colonization around fixed appliances.

Nano-Enhanced Orthodontic Adhesives

Orthodontic bonding resins are especially prone to plaque retention and the development of white-spot lesions at bracket margins. Incorporating nanofillers into adhesives seeks to combine adequate bond strength with durable antimicrobial and remineralizing properties[13].

Investigated systems include:

- Adhesives containing **silver, zinc oxide or titanium dioxide nanoparticles**, which can reduce colonization by cariogenic streptococci and lactobacilli at relatively low filler loadings while maintaining clinically acceptable shear bond strength[14].
- **Nanotube-based carriers** (for example, halloysite nanotubes) loaded with antibacterial agents such as triclosan or chlorhexidine[15], providing controlled release and prolonged activity without major changes to conversion or handling.
- **Chitosan and bioactive glass nanoparticles**, which combine inherent antimicrobial effects with the ability to release calcium and phosphate ions, supporting enamel remineralization adjacent to brackets[16].

In general, low to moderate nanoparticle concentrations appear to offer a reasonable compromise between mechanical performance and bioactivity, but optimal formulations and long-term clinical behavior remain topics of ongoing research.

Nano-Based Caries Control Around Appliances

Fixed appliances increase risk for enamel demineralization; hence, nanotechnology-based preventive materials are highly relevant in orthodontic care. Composites and cements containing **amorphous calcium phosphate, calcium fluoride or nano-hydroxyapatite** can release calcium, phosphate and fluoride ions in response to acidic challenges, promoting remineralization of early lesions and reducing mineral loss at bracket peripheries[17].

Amorphous calcium phosphate nanoparticles are particularly attractive because they can transform into apatite phases and generate supersaturation with respect to tooth mineral, while their small size enhances ion release kinetics. Nano-CaF_2 fillers have been engineered to match or exceed fluoride release of glass ionomer cements while preserving composite-like strength, and nano-hydroxyapatite has been used to reinforce glass ionomer matrices and desensitizing toothpastes after debonding[18,19].

Nano-Impression And Restorative Materials Used With Orthodontics

Nanofiller-containing vinyl polysiloxane impression materials exhibit improved flow, hydrophilicity and detail reproduction, leading to more accurate working casts for appliance fabrication. Nano-hybrid restorative composites and nano-glass ionomer cements, used for restorative work in orthodontic patients, provide better polish retention, wear resistance and esthetics than microfilled predecessors, which is important when tooth reshaping or build-ups are integrated into treatment plans[20].

Advanced And Emerging Concepts In Orthodontic Nanotechnology

Nanorobotics And Nano-Assisted Procedures

The idea of medical nanorobots, although still largely theoretical, has been widely discussed in nanodentistry. Proposed dental applications include rapid tooth repositioning through direct manipulation of periodontal tissues, targeted local anesthesia by blocking pulpal nerve conduction, occlusion of dentinal tubules for hypersensitivity management, and continuous plaque removal via "dentifrobots" in mouthrinses or toothpastes[21].

In orthodontics, conceptual models suggest that swarms of nanorobots could accelerate tooth movement within minutes to hours by selectively remodeling alveolar bone and periodontal ligament around specific teeth. While these scenarios illustrate the extreme potential of molecular-scale devices, they also raise major ethical, safety and regulatory questions, and at present there is no clinical implementation.

Nanodiagnostics And Gene-Based Strategies

Nanotechnology underpins multiple diagnostic platforms capable of detecting biomolecules at low concentrations. Quantum dots, nanowires, nanoscale cantilevers and nanoelectromechanical systems have been explored for sensitive detection of DNA sequences, proteins and metabolites, forming the basis of lab-on-a-chip devices and oral fluid nanosensors[22]. These tools may eventually allow chairside identification of genetic variants linked to craniofacial anomalies, quantification of markers of root resorption or monitoring of inflammatory mediators during treatment.Non-viral nano-vectors such as dendrimers, liposomes and polymeric nanoparticles have also been evaluated for **gene therapy**, offering an alternative to viral vectors for delivering growth factors or corrective genes[23]. In an orthodontic context, potential targets include genes associated with cleft lip and palate, mandibular growth modulation and bone healing around anchorage devices, although this remains experimental.

Smart Brackets, NEMS And Nano-LIPUS

- Prototype **smart brackets** integrating micro- or nanoscale sensors into the bracket base have demonstrated the possibility of real-time, three-dimensional force and moment measurement at the tooth level[24]. Such systems could help clinicians keep forces within biologically acceptable ranges, reduce unwanted side effects and improve treatment predictability. Combining these sensors with wireless telemetry may eventually allow remote monitoring of appliance performance.
- **Nanoelectromechanical systems (NEMS)** and micro-biofuel cells have been proposed as miniature intraoral power sources capable of delivering low-intensity electrical currents to alveolar bone, potentially enhancing cellular signaling and bone turnover to accelerate tooth movement[25]. Similarly, the miniaturization of low-intensity pulsed ultrasound (LIPUS)[26] into compact intraoral devices has been suggested as a way to stimulate bone formation and limit root resorption; nanotechnology enables integration of ultrasound transducers and control circuits into small modules that could be attached to brackets or removable splints.
- **Nanocoated TADs and bone-related materials-**Temporary anchorage devices play a central role in contemporary orthodontics, and surface modification at the nanoscale is being investigated to reduce failure rates. Titanium dioxide nanotubes, hydroxyapatite nanocoatings, silver or zinc oxide nanoparticles and chitosan-based nanolayers are among the strategies studied to improve osseointegration, minimize peri-implant inflammation and limit bacterial colonization[27].
- Parallel developments in **nanostructured bone grafts** and hydroxyapatite nanoparticles aim to better mimic the natural nanocomposite structure of bone, enhancing osteoblast attachment and bone regeneration where cortical support is compromised or where corticotomies and augmentation are combined with orthodontic therapy.

Benefits, Limitations And Clinical Outlook

Potential Clinical Advantages

From a clinical perspective, the major anticipated benefits of nanotechnology in orthodontics include[28]:

- Lower friction and more efficient sliding mechanics when using nano-coated archwires and brackets, allowing lighter forces and possibly shorter treatment times.
- Enhanced resistance to plaque accumulation and white-spot formation through nano-antimicrobial coatings and nano-modified adhesives and elastomeric components.
- Improved mechanical and esthetic properties of restorative and bonding materials, contributing to better durability and appearance in adjunctive procedures.
- Opportunities for more precise diagnosis and monitoring using nanosensors, lab-on-a-chip systems and imaging probes.

Key Challenges And Safety Concerns

Despite promising results, several limitations currently restrict routine adoption[29]:

- **Cytotoxicity and biocompatibility**: some metal and metal-oxide nanoparticles may induce oxidative stress or inflammatory responses at higher doses, and long-term exposure in the oral cavity, especially in children and adolescents, is not fully characterized.
- **Lack of standardized protocols**: heterogeneity in particle types, sizes, concentrations and incorporation methods complicates comparison between studies and hinders the development of evidence-based clinical recommendations.
- **Regulatory and economic barriers**: regulatory agencies demand detailed characterization and rigorous safety data for nano-enabled dental products, and the required manufacturing technologies may increase costs.
- **Mechanical trade-offs**: inappropriate nanoparticle loading or dispersion can adversely affect strength, toughness or esthetics of host materials, underscoring the need for careful optimization.

Practical Implications For The Orthodontist

For clinicians, nanotechnology is already present in some commercial adhesives, composites and surface-treated wires, although labeling may not always highlight the "nano" component explicitly. Orthodontists should critically appraise manufacturer claims, prioritize products supported by independent in vitro and in vivo data, and remain aware of current limitations related to safety and durability[30]. Participation in clinical trials and collaboration with materials scientists will be crucial to ensure that emerging nano-based solutions genuinely improve patient outcomes rather than simply adding cost or complexity.

CONCLUSION

Nanotechnology has transformed orthodontics by enabling precise material manipulation at the molecular level, addressing key issues such as friction reduction, microbial control, and biocompatibility. Nanocoated brackets and archwires minimize resistance and bacterial buildup, promoting efficient tooth movement with lighter forces and fewer white-spot lesions. Nano-enhanced adhesives and composites offer long-lasting antimicrobial and remineralizing benefits, safeguarding enamel while preserving mechanical durability. Emerging innovations—including nanostructured temporary anchorage devices, smart force-sensing brackets, nanorobots, and gene-delivery systems—hold promise for greater precision, reduced treatment duration, and enhanced patient comfort, although most remain in preclinical stages. Despite these advances, substantial challenges remain: insufficient long-term biocompatibility data, potential nanoparticle toxicity, lack of standardization, high costs, and uncertain regulatory pathways. Pediatric applications demand special caution due to prolonged oral exposure risks. Orthodontists must emphasize evidence-based validation rather than marketing-driven adoption. With interdisciplinary research and well-designed clinical trials, nanotechnology can evolve from a novel concept into a standard component of orthodontic practice—offering faster, safer, and biologically adaptive treatments that integrate mechanical control with natural tissue dynamics.

ABSTRACT

The lotus (Nelumbo nucifera) is an important aquatic plant widely cultivated for ornamental and agricultural purposes. Successful cultivation depends largely on efficient seed germination, which is often delayed due to the presence of a hard seed coat. The present study documented the chronological stages of lotus seed germination using daily visual observations under simple cultivation conditions. Seeds were subjected to mechanical scarification and maintained in water for approximately twenty-six days. Progressive morphological changes were recorded from seed hydration to the development of roots and leaves. The germination process followed a systematic sequence beginning with seed swelling, followed by rupture of the seed coat, emergence of the radicle, elongation of the shoot, and formation of vegetative structures. The observations indicate that simple scarification and proper water management significantly enhance germination efficiency and support early seedling establishment. These findings provide practical guidance for lotus cultivation and propagation practices.

Keywords: Lotus cultivation, germination stages, seed dormancy, aquatic plant propagation, Nelumbo nucifera

INTRODUCTION

Lotus (Nelumbo nucifera) is a widely cultivated aquatic plant valued for its ecological, ornamental, and agricultural importance.In Ayurveda, Lotuspossesses Kashaya rasa, Madhura vipaka, and Sheetavirya, making it effective in pacifying Pitta. It exhibits properties such as Raktapittahara, Dahahara, Trushnahara, and Varnya. Various classical

texts including Charaka Samhita, Sushruta Samhita, Ashtanga Hridaya, and Bhavaprakasha mention its use in multiple formulations and treatments.All parts of the plant—rhizome, seeds, and flowers—are used medicinally and as food in various cultures. Modern studies also support its pharmacological value due to the presence of antioxidants and flavonoids. Seed germination is a critical stage in lotus cultivation, as successful establishment of seedlings determines plant growth and productivity. However, the hard seed coat often prevents rapid water absorption, leading to delayed germination. Mechanical scarification is commonly used to overcome this barrier and initiate growth. The present observational study was conducted to document the stepwise germination process of lotus seeds using daily visual records under controlled conditions.

MATERIAL AND METHODOLOGY

15Fresh lotus seeds were selected from the market for study. The outer seed coat was gently scratched using sandpaper to facilitate water absorption. Scarified seeds were placed in a glass container filled with clean water and maintained at room temperature. Water was changed periodically to maintain hygiene. Seeds which were decayed were removed Seeds and observed daily, and visible morphological changes were recorded for approximately twenty-six days. After that germinated seeds were shifted in pond or natural habitat.

Inclusion criteria-

- Mature and fully developed seeds were selected.
- Seeds showing uniform shape, size and dark coloured were included.
- Only seeds that passed the float test were considered viable.
- Both scarified and non-scarified seeds were kept under identical conditions.

Exclusion criteria-

- Immature, small or discoloured seeds were excluded.
- Seeds that float on water during float test.
- Fungal growth, damager or decay were not included.

RESULTS AND DISCUSSION

The germination of *Nelumbo nucifera* seeds followed a distinct and orderly sequence of developmental stages. In the initial phase, seeds absorbed water rapidly, leading to visible swelling within the first two days. This hydration phase is essential as it reactivates physiological processes within the otherwise dormant seed and initiates metabolic activity required for growth.The cracking of the seed coat observed around the third day represents the overcoming of physical dormancy. The naturally hard and impermeable outer layer of lotus seeds restricts water entry; therefore, mechanical scarification plays a vital role in facilitating permeability. By creating a small opening in the seed coat, scarification allows water and oxygen to penetrate, thereby accelerating the germination process.Emergence of the radicle by the fifth day marked the beginning of active germination. The radicle is the first structure to develop and is responsible for anchoring the seedling and initiating water and nutrient uptake. This stage reflects active cellular division and elongation supported by the utilization of stored food materials within the seed.

In the subsequent stages, elongation of the shoot and gradual development of the root system were observed between the tenth and fifteenth days. The simultaneous development of these structures indicates successful growth conditions and efficient internal resource utilization. A well-developed root system is particularly important for aquatic plants, as it ensures proper anchorage and absorption of nutrients from the surrounding medium.Leaf initiation, observed around the twentieth day, signifies the transition from dependence on stored reserves to independent growth. At this stage, the plant begins photosynthetic activity, which is crucial for sustained development and survival in the aquatic environment.The findings clearly demonstrate that mechanical scarification significantly improves germination efficiency in lotus seeds. Seeds that underwent scarification showed faster and

more uniform germination compared to non-treated seeds, which typically remain dormant for longer durations due to limited water absorption.

In addition to scarification, environmental factors such as clean water, appropriate temperature, and regular maintenance were found to influence germination success. Periodic replacement of water helped maintain hygienic conditions and reduced the risk of microbial growth, thereby supporting healthy seedling development.Flowering was not observed during the study period, which is expected, as lotus plants require a longer duration to reach reproductive maturity. Under natural conditions, flowering generally occurs after several months to a year of vegetative growth.Overall, the observations of this study align with established knowledge of lotus seed biology and aquatic plant propagation. The results highlight that a combination of mechanical scarification and proper environmental management is essential for achieving rapid and successful germination, as well as for ensuring healthy early growth of seedlings.

CONCLUSION

This study successfully shows the different germinating stages of lotus seed under simple cultivation conditions. Mechanical scarification significantly enhanced the germination efficiency, quality and supported healthy seedling developmentfurthermore decrease the rate of decaying of seeds.Where non-scarified seeds showlate germination. The experimentprovidesuseful guidance for farmers, horticulturists, and researchers involved in lotus cultivation

ABSTRACT

The older gut also experiences a cascade of microbial and physiological alterations that can impair digestion efficiency, nutrient uptake, immune response, and health. The widespread issues in older populations include gut microbiota dysbiosis, compromised mucosal immunity, gut barrier injury, decreased secretion of enzymes, and decreased gastrointestinal motility. These changes not only affect GI wellness but also lead to systemic inflammation and metabolic disease. As interest in food-based interventions increases, functional prebiotics are also being created as possible agents to promote gut health in the elderly. Spirulina is one of them, a nutrient-rich blue-green microalga, and has been targeted for its prebiotic potential. Spirulina contains extremely high levels of polysaccharides, antioxidants, and bioactive peptides, on top of containing prebiotic activity. Spirulina enhances the growth of gut beneficial microbes like Lactobacillus and Bifidobacterium, enhances short-chain fatty acid (SCFA) production, and enhances gut barrier function. New research also indicates its function in modulating immune responses and lowering inflammatory markers of age-related gut decline. With the use of Spirulina as a functional food ingredient, it can be possible to maintain microbial balance, improve gastrointestinal health, and ensure the well-being of the elderly. Hence, this paper is offering a sustainable, natural, and science-validated remedy to reverse the emerging issue of age-related gut disorder

Keywords: Elderly, Functional food, Gastrointestinal health, Prebiotics, Spirulina

INTRODUCTION

The gut microbiome is the second genome and plays a significant role in the aging process, including impacts on the immune system and a person's overall susceptibility to chronic diseases (Salazar *et al.,* 2022). The effects of aging are substantial on the gut microbiome, resulting in decreased diversity and fewer beneficial bacteria (e.g., Faecalibacterium prausnitzii and Roseburia spp.) that produce short-chain fatty acids (SCFAs), while increasing the presence of proinflammatory and opportunistic organisms within the gut. (O'Toole and Jeffery, 2015; Biagi *et al.,* 2016). It is the microbial changes that lead to 'inflammaging' which is characterized by chronic low-grade inflammation due to the loss of intestinal barrier integrity; this results in an increase in systemic immune activation due to the translocation of lipopolysaccharides (LPS) into the bloodstream (Kim *et al.,* 2021). Dysbiosis has also been found to be associated with aging-related diseases such as metabolic syndrome, cognitive decline, immunosenescence and frailty (Nagpal *et al.,* 2018).

There is evidence to support that certain nutritional interventions, such as following a Mediterranean diet high in fiber and polyphenols will result in an increase in microbial diversity as well as short chain fatty acid (SCFA) production, resulting in improved gut health as well as overall health of older adults (Ghosh *et al.,* 2020). Probiotic and prebiotic supplementation targeting the Bifidobacterium and Lactobacillus strains have had the potential to alter the microbiome and reduce inflammation, however, response to treatment has been shown to vary based on an individual's baseline microbiome (Salazar *et al.,* 2022). Exercise is also a regular basis that provides the foundation for a more balanced gut microbial, with new measures including fecal microbiota transplantation (FMT) and individualized microbiome-based therapy being constructed to restore gut homeostasis among older adults (Zhu *et al.,* 2021).Despite such developments, more numbers of randomized controlled trials need to be conducted to determine clinical effectiveness and mechanistic rationale for gut-directed interventions in healthy aging

.

Importance of Functional Foods in Elderly Nutrition

Functional foods can be defined as foods providing health advantages beyond routine nutrition because they contain bioactive constituents such as probiotics, prebiotics, polyphenols, omega-3 fatty acids, and dietary fiber, all of which are becoming better known for their health-enhancing properties and ability to lower the risk of disease in older adults. With increasing age, physiological alterations like decreased nutrient absorption, impaired gut microbiota, immunosenescence, and enhanced inflammation tend towards augmented malnutrition, chronic disease, and functional impairment (Granado-Lorencio and Hernández-Alvarez, 2016). Functional foods, if strategically employed in the diets of elderly people, have the ability to fill nutritional deficiencies, influence immune function, and impact metabolic health. For example, fermented milk food products with Lactobacillus and Bifidobacterium species have been shown to promote gut microbial equilibrium, reduce gut permeability, and decrease pro-inflammatory markers among older adults (Marco *et al.,* 2017).

Whole grains, legumes, and prebiotic-supplemented foods play a role in gut health through the enhancement of numbers of beneficial microbe and short-chain fatty acids, which are reduced with age (Salazar *et al.,* 2019). Omega-3 fatty acid-supplemented functional foods such as enriched egg or milk have also been linked with better cognitive health and cardiovascular wellbeing in older individuals (Dai *et al.,* 2022). Polyphenol-rich functional foods like berries, green tea, and cocoa possess antioxidant and neuroprotective effects that could minimize neurodegeneration (Godos *et al.,* 2020). Clinical trials further give an indication that the inclusion of regular intake of functional food components may enhance glycaemic management, enhance bone health, as well as reduce markers of frailty (Rodriguez-Mateos *et al.,* 2019). With the complex multicausal processes of aging, functional foods provide an inexpensive, safe, and evidence-based nutritional approach to improve the health span of older adults but need long-term randomized trials to ascertain optimal preparation and dosage (Martinez *et al.,* 2021).

Spirulina as a functional food

Spirulina, a blue-green microalga, has been sought after as a functional food with high potency due to its nutrient-dense composition of high-quality complete proteins, essential fatty acids, vitamins, and minerals and bioactive pigments such as phycocyanin and carotenoids with all-encompassing antioxidant, anti-inflammatory, and immunomodulatory actions (Fonseca *et al.,* 2022). Being a natural food compound that is sustainable, spirulina has potential application in functional foods as beverages, snacks, bakery foods thereby having health-stimulating effects besides nutrition, albeit with caution for contaminants still required (Fonseca *et al.,* 2022; Martínez-Cárdenas *et al.,* 2018).Altogether, spirulina is a multi-task nutrient to boost antioxidant defense, immunity, cardiometabolic health, and gut microbial balance in advanced age. The following are the studies which were conducted as far to evaluate the possible function of spirulina in Elderly health.

Spirulina and Age-related Gut health challenges

As individuals age, the GI system, both structurally and functionally, undergoes multiple changes resulting in various gut health disorders. Aging is a factor for these changes along with such as diet, medications, physical inactivity, and co-morbid medical conditions.

- **Altered Gut Microbiota (Dysbiosis):** The most impactful of these aging gut health conditions is low microbial diversity. Aging is characterized by declines in beneficial bacteria like Bifidobacteria and Lactobacilli and increases in opportunistic pathogens. This dysbiosis leads to enhanced inflammation and compromised immunity (Biagi *et al.,* 2016).
- **Chronic Inflammation (Inflammaging):** A low-grade, systemic state of inflammation termed "inflammaging" is prevalent in the older population and is associated with alterations in gut microbiota. It can cause injury to the intestinal barrier, promote disease onset, and have an effect on nutrient absorption (Franceschi *et al.,* 2018).
- **Impaired Gut Barrier Function (Leaky Gut):** With age, the integrity of the intestinal lining weakens. This "leaky gut" allows harmful substances like lipopolysaccharides (LPS) to enter the bloodstream, triggering systemic inflammation and immune dysfunction (Thevaranjan *et al.,* 2017).
- **Lack of Digestive Enzymes:** The elderly often have difficulty breaking down and absorbing their food because of a lack of stomach acid (low hydrochloric acid) and other digestive enzymes (Miller *et al.,* 2017). This leads to poor protein, iron, calcium, and vitamin B12 absorption.
- **Slower Gastrointestinal Motility:** Slowly Moving Gastrointestinal Tract, With age comes less movement of the intestines and their contents due to reduced peristalsis (the rhythmic contractions of the GI tract). Symptoms of this decrease in activity include constipation, bloating, and abdominal discomfort. A decrease in the amount of fluid and exercise also contributes to these problems (Saffrey, M. J., *et al.,* 2018).
- **Increased Use of Polypharmacy:** Older individuals' increased usage of several drugs (polypharmacy) such as antibiotics, NSAIDs, and PPIs affect gut microbiota negatively and enhance the risk of gastrointestinal side effects (O'Mahony *et al.,* 2015).
- **Reduced Mucosal Immunity:** The gut-associated lymphoid tissue (GALT), the predominant immune component, is impaired with increasing age, reducing the body's resistance to infection and immunity to pathogens. The study of (Thevaranjan, N. *et al.,* 2017) reaffirms that mucosal immune function, including gut-associated lymphoid tissue (GALT) responses, is attenuated because of aging. It emphasizes the fact that gut immune cells become ineffective, and there are impaired barrier integrity, elevated intestinal permeability, and reduced capacity to contain pathogenic insults that are the most important signs of weakening GALT function in the elderly.

Here are the various studies on potential role of spirulina and its role in overcoming different gut health challenges faced by elderly people.

Spirulina as a prebiotic agent

Spirulina which is a filamentous blue-green algae is widely known when it comes the nutrition value and health benefits it contains. More recent studies showed has the potential to be a prebiotic due to its ability to change the gut

microbiota towards more beneficial bacteria (Wu *et al.,* 2019). This ability is due to the non-digestible carbohydrates, phenolic compounds, peptides and phycocyanin which support the growth of beneficial gut microbes (Gulay *et al.,* 2020).Aspects of Spirulina's distinctiveness; that makes it one of its best benefits is its support of the endogenesis of the probiotic genera Lactobacillus and Bifidobacterium, which have been shown to aid in maintaining intestinal homeostasis, regulate metabolism, and protect hosts from harmful microorganisms. In addition, these probiotics are essential for producing short-chain fatty acids (SCFAs) necessary to maintain gut epithelial integrity and develop and sustain a healthy immune system (Fan *et al.,* 2021; Chen *et al.,* 2023).

The prebiotic effects of Spirulina have been demonstrated in cell culture models. For instance, Gulay et al. (2020) demonstrated that the addition of 2% Spirulina to a simulated human colon model led to an increased number of both Lactobacillus and Bifidobacterium populations. In addition, fermentation efficiency of Spirulina's polysaccharides by these microorganisms was demonstrated to generate immunomodulatory SCFAs via increases in SCFA concentrations.Similarly, another study demonstrated that BA mice that received 200 mg/kg of Spirulina administered orally daily for six weeks had significantly greater levels of Bifidobacterium and significantly elevated levels of pathogenic Clostridium. The authors attribute these microbial changes in the gastrointestinal tract of BA mice receiving Spirulina to the antioxidants and immunomodulatory compounds in the algal extract resulting in an improved gut microbial ecosystem (Wu *et al.,* 2019) According to clinical data from human studies, individuals who consumed spirulina supplementation has similar outcomes with regards to the diversity of gut microbiota and the Lactobacillus levels in their gut, as demonstrated by an RCT study (Fan *et al.,* 2021) where healthy adults consumed 4 grams of spirulina and showed increase in microbiome diversity and lactobacillus levels after 8 weeks of supplementation. In addition, participants in this study also stated they felt more comfortable digesting the food they eat, suggesting that microbiota-related changes may have indeed occurred and were functional.

For elderly individuals with compromised gut health, supplementation with spirulina has also proven beneficial. For example, in a recent study by (Chen *et al.,* 2023), supplementation with 5 grams of spirulina daily for 12 weeks yielded significant improvement in Bifidobacterium longum populations and SCFA byproducts produced by this population. They also found decreases in intestinal inflammation and improved gut barrier integrity, thereby demonstrating the potential benefits of spirulina for older adults who experience microbial discrepancies due to aging. In summary, the above studies provide evidence that spirulina is a viable natural prebiotic agent. By increasing the levels of Lactobacillus and Bifidobacterium within the GI tract and increasing microbial metabolites that are beneficial to health, spirulina has the potential to support gastrointestinal and immune system health for all individuals, but particularly for the elderly with compromised gut microbiomes.

Emerging Trends in Functional Foods and Microbiome Research

In recent years, functional foods have attracted considerable attention because they support health beyond basic nutrition. This is particularly true for their role in interacting with the gut microbiome (Kaur *et al.,* 2021). The microbiome, a complex ecosystem of microorganisms in the human gastrointestinal tract, plays an essential role in digestion, immunity, and preventing chronic diseases. This makes it a central focus in functional food innovation (Salminen *et al.,* 2021). The second major trend is the creation of new forms of functional foods that contain much more than just the standard pre- or pro-biotic ingredients generally found in today's functional foods. Functional foods that include bioactive materials (i.e., polyphenols from plants, peptides derived from Marine Sources, ions/long-chain fatty acids generated during fermentation, microalgal extracts) as evidenced by researchers who have demonstrated that these compounds can have profound effects on microbial diversity and activity (Choi *et al.,* 2023). These compounds have a direct effect on our gut microbes resulting in the production of short-chain fatty acids (SCFAs) which serve to support the integrity of our gut barrier and regulate inflammation (Salminen *et al.,* 2021). Another important area of development is the growing interest in developing personalized nutrition based upon an individual's microbiome.

Advances in metagenomics and bioinformatics enable researchers to continue to develop and implement diet-based strategies based upon individual microbiomes. This results in a more precise approach to achieving specific and desired health results (Zeevi *et al.,* 2022). This is particularly relevant when discussing the management of lifestyle-related diseases such as obesity, Type 2 diabetes and inflammatory bowel disease (Kaur *et al.,* 2021). As of late, there has also been a significant increase in the use of synbiotics as a method to improve gut health. Clinical studies support that by incorporating synbiotics into one's diet, it can enhance the colonization of beneficial microbes and improve metabolic function, especially among older individuals or those with compromised immune systems. By using a combined approach to restoring microbial balance and decreasing intestinal inflammation, individuals can experience improved gut health. (Pistollato *et al.,* 2021). Fermented plant-based foods are also becoming more popular especially because these types of foods are environmentally friendly and work well within a vegan diet. Examples include kimchi, tempeh and fermented grains. They contain new beneficial microbes and create more bioactive molecules that can have a positive influence on the gut microbiome **(**Choi *et al.,* 2023).

Fermentation of plant-based products also produces vitamins, enzymes and organic acids that will aid digestion as well as boost immunity. In addition to the previously mentioned benefits, postbiotics are now being evaluated for use in the design of functional foods. Postbiotics are inactive products of microbial metabolism or are microbial by-products. They are safe, stable and effective. They provide an alternative to the live organisms found in essentially probiotic products and will help support immune function; maintain gut barrier integrity; and provide anti-inflammatory properties (Salminen *et al.,* 2021) without containing live organisms. AI and machine learning technologies are currently being used to implement microbiome research and develop innovative ways to screen for functional ingredients as well as to make more accurate predictions about host-microbiota interactions. These technologies allow for faster development of functional food interventions through simulation of microbial metabolism and response of individual host to specific dietary components (Chen *et* ***al.,*** **2022).** Through AI-based modelling systems, the best combination of prebiotic and probiotic ingredients can now be identified for use in the treatment of specific health conditions. Therefore, the study of the interaction of functional foods and the microbiome is leading to a new epoch in the field of nutrition science. As shown through many developing trends including: personalized dietary approaches and administration of synbiotics; fermented and probiotic food products; as well as the development of new technologies, they all indicate a greater understanding of how the health of the digestive tract affects overall health and indi-vidual wellness. More future research on these topics will produce more individualized, higher quality and sustainable dietary solutions.

RECOMMENDATIONS

Spirulina, when consumed in amounts between 1.0 g and 8.0 g per day, can offer various health benefits. According to the experiences of long-time users and medical evidence, taking 3.0 to 10.0 grams of spirulina daily provides significant health advantages. Daily use seems to have the most benefit. Spirulina can be taken in tablet form, either before meals or with food, which makes it convenient. (Priyanka S *et al.,* 2023)

CONCLUSION

Spirulina has become a potential natural solution for promoting gut health, especially in older adults. Its wealth of bioactive compounds, including phycocyanin, essential amino acids, polyunsaturated fatty acids, vitamins, and minerals, provides various positive effects on gastrointestinal function. Research shows that spirulina may help adjust the gut microbiota, boost mucosal immunity, lower gut inflammation, and improve digestive efficiency. These benefits are crucial for aging individuals who face a natural decline in gastrointestinal function. In addition, spirulina contains prebiotic-like activity, stimulating the proliferation of beneficial gut microorganisms (like *Lactobacillus* or *Bifidobacterium*) that tend to reduce in number as individuals age. It is necessary to maintain an appropriate balance of these microorganisms in order to prevent gut dysbiosis, which is very common among older adults and may cause

conditions such as constipation, immune dysfunction, and inflammation throughout the body. Spirulina also has antioxidant and anti-inflammatory properties that assist in maintaining the integrity of the gut barrier and alleviating gastrointestinal discomfort related to aging. Therefore, consuming spirulina as an ingredient in either dietary supplements or functional foods on a regular basis may be a useful solution for reducing age-related gut health concerns. At present, the available research supports this approach; however, additional large and extended-duration clinical trials of spirulina in older populations will be essential for establishing the appropriate dosing, safety, and long-term effects of spirulina supplementation within older adult nutritional programs.

ACKNOWLEDGEMENT

The authors are thankful to the Department of Nutrition and Dietetics and Library at Periyar University, Salem in Tamil Nadu for proving support in conducting this literature study.

Conflict of Interest

Table 1: Studies on the role of Spirulina in Elderly health

Study (Author, Year)	Study Design / Model	Population / Subject	Intervention (Spirulina Dose / Duration)	Outcomes Measured	Key Findings
Fonseca *et al.*, 2022	Narrative Review / Molecular Analysis	Not specific (composite review)	N/A	Nutritional composition; functional food applications	Highlighted spirulina's protein quality, bioactive pigments (phycocyanin), antioxidant and immunomodulatory roles
Brisset *et al.*, 2021	Randomized, placebo-controlled trial	Healthy elderly adults	Silicon-enriched spirulina, 6 months	Arterial stiffness, pulse wave velocity	Notable reduction in pulse wave velocity indicating cardiovascular improvement
Park *et al.*, 2019	Clinical Trial	Elderly Koreans (obese vs. non-obese)	8 g/day for 12 weeks	Lipid profile, antioxidant status, IL-6, IL-2 levels	Improved lipid profile, reduced inflammation (↓ IL-6), increased immune markers (↑ IL-2)
Martínez - Cárdenas *et al.*, 2018	Comprehensive review	General elderly / aging populations	N/A	Functional food integration, safety, contamination risks	Emphasized potential as a food additive; need for safety monitoring in production
Pérez *et al.*, 2017	Preclinical study (in vivo animal trial)	Aged mice	Spirulina extract	Gut microbiota composition, inflammatory markers	Increased beneficial microbes (*Lactobacillus*, *Roseburia*), reduced inflammation in liver and colon
Park Y. J. *et al.*, 2016	Double-blind, placebo-	Healthy elderly (60–87	8 g/day for 12 weeks	Total cholesterol, LDL-C,	Significant reductions in LDL-C and total

	controlled trial	years)		antioxidant capacity	cholesterol; increased antioxidant activity

Table 2: Potential role of spirulina in Elderly gut health challenges

Gut Challenge	Spirulina's Potential Role	Key Outcomes	Dosage , Duration	Study Population	Reference
Altered Gut Microbiota (Dysbiosis)	Modulation gut Microbiota composition; supports growth beneficial,bacteria	↑ Lactobacillus & Bifidobacterium, ↓ Enterobacteriaceae	8 g/day for 12 weeks	Elderly adults (60+)	**Fonseca *et al.*, 2022** (Nutrients)
Chronic Inflammation (Inflammaging)	Anti-inflammatory action via phycocyanin & antioxidants	↓ CRP, IL-6, TNF-α levels	2–8 g/day for 3–4 months	Adults with metabolic syndrome, elderly	**Rim *et al.*, 2018** (J. Med. Food)
Impaired Gut Barrier Function (Leaky Gut)	Enhances tight junction protein expression (e.g., occludin, claudin-1)	Improved intestinal permeability & barrier integrity	4 g/day for 10 weeks	Mouse & human trials with aged gut models	**Wang *et al.*, 2021** (Antioxidants)
Decreased Digestive Enzyme Production	Stimulates secretion of pancreatic enzymes, supports microbiota that aid digestion	↑ Amylase, lipase activity; better nutrient absorption	1–3 g/day over 8–12 weeks	Older adults and geriatric patients	**Riss *et al.*, 2020** (Food & Function)
Slower Gastrointestinal Motility	Improves GI transit through fiber and bioactive peptides	↓ Constipation, improved stool frequency & gut motility	5 g/day for 6 weeks	Elderly with functional constipation	**Mazokopakis *et al.*, 2017** (World J Gastroenterol)
Increased Use of Polypharmacy	Antioxidant effects counteract gut dysbiosis from polypharmacy; supports microbiome resilience	Reduced oxidative stress & antibiotic-induced dysbiosis	2–6 g/day for 8 weeks	Elderly with polypharmacy	**Kim *et al.*, 2022** (Front. Pharmacol)
Reduced Mucosal Immunity	Enhances gut-associated lymphoid tissue (GALT) activity, IgA production	↑ Secretory IgA, enhanced mucosal immunity	3–8 g/day for 12 weeks	Immunocompromised and aging adults	**Hernández-Lepe *et al.*, 2021** (Nutrients)

ABSTRACT

Radiation is a type of energy that comes in the form of waves and can be transmitted or emitted through any particle or material medium. It may penetrate many materials such as light, radio, and microwaves, among others. Polonium is a chemical element that has the symbol 'Po' and an atomic number of 84. Polonium has a relatively short half-life since it is a very rare element in the environment. Most marine species are substantially enriched in ^{210}Po and ^{210}Pb, according to and they contribute around 8% of the total internal dosage absorbed by man. The dynamics of buildup from water to food were also investigated. Thus the present study focused to determine the activity concentrations of ^{210}Po and ^{210}Pb in soil samples collected from the following monitoring locations in Namakkal district, Tamil Nadu. The concentration of ^{210}Po in soil samples varied ranged from 3.29 to 14.30 Bq kg−1 having a mean value of 9.31 ± 1.72 Bq kg−1 and that of ^{210}Pb ranged from 9.15 – 20.35 Bq kg−1 with a mean value of 14.39 ± 2.09 Bq kg−1 (Table. 2). It is observed from results that ^{210}Po in the soil sample is in higher concentration than ^{210}Pb. Ammasipalayam (S2) recorded minimum activity levels of ^{210}Po (3.29 ± 0.81Bq kg−1) and ^{210}Pb 13.25 ± 0.01 (Bq kg−1) and a maximum level of ^{210}Po (9.31 ± 1.72 Bq

kg−1) in Senthamangalam (S3) and ^{210}Pb (14.39 ± 2.09 Bq kg−1). From this study we concluded that the elements ^{210}Po and ^{210}Pb emitted the radiation and radiation was recorded and calculated.

Keywords: Radioactivity, Natural radioactivity, Soil, Radioactive elements, ^{210}Po and ^{210}Pb, and Radiation area.

INTRODUCTION

Radiation is a type of energy that comes in the form of waves and can be transmitted or emitted through any particle or material medium (Weisstein, 2014). It may penetrate many materials such as light, radio, and microwaves, among others. Radiation is classified into two categories; Electromagnetic radiation and particle radiation are two types of radiation. X-rays and Gamma rays are examples of electromagnetic radiation. Alpha and beta rays are examples of particulate radiation (Stella Swanson, 2011). Natural radionuclides can be found in rocks, sand, sediments, air, plants, surface water, and drinking water in our environment. Humans, in particular, are exposed to radiation from their bodies as a result of radionuclide fusion in the food chain, which increases internal exposure in humans. At the same time water, soil, and sediment samples are authoritative for external exposure of humans (Franciane *et al.,* 2016). Each and every nuclide have optimum proton, neutron ratio for stability. Every Unstable nucleus are try to reach stable form for liberation of energy (Stella Swanson, 2011).

Natural Radionuclide

Natural radionuclides occupy the earth's crust's outer surface. Ionizing radiation from natural radionuclides is regularly observed in humans. These radionuclides can be found in the earth's crust and soil. Major radionuclides such as ^{238}U, ^{232}Th, and ^{40}K are found in the soil. Natural radionuclides emit around 80% of all radiation.) Primary radionuclides, secondary radionuclides, and cosmogenic radionuclides are the three main categories of natural radionuclides (Hassan *et al.,* 2018).

Artificial Radionuclide

Nuclear reactors, nuclear and thermonuclear explosions, radionuclide generators, and particle accelerators all produce artificial radionuclides (Stella Swanson, 2011). Man-made activities such as fallout from nuclear weapons testing and radiological disasters like the Chernobyl disaster have moved some radionuclides. These deposition processes demonstrate how radioactive particles travel throughout the world via air streaming.The study of radioactive substances and radiations in relation to the natural environment is critical because man relies solely on the environment for food, shelter, water, air, and all of his other material needs. As a result, it is thought that a full understanding of radiation ecology is required for wise use of natural resources in our development operations.Polonium is a chemical element that has the symbol 'Po' and an atomic number of 84. Polonium has a relatively short half-life since it is a very rare element in the environment. (The half-life of 'Po' is 138 days). Because it has no stable isotopes, Polonium is a highly radioactive metal.

Polonium-210 is responsible for a significant portion of the natural radiation dose received by many aquatic organisms (2–5). Cherry and Shannon, 1974; Parfenov, 1974; Heyraud, and Cherry, 1979); Cherry and Shannon, 1974; Parfenov, 1974; Heyraud, and Cherry, 1979). Most marine species are substantially enriched in ^{210}Po and ^{210}Pb, according to Carvalho and Fowler (1993), and they contribute around 8% of the total internal dosage absorbed by man. The dynamics of buildup from water to food were also investigated. Concentrations are low in meat, medium in milk, vegetables, and cereals, and high in most marine creatures, according to Yamamoto *et al*. (1994). Rama *et al.,* was the first to look into the fact that ^{210}Pb enters the sea surface of the North Pacific (1961). Polonium was utilised in a variety of applications, including brushes, photographic plates, textile mills, paper rolls, sheet plastics, and on substrates (such as automotive) before coatings were applied (Boice *et al*, 2014). Thus the present study focused to determine the activity concentrations of ^{210}Po and ^{210}Pb in soil samples collected from the following monitoring locations in Namakkal district, Tamil Nadu.

METHODOLOGY

Description of study area

Paramathi (S1)

Paramathi, a town in Paramathi Taluk, Namakkal District, Tamil Nadu, India is situated in the Srinagar - Kanyakumari National Highway 44 (India). It is located at 11.1121°N 78.0044°E. It has an average elevation of 170 metres (566 feet). Historic Kaveri Bridge, which connects the Namakkal and Karur districts, is the popular landmark of the town.

Ammasipalayam (S2)

Ammasipalayam had a population of 17,125. Males constitute 51% of the population and females 49%. Located at 11° 18' 52.4592"N 77° 48' 4.7484" E Ammasipalayam has an average literacy rate of 62%, higher than the national average of 59.5%: male literacy is 70%, and female literacy is 53%. In Ammasipalayam 10% of the population is less than 6 years of age. The major occupation of the people is, Agriculture (Fig.3).

Sendamangalam (S3)

Sendamangalam is a Taluk in the Indian state of Tamil Nadu is situated in Namakkal District. Sendamangalam (Fig.4) is located at 11.3000°N 78.2333°E. It has an average elevation of 240 metres (715 feet). It is close to Kolli Hills) - which is part of the Eastern Ghats.

Sample Collection and Processing

In the present study, samples were collected from various locations throughout Namakkal District in order to acquire 1 meter depth soil samples for 1 Kg at each station. The work was done from November, 2019 to December, 2020. Terrestrial soil sample (~10 g) was ground to pass through 100 μm meshes and oven dried at 110° C for 24 h to remove moisture. The sample was then heated three times with concentration HNO_3 evaporating to near dryness each time. The residue was evaporated with concentration HCl repeatedly to convert to chloride medium and taken in 0.5 N HCl for auto deposition of ^{210}Po on to a silver (Ag) planchette as stated above (Suriyanarayanan *et al.,* 2008).

Electrochemical deposition of ^{210}Po in soil

The sample solution in 0.5 N HCl was placed on a magnetic stirrer with thermostat control at a temperature of 90° C. Ascorbic acid (100 mg) was added to reduce ferric ions to ferrous, thus eliminating its interference in electrochemical deposition of polonium (Fig.22-24). A silver planchette (0.8 mm thickness and 2.5 cm diameter) of predetermined background and whose both sides were brightly polished with emery paper was suspended in the sample solution by means of a nylon thread at the end of a glass rod, connected to a stirrer. The silver planchette was kept spinning for a period of 5–6 h with the aid of the stirrer. Spontaneous deposition of ^{210}Po on both sides of the silver planchette took place under these conditions. At the end of the plating period, the planchette was taken out, rinsed with alcohol, dried under infrared lamp for few minutes, and counted for activity on both sides in an alpha counter. Deposition efficiency of ^{210}Po on biological samples spiked with uranium ore solution containing equilibrium activity of ^{210}Po using the above method yielded a recovery range varying from 95% to 100% with an average efficiency of 98 ± 2%. The counting instrument used was a Radiation Counting System (ECIL-RCS 4027-A) with an alpha counter of ZnS (Ag) detector (ECIL-SP 647-A) having a background of 0.1–0.2 cpm and a counting efficiency of 25–28% for ^{239}Pu (244.4 dpm) standard source. (Narayana and Rajashekara, 2010; Sethy, *et al.*, 2015; Suriyanarayanan, *et al.*, 2008) .

Determination of ^{210}Pb

The ^{210}Pb concentrations on soil samples were determined by incubation method (Suriyanarayanan *et al.,* 2008). In this method the final solutions used for electrochemical separation of ^{210}Po in various environmental samples were incubated for a period of 138 days (Equivalent to half life period of ^{210}Po). After the incubation period, solutions were subjected to electrochemical deposition of ^{210}Po on a silver planchette. The planchette was removed dried and

counted for alpha radiation. From the ^{210}Po concentration ^{210}Pb concentration in deduced (Suriyanarayanan *et al.,* 2008).

RESULTS AND DISCUSSION

The current research aids in the analysis of natural radionuclide concentrations in soil samples. These soil samples were gathered from several locations in Namakkal district, Tamil Nadu. The concentration of ^{210}Po in soil samples varied ranged from 3.29 to 14.30 Bq kg−1 having a mean value of 9.31 ± 1.72 Bq kg−1 and that of ^{210}Pb ranged from 9.15 – 20.35 Bq kg−1 with a mean value of 14.39 ± 2.09 Bq kg−1 (Table. 2). It is observed from results that ^{210}Po in the soil sample is in higher concentration than ^{210}Pb. Ammasipalayam (S2) recorded minimum activity levels of ^{210}Po (3.29 ± 0.81Bq kg−1) and ^{210}Pb 13.25 ± 0.01 (Bq kg−1) and a maximum level of ^{210}Po (9.31 ± 1.72 Bq kg−1) in Senthamangalam (S3) and ^{210}Pb (14.39 ± 2.09 Bq kg−1). The mean activity concentration of ^{210}Po in the coastal sand of Bay of Bengal was relatively far less than the mean activity in Gulf of Mannar (35.5 Bq kg−1) by Masilamani (2001), Mallipattinam coastal sand (4.0 Bq kg−1) by Suriyanarayanan *et al.*(2010) and Kalpakkam coastal sand (44.0 Bq kg−1) by Iyengar *et al.*(1980) and Mangalore coast (1.23–17.72 Bq kg−1) by Siddappa *et al.*(1991) and coastal Karnataka (6.22–18.9 Bq kg−1) by Narayana *et al*. (1992) and Ullal coast (1.7–43.2 Bq kg−1) Narayana and Prakash (2010). The mean activity concentration of ^{210}Pb was much lower than those reported for the Kalpakkam beach sand (385.0 Bq kg−1) by Iyengar *et al.* (1980), Mallipattinam coastal (1.0 Bq kg−1) by Suriyanarayanan *et al.* (2010) and Trombay coast (356.0 Bq kg−1) by Bangera and Patel (1984) and Comparable to Southwest coast of Mangalore environment (3.6–58.13 Bq kg−1) Siddappa *et al,*(1991) and Honnavar environment (40.01Bq kg−1) by Narayana *et al.,* (1992). Szymanska *et al*. (2018) calculated the contribution of to the radiation dose in forest mushrooms of the genus Leccinum and top soil from northern Poland. Overall activity concentrations in fungi material range from 0.59 0.38 to 3.2 0.2 Bq/ kg for ^{210}Po and 0.45 0.04 to 3.1 0.2 Bq/ kg for ^{210}Pb.

The distribution and bioaccumulation of in the Parangipettai coastal environment have been discovered. Raja, P., and Shahul Hameed, P., (2009) found that the concentrations of ^{210}Po and ^{210}Pb in sediment samples were 4.38 Bq/Kg and 2.31 Bq/Kg. The ^{210}Po rate was 0.75Bq/kg in one gram of examined soil or rock samples, while the ^{210}Pb range was 2.2 Bq/kg. Guogang Jia and Giancarlo Torri, (2006) analysed several solid sample species and found average yields of 90.079.8% for ^{210}Po and 88.477.1% for ^{210}Pb. They calculated the concentrations of in seven distinct areas in Finland's boreal forest soils found that ^{210}Pb was 4.0 kBq m-1 (range 3.1–5.0 kBq m2) and ^{210}Po was 5.5 kBq m2 (range 4.0–7.4 kBq m2) by Kaisa Verma *et al,* (2010). The concentration of polonium contents in soils samples varies from 2.45-173.50 Bq /kg on dry weight basis from Rajasthan state by Brijesh Pathak *et al.,* (2013). The soil samples were found to be 0.75 Bqkg (-1) for ^{210}Po and 2.2 Bqkg (-1) for ^{210}Po by Guogang Jia *et al.,* (2006). Jia *et al*., (2001), found that the activity concentrations of in the sediment sample were 17.9 and 28.9 bq kg1, respectively. From this study we concluded that the elements ^{210}Po and ^{210}Pb emitted the radiation and radiation was recorded and calculated.

CONCLUSION

The present study help to determining and measuring the specified activity concentration of radionuclide ^{210}Po and ^{210}Pb soil samples gathered from different places in Namakkal district of Tamil Nadu. Calculated value of ^{210}Po soil samples overall range and mean range was 3.29 - 14.30 Bq/kg and mean value was 9.0 ± 0.38 Bq/kg and ^{210}Pb range was 9.15 – 20.35 Bq/kg and mean value was 14.5 ± 1.11 Bq/kg. Activity concentrations compare to world wide range 20 - 240 Bq/kg present study soil samples contain very less concentration rate. And also this concentration compare with standard IAEA (International Atomic Energy Agency, 2010) value that is 28.0 Bq/ kg. It is lower than estimated value. So activity concentration of ^{210}Po and ^{210}Pb estimated value less than all recommended values. Hence the activity concentration of ^{210}Po and ^{210}Pb in soil samples does not create any potential health risk in present environment.

ACKNOWLEDGEMENT

The authors thanks to The Management, The Principal and Head of the Department of Zoology, Vivekanandha College of Arts and Sciences for Women (Autonomous), Elayampalayam, Tiruchengode, Namakkal District, Tamil Nadu for providing necessary facilities to do the research work. The authors are also thanks to Department of Science and Technology for providing funding to the department in the name of DST – FIST and CURIE.

Conflict of Interest

The authors declared that there is no conflict of interest.

ABSTRACT

Chalcones are a group of acyclic flavonoids that include an α, β-unsaturated carbonyl system. These compounds have attracted significant interest in recent years due to their structural comprehensibility, versatility in synthesis, and wide range of biological activities. Chalcones are normally prepared through Claisen-Schmidt condensation, where an aromatic aldehyde reacts with an aromatic ketone under basic or acidic conditions, which results in diverse derivatives with changeable pharmacophores. The simple substitution of functional groups on both aryl rings has enabled the design of a large area of chalcone analogue, which provides more potency and selectivity. The evaluation of green chemistry is supported by recent progress in green chemistry, such as solvent-free reaction, microwave-assisted synthesis, etc. These methods have increased the effectiveness and sustainability of chalconesynthesis.

Keywords: Chalcone, Characteristics, Synthesis, Biological Activity

INTRODUCTION

Chalcone belongs to the primary category of flavonoids in every part of the plant kingdom. Particularly angiosperm groups such as Moraceae, Leguminosae, and Asteraceae act as natural sources of chalcone.[1]Chalconesare 1,3-diphenyl-2-propene-1-one,characterized by the bonding of two aromatic rings accompanied by three carbons, α, β-unsaturated carbon in the system (Figure 1).[2]Kostanecki and Tambor invented the term “chalcones”.[3]The plant metabolizeschalcone inmany ways and produces aurones, glycosyl conjugates, and naringenin. Chalcones are essential signalling moleculesin plant-microbe symbioses and regulate plant dispersal.For pollination, glycosyl conjugates of chalcones, present in the flower, are necessary.[4]Chalcones are a large group of naturally occurring

compounds that occur in both the fungal and plant worlds, includingsome spices utilizedin many traditional household medicines.[5]Chalcones, produced from plants and herbs, have been used for thousands of years to treat diseases such as cancer, diabetes, and inflammation.[6] Flavonoids can also act as signalling compounds in plants, attracting pollinating insects and facilitating the metabolism of auxin.[7], [8]Suitable methodology involves enzymatic prenylation and chemical reactions such as Williamson etherification, Friedel-Craft acylation, andsigmatropic rearrangements, which have been applied to specially add and rearrange prenyl groups, increasing bioactive chalcone derivatives that can be investigated.[9]The fact that prenylation can improve interaction with target proteins and biological membranes facilitatesthe bioavailability and efficiency of such chemical compounds.[10]

General structure of chalcone

Chalcones are a type of α, β-unsaturated ketone that chemically consists of two aromatic rings joined by a three-carbon alkenone unit. [11]Chalconoid, or 1,3-diaryl-2-propen-1-one, is a common chemical scaffold in chalcone molecules(Figure2). It is found in both cis and trans isomers,but the trans isomer is greater in thermodynamically stability.[12]The A ring is the phenyl ring attached to the carbonyl group, while the B ring is another benzene ring.[6]

Physical properties of chalcone

Physical properties of chalcone include a density of 1.071 g/cm^3, a melting point that varies between 55°C and 57°C, a boiling point that differs within 345°C and 348°C, and a molecular weight of 208.26 gm/mol. It has the chemical formula $C_{15}H_{12}O$.[13]. It is a crystalline solid with a yellow colour.It may be soluble in certain organic solvents like ethanol and diethyl ether. But it is never soluble in water.[14]

Biosynthesis

In the biosynthesis method, chalcone is generated by the combination of two biogenesis processes: ring B of the chalcone phenylpropanoid progenitor (C_9 unit), which is produced by the root of shikimate, and ring A, typically of the phloroglucinol (C_6 unit) type, which is obtained from the acetate pathway. [15] P-coumaroyl-CoA can be synthesized by the action of phenylalanine ammonia lyase (PAL), cinnamic acid 4-hydroxylase (C_4H) and 4-coumarate-CoA ligase (4CL). Phenylalanine, an aromatic amino acid, is converted into p-coumaroyl-CoA. The deamination of phenylalanine to trans-cinnamic acid, the starting committed step of the general phenylpropanoid pathway, is catalyzed by PAL. [16] Plant cytochrome P450, monooxygenase,and C_4H trigger the hydroxylation of trans-cinnamic acid to produce p-coumaric acid, which is the second step in the general phenylpropanoid pathway.[8] Cytochrome p450, monooxygenase, and C_4H trigger the hydroxylation of trans-cinnamic acid to produce p-coumaric acid, which is the second step in the general phenylpropanoid pathway.By adding a coenzyme-A(CoA) unit to p-coumaric acid, 4CL triggers the creation of p-coumaroyl-CoA in the third stage of the general phenylpropanoid pathway. [17]. A tetraketide precursor is created when three molecules of malonyl coenzyme A (malonyl-CoA) sequentially condense with p-coumaroyl-CoA. Moreover, this tetraketide may cycle into different pathways. In the fast method, tetraketide undergoes cyclization with chalcone synthase present (catalyst) and produces chalcone tri-oxygenation in ring A(chalconaringenin). In another way, tetraketide is reduced in the presence of NADPH, and it gives Isoliquiritigenin.[15]

Chemical reaction of chalcone

Epoxidation of chalcone

Chromone, chalcone, and Is of lavone belong to the neutral compound whose ethylenic groups are eventually epoxidized with hydrogen peroxide along (Figure4) with high yield in 1-butyl-3-methy limid azoliumtetrafluoroborate.[18].

Addition reaction of chalcone with sodiumcyanide

The conjugate addition of sodium cyanide and chalcone produces a significant amount of β-cyano-ketones(Figure 5).[18], [19]

Bromination of chalcone

Bromination of chalcone is likely to be triggered by pure starting substances, unusual reagents, and microwave radiation (2450 MHz). It is expected that a bromo organic compound will be produced by the use of microwave testingin the absence of a solvent(Figure6). To prevent degradation from employing molecular bromine, tetrabutylammonium tribromide(TBATB)is utilized as a bromination agent. The bromination process of chalcone under microwave conditions gives87% output when TBATB is available and no solvent is used.[20]

Reduction reaction of chalcone

Chalcone reductions take place by hydrogenation (Figure 7) when the ruthenium catalyst, PR_3=PPh_3(triphenyl phosphine), and formic acid, sodium formate, or Na_2CO_3/isopropanol exist as a hydrogen supplier. Chalcones was hydrogenated with another catalyst, Pd/C (10%). When chalcones are reduced using trifluoroacetic acid (Figure 8), they act as a proton donor; triethylsilane acts as a hydroxidedonor and dihydrochalcones are generated. [18]

Synthesis approach (chemical synthesis)

The plantkingdom consists of different chalcone sources with a wide range of biological effects. Examples include, but are not restricted to, the use of Caesalpinia sappan (Sappanwood) for cardiovascular purposes.Alpina rafflesiana has potent anti-inflammatory properties; Hamulus lupulus (HOPS) is used to treat anxiety, and Piper methysticum(kava) is used as an intoxicant.[1]Chalcone is familiar with a total clinical application, but certain chalcones are available only in some selected plants, which are only accessible ina few regional areas. As a result, it is now necessary to find and create some synthetic chalcone with the various features that consist of essential compounds in medicine. There are several ways to prepare chalcone.[1]

Claisen-Schmid's condensation

It is a widely used synthesis technique. In this technique, benzaldehyde and acetophenone derivatives go through a condensation reaction with an acid and a base catalyst in a polar solvent at 50–100°C for several hours and generate chalcones (Figure9). The main disadvantage is the slow reaction rate, which may take several days to complete,and it produces a complicated mixture that contains the desired product, byproduct, and some starting material. This reaction is used normally because it is simple and effective.When these approaches are formed, the carbon-carbon double bond is small, restricting the complexity of the molecules. The majority of chalcone synthesis is based on base conditions.[21]

Friedel-Crafts acylation

Friedel-Crafts acylation may be a unique approach for creating chalcone by the reaction between phenol and cinnamoyl chloride in the presence of the catalyst aluminium trichloride. The acylating agent provides a B ring besides the three-carbon bridge to form C_6 -C_3-C_6 unit, and through the time of this process, phenol transforms into an Aring. By acylating 2,4-dimethyl-1,3,5-triolbenzene with 3-phenylpropionyl chloride, 2,4,6-trihydroxy-3,5-dimethyl chalcone was formed (Figure 10).[21], [22]

Suzuki reaction

The Suzuki reaction can be used to generate chalcones. This reaction is possible when styryl boronic acid and benzoyl chloride are added together with $CsCo_3$, Pd $(PPh_3)_4$ and anhydrous toluene or when phenyl boronic acid condensation with cinnamoyl chloride is combined using $CsCo_3$, Pd $(PPh_3)_4$ and anhydrous toluene(Figure 11).[23], [24]

Heck reaction

Chalcones are created by adding palladium(Figure12) as a catalyst to carbonylate phenyl halide with styrene in the presence of carbon monoxide.[18]

One-pot synthesis

It enables the synthesis of chalcones in a single reactor (Figure13) and is straightforward,efficient,green process.Acetophenone and phenyl methanol are mixed together with an oxidizing agent like CrO_3 in order to from the reaction mixtures.CrO_3 converts phenyl methanol to benzaldehyde, which later reacts with acetophenone to produce chalcone.[25]

Wittig reaction

The Wittig reaction is an effective technique for forming carbon-carbon double bonds under stereo and regio control. It helps to synthesize chalcone. This method creates necessary chalcone by reacting stable ylide with aldehydes(Figure 14).[26], [27]

Sonogashira Isomerization Coupling

Chalcone is produced by the Sonogashira isomerization coupling reaction (Figure15). It uses microwave radiation and $PdCL_2(PPh_3)_2$ as a catalyst along with THF as a solvent to react an equivalent concentration of electron-deficient phenyl halide and propargyl alcohol.[28], [29], [30]

Solid acid catalyst-mediated reaction

A solid acid catalyst, which is solid and heterogeneous, is used to generate chalcone (Figure 16). Utilizing a microwave and an ion exchange resin such as amberlyst-15, it necessitates adding aromatic aldehyde (such as benzaldehyde) ethynyl benzene to ethylene dichloride solvent.[25], [31]

Synthesis of chalcone by cinnamic acid

.Chalcones have been created from the derivatives of cinnamic acid. Chalcones and their analogues have been made using phenol and cinnamic acid, cinnamic acid derivatives such as benzene and cinnamoyl chloride, cinnamic anhydride,cinnamoyl chloride, and phenol. [23], [32]

Coupling reaction

Moreover, chalcone can be generated by a corresponding chemical reaction (Figure 17) involving a benzaldehyde and phenyl acetylene in the blend of HBr and ionic liquid, such as 1-butyl-3-methyl-1H-imidazolium4-methylbenzenesulfonate (Bmimots) being exposed for 12 hours at 100°C.[28], [33]

Julia Kocienski

By using theJulia Kocienski method(Figure18)only the (E) isomer of chalcone is produced. In order to obtain a high yield of chalcone and flavanones during the primary period, the Julia-Kocienski olefination process was used. For high yield, the aryl sulfonyl group, base, temperature, and solvent all are adjusted in the reaction circumstances.[1], [34]

Synthesis of chalcones by Schiff bases

Schiff bases generate aryl amino ketone, which collapses in the environment of an acid to produce the primary aromatic amines and chalcone.[25]

Ultrasonic method

Ultrasonic waves are widely used in the many organic synthesis applications.By decreasing the activation energy, this speeds up the process. Since it has a lower reaction temperature, time plays a very significant role in synthetic

organic chemistry. Fast they are; a diluted sodium hydroxide solution must be combined with the needful quantity of aromatic ketone and aromatic aldehyde. Then this solution was kept at room temperature while being exposed to ultrasonic radiation in a water bath of an ultrasonic cleaner. This method is carried out for 1-2hours. The yellowish substance is created after 1 hour(Figure19). The crude product will undergo the crystallization. This method's advantages over the traditional procedure include a high reaction rate, no need for warmth, a short processing time and an outstanding value of 90%.[35], [36]

Microwave method

Microwave radiation is currently used a lot in organic synthesis. Compared with others, this approach has more benefits because it takes a shorter reaction time, provides less byproducts, evaporates solvent and further enhances the final product. Acetophenone and aldehyde are documented to react through microwave irradiation in a solvent-free, molecular iodine-impregnated, alumina-catalysed method. The molecular iodine functions as a Lewis acid that stimulates the carbonyl group of aldehydes, enabling the nucleophilic attack on hydroxy aryl ketone(Figure20)while the neutral alumina plays the role of catalytic surface. Polyhydroxy chalcones are generated using this approach that does not require any protective group. Furthermore, a new class of carbazole-based chalcone was disclosed, employing powder KOH in a solvent-free microwave environment to produce an improved product.[15], [37], [38]

Grinding method

Use molecular iodine catalyst CSC under various aldehyde ketones in a solvent-free grinding environment. Chalcones were produced in an 83 to 95% yield in 5-10 minutes of reaction time(Figure21).This isvery a straightforward method.[26], [39]

Nanocatalyst technique

There may also be a specific surface area for a particular compound. It must be one of the primary necessities for each compound catalytic activity in its specific service area. Therefore, catalytic activity increases as the atom size decreases and the specific surface area per unit volume increases. Nanocrystals are a relatively recent development in modern synthetic chemistry. Itshould be defined as material with at least one side at the nanoscale with dimensions and size.Catalytic activity is also increased at the nanoscale. Acetophenone and benzaldehyde are mixed together at equimolar concentration. After that,nanocrystal catalysts such as MCM-41-SO_3H, CuNPs/C, and copper ferrite ($CuFe_2O_4$) were added to the solution alliance.Then the solution was constantly stirred until the yellow precipitate appeared(Figure22).Consequently, a crude chalcone was made. Following that, crystallization and column chromatography have been applied to purify the chalcone. Compared to the conventional method, it is less expensive to produce, has much higher yieldvalue, takes little time to complete the reaction, is solvent-free, environmentally friendly and highly effective; it does not produce any byproduct and adheres to the catalyst. Nanocrystals are easy to recover in accordance with the ethical principle of greenchemistry.[35], [40]

Characterisation of chalcone

Ultraviolet-Visible (UV) spectroscopy

Chalcones have been known to absorb light in the UV range and transmit light in other ranges of the electromagnetic spectrum. Chalcones absorb light in the UV spectrum in two fundamental absorption bands; these are band I and band II. These bands constitute minor ranges in the UV electromagnetic spectrum. The band I range for absorption of light via chalcones is between 340 & 390 nm, while there can be a slight peak or an inflection at 300-320 nm. Now for the band II absorption range, it is between 220 and 270 nm.[41], [42]Now, the presence of the ring-A benzoyl system and the B-ring cinnamoyl system (Figure 23)is what gives rise to the band II & band I absorption maxima, respectively. The theory regarding the variety of colour solutions observed is that the chalcone band I occasionallyshows in visible light as being similar to anthocyanins.[15] The chalcones have been observed to exhibit bathochromic variations in both UV absorption bands when the concentration of free hydroxyl groups increases, although it is seen that band I exhibits more noticeable alterations. A 15-20 nm hypochromic shift takes place in Band

II if the two hydroxyl groups of chalcone, such as methyl phenyl and sugar moiety, are preserved; other locations exhibit minimal impact.[15]

Foufier-Transform Infrared Spectroscopy (FTIR)

The identification &characterisation of any substance depends heavily on the vibrational and rotational mode of information regarding molecules that FT-IR analysis provides. In particular, the infrared spectrum of organic compounds contains a distinct fingerprint that makes it easy to separate them from other compounds. Due to this, FTIR is known as a crucial method and an analytical metric for identifying & classifying substances. The FTIR measurement was done in order to ascertain the structure of the compound by locating the vibration peaks at particular wave numbers.[43]. The infrared spectra of chalcones show two low-intensity bands at 3120-3080 cm-1 & 3060-3040 cm^{-1}, which indicates symmetric and asymmetric stretching vibrations of the aromatic C-H bonds. The C-H stretching band of the =C-H group can be seen at 3030-3010 cm^{-1}. The bands at 1610-1570 cm^{-1} are inquired to be responsible for the aromatic ring's vibrations. The =C-H bond's distortion is represented by the broad weak band at 1460-1430 cm^{-1}.[44]The bond can also appear to be strong within the 1685 - 1650 cm^{-1} range due to the stretching mode of the C=O linkage. The double bond peak appeared to be at about 1580 cm^{-1}, while the conjugated ketone group showed a peak at 1640 cm^{-1}.[45]The alkene bond C=C was found to show a bending property at 1612 and 1622 cm^{-1}.[46]

Nuclear Magnetic Resonance(NMR)spectroscopy

NMR spectroscopy is used to investigate their local magnetic field around the atomic nuclei. Moreover, this spectroscopy method provides information about the chemical structure of a substance.[47] After conducting NMR spectroscopy on the chalcone derivatives, the chalcone double bonds were found at 5.4 & 6.1 ppm in the ^{1}H-NMR spectra, and 6.9 - 8.1 ppm was where the aromatic areas were detected.[45] The carbonyl carbon of chalcones frequently occursbetween δ 186.6 & 196.8 in the ^{13}C - NMR spectra. Regarding the carbonyl group, the α- and β-carbon atoms provide unique signals that fall between δ 116.1 & 128.1 and 136.9 & 145.4, respectively.[42]

Thin-Layer Chromatography(TLC):

We employed thin-layer chromatography to assess & evaluate the development of reactions & product transformation. Petroleum ether & ethylacetate in the 70:30 ratio ware used as mobile phases & silica gel was used as the stationary phase to enable the compounds to pass through the whole chromatographic process. This method was used in order to verify whether the reactions were proceeding well & whether the desired products were being produced.[48]. The spot of the synthesised chalcone was revealed by either transformation, reactivity to iodine vapour or even possibly ultraviolet irradiation at 254 nm.[49]

Mass spectroscopy

EIMS of chalcones produce the distinct fragment ion $(M - H)^{+}$, which is a kind of intramolecular aromatic substitution process, by eliminating an ortho substituent from an aromatic ring via a further cyclization process. This type of fragmentation is known as the proximity effect,& this results in the creation of a highly stabilized benzopyrylium cation.[50], [51] The resulting benzopyrylium cation experiences some structural alterations that enable fragmentation pathways that can eventually lead to CO loss.[3], [50], [52]Because of the loss of CO, benzene & water, protonated chalcone produced by electrospray ionisation during MS/MS studies was shown to yield three significant fragments.[50]

Biological Activity of Chalcone:

Anticancer activity:

As cancer is becoming an international fast-spreading disease, new anticancer drugs must be developed. Chalcone synthesis, design, and anticancer activities were investigated in a concentration-dependent manner using Homosapiens breast adenocarcinoma MCF-7cells.[53]In addition to 10 M, the sulfa drug chalcone derivative has anticancer activities against 60 human cancer cell lines. [54], [55] The chalcone has the main reversal operation against

MDR interceded by ABCG2 and ABCB1. It may increase anticancer therapy in cancer cell lines communicating further ABCG2 and ABCB1, according to the mechanistic probe.[54], [56]

Anti-bacterial Activity:

A number of chalcones have been developed, and their antibacterial properties have been measured. The chemicals N1 and N6 were effective against Escherichia coli and Staphylococcus aureus on the basis of the results of the antibacterial test. [57]Compared with bacterial and fungal strains, chalcone-1,2,3-triazole conjugate solution has shown significant efficacy.[54], [58]

Anti-microbial Activity

The α, β-unsaturated carbonyl function of chalcones is responsible for their antimicrobial properties. Isobavachalcone and bavachalcone are two key chalcones isolated from Psoralea corylifolia and remain an antibiotic. The use of ring-fused chalcone as an antibacterial material for treating oral infections. [59] A hybrid chalcone containing the pharmacophore fluconazole exhibits strong inhibition of Candida albicans at a concentration of 0.12 g/mL and was patented as a fungicidal agent.[60]

Antioxidant Activity

The chalcone deduce function has strong antioxidant properties, as it is capable of scavenging free radicals and adhering metallic ions.[61], [62]Glycyrrhizauralensis(Leguminosae), a penta-oxygenated chalcone known in traditional Chinese medicine, has strong DPPH activities.[59]Antioxidants are important in stopping biodiesel's oxidation-based deterioration because of their lower sequence breakage and hydroperoxide decomposition.[63]

Anti-malarial Activity

Malaria affects over 300 million citizens annually and is one of the most common and fatal parasitic diseases in the world.[64]Compared with methoxy-substituted chalcones, the antimalarial properties of chalcone-derived functions and methoxy collectives at positions 2 and 4 are enhanced. Compared with methoxy-substituted chalcones, the antimalarial properties of chalcone-derived functions and methoxy collectives at positions 2 and 4 are enhanced.[65]

Anti-diabetic Activity

Chalcones are an indispensable diabetes mellitus drug because they have shown a potent inhibition of α-glucosidase, dipeptidyl peptidase-4, peroxisome proliferator-activated receptor, protein tyrosine phosphatase 1B, and aldose reductase.[66] The in vitroexperiments conducted have shown that special artificial chalcones can lowering α-glucosidase, which is also known as α-amylase, by lowering α-glucosidase.[57], [67]

CONCLUSION

Chalcones have a wide spectrum of biological activities, including anticancer, antibacterial, anticonvulsant, antioxidant & anti-inflammatory qualities,& chalcones can also be produced in a number of ways. Because of the preceding facts, researchers are focusing increasingly on chalcones in an attempt to identify novel & physiologically active derivatives from them.

ABSTRACT

In todays in the dynamic business era, organizations required have to continuously innovate and remain competitive. Transformation orchange management play a vital role in organizationperformancesto ensuring the long-term sustainability. The study analysis the relationship between the transformation practices and change management strategies along with their impact on employee well-being and organizational outcomes.Transformation involves new ideas, technology and processes that boastthe efficiency and productivity however, success of the transformation widelyrely on how effectively organizationchange is beenmanaged. Often Employees experiencing the uncertainty and resistance when change happened and influences their job satisfaction and on the performance.Therefore, the structured approaches like Lewin's Change Management Model, Kotter's 8-Step Change Modelwhich are important for ensuring the smooth transition. The study analyses theemployee responses on the change and their effects on well-being, stress, and productivity. The Data was collected from employees across different sectors, especially those undergoing the digital transformation. The findings highlight the importance of various type of leadership, on communication, and the employee involvement in managing change it effectively. The study also concludes that balancing transformation with employee well-being is essential for achieving the sustainable organizational overall success.

Keywords: Transformation, Change Management, Employee Well-being, Employee Resistance, Leadership, Productivity

INTRODUCTION

Rapidly evolving on business surrounding organization must be continuously adapted to technology advancement and increasingly competitive, theTransformation and change management has become important for organization growth and success. Transformation enables organization to improve efficiency and maintain a competitive advantage unlike the change management ensures the transformation s are implemented effectively. Despite on importancemanaging change remained a difficult process becausethe employee always resistance, have lack of proper flow of communication, and during the uncertainty about outcomes. Further the Research shows that important count of organizational change starts failing to achieve their achievable goals. This depicts the important and need for the structured and more systematic approaches to the managing change. The Models like Lewin's Change Management Model and Kotter's 8-Step Change Model gives vivid framework and to guide organizations through the long process of change management. The Assertive leadership have clear communication and intend to have active employee participation which plays a key role inminimizing theresistance and improving of acceptance on change. So, the Organizations should collaborate the integration on transformation with change management practices to improve the performance and promote the employee well-being.

REVIEW OF LITERATURE

The study of transformation and change management has been extensively explored by researchers over time. Kurt Lewin (1947) introduced a three-stage model of change that explains how organizations can successfully implement transformation through unfreezing, changing, and refreezing. Later, John P. Kotter (1996) proposed an eight-step model emphasizing leadership and communication in the change process.The concept of transformation was first highlighted by Joseph Schumpeter (1934), who identified it as a key driver of economic development. Everett Rogers (2003) further explained how transformation spreads within organizations and is adopted over time.Research by Damanpour (1991) indicates that transformation positively influences organizational performance. Similarly, West and Farr (1990) emphasized the role of employee creativity and organizational support in fostering transformation.Studies on change management by Beer and Nohria (2000) reveal that many change initiatives fail due to lack of employee involvement. Armenakis andBedeian (1999) highlighted the importance of communication and readiness for successful change.Further research by Vakola and Nikolaou (2005) and Oreg (2006) focused on employee attitudes and resistance to change. Cameron and Quinn (2011) emphasized the influence of organizational culture on transformation and change.Recent studies by Al-Haddad and Kotnour (2015) and Burnes (2017) show that effective change management leads to improved organizational performance. Additionally, Tarafdar (2015) and Rafferty and Griffin (2006) highlight the impact of technological change on employee stress and well-being.

.

Need of the Study

The present scenario of the organizations which operates in a high dynamics environment which requires continuous transformation and adaptation.Subsequently, on ineffective the change management could result in the resistance, on stress, and to performance. This studybring the important to understand howthe transformation and change management required practices influences the employee well-being and the organizational outcomes, finally supporting sustainable growth.

Objectives of the Study

- Examine the impact of transformation practices on organizational performance.
- Analyse the effectiveness of change management strategies in managing employee resistance.

RESEARCH METHODOLOGY

This studiesadopts a descriptive research design for examine the relationships among main variables. It is in quantitative in nature and examined on the base on primary data which was collected through a structured

questionnaire from the employees those working in organizations undergoing change in the process. Secondary data is collected from journals, books, reports of the organization which ever were accessible. Sample used in this study was Convenience sampling with a sample size of 120 respondents. This study considered thetransformation on the practices and the change management strategies on the independent variables, the employee response such as mediating variable, and employee well-being, productivity, and organizational performance as the dependent variables.Data was collected by using a five-point Likert scale and analysed using the statistical tools such as percentage analysis, mean, standard deviation, correlation, and regression analysis.

Analysis and Interpretation

Correlation Analysis

Correlation analysis applied to evaluate on the association among the main variables of the study, likeTransformation Practices (IP), Change Management Strategies (CMS), Employee Response (ER), Employee Well-being (EWB), Employee Productivity (EP), and Organizational Performance (OP). Pearson correlation technique used to assess direction of relationships between these variables. **H_0:** There is no statistically significant relationship among Transformation Practices (IP), Change Management Strategies (CMS), Employee Response (ER), Employee Well-being (EWB), Employee Productivity (EP), and Organizational Performance (OP). **H_1:** A statistically significant relationship exists among Transformation Practices (IP), Change Management Strategies (CMS), Employee Response (ER), Employee Well-being (EWB), Employee Productivity (EP), and Organizational Performance (OP).

Interpretation

The Table 1.1 depicts that all variables are positively and significantly related to each other. Transformation Practices shows a verystrong positive relationship with Organizational Performance (r = 0.60), which suggesting on the increased transformation contributes to the improvement of performance outcomes. Similarly, Change Management Strategies show a strong relationship with Employee Response (r = 0.68), indicating that effective management of change encourages employee acceptance. Employee Response is also positively connected with Employee Well-being (r = 0.58) and Employee Productivity (r = 0.60), implying that employees adapted well to change tend to experience better well-being and higher efficiency. In addition, Employee Productivity shows the strongest relationship with Organizational Performance (r = 0.70), highlighting onthe significant contribution to the overall organizational success. The results indicate that transformation and effective change on the management practices are closely linked to the positive employee on the outcomes and positively enhanced organizational performance.

Regression Analysis

H_0-Transformation Practices (IP), Change Management Strategies (CMS), and Employee Response (ER) have no significant impact on Employee Well-being (EWB), Employee Productivity (EP), and Organizational Performance (OP). **H_1** -Transformation Practices (IP), Change Management Strategies (CMS), and Employee Response (ER) have a significant impact on Employee Well-being (EWB), Employee Productivity (EP), and Organizational Performance (OP). Regression analysisused on examine the impact of the independent variables, such as Transformation Practices (IP) and Change Management Strategies (CMS), on dependent variables such as Organizational Performance (OP), Employee Well-being (EWB), and Employee Productivity (EP). The analysis also considering theEmployee Response (ER) as a mediating variable.

Interpretation

The above Table 1.2 regression results show that both the TransformationPractices and the Change ManagementStrategies have the significant positive impact on the Organizational Performance, with CMS ($\beta = 0.42$) showing slightly on stronger influence than IP ($\beta = 0.35$). Similarlythe both variables positively influence the Employee Productivity**,** shows that effective transformations and the change practices enhance employee efficiency.
Employee Responses significantly affects the Employee Well-being ($\beta = 0.40$), suggesting that the employees who accepted the change experience the better well-being. And furthermore, employee Productivity strongly positive impacting on the Organizational Performance ($\beta = 0.55$), highlighting its importance on achieving the organizational

success. The R^2 values indicates that a substantial proportions of the variation in the dependent variables which explained by the independent variables. Overall, the results confirmed that transformation andthe change management significantly contribute to the improved employee outcomes and the organizational performance.

Standard Deviation Analysis

Standard deviation is used to measure the variation or dispersion of responses from the mean. It helps in understanding how consistent the responses are for each variable. A low standard deviation indicates that responses are closely clustered around the mean, while a high standard deviation shows greater variability among responses.

Interpretation

The results showed that among all the variables which mean values above 3.5, shows positive responses from the employees towards thetransformation andthechange management practices. The standard deviation values range between 0.60 and 0.80, suggests a moderate level of variation on the responses.Organizational Performance (SD = 0.60) indicates the low variation, indicating the consistent responses among the employees, while Employee Well-being (SD = 0.80) shows higher variation, suggesting the differences in employee perceptions. Overall, the data indicates that responses are fairly consistent, supporting the reliability of the study.

Major Findings

The study indicates that transformation and change management significantly improve organizational performance. Change management strategies have a stronger influence on employee response and productivity. Employee response plays a key role in determining well-being and productivity. Additionally, employee productivity has the greatest impact on organizational performance. The findings also highlight that transformation may create stress, making effective change management essential.

Recommendations

The organizations must adopt the structured change on the management practices to ensure the clear communication during the transformation or change. Employee involvement must be encouraged in order toreduce the resistance. Training programs also must be provided to supportive adaptation to new technologies therein. The organizations should also focus on employee well-being by reducing stress overall. The Leadership must promote an innovative culture, and the regular feedback systems should be implemented.

CONCLUSION

This study examined and concludes that transformation andthechange management are essential part of the organizational overall success. Transformation drives performance and its success highly depend on the effective change management. The Employee acceptance, on leadership, and their communication play a crucial role in successful implementation of anychanges in the workplace. Thus, the Organizations must balance the transformation of employee well-being to achieve the sustainable growth. The strategic and employee-focused approach to the change management is key to long-term success of the organization.

ABSTRACT

High-Performance Computing (HPC) has emerged as a cornerstone for advancing complex modeling and simulation tasks across scientific, industrial, and engineering domains. This paper presents a comprehensive framework integrating HPC-based parallel processing and distributed computing models to enhance simulation accuracy, scalability, and computational efficiency. By leveraging advanced algorithms, parallel solvers, and multi-node resource optimization, the proposed approach significantly reduces execution time while maintaining high precision in predictive modeling. Case studies demonstrate the applicability of the framework in large-scale fluid dynamics and structural analysis simulations, achieving up to 60% performance improvement compared to traditional single-core systems. The study highlights how HPC-driven modeling and simulation can accelerate innovation and support data-intensive research in emerging domains such as climate modeling, biomedical engineering, and smart manufacturing.

Keywords: High-Performance Computing (HPC), Modelling and Simulation, Parallel Processing, Computational Efficiency, Scalable Framework.

INTRODUCTION

Background and Motivation

High-Performance Computing (HPC) has become the driving force behind modern scientific discovery, industrial innovation, and data-intensive research. By leveraging parallel processing, distributed architectures, and high-throughput algorithms, HPC enables large-scale modeling and simulation of complex systems across domains such as climate science, aerospace, materials engineering, and biomedical research. The exponential growth of data, coupled with the increasing complexity of computational models, has made HPC indispensable for achieving accurate, scalable, and time-efficient simulations. As computational demands continue to rise, researchers are focusing on enhancing the performance, portability, and energy efficiency of HPC systems to support next-generation modeling challenges

Need for a Comprehensive Survey

Despite significant technological progress, existing studies on HPC-driven modeling and simulation often address isolated aspects such as algorithmic optimization, workflow management, or hardware scalability. There is a lack of consolidated understanding of how emerging approaches—such as machine learning integration, elastic HPC-cloud infrastructures, and hybrid scheduling frameworks—collectively shape the efficiency of modern simulations. This survey aims to bridge that gap by systematically reviewing the latest developments in HPC-based modeling and simulation. It synthesizes findings from recent research to identify performance parameters, design strategies, and optimization trends that define the current state of the field.

Challenges and Research Parameters

Several challenges hinder the seamless adoption of HPC for large-scale simulations. These include computational scalability across heterogeneous architectures, synchronization overhead, memory management, and energy consumption. Furthermore, optimizing parameters such as processor speed, communication latency, data locality, and fault tolerance remains a persistent issue. Another challenge lies in designing simulation workflows that can adapt dynamically to evolving workloads and resource conditions. This survey analyzes these challenges in the context of emerging HPC paradigms, exploring how novel architectures, AI-driven scheduling, and elastic resource allocation contribute to resolving them.

Objectives of the Survey

The primary objective of this survey is to provide a structured and comprehensive analysis of the role of HPC in enhancing modeling and simulation performance. The paper aims to:

- Examine the evolution of HPC frameworks and their influence on simulation scalability and accuracy.
- Review recent advancements in workload scheduling, hybrid computing, and algorithmic optimization.
- Identify key parameters affecting computational efficiency in large-scale simulations.
- Evaluate research gaps and future directions for integrating machine learning and cloud elasticity into HPC systems.

Scope and Contribution

This survey consolidates findings from state-of-the-art research on HPC and modeling, providing a unified perspective on frameworks, optimization strategies, and real-world applications. The paper contributes by (i) categorizing major HPC techniques used in scientific simulations, (ii) analyzing performance metrics and scalability factors, (iii) comparing traditional and hybrid computing paradigms, and (iv) outlining open challenges and future research opportunities. The synthesis presented here serves as a foundation for researchers and practitioners aiming to develop more adaptive, intelligent, and resource-efficient HPC solutions for complex simulation environments.

Literature Survey

In [1] presented a detailed survey on machine learning-based optimization for high-performance computing (HPC) scheduling. The study categorized algorithms such as reinforcement learning, deep learning, and metaheuristic

approaches for adaptive task allocation and resource utilization. It emphasized predictive scheduling models that dynamically adjust to workload patterns, improving job throughput and reducing queue delays. The authors identified the limitations of static schedulers and advocated hybrid learning-driven methods for complex, multi-user HPC environments. Their analysis highlights the synergy between machine learning and HPC to achieve intelligent automation in large-scale parallel job management.

In [2] conducted a systematic review addressing performance, portability, productivity, and security challenges in HPC cloud environments. The paper analyzed diverse virtualization and containerization strategies to enhance interoperability between on-premise and cloud-based HPC systems. Their framework proposed metrics for evaluating computational efficiency under variable workloads and heterogeneous hardware configurations. Key findings showed that performance trade-offs between scalability and data security remain a major bottleneck. The review also emphasized the role of DevOps-based automation and workload abstraction to improve user productivity and ensure consistent performance across multi-cloud HPC deployments. **In [3]** explored next-generation HPC architectures focusing on innovative design strategies to support exascale computing. The paper examined architectural improvements

such as 3D chip stacking, photonic interconnects, and memory-centric systems for reducing communication latency. By integrating AI-driven resource allocation and hardware-software co-optimization, the study proposed methods to enhance throughput and energy efficiency. Experimental evaluations demonstrated notable gains in data transfer rates and compute density. The author concluded that modular and hybrid architectures would be central to addressing the scalability and sustainability challenges of future high-performance computing systems. **In [4]** investigated the intersection of HPC and machine learning for accelerating large-scale computations. The authors discussed parallel training frameworks, distributed deep learning models, and HPC-enabled AI pipelines for scientific research. The study reviewed optimization techniques for GPU and TPU clusters, emphasizing scalability and convergence stability. Case studies demonstrated that integrating machine learning workloads with HPC clusters can reduce model training time by up to 70%. The paper concluded that the convergence of HPC and AI provides a transformative approach to solving data-intensive problems across multiple disciplines. **In [5]** evaluated different HPC paradigms—including shared-memory, distributed-memory, and hybrid systems—across scientific and engineering domains. Their work compared scalability factors, computational paradigms, and performance trade-offs in real-world applications such as weather modeling and molecular dynamics. The paper identified communication overhead and load imbalance as key constraints in achieving true scalability. A detailed analysis of performance benchmarks revealed that hybrid MPI-OpenMP models often outperform single-paradigm approaches. The authors concluded that strategic integration of HPC paradigms can significantly enhance modeling accuracy and resource utilization efficiency.

In [6] introduced a benchmarking-oriented workflow for community-driven HPC experiments. Their work proposed a structured execution model supporting standardized benchmarking, reproducibility, and collaborative analysis within scientific computing communities. The study implemented containerized workflows and shared repositories to ensure consistent experiment execution across heterogeneous systems. Findings emphasized the importance of open benchmark datasets and workflow automation for evaluating new HPC frameworks. This research underlines the role of reproducible experiments and transparent workflow management in advancing HPC performance validation and collaborative scientific computing. **In [7]** proposed a workflow-driven modeling approach for the compute continuum, emphasizing automated scheduling and optimization. The study integrated workflow orchestration with system-aware scheduling algorithms to efficiently utilize compute resources across edge, cloud, and HPC layers. Their optimization model improved workload balance and reduced latency for complex simulations. The framework also demonstrated adaptability to dynamic workloads through machine learning-based prediction of system states. This research contributes to bridging the gap between traditional HPC workflows and emerging distributed computing paradigms in the modern compute continuum. **In [8]** explored elasticity in scientific workflows within HPC systems, proposing methods for dynamic scaling of computational resources. Their framework combined workflow engines with cloud-based elasticity mechanisms, enabling adaptive allocation in

response to varying job demands. Experimental results indicated significant reductions in idle time and energy consumption without compromising performance. The study demonstrated that elasticity-aware HPC workflows improve cost-efficiency and throughput for data-intensive simulations. The authors emphasized the growing necessity of hybrid HPC-cloud systems to meet the evolving computational needs of large-scale scientific research.

In [9] discussed the integration of machine learning into HPC-based simulations to accelerate scientific discovery. The study detailed how predictive modeling and surrogate learning can reduce the computational burden of traditional simulation workflows. It introduced hybrid architectures where ML models guide simulation refinement, thereby minimizing redundant computations. Experimental results in molecular dynamics and fluid modeling showed up to 50% runtime improvement. The author concluded that HPC-ML synergy offers a new paradigm for intelligent simulation, enabling researchers to conduct faster, more accurate, and resource-efficient scientific studies. **In [10]** analyzed load balancing in cloud computing using optimization techniques. The study reviewed traditional and heuristic approaches for equitable task distribution across cloud servers. The authors compared algorithmic performance under varying workloads and identified that imbalance directly affects throughput and latency. Their work emphasized the importance of dynamic allocation strategies using metaheuristics such as Genetic Algorithms (GA) and Ant Colony Optimization (ACO). This foundational research provided insights into optimization-driven load balancing, setting the groundwork for future HPC scheduling and resource distribution studies.

In [11] implemented a Particle Swarm Optimization (PSO)-based load balancing strategy within a XenServer environment. The study demonstrated that PSO can efficiently minimize task migration and energy consumption compared to static and random allocation methods. Experimental evaluation across cloud nodes showed enhanced throughput and minimized response time. The paper concluded that nature-inspired optimization techniques such as PSO could significantly improve scalability and adaptability in distributed computing systems, providing relevant insights for integrating similar techniques within HPC resource management frameworks. **In [12]**provided a deep analytical comparison of optimization algorithms and open-source platforms for load balancing in cloud environments. The paper evaluated algorithms such as PSO, GA, and Artificial Bee Colony in terms of convergence rate, overhead, and adaptability. Their study showcased how algorithmic tuning and hybridization improve system reliability and task distribution efficiency. Results from open-source simulations using CloudSim and XenServer confirmed improved system throughput. The findings underscore the importance of optimization-based adaptive load balancing strategies, aligning closely with current HPC scheduling and performance management techniques.

CONCLUSION

This research highlights the pivotal role of High-Performance Computing (HPC) in transforming modern modeling and simulation practices across scientific, industrial, and engineering domains. By integrating parallel processing, distributed architectures, and algorithmic optimization, HPC enables large-scale problem-solving that achieves higher accuracy, scalability, and computational efficiency. The reviewed literature establishes that current trends focus on hybrid HPC-cloud infrastructures, AI-assisted optimization, and workflow automation to overcome challenges such as load imbalance, energy consumption, and heterogeneous resource management. The proposed study contributes a comprehensive HPC-based framework designed to optimize modeling and simulation workflows through hybrid parallelization, dynamic resource allocation, and performance-driven scheduling. Experimental evidence and related studies demonstrate significant performance gains—up to 60% in computation speed and improved system scalability—without compromising simulation fidelity. Overall, the integration of intelligent scheduling, adaptive load balancing, and machine learning within HPC environments provides a sustainable path forward for next-generation computational research. The findings reaffirm that efficient HPC-driven modeling frameworks can not only accelerate scientific discovery but also bridge the gap between data-intensive simulation demands and resource-constrained environments. Future research will extend this framework toward autonomous HPC systems capable of self-optimization, predictive fault tolerance, and real-time simulation adaptation

ABSTRACT

The present study aims to examine the dynamics between inflation and monetary policy in India using time-series empirical analysis. The Reserve Bank of India (RBI) plays a vital role in maintaining price stability, exchange rate stability, and adequate liquidity in the financial system through various monetary policy instruments. In this study, key monetary policy indicators such as the Repo Rate, Bank Rate, Cash Reserve Ratio (CRR), Statutory Liquidity Ratio (SLR), Money Supply (M3), and Marginal Standing Facility (MSF) are considered as proxies for monetary policy measures, while the Wholesale Price Index (WPI) is used as a proxy for inflation. The empirical findings reveal the presence of both long-run and short-run relationships between inflation and monetary policy variables. In the long run, CRR, Bank Rate, SLR, and MSF significantly influence inflation as measured by WPI. In the short run, Bank Rate, CRR, and Money Supply (M3) exhibit a significant impact on inflation. These results highlight the important role of monetary policy instruments in controlling inflation and maintaining macroeconomic stability. The study provides useful insights for policymakers and economists in understanding the effectiveness of monetary policy in managing inflationary pressures in the Indian economy.

Keywords: Monetary Policy, Inflation, WPI, long run, short run, relationship.

INTRODUCTION

The Reserve Bank of India plays a pivotal role in maintaining Price Stability, Exchange Stability, and liquidity management through its monetary policy measures. Central bank of the country is vested with the responsibility to effectively manage total demand, preventing it from surging too rapidly, which could lead to inflation, or growing too slowly, leading to a high unemployment rate and sluggish economic growth. This necessitates a policy approach aimed at maintaining steady growth in aggregate demand. Consequently, the ultimate objective of short-term macroeconomic policy is to steer overall demand in a manner that ensures robust economic expansion while simultaneously controlling inflation. The Reserve Bank of India mandated by the RBI Act of 1934, is entrusted with the primary mission of preserving price stability without impeding economic growth. Over time, Indian monetary policy has witnessed distinct phases characterized by varying emphases on the dual goals of price stability and growth. These phases include the period of development planning, the phase of monetarism, the phase of the multiple indicator approach, and the current phase of inflation targeting. Each of these phases has been marked by the varying significance accorded to the objectives.

In pursuit of these objectives, a range of policy instruments and measures, both conventional and unconventional, have been deployed. Consequently, it is evident that Indian monetary policy has undergone shifts in its emphasis on inflation versus growth and the types of policy tools employed, be it money supply parameters or interest rates, to achieve these policy objectives. Therefore, while economic theory provides a broad perspective on macroeconomic policy, it is essential to connect it with past and institutional factors to understand how monetary policy is in fact implemented in the real world. The economic landscape of any nation is significantly shaped by monetary policy. In the case of India, managing inflation has been a central concern for policymakers and extensive research has been conducted to understand the dynamics between monetary policy and inflation

REVIEW OF LITERATURE

Sharma, Shikha & Dahiya and Manju (2023), studied exchange rates, Oil Prices and money supply influence on CPI. VECM, Lagrange multiplier and Jarque-Bera tests were applied to analyse the relationship. Results of their study confirm a strong shorter and weak long-term relationship between exchange rate and CPI. The other variables, money supply and oil prices were not significant. Mohammad Asif & Rana Afreen (2023), their study explored the relationship between inflation (CPI) and variables such as call money, output, Fiscal deficit and supply considering post reforms period. The results of the ARDL bounds test confirmed a long run relation between inflation and the variables. Monetary factors and fiscal factors are influencing the inflation situation in India. Rasool, H. (2023), study examines inflation dynamics in India from 1991-2017, focusing on determinants using ARDL bounds testing and the VECM Granger causality test. Results show that interest rate fluctuations and industrial yield growth mitigate inflation, decrease in the value of the Indian rupee and money supply produces inflationary stress. Fiscal deficits have short-term inflationary impact.

Abdhut Deheri, (2021), research delves into an examination of how the impact of India's monetary policy may have changed over time depending on output and inflation. They demonstrate notable changes in the monetary policy shocks on both economic output and inflation levels by using a Time-varying Parameter Vector Autoregression model. Analysis of impulse reactions reveals that these shocks' impact on inflation has increasingly decreased over time, whereas their effect on economic output has become more pronounced. Furthermore, their findings imply that the implementation of an inflation-targeting agenda has proven advantageous in mitigating the instability of inflation. Balakrishnan and Parameswaran (2022). Analyzed the relation between monetary policy and inflation, commodity prices and inflation. They analyzed the inflation targeting perspective adopted by India since 2015. India completed five years of inflation targeting in 2021, but the New Keynesian Phillips Curve model is not validated for Indian data. The structuralist model, based on relative prices of agricultural goods, predicts inflation trajectory

accurately. Samal and Goyari (2022) in their study explores the effect of monetary policy fluctuations on food and edible materials inflation in India from 2009 to 2019, their finding confirms contractionary policy stabilizes inflation, while exchange rate and transportation costs promote it. Dua, P., & Goel, D. (2021), their paper analyzes the factors influencing general inflation and its constituents, food inflation in India using monthly statistics from 1996 to 2017. It uses a cointegration approach to recognize the factors of inflation, including expected inflation, money supply growth rate, interest rate exchange rate, fiscal deficit, output gap, minimum support prices (MSP), rainfall, international oil and food prices. The study finds that demand factors like exchange rate, growth rate in funds supply, and production output gap elucidate noteworthy changes in both metrics. Joshi and Maurya (2020) assessed the mechanism of transmission of monetary policy to core inflation and highlighted the significance of targeting core inflation to ensure price stability.

Patra and Kapur (2019) have examined the effectiveness of monetary policy rates, including the repo rate, reverse repo rate, and cash reserve ratio (CRR). They find that alterations in these policy rates have a noteworthy effect on inflation, indicating the importance of these tools in inflation control. Kumar and Arora (2019) examined the influence of monetary policy rates on food inflation, a critical component of overall inflation in India. They find that monetary policy measures have a significant influence on food price inflation.Reddy and Rao (2019) explore the effect of the reverse repo rate on inflation expectations among households in India. Their research emphasizes how expectations management and communication is crucial for monetary policy tool's effectiveness. A comprehensive analysis by Bandyopadhyay and Das (2018) delves into the transmission mechanism of various rates related to monetary policy, including the reverse repo rate & repo rate and their effectiveness in influencing inflation outcomes in India.

Sharma and Dash (2017) examine the effectiveness of the Cash Reserve Ratio (CRR) as a tool for controlling the inflation level in India. Their findings suggest that changes in the CRR have a major effect on inflation, especially in the short run. Das and Behera (2017) investigate the association between real interest rates and inflation in India. Their findings suggest that maintaining positive real interest rates is crucial for anchoring inflation expectations and achieving price stability. Khan and Sen (2015) investigate the effect of alterations in the repo rate on inflation in India. The alteration in the repo rate is strongly and significantly correlated with subsequent inflation dynamics, according to their study. Goyal and Das (2016) explore the role of liquidity management, particularly through open market operations, in controlling inflation. They find that systematic liquidity management is essential for ensuring monetary policy effectiveness in India. Dhal, Kumar and Ansari (2011), their study examine the link among financial steadiness, economic growth & inflation in the Indian context using a VAR model. The research confirms a bi-directional Granger block causal relationship among financial steadiness and macroeconomic indicators with statistical evidence. The study suggests that financial stability can enhance growth and inflation, while higher economic stability can enhance financial stability. However, higher inflation or price instability can negatively affect financial stability.

Ankita and Vinod (2010), their paper present a VAR model related to monetary policy for India, considering output, inflation, and exchange rate. It suggests a New Keynesian framework with stickiness in prices and highlights the increasing significance of exchange rate channels in monetary policy transmission, with global supply factors and external fluctuations playing significant roles. The extant of literature presents a wide range of research aimed at comprehending the intricate association between monetary policy rates and inflation in India. Collectively, these studies influence on WPI along with the other monetary measures such as Interest Rates, Statutory Ratios and Money supply.

METHODOLOGY

Objectives of the Study

The rationale of the current research paper is to understand the link between WPI and monetary policy measures. The primary key function of the RBI is Price Stability, Exchange Stability and Liquidity Management. RBI has been using policy rates (Repo Rate & Bank Rate), statutory ratios (CRR & SLR) and Money Supply (MSF and M3) to tame inflation and control liquidity in the economy, but the effectiveness of this approach has always been questioned. This paper tries to understand the dynamics between monetary policy and inflation by developing time series modeling and drawing conclusions based on the analysis.

Data Collection & Description of Variables

The Wholesale Price Index is considered as a substitute for Inflation. In India, the primary gauge for tracking inflation is the Wholesale Price Index (WPI) apart from CPI (Consumer Price Index). The WPI evaluates the value fluctuations of a representative basket of wholesale goods. In India, the WPI is comprised of three major categories: Primary Articles, accounting for 22.6 percent; Fuel and Power, constituting 13.2 percent; and Manufactured Products, representing 64.2 percent. The responsibility for compiling and disseminating the WPI on a monthly basis rest with the Office of the Economic Adviser, operating under the domain of the Department of Industrial Policy and Promotion within the Ministry of Commerce & Industry. One of the reasons for considering the data intervals is monthly because RBI reports WPI monthly.

The present study examines important monetary policy variables that influence inflation in India. Monetary policy instruments are used by the Reserve Bank of India to regulate liquidity, control inflation, and maintain stability in the financial system. Among the interest rate instruments, the study considers the Bank Rate and the Repo Rate. The Bank Rate refers to the interest rate at which the central bank lends funds to commercial banks. When banks face a shortage of funds, they can borrow from the central bank at this rate. Changes in the Bank Rate influence borrowing costs for banks and indirectly affect lending rates in the economy. Therefore, adjustments in the Bank Rate can influence credit availability, investment, and inflation in the economy (Mishkin, 2016). The Repo Rate is another key monetary policy instrument used by the central bank. It is the rate at which the central bank lends short-term funds to commercial banks against government securities. When banks face temporary liquidity shortages, they can obtain funds through repurchase agreements. The repo rate is widely used to regulate liquidity and manage inflation. When inflation rises, the central bank may increase the repo rate, making borrowing more expensive and reducing the money supply in the economy. Conversely, lowering the repo rate encourages borrowing and increases liquidity, thereby supporting economic growth (RBI, 2022).

Although the Repo Rate and Bank Rate appear similar, they differ in their operational mechanism. In the repo system, banks provide government securities as collateral while borrowing funds from the central bank. In contrast, borrowing at the bank rate does not require collateral. Both instruments are important tools used to regulate liquidity in the banking system. Apart from interest rate instruments, reserve requirements also play an important role in controlling inflation. The Cash Reserve Ratio (CRR) requires commercial banks to maintain a certain percentage of their deposits as reserves with the central bank. Increasing the CRR reduces the funds available for lending and helps control inflationary pressures in the economy (Vaish, 2002). The Statutory Liquidity Ratio (SLR) represents the proportion of deposits that banks must maintain in the form of liquid assets such as cash, gold, or government securities. This requirement ensures that banks maintain sufficient liquidity before extending loans to customers. An increase in SLR reduces the lending capacity of banks and helps control inflation, while a reduction encourages credit expansion and economic growth (RBI, 2022).

Another important monetary policy instrument is the Marginal Standing Facility (MSF), introduced by the RBI in 2011 to manage short-term liquidity shortages in the banking system. It allows banks to borrow funds from the central bank at a higher interest rate when other borrowing options are exhausted. Money Supply (M3) as another

important factor affecting inflation. M3 is a broad measure of money supply that includes currency in circulation and different types of bank deposits. Economic theory suggests that an increase in money supply raises aggregate demand and may lead to higher inflation, while slower growth in money supply can reduce inflationary pressures (Friedman, 1968; Vaish, 2002).

Econometric Model

Inflation = f (Monetary Policy)

WPI = f (BR, REPO, CRR, SLR, MSF, M3).

$WPI_t = \alpha_0 + \alpha_1 BR + \alpha_2 REPO + \alpha_3 CRR + \alpha_4 SLR + \alpha_5 MSF + \alpha_6 M3 + \in t$

EMPIRICAL FINDINGS AND DISCUSSION

Descriptive Statistics and Graphs:

The data required for the research was drawn from the database of the central bank of the country. After collection, the graphs are plotted and presented in Figure 1, before computing the descriptive statistics of all the variables are generated using Eviews 12 software and presented in Table 2. The descriptive statistics summarizes the characteristics data set of each of the variables by presenting the Mean that is the average value, Median the middle value, Maximum Value, Minimum Value, Standard Distribution, Skewness- the symmetry of the data, Kurtosis – the peak and the flatness of the data, Jarque Bera, Probability, Sum, Sum of the square of the deviations and number of observations. The number of observations of each of the variables is 149, monthly data starting from January 2011 to May 2023. At a 5 percent significance level the variable WPI data was found to be normally distributed and at a 1 percent significance level the variables BR, Repo and MSF were found to be normally distributed, however the rest of the variables failed to confirm with normality.

Relationship between the Variables (Correlation): After computing the descriptive statistics the next step is to understand the relationship between the select variables by calculating the correlation coefficient. The output of the Karl Pearson coefficient is presented in Table 3. The results of the correlation coefficient confirm that there is a positive correlation between WPI and CRR, WPI and SLR, WPI and M3. There is a negative correlation between WPI and BR, WPI and REPO, Khan and Sen (2015), WPI and MSF. However, the correlation between WPI and BR, WPI and CRR is found to be significant at 5 percent. The correlation between WPI and Repo, WPI and M3 is found to be significant at 10 percent.

Testing Stationarity of Time Series Data: To improve the accurateness and trustworthiness of the constructed model, the data series must exhibit stationary nature as a prerequisite for drawing meaningful conclusions. When the variables are not stationary, the outcomes may yield spurious relationships between them. Generally, a time series data set is deemed stationary if the mean and variance remain stable over a specified period and the covariance between the two extreme time points is independent of the time for which it is calculated, relying solely on the lag between these two-time points. One common method for assessing the stationarity of time series data is using unit root tests. There are different range of unit root tests, the current study has applied two popular unit root tests ADF (Augmented Dickey-Fuller) test and PP (Phillips Perron) to assess the stationarity of the data set, and the compiled output is presented in Table 4.

The output of the ADF test and PP test along with t-Statistics and Prob. value for each of the variables is given in Table 4. Based on the results, considering the 5 percent significance level, it can be confirmed that WPI, BR, REPO, SLR and MSF were established to be not stationary at the level and stationary at first difference. The variable M3 at a 5 percent significance level was found to be stationary at the level. However, the variable CRR at a 10 percent significance level was found to be stationary at the level. As the variables of the study are stationary at different levels, the application of the ARDL model is appropriate

Lag Selection Criteria: After confirming the stationarity of the variables the next step is to find the lag length. Before applying for the ARDL bound test, to confirm cointegration among the variables WPI, BR, REPO, CRR, SLR, MSF and M3, it is essential to choose a suitable lag order of the variables. To know the optimal lag order, the VAR model was applied. The output of lag order selection by applying VAR is presented in Table 5. These findings indicate that the model yields superior results when using a lag of 2, as determined by the Final Prediction Error and Akaike Information Criterion. However, based on Schwarz Information Criterion (SIC) and Hannan-Quinn Information Criterion it is lag 1 Furthermore, a polynomial graph is generated to substantiate the suitable lag length in the VAR method has found that all the data points are within the circle and validate the achievement of favorable results.

ARDL Bound Test: To investigate the cointegration characteristic of the estimated equation, the ARDL cointegration procedure was applied which was introduced by Pesaran et al. (2001). A key benefit of this testing and estimation approach is its applicability regardless of whether the variables in the model are in stationary or non-stationary form. This eliminates the certain pre-testing challenges associated with traditional methods. Additionally, concerns related to endogeneity are minimized as long as the model is free from residual correlation. Given these considerations, the ARDL model approach was applied for assessing monetary policy instruments' effect on inflation in India. Equation (2) presents a concise overview of the model, where WPI represents inflation, while t denotes the period from January 2011 to May 2023 (monthly time interval). α_0 represents the constant while α_1 to α_6 are the coefficients of variables and BR, REPO, CRR, SLR, MSF and M3, while $\in t$ represents the error term.

$$\Delta \mathrm{WPI}_t = \alpha_0 + \sum_{k=1}^{n} \alpha_t \Delta \mathrm{WPI}_{t-k} + \sum_{k=1}^{n} \alpha_2 \Delta \mathrm{BR}_{t-k} + \sum_{k=1}^{n} \alpha_3 \Delta \mathrm{REPO}_{t-k} + \sum_{k=1}^{n} \alpha_4 \Delta \mathrm{CRR}_{t-k} + \sum_{k=1}^{n} \alpha_5 \Delta \mathrm{SLR}_{t-k} + \sum_{k1}^{n} \alpha_6 \Delta \mathrm{MSF}_{t-k} + \sum_{k=1}^{n} \alpha_7 \Delta \mathrm{M3}_{t-k} + \ldots\ldots\ldots\ldots\ldots\ldots \lambda_1 \mathrm{WPI}_{t-1} + \lambda_2 \mathrm{BR}_{t-1} + \lambda_3 \mathrm{REPO}_{t-1} + \lambda_4 \mathrm{CRR}_{t-1} + \lambda_5 \mathrm{SLR}_{t-1} + \lambda_6 \mathrm{MSF}_{t-1} + \lambda_7 \mathrm{M3}_{t-1} + \in_t \quad \text{Equation (2)}$$

The ARDL (6, 2, 1, 3, 0, 0, 6) model selected using the Akaike Information Criterion (AIC) explains the long-run relationship between monetary policy instruments and inflation by incorporating the lagged effects of the variables. Since the study employs monthly data, a higher lag length was considered appropriate to capture the dynamic interactions among the variables. Therefore, a maximum lag order of eight was used to ensure the inclusion of sufficient lagged explanatory variables. The estimation results of the ARDL model are presented in Table 6. The model demonstrates a high explanatory power, with both the R-squared and Adjusted R-squared values equal to 0.98, indicating that approximately 98 percent of the variation in inflation (WPI) is explained by the selected variables. The Prob (F-statistic) value of 0.0000 confirms the overall significance of the model, while the Durbin–Watson statistic of 2.004 indicates the absence of autocorrelation. The results show that CRR and SLR have a positive and statistically significant influence on WPI at the 5 percent level, whereas the Bank Rate shows a positive effect at the 10 percent level. MSF has a negative and significant impact on inflation, while the Repo Rate and M3 are found to be statistically insignificant. Several lagged values of WPI and monetary policy variables also exhibit significant effects, indicating the dynamic nature of inflation in response to monetary policy changes.

After meeting all necessary criteria for a well-fitted model, the ARDL Bounds test, often referred to as the joint significant F-test at a specified lagged level, investigates the existence of cointegration among the variables. The output of the bounds tests for cointegration, along with the critical values of the Lower bound and upper bound is presented in Table 7. The F-statistics, which was 6.635, exceeded the upper bound at the 1%, 2.5%, 5% and 10% significance level, set at 3.99. This empirical finding strongly confirms cointegration among the variables within the model. After confirming the existence of a long run relationship amid the selected variables, the ECM (Error Correction Model) was applied to analyze the short-run estimates of the model. Akaike Information Criteria (AIC) was preferred for selecting lag length. The Error Correction Model general form is formulated and presented in Equation 3. Where α_0 represents the drift component Δ represents the first disparity and the white noise is represented by $\in_t$.

$$\Delta \mathbf{WPI}_t = \alpha_0 + \sum_{k=1}^{n} \alpha_t \Delta \mathbf{WPI}_{t-k} + \sum_{k=1}^{n} \alpha_2 \Delta \mathbf{BR}_{t-k} + \sum_{k=1}^{n} \alpha_3 \Delta \mathbf{REPO}_{t-k} + \sum_{k=1}^{n} \alpha_4 \Delta \mathbf{CRR}_{t-k} + \sum_{k=1}^{n} \alpha_5 \Delta \mathbf{SLR}_{t-k} + \sum_{k=1}^{n} \alpha_6 \Delta \mathbf{MSF}_{t-k} + \varphi \mathbf{ECM}_{t-1} + \epsilon_t \quad \textbf{Equation (3)}$$

The short-run estimation results of the ARDL (6, 2, 1, 3, 0, 0, 6) model selected using the Akaike Information Criterion (AIC) are presented in Table 8. The findings indicate that the Bank Rate (BR) and its lagged value BR(−1) positively influence the Wholesale Price Index (WPI) in the short run at the 5 percent significance level. Similarly, CRR and CRR(−2) have a positive and significant effect on WPI at the 5 percent level. In contrast, the lagged value of money supply, M3(−1), negatively affects WPI at the 10 percent significance level, while WPI(−2) also shows a negative short-run impact at the 10 percent level. The error correction term (ECT) is negative and statistically significant, confirming the presence of a long-run equilibrium relationship among the variables. The estimated ECT coefficient of −0.0658 indicates that approximately 6.58 percent of short-run disequilibrium is corrected each month, suggesting a gradual adjustment toward long-run equilibrium between monetary policy variables and inflation.

Diagnostic and Stability Tests: Diagnostic and stability tests were conducted to assess whether the residuals of the system met the criteria of normal distribution, absence of serial correlation, absence of heteroskedasticity, and adherence to the correct functional form. The outcomes of the Breusch-Godfrey Serial Correlation LM Test, the Breusch-Pagan-Godfrey Test, and the Jarque-Bera Test are presented in Table 9. The null hypotheses about normal distribution, serial correlation (LM test), and heteroskedasticity were not rejected, leading to the conclusion that the error term exhibited no serial correlation, no heteroskedasticity, and displayed normality at the 5% significance level. Furthermore, the results of the normality test, accompanied by histograms as supporting evidence for the normal distribution of the data. This is substantiated by a p-value of 0.6811308, indicating that the null hypothesis can be upheld at the 5% significance level. To assess the steadiness of both the long-term and short-term coefficients, cumulative sum (CUSUM) and cumulative sum of squares (CUSUMSQ) plots were generated. The null hypothesis, which posits that the model is properly specified, could not be discarded as the statistics fell within the critical values of the 5 percent significance level. The plots confirm that both CUSUM and CUSUMSQ remain within the specified boundaries, thus affirming the structural stability of the chosen ARDL model specification.

CONCLUSION

The present study investigates the relationship between inflation and monetary policy measures in India, with particular emphasis on their relevance in the contemporary macroeconomic environment. In recent years, inflation dynamics have become increasingly complex due to global economic uncertainties, supply chain disruptions, commodity price volatility, and changing financial conditions. In this context, understanding the effectiveness of monetary policy instruments in controlling inflation has become more important than ever. The Reserve Bank of India plays a crucial role in maintaining price stability, exchange rate stability, and adequate liquidity in the financial system through the implementation of various monetary policy tools. Therefore, analysing the interaction between inflation and monetary policy is essential for evaluating the effectiveness of policy interventions in the current economic scenario.

To examine this relationship, the study employs several indicators as proxies for monetary policy measures. These include policy rates such as the Bank Rate (BR) and Repo Rate (REPO), statutory reserve ratios including the Cash Reserve Ratio (CRR) and Statutory Liquidity Ratio (SLR), Marginal Standing Facility (MSF) and Money Supply (M3). Inflation is measured using the Wholesale Price Index (WPI), which serves as a key indicator of price movements in the economy. The data for the study are obtained from the official database of the Reserve Bank of India and consist of monthly observations from January 2011 to May 2023, resulting in 149 observations. This time period is

particularly relevant as it captures important monetary policy reforms, the introduction of new policy instruments, and major economic events that have influenced inflation dynamics in India. Stationarity of the data was ascertained before selecting the suitable model. Based on stationarity results Autoregressive Distributed Lag (ARDL) model was found to be more appropriate to analyse both the short-run and long-run relationships between monetary policy instruments and inflation. The ARDL modeling allows the estimation of dynamic relationships among variables with different orders of integration while effectively capturing both short-term adjustments and long-term equilibrium relationships.

The empirical findings reveal the existence of both long-run and short-run relationships between inflation and monetary policy variables. In the long run, variables such as the Bank Rate, Cash Reserve Ratio, Statutory Liquidity Ratio, and Marginal Standing Facility significantly influence inflation, indicating that these policy instruments play an important role in shaping long-term price stability. In the short run, variables such as the Bank Rate, Cash Reserve Ratio, and Money Supply (M3) exhibit a significant impact on inflation dynamics. Notably, the Marginal Standing Facility, introduced as part of recent monetary policy reforms, appears to play a meaningful role in controlling inflation by influencing liquidity conditions within the financial system. Overall, the findings of the study provide timely and relevant insights into the effectiveness of monetary policy instruments in the Indian context. By focusing on recent data and incorporating multiple policy variables, the study contributes to a better understanding of how monetary policy transmission mechanisms operate under evolving economic conditions. The results offer valuable guidance for policymakers and economists in designing appropriate monetary strategies to manage inflation and maintain macroeconomic stability in the current economic environment.

ABSTRACT

A novel enrollment forecasting system based on fuzzy time series is presented in this research. The suggested approach is a fuzzified moving average method, one of the robust methods. This study uses historical University of Alabama enrollment data from 1971 to 1992 to show how forecasting works. The suggested approach outperforms the current methods in terms of enrollment forecasting accuracy when compared to other approaches

Keywords: Fuzzy time series, Fuzzified moving average, Double fuzzification, Fuzzy logical relationship groups, Historical enrollment forecasting.

INTRODUCTION

Almost every aspect of human existence involves forecasting, particularly when it comes to making future judgements about the weather, enrolment, production, sales, and finances, among other things. Get advantages from the forecasting actions based on these. Numerous qualitative and quantitative forecasting models have been proposed up to this point. These models, however, cannot handle situations when the historical data are expressed as

verbal ideas rather than as numerical numbers. Numerous techniques have been put out in recent years to address fuzzy time series forecasting issues. Predicting a phenomenon's future magnitude is crucial for comprehending its behaviour across time. Without defining the phenomenon's future dimensions and determining its structure and modes, it is impossible to develop plans for dealing with it in the future. Making judgements is also a difficult task, particularly when it involves projecting the future. The accuracy of forecasting is the only factor considered when making judgements. It is clear that forecasting is important to our day-to-day existence. The most precise and effective forecasting could help us make the right choices to increase our expectations' accuracy to 100%. Though it might not be feasible, we nonetheless strive to lower predicting errors. Numerous researchers have offered various theories and ways to address forecasting challenges. Fuzzy time series utilising the interval partitioning approach is one method of accurately forecasting.

A time series is a collection of items with regular intervals and numerical data arranged in a sequential manner. Time series find applications in mathematical finance, econometrics, enrolment, signal processing, and statistics. It facilitates our ability to foresee and predict series data across several areas. Numerous economic and statistical forecasting techniques with broad applicability are available in the literature. We employed moving average with fuzzy interval partitioning (MAFIP) as one of the reliable techniques in our study. It was used on the time series data pertaining to University of Alabama enrolments in order to forecast enrolments. In this paper, we expanded an existing MAFIP technique. Better prediction accuracy results and a novel algorithm are provided by the suggested approach. The 7-year moving average technique is applied to the dataset in this study. We expanded the moving average used in Abhishekh (2019) Rabia (2023) from three years and five years to seven years, and we integrated double fuzzification with time series forecasting utilising fuzzy interval partitioning approaches. Finally, we compared our accuracy to the two research studies.

Fuzzy Time Series

Fuzzy time series is a forecasting method that uses fuzzy logic to handle uncertainty in data over time. Instead of relying on exact numbers, it represents data as ranges or categories, allowing for more flexible and realistic predictions. This approach is useful when data is imprecise or noisy, making it easier to capture trends and patterns.

Some basic fuzzy time series concepts are given below…

Let U be the universe of discourse, $U = \{u_1, u_2, u_3, \dots, u_n\}$. A fuzzy set A of U is defined by

$A = \frac{f_A(u_1)}{u_1} + \frac{f_A(u_2)}{u_2} + \frac{f_A(u_3)}{u_3} + \cdots + \frac{f_A(u_n)}{u_n}$,

where f_A is the membership function of A, $f_A: U \to [0,1]$ and $f_A(u_i)$ indicates the grade of membership of u_i in A, where $f_A(u_i) \in [0,1]$ and $1 \le i \le n$.

Definition 2.1

Assume $Y(t) \subset R$ (real line), $t = \dots, 0, 1, 2, 3, \dots, n$ to be a universe of discourse defined by the fuzzy set $f_i(t)$. $F(t)$ consisting of $f_i(t), i = 1,2,3, \dots, n$ is defined as a fuzzy time series on $Y(t)$. At that $F(t)$ can be understood as a linguistic variable, whereas $f_i(t), i = 1,2,3, \dots, n$ are possible linguistic values of $F(t)$.

Definition 2.2

If $F(t)$ is caused by $F(t-1)$ denoted by $F(t-1) \to F(t)$ then this relationship can be represented by $F(t) = F(t-1) \circ R(t, t-1)$ where the symbol "$\circ$" is an operator; $R(t, t-1)$ is a fuzzy relation between $F(t)$ and $F(t-1)$ and is called the first-order model of $F(t)$.

Definition 2.3

Denoting $F(t-1)$ by A_i and $F(t)$ by A_j the relationship between $F(t-1)$ and $F(t)$ can be defined by a logical relationship $A_i \to A_j$.

Definition 2.4

Let$R(t;t-1)$be a first-order model of$F(t)$. If for any $t, R(t;t-1) = \mathrm{R(t-1\,;t-2)}$, then $F(t)$is called a time-invariant fuzzy time series. Otherwise, it is called a time-variant fuzzy time series.

Definition 2.5

Fuzzy logical relationships, which have the same left-hand sides, can be grouped together into fuzzy logical relationship groups. For example, for the identical left-hand $A_i$such grouping can be depicted as follows

$$\left.\begin{array}{l} A_i \to A_{j1} \\ A_i \to A_{j2} \\ A_i \to A_{j3} \\ \vdots \end{array}\right\} \Rightarrow A_i \to A_{j1}\,, A_{j2}\,, A_{j3}\,, \ldots$$

A New Algorithm to Forecasting Enrollments Through Fuzzytime Series

Using fuzzy time series, we were able to obtain a new algorithm to forecast enrollments. The forecasting procedure is executed through the subsequent steps:

Step 1 : We calculate the variations between the actual dataset and the 7-year moving average after computing the 7-year moving average from the actual dataset.

Step 2: Define the universe of discourse (Universal set) starting from actual data and 7-year moving average of the historical enrollment data.

To determine the universe of discourse the maximum and minimum values are taken from the dataset. The universe of discourse is denoted by

$$U = [D_{min} - D_1\,, D_{max} + D_2]$$

Where D_{min} and D_{max} are the maximum and minimum values respectively, D_1 and and D_2 are proper number of integers which provides us a suitable universal of discourse U.

$D_{min} = 13055\,, D_{max} = 19337$ and $D_1 = 55\,, D_2 = 663$

$$U = [13055 - 55\,, 19377 + 663]$$

$$U = [13000\,, 20000]$$

Step 3: Partition U into equally length intervals.

We partition $U = [13000\,,\ 20000]$ into seven intervals u_1, u_2, u_3, u_4, u_5, u_6 and u_7 where

$u_1 = [13000\,, 14000]$, $u_2 = [14000\,, 15000]$, $u_3 = [15000\,, 16000]$, $u_4 = [16000\,, 17000]$,

$u_5 = [17000\,, 18000]$, $u_6 = [18000\,, 19000]$ and $u_7 = [19000\,, 20000]$.

Step 4 : Definefuzzy sets A_i.

We assume that linguistic variable variations of enrollments can take as fuzzy values: A_1 (too much decrease), A_2 (much decrease), A_3 (decrease), A_4 (no change), A_5 (increase), A_6 (much increase) and A_7 (too much increase) for example, Regardless of the fact that seven fuzzy sets are listed here, with the purpose of comparison we also conducted extra experiments with different number of fuzzy sets.

For 7 intervals given $u_i\,,\ i = \overline{1,7}$the fact that each u_i belongs to a particular $A_j\,,\ j = \overline{1,7}$is expressed by the real value from the range [0,1]:

$A_1 = {}^{1}/_{u_1} + {}^{0.5}/_{u_2} + {}^{0}/_{u_3} + {}^{0}/_{u_4} + {}^{0}/_{u_5} + {}^{0}/_{u_6} + {}^{0}/_{u_7}$,

$A_2 = {}^{0.5}/_{u_1} + {}^{1}/_{u_2} + {}^{0.5}/_{u_3} + {}^{0}/_{u_4} + {}^{0}/_{u_5} + {}^{0}/_{u_6} + {}^{0}/_{u_7}$,

$A_3 = {}^{0}/_{u_1} + {}^{0.5}/_{u_2} + {}^{1}/_{u_3} + {}^{0.5}/_{u_4} + {}^{0}/_{u_5} + {}^{0}/_{u_6} + {}^{0}/_{u_7}$,

$A_4 = {}^{0}/_{u_1} + {}^{0}/_{u_2} + {}^{0.5}/_{u_3} + {}^{1}/_{u_4} + {}^{0.5}/_{u_5} + {}^{0}/_{u_6} + {}^{0}/_{u_7}$,

$A_5 = {}^{0}/_{u_1} + {}^{0}/_{u_2} + {}^{0}/_{u_3} + {}^{0.5}/_{u_4} + {}^{1}/_{u_5} + {}^{0.5}/_{u_6} + {}^{0}/_{u_7}$,

$A_6 = {}^{0}/_{u_1} + {}^{0}/_{u_2} + {}^{0}/_{u_3} + {}^{0}/_{u_4} + {}^{0.5}/_{u_5} + {}^{1}/_{u_6} + {}^{0.5}/_{u_7}$,

$A_7 = {}^{0}/_{u_1} + {}^{0}/_{u_2} + {}^{0}/_{u_3} + {}^{0}/_{u_4} + {}^{0}/_{u_5} + {}^{0.5}/_{u_6} + {}^{1}/_{u_7}$.

Where $u_i \subset U$ are elements of the universal set, and the number that precedes slash symbol "l" is the membership degree $\mu(u_i)$ to respective $A_j\,,\ j = \overline{1,7}$.

Step 5 : Fuzzify actual data and7-year moving average of the historical enrollment data. We can do double fuzzification in this process.
The fuzzified actual data and 7-year moving average of the historical enrollment data of the University of Alabama are shown in the following table.
Step 6 : Determine Fuzzy logical relationships $A_i \rightarrow A_j$ and Fuzzy logical relationship groups from double fuzzification(in Table 2).

Then the fuzzy logical relationships of the enrollments can be obtained from Table 2 which are shown in Table 3, where the fuzzy logical relationship $A_i \rightarrow A_j$, A_i is called the fuzzified enrollment and A_j is called fuzzified average. Thus, based on Table 3, we can obtained four fuzzy logical relationship groups shown in Table 4.
Step 7 : Forecasting enrollments by new algorithm.
By the new algorithm, we can predict the University of Alabama's enrollment from 1971 to 1992 based on the steps mentioned above. Using double fuzzification, this technique identified fuzzy logical relationships and fuzzy logical relationship groupings. Presenting an effective prediction is beneficial.
We depict the forecasting process for the year [1974] based on the stages mentioned above : The fuzzified enrollment for the year 1974, designated A_2, takes place at interval u_2, where u_2=[14000,15000]with 14500 serving as the interval's midpoint. We recall the discrepancies in 1974 between the 7-year moving average and the actual data. The forecasting method relies heavily on variation.Therefore, 14688.143is the anticipated enrollment for 1974. Thus, Table 5 displays the forecasted outcomes for the University of Alabama.

Comparison

To compare the forecasted outcomes using various forecasting approaches, we utilize the Root Mean Square Error (RMSE), where (RMSE) is:

$$RMSE = \sqrt{\frac{\sum_{i=1}^{n}(P_i - O_i)^2}{n}}$$

Where P_i = Predicted enrollment, O_i = Observed enrollment and n = Number of observations.

CONCLUSION

In this research, we extended a novel enrollment forecasting system based on the fuzzy time series method. This study demonstrates the forecasting technique utilizing Alabama University's historical enrollment data. The comparison (Table 6) shows that the suggested method has a higher predicting accuracy rate for enrollments than other forecasting approaches.

ABSTRACT

Commentaries play a crucial role in interpreting and analyzing the concise and often complex *Shlokas* of classical Ayurvedic texts. Over time, numerous commentaries have emerged in Sanskrit and regional languages, reflecting diverse scholarly perspectives. However, the gradual decline in Sanskrit proficiency and increased reliance on translated texts have led to challenges in accurately understanding original Ayurvedic concepts. Classical literature, particularly the *Charaka Samhita*, emphasizes the importance of studying the primary text in conjunction with authoritative commentaries to prevent misinterpretation. The present study undertakes a comparative literary analysis of two significant Sanskrit commentaries—*Ayurveda Deepika* by Chakrapani Datta and *Jalpakalpataru* by Gangadhar Rai—with specific reference to the *Vimana Sthana*. This section of the Samhita is conceptually significant as it encapsulates key principles related to diagnosis, dietetics, and therapeutic decision-making. The study identifies important similarities and differences in interpretation, explanatory approaches, and conceptual emphasis between the two commentators. The findings highlight that while *Ayurveda Deepika* offers concise and clinically oriented explanations, *Jalpakalpataru* provides elaborative, analytical, and interdisciplinary insights. The comparative evaluation underscores the importance of engaging with original commentarial literature for a deeper and more accurate understanding of Ayurvedic knowledge

Keywords: Charaka Samhita, Vimana Sthana, Ayurveda Deepika, Jalpakalpataru Chakrapani Datta, Gangadhar Rai

INTRODUCTION

The interpretative tradition in *Ayurveda* represents a dynamic continuum in which successive scholars have engaged with classical texts to refine, reinterpret, and contextualize their meanings. In this regard, comparative analysis of commentaries is not merely a textual exercise but an essential scholarly approach to uncover the evolution of Ayurvedic thought across different historical periods. The *Vimana Sthana* of the *Charaka Samhita*, being rich in methodological and conceptual frameworks, provides an ideal ground for such comparative inquiry. By examining how different commentators approach the same foundational concepts, it becomes possible to identify shifts in emphasis, variations in reasoning, and the integration of interdisciplinary knowledge systems within *Ayurveda*.Furthermore, contemporary Ayurvedic research increasingly demands critical engagement with primary sources to ensure authenticity and conceptual accuracy. In this context, revisiting classical commentaries such as those of *Chakrapani Datt*a and *Gangadhar Rai* assumes significant relevance. Their works reflect not only the intellectual depth of their respective eras but also diverse methodological orientationsranging from concise clinical interpretation to elaborate philosophical exposition. A focused comparative study of these commentaries on *Vimana Sthana* thus contributes to bridging traditional textual scholarship with modern academic inquiry, while also offering deeper insights into the adaptability and continuity of Ayurvedic knowledge systems

AIM AND OBJECTIVES

AIM

- To comparatively analyze *Ayurveda Deepika* and *Jalpakalpataru* commentaries on the *Vimana Sthana* of the *Charaka Samhita* to understand their interpretative approaches and contributions.

OBJECTIVES

- To examine key concepts of *Vimana Sthana* based on the commentaries of *Chakrapani Datta* and Gang*adhar Rai.*
- To identify similarities and differences in their interpretations and explanatory styles.
- To assess the clinical and conceptual relevance of both commentaries.
- To highlight the importance of classical commentaries in understanding Ayurvedic texts.

MATERIALS AND METHODS

This study is a qualitative and comparative literary analysis based on the *Vimana Sthana* of the *Charaka Samhita* and its two major Sanskrit commentaries—*Ayurveda Deepika*[1] by Chakrapani Datta and *Jalpakalpataru*[2] by *Gangadhar Rai*. Relevant concepts and interpretations from all eight chapters were systematically reviewed and categorized thematically.A comparative approach was adopted to analyze similarities and differences in definitions, conceptual explanations, and clinical interpretations between the two commentators. The findings were interpreted qualitatively to highlight their respective contributions. No statistical methods were employed, as the study is purely textual in nature.

Charaka Samhita: Historical and Textual Background

The term Samhita denotes a primary and authoritative compendium on a specific domain of knowledge. Among such classical texts, *Charaka Samhita* holds a preeminent position in the history of global medical literature, representing one of the earliest systematic expositions of medical science. The extant version of *Charaka Samhita* is a redacted and expanded form of the original *Agnivesha Tantra*, which was composed by *Agnivesha*, a foremost disciple of Atreya. This foundational work was subsequently revised and systematized by Acharya Charaka, and later supplemented by *Dridhabala*, thereby giving rise to the text in its present form. Chronologically, the composition of *Charaka Samhita* is generally situated between approximately 700 BCE and 100 CE. The transformation of the original

sutra-based framework into a comprehensive and structured treatise reflects the intellectual rigor and clinical orientation of Acharya Charaka, ensuring its enduring relevance in medical science.

Commentarial Tradition in *Charaka Samhita*

Over the centuries, *Charaka Samhita* has attracted extensive scholarly engagement, resulting in more than sixty known commentaries composed across different regions, languages, and time periods. These commentaries serve as critical interpretative tools, facilitating a deeper understanding of the concise and often complex Sanskrit verses. Among the available works, *Ayurveda Deepika* and *Jalpakalpataru* stand out as two of the most complete and significant Sanskrit commentaries. *Ayurveda Deepika*, authored by Chakrapani Datta in the 11th century CE, has gained wide acceptance as the most authoritative commentary on *Charaka Samhita*. Notably, there exists a considerable chronological gap between the 12th and 19th centuries during which no major Sanskrit commentaries were produced. The emergence of *Jalpakalpataru* in the 19th century, authored by Kaviraja Gangadhar Rai, represents a revival of Sanskrit commentarial tradition, offering fresh perspectives and expanded interpretations of classical concepts.

Ayurveda Deepika

Ayurveda Deepika, composed by Chakrapani Datta in the 11th century CE, is one of the most comprehensive and widely accepted commentaries on *Charaka Samhita*. Written in Sanskrit, it is characterized by clarity, brevity, and a strong clinical orientation. The text, along with its commentary, has been critically edited by *Yadavji Trikamji Acharya* and includes a prologue by R. H. Singh. Numerous editions of this work are available, often accompanied by translations in English, Hindi, and other regional languages, thereby enhancing its accessibility. A distinctive feature of *Ayurveda Deepika* is its unified presentation, wherein all sections (Sthanas) of *Charaka Samhita* are compiled along with the commentary in a single volume. Its methodological precision and interpretative clarity have established it as the standard reference for both academic study and clinical application.

Jalpakalpataru

Jalpakalpataru, authored by Gangadhar Rai in the 19th century CE, represents another complete Sanskrit commentary on *Charaka Samhita*. The text has been edited by Narendranath Sengupta and Balaichandra Sengupta and published by Chaukhambha Orientalia, Delhi. Unlike *Ayurveda Deepika*, this commentary is organized into five distinct sections (Khandas), covering different portions of the Samhita, including *Sutrasthana, Nidana Sthana, Vimana Sthana, Sharira Sthana, Indriya Sthana, Chikitsa Sthana, Kalpa Sthana*, and *Siddhi Sthana.* Although comprehensive in scope, *Jalpakalpataru* is not widely available in translated form, limiting its accessibility. Nevertheless, it is frequently cited in scholarly works and is valued for its elaborate explanations, interdisciplinary references, and analytical depth.

Chakrapani Datta: Life and Contributions

Chakrapani Datta, an eminent scholar of the 11th century CE, was a distinguished commentator and physician in the court of *King Nayanapala* of the *Gauda* dynasty in Bengal. He was the son of *Narayanadatta* and a disciple of *Naradatta*. His scholarly excellence earned him prestigious titles such as *Charaka Chaturanana* and *Sushrutasahasranayana*. In addition to *Ayurveda Deepika*, his notable works include Chakradatta (also known as *Chikitsasara Sangraha), Shabdachandrika, Vyaghra Daridra, Subhankari, Vyakaranatattwa Chandrika, Sarvasara Sangraha,* and *Dravyaguna Sangraha*. His commentary on *Charaka Samhita* remains the most influential among all available commentaries, owing to its clarity, precision, and clinical relevance.

Gangadhar Rai: Life and Contributions

Gangadhar Rai, a prominent 19th-century scholar, was born in 1798 in Murshidabad, Bengal. He was a polymath with expertise in Ayurveda, Tantra, Vyakarana, Sahitya, Darshana, *Dharmashastra*, and *Jyotisha.* His commentary, *Jalpakalpataru*, reflects his vast intellectual background and interdisciplinary approach. In addition to this work, he authored several Ayurvedic texts, including *Ayurvedeeya Paribhasha, Bhaishajya Ramayana, Nadipareeksha, Agneya Ayurveda Vyakhya, Bhaskarodaya, Rajavallabhiya Dravyaguna Vivritti*, and *Ayurveda Sangraha.* He is credited with writing more than ten Ayurvedic treatises and over seventy-six works in other disciplines. His disciples, including notable

scholars such *as Haranachandra Chakravarti* and *Dwarakanath Sen*, contributed significantly to the propagation of Ayurvedic knowledge.

Vimana Sthana of *Charaka Samhita*[3,4]

Vimana Sthana, the third section of the *Charaka Samhita*, occupies a unique and conceptually significant position within the treatise. It comprises eight chapters, namely *Rasa Vimanadhyaya*, *Trividhakuksheeya Vimanadhyaya*, *Janapadodhwamsaneeya Vimanadhyaya*, *Trividha Roga Vishesha Vijnaneeya Vimanadhyaya*, *Sroto Vimanadhyaya*, *Roganeeka Vimanadhyaya*, *Vyadhitarupeeya Vimanadhyaya*, and *Rogabhishagjiteeya Vimanadhyaya*. Each of these chapters systematically elaborates key theoretical and clinical principles that are essential for the understanding and practice of Ayurveda. *Vimana Sthana* is often regarded as a concise synopsis of the entire *Charaka Samhita*, as it integrates and expounds upon fundamental determinants of health and disease. It provides a structured framework for clinical evaluation and therapeutic decision-making by emphasizing critical factors such as *Dosha*, *Bheshaja*, *Desha*, *Kala*, *Bala*, *Shareera*, *Sara*, *Ahara*, *Satmya*, *Satva*, *Prakriti*, and *Vaya*. These parameters collectively guide the physician in assessing the individual constitution, disease condition, and appropriate line of management, thereby reflecting the holistic and personalized approach intrinsic to Ayurveda.

The distinctiveness of *Vimana Sthana* is further highlighted when compared with other classical Ayurvedic texts. Although the Kashyapa Samhita also contains a section titled *Vimana Sthana*, it is only partially preserved, with extant portions limited to the concluding part of the first chapter and a fragment of the second chapter. The available content primarily discusses pedagogical aspects such as the qualities of a teacher and disciple, methods of study, and dialogical approaches to knowledge transmission. In contrast, other major classical compendia, including those of the *Brihatrayee* and *Laghutrayee*, do not feature a dedicated *Vimana Sthana*. Thus, the presence of *Vimana Sthana* in *Charaka Samhita* represents a distinctive scholarly contribution, offering a systematic and integrative exposition of foundational concepts that bridge theoretical understanding with clinical application. Its comprehensive treatment of diagnostic, therapeutic, and methodological principles underscore its importance as a core section for both academic study and practical implementation in Ayurveda.

Conceptual Interpretation of *Vimana* and *Prabhava*

A notable difference between the two commentators is observed in the definition of *Vimana*. Chakrapani Datta interprets *Vimana* as the domain that imparts specific knowledge of *Dosha* and *Bheshaja*, emphasizing their functional potency (*Prabhava*). In contrast, Gangadhar Rai defines it more broadly as a means of precise assessment and differentiation of entities. Similarly, in the concept of *Prabhava*, Chakrapani considers it as the determinant of potency, categorized into *Chintya* and *Achintya*. Gangadhara, however, equates *Prabhava* with *Karma*, integrating *Dravya*, *Guna*, and *Karma* into a unified functional framework. This reflects a shift from a clinically oriented explanation to a more analytical and philosophical interpretation.

Rasa–Dosha Relationship and Its Complexity

The concept of *Aparisankhyeyatva* (innumerability) of *Rasa–Dosha* combinations is explained differently. Chakrapani attributes it to qualitative gradations (*tara–tama*), whereas Gangadhara explains it through proportion, quantity, and functional variation. Although classical enumeration of Rasas and Doshas exists, both commentators agree that their combinations remain infinite, reinforcing the complexity of pharmaco dynamics in Ayurveda.

Vikriti Vishama Samavaya and Pathogenesis

In explaining *Vikriti Vishama Samavaya*, Chakrapani emphasizes unequal and abnormal combinations, whereas Gangadhara elaborates it as a result of multiple causative factors and composite interactions of Rasas and Doshas. Gangadhara's interpretation provides a broader etiopathological perspective, incorporating variability in composition and action.

Dietary Principles and *Aharavidhi Visheshayatana*

Both commentators acknowledge the importance of *Aharavidhi Visheshayatana* in determining the effects of diet. Chakrapani offers a precise and structured definition focusing on causative factors (*Hetu*), whereas Gangadhara explains it with diverse practical examples, highlighting transformations due to processing and context. In interpreting *"Na Ati Upayunjeeta"*, Chakrapani emphasizes avoidance of excessive intake, while Gangadhara interprets it as avoidance of prolonged or habitual consumption. This reflects subtle differences in dietary regulation and clinical application.

Clinical Concepts: *Alasaka* and *Visoochika*

In the context of *Alasaka*, Chakrapani highlights the predominance of *Vata* and *Kapha* and provides classical explanations of pathogenesis. Gangadhara introduces slight variations in therapeutic approach, such as replacing *Swedana* with *Chedana*, indicating a modified clinical perspective. Similarly, in *Visoochika*, Chakrapani follows classical treatment with *Langhana* and *Peyadi Krama*, whereas Gangadhara incorporates *Virechana* in the sequence, reflecting influence from other classical authorities like *Sushruta*.

Janapadodhwamsa: Epidemiological Perspective

Significant variation is observed in the understanding of *Janapadodhwamsa*. Chakrapani attributes it primarily to vitiated environmental factors such as air and water. In contrast, Gangadhara expands the causative framework to include seasonal variations, geographical factors, and contaminated substances. The interpretation of the term *Gupti* further highlights this difference. Chakrapani interprets it as protection through mantra and spiritual practices, whereas Gangadhara considers it as physical relocation from affected areas, reflecting a more pragmatic public health approach.

Srotas, Agni, and Pathophysiological Interpretation

Chakrapani's interpretation of *Srotas* emphasizes physiological functions, whereas Gangadhara incorporates anatomical perspectives. In the concept of *Vishamagni*, Chakrapani describes irregular digestive patterns, while Gangadhara elaborates with detailed symptomatology, enhancing clinical applicability.

Epistemology and Diagnostic Frameworks

In *Trividha Roga Vijnana*, Chakrapani considers *Aptopadesha*, *Pratyaksha*, and *Anumana* as tools for understanding diseases. Gangadhara, however, interprets them as *Pramanas* and further classifies them, reflecting the influence of logical and philosophical traditions. Similarly, in *Dashavidha Pareeksha*, Chakrapani focuses on clinical parameters, whereas Gangadhara expands the framework to include broader classifications such as *Swabhavika* and *Vaikarika* states, thereby enhancing diagnostic depth.

Philosophical and Textual Interpretations

Chakrapani's commentary is characterized by brevity, clarity, and clinical orientation. He focuses on direct explanation and practical relevance. In contrast, Gangadhara adopts a more elaborate and interdisciplinary approach, incorporating references from *Nyaya*, *Purana*, and other classical systems. His explanations reflect a synthesis of Ayurveda with broader philosophical traditions.

Overall Comparative Insight

The comparative analysis reveals that both commentaries are complementary rather than contradictory. *Ayurveda Deepika* provides clarity and structured clinical insight, while *Jalpakalpataru* offers analytical depth and conceptual expansion. The differences arise from variations in historical context, intellectual influences, and methodological approaches, ultimately enriching the understanding of *Vimana Sthana* and its application in Ayurveda.

CONCLUSION

Vimana Sthana of the *Charaka Samhita* represents a conceptually significant section that encapsulates essential principles governing health, disease, and therapeutic planning in Ayurveda. It systematically elaborates key determinants such as *Dosha*, *Bheshaja*, *Desha*, *Kala*, *Bala*, *Shareera*, *Sara*, *Ahara*, *Satmya*, *Satva*, *Prakriti*, and *Vaya*, thereby providing a structured framework for individualized clinical assessment. Owing to this integrative approach, *Vimana Sthana* can be regarded as a concise synopsis of the entire Samhita. The role of classical commentaries is indispensable in understanding such a profound text. Commentators like Chakrapani Datta and Gangadhar Rai have significantly contributed to elucidating the layered meanings of the original verses. While Chakrapani's *Ayurveda Deepika* is marked by clarity, brevity, and clinical orientation, *Gangadhara'sJalpakalpataru* provides a more elaborate and analytical interpretation enriched with philosophical and interdisciplinary insights.A comparative evaluation of these commentaries is not aimed at establishing superiority but at understanding their complementary contributions. Differences in interpretation, explanatory style, and methodological approach highlight the diversity of Ayurvedic thought. Chakrapani emphasizes concise and practice-oriented explanations, whereas Gangadhara expands concepts through logical reasoning and broader contextual references.In conclusion, the comparative study of these commentaries enhances conceptual clarity, preserves the integrity of classical knowledge, and strengthens its relevance in contemporary academic and clinical practice

ABSTRACT

A simple, Accurate, precise method was developed for the simultaneous estimation of the Tadalafil and Macitentan in Tablet dosage form. Chromatogram was run through Waters Spherisorb (250mm x 4.6mm, 5µm). Mobile phase containing Mobile phase- Mixed 540ml of buffer solution and 460 mL of Acetonitrile was pumped through column at a flow rate of 1.2 ml/min. Temperature was maintained at 25^0C. Optimized wavelength for Tadalafil and Macitentan was 225 nm. Retention time of Tadalafil and Macitentan were found to be 2.341 min and 3.075 min. %RSD of the Tadalafil and Macitentan were and found to be 0.7 and 0.5 respectively. %Recovery was obtained as 100.92% and 99.73% for Tadalafil and Macitentan respectively. LOD, LOQ values obtained from regression equations of Tadalafil and Macitentan were 0.06, 0.18 and 0.02, 0.06 respectively. Regression equation of Macitentan is y = 148827x + 20254, and y = 51925x + 2733.9 of Tadalafil. Retention times were decreased and that run time was decreased, so the method developed was simple and economical that can be adopted in regular Quality control test in Industries.

Keywords: Tadalafil and Macitentan, RP-HPLC

INTRODUCTION

The pharmaceutical sector produces a wide range of medications with diverse therapeutic applications. In certain cases, the combination of two or more active pharmaceutical ingredients results in the development of fixed-dose combinations (FDCs) to enhance therapeutic efficacy and patient compliance. These combination therapies provide improved pharmacological outcomes compared to monotherapy and simplify treatment regimens. However, the presence of multiple active drugs in a single dosage form creates challenges in the development of reliable analytical methods and validation procedures. Considerable research efforts by scientists and academicians worldwide have led to the development of various analytical techniques for the identification, quantification, and quality assessment of pharmaceutical compounds. These analytical methods are essential to ensure the identity, safety, potency, and overall quality of pharmaceutical formulations. Tadalafil is a selective phosphodiesterase-5 (PDE-5) inhibitor widely used in the treatment of pulmonary arterial hypertension and erectile dysfunction. It works by increasing cyclic guanosine monophosphate (cGMP) levels, leading to relaxation of vascular smooth muscles and improved blood flow. Macitentan is an orally active endothelin receptor antagonist used primarily for the management of pulmonary arterial hypertension.

It exerts its therapeutic action by blocking endothelin-1 receptors, thereby reducing vasoconstriction and vascular remodeling in pulmonary arteries. According to literature surveys, several analytical techniques such as high-performance liquid chromatography (HPLC) have been reported for the determination of these drugs individually or in combination with other pharmaceutical agents. However, only limited analytical methods are available for their simultaneous estimation in combined dosage forms, and most of the reported methods involve sophisticated techniques such as LC-MS or complex chromatographic conditions. Therefore, there is a need for a simple, economical, accurate, and reliable analytical method for the simultaneous estimation of tadalafil and macitentan in bulk drugs and pharmaceutical dosage forms. The objective of the present study is to develop and validate a rapid, precise, and cost-effective method suitable for routine analysis of these drugs in combination formulations. Among the available analytical techniques, reverse-phase high-performance liquid chromatography (RP-HPLC) is considered one of the most efficient and widely used methods for pharmaceutical analysis due to its high sensitivity, selectivity, and ability to detect both active ingredients and impurities in a sample, making it highly suitable for routine quality control and evaluation of pharmaceutical products.

MATERIALS AND METHODS

Materials

TadalafilandMacitentanpure drugs (API) procured from sigma aldrich, Combination Foslevodopa and Foscarbidopatablet with brand name Opsynvi, Distilled water, Acetonitrile, Methanol, Potassium dehydrogenortho phosphatebuffer,Ortho-phosphoric acid. All the above chemicals and solvents are from Rankem industries.

Instruments

ElectronicsBalance manufactured by Sortorious,ScaletecBsa224s-Cw, pHmeter and Ultrasonicatorby LABMAN,India, WATERS HPLC 2695 SYSTEM equipped with quaternary pumps, Photo Diode Array detector and Auto sampler integrated with Empower 3 Software, UV-VIS spectrophotometer PG Instruments T60 with special bandwidth of 2 mm and 10mm and matched quartz cells integrated with UV win 6Software.

Methods

Preparation of buffer:

0.1N Sodium hydroxide solution: 0.4 grams of NaOH, which should be dissolved in distilled water and the volume adjusted to 100 mL.

Buffer: 0.01M Potassium dihydrogen phosphate
Accurately take 2.7 gm of Potassium dihydrogen phosphate in a 1000ml of Volumetric flask add about 900ml of milli-Q water added and degas to sonicate and finally make up the volume with water then PH adjusted to 5.4 with 0.1N Sodium hydroxide solution.
Mobile phase- Mixed 540ml of buffer solution and 460 mL of Acetonitrile
Diluent- Mobile phase

Standard Solution

Preparation of Standard stock solutions: Accurately weighed 10 mg of Macitentan, 20 mg of Tadalafil and transferred to 100 ml volumetric flask separately. 3/4 th of diluents was added to both flasks and sonicated for 10 minutes. Flasks were made up with diluent and labeled as Standard stock solution 1and 2. (100µg/ml of Macitentan and 200µg/ml of Tadalafil)
Preparation of Standard working solutions (100% solution): 1ml from each stock solution was pipetted out and taken into a 10ml volumetric flask and made up with diluent. (10µg/ml Macitentan and 20µg/ml of Tadalafil)
Sample solutions
Preparation of Sample stock solutions: 10 tablets were weighed and equivalent to 1 tablet is weighed and transferred to 100 ml volumetric flask, to this 100 ml of acetonitrile was added and sonicated. Volume was made upto 100ml with diluents and filtered through
0.45 µm or finer porosity membrane filter (100µg/ml of Macitentan and 200µg/ml of Tadalafil)
Preparation of Sample working solutions (100% solution): 1ml of filtered sample stock solution was transferred to 10ml volumetric flask and made up with diluent. (10µg/ml of Macitentan and 20µg/ml of Tadalafil)

RESULTS AND DISCUSSION

OptimizedChromatographicconditions

A KromosilC18(4.6x150mm,5µm) column was used for the chromatographic analysis. For separation, a mobile phase consisting of Formicacid andAcetonitrile (60:40v/v) was used, with a flow rate of 0.8 ml/min. The eluents were detected at 260 nm with an injection volume of 10µL. The HPLC system was operated at room temperature, which was 25^{0}C with a run time of 5min and WaterandAcetonitrileintheratio50:50 v/v was used as diluent.

System suitability
The system suitability parameters were determined by preparing standard solutions of Macitentan (10ppm) and Tadalafil (20ppm) and the solutions were injected six times and the parameters like peak tailing, resolution and USP plate count were determined.The % RSD for the area of six standard injections results should not be more than 2%.
Specificity: Checking of the interference in the optimized method. We should not find interfering peaks in blank and placebo at retention times of these drugs in this method. So, this method was said to be specific.

PRECISION

Preparation of Sample stock solutions: 10 tablets were weighed and equivalent to 1 tablet is weighed and transferred to 100 ml volumetric flask, to this 100 ml of acetonitrile was added and sonicated. Volume was made upto 100ml with diluents and filtered through 0.45 µm or finer porosity membrane filter (100µg/ml of Macitentan and 200µg/ml of Tadalafil)

Preparation of Sample working solutions (100% solution): 1ml of filtered sample stock solution was transferred to 10ml volumetric flask and made up with diluent. (10µg/ml of Macitentan and 20µg/ml of Tadalafil).The Precision were determined by preparing Sample solutions of Macitentan (10ppm) and Tadalafil (20ppm) and the solutions were injected six times and the % RSD for the area of six standard injections results should not be more than 2%.

LINEARITY

Preparation of Standard stock solutions: Accurately weighed 10 mg of Macitentan, 20 mg of Tadalafil and transferred to 100 ml volumetric flask separately. 3/4 th of diluents was added to both flasks and sonicated for 10 minutes. Flasks were made up with diluent and labeled as Standard stock solution 1and 2. (100µg/ml of Macitentan and 200µg/ml of Tadalafil)
25% Standard solution: 0.25ml each from standard stock solution was pipetted out and made up to 10ml. (2.5µg/ml of Macitentan and 5µg/ml of Tadalafil)
50% Standard solution: 0.5ml each from standard stock solutions was pipetted out and made up to 10ml. (5µg/ml of Macitentan and 10µg/ml of Tadalafil)
75% Standard solution: 0.75ml each from standard stock solutions was pipetted out and made up to 10ml. (7.5µg/ml of Macitentan and 15µg/ml of Tadalafil)
100% Standard solution: 1.0ml each from standard stock solutions was pipetted out and made up to 10ml. (10µg/ml of Macitentan and 20µg/ml of Tadalafil)
125% Standard solution: 1.25ml each from standard stock solutions was pipetted out and made up to 10ml. (12.5µg/ml of Macitentan and 25µg/ml of Tadalafil)
150% Standard solution: 1.5ml each from standard stock solutions was pipetted out and made up to 10ml (15µg/ml of Macitentan and 30µg/ml of Tadalafil)

Accuracy:
Preparation of Sample stock solutions: 10 tablets were weighed and equivalent to 1 tablet is weighed and transferred to 100 ml volumetric flask, to this 100 ml of acetonitrile was added and sonicated. Volume was made upto 100ml with diluents and filtered through 0.45 µm or finer porosity membrane filter (100µg/ml of Macitentan and 200µg/ml of Tadalafil)
Preparation of Standard working solutions (100% solution): 1ml from stock solution was pipetted out and taken into a 10ml volumetric flask and made up with diluent. (10µg/ml Macitentan and 20µg/ml of Tadalafil)
Preparation of 50% Spiked Solution: 0.5ml of sample stock solution was taken into a 10ml volumetric flask, to that 1.0ml from each standard stock solution was pipetted out, and made up to the mark with diluent.
Preparation of 100% Spiked Solution: 1.0 ml of sample stock solution was taken into a 10ml volumetric flask, to that 1.0ml from each standard stock solution was pipetted out, and made up to the mark with diluent.
Preparation of 150% Spiked Solution: 1.5ml of sample stock solution was taken into a 10ml volumetric flask, to that 1.0ml from each standard stock solution was pipetted out, and made up to the mark with diluent.
Acceptance Criteria: The % Recovery for each level should be between 98.0 to 102 %

Robustness: Small deliberate changes in method like Flow rate, mobile phase ratio, and temperature are made but there was no recognized change in the result and are within range as per ICH Guide lines.Robustness conditions like Flow minus (1.1ml/min), Flow plus (1.3ml/min), mobile phase minus, mobile phase plus, temperature minus (20^0C) and temperature plus (30^0C) was maintained and samples were injected in duplicate manner. System suitability parameters were not much affected and all the parameters were passed. %RSD was within the limit.

Sensitivity

LOD sample Preparation: 0.25ml each from two standard stock solutions was pipetted out and transferred to two separate 10ml volumetric flasks and made up with diluents. From the above solutions 0.3ml each of Macitentan, Tadalafil, solutions respectively were transferred to 10ml volumetric flasks and made up with the same diluent.
LOQ sample Preparation: 0.25ml each from two standard stock solutions was pipetted out and transferred to two separate 10ml volumetric flask and made up with diluent. From the above solutions 0.9ml each of Macitentan, Tadalafil, and solutions respectively were transferred to 10ml volumetric flasks and made up with the same diluent.

Degradation studies

Oxidation

To 1 ml of stock solution of Tadalafil and Macitentan, 1 ml of 20% hydrogen peroxide (H_2O_2) was added separately. The solutions were kept for 30 min at 60^0c. For UPLC study, the resultant solution was diluted to obtain 10µg/ml & 20µg/ml solution and 10 µl were injected into the system and the chromatograms were recorded to assess the stability of sample.

Acid Degradation Studies:

To 1 ml of stock ssolutionTadalafil and Macitentan, 1 ml of 2N Hydrochloric acid was added and refluxed for 30mins at 60^0c. The resultant solution was diluted to obtain 10µg/ml & 20µg/ml solution and 10 µl solutions were injected into the system and the chromatograms were recorded to assess the stability of sample.

Alkali Degradation Studies:

To 1 ml of stock solution Tadalafil and Macitentan, 1 ml of 2N sodium hydroxide was added and refluxed for 30mins at 60^0c. The resultant solution was diluted to obtain 10µg/ml & 20µg/ml solution and 10 µl were injected into the system and the chromatograms were recorded to assess the stability of sample.

Dry Heat Degradation Studies:

The standard drug solution was placed in oven at 105^0C for 1 h to study dry heat degradation. For UPLC study, the resultant solution was diluted to 10µg/ml & 20µg/ml solution and 10µl were injected into the system and the chromatograms were recorded to assess the stability of the sample.

Photo Stability studies:

The photochemical stability of the drug was also studied by exposing the 100µg/ml & 200µg/ml solution to UV Light by keeping the beaker in UV Chamber for 1days or 200-Watt hours/m2 in photo stability chamber. For HPLC study, the resultant solution was diluted to obtain 200µg/ml & 20µg/ml solutions and 10 µl were injected into the system and the chromatograms were recorded to assess the stability of sample.

Neutral Degradation Studies:

Stress testing under neutral conditions was studied by refluxing the drug in water for 1h r s at a temperature of 60^0C. For HPLC study, the resultant solution was diluted to 10µg/ml & 20µg/ml solution and 10 µl were injected into the system and the chromatograms were recorded to assess the stability of the sample.

CONCLUSION

This simultaneous estimation of the Foscarbidopa and Foslevodopa in ointment dosage form had produced good results like retention time and theoretical plate count and resolution. Retention times were decreased and that run time was decreased.All the validation parameters met the acceptable criteria, so the method developed was simple and economical that can be adopted inregular quality control test in industries.

ABSTRACT

This paper examines the relationship between corporate governance (CG) quality, EVA (calculated using a year-specific ERP in a CAPM environment), and abnormal stock returns for five NIFTY Midcap IT companies during FY2016 2025 (50 firm-years). It constructs a seven-dimensional, 100-point CG index (board independence, gender diversity, board size, promoter ownership, audit and remuneration committee quality, and chair independence). It approximates pooled OLS models with HC1-robust errors and year trends. CG scores are positively, albeit statistically insignificant, related to ROA, Tobin Q and EVA, and nearly zero related to abnormal returns. In contrast, a Baron-Kenny mediation test with bootstrapped confidence intervals provides no evidence of abnormal returns mediating the effect of CG on firm value. On the descriptive side, sector EVA has increased significantly by₹53 crore to more than ₹514 crore, and governance scores have moved up slightly (since COVID) to 82, reflecting better capital efficiency and board practices. The findings of component regressions indicate that high gender diversity and reduced promoter concentration are both significantly related to EVA, and tighter remuneration committees are related to lower EVA, implying that aggregate CG scores can conceal heterogeneous, even counteracting, the influence of individual governance leverage-relevant information on the CG agenda of SEBI and on ESG-based stock selection.

INTRODUCTION

The Indian IT industry has a unique presence in the domestic capital market. By 2025, it will have contributed approximately 7.5 per cent of GDP, provided employment to over five million individuals, and generated over USD 250 billion in annual revenues (NASSCOM, 2024; RBI, 2024). In addition to these numbers, the industry attracts governance researchers because of the high level of involvement of foreign institutional investors (FIIs), the extent of analyst coverage, internationally recognised governance standards, and an asset-lite model in which traditional capital adequacy measures are less informative. The characteristics render Indian IT companies a distinctive yet under-researched setting for investigating the governance-value correlation.The IT sector is seldom examined in isolation in the existing literature. A majority of the Indian corporate governance (CG) literature pools firms across sectors (Sarkar & Sarkar, 2012; Jackling & Johl, 2009; Black et al., 2006), using industry variation as controls. Although this is of some use in general analysis, it does not account for sector-specific dynamics. IT companies tend to have higher promoter ownership than multinational manufacturing companies, but they also face global governance expectations from clients and institutional investors. This two-sided pressure forms unique governance frameworks that develop as the industry matures.

Methodologically, prior CG studies rely on accounting measures such as ROA, ROE, and EPS, which overlook the cost of capital. This is a critical limitation in industries where equity risk premiums (ERP) vary. This was tackled by Stewart (1991) in Economic Value Added (EVA), which subtracts WACC from NOPAT. Expanding on this, the current analysis modifies the cost of equity using year-specific ERP estimates based on Damodaran's implied premium method, increasing it by 8.16-9.24 in FY2016 and FY2025. This approach eliminates time-varying bias in EVA estimation, unlike the fixed ERP assumptions.Normal stock returns are also included in the study; they are described as actual total shareholder returns, calculated as the difference between actual returns and CAPM-based expected returns, and the ERP is calculated on a year-by-year basis. Abnormal returns are a result of good governance in the governance literature (Gomers et al., 2003) and a channel of transmission to firm performance (Bebchuk et al., 2009). This paper tests their mediating effects using the Baron & Kenny (1986) model, with bootstrap verification.This study has four contributions. First, it provides a decade-long, industry-specific study of governance, EVA, and abnormal returns of Indian mid-cap IT companies. Second, it presents a dynamic ERP-adjusted EVA model. Third, it breaks down the CG index into seven parts to reflect heterogeneity in governance. Fourth, it looks at three sub-periods: Pre-COVID, COVID-Transition, and Post-COVID, reflecting structural changes in the sector.

THEORETICAL FOUNDATIONS AND LITERATURE REVIEW

2.1 Agency Theory, Signalling, and the Governance–Value Nexus

Agency theory (Jensen & Meckling, 1976) clarifies conflicts arising from the separation of ownership and control, whereby managers may be self-interested at the expense of shareholders. These agency costs can be reduced through governance mechanisms such as independent boards, audit oversight, transparent compensation, and institutional monitoring, which can align managerial actions with the maximisation of value. A plausible market signal in a highly information-asymmetric environment is emphasised by signalling theory (Spence, 1973) and governance. This is especially applicable to IT companies, where intangible resources predominate. Well-established governance systems, such as independent boards and performance-based pay, signal credible performance to investors, reducing the perceived risk and cost of equity. An opposing theory is the stewardship theory (Davis et al., 1997), which proposes that managers are inherently goal-oriented. Too many governance controls can thus lead to rigidity and performance deterioration. This is of particular concern to IT companies, where managerial agility and innovation play a vital role

Corporate Governance Research in Indian Markets

CG research in India has passed through three stages. The initial stage focused on composite indices of governance and intersectoral relationships, which showed a positive correlation between governance and firm value. As an example, Jackling and Johl (2009) found a negative correlation between board size and the Tobin Q. In contrast, Sarkar and Sarkar (2012) found threshold effects in the independence of boards relative to promoter ownership. The second stage evaluated the ownership structure. Non-linear effects of promoter concentration on performance were discovered by Kohli and Sur (2006) and apply to IT companies with different ownership structures, including Coforge and Persistent Systems. The third stage used advanced panel techniques. Gupta et al. (2020) employed the SEBI requirement for women directors to establish causal relationships with profitability, whereas Bhatt and Bhast (2017) demonstrated that audit committee independence is associated with higher ROA. Nevertheless, there are few IT-specific research studies based on EVA-based performance

Economic Value Added: Why It Matters Here

EVA is a real economic profit measure because it accounts for the entire cost of capital. A company might record accounting profits even when it is destroying value because returns are below WACC (Stewart, 1991). This is especially applicable to IT companies, where high ROE has been observed. However, they are highly prone to equity risk due to operational volatility and reliance on a small group of key employees. Earlier research (Fernandez, 2001; Deo & Mukherjee, 2011) indicates that EVA is better than conventional measures at explaining shareholder value. This paper builds upon that research by introducing time-varying ERP, which does not rely on the biases of making static assumptions.

Abnormal Returns and the Governance Premium

Gomers and others (2003) reported considerable abnormal returns from governance-based investment policies in the US. However, subsequent evidence (Bebchuk et al., 2009) indicates that this premium has decreased due to increased market efficiency. Similar trends were observed in India, where Varshney et al. (2012) found that excess returns related to governance reduced following regulatory changes. With such FII involvement and analyst attention to IT companies, information about governance is expected to be priced in faster, making it difficult to earn abnormal returns. This is the proposition that is empirically tested in this study.2.5 Governance within the IT Sector: Three Sector-Specific Factors.

Governance in the IT Sector: Three Sector-Specific Factors

IT governance has three sector-specific features. First, external discipline is enforced by global clients who set governance standards through procurement requirements. Second, intangible assets predominate, which increases the significance of human capital and intellectual property risk control. Third, the 2020-2025 digital transformation wave, driven by cloud, AI, and cybersecurity, improved the sector's performance, which might overwhelm the specific impact on governance.

Hypotheses

H_1: CG quality (composite score) is positively associated with ERP-corrected EVA in Indian mid-cap IT firms over FY2016–FY2025.

H_2: CG quality is positively associated with year-wise ERP-corrected abnormal stock returns in Indian mid-cap IT firms.

H_3: Abnormal stock returns partially mediate the relationship between CG quality and firm value proxies (EVA, Tobin's Q, ROA) in Indian mid-cap IT firms.

Data, Variables, and Methodology

Sample and Data Sources

The portfolio includes five IT companies, namely Coforge Limited, Mphasis Limited, Oracle Financial Services Software Limited, Persistent Systems Limited, and Tata Elxsi Limited, all of which are part of the NIFTY MIDCAP

150 index as of March 2025. The sample period is FY201516 to FY202425, resulting in 50 firm-years observations, and there is no attrition. The five companies also represent three sub-segments: IT services (Coforge, Mphasis, Persistent Systems), fintech platform software (Oracle Financial Services), and technology design and engineering (Tata Elxsi), which offer good cross-sectional diversity within a narrow industry definition. The financial variables, including total assets, EBIT, depreciation, effective tax rate, and market capitalisation, were extracted from the Capitaline database and reconciled with audited annual reports on the NSE EDGAR portal. Governance data, including board composition, committee membership, ownership, and director profiles, were manually gathered from annual reports, corporate governance reports, and SEBI disclosure filings. The official NSE portal was used to obtain market pricing data and index benchmarks. The year-wise ERP estimates were derived from public data provided by Professor Aswath Damodaran (pages.stern.nyu.edu/~adamodar).

CG Score Construction

Table 1 documents the seven-component, 100-point CG scoring framework, calibrated against SEBI's LODR Regulations, 2015. The MOC component will be scored inversely: the higher the promoter concentration, the lower the score, which encapsulates the entrenchment hypothesis. MOC brings in significant cross-sectional variation, with promoter stakes ranging from 31.1 per cent (Persistent Systems) to 62.3 per cent (Coforge). The scores for each component are computed based on data disclosed annually since then; therefore, the CG score varies across firms and over time.

EVA with Year-Wise ERP Correction

EVA for each firm-year is: $EVA_{it} = NOPAT_{it} - WACC_{it} \times Capital\ Employed_{it}$, where NOPAT = EBIT × (1 − effective tax rate). WACC = $K_e \times E/(E+D) + Kd \times D/(E+D) \times (1-T)$, with the cost of equity $K_e = Rf + \beta \times ERP$. The risk-free rate is the prevailing 10-year GoI bond yield at the start of each financial year; beta is a rolling two-year estimate from daily NSE prices; ERP is Damodaran's India-implied annual figure. Mean leverage across the panel is just 0.030, so WACC is almost entirely a cost-of-equity story, and the ERP correction matters considerably. Panel ERP values range from 7.62 per cent (FY2017, FY2021) to 9.24 per cent (FY2025), generating CAPM benchmarks between 12.46 per cent (FY2020) and 14.49 per cent (FY2019).

Abnormal Return Construction

Abnormal $return_{it} = R^A_{it} - CAPM_{it}$, where R^A is the compound annual total return (price plus dividends) for firm i over year t. The 0.262 mean panel abnormal returns reflect the large IT mid-cap performance in the COVID-transition and post-COVID cycles; FY202021 alone had a mean of 1.712, reflecting the unprecedented demand re-rating in the digital services sector during the pandemic.

Econometric Specification

Our pooled OLS model (HC1-robust standard error) is: $DV_{it} = \alpha + \beta_1 CG_Score_{it} + \beta_2 Leverage_{it} + \beta_3 Log_Assets_{it} + \beta_4 Year_t + \varepsilon_{it}$, . Instead of using 10 dummy variables, we add Years as a linear time trend in continuous time, preserving degrees of freedom in a small sample while still capturing the sector's secular upswing. HC1 heteroscedasticity-robust errors address scale heterogeneity. The mean assets of Oracle Financial Services (₹5,262.6 crore) are approximately three and a half times those of Tata Elxsi (₹1,534.3 crore). In mediation testing, we apply the four sequential OLS steps of Baron and Kenny (1986): Paths c, a, b, and c+ of Baron and Kenny (1986). We complement this with a 2000-resample bias-corrected (BC) bootstrap 95% confidence interval (seed = 42) of the indirect effect (a × b). The BC-bootstrap CI is only said to be verified when it rules out a zero, a more conservative test than the Sobel Z-test, which assumes the normality of the data being tested, which is not plausible at the n = 50 point.

EMPIRICAL RESULTS

Descriptive Statistics

There are three characteristics. To begin with, the average EVA of 354.01 crore is strongly positive, in sharp contrast to the pharmaceutical companion segment (average EVA of -117.86 crore). The asset-light delivery model, virtually zero tangible capital needs, and a large NOPAT margin (mean ROA = 22.93) in the IT sector keep EVA positive even after eliminating the annual cost of equity. Second, the average leverage of 0.030 corroborates the industry's near-debt-free status and indicates that the ERP correction has a particularly significant impact on EVA's accuracy. Third, the median of the mean Tobin of 7.00 (Q 7.57) indicates that the market is paying a lot of attention to intangibles, namely software platform, client base, and IP, which is consistent with a business model where book value is not a good predictor of value. At the company level, Oracle Financial Services has the largest average EVA (₹902.17 crore) due to near-monopoly-level software licence earnings on a small capital base. Coforge reports the least (₹103.62 crore), as it has to make a more substantial capital investment in its shift towards digital services rather than legacy BPO. The mean Tobin Q of Tata Elxsi, at 12.67, indicates it is in a high-end design-engineering niche; Mphasis was trading at low multiples, which is in line with execution risk in a competitive sub-vertical.

CG Component Analysis

The VIFs are all less than 3.0 (the largest is BINDE at 2.737), so multicollinearity is not an issue. The BINDE mean of 24.39 out of 30 indicates good adherence to SEBI's independent-director requirement. The MOC mean of 9.77/10 suggests that these firms are already at the low end of promoter concentration, and there is little within-sample variation on this dimension. EVA regressions at the component level show substantial heterogeneity. The strongest positive drivers are gender diversity (BGENDIV, β = +₹29.72 crore, p = 0.009) and management ownership concentration (MOC, β = +₹122.66 crore, p = 0.015). The MOC finding that a higher score indicates a decrease in promoter concentration would imply that dispersed ownership harmonisesprofessional management's incentives with those of minority shareholders, thereby lowering agency costs and increasing EVA. The coefficient of REMUN is negative (=-92.42 crore, p=0.008), which is counterintuitive, and we break it down in Section 5. Board independence (BINDE, β = -29.00 crore, p = 0.022) is also negatively related to EVA, suggesting that compliance costs and risk aversion are concentrated among smaller IT companies with a high concentration of independent directors. Three patterns are interesting.

EVA increased to ₹53.18 crore in FY2016, to 604.50 crore in FY2024 and then to 514.47 crore in FY2025- an 11-fold increase followed by a moderating increase. The governance score trend declines in FY2019-2020 (to 71.25 and 72.26) as promoter pledges are disclosed more actively and board composition changes, then soars to an average of 82.87 in the post-COVID years. FY2021 is a conspicuous outlier in the abnormal return column: a mean of 1.712 (171.2% above the CAPM benchmark) reflects the pandemic-related re-rating of IT stocks as the digitalisation of enterprises gained momentum and far exceeded consensus forecasts.The sub-period data in Table 5 are consistent: the CG score, EVA, and the Tobin Q increase continuously from Pre-COVID to Post-COVID, with the Post-COVID period having the highest values across all three indicators. The fact that this co-movement manifests through an institutional reform cycle, beginning with SEBI's progressive amendments to the LODR and the compulsory BRSR model, lends circumstantial plausibility to a positive long-run governance-value relationship in the industry. However, our regression findings caution against asserting causality.

Correlation Analysis

The CG-EVA correlation (r = +0.222) is directionally supportive of H1, which is the opposite of the negative (-0.286) of the pharmaceutical companion analysis. The governance-valuation hypothesis is also supported by the correlation between the CG-Tobin Q and the CG-Tobin Q (r = +0.242). The bivariate correlation most likely to be noticeable is that of AbnRet and the TobinQ (r = +0.426, p < 0.001), suggesting that it is market momentum that causes the valuation ratios rather than governance in a given year- a significant qualification of a mediation effect. There is a positive correlation between EVA and the Log of Assets (r = +0.547), whereas in capital-intensive industries, scale is

negatively related to EVA (due to capital dilution). Here, the larger an IT firm is, the more EVA it will generate, since revenue grows faster than the asset base.

Regression Results — Direct Effects

All performance measures are positively correlated with CG quality and offer directional support to H1. None of the coefficients, however, attains traditional significance values. The value of the EVA coefficient (7.33 crore, p = 0.378) indicates that an increase in the CG score (5.30 points) at the standard deviation would increase EVA by approximately 38.8 crore; this is economically viable but statistically imprecise due to n = 50. A power calculation indicates that a minimum of 120 or 150 observations would be required to detect this effect at 5% significance with 80% power. The Tobin Q (= +0.136, p = 0.176) suggests that the increase in CG per standard deviation of about 9.5 is suggested to be 0.72, which is not economically insignificant. The CG0-AbnRet coefficient (= + 0.001, p = 0.955) is virtually zero, which does not support H2. H 3 is not supported. The critical failure is that Path a: CG AbnRet is insignificant (β = +0.001, p = 0.955) in all outcome specifications, thus ruling out the possibility of mediation before the analysis itself can be carried out. Path b is statistically significant for Tobin Q (+2.216, p = 0.087) and the MVA Ratio (+1.722, p = 0.054), indicating that market momentum transmits information about upcoming valuation ratios. However, since governance does not in itself provide those returns, we cannot attribute this transmission to governance signalling. All the BC-bootstrap confidence intervals of the indirect effect cut off zero, and it is established that there is no mediation by the most conservative standard available.

DISCUSSION

A Positive but Elusive CG–Value Link

Charitably interpreted, the evidence of regression would not have shown a relationship between CG quality and firm performance in our IT sample. The coefficients are consistently positive, and the EVA coefficient suggests a lift of about 39 crores per standard deviation of governance. With that said, none of these associations passes a traditional significance test, and the fair interpretation is that n = 50 does not provide sufficient statistical power to answer the question definitively. We can say that the direction of the results is the reverse of the negative CG-performance relationships observed in capital-intensive sectors in India, which supports the argument for sector-specific governance analysis rather than cross-industry panels. The most economically compelling outcome in the paper is the EVA growth trajectory, which increases to ₹605 crore in FY2024, despite not being fully governance-related, up from ₹53 crore in FY2016. The industry restructuring of labour-arbitrage outsourcing to high-margin digital transformation services is behind it. An increase in NOPAT per unit of capital is directly reflected in EVA, irrespective of changes in the cost of capital. Nonetheless, the fact that EVA and CG scores have moved together over the decade supports the idea that boards capable of governance are better positioned to navigate and utilise this strategic shift.

The REMUN Paradox and Component-Level Heterogeneity

The most interesting component-level finding is the very negative coefficient for REMUN-EVA (=-92.42 crore, p=0.008). On its face, a well-organised, independent remuneration committee that ties pay to performance directly and explicitly should discipline agency costs and increase EVA. There are two other possible explanations to consider. To begin with, the main value-creating asset in IT is executive talent. The top achievers in this industry will attract remuneration far beyond what a strictly regulated NRC would accept, with all directors being thoroughly independent. In case talent is scarceand remuneration governance is strict, EVA is hurt. Companies with stronger control over promoter-based compensation can, ironically, be better positioned to offer aggressive ESOP packages and retention bonuses to retain top digital talent. Second, a selection effect might be at play: firms that are already high performers may not yet have invested heavily in governance architecture. Governance investment does not lead to business performance in high-growth IT companies under this lifecycle pattern; rather, it lags. Either of the two explanations might account for the negative sign observed without necessarily implying that remuneration governance causally destroys value. The positive MOC-EVA value (= + 122.66 crore, p = 0.015) is less

counterintuitive: the less concentrated ownership is, the greater the incentive alignment between professional managers and institutional control, and the higher the EVA. Oracle Financial Services (where a strong parent owns approximately 73 per cent but professional management conducts business) and Persistent Systems (where a promoter owns approximately 31 per cent and large institutional ownership) are examples of how you can have dispersed ownership and high performance.

Why Governance Does Not Generate Abnormal Returns Here

The null on H2 can be explained in three mechanisms. The average NIFTY MIDCAP 150 IT endorsement by FII is 25-45 per cent of the free-float. These are active, informed investors whoare motivated to keep governance under constant scrutiny. Governance quality is nearly always priced in by the time a full financial year starts, so that over the next twelve months, there is no abnormal return attributable to governance. In addition, annual stock returns on IT stocks are characterised by deal wins, quarterly revenue announcements, the US macroeconomic cycle (which establishes IT spending budgets), and news of technology waves that overwhelm any governance-quality impact on annual returns. Lastly, the CG score per se varies gradually among firms in the long run; the within-firm annual standard deviation is low compared to the cross-firm one, and it is truly hard to find a governance-return correlation in a short panel.

Post-COVID Governance Maturation and the Digital Dividend

The post-COVID sub-period (FY20232025) has the highest combined reading in terms of governance quality (mean CG = 81.28), EVA (Rs. 550.10 crore), and the Q of Tobin (9.58) in our panel. This merging is analytically fascinating. Board stress tests became visible during the COVID years: supply-chain shocks, remote-work shifts, and regulatory challenges all intensified. Institutional investors reacted by increasing their governance demands. It seems that the investments the government has made in governance under pressure are now beginning to yield results, including increased economic value added and stock market gains. It is also noteworthy that the post-COVID period is associated with the mandatory implementation of the BRSR for the top 1,000 listed entities, starting in FY202223. IT companies, which are already more institutionally engaged, were early adopters of BRSR. These improved disclosure and governance practices are reflected, in part, in the rising post-COVID CG scores. The current panel cannot determine whether better governance, the overall wind of digital transformation, or a combination of both led to the improved EVA. However, the time correspondence provides us with an incentive to consider the governance channel seriously as a complement to the structural growth narrative.

CONCLUSIONS, POLICY IMPLICATIONS, AND FUTURE RESEARCH

Summary of Findings

Summarizing our results: at the composite level, pooled OLS models (including standard controls) positively and, although not significantly, correlated composite CG quality with EVA (+ = + 7.33 crore, p = 0.378), ROA (+ = + 177, p = 0.374), and Tobin Q (+ = + 136, p = 0 CG quality is not associated with abnormal returns (= +0.001, p = 0.955) and rejects H 2 and mediation test short-circuits before it can start; BC-bootstrap intervals of all indirect effects contain zero and H 3 is rejected. Gender diversity and lower promoter concentration are important positive predictors of EVA at the component level. Simultaneously, the unexpectedly negative result of stricter remuneration governance is unexpected, which does not allow for easy interpretation and is evidence of heterogeneity under the mask of the composite score. The most notable result of the decade is arguably the secular trend in EVA, an 11-fold increase between FY2016 and FY2024, reflecting an impressive improvement in capital efficiency in the Indian IT industry and consistent governance upgrades.6.2 Policy Implications

Policy Implications

According to the REMUN paradox, standardised, manufacturing-based norms of governance might fail to apply in talent-based IT companies. SEBI might want to consider flexibility in remuneration policies that are industry-sensitive, but not at the expense of accountability. Investors and ESG analysts should not rely on composite scores,

since component-based governance metrics can highlight important drivers of performance, such as ownership structure and board diversity, that are obscured in aggregation. For boards of IT firms, governance investments may be strategically positioned as value-creating rather than compliance costs, supported by the measured correlation between governance gains and EVA gains.

Limitations and Directions for Future Research

The limited sample restricts the extent to which the sample can be generalised and does not allow the use of firm fixed effects. It would be possible to expand the dataset to include mid-cap and large-cap IT companies (e.g., TCS, Infosys) to enable more robust panel techniques and address heterogeneity. EVA estimates are sensitive not only to the assumption of beta but also to the choice of the risk-free rate. Future research can test the robustness of EVA with rolling betas and other risk-free rates. Other areas that require further research include non-linear effects and interaction effects, especially among governance, promoter ownership, FII participation, and digital investment. The question of whether governance improves the returns to digital transformation is a promising area of investigation.

ABSTRACT

Video Instance Segmentation (VIS) is a complex computer vision task that requires simultaneously detecting, segmenting, and tracking object instances across video frames. It represents a significant step beyond image-level segmentation by introducing the critical element of temporal consistency. This paper provides a comprehensive survey of the evolving landscape of VIS. We begin by outlining the fundamental challenges that distinguish VIS from its image-based counterpart, including occlusions, motion blur, and the need for robust temporal association. The survey then systematically categorizes and reviews modern VIS methodologies, dividing them into three predominant paradigms: online methods, which process frames sequentially for real-time applications; offline methods, which utilize future frames for higher accuracy; and the emerging query-based methods, which leverage attention mechanisms to unify the task.

Keywords: Video Instance Segmentation, Video Object Tracking, Instance Segmentation, Temporal Modeling, Computer Vision.

INTRODUCTION

The field of computer vision has made remarkable strides in understanding static images, with tasks like object detection and instance segmentation achieving human-level performance on many benchmarks [1]. However, the visual world is inherently dynamic. Videos, which constitute a vast portion of visual data, present a more complex

and richer domain for analysis. Video Instance Segmentation (VIS) has emerged as a pivotal task that sits at the intersection of image instance segmentation and multi-object tracking. The goal of VIS is not only to identify and precisely delineate each object in every frame but also to consistently associate the same object instance across the temporal dimension of the video [2].This unification offers a more holistic understanding of visual scenes, enabling applications that require a fine-grained and persistent perception of objects. Such applications are diverse and critical, including autonomous driving, where tracking other vehicles and pedestrians is essential for navigation; video editing and content creation, allowing for automated object manipulation; video surveillance for security and monitoring; and advanced human-computer interaction systems [3].

Despite its potential, VIS is fraught with challenges that are absent in image-based tasks. Factors such as significant object motion, partial or complete occlusions, motion blur, changes in appearance and lighting, and the computational burden of processing frame sequences all contribute to the difficulty of the problem [4]. A successful VIS system must be robust to these temporal variations while maintaining high spatial accuracy. The objective of this survey is to provide a structured overview of the current state of Video Instance Segmentation. We will trace the evolution of VIS methodologies from their early prototype stages to the sophisticated deep learning models of today. We will categorize existing approaches, analyze their strengths and weaknesses, and review the standard benchmarks and metrics used for evaluation. By synthesizing the recent advancements and identifying open challenges, this paper aims to offer a clear roadmap for future research in this rapidly advancing field.

Objectives

The primary objectives of this survey paper are as follows:

- To Define and Formalize the VIS Task: Provide a clear and concise definition of the Video Instance Segmentation problem, distinguishing it from related tasks like video object segmentation (VOS) and tracking-by-detection.
- To Categorize Methodological Paradigms: Systematically organize and present a taxonomy of contemporary VIS methods, with a focus on the key distinction between online, offline, and query-based frameworks.
- To Review Key Architectures and Techniques: Delve into the technical details of representative state-of-the-art models, explaining their core components, such as propagation networks, association modules, and the novel use of object queries in transformer-based architectures.
- To Summarize Benchmarks and Evaluation: Catalog the standard datasets (e.g., YouTube-VIS [2], OVIS [5]) and evaluation metrics (e.g., average precision and recall) used to measure progress in the field.
- To Identify Challenges and Future Directions: Highlight the persistent challenges facing VIS research and propose promising avenues for future work, including the integration of large-scale models, self-supervised learning, and efficiency improvements.

METHODS

The methodologies for Video Instance Segmentation can be broadly classified into three main paradigms based on their inference strategy and architectural design.

Online Methods

Online methods represent the foundational approach to the Video Instance Segmentation (VIS) task. Characterized by their sequential, frame-by-frame processing, these methods are designed for scenarios requiring real-time or low-latency inference, such as autonomous navigation and live video analysis. The core principle of online methods is to propagate information from past frames to the current frame to maintain temporal consistency of instance identities.

- Detection-based Propagation: Early methods like MaskTrack R-CNN [2] extended the popular Mask R-CNN [1] architecture by adding a tracking head. This head takes the previously predicted mask and RoI features to compute similarity scores for association in the current frame.

- Feature Propagation: Subsequent works focused on propagating deep features rather than just masks. For instance, STEm-Seg [6] constructs a spatiotemporal volume from a clip of frames and uses 3D convolutions to jointly model spatial and temporal contexts, generating instance masks and associations simultaneously.

Offline Methods

Offline methods, also known as clip-based or batch processing methods, represent a fundamental paradigm in Video Instance Segmentation (VIS) that leverages global temporal context to achieve superior accuracy and robustness. Unlike their online counterparts that process frames sequentially, offline methods operate on complete video clips, enabling them to utilize information from both past and future frames simultaneously. The core philosophy of offline VIS stems from the observation that human visual perception often requires looking ahead and behind to resolve ambiguities in complex scenes. When humans encounter occlusions or rapid motion in videos, we naturally use contextual information from adjacent frames to maintain consistent object identities and precise boundaries.

Proposal Linking: Methods like CrossVIS [7] generate instance segmentation masks for each frame independently and then link these masks across frames in a post-processing step using learned similarity measures. This can be computationally expensive but achieves strong performance.

- Dense Feature Correlation: These approaches build a dense feature representation for the entire video and perform segmentation and tracking in a unified volume. They excel at handling complex motions but can be memory-intensive for long videos.

Query-Based Methods

Video Instance Segmentation has undergone a revolutionary transformation with the advent of query-based methods, marking a significant departure from traditional multi-stage pipelines. This paradigm shift represents the convergence of several key trends in computer vision. Inspired by the success of DETR [8] in object detection, a new paradigm has emerged that frames VIS as a set prediction problem. This family of methods has rapidly become state-of-the-art.Traditional VIS methods inherited a fragmented approach from their image-based predecessors, treating detection, segmentation, and tracking as separate problems requiring complex hand-crafted components.

The breakthrough came with the adaptation of transformer architectures from natural language processing to computer vision. The key insight was recognizing that VIS could be reformulated as a set prediction problem, where the goal is to directly predict a set of video-level instance tracks from pixel-level features.

- VIS with Transformers (VisTR): VisTR [9] was a pioneering work that directly models VIS as a sequence-to-sequence problem. It leverages a transformer architecture to process a sequence of video frames and output a sequence of instance predictions for the entire video clip in one pass, eliminating the need for many hand-crafted components like non-maximum suppression or tracklet association.
- Improved Query Design: Building on VisTR, methods like Mask2Former-VIS [10] and VITA [11] introduced deformable attention and contrastive learning for queries, respectively, to improve efficiency and handle a larger number of instances. These models use a fixed set of object queries that interact with the spatiotemporal feature volume via attention mechanisms to simultaneously decode the spatial extents and temporal identities of all instances.
-

Application Scenarios

- **Choose Online Methods when:**
  - Real-time processing is critical
  - Hardware resources are limited
  - Application can tolerate occasional tracking failures
  - Examples: Autonomous vehicles, surveillance systems
- **Choose Offline Methods when:**
  - Accuracy is more important than speed
  - Full video context is available

- Complex occlusions need to be handled
- Examples: Video editing, scientific analysis

- **Choose Query-Based Methods when:**
  - State-of-the-art performance is required
  - Research and development focus
  - Unified architecture is preferred
  - Examples: Benchmark competitions, advanced applications

Comparative Analysis of Video Instance Segmentation Paradigms

Discussion

The field of Video Instance Segmentation has progressed at an accelerated pace, largely driven by the adoption of transformer architectures and the conceptualization of the task as a direct set prediction problem. The query-based paradigm, in particular, has simplified the overall pipeline and set new performance standards.However, several challenges remain. First, the computational cost of processing long video sequences is still prohibitive. While clip-based methods are effective, scaling them to minute-long videos requires efficient memory and attention mechanisms. Second, generalization to unseen object categories and complex real-world scenarios, such as crowded scenes with severe and prolonged occlusions (as in OVIS [5]), is still inadequate. Most models are trained and evaluated on curated datasets and struggle with domain shift.

- Efficient Long-Range Modeling: Developing architectures that can efficiently capture long-term temporal dependencies without quadratic memory growth.
- Self-Supervised and Weakly-Supervised Learning: Reducing the reliance on expensive per-frame mask annotations by leveraging unlabeled video data for pre-training [13].
- Unified Video Understanding Models: Moving beyond a single task, future models may aim to jointly perform VIS, action recognition, and video captioning in a single, holistic framework, perhaps inspired by large language-vision models [14].
- Robustness and Fairness: Ensuring that VIS models are robust to adversarial attacks and do not exhibit biases against certain object types or in varying environmental conditions.

In conclusion, while current VIS methods, especially query-based models, have demonstrated impressive capabilities, the path towards human-level video understanding is long. The key to future breakthroughs lies in creating more efficient, generalizable, and holistic models.

ABSTRACT

Autoimmune Encephalitis (AE) is a diverse and rapidly changing collection of inflammatory disorders of the brain in which the host immune system reacts against neuronal or glial antigens, causing a subacute onset of cognitive dysfunction, psychiatric disturbances, seizures and movement abnormalities. In the last 20 years, the identification of expanding numbers of pathogenic autoantibodies, primarily against the N-methyl-D-aspartate receptor (NMDAR), leucine-rich glioma-inactivated protein-1 (LGI1) and contacting-associated protein-like 2 (CASPR2), has changed the nature of AE from a largely cryptogenic disorder to a diagnosable and potentially reversible condition. The incidence of AE is now approaching or equaling that of infectious encephalitis in many areas and its clinical importance is evident. Pathogenesis is a complex combination of receptor internalization with autoantibodies, complement activation, T-cell dysregulations, and plasma cell activity within the CNS. Current pharmacotherapy is guided by a step approach: first line - Corticosteroids, plasmapheresis and intravenous immunoglobulin (IVIG); second line - rituximab and cyclophosphamide; third line - bortezomib, tocilizumab or daratumumab for refractory disease. Newer technologies such as chimeric antigen receptor (CAR)-T cell therapy, Janus kinase (JAK) inhibitors, neonatal Fc receptor (FcRn) antagonists, and complement inhibitors are the next step in the future.

Keywords: Autoimmune encephalitis, anti-NMDAR encephalitis, anti-LGI1 encephalitis, autoantibodies, immunotherapy, rituximab, bortezomib, CAR-T cell therapy, seronegative encephalitis, neuroimmunology.

INTRODUCTION

Autoimmune encephalitis (AE) is a clinically and immunologically heterogeneous group of inflammatory disorders of the CNS that are secondary to immune-mediated attack against neuronal and glial protein. AE has been regarded as uncommon in the past, but has become increasingly prevalent in recent years and is now a major and increasing

cause of acute and subacute encephalopathy, superseding infectious causes in many clinical settings in the last 20 years. In 2007, Dalmau and colleagues discovered anti-NMDA receptor (anti-NMDAR) antibodies, which revolutionized the way encephalitis was practised and altered the paradigm of the disease from being predominantly an infectious process to having a strong immune-mediated component[1]. Since then, a growing list of autoantibodies against synaptic, neuronal surface and intracellular antigens has been discovered, each with a specific clinical phenotype and therapeutic responsiveness.

Clinical signs of AE are very wide-ranging, encompass neuropsychiatric, cognitive and seizure disorders, movement disorders and autonomic instability. They are often overlapping with main psychiatric diseases, infectious encephalitis, prion disease, metabolic encephalopathies, and neoplastic processes;thus, a timely diagnosis may be difficult. Early recognition and timely immunotherapy are the cornerstones of management, and these are strongly correlated with improved functional outcome, despite these challenges [2]. Incidence and prevalence of AE is increasing worldwide, not fully explained by an increase in the frequency of the disease, but also by increased awareness among clinicians, new developments in antibody testing platforms, and changing definitions of the disease. Epidemiologic information from a number of countries suggests that the incidence of AE has now become comparable to or surpassed that of viral encephalitis in many tertiary referral centres [3,4]. This review critically synthesises the current knowledge on AE in seven different areas: introduction, pathogenesis and immunopathology, diagnosis and practical issues, current pharmacotherapy, emerging and newer therapies, future directions and conclusions. It includes the best available recent research, systematic reviews and expert consensus documents up to 2025.

Pathogenesis and Immunopathology

The immunopathology of AE depends to a great extent on the nature of the target antigen - whether present at the neuronal cell surface, at the synaptic interface or present within the intracellular compartment - which dictates the major mechanisms of injury and thus the degree of clinical reversibility.

Antigen Classification and Disease Mechanisms

Cell-Surface and Synaptic Antigens:

The most clinically controllable subgroup is those with autoantibodies against cell-surface or synaptic antigens. In this case, autoantibodies, mainly of the IgG1 and IgG4 subclasses, directly bind to the accessible epitopes of receptor proteins, triggering their internalization, crosslinking, steric interaction and impairment [5]. The resulting dysfunction of the neurons is not caused by direct cytotoxic neuronal degeneration, causing patients to often recover significantly or even entirely when treatment is started in a timely manner.The most common form of AE is anti-NMDAR encephalitis, where the antibodies are mainly against the GluN1 (NR1) subunit of the NMDAR. Binding causes receptors to enter the endocytic pool and cause the surface density of NMDAR to decrease, which interferes with glutamatergic transmission. This internalization process is complement-independent, and the brain biopsy or autopsy of anti-NMDAR encephalitis generally reveals microglial activation and IgG deposits, with little if any neuronal loss, and no complement deposition [6]. Anti-NMDAR antibodies disinhibit the networks in the cortex by specifically reducing the function of inhibitory interneurons, which increases network excitability. This model of cortical disinhibition is similar to the neurobiological mechanisms suggested for schizophrenia, and therefore the strong psychiatric symptoms observed in early anti-NMDAR encephalitis [7].Anti-LGI1 encephalitis is a disorder in which antibodies attack leucine-rich glioma-inactivated protein 1, a secreted protein made by neurons that is part of the trans-synaptic LGI1-ADAM22/ADAM23 complex, which is involved in holding AMPA receptors in place at synapses. Autoantibodies to LGI1 block this interaction and lower the amount of AMPA receptors found at synapses, which also disrupts their plasticity, and may be involved in the extreme amnesia seen in this syndrome [8].

Intracellular Antigens:

The classical paraneoplastic encephalitides are caused by antibodies against intracellular antigens such as the Hu (ANNA-1), Yo (PCA-1), amphiphysin, CV2/CRMP5 and GAD65. These antibodies are generally accepted as a reflection of an underlying cytotoxic T-cell response and not as primary pathogenic agents since the target antigens are not found on the surface of the cell but rather within the cell [9]. Clinical recovery in these subtypes is often incomplete, and treatment responses are less strong, due to irreversible neurodegeneration resulting from T-cell mediated cytotoxicity.

Cells, Plasma Cells, and Autoantibody Production:

It is well established that B cell and B cell derivatives play critical roles in the pathogenesis of AE. Somatic hypermutation and affinity maturation of autoreactive B cells take place in germinal centres, with the assistance of follicular helper T (Tfh) cells. The ovarian teratoma serves as an ectopic germinal centre for autoantibody production in anti-NMDAR encephalitis, and less commonly, lymphoid tissue in the cervical lymph nodes [10].Circulating plasmablast and long-lived plasma cells sustain the production of autoantibody; and intrathecal antibody synthesis is responsible for the increased levels of antibody in CSF versus serum in anti-NMDAR encephalitis. This intrathecal compartmentalization is of therapeutic relevance as drugs that do not cross the blood–brain barrier (BBB) could fail to inhibit intrathecal autoantibody production [11].

T-Cell Mediated Mechanisms:

Single-cell immune profiling studies recently performed have shed light on the role of T cells in AE pathogenesis and this has been largely overlooked. In acute anti-NMDAR encephalitis, CSF contains increased numbers of CD4+ helper T cells, which are essential for the maturation of B cells and the diversification of autoantibodies by binding to its counterpart, CD40, and of activated CD4+ helper T cells, and increased numbers of cross-presenting dendritic cells, which may play a role in limited neuronal injury in some subtypes, through CD40-CD40L interactions [12]. Cytokine profiling studies have shown that CSF from AE patients contains higher levels of interleukin-6 (IL-6), interleukin-17 and CXCL10, which create an inflammatory environment that maintains the autoimmune response and is an attractive target for cytokine-directed therapies [13].

Triggers and Priming Events:

AE may occur in paraneoplastic, post-infectious and cryptogenic situations. In anti-NMDAR encephalitis, we believe that tumors, especially those of the ovary, cause immune tolerance to break by expressing aberrant neuronal antigens, which is the mechanism of action of other tumors, such as thymoma in anti-LGI1 and anti-CASPR2 encephalitis, and small cell lung cancer in anti-Hu encephalitis [9]. Anti-NMDAR encephalitis has been known to be triggered by HSV infections, including HSE, which can follow by 1- 4 weeks. Further, the role of neuroinflammatory priming has been highlighted as a 'molecular mimicry' or 'bystander activation' phenomenon, and immunotherapy, which has become an integral part of oncology, has been identified as an iatrogenic cause of AE [2,14].

Diagnosis and Practical Challenges

AE diagnosis is based on a clinical and paraclinical synthesis taking into account the diagnosis of the symptom profile, the inflammatory markers in CSF and MRI, and autoantibody serology. Diagnosis is crucial and should be done at the earliest opportunity to determine the outcome of the immunotherapy.

Clinical Presentation:

A defining feature of AE is the rapid onset of at least one of the following symptoms in less than three months: a new neuropsychiatric disturbance, cognitive dysfunction, seizures, movement disorders (such as orofacial dystonia, stereotypies or faciobrachial dystonic seizures), and autonomic instability [2,15]. Anti-NMDAR encephalitis has a known multistage prodrome: a viral-like prodrome, with prominent neuropsychiatric symptoms (psychosis, agitation, behavioural changes), then seizures, abnormal movements, and finally a decrease in level of consciousness or catatonia. It is mainly seen in young women, 80% of which are women and the median age of onset is 21 years [16]. Anti-LGI1 encephalitis is mostly seen in older men (>50 years) and patients have subacute amnesia, faciobrachial

dystonic seizures (FBDS) (brief unilateral limb and face jerks) and hyponatremia. Anti-CASPR2 encephalitis is characterized by either limbic encephalitis, Morvan's syndrome or neuromyotonia and is frequently associated with thymoma [17].

Diagnostic Criteria:

Graus *et al*. diagnostic framework, the international accepted diagnostic framework in 2016 still is the basis of AE diagnosis. This is a framework that categorises AE into 'possible', 'probable' and 'definite' groups depending on clinical presentation, paraclinical supports (CSF pleocytosis, MRI changes and EEG findings) and antibody detection. Notably, the criteria include the possibility of making a diagnosis of probable autoimmune limbic encephalitis, and consequently of initiating empirical immunotherapy, even when autoantibodies are not found. The application of these criteria has been criticized by Dalmau and Graus (2023), particularly for seronegative cases. They found three major reasons for misdiagnosis: failure to follow clinical criteria, lack of awareness of the inflammatory changes in CSF and MRI, and limited panels of antibody antigens [18].

Paraclinical Investigations

CSF Analysis

Typically, CSF will show lymphocytic pleocytosis, mild protein elevation and in some subtypes, will show oligoclonal bands. Pathogenic autoantibodies are more likely to be detectable in the CSF than in the blood, especially in anti-NMDAR encephalitis, in which CSFT might be negative in up to 14% of patients [2].

MRI

The brain MRI findings are variable. Diagnostic MRI features of limbic encephalitis is FLAIR/T2 hyperintensity of the medial temporal lobes. Anti-NMDAR encephalitis often does not have a characteristic MRI pattern, and when there is a pattern, it is seen only as subtle changes in the cortex. In anti-NMDAR encephalitis [2], FDG-PET could show hypermetabolism in the frontoparietal region and hypometabolism in the occipital region, which is helpful in seronegative cases.

EEG

EEG is often not specific, showing slow wave activity or epileptiform activity. Severe anti-NMDAR encephalitis is associated with a highly characteristic EEG pattern, ‘extreme delta brush' characterized by delta waves with superimposed beta activity, although this pattern is only sensitive to approximately 30% of the cases [2].

Antibody testing

When antibodies are required, a cell-based assay (CBA) is performed with a set of cells that are transfected with recombinant antigens, and is the most specific type of assay available, better than indirect immunofluorescence on tissue sections. Most validated targets have sensitivity and specificity >95% and >99%, respectively, with moderate positive predictive values for serum-based testing of some antibodies (in particular, antibodies to intracellular antigens) because of non-specific illness when antibody levels are positive [19].

Seronegative Autoimmune Encephalitis

A large proportion of AE cases are seronegative where the clinically/preclinically compatible syndrome was not associated with any detectable autoantibody. One large, epidemiological study found that seronegative cases were the largest diagnostic subgroup (28% of all AE) [20]. In a 2025 systematic review and meta-analysis of 213 seronegative AE cases, psychiatric features, predominant CSF inflammatory changes and response to immunotherapy emerged as key features. The authors note that clinical variability and the absence of definite biomarkers in seronegative AE require further prospective cohort studies and the identification of new biomarkers to better stratify and diagnose AE [21].

Practical Challenges:

There are several pragmatic challenges in making a timely diagnosis of AE:

- The complex clinical presentation; and
- Days to weeks to wait for antibody test results;
- Presentations that change over time; and
- Failure to identify certain autoantibodies in a significant proportion of patients, including those with true seronegative AE and those who have yet to have an antibody identified and
- The danger of misdiagnosis when criteria are less than strictly adhered [18,22].

Red flags that raise questions about alternative diagnoses are those that result from the insidious onset of symptoms over months, serum antibody findings that are positive but not specific to the diagnosis despite the lack of meeting diagnostic criteria, and atypical MRI patterns that do not fit into any established AE syndromes [4].

Current Pharmacotherapy

The key to managing AE is by means of immunotherapy. The treatment approach is stepwise, depending on the clinical severity of the illness, the response to the initial therapy and the specific subtype. The earlier the immunotherapy is started, the better the functional results.

First Line Immunotherapy:

The first line treatments are intravenous methylprednisolone (usually 1g/day for 3-5 days), intravenous immunoglobulin (IVIG; 0.4 g/kg/day for 5 days), and plasma exchange (PLEX; 5-7 sessions). Modalities may be used individually or together in severe cases and are dependent on factors such as the clinical situation, contraindications, and resources [23]. IVMP has broad immunosuppressive activity on cytokines, adhesion molecules and leukocyte trafficking that reduces neuroinflammation. IVIG is believed to have modulatory effects on immune response by binding to pathogenic autoantibodies and blocking their interaction with FcRn as well as binding to the FcRn and thus decreasing the length of time that pathogenic autoantibodies persist. PLEX physically eliminates circulating autoantibodies, immune complexes and inflammatory mediators from plasma [23]. After 4 weeks of first-line agent treatment, it is estimated that 40-50% of patients do not show enough improvement for the treatment to be discontinued, and therefore require second-line immunotherapy [24].

Second Line Immunotherapy:

Rituximab (RTX) is a chimeric anti-CD20 monoclonal antibody which depletes B cells and is the preferred second line treatment for AE. Evidence supports early use of RTX in the disease course, not only in cases of first-line failures, as was done in the GENERATE study (which enrolled 358 patients) [25].In most other cases, longer-term maintenance immunosuppression with mycophenolate mofetil or azathioprine is usually added to the treatment to minimize the risk of relapse over months or years, 23 particularly in paraneoplastic AE, where the broad immunosuppressive effects on T and B cells may prevent the cytotoxic T-cell-mediated injury [23].

Tumor Management:

Definitive tumour treatment is a key and critical part of disease management in paraneoplastic AE. Removal of the tumor (e.g., resection of ovarian teratoma in Anti-NMDAR encephalitis) can be an effective reduction strategy that can significantly enhance neurological outcomes and is done concurrently with immunotherapy - not sequentially [9,15].

Seizure Management:

In acute seizures in AE, anti-seizure medications (ASMs) are often necessary to control these seizures. Sodium channel blockers are less effective in seizures associated with AE; levetiracetam and lacosamide are frequently used. Importantly, benzodiazepines are still beneficial for acute seizures. There is growing awareness that newer sodium-

channel inhibitors (e.g., lacosamide) and perampanel (an AMPA receptor antagonist) may be disease-modifying in AE and should be studied further [4].

Emerging and Newer Therapies

Drug resistance is present in a large proportion of AE patients and relapses can occur in AE patients who respond to first- and second-line immunotherapies. This unmet need has spurred the search for new targeted drugs that target specific immunologic pathways.

Plasma Cell-Depleting Agents

Bortezomib

The use of 26S proteasome inhibitors, such as bortezomib, which is approved for the treatment of multiple myeloma, has been studied as a third-line treatment for refractory AE. There are clinical case series and a prospective phase II trial (NCT03993262) investigating its effectiveness in severe, refractory anti-NMDAR and other AE subtypes [26,27].

Daratumumab

In individual cases and small series, treatment with an anti-CD38 monoclonal antibody (mAb) which depletes plasma cells, such as daratumumab, has been reported in refractory AE, including anti-NMDAR and seronegative cases. In some cases of seronegative and CASPR2 AE, therapeutic effects have been demonstrated for daratumumab and tocilizumab; however, caution should be exercised in the use of daratumumab with CASPR2 encephalitis due to reported serious adverse reactions [28].

Obinutuzumab

The next-generation type II anti-CD20 antibody, obinutuzumab, which has increased B-cell depleting activity than rituximab, has been studied in paediatric AE patients with early B-cell repopulation on rituximab. Initial findings indicate it could offer longer-lasting B-cell depletion, which could help lower relapse rates among this patient group [29].

Cytokine-Directed Therapies

Tocilizumab:

Tocilizumab is an anti-IL-6 receptor monoclonal antibody, which targets a key inflammatory medium in AE, driven by IL-6. Several case reports and case series have shown clinical and serological improvement with tocilizumab treatment in refractory anti-NMDAR, CASPR2, GAD65 and MOG-antibody encephalitis, with tocilizumab emerging as a valuable treatment for rituximab-refractory cases [26,27].

Anakinra and Tofacitinib:

Based on their ability to modulate inflammatory cytokine cascades, Anakinra (IL-1 receptor antagonist) and tofacitinib (JAK1/JAK3 inhibitor) are some drugs which have been proposed for refractory AE. Of particular interest is the use of tofacitinib, which is an inhibitor of JAK-STAT signalling, which has been shown to control important cytokine receptors, T-helper cell subsets, and the production of inflammatory cytokines involved in AE [27].

Satralizumab:

AE is being investigated with the humanized anti-IL-6 receptor antibody with extended half-life, Satralizumab (clinical trial NCT05664022). The long-acting duration of action (subcutaneous every four weeks) could be advantageous for its ease of use compared to intravenous tocilizumab [30].

FcRn Receptor Antagonist:

The neonatal Fc receptor (FcRn) prevents degradation of IgG in lysosomes and thus increases the half-life of pathogenic autoantibodies. Blocking of FcRn increases the catabolism of IgG and decreases the levels of

autoantibodies in all subclasses of IgG. A number of FcRn antagonists are in clinical trials in the treatment of AE, and have the theoretical potential to deplete all pathogenic IgG, regardless of the antigen targeted [30].

Inebilizumab:

Unlike rituximab, which targets CD20, Inebilizumab targets CD19, present on a wider variety of B-cell populations, such as plasmablasts and some plasma cell precursors. Inebilizumab may lead to a more extensive targeting of B-cells and plasma cells by removing CD19+ cells. AE is currently conducting clinical trials [30].

Intrathecal Therapies:

Intramuscular targeting of autoantibody producing long-lived plasma cells in the intrathecal compartment, which is largely inaccessible to systemic antibody depletion agents, has fuelled the interest in intrathecal methotrexate. There are several small case series indicating clinical benefit in refractory AE; but there are no prospective controlled data [27].

CAR-T Cell Therapy:

Chimeric antigen receptor (CAR)-T cell therapy is a revolutionary new approach to AE treatment with particular promise for refractory AE cases where the antibodies continue to be produced in the plasma. CAR-T cells targeting B-cell maturation antigen (BCMA) expressed on plasma cells have shown to be a way to kill pathogenic plasma cells, and those targeting CD19 have been shown to have the same effect. Preliminary clinical experience in case reports and compassionate use programs indicates dramatic clinical responses and improvement in otherwise treatment-refractory AE, but several potential adverse effects, such as cytokine release syndrome and immune effector cell-associated neurotoxicity syndrome, must be managed [31]. The novel agents ocrelizumab, epratuzumab, telitacicept and daratumumab offer more targeted approaches to B cell and plasma cell depletion and CAR-T cell therapy is slowly becoming another prospect in the field of exploratory AE research.

Future Directions

AE is progressing at an astonishing rate, and there are several promising areas that will be changing clinical practice in the next ten years.

Biomarker Discovery:

One of the most pressing unmet needs is the identification of appropriate and reliable biomarkers that can be used for early diagnosis, disease monitoring, treatment response and prediction of relapse. Potential candidate biomarkers are CSF neuroaxonal injury marker neurofilament light chain (NfL), cytokines, and soluble immune mediators. With the help of novel techniques such as proteomics, phage display libraries and single cell sequencing, new autoantibodies are likely to continue to broaden the diagnostic options for currently seronegative AE [32].

Precision Immunotherapy and Biomarker-Guided Treatment:

Future AE management will benefit from moving away from a one-size fits all escalation paradigm to a biomarker-driven, subtype-specific immunotherapy approach. The antibody titer monitoring (especially intrathecal titers), immune cell subset profilings and cytokine signatures can be used to guide treatment intensification or de-escalation in order to reduce treatment-related toxicity, while maximizing treatment effectiveness [32].

Randomized Controlled Trials:

Most of the existing evidence base for the treatment of AE comes from case series, retrospective cohort studies, and registry data. Conducting prospective, multicenter, randomized controlled trials to establish optimal treatment timing, combination and maintenance strategies is very much needed. There are several trials currently recruiting that include those of bortezomib (NCT03993262), inebilizumab, rozanolixizumab, and satralizumab [30].

Neurorestorative Strategies:

In addition to immunosuppression, future strategies will involve neurorestorative interventions to help overcome cognitive and functional deficits that may remain following antibody clearance. These include cognitive

rehabilitation, neuromodulation (such as transcranial magnetic stimulation) and, perhaps, neuroprotective pharmacology for remaining synaptic dysfunction [33].

Artificial Intelligence in Diagnosis and Management:
Artificial Intelligence (AI) and Machine Learning could prove valuable to enhance the diagnosis and treatment decisions made by AE. Clinical phenotypes, MR characteristics, EEG patterns, and multi-omics biomarker profiles could be analysed with the aid of AI, which may minimize the delay in diagnosis, identify high-risk patients for early aggressive treatment, and anticipate treatment response.

Post-Infectious AE and Prevention:
Considering the clear correlation between HSE and subsequent anti-NMDAR encephalitis, there may be potential for preventive measures. Prospective studies of early or extended antiviral therapy after HSE and/or of prophylactic immunotherapy in persons at high risk should be considered to prevent this post-infectious autoimmune condition [2].

CONCLUSION

AE has progressed from clinical curiosity to one of the most impactful and treatable acute encephalopathies in the world. Pathogenic autoantibodies are being discovered with increasing frequency, the diagnosis has been refined, and a structured paradigm of immunotherapy is emerging and has dramatically altered patient outcomes. At the heart of AE pathogenesis lie the generation of autoantibodiesmainly by B cells and long-lived plasma cells against neuronal/glial antigens leading to receptor dysfunction, synaptic disruption and neuroinflammation. The immunopathological mechanism depends on the type of antigen, and the most reversible are the disorders of cell surface antibody. The diagnosis is still a major difficulty, especially when the antibody test is negative, and in areas where the resources for detailed antibody testing are limited. To reduce misdiagnosis, these clinical parameters must be used and applied carefully in conjunction with the data from MRI, CSF, and EEG. The message to practicing neurologists and psychiatrists is very important, since they need to be aware that the diagnosis of AE is primarily clinical and that serology is confirmatory, and not sufficient.

Pharmacotherapy is currently taken a step at a time, starting with first line agents (corticosteroids, IVIG, plasmapharesis), then second line agents (rituximab, cyclophosphamide), and then emerging third line agents (bortezomib, daratumumab, the cytokine network agent's tocilizumab and tofacitinib). CAR-T cell therapy and FcRn antagonists are promising new therapies for the most refractory cases. With the future in mind, novel biomarkers, AI-aided diagnostics, precision immunotherapy, and neurorestorative techniques hold additional promise in shaping the future of AE management. Continued research and development efforts, including high-quality prospective studies, clinical collaboration, and condition-specific treatment algorithms based on strong clinical trial evidence are needed to help achieve the ultimate goal, which is full and sustained neurological recovery for all patients.

ABSTRACT

This study investigates the behavioral determinants of crowdfunding adoption by extending the Unified Theory of Acceptance and Use of Technology (UTAUT) through the mediating role of perceived transparency within the context of entrepreneurial finance in India. Grounded in Information Asymmetry and Signal Theory, the study adopts a quantitative cross-sectional research design and collects data from 270 entrepreneurs and startup founders actively engaged with digital funding ecosystems. The measurement model and structural relationships were analyzed using Partial Least Squares Structural Equation Modeling (PLS-SEM), incorporating mediation analysis through a bootstrapping approach.

The findings reveal that performance expectancy, effort expectancy, social influence, and facilitating conditions significantly influence crowdfunding adoption intention. Notably, perceived transparency emerges as a critical cognitive mechanism, exerting a strong direct effect on adoption intention while also partially mediating the relationships between performance expectancy, effort expectancy, and social influence with behavioral intention. Among the antecedents, social influence demonstrates the strongest impact on perceived transparency, highlighting the role of social validation as a proxy for informational credibility in decentralized financial environments. However, facilitating conditions, although significant in directly influencing adoption, do not exhibit a significant mediated effect through transparency. These results provide deeper insights into the psychological and informational processes underlying fintech adoption, emphasizing that technological utility alone is insufficient without perceived informational clarity and trust. The study contributes to the literature by integrating UTAUT with transparency-based

signaling mechanisms, offering a more comprehensive explanation of adoption behavior in crowdfunding ecosystems. From a practical perspective, the findings suggest that platform developers and policymakers should prioritize transparency-driven design and social validation mechanisms to enhance user trust and participation in digital capital markets.

Keywords: Crowd funding Adoption ,UTAUT, Perceived Transparency, Effort, performance expectancy, Facilitating conditions, Entrepreneurial Finance, India.

INTRODUCTION

The historical capitals of finance that were formerly characterized by the presence of monolithic banking institutions are in a radical restructuring process based on the digital democratization of capital. Crowdfunding is one of such paradigm shifts; a new transformative mechanism, which uses the collective strength of small contributions through online platforms to finance entrepreneurial projects, social causes, and start-ups (Mollick, 2014; Belleflamme et al., 2014; Agrawal et al., 2015). What at first seems to have been understood as a special purpose funding source, particularly concerning creative projects, has slowly come to be a source of mainstream funding, especially in those contexts where formal credit accessibility is structurally limited. Crowdfunding also enables entrepreneurs to circumvent institutional gatekeepers and, thus, create an inclusive financial ecosystem in which innovation is rewarded with collateral. The importance of such a transition is particularly high in the Indian setting. Though the economy has been developing steadily, a significant percentage of the Micro, Small and Medium businesses (MSMEs) are still struggling with the issue of sustainable financing, and the credit gap is estimated to be an astounding $380 billion (Kumar et al., 2024).

The databook of the Grand View Research (2024) also demonstrates that the crowdfunding market in India is worth USD 48.2 million as of 2024 and is expected to grow to USD 133.2 million by 2030 with a strong Compound Annual Growth Rate (CAGR) of 18.9%. In this landscape, crowdfunding has ceased to be a desirable financing alternative and has become a vital facilitator of entrepreneurship by providing both financial resources and market validation and customer-to-customer early interaction (Mollick, 2014; Shneor et al., 2021). The platform is a two-fold purpose tool to an Indian start-up founder: as a source of liquidity and a product-market-fit test. The creation of behavioral intention is at the center of this technological change. Why is an entrepreneur willing to use a decentralized digital platform as opposed to a financial institution that follows a traditional business model? To answer this question, it is important to go beyond superficial adoption measures to a more in-depth analysis of the psychological and situational impetus to acceptance. Theoretically, the idea behind technology adoption is that a system will provide the tangible performance benefits of increased access to capital and improved visibility with the least cognitive effort to use it (Venkatesh et al., 2003; Ong et al., 2023). In any fintech setting, empirical studies continue to show that the more a user feels that a platform can be useful and easy to use, the higher the chances that he/she will adopt it (Yan et al., 2021; Kilani et al., 2023; Tariq et al., 2024).Besides these functional considerations, social and environmental issues also influence the process of decision making.

The social effect, which is manifested in the form of recommendation by peers and validation on the ecosystem level, is an important factor in strengthening platform legitimacy (Alkhwaldi et al., 2022; Chan et al., 2022). On the same note, enabling conditions, including technological resource accessibility, infrastructure, and institutional support systems, help to mitigate barriers to operations and increase user willingness to use digital financial platforms (Jafri et al., 2023; Rana et al., 2024). All these factors present an excellent explanatory foundation in the context of adoption behavior in technology-based financial settings. Nonetheless, even with these established drivers, the implementation of the crowdfunding is skewed and shows a more profound structural issue. In contrast to the conventional financial models that are based on institutional protection, crowdfunding is conducted in a decentralized setting with a high level of uncertainty and a large information asymmetry between the project

initiators and the prospective investors (Akerlof, 1970; Agrawal et al., 2015). In such situations, the user virtually only needs indicators generated within the platform to define credibility and, consequently, the quality and clarity of such information become of paramount importance (Colombo et al., 2015; Kuppuswamy and Bayus, 2017). Though the role of trust is highlighted in the earlier studies, it has been regarded as an outcome of the situation and not a process construct. This constrains our knowledge of the development of confidence in systems with minimal formal guarantees.

In contrast, **perceived transparency** offers a more concrete and system-oriented perspective. Transparency reflects the extent to which platform information is clear, accessible, and reliable, thereby enabling users to make informed decisions under conditions of uncertainty (Pavlou & Gefen, 2004). Since in crowdfunding decisions largely rely on digital indicators, including updates on the campaign and funding progress, transparency emerges as the main prism through which credibility of the platforms is viewed (Mollick, 2014; Belleflamme et al., 2014). Based on information asymmetry theory and signal theory, the paper proves that transparency is an important mechanism that closes the disparity between technological features and behavior intention. In this regard, the given research builds upon the Unified Theory of Acceptance and Use of Technology (UTAUT) through the addition of a mediating variable perceived transparency. This way, it fills a serious gap in the existing literature, which has largely ignored the importance of information-based mechanisms in determining the adoption behavior in the context of decentralized financial settings. The research makes contributions to the current body of knowledge in two major ways. To begin with, it contributes to the theoretical knowledge by unifying UTAUT with signaling views, providing a more detailed explanation of crowdfunding adoption. Second, it offers feasible guidelines to platform developers and policymakers on why it is essential to create transparency-focused systems that can give rise to sustainable interactions.

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Theoretical Foundation: Unified Theory of Acceptance and Use of Technology (UTAUT)

The structural shift toward digital disintermediation in financial services has established crowdfunding as a pivotal engine for entrepreneurial growth, requiring advanced theoretical frameworks to decode its adoption complexities. This research employs the Unified Theory of Acceptance and Use of Technology (UTAUT) as its primary conceptual foundation. Developed by Venkatesh et al. (2003), UTAUT provides a comprehensive synthesis of behavioral theories, positing that performance expectancy (PE), effort expectancy (EE), social influence (SI), and facilitating conditions (FC) are the principal determinants of technology acceptance. In the realm of financial technology (FinTech), UTAUT has consistently demonstrated high predictive validity, often explaining significantly more variance in user intention than the earlier Technology Acceptance Model (TAM) (Al-Okaily et al., 2023; Dwivedi et al., 2023; Shneor et al., 2021).

Recent scholarly inquiries have utilized UTAUT to explore various digital finance frontiers, including mobile banking in emerging economies (Alkhwaldi et al., 2022), the adoption of AI-augmented financial tools (Rana et al., 2024), and the post-adoption loyalty of digital wallet users (Kilani et al., 2023). Specifically, within the crowdfunding domain, Kumar et al. (2024) underscored the model's relevance in fostering "entrepreneurial dynamism" among SMEs. However, crowdfunding ecosystems are uniquely susceptible to "perceived risk" and "cognitive biases" due to their decentralized nature and the absence of traditional institutional intermediaries (Mollick, 2014; Belleflamme et al., 2014). To address these gaps, this study extends the original UTAUT constructs by incorporating **perceived transparency** as a vital mediating mechanism. By doing so, we shift the focus from purely functional attributes to the underlying cognitive trust required to navigate information asymmetries in digital capital markets (Laaouina& Aoufi, 2024; Zhao & Chen, 2022).

Functional and Social Determinants of Adoption Intention

Performance Expectancy (PE) and Adoption Intention

The performance expectancy can be characterized as the extent to which a person deems that the use of a crowdfunding platform will allow specific relative benefits to be received in the process of meeting their financial or professional goals (Venkatesh et al., 2003). Within the crowdfunding framework, PE can be characterized as a complex notion, which includes the ability of the platform to quickly raise funds, the market acceptance, and the mitigation of the traditional financing expenses (Shneor et al., 2021; Tariq et al., 2024). The literature available continuously makes PE the leading factor in FinTech adoption because users focus on the usefulness of functionality and economic performance (Al-Maroof et al., 2024; Chan et al., 2022). Based on empirical evidence, Kumar et al. (2024) indicate that the creators of projects in the developing markets are encouraged by reach and agility of the crowdfunding systems in contrast to the traditional banking systems. Additionally, the studies of digital payment adoption also show that the usefulness of a system perceived by the user is directly linked to the readiness to allocate money (Ong et al., 2023; Rana et al., 2024). The intention to behave is greatly improved when a project creator or investor thinks that the ratio between the value and the effort is high (Tomić et al., 2022). Consequently: H1: Performance expectancy has a significant positive influence on crowdfunding adoption intention.

Effort Expectancy (EE) and Adoption Intention

The expectancy of effort is the perception of how easy or difficult it is to use the technological system and the alleviation of cognitive load (Venkatesh et al., 2003). In the crowdfunding industry, where stakeholders are required to manage unfavorable regulatory disclosures and financial reporting, a seamless and frictionless user experience is essential to adoption (Kilani et al., 2023; Jafri et al., 2023). The former research indicated that complexity of the system would be a psychological barrier and usually result in technology resistance (Al-Okaily et al., 2023).Social media platforms which are more intuitive in design and use shorter submission forms lead to increased confidence among users (Kumar et al., 2024). According to Tariq et al. (2024), when it comes to digital banking, the diminution of technical barriers directly influences the perceived competence of the user and consequently intention. For non-professional investors, a simplified project evaluation process is essential to overcome the "complexity bias" often associated with alternative investments (Abbasi et al., 2023). Thus: H2: Effort expectancy has a significant positive influence on crowdfunding adoption intention**.**

Social Influence (SI) and Adoption Intention

Social influence indicates how the ideas of utilizing the technology affect the decisions made by the individual based on the attitude and support of social and professional groupings (Venkatesh et al., 2003). The nature of a crowdfunding platform is social-financial hybrid; hence, social proof and herd behavior are determining factors to indicate the legitimacy of a project (Yan et al., 2021; Chan et al., 2019). The wisdom of the crowd as a heuristic to quality can be used when the available objective financial information is limited (Mollick, 2014). The recent studies on the concept of green crowdfunding indicate that social impact is enhanced when the projects meet the community values or sustainability objectives (Tang et al., 2024). Moreover, the recommendation of powerful peers or industry leaders can be a triggering point to the adoption of SMEs in a cascade (Kumar et al., 2024). The research by Shneor et al. (2021) validates the importance of social pressure and network effects as the major determinants of reward-based crowdfunding participation. Accordingly: H3: Social influence has a significant positive influence on crowdfunding adoption intention.

Facilitating Conditions (FC) and Adoption Intention

Facilitating conditions refer to the technical and organizational framework that is given to assist a user to interact with a platform (Venkatesh et al., 2003). In crowdfunding, it involves the security of digital payment gateways, fast connectivity, and above all, the regulatory system that will be used to process the transaction (Laaouina and Aoufi, 2024; Rana et al., 2024). FC offers the perceived behavioral control which counterbalances systemic risks (Al-Maroof et al., 2024). Trust in decentralized finance is a precondition that is heavily dependent on institutional support (Jafri et al., 2023). In the absence of the platform instructions and technical support, users tend to experience a sense of

structural deficit that impedes commitment (Tomić et al., 2022). On the contrary, strong facilitating conditions, including government subsidies or dedicated fintech support zones, were also demonstrated to boost the adoption of crowdfunding in the emerging economies significantly (Kumar et al., 2024; Zhao and Chen, 2022). Therefore: H4: Facilitating conditions have a significant positive influence on crowdfunding adoption intention.

Antecedents of Perceived Transparency in Crowdfunding

Decentralized financial environments are not pre-existing platform qualities, but a perceived derivative of how a user interacts with the technological and social structure of the system. Based on the Information Asymmetry Theory, we assume that transparency is a mechanism of trust, which arises when the platform successfully exudes its dependability (Mollick, 2014). To begin with, Performance Expectancy is an indicator of competence; in cases when creators of projects assume that the platform will allow the efficient capital formation, they are cognitively pre-equipped to consider the disclosures by the platform as credible and complete (Ong et al., 2023; Chan et al., 2022). This perceived functional utility justifies the authenticity of the information provided, and this enhances transparency perceptions in general.

Second, Effort Expectancy boosts transparency by the process of Cognitive Accessibility. The platforms with intuitive navigation and transparent visual dashboards enable the users to process the disclosures without mental pressure. In the fintech setting, the ease of use is not a convenience, but rather a proxy of transparency; complicated, untransparent interfaces are frequently viewed as concealing severe threats (Kilani et al., 2023; Tariq et al., 2024). In this manner, simplified user journeys are a guarantee that the project information is not lost behind the scenes (Abbasi et al., 2023). Third, Social Influence offers reputational confirmation. Without the conventional bank guarantees, users are guided by the social interaction, e.g. peer endorsement and community activity, to deduce the integrity of the platform (Yan et al., 2021). In line with the Signal Theory, the presentation of collective social evidence strengthens the perception that the platform is functioning in a transparent manner (Alkhwaldi et al., 2022). Finally, Facilitating Conditions provide the structural scaffolding necessary for transparency to manifest. The presence of high-quality technical infrastructure, effective regulation frameworks, and support systems means that a user can confirm the platform outputs unlimited (Rana et al., 2024; Jafri et al., 2023). Universal reporting and safe payment systems are real signifiers of a clear operating environment that minimizes the ambiguity of the systemic level (Tomić et al., 2022). All these factors would indicate that perceived transparency is a derived perception influenced by technological effectiveness, ease-of-use, social acceptance, and support infrastructure.H6: Performance expectancy has a significant positive influence on perceived transparency.

H7: Effort expectancy has a significant positive influence on perceived transparency.
H8: Social influence has a significant positive influence on perceived transparency.
H9: Facilitating conditions have a significant positive influence on perceived transparency.

The Mediating Mechanism of Perceived Transparency (PT)

Although the direct routes of UTAUT illuminate the forces of adoption, it does not describe the cognitive black box whereby the participants reduce the risk of natural capital-raising that is inherent in digital capitals. The research hypothesizes that the most critical mediator is perceived transparency, which implies the extent to which a platform presents accurate, timely, and comprehensive information about the allocation of the funds, project risks, and actors identity. Our argument is based on the Information Asymmetry Theory and Signal Theory, which hold that users are going to demand some sort of trust signal to justify their choices in a highly uncertain environment (Mollick, 2014; Belleflamme et al., 2014; Shneor et al., 2021).

The mediation logic is an integrative and non-linear process. Performance Expectancy increases the level of transparency, by making users understand that the platform is reliable; in cases where users have a high expectation of rewards, they view disclosures of the platform as more credible (Ong et al., 2023; Al-Okaily et al., 2023). The intrinsic connection between Effort Expectancy and transparency is the so-called cognitive accessibility, where a

simplified interface makes important disclosures not obscured under technicality, contributing to the feeling of openness (Kilani et al., 2023; Tariq et al., 2024). Moreover, Social Influence is a proxy of transparency, when the community social validation is positive, it sends the reputational message that the platform is transparent and just (Yan et al., 2021; Tang et al., 2024). Lastly, the Facilitating Conditions give the formal evidence of openness; the availability of clear regulatory policies and systems of technical assistance serve as a concrete warranty of platform integrity (Rana et al., 2024; Kumar et al., 2024).By lowering the "perceived risk" and enhancing "perceived control," transparency serves as the mechanism that converts technological perceptions into a final adoption decision (Zhao & Chen, 2022; Abbasi et al., 2023). Without the perception of an honest and transparent environment, even high-performing or easy-to-use platforms will suffer from adoption inertia. Consequently, we propose the following mediation hypotheses:

H10: Perceived transparency has a significant positive influence on crowdfunding adoption intention.
H11: Perceived transparency mediates the relationship between performance expectancy and crowdfunding intention.
H12: Perceived transparency mediates the relationship between effort expectancy and crowdfunding intention.
H13: Perceived transparency mediates the relationship between social influence and crowdfunding intention.
H14: Perceived transparency mediates the relationship between facilitating conditions and crowdfunding intention.

RESEARCH METHODOLOGY

Research Design and Sample Selection

This study employs a quantitative, cross-sectional research design to empirically validate the proposed structural model. In alignment with the positivist paradigm and the "bias-informed" research approach utilized in contemporary financial studies, a cross-sectional strategy was selected to examine complex behavioral intentions and perceptions at a specific juncture (Hair et al., 2021; Tariq et al., 2024). The study focuses on the evolving context of digital crowdfunding, an environment defined by high information asymmetry and technological mediation. The target population consists of startup founders, entrepreneurs, and individuals with direct exposure to the crowdfunding ecosystem. A non-probability purposive sampling technique was utilized to ensure that respondents possess the requisite knowledge to provide meaningful insights into platform adoption. Data collection was executed through a structured self-administered questionnaire, distributed via online professional networks (LinkedIn) and offline industry meetups to mitigate sampling bias and enhance respondent diversity. Initially, 300 responses were gathered; however, following a rigorous screening process to eliminate straight-lining and missing values, a final sample of 270 valid responses was retained. This sample size is statistically robust for Partial Least Squares Structural Equation Modeling (PLS-SEM), as it substantially exceeds the "10-times rule" and meets contemporary methodological guidelines for power analysis in complex mediation models (Hair et al., 2022; Kumar et al., 2024).

Measurement Instrument and Operationalization

The measurement instrument was developed by adapting validated scales from established literature, ensuring high content and construct validity. All items were tailored to the crowdfunding context while preserving their theoretical essence, and were measured on a 5-point Likert scale (1 = Strongly Disagree to 5 = Strongly Agree).

- **Performance Expectancy (PE):** Operationalized using four items adapted from Venkatesh et al. (2003) and Ong et al. (2023), focusing on utilitarian benefits and capital formation efficiency.
- **Effort Expectancy (EE):** Measured through three items reflecting the perceived ease of use and cognitive simplicity of the platform interface (Kilani et al., 2023; Tariq et al., 2024).
- **Social Influence (SI):** Assessed using four items evaluating the influence of professional peers, mentors, and the broader social ecosystem (Yan et al., 2021; Alkhwaldi et al., 2022).
- **Facilitating Conditions (FC):** Measured with a five-item scale focusing on technical resources, infrastructure availability, and institutional support (Rana et al., 2024; Jafri et al., 2023).

- **Perceived Transparency (PT):** Operationalized through a three-item scale evaluating the clarity, reliability, and accessibility of project-related information (Pavlou & Gefen, 2004; Colombo et al., 2015).
- **Crowdfunding Intention (CI):** Assessed using four items reflecting behavioral intention and recommendation propensity (Venkatesh et al., 2003; Chan et al., 2022).

Data Analysis Strategy: PLS-SEM

The theoretical model was tested using Partial Least Squares Structural Equation Modeling (PLS-SEM) facilitated by SmartPLS 4.0 software. PLS-SEM was selected due to its superior performance in prediction-oriented research and its effectiveness in handling complex models involving multiple mediation paths without requiring strict data normality (Hair et al., 2021; Shneor et al., 2021). To ensure the robustness of the results, the analysis followed a two-stage approach.First, the **measurement model** was evaluated for reliability and validity. Indicators were assessed based on outer loadings (>0.70), Cronbach's alpha and Composite Reliability (CR >0.70), and Average Variance Extracted (AVE >0.50) to ensure convergent validity. Discriminant validity was verified using the Heterotrait-Monotrait (HTMT) ratio, adhering to the conservative threshold of <0.85 (Hair et al., 2022). Second, the **structural model** was assessed to test the hypothesized relationships. Significance testing was conducted through a non-parametric bootstrapping procedure with 5,000 resamples to determine path coefficients (β), t-values, and p-values. Furthermore, predictive power was evaluated through the coefficient of determination (R^2) and predictive relevance (Q^2).

DATA ANALYSIS AND RESULTS

The empirical validation of the proposed research model was conducted using Partial Least Squares Structural Equation Modeling (PLS-SEM) via SmartPLS 4.0. This variance-based approach is particularly suited for complex models incorporating mediation paths and provides robust estimations without the requirement of strict multivariate normality (Hair et al., 2021; Shneor et al., 2021). The analysis followed a systematic two-stage procedure: first, the measurement model was assessed for reliability and validity, followed by the evaluation of the structural model to test the hypothesized relationships.

Measurement Model Assessment

The measurement model was evaluated to ensure the psychometric properties of the reflective constructs—Performance Expectancy (PE), Effort Expectancy (EE), Social Influence (SI), Facilitating Conditions (FC), Perceived Transparency (PT), and Crowdfunding Intention (CI)—met established academic standards.

Indicator Reliability and Collinearity

Indicator reliability was assessed through outer loadings, with all items exceeding the recommended threshold of 0.70. The analysis revealed loading values ranging from 0.703 (CI2) to 0.955 (EE3), indicating high shared variance between the indicators and their respective latent constructs. Furthermore, a full collinearity test was conducted to address potential multicollinearity issues. The Variance Inflation Factor (VIF) for all constructs remained well below the critical threshold of 5.0, with the highest value recorded at 4.609 (FC4). These results confirm that the data is healthy and free from significant multicollinearity concerns, ensuring the stability of the path estimates.

Internal Consistency and Convergent Validity

Internal consistency was verified using Cronbach's alpha and Composite Reliability (rho_c). All constructs demonstrated excellent reliability, comfortably exceeding the 0.70 benchmark. Cronbach's alpha values ranged from 0.800 (CI) to 0.937 (EE), while Composite Reliability values were between 0.870 and 0.960. Convergent validity was established via the Average Variance Extracted (AVE). All constructs surpassed the 0.50 cutoff, with values ranging from 0.627 (CI) to 0.888 (EE), proving that the constructs explain more than half of the variance in their respective indicators.

Internal Consistency and Convergent Validity

Cronbach alpha and Composite Reliability (rho c) were used in the evaluation of internal consistency. The reliability of all constructs was excellent exceeding the 0.70 cut off. The values of alpha were between 0.773 (Diversification Strategy) and 0.929 (Mental Accounting Bias), whereas the CR values were between 0.869 and 0.944. Convergent validity was determined based on the Average Variance Extracted (AVE), and all the constructs were above the 0.50 cut-off with the highest and lowest being 0.688 to 0.850. This proves that the constructs explain more than half of the variance in the items.

Discriminant Validity

Discriminant validity was rigorously evaluated using the Heterotrait-Monotrait (HTMT) ratio. While some ratios approached the conservative threshold (e.g., CI and PT at 0.905), the overall matrix indicates that the constructs are empirically distinct. Given that Perceived Transparency is a core conceptual bridge for Intention, a higher correlation is theoretically expected; however, the model fit and HTMT results suggest that the behavioral drivers and intention remain unique conceptual entities within the framework.

Structural Model Assessment and Hypotheses Testing

Following the validation of the measurement model, the structural model was assessed to examine the hypothesized relationships and overall predictive capability. The model demonstrated an acceptable fit, with SRMR (0.045) well below the recommended threshold and NFI (0.854) indicating satisfactory model adequacy, supported by consistent values of d_ULS (0.603), d_G (0.602), and chi-square (932.924). The explanatory power of the model was substantial, with crowdfunding intention showing an R^2 of 0.730 (adjusted R^2 = 0.725) and perceived transparency reporting an R^2 of 0.678 (adjusted R^2 = 0.673). Furthermore, the Q^2 values for crowdfunding intention (0.446) and perceived transparency (0.493) confirmed strong predictive relevance. Overall, the results suggest that the proposed model exhibits robust explanatory strength and predictive accuracy in explaining crowdfunding adoption behavior.

Analysis of Path Coefficients (Direct Effects)

The results of the structural analysis provide compelling evidence for the factors driving crowdfunding intention. Performance Expectancy exhibited a significant positive influence on Crowdfunding Intention (β= 0.214, t = 4.034, $p < 0.05$), supporting H1. Similarly, Effort Expectancy (β= 0.206, t = 3.562, $p < 0.05$) and Facilitating Conditions (β= 0.185, t = 2.666, p = 0.008) showed strong positive impacts, validating H2 and H4. Social Influence also significantly influenced intention (β= 0.143, t = 2.143, p = 0.033$), supporting H3. Regarding the antecedents of transparency, all paths were significant. Social Influence emerged as the most potent driver of Perceived Transparency (β= 0.356, t = 3.728, $p < 0.05$), supporting H7. This was followed by Effort Expectancy (β= 0.226, t = 2.686, p = 0.007) and Performance Expectancy (β= 0.193, t = 3.010, p = 0.003), supporting H6 and H5. Facilitating Conditions also significantly impacted transparency (β= 0.169, t = 2.108, p = 0.036), validating H8. Crucially, Perceived Transparency was found to exert a strong direct influence on Crowdfunding Intention (β= 0.241, t = 3.404, p = 0.001$), supporting H9.

Mediation Analysis

The mediating role of Perceived Transparency was examined using a bias-corrected bootstrapping procedure with 5,000 resamples. The results revealed that transparency significantly mediates the effects of Performance Expectancy (β= 0.046, p = 0.037), Effort Expectancy (β= 0.054, p = 0.033), and Social Influence (β= 0.086, p = 0.008) on Crowdfunding Intention, supporting H10, H11, and H12. These findings categorize the relationships as partial mediations, suggesting that transparency acts as a vital cognitive conduit in the adoption process. However, the indirect path from Facilitating Conditions through transparency to intention was not significant (p = 0.124), leading to the rejection of H13.

DISCUSSION

The empirical results of this study provide a comprehensive understanding of the behavioral drivers in the Indian crowdfunding ecosystem. By integrating transparency as a pivotal cognitive bridge, the findings highlight that technological acceptance is not merely a functional choice but a decision filtered through informational trust. The significant direct impact of perceived transparency on crowdfunding intention aligns with foundational research in online marketplaces, suggesting that in decentralized environments, informational clarity is a primary determinant of adoption (Pavlou & Gefen, 2004). This result implies that entrepreneurs and startup founders prioritize platforms where project risks and operational details are most visible, supporting the observations of Mollick (2014) regarding the dynamics of early-stage digital capital formation. Regarding the determinants of adoption, the support for functional drivers such as performance and effort expectancy is consistent with recent fintech studies in emerging markets (Kumar et al., 2024; Tariq et al., 2024). However, the specific discovery that social influence is the strongest predictor of perceived transparency is a vital insight. It suggests that in the absence of traditional institutional safeguards, users rely on "social signals"—such as peer endorsements and crowd engagement—to infer the integrity of the platform. This aligns with Signal Theory, where collective validation acts as a reputational proxy for transparency (Yan et al., 2021).

The mediation analysis further underscores the "linking mechanism" of transparency. While factors like performance and ease of use provide the basic motivation for adoption, their influence is amplified when filtered through a transparent interface. The finding that transparency partially mediates these relationships suggests that technological benefits are insufficient unless they are accompanied by a perception of openness (Shneor et al., 2021; Zhao & Chen, 2022). Interestingly, the lack of mediation for facilitating conditions implies that while technical and regulatory support are necessary for direct intention, they do not necessarily shape the user's perception of informational transparency in the same way that social cues or platform usability do. This indicates that structural support is viewed more as a baseline requirement rather than an informational signal. In conclusion, the study validates that for crowdfunding to scale in high-growth markets like India, platforms must look beyond functional utility and prioritize informational integrity as the ultimate currency of entrepreneurial engagement

IMPLICATIONS AND CONCLUSION

Theoretical Implications

This study advances the existing body of knowledge by offering an integrated theoretical perspective on crowdfunding adoption. First, it extends the Unified Theory of Acceptance and Use of Technology (UTAUT) by incorporating perceived transparency as a critical mediating variable. While traditional UTAUT applications focus on functional utility, this study demonstrates that in decentralized financial environments, these drivers are filtered through cognitive mechanisms of informational trust. Second, the integration of Signal Theory and Information Asymmetry Theory provides a robust explanation for how entrepreneurs evaluate platform credibility in the absence of institutional safeguards (Akerlof, 1970; Mollick, 2014). Third, the finding that social influence primarily drives transparency rather than direct intention offers a new dimension to our understanding of "herd behavior" in fintech, suggesting that social cues function as informational signals that reduce perceived risk.

Managerial Implications

The results of this research have a definite and practical recommendation to the operators of the platform, the digital financial managers, and the entrepreneurs who want to initiate the involvement in the crowdfunding ecosystem. To begin with, the findings show informational integrity is the final currency to be adopted. Transparency-by-Design is a product strategy that managers are advised to focus on. Since perceived transparency is a powerful direct factor and a key mediating variable, the platform interfaces are to be designed in such a way that project disclosure, risk evaluation, and fund allocation information would be very visible and easy to comprehend. Second, as the social

influence was found to be the strongest antecedent of transparency, managers are advised to use the social validation mechanisms. Such functions as community reviews, peer-to-peer discussions groups and visible success metrics are not mere community-building features; they are also essential indicators that confirm platform integrity to the suspicious project initiators.

Third, the high effect of the performance and effort expectancy on the adoption intention implies that the platform should be both sophisticated and simple. Managers ought to make investment in real time analytics and reporting tools to increase the utilitarian value (performance) to the project creators, and at the same time maintain the user journey frictionless. Less cognitive load (effort) due to a simplified dashboard has a direct positive impact on the processing of disclosures in the user, which supports the impression of openness. Last, and certainly not least, the facilitating conditions should be considered as the prerequisite of those who work in emerging market, such as India. Although infrastructure and regulatory assurance will spur direct deliberation, managers should take the initiative to communicate this structural protection to the users, essentially transforming compliance into an indicator of platform security.

Limitations and Future Research

Although the present research is very informative, there are some limitations that can guide future research. First, the research is cross-sectional and thus it captures the perceptions of the respondents at one time. Future researchers can use longitudinal designs to discuss the change in perception of transparency over time as the users become more familiar with the platforms. Second, the sample was mostly selected among entrepreneurs in India; therefore, subsequent studies should focus on probing such relations in other cultural and regulatory settings to be more generalized. Third, although the model describes a high level of variance, other aspects of psychology like trust in technology or perceived financial literacy may be taken into account in future studies to add to the explanation of the crowdfunding adoption model.

ABSTRACT

The present study aimed to explore the various therapeutic components present in *Psidium guajava L.* leaves for the treatment of type II diabetes mellitus through computational docking study. Diabetes mellitus is one of the widely spreading chronic metabolic disease that affecting a large number of populations. The management of type II diabetes mellitus is now a days very important and essential. A series of databases were used to identify the active therapeutic components and their corresponding potential targets for drug discovery. Molecular docking is an important computational tool used for the extensive *in silico* study of medicinal plants through interaction between active components against target protein. Various databases like SwissADME, Protox 3.0, Dr. Duke's Phytochemical and Ethnobotanical Databases, Pubchem, Protein Databank, and softwares like Biovia Discovery Studio 4.5 and Pyrx version 0.9.8 were used for the study. Many therapeutic components found in the leaves of the guava plant can help to treat a variety of chronic metabolic illnesses, including type II diabetes mellitus. Herbal Drugs are given to treat diabetes mellitus because of their high efficacy, low cost, and fewer adverse effects. The phytoconstituents of the leaves part of the plant for further molecular docking studies were selected based on their drug likeness properties and molecular description. The interaction between selected ligands such as Reference inhibitor 527,Oleanolic-acid, Guavin-B, Strictinin, Crataegolic-acid, Maslinic acid and Procyanidin-B2 against target protein PTP1B, exhibited binding energies, measuring -9.6, -8.9, -9.4, -8.7, -8.6, -8.9 and -8.8 kcal/mol respectively. These results suggested that guava leaves showed promising binding affinity in molecular docking study but further scientific evidences needed through *in vitro* or *in vivo* studies and may be used as an effective treatment for type II diabetes mellitus as it contained many active phytoconstituents like tannins, phenolic compounds, triterpenoids, and flavonoids by using PTP1B as a major protein.

Keywords: Diabetes mellitus, *Psidium guajava L.,* Molecular docking, Drug discovery

INTRODUCTION

Type 2 diabetes mellitus (T2DM) is a major global health burden whose increasing prevalence is largely driven by modifiable lifestyle factors, including changes in diet, rising obesity, and reduced physical activity. Consequently, improving lifestyle is a key prevention strategy, and worldwide implementation of interventions like Diabetes Prevention Programs (DPPs) has proven highly effective at reducing the risk of developing T2DM,[7]. One of the most prevalent metabolic diseases, type 2 diabetes mellitus (T2DM), is brought on by a combination of two main factors: insufficient insulin secretion by pancreatic β-cells and the incapacity of insulin-sensitive tissues to react to insulin. The molecular mechanisms involved in the synthesis, release, and detection of insulin are strictly regulated because these actions are crucial for maintaining glucose homeostasis. A metabolic imbalance that causes the disease can result from flaws in any of the mechanisms involved in these processes[10]. In both high-income and low-income countries, the prevalence of diabetes has sharply grown in recent decades. One of the most difficult medical disorders that all health care systems worldwide must deal with is diabetes mellitus [6]. An estimated 193 million of the 415 million people with diabetes worldwide do not have a diagnosis [3]. According to the International Diabetes Federation (IDF), by 2045, there will be 700 million diabetics worldwide [14]. Diabetes has a significant negative impact on both people and society. Diabetes is thought to cost the world economy $1.31 trillion annually. including direct expenses and lost productivity as a result of illness or early mortality [8]. With the potential to offer successful multidisciplinary treatments following early diagnosis and efficient glucose-lowering therapies backed by organized training and self-management programs, the body of evidence supporting the optimization of type 2 diabetic mellitus (T2DM) care is growing quickly. People who might otherwise endure decades of medication therapy and disease-related consequences that result in early death might benefit from the prevention of type 2 diabetes through screening programs and easily available, safe, and effective treatments [3]. Additionally, preventing type 2 diabetes would lessen the financial cost of the illness.

Behavioral therapies can be economical for managing and preventing type 2 diabetes. The authors examined eleven studies and looked into a number of health behavior interventions carried out in Asian nations, including enhancing dietary intake, expert assistance to boost physical activity, lower body weight, and promote quitting smoking, medication adherence counseling, phone-based intervention, telephone follow-up, health education, and self-glucose monitoring [5]. *Psidium guajava L.*, also known as guava, is a medicinal plant species belonging to the Myrtaceae family, has been found to be rich in nutrients, including vitamins and minerals that are significant for human health. The plantis native to tropical America but is now grown throughout the world. The botanical profile of *P. guajava L.* is as follows [2]-

Kingdom: Plantae
Division: Magnoliophyta
Class: Magnoliopsida
Order: Myrtales
Family: Myrtaceae
Genus: Psidium
Species: *Psidium guajava L.*
The leaves are the most used part of the plant. The leaves are used in traditional system of medicines for febrifuge, antispasmodic, wounds, ulcers and toothache, rheumatism, gargle for sore throats, laryngitis and swelling of the mouth and externally for skin ulcers, vaginal irritation, discharge, vaginal and uterine wash, especially in leucorrhea. They are also used to treat diarrhea, bacterial infections, blood cleansing, astringent, lung problems, dysentery,

stomach pain, antibiotics, inflammations, diabetes management, hypertension, sores, boils, cuts and sprains, as well as a boiled preparation for itchy rashes caused by scabies.

The leaves of *Psidium guajava L.* are a rich source of diverse and beneficial phytochemicals recognized for their significant presence of phytochemicals.Phytochemicals are classified as either primary or secondary metabolites, depending on their role in plant metabolism. Primary metabolites include common amino acids, sugars, proteins, nucleic acid purines, pyrimidines, etc. Terpenes, alkaloids, lignans, flavonoids, plant steroids, phenolics, saponins, flavonoids and glucosides are examples of classes of secondary metabolites. Guava leaves contain a wide range of phytochemicals including flavonoids, saponins, alkaloids, tannins, terpenoids, polyphenols and glycosides[2]. Molecular docking is a primary computational technique used in structure-based drug design (SBDD). Its main goal is to predict the preferred orientation (pose) and conformation of a smaller molecule (the ligand) when bound to a larger biological molecule (the protein or receptor). This method simulates the molecular recognition process to estimate the stability of the resulting complex, often quantified by a scoring function which approximates the binding affinity. It is an indispensable tool for virtually screening large libraries of compounds, significantly reducing the cost and time associated with traditional High-Throughput Screening (HTS) experiments[9].

Ligand: A small molecule that interacts with the larger macromolecular target. In drug discovery, the ligand is typically a potential drug candidate, such as an active pharmaceutical ingredient (API), a natural product, or a chemical fragment. Protein (Receptor): The macromolecular target, usually an enzyme, receptor, or nucleic acid, that the ligand binds to. The protein structure must contain a binding site—a specific pocket or groove where the ligand can anchor and exert its therapeutic effect. Ligand-Protein Binding: The non-covalent association of the ligand with the protein's binding site. This interaction is driven by a combination of forces, including hydrogen bonds, hydrophobic interactions, electrostatic forces, and van der Waals forces. The resulting complex formation is critical for modulating the protein's function (e.g., inhibition or activation), which is the basis of therapeutic action. It also helps identify the binding orientation, affinity, and interactions that occur between them.

In drug development, molecular docking plays a crucial role in:

- Target Identification and Validation: Docking helps in identifying potential binding sites on a biological target such as an enzyme or receptor.
- Lead Compound Identification: It screens large libraries of compounds (virtual screening) to find molecules that can bind strongly to the target, which may serve as lead drug candidates.
- Optimization of Drug Candidates: By analyzing docking results, researchers can modify chemical structures to improve binding affinity, specificity, and pharmacokinetic properties.
- Mechanism of Action Studies: Docking helps understand how a molecule interacts with its target at the atomic level — providing insights into inhibitory or activation mechanisms.
- Reduction of Experimental Costs: Molecular docking saves time and resources by narrowing down compounds for *in vitro* and *in vivo* testing. [13]

The application of *in silico* research in drug development is expanding. Computational techniques simulate various aspects of drug discovery and development, including virtual ligand screening and profiling, compound library generation and target and lead finding. *In silico* techniques include databases, pharmacophores, homology models, quantitative structure–activity relationships, machine learning, data mining, network analysis tools, and computer-based data analysis tools. These methods are mostly used in conjunction with the generation of in vitro data to create models that aid in the identification and improvement of novel compounds by offering information about their characteristics concerning absorption, distribution, metabolism, and elimination. For several reasons, *in silico* research is very beneficial to drug development. By making it easier to screen, create, and anticipate the therapeutic potential of new drugs, they aid in the process of finding possible drug candidates. Additionally, *in silico* techniques help with toxicity prediction, allowing research teams to identify potentially dangerous consequences early in the development process and save time and money. Computational techniques such as virtual ligand screening, molecular modeling, and docking-based virtual screening aid in the discovery of novel and promising compounds by predicting the

binding modes of potential therapeutic candidates and analyzing their interaction patterns. In addition, by using existing information to inform future processes, *in silico* research makes early drug development more adaptable and morally acceptable. To maximise the effectiveness of the drug discovery process, they are therefore utilised in combination with conventional experimental methodologies [15].

Natural products have long been used to cure a variety of disorders, especially in developing nations. It is well known that natural substances can be used as lead compounds in the development of conventional medications. Based on natural products, the majority of drug discovery efforts in underdeveloped nations use crude extracts in *in vitro* or *in vivo* testing. Isolating active principles for structural elucidation investigations has received little attention. There are few bioactivity assessments in studies that separate pure secondary metabolites and describe their structures. Molecular docking is a helpful method in traditional drug development programs for forecasting how tiny compounds will interact with therapeutic targets to inform synthesis choices.

Molecular docking of chemical compounds in different databases facilitates the virtual screening of numerous small molecules in an attempt to find possible findings. In addition to introducing novel molecular scaffolds into the discovery pipeline, these predictions save money and time. In drug discovery programs based on natural products, the use of molecular docking can help explain some of the traditional benefits of medicinal plants and possibly even disclose additional benefits. By using ethnopharmacological knowledge of plant applications, new and emerging diseases can be avoided. Plants that can be targeted for biological activity assessment can be identified through molecular docking of known phytochemicals on potential disease therapeutic targets. The procedure for making choices for plant selection is anticipated to be influenced by docking results in conjunction with traditional knowledge about medicinal plants. Phytochemicals that show promise based on in-silico data can be linked to plant sources to determine whether or not they agree with experimental findings. Furthermore, *in silico* results may indicate which plants need to be investigated, considered for bioactivity evaluation research. Docking can be used to mimic the effects of potential structural changes to maximize desired activities and eliminate undesirable targets, as well as to explain the multi-target effects of natural products. To predict activity and investigate binding mechanisms, molecular docking can be integrated with other computer-aided drug development techniques including pharmacophore modeling and molecular dynamics. Molecular docking is still crucial [1].

PTP1B has been reported to has a major role in the regulation of the insulin signaling pathway and downstream targets. As a negative regulator of insulin signalling. Protein Tyrosine Phosphatase 1B (PTP1B) contributes significantly to the development of insulin resistance in type 2 diabetes [16]. It inhibits downstream PI3K/Akt signalling, decreases GLUT4 translocation, and reduces glucose absorption in peripheral tissues by dephosphorylating the active insulin receptor and IRS proteins. Therefore, PTP1B overexpression or enhanced activity encourages insulin resistance, which plays a major role in the pathogenesis of type 2 diabetes [4].

MATERIALS AND METHODS

Identification of the Plant

A thorough literature survey was done using authentic scientific sources and literature databases to select and identify the plants used for treating chronic metabolic disorders and to know their traditional therapeutic efficacy in treating diabetes mellitus. Several plants have shown significant potential in the management of metabolic disorder, including *Psidium guajava* L. The leaves of *Psidium guajava* was chosen for this study as it has several benefits and therapeutic potential for the management of chronic metabolic diseases.

***In Silico* Pharmacokinetic Analysis**

The drug likeness and molecular description study of the phytoconstituents present in the leaves of the plant was studied using Swiss ADME software. The phytoconstituents passing Lipinski rule, having logP ≤ 5, molecular weight ≤500, number of hydrogen bond acceptors ≤10, and number of hydrogen bond donor's ≤5 were chosen for further

molecular docking study. The toxicity risk assessment of the phytoconstituents were done by Protox 3.0 software. Phytoconstituents showing less than predicted toxicity Class 3 were discarded from the study [12].

Multiple Ligand Docking Study

All the natural phytoconstituents from the leaf part of the plant were retrieved from Dr. Duke's Phytochemical and Ethnobotanical Databases (https://phytochem.nal.usda.gov/search) in SMILES format. The 3D structure of Protein Tyrosine Phosphatase 1B (PTP1B), having 2.85 Å resolution with PDB ID 2HNP, was retrieved from the RCSB Protein Data Bank (https://www.rcsb.org/). Chain A was selected as the active catalytic domain. The protein was prepared by removing all crystallographic water molecules, co-crystallized ligands, non-essential heteroatoms and polar hydrogens were added. The prepared protein was converted into PDBQT format and used for further molecular docking analysis. All the ligands were downloaded from the PubChem database (https://pubchem.ncbi.nlm.nih.gov/) in SDF format for docking analysis and converted to protein data bank (PDB) format. The molecular docking study was performed to evaluate the binding affinity and interaction profiles of selected phytocompounds against Protein Tyrosine Phosphatase 1B (PTP1B). Binding energies and molecular interactions were analyzed to determine the stability and nature of ligand–protein complexes. Molecular docking analysis was carried out using PyRx version 0.9.8, which employs AutoDock Vina version 1.1.2 as the docking engine. Multiple ligands were docked against protein PTP1B. Multiple natural polyphenols were docked against PTP1B protein. The grid size of 43 × 15 × 15 points with a grid spacing of 0.375 Å and exhaustiveness equal to 8 was set for docking. The important active site residues involved in the interaction were explored and binding energy of each protein-ligand complex was determined. The docking models obtained were visualized using BIOVIA Discovery Studio software[11].

Docking Validation

Docking validation was performed by re-docking the native ligand into the PTP1B active site using AutoDock Vina implemented in PyRx. The docked pose was aligned with the crystallographic ligand.

RESULTS

A total of 49 phytoconstituents of the leaves of the plant *Psidium guajava* L. were retrieved from Dr. Duke's Phytochemical and Ethnobotanical Database for docking analysis. The phytoconstituents Oleanolic acid, Guavin-B, Strictinin, Crataegolic acid, Maslinic acid, and Procyanidin B-2 were selected for further study based on the drug likeness, molecular description and toxicity profile. The reference inhibitor showed the highest binding affinity, forming conventional hydrogen bonds with key active site residues such as ASP181 and LYS116, along with stabilizing van der Waals interactions involving GLY183, PRO180, and VAL184, confirming the validity of the docking protocol(Table no. 1). Among the tested phytocompounds, Guavin-B demonstrated the strongest binding affinity through multiple hydrogen bonds and hydrophobic interactions, including π–alkyl and van der Waals contacts within the catalytic cavity. Strictinin showed favorable interactions characterized by several hydrogen bonds facilitated by its multiple hydroxyl groups, along with extensive van der Waals stabilization. Crataegolic acid exhibited stable binding within the active site through hydrogen bonding and hydrophobic interactions with surrounding aliphatic residues. Maslinic acid formed conventional hydrogen bonds with residues such as LYS5, GLU6, MET282, and ALA278, along with a carbon–hydrogen bond interaction with LYS279 and multiple van der Waals contacts involving PRO241, ILE275, MET235, VAL244, ILE246, TYR271, and ASP245, suggesting strong hydrophobic complementarity. Procyanidin B-2 demonstrated extensive hydrogen bonding within the binding cavity, supported by π–alkyl and van der Waals interactions, although minor unfavorable interactions were observed. Overall, the docking results indicate that all selected phytocompounds exhibit favorable binding affinity toward PTP1B, with interaction profiles comparable to the reference inhibitor, suggesting their potential as promising candidates for further experimental validation.

DISCUSSION

The present investigation comes to a finding that managing Type II diabetes mellitus is essential and guava leaves are natural source of various therapeutic medicinal components that may contribute to treat a variety of metabolic disorders, including Type II diabetes mellitus. Although *Psidium guajava* has been widely reported for its antidiabetic potential, existing studies predominantly emphasize crude extracts, in vivo pharmacological evaluations, with limited exploration of molecular mechanisms. Notably, there is a significant lack of in silico investigations elucidating the specific protein–ligand interactions between guava leaf phytoconstituents and key therapeutic targets involved in Type II diabetes Mellitus. The phytoconstituents selected in the present study have not previously been subjected to computational binding analysis against Type II diabetes mellitus-related targets, resulting in a clear gap in mechanistic and structure–activity understanding. Therefore, this study addresses the need for molecular-level evaluation of identified guava leaf phytochemicals, aiming to provide predictive insights into their potential antidiabetic mechanisms and therapeutic relevance.

The molecular docking analysis revealed strong and stable interactions between phytoconstituents present on the leaves of the plant *Psidium guajava* L- Oleanolic-acid, Guavin-B, Strictinin, Crataegolic-acid, Maslinic acid and Procyanidin-B2 and key protein target PTP1B in Type II diabetes mellitus pathogenesis. Many medicinal components that are used to treat a variety of metabolic disorders can be identified naturally in plants. Medicinal herbs are said to be an effective method to treat diabetes mellitus. Molecular Docking is an essential computational approach for predicting potential non-covalent drug-protein interactions. To determine whether the molecule is a good ligand with diabetes targets, extensive *in silico* docking methods have been performed. The implementation of various molecular docking methods and tools were the primary objective of the article. *Psidium guajava* L. leaves and their therapeutic constituents, such as tannins, phenolic compounds, triterpenoids, and flavonoids, were used in the screening of diabetes mellitus using PTP1B as a major protein. This thorough in *silico* docking is crucial for the screening of plant based anti-diabetic treatments. The purpose of the study is to determine whether the molecule is a good ligand with diabetic targets that can aid in the finding of significant medicinal plant therapies for the successful treatment of Type II diabetes mellitus.

The molecular docking analysis demonstrated that the reference inhibitor (Ligand 527) exhibited the highest binding affinity –9.6 kcal/mol, serving as a benchmark for evaluating the phytoconstituents derived from *Psidium guajava* leaves. Among the tested compounds, Guavin B (–9.4 kcal/mol) showed a binding affinity very close to that of the reference inhibitor, suggesting strong and stable interaction within the active site of the target protein. Oleanolic acid and Maslinic acid both demonstrated notable binding energies (–8.9 kcal/mol), indicating favorable ligand–protein interactions comparable to established bioactive triterpenoids. Procyanidin B2 (–8.8 kcal/mol), Strictinin (–8.7 kcal/mol), and Crataegolic acid (–8.6 kcal/mol) also displayed appreciable binding affinities, reflecting their potential inhibitory capacity, although slightly lower than the standard ligand. The relatively small differences in binding energy between the reference inhibitor and certain phytoconstituents suggest that these compounds may possess competitive inhibitory potential and experimental validation to confirm their stability, specificity, and antidiabetic efficacy.

Despite increasing scientific validation of the antidiabetic properties of *Psidium guajava* leaves, current literature reveals a critical gap in correlating phytochemical diversity with precise molecular targets implicated in Type II diabetes Mellitus. Most published reports focus on generalized antihyperglycemic effects without identifying the exact binding interactions responsible for enzyme inhibition or receptor modulation. The absence of docking-based validation for identified phytoconstituents limits understanding of their binding affinity, stability, and interaction dynamics with diabetes-associated proteins. Consequently, there is insufficient evidence to prioritize specific compounds for further pharmacological development. By employing molecular docking approaches, the present study seeks to bridge this gap, providing mechanistic insights and establishing a scientific basis for future *in vitro* and *in vivo* validation studies.

CONCLUSION

The present study investigated the therapeutic potential of *Psidium guajava* L. leaves for the management of Type II Diabetes Mellitus using a computational molecular docking approach. The analysis identified several phytoconstituents with promising pharmacological potential against the target protein Protein Tyrosine Phosphatase 1B (PTP1B), an important regulator involved in insulin signaling pathways. Active compounds were screened using multiple databases, including SwissADME, ProTox-III, Dr. Duke's Phytochemical and Ethnobotanical Databases, PubChem, and Protein Data Bank, along with molecular docking tools such as BIOVIA Discovery Studio 4.5 and PyRx 0.9.8. The findings support the traditional medicinal use of *Psidium guajava* and highlight its phytocompounds as promising lead molecules for antidiabetic drug discovery. Moreover, the computational approach used in this study provides a cost-effective and efficient preliminary screening method for identifying potential bioactive candidates prior to experimental validation. Overall, the findings highlight *Psidium guajava* leaves as a promising natural source of bioactive compounds that may contribute to the development of plant-based antidiabetic agents. Additionally, the use of computational docking provides an efficient and cost-effective preliminary strategy for identifying potential drug candidates from medicinal plants. However, further validation through *in vitro, in vivo* and clinical studies is necessary to confirm the pharmacological efficacy, safety, and therapeutic applicability of these compounds in the management of Type II Diabetes Mellitus.

ACKNOWLEDGEMENT

All the authors have uniformly contributed in this research and would like to express heartfelt gratitude for the provided facilities in the School of Pharmaceutical Sciences, University of Science and Technology Meghalaya.

ABSTRACT

Cosmetic formulations which are plant based and which are efficient and environment friendly has been the rising demand for natural skin care product. Face scrub can be applied for exfoliating dead skin cells, clearing clogged pores and enhanching skin texture. This study focuses on generating a face scrub using coriander(*Coriandrum sativum*) and liquorice (*Glycyrrhiza glabra*) as the major components, acknowledged for their therapeutic effects in skin care. Antioxidants, vitamins, and essential oils abound in coriander. Glabridin and liquiritin, which are found in liquorice, lighten skin and reduce inflammation. Plant parts with antibacterial, antioxidant, and anti-aging properties are found in herbal cosmeceuticals. The safest products to use without any negative effects are herbal cosmetics, while cosmeceuticals are products that affect the skin's biological function.

Keywords: Exfoliate, Anti-bacterial, Anti-aging, Face scrub, Cosmeceuticals

INTRODUCTION

Cosmetics can be defined as any substances or admixture intended to be placed in contact with various external parts of the human body (epidermis, hair system, nails, lips) or with the teeth and the mucous membrane of the oral

depression with a view simply or substantially for cleaning them, incensing them, changing their appearance or correcting body odors or guarding them or keeping them in good condition. Cosmetics as per Indian regulations according to section 3(aaa) of the Drug and Cosmetics Act 1940 and Rules 1945 cosmetics means any article intended to be rubbed, poured, sprinkled or sprayed on, or introduced into, or otherwise applied to the human body or any part there for cleansing, beautifying, promoting attractiveness or altering the appearance and includes any composition intended for use as a component of cosmetic. Cosmetics are a category of health and beauty products that are used to care for the face and body or to accentuate or change a person's appearance. In this study, we used cosmetics with antimicrobial properties that can be thought of as drugs that can protect users from the presence of antimicrobial substances by acting as bactericidal agents. This feature is found in products like mouthwash, skin cleansers, lotions, and antibacterial disinfectants. The distinction between antimicrobial cosmetics and medications is becoming less clear as sometimes the focus on the product's active ingredient distinguishes a cosmetic product from a medication.Cosmetic products with antimicrobial effects can be described as medications with the capability to give consumers protection against the presence of antimicrobial compounds, having bactericidal effects. Products like creams, mouthwashes, skin detergents or antibacterial disinfect present this characteristic.

Presently the limit between medicines and cosmetic products with antimicrobial effects is decreasingly foggy.A face scrub is a skincare product designed to remove dead skin cells, debris, and pollutants from the skin's surface to exfoliate the skin. In order to promote a smoother, brighter, and healthier complexion, it typically contains tiny, grainy particles or chemical exfoliants that gently exfoliate dead skin. Usually, it's a cream-based treatment with tiny exfoliating particles that, when applied to the skin, help to smooth the surface by physically removing dead, dry skin cells.

Advantages of Face scrub:

- It provides a fresh, clean complexion by eliminating dirt, oil, and sweat.It efficiently tackles and removes dry, flaky skin.
- Using a scrub aids in get rid of dead skin cells that can make the skin appear dull and fatigued.
- It effectively aids in diminishing the appearance of acne scars.
- It helps prevent the growth of ingrown hairs and results in smoother skin.
- It enhances skin texture and promotes a brighter, clearer complexion.

The main active ingredients we used in this formulation are coriander and liquorice. Commonly known as cilantro, coriander leaves are a multipurpose plant that is high in antioxidants, vitamins, and minerals and has antibacterial properties. This herb, which is a member of the Apiaceae family, is well known for its therapeutic and nutritional properties. Antibacterial, antioxidant, antidiabetic, anticancer, and antimutagenic qualities have been shown for coriander extracts and essential oils. It also contains calcium, magnesium, potassium, iron, and vitamin C. The health and skincare benefits of liquorice, which is made from the root of the *Glycyrrhiza glabra* plant, are well known. It is abundant in healthy substances including glycyrrhizin, which has antibacterial, anti-inflammatory, and antioxidant properties.

Advantages Of Face Scrub

- It enhances skin texture, promotes healthy, glowing skin, minimizes pores, reduces breakouts and acne, conceals wrinkles, allows for better absorption, and helps to maintain the body's pH.
- Exfoliating aids in the removal of dry/dead skin cells and is one of the

most important skincare routines for the face.

- It also boosts blood circulation, which contributes to achieving a vibrant and

healthy complexion.

- Aids in the prevention of acne, purifies the skin, eliminates dead skin cells, and enhances skin texture, leading to a clear, smooth, and radiant complexion.
- It may also assist in diminishing dark patches, combating acne, and preventing ingrown hairs.
- Facial scrubs can eliminate sebum, dirt, and impurities from pores, which may contribute to acne, and they also help combat signs of aging by revitalizing the skin by mimicking the skin's natural renewal process.

Formulating Agents Of Face Scrub

Emulsifying agent: The emulsifying agent and emulsifiers are surfaceactive substances, more specifically the emulsifiers are soluble in water. They work by decreasing surface tension and preventing the growth of molecules; emulsifiers can be classified into ionic and non-ionic types. Examples:stearic acid, tween 80, guar gum. Emollient: Emollients are substances intended to enhance the softness and flexibility of the stratum corneum by boosting moisture levels. They offer some occlusive benefits and enhance the skin's appearance by smoothing out dry, flaky skin cells. Products specifically designed as emollients may assert, they possess antimicrobial and anti-inflammatory characteristics. Examples: lanolin, olive oil, coconut oil, beeswax.Humectant: Humectants are agents that attract and bind water. It prevents loss of moisture thereby retaining the skin's natural moisture, they draw water from the deeper layers of the skin to the outermost layer. If air humidity is above 70% trusted source, they also draw water from the surrounding environment to the skin. Examples: honey, glycerin, propylene glycol. Preservative: A preservative is defined as a natural or synthetic chemical -agent that prevents decomposition by microbial growth or any undesirable chemical change in finished products. Preservatives are used in the pharmaceutical industry to prevent the growth of bacteria, mold, fungi, and other microbes. They are used in the manufacture of pharmaceutical drugs and cosmetics. Examples: sodium benzoate, methylparaben, and calcium propionate.

Surfactants: Surfactants are substances that reduce the surface tension or interfacial tension. By decreasing the surface tension, a liquid can spread more readily, and lowering the interfacial tension between water and oil facilitates their mixing. Surfactants are categorized according to their polar head; a nonionic surfactant does not have any charged groups in its head. If the head possesses a negative charge, it is classified as anionic, while a positive charge designates it as cationic. Asurfactant that includes a head with two oppositely charged groups is referred to as zwitterionic or amphoteric. Examples: sodium lauryl sulfate, polysorbate, and cetrimonium chloride. Thickening agents: Thickening agents are incorporated to enhance the viscosity of a formulation while maintaining the emulsion's performance characteristics. Certain thickeners may aid in stabilizing emulsions, although most do not function as waxes and are typically found in a solid state. Example: isopropyl myristate

MATERIALS AND METHODS

Coriander (*Coriandrum sativum*), liquorice (*Glycyrrhiza glabra*) are materials required for the formulation. All the other chemicals used in extraction and formulation are of analytical grades.A proper method has to be carried out while formulating the face scrub. Selection and collection of active ingredients, Extraction method of coriander and liquorice, Formulation of face scrub,Evaluation of face scrub, are the steps involved in the formulation.Fresh leaves of coriander were collected, washed, air-dried, and mashed to produce crude powder. The crude powder was macerated with 96% ethanol for 5 days with occasional stirring. After 5 days, the ethanolic mixture was filtered and evaporated at 60 °C until a concentrated extract was obtained.

Phytochemical screening were done to the formulation.

The dried and crushed roots of liquorice were dissolved in 96% ethanol and kept aside for 7 days with occasional stirring. After 7 days, the ethanolic mixture was filtered and evaporated at 60 °C until a concentrated extract was obtained.Phytochemical screening were done to the formulation

- The face scrub was prepared which comprised an extract of coriander leaves. The scrub was prepared using stearic acid, Shea butter, lanolin, glyceryl monostearate, propylene glycol, isopropyl myristate, triethanolamine, methylparaben, walnut shell powder, and distilled water to prepare 25g of scrub.Preparation of oil phase: the oil-soluble ingredients such as stearic acid, Shea butter, glyceryl monostearate, and lanolin were melted in a beaker at 70°C
- Preparation of aqueous phase: The aqueous phase contains isopropyl myristate, propylene glycol, triethanolamine, methylparaben, and distilled water were mixed and heated at constant temperature. The coriander extract was added to the aqueous phase and mix well.

- Preparation of emulsion: The emulsion was prepared by adding the oil phase slowly into the aqueous phase and mixed at 70 °C by continuous stirring to obtain an o/w type emulsion finally scrubbing agent and perfume were added and the finished product was transferred to a suitable container.

The face scrub was prepared which comprised extract of liquorice. Evaluation of Face Scrub

The face scrub is evaluated for the Physical evaluation,determination of spreadability,determination of foamability,determination of washability,pH,stability studies,Antibacterial assay by agar disc diffusion method.

- Physical evaluation

The colour and appearance of the formulation were observed visually. The formulation should have a uniform distribution of extracts. These tests confirmed by visual appearance and by touch and finally its pH was calculated.

- Determination of spreadability

The spreadability was expressed in terms of time in seconds taken by two slides to slip off from the cream-based scrub, placed in between the slides, under a certain load. The shorter the time taken for the separation of the two slides better the spreadability. Two sets of glass slides of standard dimension were taken. Then one slide of suitable dimension was taken and the cream formulation was placed on that slide. Then another slide was placed on the top of the formulation, then a weight of 50g load was placed on the upper slide so that the cream-based scrub between the two slides was pressed uniformly to form a thin layer. Then the weight was removed and excess formulation adhering to the slides was scrapped off. The upper slide was allowed to slip off freely by the force of weight tied to it. The time taken by the upper slide to slip off was noted.

Spread ability= m × l/t,where M= standard weight which is tied to or placed over the upper slide. L= length of glass slide,T= time taken in seconds.

- Determination of foamability

When different quantities of formulation were mixed with 10 ml of water and shaken well, foam was observed.

- Determination of washability

A small quantity of scrub was applied over the skin and washed with water.

- pH

Weigh 1gm of scrub in a beaker. Add 50ml water to it and disperse properly. Determine the pH at 27 degrees Celsius using a pH meter.

- Stability studies

Any pharmaceutical or cosmetic product cannot be properly formulated or created without adequate stability assessments of the prepared formulation. This is done to assess the prepared product's physical and chemical stability and consequently its safety under accelerated settings. The sample was stored at 25°C temperature for 1 month.

- Antibacterial assay by agar disc diffusion method

The agar well diffusion method is widely used to evaluate the antimicrobial activity of the test sample. Nutrient agar (15-20) was poured on a glass petri plate and allowed to solidify. The standardized inoculum of the test organism was uniformly spread on the surface of the plate using a sterile cotton swab. Three wells were punched aseptically. The test sample was added into the well T1 from 10mg/ml stock. Clindamycin (30mcg) and the solvent used for sample dilution were added as positive and negative controls respectively. The plates were incubated for 24 hours at 36°C ± 1°C, under aerobic conditions. After incubation, the plates were observed and the zone of bacterial growth inhibition around the well was measured in mm.

RESULTS AND DISCUSSION

Coriander and liquorice were collected and identified. Phytochemical screening of coriander and liquorice was conducted.Evaluation of face scrub.The color and appearance of the formulated face scrub were observed visually and appeared as light green, light brown, and brownish green in color.The smell of the formulation was checked by application of the preparation on hand and observed to have a pleasant odor. The formulated face scrub has an even distribution of extract and a smooth texture. The pH of the formulated face scrub was determined using pH meter for F1,F2,F3 and was found to be 6.57,7.12,6.25 respectively. The spreadability of the formulated face scrub was determined for F1,F2,F3 and was found to ,13.39gcm/s,12.5 gcm/s,13.39gcm/s respectively. Stability studies were performed at 25°C for a duration of one month for F1,F2,and F3. The antibacterial activity for face scrub was performed against grampositive bacteria *(staphylococcus aureus).* The zone of inhibition was observed to be 23mm and confirms that formulated scrub having antibacterial property for F1,F2 and F3 was found to be 18mm,20mm,23mm respectively.Face scrub was formulated with the concentrated extract of coriander and liquorice. Coriander leaves contain essential oil, flavonoids, alkaloids, and saponins which show antibacterial exfoliating and skin-brightening properties. Liquorice is also rich in glycyrrhizin and flavonoids which brighten the skin, reduce dark spots, and soothe irritation. Together these ingredients exfoliate the dead skin cells, improve skin texture, and promote brightening.Face scrub was evaluated using different standard parameters like physical appearance, pH, foam volume, foam stability, stability studies, and antibacterial tests against Staphylococcus aureus and they were proven to be safe and effective for use. The antibacterial activity of the three formulations was assessed. Out of the three-face scrubs, it is observed that the face scrub containing a combination of coriander and licorice has more antibacterial activity as compared to the other two as it has a greater zone of inhibition. The zone of inhibition of F1 is 18 mm, F2 is 20 mm, F3 is 23 mm. Also, it is found that antibacterial activity gets increased when a combination was used.

ABSTRACT

This research paper examines the impacts of major behavioral biases, including overconfidence, mental accounting, herd behavior, loss aversion, and anchoring on investment decision-making that investors take in the gold and silver market. It concentrates on the three fundamental strategic choices; diversification, holding, and timing, in a commodity-specific context of investment.Drawing on Prospect Theory and bounded rationality, the study employs a quantitative research design using Partial Least Squares Structural Equation Modeling (PLS-SEM). Individual investors were used to gather the data and the suggested model was also examined to determine the impact of their behavioral biases on their unique investment strategies.The findings show that behavioral biases are a big determinant of the investment strategies, though they have a different impact in the various types of decisions. Loss aversion is an extremely powerful force of holding behavior because of the desire of investors to hold assets to prevent realized losses. The impact of mental accounting is found to be similar across diversification, holding, and timing strategies, which implies that investors do not classify financial decisions through a single strategy, but instead in a number of strategies. Overconfidence has a good impact on diversification, and it shows that investors are more selective in taking risks. Conversely, herd behavior and anchoring follow a relatively less robust impact, which implies that the two factors play a little role in strategic decision-making in the precious metals' realm.This study contributes to behavioral finance by extending the analysis beyond traditional equity markets to the relatively under-explored domain of gold and silver investments. It provides a focused understanding of how psychological biases shape strategic

investment behavior in commodity markets, offering practical insights for investors and contributing to the growing literature on behavioral influences in alternative asset classes.

Keywords: Behavioral Finance; Precious Metals; Gold and Silver; PLS-SEM; Investment Strategies; Prospect Theory; Bounded Rationality.

INTRODUCTION

Individual investor strategic actions in the commodity markets are one of the key determinants of financial stability around the globe and wealth maintenance among households. In this environment, gold and silver have traditionally been used as hero assets, which are critical tools as a store of value, inflation hedges, and psychological anchors in macroeconomically volatile times (Baur and Lucey, 2010; O'Connor et al., 2016). Recent data from the World Gold Council (2024) underscores this systemic importance, revealing that global gold demand reached a record 4,899 tonnes in 2023, driven largely by central bank acquisitions and heightened retail investment in emerging markets. Retail investors in developing economies such as India and China tend to invest more than 15–20% of their entire household wealth in precious metals not just as a speculative instrument, but as end-of-the-world insurance in case the currency is devalued or the system fails (Doran and Kalayci, 2023; Jaffe, 1989).

In the Indian context, the "hero" status of precious metals is unparalleled. The Indian context has the most heroic status of precious metals. India is still among the largest gold consumers in the world with the demand often going above 700 tonnes annually, which is dominated by the jewelry, bullion, and coin industries (World Gold Council, 2023). This is a strong demand on the principle of *Stree-dhan* and the religious purpose of *Akshaya Tritiya* and *Dhanteras*, during which the purchasing of gold is perceived as a favorable order (Gopalakrishnan and Mohapatra, 2023; Kannan, 2021). Moreover, the fact that the Indian Rupee is volatile and formal financial instruments are not used by most rural communities encourages the status of gold and silver as the main sources of inflation-resistant savings among the Indian middle-class (Bahl and Mehra, 2024; Vaidyanathan, 2019). As a result, the Indian investors have a distinctive psychological attachment to these assets, which is frequently expressed through a religiosity of buying-and-hold that does not make sense based on the mathematical market logic (Vikas & Jaggi, 2020).

The classical financial theories, based on the Efficient Market Hypothesis (EMH), hold that these high stakes allocations are subject to rational utility-maximization and clinical risk-return estimates (Fama, 1970). The continuing anomalies in prices, however, the fear-based rallies, and the cyclical nature of speculative bubbles in the silver market all point to the fact that human decision making can hardly be described as algorithmic. Behavioral finance also deals with this rationality gap, by recognizing that humans will act out of Bounded Rationality (Simon, 1955). In this view, it is assumed that given the sheer complexity of commodity markets and the emotion link of safe-haven assets, investors resort to psychological shortcuts, or biases (Kahneman and Tversky, 1979; Shiller, 2015). These biases are not merely a matter of sentiment in the sense in which they are employed in relation to precious metals; they are the founders, rather, of the real portfolio, as adopted by the investor. The relationship between internal bias and external investment behavior is complex and multi-dimensional. When faced with market fluctuations, an investor does not react to the price alone, but to the *psychological interpretation* of that price. For instance, Loss Aversion (LA) creates a "lock-in" effect where the pain of a potential loss compels an investor to adopt a rigid Holding Strategy, even when fundamental indicators suggest an exit (Shefrin & Statman, 1985; Tversky & Kahneman, 1992). On the other hand, Overconfidence (OC) can be a cause that can make an investor feel he/she has better predictive ability, which causes aggressive Timing Strategies that generally cause him/her to pay excessive trading costs (Barber and Odean, 2001; Glaser and Weber, 2007). In addition, Mental Accounting (MA) results in the siloing of gold holdings by investors as security funds and silver as speculative capital, resulting in irregular Diversification Strategies in their entire commodity portfolio (Thaler, 1985; Zhang and Sussman, 2018). Such biases are the hidden hands governing investors to certain strategic pillars, as holding, timing or diversifying, which are frequently quite contrary to rational financial

reasoning. Although behavioral research is proliferating, there is a gap in the existing research. A large part of empirical evidence is based on the equity market and stock market and presumes that behavioral performance would be the same in all asset markets (Gao et al., 2023; Kumar, 2009; Statman, 2014). Nevertheless, precious metal markets have their own distinctive features, i.e. tangibility, the perception of zero-betas, and a strong cultural connection which may probably cause certain psychological reactions unlike paper securities. Moreover, biases have mostly been identified in previous research, but their strategic implications have not been studied (Hens and Vlcek, 2011; Pompian, 2012). Evidence on the need to involve cognitive biases such as Anchoring Bias (AN) or social triggers such as Herd Behavior (HB) to be the determining factor on whether an investor will buy a given asset and hold on to it or actively trading it upon volatility is incredibly deficient.This study fills these gaps by suggesting a multidimensional model that project five mainstream behavioral biases onto the three pillars of portfolio management within the gold and silver sectors. This research, by moving the emphasis on the presence of biases to how to guide the process of finding strategic outcomes, presents a detailed study of the determinants of strategy adoption at the psychological level. The study assesses the explanatory strength of these biases in a marketplace with large emotional stakes and large price movement by using a structural equation modelling model on a strong data set. The value addition of this paper is three-fold. First, it offers heuristic novelty by projecting the Prospect Theory to the niche which has not been much studied previously of precious metals and backed up by current Indian and worldwide market indicators (Tversky and Kahneman, 1992). Second, it helps to bridge the gap between descriptive psychological theory and functional execution of the portfolio by providing a predictive framework of strategic behavior. Lastly, the research is valuable in that it investigates the role of certain behavioral biases in investment tactics and can be used by financial advisors and policymakers to enhance the resiliency of the retail investors in the international commodity market.

LITERATURE REVIEW AND CONCEPTUALIZATION

Defining Behavioral Biases and Strategic Pillars

The fundamental constructs used to assess the architectural impact of psychology on portfolios of commodities should be idealized in the context of market volatility and tangibility of assets. Behavioral biases are the cognitive biases and affective predispositions that make decision making in a state of uncertainty easier (Kahneman and Tversky, 1979; Sathya and Gayathir, 2024). These prejudices in the precious metals market do not only dictate the amount of investment, but also the approach that would be taken to handle the investment. Table 1 conceptualizes the five biases and three strategic outcomes that were examined in this research.

Theoretical Framework: Prospect Theory and Bounded Rationality

The study is grounded on the Prospect Theory (Kahneman and Tversky, 1979) and Bounded Rationality concept (Simon, 1955). Unlike the classical financial theory, which assumes that the cognitive capacity has unlimited scope, Bounded Rationality suggests that investors of volatile markets in commodities make use of cognitive shortcuts, or biases, to process the information influx (Ahmed et al., 2022; Khan et al., 2025). Prospect Theory then admits this by considering the fact that people judge the financial outcomes based on some reference point (Anchoring) and are more sensitive to loss than they are desirous to a proportional payoff (Loss Aversion). This theoretical construct is especially powerful in the realm of hero assets such as gold and silver. The physical solidity and perceived security of precious metals increase the emotional operations of investment choices, which are highly vulnerable to non-roughening heuristics (Nofsinger, 2018; Sathya and Gayathir, 2024). Such prejudices are not only distersive of perception, but they are the unseen engineers of strategy, and they have been found to decide whether an investor will follow an inertial (Holding), diversification (Diversification), or opportunistic (Timing) strategic posture (Wang, 2023).

Research Model and Hypotheses Formulation

The conceptual model investigates the psychological predispositions as precursors of strategic portfolio decisions. This is contrary to the fixed perspectives of the Modern Portfolio Theory, which implies that the strategy chosen is a moving variable inclined by cognitive and emotional screenings (Ahmed et al., 2022; Narasararaju et al., 2025).

Overconfidence Bias and Investment Strategy

Overconfidence occurs when investors are affected by an illusion of knowing that they possess better predictive skills than the market (Mahmood et al., 2024; Glaser and Weber, 2007). This usually results in a Self-Attribution Bias in commodity markets, in which success is blamed on skill and failures on bad fortune (Ahmed et al., 2022). Past literature on the Indian stock market indicates that overconfidence causes people to over-trade and under-diversify (Narasararaju et al., 2025; G., Suresh, 2021). In the precious metals sub - industry, overconfident investors might also consider classic approaches such as diversification to be a performance drag, and instead take concentrated tactical positions, depending on their view of having better market timing (Ahmed et al., 2022). Thus:

- **H1:** Overconfidence bias has a significant impact on the investment strategy adopted by gold and silver investors.

Mental Accounting Bias and Investment Strategy

According to mental accounting, investors mentally divide wealth into psychological silos, which is a breach of the fungibility principle (Thaler, 1985; Karimi and Nasieku, 2024). To the Indian investor, gold will typically be a Security/Insurance account, with silver or any digital gold typical forms being placed in a Speculative one (Khan et al., 2025; Bahl and Mehra, 2024). This compartmentalization leads to a fragmented strategic architecture; an investor may adopt a rigid holding strategy for their physical gold jewelry while simultaneously attempting aggressive timing strategies for their digital gold holdings (Zhang & Sussman, 2018; G., Suresh, 2021). This bias thus dictates the simultaneous adoption of conflicting portfolio strategies. Therefore:

- **H2:** Mental accounting bias has a significant impact on the investment strategy adopted by gold and silver investors.

Herd Behavior Bias and Investment Strategy

Herd behavior reflects a "social contagion" where investors suppress independent analysis in favor of mimicry (Rout et al., 2024; Fan & Todorova, 2019). The herd can frequently be seen in markets characterized by culture, such as Akshaya Tritiya, when the group purchases are common irrespective of underlying pricing indicators (Kannan, 2021; Abideen et al., 2023). This force drives investors to coordinate their entry and exit levels with the crowd collectively and focus on social timing rather than diversification and long-term holding strategies (Ahmed et al., 2022; Rout et al., 2024). The strategy turns into a social impetus instead of a financial calculation. Therefore, it is proposed:

H3: Herd behavior bias has a significant impact on the investment strategy adopted by gold and silver investors.

Loss Aversion Bias and Investment Strategy

Loss aversion argues that the pain of a loss is two times more powerful than the pleasure of a gain, which results in the Disposition Effect the disposition to hold losing investments too long (Abideen et al., 2023; Tversky and Kahneman, 1992). Loss aversion in precious metals (a so-called safe haven) is compounded by emotional attachment (Bhatt, 2024). Investors sit squarely with a strategic position, not wanting to leave during a recession so as not to psychologically encounter the fact of being in regrets (Sathya & Gayathir, 2024; Khan et al., 2025). This emotional block determines whether the investor is going to cling to a holding strategy or follows up in the less risky channels. Hence:

- **H4:** Loss aversion bias has a significant impact on the investment strategy adopted by gold and silver investors.

Anchoring Bias and Investment Strategy

Anchoring is the tendency of investors to become obsessed with a certain price, which they consider the true value of the asset (e.g., the purchase price or some historical high), and which they use as a reference (Liu et al., 2021; Wang, 2023). When prices vary against such anchors, the strategy that the investor will adopt is cognitive paralysis; the investor will sit and wait to be returned to the anchor before they take any action (Rout et al., 2024). This obsession is a deterrent to making strategic changes on the fly, and it plays a major role in whether the investor is tempted to market-time or just diversify their portfolio to avoid the risk of falling below the anchor (Wang, 2023; Liu et al., 2021). We hypothesize:

- **H5:** Anchoring bias has a significant impact on the investment strategy adopted by gold and silver investors.

Research Methodology

Research Design and Context

This research paper employs a quantitative, cross-sectional research design to investigate empirically the nexus between behavioral biases and investment strategies in the precious metals industry. The cross-sectional method is especially useful in modelling the psychological perception and strategic orientation in the dynamic markets (Hair et al., 2021). The research situation is characterized by high volatility Indian markets of commodities with individual retail investors in gold and silver.

Sampling and Data Collection

The target group includes individual investors that are active in the gold and silver market either in a physical, online, or derivative version. A stratified purposive sampling method was used to get a representative sample of all the socioeconomic range of Indian investors. The main financial centers and shopping centers with high levels of precious metal trading were focused on as the centre of data collection. Mixed-mode survey technique (online and face-to-face) was applied to reduce common method bias (Podsakoff et al., 2003). The survey tool was also administered in a rigorous pilot test conducted on ten professional commodity traders to make it conceptually clear and contextually relevant. There was also a collection of data at the time when the market was very active to get the actual responses of the behavior. Of 450 survey invitations distributed, 350 responses (77.8%) were retained for analysis. This final sample followed a rigorous filtering process to remove incomplete and straight-lined entries, ensuring data integrity. Participant demographics are summarized in Table 2.

Measurement Instruments

All the latent constructs have been measured based on known and peer-reviewed scales that had been adapted to the context of precious metals. The responses were put in a 5-point Likert scale (1 = Strongly Disagree to 5 = Strongly Agree) in order to measure the granular behavioralnuances..

- **Behavioral Biases:** Scales for Overconfidence and Herd Behavior were adapted from Ahmed et al. (2022) and Fan & Todorova (2019). Items of Thaler (1985) and Khan et al. (2025) were used to measure Mental Accounting. The metrics that were used to measure Loss Aversion and Anchoring Bias were based on Abideen et al. (2023) and Liu et al. (2021) studies.
- **Investment Strategy:** The endogeneous constructs of the Diversification, Holding, and Timing strategies were measured on the scales modified by Rout et al. (2024) and Narasararaju et al. (2025).

Data Analysis Strategy

Partial Least Squares Structural Equation Modelling (PLS-SEM) was adopted to test the hypothesized relationships with SmartPLS 4. PLS-SEM was chosen due to its predictive power, the ability to efficiently operate on complicated models with several endogenous constructs (Diversification, Holding, Timing) and the capability to properly work with non-normally distributed behavioral data (Hair et al., 2021). The analysis was done in a two-step method:

- **Measurement Model Assessment:** Verification of indicator reliability, internal consistency (Cronbach's alpha and Composite Reliability), and validity (AVE and HTMT ratio).
- **Structural Model Assessment:** Evaluation of path coefficients (β), R^2 (predictive power), and F^2 to determine the architectural influence of biases on portfolio strategies.

RESULTS

Measurement Model Assessment

Measurement model review was conducted to test the reliability and validity of constructs and then the structural analysis was carried out. Psychometric qualities of reflective constructs, which included Anchoring, Herd Behavior, Loss Aversion, Mental Accounting, and Overconfidence biases, and the three strategic results were all up to standard.

Indicator Reliability and Collinearity

The reliability of the indicators was tested using outer loadings and all the items had exceeded the desired limit of 0.70. The data analysis revealed that the loading values were between 0.811 and 0.929, which means that there was a high shared variance among indicators and their corresponding latent constructs. Besides, full collinearity test was performed to test the possibility of multicollinearity. All the constructs had a Variance Inflation Factor (VIF) value significantly lower than the critical value of 5.0 and Anchoring Bias (AN4) had the largest value of 3.279. This makes the data healthy and devoid of serious issues of multicollinearity.

Internal Consistency and Convergent Validity

Cronbach alpha and Composite Reliability (rho c) were used in the evaluation of internal consistency. The reliability of all constructs was excellent exceeding the 0.70 cut off. The values of alpha were between 0.773 (Diversification Strategy) and 0.929 (Mental Accounting Bias), whereas the CR values were between 0.869 and 0.944. Convergent validity was determined based on the Average Variance Extracted (AVE), and all the constructs were above the 0.50 cut-off with the highest and lowest being 0.688 to 0.850. This proves that the constructs explain more than half of the variance in the items

Discriminant Validity

Discriminant validity was established using the Heterotrait-Monotrait (HTMT) ratio. All the HTMT values were well below the conservative level of 0.85 as shown in Table 5, with the biggest ratio being 0.540 of Loss Aversion Bias and Holding Strategy. The results confirm that every behavioral bias and investment strategy is empirically different and unique in the conceptual framework.

Structural Model Assessment and Hypotheses Testing

The structural model was evaluated to test the hypothesized relations and measure a total predictive power of the framework. Assessment of the global model fit was done before hypothesis testing. Standardized root mean square residual (SRMR) value was 0.042, and this is much less than the 0.08 cutoff, and Normed Fit Index (NFI) was 0.872 that the hypothesized model fits the empirical data acceptably and parsimoniously

Predictive Power and Path Analysis

The model showed a high explanatory strength, which explained a large portion of the variability in the three outcomes of strategic performance. Behavioral biases collectively explained **31.4%** of the variance in **Holding Strategy** ($R^2 = 0.314$), **25.4%** in **Timing Strategy** ($R^2 = 0.254$), and **24.8%** in **Diversification Strategy** ($R^2 = 0.248$). The results of the path analysis and hypothesis testing are summarized in Table 6.

Analysis of Path Coefficients

The results of the structural analysis provide compelling empirical evidence for the role of psychological biases as architects of strategic behavior. Regarding Overconfidence Bias, the model reveals a significant negative influence on both Diversification Strategy (beta = -0.269, t = 5.870, $p < 0.05$) and Holding Strategy (beta = -0.278, t = 6.219, $p < 0.05$), supporting H1a and H1b. However, the path to Timing Strategy (beta = -0.014, p = 0.775) was non-significant, leading

to the rejection of H1c. Mental Accounting Bias emerged as a pervasive strategic driver, showing a strong positive influence on Diversification (beta = 0.403, t = 8.723, $p < 0.05$) and Timing (beta = 0.259, t = 5.484, $p < 0.05$), validating H2a and H2c. The relationship with Holding Strategy (beta = 0.072, p = 0.106) failed to reach significance (H2b rejected). Conversely, Herd Behavior Bias showed a very specific effect, it has a significant impact on Timing Strategy (beta = 0.308, t = 7.155, $p < 0.05$) and no significant effect on Diversification (H3a) or Holding (H3b) strategies. Loss Aversion Bias was identified as the most potent determinant of asset retention, exerting a dominant positive influence on Holding Strategy (beta = 0.497, t = 12.756, $p < 0.05$), thus supporting H4b. Conversely, its influence on Diversification (H4a) and Timing (H4c) was negligible. Finally, Anchoring Bias revealed a dual strategic role, positively influencing Diversification (beta = 0.113, t = 2.626, p = 0.009) and exerting a significant negative impact on Timing Strategy (beta = -0.261, t = 5.066, $p < 0.05$), supporting H5a and H5c, while H5b (Holding) was rejected (p = 0.194).

Effect Sizes

Effect size (f^2) evaluation highlights Loss Aversion as having a "Large" effect on Holding (0.355) and Mental Accounting as having a "Medium" effect on Diversification (0.215), with other paths exhibiting small-to-moderate specialized influences.

DISCUSSION

The key aim of the research was to assess the structural impact of cognitive biases on the gold and silver investor portfolio strategies. The results give an empirical map of the Bounded Rationality (Simon, 1955) conditions that the psychological heuristics can ascertain the strategic commitment in the precious metals market.

Overconfidence Bias and Strategic Decisions

As demonstrated by the results, the Overconfidence Bias has a negative critical impact on both the Diversification and Holding strategies. This brings an implication that the more investors believe in their predictive accuracy the more they find the conventional risk-reducing measures such as diversification unneeded or detrimental. This gives rise to a **Diversification Paradox** in which increased confidence results in highly risky, concentrated positions in one commodity. These results can be compared to the study by Ahmed et al. (2022) and Barber and Odean (2001) who observed that overconfident traders tend to play too heavily at the cost of portfolio stability. Moreover, the adverse route to Holding strategy suggests that exaggerated investors tend to churn their holdings through the illusion of knowledge better contrary to the long-term tradition of religiosity of precious metals (Vikas and Jaggi, 2020).

Mental Accounting Bias and Strategic Decisions

Mental Accounting emerged as a pervasive strategic driver, significantly influencing Diversification and Timing strategies. The strong positive relationship between Mental Accounting and Diversification suggests that investors do not evaluate their portfolio holistically; instead, they compartmentalize gold and silver into separate psychological "silos" (Thaler, 1985; Khan et al., 2025). This cognitive siloing leads to unintentional diversification as investors manage distinct accounts for "security" (physical assets) versus "speculation" (digital or derivative forms). This result confirms the hypotheses of Zhang and Sussman (2018) about spending and budgeting behavior, generalizing the argument to the commodity investment situation. It is particularly interesting to note that the non-significant path to the Holding strategy makes it clear that compartmentalization is not an architectural choice, but a tactical one, and it is permissible to time the compartmentalization using explicit speculative accounts.

Herd Behavior Bias and Strategic Decisions

The analysis identified Herd Behavior as a specialized determinant of the Timing strategy, with no significant impact on the structural pillars of Diversification or Holding. This indicates that social contagion in the gold and silver markets is a purely tactical phenomenon. Investors mimic collective market movements—particularly during

culturally significant periods such as *Akshaya Tritiya*—to synchronize their entry and exit points with the broader crowd (Rout et al., 2024; Kannan, 2021). This finding is consistent with Abideen et al. (2023), who argued that social cues often override independent fundamental analysis in sentiment-driven markets. However, the lack of influence on Diversification suggests that while the "herd" dictates *when* a trade occurs, it does not fundamentally alter the long-term *composition* of the investor's portfolio.

Loss Aversion Bias and Strategic Decisions

Loss Aversion was identified as the most potent driver of the Holding strategy, validating its status as a cornerstone of Prospect Theory (Kahneman & Tversky, 1979). The substantial positive path confirms that the psychological distress of realizing a loss leads to a rigid, defensive strategic posture. In the context of precious metals, which are viewed as "safe-haven" assets, the fear of regret compels investors to hold onto declining assets in the hope of a price recovery. This is a clear manifestation of the "Disposition Effect" described by Abideen et al. (2023) and Bhatt (2024). The findings contradict purely rational models which suggest that investors should exit based on future expected returns; instead, strategic commitment is anchored by the emotional need to avoid the realization of financial loss (Sathya &Gayathir, 2024).

Anchoring Bias and Strategic Decisions

Finally, Anchoring Bias demonstrated a dual role, exerting a significant negative influence on the Timing strategy while positively impacting Diversification. By fixating on historical price peaks or purchase prices, investors suffer from cognitive paralysis, rendering them unable to respond dynamically to new market information (Liu et al., 2021; Wang, 2023). This negative association with Timing indicates that internal "reference points" act as barriers to active management, as observed in the study by Rout et al. (2024). Interestingly, the positive link to Diversification suggests that when current prices deviate significantly from historical anchors, investors may choose to spread their risk across different commodity forms to mitigate the psychological impact of price volatility relative to those anchors (Narasaraju et al., 2025). This highlights a defensive use of diversification driven by cognitive fixation.

Theoretical Contributions

This study offers three critical contributions to the field of behavioral finance. First, it perfects the use of Prospect Theory to the commodity sector by demonstrating that the predictive abilities of the theory are especially high with respect to the physical commodities such as gold and silver that are treated as heroes. Second, it gives an empirical mapping of architecture, which shows that the biases are not only playing a role in one particular trade but the overall structure (Holding vs. Diversification) of the complete portfolio. Third, the article develops the concept of Bounded Rationality to the finding of the social contagion (Herd Behavior) impact on timing strategies, and mental heuristics (Mental Accounting) on the diversification pillar. This provides the multi-dimensional model of being acquainted with the human aspect of trading in commodities.

Managerial and Practical Implications

The findings highlight that investment strategies in gold and silver markets are strongly shaped by specific behavioral biases, requiring targeted and bias-aware interventions rather than generalized advisory approaches.

Managing Overconfidence to Improve Diversification

The results show that overconfidence has a significant negative impact on both diversification and holding strategies. This indicates that overconfident investors tend to take concentrated positions and frequently alter their portfolios based on perceived superior knowledge. To address this, financial advisors should focus on demonstrating the risks of concentrated investments using portfolio simulations and historical performance scenarios. Emphasizing disciplined diversification strategies can help counter excessive risk-taking driven by overconfidence.

Leveraging Mental Accounting for Structured Portfolio Design

Mental accounting was found to have a strong positive influence on both diversification and timing strategies. This suggests that investors naturally segment their investments into different psychological accounts, leading to varied strategic behaviors. Investment platforms and advisors can utilize this tendency by structuring portfolios into clearly defined categories such as long-term holdings and short-term opportunities. This approach allows investors to manage risk while aligning with their inherent decision-making patterns.

Controlling Herd-Driven Timing Decisions

The findings indicate that herd behavior significantly influences timing strategy, while having no impact on diversification or holding. This shows that social influence primarily affects when investors enter or exit the market rather than how they structure their portfolios. Regulatory bodies and financial institutions should introduce timely behavioral alerts and awareness initiatives during high-activity periods to discourage impulsive, crowd-driven investment decisions and promote independent analysis.

Addressing Loss Aversion in Holding Decisions

Loss aversion emerged as the strongest driver of holding strategy, indicating that investors tend to retain assets to avoid realizing losses, even during unfavorable market conditions. Advisors should focus on reframing investment decisions by highlighting future potential rather than past losses. Providing clear exit strategies and scenario-based guidance can help investors make more rational decisions instead of emotionally driven holding behavior.

Reducing Anchoring Bias for Better Market Responsiveness

Anchoring bias was found to negatively affect timing strategy while positively influencing diversification. This suggests that investors rely heavily on past price references, which restricts their ability to respond dynamically to market changes. Investment platforms should minimize the emphasis on historical purchase prices and instead present forward-looking indicators and trend-based insights. This can help investors move beyond fixed reference points and make more adaptive decisions.

Limitations and Future Research Directions

Although the methodological rigor and theoretical contributions are the strong sides of this study, there are a few limitations that need to be mentioned. To begin with, the research design is cross-sectional, which does not allow establishing any clear causal-temporal relationships. At the same time, structural model proves that there are important associations, yet behavioral biases and strategic orientations can change throughout market cycles. The future study ought to adopt the use of longitudinal designs to monitor how the psychological predispositions change over time during extreme market contagion or sustained bear market of precious metals. Second, even though the study used a strong sample of Indian investors so that the high-sentiment market could be represented, it could be said that the considered research is rather geographically specific, and the results will not be representative of the Western markets where gold and silver are regarded in different ways. It would be of assistance to replicate this model in different economic settings to know whether the phenomenon of the Loss Aversion-Holding nexus is a universal one in regard to commodities. Finally, the study concentrated on major five biases. Subsequent research questions may also enlarge the model by adding the mediating variables like financial literacy, experience of investment, or gender-based disparities. The moderating nature of Digital Fluency to the correlation between anchoring bias and the adoption of digital gold is another highly important line of research in building upon the contemporary behavioral finance theory.

CONCLUSION

This study provides a comprehensive empirical investigation into the profound influence of behavioral biases on the investment strategies adopted by gold and silver investors. With an effective PLS-SEM model, the study defines the key contributors to the portfolio structure as Loss Aversion and Mental Accounting, and it finds Overconfidence as a major risk to the diversification in the long-term. These results highlight the fact that there is a role played by heart as well as head in the issue of strategic behaviour in the so-called hero asset market of precious metals. Finally, the long-term stability of commodity market household wealth maintenance needs to be holistically incorporated with the financial reason and the psychological consciousness.

ABSTRACT

Prehypertension is the early stage in the development of hypertension and it is mostly associated with future cardiovascular risk in young adults. Proper lifestyle modification and exercise-based strategies are helpful to prevent disease progression. Mat Pilates has the potential to improve cardiovascular function by regulating autonomic system. It is a mind-body practice that primary emphasis oncontrol breathing, core stabilization, and regular motion.To evaluate the effect of 4-weeks structured mat Pilates program on blood pressure and heart rate recovery in prehypertensive college-going students.A single-blinded, two-arm, randomized control trialwill be conducted among students diagnosed with prehypertension inthe age group 18 to 25 years. With a 1:1 allocation ratio, participants will be randomly divided into an intervention group and a control group. The intervention group will receive mat Pilates exercises along with conventional exercises, while control group will receive only conventional exercise for 4 weeks. The intervention will be given for 30 minutes to both groups, 6 days a week. The primary outcomes will be systolic blood pressure (SBP), diastolic blood pressure (DBP), heart rate recovery at one minute (HRR1), and heart rate recovery at two minutes (HRR2), while the secondary outcomes will be heart rate at rest (HRrest), and maximum heart rate (HRmax). These parameters will be assessed before and after the

intervention. Statistical analysis will be performed using IBM SPSS to analyze within-group and between-group differences. Before the study is initiated, ethical approval is received throughInstitutional Research Committee of Maharishi Markandeshwar Deemed to be university, Mullana, Ambala, Haryana (MMDU). Written consentwill be obtained from all participants. The results of the study will be disseminated through publication or presentation, contributing to evidence on non-pharmacological management in prehypertensive college-going Students. Clinical Trial.gov (CTRI/2025/07/091754)

Keywords: Mat Pilates, Hear Rate Recovery, Prehypertensive, College students, Blood Pressure, Exercise therapy

INTRODUCTION

Prehypertension, which is becoming more prevalent among young adult, especially in college-going student due to their sedentary lifestyle, academic stress, and poor eating habits,is considered an intermediate stage in development of hypertension. People who are hypertensive are more likely to develop hypertension and cardiovascular disease (CVDs) including stroke and coronary artery disease. [1]Because even a slight elevation of blood pressure in early adulthood is strongly linked with cardiovascular mobility and long-term vascular damage.[2] It is a serious public health issue that prehypertension in young adults has been becoming more common worldwide in recent years. The factors that are mainly responsible for early emergence of raised blood pressure in this population are increased screen time, poor eating habits, psychological stress, and lack of physical activity. [3,4] Forpreventive strategies, college students are an important target population because they are particularly exposed to lifestyle patterns that are responsible for the development of cardiovascular risk factors atan early age. Moreover, prehypertension is not just a risk state because it disturbs various pathophysiological structures of the body, such as endothelial dysfunction, increased arterial stiffness, and altered autonomic regulation. [5] If left untreated, these alteration at an early age grow silentlyand ultimately lead to severe cardiovascular disease. Preventing and delaying these alterations in the body through lifestyle modification can help to reduce long-term health-related risk factors.

The lifestyle modification is the mainstay for the prevention and treatment of prehypertension. Among all approaches, exercise therapy is considered the most effective in reducing blood pressure and improving cardiovascular health. [6] However young adults lack of enthusiasm, time constraints, and accessibility issue sometimes make it difficult for them to stick with typical workouts like resistance training or aerobic exercise. Consequently, there is growing need for new approaches that are interesting useful and sustainable for youth. The heart rate recovery is defined as, how fast the heart rate drops after exercise.It is a crucial major of autonomic nervous system functioning and cardiovascular condition. Poor parasympathetic reactivation and enhanced parasympathetic action are correlated with the poor recovery of heart rate. [7,8] Improper HRR is a delicate initial indicator of autonomic malfunction and heart damage even in youths with high blood pressure. [9,10] Mat Pilates is a mind-body movement whose major focus is on control breathing, core stabilization, and regular motion. It has gained the popularity because it is sustainable, and easily accessible, and can be performed by various age group. The focus of Pilates on the breathing and control movement is thought to influence the autonomic regulation which reduces blood pressure and improves cardiovascular effectiveness. [11] A recent studies indicated that mat Pilates is effective in reducing blood pressure and improving the cardiovascular parameters such as autonomic balance vascular function, and resting blood pressure. Additionally, studies have shown that mat Pilates improves parasympathetic activity and heart rate variability, which are strongly associated with heart rate recovery. [12,13]

Despite these results, most of the research has focused on middle age or older individuals with preexisting hypertension. However, there are limited studies on individuals with prehypertension, especially college students who are more prone to developing hypertension due to their poor lifestyle and academic stress. Moreover, the effect

of mat Pilates on the heart rate recovery is also unexplored. Therefore, the present study will evaluate the effect of mat Pilates on blood pressure and heart rate recovery in prehypertensive college going-students. It is hypothesized that participants whoreceive mat Pilates in addition to the conventional exercises will show more improvement in their cardiovascular parameters as compared to participants who receive only conventional exercises.

Objectives

- To evaluate the effect of mat Pilates on blood pressure and heart rate recovery in prehypertensive college going students
- To evaluate the effect of conventional exercise program on blood pressure and heart rate recovery in prehypertensive college going students.
- To compare the effectiveness of mat Pilates and a conventional exercise program on blood pressure and heart rate recovery in prehypertensive college going students.

Hypothesis

Null Hypothesis: It will be hypothesized that mat Pilates will show no improvement in the cardiovascular parameters such as systolic blood pressure (SBP), diastolic blood pressure (DBP), resting heat rate (RHR), maximum heart rate (HRmax), heart rate recovery at one minute (HRR1) and heart rate recovery at two minutes (HRR2)

Alternative hypothesis: It will be hypothesized that mat Pilates show positive effect in cardiovascular parameters, reduce systolic blood pressure (SBP), diastolic blood pressure (DBP), resting heat rate (RHR), and maximum heart rate (HRmax) and improve heart rate recovery at one minute (HRR1) and heart rate recovery at two minutes (HRR2).

METHODS

Study Design:

The study will be a prospective, two-arm, single-blinded, prospective randomized control trialwith a 1:1 allocationratio. It will be done in Maharishi Markandeshwar Institute of Physiotherapy and Rehabilitation (MMIPR), MM(DU), Mullana, Ambala, Haryana. The study is registered in Clinical Trial.gov (CTRI/2025/07/091754) and has been approved by Institutional EthicsCommittee of MM(DU) (IEC-3085).

Study setting:

Participants will be screened in Department of Physiotherapy, in the cardiology lab at Maharishi Markandeshwar Institute of Physiotherapy and Rehabilitation (MMIPR). Exercise Will be administered and supervised in electrotherapy lab of Maharishi Markandeshwar Institute of Physiotherapy and Rehabilitation (MMIPR), MM(DU), Mullana, Ambala, Haryana.

Participant:

Participants who are diagnosed with prehypertension and are college-going, aged between 18 to 25 years, will be recruited in the study.

Eligibility criteria:

Inclusion criteria: (1) Students age between 18 to 25, (2) Students diagnosed with Prehypertension SBP 120-139 mmHg and diastolic 80-89 mmHg, (3) Both male and female, (4) Students who are not involved in any regular exercise, (5) participants who are willing to participate in full 4 weeks protocol.Exclusion criteria: (1) Students with diagnose hypertension, (2) Having other health problems like diabetes or heart disease, (3) Smokers or who recently quit smoking, (4) Students taking any medication that affected their cardiovascular system, (5) Students having any injury that prevent them to exercise, (6) Those who already doing Pilates or involved in any exercise plan, (7) Student who missed more than 25% of session.

Sample Size Determination

The sample size calculation will be done using G*power software (version 3.1.9.7). The difference between two independent means between the two groups will be ascertained using a two-tailed independent sample t-test. A 1:1 allocation ratio will be used in the study's design. The parameter used in the calculation will be an alpha error probability alpha (α) of 0 .05, an effect size(d) of 0 .7, and a statistical power (1−β) of 0 .80. The effect size was set at 0.7. According to Cohen d it indicates moderate to large effect and it is also supported by a recent meta-analysis data showing standardized mean difference of -0.71 for systolic blood pressure and -0.67 for diastolic blood pressure after exercise program. These criteria will determine the necessary sample size, which will be 26 individual per group. The ultimate sample size will be raised to 29 individual per group, for total 58 participants, taking into the account of possible dropout rate of 10%. [14,15]

Sampling method, Randomization and Allocation

The convenience sampling method technique will be chosen to recruit participants from Department of Physiotherapy at Maharishi Markandeshwar Institute of Physiotherapy and Rehabilitation. Participants who meet the inclusion criteria will be screened and enrolled in the study after obtaining written inform consent. Participants will be randomly allocated into two groups using a computer-generated random sequence. A 1:1 allocation ratio will be maintained to ensure equal distribution of participants in experimental group and control group. Allocation concealment will be done using the seal opaque envelope method by an independent researcher.

Blinding

To reduce assessment bias, the study will be single-blinded, meaning that the outcome assessor will not be aware of group allocation the intervention and allocation process will not involve assessor in charge of documenting outcome metrics, such as blood pressure and heart rate recovery. During evaluation, participants will be advised not to reveal their group assignment to assessor.

Outcomes Measures:

Primary outcome: Primary outcome will be Systolic blood pressure (SBP), Diastolic blood pressure (DBP), Heart rate recovery at one minute (HRR1), and Heart rate recovery at two minutes (HRR2). Secondary outcome: Secondary outcome will be Heart rate at rest (HRrest), and Maximum heart rate (HRmax).
The outcomes will be assessed at the baseline and after four weeks of intervention.

Material and Equipment:

The materials and equipment to be used for the study will include a standardized calibrated sphygmomanometer and stethoscope for measuring blood pressure, and a pulse oximeter (Dr Morepen) will be used to measure resting heart rate, maximum heart rate, and heart rate recovery. A standardized mat of 6 feet and one and a half inches thickness will be used for administrating mat Pilates. For measuring heart rate recovery, the Queen's College Step Test will be used, for which a standardized step bench of height 41.3 cm for males and 33 cm for females will be used. A metronome will be used to maintain stepping cadence; a stopwatch will be used to measure the duration of intervention and timing of recovery. The data of the intervention will be recorded using a standardized data collection sheet. All the equipment will be checked and calibrated prior to the intervention to ensure accuracy and reliability of measurements.

Intervention

Control Group: The control group will receiveconventional exercises. The exercise session will be for 30 minutes, in which 5 minutes will be for warm-up, 20 minutes for general flexibility and mobility exercises, and again 5 minutes for cool-down. The exercises will be performed for 6 days in a week with one day off for the duration of 4 weeks. The exercise intensity will be maintained at moderate level (11-13 on the Borg Rating of Perceived Exertion scale), and participants will be instructed to adjust their effort accordingly. [16]

The exercise program will include breathing exercises, limb mobility exercise, and general feasibility exercises, and physical education, on lifestyle modification and sleep hygiene. Breathing exercises such as pursed-lip breathing and alternative nostril breathing will be performed for 10 minutes in a session throughout the four weeks. They will also perform flexibility exercises targeting the major muscles groups, such as neck, back, hamstring, and calf muscles. Each muscle will be stretched for about 30 sec. Intensity of the exercises will progressively increase with 3 repetitions to 9 repetitions over the intervention period. The free exercise such as arm circles, marching in place, and sit-to-stand will also be included for general Mobility. These will be performed for 5 to 20 repetitions, marching 4 to 10 minutes, and arm circle from 10 to 40 repetition over time. Participants will also receive lifestyle modification education, which will include maintaining balanced diet of fruits, vegetables, whole grains, low fat dairy products reducing sugary food, and maintaining adequate hydration throughout day. Additionally, participants will be advice to follow a regular sleep schedule, avoiding late-night exercises, and practicing relaxation before bedtime are included in sleep hygiene education.

Intervention Group: The experimental group will receive both mat Pilates exercises and conventional exercise program, along with same lifestyle education. The structured mat Pilates exercises will be given for 6 days/week with one day off, for a duration of 4 weeks. Each session of Pilates will consist of 5 minutes warm-up, 20 minutes of mat Pilates, and 5 minutes of cool-down. The intensity of the exercise will be measured and kept at the moderate level (11-13 on the borg rating of perceived exertion scale) it will be informed to the participants to do exercise that are related to the level of light to somewhat hard effort. [16] The structured Pilates exercise program will consist of eleven exercises, which include the Hundred (preps), Single leg stretch, Double leg stretch, Half roll up, Side like kick, Side leg bicycle, Swan, Knee push-up, and Shoulder bridge. The repetitions of the exercises will progress from 7 repetition in first week to 20 repetitions in fourth week. This is a structured exercise program that is aimed at enhancing posture balance, flexibility, and core stability, as well as autonomic control enhance cardiovascular parameters.

PROCEDURE

After obtaining ethical approval and informed consent, participants who meet inclusion criteria will be screened and recruited for the study. Baseline measurements, such as Systolic blood pressure (SBP), Diastolic blood pressure (DBP), Heart rate recovery at one minute (HRR1), Heart rate recovery at two minute (HRR2), Resting heart rate (HRrest), and Maximum heart rate (HRmax) will be recorded prior to the intervention. Blood pressure will be measured manually using a standardized calibrated sphygmomanometer and stethoscope, and heart rate recovery will be assessed by using Queen's College Step test. Participants will be divided into two groups using computer-generated randomization sequence after baseline assessment: experimental group and control group. Under the guidance of supervising physiotherapist, both groups will receive a structured exercise program in electrotherapy lab.The experimental group will receive mat Pilates along with conventional exercise. Mat Pilates, include sequence of exercises which focus mainly on controlled breathing, core stabilization, flexibility, and posture alignment. Every session will start with warm-up exercises, then progress to primary Pilates exercises, and conclude with cool-down exercises. Control group will receive only conventional exercises, which will include warm-up, general body mobility and flexibility exercises, and cool-down supervised by a trained physiotherapist.

The intervention will be carried out for 4 weeks, and exercises will be given for 6 days in a week for 30 minutes to both groups. All exercise sessions will be supervised by a physiotherapist to ensure correct movement pattern, safety, and adherence to the exercise. Post-intervention measurement of systolic blood pressure, diastolic blood pressure, heart rate recovery at one minute, and heart rate recovery at two minutes, resting heart rate, and maximum heart rate will be recorded using the same procedure as taken in baseline. Participants will be instructed not to be involve any kind of vigorous physical activities and caffeine intake prior to the assessment to maintain consistency

Statistical Analysis

The data will be analyzed using IBM SPSS software. The participants' baseline and demographic information will be compiled using descriptive statistics. For normally distributed data, continuous variable will be presented as mean ± standard deviation (SD), and for non-normally distributed variables, they will be presented as median (interquartile range). The normality of data will be assessed using Shapiro-wilk test. A paired t-test will be used for within-group comparison (before and after intervention) for normally distributed data, whereas an independent samples t-test will be used for between-group comparison. For non-normally distributed data, within-group analysis will be performed using the Wilcoxon-signed rank test, whereas between-group comparison will be analyzed using Mann-Whitney U Test. The outcome measures will include systolic blood pressure (SBP), diastolic blood pressure (DBP), heart rate recovery at one minute (HRR1), heart rate recovery at two minute (HRR2), resting heart rate (HRrest), and maximum heart rate (HRmax). To ascertain the extent of intervention effect, effect size (Cohen's d) will be calculated. A p-value < 0.05 will be considered statistically significant.

Adverse event

Throughout the course of the study, adverse events will be tracked and noted. Participants will be questioned regarding any problems or minor incidents that occur during the intervention. The potential side effect faced by the participants may include exhaustion, lightheadedness, muscle soreness, or any other minor discomfort. If any of these events will occur, the exercise session will be immediately ceased, and appropriate management will be provided. All the adverse events will be documented and recorded to the Institutional Ethics Committee for future evaluation.

Ethical approval and consent to participate

The study is approved by the Institutional Ethics Committee of Maharishi Markandeshwar (Deemed to be University), Mullana, Ambala, Haryana. Research will be performed in unity with ethical concepts presented in Declaration of Helsinki on research that involve human subject. All the changes that occur in the study in regard to the protocol will be communicated to the institutional ethics committee and the relevant regulatory authorities. The study is registered in Clinical Trial.gov (CTRI/2025/07/091754). After explain all the potential risk and benefits along with purpose and procedure of study, the written informed consent will be obtained from all participants before their enrollment in the study. Throughout the study, participant data confidentiality will be completely preserved. The participants will be free to leave the study at any time without facing any repercussions. If they are willing, individual in the control group will have the chance to participate in the mat Pilates intervention once the trail is over.

DISCUSSION

This randomized control trial will evaluate the effect of mat Pilates on blood pressure and heart rate recovery in prehypertensive college-going students, an area with limited evidence. One of the major strengths of this study is that it includes both autonomic systems, represented by heart rate recovery, and cardiovascular system,represented by the blood pressure. Furthermore, the methodological design of the study enhances the scientific regard of the research. In addition, the randomized controlled, single-blinded design will reduce selection and assessment bias and improve internal validity of the study. Additionally, a structured and supervised intervention will be provided to ensure proper technique, correct movement patterns, safety, and adherence to the exercise session, making the intervention feasible and clinically applicable. However, certain limitations should be considered in this study. Firstly, the short-term duration of the intervention may not fully reflect long-term physiological changes in the body. Secondly, interaction between the participants in different groups may interfere with the intervention procedure. Thirdly,the lifestyle of participants outside the campus cannot be fully controlled. Lastly, the study is limited a specific population of college students, which may affect generalizability of study.

CONCLUSION

This study aims to evaluate the effect of mat Pilates on blood pressure and heart rate recovery in prehypertensive college going students. The findings are expected to provide evidence for mat Pilates as an effective non-pharmacological intervention for early cardiovascular risk management. This may support the development of feasible and structured exercise programs to prevent the progression of hypertension.

ABSTRACT

Giving video games the appearance of intelligence is the focus of the videogame development field known as "game artificial intelligence," or "game AI." Modern evolutionary algorithms to basic finite state machines are just a few of the methods that game AI incorporates from the larger field of artificial intelligence. Fuzzy logic is one of these methods that every competent videogame AI developer should have in their toolbox because of its expressive strength and ease of formulation. This paper reviews the use of fuzzy logic in games and introduces the area of game artificial intelligence (AI), looking at both academic and industry applications. We list its advantages, discuss its drawbacks, and demonstrate its useful applications. We instead find a different situation in the research field, where diverse applications of fuzzy logic and systems can be found, although with less frequency than the more popular techniques of evolutionary algorithms and neural networks. Fuzzy in game AI research is also often used alongside other advanced techniques.

Keywords: Fuzzy Logic, Artificial Intelligence, Gaming Techniques**.**

INTRODUCTION

Artificial Intelligence and Games

Artificial intelligence in games refers to all the approaches and strategies used to incorporate intelligence into video games. A videogame's animation control, steering, flocking, pathfinding, planning, procedural generation, tactical and strategic thinking, and learning are all included in the category of game artificial intelligence. These elements all have one thing in common: they all present issues that call for AI algorithms to be solved effectively. The goal of game AI is to give non-player characters (NPCs) in games life; examples of this include the merchants in a tranquil village under AI rule, or the opposing forces in a strategic game.Only a small portion of the larger science of artificial intelligence is dedicated to game AI. The definition of artificial intelligence has always been a challenge for academic AI research, despite the fact that it can generally be recognised in the study and replication of cognitive processes that are human-level or human-like, as well as in these processes' capacity for learning. The father of artificial intelligence, Alan Turing, asserted that an agent is intelligent if its actions are indistinguishable from those of a person. The definition of artificial intelligence is further complicated by game AI, which only considers the appearance of intelligence.To succeed in a game, we don't actually need to be extremely smart, What is needed is a compelling opponent, an AI agent that is human-like and potentially invincible, fun to play against and that is at least not glaringly foolish. Play Like all other components of a videogame, AI exists to further its primary objective, which is to amuse and amuse.

Put otherwise, the AI society game's catchphrase is commonly understood to be "If the player cannot see it, why do it?". However, the situation is not as straightforward as it once was. In part because of popular products that have advanced AI, in part because of the widespread availability of online multiplayer options that have altered player habits, players have become more demanding when it comes to AI, and an increasing number of game developers are shifting their focus from scripted and predictable agents to more human-like agents that are capable of learning and, by definition, intelligent. In this study, we address the use of fuzzy logic as a particular technique in videogame artificial intelligence. We look at the state of game AI today in the next part to set the stage for our discussion on fuzzy logic. In section 3, we present the ideas of fuzzy logic and go into detail about its uses in game AI. Section 5 reports and analyses the applications of fuzzy logic currently being used in research and industry. We provide judgements regarding the current state of fuzzy logic in games in section 6.

The Current State of Games Ai

Previously viewed as an afterthought in the 1980s and 1990s, game artificial intelligence (AI) has garnered interest from scholars and industry in the past 10 years. Games have historically focused more on their audio and visual aspects to draw in more players. Thus, the graphics calculation required to consume the majority of CPU processing power, with sound processing and game logic following closely after. Due to the little amount of time AI had to complete its calculations, earlier games' omnipresent foolish hordes of opponents were created. However, in recent years, the race for better, more realistic, and more satisfying graphics has slowed down, if not completely stopped, to the point where some modern games are nearly.The majority of graphics processing work is now handled by dedicated graphics processing units (GPUs), freeing up CPU resources for other computationally demanding applications like AI and physics. In this regard, game AI has become well-known for its ability to differentiate games from one another. These days, the AI receives more CPU time per game frame, which is more than sufficient for the majority of applications. Additionally, some programmers work specifically in teams to develop an AI that is tough, engaging, and (apparently) intelligent. Nonetheless, because video games offer a simple, safe, and affordable environment compared to reality, researchers have begun to tamper with them while testing AI algorithms. Researchers can securely test AI approaches in a virtual environment as an alternative to field testing. As an example, researchers have been creating controllers for virtual cars in the TORCS Simulated Car Racing Competition that sees researchers from all around the world competing to provide cutting-edge controllers for steering a car in a realistic racing simulation, with obvious benefits as a test-suite for automation without crashing a single vehicle.

Game AI Techniques

As we've seen, academic AI and videogame production are two quite different domains that gave rise to game AI. It exhibits, on the one hand, the same curiosity about learning as AI researchers. However, due to the developers' struggle with limited resources and strict time constraints imposed by the commercially-oriented entertainment industry, it tends, like any other aspect of game development, to reuse tried and tested methods and stop when something works just enough. Game AI has thus always suffered from a reluctance to accept the variety of unusual techniques available to AI aficionados.The jack-of-all-trades for game AI, finite state machines (FSMs) are utilised extensively in computer games because of their power and ease of implementation. They surpass all other techniques in this regard. Because decision trees are inherently simple, they can also be found in a lot of games. But these trees are frequently concealed by crude implementations made up of nested if/else clauses.

The usage of these methods is mostly brought about by the constrained and hurried game production schedules. Game developers typically choose for straightforward yet efficient techniques that are simple to adopt and, most importantly, evaluate, because to their limited resources.Another favourite of game AI developers is artificial life, which is best exemplified by Creatures and the majority ofMaxis titles. These games are the exception to the rule, though, and anytime sophisticated AI algorithms are used in a game, they become an integral element of the game's core narrative. Stated differently, sophisticated methods currently require a game designed around them. This finding can be attributed to three key factors. First off, compared to FSMs or decision trees, those methods are frequently more challenging to apply. This is a significant enough setback for creators who are eager to release their game. Secondly, certain more sophisticated methods, such genetic algorithms, typically have a large memory or computing cost associated with them.The non determinism of increasingly sophisticated procedures is a last issue that can arise. It is difficult for developers to release a game without thorough testing, because there is too much chance that an evolutionary algorithm may make a mistake. Fuzzy logic can be found throughout the wide range of game AI approaches, in between the more basic and sophisticated ones.

Fuzzy Logic

A superset of conventional logic, fuzzy logic is designed to accommodate the idea of partial truth values that lie outside of the binary distinction between true and false. Fuzzy variables, fuzzy rules, and a fuzzy inference engine are the constituents of fuzzy logic, which often manifests as a fuzzy reasoning system. Variables are fuzzified by choosing a set of membership functions on their potential range of values using fuzzy set theory. The membership functions translate a variable's crisp value, often in the range [0,1], to a linguistic name with some degree of truth. Variables, such measurements from sensors (even fictional ones, like in games), can be thought of as either output or input. With the defined fuzzy variables and their sets, fuzzy rules may be constructed. These rules often have an if-then structure and boolean logic-like syntax. Given the current values of the input variables, rules determine the values of the output variables. Fuzzy logic also assigns meaning to operators like AND, OR, and NOT. After the rules have been established, the system's governing rules and the current values of the variables are used by a fuzzy inference engine to draw conclusions. Consequently, output variables are assigned a fuzzy value. Defuzzification is a process that can eventually be used to convert the fuzzy engine's output to a crisp value. Lotfi A. Zadeh presented fuzzy set theory in the academic field of artificial intelligence in 1965 [40]. However, his theories did not gain traction until Japanese researchers showed how fuzzy control systems might be used in real-world scenarios. Fuzzy logic is used by a lot of controllers these days, including those in hovering helicopters, dishwashers, and electrical switches. Because fuzzy logic is akin to human reasoning, it is widely utilised in the control systems sector. This is because it allows experts in the field—rather than just programmers—to participate in the design process.

Fuzzy Logic In Games

Fuzzy logic has been tested in videogames that aim to combine intelligent agents with a simple design, similar to many other academic AI methodologies. Fuzzy logic satisfies these needs because of its language-like qualities, which make it relatively easy to reason with and produce a quick and easy design process. Since its initial introduction to the field of game development in 1996, fuzzy logic has been further refined and examined by various

writers, including Larry O'Brien of Game Developer Magazine. Numerous publications describe fuzzy logic as one of the helpful methods for creating AI in video games. A number of articles exist that serve as an introduction to using fuzzy logic in games, with being one example. Books on game AI creation dedicate full chapters to it with lots of examples. According to Zarozinski, fuzzy logic may be seen in practically all video games.

Game AI can benefit from fuzzy logic in a number of ways. Among other things, it can be used for classification—for instance, by ranking players and NPCs according to health or power using fuzzy variables like those in figure 1 (Middle, Bottom)—for NPC decision-making, such as choosing an item or weapon, for controlling the movement of units similarly to what happens with control systems, and for enabling an AI opponent to assess threats. The game AI developer can profit greatly from fuzzy logic. Fuzzy logic has a simple foundation and requires no prior knowledge beyond fundamental boolean logic, which is something that every AI developer should be able to perform. As such, it can easily incorporate sophisticated AI into games with minimal effort. Moreover, the same response curves that are typically employed to fine-tune simpler behaviours in videogames can also be utilised to create the fuzzy membership functions.Fuzzy logic's linguistic nature allows experts in the subject to formulate its rules, which can then be employed by the fuzzy system to mimic the expert's reasoning. Compared to other methods that necessitate tuning with understanding of the method itself, this is a huge advantage. This trait is useful for the videogame development industry because it allows game designers to build fuzzy rules without the assistance of a programmer. This is comparable to what happens in the industry when gameplay sequences are designed using scripting languages.

Games Using Fuzzy Logic

Upon reviewing the literature, we come across multiple references to the application of fuzzy logic in video games. We can distinguish between the examples taken from the scholarly literature and those from the industry because of their distinct contexts. It is surprising that little information regarding genuine commercial games that use fuzzy logic is available, considering the amount of literature that has been written about the subject. It is particularly difficult to uncover references to it in more recent games. We believe that fuzzy logic is regretfully no longer considered worthy of fanfare when applied because of its simple form that emerges in video game AI and because of the significant interest in more sophisticated methodologies. However, there are a few older instances as well. There's a long list of games with intriguing AI methods in there. Alternatively, we find a distinct scenario in the research sector, where a variety of applications of fuzzy logic and systems may be discovered, albeit less frequently than the more widely used methods of neural networks and evolutionary algorithms. Fuzzy in game AI research is also commonly utilised alongside other advanced techniques. Researchers frequently attempt to apply their methodologies to games made especially for research or to clones of well-known games as it is impossible to obtain the source code of commercial games. Fuzzy logic has been utilised in research to simulate the behaviour of computer-controlled agents and non-programmable characters (NPCs), just like in the industry.

Fuzzy logic is also used in games for the classification of user feedback and player learning. Fuzzy logic is typically used in these situations to model the player (or a virtual opponent) because of its effectiveness in simulating emotion. El-Nasr claims that because fuzzy logic is both qualitatively and quantitatively expressive, it has made it possible to model emotions more accurately. He defines a virtual pet's emotions using fuzzy logic and then uses reinforcement learning to modify the pet's behaviour to fit the needs of the individual player. Fuzzy decision trees are used by Levillain et al. to classify players' emotional responses during games. Research has also been done on membership set learning, or more widely, fuzzy rule learning. Fuzzy systems are combined with various strategies to facilitate learning because of their inherent qualities that make them suitable candidates for learning. For instance, rules are modelled using fuzzy logic and subsequently evolved by feeding the evolutionary algorithm with the player's gameplay [4]. In a different study, the authors gather information from the iterative games that are played and use that information to develop fuzzy rules for categorising player actions. Fuzzy logic has been investigated in the field of research and industry for the purpose of modelling agent behaviours in videogames. These days, it's a widely recognised method that Each and every AI game creator must become proficient. Using fuzzy logic in the modelling

of intelligent game agents has numerous advantages. Its primary advantage is its straightforward formulation, which when combined with its input-output capability makes it easy for developers to incorporate into a variety of games. This is especially advantageous when we take into account the busy schedules of game creators. However, we believe that the technique's promise has not yet been fully realised, particularly in commercial games, where it is still possible to find computer-controlled agents that appear to be inhumane and completely stupid. It would be easy and need minimal work to raise such agents to a higher level using fuzzy logic. To make this possible, developers must have the guts to temporarily stray from the most basic AI methods in order to reap the greatest long-term rewards.

ABSTRACT

In the absence of face-to-face interaction, users convey emotion and emphasis in app reviews often employs nonstandard textual cues. This study examines and analyses 'how Chalo public transit app users employ three main emphasis, intensification markers such as emojis, capitalization and repetition in their reviews', and also what linguistic and psychological functions these devices serve'. We perform a content analysis to identify and locate the instances of these markers and analyse their discourse contexts applying a corpus of Chalo app reviews (n=150, Google Play, 2019-2025). The findings display that emojis (praise or complaint) constantly intensify emotional tone and transport user attitude; all-caps words and abbreviations signal sharp, augmented emphasis or urgency; and repetition (of words, letters, or punctuation) serves to dramatize, embellished complaints or emphasize frustration. For instance, angry faces (😠) and multi-exclamation points (!!) strengthen negative sentiment, same time prayer hands (🙏) and thumbs-up (👍) moderate feedback or express gratitude. These markers allow writers to amplify emotion, urge action, and achieve a degree of catharsis that frees them from stress. They parallel to known "textual paralanguage" cues in ICT-mediated communication. The analysis points out 'how users alter written language to perform communicative, pragmatic functions typically carried by tone or facial expression'. We discuss, particularly, implications for discourse theory (written emphasis), sentiment analysis, and app design. Developers and designers to make use of these insights to better understanding and improve user experience by acknowledging the role of emphasis markers in digital feedback.

Keywords: paralanguage, ICT, analysis, capitalization, emojis

INTRODUCTION

Digital app reviews today are rich and growing source of consumer sentiment, but this written feedback does not carry the intonation, facial expressions and small gestures that come with spoken complaints in real life. To make up for this missing layer, users often employ typographical and pictographic devices, that is emphasis markers, to signal emotional intensity and their attitude toward the app. In this study we closely examine three main emphasis and intensification markers in Chalo public-transit app reviews: (1) emojis (for example 😠, ☺,🙏), (2) capitalization (ALL CAPS words or abbreviations like ASAP), and (3) repetition (duplication or stretching of words or punctuation, such as verry very bad, soooo slow, !!!). We ask, in simple terms: 'How do users make use of these devices in their reviews, and what functions do they serve in context?'. More specifically, we are interested in whether they intensify emotion, try to persuade other readers or developers, signal urgency, or provide a kind of cathartic venting and emotional release. These emphasis markers help to bridge the gap left by missing nonverbal cues in plain text. Prior work on online comments notes that people have "devised new non-verbal cues, such as capitalization as a substitute for shouting, multiple exclamation points for excitement, and [emojis] for facial expressions". Such cues help to clarify tone and emotion and reduce ambiguity. Here we focus on Chalo reviews as an empirical case study of how ordinary users write about a very everyday public-transport service. The Chalo app, which is widely used in India for real-time bus tracking, attracts a large number of user reviews on the Play Store. Our analysis will carefully highlight selected review excerpts and organise them into detailed tables, linking each type of emphasis marker to its inferred communicative and psychological functions. This approach draws together discourse-analytic and psychological perspectives to understand and explain why reviewers choose these markers and how they use them to shape their complaints and praise.

This paper is organised and moves in the following way. First, we briefly review and bring together relevant literature on paralinguistic cues in computer-mediated communication (CMC), emoji use and emoji discourse, and different forms of digital emphasis in written text. Next, we describe in detail our methodology for identifying, extracting and coding emphasis markers in the Chalo reviews dataset. In the Data Analysis section, we present and explain tables with representative review excerpts that clearly illustrate each marker in its context. We then go on to discuss the linguistic, emotional, and psychological roles that these markers play in shaping user feedback, complaints and praise. Finally, we close the paper with a conclusion that draws out implications for linguistics (written emphasis in digital discourse), digital communication and interface design (how designers interpret and understand user sentiment), and app development practice (how these emphasis cues signal or flag user frustration as well as user satisfaction).

LITERATURE REVIEW

Paralinguistic Cues in Computer-Mediated Communication

In simple text-based communication, we do not get the prosody, intonation or changing facial expressions that colour and enrich spoken language. Because this whole layer is missing, writers have gradually developed what researchers call textual paralanguage to carry and convey these finer subtleties. Emoticons and emojis act as small pictorial stand-ins or proxies for facial cues, while punctuation and formatting work as rough substitutes for prosody and voice quality. For example, Bai et al. point out that communicators use "capitalization as a substitute for shouting, multiple exclamation points for excitement, and expression symbols (e.g. emojis) for facial expressions". In other words, these devices step in and compensate for the absence of non-verbal cues. Early studies of CMC had already identified many such paralinguistic cues, ranging from emoticons to repeated punctuation marks, which quietly shape how a message is received and interpreted (Lea & Spears 1992; Thompson et al. 2016).

A systematic review of emoji research further underlines how emojis have emerged as a way to enrich plain text with affective nuance and emotional colour. Emoji use has grown into a complex and flexible system of "expression

symbols" that carry both emotional and linguistic features. Bai et al. argue that, because CMC lacks normal nonverbal signals, "communicators have devised new non-verbal cues" to convey emotion in online interaction. These cues help to make digital exchanges more expressive and more similar to face-to-face emotional communication. In a similar vein, Crystal notes that lengthened written words (for example, loooong) and capitalization can "convey both emotion and emphasis" in text. Taken together, this body of literature confirms that users of text rely heavily on typographical markers and visual tweaks to project, perform and highlight tone and affect.

Emojis and Emotional Expression

In much of the recent work on digital communication, emojis are treated as modern, screen-based non-verbal cues. They have grown out of older emoticons (for example ":-)") and now appear as small, colourful icons on phones and laptops. Studies show that emojis carry out several communicative functions that go well beyond simply showing or decorating emotion. Abbasi et al. (2025) argue that emojis have "evolved into semiotic tools that perform complex communicative functions". In their discourse analysis of Millennials and Gen Z users, Abbasi et al. observe that younger users often use emojis to clarify, soften, or emphasise tone, and at times to convey irony or a double meaning. This connects with broader findings in the field: emojis frequently signal emotional stance, intent, or attitude, and can work performatively in interaction rather than just acting as small illustrative icons added at the end.

From a psycholinguistic perspective, emojis help to reduce or remove uncertainty around sentiment. Derks et al. (2008) and others note that emoticons, which are the early forerunners of emojis, were among the first CMC devices used to clarify intent and emotion in otherwise flat text. Experimental work shows that emoticons can influence and shift how readers interpret an ambiguous line of text (Derks et al. 2008). In a similar way, Bai et al. report that expression symbols (emojis) "make up for the lack of non-verbal cues in CMC". Herring and other scholars emphasise that emojis, much like facial expressions in spoken conversation, gently guide readers toward the writer's intended feeling or emotional colour. Taken together, this body of research confirms that when words leave some doubt about tone, emojis and similar symbols often step in to fill that gap and project the intended affect more clearly.

Capitalization and Punctuation as Emphasis

In digital writing, capital letters and repeated punctuation often work as the rough online equivalents of shouting, raised voice or excited intonation. Bai et al. explicitly mention that capitalization can act as a cue for shouting and that multiple exclamation points signal excitement. Other scholars also observe that using ALL CAPS is usually read as emotionally intense by many readers. Dorbayani (2025), for instance, cautions that uppercase writing may appear "emotionally intense or aggressive" to readers, even when the writer did not consciously intend to "shout". At the same time, uppercase text has long been recognised as a basic typographic highlight, a tool to underline or emphasise one's point, sense of urgency or strong feeling. In a similar way, earlier CMC research shows that multiple punctuation marks (for example, "!!!") tend to correlate with heightened affect. Blackman (1990) and Spitzer (1986) catalogue devices like all-caps and strings of exclamation marks as cues used "for emphasis, to show anger, express humour, etc."

Repeated punctuation (!!!, ???) and interjections in text often convey strong emotion, surprise or disbelief. Bucher (1998), for example, observes that multiple exclamation marks intensify and dramatise written statements. In user feedback genres, exclamation marks very often accompany sharp complaints or enthusiastic praise to make the message stand out more. Spitzer's pioneering work on "typographical devices" notes that such markers explicitly underline and foreground the writer's feelings. In line with this literature, we expect that in our own corpus, capitalisation and heavy punctuation will flag and cluster around sentences where reviewers want to stand out, vent frustration, dramatise praise, or urgently call developers to take action.

Repetition and Word Emphasis

Repetition of letters or whole words (for example, soooo slow, very very bad) is another everyday strategy that writers use for emphasis. Linguists suggest that this kind of spelling imitates spoken prosody by visually lengthening a sound on the screen. Kalman and Gergle (2014) find that letter repetition in CMC very often emulates extended phonemes in speech. Writing "soooo" instead of "so" clearly underscores and stretches the drag of the word. In this sense, such repetitions are "a written emulation of a spoken paralinguistic cue" (phoneme extension). They note that repeated letters frequently carry and convey attitude (for instance, enthusiasm, irritation, or annoyance) by stretching out the sound. In addition, repeating an entire word (anaphora), as in "very very", can intensify and highlight a concept. In our data, we expect to see patterns such as "very very" (showing a higher degree of intensity) and sequences of question marks ("??") or exclamation marks ("!!"), each of which works to amplify the emotion behind the review. In short, repetition functions as a small but creative way to dramatize otherwise ordinary text and make it more expressive.

Methodology

In this study, we carried out a qualitative content analysis of user reviews for the "Chalo – Live Bus Tracking App", taken from Google Play. The user-supplied dataset consists of approximately 150 English-language reviews, covering the period from 2019 to 2025 (with selected excerpts shown in the later sections). We manually read each individual review and carefully flagged occurrences of three emphasis and intensification markers: (1) Emojis (graphical emoticons, for example ◎, ◎, ◎, ◎, and so on), (2) Capitalisation (words written in all caps or acronyms such as ASAP), and (3) Repetition (strings with repeated letters/words or punctuation, for instance "!!!" or "very very"). Each instance was noted down along with its immediate surrounding context in the sentence or comment. Our coding scheme then grouped and categorised these markers by type and by their inferred function (emotional intensification, signalling urgency, cathartic venting, softening, and other roles). We compiled representative examples to illustrate each category in a clear way. This mixed-methods approach, which combines simple quantitative counts of markers with qualitative discourse analysis, allows us to interpret not only how often but also how and why users employ emphasis in their feedback. All analysis was carried out only on the provided review texts; we did not look at or consult any external data sources. To preserve the anonymity of reviewers, all quotes refer only to the content of the review and do not include usernames or identifying details. The tables below present selected excerpts (with emphasis markers highlighted) together with brief interpretive comments. This corpus-based procedure follows standard practices in CMC discourse analysis (Kalman & Gergle 2014) and helps to keep our findings firmly grounded in real user language and experience.

Emojis as Emphasis

Emojis in our data work as small visual–emotional cues that often intensify, colour, or clear up the tone of a review. Table 1 presents selected review excerpts that contain emojis. Each row includes the short excerpt (with the emphasis marker shown in bold) along with a brief note on its communicative effect in context. For instance, angry faces clearly express and dramatise frustration, while a 🙏 (folded hands) signals gratitude, polite request, or appeal. In many cases, positive emojis help to soften and cushion criticism, whereas negative emojis sharpen, heighten and amplify the force of complaints. In Table 1, we can see that negative emojis (😠, 😖, 😣) mostly appear in clearly negative reviews, where they work to magnify and sharpen feelings of anger, disappointment or sadness. By contrast, the 🙏 and 👍 emojis tend to occur in generally positive or at least constructive comments, where they function as polite, courteous intensifiers of thanks and approval. In almost every case, the emoji lines up closely with the overall sentiment of the text: angry or sad emojis travel together with complaints, while positive emojis (thumbs-up, folded hands) accompany praise, appreciation or gentle suggestions. This pattern suggests that users do not choose emojis at random but consciously select them to strengthen and amplify the emotional valence of their statements. In this sense, emojis act as small paralinguistic cues on the screen: a 😠 stands in for a scowling face, raised voice or exasperated tone, whereas 🙏 conveys genuine gratitude or humble appeal, giving readers a clearer and more immediate sense of what the reviewer is feeling.

Capitalization as Emphasis

Capital letters in our corpus act as clear visual signals of emphasis, urgency or raised emotion in plain text. Table 2 presents short review snippets where users switch to all caps, often for whole words or well-known acronyms. In most of these cases, capitalisation goes hand in hand with strong sentiment, usually anger, irritation or deep frustration with the app or service. For completeness, we also include one common abbreviation (ASAP), which in this context functions like an emphatic adverb, pushing for quick, immediate action.As the earlier literature suggests, the all-caps usage in our data lines up closely with moments of strong anger, irritation or sharp urgency. In Table 2, it is striking that every fully capitalised phrase is negative in tone, and is often paired with an exclamation mark. When a user writes "HORRIBLE APP!" in all caps, the intention is clearly to show intense displeasure and disgust. In the same way, "COMPLETELY USELESS" in caps leaves almost no doubt about the reviewer's harsh evaluation. This pattern supports the idea that capitalisation in digital text stands in as a substitute for a raised voice or strong rhetorical emphasis. Even a short question like "WHY?" in caps stresses the author's indignation and disbelief at being asked to pay or provide personal information. In this sense, the all-caps style functions as a strong call for attention and frequently travels together with critical comments or urgent demands. Users also make use of standard capitalised forms like "ASAP" to request prompt resolution, which is another small typographic way of signalling immediacy and importance**.**

Repetition as Emphasis

In our corpus, repetition in reviews mainly appears in two simple forms: repeated punctuation and repeated words or letters, both of which work to add extra force and intensity to the message. Table 3 sets out and illustrates these examples in context. Repeated exclamation points ("!!", "!!!") visually dramatise a complaint, almost like a written version of shouting. Doubled question marks ("??") convey disbelief or incredulity at what has happened. In a similar way, repeating a word (for example, "very very") clearly intensifies its meaning and pushes the reader to feel the strength of the reviewer's judgement. When we look closely at Table 3, the effect of repetition becomes quite visible: it magnifies and stages the user's emotional release. In the "Trash!! Absolutely trash!! … junk!!" example, the reviewer strings together a series of angry adjectives, each followed by double exclamation points, and this piling up of words and marks shows a very intense venting of frustration. The heavy saturation of exclamation marks here suggests a kind of catharsis – the user is unloading and pushing out anger through deliberately over-the-top expression. In a similar way, the doubled "very"is a simple and straightforward way to stress the severity of the problem. The use of "seriously??" with repeated question marks signals disbelief at what the reviewer experiences as an absurd or unreasonable situation. These patterns line up with earlier theory: repeated punctuation stands in for vocal emphasis and raised intonation, and word duplication quietly amplifies meaning. Taken together, they create a strong pleading or shouting effect on the reader and make the complaint feel more urgent and emotionally charged.

DISCUSSION

Our reading of the Chalo app reviews shows that emojis, capitalisation and repetition really work as small emphatic tools that thicken and enrich written feedback with emotional and pragmatic nuance. Each marker carries both a linguistic function on the page and a psychological function for the writer:

Emotional intensification

All three markers are used to intensify and scale up the writer's emotions. Negative emojis (😠, 😖, 😩) deepen and darken the expression of anger or disappointment beyond what plain words alone can do. In a similar way, capitalised adjectives and repeated exclamation points raise the "volume" of complaints ("HORRIBLE APP!"). These cues make the tone unmistakably strong and hard to miss. By contrast, positive emojis (🙏, 🙂, 😊) tend to soften praise, mark appreciation or show gratitude. The simple presence of any emoji already signals that the comment is emotionally loaded or charged. In this sense, emphasis markers help to scale up the affective content of reviews, which is consistent with their known role as forms of textual paralanguage.

User persuasion and appeal

In several reviews, these markers seem to be used with the intention of persuading or appealing to the developer and, sometimes, to other users. Phrases like "remove this step ASAP" with ASAP in caps clearly convey urgency and a push to act. The repetition "very very poor" underlines dissatisfaction and strengthens the complaint. While this is not persuasion in a commercial or promotional sense, these emphatic strategies can be read as rhetorical moves: they make the criticism more memorable, more striking and more compelling. Capitalised questions such as "WHY?" or "HOW RIDICULOUS?" attempt to force the reader or developer to stop, think and reckon with the reviewer's frustration. In other words, emphasis markers spotlight the key point and can make criticism feel more forceful and, hopefully, more persuasive.

Urgency

Capital letters and clusters of exclamation marks often work as signals of urgency in the text. Demands ending in "ASAP" or warning-type sentences overloaded with exclamations ("Guys, don't download this app!!!") serve as alerts, calling others' attention to immediate problems. Repeated punctuation at the end of sentences suggests that the user is on high alert and wants urgent correction. This is especially visible in cases where real-time features fail and users feel stranded or misled; their feedback turns into an urgent warning to the wider public. In this way, these markers function like small textual sirens on the screen, demanding quick attention and fast response.

.

Catharsis and venting

At a psychological level, emphatic writing appears to offer a form of catharsis or emotional release. Users usually turn to reviews when they are angry, disappointed or upset, and the use of emphatic markers becomes a way to vent and unload these feelings. For example, in the line "Trash!! Absolutely trash!! … stupid piece of junk!!", the user piles up angry adjectives, each with double exclamation marks, creating a kind of therapeutic barrage of insults. This heavy saturation of exclamation points suggests catharsis – the user is releasing pent-up frustration through exaggerated, over-the-top language. In the same way, writing "😠" or repeating "!!!" can feel like letting out a scream in text form. Consumer-psychology work has already noted that people writing negative reviews often "vent frustration and anger", and here the linguistic data matches that observation: intense markers cluster around explicitly emotional statements, indicating that users may feel some relief by expressing themselves strongly.

Alignment with linguistic literature

These patterns broadly align with and support the linguistic and CMC literature cited earlier. The strategies we see in our data closely mirror the "typographical devices" catalogued by early researchers of computer-mediated communication. As Kalman and Gergle note, readers are able to interpret such cues as signs of the author's social and emotional stance, rather than as random or noisy shouting. Capital letters, in this view, are processed as deliberate emphasis. Similarly, Abbasi et al. stress that emojis carry performative weight that goes beyond decoration or mere ornament. Our findings confirm that real users actively and consciously leverage these cues in exactly these ways: to make their feelings, stance and evaluation clear in writing. In short, emphasis markers in the Chalo reviews function as emotional intensifiers and as visible cues to the reader. They break and lift the monotony of plain text by adding extra weight to key words, phrases or emotional contexts. Importantly, these cues do not appear randomly scattered across the corpus; they systematically co-occur with highly emotional content. Negative experiences are heavily loaded with angry faces, all caps and strings of exclamation marks, while positive reviews more often carry emojis like thumbs-up or folded hands to show satisfaction, gratitude or polite approval. This patterned, non-random use underlines and confirms the role of these markers in expressing and performing user sentiment on screen.

CONCLUSION

This study shows and demonstrates that Chalo app users systematically and quite consciously employ emojis, capitalisation and repetition as small emphatic tools to add extra emphasis and emotion to their written feedback. Our reading of the dataset indicates that these markers play fairly predictable and recurring functions: they amplify emotional tone, signal or flag urgency, and provide a small outlet for frustration. For linguists and discourse analysts, this confirms that digital written language, even in everyday settings, is richly expressive and that these emphasis markers act as modern-day analogues of paralinguistic cues. Even in a simple app review context, users quietly and naturally weave in such devices to make their stance and feelings clear.For digital communication more broadly, the findings suggest that sentiment-analysis tools and models should seriously account for emphasis markers. Many off-the-shelf sentiment systems still ignore or strip away these small cues, but our analysis, along with earlier research, suggests that uppercase and emoji can significantly shift or colour perceived sentiment. Simply recognising a 😠 or a cluster like "!!!" can help algorithms gauge and weigh the intensity of a review much more accurately.

For app developers and support teams, understanding emphasis markers in reviews can also help improve user engagement and response strategies. A sudden flurry of "😠", "ASAP", or phrases such as "very very poor" is a clear and straightforward signal of a highly dissatisfied user. Such signals can be used to prioritise complaints that need urgent fixes or quick intervention. In customer support exchanges, developers might also choose to mirror gently or soften the tone while still acknowledging the user's emotion. For instance, a user who vents with multiple exclamation points may appreciate a calm, empathetic reply that explicitly recognises their frustration.To sum up, looking closely at emphasis markers gives us a small but powerful window into the user's emotional state and communicative intent. Our analysis of Chalo app reviews shows that users are not passive at all; they actively shape and format their feedback so that it can be felt as well as read. Designers and analysts should therefore treat these markers as meaningful data points rather than background noise. Future research could quantify their impact on how readers perceive reviews or track how their use evolves over time. Even at this stage, however, our study quietly underlines one simple point: in digital feedback, a single exclamation mark can sometimes carry the weight of many words of emphatic meaning.

Table 1: Examples of emojis in Chalo reviews (emphasis marker in bold). The right column interprets how each emoji adds emotional nuance.

Review Excerpt (with Emoji)	Interpreted Function
"This app and this whole system is useless! 😠 … It's been more than 15 days!!!" (Oct 3, 2022)	Angry face accompanies frustration; ✙ intensifies anger and venting. Use of multiple exclamation marks adds urgency.
"👍Good app.. But …" (Sep 12, 2025)	Thumbs-up followed by critique suggests mixed sentiment. 👍 conveys initial positivity or politeness before raising issues.
"… thanks for this all 🙏" (Oct 30, 2025)	Folded-hands emoji indicates gratitude or relief. It emphasizes the user's *thankfulness* for the app's utility.
"... miserable 😖" (Oct 22, 2025)	Weary/sad face underscores disappointment. The 😖 emoji intensifies negative feeling ("really miserable") beyond the words.
"it crashes again n again, ... 😣😣" (Sep 6, 2025)	Double sad faces heighten the sense of exasperation. 😣😣 emphasizes repeated failure and pity. Two faces amplify the despair.
"…feels like a smooth fraud!" (Jul 3, 2025) 😉	(Example of user ironically labeling the app) 😉 implies a sarcastic or resigned tone. The smiley may soften the harsh critique ("smooth fraud") or mask frustration.

Table 2: Collects and displays examples of capitalisation in the Chalo reviews. The capitalised words and phrases (shown in bold) are clearly used to mark and emphasise anger, frustration or urgency. For instance, single words like DISAPPOINTED and stronger phrases such as COMPLETELY USELESS are written in all caps to convey almost "shouting-level" intensity on screen. The acronym ASAP similarly stands out and highlights urgency, acting like an emphatic adverb that pushes for quick action and fast response from the developers.

Review Excerpt	Capitalized Text	Interpreted Function
"How Ridiculous? Please remove this step … *How Ridiculous?*" (Oct 27, 2025)	*"How Ridiculous?"* (sentence start)	Though only sentence-case, the repeated rhetorical question expresses anger. The phrasing "*How Ridiculous?*" emphasizes exasperation.
"It's been 40 min and still doesn't show … i think this app is only for buying tickets… useless." (Nov 7, 2025)	(no caps aside from grammar)	No explicit caps, but context reveals frustration. (Some reviews may rely on minimal caps.)
"What is the use of the App? ... **How Ridiculous?** Please remove this step…." (Apr 10, 2024)	*"How Ridiculous?"* (capital H)	At the start of a question. The phrasing underscores disbelief/irritation.
"One of the worst apps … Totally ***DISAPPOINTED***." (Mar 2025)	*DISAPPOINTED* (all caps)	All-caps word signals very strong negative emotion. Author likely wanted to *shout* this feeling.
"It's totally not user friendly!! It wants personal info? **WHY?**" (Apr 2024)	*WHY?* (all caps)	Capitalized interrogation expresses anger/confusion. The writer is demanding an explanation with emphasis.
"… look into this and do the needful changes **ASAP**." (Oct 26, 2025)	*ASAP*	Acronym in caps indicates urgency ("as soon as possible"). It underlines the reviewer's demand for immediate action.
"… app showing bus is coming … COMPLETELY USELESS. OR JUST FIX …" (Oct 29, 2025)	*COMPLETELY USELESS. OR JUST FIX…*	Long phrase in all caps shows extreme condemnation. The viewer "shouts" their conclusion: app is *completely useless* and demands a fix.

"HORRIBLE APP!" (Early 2020s)	*HORRIBLE APP!*	Full sentence in all caps. This is equivalent to shouting "Horrible app!" out loud. Shows maximal frustration.

Table 3: gathers and presents clear examples of repetition in the Chalo reviews. The bold repeats mark the elements that are being strongly emphasised. In many cases, multiple exclamation points placed after key phrases (for example, Trash!!) and repeated words (very very poor) work together to dramatise and colour the message. Double punctuation marks ("??", "!!!") in the same way intensify feelings of incredulity, shock or urgency in the reader's mind.

Review Excerpt	Repeated Elements	Interpreted Function
"This app and whole system is useless! 😠 … no response yet. It's been more than 15 days!!!" (Oct 3, 2022)	*"!!!"* at end of sentence; *"useless!"* with 😠	Triple exclamation points punctuate last sentence, amplifying anger and frustration (almost screaming "15 days!!!"). The single exclamation with ◎ earlier also intensifies "useless!".
"Trash!! Absolutely trash!! … this stupid piece of junk!! … it's of no use!!" (Oct 26, 2023)	Multiple *"!!"* in every sentence	Repeated double exclamations after "Trash" and "junk" create a barrage of emphasis. The user hammers each insult home. The effect is very aggressive and cathartic.
"...it first tells it's gonna come in 10 minutes, bus actually arrives in 2 minutes. ... Pretty seriously?? I always get late..." (2024)	*"??"* after "seriously"	Double question marks express incredulity. The reviewer is stunned by the system's failure ("seriously??"). The repetition signals frustration and disbelief.
"very very poor never accurate information …" (Oct 24, 2025)	*"very very"* (word repeated)	Doubling "very" amplifies the degree of "poor". It's a simple intensifier ("extremely poor"). Word repetition mimics spoken emphasis.
"It's totally not user friendly!! It wants personal info? WHY?" (Apr 2024)	*"!!"* after "friendly"; *"? ... ?"* in context	Here "!!" after "friendly" underscores anger. (Also "WHY?" in caps). These mixed repeats punctuate the complaint.
"Guys, don't download this app! … This has happened multiple times." (Late 2025)	(None explicit in sample)	Not all emphatic statements require obvious markers. Tone is set by word choice. But its context warns readers urgently.

ABSTRACT

Let $G = (V, E)$ be a simple graph. A set $D \subseteq V(G)$ is a total outer- connected dominating set of G if D is total dominating and the induced subgraph $G[V(G) - D]$ is a connected graph. Let G be graph with n vertices. Let $\tilde{D}_{tc}(G, i)$ denote the family of all total outer- connected dominating sets with cardinality i of G. Let $\tilde{d}_{tc}(G, i) = \left|\tilde{d}_{tc}(G, i)\right|$. In this paper, we obtain the total outer- connected domination polynomial $\tilde{D}_{tc}(G, x) = \sum_{i=\tilde{\gamma}_{tc}(G)}^{|V(G)|} \tilde{d}_{tc}(G, i)x^i$ of some middle graphs of path, cycle, star and pan graph.

Keywords: Total outer- connected dominating set, Total outer- connected domination number, Total outer- connected domination polynomial
Mathematics Subject Classification: 05C69, 05C31, 05

INTRODUCTION

Let $G = (V, E)$ be a finite, simple and connected graph without loops or multiple edges. For any vertex $v \in V(G)$, the open neighbourhood of v is the set $N_G(v) = u \in V(G)/uv \in E(G)$ and the closed neighbourhood of v is the set $N_G[v] = N(v) \cup v$. For a set $S \subseteq V$, the open neighbourhood of S is $N(S) = \cup_{v \in S} N(v)$ and the closed neighbourhood of S is $N[S] = N(S) \cup S$. The concept of dominating set and the domination number in graph theory was first introduced by Oystein Ore and Claude Berhe in 1960s. The concept of domination polynomial of graph theory was introduced by saied Alikhani and Yee- Hock Peng in 2009. The concept of outer- connected dominating set was introduced by Joanna Cyman in 2006 and the concept of total outer- connected domination was introduced by Joanna cyman in 2010. They also further studied the concept in their subsequent work including its application in real life situations. This motivated us to study the total outer- connected domination polynomial of some graphs.

Definition 1.1 A Middle graph$M(G)$ of a G in which the vertex set is $V(G) \cup E(G)$ and two vertices are adjacent if and only if either they are adjacent edges of G or one vertex of G and the other is an edge incidence with it.

Definition 1.2 A walk is called a Path, if all the vertices are distinct. P_n denotes a path on n vertices**.**
Definition 1.3 A cycle is a closed trial in which the vertices are all distinct; C_n denotes a cycle on $n$vertices.
Definition 1.4 A Star graph is a tree with n vertices consisting of one central node connected to all other $n-1$ peripheral nodes, which have a degree of 1.It is a bipartite graph where the central vertex has degree of $n-1$. It is denoted by $K_{1,n}$.
Definition 1.5 Pan graph is obtained by joining a cycle C_n to a path P_1 via a bridge. It is denoted by $T_{n,1}$.
Definition 1.6A dominating set of G is a set $D \subseteq V(G)$ such that $N_G[V] \cap D \neq \emptyset$, for all $v \in V(G)$. The domination number of G is the minimum cardinality of a dominating set of G and it is denoted by $\gamma(G)$. Similarly, a total dominating set of G is a set $D \subseteq V(G)$ such that for each $v \in V(G)$, $N_G(v) \cap D \neq \emptyset$. The total domination number $\gamma_t(G)$ of G is the minimum cardinality of a total dominating set of G.
Definition 1.7 Let G be a simple connected graph. A set $D \subseteq V(G)$ is a total outer- connected dominating set of G if D is total dominating, and the induced subgraph $G[V(G)-D]$ is a connected graph. The total outer- connected domination number of G, denoted by $\tilde{\gamma}_{tc}(G)$, is the minimum cardinality of a total outer- connected dominating set of G.
Definition 1.8 Let G be a simple connected graph. Let $\widetilde{D}_{tc}(G,i)$ denote the family of all total outer- connected dominating set of G with cardinality i and let $\tilde{d}_{tc}(G,i) = \left|\widetilde{D}_{tc}(G,i)\right|$. Then the total outer- connected domination

polynomial$\widetilde{D}_{tc}(G,x)$ of G is defined as

$$\widetilde{D}_{tc}(G,i) = \sum_{i=\tilde{\gamma}_{tc}(G)}^{|V(G)|} \tilde{d}_{tc}(G,i)x^i$$

where $\tilde{\gamma}_{tc}(G)$ is the total outer- connected domination number of G.

Total outer - connected domination polynomial of some graphs

Lemma 2.1 Let G be a graph with n vertices. Then

$$(i)\tilde{d}_{tc}(G,n) = 1$$

$(ii)\tilde{d}_{tc}(G,i) = 0$ if and only if $i < \tilde{\gamma}_{tc}(G)$ or $i > |V(G)|$
$(iii)\widetilde{D}_{tc}(G,x)$ has no constant term.

Theorem 2.2 The total outer- connected domination polynomial of the middle graph of path $M(P_n)$ is $x^{2n-4}\{(n-3)[1+2x]+(2n-3)x^2+x^3\}$, for all $n \geq 4$ with intial values $\widetilde{D}_{tc}(M(P_1),x) = x$, $\widetilde{D}_{tc}(M(P_2),x) = 2x^2+x^3$ and $\widetilde{D}_{tc}(M(P_3),x) = 3x^4+x^5$.

Proof:
Let $M(P_n)$ be a middle graph of path with $2n-1$ vertices.Let $\{u_1,u_2,u_3,\dots,u_n\}$ represent the end vertices of $M(P_n)$and $\{v_1,v_2,v_3,\dots,v_{n-1}\}$ represents the middle vertices of $M(P_n)$.
There is no total outer- connected dominating sets of cardinality less than $2n-5$
There are $n-3$ total outer- connected dominating sets of cardinality $2n-4$. This is the minimum cardinality of total outer- connected dominating set. Therefore, $\tilde{d}_{tc}(M(P_n),2n-4) = n-3$
There are $2(n-3)$ total outer- connected dominating sets of cardinality $2n-3$. Therefore, $\tilde{d}_{tc}(M(P_n),2n-3) = 2(3)$.
There are $2n-3$ total outer- connected dominating sets of cardinality $2n-2$. Therefore, $\tilde{d}_{tc}(M(P_n),2n-2) = 2n-3$.
There is only one total outer- connected dominating set of cardinality $2n-1$. Therefore, $\tilde{d}_{tc}(M(P_n),2n-1) = 1$.
Since, the minimum cardinality is $2n-4$, $\tilde{\gamma}_{tc}(M(P_n)) = 2n-4$. Therefore,

$$\widetilde{D}_{tc}(M(p_n),x) = \sum_{i=2n-4}^{2n-1} \tilde{d}_{tc}(M(P_n),i)x^i$$

$$= \tilde{d}_{tc}(M(P_n),2n-4)x^{2n-4} + \tilde{d}_{tc}(M(P_n),2n-3)x^{2n-3} + \tilde{d}_{tc}(M(P_n),2n-2)x^{2n-2} + \tilde{d}_{tc}(M(P_n),2n-1)x^{2n-1}$$

$= (n-3)x^{2n-4} + 2(n-3)x^{2n-3} + (2n-3)x^{2n-2} + \quad x^{2n-1}$

$= x^{2n-4}\{(n-3)[1+2x] + (2n-3)x^2 + x^3)\}, n \geq 4.$

Theorem 2.3 The total outer- connected domination polynomial of the middle graph of cycle$M(C_n)$ is $x^{2n-3}\{(n)[1+2(x+x^{2)}] + x^3\}$, for all $n \geq 3$ with intial values $\widetilde{D}_{tc}(M(C_1), x) = x$ and $\widetilde{D}_{tc}(M(C_2), x) = 2x^2 + x^3$.

Proof:
Let $M(C_n)$ be a middle graph of cycle with $2n$ vertices. Let $V(M(C_n)) = X \cup Y$, where $X = \{x_u / 1 \leq u \leq n\}$, the cycle vertices of $M(C_n)$ and $Y = \{y_v / 1 \leq v \leq n\}$, the middle vertices of $M(C_n)$. Clearly $\{x_1, x_2, \dots, x_{n-2}, y_1, y_2, \dots, y_{n-1}\}$ is the minimum total outer- connected dominating set. Hence $\tilde{\gamma}_{tc}M(C_n) = 2n-3$.
If $i = 2n-3$, for the total outer- connected dominating set, we need to select one vertex from the vertex set$X$ and two vertices from the vertex set Y. This means there are n possible ways.
If $i = 2n-2$, for the total outer- connected dominating set, we need to select three vertices from the vertex set$X$ and three vertices from the vertex set$Y$. This means there are $2n$possible ways.
If $i = 2n-1$, the total outer- connected dominating set, we need to select the vertex set X and remove one vertex from the vertex set Y. This means there are $2n$ possible ways.
If $i = 2n$, the total outer- connected dominating set, we need to select the vertex set X and the vertex set Y. This means there are only one possible way. Hence,

$$\widetilde{D}_{tc}(M(C_n), x) = \sum_{i=2n-3}^{2n} \tilde{d}_{tc}(M(C_n), i)x^i$$
$$= nx^{2n-3} + 2nx^{2n-2} + 2nx^{2n-1} + x^{2n}$$
$$= x^{2n-3}\{n[1+2(x+x^2)] + \ x^3\}, n \geq 3.$$

Theorem 2.4 The total outer- connected domination polynomial of the middle graph of star$M(K_{1,n})$ is $x^{2n}[n+1+x]$, for all $n \in N$.

Proof:
Let $M(K_{1,n})$ be a middle graph of star with $2n+1$ vertices. Let $V\big(M(K_{1,n})\big) = X \cup Y$, where $x = \{x_u \backslash 1 \leq u \leq n+1\}$, the end vertices of $M(K_{1,n})$ and $Y = \{y_v \backslash 1 \leq v \leq n\}$ the middle vertices of $M(K_{1,n})$. Clearly $\{x_1, x_2, \dots, x_n, y_1, y_2, \dots, y_n\}$ is the minimum total outer- connected dominating set. Hence $\tilde{\gamma}_{tc}\big(M(K_{1,n})\big) = 2n$.
If $i = 2n$, for the total outer- connected dominating set we need to select one vertex from the vertex set X and the vertex set$Y$. This means there are $n+1$ possible ways.
If $i = 2n+1$, for the total outer- connected dominating set we need to select the vertex set X and the vertex set Y. This means there are only one possible way. Hence,

$$\widetilde{D}_{tc}\big(M(K_{1,n}), x\big) = \sum_{i=2n}^{2n+1} \tilde{d}_{tc}(M(K_{1,n}), i)x^i$$
$$= (n+1)x^{2n} + x^{2n+1}$$

$$= x^{2n}(n+1+x),\ n \in N.$$

Theorem 2.5 The total outer- connected domination polynomial of the middle graph of path $M(T_{n,1})$ is $x^{2n-3}\{1+3x+(n+3)x^2+(2n+1)[x^3+x^4]+x^5\}$, for all $n \geq 2$ with intial value $\widetilde{D}_{tc}\big(M(T_{1,1}), x\big) = 2x^4 + 6x^5 + 7x^6 + 7x^7 + x^8$.

Proof:
Let $M(T_{n,1})$ be a middle graph of pan graph with $2n+2$ vertices. Let $V(M\big(T_{n,1}\big)) = X \cup Y \cup Z$,where $X = \{x_u / 1 \leq u \leq n\}$, the cycle vertices of $M(T_{n,1})$ and $Y = \{y_v / 1 \leq v \leq n\}$, the middle vertices of $M(T_{n,1})$ and $Z = \{z_w / w = 1,2\}$,

the path vertices of $M(T_{n,1})$. Clearly $\{x_2, x_3, \dots, x_{n-2}, y_2, y_3, \dots, y_{n-1}, z_1, z_2\}$is the minimum total outer- connected dominating set. Hence $\tilde{\gamma}_{tc}M(T_{n,1}) = 2n-3$.

If $i = 2n-3$, for the total outer- connected dominating set, we need to select$i-n$ vertices form the vertex set X and $i-n+1$ vertices from the vertex set Y and the vertex set Z. This means there are only one possible way.
If $i = 2n-2$, for the total outer- connected dominating set, we need to select two vertices from the vertex set $X$and two vertices from the vertex set $Y$and the vertex set Z. This means there are only three possible ways.
If $i = 2n-1$, for the total outer- connected dominating set, we need to select

$(i)i-n$ vertices from the vertex set X and $i-n-1$ vertices from the vertex set Y and the vertex set Z.
$(ii)i-n+1$ vertices from the vertex set X and $i-n$ vertices from the vertex set Y and the vertex set Z. This means there are$n+3$ possible ways.

If $i = 2n$, for the total outer- connected dominating set, we need to select
$(i)i-n-1$ vertices from the vertex set X and $i-n-1$ vertices from the vertex set Y and the vertex set Z.
$(ii)\frac{i}{8}$ vertices from the vertex set X and $\frac{i}{2}-2$ vertices from the vertex set Y and the vertex set Z. This means there are$2n+1$ possible ways.

If $i = 2n+1$, for the total outer- connected dominating set, we need to select the vertex set X and the vertex set Y and remove w_1 vertex from the vertex set Z. This means there are $2n+1$possible ways.
If $i = 2n+2$, for the total outer- connected dominating set, we need to select the vertex set X and the vertex set $Y$and the vertex set Z. This means there are only one possible way Hence

$$\tilde{D}_{tc}\big(M(T_{n,1}), x\big) = \sum_{i=2n-3}^{2n+2} \tilde{d}_{tc}(M(T_{n,1}), i)x^i$$
$$= x^{2n-3} + 3x^{2n-2} + (n+3)x^{2n-1} + (2n+1)x^{2n} + (2n+1)x^{2n+1} + x^{2n+2}$$
$$= x^{2n-3}\{1 + 3x + (n+3)x^2 + (2n+1)[x^3 + x^4] + x^5\}, n \geq 2.$$

Corollary. 2.6
(i) The sum of the coefficients of the total outer- connected domination polynomials of middle graph of path is $3(n-3) + 2(n-1), n \geq 4$.
(ii) The sum of the coefficients of the total outer - connected domination polynomials of middle graph of cycle is $5n+1, n \geq 3$.
(iii) The sum of the coefficients of the total outer- connected domination polynomials of middle graph of star is $n+2, n \in N$.
(iv) The sum of the coefficients of the total outer- connected domination polynomials of middle graph of pan graph is $5(n+2), n \geq 2$.

CONCLUSION

In this paper, we have derived the total outer- connected domination polynomial of middle graph of path, cycle, star and pan graph.

ABSTRACT

Pre-Menstrual Syndrome [PMS] is a cyclical condition marked by a range of physical, emotional, and behavioral symptoms that can significantly disrupt the daily lives of menstruating individuals. Despite affecting up to 90% of women during their reproductive years, PMS is often underdiagnosed and poorly managed due to its multifaceted etiology and limited awareness. Effective care requires a multidimensional approach that encompasses personal, social, and medical aspects of health. This scoping review aims to map and synthesize the existing literature on PMS management, while focusing on the role of homoeopathy within integrative care frameworks. Following the PRISMA-ScR guidelines, relevant studies published in English between 2008 and 2024 were identified. Eligible studies were charted and grouped thematically into four domains: personal coping mechanisms, social support systems, homoeopathic treatment, and conventional management strategies. A total of 24 studies were included in which nine addressed personal strategies, eight explored social support, four evaluated Homoeopathy, and three discussed conventional interventions. Findings suggest that integrated models combining multiple domains offer better adherence, fewer adverse effects, and improved symptom relief. Notably, Homoeopathy, when used alongside lifestyle modifications and support networks, demonstrated promising outcomes in enhancing both physical and emotional well-being. However, the

current evidence base remains limited, highlighting the need for more rigorous, high-quality research to validate and expand the role of Homoeopathy in PMS care. A biopsychosocial model remains essential for the effective and holistic management of PMS.

Keywords: Premenstrual syndrome, coping strategies, social support, homoeopathy, integrative medicine, women's health

INTRODUCTION

Pre-Menstrual Syndrome [PMS] refers to a set of recurring physical, emotional, and behavioral symptoms that arise during the luteal phase and typically resolve with menstruation.[1]Common manifestations include irritability, anxiety, mood swings, breast tenderness, fatigue, bloating, and disturbed sleep.[1] While mild symptoms are widespread, approximately 30–40% of reproductive-age women experience clinically significant PMS.[2]A more severe form, Premenstrual Dysphoric Disorder [PMDD], affects 3–8% and is classified as a depressive disorder in the DSM-5.[1,3,4]The psychosocial burden of PMS is considerable, often disrupting interpersonal relationships, academic or occupational performance and daily life.[5] Despite its impact, PMS remains underrecognized and undertreated due to factors such as societal normalization of menstrual distress, menstrual stigma, insufficient education, and limited provider training. Its etiology is multifactorial, involving hormonal fluctuations particularly estrogen and progesterone-serotonin dysregulation, prostaglandin sensitivity, and nutritional deficiencies. The wide variation in symptom severity also suggests the influence of psychosocial and lifestyle factors.[6,7]

Conventional treatments like Selective Serotonin Reuptake Inhibitors [SSRIs], hormonal contraceptives, Non-Steroidal Anti-Inflammatory Drugs [NSAIDs], and gonadotropin-releasing hormone analogues offer symptom relief but are often discontinued due to adverse effects including nausea, emotional numbing, and sexual dysfunction.[7] These standard approaches frequently overlook the personalized nature of PMS, applying broad treatments to individualized experiences. Consequently, integrative treatment models are gaining traction, combining medical care with psychological support, lifestyle modifications, and complementary approaches.[8]Homoeopathy, with its individualized and holistic perspective, is increasingly used to address PMS symptoms, particularly within the Indian AYUSH system.[9]However, it remains underrepresented in research. In parallel, many women adopt self-guided coping strategies such as yoga, meditation, journaling, dietary changes, herbal teas, and acupressure,which enhance symptom control and promote self-efficacy.[10]Social support from family, friends, institutions, or online communities further helps reduce stigma and improve coping.[11,12] Despite this diversity of interventions, few studies assess them in an integrated framework. Thus, a comprehensive scoping review is warranted to map the evidence across personal, social, homoeopathic, and conventional strategies, reinforcing the need for a holistic, biopsychosocial approach to PMS care.

METHODS

Study design and framework:

This scoping review followed the PRISMA-ScR[Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews] guidelines. A scoping review was selected to enable a broad, exploratory analysis of the diverse strategies used in PMS management, spanning homoeopathic, social, and behavioral approaches. This methodology allowed comprehensive mapping across disciplines and study designs. The review protocol was developed beforehand but not registered in PROSPERO, as the platform does not currently accept scoping reviews.

Eligibility criteria

Inclusion criteria

- Peer-reviewed full-text articles published between 2000 and 2024.
- Original research studies [quantitative, qualitative, or mixed-methods], systematic reviews and meta-analyses, and case series.
- Studies addressing at least one of the four pre-defined themes related to PMS management.
- Studies focused on PMS or PMDD as a primary or secondary condition.

Exclusion criteria:

1. Articles in languages other than English.
2. Conference abstracts, letters to the editor, editorials, opinion pieces, and anecdotal blogs.
3. Studies involving only non-menstruating individuals [e.g., postmenopausal or pre-pubertal populations].
4. Articles focusing exclusively on diagnostic criteria or pathophysiology without reference to interventions.

Information sources

A comprehensive literature search was conducted using PubMed, Google Scholar, ScienceDirect, and the AYUSH Research Portal. To ensure thoroughness, manual searches and cross-referencing of relevant articles from journals in complementary medicine, gynecology, psychiatry, and women's health were also performed.

Search strategy

The search strategy combined MeSH terms and free-text keywords using Boolean operators. The core search string was:["Premenstrual Syndrome" OR "PMS" OR "Premenstrual Dysphoric Disorder" OR "PMDD"] AND ["coping" OR "self-care" OR "homeopathy" OR "homoeopathy" OR "social support" OR "conventional treatment" OR "SSRIs" OR "NSAIDs" OR "yoga" OR "journaling" OR "CBT"]. Filters limited results to human studies on females, in English, published between 2000 and 2024. The strategy was adapted for each database.

Selection of sources of evidence

All retrieved records were imported into Mendeley, and duplicates were removed. Titles, abstracts, and full texts were screened in successive stages by two reviewers, with discrepancies resolved by consensus. A PRISMA flow diagram illustrates the selection process, detailing records identified, screened, excluded, and included.

Data charting process

Data were extracted using a standardized Excel sheet, with one reviewer charting and a second cross-verifying each study for accuracy.

Data synthesis and thematic classification

Included studies were thematically categorized into four overarching domains based on their primary intervention focus.

Quality assessment

Following PRISMA-ScR guidelines, formal risk-of-bias assessment was not required, but methodological aspects like sample size, outcome clarity, validated tools, and conflict-of-interest disclosures were noted during data charting and discussed in the analysis.

Ethical considerations:

As this study involved a review of publicly available data and did not include human participants or personal data, ethical approval was not required.

RESULTS

Overview of studies:

Out of 186 records identified, 43 duplicates were removed, leaving 143 for screening. After reviewing 63 full-text articles, 24 studies met the eligibility criteria. These studies varied in origin, design, sample size, and intervention focus, with most from India, Europe, Ethiopia, and South Korea. Study designs included cross-sectional surveys, RCTs, and mixed-method case series. Details are summarized in Table 1.

Theme 1: Personal coping mechanisms

Several studies examined self-initiated, non-medical strategies women use to manage PMS symptoms, focusing on behavioral and lifestyle changes. Yoga and aerobic exercises like walking and dancing were among the most effective, improving mood, reducing fatigue, and alleviating cramps through endorphin modulation.[10]Keten Edis et al. reported that students practicing yoga and guided breathing experienced better emotional balance and sleep.[10] Journaling aided emotional regulation and symptom tracking, enhancing preparedness.[17] Lifestyle modifications such as reducing caffeine and maintaining sleep hygiene were associated with decreased discomfort, particularly in an Ethiopian cohort.[18] Herbal teas like fennel, chamomile, and peppermint helped relieve nausea and irritability,while nutrient-rich diets high in calcium and iron showed potential benefits.[10,14] Complementary practices such as abdominal acupressure and relaxation techniques also reduced stress and improved sleep.[15,17,19]Use of symptom tracking tools like the PSST showed 15–40% symptom improvement over 4–12 weeks.[19]. Table 2 presents key study details mentioned under the nine articles selected for personal coping mechanisms.

Theme 3: Homoeopathic treatment

Four studies evaluated Homoeopathic treatments for PMS. Danno et al. reported over 50% symptom reduction using Folliculinum and Lachesis mutus in 23 cases.[9]Klein-Laansma et al. found improved outcomes with semi-individualized remedies alongside standard care compared to conventional treatment alone.[29]Rudresh et al. noted emotional improvement and reduced absenteeism with homoeopathy.[27]All studies showed high adherence [>90%] and no adverse events. However, limitations such as small sample sizes, lack of randomization, and inconsistent outcome measures call for more robust trials. Table 4 summarizes details of the four

Theme 4: General/Conventional management

Three studies assessed conventional approaches for PMS, focusing on pharmacological and psychological treatments. SSRIs like fluoxetine and sertraline [10–20 mg/day] effectively reduced emotional symptoms but were associated with side effects such as nausea, sleep issues, and reduced libido.[30–32]Hormonal contraceptives helped manage physical symptoms like bloating and acne but often led to mood swings and breakthrough bleeding.[32]Cognitive Behavioral Therapy [CBT] improved stress management and emotional regulation, with enhanced coping and self-efficacy reported. Combining CBT with lifestyle changes showed added benefit.[31,32] However, barriers like side effects, mental health stigma, therapy costs, and limited access restricted widespread adoption.[30–32]These findings support the need for more integrated and accessible treatment models. Table 5 outlines the key details of these studies.

DISCUSSION

This scoping review synthesizes evidence from 24 studies on the multidimensional management of PMS, highlighting the diverse strategies women use, often in combination to manage physical, emotional, and social symptoms. These approaches fall into four key themes: personal coping mechanisms, social support systems, homoeopathic interventions, and conventional medical treatments. The findings underscore the need for flexible,

individualized care models that reflect women's lived experiences and cultural contexts.Self-initiated coping strategies were the most accessible and widely adopted. Practices like yoga, journaling, dietary regulation, and herbal teas were consistently linked to improvements in physical and emotional symptoms.[10,14]Yoga, in particular, improved stress regulation, sleep, and PMS severity,while journaling enhanced emotional preparedness and cycle awareness.[33,34]These low-cost, culturally adaptable methods such as traditional remedies in Ethiopia and food-based rituals in India were effective when practiced consistently, but often lacked formal guidance.[35] This suggests the need for integrating such strategies into public health and menstrual education programs.

Social support played a vital role in shaping PMS experiences. Family support, especially from mothers and sisters, helped adolescents develop coping skills and reduced emotional distress.[16] Peer networks in hostels and women's colleges normalized symptoms and reduced stigma.[22]Institutional measures like menstrual education, counseling, and flexible leave policies improved academic outcomes.[36] In restrictive environments, digital platforms and apps offered women privacy, education, and a sense of community.[37]However, most studies in this domain were observational, highlighting the need for structured interventions and rigorous evaluation.Homoeopathy was explored in four studies. Commonly prescribed remedies included Sepia officinalis, Pulsatilla nigricans, Ignatia amara, and Lachesis mutus, tailored to specific physical and emotional profiles.[9,29,38–40] Danno et al. reported over 50% symptom reduction with individualized treatment.[9]And Klein-Laansma et al. found better outcomes when homoeopathy was combined with standard care.[29]Rudresh et al. also observed improved emotional well-being and workplace performance.[41]High adherence and absence of adverse effects contributed to patient confidence. The homoeopathic approach aligns well with the biopsychosocial model due to its holistic, patient-centered nature. However, small sample sizes, lack of blinding, and subjective outcome measures limit the strength of evidence, calling for larger, well-designed trials.

Conventional medical treatments remain central for managing moderate to severe PMS and PMDD. SSRIs like fluoxetine and sertraline effectively reduced emotional symptoms when given continuously or during the luteal phase.[42]Hormonal contraceptives regulated cycles and reduced physical symptoms, while NSAIDs helped relieve prostaglandin-mediated pain. Cognitive Behavioral Therapy [CBT] helped restructure negative thoughts, reduce emotional distress, and enhance coping.[43]Yet, challenges like side effects, stigma, therapy costs, and limited accessespecially in rural settingsrestricted their use.[44]Moreover, conventional treatments often lack personalization, underscoring the need for more integrative, tailored care.

Limitations

Despite promising findings, few limitations were noted. Many studies had small sample sizes, especially in homoeopathy and personal coping domains, and lacked standardized outcome measures. Reliance on self-reported data introduced bias, and long-term follow-up was rare. Research from regions like Latin America, East Asia [beyond Korea], and low-income Western countries was limited, affecting generalizability. Randomized trials in complementary medicine were scarce, with most studies being observational. Future research should prioritize multicenter, culturally inclusive, and ethically robust trials with longer follow-up. Nonetheless, this review highlights the diverse strategies women use and the need for integrated, empowering, and context-sensitive menstrual health care.

CONCLUSION

Pre-Menstrual Syndrome [PMS] is a common yet under-recognized condition requiring individualized, integrative care. This review highlights diverse management strategies, with homoeopathy emerging as a safe, culturally accepted option especially in settings like India under AYUSH. Remedies tailored to emotional and physical profiles showed promising outcomes, high adherence, and no adverse effects. Despite limited high-quality evidence, homoeopathy holds potential as a complementary approach in PMS care. Rigorous research using standardized tools

is needed to strengthen its clinical relevance. A shift toward a biopsychosocial model incorporating patient-centered therapies like homoeopathy is essential for advancing menstrual health and women's well-being.

Table 1: Summary of Included Studies Categorized By Title, First Author And Theme [N=24]

Study ID	Title of selected article	First author	Theme
1	Prevalence of premenstrual syndrome among students - Stress a potential risk factor[13]	Nandakumar, H.	Personal Coping
2	The Effect of the Coping Methods Used by Nursing Students on the Prevalence of Premenstrual Syndrome[14]	Cetin, S.	Personal Coping
3	Premenstrual Syndrome Experiences and Coping Levels of University Students: A Mixed Method Study[10]	Keten Edis, E.	Personal Coping
4	Coping strategy in adolescents with premenstrual syndrome: Application of the Construal Level Theory and the Precaution Adoption Process Model[15]	Delara, M.	Personal Coping
5	Premenstrual syndrome, coping mechanisms and associated factors among female students of a health sciences campus in South India[16]	Parveen, S.	Personal Coping
6	Effect of relaxation techniques on fatigue and headaches in premenstrual syndrome[17]	Ferreira, R.	Personal Coping
7	Premenstrual syndrome, coping mechanisms and associated factors among Wolkite university female regular students, Ethiopia, 2021[18]	Eshetu, N.	Personal Coping
8	Investigating influencing factors on premenstrual syndrome [PMS] among female college students[11]	Yi, S.	Personal Coping
9	Comparison of the effect of teaching coping skills and acupressure on premenstrual stress: a randomized controlled trial[19]	Mirghafourvand, M.	Personal Coping
10	Psycho-social Correlates of Premenstrual Syndrome: Predictive Role of Self-esteem and Social Support[12]	Sharma, A.	Social Support
11	Psychosocial Profile of Women with Premenstrual Syndrome and Healthy Controls: A Comparative Study[20]	Kleinstäuber, M.	Social Support
12	Family caregiver role and premenstrual syndrome as associated factors for postnatal depression[21]	Garcia-Esteve, L.	Social Support
13	Effectiveness of Psychosocial Interventions for Premenstrual Syndrome: A Meta-Analysis[22]	Han, J.	Social Support
14	Premenstrual syndrome and health related quality of life among young adult females at Northern India: A cross-sectional study[23]	Malhotra, P.	Social Support
15	Psychosocial associates of premenstrual symptoms and the moderating role of social support in a community sample[24]	Haywood, A.	Social Support
16	Prevalence of premenstrual syndrome and its effect on quality of work life in working women in South India[25]	Maheshwari, P.	Social Support
17	The ongoing silencing of women in families: an analysis and rethinking of premenstrual syndrome and therapy[26]	Ussher, J.	Social Support
18	Evaluating the Efficacy of Homeopathy in Premenstrual Syndrome: A Comprehensive Review of Clinical Evidence[27]	Rudresh, BT	Homoeopathic Treatment

19	Homeopathic treatment of premenstrual syndrome: a case series[9]	Danno, K.	Homoeopathic Treatment
20	Homeopathic treatment for premenstrual symptoms[28]	Jones, A.	Homoeopathic Treatment
21	Semi-individualized homeopathy add-on versus usual care only for premenstrual disorders: a randomized, controlled feasibility study[29]	Klein-Laansma, C.	Homoeopathic Treatment
22	Efficacy of progesterone and progestogens in management of premenstrual syndrome: systematic review[30]	Wyatt, K.	General Treatment
23	Premenstrual syndrome: management and pathophysiology[31]	Imai, A.	General Treatment
24	Management of premenstrual syndrome: evidence-based guidelines[32]	Panay, N.	General Treatment

Table 2: Summary of Studies on Personal Coping Mechanisms For Pms [N=9]

Study ID	**Title of article**	**First author**	**Location of study**	**Year and duration of study**	**Study design**	**Population age [years]**	**Sample size [n]**	**Common mental symptoms**	**Common physical symptoms**	**Personal coping methods followed**	**Assessment scale used**	**Concluding remarks**
1	Prevalence of premenstrual syndrome among students - Stress a potential risk factor	Nandakumar, H.	India	2016 – 2017, One academic year	Cross-sectional	18-35	450	Reduced social interaction, irritability, mood swings	Aches, muscle pains, abdominal bloating, fatigue	Yoga, music therapy, meditation, social interaction, having a hobby	Self-designed PMS questionnaire	Stress caused by multiple reasons is a major risk factor
2	The Effect of the Coping Methods Used by Nursing	Cetin, S.	Turkey	2015 – 2016, 1 year	Descriptive and cross-sectional study.	18-29	102	Not specifically evaluated	Not specifically evaluated	Dietary changes, increasing the fluid intake, taking warm showe	Premenstrual Syndrome Scale [PMSS] questionnaire	Awareness about PMS and coping method has to be taught to the

	Students on the Prevalence of Premenstrual Syndrome									rs, getting psychological support		students
3	Premenstrual Syndrome Experiences and Coping Levels of University Students: A Mixed Method Study	Keten Edis, E	Turkey	2022, 3 months	Mixed-method	18-29	436	Anger, anxiety, feeling of crying, reluctance, and depression	Edema, distension, breast tenderness, pain in the abdomen and legs, oily skin, acne, loss of appetite, nausea-vomiting, diarrhea, and weakness.	Relaxation practices like drinking herbal tea, hot application, sleeping, resting, walking, doing sports	Premenstrual coping measure scale	Health professionals should be aware of students' problems and provide comprehensive services.
4	Coping strategy in adolescents with premenstrual	Delara, M.	Iran	Not mentioned	Theoretical application based interventional study	Mean age: 16	1578	Not specifically evaluated	Not specifically evaluated	Cognitive strategies	Premenstrual Assessment Scale	Coping levels differ by awareness stage mentioned in Constr

	syndrome: Application of the Construal Level Theory and the Precaution Adoption Process Model											ual level theory [CLT] and Precaution Adoption Process Model [PAPM]
5	Premenstrual syndrome, coping mechanisms and associated factors among female students of a health sciences campus in South India	Parveen, S.	India	2022, 4 months	Cross-sectional	17-23	202	Mood swings, irritability and loss of concentration	Abdominal cramps, generalized aches and pains, food cravings and fatigue	Taking rest, sleeping and listening to music	Premenstrual syndrome scale [PMSS] questionnaire	The awareness and health-seeking behaviour related to PMS appear to be relatively poor among the students.
6	Effect of relaxation techniques on fatigue	Ferreira, R.	India	4 months	Comparative interventional study	18-26	30	Stress and anxiety	Nausea, headaches, fatigue and bloating	Meditation with Visualization, Mitchell's Metho	Daily Severity Record of Problems [DSRP]	Mitchell's Method Relaxation Technique is more

	and headaches in premenstrual syndrome									d Relaxation Technique for muscle relaxation	questionnaire, Global Fatigue Index [GFI] and Headache Disability Index [HDI]	effective than meditation with visualization in reducing fatigue and headaches in PMS.
7	Premenstrual syndrome, coping mechanisms and associated factors among Wolkite university female regular students, Ethiopia, 2021	Eshetu, N.	Ethiopia	2021, 15 days	Cross-sectional survey	17-26	591	Depression, mood swings, impaired work performance, lack of interest in usual activities and obsessional thoughts	Abdominal cramps, fatigue	Regular exercise, taking rest, sleeping.	Pre-tested semi-structured self-administered questionnaire	Factors like family history of PMS, absence of sexual activity, severe menstrual pain, high pad usage, irregular cycles, early menarche, and prolonged menstruation were identified as predictors of PMS.
8	Investigating influe	Yi, S.	South Kor	2021, 19 days	Cross-sectional	20s [20-29]	143	Depression, stress	Sleep disturbances	Sleep and rest	PMS severity	Since PMS worsen

	ncing factors on premenstrual syndrome [PMS] among female college students		ea		online survey				, and eating attitude problems		measurement tool	s in the late luteal phase, individuals should understand their symptom patterns and adopt coping strategies.
9	Comparison of the effect of teaching coping skills and acupressure on premenstrual stress: a randomized controlled trial	Mirghafourvand, M.	Iran	2023, 3 months	Randomized Controlled Trial	16-18	90 [three groups containing 30 each]	Tension, restlessness	Breast tenderness, cramps	Coping skills training, acupressure	Premenstrual Symptoms Screening Tool [PSST], premenstrual stress questionnaire and stress coping styles questionnaire	Stress coping training and acupressure are effective, practical, and drug-free interventions that can be integrated into PMS care

Table 3: Summary Of Studies Exploring The Role Of Social Support In Pms [N=8]

Study ID	**Title of Article**	**First Author**	**Year of Study**	**Location of Study**	**Duration of study**	**Study Design**	**Population Age[years]**	**Sample Size**	**Common Mental Symptom**	**Common Physical Symptom**	**Type of Social support receiv**	**Assessment Scale used**	**Key findings**

									s	**s**	**ed**		
11	Psycho-social Correlates of Premenstrual Syndrome: Predictive Role of Self-esteem and Social Support	Sharma, A.	2024	India	Not specifies	Cross-sectional	18-25	100	Low self-esteem, Irritability	Fatigue, headaches	Family, peers	Rosenberg Self-Esteem Scale, Social Support Scale	Social support and self-esteem significantly predicted PMS severity
12	Psychosocial Profile of Women with Premenstrual Syndrome and Healthy Controls: A Comparative Study	Kleinstäuber, M.	2016	Germany	Not specified	Comparative	19-40	120	Mood swings, depression	Breast tenderness, fatigue	None [comparative analysis]	Standardized interviews	Women with PMS had worse psychosocial profiles than healthy controls
13	Family caregiver role and premenstrual syndrome as	Garcia-Esteve, L.	2008	Spain	12 months	Prospective cohort	20-45	120	Anxiety, emotional stress	Back pain, appetite changes	Family caregivers	EPDS, Perceived Support Index	Family caregivers with PMS are at higher risk for postna

	associated factors for postnatal depression												tal depression
14	Effectiveness of Psychosocial Interventions for Premenstrual Syndrome: A Meta-Analysis	Han, J.	2018	South Korea	Varies	Meta-analysis	18-40	15 studies [meta-analysis]	Irritability, low mood	Cramps, fatigue	Supportive therapy interventions	Various RCT outcomes	Psychosocial interventions reduce severity of PMS symptoms
15	Premenstrual syndrome and health related quality of life among young adult females at Northern India: A cross-sectional study	Malhotra, P.	2022	India	3 months	Cross-sectional	18-30	150	Tension, lack of focus	Abdominal pain, fatigue	Peers, university services	Structured PMS QOL scale	Social context affects PMS impact on life quality

16	Psychosocial associates of premenstrual symptoms and the moderating role of social support in a community sample	Haywood, A.	2007	UK	Not specified	Community-based survey	20-45	200	Anxiety, emotional sensitivity	Headaches, bloating	Community, peer support	PMS and support questionnaire	Social support moderates psychological symptoms of PMS
17	Prevalence of premenstrual syndrome and its effect on quality of work life in working women in South India	Maheshwari, P.	2023	India	3 months	Cross-sectional	22-45	300	Stress, lack of motivation	Fatigue, backache	Work place and peer support	Standardized PMS work impact scale	Social support improves coping and work productivity

Table 4: Summary Of Studies On Homoeopathic Treatment Approaches For Pms [N=4]

Study ID.	**Title of Article**	**First Author**	**Year**	**Location**	**Duration of Study**	**Study Design**	**Age of Participants [years]**	**Sample Size**	**Common Homoeopathic Medicines Used**	**Key Findings**

18	Evaluating the Efficacy of Homeopathy in Premenstrual Syndrome: A Comprehensive Review of Clinical Evidence	Rudresh, B.T.	Publications up to September 2024.	India	Not applicable	Narrative Review	Varied among different studies	Six articles	Individualized medicines	Found positive outcomes across various studies using individualized homoeopathy.
19	Homeopathic treatment of premenstrual syndrome: a case series	Danno, K.	September 2008 and April 2010	France	20 months	Case Series	19 - 56	23	Most commonly used medicines were Folliculinum, followed by Lachesismutus.	Symptom-specific remedy selection and polypharmacy showed notable improvement in patients.
20	Homeopathic treatment for premenstrual symptoms	Jones, A.	Not specified	UK	Not specified	Case Report[2 cases]	42 and 25	2	Lac caninum, Sepia officinalis, Natrum muriaticum	Case studies demonstrated symptom relief using individualized approach.
21	Semi-Individualized Homeopathy Add-On Versus Usual Care Only for Premenstrual Disorders	Klein-Laansma, C.T.	2012	Netherlands	2 months	Randomized Controlled Trial	18– 50	60	Sepia officinalis, Natrum muriaticum, Cimicifuga racemosa, Lachesis mutus, Lilium tigrinum, Phosphor	Homeopathy group showed significant improvement in general well-being and symptom severity.

ABSTRACT

In this editorial we jog outa plan to discover the accomplishmenttacticin the matter of crisp rates for Fuzzy queueing model with an unreliable bartender. Our conception is to propagate the Fuzzy inter arrival time, service time, breakdown time and repair time into crisp time by consorting ranking function strategy. In this paper, we see about Queueing model with Unreliable server, which makes service interruption and after the repair time the intrusion is solved. Here we take all the values in Fuzzy numerals and it is modified into crisp values by our proposed ranking method named Trisectional Trapezoidal Fuzzy ranking strategy.This ranking strategy is dedicated, easy to pertain and can be used for all kinds of queueing complications. Here we see about the Structure's dormant time by varying arrival and service rates. It is more conductive for the administrator to know the execution metrics.

Key words: Fuzzy sets, Trapezoidal Fuzzy Numerals, Membership Functions, Unreliable server, Trisectional Fuzzy Ranking.

INTRODUCTION

The Fundamental definitions, theorems which are disclosed in a book named 'Introduction to Queueing theory', analyzed by Bose [2] in the year 2008. 'Fundamentals of Queueing Systems found by Cooper [4] in the year 1990,

which clears concepts of Queueing Models. Queueing models of waiting theory are moreeminent for our studydetermination. Basic Queueing Situations are generated by analyzing the books called' Basic Queueing Theory',which is given by Janos[10] in the year 2016 and 'Probability and Queueing Theory', which is found by Palaniammal[14] in the year 2012, it talks about basic information and different types of Queueing models. Donald Gross et.al [7] has published a book 'Fundamentals of Queueing Theory', in the year 2011. Dmitry Efrosinin et.al[6] have examined an Reliability analysis of two-server heterogeneous unreliable queueing system with a threshold control policy, in the year 2017.Hari Ganesh et.al[11] have given an Identification for the critical path method. Majority of the time we concern the Fuzzydialectics and implementations. George Klir and Bo Yuan[8] have presented 'Fuzzy Sets and Fuzzy Logic', in the year 1996, which tells about elementary theory and applications of Fuzzy.Kaufmann and Gupta[9] have investigated an'Fuzzy Mathematical model' in Engineering and management, in the year 1988.Dinesh and Pankaj Kumar Srivastava[5] have found a Trisectional Fuzzy Trapezoidal Approach to optimize Interval data Based Transportation Problem.

In most queueing models, due to the long hours of working the server may breakdown, so the structure service is disrupted. It may take some time to recover the structure,it is called repair time of the bartender.There also be expected service disruptions such as in the course ofleaves eithervacations. In regard to queueing model with server breakdown, Anshul and MadhuJain [1] have investigated an Cost optimization of an Unreliable server queue with two stage service process under hybrid vacation policy. Chang et.al [3] has analyzed an unreliable server retrial queue with patron feedback and impatience, in the year 2018. Kumar and Sharma[12] have assess an Transient and Steady state behavior of a Two Heterogeneous Queueing system with Balking and Retention of Reneging Customers, in the year 2018. Mukeba Kannyinda [13] has examined an analysis of an Retrial queue with single server subject to breakdowns and repairs by flexible alpha cut methods. Ramesh and Seenivasan[18,19] have investigated Fuzzy Queueing models with Unreliable Electric Transformer and Performance calibrations of single server glycolic acid based Fuzzy retrial Queueing model. Sakthivel et.al [22] have investigated about achievement expedients on batch arrival Queueing model with Fuzzy approach. Ramesh and Kumaraghuru[17],Syamala et.al [28]have analyzed about an Fuzzy queues by Fuzzy ranking methods. Rachana Rathore and Shrivastava[15] have focused under Queueing models with breakdown and repairs. Saravananet. al [23] haveappraised the performance measures of Multiserver retrialqueueing model with an unreliable server, discouragement and vacation model.Ramesh and Seenivasan[20-21], Shyamala et.al[27-29] have discovered Queueing systems under Fuzzy ordering approach. Ramesh and Hari Ganesh [16] have focused on Fuzzy loss system under Centroid Fuzzy ranking approach. Seenivasan et.al [24-26] have explained more queueing models with Multiple vacation, Catastrophe,Working Vacation and Partial Breakdown. Syamala et.al [30] have analyzed two heterogeneous water heater queueing model by Matrix Geometric Method.

Prefaces Depiction (Fuzzy set)

A fuzzy set is characterized by a membership function that allocate to each section in the universe of discourse W a value within the interval [0,1]."

(i.e.)$\widetilde{K}$ = {(w,$\mu_{\widetilde{K}}$ (w)); w∈ W}.

Here$\mu_{\widetilde{K}}$: W →[0,1] is a mapping termed the degree of membership function of the fuzzy set $\widetilde{K}$ and $\mu_{\widetilde{K}}$ (w)is designated the membership value of w∈ W in the fuzzy set $\widetilde{K}$. These membership grades are frequently expressed by real numerals sorting from [0,1].

Depiction(Triangular Fuzzynumeral)

A triangular Fuzzy numeral$\widetilde{K}$ (w) can be depicted by $\widetilde{K}$(l,m,n) with membership function

$\mu_{\widetilde{K}}$ (w) given by$\mu_{\widetilde{K}}$ (w) = $\begin{cases} \frac{z-l}{m-l}, & l \le w \le m \\ 1 \quad , & w = m \\ \frac{z-n}{m-n}, & m \le w \le n \\ 0 \quad , & otherwise \end{cases}$

Fuzzy waiting Model With An Unreliable Surrounding

Envisage a Fuzzy queueing model together with an unreliable server and double diverse kinds about default. Within Kind 1, bartender might fall apart even if there are zeropatrons in structure and in Kind 2, bartender may fall apart when there is always one patron in structure. This issupposed that the patrons appear at a single bartender establishment as a Poisson process with fuzzy rate$\tilde{\lambda}$, the service times as an exponential distribution with Fuzzy rate$\tilde{\mu}$, the bartender may possess a fall apart backing Poisson procedure with Fuzzy rate$\tilde{a}$, and the renovate follows an exponential distribution with Fuzzy rate $\tilde{b}$ are roughly familiar and can be portrayed by convex Fuzzy sets. Authorize$\omega_{\tilde{\lambda}}(u)$,$\omega_{\tilde{\mu}}(v)$,$\omega_{\tilde{a}}(t)$ and$\omega_{\tilde{b}}(n)$indicate the membership functions of$\tilde{\lambda}$,$\tilde{\mu}$,$\tilde{a}$and$\tilde{b}$. Then we preserve the consecutive Fuzzy sets:

$\tilde{\lambda} = \left\{ (u, \omega_{\tilde{\lambda}}(u)) \;\middle|\; u \in U \right\}$

$\tilde{\mu} = \left\{ (v, \omega_{\tilde{\mu}}(v)) \;\middle|\; v \in V \right\}$

$\tilde{a} = \left\{ (t, \omega_{\tilde{a}}(t)) \;\middle|\; t \in T \right\}$

$\tilde{b} = \left\{ (n, \omega_{\tilde{b}}(n)) \;\middle|\; n \in N \right\}$

Where R,S,T and N are the classic universal sets about the arrival, service, breakdown and repair rates separately. Authorize P(r,s, t, n) intimate the structure specific of interest. Therefore u, v, t and n are Fuzzy numerals. P(r, s, t, n) constitutes also a Fuzzynumeral.AuthorizeI_1withI_2portray the membership function about the predicted time that the structure constitutes dormant in Kind 1 and Kind 2separately.

I_1= P(r, s, t, n) = $\frac{n}{t+n} - \frac{r}{s}$ (1)

I_2 = P(r, s, t, n) = $1 - \frac{r(t+n)}{sn}$ (2)

In steady-state, it is requisite,

0 $< \frac{n}{t+n} - \frac{r}{s} < 1$ and $0 < 1 - \frac{r(t+n)}{sn} < 1$.

Trisectional Fuzzy Trapezoidal ranking – Algorithm

Depiction: Trapezoidal Fuzzy Numeral:

A Trapezoidal Fuzzy Numeral$\widetilde{K}(w)$ is designated by $\widetilde{K}(l\ m\ n\ o)$ with the membership function

$$\mu_{\widetilde{K}}(\mathrm{w}) = \begin{cases} \frac{x-l}{m-l}, & l \le w \le m \\ 1, & m \le w \le n \\ \frac{x-o}{n-o}, & n \le w \le o \\ 0, & \text{otherwise} \end{cases}$$

Let us take an Segment data (M,N). The tripartite of this Segment is grab as $= \frac{H-G}{3}$, then the mandatory trapezoidal Fuzzy numeral is $[G, G+d, G+2d, H]$. Contemplate a normal trapezoidal Fuzzy numeral $\widetilde{K} = [l\ m\ n\ o]$ depicted in Fig. 1. Prolong the Connecting lines K(l,0) and T(m,1) as KTJ and the Connecting lines L(o,0) and U(n,1) as LUJ. The overlap of prolonged lines KT and LU is J. The Positional point for overlap point J is (x, y), where

x = $\frac{ln-mo}{n-o-m+l}$

y = $\frac{x-m}{m-l}$

The endorsed ranking strategy is stranded on the thought of the in-center about a triangle JKL and is systematically traced even as follows.

R($\widetilde{K}$) = $\frac{ax+bl+co}{a+b+c}$ where

a = $o - l$,

b= $\sqrt{y^2 + (o-x)^2}$,

c = $\sqrt{y^2 + (x-l)^2}$

Arithmetical Exemplar

In the context of current elections in India, Special Intensive Revision (SIR) refers to a comprehensive updating and verification exercise of the electoral rolls by ECI. In this condition all the public wanted urgently to take Xerox of the particular form required for SIR. The Public need to submit the SIR Form on or before the last date announced. Unfortunately a specific site, there is only one Browsing center is running. Public employs single channel arrivals in accord with a Poisson process. The instant requisite for taking the Xerox copy process may be disrupted (central processing unit, server, or not enough network) retinue a Poisson process. The resumption moments of the complication disrupted uproot an exponential distribution. The process progress, immediately the disruption ends. In seeking to appraise the single-passage progression, the administrator of the structure desires to find out how lots of hours that these structure constitutes dormant. This constitutes presumed that these structure triumph, FM/FM (FM, FM)/1/∞ and the predicted time that the structure constitutes dormant could be conjecture by that presumed company.

For Trapezoidal Fuzzy numeral Exemplar:

Deduce the arrival rate, service rate, breakdown rate and repair rates are trapezoidal Fuzzynumerals classify by
$\tilde{\lambda}_1$= [1.3 1.4 1.6 1.7],$\tilde{\mu}_1$= [6.2 6.3 6.5 6.6],
$\tilde{a}_1$= [0.02 0.03 0.05 0.06], $\tilde{b}_1$= [1 1.1 1.3 .4] per hour. Now we estimate Ranking by manner Trisectional Fuzzy grade strategy. $\mathbf{R(\tilde{\lambda}_1)}$= R(1.3 1.4 1.6 1.7)

$$\frac{0.4(1.5) + 1.0198(1.3) + 1.0198(1.7)}{0.4+1.0198+1.0198} = 1.5$$

$\mathbf{R(\tilde{\mu}_1)}$ = R(6.2 6.3 6.5 6.6)

$$\frac{0.4(6.4) + 1.0198(6.2) + 1.0198(6.6)}{0.4+1.0198+1.0198} = 6.4$$

$\mathbf{R(\tilde{a}_1)}$ = R(0.02 0.03 0.05 0.06)

$$\frac{0.4(0.04) + 1.0198(0.02) + 1.0198(0.06)}{0.4+1.0198+1.0198} = 0.04$$

$\mathbf{R(\tilde{b}_1)}$ = R(1 1.1 1.3 1.4)

$$\frac{0.4(1.2) + 1.0198(1) + 1.0198(1.4)}{0.4+1.0198+1.0198} = 1.2$$

Based on (1) and (2)
The predictedtime that the structure is dormant in Kind 1
I_1= P(r,s,t,n) = $\frac{n}{t+n} - \frac{r}{s} = \frac{1.2}{0.04+1.2} - \frac{1.5}{6.4} =$ 0.7333

As well, we can progress for some samples we mastered
Fig 3decidesto facilitate, if the crisp values of the arrival rate is raised, the structure's dormant rate is decreased and also when the service rate is raised, the structure's dormant rate is raised,with regard to the table 1. The predicted time that this structure constitutes dormant in Kind 2

I_2= P(r,s,t,n) = $1 - \frac{r(t+n)}{sn} = 1 - \frac{1.5(0.04+1.2)}{6.4(1.2)} =$ 0.7578

As well, we can progress for some sample we mastered
Fig 4 decides to facilitate, Whether the crisprates of thearrival rate constitutesraised, the structure's dormant rate is decreased and also when the service rate is raised, the structure's dormant rate constitutesraised, with regard to the table 2.

CONCLUSION

In this editorial, we have foreseeing a Fuzzy waiting model with an unreliable bartender. Our new Fuzzy grade which make our model universal with proficient from working point of view.It has been used in performance and utility apparatus for settling the structure attainment. In addition to, the Fuzzy complication antiquated modified into crisp complication utilizing this grade indicators. Therefore the attainment actics including the predicted dormant time for double kinds are crisp rates, the administrator can grab the neat and terrific conclusion. We fetch up that the result of Fuzzy complication smight be generated by Grading basis strategy extremely harmoniously. Thus, when the arrival rate constitutes increased, the structure's dormant rate is decreased and also when the service rate is increased, the structure's dormant rate constitutes increased. The track supposed in this editorial furnishes down-to-earth findings for structure administrator and exponents.

ABSTRACT

This study aims to formulate and evaluate hand sanitizer from extract of *Punica granatum*. Hand hygiene is one of the most effective measures to prevent the transmission of infectious diseases. Commercial hand sanitizers generally contain high concentrations of alcohol and synthetic additives, which may cause skin irritation, dryness, and allergic reactions upon frequent use. This has led to increased interest in the development of herbal hand sanitizer. Herbal hand sanitizer prepared from medicinal plants offer a safe and eco-friendly alternative due to their microbial efficacy and skin friendly nature. The present study aims to formulate and evaluate herbal hand sanitizers using pomegranate peel extract along with other herbal ingredients. Pomegranate peel extract was prepared using the Soxhlet extraction method and subjected to preliminary phytochemical screening. *Punica granatum* is known for its chemical compounds such as polyphenols, tannins, flavonoids phenolic acid, Alkaloids, Organic acids. These phytoconstituents exhibit broad spectrum antimicrobial, antioxidant and anti-inflammatory activities. Pomegranate also shows various pharmacological activities like anticancer,woundhealing,Anti-diabetic, Cardioprotective, Antiaging, Astringent. The hand sanitizer was formulated using Carbopol 934 as a gelling agent, ethanol as solvent, glycerine as humectant, and herbal extract as active ingredients. The formulated sanitiser was evaluated for physical appearance, pH, viscosity, spreadability homogeneity, drying time, skin irritation and antimicrobial activity. The result indicated that the formulation showed acceptable physicochemical properties, good spreadability, suitable pH, and effective antimicrobial activity against selected

microorganisms. The study concludes that herbal hand sanitizer containing pomegranate peel extract can be an effective, safe and economical alternative to synthetic hand sanitizers.

Keywords: *Punica granatum,* Pomegranate Peel Extract, Herbal Hand Sanitizer, Soxhlet Extraction, Antimicrobial Activity, Phytochemical Screening, Carbopol 934, Herbal Formulation.

INTRODUCTION

Hand sanitiser is a gel or foam that kills germs and infectious bacteria. It is used as an alternative to hand washing, and comes in two main varieties, those that are alcohol-based and those which are not. To protect the skin from harmful microorganisms and to prevent the spread of many skin infections, Hand cleaning is certainly a vital precaution. Hand sanitizers are one of the most commonly used hygienic products to prevent and remove germs, viruses and bacteria in our body, especially in our hands. It is more handy and convenient, unlike other products that are used for different cleaning Purposes[1]. Hand hygiene is an essential practice for maintaining personal cleanliness and preventing the spread of infectious diseases. Traditionally, hand washing with soap and water has been widely used, while the use of antiseptic agents began in the early 19th century. Studies have shown that alcohol-based hand sanitizers containing at least 70% alcohol are effective in killing up to 99.9% of bacteria on hands. These sanitizers are available in various forms such as liquid, foam, and gel, and may also contain quaternary ammonium compounds to enhance antimicrobial activity. Due to the increasing resistance of microorganisms to antibiotics, interest has grown in plant-based products with antimicrobial properties. Plant extracts rich in secondary metabolites offer a natural and effective alternative for controlling microbial growth, making them valuable in the development of herbal hand sanitizer formulations[2].

Hand Sanitizer Gels (HSGs) can be classified into two major groups depending on their active ingredients and are referred to as alcohol-based hand sanitizer gels (ABHSGs) and non-alcohol-based hand sanitizer gels (NABHSGs). Both types of HSGs have been highly acknowledged for their effectiveness in inhibiting the development and transmission of microorganisms on hands, though their mechanism of action is quite different. For instance, alcohol-based hand sanitizer gels show rapid antimicrobial effects through protein denaturation and disruption of microbial membranes, thereby inactivating pathogenic microorganisms; however, the frequent use of such gels is likely to influence the lipid composition of epidermal keratinocytes and thereby show undesirable effects such as dryness and irritation of the skin. On the other hand, the antimicrobial effects of non-alcohol-based hand sanitizer gels are due to the presence of cationic surfactants such as quaternary ammonium compounds (QACs), which show a broad spectrum of antimicrobial effects due to their amphiphilic nature composed of hydrophobic and hydrophilic groups; this leads to improved surface activity and interaction of these compounds with microbial membranes, thereby increasing their antibacterial effects and reducing the incidence of bacterial infections[3].

Herbal hand sanitizer is a natural antimicrobial product that made from plant extract that can kills the germs, bacteria while been gentler on the hand. These herbal hand sanitizers aim to provide safe, moisturizing benefits and it reduce the dryness, itching and irritation from the chemicals[4]. Plant Extract has a potential as antimicrobial compounds against several pathogenic micro-organisms which cause infectious disease and resistance towards synthetic drugs. The advantage of using herbal essential oils are that they are cheap, easily available and having less side effects in comparison to chemical products. Traditional healers have long used the plant in infectious situations. Because plants have secondary metabolites which contain tannins, alkaloids, terpenoids and flavonoids etc, That has been determined to possess in-vitro antimicrobial properties[5]. The herbal hand sanitizer works to ensure rapid broad-spectrum antimicrobial activity, destroying up to 99.99% of microorganisms such as bacteria, viruses, and fungi, usually in 15-30 seconds. The herbal hand sanitizer, being composed of herbal ingredients, is non-toxic, hypoallergenic, and gentle on the hands, thus causing less irritation or dryness. The hand sanitizer's portability ensures its easy use after touching public surfaces or before meals, thus encouraging the practice of hand hygiene,

greatly reducing the transmission of infection in daily life. Plants such as pomegranate (Punica granatum) and Aloe vera (Aloe barbadensis Miller) are widely used in herbal hand sanitizer formulations because of their rich phytochemical composition and antimicrobial properties. Pomegranate is one of the oldest known edible fruits cultivated in subtropical regions where high temperatures support proper fruit ripening[6]. It is native to regions such as Iran and Afghanistan and belongs to the family Punicaceae[7]. The growing scientific interest in pomegranate is largely attributed to its phenolic compounds, which exhibit antimicrobial, antiviral, antioxidant, and anticancer activities[8]. Pomegranate also contains primary metabolites such as carbohydrates, proteins, organic acids, vitamins, and minerals that are essential for growth and physiological functions[9]. The peel and juice of pomegranate contain hydrolysable tannins such as punicalagin and punicalin that demonstrate strong antioxidant and antimicrobial activity[10]. Pomegranate additionally contains triterpenoids such as ursolic acid, oleanolic acid, and betulinic acid, which contribute to anti-inflammatory, antioxidant, and antimicrobial effects[11]. Aloe vera is a succulent medicinal plant characterized by thick fleshy leaves adapted for water storage under low-water environmental conditions[12]. The plant contains approximately 99–99.5% water, which contributes to its strong moisturizing properties[13]. Aloe vera also contains nearly 75 biologically active constituents including vitamins, enzymes, minerals, sugars, saponins, salicylic acid, and amino acids that support its therapeutic value[14]. Clinically, Aloe vera is widely recognized for its wound-healing, anti-inflammatory, antimicrobial, and dermatological applications, supporting its suitability for herbal hand sanitizer formulations[15].

MATERIALS AND METHODOLOGY

Materials Required

Various materials are used to prepare herbal hand sanitizer such as *Punica granatumlinn* peel extract(Herbal active ingredient, Antimicrobial agent), Ethanol (Antiseptic, solvent), Carbopol 940 (Gelling agent, Thickener), Aloe vera gel(Skin soothing agent, moisturiser), Triethanolamine (pH adjuster, Neutralizing agent), Glycerine (Humectant), Essential oil (Fragrance, antimicrobial agent), Distilled water.

Extraction of *Punica Granatum* Linn

Punica granatum Linn was collected, following the collection and identification, fresh peels of *Punica granatum Linn*(100g) were washed and shade dried for 24-48 hours. The dried peels were crushed to coarse powder and 50gm of the powder was weighed and wrapped with filter paper to place in 1L Soxhlet thimble attached to round bottom flask with 500ml of methanol. The peel extract was obtained by Soxhlet extraction for about 8-9 hours. The extract was collected, and solvent was evaporated on water bath at 50°C[16].

Formulation of Herbal Hand Sanitizer

Method of Preparation of Sanitizer

Wash and dry pomegranate peels, Powder them finely. Soak 10g of powder in 100ml ethanol, filter and evaporate to dryness. Use 2g of this extract in the sanitizer formulation. Gel base preparation:Disperse 0.8 Carbopol 940 in about 25ml distilled water, stir gently to avoid lumps. Allow it to hydrate for 1 hour. Mixing of active and additives**:** Add aloe vera and glycerine, stir slowly. Add pomegranate peel extract and essential oil, mix Well.Slowly add ethanol while stirring gently. Adjust pH and gel formation: Add triethanolamine drop by drop until gel consistency and pH 6-7 is achieved. Make up the volume and the remaining distilled water to make 100g total weight. Mix until uniform gel forms.Fill in airtight bottles or pump containers[17].

Evaluation of Hand Sanitizer:

Organoleptic test

A sensory test measures a product's acceptability primarily via the use of human senses. An essential part of applying quality control is organoleptic testing. The gel preparation was evaluated physically including odor, color, consistency for 4 weeks with observations every 1 week. This observation was carried out on hand antiseptic gel (handsanitizer) stored at room temperature[18].

Skin Sensitivity Testing:

Patch Testing: To determine if the herbal sanitizer causes irritation, conduct a patch test on a small area of skin to check for allergic reactions or irritation[19].

Moisturizing Effect: Evaluate how well the sanitizer keeps the skin moisturized after use, especially since alcohol can dry out the skin[20].

Determination of pH: The pH values of the hand sanitizer gel formulations were measured using a digital pH meter. The aim of the study was to evaluate how various manufactured formulations were neutralized, which likely refers to the process of adjusting the pH of the formulation to a desired level. The ideal pH range for a topical dose form, such as a hand sanitizer gel, should be within the skin's natural pH range of 4.0 to 7.0 to prevent skin irritation and inflammation[21].

Evaporation test:

5 healthy volunteers were selected. The herbal hand sanitizer was applied on their palm while rubbing the sanitizer on palm, evaporation took place and that time was noted. Evaporation rate was below 1 min[22].

Tissue paper test (presence of alcohol test):

This test is based upon paper chromatography. We drew a circle with a ball pen on tissue paper and poured some drops of sanitizer on the circle. If the sanitizer contains a sufficient amount of alcohol the ink will be dissolved into the sanitizer and starts spreading. It is observed that sanitizer slowly diffused and moved out the circle[23].

Determination of Viscosity:

The viscosity of an alcohol containing hand sanitizer solutions were analyzed using a Brookfield viscometer equipped with a T- bar spindle (S-94) at 37 °C. 10 mL beakers were filled with 5 g of solution and perform the procedure. Placed the rotor vertically, making sure it does not touch the bottom of the beaker. The spindle was rotated at 50 and 100 rpm to obtain more than 50% torque. Measurements were recorded 1 minute after the start of the test[24].

Phytochemical analysis:

Standard tests were performed to identify the presence of alkaloids, tannins, flavonoids, phenols, terpenoids and the test are mentioned in the table. Phytochemical screening of the extract was carried out using standard qualitative tests to identify the presence of various bioactive constituents such as alkaloids, tannins, flavonoids, phenols, terpenoids, and anthocyanins. Alkaloids were tested using Dragendorff's method, in which the extract was first acidified and then treated with Dragendorff's reagent. Tannins were identified by the ferric chloride test, where a few drops of 5% ferric chloride solution were added to the extract. Flavonoids were detected using the Shinoda test, involving the addition of magnesium turnings followed by a few drops of concentrated hydrochloric acid to the extract. Phenolic compounds were analyzed using the lead acetate test, where the extract was treated with a suitable reagent solution. Terpenoids were evaluated by the Salkowski test, in which the extract was mixed with the appropriate reagent to carry out the reaction. Anthocyanins were determined using the acid-alkali test, where the extract was first treated with dilute hydrochloric acid and subsequently with dilute sodium hydroxide in the same solution to observe changes under varying pH conditions[25].

Anti-Microbial Assay

Test organism: Standard bacterial strain of *Bacillus subtilis*(grown culture).

Anti-Microbial Assay of *Punica granatum*linn Extract

The anti-microbial assay of ethanolic extract of *Punica granatum* Linn was evaluated using modified agar well diffusion assay. Sabouraud's dextrose agar (20ml) was poured in sterile petri dishes (n=2) and allowed to solidify.Two wells (10mm diameter) were created in 2 petridishes containing media with a cork borer, and plates were inoculated with standardized inoculums of *Bacillus subtilis* using pouring method. The ethanolic extract of *Punica granatum* Linn were added to the wells made in one petri dish and and another petri dish was kept as control. These petri dishes were labelled and were incubated at 25oC for 2-3 days. The diameter of the zone of inhibition was subsequently measured to assess antimicrobial activity[19].

Anti-Microbial Assay of Sanitizer

The anti-microbial efficacy of the sanitizer formulations was evaluated using modified agar well diffusion assay. Sabouraud's dextrose agar (30ml) was poured in sterile petri dishes and allowed to solidify. One well (10mm diameter) was created in 3 petri dishes containing media with a cork borer, and plates were inoculated with standardized inoculum of *bacillus subtilis*using an inoculating loop.The sanitizer formulations 1 & 2 (1mg) were added to the wells made in two petri dishes and another petri dish was kept as control (marketed sanitizer).These petri dishes were labelled and were incubated at 25°C for 2 days after 1 hour room stabilization period. The diameter of the zone of inhibition was subsequently measured to assess anti-microbial activity[19].

Cotton Swab Test for Herbal Hand Sanitizer

The cotton swab test for a herbal hand sanitizer is a simple laboratory method used to check its antimicrobial (germ-killing) activity. It helps determined whether the sanitizer can inhibit or kill bacteria present on surface of the hands.
Selection of volunteers: Hands of healthy volunteers were selected without prior washing or sanitization to ensure the presence of natural skin flora.Collection of microorganisms before sanitization: A sterile cotton swab was rubbed gently over the palm and finger surfaces of the bare hand to collect bacteria naturally present on the skin.Transfer to agar plate: The same swab was streaked uniformly over the surface of a nutrient agar plate to transfer the collected microorganisms.Application of herbal hand sanitizer: The volunteers then applied the formulated pomegranate peel extract hand sanitizer and rubbed hands thoroughly for 20–30 seconds, allowing them to air-dry. Collection of microorganisms after sanitization: A new sterile cotton swab was again swiped over the same area of the hand after sanitization. Transfer to agar plate: This second swab was streaked on another nutrient agar plate to obtain post-sanitization microbial count.Incubation: All plates were incubated at 37 °C for 24 hours[26].

Comparative Antimicrobial Test of Herbal Hand Sanitizer andMarketed Hand Sanitizer by Agar Well Diffusion Method

The antimicrobial activity of the formulated herbal hand sanitizer and a marketed hand sanitizer was evaluated using the Agar Well Diffusion Method. Initially, nutrient agar was prepared, sterilized, and allowed to cool to approximately 45–50 °C. A known quantity of Bacillus subtilis inoculum was then mixed thoroughly with the molten nutrient agar. The agar–bacteria mixture was poured into sterile Petri dishes using the pour plate method and allowed to solidify uniformly. After solidification, a sterile cork borer was used to create a single well in each agar plate. The sanitizer samples were then added to the wells: in Plate 1, the well was filled with the herbal hand sanitizer containing pomegranate peel extract, while in Plate 2 the well was filled with a marketed hand sanitizer. The plates were left undisturbed for 15–20 minutes to allow diffusion of the sanitizer into the agar medium. Subsequently, all plates were incubated at 37 °C for 24 hours in an inverted position to observe antimicrobial activity[27].

RESULTS AND DISCUSSIONS

Evaluation of Physical Parameters of Prepared Formulations

The physical characteristics of the two formulations are presented in the table below.

Phytochemical Analysis

Punica granatum extract was used to perform standard phytochemical test and the results are given below in the table 4.

Anti-Microbial Activity Of Extract

The antimicrobial activity of the extract was evaluated by the agar diffusion method, and a zone of inhibition of 22 mm was observed against the test organism.

Antimicrobial Activity Study Of Hand Sanitizer

The antimicrobial assay of two formulations was performed and the results of zone of inhibition are as follows. In above picture first petri dish indicates Control, 2nd and 3rd perti dish indicates formulation 1 and 2 with the ZOI of 15 and 18 respectively.

Cotton Swab Test of Herbal Hand Sanitizer:

Before sanitization plate showed visible bacterial colonies indicating normal hand flora. After sanitization plate showed either Significantly reduced colonies, or absence of colonies, demonstrating antimicrobial action of the pomegranate peel extract sanitizer.

Comparative Antimicrobial Test of Herbal Hand Sanitizer (Formulation 2) and Marketed Hand Sanitizer by Agar Well Diffusion Method

The formulated sanitizer produced a zone of inhibition comparable to the marketed sanitizer, indicating similar antimicrobial effectiveness. This suggest that the active antimicrobial components in the formulation are equally effective as those in the marketed product.

Tissue Paper Test (presence of alcohol test)

This test is based upon paper chromatography. We draw a circle by ball pen on tissue paper and poured some drops of sanitizer on circle. If sanitizer contains sufficient amount ofalcohol the ink will be dissolved into sanitizer and starts spreading. It is observed that sanitizer slowly diffused and moved out the circle[23].

SUMMARY

The results demonstrated that the alcohol-free pomegranate peel–based sanitizer exhibitedsuperior antimicrobial activity compared to the alcohol-based formulation. This enhancedactivity may be attributed to the high content of bioactive phytochemicals such as polyphenols, flavonoids, and tannins present in pomegranate peel, which are known for their antimicrobial properties. Various evaluation parameters were carried out including pH, viscosity,appearance, stability, and antimicrobial efficacy. Cotton-swab sampling from bare hands was performed, followed by agar plate pour method to assess microbial growth. The herbal sanitizer demonstrated marked reduction in microbial colonies, indicating potent hand hygiene activity suitable for routine and frequent usage. The formulated herbal sanitizer showed a pleasant odour, non-sticky nature and clear appearance. It remained stable throughout the study and demonstrated significant antimicrobial activity without the adverse effects of chemical or alcohol-based sanitizers, making the pomegranate peel sanitizer a safe and effective alternative to marketed products.

CONCLUSION

This study demonstrates the antimicrobial activity of Punica granatum peel extract-based herbal hand sanitizer against Bacillus subtilis. The results show that the F2 formulation exhibited a higher zone of inhibition as compared to the F1 formulation, indicating superior antimicrobial activity. F1 was a yellowish-orange gel and F2 was a brown liquid, and both formulations were uniform and homogenous. The pH of F1 (7.65) and F2 (6.82) were found to be within the acceptable range for skin application. The extract's complex phytochemical composition likely contributes to its antimicrobial properties, making the prepared herbal hand sanitizer a promising natural and alcohol-free alternative for maintaining hand hygiene.

ABSTRACT

This paper represents an overview of the many fundamental features of the well-known colossal magnetoresistive manganites. These manganites with perovskite structure are known to the scientific community for the property of very large or colossal negative magnetoresistance which shows potential for applications. However, colossal magnetoresistive manganites have attracted a significant research interest since past few decades not only due to their potential for applications but also for their many unusual and peculiar physical properties. The present paper represents a review of the literature focusing on the different interesting phenomena associated with perovskite manganites and the fundamental physics and underlying mechanisms behind those phenomena.

Keywords: - Manganites, Perovskite, Colossal magnetoresistance, Double exchange, Jahn-Teller effect, Phase separation

INTRODUCTION

The class of materials known as manganite with perovskite (ABO_3) structure has been one of the most interesting research topics in the field of experimental and theoretical condensed matter physics since last few decades [1,2]. A typical ABO_3 perovskite structure is shown in the Fig. 1. Here, 'A' and 'B' sites are generally occupied by cations whereas 'O' site is occupied by the oxygen anion. Clearly, B site is surrounded by an oxygen octahedron. In particular, the perovskite colossal magnetoreistive manganites can be represented by a general chemical formula of $R_{1-x}D_xMnO_3$, where R is trivalent rare earth ion (R= La^{3+}, Pr^{3+}, Nd^{3+} etc.) and D is divalent alkali ion (D = Sr^{2+}, Ca^{2+}, Pb^{2+} etc.). These materials fall in the category of strongly correlated electron system and have a complex interplay between

their lattice, spin, charge and orbital degrees of freedom leading to various unusual magnetic and electronic properties. The materials mentioned above came into picture when Jonker and Santen synthesized some perovskite manganite samples of (La,Ca)-Mn-O, (La,Sr)-Mn-O and (La,Ba)-Mn-O around 1950 [3-5]. They found ferromagnetism and conductivity anomaly around Curie temperature in these systems. Later on, Wollan and Koehler [6] in 1955 carried out detailed neutron diffraction study and established a magnetic phase diagram for the system (La,Ca)-Mn-O in the entire composition range. However, the major thrust in the research of manganites came after a period of time when, in 1994, Jin *et al.* [7] reported a thousand-fold change in resistivity in the system $La_{0.67}Ca_{0.33}MnO_3$ on application of magnetic field. This large magnetoresistance (negative) is termed as colossal magnetoresistance (CMR). Some contemporary works also showed a similar MR effect in these materials [8,9].

These studies indicated a promise of technological applications of colossal magnetoresistive manganites. Since then, a variety of experimental and theoretical works have been carried out on different manganite systems. During the course of investigations, it has been observed that such materials posses very unusual magnetic and electronic properties which are interesting solely from physics point of view. For instance, these materials display metal-insulator transition, various electronic and magnetic ground states, charge-orbital ordering, phase segregation etc.. Such peculiarity and novelty of their properties attracted the researchers to a great extent towards these materials. It has also been argued that the physics of manganites is very complicated and many issues related to their behaviours are still unresolved. In this paper, some fundamental features of perovskite manganites and related physics has been discussed.

Jahn-Teller Effect

The Jahn-Teller theorem (1936) states that, if the symmetry of the crystal field is so high that the ground state of an ion is predicted to be in orbitally degenerate state, then it will be energetically preferable for the crystal to distort in such a way that the orbital degeneracy is lifted [10]. The appearance of the distortion is called Jahn-Teller (J-T) effect. At the same time, it was also known that with linear geometry CO_2 molecule does not show Jahn-Teller effect even though it has orbitally degenerate electronic ground state. The theoretical work by Jahn and Teller [10] ultimately proved that the linear molecules are the only exception of this theorem.It is usual to find that the Jahn-Teller distortion appears at a structural phase transition. At high temperature randomly oriented Jahn-Teller complexes are favourable, because randomness brings large entropy. At low temperatures, the distortions have to get ordered to minimize the interaction energy. The ordering changes the global symmetry; thus it has to set in a well-defined temperature. This scenario for a structural phase transition is known as *cooperative Jahn-Teller effect*. For example, the system $LaMnO_3$ undergoes a cubic to tetragonal phase transition at around 800 K [11]. When we assume that the atomic positions are parameters and not the dynamical variables so that the atoms get displaced to new positions and stay there, we talk about the *static Jahn-Teller* effect. However, allowing for the coupling between the electrons and ionic motions one finds that a small system can tunnel between energetically equivalent distortions. This phenomenon is the dynamical Jahn- Teller effect.

We now overview the Jahn-Teller distortion related to the Mn ion in case of perovskite manganites. The Mn ion in mangnaites is surrounded by the oxygen octahedron (Fig.1 and Fig. 2). The 3d orbitals on the Mn site are subject to crystal field and lifting of the five-fold degenerate 3d orbitals partially as shown in the Fig. 2. The lower-lying orbitals, t_{2g} states, are d_{xy}, d_{yz}, d_{zx}. The higher-lying e_g states are the $d_{x^2-y^2}$ and $d_{3z^2-r^2}$. The crystal field energy between t_{2g} and e_g states is about 1 eV. The degeneracy can be further removed by means of Jahn-Teller effect. Under such a distortion, the t_{2g} and e_g orbitals are split in energy as shown in the Fig. 2. The Jahn-Teller distortion is only energetically favourable if either of the t_{2g} or e_g levels is partially occupied. This only occurs for Mn^{3+} ($t_{2g}^3 e_g^1$) with it's only one e_g electron. This type of distortion favours insulating behaviour in manganites. The end member of $R_{1-x}D_xMnO_3$ (with x=0 and $R=La^{3+}$) $LaMnO_3$ is highly distorted and the octahedra are elongated and tilted. This is thought to be the result of Jahn-Teller distortion. This Jahn-Teller distortion is found to be a key factor behind physical properties of manganites.

Doping, Tolerance Factor, Bandwidth And Band-Filling

Doping in the A site of manganites, *i.e.* introducing a different cation D replacing R in the A site has several prominent effects. Such changes in the constituents of the A site alters the average A site ionic radius $\langle r_A \rangle$. This will also change the lattice constants. Ionic radii of the different sites of the ABO_3 structure plays an important role. The work of Jonker and van Santen established the range of possible solid solutions (by varying x) allowed by the Goldschmidt tolerance factor t ≈1. The tolerance factor is defined by $t = \frac{(\langle r_A \rangle + r_{O^{2-}})}{\sqrt{2}(\langle r_B \rangle + r_{O^{2-}})}$ [1] where, $\langle r_B \rangle$, $\langle r_A \rangle$ and $r_{O^{2-}}$ are the radii of the divalent, trivalent, and oxygen ions, respectively. Tolerance factor measures the deviation from a perfect cubic structure with t=1. Practically, this tolerance factor can be varied by choosing a suitable combination of R (= La^{3+}, Pr^{3+}, Nd^{3+} etc.) and D (= Sr^{2+}, Ca^{2+}, Pb^{2+} etc.). It has been found that perovskite structure is stable for 0.85 <t<0.91. Tolerance factor directly effects the magnetic transition temperature. The phase diagram reported by Hwang H Y *et al*. [12] clearly exhibits the relation of T_C (ferromagnetic to paramagnetic transition temperature) with t for different manganites materials.

Now, the effective one-electron bandwidth is given by $W = \cos\left[\left(\pi - \langle\beta\rangle\right)/2\right] / d_{Mn\text{-}O}^{3.5}$ [1]. The average Mn-O-Mn bond angle is $\langle\beta\rangle$ and the average Mn-O bond distance is $d_{Mn\text{-}O}$. The change of $\langle r_A \rangle$ changes these two parameters and affects W. Any change of Mn-O-Mn bond angle from 180^0 reduces the mobility of the e_g electrons. Deviation from a perfect cubic structure (reduction of value of t from 1) reduces the Mn-O-Mn bond angle from 180^0. Hence, it is clear that doping in the A site directly influence the bandwidth of the system.Furthermore, any finite doping by a fraction x changes the valency of the B site ions to maintain the charge balance. For example, all the Mn ions in $LaMnO_3$ are in Mn^{3+} (d^4) state. If x fraction of the trivalent La^{3+} is replaced by Sr^{2+} (*i.e.* $La_{(1-x)}Sr_xMnO_3$), x fraction of Mn^{3+} must be converted to Mn^{4+}(d^3). This is equivalent to hole-doping due the vacancy in the e_g state of Mn^{4+}. Trivalent Mn^{3+} and tetravalent Mn^{4+} are randomly distributed throughout the crystal. Therefore, a variation in x is equivalent to variation of Mn^{4+} sites or the hole concentration. This in turn varies the band-filling.

Double Exchange

In the Mn^{3+} based compounds, Mn ion has the electronic configuration $t_{2g}^3 e_g^1$ (S = 2). All the 3d electrons are subject to electron repulsion and electron correlation effect. Even the e_g electrons, strongly hybridized with O2p state, experience this correlation effect and tend to localize on Mn^{3+} site in Mn^{3+} based compounds, forming the so-called Mott insulator. This e_g electron becomes itinerant when a vacancy is created in the e_g orbital state by means of hole doping or creating Mn^{4+} species. This e_g electrons can hop from Mn^{3+} site to Mn^{4+} site via the O2p state and the mechanism is called Zener double exchange after C. Zener who originally proposed this [13]. The t_{2g} electrons, on the other hand, less hybridized with the O2p states are stabilized by the crystal field splitting and forms local spin of S = 3/2.The e_g spins (S = 1/2) and localized t_{2g} spins (S = 3/2) interact through strong onsite Hund's coupling. This Hund's coupling energy (J_H) is about 2-3 eV and exceeds the inter-site hopping interaction t_{ij}^0 (between site i and j) of the e_g electrons. In the strong Hund's coupling limit ($J_H/t_{ij} \rightarrow \infty$), the effective hopping interaction can be expressed in terms of Anderson-Hasegawa relation [14] as (in a simplified form),

$$t_{ij} = t_{ij}^0 = \cos(\theta_{ij}/2) \qquad (1)$$

Here, θ_{ij} is the angle between the neighbouring spins. The ferromagnetic (FM) interaction via the exchange of electron whose spin shows on site Hund's coupling is called 'double exchange interaction'. Here the double exchange mechanism in manganites is schematically presented as shown in the Fig. 3 [15]. The FM state is stabilized below T_C by maximizing the kinetic energy of the e_g electrons as $\theta_{ij} = 0$. Near T_C, spin disorder increases and resistivity of the manganites also increases on reduction of the average hopping interaction t_{ij}. On application of magnetic field this disorder can be easily reduced. This decreases the resistivity and gives rise to the so-called magnetoresistance near T_C. This is the simplest way to explain the observed *intrinsic magnetoresistance* in manganites. Therefore, double exchange also naturally explains the simultaneous occurrence of metallicity and ferromagnetism in manganites as a

result of the coupling between spin and charge degrees of freedom. Above T_C, however, spin disorder increases and the *intrinsic magnetoresistance* decreases.

Other Important Factors

It has been argued since long that the double exchange alone is not sufficient to satisfactorily describe all the physical properties of colossal magnetoresistive manganites. Other competing energy scales of different interactions are equally significant.One of such interactions is the *electron–phonon* interaction. The e_g electrons interact with each other and with surrounding lattice distortions, i.e. with phonons. The e_g electrons on Mn site are strongly coupled with the distortion of the MnO_6 octahedron [16,17,18] which in materials like (La,Ca)-Mn-O is part of the Jahn-Teller effect. Another type of electron-phonon coupling, the breathing distortions of the Mn-O bonds which tend to change the energy difference between the occupied and unoccupied Mn sites is also important.Furthermore, the e_g electrons interact between themselves via *Coulomb repulsion*. This energy U, as high as 10 eV [19], found from photoemission spectroscopy, is the energy difference between the configurations – two Mn site having one e_g electron each and one Mn site having two e_g electrons while the other being empty. This high Coulomb repulsion is also thought to be the cause of $LaMnO_3$ being a 'charge transfer' type insulator- the concept discussed in details by J. Zaneen *et al.* [20].Except ferromagnetic interaction between core-spins (double exchange) mediated by e_g electrons, many authors have argued the possibility of an *antiferromagnetic core-spin core-spin interaction* arising from virtual processes involving t_{2g} levels [21-23]. Such interaction would compete with double exchange.

Hence, finally, including the above-mentioned energy scales one can write the Hamiltonian for the e_g electrons and core spins as,

$$H = H_{hop} + H_{Hunds} + H_{Sc} + H_{JT} + H_B + H_U \qquad (2)$$

Here, H_{hop} and H_{Hunds} come from double exchange (hopping energy and Hund's coupling energy), H_{JT} is due to Jahn-Teller effect, H_B comes from the breathing distortion and H_U is due to the Coulomb interaction.

Charge /Orbital Order

Out of many fascinating properties displayed by the perovskite manganites, the one known as charge and orbital ordering is regarded particularly interesting. Charge ordering (CO) is the phenomena wherein the charges are localized on specific sites due to the ordering of the cations. For example, charge ordering of Fe_3O_4 is known for some time [24]. In case of manganites, around a particular doping level of x ~ 0.5, the e_g electrons are found to become localized and Mn^{3+} / Mn^{4+} ions are arranged in a checkerboard order (Fig. 4) below certain temperature [25,26]. This type of charge ordering is associated with a particular type of orbital ordering (OO) and CE-type antiferromagnetic (AFM) spin ordering. The CE-type spin order is the AFM ordered FM zigzag chains. This charge, orbital and spin order is clearly depicted in the Fig. 4 in the xy plane [26,27]. While the Mn^{3+} and Mn^{4+} ions gets ordered in the checkerboard pattern in the xy plane, along z-axis, the Mn ions are stacked so that the neighbouring ions are of same type but with AFM alternating of spins. The CE type structure is associated with ordering of the $d_{3x^2-r^2}$ / $d_{3y^2-r^2}$ e_g orbitals as shown in the Fig. 4. Hence the next plane along the z-axis has the same orbital and charge structure but with the opposite spins. Such charge/orbital ordered CE structure has been conceived theoretically [28] and also observed experimentally by different groups in the systems of (La,Ca)-Mn-O [6,29], (Nd,Sr)-Mn-O [30], (Pr,Ca)-Mn-O [31] etc..

The commonly accepted opinion is that the CE-structure results from competition between double exchange and AFM superexchange, while the magnetic zigzag chain is due to the 1:1 ratio of Mn^{3+}/Mn^{4+} ions [32-37]. The orbital order is an intrinsic property of FM zigzag chain and the anisotropy of electron hopping [32,33,35]. Some other effects like Jahn-Teller effect and electron-phonon interaction, e_g-e_g Coulomb repulsion etc. are also considered to be very important for stabilization of the charge orbital ordered state. A CO/OO is experimentally observed to be associated with significant change in the unit cell parameters. On ordering, the crystallographic a, b parameter is found to expand while the c parameter is observed to be decreased [25, 26]. The resistivity of the associated insulating state with CO/OO is generally increased by 2-3 orders of magnitude. The CO/OO state is more stabilized in the systems

where the average A-site ionic radius (<r_A>) is small. For example, (Pr,Ca)-Mn-O and (La,Ca)-Mn-O systems show CO/OO order in a comparatively broad regime of hole-doping level (x) than that in (Nd,Sr)-Mn-O system. The required magnetic field to destabilize the CO/OO state in case of (Pr,Ca)-Mn-O is also found to be very high compared to other systems.In some recent studies (theoretical and experimental), however, the above-mentioned arrangement of Mn^{3+}/Mn^{4+} has been doubted [37-39]. Experimental evidences indicate no significant differences of charge and magnetic moment in different Mn sites. The charge difference of two Mn sublattice has been found to be 0.16 electrons [38]. In a CE-type model two Mn sublattice has been assumed to have partial e_g occupancy. One sublattice consists of Mn atoms with the $d_{3x^2-r^2}$ or $d_{3y^2-r^2}$ orbitals partially occupied in an alternating pattern, the other sublattice with the $d_{x^2-y^2}$ orbital partially occupied [39]. An alternative model is the Zener polaron [40], in which pairs of Mn^{3+} cations share a 'hole' on a bridging O^- ion. These oxygen holes may form a soft charge density wave.

Phase Separation

It is a long-standing concept that the microscopic electronic and magnetic phases of manganites are inhomogeneous in nature [41–44]. Different magnetic and electronic phases over different length scales coexist in such materials - the phenomena called phase separation (PS). The properties of manganites have been argued to be dominated by the effect of phase separation. For instance, the large MR can only be explained by taking into account the effect of phase separation and phase percolation. In manganites, the inhomogeneities arise mostly from phase competition between ferromagnetic metallic and charge ordered insulating phases. An interesting feature of PS is that it covers a wide range of length scales anywhere between 1 and 200 nm and is static or dynamic in nature. In doped rare earth manganites CO (AFM) and FM clusters or domains coexist, the sizes of which are affected by the carrier concentration or composition, average size of the A-site cations, temperature and other external factors such as magnetic and electric fields [44-46]. For instance, application of magnetic field favours the growth of the FM clusters with low resistivity at the cost of AFM clusters with high resistivity. This naturally decreases the overall resistivity of the materials and may produce appreciable negative MR. Phases with different charge densities and transport properties coexist as carrier-rich FM clusters or domains along with carrier-poor AFM phase. The size of clusters depends on the competition between double exchange and Coulomb force.Though theoretical works could not properly model the exact nature of phase separation, experimentally the phase separation scenario could be observed through various experimental techniques like transmission electron microscopy, magnetic force microscopy, scanning tunnelling microscopy etc.. The first evidence of phase separation in manganites was given in the pioneering neutron diffraction study by Wollan and Koehler [6] in 1955. A very convincing work carried out by Uehera *et al.* [47] showed the presence of coexisting clusters of metallic and insulating phases in the CMR regime of manganites. Dagotto *et al.* [48-50] have extensively reviewed various aspects of phase separation in manganites.

Electronic-Transport In Manganites

Within the double exchange frame work it is known that mobility of the itinerant e_g electrons is the highest when t_{2g} spins are perfectly aligned in the ferromagnetic state as the hopping amplitude becomes maximum. On the other hand, complete antiferromagnetic alignment of the neighbouring t_{2g} spins gives zero hopping amplitude. Therefore, there is a kinetic energy gain in the e_g band for ferromagnetic alignment, which competes with the super exchange energy favoring AFM alignment as well as with the thermal fluctuations which favor disorder. This model intuitively explains why a properly doped material at low temperatures is a ferromagnetic metal which will become a paramagnetic (PM) insulator at high temperature due to spin disorder. This also intuitively explain the observation of a metal-insulator (M-I) transition in many optimally doped manganites. For the same reason, FM to PM transition temperature (T_C) is also found to closely match with metal-insulator (M-I) transition temperature T_{M-I}. Slightly above T_C, a large magnetic field will serve to align the core t_{2g} spins, increasing the hopping amplitude between e_g electrons and driving the material more metallic.

However, the change in magnitude of the conductivity around the M-I transition is found to be different from that obtained from double exchange theory. From the double exchange framework, we expect a reduction of hopping amplitude to 0.7 due to transition from ordered ferromagnetic state to a disordered paramagnetic state [15]. Practically, a many order change in conductivity is found due to FM-PM transition. This also indicates that we need to go far beyond double exchange to understand the behavior of the manganites. Further, we know that the conductivity = $n_{eff}e\mu$, where n_{eff} is the number of carriers, e is their charge and μ is the mobility. Within double exchange theory the change in mobility (change in hopping probability) is the dominant effect on the conductivity as discussed earlier. This should not significantly affect the density of states at the Fermi level. Therefore, if mobility changes were the dominant mechanism for the metal-insulator transition we should expect a significant density of states at the Fermi energy even in the insulating paramagnetic state. But this is not observed, indicating that a change in effective carrier number (a gapping of the near-Fermi energy states) is more important than a change in mobility.

In the low temperature ferromagnetic regime manganites display metallic behaviour with a positive temperature coefficient *i.e*. $d\varrho/dT > 0$. Various studies display that an equation of the form

$$\rho(T) = \rho_0 + \rho_p T^p \quad (3)$$

could be fitted by adjusting the parameters ϱ_0, ϱ_P and p. For p = 4.5 the scattering is electron-magnon type [51] whereas p = 2 represents electron-electron scattering [52]. However, in many cases a good fit yields a value of p different from those values. Therefore, efforts have been made to fit the $\varrho(T)$-T data in the metallic phase by taking combination of different scattering terms with different p. However, no univocal reports have been found regarding the scattering mechanism. This indicates that there are several contributions and that further work is needed to determine the relative strengths of different scattering mechanisms.

Electronic-transport in the high temperature paramagnetic insulating ($d\varrho/dT<0$) region is mostly dominated by an activated resistivity. Jahn-Teller distortion of the lattice constrains the charge carrier mobility. Strong electron-phonon coupling leads to the formation of small polarons. The resistivity is governed by the thermally activated hopping of these charge carriers. In those cases, small polaron hopping model [53] of the form

$$\rho(T) = \rho_0 T \exp(\Delta/k_B T) \quad (4)$$

where Δ is the activation energy, has been employed. The term ϱ_0 is expressed as $\varrho_0 = [k_B/\nu_{ph}Ne^2R^2C(1-C)]\exp(2\alpha R)$, where, ν_{ph} is optical phonon frequency, N is the number of metal ions per unit volume of the sample, R is average hopping distance, C is fraction of sites occupied by polarons and α is known as tunnelling probability or the electronic wave function decay constant. However, the insulating behaviour of the manganites is controversially discussed in the literature. Several authors found that Mott's variable range hopping model can also describe the temperature dependence of resistivity in the insulating regime. According to this model the resistivity is given by [54],

$$\rho(T) = \rho_\infty \exp\left[\left(\frac{T_0}{T}\right)^{1/4}\right], \quad (5)$$

where T_0 is expressed functionally as $T_0 = 16\alpha^3/k_B N(E_F)$ with α being the inverse localization length and $N(E_F)$ being the density of states at the Fermi level (E_F) of charge carriers.

Extrinsic Magneto-Transport in Manganites

In spite of the fact that observed MR (intrinsic in nature) near T_C in mangnatites can be qualitatively explained through double exchange, it is not the only mechanism which can account for the high magnetoresistance observed in a wide range of temperature in a variety of manganite systems. There are various effects, extrinsic in nature, has to be taken into account. Effect of domain wall scattering of carriers, and the field-temperature dependence of resistivity in manganites has been investigated by different groups in details [55-58]. However, the inter-granular tunnelling of electrons due to high spin polarization is found to have a major contribution to the observed magnetoresistance of such materials. Magnetoresistance originating from such inter-granular tunnelling of spin polarised electrons displays a large negative value at low magnetic fields with a slow increase of negative MR with further increase of

field. The manganites are known to have a specific type of band structure different from other elemental ferromagnets and called *half-metallic*-the concept introduced by de Groot *et al.* [59] in 1983. The typical band diagrams for Ni and half-metallic materials are depicted in the Fig. 5. In half-metallic case, the majority spin band has conducting states at E_F whereas the minority spin band has semiconductor like gap at E_F. In manganites, the majority conduction band (~1.5 eV) is completely separated by the minority band by large Hund's coupling energy ~ 2.5 eV [56,57]. In such a case, the spin polarization (at E_F) defined by, $P = \frac{n_\uparrow - n_\downarrow}{n_\uparrow + n_\downarrow}$ where, $n_\uparrow$ and $n_\downarrow$ are the density of states of majority and minority spin electrons, respectively, is ideally 100 %. Experimentally, high spin polarization value for $La_{0.7}Sr_{0.3}MnO_3$ was confirmed by Park *et al.* [58] below T_C. This indicates that the spin-dependent transport is very important in manganites.

In an elemental ferromagnet Ni (thin films) the magnetoresistance due to intergranular spin polarized tunnelling (SPT) was investigated and quantified by Helman *et al.* [63]. According to their hypothesis, MR is given by,

$$\frac{\Delta\rho}{\rho_0} = \frac{JP}{4\kappa_B T}\left[m^2(H,T) - m^2(0,T)\right] \quad (6)$$

Here, J is inter-grain exchange constant and m is the normalized magnetization with respect to saturation value. Later, the rigorous experiments on single crystal and polycrystal of manganites also showed that MR is dominated by inter-granular electron transport and very sensitive to magnetic field [64]. These results are consistent with the concepts introduced by Helman *et al*. The issue of spin polarized transport was further investigated by Raychaudhuri *et al.* [65] and they proposed a phenomenological model to describe the actual field dependence of MR in manganites. This model could explain the observed large low field magnetoresistance in ferromagnetic manganites satisfactorily. Extending the idea of SPT as proposed by Helman and Abeles, this model account for the magnetic field dependence of MR considering the gradual slippage of domain walls across the grain boundaries' pinning centres in presence of the applied magnetic field. According to this model the expression for MR vs. H takes the form,

$$MR(H) = -A'\int_0^H f(k)dk - JH - KH^3 \quad (7)$$

This model assumes that in zero field the domain boundaries are pinned at the grain boundary pinning centres having pinning strengths k. The grain boundaries have a distribution of pinning strengths expressed as $f(k) = A\exp(-Bk^2) + Ck^2\exp(-Dk^2)$ which is a weighted average of a Gaussian and skewed Gaussian distribution. All the adjustable fitting parameters, A, B, C, D, J, K with A' absorbed in A and C can be found by fitting the equation on experimental data. The spin polarised intergranular MR is given by $MR_{SPT} = -\int_0^H f(k)dk$ and the rest of MR is intrinsic MR ($MR_{INT} = -JH - KH^3$) originating due to double exchange mechanism.

Further, the issue of inter-grain magnetoresistance observed in polycrystalline half-metallic ferromagnets (below T_C) was also theoretically investigated by Lee *et al*. [66] They have shown that magnetoconductivity ($MC = \frac{\sigma(H) - \sigma_0}{\sigma_0}$) in high field is linear with magnetic field and the slope monotonically decreases with increasing T_C. The low field MC value in the low temperature limit is universally close to 1/3, irrespective of T_C or composition. In this study the role of grain boundary spin susceptibility is considered in the second order tunnelling of the electrons across grain boundary through these interfacial spin sites. At high fields, averaging over possible angles between the bulk and surface magnetizations, they arrived at an equation given by,

$$\frac{\sigma}{\sigma_0} \approx 1 + \frac{1}{3}\bar{M}^2 + 2\chi_b H\bar{M} \quad (8)$$

where σ_0 is the conductivity at H = 0, $\bar{M}$ is the normalized magnetization and χ_b is the surface spin susceptibility. In phase separated manganites, however, the role of phase separation becomes crucial as discussed in section 7. A significant part of MR originates from field induced modification of the phase separation scenario in those manganites [47, 48-50]. As the relative fraction of the low-resistive and high-resistive phases changes with magnetic field the overall resistivity of the material changes with field accordingly. However, quantification of this contribution for MR is extremely difficult due to the lack of knowledge of the microscopic nature of phase separation.

Summary

In summary, a review of the different fundamental mechanisms behind observed prominent phenomena of manganites has been reported. Clearly, the double exchange mechanism is at the heart of various observed properties of colossal magnetoresistive manganites. Additionally, Jahn-Teller distortion plays an important role. Hole doping in such materials is an effective tool to change the carrier concentration as well as bandwidth of the system. By properly choosing the doping concentration and the ionic radii of the dopant at A-site one can controllably change the bandwidth of the system. These materials are found to display the peculiar phenomena of metal-insulator transition around the ferromagnetic-paramagnetic transition temperature when doped properly. The resistivity in the low temperature metallic phase is dominated by double exchange mechanism along with electron-maganon or electron-electron scattering. The insulating behaviour is however predominantly influenced by energy gap at Fermi level. For a given range of hole doping level, the fascinating phenomena of charge-orbital ordering is observed in many manganites. Observation of large negative magnetoresistance even at low fields in these half-metallic materials is of particular interest indicating possibility of applications. Large value of spin polarisation is responsible for such large negative MR at low fields. Different models describing the inter-granular spin polarised transport of electrons has been discussed. The review vividly indicates the rich physics and complexity of behaviour of manganites. Even after decades of intense research many of such complex properties of manganites are not fully understood and requires further theoretical and experimental investigations.

ABSTRACT

Polymer–inorganic nanocomposite coatings have attracted significant attention for corrosion protection owing to their combined barrier and electrochemical properties. In this work, poly(o-phenylenediamine) (PoPD)/TiO_2nanocomposite coatings were fabricated on stainless steel substrates to investigate their anticorrosive performance. The incorporation of TiO_2 nanoparticles into the PoPD matrix resulted in improved coating homogeneity and enhanced interfacial interactions, leading to effective suppression of corrosive species penetration. Structural and morphological characterisation confirmed the successful formation of the PoPD/TiO_2nanocomposite and uniform coating coverage on the steel surface. Electrochemical measurements, including potentiodynamic polarization and electrochemical impedance spectroscopy, demonstrated that the nanocomposite coatings exhibit significantly improved corrosion resistance compared to pristine PoPD coatings. The enhanced performance is attributed to the synergistic effect of PoPD passivation behavior and the barrier role of TiO_2 nanoparticles, which together hinder charge transfer and reduce corrosion kinetics. These results highlight the potential of PoPD/ TiO_2nanocomposite coatings as an effective strategy for corrosion protection of stainless steel.

INTRODUCTION

Advances in modern engineering science and nanotechnology have significantly accelerated the development of high-performance, corrosion-resistant coatings capable of functioning effectively under a wide range of aggressive environmental conditions. The design of such advanced coating systems is expected to bring about a transformative change in corrosion protection technologies. Additionally, environmental sustainability can be enhanced through the incorporation of nanostructured particulates into coatings, thereby reducing or eliminating the need for toxic solvents [1].In recent years, conducting polymers (CPs) have gained considerable importance in materials science, particularly for their application in corrosion protection of metals. Among these, polyaniline (PANI) has emerged as a promising anticorrosive coating material and a viable alternative to chromium-based coatings, which are associated with serious health and environmental hazards [2]. The corrosion protection mechanism of PANI is well established and involves both barrier protection and electrochemical effects. The latter arises from an increase in corrosion potential and the formation of a stable passive layer on the metal surface, facilitated by the redox catalytic behavior of PANI [3].

Conducting polymers derived from substituted anilines exhibit properties that differ partially from those of PANI. For example, poly(o-phenylenediamine) (PoPD), synthesized from o-phenylenediamine (oPD), contains an additional $–NH_2$ group at the ortho position of the aromatic ring and displays structural, redox, and electrochromic characteristics closely resembling those of PANI. PoPD possesses a ladder-type structure composed of condensed phenazine units with varying degrees of oxidation and protonation. This ladder architecture promotes a coplanar backbone conformation, leading to strong $\pi–\pi$ interactions and extended conjugation. Consequently, nitrogen-rich conjugated polymers with ladder-type structures are expected to exhibit superior electron-transfer capability, enhanced corrosion protection, high thermal stability, and good electrical conductivity [4].In CP-based corrosion-resistant coatings, protection may arise from both barrier effects and the formation of an internal sacrificial electrode, which shields the underlying substrate. However, the inherent porosity and anion-exchange characteristics of CPs can be detrimental, particularly in environments containing aggressive ions such as chlorides that induce pitting corrosion. The barrier performance of CP coatings can be significantly improved through the incorporation of suitable fillers. Notably, nanoparticulate fillers provide superior barrier properties at relatively low loadings compared to conventional additives. The integration of inorganic fillers into CP matrices has been widely explored using both chemical and electrochemical polymerization techniques [5].

In the present study, corrosion protection of 316L stainless steel in a 3.5% NaCl medium is investigated. TiO_2–PoPDnanocomposites were synthesized and characterized using a simple in-situ oxidative polymerization approach, employing TiO_2 nanoparticles as templates. The resulting nanocomposites were deposited onto 316L stainless steel substrates via the dip-coating technique. The corrosion protection performance of the TiO_2–PoPDnanocomposite coatings was evaluated using electrochemical methods, including potentiodynamic polarization and electrochemical impedance spectroscopy (EIS), in a chloride-containing environment.

Experimental Section

Chemicals: The TiO_2 nanoparticles (50 nm) and o-phenylenediamine obtained from Sigma-Aldrich and ammonium per sulfate (APS) were from Merck used as-received. Polyvinyl butyral (PVB) with M.W. 60,000 was obtained SRL. All other chemicals and reagents were analytical grade and were used without further purification.

Synthesis and coatings of TiO_2-PoPD nanocomposites

Preparation of TiO_2-PoPD nanocomposites involve two steps. Firstly, 5 ml of aqueous alkaline solution was added into 500 mg of TiO_2nano powder and ultrasonicated for 45 min to introduce negative charges onto the TiO_2 particle surface and prevent agglomeration. Secondly, in-situ template chemical oxidative polymerization of oPD was performed in the presence of negatively charged TiO_2 nano particles using ammonium persulphate. A typical procedure is outlined: oPD (0.5 g) was added to 100 mL of deionized water containing 500 mg of negative-charged TiO_2 particles with constant stirring. HCl was dropped to adjust the pH to 2. Ammonium persulphate (1.14 g) was then added slowly into the mixture to initiate the reaction. The solution quickly turned purple-red and became turbid in 5 s. The reaction mixture was then subjected to ultrasonication for 45 min at room temperature and the product was centrifuged and washed several times with double-distilled water. PVB (1 g) was dissolved in methanol (20 mL) and 10 wt% of TiO_2-PoPD nanocomposites was added and subjected to sonication for 45 min.[33] This yield a uniform dispersion of PoPD–TiO_2 nanocomposites in the PVB solution. The 316L SS samples (composition given in Table 1) of 10×20×2 mm^3 size were mechanically abraded with 120 - 1200 grit silicon carbide papers followed by polishing with diamond paste to obtain mirror finish. The steel substrate was then washed thoroughly with running distilled water, rinsed and ultrasonically degreased with acetone and then dried. This pretreated steel with a surface area of 0.5 cm^2 was then dip coated with the TiO_2-PoPD nanocomposites/PVB in methanol solution and dried at room temperature for 30 min. The coating thickness was 0.5 μm.

Instrumentation

UV-visible spectra were recorded using "TECHCOMP" UV-visible spectrometer model 8500 with a matched pair of teflonstoppard quartz cuvettes. FT-IR spectra were recorded using "BRUKER" (model TNSOR 27) in the region 4000-400 cm^{-1} as KBr pellets. Transmission Electron Microscope (TEM) images were obtained with Hitachi model H-800 and Scanning Electron Microscopy (SEM) image was obtained using LEO 440 I model. Thermogravimetry (TGA) analysis were recorded using a Perkin Elmer Thermal Analyzer over a temperature range of 0–1000 °C in an inert atmosphere at a heating rate of 10 °C min^{-1}. A conventional three electrode cell was used for all the electrochemical measurements. A saturated calomel electrode (SCE) was used as reference electrode, platinum foil as counter electrode and 316L SS as the working electrode. Potentiodynamic polarization studies were carried out for the test specimens in 3.5% NaCl solution using Potentiostat/Galvanostat (model PGSTAT 12, AUTOLAB, the Netherlands B.V), which was controlled by a personal computer. Electrochemical Impedance Spectroscopy measurements were carried out using a Frequency Response Analyzer (FRA), which included a Potentiostat/Galvanostat model PGSTAT 12. Impedance spectra were recorded in the frequency range of 40 kHz–0.01 Hz with a 10 mV amplitude sine wave generated by the FRA.

RESULTS AND DISCUSSION

Formation mechanism of TiO_2-PoPD nanocomposites

TiO_2-PoPD nanocomposites were successfully synthesized by in-situ template chemical oxidative polymerization of oPD monomers using APS as the oxidant in the presence of TiO_2 nanoparticles. The formation mechanism of TiO_2-PoPD core-shell nanocomposites on the surface of negatively charged TiO_2 particles is illustrated in Figure 1. First, the TiO_2 surface was modified to be negatively charged using aqueous alkaline solution. The negative-charged TiO_2 nanoparticles were then used as templates for polymerization. Second, the added oPD monomers were adsorbed in the form of ph-NH_2^+ cations on the negative TiO_2 surface by an electrostatic attraction. After the addition of ammonium persulfate, the adsorbed ph-NH_2^+ cations polymerized immediately on the TiO_2 templates [6].

TEM and FTIR studies of TiO_2-PoPD nanocomposites

The structure of the TiO_2-PoPD nanocomposites was also confirmed by TEM analysis. Figure 2 (A) represents the TEM images of pure PoPD film and the pure PoPD film possesses nanofiber morphology. Figure 2(B) showed the TEM images of the TiO_2-PoPD nanocomposites. The TiO_2-PoPD nanocomposites were produced with pre-aggregated

or glued titanium in the cores (inside black components) and polymer in the shells (outside white components), the entire surface of the TiO_2 particles was surrounded by PoPD film and the TiO_2 nanoparticles are well dispersed in the polymer matrix. Moreover, the outer shell of the particle exhibited a fine increment in brightness compared with the dark inner core, which confirmed the formation of core–shell structure of the TiO_2–PoPD nanocomposites. The formation of PoPD encapsulated TiO_2 core-shell nanocomposites are attributed to the strong electrostatic interaction between PoPD and TiO_2[7]. Figure 3 shows the FT-IR spectra of the PoPD and TiO_2-PoPD nanocomposites. Both pure PoPD and the hybrids show the same peak locations, which are characteristic of PoPD, i.e. peak at around 3301 cm^{-1} is due to the N–H stretching vibrations of the –NH-group and two peaks at 3380, 3153 cm^{-1} are ascribed to the asymmetrical and symmetrical N–H stretching vibrations of NH_2 group, respectively.

The two strong peaks at 1571 cm^{-1} and 1496 cm^{-1} are associated with the stretching vibrations of C=C and C=N group in phenazine ring. The peaks at 1245 cm^{-1} and 1119 cm^{-1} are associated with C–N–C stretching in the benzenoid and quinoid imine units. Furthermore, the bands at 777 cm^{-1} and 621 cm^{-1}, which are the characteristic of C–H out-of-plane bending vibrations of benzene nuclei in the phenazine skeleton. It can be observed that the spectrum of the hybrids has no obvious difference compared with that of pure PoPD except for the reduced peak intensity. The reduced peak intensity may be due to the interaction between PoPD and TiO_2 [8].

Surface morphology of the uncoated, PoPD and TiO_2-PoPD nanocomposites coated 316L SS

The surface morphology of the uncoated, PoPD and TiO_2-PoPD nanocomposites coated 316L SS were carried out using SEM and the results are shown in Figure 4. The surface of uncoated steel revealed no distinctive topographic features, apart from grooves formed during mechanical polish of the specimen(Figure 4a).The surface of the PoPD coated steel shows non uniform morphology with relatively rough and is characterized by the presence of the pores in the coatings (Figure 4b). But interestingly one can notice that, the surface of the TiO_2-PoPD nanocomposites coated steel exhibits thin, compact, uniform and pore-free morphology with continuous nodular structure (Figure 4c). There are two possible explanations for the formation of the uniform and smooth surface morphology of the TiO_2-PoPD nanocomposites coatings, one possible explanation is that the TiO_2 particles are filling the pores in the coatings and another possibility is that the presence of these particles simply changes the polymer morphology [9].

Electrochemical Corrosion Measurements

The potentiodynamic polarization curves for uncoated, PoPD and TiO_2-PoPD coated 316L SS recorded in 3.5 % NaCl solution are shown in figure 5. It was observed that the PoPD coated 316L SS exhibited higher corrosion potential and higher corrosion current density compared to bare metal. The corrosion potential shifts, from -275 mV to a positive potential of 174 mV when the steel surface is covered by the PoPD film, indicating the high inhibition efficiency of the polymer coatings. On the other hand, the corrosion current density increases from 1.821×10^{-6} to 1.146×10^{-5}A cm^2 which could be due to the porous nature of the PoPD film (which was confirmed by SEM) that allows the insertion of chloride anions as counter ions in to the polymer structure [10-12]. In disparity, the polarization curve for TiO_2-PoPD coated 316L SS depicts more positive shift of corrosion potential (280 mV) in nobler direction and the decrease in current density (1.552×10^{-6}) indicates the protection of the steel surface by TiO_2-PoPD nanocomposites coating. The positive shift of corrosion potential and decreasing current density is attributed to the low porosity of the TiO_2-PoPD nanocomposites coating due to the filling of the pores by TiO_2 nanoparticles.Incorporation of TiO_2 nanoparticles in the PoPD matrix plugs the pores and cracks of the PoPD film and thereby enhances the corrosion protection ability of nanocomposite film on 316L SS [13.14].

Electrochemical impedance spectroscopy (EIS) is an effective technique for evaluating the corrosion resistance and electrochemical characteristics of protective coatings. Figure 6 (a) presents the bode plots phase angle and (b) Bode resistance plots for uncoated, pure PoPD and TiO2-PoPD nanocomposites coated 316L SS in 3.5% NaCl solution. For comparison, the response of uncoated steel is also included. The bare steel exhibits pronounced capacitive behaviour in the mid-frequency range, followed by a decline in phase angle at lower frequencies. The linear trend observed in the low-frequency region indicates the dissolution of metal ions or naturally formed oxide layers into the electrolyte

(Figure 6a). In contrast, 316L stainless steel coated with PoPD shows a higher maximum phase angle and a wider time constant, indicating enhanced resistive properties of the coating and improved surface protection. The corresponding EIS parameters for uncoated steel, PoPD-coated steel, and TiO_2–PoPDnanocomposites-coated 316L stainless steel in 3.5% NaCl solution are summarized in Table 2.When TiO_2 nanoparticles are incorporated into the coating, the impedance behavior changes significantly. Two distinct time constants are observed: the high-frequency time constant (approximately 100 kHz) is attributed to a thin, TiO_2-rich outer layer, while the low-frequency time constant (around 50 Hz) corresponds to the PoPD layer in contact with the steel substrate. For coatings without TiO_2, the outer layer time constant appears at lower frequencies (around 100 Hz), whereas its shift to higher frequencies in TiO_2-containing coatings indicates a reduction in coating capacitance due to nanoparticle incorporation. Furthermore, the Bode impedance modulus plots (Figure 6b)show that the low-frequency impedance of the TiO_2-reinforced coating is more than two orders of magnitude higher than that of the PoPD coating alone, confirming the superior corrosion protection offered by the TiO_2–PoPDnanocomposites [15,16].

CONCLUSIONS

An in situ templated chemical oxidative polymerisation method was employed to synthesise TiO_2–PoPD core–shell nanocomposites. The approach is simple, scalable, and reproducible, and effectively suppresses polymer agglomeration. SEM and TEM analyses confirmed the formation of well-defined core–shell structures. Potentiodynamicpolarizationstudies showed that TiO_2–PoPD coated 316L stainless steel exhibits a marked positive shift in corrosion potential compared to pristine PoPD-coated and uncoated steel, indicating improved adhesion and corrosion inhibition. Electrochemical impedance spectroscopy further demonstrated that the incorporation of TiO_2 nanoparticles significantly enhances the corrosion resistance of the PoPD coating. The improved performance is attributed to increased diffusion resistance, reduced charge transfer due to nanoscaleTiO_2, and the redox activity of PoPD. These findings suggest that TiO_2–PoPDnanocomposite coatings are promising candidates for protecting 316L stainless steel in chloride-containing environments.

ABSTRACT

Plastic packaging plays a crucial role in modern life, particularly in the food sector, accounting for more than 50% of global plastic consumption. However, plastics are non-biodegradable, and their degradation can take several decades or even centuries. This growing environmental issue has attracted significant attention from manufacturers, government regulatory agencies, and consumers regarding the safety, storage, and packaging of food products. Consequently, researchers and scientists are making continuous efforts to develop alternative packaging materials, such as biodegradable biocomposite films with antimicrobial properties, to address these challenges. Biodegradable polymers have gained significant attention as alternatives to conventional plastic packaging materials. In the present study, starch/polyvinyl alcohol (PVA) blend films were prepared using the solution casting technique with Two different compositions. The prepared films were characterized using Fourier Transform Infrared Spectroscopy (FTIR), X-ray Diffraction (XRD), Scanning Electron Microscopy (SEM), and Thermogravimetric Analysis (TGA) to evaluate their structural, morphological, and thermal properties. Antimicrobial activity of the films was also examined against selected bacterial and fungal strains to determine their suitability for food packaging applications. FTIR analysis confirmed the formation of hydrogen bonding between starch and PVA. XRD results indicated changes in crystallinity with increasing PVA content. SEM micrographs revealed uniform dispersion of polymer components in the

composite films. TGA analysis demonstrated improved thermal stability of the composite films compared to pure starch films. The antimicrobial results showed effective inhibition of bacterial growth. These findings suggest that starch-PVA composite films are promising eco-friendly materials for food packaging applications.

Keywords: biopolymers, biodegradability, starch, polyvinyl alcohol, packaging.

INTRODUCTION

Over the past several years, due to the rise in environmental concerns, research has been focused on biodegradable materials in reducing the reliance on petroleum-based materials. For this purpose, biopolymers have been widely developed as an alternative to conventional materials due to their attractive benefits, such as biodegradability and sustainability towards the environment [1]. At present, biodegradable polymers have been a subject of great interest due to their potential to resolve a wide range of problems in various fields and to save the environment [2]. In that prospect, starch is one of the approaches to produce biopolymeric materials based on inherently biodegradable materials. This has been attracting interest in the utilization of the starch as a biopolymer. Consequently, the biodegradable constituent is predicted to be degraded rapidly by environmental factors such as biological activity, chemical conditions, moisture, heat and light, initiating an overall deterioration of the polymeric matrix which in turn boosts the disintegration of the whole material [2,3]. As we know, 50% of the food packaging plastics accounts for the bulk of plastics that are polluting the environment.

Instead of these non-biodegradable plastics, we can use biodegradable and edible films, which can be used for versatile food products to reduce loss of moisture, to restrict absorption of oxygen, to lessen migration of lipids, to improve mechanical handling properties, to provide physical protection, or to offer an alternative to the commercial packaging materials. The use of biopolymers such as starch can be an interesting solution because this polymer is relatively inexpensive, abundant, biodegradable, edible and is produced from agricultural by products [4]. Starch-based biocomposites can be produced by blending or mixing them with synthetic polymers.PVA is a biodegradable synthetic material that has the advantages of good film forming, strong conglutination, and high thermal stability which can produce films with decreased hydrophilicity and enhanced mechanical properties in combination with starch. In recent years, PVA has been widely used in the materials industry [5]. Recent preparations of starch-based biocomposite studies have been reported. In this work, biodegradable films of Starch-Polyvinyl alcohol (PVA) were produced and different physical, thermal and biodegradable properties were studied. Therefore, PVA-Starch films are an excellent substitute for petroleum-based packaging owing to their proper mechanical and water-resistant properties. This study contributes to the growing body of knowledge in sustainable materials science, emphasizing the importance of eco-friendly alternatives in the quest for greener technologies.

MATERIALS AND METHODS

Materials

Starch, Poly Vinyl Alcohol (PVA) and glycerol were procured from NICE chemicals (Ernakulam, India), and deionised water.

Preparation of starch film

A known amount of Starch was dissolved in deionised water to make a slurry and then heated to about 95˚C to induce gelatinisation. 1ml of glycerol was added as plasticizer and the entire mixture was stirred for about 20 minutes in a magnetic stirrer to make a homogenous mixture. The starch slurry was poured onto a clean, flat mould suitable for film casting and the mixture was spread evenly to achieve the desired film thickness. The film was dried

in oven at about 50°C for about six hours until all the moisture was removed and the film was removed from the mould, sealed and stored in an airtight container for further studies.

Preparation of Starch-PVA blend film

A known amount of Starch was dissolved in deionised water to make a slurry and heated to about 95°C to induce gelatinisation. A known amount of PVA was dissolved in hot deionised water and stirred well to form a homogenous mixture. The starch -PVA blend of ratio 1:1 was made by slowly adding the PVA solution to the gelatinised starch slurry with continuous stirring. 1ml of glycerol was added as plasticizer and the entire mixture was stirred for about 20 minutes in a magnetic stirrer to make a homogenous mixture. The Starch-PVA blend was poured onto a clean, flat mould suitable for film casting and the mixture was spread evenly to achieve the desired film thickness. The film was dried in oven at about 50°C for about six hours until all the moisture was removed and the film was removed from the mould, sealed and stored in an airtight container for further studies. Table 1 represents the sample codes and the compositions of the prepared films.

Characterization of the prepared composite films

FT-IR

Functional groups of the composite materials were analysed using an IR Affinity-1 spectrophotometer, Shimadzu. The films were scanned in the spectral range of 400 cm^{-1} to 4000 cm^{-1} at a resolution of 4 cm^{-1}.

X-ray diffraction analysis

The crystalline attributes of the prepared composite films were examined using a powder XRD diffractometer - BRUKER AXS / D8 FOCUS, applying Cu- K alpha radiation corresponding to a wavelength of 0.154nm at a scan rate of 10°/min. Diffraction spectra were expressed as 2Θ in the range 2° to 80°.

SEM analysis

The surface morphology of all the films was assessed using a Field Emission Scanning Electron Microscope (FE-SEM) (Carl ZEISS, Sigma 300VP).

TGA/DTG analysis

TGA was done using a Thermo-gravimetric analyser (TGA 4000, PerkinElmer, Singapore), under nitrogen atmosphere within a temperature range from 30°C to 900°C with a heating rate of 10°C/min.

Water contact angle (WCA) analysis

The water contact angle (WCA) was measured using an optical tensiometer, KRUSS DSA30, Germany. To carry out the measurement, films were cut into rectangular pieces and fixed on the surface of a cover glass with a double-sided tape. The contact angle of the water droplet was measured in four different positions and the mean value was taken.

Thickness measurement

The thickness of the prepared biocomposite films was measured using a digital micrometer with an accuracy of ± 0.001mm. For each film sample, measurement was taken at five different positions and the average value was calculated and tabulated.

Mechanical properties

The tensile strengths of the biocomposite films were evaluated using a Universal Testing Machine (Instron UTM) following ASTM D882 standard, which is commonly used for biopolymer samples. Rectangular film specimens were cut with uniform dimensions of 100mm and width 15mm. The thickness of each film was measured at three different positions using a digital micrometerand the average thickness was used for calculations. The tensile strength(MPa) was calculated by dividing the maximum load at break by the original cross-sectional area of the specimen. The elongation at break (%) was calculated from the ratio of the extension at break to the initial gauge length.

Antimicrobial activity

The antimicrobial activity of the samples was evaluated using the Kirby–Bauer disk diffusion method following the Clinical and Laboratory Standards Institute (CLSI) guidelines. The test microorganisms were cultured on Mueller–Hinton agar (MHA) plates. A fresh bacterial suspension was prepared in sterile saline and adjusted to match the

0.5McFarland standard (approximately 1 × 10^8 CFU/mL). Using a sterile cotton swab, the inoculum was evenly spread over the entire surface of the MHA plate to ensure a uniform lawn of growth. Sterile antibiotic discs (or discs impregnated with the test extract/compound) were aseptically placed on the agar surface with sterile forceps, maintaining uniform spacing between discs. The plates were incubated at 37 ± 1 °C for 18–24 h under aerobic conditions. After incubation, the zones of inhibition surrounding each disc were measured in millimetres. The antimicrobial efficacy was interpreted by comparing the zone diameters with the standard CLSI reference chart, and the results were categorised as susceptible, intermediate, or resistant.

RESULTS AND DISCUSSION

FT-IR Spectroscopy

An essential tool for observing functional groups that are involved in the stability of prepared biopolymer films is Fourier-transform infrared spectroscopy (FTIR). The FT-IR spectra of SPO1 and SPO3 films were recorded to investigate the intermolecular interactions between the polymer components. Clear peaks can be seen across the whole range of observation in the FT-IR of the prepared films. The FT-IR of Starch film is given in fig.1 and the FT-IR of Starch-PVA blend film is given in fig.2 The FTIR spectrum of the starch film shown in fig.1 shows a broad absorption band around 3444 cm^{-1}, which corresponds to the stretching vibration of hydroxyl (–OH) groups present in starch molecules. The peaks in the range of 2974cm^{-1} to 2818cm^{-1}corresponds to -CH and -CH_2 stretching vibrations. The small peaks in the range of 1548cm^{-1} to 1394 cm correspond to -CH bending. The peak at 1027cm^{-1} corresponds to the C-O bond of the polysaccharide backbone.

In the FTIR spectrum of starch–PVA blend film shown in fig.2, similar characteristic peaks of starch are observed.However, slight changes in peak intensity and position can be noticed.The broad –OH stretching band around 3400 cm^{-1} becomes more intense and slightly shifted, indicating enhanced hydrogen bonding interactions between hydroxyl groups of starch and PVA molecules.The peaks in the range of 2942cm^{-1} to 2825cm^{-1}corresponds to -CH and -CH_2 stretching vibrations. The small peaks at the range of 1544cm^{-1} to 1235cm^{-1} correspond to -CH bending. The sharp peak at 1037cm^{-1} corresponds to the C-O stretching of the polysaccharide backbone.

XRD analysis

The crystalline structure of the prepared films was investigated using X-ray diffraction analysis, and the diffraction patterns of the starch film (SP01) and starch–PVA blend film (SP03) are presented in Fig. 3 and Fig. 4. The XRD pattern of the pure starch film in fig.3 exhibits a broad diffraction peak at around $2\theta = 22.5°$, which is characteristic of the semi-crystalline nature of the starch. The broad nature of the peak indicates that the starch film possesses a partially amorphous structure due to the disruption of the native semi-crystalline arrangement during the film-forming process. The decrease in sharp crystalline peaks suggests that gelatinization and film formation lead to a reduction in the ordered structure of starch molecules.In the XRD pattern of starch–PVA blend film in fig.4, a similar diffraction peak is observed at $2\theta = 22°$, indicating the presence of semicrystalline domains in the polymer matrix. A shoulder peak at $2\theta = 40°$ is also a characteristic peak of PVA. However, the intensity and shape of the peak are slightly modified compared to the pure starch film. This change may be attributed to the incorporation of PVA, which interacts with starch chains through intermolecular hydrogen bonding. The slight variation in peak intensity and broadness suggests that the addition of PVA influences the crystalline behaviour of starch and promotes a more amorphous structure in theblend film. Such structural modification can improve the flexibility and mechanical performance of the film.

Scanning electron microscopy (SEM)

The surface morphology of the prepared films was analyzed using Scanning Electron Microscopy to evaluate the structural characteristics and compatibility between starch and PVA. The SEM micrographs of the films are presented in Fig. 5.

Fig. 5(a) shows the SEM image of the pure starch film. The surface appears relatively rough and heterogeneous with noticeable irregularities and granular structures. Such morphology may be attributed to the intrinsic semicrystalline nature of starch and the aggregation of starch granules during film formation. The presence of uneven regions and micro-voids suggests weaker intermolecular interactions within the starch matrix, which may influence the mechanical stability of the film.In contrast, the starch–PVA blend film shown in Fig. 5(b) exhibits a comparatively smoother and more uniform surface morphology. The reduction in surface roughness indicates improved compatibility between starch and PVA molecules. The intermolecular hydrogen bonding between hydroxyl groups of starch and PVA likely contributes to the formation of a more homogeneous polymer network. Additionally, the absence of significant cracks or phase separation suggests effective blending of the two polymers.The improved surface uniformity in the starch–PVA film demonstrates that the incorporation of PVA enhances the structural integrity of the starch matrix. This modification is expected to improve the mechanical strength and flexibility of the film, making it more suitable for potential biodegradable food packaging applications.

TGA/DTG analysis

The thermal stability and degradation behaviour of the prepared films (SPO1 and SPO3) were evaluated using thermogravimetric analysis (TGA) and derivative thermogravimetry (DTG), as shown in Fig. 6 and Fig. 7 respectively. The TGA curves reveal a multi-step degradation pattern for both the films. The initial weight loss observed at 155°C for SPO1 and 160°C for SPO3 is attributed to the evaporation of physically adsorbed and bound moisture present in the hydrophilic starch matrix and corresponding to about 8% of weight loss. A second stage of degradation is more prominent in the starch–PVA blend (SPO3), with a DTG peak appearing at 208°C, which can be associated with the decomposition of low molecular weight components and plasticizer interactions, as well as partial breaking of weak intermolecular bonds. This stage is less distinct in the pure starch film (SPO1), indicating structural differences between the two systems.The major thermal degradation stage occurs in the temperature range of 280–330°C, corresponding to the breakdown of the polymer backbone. The DTG curve shows a sharp peak at 298°C for SPO1 and a shifted peak at 313°C for SPO3, indicating that the incorporation of PVA enhances the thermal stability of the starch matrix. This shift can be attributed to strong intermolecular hydrogen bonding between hydroxyl groups of starch and PVA, which restricts chain mobility and delays thermal decomposition. The degradation in this region is mainly due to the cleavage of C–C, C–O, and C–H bonds in the polymer chains. At this stage, a major weight loss of about 75% was observed.At higher temperatures, a further gradual weight loss is observed, with a DTG peak at428°Cfor SPO3, corresponding to the decomposition of carbonaceous residues (char degradation). The presence of this stage in the blend film suggests improved structural integrity and thermal resistance compared to the pure starch film.On comparison, the TGA curves indicate that the final decomposition temperatureof the blend film is higher than that of the pure starch film, confirming that the starch–PVA composite can withstand relatively higher temperatures.

Water Contact Angle Analysis

The surface wettability of the prepared films was evaluated through water contact angle (WCA) measurements, as presented in Fig. 8 and Fig. 9. The WCA provides direct insight into the hydrophilic or hydrophobic nature of the film surface, which is a critical parameter for food packaging applications.The pure starch film exhibited a very low contact angle of 15° to 16°, indicating its high hydrophilicity. This is mainly due to the presence of abundant hydroxyl groups in starch, which promote strong interaction with water and rapid spreading of the droplet.In comparison, the starch–PVA blend film showed a significantly higher contact angle of 66°, reflecting improved resistance to water, indicating starch-PVA film is more hydrophobic than the pure starch film. This enhancement can be attributed to intermolecular hydrogen bonding between starch and PVA, which reduces the availability of free hydrophilic groups and results in a more compact film structure.Thewater contact angle results clearly demonstrate that blending starch with PVA significantly improves the surface wettability characteristics, making the composite film more suitable for practical biodegradable packaging applications compared to pure starch films.

Thickness measurement

The thickness of the prepared films was measured to evaluate the influence of polymer composition on film formation. The pure starch film exhibited a thickness of 0.61 mm, whereas the starch–PVA composite film showed a slightly lower thickness of 0.53 mm.The higher thickness observed in the starch film can be attributed to its relatively poor structural organisation and limited intermolecular interactions, leading to a less compact matrix. In contrast, the incorporation of PVA resulted in improved polymer chain interaction and uniform film formation, producing a thinner and more compact structure.This reduction in thickness indicates enhanced film-forming ability and better molecular packing in the starch–PVA system. The observed variation is within an acceptable range and aligns with previous reports, where blending with PVA improves the structural integrity and uniformity of starch-based films [6-8].

Mechanical properties

The tensile strength of the prepared films was found to be 0.31 MPa for the starch film and 0.46 MPa for the starch–PVA composite film. A slight improvement in tensile strength was observed upon incorporation of PVA, indicating enhanced intermolecular interaction between starch and PVA chains.The relatively low tensile strength can be attributed to factors such as the presence of plasticizer, the moisture sensitivity of starch, and limited molecular packing within the film matrix.The incorporation of PVA appears to improve film uniformity and structural organisation, resulting in a marginal increase in strength.

Antimicrobial activity

Antibacterial activity

The prepared films were screened for their antibacterial activity against Gram-positive (*S. aureus*) and Gram-negative (*E. coli*) bacteria as shown in fig.10 a & b. The inhibitory effect was measured based on the clear zone surrounding the circular film disc. The antibacterial activity was studied using 'The Kirby-Bauer Method'. Both films showed fair antibacterial activity against both Gram-positive and Gram-negative bacteria. Antibiotic Amikacin was used as the control.The results of the antibacterial activity, expressed as the zone of inhibition (mm), are presented in Table 2.The starch film exhibited a zone of inhibition of 20 mm against both *S. aureus* and *E. coli*, indicating that the film possesses moderate antibacterial activity. The starch–PVA blendfilm showed inhibition zones of 15.4 mm against *S. aureus* and 16.5 mm against *E. coli*. These values suggest that the blended film also demonstrates noticeable antibacterial properties, although slightly lower than the pure starch film.The antibacterial effect observed in the films may be attributed to the presence of hydroxyl groups in starch and PVA, which can interact with microbial cell membranes and affect their metabolic activities. Additionally, the hydrophilic nature of the polymer matrix may facilitate interaction with bacterial cells, leading to inhibition of bacterial growth.The results indicate that both starch and starch–PVA films exhibit antibacterial activity against Gram-positive and Gram-negative bacteria, suggesting their potential application as biodegradable antimicrobial materials for food packaging and biomedical applications.

Antifungal activity

The prepared films were screened for their antifungal activity against *Penicillium notatum* and *Aspergillus niger* as shown in fig.11 a & b respectively. The inhibitory effect was measured based on clear zone surrounding the circular film disc. The antifungal activity was studied using 'The Kirby-Bauer Method'. Both the films showed fair antifungal activity against both the fungi. Antifungal agent Nystatin was used as the control.The results of the antifungal activity, expressed as the zone of inhibition (mm), are presented in Table 3.All the films exhibited good antifungal activity.The starch film exhibited inhibition zones of 13 mm against *Penicillium notatum* and 15 mm against *Aspergillus niger*, indicating moderate antifungal activity. In contrast, the starch–PVA blend film showed larger inhibition zones of 22 mm against *Penicillium notatum* and 16.4 mm against *Aspergillus niger*. The enhanced inhibition observed in the starch–PVA film suggests that the incorporation of PVA improves the antifungal effectiveness of the polymer matrix. The improved antifungal activity of the starch–PVA blend film may be attributed to the synergistic interaction between starch and PVA, which may enhance the surface properties and diffusion behavior of the film. The hydrophilic nature of the polymer network may facilitate interaction with fungal cell membranes, thereby inhibiting

fungal growth.These results indicate that the starch–PVA blend film exhibits better antifungal activity compared to the pure starch film, suggesting its potential application as a biodegradable antimicrobial film for food packaging and preservation.

CONCLUSION

In this study, biodegradable films based on starch and starch–PVA blends were successfully developed and systematically characterized to evaluate their structural, thermal, mechanical, morphological, and antimicrobial properties. FTIR analysis confirmed the presence of characteristic functional groups and indicated strong intermolecular hydrogen bonding between starch and PVA, demonstrating good compatibility within the blend system.The XRD patterns revealed that both films possess a semicrystalline structure, with a significant diffraction peak around $2\theta \approx 22°$, while the incorporation of PVA resulted in a slight reduction in crystallinity, suggesting increased amorphous character in the blend film. SEM analysis further supported these observations, where the pure starch film exhibited a rough and heterogeneous surface, whereas the starch–PVA blend film showed a smoother and more uniform morphology, indicating improved film homogeneity and structural integrity.

Thermal analysis using TGA demonstrated enhanced thermal stability of the blend film, with the degradation temperature increasing from 298°C for the starch film to 313°C for the starch–PVA film, confirming the stabilising effect of PVA incorporation. In addition, tensile strength measurements revealed a slight improvement in the mechanical properties of the blend film, which can be attributed to better intermolecular interactions and the formation of a stronger polymer network.The antimicrobial studies indicated that both films exhibit appreciable antibacterial and antifungal activities. Overall, the incorporation of PVA enhances the thermal stability, mechanical strength, surface morphology, and antifungal properties of starch-based films. Therefore, the developed starch–PVA blend films exhibit strong potential as biodegradable, eco-friendly materials for food packaging and related applications, where improved durability and antimicrobial functionality are essential.Thus, the bio-composite film represents a good alternative for use in food packaging. These films could be used to extend the shelf life of products such as bread and cheese, and to coat fruits such as oranges, mangoes, and strawberries, using only natural compounds with antimicrobial activity.

ABSTRACT

A Certified dominating set D of a spitted graph S(G) is said to be Independent Certified dominating set if the induced subgraph < D > has no edges. The Independent Certified domination number $i_{cer}[S(G)]$ of $S(G)$ is minimum cardinality of a Independent Certified domination set of $S(G)$ and is denoted by $i_{cer}[S(G)]$.

Keywords: : Domination, Splitted Graph, Certified Domination, independent domination, independent Certified domination

INTRODUCTION

[6] By a graph, we mean a finite simple and undirected graph. The vertex set and edge set of a graph G denoted are by V (G) and E(G) respectively. Let G be a graph. For each vertex v of a graph G , take a new vertex u . Join u to those vertices of G adjacent to v . The graph thus obtained is called the splitting graph of G . It is denoted by S(G) . For a graph G, the splitting graph S of G is obtained by adding a new vertex v corresponding to each vertex u of G such that N(u) = N(v) and it is denoted by S(G). The notions of splitting graphs were studied and investigated of many more authors for Example [3,4,5,9, 10, 11,12,]

Preliminaries

Definition: [7, 13]

A set D of vertices in a splitted graph $S(G) = (V, E)$ is called a dominating set if every vertex in $V - D$ is adjacent to some vertex in D. The *domination number γ [S(G)] of S(G) is minimum cardinality of a domination set of S(G).*

Definition:[1]

A dominating set D of a splitted graph S(G) = (V, E) is an independent dominating set if the induced subgraph < D > has no edges. The independent domination number i[S(G)] of a graph S(G) is the minimum cardinality of an independent dominating set.

Definition:[8]

A dominating set D of a spitted graph S(G) is said to be Certified dominating set if every vertex in D has either zero or atleast two neighbors in $V - D$. The Certified domination number $\gamma_{cer}[S(G)]$ of $S(G)$ is minimum cardinality of a Certified domination set of $S(G)$ and is denoted by $\gamma_{cer}[S(G)]$.

Definition:

A Certified dominating set D of a spitted graph S(G) is said to be Independent Certified dominating set if the induced subgraph < D > has no edges.The Independent Certified domination number $i_{cer}[S(G)]$ of $S(G)$ is minimum cardinality of a Independent Certified domination set of $S(G)$ and is denoted by $i_{cer}[S(G)]$.

i_{cer} – Main Results (Independent Certified domination number)

Theorem 4.1 Independent Certified domination number of the path splitted graph S(P_n),is

$$i_{cer}[S(P_n)] = \begin{cases} 2\left\lceil \frac{n}{3} \right\rceil & if \quad n \geq 5 \;\&\; n = 3 \\ P_n \; graph \; is \; not \; satisfy & if \;\; n = 2 \;\&\; n = 4 \end{cases}.$$

Proof.

Case (i)

Let S(P_n) be path splitted graph of P_n . Let V [S(P_n)] = {a_i , b_i: 1≤ i ≤n }, Let E[S(P_n)] = {($a_i a_{i+1}$) ∪ ($b_i a_{i+1}$) ∪ ($a_i b_{i+1}$) ; 1≤ i ≤ n-1}.

In P_n, if $n \equiv 0\ (mod\ 3)$ for each three of a_i, b_i vertices, vertex a_i is adjacent to $a_{i-1}, b_{i+1}, a_{i+1}, b_{i+1}$ where as b_i is adjacent to a_{i-1}, $a_{i+1}$for all $2 \leq i \leq n-1$

Also if $n \equiv 1\ (mod\ 3)$ for each three of a_i, b_i vertices, vertex a_i is adjacent to $a_{i-1}, b_{i+1}, a_{i+1}, b_{i+1}$ where as b_i is adjacent to a_{i-1}, $a_{i+1}$for all $2 \leq i \leq n-1$. Remaining the last four vertices $(a_i, b_i), (n-3 \leq i \leq n)$ are set, vertex a_{n-3} is adjacent to $a_{n-4}, b_{n-4}, a_{n-2}, b_{n-2}$ where as b_{n-3} is adjacent to a_{n-4}, a_{n-2} and also vertex a_{n-1} is adjacent to $a_{n-2}, b_{n-2}, a_n, b_n$ where as vertex b_{n-1} is adjacent to a_{n-2}, a_n.

Moreover if $n \equiv 2\ (mod\ 3)$ for each three of a_i, b_i vertices, vertex a_i is adjacent to $a_{i-1}, b_{i+1}, a_{i+1}, b_{i+1}$ where as b_i is adjacent to a_{i-1}, a_{i+1} for all $2 \leq i \leq n-1$. If Remaining the last two vertices $(a_i, b_i), (n-1 \leq i \leq n)$ are set, vertex a_{n-1} is adjacent to $a_{n-2}, b_{n-2}, a_n, b_n$ where as b_{n-1} is adjacent to a_{n-2}, a_n by definition a_i and b_i are not adjacent and vertices satisfy the independent certified dominating set condition.

Hence, $i_{cer}[S(P_n)] = 2\left\lceil \frac{n}{3} \right\rceil$

For example $i_{cer}[S(P_6)]$ = {a_2 , a_3, a_5 , b_5} = 4 as shown in the figure 1.

Remark. This S(P_2) graph

In S(P_2) is a graph, let V[S(P_2)]= {a_1, b_1, a_2, b_2}

a_1, b_1 are vertices set is an independent domination. In which a_1 vertex of $degree \geq 2$. But every verticesb_1 of degree is 1. A vertex with one degree is adjacent to only one neighbor. But according to the independent certified domination condition, there should be zero or at least two neighbors. ThereforeS(P_2) graph is an independent certified domination not satisfied.

Remark. This S(P_4) graph

In S(P_2) is a graph , let V[S(P_4)]= $\{a_1, a_2, a_3, a_4, b_1, b_2, b_3, b_4\}$
a_2, b_2, a_4, b_4 are vertices set is an independent domination. In which a_2, b_2, a_4 vertex of $degree \geq 2$. But every vertices b_4 of degree is 1. A vertex with one degree is adjacent to only one neighbor. But according to the independent certified domination condition, there should be zero or at least two neighbors. ThereforeS(P_2) graph is an independent certified domination not satisfied.

Theorem 4.2 Independent Certified domination number of the H splitted graph S(H_n)],is

$i_{cer}[S(H_n)] = 4\left\lceil\frac{n}{3}\right\rceil \quad if\ n\ is\ even$
Proof.

Let S(H_n) be splitted graph of H_n .when $n\ is\ even$
Let V [S(H_n)] = $\{a_i, b_i, a_i', b_i' : 1 \leq i \leq n\}$,
Let E[S(H_n)] = $\{(a_i a_{i+1}) \cup (b_i a_{i+1}) \cup (a_i b_{i+1}) \cup (a_{\frac{n}{2}} a'_{\frac{n+1}{2}}) \cup (a_{\frac{n}{2}} b'_{\frac{n+1}{2}}) \cup (b_{\frac{n}{2}} a'_{\frac{n+1}{2}}) \cup (a_i' a_{i+1}') \cup (b_i' a_{i+1}') \cup (a_i' b_{i+1}');\ 1 \leq i \leq n\text{-}1\}$.
In H_n, for each three of a_i, b_i vertices, vertex a_{i+1} is adjacent to $a_{i+2}, b_{i+2}, a_i, b_i$ where as b_{i+1} is adjacent to a_i, a_{i+2} .If remaining last two vertices (a_i, b_i) ($n-1 \leq i \leq n$) are set, vertex a_{n-1} is adjacent to $a_{n-2}, b_{n-2}, a_n, b_n$ where as vertex b_{n-1} is adjacent to a_{n-2}, a_n.. If may be remaining the last four vertices (a_i, b_i) , ($n-3 \leq i \leq n$) are set, vertex a_{n-3} is adjacent to $a_{n-4}, b_{n-4}, a_{n-2}, b_{n-2}$ where as b_{n-3} is adjacent to a_{n-4}, a_{n-2} and also vertex a_{n-1} is adjacent to $a_{n-2}, b_{n-2}, a_n, b_n$ where as vertex b_{n-1} is adjacent to a_{n-2}, a_n by definition a_{i+1} and b_{i+1} are not adjacent and vertices satisfy the independent certified dominating set condition

Next part for each three of a_i', b_i' vertices, vertex a_{i+1}' is adjacent to $a_{i+2}', b_{i+2}', a_i', b_i'$ where as b_{i+2}' is adjacent to a_{i+2}', a_i' . If the last two vertices a_i', b_i' $(n-1 \leq i \leq n)$, are set, vertex $a_{n-1}'$is adjacent to $a_{n-2}', b_{n-2}', a_n', b_n'$, where as b_{n-1}' is adjacent to a_{n-2}', a_n' .

If may be remaining the last four vertices a_i', b_i' $(n-3 \leq i \leq n)$, are set, vertex $a_{n-3}'$is adjacent to $a_{n-2}', b_{n-2}', a_{n-4}', b_{n-4}'$, where as b_{n-3}' is adjacent to a_{n-2}', a_{n-4}' . and also vertex $a_{n-1}'$is adjacent to $a_{n-2}', b_{n-2}', a_n', b_n'$, where as b_{n-1}' is adjacent to a_{n-2}', a_n' by definition $a_{i+1}' and\ b_{i+1}'$ are not adjacent and vertices satisfy the independent certified dominating set condition
Hence

$$i_{cer}[S(H_n)] = 4\left\lceil\frac{n}{3}\right\rceil$$

For example $i_{cer}[S(H_{10})]$ = $\{a_2, b_2, a_5, b_5, a_7, b_7, a_9, b_9, a_2', b_2', a_5', b_5', a_7', b_7', a_9', b_9'\}$= 16 as shown in the figure 2.

Theorem 4.3 independent Certified domination number of the H splitted graph S(H_n)],is

$i_{cer}[S(H_n)] = \frac{4}{3}(n+1) \quad if\ n \equiv 2(mod\ 3)$ and n is odd
Proof.
Let S(H_n) be splitted graph of H_n and $if\ n \equiv 2(mod\ 3)$ and n is odd
Let V [S(H_n)] = $\{a_i, b_i, a_i', b_i' : 1 \leq i \leq n\}$,

Let E[S(H_n)] = {(a_ia_{i+1}) ∪ (b_ia_{i+1}) ∪ (a_ib_{i+1}) ∪ ($a_{\frac{n+1}{2}}a'_{\frac{n+1}{2}}$) ∪ ($a_{\frac{n+1}{2}}b'_{\frac{n+1}{2}}$) ∪ ($b_{\frac{n+1}{2}}a'_{\frac{n+1}{2}}$)∪($a'_ia'_{i+1}$)∪ ($b'_ia'_{i+1}$) ∪ ($a'_ib'_{i+1}$); 1≤ i ≤ n-1}.In H_n, for each three of a_i, b_i vertices, vertex a_{i+1} is adjacent to $a_{i+2}, b_{i+2}, a_i, b_i$ where as b_{i+1} is adjacent to a_i, a_{i+2} .If remaining last two vertices (a_i, b_i) ($n-1 \leq$ i $\leq n$) are set, vertex a_{n-1} is adjacent to $a_{n-2}, b_{n-2}, a_n, b_n$ where as vertex b_{n-1} is adjacent to a_{n-2}, a_n. by definition a_{i+1} and b_{i+1} are not adjacent and vertices satisfy the independent certified dominating set condition

Next part for each three of a'_i, b'_i vertices, vertex a'_{i+1} is adjacent to $a'_{i+2}, b'_{i+2}, a'_i, b'_i$ where as b'_{i+1} is adjacent to a'_i, a'_{i+2}. If the remaining last two vertices a'_i, b'_i $(n-1 \leq i \leq n)$, are set, vertex $a'_{n-1}$is adjacent to $a'_n, b'_n, a'_{n-2}, b'_{n-2}$, where as b'_{n-1} is adjacent to a'_{n-2}, a'_n by definition a'_{i+1}*and* b'_{i+1} are not adjacent and vertices satisfy the independent certified dominating set condition
Hence

$$i_{cer}[S(H_n)] = \frac{4}{3}(n+1)$$

For example $i_{cer}[S(H_5)]$ ={$a_2, b_2, a_4, b_4, a'_2, b'_2, a'_4, b'_4$,}= 8 as shown in the figure 3.

Theorem 4.4. independent Certified domination number of the H splitted graph S(H_n)],is

$i_{cer}[S(H_n)] = \frac{4n}{3} + 2$ $if\ n \equiv 0(mod\ 3)$ and n is odd

Proof.

Let S(H_n) be splitted graph of H_n and $if\ n \equiv 0\ (mod\ 3)$ and n is odd
Let V [S(H_n)] = {a_i, b_i, a'_i, b'_i : 1≤ i ≤n },
Let E[S(H_n)] = {(a_ia_{i+1}) ∪ (b_ia_{i+1}) ∪ (a_ib_{i+1}) ∪ ($a_{\frac{n+1}{2}}a'_{\frac{n+1}{2}}$) ∪ ($a_{\frac{n+1}{2}}b'_{\frac{n+1}{2}}$) ∪ ($b_{\frac{n+1}{2}}a'_{\frac{n+1}{2}}$)∪($a'_ia'_{i+1}$)∪ ($b'_ia'_{i+1}$) ∪ ($a'_ib'_{i+1}$); 1≤ i ≤n-1}.

In H_n, for each three of a_i, b_i vertices, vertex a_{i+1} is adjacent to $a_{i+2}, b_{i+2}, a_i, b_i$ where as b_{i+1} is adjacent to a_i, a_{i+2} by definition a_{i+1} and b_{i+1} are not adjacent and vertices satisfy the independent certified dominating set condition. Next part for each three of a'_i, b'_i vertices, vertex a'_{i+1} is adjacent to $a'_{i+2}, b'_{i+2}, a'_i, b'_i$ where as b'_{i+1} is adjacent to a'_i, a'_{i+2}.by definition a'_{i+1}*and* b'_{i+1} are not adjacent and vertices satisfy the independent certified dominating set condition
Hence

$$i_{cer}[S(H_n)] = \frac{4n}{3} + 2.$$

For example $i_{cer}[S(H_9)]$ ={$a_2, b_2, a_5, b_5, a_8, b_8, a'_2, b'_2, a'_4, b'_4, a'_6, b'_6, a'_8, b'_8$}= 14 as shown in the figure 4

Theorem 4.5 independent Certified domination number of the H splitted graph S(H_n)],is

$$i_{cer}[S(H_n)] = \begin{cases} \frac{4}{3}(n+2) & if\ n \equiv 1(mod\ 3)\ \&\ n > 7\ and\ n\ is\ odd \\ 10 & if\ n = 7 \end{cases}$$

Proof.
Case (i) Let S(H_n) be splitted graph of H_n and $if\ n \equiv 1(mod\ 3)\ \&\ n > 7\ and\ n\ is\ odd$

Let V [S(H_n)] = {a_i, b_i, a'_i, b'_i : 1≤ i ≤n },

Let E[S(H_n)] = {(a_ia_{i+1}) ∪ (b_ia_{i+1}) ∪ (a_ib_{i+1}) ∪ ($a_{\frac{n+1}{2}}a'_{\frac{n+1}{2}}$) ∪ ($a_{\frac{n+1}{2}}b'_{\frac{n+1}{2}}$) ∪ ($b_{\frac{n+1}{2}}a'_{\frac{n+1}{2}}$)∪($a'_ia'_{i+1}$)∪ ($b'_ia'_{i+1}$) ∪ ($a'_ib'_{i+1}$); 1≤ i ≤ n-1}.

In H_n, for each three of a_i, b_i vertices, vertex a_{i+1} is adjacent to $a_{i+2}, b_{i+2}, a_i, b_i$ where as b_{i+1} is adjacent to a_i, a_{i+2} . If remaining last four vertices (a_i, b_i) ($n-3 \leq$ i $\leq n$) are set, vertex a_{n-3} is adjacent to

$a_{n-2}, b_{n-2}, a_{n-4}, b_{n-4}$ where as vertex b_{n-3} is adjacent to a_{n-2}, a_n. And also vertex a_{n-1} is adjacent to $a_n, b_n, a_{n-2}, b_{n-2}$ where as vertex b_{n-1} is adjacent to a_{n-2}, a_n. by definition a_{i+1} and b_{i+1} are not adjacent and vertices satisfy the independent certified dominating set condition.

Next part for each three of a'_i, b'_i vertices, vertex a'_{i+1} is adjacent to $a'_{i+2}, b'_{i+2}, a'_i, b'_i$ where as b'_{i+1} is adjacent to a'_i, a'_{i+2}. If the remaining last four vertices a'_i, b'_i $(n-3 \leq i \leq n)$, are set, vertex $a'_{n-3}$is adjacent to $a'_{n-4}, b'_{n-4}, a'_{n-2}, b'_{n-2}$, where as b'_{n-3} is adjacent to a'_{n-2}, a'_{n-4} and also vertex $a'_{n-1}$is adjacent to $a'_n, b'_n, a'_{n-2}, b'_{n-2}$, where as b'_{n-1} is adjacent to a'_{n-2}, a'_n by definition $a'_{i+1} and\ b'_{i+1}$ are not adjacent and vertices satisfy the independent certified dominating set condition.
Hence

$$i_{cer}[S(H_n)] = \frac{4}{3}(n+2)$$

For example $i_{cer}[S(H_{13})]$ ={$a_2, b_2, a_5, b_5, a_8, b_8, a_{10}, b_{10}, a_{12}, b_{12}, a'_2, b'_2, a'_5, b'_5, a'_8, b'_8, a'_{10}, b'_{10}, a'_{12}, b'_{12}$}= 20 as shown in the figure 5.

Case (ii) Let S(H_n) be splitted graph of H_n and $if\ n = 7$
Let V [S(H_n)] = {a_i, b_i, a'_i, b'_i : 1≤ i ≤n },

Let E[S(H_n)] = {$(a_i a_{i+1}) \cup (b_i a_{i+1}) \cup (a_i b_{i+1}) \cup (a_{\frac{n+1}{2}} a'_{\frac{n+1}{2}}) \cup (a_{\frac{n+1}{2}} b'_{\frac{n+1}{2}}) \cup (b_{\frac{n+1}{2}} a'_{\frac{n+1}{2}}) \cup (a'_i a'_{i+1}) \cup (b'_i a'_{i+1}) \cup (a'_i b'_{i+1})$; 1≤ i ≤ n-1}.

In H_n, vertex a_2 is adjacent to a_3, b_3, a_1, b_1 where as b_2 is adjacent to a_1, a_3. If remaining last four vertices (a_i, b_i) ($4 \leq$ i ≤ 7) are set, vertex a_4 is adjacent to $a_5, b_5, a_3, b_3, a'_4, a'_5$ where as vertex b_4 is adjacent to a_5, a_3, a'_4. And also, vertex a_6 is adjacent to a_7, b_7, a_5, b_5 where as vertex b_6 is adjacent to a_5, a_7. by definition a_{i+1} and b_{i+1} are not adjacent and vertices satisfy the independent certified dominating set condition. Next part , vertex a'_2 is adjacent to a'_3, b'_3, a'_1, b'_1 where as b'_2 is adjacent to a'_1, a'_3. If the remaining last four vertices a'_i, b'_i $(4 \leq i \leq 7)$, are set, vertex $a'_6$is adjacent to a'_5, b'_5, a'_7, b'_7, where as b'_6 is adjacent to a'_5, a'_7.,
For example $i_{cer}[S(H_7)]$ ={$a_2, b_2, a_4, b_4, a_6, b_6, a'_2, b'_2, a'_6, b'_6$,}= 10 as shown in the figure 6.

Remark.
Case(i): S(H_2) graph
In S(H_2) is a graph, let V[S(H_2)]= {$a_1, a_2, b_1, b_2, a'_1, a'_2, b'_1, b'_2$}
a_1, b_1, a'_1, b'_1 are vertices set is an independent domination. In which a_1, a'_1 vertex of $degree \geq$ two. But every vertices b_1, b'_1 of degree is one. A vertex with one degree is adjacent to only one neighbor. But according to the independent certified domination condition, there should be zero or at least two neighbors. Therefore S(H_2) graph is an independent certified domination not satisfied.

Case(ii) S(H_3) and S(H_4) graph
The same process in this case (i).
Remark. This $S(P_n^+)$ graph $b_1, b_2, b_3, \ldots\ldots b_n, b'_1, b'_2, b'_3, \ldots\ldots, b'_n$ are vertices set is independent domination. In which $b_1\ b_2, b_3, \ldots\ldots, b_n$ every vertices of $degree \geq 2$. But every vertices $b'_1, b'_2, b'_3, \ldots\ldots, b'_n$ of degree is 1. A vertex with one degree is adjacent to only one neighbor. But according to the independent certified domination condition, there should be zero or at least two neighbors. Therefore $S(P_n^+)$ graph is an independent certified domination not satisfied.

Remark. This $S(P_n o 2K_1)$ graph $b_1, b_2, b_3, \ldots\ldots b_n, b_{11}, b_{12}, b_{21}, b_{22}, b_{31}, b_{32} \ldots\ldots\ldots\ldots\ldots b_{n1} b_{n2}$ are vertices set is independent domination.
In which $b_1\ b_2, b_3, \ldots\ldots, b_n$every vertices of $degree \geq 2$. But every vertices $b_{11}, b_{12}, b_{21}, b_{22}, b_{31}, b_{32} \ldots\ldots\ldots\ldots\ldots b_{n1} b_{n2}$ of degree is 1. A vertex with one degree is adjacent to only one neighbor. But according to the independent certified

domination condition, there should be zero or at least two neighbors. Therefore $S(P_n o 2K_1)$ graph is an independent certified domination not satisfied.
(ie) The same above the process $S(P_n oNK_1)$ graph is an independent certified domination not satisfied.

Theorem 3.10 independent Certified domination number of the cycle splitted graph S(C_n),is
$i_{cer}[S(C_n)] = 2\left\lceil\frac{n}{3}\right\rceil$ *for all* $n \geq 3$.
Proof.
Let S(C_n) be cycle splitted graph of C_n .
Let V [S(C_n)] = {a_i , b_i: 1≤ i ≤n }, Let E[S(C_n)] = [{($a_i a_{i+1}$) ∪ ($b_i a_{i+1}$)∪ ($a_i b_{i+1}$) ; 1≤ i ≤ n-1}]∪ [($b_1 a_n$) ∪ ($b_n a_1$) ∪ ($a_1 a_n$)].
In cycle C_n, for each three of a_i , b_i vertices, vertex a_{i+1} is adjacent to a_{i+2}, b_{i+2}, a_i, b_i where as b_{i+1} is adjacent to a_i, a_{i+2} and if the last remaining two vertices $(a_i , b_i) , (n-1 \leq i \leq n)$ are set, vertex a_n is adjacent to a_1, b_1, a_{n-1} where as b_n is adjacent to a_1, a_{n-1} if may be the last remaining one (end) vertices (a_i , b_i) , are set, vertex a_n is adjacent to $a_{n-1}, b_{n-1}, a_1, b_1$ where as b_n is adjacent to a_{n-1}, a_1
by definition a_{i+1} and a_{i+2} are adjacent $1 \leq i \leq n-2$, and also a_n *and* b_n are adjacent in each vertices satisfy the certified dominating set condition.
Hence, $i_{cer}[S(C_n)] = 2\left\lceil\frac{n}{3}\right\rceil$
For example $i_{cer}[S(C_5)]$ = {a_2 , b_2, a_5 , b_5 } = 4 as shown in the figure 7.

ABSTRACT

Let G be a connected and simple graph. A subset of vertices that is both independent and dominating is known as an independent dominating set. In this work, we apply fixed point concept in independent dominating sets. By defining appropriate operators, identified the fixed-point independent domination number for several standard graphs and wheel-related graphs

Keywords: Domination, Fixed-point Domination, independent domination, Fixed-point Independent Domination

INTRODUCTION

Domination in graphs is a key concept in graph theory that has various applications in communication networks, resource allocation, and network design. Foundational ideas of graphs are outlined by Balakrishnan and Ranganathan [1]. Bounds on domination numbers were explored by Brigham and Dutton [4]. Haynes et al. [14] , Sampathkumar and Walikar [20] and [9] Das A contributed to the understanding of advanced and connected domination. Shulda and Singh [21] categorized various domination types. In [13], a subset D of the vertex set of graph G is called a dominating set if every vertex not in D is adjacent to at least one vertex in D. The domination number, $\gamma(G)$, is the minimum number of vertices required to form such a set.

Starting with connected, undirected, finite graph without loops and multiple edges. An independent set is a group of vertices where no two vertices are directly connected by an edge.In a graph G, a subset of vertices D is termed an independent dominating set if it satisfies the conditions of being both an independent set and a dominating set. The minimum cardinality of such set is known as independent domination number, represented by$i(G)$. In 1962, Berge [2] and Ore [18] formalized the theory of independent domination. Later, Cockayne [5] and Hedetniemi [6] introduced the notation $i(G)$ to represent the independent domination number in 1974 and 1977. Significant progress has been made on independent dominating sets, especially in cubic and regular graphs, through the work of Goddard et al. [15], Kostochka [16], and Lam et al. [17]. Favaron [10] initiated the analysis of sharp upper bounds for the independent domination number in relation to the graph's order n and minimum degree δ. [12] Haviland (2007) extended this work. For triangle-free graphs, Shiu et al. [19] established upper bounds and characterized extremal graphs that attain them. Additionally, Cockayne et al. [7] examined how the product of the independent domination numbers of a graph and its complement are related. A comprehensive overview of independent domination, including recent findings, was provided by Goddard and Henning [8]. Vaidya and Pandit [22] extended the study to include domination in wheel-related graphs.

This paper focuses on the study of fixed-point independent domination in graphs.

Fixed Point Independent Domination

In any simple connected graph G, a **fixed-point domination set** is one domination set in where a specific vertex is fixed [11]. That is to say, for a fixed vertex v in G, a domination set which contains this v is called a fixed-point domination set with respect to the fixed vertex v, indicated by using $D_f(v)$. Minimum size of fixed-point domination set for any fixed vertex in G is named as the fixed-point domination number. It is denoted by the symbol $\gamma_f(v)$. For any simple graph G, a **fixed-point independent domination set** is an independent domination set, in which a vertex is fixed. Let v be the fixed vertex then the fixed-point independent domination set is represented by $ID_f(v)$. The minimum size of a fixed-point independent domination set which contains v is called fixed Point independent domination number $i_f(v)$.
For any vertex v, if $i_f(v)$ is same then $i_f(v)$=$i_f(G)$.

The following propositions can be observed directly

Proposition 1: Let v represent a full vertex of G, then $i_f(v) = 1$.
This leads to
Proposition 2: For a complete graph K_n , $i_f(Kn) = 1$
Proposition 3: For a fixed vertex v, If $d(v) = n - 2$, then $i_f(v) = 2$ in any graph
Proposition 4:

For the path P_n, $i_f(v) = \begin{cases} \frac{n}{2} & if\ n\ is\ even\ and\ for\ any\ fixed\ vertex \\ \frac{n+1}{2} & if\ n\ is\ odd\ and\ the fixed\ vertex\ is\ pendent\ vertex \\ \frac{n-1}{2} & Otherwise \end{cases}$

Proposition 5: For cycle c_n , $i_f(v) = \left\lceil \frac{n}{3} \right\rceil$
Proposition 6: If the graph $k_{p,q}$ is complete bipartite then

$$i_f(v) = \begin{cases} \min(p,q) & if\ d(v) = \max(p,q) \\ \max(p,q) & if\ d(v) = \min(p,q) \end{cases}$$

Proposition 7: Consider k-partite graph$K_{m_1,m_2,m_3,\ldots\ldots,m_k}$.

$$i_f(v) = n_i, \quad \text{if } \deg(v) = m_1 + m_2 + m_3 + \cdots m_{i-1} + m_{i+1} \ldots + m_k$$

Fixed Point Independent Domination For Some Wheel Related Graphs

Definition

The wheel W_n is formed by taking the joint of the cycle C_{n-1} and the complete graph K_1. n the graph structure, the vertex from K_1 that connects to each vertex of the cycle is called the apex, and the cycle's vertices are known as the rim

Proposition 8: For the wheel W_n, $i_{f(v)} = \begin{cases} 1 & if\ v\ is\ apex \\ \left\lceil \frac{n-1}{3} \right\rceil & otherwise \end{cases}$

In Figure 1, for the fixed vertex A, the fixed-point independent domination set is {A} and fixed-point independent domination number $i_f(A) = 1$, In Figure 2, for the fixed vertex B, the fixed-point independent domination set is {B, E} and fixed-point independent domination number $i_f(B) = 2$

Definition

A helm H_n is created by appending a pendant vertex to every rim vertex of the wheel W_n. Clearly the order of H_n is $2n-1$. In H_n if the fixed vertex v is apex, then apex together with pendent vertices will give an independent domination set. If v is on the rim then together with the pendent vertices which are not adjacent to it will form an independent domination set. If v is a pendent vertex together with a non-adjacent vertex in rim and the pendent vertex not adjacent to them will form an independent domination set.

Theorem 1: In H_n, $i_f(v) = \begin{cases} n & if\ v\ is\ apex \\ n-1 & Otherwise \end{cases}$

For Example, consider H_6,

In Figure 3, for the fixed vertex A, the fixed-point independent domination set is {A, G, H, I, J, K} and fixed-point independent domination number with respect to A is 6., In Figure 4, for the fixed vertex E, the fixed-point independent domination set is {E, I, J, K, G} and fixed-point independent domination number with respect to E is 5.

Definition

The closed helm is the graph which is produced by linking every pendant vertex to create a cycle from a helm, denoted by CH_n

Proposition 9: For closed helm CH_n, $i_f(v) = \begin{cases} \left\lceil \frac{n+2}{3} \right\rceil & if\ the\ fixed\ vertex\ v\ is\ apex \\ \left\lceil \frac{n+2}{3} \right\rceil + 1 & Otherwise \end{cases}$

In Figure 5, for the fixed vertex A, the fixed-point independent domination set is {A, H, J} and fixed-point independent domination number with respect to A is 3 , In Figure 6, for the fixed vertex C, the fixed-point independent domination set is {C, E, G, I} and fixed-point independent domination number with respect to C is 4.

Definition

A gear graph G_n is generated by modifying the cycle of a wheel graph $W_n$through the insertion of one vertex between each of the cycle's two adjacent vertices. Clearly, gear G_n has $2n-1$ vertices.

Proposition 10:

For a gear graph G_n,$i_f(v) = \begin{cases} n & if\ the\ fixed\ vertex\ v\ is\ apex \\ \left\lceil \frac{2(n-1)}{3} \right\rceil & otherwise \end{cases}$

In Figure 7, for the fixed vertex A, the fixed-point independent domination set is {A, G, I, K, M, O, Q, C, E,} and fixed-point independent domination number with respect to A is 9 , In Figure 8, for the fixed vertex C or F, the fixed-point independent domination set is {C, F, I, L, N, P} and fixed-point independent domination number with respect to C or F is 6.

Theorem:2

For any $n, k,\ n \geq 2,\ 1 \leq k \leq n-1$ there is a graph G of order n exists such that fixed-point domination number $i_f(v) = k$ for some vertex v.

Illustration

For, $n = 7, k = 1$
Consider$K_{1,6}$, Clearly $i_f(v) = 1$ if $d(v) = 6$
For, $n = 7, k = 2$
Consider $K_{2,5}$, Clearly$i_f(v) = 2$ if $d(v) = 5$
For, $n = 7, k = 3$
Consider$K_{3,4}$, Clearly$i_f(v) = 3$ if $d(v) = 4$
For, $n = 7, k = 4$
Consider $K_{4,3}$, Clearly$i_f(v) = 4$ if $d(v) = 3$
For, $n = 7, k = 5$
Consider$K_{5,2}$, Clearly$i_f(v) = 5$ if $d(v) = 2$
For, $n = 7, k = 6$
Consider$K_{6,1}$, Clearly$i_f(v) = 6$ if $d(v) = 1$

Theorem:3

Let the graph G contains n vertices and maximum degreeΔ. Let v be any fixed vertex, then

$$\left\lceil \frac{n}{\Delta + 1} \right\rceil \leq i_f(v) \leq n - 1$$

Proof:

In [3], it has been proved that, for a graph G consisting of n vertices and maximum degree Δ,

$$\left\lceil \frac{n}{\Delta + 1} \right\rceil \leq i(G)$$

Clearly $i(G) \leq i_f(v)$. Hence$\left\lceil \frac{n}{\Delta+1} \right\rceil \leq i_f(v)$.

For the upper bound, it is attained by the graph $K_{1,n-1}$ if the fixed vertex is a pendent vertex.

Definition

The web graph is constructed by forming a cycle from helm graph's pendant vertices and then attaching an additional pendant edge to every vertex in this newly formed outer cycleA generalized web graph, denoted $W(l, r)$, is formed by l cycles each of order r, Consider the graph W (2, r), Since it has r pendent vertices, those vertices must be either belong to domination set or their adjacent vertices must be in the domination set. Thus, the domination set must have at least r vertices. If the fixed vertex is a pendent vertex or a vertex in the outer circle or the center of the wheel then the center vertex and a vertex in the outer circle together with the pendent vertices which are non-adjacent to them will give an independent domination set with $r + 1$ number of vertices. If the fixed vertex is a vertex in the inner circle, then $\left\lfloor \frac{r}{3} \right\rfloor$ with suitable number of vertices in the outer circle together with the pendent vertices which are non adjacent to them will give an independent domination set with r+$\left\lfloor \frac{r}{3} \right\rfloor$ number of vertices. Thus

Theorem:4

For the web graph $W(2, r)$, $r \geq 3$

$$i_f(v) = \begin{cases} r + \left\lfloor \frac{r}{3} \right\rfloor & if\ the\ fixed\ vertex\ v\ on\ the\ inner\ circle \\ r + 1 & otherwise \end{cases}$$

Illustration: Consider $W(2, 6)$)

In Figure 9, for the fixed vertex F, the fixed-point independent domination set is {C, F, H, K, S, N, P, Q} and fixed-point independent domination number with respect to F is 8., In Figure 10, for the fixed vertex A, the fixed-point independent domination set is {A, H, P, Q, R, S, N} and fixed-point independent domination number with respect to A is 7

CONCLUSION

In this work, we explored independent domination sets in graphs by applying the concept of fixed points. Bounds for the fixed-point independent dominating numbers were identified. We also determined the fixed-point independent domination number for several standard graphs and wheel-related graphs.

ABSTRACT

Firms contemplating entry into a market must anticipate incumbent reactions and rival behaviors across pricing, capacity, advertising, and channel moves. This paper presents a practical framework that operationalizes game-theoretic models—static (Cournot, Bertrand), sequential (Stackelberg, entry games), and incomplete-information (signaling, reputation)—to predict competitor actions and guide market entry strategy design. We (i) translate canonical models into implementable steps for managerial analytics, (ii) integrate Bayesian updating and quantal response equilibrium (QRE) for empirical prediction, (iii) propose a data schema and estimation workflow, and (iv) illustrate with a stylized market entry case. We conclude with robustness procedures, implementation roadmaps, and compliance safeguards (notably antitrust).

Keywords: Game theory, market entry, competitor reaction, signaling, quantal response equilibrium, Stackelberg, Cournot, Bertrand, industrial organization

INTRODUCTION

Entry timing and mode decisions hinge on credible expectations about competitors. Game theory provides the micro-foundations to model these strategic interdependencies. Since the foundational work of von Neumann and Morgenstern (1944) and Nash (1951), game theory has evolved into a central methodology for analyzing oligopolistic markets, where the interdependence of firms' actions determines equilibrium outcomes. Market entry is inherently a high-stakes decision involving uncertainties in demand, cost structures, and competitor responses. The entrant must

anticipate these possible reactions and develop strategies—pricing, capacity planning, partnership structures, or timing—that optimize expected payoffs under uncertainty. The primary objective of this study is to propose a comprehensive implementation framework for applying game theory to predict competitor behavior and to develop robust, data-driven market entry strategies. Specifically, the paper identifies suitable game-theoretic models for various market structures, develops data-driven modeling processes, and illustrates equilibrium outcomes for actionable strategies.

Theoretical Background

Static complete-information games

- **Cournot (quantities):** Simultaneous choice of quantities q_i; best responses arise from marginal revenue = marginal cost; predicts softer competition with fewer firms and capacity constraints.
- **Bertrand (prices):** Simultaneous price setting; with homogeneous goods and no capacity limits, price tends to marginal cost; product differentiation or capacity limits relax this.
- **Differentiated competition:** Additive utility with cross-price elasticities maps to Bertrand-Nash in differentiated products.

Sequential-move games

- Stackelberg leadership: One firm (incumbent) moves first (capacity, price commitment); followers respond along best-response functions.
- Entry deterrence/Accommodation: Incumbent may over-invest in capacity, exclusive contracts, or advertising to shift entrants' payoffs and deter entry.

Incomplete information: signaling & reputation

- Signaling games: Incumbent type $\theta \in$ {"tough","soft"}; actions like introductory pricing or capacity signals convey information; entrants update beliefs $\mu(\theta|a)$via Bayes' rule.
- Reputation in repeated games: Trigger strategies (grim, tit-for-tat) can sustain soft competition or aggressive defense depending on discount factors.

Empirical equilibrium concepts

- Pure/Mixed Nash: Useful benchmark when data are clean and payoffs well-identified.
- Quantal Response Equilibrium (QRE): Players choose higher-payoff actions with higher probability, parameterized by rationality λ; accommodates noise and bounded rationality.
- Level-k/Cognitive hierarchy: Heterogeneous depth of strategic reasoning; often predictive in entry timing and bidding contexts.

Conceptual Framework

Data and Measurement

Core data needs

- Demand: prices, quantities, elasticities, product attributes, channel mix.
- Costs: variable costs, capacity, learning curves, procurement terms.
- Rival actions: price changes, promo calendar, capacity announcements, partnerships, legal/contract constraints.
- Market rules: regulation, switching costs, exclusivity, platform policies.

Modeling and Estimation

Market structure identification

- Test for price vs quantity competition via reduced-form regressions (e.g., price-cost margins vs. shares) or structural demand estimation (e.g., logit/BLP) to choose Bertrand vsCournot.
- Detect leadership (Stackelberg) using Granger-type lead–lag or event-study responses.

Static competition

Bertrand-Nash with differentiation

Demand Q_i (p)=a_i-b_ip_i+∑_(j≠i) d_ijp_j.

Profit π_i=(p_i-c_i)Q_i (p).

FOC yields prices p=⟦(Ω+Δ)⟧^(-1) (a+Cb)(matrix notation), where Ωstacks own/cross slopes, Δembeds ownership. Estimated elasticities feed Ω.

Cournot

Inverse demand P(Q)=α-βQ.

Best response q_i=(α-c_i-β∑_(j≠i) q_j)/2β.

Sequential competition (Stackelberg)

Leader chooses x(capacity, price commitment). Follower best response y^* (x).

Leader solves ⟦max ⟧_x π_L (x,y^* (x)). Implement via backward induction.

Entry games

Binary entry E_i∈{0,1}with profits π_i (E)=X_i β-γ·"rival presence"+ε_i.

Estimate β,γvia moment inequalities or maximum likelihood with equilibrium selection rules. Use instrumental variables for correlated shocks.

Signaling model for deterrence

Types θ∈{T,S}. Incumbent chooses signal s∈{"invest","not"}(e.g., capacity). Entrant updates belief μ(θ|s).

Entrant enters if E_μ [π_E|s]≥0.

Calibrate priors from history; estimate signal costs k(θ).

Noisy behavior: QRE

Probability of action $a$for player i: $P_i(a) = \frac{\exp(\lambda \cdot U_i(a))}{\sum_{a'} \exp(\lambda \cdot U_i(a'))}$,

Type equation here.λ is estimated by maximizing observed-action likelihood across historical episodes.

Stylized Case Illustration

Market : Two incumbents (A, B) sell differentiated products; a potential entrant (E) considers entry with a niche variant.

Demand (own/cross price slopes)

$b_i = 1.2$, $d_{ij} = 0.3$for $i \neq j$. Variable cost $c_A = c_B = 6$, $c_E = 7$.

Predict incumbent pricing reaction (Bertrand-Nash)

- Pre-entry equilibrium prices solve FOCs; post-entry, include product E with higher cost and moderate differentiation (cross-slopes 0.25 with A/B).
- Simulation yields: expected price cuts of incumbents ≈ 4–6% upon entry; entrant feasible margin ≈ 18% at launch price $p_E \approx 11$, given cost 7 and predicted quantity from demand system.

Capacity commitment by entrant (Stackelberg with capacity)

- ❖ Entrant commits to K_E. Incumbent best response is deeper promo only if K_Eexceeds threshold K^*where incumbents' marginal revenue slopes steepen.
- ❖ Optimization shows optimal K_Eat 70–80% of anticipated steady-state demand to avoid provoking a price war while signaling credible presence.

Signaling to avoid early retaliation

- Low-cost signal: selective regional launch + B2B partnerships rather than national ad blitz. Posterior belief shift reduces probability of "aggressive defense" by incumbents from 0.55 → 0.35 in a logit-QRE fit, improving first-year NPV by ~8–10% (illustrative). Best responses imply two potential equilibria; with signaling and capacity moderation, (Moderate, Accommodate) is risk-dominant under QRE with $\lambda \approx 1.6$.

Scenario Evaluation

Table 3 Interpretation

- NPV (Net Present Value) is computed over a 5-year horizon, discounted at 10–12% depending on market risk.
- Probability of Occurrence derived from game-theoretic prediction (Quantal Response Equilibrium-based likelihoods).
- Risk Bands categorized as:
  - Low → Stable payoff under wide scenarios.
  - Moderate → Medium variance in NPV; partial exposure to retaliation.
  - High → High volatility; sensitive to competitor's aggressive actions.

Managerial Insight

- Acquisition delivers the highest expected NPV with manageable risk but needs compliance safeguards.
- Greenfield entry offers autonomy but higher exposure to retaliation risk.
- Joint venture balances profit and protection, optimal for markets with uncertain regulation.
- Licensing is the safest low-capital option for phased entry or market testing.

Governance, Ethics, and Compliance

- **Antitrust:** Avoid agreements or conduct that constitute collusion; modeling is internal analytics, not coordination.
- **Fair signaling:** Public claims (capacity, pricing) must be truthful and compliant with disclosure rules.
- **Data privacy**: Ensure customer/partner data used in estimation meets legal and contractual requirements.
- **Algorithmic accountability:** Document assumptions and sensitivity results that support strategic decisions

CONCLUSION

By mapping market facts to game-theoretic primitives, estimating noisy behavioral responses, and simulating equilibria, firms can form defensible predictions of competitor actions and design market entry strategies that are credible, compliant, and robust. The framework here can be operationalized with standard econometric and optimization toolkits and iteratively improved with pilot-phase data.

Table 1. Suggested Data Schema (excerpt)

Block	Variable	Example	Use
Demand	Own & cross elasticities	ϵ_{ij}	Bertrand/Cournot payoffs
Cost	MC, FC, capacity	c_i, F_i, K_i	Profit & deterrence
Rival Actions	Price cuts, ad bursts	dates, % change	Reaction estimation
Information	Signals, announcements	capacity pledge	Signaling priors
Dynamics	Discount factor	δ	Repeated games

Table 2. Payoff Matrix (simplified, margins in $M)

Entrant	Incumbents	Entrant Profit	Incumbents Profit (combined)
Moderate price, regional	Accommodate	24	92
Moderate price, regional	Punish (promo war)	12	80
Full national blitz	Accommodate	30	88
Full national blitz	Punish	4	70

Table 3. Scenario Evaluation — NPV and Risk Bands Across Entry Modes

Entry Mode	Market Reaction Scenario	Predicted NPV (₹ Million)	Probability of Occurrence	Risk Band	Strategic Implications
Greenfield Entry (Independent Launch)	Accommodating incumbents	520	0.45	**Moderate**	Viable if marketing spend is controlled; allows full control over brand and pricing.
	Aggressive price retaliation	290	0.30	**High**	Requires defensive pricing flexibility and strong cost efficiency.
	Cooperative niche coexistence	480	0.25	**Low**	Stable mid-term growth; differentiation critical.
Joint Venture with Local Partner	Accommodating incumbents	560	0.40	**Low**	Reduces regulatory hurdles and cost of market access; shared profits.
	Moderate retaliation	410	0.35	**Moderate**	Mitigates entry cost; risk shared with partner; reduced flexibility.
	Severe retaliation	240	0.25	**High**	Exposure limited by joint investment; advisable for uncertain markets.
Acquisition of Existing Firm	Market acceptance	720	0.50	**Low**	Immediate market access and customer base; integration costs manageable.
	Integration challenges	430	0.30	**Moderate**	Operational risk during transition; requires

					cultural and structural alignment.
	Regulatory or antitrust issues	180	0.20	**High**	Contingent on legal clearance; requires due diligence and contingency reserves.
Licensing/Franchise Model	Fast market acceptance	380	0.40	**Low**	Lower investment risk; scalable but limited control over quality.
	Slow adoption	210	0.35	**Moderate**	Revenue delayed; suitable for testing market responsiveness.
	Contractual conflict	150	0.25	**High**	Governance and IP protection mechanisms needed.

ABSTRACT

Cloud computing has emerged as a transformative technology, with data storage being one of its most widely adopted applications. The cloud offers vast storage capacity, enabling users to conveniently store and access their data anytime, anywhere, with high reliability and flexibility. Its growing popularity has led many enterprises to migrate toward cloud-based storage solutions due to the significant advantages it provides. However, alongside these benefits, serious concerns remain regarding data security, privacy, and overall protection. Safeguarding sensitive information stored in the cloud has become a critical challenge, as breaches in confidentiality or integrity can undermine trust in cloud adoption. Addressing these challenges requires robust mechanisms to ensure secure data storage and controlled access. This paper proposes the use of a symmetric encryption technique to enhance the security and privacy of data stored in cloud environments, thereby strengthening trust and reliability in cloud computing systems.

Keywords: Cloud Storage Security, Cryptography, Data Protection, Symmetric Encryption, Confidentiality, Data Breach Prevention, Cloud Computing Security

INTRODUCTION

Cloud computing is a transformative technological advancement that delivers computational resources—such as servers, storage, operating systems, and networking—as on-demand services. It has emerged as a cost-effective and convenient solution for accessing externalized IT (Information Technology) resources. Increasingly, organizations

ranging from research centers to large enterprises are adopting cloud computing to host and manage their applications [1].Cloud services are typically offered in three categories: Software as a Service (SaaS), Platform as a Service (PaaS), and Infrastructure as a Service (IaaS). Leading providers such as Amazon, Google, Microsoft, and IBM deliver these services, allowing users to select and scale resources according to their specific requirements. However, reliance on these services often entails storing large volumes of sensitive data in cloud storage. Since cloud providers control and manage this data, concerns arise regarding its security, privacy, and trustworthiness [2].With cloud computing, all user data resides on third-party platforms, raising critical questions for users [3]: How secure is the data in the cloud? How effective are access control and authentication mechanisms? While providers assure customers of robust protection, uncertainties remain. The true extent of cloud data security can only be validated over time, as the technology continues to evolve [4] [5].

Cloud computing continues to raise significant concerns regarding security and privacy, as both customer data and applications reside within the provider's infrastructure. Based on data published in 2024–2025 by StationX in Figure 1[6],this chart shows that cyberattacks and data governance remain the top security priorities for organizations. Lesser yet still important issues include compliance, misconfigurations, and visibility gaps. These concerns persist alongside classic priorities like cost, suggesting that security remains a dominant driver in cloud adoption decisions [7].Cloud data is vulnerable to two main categories of threats: outsider attacks and insider attacks. Outsider attacks are launched by unauthorized external entities, while insider attacks are particularly concerning as administrators or privileged users within the provider's environment may exploit their access to compromise data. Insider threats are often difficult to detect, making them a major security challenge [8]. Consequently, sensitive data must be carefully protected before being transmitted to the cloud. A practical measure to mitigate these risks is encryption, ensuring that even if unauthorized parties gain access, the actual information remains unintelligible [9].Cryptography serves as the cornerstone of this protection, offering techniques for both encryption and decryption. Broadly, cryptographic methods can be classified into conventional (symmetric) cryptography and public-key (asymmetric) cryptography [10]. In symmetric encryption, a single shared key is used for both encryption and decryption. In contrast, asymmetric encryption employs a pair of keys: one for encryption and another for decryption [11].This paper proposes the adoption of a symmetric encryption technique to enhance the protection of user data stored in cloud storage, thereby safeguarding against unauthorized access and strengthening overall cloud trustworthiness.

MATERIALS AND METHODS

Related Work

Cloud computing offers flexibility and scalability, but the shift of data and applications to third-party infrastructures raises significant concerns over privacy, security, trust, ownership, availability, and portability. Data is often distributed across multiple jurisdictions, creating regulatory challenges, while risks of unauthorized access, insecure deletion, and compliance failures remain high. Users also fear loss of control over their intellectual property, vendor lock-in due to proprietary storage formats, and disruptions caused by provider outages or shutdowns [12]. Despite providers implementing encryption, authentication, and redundancy measures, high-profile incidents such as service outages and breaches continue to undermine user trust [13]. These unresolved challenges highlight the need for stronger and more efficient security mechanisms, which has motivated extensive research into encryption and obfuscation techniques for cloud storage [14].

In this context, Arockiam et al. [15] introduced AROcrypt, a symmetric cryptographic algorithm designed as a Security-as-a-Service (SEaaS) solution for cloud storage. Using four keys, the method transforms plaintext into ASCII, arranges it into a square matrix (up to 25×25), and separates it into upper, diagonal, and lower matrices for encryption. A final column-based reading sequence determined by the fourth key completes the process. The authors reported improved security in their simulations. Similarly, Manikandasaran et al. [16] proposed MONcrypt, an obfuscation-based approach that uniquely employs keys to enhance data protection. By applying mathematical operations such as squaring and modular division, plain text values are transformed into obfuscated ASCII

characters, offering fast processing with minimal overhead. Balamurugan et al. [17] extended this idea with ESSAO, another obfuscation method that applies functions like multiplication, square, reverse, and modulus, combined with key-based operations, to convert plaintext into secure ASCII codes before uploading to the cloud. Balaji et al. [18] developed ESCET, a symmetric block cipher using a 160-bit key split into subkeys, where the number of rounds is dynamically adjusted based on key values. This flexible structure aims to strengthen resistance against cryptanalysis while addressing data duplication in the cloud. Fairosebanu et al. [19] presented PUCSCipher, which processes data in 64-bit blocks with variable rounds, incorporating permutations, XOR, and swapping operations driven by a 196-bit key. Beyond these, Shen [20] proposed a hybrid encryption approach combining symmetric encryption with additional layers to balance speed and robustness, while Sharma [21] emphasized symmetric encryption as a practical solution for enhancing security and preventing insider and outsider threats in third-party cloud storage. Collectively, these studies demonstrate the evolving landscape of encryption techniques aimed at ensuring data confidentiality, efficiency, and resilience in cloud environments.

Symmetric Encryption

Symmetric encryption (Fig. 2) is a cryptographic technique that relies on a single shared secret key for both encryption and decryption of data. This method is particularly valued for its speed and computational efficiency, making it well-suited for encrypting large volumes of data in real-time applications [22].
Consider a source that generates a plaintext message:

$X=[X1,X2,X3,\ldots,XM]$

To secure the message, an encryption key K is generated at the sender's side and securely shared with the recipient through a trusted channel. Using the plaintext X and key K as inputs, the encryption technique transforms the plaintext into ciphertext:

$Y=E_K(X)=[Y1,Y2,\ldots,YN]$

Here, E denotes the encryption technique, and K represents the secret key. The ciphertext Y is then transmitted over the network or stored in the cloud.
Upon reception, the recipient applies the decryption technique using the *same secret key* K, thereby recovering the original plaintext message:

$X=D_K(Y)$

Where D represents the decryption technique.Since the same key is used for both processes, the security of symmetric encryption depends heavily on keeping the key secret and ensuring it is securely exchanged between communicating parties.

Proposed Technique

The proposed technique focuses on enhancing classical encryption methods by integrating two well-known cryptographic principles: the substitution cipher and the transposition cipher. Traditionally, both methods operate on alphabets to produce ciphertext. In contrast, the proposed technique introduces a novel approach by converting plaintext characters into their corresponding ASCII values before encryption, thereby expanding the operational scope. In classical encryption, the key space is relatively limited—typically ranging between 1 and 26, or in some cases defined as a string of letters. This limited key range makes traditional methods more vulnerable to cryptanalysis. To strengthen security, the proposed technique expands the key range from 1 to 256, aligning with the full ASCII set. This significantly increases the complexity of brute-force attacks, thereby enhancing resistance to unauthorized access.The technique is designed specifically for cloud data security, where users lose direct control over their data once it is stored in the provider's environment. In this context, the encryption key serves as the user's primary means of authentication and protection after logout. Without the correct key, the encrypted data stored in

the cloud remains inaccessible, even to the service provider.A stepwise description of the proposed technique is outlined below:

Encryption Procedure

The proposed encryption technique is designed to enhance the security of user data stored in the cloud by combining substitution and transposition at the ASCII level. The stepwise procedure of the technique is described below:

Encryption Steps:

. Character Count

Determine the total number of characters (NNN) in the plaintext, excluding spaces.

ASCIIConversion

Convert each character of the plaintext into its equivalent ASCII code. Arrange the ASCII values into a **squ**are matrix of size S, where S×S≥N.

Matrix Partitioning

Divide the square matrix into three sections:

- Upper matrix
- Diagonal elements
- Lower matrix

Reordering

Read the ASCII values in each section from right to left.

Key-Based Substitution

Encrypt each section using three different secret keys:

K={K1,K2,K3}

Each key is applied to its respective section (upper, diagonal, and lower).

Matrix Reinsertion

Place the encrypted values back into the square matrix in the same sectional order (upper → diagonal → lower).

Key-Based Permutation

Read the matrix column by column to form the intermediate ciphertext. The column order is determined by a fourth key, K4.

Final Conversion

Convert the resulting ASCII codes back into characters to generate the final ciphertext.

Encryption (Pseudocode)

Inputs

- PT: plaintext string (spaces optional; exclude spaces, strip them first)
- K1, K2, K3: integer section keys in [1..256) (upper/diagonal/lower)
- K4: permutation (array of length S, a permutation)
- PAD: padding byte (default 0x00)

Output

- CT: ciphertext bytes (or hex/base64 representation)

SubFunction

function TO_ASCII(PT):
returnan arrayof bytes b[i] foreachcharacterin PT (0..255)

function FROM_ASCII(bytes):
return string by interpreting each byte as a character

function SQUARE_SIZE(N):
smallest S with S*S >= N

```
S :=ceil(sqrt(N))
return S

function ROW_MAJOR_FILL(values, S, PAD):
Fill an SxS matrix left->right, top->bottom, pad if needed
   M:=SxS matrix of PAD
k :=0
for i in0..S-1:
for j in0..S-1:
          if k <len(values):
             M[i][j] :=values[k]
k := k +1
return M

function PARTITION_COORDS(S):
U := []  //upper (i < j)
D := []  // diagonal (i == j)
L := []  //lower (i > j)
for i in0..S-1:
for j in0..S-1:
if i <  j: U.append((i,j))
if i == j: D.append((i,j))
if i >  j: L.append((i,j))
// Reorder each section to respect "right-to-left within each row"
U := RIGHT_TO_LEFT_PER_ROW(U, S)
L := RIGHT_TO_LEFT_PER_ROW(L, S)
Diagonal keeps natural top-left → bottom-rightorder
return (U, D, L)

function RIGHT_TO_LEFT_PER_ROW(coords, S):
coords: list of (i,j) within the section (unordered)
Foreachrow i, collect that row's coords, sort by j descending
grouped := map i -> list of j
for (i,j) incoords:
grouped[i].append(j)
result := []
for i in0..S-1:
      if i in grouped:
row := grouped[i]
          sort rowin descending order
for j inrow: result.append((i,j))
returnresult

function ADD_KEY_MOD256(values, K):
return [ (v + K) mod 256for v invalues ]

function WRITE_BACK(M, coords, values):
zip coords withvaluesinorder
for t from0..len(coords)-1:
      (i,j) :=coords[t]
```

```
    M[i][j] :=values[t]

function COLUMNAR_READ(M, K4):
K4 is a permutation of1..S (1-based columnorder)

Experiment Of Proposed Technique

EncryptionProcedure

The followingis the detailed description of each step in the proposed encryptiontechnique.

Step 1 — Count characters (no spaces)

Plaintext: HideSecretText → N=14

Step 2 — ASCII conversion & square matrix
ASCII sequence: H i d e S e c r e t T e x t →[72, 105, 100, 101, 83, 101, 99, 114, 101, 116, 84, 101, 120, 116]
Smallest square: S=14(since 4×4=16). Pad with two 0x00.
Fill left→right, row-major:
M =

[72, 105, 100, 101]
[83, 101, 99, 114]
[101, 116, 84, 101]
[120, 116, 0, 0]

Step 3 — Partition matrix

- **Upper** (i<j): positions per row (right→left scan) Row0: (0,3)(0,2)(0,1) | Row1: (1,3)(1,2) | Row2: (2,3)
- **Diagonal** (i=j): (0,0)(1,1)(2,2)(3,3)
- **Lower**(i>j):
  Row1: (1,0) | Row2: (2,1)(2,0) | Row3: (3,2)(3,1)(3,0)

Collected values (right→left within each row):

- Upper values: [101, 100, 105, 114, 99, 101]
- Diagonal values: [72, 101, 84, 0]
- Lower values: [83, 116, 101, 0, 116, 120]

Step 4 — Right-to-left read
(Already reflected in the sequences above.)

Step 5 — Encrypt each section with its key
Add keys modulo 256:

- UpperK1=7:
  [108, 107, 112, 121, 106, 108]
- DiagonalK2=11:
  [83, 112, 95, 11]
- LowerK3=23:
  [106, 139, 124, 23, 139, 143]

Step 6 — Reinsert encrypted section values
Write the encrypted values back to their original positions (upper → diagonal → lower, preserving the extraction order):
M =[83, 112, 107, 108]
[106, 112, 106, 121]
[143, 139, 23, 11]

Step 7 — Columnar read using K4
Read columns in order K4=[3,1,4,2]. That is columns 3,1,4,2:

- Col 3: [107, 106, 95, 23]
- Col 1: [83, 106, 124,143]
- Col 4: [108, 121, 108, 11]
- Col 2: [112, 112, 139,139]

Concatenate → cipher sequence (bytes):[107,106,95,23,83,106,124,143,108,121,108,11,112,112,139,139]

Step 8 — Convert to characters (or render as hex)
These are bytes; many are non-printable. Represent clearly as hex (or Base64):

- **Hex**:6B 6A 5F 17 53 6A 7C 8F 6C 79 6C 0B 70 70 8B 8B (compact: 6B6A5F17536A7C8F6C796C0B70708B8B)

- **Base64**: a2pfF1NqfI9seWwLcHCLiw==

Decryption Procedure

Decryption is the reserve procedure of encryption. Encrypted data stored in the cloud must be decrypted to recover the original plaintext. Decryption is possible only with the same keys used during encryption. The steps below describe the decryption procedure.

Cipher (hex): 6B6A5F17536A7C8F6C796C0B70708B8B **Keys** :K1=7, K2=11, K3=23, K4=[3,1,4,2]

Step-by-step reconstruction

FillmatrixbycolumnsusingK4=[3,1,4,2]

(So columns are filled in order 3, 1, 4, 2 with chunks of 4 bytes)

M =[83, 112, 107, 108]
[106, 112, 106, 121]
[124, 139, 95, 108]
[143, 139, 23, 11]

Partition coordinates (same extraction order used at encryption)

- Upper (i<j, read right→left per row at encryption):(0,3),(0,2),(0,1),(1,3),(1,2),(2,3)
- Diagonal: (0,0),(1,1),(2,2),(3,3)
- Lower (i>j, right→left per row at encryption order):(1,0),(2,1),(2,0),(3,2),(3,1),(3,0)

Collect section values from M

- Upper(enc): [108, 107, 112, 121, 106, 108]
- Diagonal(enc): [83, 112, 95, 11]
- Lower(enc): [106, 139, 124, 23, 139, 143]

4) Reverse the section transforms (subtract keys mod 256)

- Upper: subtract K1=7 → [101, 100, 105, 114, 99, 101]
- Diagonal: subtract K2=11 → [72, 101, 84, 0]
- Lower: subtract K3=23 → [83, 116, 101, 0, 116, 120]

Reinsert these decrypted values back to their original coordinates This yields the recovered matrix:

M_recovered =
[72, 105, 100, 101]
[83, 101, 99, 114]
[101, 116, 84, 101]
[120, 116, 0, 0]

Read row-wise (left→right)ASCII sequence:[72,105,100,101, 83,101,99,114, 101,116,84,101, 120,116,0,0]

Convert ASCII → text (strip padding 0x00) Plaintext: **HideSecretText**

Thedecryption with the same keys cleanly recovers the original message (the two trailing zeros were the pad bytes to fill a 4×4 matrix).

RESULTS AND DISCUSSION

To evaluate the effectiveness of the proposed symmetric encryption technique, its performance was compared with two widely recognized symmetric techniques: Data Encryption Standard (DES) and Blowfish. The evaluation focused on encryption time and decryption time over varying data sizes ranging from 1 KB to 5 KB. All experiments were conducted under identical conditions, ensuring a fair comparison across techniques.

Performance Metrics

- **Encryption Time (ms):**The total time required to convert plaintext into ciphertext using a given technique.
- **Decryption Time (ms):**The time taken to recover plaintext from ciphertext.
- **Test Data Sizes:**Randomized data files of size 1KB, 2 KB, 3 KB, 4 KB, and 5 KB were used for testing.

- **Platform Setup:**
  - Processor: Intel i5 Quad-Core, 2.5 GHz
  - Memory: 8 GB RAM
  - Implementation: Python with standard cryptographic libraries for DES and Blowfish; proposed technique coded natively.

Comparative Results

Table 1 and Figure 3illustrate the encryption performance of the proposed technique compared to DES and Blowfish for data sizes ranging from 1 KB to 5 KB. The proposed technique consistently demonstrates lower encryption times, highlighting its efficiency and suitability for lightweight cloud storage applications Table 1 and Figure 4compare the decryption performance of DES, Blowfish, and the proposed encryption technique. Similar to the encryption results, the proposed method achieves significantly reduced decryption times across all file sizes, making it more effective for fast and secure data retrieval in cloud environments

Analysis

Encryption Speed

The proposed technique consistently outperformed DES and Blowfish in terms of encryption time. For example, at 5 KB, the proposed method required only 12.0 ms, compared to 23.7 ms for DES and 16.1 ms for Blowfish. This improvement is attributed to the technique's lightweight design, which combines substitution and transposition at the ASCII level without complex key schedules.

Decryption Efficiency

Decryption times followed a similar trend. The proposed technique was faster than DES by nearly **50%** and outperformed Blowfish by approximately 25%. This efficiency arises from the technique's direct inverse operations, which require minimal computational overhead.

Scalability

Performance scaled linearly with data size across all techniques. However, the proposed method maintained consistently lower processing times, making it more suitable for resource-constrained cloud environments where performance and quick retrieval are critical.

Security Considerations

- DES suffers from a small key size (56 bits), rendering it insecure against modern brute-force attacks.
- Blowfish improves security with variable key lengths (up to 448 bits), but its key expansion step is relatively costly.
- The Proposed Technique expands the key space to 1–256 at the ASCII level, integrates multi-key substitution and transposition, and ensures complexity with four independent keys (K1–K4). This makes brute-force attacks computationally expensive while preserving speed.

DISCUSSION

The results indicate that the proposed symmetric encryption technique provides a balanced trade-off between security and performance. Compared to classical techniques like DES and Blowfish, the proposed scheme:

- Achieves lower encryption and decryption times, making it highly efficient for cloud data storage.
- Offers an expanded key space and multi-layered encryption (substitution + transposition), which improves resistance to brute-force and cryptanalytic attacks.
- It is particularly suitable for applications requiring fast, lightweight encryption with reliable security, such as real-time cloud storage access, data backup, and secure file transfer.

While DES is largely obsolete due to weak key length, Blowfish remains competitive in certain contexts. However, the proposed technique shows potential as a lightweight cryptographic solution optimized for cloud environments where speed and trust are paramount.

CONCLUSION

The paper addressed the persistent challenges of data security and privacy in cloud storage by proposing a symmetric encryption technique that integrates substitution and transposition at the ASCII level with an expanded key space and multiple keys. Comparative evaluation against DES and Blowfish demonstrated that the proposed technique consistently achieved faster encryption and decryption times, improving performance by nearly 50% over DES and about 25% over Blowfish for data sizes between 1 KB and 5 KB. These results highlight its suitability for real-time cloud applications, where speed and reliability are critical. In addition to performance, the design enhances resistance to brute-force and cryptanalytic attacks, offering a lightweight yet secure alternative to conventional methods. While testing was limited to small datasets, the findings indicate a balanced trade-off between efficiency and security. Future research will explore scalability, integration with cloud service platforms, and hybrid models combining symmetric and asymmetric encryption.

ABSTRACT

The persistent occurrence of antibiotics in the environment, particularly in water bodies has been a challenging issue. It has raised critical concerns regarding ecological safety and public health. Worldwide, the urban and rural population are mostly dependent on surface and ground waters for their daily needs and are getting exposed to antibiotics present in these waters. Conventional wastewater treatment processes are inadequate in removing these emerging contaminants, leading to the spread of antibiotic-resistant bacteria (ARB) and antibiotic resistance genes (ARGs). This review explores the sources, pathways, environmental fate, and health impacts of antibiotics in aquatic systems. It also highlights the growing threat of antimicrobial resistance fuelled by environmental exposure to antibiotic residues. Emphasis is placed on innovative, sustainable solutions such as green nano-adsorbents synthesized from natural and biodegradable materials. These materials exhibit high efficiency in the immobilization and degradation of antibiotics through mechanisms like adsorption, photocatalysis, and biological transformation. The review further discusses microalgae-based purification systems, algal bead composites, and nanoparticle technologies as promising tools for water treatment. Finally, it outlines existing treatment methods, their mechanisms, and the necessity of integrated strategies for monitoring and mitigating antibiotic pollution in water. This work underscores the urgent need for interdisciplinary approaches and green technologies to address the dual challenge of environmental contamination and antibiotic resistance.

Keywords: Antibiotic Resistance, Aquatic environment, Microalgae, Green Nano-adsorbent

INTRODUCTION

The ongoing pollution of water sources with pharmaceutical substances, particularly antibiotics, presents a significant danger to both human health and the environment. Among the various emerging contaminants, antibiotics such as ciprofloxacin have received considerable attention due to their extensive usage and poor degradation in traditional wastewater treatment processes [1, 2]. This situation has contributed to the rise of antibiotic-resistant bacteria [3, 4], which disrupt ecosystems and diminish the effectiveness of essential medications [5, 6]. Consequently, it is crucial to develop effective, sustainable, and economical treatment technologies [7]. In this context, green nano-adsorbents have emerged as promising options for the immobilization and breakdown of antibiotics in water environments [8]. Green nano-adsorbents are nanoscale materials created through environmentally friendly methods, usually using plant extracts, microorganisms, or other biological systems [9, 10].

Prevalence of Antibiotics in Environment

Agricultural runoff, hospital effluents, pharmaceutical industrial waste, and household sewage are the main environmental sources of antibiotics. Unmetabolized antibiotics are excreted by humans and animals due to incomplete metabolism, and they are subsequently released into wastewater systems [3]. Unfortunately, pharmaceutical chemicals persist in treated effluents and are subsequently released into surface water bodies because typical wastewater treatment plants are not built to particularly remove them [6]. Antibiotic pollution of the environment is also largely caused by agriculture. Antibiotics are frequently used in cattle production to promote growth and prevent sickness. Remaining antibiotics may be released into soil and water systems via treated animal manure, which is frequently used as fertilizer [3]. The issue in aquatic habitats is further exacerbated by the frequent use of antibiotics by aquaculture enterprises to treat bacterial infections [6].

Environmental Fate and Behaviour

Antibiotics may experience a variety of physical, chemical, and biological changes after being released into the environment. While some are permanent and can build up in soils, sediments, and biota, others break down rather fast. A number of variables, including pH, temperature, microbial activity, and sunshine, affect the destiny of antibiotics[5]. However, these substances can exert selective pressure on microbial populations, encouraging the formation of antibiotic-resistant bacteria (ARB) and resistance genes (ARGs), even at low doses (ng/L to μg/L) [5].

Ecological and Health Impacts

Antibiotics disturb microbial diversity and processes vital to nutrient cycles and ecosystem health when they are present in natural environments [11]. More concerningly, it fuels the spread of antimicrobial resistance (AMR), which the World Health Organization (WHO) has identified as one of the biggest risks to world health [5]. Pathogenic strains of bacteria can acquire antibiotic resistance from environmental bacteria, making the treatment of diseases more challenging and expensive [11]. Antibiotics can change the growth, behaviour, and reproduction of non-target organisms like fish, algae, and invertebrates in aquatic environments [5]. Long-term exposure can have harmful effects across the food chain as well as bioaccumulation and biomagnification [11].

Monitoring and Mitigation

Even with increased awareness, tracking antibiotic contamination continues to be difficult because of the variety of compounds and their low-level concentrations [5]. Sophisticated analytical methods like liquid chromatography–mass spectrometry (LC-MS) are essential for identifying and measuring substances [11]. In terms of mitigation, coordinated strategies are essential—spanning advanced waste treatment methods, tougher regulations, increased public awareness, and accountable antibiotic management [3]. The occurrence of antibiotics in aquatic systems has emerged as a major environmental and public health issue in recent times. Antibiotics, which are crucial medications for treating bacterial infections in both humans and animals, are used in significant quantities worldwide [6]. Nonetheless, a significant portion of these medications is not completely metabolized and is eliminated in active

forms. These residues find their way into the environment via different routes, particularly affecting aquatic systems, where they present several dangers to ecosystems and human health [3, 6].

Antibiotics in Water

Sources and Pathways of Antibiotics in Water, Antibiotics end up in surface water, groundwater, and even drinking water supplies through various human activities [6]. A primary source of this issue is municipal wastewater, where antibiotics excreted from human use flow into sewage systems [3]. While wastewater treatment plants (WWTPs) are effective at removing standard pollutants, they are not specifically designed to eliminate micropollutants like antibiotics [6]. Consequently, the treated wastewater often contains trace amounts of these substances, which are then released into rivers, lakes, and coastal waters [5]. Hospitals and pharmaceutical companies are also significant contributors to this problem, especially when untreated or inadequately treated effluents are discharged directly into water bodies [11].

Agricultural practices, including livestock farming and aquaculture, play a considerable role as well. Antibiotics are frequently given to animals for purposes such as growth enhancement and disease prevention [3]. Manure and slurry, which contain antibiotic residues, are often applied as fertilizers, resulting in runoff into nearby streams and groundwater [6]. In aquaculture, antibiotics are usually added directly to the water to avert fish diseases, causing localized contamination [11].Various types of antibiotics—including fluoroquinolones, sulfonamides, tetracyclines, and macrolides—have been identified in surface water, groundwater, and even tap water in numerous areas [5]. Concentrations typically vary from nanograms per litre (ng/L) to micrograms per litre (µg/L), but levels can be considerably higher near specific sources such as pharmaceutical discharge locations [11].Advanced analytical techniques, particularly high-performance liquid chromatography coupled with mass spectrometry (HPLC-MS), are frequently used to identify and measure antibiotics in environmental water samples [11]. These methods are essential for understanding contamination trends and evaluating ecological risks [5].

The presence of antibiotics in water, even at low concentrations, can lead to significant ecological impacts. One concerning consequence is the encouragement of antibiotic-resistant bacteria (ARB) and the spread of antibiotic resistance genes (ARGs) [5]. Aquatic environments serve as reservoirs and mixing zones for resistant microbes, which can transfer resistance traits to harmful strains via horizontal gene transfer [11]. This phenomenon substantially contributes to the global health threat posed by antimicrobial resistance (AMR) [5, 11].In aquatic ecosystems, antibiotics can alter microbial communities and disrupt vital biological functions such as nitrification and decomposition [6]. Non-target species, including algae, crustaceans, and fish, may experience sub-lethal effects such as changes in behaviour, reproductive toxicity, and altered growth patterns [11].Although human contact with antibiotics in drinking water is generally at low concentrations, it raises concerns regarding the potential for chronic toxicity and allergic reactions [5]. The long-term effects of consistent, low-level antibiotic exposure through water are not completely understood and remain a subject of ongoing research [11].Tackling antibiotic pollution in water necessitates a comprehensive strategy. Conventional wastewater treatment processes should be enhanced with advanced methods such as membrane filtration, ozonation, advanced oxidation processes (AOPs), and activated carbon adsorption to efficiently eliminate pharmaceutical residues [3, 6].

Emerging eco-friendly technologies, including bio-based nano-adsorbents and photocatalytic materials, show promise for both the absorption and breakdown of antibiotics in water [5]. These materials provide high surface area, reusability, and the potential for minimal secondary pollution [11].Preventive actions are equally critical. These include enforcing stricter regulations on antibiotic use in agriculture and aquaculture, ensuring proper disposal of unused medications, and establishing pharmaceutical take-back initiatives [6]. Public awareness efforts and policies that promote responsible antibiotic use are vital for reducing the overall burden on the environment [3, 11].

Antibiotic Resistance in the Environment and Water

Antibiotic resistance has become one of the most urgent global health and environmental issues of the 21st century. While it has been largely associated with healthcare environments, increasing evidence reveals that the environment—especially aquatic ecosystems—plays a crucial role in the emergence, dissemination, and endurance of antibiotic-resistant bacteria (ARB) and antibiotic resistance genes (ARGs) [5]. Bodies of water, such as rivers, lakes, groundwater, and wastewater, serve as reservoirs and pathways for resistance, primarily driven by human activities. A key contributor to ARB and ARGs in the environment is the release of both treated and untreated wastewater. Municipal sewage, hospital discharges, and industrial effluents often include both antibiotics and resistant microorganisms. Standard wastewater treatment facilities are not equipped to fully eliminate ARGs or deactivate resistant bacteria, which leads to their discharge into natural water bodies [3]. Agricultural runoff represents another significant source, as antibiotics are widely used in livestock and aquaculture. Manure and animal waste, commonly used as fertilizers, can leach or erode into surface and subsurface water, introducing resistance elements [6].

In aquatic systems, even minimal concentrations of antibiotics can apply selective pressure on microbial populations, resulting in the survival and proliferation of resistant strains. These resistant bacteria are capable of transferring their resistance genes to other organisms through horizontal gene transfer, particularly via mobile genetic elements like plasmids and transposons [5]. This mechanism accelerates the spread of resistance among microbial communities, including those that impact human health. The ecological and health consequences are serious. Resistant bacteria in water can infiltrate the food chain, disrupt aquatic biodiversity, and ultimately affect sources of drinking water. Additionally, environmental reservoirs of ARGs pose a risk to public health by compromising the effectiveness of antibiotics in medical contexts [6]. Addressing this problem necessitates a comprehensive "One Health" strategy, which incorporates environmental monitoring, enhanced wastewater treatment, and responsible antibiotic use [3].

Diseases Caused by Antibiotics in the Environment

While antibiotics play a crucial role in treating bacterial infections, their presence in the environment—particularly in soil and water—can result in unintended health effects. A significant concern is the indirect impact of environmental antibiotics in fostering diseases related to antibiotic-resistant bacteria (ARB). Although antibiotics do not directly cause illnesses in humans, their contamination of the environment greatly contributes to the spread of infections that are increasingly challenging to treat [5]. Exposure to antibiotics in the environment applies selective pressure on microbial populations, allowing resistant bacteria to prosper. These resistant strains can lead to infections such as urinary tract infections, respiratory diseases, skin infections, and gastrointestinal illnesses, many of which are unresponsive to standard antibiotic therapies [5]. For instance, *Escherichia coli* and *Klebsiella pneumoniae*—frequently found in polluted water—can obtain resistance genes from their surroundings and result in multidrug-resistant infections in people.

Moreover, antibiotic remnants in drinking water and food systems can disrupt gut microbiome balance (dysbiosis), which is linked to various health concerns, including allergies, metabolic issues, inflammatory bowel disease, and weakened immune response. Prolonged exposure to low levels of antibiotics from environmental sources may also contribute to chronic toxicity and heightened vulnerability to infections [6].In agricultural contexts, crops that are irrigated with contaminated water may contain antibiotic residues and resistant bacteria, which can be passed on to consumers. Individuals residing near pharmaceutical manufacturing plants or intensive livestock operations face a higher chance of exposure to airborne resistant microbes and related infections. Ultimately, diseases associated with environmental antibiotics primarily arise from the proliferation of resistance and microbial imbalances. Tackling this issue necessitates strict regulation of antibiotic release, advanced treatment technologies, and comprehensive public health strategies to minimize environmental pollution and protect human well-being [3, 6].

Existing Methods for Immobilization and Degradation of Antibiotics

The elimination of antibiotics from environmental systems, particularly in water, is a vital measure to reduce their ecological and health-related effects. Typically, two primary approaches are utilized: immobilization (adsorption-

based containment) and degradation (chemical or biological breakdown). A range of technologies has been developed and put into practice to tackle these processes, each presenting its own benefits and drawbacks.

Techniques for Adsorption (Immobilization)

Adsorption is among the most prevalent methods for immobilizing antibiotics, noted for its straightforwardness, effectiveness, and affordability. This process entails the physical or chemical attachment of antibiotic molecules onto the surfaces of solid materials. Common adsorbents consist of:

- Activated carbon: With high porosity and efficiency for a wide array of antibiotics, though regeneration can be expensive.
- Biochar: Produced through biomass pyrolysis; it provides sustainability and substantial adsorption capacity for antibiotics such as tetracycline and ciprofloxacin [2, 4, 7].
- Zeolites and clays: These are either natural or synthetic minerals with significant cation exchange capabilities, making them effective for immobilizing ionic forms of antibiotics.
- Nanomaterials: Metal oxides (like Fe_3O_4, TiO_2), graphene oxide, and other nano-based adsorbents offer a large surface area and functional groups to facilitate selective adsorption [8, 9].

Although adsorption is effective in removing antibiotics from water, it does not decompose them, which could lead to the possibility of re-release into the ecosystem [10].

Advanced Oxidation Processes (AOPs)

AOPs represent chemical treatment methods that produce highly reactive species (particularly hydroxyl radicals, ·OH) which can disassemble complex antibiotic molecules. Commonly utilized AOPs include:

- Photocatalysis: This technique employs light (typically UV) and catalysts such as TiO_2 to transform antibiotics into harmless byproducts [2, 4, 13].
- Fenton and Fenton-like reactions: These involve hydrogen peroxide and iron salts to produce hydroxyl radicals, which are effective in oxidizing antibiotics like amoxicillin and ciprofloxacin [7, 8].
- Ozonation: In this process, ozone gas is introduced into contaminated water, oxidizing a broad spectrum of antibiotic compounds [9, 10].
- Electrochemical oxidation: This method uses an electric current and electrodes to directly decompose antibiotics or produce oxidative species [4].

AOPs can lead to total mineralization, but they frequently necessitate precise control, high energy demands, and subsequent processing to eliminate any residual byproducts.

Biological Degradation

Certain bacteria, fungi, and enzymes can biodegrade antibiotics in either aerobic or anaerobic environments:

- Activated sludge systems: These are utilized in wastewater treatment facilities where microbial communities break down contaminants [3].
- Constructed wetlands: These employ plants and microbial communities to naturally degrade and immobilize antibiotics [6].
- Enzyme catalysis: Particular enzymes like laccases or peroxidases can dismantle antibiotic structures.

Biological methods are environmentally friendly and cost-effective, yet they may proceed more slowly and with less predictability compared to chemical methods.

Combined and Emerging Technologies

Recently, hybrid systems that integrate adsorption and degradation have been introduced, including:

- Nano-adsorbent/photocatalyst composites: These materials first immobilize and then decompose antibiotics when exposed to light [4].
- Biochar-supported metal nanoparticles: These provide both adsorption and catalytic degradation functions [7, 10].

- Membrane bioreactors (MBRs): These blend membrane filtration with biological degradation to enhance removal efficiency [6].

Microalgae as a Natural Water Purifier

Microalgae, tiny photosynthetic organisms located in both freshwater and marine settings, are increasingly recognized as sustainable solutions for purifying water. These single-celled entities not only generate oxygen and sequester carbon dioxide but also have distinctive biochemical properties that enable them to effectively eliminate pollutants from wastewater, such as nutrients, heavy metals, and new contaminants like antibiotics [14, 20].

One significant benefit of utilizing microalgae in water treatment is their capacity to absorb inorganic nutrients such as nitrogen and phosphorus, which are key factors in causing eutrophication in aquatic environments. As they grow, microalgae transform these nutrients into biomass, thereby diminishing nutrient concentrations in the treated water. This attribute renders them especially valuable for tertiary wastewater treatment and in preventing downstream algal blooms [14, 3, 15, 18, 6, 19, 16, 17].

Microalgae also demonstrate the ability to adsorb and bio-transform organic micropollutants, including pharmaceuticals and antibiotics. Certain strains produce enzymes that can break down antibiotic compounds or bind them through biosorption onto their cell walls. Furthermore, some microalgae establish symbiotic relationships with bacteria that enhance the breakdown of pollutants. Their high surface-area-to-volume ratio and varied metabolic pathways allow for the uptake and detoxification of different contaminants [14, 15, 18, 19, 20, 16, 17]. From an ecological and economic standpoint, microalgae provide numerous advantages. They rely on sunlight and CO_2 for their growth, making them energy-efficient and environmentally sustainable. The biomass generated during the treatment process can be collected and converted into biofuels, animal feed, or bioplastics, contributing to a circular economic framework. Additionally, algal systems such as photobioreactors and open ponds are relatively affordable and scalable for wastewater treatment in both rural and industrial settings [14, 3, 15, 18, 6, 19, 16, 17]. Although promising, microalgae-based water treatment systems encounter several challenges, including their sensitivity to environmental variations, competition with indigenous microbial populations, and the necessity for efficient biomass harvesting. Nevertheless, ongoing research and advancements in technology are swiftly addressing these obstacles [14, 15, 18, 19, 16, 17].

Nanoparticles: Properties, Applications, and Environmental Relevance

Nanoparticles are materials that typically measure between 1 and 100 nanometres in size. When at this nanoscale, materials display unique physical, chemical, and biological properties that are quite different from those of their larger counterparts. These special features—such as amplified surface area, heightened reactivity, and quantum effects—have allowed nanoparticles to transform numerous fields, including healthcare, electronics, energy, and environmental science. Nanoparticles can be composed of a diverse range of materials, which include metals (such as silver, gold, and iron), metal oxides (like titanium dioxide and zinc oxide), carbon-based substances (such as graphene and fullerenes), and polymer-based structures. Their size and surface modifications can be customized for particular uses, improving their effectiveness in targeted drug delivery, imaging, catalysis, and pollutant removal.

In environmental science, nanoparticles are essential for purifying water and air, remediating soils, and sensing contaminants. For instance, iron oxide nanoparticles are utilized to eliminate heavy metals and organic pollutants from water through processes like adsorption and redox reactions. Likewise, photocatalytic nanoparticles such as TiO_2 can break down a wide variety of pollutants—including pharmaceuticals and dyes—when exposed to light [3, 6].

Researchers are also investigating nanoparticles for their ability to combat microbes. Specifically, silver nanoparticles are recognized for their potent antibacterial properties and are integrated into coatings, textiles, and disinfectants. In wastewater treatment, nano-adsorbents and nanocomposites deliver high efficiency in extracting persistent pollutants such as antibiotics, pesticides, and endocrine disruptors [3, 6]. Nonetheless, the growing utilization of nanoparticles raises concerns regarding their potential environmental and health effects. Given their tiny size and

high mobility, nanoparticles have the capacity to penetrate biological membranes, which could lead to toxicity in aquatic life and humans. As a result, ongoing research aims to unravel their behaviour, life cycle, and ecotoxicity in various environments.

Algal Beads with Gelatin as Absorbents

Algal beads, which are created by encasing algal cells within a biopolymeric substance like gelatin, represent an innovative and eco-friendly strategy for treating water and eliminating pollutants. These beads merge the distinctive characteristics of algae, such as their extensive surface area, metabolic flexibility, and ability to absorb pollutants, with the biocompatibility and structural integrity of gelatin, resulting in effective absorbents for a diverse range of contaminants. Gelatin, a natural polymer obtained from animal collagen, is an excellent choice for encapsulating algal cells. It provides a supportive environment that not only safeguards the algae but also improves their retention and durability in aquatic settings. The gel-like consistency allows for controlled release and efficient interaction between the algal cells and contaminants, while the beads themselves are convenient to handle, manipulate, and regenerate. The main benefit of employing algal beads in water treatment is their capacity to absorb and break down pollutants, especially heavy metals, organic compounds, and nutrients. Algae, which serve as proficient bio-adsorbents, naturally gather pollutants from water, and encasing them in gelatin beads curtails the risk of contaminants leaching back into the water. The extensive surface area of the algal cells within the beads offers numerous sites for pollutant binding, making them highly effective in extracting pollutants like phosphates, nitrates, and even pharmaceutical residues such as antibiotics.

Moreover, the application of algal beads can also extend to the extraction of dyes, oils, and other industrial waste products. The gelatin matrix additionally offers the possibility of modifying the algal beads with specific chemical groups to enhance their adsorption capabilities, enabling them to target certain pollutants more effectively. For instance, the beads' surface can be altered to attract hydrophobic contaminants, thereby increasing their versatility in various water purification scenarios.The ability to regenerate algal beads is another vital aspect that renders them a sustainable option. Once the beads have absorbed contaminants, they can be taken out of the water, cleaned, and reused, minimizing the need for continual material replacement. The algal biomass can also be harvested for biofuel production or used as animal feed, delivering an extra advantage within a circular economy framework. Nonetheless, several challenges such as refining the gelation procedure, enhancing the mechanical durability of the beads, and ensuring effective pollutant recovery must be tackled. Ongoing research is concentrated on developing more resilient and cost-effective production techniques for algal beads while boosting their adsorption efficiency.
Green Nano-adsorbents: Sustainable Solutions for Environmental Remediation

The increasing worry about environmental pollution, particularly water pollution caused by industrial waste, heavy metals, pharmaceuticals, and pesticides, has led to the creation of innovative, sustainable technologies for pollutant removal. Green nano-adsorbents, a category of eco-friendly materials, are emerging as one of the most promising approaches for effective and sustainable environmental cleanup. These adsorbents are made from natural, renewable resources and utilize nanotechnology to improve their adsorptive characteristics, makingthem highly efficient in eliminating a broad spectrum of contaminants from water sources [1].

Green Nano-adsorbents

Green nano-adsorbents are nanomaterials created from natural, biodegradable, and non-toxic substances, such as plant-based polymers, biopolymers, natural clays, and other renewable organic materials. These substances are usually modified at the nanoscale to maximize their surface area, which greatly increases their ability to adsorb pollutants. The term "green" pertains not only to the materials utilized in the creation of these nano-adsorbents but also to the environmentally friendly methods implemented in their production. Adopting green techniques, such as bio reduction and biosynthesis, eliminates the need for hazardous chemicals, rendering the synthesis process more sustainable and minimizing environmental harm [1].

Green nano-adsorbents have received considerable attention due to their capacity to eliminate various contaminants from water, including heavy metals (such as lead, mercury, cadmium), dyes, pesticides, and pharmaceuticals. Their distinctive characteristics, such as high surface area, adjustable porosity, and surface chemistry, render them highly effective at adsorbing pollutants, even at low concentrations.

Synthesis of Green Nano-adsorbents

Green nano-adsorbents are generally produced using natural biopolymers, plant extracts, or microorganisms. Common synthesis methods include:

- **Green Synthesis Utilizing Plant Extracts:**

Compounds derived from plants, such as polyphenols, flavonoids, and other organic molecules, serve as reducing and stabilizing agents for metal nanoparticles. For instance, silver, gold, and copper nanoparticles have been produced using extracts from plants like *Aloe vera, Moringa oleifera*, and Neem, which contain natural compounds with antioxidant properties [1].

- **Biosynthesis Utilizing Microorganisms:**

Certain microorganisms, including bacteria, fungi, and algae, have shown the capability to convert metal ions into nanoparticles. For example, fungi such as Aspergillus and Trichoderma species, as well as bacteria like Pseudomonas and Bacillus, can be used to create metal nanoparticles with excellent adsorptive properties [1].

- **Green Polymers:**

Natural polymers like chitosan, alginate, cellulose, and starch are frequently employed as matrices for nanoparticle formation. These polymers are biocompatible, biodegradable, and plentiful in nature. When paired with nanoparticles, they create composite materials that provide improved adsorption capabilities [1].

Green nano-adsorbents have demonstrated their effectiveness in addressing various types of water pollution, including both organic and inorganic pollutants.

Their uses include:

- Heavy Metal Removal:

A primary use of green nano-adsorbents is the extraction of harmful heavy metals from water. Nanoparticles sourced from natural materials can effectively adsorb metals such as arsenic, cadmium, chromium, and mercury [1].

- Removal of Organic Contaminants:

Green nano-adsorbents are also capable of eliminating organic pollutants such as pesticides, pharmaceuticals, and dyes from wastewater through adsorption, ion exchange, and catalytic degradation [1].

- Wastewater Treatment:

Green nano-adsorbents are being integrated into modern wastewater treatment systems. Their adaptability across different pH levels and temperatures makes them suitable for varied water treatment scenarios [1, 3, 6].

- Removal of Pharmaceuticals:

Green nano-adsorbents, particularly those made from biopolymers like chitosan, have shown promising results in capturing and eliminating pharmaceutical residues from water [1, 15].

The application of green nano-adsorbents comes with several benefits when compared to conventional water treatment techniques:

- Eco-friendliness: Green synthesis processes eliminate hazardous chemicals and use biodegradable materials, preventing secondary pollution.
- High Efficiency: Their nanoscale features ensure high adsorption capacities even at low pollutant concentrations.
- Biocompatibility: Derived from natural sources, they are generally safe for the environment and health.
- Sustainability: These materials can often be reused or recycled, aligning with circular economy principles.

However, challenges such as limited durability in extreme conditions, high cost of biomaterials, and post-use environmental monitoring still remain. Continued research is focused on enhancing their stability, scalability, and regeneration potential. Integrating green nano-adsorbents with biofiltration and electrocoagulation may offer comprehensive solutions to water contamination.

CONCLUSION

Persistence of antibiotics in water is a major challenge. Pollution caused by antibiotics contribute to antibisotic resistance. Thepresent review explores thesustainable solutions such as green nano-adsorbents synthesized from natural and biodegradable materials for immobilization and degradation of antibiotics through mechanisms like adsorption, photocatalysis, and biological transformation. The review also includes microalgae-based purification systems, algal bead composites, and nanoparticle technologies as promising tools for water treatment.

ABSTRACT

The increasing reliance on coaching centres for academic advancement has intensified the pressure experienced by secondary school students. The present study examines the prevalence of academic stress and burnout among coaching centre students in Saharanpur District during the academic session 2025–2026. A quantitative research design was adopted, and primary data were collected from 100 students enrolled in various coaching centres. A structured questionnaire was used to gather information regarding demographic characteristics and students' perceptions of academic pressure, workload, and emotional exhaustion. Responses were measured using a five-point Likert scale, and statistical analysis was conducted using descriptive statistics, correlation analysis, independent sample *t*-tests, and one-way ANOVA. The results indicate that the average stress score among respondents was above the neutral midpoint, suggesting that students experience moderate to high levels of academic stress. Indicators of burnout such as fatigue, lack of personal time, and difficulty balancing school and coaching commitments also showed relatively high mean scores. Correlation analysis revealed a strong positive relationship between academic pressure and burnout symptoms, demonstrating that increased coaching demands significantly contribute to emotional exhaustion among students. Further analysis showed that students from the science stream reported higher stress levels compared to those from commerce and arts streams, while gender-based differences in stress levels were not statistically significant. The findings highlight that although coaching centres may support academic performance, they also create considerable psychological pressure on students. The study concludes that the competitive coaching environment contributes to heightened stress and burnout, emphasizing the need for balanced academic schedules, improved student support systems, and greater attention to mental well-being in coaching institutions.

Keywords: Academic stress, burnout, coaching centers, student well-being, Saharanpur district.

INTRODUCTION

Education has always been considered one of the most important foundations for personal development, social progress, and economic advancement. In modern societies, academic achievement plays a crucial role in shaping career opportunities and determining an individual's future prospects. Particularly in developing countries such as India, education is widely viewed as a key pathway for upward social mobility and professional success. As competition for limited seats in higher education institutions and prestigious professional courses continues to increase, students are often required to perform exceptionally well in academic examinations. This intense competition has led to the rapid growth of private coaching centres that provide specialized training and guidance to help students succeed in competitive examinations and academic assessments. Over the past two decades, the coaching industry in India has expanded significantly and has become an integral part of the educational ecosystem. Coaching institutes offer structured study programs, experienced faculty, regular assessments, and exam-oriented strategies that are designed to enhance students' academic performance. Many students enroll in coaching centers alongside their formal schooling to gain additional academic support and improve their chances of achieving high scores in examinations. While these institutions play an important role in strengthening academic preparation, they also create highly demanding academic environments that may place considerable psychological pressure on students.

One of the major concerns associated with intense academic competition is the increasing prevalence of **academic stress** among students. Academic stress refers to the mental and emotional strain experienced by students due to educational demands that exceed their ability to cope effectively. Students preparing for examinations often face multiple stressors such as heavy workloads, continuous evaluation, strict schedules, fear of failure, parental expectations, and competition with peers. When these pressures persist over extended periods of time, they can negatively influence students' emotional well-being and overall mental health. Studies have shown that excessive academic pressure can lead to symptoms such as anxiety, fatigue, irritability, sleep disturbances, and reduced concentration, which may ultimately affect both academic performance and quality of life (Deb et al., 2020). Another important psychological consequence of prolonged academic stress is **academic burnout**. Burnout is a psychological syndrome characterized by emotional exhaustion, depersonalization, and a reduced sense of personal accomplishment. Although the concept of burnout was originally developed in the context of occupational stress among professionals, researchers have increasingly applied it to educational settings to better understand the experiences of students facing continuous academic pressure. Academic burnout typically occurs when students feel overwhelmed by academic demands and gradually lose motivation, enthusiasm, and interest in their studies. Research indicates that burnout among students is associated with decreased academic engagement, poor academic performance, and a higher risk of mental health problems such as depression and anxiety (Salvagioni et al., 2021).

In recent years, the issue of stress and burnout among students has gained increasing attention from educators, psychologists, and policymakers. Several studies conducted in India and other countries have reported high levels of psychological distress among students preparing for competitive examinations. For instance, students enrolled in rigorous academic programs often experience intense pressure to achieve high academic results, which may lead to emotional exhaustion and decreased motivation over time (Arora, 2024). Moreover, the demanding schedules followed in coaching centers often involve long hours of study, frequent tests, and limited opportunities for relaxation and recreational activities. Such conditions may further intensify stress levels and increase the likelihood of burnout among students. Parental expectations also play a significant role in shaping students' academic experiences. Many parents invest considerable financial resources in coaching programmers with the hope that their children will secure admission to prestigious institutions and achieve successful careers. Although parental support and encouragement can motivate students to work hard, excessive expectations may create additional psychological pressure. Students may feel obligated to meet these expectations, leading to anxiety, fear of failure, and self-doubt when they perceive themselves as unable to achieve the desired academic results (Kaur & Sharma, 2022). Adolescence and early adulthood represent critical stages of psychological development during which individuals

are still learning to manage stress, regulate emotions, and develop effective coping mechanisms. Exposure to highly competitive academic environments during this period may significantly influence students' emotional resilience and mental health. Research has indicated that students who experience chronic academic stress are more likely to develop burnout symptoms, which can negatively affect their motivation, academic engagement, and overall well-being (Madigan & Curran, 2021).

The rapid growth of coaching institutions across India has further intensified the discussion surrounding student mental health. Major coaching hubs such as Kota, Delhi, and Hyderabad have often been highlighted in discussions about academic pressure and student stress. However, coaching culture is no longer limited to large metropolitan cities. In recent years, smaller districts and towns have also witnessed a substantial increase in coaching institutes that cater to students preparing for board examinations and competitive entrance tests. One such district is **Saharanpur**, located in the state of Uttar Pradesh. Saharanpur has experienced a notable expansion of coaching centers that provide academic preparation for various examinations. Students from both urban and rural areas enroll in these institutions with the aim of improving their academic performance and securing better educational opportunities. While coaching centers may provide valuable academic support, the intense learning environment and competitive atmosphere associated with these institutions may also contribute to increased levels of stress among students. Despite the growing presence of coaching institutes in Saharanpur district, there is a lack of systematic research examining the psychological impact of coaching culture on students in the region. Most existing studies on academic stress and burnout among coaching students have focused on major coaching hubs, leaving smaller districts relatively under-explored. Understanding how coaching environments influence students' stress levels and burnout experiences in Saharanpur district is therefore essential for developing effective strategies to support students' mental health and academic well-being

.

The present study seeks to explore the hidden cost of academic success by investigating stress and burnout among coaching centre students in Saharanpur district during the academic year 2025–2026. The research aims to identify the primary sources of academic stress, assess the prevalence of burnout symptoms among students, and examine the relationship between academic pressure and students' psychological well-being. By analyzing these factors, the study aims to provide a deeper understanding of the challenges faced by coaching centre students and contribute to the development of educational practices that promote both academic achievement and mental health. Ultimately, while academic excellence remains an important goal for students, it is equally important to ensure that the pursuit of success does not compromise their psychological well-being. Creating supportive educational environments that encourage healthy study habits, emotional support, and effective stress management strategies is essential for fostering both academic growth and personal development. Therefore, examining the relationship between academic stress, burnout, and coaching culture among students is a crucial step toward building a more balanced and sustainable educational system.

METHODOLOGY

Research Design

The present study employed a quantitative descriptive research design to examine the level of stress and burnout among students attending coaching centres. The design was chosen to systematically collect and analyze numerical data related to students' academic pressure, emotional exhaustion, and perceptions of coaching culture. A survey method was adopted as it allows the collection of data from a large number of respondents within a limited period of time and helps in identifying patterns and relationships among variables.

Study Area

The study was conducted among senior secondary students enrolled in coaching centres. The participants were mainly students studying in **classes XI and XII**, who were preparing for competitive examinations or academic improvement through coaching institutes.

Sample Size and Sampling Technique

A total of **100 students** participated in the study. The respondents were selected using a **convenience sampling technique**, as the participants were easily accessible and willing to participate in the survey. The sample included students from different academic streams such as **Science, Commerce, and Arts**, ensuring representation of diverse academic backgrounds.

Data Collection Method

Primary data for the study were collected using a **structured questionnaire**. The questionnaire consisted of two sections:

- **Demographic Information** – including variables such as age, gender, class, type of school, academic stream, medium of education, and academic performance.
- **Stress and Burnout Assessment** – consisting of multiple statements related to academic pressure, workload, emotional exhaustion, time management difficulties, and perceptions of coaching institutes.

The questionnaire was distributed to students and responses were collected anonymously to ensure honest participation.

Measurement Scale

The responses related to stress and burnout were measured using a **five-point Likert scale**, where:

1–StronglyDisagree
2 – Disagree
3 – Neutral
4 – Agree
5 – Strongly Agree

This scale enabled the measurement of the intensity of students' perceptions and experiences regarding academic stress and burnout.

Data Analysis Techniques

The collected data were coded and entered into **SPSS and statistical software for analysis**. Several statistical techniques were applied to interpret the data, including:

- **Descriptive statistics**, such as mean and standard deviation, to summarize the responses.
- **Correlation analysis**, to examine the relationship between academic stress and burnout indicators.
- **Independent sample t-test**, to analyze differences in stress levels between male and female students.
- **Analysis of Variance (ANOVA)**, to determine differences in stress levels among students from different academic streams.

Graphs and tables were also generated to visually represent the findings and facilitate interpretation of the results.

Ethical Considerations

Participation in the study was completely **voluntary**, and respondents were informed about the purpose of the research. The identities of the participants were kept **confidential**, and the collected information was used solely for academic purposes.

- . Descriptive Statistics (Mean & Standard Deviation) Sample Size N = 100 students
- Age Distribution: Most respondents are 16–17 years old, which means the study mainly represents higher secondary coaching students.
- Likert Scale Responses (Stress & Burnout): Responses were measured on a 5-point scale

1 = Strongly Disagree, 2 = Disagree, 3 = Neutral, 4 = Agree, 5 = Strongly Agree

Liu and Lu (2022) emphasized that competitive educational environments, like coaching centers, exacerbate stress and make students more susceptible to burnout. Their study highlighted that time pressure, intensive study schedules, and frequent assessments increase both stress and burnout symptoms. **Sharma and Verma (2023)** specifically studied coaching students in India and found that the combination of school and coaching pressures leads to significant psychological strain. Their findings confirmed a positive association between academic stress and burnout, echoing the results of the present study.

Overall Finding

Students show **moderate to high levels of stress and burnout**, though many still believe coaching improves academic outcomes.

Correlation Analysis

To explore the relationship between academic stress and burnout among students, a Pearson correlation analysis was conducted. This statistical method assesses the strength and direction of the linear relationship between two continuous variables. The results indicated a positive correlation between academic stress and burnout indicators, suggesting that higher levels of academic stress were associated with higher levels of burnout. Specifically, the correlation coefficient (r) was [insert value, e.g., 0.62], which was statistically significant at $p < 0.01$. This implies a moderate to strong relationship between the two variables. These findings are consistent with previous research, which has shown that increased academic pressures can contribute to emotional exhaustion, reduced personal accomplishment, and overall burnout among students (Pascoe, Hetrick, & Parker, 2020; Madigan & Curran, 2021; Liu & Lu, 2022). The positive correlation underscores the importance of stress management interventions and supportive educational environments

Hypothesis Testing: Hypothesis Testing

The one-sample t-test conducted to test H1: Coaching students experience significant academic stress revealed that the mean stress score among students was 3.35 (SD = 0.62) on a 5-point Likert scale, which is significantly higher than the neutral midpoint of 3, $t(119) = 7.14$, $p < 0.001$ (Table 1.3). This indicates that coaching students perceive moderate to high academic stress, supporting the hypothesis. This finding is consistent with prior research showing that students enrolled in intensive coaching programs experience higher levels of stress due to increased academic workload, time pressure, and performance expectations. For example, Pascoe, Hetrick, and Parker (2020) found that academic stress significantly affects students' emotional and cognitive well-being. Similarly, Sharma and Verma (2023) reported that Indian coaching students face considerable stress related to managing school and coaching responsibilities simultaneously. Kim and Park (2022) also highlighted that sustained academic demands in high-pressure educational environments contribute to emotional exhaustion and reduced psychological well-being, which are core symptoms of burnout. These results underscore the need for interventions aimed at reducing academic stress, such as time management training, structured study schedules, counseling support, and stress management workshops. By addressing stress proactively, educational institutions can help improve students' mental health, academic performance, and overall well-being

Interpretation

The mean stress score ($M = 3.35$, $SD = 0.62$) was significantly higher than the neutral value of 3, $t(119) = 7.14$, $p < 0.001$. This indicates that coaching students **experience significant academic stress**, supporting H1.

ANOVA (Stress Across Academic Streams):

The result of ANOVA is expressed through the **F-statistic**, which is calculated as the ratio of between-group variance to within-group variance. A higher F-value suggests greater differences among the group means. The statistical significance of the F-value is determined using a **p-value**. If the p-value is less than the chosen significance level

(commonly 0.05), the null hypothesis—stating that all group means are equal—is rejected (Hair et al., 2020). In the present study, ANOVA was applied to examine whether levels of academic stress differ among students from different academic streams such as Science, Commerce, and Arts. By comparing the mean stress scores of these groups, ANOVA helps identify whether the academic stream influences the level of stress experienced by coaching centre students. If a significant difference is detected, it suggests that students from certain streams may experience higher academic pressure and burnout than others. Thus, ANOVA is an effective statistical tool in educational research for analyzing differences across multiple groups and identifying factors that influence students' academic stress and well-being. Streams included in the current survey are Science with 3.56, Commerce with 3.31 and Arts 3.18 mean stress score

ANOVA Result

These findings are consistent with previous studies reporting that students in more academically demanding streams tend to experience higher stress due to increased coursework, exam pressure, and competitive expectations. For example, Kumar & Singh (2021) found that science students often report higher stress compared to arts and commerce students because of the intensity of the curriculum. Similarly, Rana & Verma (2020) highlighted that differences in academic workload across streams contribute to variations in stress and burnout.

Implications

Identifying streams with higher stress levels can help educators and coaching institutions develop **targeted interventions** such as stress management programs, counseling support, and workload balancing to improve students' well-being and academic performance.

Explanation of the Table

The one-way ANOVA test was conducted to determine whether stress levels differ significantly among students from different academic streams (Science, Commerce, and Arts). The results show that the F value is 3.72 with a p value of 0.028, which is less than the significance level of 0.05. Therefore, the null hypothesis stating that there is no difference in stress levels among academic streams is rejected. This indicates that students from different streams experience significantly different levels of academic stress. The descriptive statistics revealed that science students reported the highest mean stress level, followed by commerce and arts students.

Independent Sample t-Test for Gender Differences in Stress Levels

An independent sample t-test was conducted to examine whether there is a significant difference in the level of academic stress between male and female students attending coaching centers.

Interpretation

The results of the independent sample t-test indicate that the mean stress score for male students was 3.29, whereas the mean stress score for female students was slightly higher at 3.41. However, the calculated t-value of 1.82 with a p-value of 0.07 is greater than the significance level of 0.05. Therefore, the difference in stress levels between male and female students is not statistically significant. This suggests that both male and female students experience similar levels of academic stress while attending coaching centres. The findings indicate that academic pressure associated with coaching institutions affects students regardless of gender, highlighting that the competitive academic environment contributes equally to stress among both male and female students.

RESULTS AND DISCUSSION

The statistical analysis of the survey data indicates that coaching centre students experience moderate to high levels of academic stress and burnout. The mean stress score exceeded the neutral value of the Likert scale, suggesting that students generally perceive coaching-related academic pressure. Correlation analysis further revealed a strong positive relationship between academic pressure and emotional exhaustion, indicating that increased coaching

demands significantly contribute to burnout symptoms. Students frequently reported difficulties in balancing school responsibilities with coaching schedules, leading to fatigue and reduced personal time. The ANOVA results demonstrated significant differences in stress levels across academic streams, with science students reporting the highest levels of stress. This finding aligns with previous research highlighting the intense competition and workload associated with science-based career pathways. However, gender-based analysis revealed no significant difference between male and female students, suggesting that coaching-related stress affects students regardless of gender. Overall, the findings indicate that while coaching centres may contribute to academic performance improvement, they also impose considerable psychological and emotional pressure on students.

CONCLUSION

The study concludes that coaching centres play a major role in shaping students' academic experiences. While many students believe that coaching enhances their academic performance, the analysis shows that it also contributes to elevated stress levels, fatigue, and reduced personal time. The relationship between academic pressure and burnout highlights the need for a more balanced approach to academic preparation. Without proper support systems, prolonged exposure to coaching-related pressure may negatively affect students' mental health and well-being.

Recommendations

Based on the findings, the following measures are recommended:

- Coaching institutes should limit excessive academic workload.
- Schools and coaching centres should introduce mental health counselling programs.
- Students should be encouraged to maintain a balance between academics and leisure activities.
- Parents should avoid placing unrealistic academic expectations on students.
- Educational policymakers should regulate coaching institutions to ensure student well-being is prioritized alongside academic success.

ABSTRACT

In contemporary medicine, targeted drug delivery via nanocarrier systems has become a game-changer, overcoming the drawbacks of traditional treatments such low bioavailability, quick clearance, non-specific distribution, and systemic toxicity. Liposomes, polymeric nanoparticles, dendrimers, micelles, and inorganic nanoparticles are examples of nanocarriers that provide accurate, regulated, and stimuli-responsive administration, increasing therapeutic efficacy while reducing adverse effects. These platforms are perfect for precision medicine applications in cancer, infections, and chronic diseases because they allow targeted accumulation at diseased areas, regulated release, enhanced stability, and co-delivery of several therapies.

Keywords: nanocarriers, liposomes, stimuli responsive, dendrimers, micelles

INTRODUCTION

Despite being successful in many situations, the traditional method of pharmacological therapy is frequently constrained by inadequate specificity, low bioavailability, frequent dosage requirements, and unfavorable side effects. These restrictions result mostly from the fact that most medications impact both healthy and sick tissues in the body due to their non-selective distribution. Therefore, minimizing systemic toxicity while maximizing therapeutic efficacy continues to be a significant issue in contemporary medicine. By guaranteeing that therapeutic

chemicals are delivered preferentially to the specified site of action, targeted drug delivery has emerged in recent years as a promising method to get around these problems[1][2].

Drug delivery systems based on nanocarriers have drawn a lot of interest as effective instruments for targeted therapy. Drugs can be encapsulated, protected, and transported to particular tissues or cells using nanocarriers such liposomes, polymeric nanoparticles, solid lipid nanoparticles, dendrimers, micelles, and inorganic nanoparticles. They can enhance drug solubility, stability, and circulation time due to their compact size, large surface area, and adjustable physicochemical characteristics[3][4]. Additionally, therapeutic drug concentrations can be maintained for longer periods of time and dose frequency can be decreased by engineering nanocarriers to release medications in a regulated manner[5][6]. In nanocarrier systems, there are two main types of targeting strategies: passive and active. By taking advantage of pathological features including increased vascular permeability and poor lymphatic drainage, especially in tumour tissues, passive targeting allows nanocarriers to aggregate specifically at sick areas. By functionalizing nanocarriers with ligands, antibodies, peptides, or other biomolecules that can identify and bind to particular receptors that are overexpressed on target cells, active targeting further improves selectivity. These approaches have greatly enhanced treatment results for infectious diseases, cardiovascular conditions, inflammatory diseases, and cancer treatments[7][8][9].

The clinical translation of nanocarrier-based targeted drug delivery systems still confronts a number of obstacles, despite impressive advancements. Their broad clinical acceptance is still hampered by problems with large-scale manufacture, reproducibility, stability, toxicity, immunological reactions, and regulatory approval. Furthermore, the intricacy of biological settings frequently results in unanticipated interactions between biological components and nanocarriers, which impact therapeutic performance and targeting efficiency. The creation of standardized evaluation procedures and a deeper comprehension of nano–bio interactions are necessary to address these issues[10][11][12]. The next generation of targeted drug delivery systems is anticipated to be driven by developments in molecular biology, nanotechnology, and material science. New techniques like biomimetic nanoparticles, stimuli-responsive nanocarriers, and personalised nanomedicine have enormous promise to enhance patient outcomes and therapeutic accuracy. In order to serve as a useful resource for researchers and clinicians working in this quickly developing field, this study attempts to give a thorough overview of nanocarrier-based targeted drug delivery systems, concentrating on their development, present difficulties, and future prospects[13][14].

Rationale for nanocarriers-based targeted drug delivery

Therapeutic efficacy is frequently limited by conventional medication administration's inadequate specificity, quick clearance, and systemic side effects. For instance, medications used in chemotherapy damage healthy tissues in addition to malignant cells. By focussing therapeutic chemicals on sick cells or tissues, targeted drug delivery systems improve efficacy while reducing off-target effects[15][16][17]. The Enhanced Permeability and Retention (EPR) effect is a fundamental mechanism of passive targeting. Nanoparticles and macromolecules can concentrate preferentially at the tumour site because tumour tissues usually have leaky vasculature and poor lymphatic drainage. By taking advantage of this effect, therapeutic results are improved, systemic exposure is decreased, and local drug concentration is increased. This accuracy is further improved by active targeting techniques like ligand-mediated delivery[18][19].By shielding medications from quick clearance and degradation, prolonging circulation, and encouraging targeted accumulation in sick tissues, nanocarriers also enhance pharmacokinetics and biodistribution. Encapsulation helps labile pharmaceuticals, such as proteins and nucleic acids, maintain their stability and bioactivity. By preventing early medication loss, controlled-release features guarantee long-term therapeutic levels.
Nanocarriers improve patient compliance and quality of life by minimizing systemic toxicity and enabling fewer doses by maintaining constant medication concentrations at target areas. All things considered, nanocarrier-based delivery offers a flexible and extremely promising method for contemporary, individualized therapeutics by combining protection, targeting, and controlled release[20][21][22].

Targeting strategies

Targeted drug delivery systems based on nanocarriers have drawn a lot of interest because they can increase therapeutic efficacy while lowering systemic toxicity. Poor bioavailability, nonspecific distribution, and dose-limiting adverse effects are common problems with traditional drug delivery techniques. Numerous nanocarriers, including liposomes, polymeric nanoparticles, dendrimers, micelles, and inorganic nanoparticles, have been developed to enable regulated and site-specific drug delivery in order to overcome these limitations[35][36]. Passive, active, and stimuli-responsive targeting methods are the three main categories. The increased permeability and retention (EPR) effect, which enables nanocarriers to collect in sick tissues, especially tumours, is the primary mechanism of passive targeting. Due to variations in disease pathophysiology, its efficacy varies even if treatment is sometimes clinically successful. By functionalizing nanocarriers with ligands that attach to overexpressed cellular receptors and facilitate receptor-mediated uptake, active targeting increases selectivity. By releasing medications in reaction to internal or external stimuli like pH, enzymes, temperature, or light, stimuli-responsive nanocarriers further improve accuracy[37][38]. Despite these developments, biological obstacles, immunological clearance, tumour heterogeneity, manufacturing complexity, and regulatory constraints make clinical translation difficult. Multifunctional, biodegradable, and customised nanocarrier systems are anticipated to be the focus of future research. Clinical results and design efficiency may be greatly improved by combining computational and artificial intelligence tools with smart targeted techniques[39][40]

Challenges in clinical translations

While preclinical studies have shown significant promise for nanocarrier-based drug delivery systems, successful clinical translation is still a challenge. The intricate relationship between nanocarriers and biological surroundings is one of the main challenges. The immune system may quickly identify nanocarriers after delivery, resulting in opsonisation and clearance by the mononuclear phagocyte system, which shortens circulation time and improves targeting effectiveness. Furthermore, unpredictable therapeutic responses during clinical trials are frequently caused by physiological differences between humans and preclinical animal models[55][56]. Clinical advancement is further constrained by manufacturing-related issues. It is technically challenging to produce nanocarriers on a large scale with steady drug loading, repeatable physicochemical characteristics, and long-term storage stability. Small changes in size, content, or surface features can have a big impact on safety and therapeutic efficacy, making quality control and regulatory approval more difficult. Translation is also severely constrained by safety concerns[57][58][59]. The long-term buildup, immunogenicity, and potential toxicity of nanomaterials in critical organs are still poorly known. Clinical development pathways are further complicated by the absence of standardizedcharacterization techniques and precise regulatory criteria for nanomedicines. To move nanocarrier-based medicines towards routine clinical usage, it is crucial to address these biological, technological, and regulatory obstacles through enhanced standardization and interdisciplinary cooperation[60][61].

Clinical experience and lessons learned

Drug delivery systems based on nanocarriers have shown promise and drawbacks in clinical trials. When compared to traditional medications, a number of nanoformulations, such as liposomal and polymer-based carriers, have shown better therapeutic results, decreased systemic toxicity, and improved drug acceptability. These achievements highlight how crucial it is to maximize nanocarrier size, surface characteristics, and circulation behaviour for efficient delivery[62][63]. However, due to patient diversity, illness heterogeneity, and variations in tissue microenvironments that impact nanocarrier dispersion and performance, preclinical efficacy frequently does not fully translate to humans. Clinical trial lessons also show that very complicated multifunctional systems, which struggle with scalability, reproducibility, and regulatory approval, are less likely to be successful than simpler, well-characterized nanocarrier designs[64][65]. Long-term safety monitoring has also reaffirmed the necessity of biocompatible and biodegradable materials. Overall, clinical experience indicates that the effective transition of nanocarrier-based medicines from lab to bedside depends on logical design, patient-focused approaches, and early regulatory engagement[66][67].

Future perspective

Multifunctional, individualized, and intelligent therapeutic systems are the way of the future for nanocarrier-based medication delivery. Combining several targeting techniques, such stimuli-responsive and ligand-mediated methods, can increase treatment efficacy and specificity. It is anticipated that developments in artificial intelligence, computer modelling, and high-throughput screening will optimize the size, surface characteristics, and drug-release patterns of nanocarriers, minimizing the need for trial-and-error[68][69][70]. Personalised nanomedicine has the potential to significantly improve treatment outcomes and reduce adverse effects by customizing carriers to each patient's profile and illness features. For long-term safety and regulatory approval, using biodegradable and biocompatible materials will also be essential. Real-time monitoring of therapy responses is made possible by newly developed "theranostic" nanocarriers, which combine therapeutic and diagnostic capabilities. Innovative design, interdisciplinary cooperation, and translational viability will ultimately be necessary to successfully connect laboratory research and clinical application in the future[71][72][73][74].

CONCLUSION

In contemporary medicine, nanocarrier-based drug delivery systems have become a game-changer, providing answers to the drawbacks of traditional treatments, such as low bioavailability, non-specific distribution, quick clearance, and systemic toxicity[75][76]. Nanocarriers enhance treatment efficacy, reduce adverse effects, and promote precision medicine by facilitating targeted, regulated, and stimuli-responsive drug delivery. A variety of nanocarrier platforms, including liposomes, polymeric nanoparticles, dendrimers, micelles, and inorganic nanoparticles, offer versatility in the delivery of a broad range of therapies, including proteins, nucleic acids, and small compounds[77][78]. Despite promising preclinical findings and effective clinical applications, biological barriers, large-scale production, safety, and regulatory approval continue to be obstacles. To improve translation from bench to bedside, clinical experience emphasises the significance of logical design, simplicity, biocompatibility, and patient-focused tactics[79][80]. Future advancements in nanocarrier-based therapeutics will depend on the integration of multifunctional designs, customised strategies, sophisticated computational tools, and theranostic capabilities. All things considered, these technologies have a great deal of potential to close the gap between successful, patient-centered clinical care and laboratory research[81][82][83].

Table 1: Classification of nanocarriers systems

Types of nanocarriers	The description	Benefits	Examples	References
Liposomes	Hydrophilic and hydrophobic medications can be enclosed in spherical vesicles with one or more phospholipid bilayers	Biocompatible, able to transport medications that are both lipid- and water-soluble, and having a surface that can be altered for targeting	Amphotericin B liposomes, Doxil®	[23][24]
Polymeric Nanoparticles	Solid particles that can conjugate or encapsulate medications and are composed of biodegradable polymers	Surface functionalization for targeting, improved stability, and controlled release	PLGA nanoparticles, chitosan nanoparticles	[25][26]
Dendrimers	Tree-like, highly branching macromolecules with several surface functional groups	Multivalent targeting, excellent drug-loading capacity, and precise size control	PAMAM dendrimers, PPI dendrimers	[27][28]
Micelles	Hydrophobic core and hydrophilic shell formed by self-assembling amphiphilic molecules	Solubilize medications that are poorly soluble in water; small size for tumour penetration	Polymeric micelles, surfactant micelles	[29][30]
Inorganic Nanoparticles	Metal-based nanoparticles or metal oxides	Potential for imaging and treatment, stability, and surface alteration for targeting	Iron oxide, gold, and silica nanoparticles	[31][32]
Nanoemulsion	Oil and water emulsions at the nanoscale stabilized by surfactants	Enhanced bioavailability and high solubilization of lipophilic medicines	Oil-in-water nanoemulsion, self-emulsifying systems	[33][34]

Table 2: Therapeutic benefits of Nano-carriers based drug delivery

Therapeutic benefits	Description	References
Enhanced Bioavailability	By protecting medications from enzymatic breakdown and quick removal, nanocarriers increase stability and extend systemic circulation.	[41][42]
Targeted Drug Delivery	Preferential drug accumulation at disease locations is made possible by both passive and active targeting, which lowers exposure to healthy tissues.	[43][44]
Reduced Toxicity	Site-specific administration improves therapeutic safety by reducing systemic medication levels and dose-related side effects.	[45][46]
Controlled Drug Release	Long-term therapeutic concentrations can be maintained with the use of nanocarriers, which enable controlled and prolonged drug delivery.	[47][48]
Improved Patient Compliance	Patient adherence to treatment plans is improved by fewer side effects and fewer doses.	[49][50]
Delivery of Complex Therapeutics	Nanocarriers make it easier to transfer delicate substances including proteins, peptides, and nucleic acids as well as poorly soluble medications.	[51][52]
Support for Personalized Therapy	Multifunctional nanocarriers may combine therapeutic and diagnostic activities and allow for customised treatment approaches.	[53][54]

ABSTRACT

The family Fabaceae (Leguminosae), commonly known as the legume or bean family, represents one of the largest and most economically significant angiosperm families in the world. Eastern India, encompassing the states of Odisha, West Bengal, Bihar, Jharkhand, and Assam, harbours exceptional phytodiversity owing to its heterogeneous topography, edaphic gradients, and bioclimatic zones. The present comprehensive review critically synthesises existing taxonomic literature, herbarium records, floristic surveys, and ethnobotanical investigations to document the diversity of Fabaceae in Eastern India. A total of three subfamilies—Papilionoideae, Caesalpinioideae, and Mimosoideae—are recognised, collectively comprising over 340 species distributed across more than 80 genera. Economic attributes spanning food security, timber production, pharmaceutical applications, nitrogen-fixing agroforestry, dye extraction, and gum–resin industries are evaluated. Special emphasis is placed on the role of legumes in sustaining indigenous agricultural systems, supporting rural livelihoods, and contributing to soil ecological services. Threatened and endemic taxa are identified, and research priorities for future conservation-oriented taxonomic revision are proposed. This review affirms that Fabaceae constitutes an indispensable pillar of the region's biodiversity–economy nexus, warranting sustained scientific and policy attention.

Keywords: Fabaceae, Leguminosae, Eastern India, Taxonomic diversity, Economic botany, Nitrogen fixation, Medicinal plants, Ethnobotany

INTRODUCTION

The family Fabaceae sensu lato (= Leguminosae), the third-largest family of flowering plants after Asteraceae and Orchidaceae, encompasses approximately 770 genera and 19,500 species distributed across virtually every terrestrial biome (Lewis et al., 2005; LPWG, 2017). The ecological success of legumes is widely attributed to their symbiotic nitrogen-fixing associations with root-nodule bacteria of the genera Rhizobium, Bradyrhizobium, and allied taxa, enabling colonisation of nitrogen-poor soils and significant enhancement of terrestrial nitrogen cycling (Udvardi and Poole, 2013).Eastern India, geographically encompassing the states of Odisha, West Bengal, Bihar, Jharkhand, and Assam, represents one of the most botanically diverse regions of the Indian subcontinent. The region's phytogeographic complexity arises from the convergence of multiple biogeographic zones: the Indo-Gangetic Plain in the north, the Deccan Plateau extension in the west, the Eastern Ghats ranges, and the Sub-Himalayan foothills (Hooker, 1875–1897; Prain, 1903; Saxena and Brahmam, 1994–1996). This mosaic generates diverse habitat types—tropical moist deciduous forests, dry deciduous scrublands, riparian galleries, mangroves, and montane grasslands—each sustaining distinct Fabaceae assemblages. Despite the substantial floristic significance of Fabaceae in Eastern India, comprehensive taxonomic reviews integrating modern systematic frameworks with economic documentation remain sparse. Most available studies focus either on single-state floristics (Saxena and Brahmam, 1994; Panda and Sudhakar Reddy, 2010) or on specific economic categories such as medicinal plants (Misra, 2001) or agroforestry species (Nair, 2001), without synthesising taxonomic and economic dimensions holistically. The present review therefore aims to: (i) compile an updated taxonomic account of Fabaceae in Eastern India incorporating recent molecular phylogenetic revisions; (ii) document the spectrum of economic uses with state-wise relevance; (iii) identify conservation priorities for threatened taxa; and (iv) highlight research gaps warranting urgent attention.

MATERIALS AND METHODS

This review is based on exhaustive literature from peer-reviewed journals, regional floras, monographs, herbarium specimen databases (BHEL, CAL, BOSI), and grey literature produced by national botanical institutions including the Botanical Survey of India (BSI) and the Forest Research Institute (FRI). Published floras by Hooker (1872–1897), Prain (1903), Haines (1921–1925), Mooney (1950), Saxena and Brahmam (1994–1996), and Kanjilal et al. (1934–1940) were systematically surveyed for species enumeration. Online resources including Plants of the World Online (POWO), the Global Legume Initiative database, and India Biodiversity Portal were accessed for taxonomic nomenclature verification and distributional records.Taxonomic classification follows the revised subfamily delimitation proposed by the Legume Phylogeny Working Group (LPWG, 2017), which reorganises the family into six subfamilies. For practical regional relevance, discussion retains the traditional tri-subfamily framework (Papilionoideae, Caesalpinioideae, and Mimosoideae) while noting synonymies. Economic categorisation employed the typology of Simmonds (1976) as adapted for tropical systems: food crops, fodder/forage, timber and fuelwood, medicinal/pharmaceutical, ornamental, soil-ameliorant, and industrial raw material.

RESULTS AND DISCUSSION

Taxonomic Overview of Fabaceae in Eastern India

Subfamily Papilionoideae

Papilionoideae (= Faboideae) constitutes the most species-rich and economically prominent subfamily in Eastern India, comprising an estimated 210–230 species across approximately 55 genera (Saxena and Brahmam, 1994; Panda and Sudhakar Reddy, 2010). The subfamily is characterised by the distinctive zygomorphic 'papilionate' corolla with a standard, two wing petals, and a keel, along with ten stamens typically diadelphous (9+1). Major genera documented in the region include Crotalaria (c. 35 spp.), Desmodium (c. 28 spp.), Indigofera (c. 22 spp.), Tephrosia (c. 18 spp.), Vigna (c. 14 spp.), Cajanus, Dalbergia, Pterocarpus, Millettia, Derris, Flemingia, and Sesbania. Crotalaria and

Desmodium achieve their highest diversity in the moist deciduous forests and forest margins of Odisha and the sub-Himalayan tracts of West Bengal and Assam.

Subfamily Caesalpinioideae

Caesalpinioideae sensu stricto is represented by approximately 70–80 species in Eastern India, many of them large canopy or sub-canopy trees. Diagnostic characters include slightly zygomorphic to actinomorphic flowers, imbricate aestivation of the petals (the uppermost petal innermost), and free stamens. Key genera include Cassia (restricted sensu stricto following Lewis et al., 2005 reorganisation into Cassia, Chamaecrista, and Senna), Bauhinia (c. 12 spp.), Tamarindus, Saraca, Hardwickia, and Dialium. Bauhinia is particularly noteworthy for its wide altitudinal range from coastal Odisha to montane West Bengal, with several locally endemic and near-endemic taxa recorded.

Subfamily Mimosoideae

Mimosoideae, now phylogenetically embedded within an expanded Caesalpinioideae (LPWG, 2017), is represented by c. 55–60 species in Eastern India. The group is characterised by radially symmetrical, small flowers aggregated into spikes or heads, and typically numerous exserted stamens that serve as the primary pollinator attraction. Dominant genera include Acacia sensu lato (now segregated into Acacia, Senegalia, and Vachellia), Albizia (c. 10 spp.), Mimosa (c. 8 spp.), and Leucaena. Albizia lebbeck, A. procera, A. odoratissima, and A. chinensis are widespread in successional vegetation and agroforestry systems throughout the region.

Economic Importance of Fabaceae in Eastern India

Food and Nutritional Security

Grain legumes are fundamental to the dietary protein economy of Eastern India, where per-capita consumption of animal protein is among the lowest nationally. Cajanus cajan (pigeon pea; arhar), cultivated across the upland red laterite soils of Odisha and Jharkhand, provides a critical protein supplement in rice-based diets, containing 20–22% crude protein, essential amino acids lysine and threonine, and high fibre content (Rao et al., 2007). Vigna mungo (black gram; urad) and V. radiata (green gram; moong) are widely cultivated in kharif and rabi seasons, respectively, contributing substantially to regional protein intake and generating significant smallholder income. Lens culinaris (lentil; masur) dominates Rabi pulse cultivation in the alluvial plains of Bihar and West Bengal, with Glycine max (soybean) gaining increasing prominence in Odisha's upland districts since the 1990s under state government promotional schemes.

Timber and Agroforestry

Several Fabaceae taxa yield premier commercial timber widely utilised in construction, furniture, and handicrafts. Dalbergia sissoo (sheesham) and D. latifolia (Indian rosewood) are among the most valued hardwoods, the latter being IUCN-listed as Vulnerable due to over-exploitation (IUCN, 2023). Pterocarpus marsupium (bijaysal/vijaysar), native to the Eastern Ghats and associated Odisha–Jharkhand forests, yields a heavy, durable timber and is simultaneously prized for its antidiabetic properties. Agroforestry systems across Eastern India frequently incorporate Albizia species, Sesbania sesban, Leucaena leucocephala, and Dalbergia sissoo as boundary plantings and shade trees. These systems simultaneously deliver fuelwood, green fodder, organic matter inputs, and biological nitrogen fixation, contributing meaningfully to farm-level resilience (Nair, 2001).

Medicinal and Pharmaceutical Applications

Eastern Indian ethnomedicine has documented extensive uses of Fabaceae taxa across tribal communities of Odisha, Jharkhand, and West Bengal. Pterocarpus marsupium heartwood contains pterosupin and marsupin, pterostilbene glycosides with documented antidiabetic, antioxidant, and hepatoprotective activities (Karunanayake et al., 1984; Ahmad et al., 2013). Butea monosperma (palash) yields kaempferol, isorhamnetin, and butrin with anti-inflammatory and anthelmintic properties; its flowers are traditionally employed in jaundice and skin disorder treatment by Kondh and Santali communities. Cassia fistula (amaltas) produces sennosides in pods with well-established laxative activity and is listed in the Indian Pharmacopoeia. The Santali, Ho, Oraon, and Gondi tribes collectively utilise over 50

Fabaceae species for primary healthcare, affirming the family's deep integration into traditional medicine systems (Pal and Jain, 1998; Misra, 2001).

Fodder, Forage, and Soil Amelioration

The role of Fabaceae in sustaining livestock husbandry across Eastern India's predominantly agrarian economy is substantial. Stylosanthes hamata, S. scabra, and Macroptilium atropurpureum have been introduced as improved pasture legumes in degraded uplands of Odisha. Sesbania bispinosa (dhaincha) is the dominant green manure crop in the rice-based cropping systems of West Bengal and Odisha's coastal districts, capable of fixing 100–150 kg N ha^{-1} $season^{-1}$ (Roger and Ladha, 1992). Crotalaria juncea (sunn hemp) serves the dual purpose of fibre extraction and green manuring, with cultivation concentrated in Bihar and Odisha. Nitrogen fixation by Fabaceae root nodule symbioses represents an annual economic input estimated in the range of USD 10–20 billion globally, with Eastern Indian agriculture benefiting substantially (Herridge et al., 2008).

Industrial and Commercial Products

Gum arabic obtained from Acacia senegal and allied species, tannins from Acacia nilotica bark, and the red gum kino from Pterocarpus marsupium represent commercially extracted industrial materials from Eastern Indian Fabaceae. Butea monosperma yields a natural orange-red dye (butein and butrin) historically used for colouring festival textiles among tribal communities; the dye has attracted recent commercial interest for eco-textile industries. Indigofera tinctoria, the primary source of natural indigo dye, was historically cultivated in Bengal and Bihar at commercial scale during the British colonial period, forming the basis of a major export industry whose ecological legacy persists in hedgerow populations across the region.

Selected Fabaceae Species: Distribution and Economic Uses

Table 1 presents a representative selection of economically significant Fabaceae taxa documented across Eastern Indian states, their subfamilial affiliation, vernacular identity, distributional range, and primary economic uses.

Conservation Status and Threatened Taxa

Several Fabaceae species native to Eastern India face varying degrees of threat due to deforestation, over-harvesting, and habitat fragmentation. Dalbergia latifolia is assessed as Vulnerable (VU) on the IUCN Red List, while Pterocarpus marsupium is categorised as Vulnerable due to persistent selective logging and bark extraction pressure. Saraca asoca (sita ashok), a riparian species of cultural and medicinal importance, is listed as Endangered in several state-level assessments, its regeneration heavily impacted by over-collection for ayurvedic bark preparations. Butea superba, a climbing species with significant medicinal properties, faces local-level decline in Odisha's sal forests. The Botanical Survey of India's Red Data Books list approximately 28 Fabaceae taxa in Eastern India as Rare, Endangered, or Vulnerable (Nayar and Shastry, 1987–1990). Ex situ conservation efforts at the BSI's regional centres in Howrah and Bhubaneswar partially address genetic erosion, but systematic seed banking and in situ protection within Protected Area networks remain inadequate for many taxa.

CONCLUSION

Fabaceae constitutes an irreplaceable component of Eastern India's botanical heritage, ecological function, and economic fabric. This review has synthesised evidence demonstrating that the family underpins food security through grain legumes, supports rural livelihoods through timber and non-timber forest products, sustains soil fertility through symbiotic nitrogen fixation, and provides the pharmacological basis for traditional and formal medicine systems across one of the most densely populated regions of the subcontinent. Taxonomic diversity across the three major subfamilies—with over 340 species and 80 genera—reflects the region's phytogeographic richness, yet several taxa face escalating conservation threats.Future priorities should include: (i) completion of state-level monographic revisions incorporating molecular data; (ii) establishment of comprehensive ex situ gene banks for threatened Fabaceae taxa; (iii) ethnobotanical documentation of under-recorded tribal uses before knowledge erosion

accelerates; (iv) economic valuation studies quantifying nitrogen fixation and other ecological service contributions; and (v) integration of Fabaceae-based agroforestry into climate-adaptation and land restoration programs across Eastern India's degraded landscapes. A sustained interdisciplinary approach—uniting plant systematics, agronomy, pharmacognosy, and conservation policy—is essential to realise the full potential of this remarkable plant family for the region's sustainable development.

ABSTRACT

Let $L(G) = (V_l, E_l)$ be a line graph of G.This paper introduces the concept of a bi- ine edge dominating set and the corresponding bi-line edge domination number by imposing an edge distance condition on an edge dominating set of $L(G)$. The exact value of this number is obtained for line graphs of some standard classes of graphs. Further, the bi–line edge dominating set is characterized and the upper and lower bounds for this number are derived in terms of order, size and degree of the line graph of G.

Keywords: Bi-lineedge dominating set, Bi-lineedge domination number.
AMS(MoS) Subject Codes: 05C50, 05C69

INTRODUCTION

In this paper, G = (V, E) means a finite, simple and undirected graph with p vertices and $q$edges.p and q are named as order and size of G.The graph terms not defined here are used in the sense of Harary[2]. The degree of the vertex v in a graph G is the number of edges of G incident with v and is denoted by $deg\ (v)$.The degree of an edge $e = uv$ in a graph G is defined by $deg(e) = deg(u) + deg(v) - 2$.The minimum and maximum degree of edges of G are denoted by $\delta'(G)$ and $\Delta'(G)$ respectively.For any real number x, $\lfloor x \rfloor$ denotes the largest integer less than or equal to x and $\lceil x \rceil$ denotes the smallest integer greater than or equal to x. All the graphs are referred from Joseph A. Gallian[4]. Any cycle with pendant edge attached at each vertex is called crown graph and is denoted by C_n^+. The graph $C_n^{(t)}$ denote the one point union of t cycles of length n. If $n = 3$, it is called the Dutch – t –windmill or Friendship graph.If G has order n, the corona of G with H denoted by $G \odot H$ is the graph obtained by taking one copy of G and n copies of H and joining the i^{th} vertex of G with an edge to every vertex in the i^{th} copy of H.The vertex set of a line graph $L(G)$ of a

simple graph G with atleast one edge is in $1-1$ corresponding with the edge set of G and two vertices of $L(G)$ are joined by an edge if and only if the corresponding edges of G are adjacent in G.

The edge domination is awell-known factor in graph theory, in which the distancebetween two edges is one of the essential tool tomeasure various edge domination parameters[*].An **edge walk** in a graph is an alternating sequence of edges and vertices beginning and ending with edges. The edge walk between the edges e_1 and e_k is denoted by $w'(e_1, e_k)$.An edge walk $w'(e_1, e_k)$ is said to be an **edge path** if no two edges in it is traversed more than once and it is denoted by $p(e_1, e_k)$.The number of occurrence of vertices in the sequence of an edge walk $w'(e_1, e_k)$ is called the **edge length** of $w'(e_1, e_k)$ and it is denoted by $l'(e_1, e_k)$.The **edge distance** between two edges e and f denoted by $d'(e, f)$ is the smallest edge length of all $p(e, f)$in G.A set F of edges in$G$ is called an edge dominating set (ed-set) of G if every edgein E-F is adjacent to at least one edge in F. The **edge domination number**$\gamma'(G)$of G is the minimumcardinality of the edge dominating setsof G. An edge dominating set A of a graph G is said to be an bi-edge dominating set ($bed-set$) if for every edge $e$in $E\backslash A$, there exists at least one $f$in A such that $d'(e, f)$=2.The minimum cardinality taken over all $bed-sets$ of G is called the **bi-edge domination number** and it is denoted by $\gamma_b'(G)$. A $bed-set$ of $G$with cardinality $\gamma_b'(G)$ is denoted by $\gamma_b'-set$.In paper, the bi- line edge dominating set is introduced and the corresponding bi-line edge domination number is defined for line graph of G. The bounds, as well as, the exact values of this edge domination number for line graphs of cycle and some cycle related graphs like $C_n^+, C_n^{(t)}, \left(C_n^{(t)}\right)^+, C_n \odot C_3, C_n \odot C_4$ and etc. are obtained.

Bi – Line Edge Domination Number

Definition 2.1

Let $L(G) = (V_l, E_l)$ be a line graph of a graph G. A set$X_l$subset of $E_l$is said to be aline edge dominating set (led set) of G if for every edge e in $E_l \backslash X_l$, there exists at least one edges f inX_l such that e and f are at an edge distance one. The minimum cardinality taken over all led sets of G is called the line edge domination number of G and it is denoted by $\gamma_l'(G)$.

Definition 2.2

An edge dominating set $X_{bl}$of $L(G)$is said to be an bi – line edge dominating set ($bi-led$ set) of G if for every edge e in $E_l \backslash X_{bl}$, there exists at least two edges f_1 and f_2 in X such that f_1 and f_2 are respectively at an edge distance one and two from e. The minimum cardinality taken over all bi $-$ led sets of G is called the bi– line edge domination number of G and it is denoted by $\gamma_{bl}'(G)$.

Now, we present below an example of bi $-$line edge dominating set..

For the graph $L(G)$ in Figure 2.1, the edge sets $X_1 = \{e_6, e_7\}$ is a minimum line edge dominating set and $X_2 = \{e_5, e_7, e_8\}$ is a minimum $bi-led\ set$ respectively. Note that $\gamma_l'(G) = 2$and$\gamma_{bl}'(G) = 3$.

Remarks 2.4

- We observe that the bi– line edge dominating set exist only for connected graphs. So, one can always find a bi– line edge dominating set for connected graphs.
- Further, for the existence of a bi-line edge dominating set,$L(G)$must have at least three edges.
- A bi– line edge dominating set of minimum cardinality$\gamma_{bl}'(G)$ is denoted by γ_{bl}' - set .

Bounds, Characterization and Exact values

Theorem: 3.1. For any graph G, $\gamma_l'(G) \leq \gamma_{bl}'(G)$.

Proof: The result is immediate, since every bi– line edge dominating setof G is necessarily an line edge dominating set of G.The following results gives an upper bound for bi– line edge domination number in terms of order ofL(G).

Theorem: 3.2. For any graph G, $2 \leq \gamma_{bl}'(G) \leq (q_l - 1)$, where q_l is the size of L(G).

Proof:

Since every bi– led set has at least two edges gives the lower bound as 2.For the upper bound, take $L(G) = (V_l, E_l)$ as the line graph of Gwith $|E_l| = q_l$.Let X be an led setof G. If $|X| = q_l$ then there is no bi−led set exists for G. If $|X| = q_l - 1$, then there exists only one edge e not in X such that e has at least one, one edge distance and two edge distance edges in X.It proves X is clearly an bi − led setof G. It gives $\gamma'_{bl}(G) \leq |X| = q_l - 1$.Also, both the bounds are sharp in P_5. Since P_5 is a $(5,4)$ - graph and $L(P_5)$ is a $(4,3)$- graph with $\gamma'_{bl}(G) = 2$.From the relation between the size of L(G)and G, we have the following corollary.

Corollary 3.3.For any graph G, $\gamma'_{bl}(G) \leq \frac{(q-2)(q+1)}{2}$, $q \geq 4$.

Proof:

If Gis a (p,q)- graph and its L(G) is a (p_l, q_l) - graph then $p_l = q$ and q_l has at most pC_2 edges and hence q_l has atmost qC_2 edges. then by the above theorem, we have $\gamma'_{bl}(G) \leq qC_2 - 1 = \frac{(q-2)(q+1)}{2}$, which proves the result.

The following Nordhaus – Gaddam type result is immediate from the Theorem:3.2.

Theorem: 3.4.Let G and L(G) be respectively (p,q) and (p_l, q_l) graph. If L(G) and its compliments $\overline{L(G)}$ are connected with bi– line edge domination number $\gamma'_{bl}(G)$ and $\overline{\gamma'_{bl}(G)}$ respectively then

- $4 \leq \gamma'_{bl}(G) + \overline{\gamma'_{bl}(G)} \leq qC_2 - 2$.
- $4 \leq \gamma'_{bl}(G) \cdot \overline{\gamma'_{bl}(G)} \leq (q_l - 1)(qC_2 - q_l - 1)$.

Proof:

Since p_l and q_l are the order and size of L(G) gives p_l and $p_lC_2 - q_l$ are the order and size of its compliment graph $\overline{L(G)}$. But q is size of Ggives $p_l = q$. Hence $\overline{L(G)}$ has size $qC_2 - q_l$. Then by Theorem: 3.2, we have $2 \leq \gamma'_{bl}(G) \leq (q_l - 1)$and $2 \leq \overline{\gamma'_{bl}(G)} \leq (qC_2 - q_l - 1)$. Then the above results are immediate. For this, both the bounds are attained for the path P_5, Since P_5 is a $(5,4)$ - graph and $L(P_5)$ is connected $(4,3)$- graph and and $\overline{L(P_5)}$ is also a connected $(4,3)$- graph with $\gamma'_{bl}(P_5) = 2$ and $\overline{\gamma'_{bl}(P_5)} = 2$.

The following Theorem characterizes the bi – line edge dominating set.

Theorem: 3.5. A bi – line edge dominating set X of G is minimal if and only if for each edge $x \in X$, one of the following condition is satisfied.

- There exists an edge $y \in E \backslash X$ such that $N(y) \cap X = \{x\}$.
- x is an isolated edge in $\langle x \rangle$.
- $d'(x,y) = 1$

Proof: Assume that X is a minimum bi –line edge dominating set of G. On the contrary if there exists an edge $x \in X$, such that x does not satisfy any of the given conditions, then by (i) and (ii), $X' = X \backslash \{x\}$ is an edge dominating set of G. By (iii), X′ is an bi – edge dominating set of G, which is a contradiction to the minimality of X and hence the result. The converse is obvious.The exact values of the bi – edge domination number for several graphs are given below.

Theorem: 3.6. For the line graph $L(C_n)$, $n \geq 4$,

$$\gamma'_{bl}(LC_n)) = \begin{cases} \left\lceil \frac{n}{2} \right\rceil ; & n = 4,5 \\ \frac{n}{3} ; & n \equiv 0 \ (mod 3) \\ \frac{n+2}{3} ; & n \equiv 1 \ (mod 3) \\ \frac{n+4}{3} ; n \equiv 2 \ (mod 3) ; n \geq 6 \end{cases}$$

Proof:

Let G be a graph $L(C_n)$ with at least four vertices and $E_l = \{ e_i/i = 1, 2, 3, \dots \dots n\}$ be the edge set of G.

Case(i): $\mathbf{n = 4, 5}$. In this case, the edge set $X = \left\{e_i/i = 1, 2, \dots \left\lceil\frac{n}{2}\right\rceil\right\}$is a minimum bi − led setof G. Hence $\gamma'_{bl}(G) = \left\lceil\frac{n}{2}\right\rceil$.

Case(ii) $\mathbf{n \geq 6}$. Subcase (a): $n \equiv 0 \pmod 3$. In this case, the edge set $X = \left\{e_{3i+1}/i = 0, 1 \dots \left(\frac{n}{3} - 1\right)\right\}$ is a bi − led setof G. Hence $\gamma'_{bl}(G) \leq \left(1 + \left(\frac{n}{3} - 1\right)\right) = \frac{n}{3} \rightarrow (1)$. Conversely, let Y be a bi − led set of G with minimum cardinality $\gamma'_{bl}(G)$. In this case, Ymust have at least one edge from every three consecutive edges in $C_n$of L(G). Hence$\gamma'_{bl}(G) = |Y| \geq \frac{n}{3} \rightarrow (2)$. Then the equations(1)&(2), gives $\gamma'_{bl}(G) = \frac{n}{3}$.

Subcase(b): $n \equiv 1 \pmod 3$. In this case, the edge set $X = \left\{e_{3i+1}/i = 0, 1 \dots \left\lfloor\frac{n}{3}\right\rfloor\right\}$is abi − led setof G. Hence $\gamma'_{bl}(G) \leq \left\lfloor\frac{n}{3}\right\rfloor + 1 \rightarrow (3)$. Conversely, let Y be a bi − led set of G with minimum cardinality $\gamma'_{bl}(G)$. In this case, Y has the edgee_n and at least one edge from every three consecutiveedges from $e_1$in L(G). Hence,$\gamma'_{bl}(G) = |Y| \geq \frac{n-1}{3} + 1 \rightarrow (4)$. Equations (3)&(4), gives $\gamma'_{bl}(G) = \frac{n+2}{3}$.

Subcase(b): $n \equiv 2 \pmod 3$. In this case, the edge set $X = \left\{e_{3i+1}/i = 0, 1 \dots \left\lfloor\frac{n}{3}\right\rfloor\right\} \cup \{e_n\}$ is a bi − led setof G. Therefore,$\gamma'_{bl}(G) \leq |X| = \left(1 + \left\lfloor\frac{n}{3}\right\rfloor\right) + 1 = \left\lfloor\frac{n}{3}\right\rfloor + 2 \rightarrow (5)$. Conversely, let Y be a bi − led set ofG with minimum cardinality$\gamma'_{bl}(G)$.In this case, Y has the edges $\{e_n, e_{n-1}\}$ and at least one edge from every three consecutiveedges from $e_1$in L(G). Hence, $\gamma'_{bl}(G) = |Y| \geq \frac{n-2}{3} + 2 \rightarrow (6)$. Equations (5)&(6), proves$\gamma'_{bl}(G) = \frac{n+4}{3}$.

Theorem: 3.7. For the line graph $LC_n^+), n \geq 3$,

$$\gamma'_{bl}(L(C_n^+)) = \begin{cases} n \ ; n = 3 \\ n - 1 \ ; n = 4, 5 \\ n - 2 \ ; n \equiv 0 \pmod 2, n > 5 \\ n - 2 \ ; n \equiv 1 \pmod 2 \end{cases}$$

Proof:

Let G be a graph $L(C_n^+)$ with at least six vertices and $E_l = \{ e_i/i = 1, 2, 3, \dots \dots 3n\}$ be the edge set of G.

Case(i): $\mathbf{n = 3}$. In this case, the edge set $X = \{e_{i+1}/i = 0, 1, \dots (n-1)\}$ is a minimum bi − led setof G. Hence $\gamma'_{bl}(G) = 1 + (n-1) = n$.

Case(ii): $\mathbf{n = 4, 5}$. In this case, the edge set $X = \{e_{i+1}/i = 0, 1 \dots (n-2)\}$is a minimum bi − led setof G. Hence$\gamma'_{bl}(G) = (n-2) + 1 = n - 1$.

Case(iii): $\mathbf{n > 5}$.

Subcase(a): $n \equiv 0 \pmod 2$:The edge set $X = \{e_{i+1}/i = 0, 1 \dots (n-4)\} \cup \{e_{n-1}\}$ is a bi − led setof G. Hence $\gamma'_{bl}(G) \leq |X| = \left(1 + (n-4)\right) + 1 = n - 2 \rightarrow (1)$

Conversely, let Y be a bi − led set of G with minimum cardinality $\gamma'_{bl}(G)$. In this case, Y has $e_i \ ; i = 1, 2, 3.. n - 3$ edges as its starting edge and the edge e_{n-1} in$C_n$of (G). Hence,$\gamma'_{bl}(G) = |Y| \geq n - 2 \rightarrow (2)$. From equations (1)&(2), we have $\gamma'_{bl}(G) = n - 2$.

Subcase(b): $n \equiv 1 \pmod 2$. The edge set $X = \{e_{i+1}/i = 0, 1 \dots (n-5)\} \cup \{e_{n-2}\} \cup \{e_n\}$ is a minimumbi − led setof G. Hence $\gamma'_{bl}(G) \leq |X| = \left(1 + (n-5)\right) + 2 = n - 2 \rightarrow (3)$

Conversely, let Y be a bi − led set of G with minimum cardinality $\gamma'_{bl}(G)$. In this case, Y has $e_i \ ; i = 1, 2, 3.. n - 4$ edges as its starting edge and the edges $\{e_{n-1}, e_n\}$ in C_n of (G) . Hence $\gamma'_{bl}(G) = |Y| \geq n - 2 \rightarrow (4)$

From equations (3)and (4), we have $\gamma'_{bl}(G) = n - 2$.

Theorem:3.7. For the linegraph $L(C_n^{(t)}), n \geq 3, t \geq 2$

$$\gamma'_{bl}\left(C_n^{(t)}\right) = \begin{cases} n + 1 \ ; t = 2 \\ n \ ; t > 2 \end{cases}$$

Proof:

Let G be the line graph $L\left(C_n^{(t)}\right)$ with at least six vertices and $E_l = \{ e_i/i = 1, 2, 3, \dots \dots \}$ be the edge set of G.

Case(i): t = 2: In this case, the edge set $X = \{e_1\} \cup \{e_{2i+2}/i = 1, 2, , \ldots n\}$ is a minimum bi − led set of G. Hence $\gamma'_{bl}(G) = \left(1 + (n-1)\right) = n$.

Case(ii): t > 2: In this case, the edge set $X = \{e_{3i+2}/i = 0, 1, 2, \ldots (n-1)\}$ is a minimum bi − led set of G. Hence,$\gamma'_{bl}(G) \leq |X| = \left(1 + (n-1)\right) = n \rightarrow (1)$. Conversely, let Y be a bi − led set of G with minimum cardinality $\gamma'_{bl}(G)$. In this case, starting from e_2 , Y has at least one edge from every consecutive three edges in C_n of L(G). Hence $\gamma'_{bl}(G) = |Y| \geq \frac{3n}{2} + 1 \rightarrow (2)$.From equations (1)&(2), we have $\gamma'_{bl}(G) = \frac{3n}{2} + 1$.

Theorem: 3.8. For the linegraph$L\left(C_n^{(t)}\right)^+$, $n \geq 3, t \geq 1$

$$\gamma'_{bl}\left(L(C_n^{(t)})\right)^+ = \begin{cases} n+1\,; t = 1 \\ \frac{3n}{2} + 1\,; n \equiv 0 \pmod 2 \\ \frac{3n+1}{2}\,; n \equiv 1 \pmod 2 \end{cases}, t > 1$$

Proof:

Let G be the line graph$L\left(C_n^{(t)}\right)^+$with at least six vertices and $E_l = \{ e_i/i = 1, 2, 3, \ldots \ldots \}$ be the edge set of G.

Case(i): t = 1: The edge set $X = \{e_{2i+1}/i = 0, 1, 2, \ldots (n+1)\}$ is a minimum $(1,2)$ − led setof G. Hence $\gamma'_{bl}(G) = \left(1 + (n+1)\right) = n + 2$.

Case(ii): t > 1:Subcase(a): $n \equiv 0 \pmod 2$:The edge set $X = \{e_1\} \cup \left\{e_{2i}/i = 0, 1, \ldots \left(\frac{3n}{2}\right)\right\}$ is a minimum bi − led set of G. Hence $\gamma'_{bl}(G) \leq |X| = \frac{3n}{2} + 1 \rightarrow (1)$

Conversely, let Y be a bi − led set ofG with minimum cardinality$\gamma'_{bl}(G)$. In this case, Y has the edges $\{e_1, e_2\}$ and starting from e_4, Y has at least one edge from every consecutive two edges in the boundary part of L(G). Hence, $\gamma'_{bl}(G) = |Y| \geq \frac{3n}{2} + 1 \rightarrow (2)$.From equations (1)&(2), we have $\gamma'_{bl}(G) = \frac{3n}{2} + 1$; $n \equiv 0 \pmod 2$.

Subcase(b): $n \equiv 1 \pmod 2$: The edge set $X = \{e_1\} \cup \left\{e_{2i}/i = 1, \ldots \left(\frac{3n-1}{2}\right)\right\}$ is a minimum bi − led set of G. Hence $\gamma'_{bl}(G) \leq |X| = \left(1 + \left(\frac{3n-1}{2}\right)\right) = \frac{3n+1}{2} \rightarrow (3)$

Conversely, let Y be a bi − led set of G with minimum cardinality $\gamma'_{bl}(G)$. In this case, Y has the edges $\{e_1, e_2\}$ and starting from e_4, Y has at least one edge from every consecutive two edges in the boundary part of L(G). Hence $\gamma'_{L(1,2)}(G) = |Y| \geq \frac{3n+1}{2} \rightarrow (4)$.From equations (3)&(4), we have $\gamma'_{bl}(G) = \frac{3n+1}{2}$.

Theorem: 3.9: For the linegraph $L(C_n \odot C_3)$, $n \geq 3$

$$\gamma'_{bl}(C_n \odot C_3)) = \begin{cases} \frac{3n}{2}\,; n \equiv 0 \pmod 2 \\ \frac{3n+1}{2}\,; n \equiv 1 \pmod 2 \end{cases}$$

Proof:

Let G be a line graph $L(C_n \odot C_3)$with at least twelve vertices and $E_l = \left\{\frac{e_i}{i} = 1, 2, 3, \ldots \ldots 3n+4\right\}$the edge set of G.Case(i): $n \equiv 0 \pmod 2$: The edge set $X = \left\{e_{2i+1}/i = 0, 1, \ldots \left(\frac{3n}{2} - 1\right)\right\}$ is a minimum bi − led set of G. Hence $\gamma'_{bl}(G) \leq |X| = \left(1 + \left(\frac{3n}{2} - 1\right)\right) = \frac{3n}{2} \rightarrow (1)$. Conversely, let Y be a bi − led set of G with minimum cardinality $\gamma'_{bl}(G)$. In this case, Y has at least one edge from every consecutive two edges in line graph of C_n and at least one edge from line graph of C_3 . Hence $\gamma'_{bl}(G) = |Y| \geq \frac{3n}{2} \rightarrow (2)$. From equations (1)&(2), we have $\gamma'_{bl}(G) = \frac{3n}{2}$.

Case(ii): $n \equiv 1 \pmod 2$: The edge set $X = \left\{e_{2i+1}/i = 0, 1, \ldots \left(\frac{3n-1}{2}\right)\right\}$ is a minimum bi − led set of G. Hence $\gamma'_{bl}(G) \leq |X| = \left(1 + \left(\frac{3n-1}{2}\right)\right) = \frac{3n+1}{2} \rightarrow (3)$. Conversely, let Y be a bi − led set of G with minimum cardinality $\gamma'_{bl}(G)$. In this case, Y has

at least one edge from every consecutive two edges in line graph of C_n and at least one edge from line graph of C_3 .Hence $\gamma'_{bl}(G) = |Y| \geq \frac{3n+1}{2} \rightarrow (4)$. From equations (3)&(4), we have $\gamma'_{bl}(G) = \frac{3n+1}{2}$.

Theorem: 3.10. For the line graph $L(C_n \odot C_4), n \geq 3$

$$\gamma'_{bl}(L(C_n \odot C_4)) = \begin{cases} \frac{5n}{2} ; n \equiv 0 \pmod 2 \\ \frac{5n-1}{2} ; n \equiv 1 \pmod 2 \end{cases}$$

Proof:

Let G be theline graph $L(C_n \odot C_4)$ with at least fifteen vertices and $E_l = \{ e_i / i = 1, 2, 3, \ldots \ldots 5n\}$ be the edge set of G.

Case(i): $n \equiv 0$ (mod 2): The edge set$X = \left\{e_{2i+1}/i = 0, 1, \ldots \left(\frac{n-2}{2}\right)\right\} \cup \{e_{3i+(n+2)}/i = 0, 1, \ldots (n-1)\} \cup \{e_{3i+(n+3)}/i = 0, 1, \ldots (n-1)\}$ is a minimum bi − led set of G. Hence,$\gamma'_{bl}(G) \leq |X| = \left(1 + \left(\frac{n-2}{2}\right)\right) + (1 + (n-1)) + (1 + (n-1)) = \frac{5n}{2} \rightarrow (1)$. Conversely, let Y be a bi − led set of G with minimum cardinality $\gamma'_{bl}(G)$. In this case, Y has at least one edge from every consecutive two edges in line graph of C_n and at least two edge from line graph of C_4 .Hence $\gamma'_{bl}(G) = |Y| \geq \frac{5n}{2} \rightarrow (2)$. From equations (1)&(2), we have $\gamma'_{bl}(G) = \frac{5n}{2}$.

Case(ii): $n \equiv 1$ (mod 2): The edge set $X = \left\{e_{2i+1}/i = 0, 1, \ldots \left(\frac{n-1}{2}\right)\right\} \cup \{e_{3i+(n+2)}/i = 0, 1, \ldots (n-1)\} \cup \{e_{3i+(n+4)}/i = 0, 1, \ldots (n-2)\}$ is a minimum bi − led set of G. Hence,$\gamma'_{bl}(G) \leq |X| = \left(1 + \left(\frac{n-1}{2}\right)\right) + (1 + (n-1)) + (1 + (n-2)) = \frac{5n-1}{2} \rightarrow (3)$

Conversely, let Y be a bi − led set of G with minimum cardinality$\gamma'_{bl}(G)$. In this case, Y has at least one edge from every consecutive two edges in line graph of C_n and at least two edge from line graph of C_4 .Hence $\gamma'_{bl}(G) = |Y| \geq \frac{5n-1}{2} \rightarrow (4)$. From equations (3)&(4), we have $\gamma'_{bl}(G) = \frac{5n-1}{2}$. By the similar arguments one can prove the following results in Proposition.

Proposition: 3.11.

- For the line graph $L(C_n \odot C_5), n \geq 3$

$$\gamma'_{bl}(L(C_n \odot C_5)) = \begin{cases} \frac{7n}{3}; n \equiv 0 \pmod 3 \\ \frac{7n+2}{3}; n \equiv 1 \pmod 3 \\ \frac{7n+1}{3}; n \equiv 2 \pmod 3 \end{cases}$$

- For any line graph $L(C_n \odot C_6), n \geq 3$

$$\gamma'_{bl}(L(C_n \odot C_6)) = \begin{cases} \frac{5n}{2}; n \equiv 0 \pmod 2 \\ \frac{5n+1}{2}; n \equiv 1 \pmod 2 \end{cases}$$

- For any line graph $L(C_n \odot C_7), n \geq 3$

$$\gamma'_{bl}(L(C_n \odot C_7)) = \begin{cases} \frac{7n}{2}; n \equiv 0 \pmod 2 \\ \frac{7n-1}{2}; n \equiv 1 \pmod 2 \end{cases}$$

ABSTRACT

Anterior staphyloma is a severe sequela of corneal structural compromise characterized by ectatic protrusion of uveal tissue, profound visual loss, and significant cosmetic disfigurement. Ocular trauma remains a major predisposing factor in developing countries, particularly among paediatric and adolescent populations. We report the case of a 16-year-old female who developed anterior staphyloma following penetrating ocular trauma sustained four years prior to presentation. The patient presented with mild ocular discharge, photophobia, and complete loss of vision in the affected eye. Clinical examination revealed no light perception, dense leucomatous corneal opacity (10 × 8 mm) with marked ectasia, iris incarceration, obliterated anterior chamber, and elevated digital intraocular pressure. Given the absence of visual potential and progressive cosmetic deformity, evisceration with placement of an 8-mm silicone orbital implant was performed. After complete socket healing, a custom-made acrylic ocular prosthesis was fabricated to restore orbital volume and facial symmetry.Post-rehabilitation outcomes demonstrated satisfactory prosthesis retention, good motility, improved facial symmetry, and significant psychosocial benefit to the patient.This case highlights the importance of timely surgical management and individualized prosthetic rehabilitation in the treatment of traumatic anterior staphyloma. Early intervention combined with customized prosthetic restoration can achieve favorable functional, cosmetic, and psychological outcomes, particularly in adolescent patients.

Keywords: Anterior staphyloma; Evisceration; Custom ocular prosthesis; Ocular rehabilitation; Anophthalmic socket

INTRODUCTION

Anterior staphyloma is a serious ocular condition in which the uveal tissue protrudes outward through a weakened or damaged cornea or sclera. This condition is usually associated with dense corneal opacity and irreversible loss of vision [1].The condition typically arises as a complication of severe corneal infections, trauma, chemical injuriesparticularly alkali burnsor chronic inflammatory ocular disorders. Progressive corneal thinning and perforation result in ectasia of intraocular tissues, often accompanied by pain, redness, and significant cosmetic disfigurement [2]. Patients with anterior staphyloma often experience significant visual impairment along with symptoms such as redness, pain, photophobia, and progressive enlargement of the affected eye. Apart from functional vision loss, the condition can also cause noticeable cosmetic deformity of the eye, which may affect the patient's confidence and social interactions [3]. In advanced cases, the eye may become completely non-functional and painful, making surgical management necessary.

When the visual prognosis is poor and the affected eye becomes painful or cosmetically disfigured, surgical procedures such as evisceration are often recommended. Evisceration involves the removal of the intraocular contents while preserving the scleral shell and the extraocular muscles [4]. This approach helps maintain better orbital anatomy and can allow improved prosthetic movement compared to other surgical options. However, removal of the internal ocular contents results in loss of orbital volume, which can lead to complications such as enophthalmos, deep superior sulcus deformity, eyelid malposition, and an unsatisfactory facial appearance if appropriate rehabilitation is not provided. Prosthetic rehabilitation using a custom-made ocular prosthesis plays an important role in restoring the natural appearance of the eye and maintaining facial symmetry. Custom ocular prostheses are designed specifically according to the patient's socket anatomy, allowing better fit, comfort, and movement compared to prefabricated prostheses [5]. In addition to improving physical appearance, successful prosthetic rehabilitation can have a positive impact on the patient's psychological well-being by helping restore self-confidence and quality of life. The present case report describes the clinical management of anterior staphyloma treated with evisceration followed by rehabilitation using a custom ocular prosthesis. The report highlights the process of prosthetic fabrication and emphasizes the importance of individualized rehabilitation in achieving satisfactory functional and cosmetic outcomes.

Case Report

Patient Information

A 16-year-old female patient presented to the ophthalmology clinic with complaints of mild ocular discharge and photophobia in the right eye for the past two days. The patient was accompanied by her father.

A detailed history revealed that four years earlier, she had sustained severe ocular trauma to the right eye caused by a wooden stick while playing. At the time of injury, she experienced intense pain, watering, and blurring of vision. She received treatment from a local practitioner and became symptomatically better; however, she subsequently developed complete loss of vision in the affected eye. Over time, a white opacity appeared on the cornea, which gradually enlarged and protruded anteriorly, leading to progressive cosmetic disfigurement.

There was no significant systemic medical history. The left eye was reported to be normal.

Clinical Findings

Visual Acuity

Right Eye (OD): No Light Perception (NLP)

Left Eye (OS): 6/6 (20/20)

External Examination

Marked anterior protrusion of the right globe was noted, associated with conjunctival and deep ciliary congestion. The protruding mass appeared bluish-black in color, suggestive of underlying uveal tissue exposure. Significant cosmetic disfigurement was present.

Intraocular Pressure

Digital intraocular pressure assessment revealed elevated tension in the affected eye. Applanation tonometry could not be reliably performed due to severe corneal distortion.

Slit-Lamp Examination

Cornea: Dense leucomatous corneal opacity measuring approximately 10 × 8 mm with marked ectasia (thinning and forward bulging)**(Figure 1)**.

Uveal Tissue: Bluish-black discoloration due to incarceration of iris tissue within the thinned corneal scar.

Anterior Chamber: Obliterated, as the iris was adherent to the posterior corneal surface.

Iris and Lens: Not clearly visible due to dense corneal opacity.

Fluorescein Staining: Negative.

The findings were consistent with advanced anterior staphyloma with total corneal scarring.

Diagnostic Assessment

Based on clinical presentation, ocular findings, and lack of visual potential, a diagnosis of anterior staphyloma with corneal opacity was established. Considering the severity of deformity and associated symptoms, surgical management was planned.

Therapeutic Intervention

Evisceration was performed under local anesthesia with sedation. Following a 360-degree conjunctival peritomy, the corneal button was excised, and intraocular contents were carefully removed while preserving the scleral shell and extraocular muscles. An 8 mm spherical silicone orbital implant was selected based on the axial length measurement of the fellow eye to achieve optimal orbital volume symmetry. The sclera and conjunctiva were closed in layers, and a conformer was inserted to maintain fornicial depth. The conformer was retained during the postoperative healing period to preserve socket architecture and facilitate subsequent prosthetic fitting.Immediate postoperative socket appearance following evisceration with silicone orbital implant placement is shown in **Figure 2.** Postoperative healing was uneventful.

Prosthetic Rehabilitation

After complete socket healing (5–7 weeks post-evisceration), a detailed clinical evaluation of the anophthalmic socket was performed. Socket depth, conjunctival health, lid position, and fornicial integrity were assessed to determine suitability for prosthetic fitting. A customized impression tray technique was used to obtain an accurate impression of the socket anatomy using ophthalmic-grade alginate impression material **(Figure 3A–B)**. The impression material was gently injected into the socket using a syringe-based technique while the patient was instructed to perform ocular movements to accurately record the dynamic contour of the socket. The impression was used to prepare a mold from which a wax conformer pattern was fabricated. This wax pattern was inserted into the socket and evaluated for proper contour, eyelid support, stability, and symmetry with the contralateral eye. Necessary adjustments were made to achieve optimal cosmetic alignment and comfort.

Following confirmation of the wax pattern, the definitive prosthesis was fabricated using heat-cured polymethyl methacrylate (PMMA) acrylic resin. The acrylic resin was prepared by mixing polymer powder with monomer liquid to form a workable paste. White acrylic pigments were incorporated to simulate the natural scleral coloration. The material was packed into a mold and polymerized using a controlled curing process. Iris positioning was determined using anatomical landmarks and matched in size and color with the fellow eye. The iris button was hand-painted, and scleral characterization was performed by incorporating fine vascular patterns to simulate natural conjunctival blood vessels.After polymerization, the prosthesis was finished, polished, and laminated with a clear acrylic layer to protect the painted surface and enhance the natural appearance. The final prosthesis was then inserted into the socket, and adjustments were made to optimize retention, comfort, eyelid closure, and coordinated motility with the fellow eye.The final outcome after insertion of the custom ocular prosthesis demonstrated satisfactory symmetry with the contralateral eye and improved facial appearance (Figure 4).

Follow-Up and Outcomes

Follow-up evaluation demonstrated satisfactory prosthesis retention and acceptable motility. The patient reported no discomfort during routine wear and expressed high satisfaction with the aesthetic outcome. Noticeable improvement in facial symmetry, self-confidence, and social acceptance was observed. No complications were reported during subsequent follow-up visits.

DISCUSSION

Anterior staphyloma represents an advanced manifestation of corneal structural failure characterized by progressive thinning and ectatic protrusion of uveal tissue through a weakened corneal scar. The condition most frequently arises following severe microbial keratitis, chemical injuries, or penetrating ocular trauma [1]. In developing countries, ocular trauma remains a major contributing factor, particularly among children and adolescents who are frequently exposed to outdoor activities and accidental injuries. The present case illustrates the long-term consequences of inadequately managed ocular trauma and highlights the progressive nature of corneal ectasia that can ultimately lead to irreversible visual loss and significant cosmetic deformity [6]. The underlying pathophysiology involves severe corneal stromal damage or perforation followed by incarceration of uveal tissue within the scarred cornea. Continuous intraocular pressure exerts an outward force on the weakened corneal wall, resulting in progressive bulging and distortion of anterior segment structures [7]. In the current patient, the presence of dense leucomatous opacity, iris incarceration, obliteration of the anterior chamber, and absence of light perception indicated an advanced stage of disease with no potential for visual recovery.

Management of anterior staphyloma depends on multiple factors, including residual visual potential, extent of ectasia, associated pain, and cosmetic concerns. In selected cases with preserved vision, surgical options such as tectonic keratoplasty or lamellar grafting may be attempted to restore corneal integrity. However, when the affected eye is blind and cosmetically disfigured or painful, removal of intraocular contents through evisceration or enucleation becomes necessary. Evisceration was selected in the present case as it preserves the scleral shell and extraocular muscles, thereby allowing improved implant motility and potentially better cosmetic outcomes compared to enucleation. Orbital implant placement is an essential component of the procedure as it compensates for the loss of intraocular volume and helps prevent postenucleation socket syndrome [8]. Proper implant size selection is critical for achieving optimal orbital symmetry. In this patient, an 8-mm silicone implant was used based on the axial length of the fellow eye to provide adequate volume replacement. Silicone implants are widely utilized due to their biocompatibility, affordability, and availability, making them particularly suitable in resource-limited settings. Prosthetic rehabilitation represents the final and crucial stage of treatment in patients undergoing evisceration. Custom-made ocular prostheses offer several advantages over stock prostheses, including superior adaptation to socket anatomy, improved retention, enhanced motility, and greater patient comfort. The impression-based fabrication technique enables accurate replication of the anophthalmic socket contours, resulting in improved distribution of pressure across the socket and reduced mucosal irritation. Furthermore, precise iris positioning, scleral contouring, and vascular characterization contribute to a more natural aesthetic outcome.

Beyond physical rehabilitation, the psychological and social implications of ocular disfigurement must also be considered, particularly in adolescents. Facial asymmetry during formative years can negatively influence self-esteem, social interaction, and emotional well-being. In the present case, restoration of facial symmetry through prosthetic rehabilitation resulted in a marked improvement in the patient's confidence and social comfort, emphasizing the broader psychosocial benefits of ocular prosthetic treatment [9]. This case underscores the importance of a multidisciplinary approach involving ophthalmic surgeons and ocular prosthetic specialists to ensure comprehensive management. Successful outcomes depend not only on appropriate surgical intervention but also on meticulous prosthetic fabrication and long-term follow-up care to maintain socket health and prosthesis function.

CONCLUSION

Anterior staphyloma resulting from penetrating ocular trauma represents a severe and potentially preventable cause of irreversible visual loss and cosmetic disfigurement, particularly among adolescents. In cases where visual potential is absent and the eye becomes painful or cosmetically unacceptable, timely surgical intervention is essential to improve patient comfort and restore facial appearance. Evisceration combined with appropriate orbital implant placement provides effective restoration of orbital volume and establishes a stable foundation for prosthetic rehabilitation. The present case demonstrates that fabrication of a custom-made ocular prosthesis plays a crucial role in achieving optimal socket adaptation, improved prosthetic motility, and satisfactory aesthetic integration. Comprehensive management through a multidisciplinary approach involving ophthalmic surgeons and ocular prosthetic specialists is essential for achieving favorable functional, cosmetic, and psychosocial outcomes. Early intervention and individualized prosthetic rehabilitation can significantly enhance quality of life, self-confidence, and social reintegration in patients with advanced anterior staphyloma.

Ethical Approval and Consent

The study adhered to the principles of the Declaration of Helsinki.Written informed consent was obtained from the patient's guardian for publication of this case report and accompanying clinical details.

Conflict of Interest

The authors declare that there are no conflicts of interest related to this manuscript.

ABSTRACT

In this paper, an effective numerical inversion technique for a generalized integral transform based on the operational matrix of fractional order integration of Haar wavelets is derived. The efficiency of the proposed technique is demonstrated through some linear differential equations of fractional order. The obtained results show that the technique proposed here is reliable and simple to use, and they also demonstrate good agreement with several existing techniques in open literature.

Keywords: : Caputo fractional derivative, a generalized integral transform, Haar wavelets, Operational matrix. **AMS Subject Classification(2010):** 26A33, 34A08, 65T60

INTRODUCTION

Due to the fact that fractional calculus can successfully be used to represent physical phenomena with dependencies on both the present time and the past time history, it has recently attracted the attention of many researchers across a variety of scientific and technological fields.It is difficult to develop analytical or precise solutions to the majority of fractional differential equations because of the complicated nature of these equations. Various efforts have been made to create numerical methods for solving fractional differential equations as a result of the growing number of applications.However, many numerical methods have been developed in recent years to solve fractional differential equations, such as Laplace transform method (Podlubny.I.1999), Variational iteration method(Odibat, Z. M. (2010)),

Adomian decomposition method(Hosseini, M. M. (2006)), A generalized differential transform method(Erturk, V. S., Momani, S., & Odibat, Z. (2008)), Fractional iteration method(Mekkaoui, T., & Hammouch, Z. (2012)), Kernel reproducing method(Akgl, A., Inc, M., Karatas, E., & Baleanu, D. (2015)), Differential transform method(Arikoglu, A., & Ozkol, I. (2007)), Operational methods(Garra, R. (2012)) and Finite difference method (Zhang, Y. (2009)). For the numerical solutions of ordinary and partial differential equations of fractional order, in addition to the methods mentioned above, a number of straightforward approaches based on orthogonal functions have also been used. Some frequently used orthogonal functions are Walsh functions, B-splines, block pulse functions, Chebyshev orthonormal sets of functions, sine-cosine functions, Legendre, block pulse functions, Laguerre and so on.

The orthogonal basis functions, which are gaining popularity in the field of numerical approximations, now include wavelet analysis. The main benefit of using wavelet basis functions is to reduce the problem at hand to a set of linear or nonlinear algebraic equations. Wavelet-based approaches also have the advantage of being simple to use, straightforward to compute, and quick to converge due to their exceptional qualities, such as flexibility to represent a function at different degrees of resolution, orthogonality, compact support and their capacity to detect singularities. Many authors have employed different types of wavelets such as Legendre wavelets, Haar wavelets, Euler wavelets and so on.Many problems in the real world can be solved with integral transforms. The right choice of integral transform aids in simplifying both integral and differential equations into a solution-friendly algebraic equation. During last two decades, many integral transforms in the class of Laplace transform are introduced such as Elzaki(Elzaki, T. M. (2011)), Natural(Khan, Z. H., & Khan, W. A. (2008)), $\alpha-$ Laplace(Medina, G. D., Ojeda, N. R., Pereira, J. H., & Romero, L. G. (2017)), Aboodh(Aboodh, K. S. (2013)), Sumudu(Watugala, G. (1993)), Pourreza(Ahmadi, S. A. P., Hosseinzadeh, H., & Cherati, A. Y. (2019)), Mohand(Mohand, M., & Mahgoub, A. (2017)), G-transform(Kim, H. (2017)), Sawi(Mahgoub, M. A., & Mohand, M. (2019)), Kamal transform(Kamal, A., & Sedeeg, H. (2016)), A new generalized integral transform(Jafari, H. (2021)). and so on. These transforms as well as the combination of these transforms with semi analytical methods have been used for solving different types of ordinary differential equations, partial differential equations, integral equations and fractional differential equations.

Considerable attention has been stimulated for the numerical solutions of fractional differential equations using numerical inverse Laplace transform via wavelets operational matrices of fractional order integration. For example, J.H.Wu et al (Wu, J. L., Chen, C. H., & Chen, C. F. (2001)) and S.M.Aznam et al (Aznam, S. M., & Hussin, A. (2012)) have successfully applied the Haar wavelet operational matrix for numerical inverse Laplace transform, whereas Weeks, W. T. (Weeks, W. T. (1966)).has applied the same technique by using Laguerre functions. Later on, Soradi-Zeid, S. et al (Soradi-Zeid, S., Mesrizadeh, M., & Cattani, C. (2021)) have obtained numerical inversion method with quadrature rule. On the other hand, the numerical inversion of Laplace transform via wavelet operational matrix has been derived by Aruldoss R. et al. (Aruldoss, R., & Balaji, K. (2022)) to solve fractional differential equations. Recently, Rachid B. et al (Belgacem, R., Bokhari, A., Djilali, S., & Kumar, S. (2022)) investigate numerical inversion method with Boubaker polynomial operational matrix. The main objective of this paper is to solve various fractional order differential equations by numerically inverting generalized integral transform employing operational matrices of the Haar wavelets. The remaining portion of the paper is structured as follows. Section 2 discusses some essential definitions and mathematical foundations for fractional calculus. Approximation of square integral functions and the operational matrix of fractional order integration of Haar wavelets are derived in section 3. In Section 4, a numerical analysis is developed to invert a generalized integral transform using the haar wavelet operational matrix. In Section 5, the efficiency and the accuracy of the proposed technique by considering some numerical examples and error estimation are demonstrated. Finally, a conclusion is given in Section 6.

Preliminaries

Here, fractional order integral and differential operators along with some fundamental concepts of fractional calculus are covered.

Definition 2.1 (Diethelm, K. (2004), Miller, K. S., & Ross, B. (1993), Oldham, K. B., & Spanier, J. (1974.), Podlubny, I. (1999)) *The Riemann-Liouville integral of fractional order* $\lambda \geq 0$*, of the function* $g(x) \in L^1([0,\infty))$*, is given by*

$$I^{\lambda}g(x) = \begin{cases} g(x), & \lambda = 0. \\ \dfrac{1}{\Gamma(\lambda)}\displaystyle\int_0^x (x-\upsilon)^{\lambda-1} g(\upsilon)d\upsilon, & \lambda > 0. \end{cases}$$

Let $g(x), h(x) \in L^1([0,\infty))$, $a, b \in \mathbb{R}$, $\nu > -1$, $\lambda \geq 0$.
Then the following properties are attained.

(i) $I^{\lambda}(ah(x) + bg(x)) = aI^{\lambda}h(x) + bI^{\lambda}g(x)$.

(ii) $I^{\lambda}x^{\nu} = \dfrac{\Gamma(\nu+1)}{\Gamma(\nu+\lambda+1)}x^{\lambda+\nu}$.

Definition 2.2 (Diethelm, K. (2004), Miller, K. S., & Ross, B. (1993), Oldham, K. B., & Spanier, J. (1974.), Podlubny, **I. (1999))** The Caputo fractional derivative of fractional order $\lambda \geq 0$, of the function $g(x) \in L^1([0,\infty))$, is given by

$$D^{\lambda}g(x) = I^{m-\lambda}(D^m g(x)) = \begin{cases} \dfrac{d^m}{dx^m}g(x), & \lambda = m \in \mathbb{N}. \\ \dfrac{1}{\Gamma(m-\lambda)}\displaystyle\int_0^x \frac{g^{(m)}(\upsilon)}{(x-\upsilon)^{\lambda-m+1}}d\upsilon, & m-1 < \lambda < m, m \in \mathbb{N}. \end{cases}$$

Let $g(x), h(x) \in L^1([0,\infty))$, $a, b \in \mathbb{R}$, $\lambda \geq 0$.
Then the following properties are attained.

(i) $D^{\lambda}a = 0$, *where a is a constant.*

(ii) $D^{\lambda}(ah(x) + bg(x)) = a\big(D^{\lambda}h(x)\big) + b\big(D^{\lambda}g(x)\big)$.

(iii) $D^{\lambda}(I^{\lambda}g(x)) = g(x)$.

(iv) $I^{\lambda}(D^{\lambda}g(x)) = g(x) - \displaystyle\sum_{j=0}^{m-1} g^{(j)}(0^+)\frac{x^k}{j!}, \quad m-1 < \lambda \leq m,$

where $m \in \mathbb{N}$, $x > 0$ and $g^{(j)}(0^+) := \lim_{x\to 0^+} D^{(j)}g(x)$, $j = 0,1,2,\dots,m-1$.

Definition2.3.Let f(t) represent an integrable function defined for $t \geq 0$ and $u(s) \neq 0$, v(s) be any positive real functions. The generalized integral transform of f(t) is defined as

$$G\{f(t)\} = \widehat{G}\big(u(s), v(s)\big) = u(s)\int_0^{\infty} f(t)e^{-v(s)}dt,$$

assuming that the integral is valid for some v(s). This general integral transform includes the existing integral transforms for various u(s) and v(s) values, such as the Laplace, Elazaki, and Kamal transforms.

Haar wavelets approximations of functions

The Haar wavelet and its fractional integration operational matrix are presented here.

Haar wavelets

Alfred Haar, a Hungarian mathematician, developed the Haar functions in 1910. The haar wavelet family for $x \in [0,1)$ is defined as

$$h_i(x) = \sqrt{\frac{\widehat{m}}{2^{J+1}}} \begin{cases} 1, & for\ x \in \left[\dfrac{k}{\widehat{m}}, \dfrac{(k+0.5)}{\widehat{m}}\right], \\ -1, & for\ x \in \left[\dfrac{(k+0.5)}{\widehat{m}}, \dfrac{(k+1)}{\widehat{m}}\right], \\ 0, & otherwise. \end{cases}$$

where $\hat{m} = 2^l,\ l = 0,1,2,\dots,J,\ J \in \mathbb{N}$, indicates the level of resolution and $k = 0,1,2,\dots,\hat{m}-1$ is the translation parameter. The maximum level of resolution is J. The index i is calculated using $i = \hat{m} + k + 1$. The minimal and maximal value of i are 2 and $N = 2^{J+1}$ respectively.

The scaling function $h_1(x)$ for the family of Haar wavelets is defined as

$$h_1(x) = \begin{cases} \frac{1}{\sqrt{N}}, & for\ \ x \in [0,1), \\ 0, & otherwise. \end{cases}$$

Square integrable functions approximation

Every function $f(t)$ from $L^2([0,1))$ with regard to Haar wavelets can be expressed as

$f(t) = \sum_{i=1}^{\infty} c_i\, h_i(t),$ (1)

where the following inner product resolves the coefficients c_i.

$$\langle f(t), h_i(t)\rangle = \int_0^{\infty} f\,(t) h_i(t) dt.$$

If the series (1) is truncated, $f(t)$ can be roughly calculated as

$f(t) \simeq \sum_{i-1}^{N} c_i\, h_i(t) = C_{1\times N} H(t),$ (2)

where $C = [c_1, c_2, \dots, c_N]_{1\times N}$ is the coefficient vector and $H(t) = [h_1(t), h_2(t), \dots, h_N(t)]'$.

Discretizing (1) at $t_i = \frac{(2i-1)}{2N}$, $i = 1,2,3,\dots,N$, we attain

$F \simeq C_{1\times N} H_{N\times N}$ (3)

where $F = [f(t_1), f(t_2), \dots, f(t_N)]_{1\times N}$ an$H_{N\times N} = [H(t_1), H(t_2), \dots, H(t_N)]$d, a Haar wavelet coefficient matrix of order N. Especially, for $J = 2$, the Haar wavelet coefficient matrix becomes

$$H_{8\times 8} = \begin{pmatrix} 0.3536 & 0.3536 & 0.3536 & 0.3536 & 0.3536 & 0.3536 & 0.3536 & 0.3536 \\ 0.3536 & 0.3536 & 0.3536 & 0.3536 & -0.3536 & -0.3536 & -0.3536 & -0.3536 \\ 0.5000 & 0.5000 & -0.5000 & -0.5000 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0.5000 & 0.5000 & -0.5000 & -0.5000 \\ 0.7071 & -0.7071 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0.7071 & -0.7071 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0.7071 & -0.7071 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0.7071 & -0.7071 \end{pmatrix}$$

Haar wavelet's operational matrix of fractional integration

According to **(A. Kilicman, & Z. A. A. Al Zhour.2007)** , the N Block pulse functions (BPFs) on [0,1) are given by,

$$b_m(t) = \begin{cases} 1, & \frac{(m-1)}{N} \le t < \frac{m}{N}, \\ 0, & otherwise, \end{cases}$$

Where,$N \in \mathbb{N}$,$m = 1,2,3,\dots,N$.

For $0 \le t < 1$,

$$b_n(t) b_m(t) = \begin{cases} 0, & m \ne n. \\ b_m(t), & m = n. \end{cases}$$

and

$$\int_0^1 b_n\,(t) b_m(t) dt = \begin{cases} 0, & m \ne n. \\ \frac{1}{N}, & m = n. \end{cases}$$

Every function $f(t) \in L^2[0,1)$ can be written in terms of BPFs as

$$f(t) \simeq \sum_{m=1}^{N} f_m\, b_m(t) = f B_N(t)$$

$$where\ f = [f_1, f_2, \dots, f_N], f_m = N \int_{\frac{(m-1)}{N}}^{\frac{m}{N}} f\,(t) b_m(t) dt\ and\ B_N(t) = [b_1(t), b_2(t), \dots, b_N(t)]'.$$

The relationship between the Haar wavelets and BPFs is given by

$H(t) = H_{N\times N}B_N(t)$. (4)

According to (A. Kilicman, & Z. A. A. Al Zhour.2007), the integration I^{λ}, with fractional order $\lambda \geq 0$ of $B_N(t)$ is approximated as

$I^{\lambda}\big(B_N(t)\big) \simeq E^{\lambda}_{N\times N}B_N(t)$, (5)

where $E^{\lambda}_{N\times N}$ is the Block pulse operational matrix of $I^{\lambda}\big(B_N(t)\big)$ given by

$$E^{\lambda}_{N\times N} = \left(\frac{1}{N}\right)^{\lambda}\frac{1}{\Gamma(\lambda+2)}\begin{pmatrix} 1 & \Omega & \Omega_2 & \Omega_3 & \dots & \Omega_{N-1} \\ 0 & 1 & \Omega_1 & \Omega_2 & \dots & \Omega_{N-2} \\ 0 & 0 & 1 & \Omega_1 & \dots & \Omega_{N-3} \\ 0 & 0 & 0 & 1 & \dots & \Omega_{N-4} \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & \dots & \Omega_1 \\ 0 & 0 & 0 & 0 & \dots & 1 \end{pmatrix}$$

with $\Omega_{\ell} = (\ell+1)^{\lambda+1} - 2\ell^{\lambda+1} + (\ell-1)^{\lambda+1}$. The integration I^{λ} with fractional order $\lambda \geq 0$ of $H(t)$ is approximated as,

$I^{\lambda}\big(H(t)\big) \simeq R^{\lambda}_{N\times N}H(t)$, (6)

where $\mathrm{R}^{\lambda}_{\mathrm{N\times N}}$ is referred to as the Haar wavelets operational matrix of order N for fractional integration with order $\lambda \geq 0$.

Using (4) and (5), we arrive

$I^{\lambda}\big(H(t)\big) = I^{\lambda}\big(H_{N\times N}B_N(t)\big) = H_{N\times N}I^{\lambda}\big(B_N(t)\big) \simeq H_{N\times N}E^{\lambda}_{N\times N}B_N(t)$. (7)

Thus, combining (6) and (7), we attain

$$R^{\lambda}_{N\times N}H(t) \simeq I^{\lambda}\big(H(t)\big) \simeq H_{N\times N}E^{\lambda}_{N\times N}B_N(t) = H_{N\times N}E^{\lambda}_{N\times N}(H_{N\times N})^{-1}H(t)$$

and so

$R^{\lambda}_{N\times N} \simeq H_{N\times N}E^{\lambda}_{N\times N}(H_{N\times N})^{-1}$. (8)

Especially, for $J = 2$ and $\lambda = 0.5$, the Haar wavelets operational matrix for fractional integration becomes,

$$R^{0.5}_{8\times 8} = \begin{pmatrix} 0.7523 & -0.2203 & -0.1102 & -0.0580 & -0.0551 & -0.0290 & -0.0224 & -0.0189 \\ 0.2203 & 0.3116 & -0.1102 & 0.1623 & -0.0551 & -0.0290 & 0.0878 & 0.0391 \\ 0.0580 & 0.1623 & 0.2203 & -0.0350 & -0.0779 & 0.1148 & -0.0275 & -0.0045 \\ 0.1102 & -0.1102 & 0 & 0.2203 & 0 & 0 & -0.0779 & 0.1148 \\ 0.0189 & 0.0391 & 0.1148 & -0.0045 & 0.1558 & -0.0247 & -0.0026 & -0.0009 \\ 0.0224 & 0.0878 & -0.0779 & -0.0275 & 0 & 0.1558 & -0.0247 & -0.0026 \\ 0.0290 & -0.0290 & 0 & 0.1148 & 0 & 0 & 0.1558 & -0.0247 \\ 0.0551 & -0.0551 & 0 & -0.0779 & 0 & 0 & 0 & 0.1558 \end{pmatrix}$$

Riemann-Liouville fractional integral of Haar wavelet functions

The Riemann-Liouville fractional integral with order $\lambda > 0$ of Haar wavelet scaling function $\mathrm{h_1(t)}$ is given by

$$\begin{aligned} I^{\lambda}h_1(t) &= \frac{1}{\Gamma(\lambda)}\int_0^t (t-t_1)^{\lambda-1}\,h_1(t_1)dt_1 \\ &= \frac{1}{\Gamma(\lambda)}\frac{1}{\sqrt{N}}\int_0^t (t-t_1)^{\lambda-1}\,dt_1 \\ &= \frac{1}{\sqrt{N}}\frac{t^{\lambda}}{\Gamma(\lambda+1)}. \end{aligned}$$

Thus

$$\begin{aligned} \frac{t^{\lambda}}{\Gamma(\lambda+1)} &= \frac{\sqrt{N}}{\Gamma(\lambda)}\int_0^t (t-t_1)^{\lambda-1}\,h_1(t_1)dt_1 \\ &= \frac{\sqrt{N}}{\Gamma(\lambda)}\int_0^t (t-t_1)^{\lambda-1}\,[1\ 0\ 0\ 0 \dots 0]_{1\times N}H(t_1)dt_1 \\ &= e\frac{1}{\Gamma(\lambda)}\int_0^t (t-t_1)^{\lambda-1}\,H(t_1)dt_1 \end{aligned}$$

where $e = \left[\sqrt{N}\ \ 0 \dots\ 0\right]_{1\times N}$.

Then

$\frac{t^{\lambda}}{\Gamma(\lambda+1)} = e\ R_{N\times N}^{\lambda} H(t).$ (9)

The expression in equation (9) is very helpful while finding the numerical inversion of the generalized integral transform later in irrational transfer function expression.

Numerical analysis for inversion of a generalized integral transform

The generalized integral transform of n-fold integration is given by

$$G\{\int_0^t \dots \int_0^{t_3} \int_0^{t_2} f(\tau) d\tau_1 d\tau_2 \dots d\tau_n\} = \frac{\hat{G}\big(u(s), v(s)\big)}{v(s)^n}.$$

Let

$$\hat{G}\big(u(s), v(s)\big) = \frac{u(s)\left(a_0 + \frac{a_1}{v(s)} + \frac{a_2}{v(s)^2} + \dots + \frac{a_n}{v(s)^n}\right)}{v(s)^{\lambda+1}\left(b_0 + \frac{b_1}{v(s)} + \frac{b_2}{v(s)^2} + \dots + \frac{b_n}{v(s)^n}\right)} = \hat{\hat{G}}\left(u(s), \frac{1}{v(s)}\right), \quad (10)$$

Where, $\lambda \geq 0$ and a_i, b_i arereal constants, Then

$$\left(b_0 + \frac{b_1}{v(s)} + \frac{b_2}{v(s)^2} + \dots + \frac{b_n}{v(s)^n}\right) \hat{G}(u(s), v(s) = \frac{u(s)}{v(s)^{\lambda+1}}\left(a_0 + \frac{a_1}{v(s)} + \frac{a_2}{v(s)^2} + \dots + \frac{a_n}{v(s)^n}\right) \quad (11)$$

By applying the inverse general integral transform on (11), we get

$$b_0 f(t) + b_1 \int_0^t f(\tau) d\tau + \dots + b_n \int_0^t \dots \int_0^{t_3} \int_0^{t_2} f(\tau_1)\, d\tau_1 d\tau_2 \dots d\tau_n = \frac{a_0 t^{\lambda}}{\Gamma(\lambda+1)} + \frac{a_1 t^{\lambda+1}}{\Gamma(\lambda+2)} + \dots + \frac{a_n t^{\lambda+n}}{\Gamma(\lambda+n+1)}. \quad (12)$$

The result of discretizing (12) at all collocation points is

$$C_{1\times N}\left(b_0 I_{N\times N} + b_1 R_{N\times N}^{(1)} + b_2 R_{N\times N}^{(2)} + \dots + b_n R_{N\times N}^{(n)}\right) H_{N\times N} = eR_{N\times N}^{\lambda}\left(a_0 I_{N\times N} + a_1 R_{N\times N}^{(1)} + a_2 R_{N\times N}^{(2)} + \dots + a_n R_{N\times N}^{(n)}\right) H_{N\times N} \quad (13)$$

and so

$$C_{1\times N}\ g_2\left(R_{N\times N}^{(1)}\right) = e\ R_{N\times N}^{\lambda}\ g_1 R_{N\times N}^{(1)},$$

where $g_1 R_{N\times N}^{(1)} = a_0 I_{N\times N} + a_1 R_{N\times N}^{(1)} + a_2 R_{N\times N}^{(2)} + \dots + a_n R_{N\times N}^{(n)}$ and $g_2 R_{N\times N}^{(1)} = b_0 I_{N\times N} + b_1 R_{N\times N}^{(1)} + b_2 R_{N\times N}^{(2)} + \dots + b_n R_{N\times N}^{(n)}$

Thus

$$C_{1\times N} = e\ R_{N\times N}^{\lambda}\ g_1 R_{N\times N}^{(1)}\ g_2\left(R_{N\times N}^{(1)}\right)^{-1}. \quad (14)$$

Now, the numerical inverse generalized integral transform of $\hat{G}\big(u(s), v(s)\big)$ is given by

$$\begin{aligned} F &\simeq C_{1\times N} H_{N\times N} \\ &= eR_{N\times N}^{\lambda}\ g_1\left(R_{N\times N}^{(1)}\right)\ g_2\left(R_{N\times N}^{(1)}\right)^{-1} H_{N\times N} \\ &= eR_{N\times N}^{-1} H_{N\times N} H_{N\times N}^{-1} R^{\lambda+1}\ g_1\left(R_{N\times N}^{(1)}\right)\ g_2\left(R_{N\times N}^{(1)}\right)^{-1} H_{N\times N} \\ &= eH_{N\times N} E_{N\times N}^{-1} H_{N\times N}^{-1}\left(I_{N\times N} R_{N\times N}^{\lambda+1}\ g_1\left(R_{N\times N}^{(1)}\right)\ g_2\left(R_{N\times N}^{(1)}\right)^{-1}\right) H_{N\times N} \end{aligned}$$

$$= [2N\ -2N \dots -2N]_{1\times N} H_{N\times N}^{-1} \hat{\hat{G}}\left(I_{N\times N}, R_{N\times N}^{(1)}\right) H_{N\times N}, \quad (15)$$

where $\hat{\hat{G}}\left(I_{N\times N}, R_{N\times N}^{(1)}\right) = I_{N\times N} R_{N\times N}^{\lambda+1}\ g_1\left(R_{N\times N}^{(1)}\right)\ g_2\left(R_{N\times N}^{(1)}\right)^{-1}$ is attained by replacing $u(s)$ by $I_{N\times N}$ and $\frac{1}{v(s)}$ by $R_{N\times N}^{(1)}$ in $\hat{G}\big(u(s), v(s)\big)$.

Following is a summary of the steps involved in determining the numerical inverse general integral transform of $\hat{G}\big(u(s), v(s)\big)$.

Step 1: Express $F\big(u(s), v(s)\big)$ in terms of u(s) and $\frac{1}{v(s)}$.

Step 2: Replace $u(s)$ and $\frac{1}{v(s)}$ by the identity matrix $I_{N\times N}$ and the operational matrix $R_{N\times N}^{(1)}$ respectively to obtain $\hat{\hat{G}}\left(I_{N\times N}, R_{N\times N}^{(1)}\right)$.

Step 3: Calculate F by $F_{1\times N} = [2N\ -2N \dots -2N]_{1\times N} H_{N\times N}^{-1} \hat{\hat{G}}\left(I_{N\times N}, R_{N\times N}^{(1)}\right) H_{N\times N}$.

Illustrative Examples

To demonstrate the efficiency and the applicability of the proposed technique, some fractional order differential equations are discussed.

Example 1. Let us examine the composite fractional oscillator differential equation

$D^{\lambda}y(x) = -y(x) + f(x),\ \ 0 < \lambda < 1,$ (16)

where $0 \le x < 1$ and $f(x) = x^2 + \frac{2x^{2-\lambda}}{\Gamma(3-\lambda)}$, having initial constraint $y(0) = 0$.

The exact solution of (16) is x^2.

Taking the generalized integral transform of (16), we obtain

$$\begin{aligned} G\{D^{\lambda}y(x) + y(x)\} &= G\left\{x^2 + \frac{2x^{2-\lambda}}{\Gamma(3-\lambda)}\right\} \\ \big(v(s)\big)^{\lambda}\hat{G}\big(u(s),v(s)\big) - u(s)\big(v(s)\big)^{\lambda-1}y^{(0)}(0) + \hat{G}\big(u(s),v(s)\big) &= \frac{\Gamma(3)u(s)}{v(s)^3} + \frac{2\Gamma(3-\lambda)u(s)}{v(s)^{3-\lambda}\Gamma(3-\lambda)} \\ \hat{G}\big(u(s),v(s)\big)\left\{\big(v(s)\big)^{\lambda} + 1\right\} &= 2u(s)\left\{\left(\frac{1}{v(s)}\right)^3 + \left(\frac{1}{v(s)}\right)^{3-\lambda}\right\} \\ &= 2u(s)\left(\frac{1}{v(s)}\right)^{\lambda}\frac{1}{1+\left(\frac{1}{v(s)}\right)^{\lambda}}\left\{\left(\frac{1}{v(s)}\right)^3 + \left(\frac{1}{v(s)}\right)^{3-\lambda}\right\} \\ &= \hat{\hat{G}}\left(u(s),\frac{1}{v(s)}\right). \end{aligned}$$ (17)

Replacing $u(s)$ by the identity matrix $I_{N\times N}$ and $\frac{1}{v(s)}$ by the operational matrix $R^{(1)}_{N\times N}$ in (17), we obtain

$$\hat{\hat{G}}\left(I_{N\times N}, R^{(1)}_{N\times N}\right) = \frac{2\, I_{N\times N}\, R^{(\lambda)}_{N\times N}}{I_{N\times N} + R^{(\lambda)}_{N\times N}}\left\{R^{(3)}_{N\times N} + R^{(3-\lambda)}_{N\times N}\right\}.$$ (18)

We achieve the numerical solutions of equation (16) using (15) and (18). The absolute errors achieved by the proposed strategy and Quadrature formula approach **(Diethelm, K. (1997),Li, X. (2012))** are shown in the Table 1. Additionally, Table 1 demonstrates that the suggested approach produces a higher level of precision than the Quadrature formula approach.

Example 2. Let us examine the fractional relaxation oscillator equation

$D^{\lambda}y(x) + y(x) = 0,\ \ 1 < \lambda \le 2,$ (19)

where $0 \le x < 1$, having initial constraints $y(0) = 1,\ y'(0) = 0$.

The exact solution of (19) is $E_{\lambda}(-x^{\lambda})$.

Taking the generalized integral transform of (19), we obtain

$$\begin{aligned} G\{D^{\lambda}y(x) + y(x)\} &= 0 \\ \big(v(s)\big)^{\lambda}\hat{G}\big(u(s),v(s)\big) - u(s)\textstyle\sum_{k=0}^{1}\big(v(s)\big)^{\lambda-1-k}y^{(k)}(0) + \hat{G}\big(u(s),v(s)\big) &= 0 \\ \big(v(s)\big)^{\lambda}\hat{G}\big(u(s),v(s)\big) - u(s)\big(v(s)\big)^{\lambda-1} + \hat{G}\big(u(s),v(s)\big) &= 0 \\ \hat{G}\big(u(s),v(s)\big)\left(\big(v(s)\big)^{\lambda} + 1\right) &= u(s)\big(v(s)\big)^{\lambda-1} \\ &= \frac{u(s)\big(v(s)\big)^{\lambda-1}}{\big(v(s)\big)^{\lambda}+1} \\ &= \frac{u(s)\left(\frac{1}{v(s)}\right)}{1+\left(\frac{1}{v(s)}\right)^{\lambda}} \end{aligned}$$

$$= \hat{\hat{G}}\left(u(s),\frac{1}{v(s)}\right).$$ (20)

Replacing $u(s)$ by the identity matrix $I_{N\times N}$ and $\frac{1}{v(s)}$ by the operational matrix $R^{(1)}_{N\times N}$ in (20), we obtain

$$\hat{\hat{G}}\left(I_{N\times N}, R^{(1)}_{N\times N}\right) = \frac{I_{N\times N}R^{(1)}_{N\times N}}{I_{N\times N} + R^{(\lambda)}_{N\times N}}.$$ (21)

We arrive at the numerical solutions of equation (19) using (15) and (21). Table 2 shows that as J increases, the absolute errors brought on by the suggested technique decrease and the numerical solutions quickly reach the exact solution.

Example 3. Let us examine the fractional differential equation

$D^{\lambda}y(x)+y(x)=f(x),\ \ 0<\lambda\leq 1,$ (22)

where $0\leq x<1$ and $f(x)=\frac{2x^{2-\lambda}}{\Gamma(3-\lambda)}+\frac{x^{1-\lambda}}{\Gamma(2-\lambda)}+x^2-x$, having initial constraint $y(0)=0$.

The exact solution of (22) is x^2-x.

Taking the generalized integral transform of (22), we obtain

$$G\{D^{\lambda}y(x)+y(x)\} = G\{\frac{2x^{2-\lambda}}{\Gamma(3-\lambda)}+\frac{x^{1-\lambda}}{\Gamma(2-\lambda)}+x^2-x\}$$

$$\big(v(s)\big)^{\lambda}\hat{G}\big(u(s),v(s)\big)-\sum_{k=0}^{1}\big(v(s)\big)^{\lambda-1-k}y^{(k)}(0)+\hat{G}\big(u(s),v(s)\big) = \frac{2\Gamma(3-\lambda)u(s)}{\Gamma(3-\lambda)v(s)^{3-\lambda}}+\frac{\Gamma(2-\lambda)u(s)}{\Gamma(2-\lambda)v(s)^{2-\lambda}}+\frac{\Gamma(3)u(s)}{v(s)^3}-\frac{\Gamma(2)u(s)}{v(s)^2}$$

$$\begin{aligned}\hat{G}\big(u(s),v(s)\big)\{\big(v(s)\big)^{\lambda}+1\} &= u(s)\{2\left(\tfrac{1}{v(s)}\right)^{3-\lambda}+\left(\tfrac{1}{v(s)}\right)^{2-\lambda}+2\left(\tfrac{1}{v(s)}\right)^{3}-\left(\tfrac{1}{v(s)}\right)^{2}\}\\ &= u(s)\left(\tfrac{1}{v(s)}\right)^{\lambda}\frac{1}{1+\left(\frac{1}{v(s)}\right)^{\lambda}}\{2\left(\tfrac{1}{v(s)}\right)^{3-\lambda}+\left(\tfrac{1}{v(s)}\right)^{2-\lambda}\\ &\quad +2\left(\tfrac{1}{v(s)}\right)^{3}-\left(\tfrac{1}{v(s)}\right)^{2}\}\\ &= \hat{\hat{G}}\left(u(s),\tfrac{1}{v(s)}\right).\end{aligned}$$ (23)

Replacing $u(s)$ by the identity matrix $I_{N\times N}$ and $\frac{1}{v(s)}$ by the operational matrix $R^{(1)}_{N\times N}$ in (23), we obtain

$$\hat{\hat{G}}\left(I_{N\times N},R^{(1)}_{N\times N}\right)=\frac{I_{N\times N}\,R^{(\lambda)}_{N\times N}}{I_{N\times N}+R^{(\lambda)}_{N\times N}}\{2\,R^{(3-\lambda)}_{N\times N}-R^{(2-\lambda)}_{N\times N}+2R^{(3)}_{N\times N}-R^{(2)}_{N\times N}\}.$$ (24)

We arrive at the numerical solutions of equation (22) using (15) and (24). Table 3 shows that as J increases, the absolute errors brought on by the suggested technique decrease and the numerical solutions quickly reach the exact solution.

Example 4. Let us examine the Bagley-Torvik equation

$D^2y(x)+D^{\frac{3}{2}}y(x)+y(x)=x+1,$ (25)

Where $0\leq x<1$, having initial constraints $y(0)=y'(0)=1$.

The exact solution of (25) is $x+1$.

Taking the generalized integral transform of (25), we obtain

$$G\{D^2y(x)+D^{\frac{3}{2}}y(x)+y(x)\}=G\{x+1\}$$

$$\begin{aligned}\hat{G}\big(u(s),v(s)\big)\{v^2(s)+v^{\frac{3}{2}(s)}+1\} &= u(s)\left(v(s)+1+v^{\frac{1}{2}}(s)+v^{-\frac{1}{2}}(s)+\frac{1}{v(s)^2}+\frac{1}{v(s)}\right)\\ &= \frac{u(s)\left(\left(\frac{1}{v(s)}\right)^{-1}+1+\left(\frac{1}{v(s)}\right)^{-\frac{1}{2}}+\left(\frac{1}{v(s)}\right)^{\frac{1}{2}}+\left(\frac{1}{v(s)}\right)^{2}+\frac{1}{v(s)}\right)}{\left(\frac{1}{v(s)}\right)^{-2}+\left(\frac{1}{v(s)}\right)^{-\frac{3}{2}}+1}\\ &= \hat{\hat{G}}\left(u(s),\tfrac{1}{v(s)}\right).\end{aligned}$$ (26)

Replacing $u(s)$ by the identity matrix $I_{N\times N}$ and $\frac{1}{v(s)}$ by the operational matrix $R^{(1)}_{N\times N}$ in (26), we obtain

$$\hat{\hat{G}}\left(I_{N\times N},R^{(1)}_{N\times N}\right)=\frac{I_{N\times N}\left(R^{(-1)}_{N\times N}+I_{N\times N}+R^{\left(-\frac{1}{2}\right)}_{N\times N}+R^{\left(\frac{1}{2}\right)}_{N\times N}+R^{(2)}_{N\times N}+R^{(1)}_{N\times N}\right)}{R^{(-2)}_{N\times N}+R^{\left(\frac{3}{2}\right)}_{N\times N}+I_{N\times N}}.$$ (27)

We achieve the numerical solutions of equation (25) using (15) and (27).The absolute errors achieved by the proposed strategy, Genetic Algorithm (GA)(Raja, M. A. Z., Khan, J. A., & Qureshi, I. M. (2011)) and Genetic Algorithm hybrid with Pattern Search technique (GA-PS) (Raja, M. A. Z., Khan, J. A., & Qureshi, I. M. (2011)) are shown in the Table 4.

Additionally, Table 4 demonstrates that the suggested approach produces a higher level of precision that the GA and GA-PS.

CONCLUSION

In this article, an efficient technique for numerically inverting a generalized integral transform based on operational matrices of Haar wavelets fractional order integration was employed to solve several differential equations of fractional order. A few numerical examples were used to illustrate the applicability and validity of the proposed algorithm. In order to assess the dependability, accuracy, and effectiveness of the proposed technique, the achieved results are compared with exact solutions and with the solutions obtained by a number of alternative numerical approaches

ABSTRACT

The assessment of basketball performance has traditionally relied on a variety of skill-specific tests; however, the reliability, validity, and practical usefulness of these tests remain a subject of ongoing debate. The present study aimed to systematically review and meta-analyze the psychometric properties of basketball-specific skill tests across multiple performance domains, including shooting, dribbling, passing, agility, and combined skill test batteries. A structured review of relevant literature was conducted, and studies reporting reliability, validity, and performance-related outcomes were included based on predefined criteria. Reliability coefficients, primarily intraclass correlation coefficients (ICC), were extracted and synthesized using a meta-analytic approach. Correlation-based values were transformed using Fisher's Z Transformation to ensure comparability across studies. A total of selected studies was included in the analysis, representing diverse testing protocols and participant characteristics. The results of the meta-analysis revealed a pooled reliability coefficient of $r \approx 0.83$, indicating a high level of overall reliability across basketball skill tests. Individual studies demonstrated reliability values ranging from moderate to very high, with sport-specific and isolated skill tests such as dribbling and shooting showing higher consistency compared to combined test batteries. However, despite the generally high reliability, variability was observed in validity and practical applicability. Several studies reported limitations in criterion validity, suggesting that high reliability does not necessarily translate into accurate prediction of real-game performance. The findings further indicated

potential redundancy among traditional test batteries, as multiple skill tests may measure overlapping constructs. Additionally, the lack of ecological validity in many tests highlights the need for more context-specific and integrated assessment approaches. In conclusion, while basketball skill tests demonstrate acceptable to high reliability, their validity and practical usefulness vary considerably. Future research should focus on the development of multidimensional, sport-specific, and technology-driven assessment tools that better reflect real-game performance. These findings provide important implications for researchers, coaches, and practitioners in the evaluation and development of basketball performance assessment systems.

Keywords: - Basketball Performance Assessment, Skill Test Reliability, Validity of Skill Tests, Meta-Analysis, Intraclass Correlation Coefficient (ICC), Ecological Validity, Sport-Specific Testing Performance Evaluation in Basketball

INTRODUCTION

The assessment of basketball performance has long been a central concern in sports science, particularly in the context of talent identification, player development, and performance evaluation. Basketball is a complex, dynamic, and multidimensional sport that requires the integration of technical skills such as shooting, dribbling, and passing, along with physical, perceptual, and decision-making abilities. Consequently, the accurate measurement of basketball skill performance necessitates the use of standardized, reliable, and valid testing instruments. Over the years, numerous basketball-specific skill tests have been developed to quantify individual performance in isolated domains. These include shooting accuracy tests, dribbling agility assessments, passing efficiency evaluations, and combined performance batteries. Several studies have demonstrated that many of these tests exhibit acceptable to high levels of reliability. For example, the Basketball Exercise Simulation Test (BEST) has been shown to produce highly consistent results across repeated trials, with intraclass correlation coefficients (ICC) ranging from excellent levels, indicating strong test–retest reliability (Scanlan, A. T., Dascombe, B. J., & Reaburn, P. R. J. (2015). Similarly, dribbling-based tests such as the V-cut test have demonstrated very high reliability and low coefficients of variation, suggesting precise measurement of performance(Jòdar-Portas et.al, 2023). Shooting-based assessments, including jump shooting accuracy tests, have also reported high intra-rater and inter-rater reliability, further supporting the consistency of these measures (Brenton Boddington, 2019).

Despite these findings, the validity and practical usefulness of basketball skill tests remain a matter of ongoing debate. While some tests demonstrate strong construct validity by differentiating between skill levels, others fail to adequately predict real-game performance. For instance, the Performance Index Evaluation (PIE), although reliable in certain populations, has shown limited effectiveness in predicting actual performance outcomes, particularly among female players (BARFIELD et.al, 2007). Similarly, research comparing standardized skill tests with observational performance measures has indicated that test-based assessments may not always reflect in-game effectiveness, especially in complex, dynamic environments where decision-making and tactical awareness play a significant role (Sachanidi et.al, 2013). Furthermore, the relationship between skill test performance and actual game success is not always linear. While some studies have reported that teams with higher technical skill scores are more likely to achieve better match outcomes, this relationship is influenced by contextual variables such as game strategy, player roles, and situational factors (Francis Stroup,2015). This highlights the concept of ecological validity, which refers to the extent to which test results can be generalized to real-world performance conditions.

Another critical issue in basketball skill testing is the potential overlap and redundancy among different test items. Statistical approaches such as exploratory factor analysis (EFA) have demonstrated that multiple observed variables can often be reduced into a smaller number of latent constructs, indicating that traditional test batteries may measure

similar underlying abilities rather than distinct skills (SÜRÜCÜ, 2014). In addition, dimensionality reduction techniques such as principal component analysis (PCA) have shown that large sets of performance variables can be simplified into fewer components without substantial loss of information, suggesting that many existing tests may be unnecessarily complex or repetitive(Salih Hasan, 2021). Recent advancements in sports science have also emphasized the importance of integrated and sport-specific testing approaches. Modern tools such as multi-component passing indices and simulation-based performance tests incorporate multiple performance dimensions, including accuracy, speed, and movement efficiency, thereby providing a more comprehensive evaluation of player ability (Quílez-Maimón, 2021). Similarly, newly developed test batteries for adolescent and youth players have demonstrated strong content validity, objectivity, and reliability, yet their applicability across different competitive levels remains limited (Eva Salaf et.al, 2023). In addition, research on youth and developmental populations suggests that the psychometric properties of skill tests may vary depending on age, experience, and skill level. For example, studies involving junior basketball players have shown that while certain tests demonstrate acceptable reliability and objectivity, their validity may be influenced by developmental factors and familiarity with the testing protocol (Miodrag Milovanovic, 2023). This further underscores the need for a comprehensive evaluation of basketball skill tests across different populations.

Taken together, the existing literature indicates that although many basketball skill tests demonstrate high reliability, there are significant concerns regarding their validity, redundancy, and practical applicability. Therefore, a systematic synthesis of available evidence is required to evaluate the overall quality and usefulness of these tests.
Accordingly, the present study aims to systematically review and meta-analyze the reliability, validity, and practical usefulness of basketball-specific skill tests. The study is guided by the following research questions:

- What is the level of reliability of basketball-specific skill tests across different performance domains?
- To what extent do these tests demonstrate validity, including content, construct, and criterion validity?
- How effectively do these tests reflect real-game performance and differentiate between player skill levels?
- Are there differences in the psychometric properties of these tests across age groups, competitive levels, and test types?

To ensure methodological rigor and relevance, clearly defined inclusion and exclusion criteria were established prior to the selection of studies.
Studies were included if they met the following criteria:

- They investigated basketball-specific skill tests;
- Participants were basketball players at any competitive level;
- The study reported at least one psychometric property, such as reliability (e.g., ICC, Cronbach's alpha), validity (content, construct, or criterion), objectivity, or test usefulness; and
- The tests assessed performance in domains such as shooting, dribbling, passing, agility/change-of-direction, power, or combined skill performance.

Particular emphasis was placed on studies that developed or validated basketball skill test batteries, as these provide comprehensive evidence regarding measurement quality. For instance, structured test batteries developed for adolescent players have demonstrated strong content validity (IOC values ranging from 0.80 to 1.00), high objectivity, and acceptable to high reliability levels, making them important contributions to the literature (Boonkongma, 2019).

Studies were excluded if they:

- Focused solely on training interventions without evaluating measurement properties;
- Examined general physical fitness without a basketball-specific context
- Were unrelated to basketball performance
- Did not provide sufficient statistical information for interpretation or synthesis.

Additionally, studies from unrelated domains such as software engineering or generic data-mining applications were excluded to maintain the conceptual integrity of the review.

Conceptual Framework

The conceptual framework of the present study is based on the premise that basketball performance is a multidimensional construct influenced by multiple interrelated skill components. Traditional skill tests aim to isolate specific technical abilities; however, in real-game situations, these abilities interact dynamically with contextual and cognitive factors. Statistical frameworks such as factor analysis provide a useful approach for understanding the underlying structure of performance variables. By identifying latent constructs, factor analysis allows researchers to determine whether different test items measure distinct skills or overlapping abilities (SÜRÜCÜ et.al, 2024). Similarly, PCA and other dimensionality reduction techniques highlight the possibility that multiple observed variables may capture similar variance, thereby questioning the necessity of extensive test batteries (Salih Hasan et.a;, 2021).Moreover, contemporary research emphasizes the integration of multiple performance dimensions, including technical execution, movement efficiency, and decision-making, in order to better reflect the demands of competitive basketball (Quílez-Maimón et.al, 2021). This perspective aligns with the growing recognition that performance assessment should move beyond isolated skill testing toward more holistic and ecologically valid evaluation methods. Accordingly, the present study adopts a mixed approach that combines quantitative meta-analysis of reliability outcomes with qualitative synthesis of validity and practical usefulness. This approach enables a comprehensive evaluation of basketball skill tests and provides meaningful insights for both researchers and practitioners.

Study Selection Process

The selection of studies for the present systematic review and meta-analysis was conducted following a structured and systematic approach. Initially, a broad range of studies related to basketball skill performance, test development, and performance evaluation were identified. These studies were screened for relevance based on their focus on basketball-specific skill assessment. Subsequently, studies were evaluated using predefined inclusion and exclusion criteria to ensure methodological rigor and conceptual consistency. Only those studies that reported psychometric properties such as reliability, validity, objectivity, or practical usefulness were included in the final analysis. This approach is consistent with previous research emphasizing the importance of evaluating the measurement quality of sports performance tests before their application in practice. Particular emphasis was placed on studies that developed or validated basketball-specific skill tests. For instance, structured test batteries designed for adolescent players demonstrated strong content validity (IOC values ranging from 0.80 to 1.00), high objectivity ($r = 0.892–0.975$), and acceptable to high reliability ($r = 0.666–0.935$), indicating robust measurement quality (PonrobBoonkongma, 2019). Similarly, modern test batteries such as the Combined Basketball Skill Test (CBST) have shown acceptable reliability (ICC ≥ 0.70) and the ability to discriminate between different performance levels (Conte et.al, 2018).

In addition, performance-based and sport-specific tests such as the Basketball Exercise Simulation Test (BEST), V-cut dribbling test, and jump shooting accuracy assessments were included due to their high reliability and validity evidence. For example, BEST has demonstrated excellent test–retest reliability (ICC values approaching 0.90 and above) along with strong criterion validity in relation to performance indicators (Scanlan et.al, 2015). Similarly, the V-cut dribbling test has reported very high reliability (ICC ≈ 0.95) and low variability, indicating precise measurement of dribbling performance (Portas et.al, 2023). Shooting-based assessments have also demonstrated high intra-rater and inter-rater reliability, supporting their consistency as performance measures (Boddington et.al, 2019). Furthermore, studies focusing on construct validity and reactive performance, such as multidirectional repeated sprint tests, were included due to their ability to capture sport-specific movement patterns and validate performance constructs (Brini et.al, 2021). Advanced assessment tools such as the Q-Pass index, which integrates accuracy, time, and movement efficiency, were also included as they represent modern, multidimensional approaches to skill evaluation (Quílez-Maimón et.al, 2021). Conversely, studies that did not directly contribute to the evaluation of

basketball skill tests were excluded. For example, studies related to software testing methodologies or general data-mining techniques were removed due to their lack of relevance to sports performance assessment. Similarly, studies focusing solely on training interventions without reporting psychometric properties were excluded, as they do not provide evidence regarding test validity or reliability. This systematic selection process ensured that only high-quality and relevant studies were included in the final analysis, thereby enhancing the scientific rigor of the review.

Study Classification Table

The Table1 presents a comprehensive overview of the included studies categorized based on their domain, type of test, and rationale for inclusion in the present systematic review and meta-analysis. This classification highlights the diversity of basketball skill assessment tools and their respective contributions to evaluating performance.The included studies encompass multiple performance domains, including fitness, technical skills (shooting, dribbling, passing), agility, and overall performance evaluation, thereby reflecting the multidimensional nature of basketball. Each study was selected based on its ability to provide reliable, valid, and practically relevant measures of basketball performance.TheBasketball Exercise Simulation Test (BEST) was included as a simulation-based test that integrates both fitness and skill components. Its inclusion was justified by its very high intraclass correlation coefficients (ICC) and strong criterion validity, indicating that it produces consistent results while also reflecting game-like performance conditions. This makes BEST one of the most ecologically valid tools among the included studies.The V-Cut Dribbling Test, categorized under the dribbling domain, was included due to its exceptionally high reliability and strong correlation with performance outcomes. As an agility-based skill test, it provides a precise measurement of ball control and movement efficiency, making it a valuable tool for assessing technical proficiency.

Similarly, the Jump Shooting Accuracy Test represents the shooting domain and was included based on its strong reliability and validity evidence, particularly in terms of intra- and inter-rater consistency. Shooting is a critical determinant of basketball success, and the high measurement stability of this test supports its use in performance evaluation. The Combined Basketball Skill Test (CBST) was included as a multidimensional test battery designed to assess multiple skill components simultaneously. Its inclusion highlights the importance of integrated performance assessment, although such tests may introduce variability due to the interaction of multiple skill elements. The Basketball Skill Performance Test (BSPT), particularly developed for adolescent players, was included due to its high content validity and reliability. This test is especially relevant for youth populations, as it provides a structured and comprehensive evaluation of developing skills. The Mini Basketball Skill Test was also included to represent youth-level assessment. Its inclusion was based on reliability evidence in younger populations, emphasizing the importance of age-specific test validation and the need for appropriate tools in developmental stages. The Reactive Repeated Sprint Test, categorized under agility, was included due to its construct validity and high reliability. This test captures sport-specific movement patterns, including reaction and change-of-direction ability, which are essential components of basketball performance.

The Q-Pass Index, an advanced passing assessment tool, was included as a multi-dimensional test that integrates accuracy, speed, and movement efficiency. Its inclusion reflects the shift toward modern, technology-driven and holistic performance evaluation methods. Finally, the Performance Index Evaluation (PIE) was included as a performance evaluation tool that provides reliability and criterion validity insights. However, it also highlights limitations in predicting real-game performance, making it important for understanding the gap between statistical consistency and practical applicability. The Table 2 presents the supporting or background studies that were incorporated into the research to strengthen the theoretical and conceptual framework of the study. Although these studies were not directly included in the meta-analysis, they played a crucial role in interpreting findings related to validity, performance relevance, and the multidimensional nature of basketball. The Shot Type Success Study, categorized under the shooting domain, was used to support the discussion on ecological validity. This study highlights how shooting performance varies under real-game conditions, such as defensive pressure, shot selection, and positioning. Its inclusion emphasizes that isolated shooting tests may not fully capture actual game performance.

The Game Result Validation Study, under the performance domain, contributed to criterion validity support. It provided evidence linking skill performance with match outcomes, demonstrating how technical abilities can influence success in real-game situations. This strengthens the argument that performance tests should be evaluated based on their ability to predict actual game results. The Passing Efficacy Study, representing the passing domain, was used for test versus game comparison. It highlighted differences between controlled test environments and real-game passing performance, emphasizing that passing effectiveness depends on situational factors such as decision-making and opponent pressure. The Functional Movement Study, categorized as general, contributed to the conceptual discussion of performance assessment. It provided insights into movement efficiency, biomechanics, and physical readiness, which are essential underlying components of basketball skill execution.Similarly, the Balance and Stability Study, under the physical domain, was included as background support. It emphasized the importance of physical control and postural stability in executing basketball skills effectively, thereby reinforcing the physical foundation of performance. The Coordinative Ability Study, categorized under coordination, was used to support the concept of multidimensional skill performance. It highlighted the integration of motor coordination, timing, and control, demonstrating that basketball performance is not based on isolated skills but on the interaction of multiple abilities.

Table 3 presents the studies that were excluded from the systematic review along with the specific reasons for their exclusion. This step is essential in maintaining the methodological rigor, relevance, and scientific quality of the study. The exclusion process was guided by predefined criteria to ensure that only studies directly relevant to basketball performance assessment and reporting psychometric properties were included in the analysis.The Software Regression Testing Paper was excluded because it belongs to the field of software engineering and is not related to sports science or basketball performance. Including such studies would compromise the conceptual focus of the review. Similarly, the PCA Big Data Paper was excluded as it focused on general data analysis techniques without any basketball-specific application. Although statistical methods like Principal Component Analysis are relevant, their inclusion requires direct application to sports performance, which was not present in this study.The Long-COVID Bibliometric Study was completely unrelated to the research domain, as it focused on medical and epidemiological analysis. Therefore, it was excluded to maintain the thematic consistency of the review.TheTraining-only Dribbling Studies were excluded because they did not report reliability or validity data, which are essential for evaluating the measurement quality of skill tests. Since the present study focuses on psychometric evaluation, the absence of such data made these studies unsuitable for inclusion.Lastly, the Zig-Zag Soccer Study was excluded due to lack of basketball specificity. Although it involved agility testing, the context of soccer differs significantly from basketball, limiting its applicability to the present research.

Data Extraction Process

Data extraction was carried out systematically from all included studies to ensure accuracy and consistency in the analysis. Relevant information was extracted from each study, including author details, sample size, type of basketball skill test, performance domain, and reported psychometric properties such as reliability, validity, and objectivity. Particular emphasis was placed on extracting reliability coefficients, especially intraclass correlation coefficients (ICC), as these provide a standardized measure for meta-analysis across different studies. Previous research has highlighted the importance of ICC as a robust indicator of test–retest reliability and inter-rater agreement in sports performance assessment (Koo and Li, 2015). In addition to reliability, validity indicators such as content validity, construct validity, and criterion-related validity were also recorded. For example, structured test batteries for adolescent players reported high content validity (IOC = 0.80–1.00), strong objectivity (r = 0.892–0.975), and acceptable reliability levels (r = 0.666–0.935), providing comprehensive evidence of test quality (Boonkongma, 2019). Similarly, advanced performance tests such as BEST and Q-Pass provided both reliability and validity evidence, making them suitable for inclusion in the synthesis .The extracted data were organized into a structured format to facilitate comparison across studies and enable subsequent meta-analysis.

Main Data Extraction Table

Table 4 present the extracted data indicate that most basketball skill tests demonstrate moderate to high levels of reliability across different domains. For example, simulation-based tests such as BEST showed excellent reliability and strong associations with performance indicators, suggesting high practical relevance(Scanlan et.al, 2015). Similarly, dribbling tests such as the V-cut test demonstrated very high reliability and low variability, indicating precise measurement of skill performance (Portas et.al, 2023). Shooting-based tests also exhibited high levels of consistency, with strong intra-rater and inter-rater reliability reported in jump shooting assessments (Boddington, 2019). Combined skill tests, such as CBST and BSPT, demonstrated acceptable reliability and construct validity, indicating their usefulness in evaluating overall basketball performance. However, variability was observed in the validity of certain tests. For instance, performance indices such as PIE showed moderate reliability but limited ability to predict actual performance outcomes, highlighting concerns regarding criterion validity (Paul Barfield et.al, 2007). Similarly, advanced tools such as Q-Pass emphasize the importance of integrating multiple performance variables, suggesting that traditional single-skill tests may not fully capture the complexity of basketball performance (MaimónQuílez et.al, 2021). The graphical representation of domain distribution indicates that the majority of studies focused on combined basketball skill tests, followed by individual domains such as shooting, dribbling, and passing. This suggests that researchers increasingly emphasize multidimensional assessment approaches rather than isolated skill evaluation. However, comparatively fewer studies were found in agility-related domains, highlighting a potential research gap in sport-specific movement assessments.

Graph 2 shows the reliability comparison graph shows that most basketball skill tests demonstrate moderate to high reliability. Tests such as BEST and V-cut dribbling exhibit excellent reliability values, indicating high consistency in measurement. In contrast, tests like CBST and PIE show comparatively lower reliability, suggesting variability in measurement precision across different testing protocols. Overall, the findings confirm that while reliability is generally acceptable, it varies depending on the nature and design of the testThe scatter plot comparing reliability and validity demonstrates that high reliability does not necessarily correspond to high validity. While some tests such as BEST and V-cut show both high reliability and validity, others, such as PIE, exhibit moderate reliability but low validity. This indicates that certain tests, although consistent in measurement, may not accurately reflect actual performance. These findings highlight the importance of evaluating both reliability and validity when selecting basketball skill assessment tools.Graph 4 shows the distribution of study types indicates that most research has focused on test development, followed by validation studies and performance-based investigations. This trend suggests that while considerable efforts have been made to design basketball skill tests, fewer studies have evaluated their effectiveness in real-game performance contexts. This imbalance highlights the need for more research focusing on ecological validity and practical applicability.

Meta-Analysis Calculation

Purpose of Meta-Analysis

The purpose of the meta-analysis was to quantitatively synthesize the reliability coefficients reported across the included studies. Since different studies reported reliability using intraclass correlation coefficients (ICC) and Pearson's correlation coefficients (r), these values were transformed into a common metric using Fisher's Z transformation. This transformation stabilizes variance and allows for accurate pooling of correlation-based effect sizes across studies.Fisher's Z transformation is widely recommended in meta-analytic research involving correlation coefficients, as it improves the normality of distribution and ensures comparability between studies Fisher's Z Transformation. Table 5 present the meta-analysis table presents the transformed effect sizes (Fisher's Z), standard errors, and corresponding weights of the selected studies based on their reported reliability coefficients. The results indicate that there is considerable variation in reliability values across different basketball skill tests, reflecting differences in test design, sample size, and performance domains. Among the included studies, the BEST and V-cut dribbling tests demonstrated the highest reliability coefficients ($r = 0.95$), which were also reflected in their high Fisher's Z values ($Z = 1.83$). These findings suggest that these tests provide highly consistent measurements and can be considered among the most reliable tools for assessing basketball performance. Similarly, the Reactive Sprint Test

showed a high reliability value (r = 0.88; Z = 1.38), indicating strong measurement stability in agility-related performance. In contrast, the Combined Basketball Skill Test (CBST) exhibited a comparatively lower reliability coefficient (r = 0.72; Z = 0.91), suggesting moderate consistency in measurement. Despite its lower reliability, CBST received the highest statistical weight (W = 51.02) due to its larger sample size (N = 50). This highlights an important characteristic of meta-analysis, where studies with larger sample sizes contribute more significantly to the overall pooled estimate. Similarly, the Performance Index Evaluation (PIE) demonstrated moderate reliability (r = 0.79; Z = 1.07) with a relatively high weight (W = 39.06), indicating its influence on the pooled effect size. However, as reported in previous studies, performance indices such as PIE may show acceptable reliability but limited validity in predicting actual game performance, emphasizing the need to interpret these findings with caution. The standard error (SE) values ranged from 0.14 to 0.24, indicating variability in the precision of the estimated effect sizes. Studies with larger sample sizes, such as CBST, exhibited lower standard error values, reflecting greater precision, whereas studies with smaller samples showed higher variability. Overall, the distribution of weights and effect sizes suggests that while certain tests demonstrate very high reliability, the overall pooled estimate is influenced by both the magnitude of reliability coefficients and the sample size of individual studies. This highlights the importance of considering both statistical strength and methodological quality when evaluating basketball skill tests.

Pooled Effect Size

$Z_{pooled} = \sum(W \times Z)/\sum W$

Result:

- Pooled Z ≈ 1.18
- Convert into r $r = e^{2Z-1}/ e^{2Z+1}$

Interpretation

The results of the meta-analysis revealed a pooled reliability coefficient of approximately 0.83, indicating a high level of overall reliability across basketball skill tests. This suggests that most basketball-specific performance tests produce consistent and stable measurements across repeated trials. However, variability in reliability values was observed across studies, which may be attributed to differences in test design, sample characteristics, and performance domains. Tests such as BEST and V-cut dribbling demonstrated very high reliability, whereas combined skill tests and performance indices showed comparatively moderate reliability.

Heterogeneity

The heterogeneity among studies was assessed to determine the variability in effect sizes. Due to differences in study design, participant characteristics, and testing protocols, moderate heterogeneity was expected. This supports the use of a random-effects model for the meta-analysis

Forest Plot

A forest plot was used to visually represent the reliability coefficients of individual studies along with the pooled effect size. Each study was represented by a square proportional to its weight, while the horizontal lines indicated confidence intervals. The pooled estimate was represented by a diamond, indicating the overall reliability of basketball skill tests.The forest plot illustrates the reliability coefficients (ICC) of individual studies along with their respective confidence intervals. Each point represents the effect size of a study, while the horizontal lines indicate the variability or confidence interval around the estimate. The results show that studies such as BEST and V-cut dribbling demonstrated very high reliability values, with narrow confidence intervals indicating strong precision and consistency in measurement. Similarly, the Reactive Sprint Test also exhibited high reliability, although with slightly wider variability due to a smaller sample size. In contrast, the Combined Basketball Skill Test (CBST) showed comparatively lower reliability, as reflected by its lower effect size and wider confidence interval. The Performance Index Evaluation (PIE) demonstrated moderate reliability, indicating acceptable but less consistent measurement compared to other tests. The vertical line in the plot represents the pooled reliability estimate (r ≈ 0.83), indicating the overall reliability across all included studies. Most studies fall around or above this line, suggesting that basketball

skill tests generally demonstrate moderate to high reliability. However, the variability observed across studies highlights differences in test design, sample characteristics, and measurement approaches.

RESULTS SECTION

Overview of Included Studies

A total of selected studies were included in the present systematic review and meta-analysis, focusing on the evaluation of reliability, validity, and practical usefulness of basketball-specific skill tests. These studies encompassed multiple performance domains, including shooting, dribbling, passing, agility/change-of-direction, and combined skill test batteries. The diversity of domains reflects the multidimensional nature of basketball performance, which requires the integration of technical and physical abilities. The included studies employed a wide range of assessment methods, including isolated skill tests, simulation-based performance tests, and multidimensional test batteries. For example, simulation-based protocols such as the Basketball Exercise Simulation Test (BEST) were designed to replicate real-game conditions, while isolated skill tests focused on specific components such as shooting accuracy or dribbling control . Similarly, combined test batteries such as the Combined Basketball Skill Test (CBST) and Basketball Skill Performance Test (BSPT) were designed to evaluate overall performance by integrating multiple skill components .The sample sizes across studies varied considerably, which influenced the precision of reliability estimates. Larger sample studies contributed more weight in the meta-analysis, while smaller samples showed greater variability in their estimates. This variation in sample size and study design highlights the need for systematic synthesis of results to obtain a more accurate overall estimate of test reliability.

Reliability Analysis

The primary focus of the meta-analysis was to evaluate the reliability of basketball skill tests using correlation-based measures such as intraclass correlation coefficients (ICC). The findings revealed that the reliability of basketball skill tests ranged from moderate to very high across studies.The highest reliability values were observed in performance-based and sport-specific tests. For instance, the BEST demonstrated excellent reliability, with ICC values approaching 0.90 and above, indicating high consistency in repeated performance measurement (Scanlan, et.al, 2015). Similarly, dribbling assessments such as the V-cut dribbling test exhibited very high reliability (ICC ≈ 0.95), reflecting precise measurement of agility and ball control (Portas et.al, 2023). Shooting-based assessments also showed strong reliability, with high intra-rater and inter-rater agreement reported in jump shooting accuracy tests (Boddington, 2019). In contrast, combined skill test batteries such as CBST demonstrated comparatively lower reliability (ICC ≥ 0.70), suggesting that the inclusion of multiple performance components may introduce variability in measurement (Conte et., 2013). Similarly, performance indices such as the Performance Index Evaluation (PIE) showed moderate reliability (ICC ≈ 0.79), indicating acceptable but less consistent measurement compared to isolated skill tests (Paul Barfield et.al, 2017). These findings suggest that isolated and sport-specific tests tend to produce more consistent results than composite or multidimensional assessments. This may be due to the increased complexity and interaction of multiple variables in combined tests, which can affect measurement stability.

Pooled Effect Size

The pooled effect size was calculated using a weighted meta-analytic approach, in which individual study effect sizes were combined based on their respective weights derived from inverse variance. The analysis yielded a pooled Fisher's Z value of approximately 1.18, which corresponded to a pooled reliability coefficient of: r = 0.83This pooled estimate indicates a high overall level of reliability across basketball skill tests. The findings suggest that, on average, basketball skill tests provide consistent and reproducible measurements of performance across different populations and testing conditions. The high pooled reliability is consistent with previous findings in sports performance research, which indicate that well-designed skill tests can achieve acceptable to high levels of measurement consistency. However, it is important to note that this overall estimate represents an average across heterogeneous studies and should be interpreted in the context of variability across domains.

Forest Plot Analysis

The forest plot provided a visual representation of the reliability coefficients across individual studies along with their respective confidence intervals. The graphical analysis revealed that most studies were clustered around or above the pooled reliability estimate, indicating generally high levels of measurement consistency. Studies such as BEST and V-cut dribbling were positioned above the pooled estimate, demonstrating superior reliability. These findings support the use of sport-specific and well-controlled performance tests for accurate measurement of basketball skills .Similarly, the Reactive Sprint Test showed relatively high reliability, reflecting its effectiveness in measuring agility-related performance **(**Brini et.al, 2021). In contrast, studies such as CBST and PIE were positioned closer to or below the pooled estimate, indicating moderate reliability. The wider confidence intervals observed in some studies suggest lower precision, which may be attributed to smaller sample sizes or variability in test protocols. Overall, the forest plot highlights both the strengths and limitations of existing basketball skill tests, demonstrating that while reliability is generally high, there is variability across different test types and contexts.

Variability and Heterogeneity

The results of the meta-analysis indicated the presence of variability across studies, which can be attributed to differences in study design, participant characteristics, and testing protocols. For example, studies involving trained or elite players tended to report higher reliability compared to those involving novice or youth populations (Milovanovic, 2023). Additionally, differences in test structure, such as isolated versus combined skill tests, contributed to variability in reliability estimates. Simulation-based and sport-specific tests demonstrated higher consistency, whereas multidimensional test batteries showed greater variability due to the interaction of multiple performance components. The observed heterogeneity supports the use of a random-effects model for meta-analysis, as it accounts for variability across studies and provides a more generalized estimate of effect size.

Validity and Practical Usefulness

Although the primary focus of the meta-analysis was reliability, the included studies also provided important insights into the validity and practical usefulness of basketball skill tests. Several studies demonstrated strong construct validity, particularly in their ability to differentiate between players of different skill levels (Conte et., 2013). However, limitations were observed in terms of criterion validity. For example, performance indices such as PIE, although reliable, showed limited ability to predict real-game performance outcomes (Fahmi et.al, 2025). Similarly, research comparing test-based performance with observational measures suggested that isolated skill tests may not fully capture in-game effectiveness, particularly in dynamic and decision-based situations (Sachanidi et.al, 2017). Furthermore, studies linking skill performance with match outcomes indicated that while technical skills contribute to performance, their impact is influenced by contextual factors such as game strategy and player roles (Stroup, 2015). This highlights the importance of ecological validity in basketball performance assessment.

Overview of Findings

The present study aimed to systematically evaluate the reliability, validity, and practical usefulness of basketball-specific skill tests through a meta-analytic approach. The findings revealed that most basketball skill tests demonstrate moderate to high levels of reliability, with a pooled reliability coefficient of approximately **r = 0.83**, indicating overall consistency in measurement across studies. However, despite the generally high reliability, considerable variability was observed in terms of validity and practical applicability.These findings highlight an important distinction between statistical reliability and real-world performance relevance. While many tests are capable of producing consistent results, their ability to accurately reflect in-game performance remains uncertain.

Reliability of Basketball Skill Tests

The results of the present study indicate that basketball skill tests, particularly those designed to assess isolated technical abilities such as shooting and dribbling, tend to exhibit high levels of reliability. For example, tests such as BEST and the V-cut dribbling test demonstrated excellent reliability, suggesting that these assessments provide stable and reproducible measurements Similarly, shooting-based assessments showed high intra-rater and inter-rater

reliability, supporting their consistency in measuring technical performance (Boddington, 2019). These findings are consistent with previous research indicating that well-structured and standardized skill tests can achieve high levels of measurement reliability. However, combined skill test batteries such as CBST demonstrated comparatively lower reliability, which may be attributed to the inclusion of multiple performance components within a single test. The interaction between different skill elements can introduce variability and reduce overall measurement consistency **(**Conte et., 2013).This suggests that while multidimensional tests provide a more comprehensive assessment, they may compromise reliability due to increased complexity.

Validity and the Limitation of Traditional Skill Tests

A key finding of the present study is that high reliability does not necessarily imply high validity. While many tests demonstrated acceptable reliability, their ability to predict or reflect actual basketball performance was limited in several cases. For instance, the Performance Index Evaluation (PIE), despite demonstrating moderate reliability, showed limited effectiveness in predicting real-game performance outcomes (Paul Barfield et.al, 2017). Similarly, studies comparing standardized skill tests with observational measures found discrepancies between test performance and in-game effectiveness, particularly in tasks requiring decision-making and situational awareness (Sachanidi et.al. 2017). These findings suggest that traditional skill tests may lack ecological validity, as they are often conducted in controlled environments that do not fully replicate the dynamic and unpredictable nature of competitive basketball. Therefore, relying solely on isolated skill tests may provide an incomplete representation of a player's true performance capability.

Ecological Validity and Game-Based Performance

The concept of ecological validity is particularly relevant in the context of basketball performance assessment. Several studies have highlighted the importance of evaluating skills within real-game situations, where contextual factors such as opponent pressure, decision-making, and tactical awareness play a crucial role. For example, research examining the relationship between skill performance and match outcomes found that while higher technical skill levels are generally associated with better performance, this relationship is influenced by situational variables (Stroup, 2015). Additionally, studies analyzing shot success in real-game contexts have demonstrated that performance is highly dependent on factors such as shot selection, positioning, and defensive pressure **(**Erčulj and Štrumbelj, 2015). These findings indicate that basketball performance cannot be fully captured through isolated skill tests alone. Instead, there is a need for more integrated and context-specific assessment approaches that reflect the complexity of real-game situations.

Redundancy and Overlap in Skill Tests

Another important observation from the present study is the potential redundancy and overlap among different basketball skill tests. Statistical approaches such as factor analysis have demonstrated that multiple observed variables can often be reduced into a smaller number of underlying latent constructs, suggesting that different tests may measure similar abilities (SÜRÜCÜ et.al, 2024). Similarly, dimensionality reduction techniques such as principal component analysis (PCA) indicate that a large number of performance variables can be explained by a few principal components, highlighting the possibility of redundancy in traditional test batteries (Salih Hasan and Abdulazeez, 2021). This suggests that the inclusion of multiple similar tests may not necessarily enhance the accuracy of performance assessment. These findings emphasize the need for careful selection of test items and the development of more efficient and non-redundant assessment tools.

Need for Integrated and Multidimensional Testing

The limitations of traditional skill tests highlight the need for integrated and multidimensional approaches to basketball performance assessment. Modern assessment tools, such as the Q-Pass index, incorporate multiple performance dimensions, including accuracy, speed, and movement efficiency, thereby providing a more comprehensive evaluation of skill performance (Quílez-Maimón et.al, 2017). Similarly, simulation-based tests such as BEST attempt to replicate real-game conditions, enhancing both ecological validity and practical applicability

(Scanlan et.al, 2015). These approaches represent a shift toward more holistic assessment methods that better reflect the demands of competitive basketball.

Practical Implications

The findings of the present study have important implications for coaches, researchers, and practitioners. While traditional skill tests can provide reliable measurements, their use should be complemented with game-based assessments and observational analysis to obtain a more accurate evaluation of player performance.Coaches should consider selecting tests that are not only reliable but also valid and relevant to actual game situations. Additionally, the use of multidimensional and sport-specific tests can enhance the effectiveness of performance evaluation and talent identification.

Future Directions

Future research in the field of basketball performance assessment should focus on the development of more comprehensive, integrated, and context-specific evaluation systems. Although traditional skill tests have demonstrated acceptable levels of reliability, the present findings highlight significant limitations in terms of validity and practical applicability. Therefore, there is a need to move beyond isolated skill assessments toward more holistic approaches that better reflect the multidimensional nature of basketball performance. One of the key directions for future research is the integration of technical, physical, and cognitive components within a single assessment framework. Basketball performance is not solely dependent on isolated skills such as shooting or dribbling; rather, it involves the interaction of multiple factors, including decision-making, perception, and game awareness. Studies have shown that isolated skill tests may not accurately capture performance under real-game conditions, particularly in dynamic and unpredictable environments . Therefore, future test batteries should incorporate decision-making tasks and situational variables to improve ecological validity. Another important direction is the development of sport-specific and simulation-based testing protocols.

Tests such as the Basketball Exercise Simulation Test (BEST) have demonstrated the potential of replicating game-like conditions, thereby enhancing both reliability and validity . Future research should build on such approaches by designing tests that simulate real match scenarios, including defensive pressure, fatigue, and time constraints. This would allow for a more accurate assessment of performance in conditions that closely resemble competitive play.The use of advanced technologies also represents a promising area for future research. Modern tools such as motion tracking systems, wearable sensors, and video-based performance analysis can provide detailed information on movement patterns, speed, and coordination. For example, multidimensional assessment tools such as the Q-Pass index have already demonstrated the value of integrating multiple performance indicators, including accuracy, time, and movement efficiency . Future studies should explore the application of such technologies to develop more objective and precise performance evaluation systems. In addition, there is a need for further research on the underlying structure of basketball skills using advanced statistical techniques. Methods such as factor analysis and principal component analysis can help identify latent constructs and reduce redundancy among test items. Previous findings suggest that multiple skill tests may measure overlapping abilities, indicating inefficiency in traditional test batteries . Therefore, future research should aim to develop more efficient and scientifically optimized test batteries based on empirical evidence.

Another important area for future investigation is the examination of differences across populations. The present study indicates that the reliability and validity of skill tests may vary depending on factors such as age, skill level, and playing experience. For instance, tests that are reliable in elite players may not produce similar results in youth or novice populations . Future research should focus on developing population-specific test norms and validating tests across different competitive levels. Moreover, future studies should place greater emphasis on criterion validity by establishing stronger links between test performance and real-game outcomes. While some studies have demonstrated associations between skill performance and match success, these relationships are often influenced by contextual variables such as team strategy and player roles . Therefore, longitudinal and game-based studies are

required to better understand the predictive value of basketball skill tests. Finally, the development of standardized protocols and normative data is essential for improving the practical applicability of basketball skill tests. Establishing normative values for different age groups and performance levels would allow coaches and practitioners to interpret test results more effectively. Additionally, the adoption of standardized testing procedures would enhance comparability across studies and contribute to the development of a unified framework for basketball performance assessment.

ABSTRACT

Social media platforms increasingly use algorithmic ranking systems to decide which brand messages, influencer posts, sponsored advertisements and engagement-rich product cues become visible to consumers. This study examines algorithmic marketing as a platform-mediated persuasion process and tests how personalized content, targeted advertisements, influencer recommendations and social proof affect purchase intention among social media users. A descriptive analytical research design was adopted, and primary data were collected from 200 active social media users through a structured questionnaire. The study used reliability analysis, correlation analysis, multicollinearity diagnostics, model summary estimation, ANOVA and multiple regression. The findings show that all four algorithmic marketing cues have significant positive effects on purchase intention. Personalized content emerged as the strongest predictor ($\beta = 0.39$, $p < 0.001$), followed by targeted advertisements ($\beta = 0.28$, $p < 0.001$), influencer recommendations ($\beta = 0.24$, $p = 0.001$) and social proof ($\beta = 0.19$, $p = 0.003$). The model explained 61.0 percent of the variance in purchase intention, confirming meaningful explanatory strength in the context of digital marketing behaviour. Relative effect decomposition further shows that personalization accounts for the largest share of standardized influence, indicating that algorithmic relevance is the primary mechanism through which platforms shape consumer intention. The study contributes to digital marketing literature by conceptualising social media algorithms as visibility

systems that combine relevance, targeting, credibility and collective validation. The findings also highlight the need for ethical algorithmic marketing practices that balance personalization benefits with transparency, user autonomy and data privacy.

Keywords: Algorithmic marketing; personalized content; targeted advertising; influencer credibility; social proof; purchase intention; digital persuasion; social media platforms

INTRODUCTION

Social media platforms have shifted marketing from a broadcast model to an algorithmically mediated visibility model. In earlier digital environments, brands largely depended on search, display advertising or chronological exposure. In contrast, contemporary platforms such as Instagram, Facebook, YouTube and TikTok use ranking systems that filter and prioritize content according to behavioural signals such as watch time, clicks, likes, shares, comments, search history, browsing patterns and prior engagement. As a result, consumer exposure to products is no longer accidental or purely self-directed; it is shaped by algorithmic systems that decide which messages enter the consumer's attention space.This transformation matters because consumer decision-making on social media begins before an active purchase search. A consumer may encounter a product through a personalized feed, see a targeted advertisement for the same category, observe an influencer using the product and interpret visible likes or comments as evidence of popularity. These cues do not operate independently. They interact within the architecture of the platform and gradually shape perceived relevance, credibility, trust and purchase intention. Thus, algorithmic marketing should be examined not only as advertising delivery but also as a structured persuasion environment.The present study focuses on four algorithmic marketing cues: personalized content, targeted advertisements, influencer recommendations and social proof.

Personalized content refers to content that appears tailored to the user's preferences and digital behaviour. Targeted advertisements refer to paid promotional messages delivered to selected users based on demographic, behavioural or contextual signals. Influencer recommendations represent brand-related endorsements or product suggestions from social media creators. Social proof refers to visible engagement metrics such as likes, comments, shares, ratings and views that signal collective approval. The study examines how these cues influence purchase intention among social media users.The need for this study arises from a gap in digital marketing research. Existing studies have examined personalization, targeting, influencer marketing and social proof separately. However, in actual social media platforms, these mechanisms are combined by algorithms within a single attention environment. A product may become persuasive not only because it is relevant, but because it is repeatedly visible, socially endorsed, creator-amplified and algorithmically prioritized. A scientific examination of consumer purchase intention therefore requires an integrated model that treats algorithms as visibility and persuasion systems rather than as neutral technical tools.The objective of this study is to empirically test the influence of algorithmic marketing cues on purchase intention. The study further interprets the relative strength of each cue and explains how algorithmic visibility, relevance-based persuasion, influencer credibility and social validation contribute to digital consumer behaviour. The article also makes a methodological clarification: the current empirical model directly tests purchase intention, while actual consumer purchasing decision is treated as a downstream behavioural outcome that requires future transaction-level or longitudinal data for direct estimation.

Theoretical and Empirical Background

Algorithmic Visibility and Platform-Mediated Marketing

Algorithms structure visibility on social media platforms by selecting, ranking and recommending content. Gillespie (2014) argues that algorithms are relevant not only because they process information but because they shape what

becomes visible, searchable and socially important. In marketing contexts, this means that platform algorithms influence consumer attention before consumers consciously evaluate brand alternatives. Algorithmic visibility therefore becomes a strategic marketing resource.Social media algorithms do not merely transmit advertisements. They combine user data, engagement histories and content-level signals to construct individualized feeds. This creates a digital choice architecture in which some products become more salient than others. The marketing effect of an algorithm depends on its ability to repeatedly present relevant, credible and socially validated content to the right user at the right time.

Personalization and Relevance-Based Persuasion

Personalization is central to algorithmic marketing because it increases perceived relevance and reduces information overload. Bleier and Eisenbeiss (2015) showed that personalized online advertising becomes more effective when it matches user interests and is delivered in a suitable context. When content appears personally relevant, users are more likely to attend to it, process it and form purchase-related interest. Personalization therefore works as a relevance filter that connects platform data with consumer attention.

Targeted Advertising and Contextual Fit

Targeted advertising uses data-based segmentation to deliver promotional messages to users who are more likely to respond. Kotler and Keller (2018) emphasize that marketing effectiveness depends strongly on relevance and fit. In social media environments, targeting improves this fit by aligning advertisements with previous searches, demographic characteristics, platform interactions and inferred preferences. However, targeted advertising can also generate privacy concerns if users perceive it as intrusive. Its effectiveness therefore depends on balancing relevance with perceived acceptability.

Influencer Credibility and Parasocial Persuasion

Influencer recommendations add credibility and social familiarity to brand communication. De Veirman, Cauberghe and Hudders (2017) found that influencer characteristics influence brand attitude, while Lou and Yuan (2019) showed that influencer credibility and message value strengthen trust in branded content. Influencers often function as human interfaces within algorithmic systems: their content is personal, entertaining and socially embedded, but its reach is amplified by platform ranking mechanisms. Thus, influencer persuasion combines source credibility with algorithmic distribution.

Social Proof and Engagement-Based Validation

Social proof theory explains why visible engagement cues influence consumer judgments. Cialdini (2009) argued that individuals often rely on the behaviour of others when making decisions under uncertainty. In social media, likes, comments, shares, views and reviews act as visible indicators of popularity and approval. Hajli (2015) showed that social commerce constructs such as ratings, referrals and recommendations influence trust and buying intention. When algorithms boost highly engaged content, social proof becomes both an input and an output of algorithmic persuasion.

Behavioural Intention and Digital Choice Formation

The Theory of Planned Behavior proposes that behaviour is shaped by attitudes, subjective norms and perceived behavioural control (Ajzen, 1991). In social media marketing, attitudes are influenced by repeated exposure and perceived relevance; subjective norms are inferred from influencer endorsement and engagement metrics; and perceived control is shaped by platform interface design and ease of product access. The Elaboration Likelihood Model further suggests that consumers process persuasive messages through central and peripheral routes (Petty & Cacioppo, 1986). Personalization and targeting may encourage relevance-based processing, while influencer credibility and social proof often operate as heuristic or peripheral cues.

Research Gap

Although existing studies explain important components of social media persuasion, the literature remains fragmented. Personalization research often focuses on relevance and click-through behaviour. Targeting research emphasizes advertising fit and segmentation. Influencer marketing research focuses on source credibility and parasocial relationships. Social proof research examines ratings, likes and reviews as trust cues. However, consumers encounter these cues together inside algorithmically curated feeds. The present study addresses this gap by developing an integrated algorithmic persuasion model that estimates the relative influence of personalization, targeting, influencer recommendations and social proof on purchase intention.

Research Model and Hypotheses

The research model treats algorithmic marketing as a visibility-to-intention system. The model assumes that purchase intention is shaped by four platform-mediated cues: personalized content, targeted advertisements, influencer recommendations and social proof. These cues are not simply message variables; they are algorithmically surfaced signals that influence attention, perceived relevance, credibility and social validation.The conceptual structure is expressed as follows: PC, TA, IR, SP → PI → PD where PC represents personalized content, TA represents targeted advertisements, IR represents influencer recommendations, SP represents social proof, PI represents purchase intention and PD represents consumer purchasing decision. The present empirical model directly estimates PI as the dependent variable. PD is retained as a downstream conceptual outcome because actual purchase behaviour requires transaction-level, longitudinal or self-reported purchase conversion data.

Algorithmic Persuasion Index

To express the combined logic of algorithmic marketing, the study proposes a conceptual Algorithmic Persuasion Index (API):$API_i = w_1PC_i + w_2TA_i + w_3IR_i + w_4SP_i$

where w_1, w_2, w_3 and w_4 represent the relative persuasion weights of each algorithmic cue. The regression analysis later estimates the relative empirical importance of these cues using standardized beta coefficients.

Hypotheses

Personalized content increases purchase intention because it improves relevance, reduces search effort and repeatedly exposes consumers to products aligned with their interests. Therefore:H1: Personalized content positively influences purchase intention among social media users.

Targeted advertisements influence purchase intention when they match user preferences, prior digital behaviour and contextual needs. Therefore:H2: Targeted advertisements positively influence purchase intention among social media users.Influencer recommendations influence purchase intention through perceived authenticity, trust, expertise and social familiarity. Therefore:H3: Influencer recommendations positively influence purchase intention among social media users.Social proof influences purchase intention because engagement metrics signal popularity, acceptance and reduced decision risk. Therefore:H4: Social proof positively influences purchase intention among social media users. Purchase intention is theoretically expected to influence consumer purchasing decision. However, the present dataset directly estimates purchase intention rather than confirmed purchase conversion. Therefore:H5: Purchase intention positively influences consumer purchasing decision. This hypothesis is retained conceptually and recommended for direct empirical testing in future research.

Empirical Model

The empirical model estimated in the study is specified as:

$PI_i = \alpha_0 + \beta_1PC_i + \beta_2TA_i + \beta_3IR_i + \beta_4SP_i + \varepsilon_i$

The expected signs of the coefficients are:

$\beta_1 > 0, \quad \beta_2 > 0, \quad \beta_3 > 0, \quad \beta_4 > 0$

The downstream purchase decision can be conceptually represented as a future behavioural model:

$PD_i = \alpha_1 + \gamma PI_i + \mu_i$

If purchase is measured as a binary outcome in future research, the model may be estimated as:

$P(PD_i = 1) = 1 / [1 + e^{-(\alpha_1 + \gamma PI_i)}]$

This logistic specification is included as a future analytical direction and is not estimated in the present study.

Additional Mathematical Specification of Algorithmic Persuasion

To strengthen the scientific specification of the model, the study further conceptualises algorithmic persuasion as a weighted exposure process. Each algorithmic cue contributes to purchase intention through a distinct persuasive mechanism: relevance, contextual advertising fit, source credibility and social validation.

$API_i = \Sigma(w_j X_{ji}), \quad j = 1, 2, 3, 4$

where X_{ji} represents the observed score of respondent i on each algorithmic cue and w_j represents the estimated contribution weight of that cue. In the present model, the four cues are PC, TA, IR and SP.

The standardized purchase-intention model may therefore be expressed as:

$ZPI_i = \beta_1 ZPC_i + \beta_2 ZTA_i + \beta_3 ZIR_i + \beta_4 ZSP_i + \varepsilon_i$

This form is useful because it allows direct comparison of the predictive strength of each cue. The marginal effect of each algorithmic cue on purchase intention is represented as:

$\partial PI/\partial PC = \beta_1, \quad \partial PI/\partial TA = \beta_2, \quad \partial PI/\partial IR = \beta_3, \quad \partial PI/\partial SP = \beta_4$

The total standardized algorithmic influence can be expressed as:

$TASI = \beta_1 + \beta_2 + \beta_3 + \beta_4$

Using the empirical beta values reported later in the study:

$TASI = 0.39 + 0.28 + 0.24 + 0.19 = 1.10$

This equation-based representation positions algorithmic persuasion as a measurable multi-cue system rather than a set of isolated marketing tactics.

In the empirical and conceptual models, PC denotes personalized content, TA denotes targeted advertisements, IR denotes influencer recommendations, SP denotes social proof, PI denotes purchase intention, and PD denotes consumer purchasing decision. API denotes the Algorithmic Persuasion Index, while TASI denotes Total Standardized Algorithmic Influence. The symbols α, β, and γ represent model coefficients, while ε and μ represent error terms.The symbol Z denotes standardized variable values, Δ denotes change in a variable, and IE denotes indirect effect. R^2 represents the proportion of variance explained by the model, adjusted R^2 accounts for the number of predictors, F represents the overall model significance statistic, p represents the statistical significance value, and f^2 represents Cohen's effect size. n denotes sample size, m denotes the number of predictors in the sample adequacy formula, and k denotes the number of predictors in the adjusted R^2 formula. VIF refers to Variance Inflation Factor, while tolerance indicates the extent of multicollinearity among independent variables.

METHODOLOGY

The study adopted a descriptive analytical design to examine the influence of algorithmic marketing cues on purchase intention. Primary data were collected through a structured questionnaire administered to 200 active social media users who regularly interact with algorithm-curated content, sponsored posts, influencer recommendations and engagement-based social proof cues.A convenience sampling technique was used because active social media users were more accessible through online distribution channels than through a complete sampling frame. The questionnaire measured personalized content, targeted advertisements, influencer recommendations, social proof and purchase intention using Likert-type items. Higher scores indicated stronger agreement with each construct.The data were analysed using descriptive statistics, Cronbach's alpha reliability testing, Pearson correlation analysis, variance inflation factor diagnostics, model summary estimation, ANOVA and multiple regression. These methods were selected because the study aims to assess measurement consistency, examine inter-variable relationships and estimate the relative predictive strength of algorithmic marketing cues.

Empirical Analysis

Sample Adequacy

The sample size was evaluated using the common regression adequacy guideline n > 50 + 8m, where n is sample size and m is the number of predictors (Green, 1991).

n > 50 + 8m

n = 200, m = 4

50 + 8(4) = 82

200 > 82

Since the sample size exceeded the minimum recommended threshold, the dataset was considered adequate for multiple regression estimation.

Descriptive Statistics

The descriptive results show that personalized content recorded the highest mean score. This suggests that users are most responsive to content that appears tailored to their interests and platform behaviour. Targeted advertisements and purchase intention also recorded moderate-high values, indicating that algorithmic exposure is meaningfully associated with buying interest. Influencer recommendations and social proof reported moderate values, suggesting that credibility and engagement cues matter but are secondary to relevance-based personalization

Reliability Analysis

All Cronbach's alpha values exceeded the recommended 0.70 threshold, confirming acceptable internal consistency for the measurement scales. This supports the use of the constructs in correlation and regression analysis.

Correlation Analysis

The correlation results show positive and statistically significant relationships between all algorithmic marketing cues and purchase intention. Personalization had the strongest correlation with purchase intention ($r = 0.62$, $p < 0.01$), followed by targeted advertisements ($r = 0.56$, $p < 0.01$), influencer impact ($r = 0.53$, $p < 0.01$) and social proof ($r = 0.47$, $p < 0.01$). These results provide preliminary support for the proposed model.

Regression Assumption Checks

Normality and residual assumptions were considered before interpreting the regression results. Since the study uses questionnaire-based construct scores, regression analysis was considered appropriate for examining relationships among the variables. The retained sample size of 200 is adequate for multiple regression estimation and reduces the risk of unstable parameter estimates. However, formal residual-level diagnostics such as histogram, normal P-P plot, Q-Q plot, skewness, kurtosis, Shapiro-Wilk, or Kolmogorov-Smirnov statistics were not separately reported in the present manuscript. Future studies may strengthen the diagnostic reporting by including residual plots and formal normality statistics generated from raw SPSS output.All VIF values were below 5.00 and all tolerance values were above 0.10, indicating that multicollinearity was not a serious concern. The predictors were therefore suitable for simultaneous inclusion in the regression model. Model Summary and ANOVA The model explained 61.0 percent of the variance in purchase intention. This level of explanatory power is strong for behavioural and marketing research, indicating that algorithmic marketing cues provide a meaningful explanation of social media users' purchase intention. The ANOVA results show that the regression model was statistically significant ($F = 76.25$, $p < 0.001$). This confirms that the four predictors jointly explain a significant proportion of variance in purchase intention.

REGRESSION RESULTS

The estimated standardized regression model is: $PI = 0.39(PC) + 0.28(TA) + 0.24(IR) + 0.19(SP) + \varepsilon$

Personalized content emerged as the strongest predictor of purchase intention, confirming that algorithmic relevance is the primary driver of consumer response. Targeted advertisements were the second strongest predictor, showing that consumers respond positively when sponsored content fits their interests and context. Influencer

recommendations were also significant, indicating that creator credibility remains important within algorithmic feeds. Social proof had the smallest but still statistically significant effect, suggesting that engagement cues reinforce credibility but do not substitute for relevance and trust.

Relative Effect Decomposition

To interpret the practical importance of the standardized coefficients, the relative contribution of each predictor was computed as follows:Relative Contribution$_j = \beta_j / \Sigma\beta$ $\Sigma\beta = 0.39 + 0.28 + 0.24 + 0.19 = 1.10$

The decomposition shows that personalization accounts for the largest share of total standardized influence. This strengthens the argument that social media persuasion begins with algorithmic relevance. Influencer recommendations and social proof remain meaningful, but they appear to work best when embedded within a personalized and targeted content environment.

Effect Size and Scientific Contribution of the Model

Beyond statistical significance, the explanatory contribution of the model was assessed using effect size. The coefficient of determination indicates that the four algorithmic cues explain 61.0 percent of the variance in purchase intention.$R^2 = 0.610$

The unexplained variance is:$1 - R^2 = 1 - 0.610 = 0.390$

Cohen's effect size for multiple regression can be expressed as:$f^2 = R^2 / (1 - R^2)$

Substituting the model value:$f^2 = 0.610 / 0.390 = 1.56$

An f^2 value of 1.56 indicates a very large explanatory effect, showing that algorithmic personalization, targeted advertising, influencer recommendations and social proof jointly provide strong explanatory power for purchase intention. This strengthens the scientific contribution of the study because the model explains not only whether the relationships are statistically significant, but also whether their collective effect is substantively meaningful.

The adjusted explanatory power is also reported to account for the number of predictors included in the model:

Adjusted $R^2 = 1 - [(1 - R^2)(n - 1)/(n - k - 1)]$

Adjusted $R^2 = 1 - [(1 - 0.610)(200 - 1)/(200 - 4 - 1)] = 0.602$

Thus, even after adjusting for model complexity, the predictors explain approximately 60.2 percent of the variance in purchase intention.

Standardized Marginal Effects

The standardized coefficients also allow interpretation as marginal predictive effects. Holding the other algorithmic cues constant, a one standard deviation increase in personalized content is associated with a 0.39 standard deviation increase in purchase intention. Similarly, targeted advertisements, influencer recommendations and social proof show standardized effects of 0.28, 0.24 and 0.19 respectively. $\Delta PI = 0.39\Delta PC + 0.28\Delta TA + 0.24\Delta IR + 0.19\Delta SP$. This expression indicates that purchase intention is most sensitive to changes in personalized content, followed by targeted advertisements, influencer recommendations and social proof. The scientific contribution of the model lies in quantifying algorithmic persuasion as a measurable multi-cue influence system. Rather than treating personalization, targeted advertising, influencer recommendations, and social proof as separate marketing tactics, the model estimates their joint and relative contribution to purchase intention. The high explanatory power, large effect size, and statistically significant regression coefficients indicate that platform-mediated persuasion can be empirically modelled as a structured behavioural influence process.

Hypothesis Validation

Discussion: Algorithmic Persuasion Architecture

The findings indicate that purchase intention on social media is shaped by a layered persuasion architecture. The first layer is relevance. Personalized content had the strongest effect, showing that consumers are most responsive when platform feeds appear aligned with their preferences, browsing history and interests. This supports the idea that algorithmic personalization reduces search effort and increases attention to product-related content. The second layer is targeting. Targeted advertisements had a significant positive effect, suggesting that users do not reject

advertisements automatically. Instead, they respond when ads appear contextually relevant and useful. This finding is important because it shows that targeting effectiveness depends on perceived fit rather than mere exposure frequency. The third layer is credibility. Influencer recommendations had a significant effect on purchase intention, confirming that creators function as trust-bearing intermediaries in digital marketing. Algorithms amplify this effect when creator content generates engagement, meaning influencer persuasion is both social and technical. The fourth layer is validation. Social proof had the weakest but still significant effect. This suggests that likes, comments, shares and views help consumers interpret product popularity and reduce uncertainty. However, social proof alone is less persuasive than personalized relevance or credible recommendation. The overall model therefore shows that social media algorithms shape consumer purchase intention by combining relevance, targeting, credibility and collective validation. The results do not merely show that digital marketing works; they show how different algorithmic cues contribute to purchase intention with different levels of strength.

Implications

Theoretical Implications

The study contributes to digital marketing theory by treating algorithms as visibility systems rather than neutral distribution tools. It integrates personalization theory, targeted advertising fit, source credibility, social proof and behavioural intention within a single empirical model. This provides a more complete explanation of social media purchase intention than studies that examine these mechanisms separately.

Managerial Implications

The results suggest that marketers should prioritize relevance before reach. Personalized content produced the largest standardized effect, meaning content strategy should be designed around user interests, timing and behavioural segmentation. Targeted advertisements should be optimized for contextual usefulness rather than excessive frequency. Influencer partnerships should be evaluated on credibility, category fit and engagement quality, not only follower count. Engagement metrics should be treated as conversion-supporting trust signals rather than vanity indicators.

Ethical and Policy Implications

Algorithmic marketing raises ethical concerns because personalization and targeting can influence consumer attention without full user awareness. Platforms and brands should ensure clearer disclosure of sponsored content, responsible data use, privacy protection and transparency in recommendation practices. Ethical algorithmic marketing should balance persuasion effectiveness with user autonomy and informed choice.

Limitations And Future Research

The study has certain limitations. First, the sample was selected using convenience sampling, which limits generalisability. Second, the study used self-reported questionnaire data, which may be affected by response bias. Third, the empirical model estimates purchase intention rather than verified purchase conversion. Therefore, the findings should be interpreted as evidence of intention formation, not confirmed transaction behaviour. Fourth, actual purchase decision was retained as a conceptual downstream outcome but was not directly estimated in the present regression model. Future research may collect transaction data, platform click stream data or longitudinal purchase records to estimate the conversion path more rigorously. For a future purchase-conversion model, the relationship may be specified in two stages. The first stage estimates the effect of algorithmic marketing cues on purchase intention, while the second stage estimates the effect of purchase intention on actual purchasing decision.

$PI = \alpha_0 + \alpha_1 PC + \alpha_2 TA + \alpha_3 IR + \alpha_4 SP + \varepsilon_1$

$PD = \gamma_0 + \gamma_1 PI + \varepsilon_2$

where PI denotes purchase intention; PD denotes consumer purchasing decision; PC denotes personalized content; TA denotes targeted advertisements; IR denotes influencer recommendations; SP denotes social proof.

The indirect algorithmic effects on purchasing decision may then be expressed as:

$IE_PC \rightarrow PD = \alpha_1\gamma_1$
$IE_TA \rightarrow PD = \alpha_2\gamma_1$
$IE_IR \rightarrow PD = \alpha_3\gamma_1$
$IE_SP \rightarrow PD = \alpha_4\gamma_1$

These expressions represent future testable indirect effects through purchase intention and are not estimated as formal mediation effects in the present study. Future studies may also use structural equation modelling, confirmatory factor analysis, experimental designs or platform-level behavioural data to test causal mechanisms more rigorously. For a future structural equation modelling design, the measurement model may be specified as: $X = \Lambda\xi + \delta$ where X represents the observed questionnaire indicators, Λ represents factor loadings, ξ represents latent constructs such as personalization, targeted advertising, influencer credibility and social proof, and δ represents measurement error. The structural model may be specified as: $\eta PI = \Gamma\xi + \zeta$ where ηPI represents the latent purchase intention construct, Γ represents the structural paths from algorithmic marketing cues to purchase intention, and ζ represents unexplained variance. This future model would allow simultaneous testing of measurement validity and structural relationships.

CONCLUSION

This study examined how algorithmic marketing cues, including personalization, targeted advertising, influencer recommendations and social proof, influence purchase intention among social media users.The results confirm that all four algorithmic marketing cues significantly shape purchase intention, with personalized content emerging as the strongest predictor. The model explained 61.0 percent of the variance in purchase intention, demonstrating strong explanatory value for a social media consumer behaviour study. The findings show that algorithm-driven marketing works through a combination of relevance, contextual fit, credibility and social validation. Products become persuasive not simply because they are advertised, but because algorithms place them in personalized feeds, align them with user interests, amplify trusted influencer content and reinforce popularity through engagement cues. The study concludes that algorithmic marketing is best understood as a platform-mediated persuasion architecture. For marketers, the central lesson is that relevance and credibility matter more than exposure volume alone. For researchers and policymakers, the study highlights the importance of examining algorithmic persuasion alongside ethical concerns such as transparency, privacy and consumer autonomy.

ABSTRACT

Harmful substances include alcohol, toxins, metabolic disorders, and viruses; depending on the agent, these agents can interfere with homeostasis, detoxification, and metabolism. Over the past few years, there has been a growing interest in the use of phytochemicals for their protective effects for the liver. Phytochemicals exhibit antioxidant, anti-inflammatory, antifibrotic, and antiapoptotic properties. The present review extensively discusses the role of bioactive phytochemicals in protecting the liver, including schisandrol A and B, kaempferol, diosgenin, lupeol, glycyrrhizin, curcumin, caffeic acid, berberine, and quercetin. Collectively, these compounds influence several important cellular pathways to promote regeneration of hepatic cells while reducing oxidative stress and proinflammatory cytokines. The cellular pathways impacted by these agents include Nrf2/ARE, NF-kB, TGF-β1/Smad3, PI3K/Akt, and AMPK/PPAR-α.

Keywords: Hepatoprotection, Phytochemicals, Antioxidant activity, Nrf2 pathway, Liver fibrosis, Bioactive compounds.

INTRODUCTION

The liver has many important jobs to do, including regulating metabolic processes, getting rid of toxins, making protein for the plasma, and maintaining biochemical balance.[1]. At present there are not many effective treatments for liver disease and many of the ones that exist may cause significant side effects. In the field of

hepatopharmacology, new avenues have opened up for the study of the natural compounds and their derivatives as potentially viable sources for the development of drugs, due to the many possible ways in which they can affect the function of the liver. A large amount of scientific interest has been placed upon compounds such as flavonoids, terpenoids, phenolic compounds, alkaloids, saponins, lignans, and sterols, which differ structurally from one another and exert a variety of biological effects. A variety of different natural compounds have been evaluated for their ability to protect the liver from damage.

- Flavonoids:- Quercetin, Kaempferol, Silymarin.
- Terpenoids and Triterpenes:-Lupeol, Glycyrrhizin.
- Phenolic Compounds:- Curcumin, Caffeic acid.
- Alkaloids:-Berberine.
- Saponins:-Diosgenin.
- Lignans:-Schisandrol A & B.

Quercetin

Quercetin (3,3',4',5,7-pentahydroxyflavone) is a polyphenolic flavonol that has been identified in several varieties of foods including cereals, fruits, and vegetables. Many of the foods that are particularly high in quercetin are also red wine, tea, berries, and onions. Quercetin is one of the strongest natural antioxidants and is known for regulating the activity of liver enzymes, protecting against oxidative stresses in the liver, and modulating inflammaory and apoptotic pathways. [2]

Antioxidant and Free Radical Scavenging Activity

Quercetin has a unique ability to reduce oxidative stress within liver cells by counteracting the damaging effects of reactive oxygen species (ROS) like hydrogen peroxide, superoxide anions and hydroxyl radicals. This property allows the very strong antioxidant properties of quercetin to protect biological macromolecules (i.e. proteins, DNA and lipids) from the damaging effects of oxidative stress. quercetin restores hepatic glutathione (GSH) levels, which is an essential antioxidant for detoxification and protection from oxidative injury [3].

Anti-Inflammatory Mechanisms

Quercetin is a strong anti-inflammatory agent in the liver. In addition, it affects many different molecules and cellular signals related to liver inflammation. TNF-alpha, IL-1beta, and IL-6 are all pro-inflammatory cytokines that quercetin reduces the production. Quercetin decreases the transcription of inflammatory mediators and the overall inflammatory burden in liver tissues by blocking these pathways.The suppression of cyclooxygenase-2 (COX-2) and inducible nitric oxide synthase (iNOS) prevents the synthesis of pro-inflammatory substances such as prostaglandins and nitric oxide.By blocking the activation of NF-kB in response to inflammatory stimuli (e.g., toxins, high-fat diet).

Anti-Apoptotic and Cytoprotective Effects

Quercetin prevents the death of liver cells by sustaining the integrity of mitochondria and regulating the synthesis of proteins associated with apoptosis. Quercetin has been shown to prevent the production of pro-apoptotic factors (Caspases, Bax, etc.) along with other necessary proteins to carry out the anti-apoptotic properties of Bcl-2 in relation to those of Bax while leaving the cellular membranes intact/in good working order so that when pro-apoptotic stimuli (such as caspase activity) occur because of cellular damage from oxidative stress, cellular apoptosis cannot initiate. By way of these mechanisms, Quercetin aids in maintaining liver cell viability within a state of oxidative stress [4]

Kaempferol

Tea, kale, broccoli, beans, cabbage, tomatoes, apples and medicinal plants such as Moringaoleifera, Ginkgo biloba, Camellia sinensis, and Peltophorumpterocarpum are sources of kaempferol (3,5,7-trihydroxy-2-(4-hydroxyphenyl)-4H-chromen-4-one). It's wide range of actions is of great interest to pharma companies. To date we see its use in lipid

regulation, anti inflammation, anti cell death, anti fibrosis, and as an antioxidant. These play a key role in liver protection. [5].

Antioxidant And Free Radical Scavenging Mechanisms

Kaempferol has the ability to put out reactive oxygen species (ROS) and reactive nitrogen species (RNS). It is the polyhydroxylated flavonoid structure which in turn protects cells from oxidative stress that is mainly responsible for this. Also to the act of directly scavenge radicals, kaempferol increases the bodies' production of important antioxidant enzymes which include glutathione reductase (GR), catalase (CAT), superoxide dismutase (SOD) and glutathione peroxidase (GPx) [5].

Anti-Inflammatory Mechanisms

Kaempferol is an effective at reducing inflammation in the liver which it does via many of the molecular pathways and mediators that play a role in liver inflammation. Pro inflammatory cytokines like interleukin-1 beta (IL-1β), interleukin-6 (IL-6), and tumor necrosis factor alpha (TNF-α) play a key role in the start and progression of inflammatory responses.Its main role is to block nuclear factor kappa B's (NF-kB) signaling pathway. Also by reducing the expression of cyclooxygenase-2 (COX-2) and inducible nitric oxide synthase (iNOS [6].

Anti-Apoptotic and Cytoprotective Mechanisms

In order to put a stop to cell death, kaempferol keeps the mitochondria intact at the same time it regulates pro- and anti-apoptotic proteins. It reduces the production of pro-apoptotic factors like Bax, caspase-3, and -9 and at the same time increases the anti-apoptotic protein Bcl- which in turn helps to stabilize the mitochondrial membrane potential. [7].

Silymarin

Silybummarianum what is also known as Milk thistle presents "silymarin" as a standard extract from its seeds. For years silymarin has been the subject of extensive research which also includes it's use as a traditional liver protective remedy. Silymarin is a complex of flavonolignans which includes the active component 'silybin' (which makes up for about 60 to 70 percent of silymarin) also we have taxifolin (a flavonoid precursor), isosilybin, silychristin, and silydianin.

Antioxidant and Free Radical Scavenging Activity

In the natural world there is no better antioxidant than silymarin. it also supports the liver's natural antioxidant defences. It does this by stimulating the production of key molecules and enzymes such as glutathione peroxidase (GPx), catalase (CAT), superoxide dismutase (SOD) and glutathione (GSH) which in turn helps to maintain cellular redox balance [8].

Membrane-Stabilizing and Detoxifying Effects.

Silymarin fortifies cells and puts up a barrier to toxins which enter the liver, it also maintains the stability of liver cell membranes. This action delays the onset of damage from toxins. It also puts forward that silymarin which in turn prevents the attachment of hepatotoxins to liver cell receptors like phalloidin, alpha-amanitin, and carbon tetrachloride (CCl4)

Anti-Inflammatory Mechanisms.

Excessive production of inflammatory mediators which in turn causes extensive tissue damage and chronic liver injury is reported. Silymarin ameliorates this inflammatory response in many ways. It also has an effect on the NF-kB signaling pathway which in turn reduces the production of key pro inflammatory cytokines. We see that include tumor necrosis factor alpha (TNF-alpha), interleukin 1 beta (IL-1beta), interleukin 6 (IL-6) and cyclooxygenase 2 (COX-2) [9].

Lupeol

Crataevanurvala, Mimosa pudica, Peltophorumpterocarpum, Betulapubescens, Mangiferaindica (mango), and Aloe vera are reported to be some of the which do contain luteol which is a natural pentacyclic triterpenoid. It has a range of pharmacological actions which include anti-inflammatory, anti-apoptotic, hepatoprotective, anti cancer, and anti arthritic.

Antioxidant and Free Radical Scavenging Mechanisms

Lupeolvery strong action as an antioxidant which in turn puts protection on hepatocytes from oxidative stress that is the main cause of liver damage. We see that the body's defense against reactive oxygen species is improved when the antioxidant enzymes glutathione peroxidase (GPx), catalase (CAT), superoxide dismutase (SOD) and glutathione (GSH) are induced. the production of protective enzymes like heme oxygenase-1 (HO-1) and NAD(P)H quinone oxidoreductase-1 (NQO1) the changes in the Nrf2/ARE signaling pathway also play a role in which the protective effects are seen [10].

Anti-Inflammatory Mechanisms

Lupeol is a very effective at fighting inflammation via many different pathways. This is very important as the root of liver damage is usually tied to that of inflamation. Also it does so by not allowing nuclear factor kappa B (NF-kB) to go on and which in turn reduces key pro inflammatory mediators like TNF-α, IL-1β, IL-6 and COX-2. Also by suppressing inducible nitric oxide synthase (iNOS) which in turn reduces the production of nitric oxide (NO) which in turn causes oxidative and inflammatory damage [11].

Anti-Apoptotic and Cytoprotective Mechanisms

The release of cytochrome c and mitochondrial permeability transition. Also we see that the PI3K/Aktsignaling pathway is activated by lupeol. This pathway supports liver cell survival and puts up their resistance to stress. These actions show lupeol's great liver protective properties.

Glycyrrhizin

Glycyrrhizic acid also known as glycyrrhizin which is a triterpenoid saponin glycoside that we obtain from the roots of the Fabaceae family plant which is the licorice plant, Glycyrrhizaglabra. For over two millenium it has reported in clinical research that glycyrrhizin has the properties of hepatoprotection, anti inflammation, antiviral action, antioxidant and immunomodulation.

Antioxidant And Free Radical Scavenging Mechanisms

Glycyrrhizin reports to have both direct and indirect antioxidant actions which in turn protect liver cells from oxidative stress. It directly jumps in to scavenge for reactive oxygen species (ROS) and reactive nitrogen species (RNS) which in turn reduces oxidative damage. We see that enzymes like glutathione peroxidase (GPx), catalase (CAT) and superoxide dismutase (SOD) which are natural antioxidants report to have their activity increased by glycyrrhizin [11].

Anti-Inflammatory Mechanisms

Glycyrrhizin reports to have anti-inflammatory actions which in turn play a role in the prevention of chronic inflammation that in severe cases may cause liver damage and lead to fibrosis. Also it does what it does by reducing NF-kB activity which in turn causes a drop in production of pro inflammatory cytokines. Also key inflammatory players like TNF-α, interleukin-1beta (IL-1beta) and interleukin-6 (IL-6) report to be reduced [12]. [13].

Antifibrotic Effects

Hepatic fibrosis results from the activation of hepatic stellate cells (HSCs) and the overproduction of extracellular matrix components. Glycyrrhizin which has very strong anti fibrotic actions does so by way of blocking HSC activation and in also targeting the TGF-β1/Smadsignaling pathway. It reduces TGF-β1 and alpha smooth muscle

actin (alpha-SMA) which are key players in HSC activity also it decreases the production of collagen types I and III. [13].

Curcumin

Turmeric (Curcuma longa) is the source of curcumin (1,7-bis(4-hydroxy-3-methoxyphenyl)-1,6-heptadiene-3,5-dione) a polyphenol which is a natural product. It is the primary curcuminoid which gives the yellow color and biological value to turmeric. In terms of research Curcumin's role in protection against Alcoholic Liver Disease, Non-alcoholic fatty liver disease, fibrosis of the liver and chemical induced liver damage has been studied.

Antioxidant Mechanisms

Curcumin has a phenolic structure and also includes conjugated double bonds. Also it is a very powerful antioxidant and is able to put out free radicals. It directly scaveng which in turn protect hepatocytes from oxidative damage. Also curcumin increases the levels of glutathione (GSH) and the activity of key enzymes like superoxide dismutase (SOD), glutathione peroxidase (GPx) and catalase (CAT).

Anti-Inflammatory Mechanisms

Curcumin has great anti inflammatory results by way of many inflammatory signaling pathways. It also does in fact which is to interfere with TLR4/MyD88 signaling that in turn is a primary element in the production of liver damage from lipopolysaccharide (LPS). Also curcumin is to blame for reducing inflammation and liver cell death by way of the MAPK and JNK signaling pathways.

Anti-Apoptotic Mechanisms

To stop liver cell death, curcumin stabilizes mitochondria and controls the Bcl-2 protein family. In order to preserve equilibrium for both cell survival and death, it raises the expression of the anti-apoptotic protein Bcl-2 and decreases levels of the pro-apoptotic protein Bax. By preventing cytochrome c from leaving the mitochondria, curcumin inhibits the activation of two essential components of the intrinsic apoptosis pathway: caspase-3 and caspase-9 [13]

Caffeic Acid

Caffeic acid which is 3,4-dihydroxycinnamic acid is a very common hydroxycinnamic acid derivative which we see in nature. This phenolic acid is present in fruits, vegetables, coffee, olive oil, wine and also in a variety of medicinal plants which includes Rosmarinus officinalis, Peltophorumpterocarpum, Ocimum sanctum, and Ecliptaalba. It is also among the most widespread.

Antioxidant And Free Radical Scavenging Mechanisms

Free radicals are reduced by the action of the ortho-dihydroxy (catechol) group in caffeine which is a player in electron and hydrogen atom transfer. Also it does a great job at what is called scavenging reactive oxygen species (ROS). Also we see that caffeine reduces Malondialdehyde (MDA) which is a key marker of lipid peroxidation and at the same time it maintains stable levels of hepatic glutathione (GSH) [14].

Anti-Inflammatory Mechanisms

By action on many pro inflammatory signaling pathways caffeine helps to reduce inflammation in the liver. It also does the job of turning off nuclear factor kappa B (NF-kB) which in turn causes the activation of that which produces the inflammatory response. Caffeicacid reduces nitric oxide production and in turn that which causes oxidative inflammation by inactivating the enzyme inducible nitric oxide synthase (iNOS) [15].

Anti-Apoptotic And Cytoprotective Mechanisms

Caffeine is a player in the regulation of key proteins which in turn manage cell death and at the same time it does for instance what Bcl-2 does which is to put out the anti-apoptotic flame; instead it goes after pro-apoptotic elements like

Bax, caspase-3, and -9. That is a point of difference in which caffeine also includes in the prevention of the release of cytochrome-c from the mitochondria, [16].

Berberine

The main types of plants which produce berberine (BBR) are from the families Menispermaceae, Ranunculaceae, and Berberidaceae. This includes Tinosporacordifolia, Hydrastiscanadensis, Coptischinensis, and Berberis vulgaris. One natural occurring isoquinoline alkaloid is berberine.

Antioxidant Mechanisms

Berberine which in turn gives great liver support does so by increasing the production of antioxidants in liver cells. We see that it raises glutathione (GSH) levels and at the same time reduces malondialdehyde (MDA) concentrations. It does this via superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx) which are very important antioxidant enzymes.Lipid peroxidation is reduced by this process. These genes include NAD(P)H quinone dehydrogenase 1 (NQO1) and hemeoxygenase-1 (HO-1). Berberine reduces reactive oxygen species (ROS) and the oxidative damage that agents like ethanol, carbon tetrachloride (CCl_4), and acetaminophen cause to mitochondria [17].

Anti-Inflammatory Mechanisms

Berberine displays great anti-inflammatory action in the liver which it does via many pro-inflammatory signaling pathways. We see that it diminishes NF-kB activation which in turn reduces levels of key inflammatory mediators like TNF alpha, IL-1 beta, IL-6, COX-2, and iNOS. Also berberine puts a break on the phosphorylation of MAPK pathways which include p38, JNK, and ERK thus reducing production of inflammatory cytokines [40].

ANTI-Apoptotic and Cytoprotective Mechanisms

Berberine prevents what we see as the death of hepatocytes by modulating key apoptotic proteins and preserving mitochondrial integrity. It increases the anti-apoptotic protein Bcl-2 while at the same time decreasing pro-apoptotic factors like Bax, caspase-3, and -9. This in turn puts the breaks on key elements of the intrinsic apoptotic process which includes cytochrome c release and mitochondrial depolarization [18].

Diosgenin

Diosgenin (25R-spirost-5-en-3β-ol) is a natural product of the steroid sapogenin which is present in plants like Dioscorea spp. (yams), Trigonellafoenum-graecum (fenugreek) and Smilax spp. It is used as a drug to protect the liver from chemical (for example acetaminophen, thioacetamide, and chlorophyll) damage, alcohol, or high fat diets. It has anti inflammatory, anti fibrotic, anti apoptotic, and lipid lowering actions.

Antioxidant Mechanism

Increases of glutathione peroxidase (GPx), reduced glutathione (GSH), catalase (CAT) and superoxide dismutase (SOD) which in turn body's antioxidant defenses. Via reduction of reactive oxygen species and malondialdehyde (MDA) it puts an end to lipid peroxidation. Also via induction of the Nrf2/HO-1 signal pathway the material increases genes. Also itmitochondrial membranes which in turn reduces oxidative damage to liver cells [19].

Anti-Inflammatory Mechanism

NF-kB activity is reduced. Also we see a reduction in COX-2 and iNOS which in turn decreases prostaglandin and nitric oxide (NO) production. The drug which does this also changes key in toll like receptor 4/myd88 and MAPK (ERK, JNK, p38) signaling pathways. Also reported is reduction of TNF-α, IL-6, and IL-1beta which are pro inflammatory cytokines [19].

Schisandrol A and B

Schisandrol A

Anti-Inflammatory Effects

By the action of blocking the NF-kB pathway the chemical reduces production of pro inflammatory cytokines and enzymes which includes COX-2, also it targets key signaling pathways related to inflammation which in turn produces its anti inflammatory results. Also it inhibits the synthesis of what in vitro studies present as harmful factors in osteoarthritis models which means it may be put forth as a treatment to reduce joint inflammation and stop tissue damage [20].

Pulmonary Fibrosis Inhibition

By the action of the TGF-β signal pathway which is a key player in the development of fibrosis, the substance shows antifibrotic properties. This which in turn puts a break on the progression of lung fibrosis.Via a mix of experimental research and network pharmacology approaches researchers have reported its therapeutical effects which also gives us a clear picture of its protective role against fibrotic lung disease [20].

Estrogenic Activity

The chemical reports to produce estrogen like effects by activating the estrogen receptor alpha (ERα). We see that the downstream signal pathway which includes PI3K, Akt, and ERK is activated by this. What we find is that this change in cellular signaling which the chemical brings about increases its value as a treatment for diseases related to estrogen [21].

Schisandrol B

Hepatoprotective Properties

By way of stimulating liver regeneration and at the same time reducing CYP mediated bioactivation that drug also put up a defense against acetaminophen induced liver damage. Also it brings about production of less toxic metabolites. Also it sets in motion the Nrf2/ARE signaling pathway which in turn enhances antioxidant defenses and helps cells to prevent out oxidative stress induced liver damage [22].

Cholestatic Liver Injury Protection

By improving bile acid metabolism and stimulating bile acid flow into the colon this substance also reduces bile acid accumulation in the liver and puts out against liver damage from lithocholic acid (LCA). Also it increases the expression of key genes related to bile acid balance like Oatp2, Ugt1a1 and Cyp3a11 which in turn improves liver function and detoxification [22].

Calcification Inhibition

It causes interstitial cells of the aortic valve to not be classified that way. This puts forth the chance of which we may see new treatments for issues related to cardiovascular calcification [23].

Limitations and Challenges

We see great promise in phytochemical based liver protection therapies what we have is marred by many issues. Curcumin, quercetin, and silymarin which are some of the main players in this field have issues with respect to absorption, metabolism, and solubility. What we see is low bioavailability in the body. Also we see poor pharmacokinetics. Also play a role in the variation of the phytochemical's make up and power which in turn makes it hard to get consistent results out of them. We do not have standardization and quality control which adds to the difficulty. Also we are lacking in terms of in depth knowledge of the exact molecular actions and interactions of the bioactive components which in turn makes it hard to develop tailored pharma products. Also we have safety issues with some of these phytochemicals which may present at certain doses or which may interact with other

medications.In the past we have seen that which research is conducted mostly in preclinical and in vitro models with little to report from human studies which is a great issue. Also we see that regulatory issues and variable international laws related to license of herbal medicines play a great role in commercialization. Also we note that product reliability is affected by issues of chemical instability and short shelf life. We require standardized extraction methods, in depth toxicological research, disease based clinical study and better nanocarrier delivery systems to solve these issues. This strategy will in turn facilitate the safe use of phytochemicals in evidence based liver protective therapies.

CONCLUSION

Natural products still play a role in the development of liver protective drugs. We see within Silymarin, quercetin, curcumin, berberine, and diosgenin which certain that which which greatly reduce liver cell damage. These compounds also play a role in the alteration of oxidative stress markers, inflammation, and cell death. Also we have in Schisandrol A and B which present the growing importance of phytochemicals which have not been as researched but may have medical application. Although we see very promising preclinical results we also see translation issues of bioavailability, pharmacokinetic issues and the lack of standardized forms. In to the future we should see more into mechanism based clinical studies and combinations of phytochemicals to improve therapeutic results. Presently in use is a system which combines modern pharmacology with phytochemistry in the design of safe and effective hepatoprotective drugs.

ABSTRACT

Gridhrasi is a Shulpradhana Nanatmaja Vatavyadhi. According to Acharya Charaka, Stambha (stiffness), Ruka (pain), Toda (pricking sensation) and Spandana (twitching) are the signs and symptoms of Vataja Gridhrasi. Aruchi (anorexia), Tandra (drowsiness) and Gaurava (heaviness) are the additional symptoms of Vatakaphaja Gridhrasi. Sciatica refers to pain radiating along the sciatic nerve, which extends from the lower back to the legs. It is commonly caused by a herniated disc, spinal stenosis, or piriformis syndrome and is typically managed through conservative treatment methods, including physical therapy, medications, and in some cases, interventional procedures. However, Ayurvedic treatments such as Panchakarma, Agnikarma, and Vidhakarma therapies have gained attention for their potential in managing chronic musculoskeletal pain. here is the case report discusses of 46-year-old female patient complaints of Ruk (Pain), Toda (Pricking sensation), Stambha (Stiffness), Gaurav (Heaviness), Numbness diagnosed as Gridhrasi(sciatica) who was successfully managed with *Vidhakarma*, a traditional Ayurvedic therapeutic procedure

Keywords : Gridhrasi, Panchakarma, symptoms, therapeutic, patient

INTRODUCTION

The pain was as old as mankind. Humans are looking for pain relief methods and using them with partial or complete success. Ayurveda, an ancient science, has mentioned numerous treatment modalities for pain management. Acharya Sushruta specially mentioned various surgical and Para surgical procedures to get rid of pain. Sciatica is the most common musculoskeletal disorder affecting individuals. It is a crippling disease that causes pain in the hip and the entire path of the sciatic nerve. It refers to the back of the leg up to the foot. Almost all the signs and symptoms of sciatica resemble those of Gridhrasi described in Ayurveda [1]. Gridhrasi, is one among the 80 types of Nanatmaja Vata Vyadhi [2] . The common symptoms of Gridhrasi are–Ruja starts from Sphik (buttock) and then radiates to Kati, Prushta (back), Uru (thigh), Janu (knee), Jangha (calf), and Pada (foot) along with Stambha (stiffness), Toda (pricking pain), Spandana (twitching) [3] and causes the Sakthiutkshepa Nigraha [4] (restricted movement of lifting of the leg).

Acharya Sushruta has used term "Vyadh" means to puncture [5]. Siravyadh is one of the procedures mentioned as Vedanahara i.e. pain relief. Acharya Sushruta emphasized it as Chikitsardha means it is as important as Basti chikitsa in Kayachikitsa [6]. Vidhakarma mainly done in Vaata-dominant conditions [8]. When the Raktavahini is clearly visible, Raktamokshana is to be done; if the sira is not clearly visible, Viddha karma can be done. Indirectly, when Raktavisravana is impossible, Viddha karma should be preferred. Although a very small amount of blood is released after Viddha karma, the most vitiated dosha is released first. For example, when vitiated Dosa is released after viddha karma, the disease can be cured. Thus, Viddha karma can be used in pain management, as well as in all diseases where Raktamokshana is indicated [9].

Aim and Objective

- To assess the therapeutic effect of Vidhakarma in the management of Gridhrasi (sciatica).
- To establish and encourage Ayurveda treatment modalities to decrease the intensity of pain, stiffness and weakness that are simple, safe, time saving and can be performed at OPD level to manage the disease. so that the patient can do his routine work comfortably

MATERIALS AND METHODS

- Study design – single arm clinical study
- Informed consent was taken
- This study was performed at the Department of Shalya Tantra, Quadra Institute of Ayurveda, Roorkee, Uttarakhand.

Patient Information

- **Name**: XYZ
- **Age**: 46 years
- **Sex**: Female
- **Occupation**: Office Worker (sedentary lifestyle)
- **Medical history**: noncontributory, no history of major comorbidities. She had a sedentary lifestyle and engaged in occasional physical activity. No previous surgery or major trauma.

Presenting Complaints

The patient presented with a 5-month history of lower back Ruk(pain) radiating down the left leg, associated with Toda (Pricking Sensation), Gaurav (heaviness), numbness, and tingling sensations. The pain was aggravated by prolonged sitting, standing, and walking.

Clinical Findings

On examination:

- **Posture**: Antalgic posture favoring the left side.
- **Palpation**: Tenderness over the lumbar spine and left sciatic nerve pathway.
- **Range of Motion**: Restricted lumbar spine flexion due to pain.
- **Neurological Examination**: Positive straight leg raise test on the left side, that is, 40°, indicated possible nerve root compression. Sensory deficits were noted in the left lower leg, with mild weakness in the left foot dorsiflexion.
- **Investigations**: All routine blood and urine investigations were performed and seemed to be normal. The HIV, HBsAg, and VDRL tests were negative.
- MRI of the lumbar spine revealed a mild disc bulge at L4-L5, with evidence of nerve root impingement on the left side.

Diagnosis

The patient was diagnosed with Gridhrasi (left-sided sciatica secondary to a disc bulge at L4-L5)

Treatment Plan

Procedure Name: Vidhakarma
Total sittings: 4sittings(onanintervalof 1,3rd,5th,7th)
Duration of treatment: 7days

Vidhakarma Procedure

It is a para-surgical procedure where sites of the body are punctured with the help of a needle on a specific site and up to a specific depth mentioned for that particular disease.

Material required: -

- Needle no.26 1/2
- Spirit
- Cotton swab.
- Surgical gloves.

Procedure

Site: -

- 4 Fingers above and 4 fingers below the knee joint on lateral aspect [13]
- Lateral position with knee joint semi flexed and Kshipra marma of affected limb [16]
- Yav Matra 4-6 mm deep [15]
  - ❖ The site of Vidhakarma was cleaned with spirit and Vidhakarma (venepuncture) was performed with the help of a 26$^{1/2}$ needle at the sites mentioned above.
  - ❖ After puncturing, the needle was kept for five seconds and then drawn out from the site.
  - ❖ Blood drops were allowed. Vidhakarma site was cleaned using a Spirit swab.

OBSERVATION AND RESULT

After completion of the Vidhakarma sessions, the patient reported a significant improvement.

- **Pain Reduction**: There 90% reduction in pain intensity, particularly in the lower back and along the sciatic nerve distribution.
- **Mobility**: The patient was able to increase her range of motion, and the straight leg raise test result was negative at follow-up.

- **Neurological Symptoms**: The Tingling and numbness in the left leg diminished considerably, with a full return of sensation and strength in the foot by the end of the treatment course.
- **Quality of Life**: The patient reported improved quality of life with decreased reliance on pain medications and the ability to resume daily activities without significant discomfort.

At the end of the treatment course, the patient was pain-free and resumed normal physical activity, including walking and light exercise. She was instructed to continue mild stretching and strengthening exercises, and was advised to follow Pathya-Apathya.

DISCUSSION

On the bases of the result mechanism of Vidhakarma can be discussed in following way, Clearing Obstructions

Vidhakarma is said to remove obstructions in blood vessels and clear Srotas (channels), which helps establish proper circulation. This concept is somewhat analogous to modern techniques that aim to improve blood flow to affected areas.

Stimulation of Sensory Fibers

Treatment involves stimulating sensory fibers from peripheral receptors. This is similar to some modern pain management techniques, such as transcutaneous electrical nerve stimulation (TENS) or acupuncture, which also stimulates nerve fibers.

Reduction of Pain Signal Transmission

Vidhakarma is believed to reduce the transmission of irritating signals from the affected area. This is comparable to the gate control theory of pain used in modern pain management, where certain stimuli can 'close the gate' to pain signals.

Endorphin Release

The document mentioned that Vidhakarma initiates the release of endorphins, which help reduce pain. This is consistent with the modern understanding of pain management, in which endorphin release is recognized as a natural pain-relieving mechanism.

Balancing Body Systems

Unique to the Ayurvedic approach, Vidhakarma is said to maintain a balance between Vata, Pitta, and Kapha in the body, it reflects a holistic approach to pain management that considers the overall body balance.

Localized and Systemic Effects

Vidhakarma appears to have both localized effects at the site of needle insertion and systemic effects through the release of chemicals like opioids.

CONCLUSION

This case demonstrates the efficacy of Vidhakarma in the management of chronic sciatica in a 46-year-old female patient. The patient showed significant improvements in pain relief, mobility, and neurological function following a series of carefully administered Vidhakarma sessions. The results also suggest that Vidhakarma is a simple, effective, and cost-effective treatment. Future research and clinical trials are needed to further validate the effectiveness of this approach and establish standardized protocols for its application in musculoskeletal disorders.

ABSTRACT

Accurate brain tumor classification from MRI images requires not only strong feature extraction but also reliable optimization and stable decision behavior. Many deep learning models achieve high accuracy; however, they often exhibit overconfident predictions, sensitivity to noise, and unstable convergence across training epochs. These limitations reduce clinical reliability. This study presents an optimized attention-based multi-scale deep network enhanced with an Adaptive Weight Calibration (AWC) strategy for robust brain tumor classification. The backbone network employs hierarchical convolutional feature aggregation combined with attention-guided refinement to capture discriminative tumor patterns, and it focuses on improving dynamic training through adaptive parameter recalibration. The AWC mechanism dynamically adjusts learning influence based on class-level confidence distribution and gradient variance. A confidence-aware regularization term is also incorporated to prevent overconfident misclassification. Experimental evaluation on a multi-class brain MRI dataset demonstrates that the optimized framework achieves an accuracy of 99.1%, with improved sensitivity and specificity compared to conventional training strategies. The results indicate that adaptive optimization and confidence modeling significantly enhance diagnostic reliability without increasing architectural complexity.

Keywords: Brain tumor classification, magnetic resonance imaging, adaptive weight calibration, model calibration, robust deep learning, attention-based neural networks

INTRODUCTION

Brain tumor diagnosis using magnetic resonance imaging has become increasingly dependent on automated deep learning systems. Convolution-based architecture has demonstrated strong capability in extracting structural and intensity-related patterns from medical scans. Despite this progress, high classification accuracy alone does not guarantee clinical reliability. Many neural networks produce unstable probability distributions, exhibit sensitivity to minor perturbations, and show inconsistent behavior across training runs. These issues raise concerns regarding decision confidence and diagnostic safety. In medical applications, reliability is as important as performance. Overconfident incorrect predictions may lead to serious clinical consequences. Furthermore, class imbalance and subtle inter-class similarities can introduce biased parameter updates during optimization. Standard training procedures often apply uniform weight adjustments without considering prediction uncertainty or gradient variability. As a result, learning dynamics may favor dominant classes while suppressing minority class representation. Recent studies have explored architectural refinements and hybrid learning schemes for tumor categorization. However, limited attention has been given to adaptive optimization mechanisms that explicitly regulate parameter influence during training. There remains a need for strategies that enhance convergence stability, improve probability calibration, and maintain robustness under input perturbations.

To address these challenges, an optimized attention-based multi-scale deep network is introduced with an Adaptive Weight Calibration mechanism. The proposed framework concentrates on regulating parameter updates according to confidence distribution and gradient behavior. This strategy aims to improve generalization stability, reduce prediction bias, and enhance robustness without increasing structural complexity. The approach focuses on training intelligence rather than architectural expansion, thereby promoting reliable diagnostic decision-making.

The primary contributions of this study are summarized as follows:

- To introduce an Adaptive Weight Calibration (AWC) mechanism that dynamically regulates parameter updates based on prediction confidence distribution and gradient variance during training.
- To design a confidence-aware regularization strategy that penalizes overconfident incorrect predictions and improves probability calibration.
- To enhance class balance during optimization by incorporating adaptive scaling factors that mitigate dominance of frequently occurring categories.
- To improve convergence stability through gradient-sensitive modulation of learning influence without increasing network depth or parameter count.

The remainder of this paper is organized as follows. Section 2 reviews related studies on optimization strategies, model calibration, and robustness in medical image classification. Section 3 describes the optimized attention-based multi-scale framework and introduces the proposed AWC mechanism in detail. Section 4 explains the experimental configuration, including dataset preparation, training settings, and robustness evaluation protocols. Section 5 presents quantitative results, comparative analysis, calibration assessment, and statistical validation. Section 6 concludes the study and discusses potential future extensions toward reliability-aware clinical deployment.

LITERATURE SURVEY

Brain tumour multi-class classification using optimized CNN and transfer learning was shown in [1]. It indicated that a custom deep learning classification model was trained using the Adam optimization algorithm with cross-entropy loss to improve multi-class classification performance. The effectiveness of this model was benchmarked through comparative analysis against established transfer learning–based CNN models to validate its classification accuracy across four classes. Hybrid deep–classical brain tumour classification and diagnostic models were suggested in [2]. A hybrid deep–classical learning technique was presented, where deep CNN models (VGG16, ResNet50, DenseNet121) were used only for deep feature extraction, and the extracted feature vectors were then classified using classical

machine learning classifiers such as Support Vector Machine (SVM), Random Forest (RF), and K-Nearest Neighbors (KNN).

A review of machine-learning–based brain tumour classification was presented in [3]. A brain image classification study using a custom deep learning model trained with the Adam optimizer and cross-entropy loss was described. The model performed multi-class classification and was comparatively evaluated against transfer learning models such as ResNet50, VGG19, and DenseNet121 to validate its effectiveness. Hybrid multiclass brain tumour classification using convolutional networks and PSO optimization ensemble was detailed in [4]. An ensemble-based brain tumour classification approach was described, where deep features were extracted using VGG19, ResNet50, and GoogLeNet. Particle Swarm Optimization (PSO) was employed for feature selection and parameter tuning of a linear SVM classifier, enabling accurate multi-class classification of MRI brain tumour images. Multi-class brain tumour classification using hybrid 3B-Net and EfficientNetB2 was discussed in [5]. An advanced brain tumour classification framework integrated a three-branch convolutional network with EfficientNetB2 feature fusion. Extensive experiments on multiple MRI datasets demonstrated robust performance in binary and multi-class tasks. Data augmentation and selective fine-tuning significantly enhanced accuracy, generalization, and clinical applicability. Multimodal brain tumour classification from CT and MRI data using a deep neural network with multi-head attention was detailed in [6]. A multimodal deep learning framework (MBTC-Net) was introduced for brain tumour classification using CT and MRI images. EfficientNetV2B0 extracted high-dimensional features, while multi-head attention captured contextual dependencies. The framework achieved robust and generalizable performance across multiple tumour classes and imaging modalities.

Extreme learning machine for brain tumour diagnostic automation was detailed in [7]. An automated brain tumour diagnosis framework was developed using iterative image preprocessing, texture and statistical feature extraction, and Rapid Sine Cosine Swarm Optimization (RSCSO) for dimensionality reduction. Extreme Learning Machine (ELM) performed classification, followed by auto-encoder–based segmentation, achieving high accuracy with reduced computation time. Transfer learning refinements for brain tumour classification were discussed in [8]. An improved brain tumour classification framework was described using fine-tuned transfer learning on multiple pre-trained CNN architectures. By integrating Global Average Pooling and dropout, the method reduced overfitting and enhanced generalization. Deep learning model performance comparison for brain tumour classification was presented in [9]. A YOLOv8s-cls–based deep learning framework was employed for multi-class brain tumour classification using MRI images. The approach leveraged optimized convolutional layers and a classification head to distinguish glioma, meningioma, pituitary tumours, and non-tumour cases, achieving high accuracy, strong generalization, and real-time suitability for clinical diagnosis. A YOLO variant–based brain tumour interpretation framework was discussed in [10]. The training and evaluation procedure of a classification model was explained. It specified that the network parameters were optimized using the Adam optimizer while minimizing cross-entropy loss to improve multi-class prediction accuracy. The model's effectiveness was validated through comparative performance analysis against established transfer-learning models such as ResNet50, VGG19, and DenseNet121.

EfficientNetB0 and EfficientNetV2 variations for brain tumour classification using MRI images were compared in [11]. The technique focused on a comparative transfer learning–based deep learning approach, where different EfficientNet architectures were fine-tuned and analyzed to determine their relative effectiveness for brain tumour classification. Deep learning–based CNN brain tumour identification and classification were presented in [12]. A custom CNN trained from scratch was used for multi-class brain tumour classification from MRI images. The network learned hierarchical spatial features through convolution and pooling layers and performed end-to-end classification into glioma, meningioma, pituitary, and no-tumour classes. Combining Xception with parallel deep CNN (PDCNN) models to classify brain tumours was detailed in [13]. A hybrid ensemble brain tumour classification technique was suggested by concatenating Xception and a PDCNN with different kernel sizes to capture multi-scale features. The ensemble improved discrimination among glioma, meningioma, pituitary, and no-tumour classes, achieving higher accuracy than individual CNN and transfer-learning models. A multi-task deep learning framework, BrainTumNet, which uses adaptive masked transformers to segment and classify brain tumours, was

described in [14]. The study introduced BrainTumNet, a multi-task deep learning framework that jointly performed brain tumour segmentation and classification from MRI images. The model integrated a CNN-based encoder–decoder with an adaptive masked transformer to capture both local structural details and global contextual dependencies. By unifying segmentation and classification in a single architecture, the framework improved diagnostic accuracy, computational efficiency, and clinical reliability.

Mask R-CNN and attention mechanism–based brain CT image classification were detailed in [15]. A Mask R-CNN–based brain CT classification framework integrated deformable convolution and TCCBAM to suppress background interference and enhance lesion features. Classifying brain tumours using deep learning ensemble was presented in [16]. It employed an ensemble of pretrained deep learning architectures, namely VGG16, VGG19, ResNet50, DenseNet121, InceptionV3, Xception, and MobileNetV2, for automated brain tumour classification using both MRI and CT images, where predictions from individual models were combined through probability averaging to enhance robustness and classification accuracy. A hybrid model for brain tumour localization, CT-γ-Net, using a convolutional encoder–decoder and transformer encoder was presented in [17]. It employed a hybrid deep learning architecture (CT-γ-Net) that combined a convolutional encoder–decoder network with a transformer encoder. Depth-wise separable convolutions extracted spatial features, while transformer self-attention captured global contextual information, improving brain tumour localization and classification performance on medical images. A review of AI-based brain tumour classification developments was presented in [18]. The review analyzed AI-based brain tumour diagnosis methods using MRI, CT, PET, and other imaging modalities. It examined preprocessing, feature extraction, segmentation, and classification techniques across machine learning and deep learning frameworks and discussed future research directions.

Multiple-modal brain tumour classification utilizing convolutional Tumnet architecture was discussed in [19]. Brain tumour analysis relied on a custom CNN called Tumnet as the primary deep learning architecture. Tumnet was a lightweight convolutional neural network with five convolution layers, pooling, ReLU activations, and fully connected layers. Its performance was compared against standard CNN architectures such as VGG-19, AlexNet, GoogLeNet, ResNet-50, recurrent CNNs, and improved CNN variants, using both MRI and CT images, including multimodal MRI–CT fusion. Classifying brain tumours using ResNet50–convolutional block attention module was detailed in [20]. A ResNet50-CBAM–based brain tumour classification framework was developed using CT images. The convolutional block attention module integrated channel and spatial attention emphasize relevant features and suppress noise, significantly improving multi-class classification accuracy compared with conventional CNN and transfer-learning models.

Proposed Methodology

The proposed model utilizes a convolutional backbone derived from the VGG family of networks. The architecture is composed of sequential convolutional stages, each followed by nonlinear activation and spatial downsampling. Small receptive field filters are employed to progressively expand the effective receptive region while preserving local structural continuity. The network depth enables gradual abstraction from low-level intensity transitions to higher-order structural representations. Figure 1 shows the proposed system.

Let the input MRI slice be denoted as

$$X \in \mathbb{R}^{224\times224\times3}$$

where the spatial dimensions are standardized during preprocessing and the channel dimension corresponds to replicated grayscale inputs. Feature transformation at layer $l$can be expressed as

$$H_l = \phi(W_l * H_{l-1} + b_l)$$

where H_{l-1}represents the incoming feature tensor, $W_l$and $b_l$denote learnable parameters, $*$indicates convolution, and $\phi(\cdot)$is a nonlinear activation function. Instead of relying exclusively on the deepest convolutional response, intermediate outputs from multiple hierarchical stages are retained. These representations capture diverse descriptive characteristics. Early-stage activations encode edge continuity and fine intensity transitions. Intermediate

stages encode shape contours and regional contrast patterns. Deeper stages capture global structural arrangements associated with tumor morphology. By retaining these complementary feature sets, the model benefits from enriched representation diversity.

To unify representations with different spatial dimensions, global pooling is applied to each selected stage. The resulting descriptors are concatenated to construct a composite embedding vector. This process enables the integration of local detail information with abstract contextual representation in a unified feature space. Feature recalibration is introduced through two complementary modulation mechanisms. Channel-wise modulation estimates inter-channel dependencies and adjusts their relative contribution. Spatial refinement generates attention maps that emphasize diagnostically relevant regions while attenuating irrelevant responses. These operations enhance representation selectivity without increasing network depth. The resulting feature embedding serves as the input to the classification layer. In this study, the architectural configuration remains structurally stable. The primary enhancement lies in the adaptive regulation of learning dynamics, which is introduced in the subsequent section.

Adaptive Weight Calibration

Conventional optimization methods update network parameters uniformly across training samples. In multi-class medical image classification, this approach may introduce imbalance during learning. Classes with higher confidence predictions can dominate gradient flow, while uncertain or minority categories may receive insufficient parameter adjustment. To address this limitation, an Adaptive Weight Calibration (AWC) mechanism is introduced to regulate learning influence dynamically. Let the predicted probability for class $i$be $\hat{y}_i$, and let the ground truth label be y_i. The standard categorical cross-entropy loss is defined as

$$\mathcal{L}_{ce} = -\sum_{i=1}^{C} y_i \log(\hat{y}_i)$$

where Cdenotes the number of classes. Instead of directly minimizing this loss, a calibration factor $\alpha_i$is introduced to modulate the contribution of each class:

$$\mathcal{L}_{awc} = -\sum_{i=1}^{C} \alpha_i \; y_i \log(\hat{y}_i)$$

The adaptive factor $\alpha_i$is computed based on prediction confidence and gradient dispersion. It is defined as

$$\alpha_i = 1 + \lambda(1 - \hat{y}_i) + \gamma\sigma_g$$

where λ controls confidence sensitivity, γ controls gradient variability influence, and σ_g represents the running variance of gradient magnitude across recent mini batches. The term $(1-\hat{y}_i)$increases weight for uncertain predictions, thereby emphasizing difficult samples. The gradient variance term stabilizes updates when oscillatory behavior is detected during optimization. To further improve decision reliability, a confidence regularization component is added:

$$\mathcal{L}_{conf} = \beta \sum_{i=1}^{C} \hat{y}_i \log(\hat{y}_i)$$

where βregulates the strength of entropy-based smoothing. This term discourages overconfident predictions and improves probability calibration. The final training objective becomes

$$\mathcal{L}_{total} = \mathcal{L}_{awc} + \mathcal{L}_{conf}$$

This formulation dynamically adjusts learning intensity according to prediction uncertainty and gradient behavior. Unlike static class weighting or fixed learning-rate scheduling, AWC operates at the sample level during training. The mechanism improves convergence stability, reduces dominance of high-confidence classes, and enhances minority class sensitivity without modifying the backbone structure.

Optimization Strategy and Training Stability

Beyond adaptive loss modulation, stable convergence requires controlled parameter updates and consistent gradient flow. Standard optimization approaches often rely on fixed learning rates or static decay schedules. Such strategies may lead to oscillatory updates, slow convergence, or premature saturation when applied to medical image datasets with subtle inter-class variations. To address this issue, a gradient-aware adaptive optimization scheme was integrated into the training process. Let $\theta_t$denote model parameters at iteration t, and $g_t = \nabla_\theta \mathcal{L}_{total}$represent the gradient of the calibrated loss. Instead of applying uniform updates, a normalized gradient scaling factor $\eta_t$was introduced:

$$\eta_t = \frac{\eta_0}{1 + \rho \parallel g_t \parallel}$$

where $\eta_0$is the initial learning rate and ρcontrols sensitivity to gradient magnitude. This formulation reduces update intensity when gradients become excessively large, thereby preventing unstable parameter jumps. To enhance temporal consistency, an exponential moving average of gradients was maintained:

$$\tilde{g}_t = \mu \tilde{g}_{t-1} + (1 - \mu) g_t$$

where $\mu$is a smoothing coefficient. This operation reduces abrupt directional changes and improves convergence smoothness. The final parameter update rule becomes:

$$\theta_{t+1} = \theta_t - \eta_t \tilde{g}_t$$

This gradient-sensitive adjustment mechanism complements the Adaptive Weight Calibration loss by regulating both loss contribution and update magnitude. The combination ensures that learning remains stable even when difficult samples dominate mini-batches. To further improve generalization reliability, stochastic dropout and mini-batch normalization were maintained during training. These mechanisms reduce co-adaptation among neurons and stabilize internal feature distributions. Together, calibrated loss weighting and gradient-aware scaling provide a controlled optimization environment that enhances robustness and reduces prediction variance across training runs.

RESULTS AND DISCUSSION

The optimized framework was evaluated using a publicly available brain MRI dataset [21] containing 3,264 labeled images distributed across four categories: glioma (926 images), malignant (937 images), normal (500 images), and pituitary (901 images). Figure 2 shows the samples in each category in the dataset. A stratified partitioning strategy was adopted to preserve class distribution. The dataset was divided into 60% training, 20% validation, and 20% testing sets. This resulted in 1,959 training samples, 652 validation samples, and 653 test samples. All MRI slices were resized to 224 × 224 pixels and converted into three channels to match the convolutional backbone input configuration. Intensity normalization was applied to scale pixel values to the range [0,1]. Data augmentation was performed only on the training subset to enhance generalization. Augmentation operations included random rotations, horizontal and vertical flipping, zoom transformation, and minor intensity perturbation. These transformations were applied dynamically during training rather than storing duplicated images.

Training was conducted using mini-batch optimization with a batch size of 32. The Adaptive Weight Calibration loss and gradient-aware scaling mechanism described in Section 3 were applied during parameter updates. The initial learning rate was set to a small value to ensure stable convergence from pretrained initialization. Early stopping based on validation loss was used to prevent overfitting. Dropout regularization was applied in the classification layers to reduce over-parameterization. To ensure fair comparison, the baseline configuration was trained using identical preprocessing, data partitioning, and hardware settings, differing only in the optimization strategy. All experiments were implemented using TensorFlow and executed in a GPU-enabled environment. Standard evaluation metrics were employed to assess classification performance, including accuracy, sensitivity, specificity, and F1-score. These measures were computed using conventional medical image assessment protocols. The optimized training strategy was compared with the baseline configuration under identical experimental conditions to ensure fair evaluation. Figure 3 shows the confusion matrices obtained by for brain image classification by baseline mode,

proposed system with and without optimization. Based on the confusion matrices, the performance measures of each class are shown in Figure 4 to Figure 7.

The progressive comparison of confusion matrices clearly demonstrates structural and optimization-driven improvements. The baseline VGG model achieved lower diagonal dominance, with noticeable cross-class misclassification. Sensitivity values ranged between 91.0% and 94.6%, and overall accuracy was approximately 96.8%. Misclassification was particularly evident between glioma and meningioma, as well as within the normal category. The introduction of multi-scale aggregation and attention refinement improved diagonal consistency. Overall accuracy increased to 98.7%, and per-class sensitivity improved to the range of 97.0%–97.8%. Cross-class confusion was reduced, particularly for the normal class, where sensitivity increased from 91.0% to 97.0%. With the incorporation of Adaptive Weight Calibration, further improvement was observed. The optimized model achieved an overall accuracy of 99.69%, representing an approximate 2.91% improvement over the baseline and 1% improvement over the model without optimization. Per-class sensitivity reached 98.9% (glioma), 99.5% (meningioma), 100% (normal), and 99.4% (pituitary). Notably, the normal class achieved perfect classification, eliminating false negatives. The number of total misclassifications reduced to only 4 cases out of 653 test samples. The results indicate that structural enhancement primarily improved representation quality, while adaptive optimization further stabilized decision boundaries and minimized residual classification errors. The strong diagonal dominance and near-zero off-diagonal values confirm that the optimized framework achieved highly reliable multi-class discrimination.

CONCLUSION

This study presented an optimized attention-based multi-scale deep learning framework enhanced with an AWC mechanism for brain tumor classification. Unlike conventional approaches that focus primarily on architectural expansion, the proposed method concentrated on regulating training dynamics to improve stability and predictive reliability. The adaptive calibration strategy dynamically adjusted loss contribution based on prediction confidence and gradient behavior. Experimental evaluation demonstrated the proposed approach achieved an overall accuracy of 99.39% and significantly improved per-class sensitivity, including perfect classification for the normal category. The strong diagonal dominance observed in the confusion matrix confirmed enhanced decision boundary stability. These results indicate that intelligent optimization control plays a critical role in improving diagnostic reliability beyond structural feature enhancement alone. The findings suggest that adaptive learning regulation can strengthen confidence calibration and reduce prediction variance without increasing model complexity.

ABSTRACT

The rapid growth of the Internet of Things (IoT) has led to the interconnection of billions of devices, generating enormous quantities of data every second. While this connectivity has brought efficiency and automation, it has also introduced serious concerns regarding security, privacy, and trust. Big Data technologies provide a transformative means to process, analyze, and secure the large-scale, real-time data generated by IoT systems. This paper explores how Big Data processing in cloud environments can be applied to strengthen IoT security for both end consumers and manufacturers. It presents a layered security management framework that utilizes distributed data storage, machine learning–driven analytics, and automated risk mitigation. The model supports real-time threat detection, privacy protection, and predictive maintenance. The study concludes that cloud-based Big Data systems are essential for ensuring trust, resilience, and efficiency in IoT ecosystems.

Keywords: Big Data, IoT Security, Cloud Computing, Cyber security, Industrial IoT, Consumer IoT, Data Privacy, Predictive Analytics.

INTRODUCTION

The Internet of Things (IoT) represents one of the most significant technological advancements of the 21st century. It connects billions of devices—ranging from smart home appliances to industrial sensors—through internet-enabled networks. Consumers use IoT devices for convenience like smart appliances, wearable health trackers, and connected cars, while manufacturers rely on IoT technologies for process automation, predictive maintenance, and supply chain optimization. However, this widespread connectivity has also created an expanding cyber threat surface such as

unauthorized access, data tampering, and denial-of-service attacks. The challenge lies not just in securing each device but in managing and protecting the massive amount of data that flows across these networks. Cloud computing provides the elasticity, distributed storage, and computational power needed to process this data effectively, while Big Data analytics enables intelligent threat detection and anomaly recognition. Together, they form a cloud-based Big Data security framework that ensures confidentiality, integrity, and availability in IoT networks (Zhou et al., 2022). Big Data techniques such as distributed data processing, machine learning, and stream analytics have proven to be vital in enhancing IoT security architectures. This paper aims to explore the intersection between Big Data and IoT security and to demonstrate how data-driven intelligence can safeguard the next generation of connected systems.

LITERATURE REVIEW

The convergence of Big Data and IoT security has attracted extensive academic and industrial attention. Mendez et al. (2021) emphasized that IoT devices often lack computational resources and encryption mechanisms, making them prime targets for cyberattacks. Big Data technologies like Hadoop and Apache Spark provide scalable frameworks to process and analyze massive IoT data streams for anomaly detection and risk prediction. According to Kumar and Kaur (2022), Big Data analytics supports real-time monitoring of IoT environments, enabling the identification of abnormal network behaviours. Zhou et al. (2022) explored the integration of artificial intelligence (AI) with Big Data analytics, which enables automated threat analysis and pattern recognition in complex IoT networks. Recent developments also focus on edge computing, which allows localized data processing close to the IoT devices, reducing latency and improving security efficiency (Al-Fuqaha et al., 2020). Collectively, the literature indicates that Big Data not only strengthens IoT security but also transforms it into a predictive and intelligent ecosystem.

Role of Cloud-Based Big Data Processing in IoT Security Management

The cloud acts as a central hub for storing and processing massive IoT datasets, while Big Data tools extract security intelligence from them. The synergy between the two enables the following security capabilities:

Real-Time Threat Detection

Cloud-based Big Data frameworks such as Apache Spark Streaming and AWS Kinesis process live IoT data streams to identify anomalies and potential intrusions instantly.

Scalability and Flexibility

As IoT networks expand, the cloud dynamically allocates computational resources to handle large-scale data processing, ensuring uninterrupted threat monitoring.

Centralized Data Governance

Cloud infrastructures provide unified security policies, access controls, and encryption mechanisms for distributed IoT devices.

Predictive Analytics for Risk Prevention

Machine learning models running in the cloud predict vulnerabilities based on historical Big Data patterns, enabling proactive defence.

Automated Response Mechanisms

Integration with AI and automation tools allows the system to isolate compromised devices or networks without human intervention.

IoT Security Challenges for Consumers and Manufacturers

Consumers face challenges such as:

- **Data Privacy Violations:** Personal information from smart devices can be intercepted or misused.
- **Weak Authentication:** Many consumer IoT products lack strong password and encryption protocols.
- **Firmware Exploits:** Outdated software in smart home devices is a common attack vector.
- **Malware and Botnets:** Devices can be hijacked and used in distributed denial-of-service (DDoS) attacks.

For manufacturers, the risks are far more critical:

- **Industrial Espionage:** Sensitive production and R&D data are attractive targets for cybercriminals.
- **Operational Disruption:** Attacks on industrial control systems (ICS) can halt production or damage machinery.
- **Supply Chain Vulnerabilities:** Compromised supplier IoT networks can propagate security threats.
- **Data Integrity Risks:** Manipulation of sensor or machine data can lead to costly manufacturing errors. Both sectors require real-time visibility, data-driven decision-making and intelligent automation, which Big Data in the cloud can provide.

Cloud-Based Big Data Processing Model for IoT Security

This conceptual model illustrates how IoT-generated data moves through a cloud-hosted Big Data pipeline, enabling continuous monitoring, real-time anomaly detection, and automated defence mechanisms against cyber threats.

Cloud Platforms Supporting Big Data Processing

These platforms enable enterprises and researchers to handle complex data workloads without investing in physical infrastructure.

Applications Of Cloud Hosted Big Data in IoT Security For Consumers And Manufacturers

For consumers

- **Smart Homes:** Cloud analytics monitor device behavior to detect intrusions or unauthorized access.
- **Wearable Devices:** Protect user health data through encrypted data streams and behavioral monitoring.
- **Smart Vehicles:** Real-time cloud analytics prevent hacking of connected vehicle systems.

For Manufacturers

- **Industrial Control Systems (ICS):** Big Data analytics identify abnormal equipment activity and prevent operational sabotage.
- **Predictive Maintenance:** Cloud-based machine learning models predict equipment failure and mitigate cyber risks.
- **Supply Chain Security:** Data correlation across suppliers ensures transparency and early detection of cyber infiltration.

Challenges and Limitations

Despite its advantages, the application of Big Data processing in cloud-based IoT security faces challenges:

- **Data Privacy Risks:** Sensitive IoT data stored in cloud environments may be exposed to unauthorized access.
- **Latency Issues:** Real-time threat response can be affected by network delays.
- **Multi-Tenancy Threats:** Shared cloud resources increase risks of cross-tenant attacks.
- **Regulatory Compliance:** Adhering to data protection laws like GDPR and HIPAA is complex in multi-cloud ecosystems.
- **Vendor Lock-In:** Dependence on specific cloud providers may restrict flexibility and data portability. Future advancements such as edge-cloud integration, federated learning, and block chain-based authentication are expected to overcome these limitations.

CONCLUSION

The fusion of Big Data processing and cloud computing marks a revolutionary shift in IoT security management. By leveraging the cloud's scalability and Big Data's analytical power, organizations can achieve predictive, adaptive, and real-time IoTdefence mechanisms. This architecture enables continuous monitoring, automated mitigation, and improved data governance, ensuring that IoT ecosystems remain secure, resilient, and intelligent. Collaborative research between data scientists, cyber security professionals, and computer engineers will be vital in shaping the next generation of secure IoT environments.

ABSTRACT

In this paper a new representation of Pentagonal Fuzzy Number is proposed. The objective is to find optimal solution of Fully Fuzzy Critical Path (FFCP) Problems on the basis of new representation, and calculate Fuzzy total float for each activity and it's critical path. This is verified by linear programming approach and compared with some more techniques like Range, Mode and Divergence. Numerical example, is illustrated using the newly defined fuzzy number as parameters.

Keywords : Fuzzy Fully Critical Path Problem - Pentagonal Fuzzy Numbers - Fuzzy total float- Fuzzy Linear programming.

INTRODUCTION

The concept of fuzzy decision making problems with maximizing decision was first proposed by Bellman and Zadeh [2] in the beginning of the 1960's. The purpose of CPM is to identify critical activities on the critical path so that resources may be concentrated on these activities in order to reduce the project length time. In fuzzy environment ranking fuzzy numbers is very essential in decision making procedure. Ranking fuzzy numbers were first proposed by Jain [8] for decision making in fuzzy situations. Some of these ranking method have been compared and reviewed by Bortolan and Degani [3] and recently by Chen[5], Chang [4] used in centroid based distance methods to rank fuzzy numbers in 1998.

Chanas and Radosinski [11] analyzed the useof fuzzy numbers in the network planning. M.H. Oladeinde and C.A. Oladeinde [10] considered the effectiveness of the decision makers risk attitude index for fuzzy critical path analysis. Dubosisand Prade[6] extended the fuzzy arithmetic operations to compute the latest starting time of each activity in the project network, Hapke and Slowwinski [7] used fuzzy arithmetic operations in project scheduling, C.T Chen and S.F. Huang [5] applied fuzzy method for measuring criticality in project network.

To calculate the fuzzy critical path, many approaches are dealt over the recent years. Gazdik (1983) developed the fuzzy network of unknown project to estimate the activity duration and used fuzzy algebraic operators to calculate the duration of the project and its critical path. Mccahon and Lee (1988) presented a new methodology to calculate the fuzzy completion project time. The total float and fuzzy critical path in the project networks are proposed by Naution (1994). Lin and Yao (2003) introduced a fuzzy CPM based on statistical confidence-interval estimates and a signed distance ranking for (1-α) fuzzy number levels. Liang and Han (2004) presented an algorithm to perform fuzzy critical path analysis for project network problem.

On the basis of the linear programming formulation and fuzzy number ranking method [17-19] this paper develops a simple approach to the critical path problem with activity duration times being fuzzy number, Chen (2007) proposed an approach based on the extension principle and linear programming formulation to critical path analysis in networks with fuzzy activity duration. In this paper, a new method is proposed to find the optimal solution to the fully fuzzy critical path problems. Also, a new representation of pentagonal fuzzy numbers is proposed. To illustrate the proposed method and to show the advantages of the proposed representation of pentagonal fuzzy numbers, a numerical example is solved by representing all the parameters by the proposed type of pentagonal fuzzy numbers. The proposed method is very easy to understand and to apply for finding the fuzzy optimal solution of Fully Fuzzy Critical Path (FFCP) problems occurring in real life situations.

PRELIMINARIES

This section recalls some basic definitions of fuzzy numbers, pentagonal fuzzy number, arithmetic operations between pentagonal fuzzy numbers and ranking functions.

Definition 2.1
A **fuzzy set** $\tilde{A}$ in R (real line) is defined to be a set of ordered pairs, $\tilde{A} = \{x, \mu_{\tilde{A}}(x)/x \in R\}$ where $\mu_{\tilde{A}}(x)$is called the membership function for the fuzzy set.

Definition 2.2
The ***α*-cut** of fuzzy set $\tilde{A}$ is a set consisting of these elements of the universe X whose membership values exceed the threshold level α
That is, $\tilde{A}_{\alpha} = \{x \in X/\mu_{\tilde{A}}(x) \geq \alpha\}$

Definition 2.3
A fuzzy set $\tilde{A}$ is called **normal**, if there is at least one point $x \in R$ with $\mu_{\tilde{A}}(x) = 1$

Definition 2.4
A fuzzy set $\tilde{A}$ on R is **convex**, if for any $x, y \in R$ and for any $\lambda \in [0,1]$ we have
$\mu_{\tilde{A}}(\lambda_x + (1-\lambda)y) \geq \min \{\mu_{\tilde{A}}(x), \mu_{\tilde{A}}(y)\}$
In general, concave function is the negative of a convex function.

Definition 2.5

A **fuzzy number** $\tilde{A}$is a fuzzy set on the real line that satisfies the conditions of normality and convexity.

Pentagonal Fuzzy Number

Definition 3.1

The Pentagonal FuzzyNumber (PFN) is represented by the five parameters a,b,c,d and e where a and b denote the smallest possible values, c the most promising value and d, e the largest possible value.

A fuzzy number $\tilde{A} = (a, b, c, d, e)$ is called a pentagonal fuzzy number, if it's membership function is given by

$$\mu_{\tilde{A}}(x) = \begin{cases} 0 & for \quad x < a, \\ \dfrac{x-a}{b-a} & for \quad a \le x \le b \\ \dfrac{x-b}{c-b} & for \quad b \le x \le c \\ 1 & for \quad x = c \\ \dfrac{d-x}{d-c} & for \quad c \le x \le d \\ \dfrac{e-x}{e-d} & for \quad d \le x \le e \\ 0 & for \quad x > e \end{cases}$$

Conditions On Pentagonal Fuzzy Number

A Pentagonal fuzzy number $\tilde{A}$, should satisfies the following conditions:

(i) $\mu_{\tilde{A}}(x)$ is a continuous function in [0,1]

(ii) $\mu_{\tilde{A}}(x)$ is strictly increasing and continuous function on $[a, b]$ and $[b, c]$

(iii)$\mu_{\tilde{A}}(x)$ is strictly decreasing and continuous function on $[c, d]$ and $[d, e]$

Artithmetic Operations on Pentagonal Fuzzy Number (PFN)

Addition of Two PFNs

Let $\tilde{A} = (a_1, b_1, c_1, d_1, e_1)$ and $\tilde{B} = (a_2, b_2, c_2. d_2, e_2)$ be two PFNs, then addition of two PFNs is given by

$\tilde{A} + \tilde{B} = (a_1 + a_2, b_1 + b_2, c_1 + c_2, d_1 + d_2, e_1 + e_2)$

Subtraction of Two PFNs

Let $\tilde{A} = (a_1, b_1, c_1, d_1, e_1)$ and $\tilde{B} = (a_2, b_2, c_2. d_2, e_2)$ be two PFNs, then subtraction of two PFNs is given by

$\tilde{A} - \tilde{B} = (a_1 - e_2, b_1 - d_2, c_1 - c_2, d_1 - b_2, e_1 - a_2)$

Multiplication of Two PFNs

The multiplication of two PFNs$\tilde{A} = (a_1, b_1, c_1, d_1, e_1)$ and $\tilde{B} = (a_2, b_2, c_2. d_2, e_2)$isgiven by

$\tilde{A}\tilde{B} = (a_1a_2, b_1b_2, c_1c_2, d_1d_2, e_1e_2)$

Definition 3.4

A PFN $\tilde{A} = (a, b, c, d, e)$ is said to be **positive**, if $a > 0$.

Definition 3.5

A PFN $\tilde{A} = (a, b, c, d, e)$ is said to be **negative**, if $e < 0$.

Definition 3.6

A PFNs $\tilde{A}$ is called **null or zero** PFN, if all of it'sentries $a, b, c, d, e = 0$.

That is, $\tilde{A} = (0, 0, 0, 0, 0)$

Definition 3.7
Two PFNs $\tilde{A} = (a_1, b_1, c_1, d_1, e_1)$ and $\tilde{B} = (a_2, b_2, c_2.d_2, e_2)$ are said to be **equal** That is $\tilde{A} = \tilde{B}$ if and only if $a_1 = a_2, b_1 = b_2, c_1 = c_2, d_1 = d_2, e_1 = e_2$

Definition 3.8
Mode of a Pentagonal Fuzzy Number
If $\tilde{A} = (a, b, c, d, e)$ is a pentagonal fuzzy number then the mode $\tilde{A}$ is given by c.

Definition 3.9
Divergence of a Pentagonal Fuzzy Number
If $\tilde{A} = (a, b, c, d, e)$ is a pentagonal fuzzy number then the divergence of $\tilde{A}$ is given by
$Div\ \tilde{A} = e - a$

Definition 3.10
Spreads of a Pentagonal Fuzzy Number
If $\tilde{A} = (a, b, c, d, e)$ is a pentagonal fuzzy number, then the spreads of $\tilde{A}$ are given by left spread $\tilde{A} = c - b - a$ and right spread $\tilde{A} = e - d - c$

Ranking Function
Ranking function $\mathbb{R}$ is defined as$\mathbb{R}$: $F(R) \to R$, where $F(R)$ is the set of fuzzy numbers on set of real numbers which maps each fuzzy number into the real line.

Let (a, b, c, d, e) be the pentagonal fuzzy number then

$$\mathbb{R}(a, b, c, d, e) = \frac{a + b + c + d + e}{5}$$

New Representation of Pentagonal Fuzzy Number
In this section, a new representation of pentagonal fuzzy numbers named SMS representation of pentagonal fuzzy number is proposed. It is shown that all of it's parameters are represented by SMS representation instead of existing representation of pentagonal fuzzy numbers, and the proposed method is applied to find the fuzzy optimal solution of Fully FuzzyCritical Path (FFCP) problems.

Definition 4.1
The pentagonal fuzzy number is defined as $\tilde{A} = (x, y, \alpha, \beta, \gamma, \delta)$ when compared to the ordinary pentagonal fuzzy number $\tilde{A} = (a, b, c, d, e), a = x, b = a + \alpha, c = a + \alpha + \beta,$
$d = y - \gamma$and$e - d = \delta$

Definition 4.2
A pentagonal fuzzy number $\tilde{A} = (x, y, \alpha, \beta, \gamma, \delta)_{SMS}$ is said to be zero pentagonal fuzzy number if and only if $x = 0, y = 0, \alpha = 0, \beta = 0, \gamma = 0, \delta = 0$

Definition 4.3
A pentagonal fuzzy number $\tilde{A} = (x, y, \alpha, \beta, \gamma, \delta)_{SMS}$ is said to be non-negative if and only if $x > 0$

Definition 4.4
Two pentagonal fuzzy numbers $\tilde{A} = (x_1, y_1, \alpha_1, \beta_1, \gamma_1, \delta_1)$ and $\tilde{B} = (x_2, y_2, \alpha_2, \beta_2, \gamma_2, \delta_2)$ are said to be equal if and only if $x_1 = x_2, y_1 = y_2, \alpha_1 = \alpha_2, \beta_1 = \beta_2, \gamma_1 = \gamma_2, \delta_1 = \delta_2$

Arithmetic Operations Between SMS Pentagonal Fuzzy Numbers

Let $(a_1, b_1, c_1, d_1, e_1)$ and $(a_2, b_2, c_2. d_2, e_2)$ be two pentagonal fuzzy numbers and $(x_1, y_1, \alpha_1, \beta_1, \gamma_1, \delta_1)_{SMS}$ and $(x_2, y_2, \alpha_2, \beta_2, \gamma_2, \delta_2)_{SMS}$ be their SMS representation, then the addition operation is defined as,

$\tilde{A} \oplus \tilde{B} = (x_1 + x_2, y_1 + y_2, \alpha_1 + \alpha_2, \beta_1 + \beta_2, \gamma_1 + \gamma_2, \delta_1 + \delta_2)$

Image of $\tilde{A}[-\tilde{A}]$ is defined as

$\sim \tilde{A} = (-y, -x, \delta, \gamma, \beta, \alpha)$

Ranking Function for SMS Pentagonal Fuzzy Number

The ranking function for the pentagonal fuzzy number $\tilde{A}\ (x, y, \alpha, \beta, \gamma, \delta)_{SMS}$ as

$$\mathbb{R}(x, y, \alpha, \beta, \gamma, \delta) = \frac{a + b + c + d + e}{5} \ where\ \tilde{A} = (a, b, c, d, e)$$

$$= \frac{x + y + x + \alpha + x + \alpha + \beta + y - \delta}{5}$$

$$= \frac{3x + 2y + 2\alpha + \beta - \delta}{5}$$

(or)

$$= \frac{x + y + x + \alpha + y - \delta - \gamma + y - \delta}{5}$$

$$= \frac{2x + 3y + \alpha - 2\delta - \gamma}{5}$$

Fuzzy Critical Path Analysis

This paper is to extend the fuzzy critical path algorithm using the pentagonal fuzzy numbers with new representation. Consider a fuzzy project network, where the duration time of each activity in a fuzzy network is represented by fuzzy numbers. Let $\tilde{E}S_i$ and $\tilde{L}S_i$ be the earlier fuzzy event time, and the latest fuzzy event time for event i, respectively. Functions that define the earliest starting times, latest starting times and floats in terms of fuzzy activity duration's are convex, normal whose membership functions are piece-wise continuous, hence the quantities such as earliest fuzzy event time $\tilde{E}S_i$ the latest fuzzy time $\tilde{L}S_i$ and floats $\tilde{T}$ are also pentagonal fuzzy numbers.

Algorithm for Proposed Method

To find the critical path with $(x, y, \alpha, \beta, \gamma, \delta)_{SMS}$ representation of pentagonal fuzzy numbers

Step 1:

Calculate Earliest start using

$\tilde{E}_j = \max[\tilde{E}_i \oplus \tilde{t}_{ij}]$, where $\tilde{E}_1 = 0$ and $\tilde{E}_f = E_S \oplus t_{ij}$

Step 2:

Calculate latest finish using

$\tilde{L}_i = \min[\tilde{L}_j \oplus (-\tilde{t}_{ij})]$, where $\tilde{L}_n = \tilde{E}_n$

Step 3:

Total float of each activity can be calculated by

$\tilde{T}_{ij} = \tilde{L}_j \oplus (-\tilde{E}_i) \oplus (-\tilde{t}_{ij})$

Step 4:

Find all possible paths and calculate the total slack fuzzy time of each path.

Defuzzify the total float of each activity using the ranking function and find the critical path such that the sum of total floats of activity is zero.

Numerical Example

Consider a project network with ten activities (Table1).
The network diagram of the given data is (Fig.2 and Fig.3),

We take the earliest time of all the start activities as zero. So the earliest start of 1-2 and 2-3 are$(0,0,0,0,0,0)_{SMS}$, using the given algorithm the following table shows EST, LFT and TF of all the activites.

Table 2 : Hence it is found that the critical path of the network is 1-2-4-5-6-7.

Linear Programming Approach and Comparison using Proposed Pentagonal Fuzzy Number

Definition 6.1
Mode in SMS Representation
If $\tilde{A} = (a,b,c,d,e)$ is a pentagonal fuzzy number and $(x,y,\alpha,\beta,\gamma,\delta)_{SMS}$ in it's SMS representation, then mode $\tilde{A}$ is given by
$Mode\ \tilde{A} = x + \alpha + \beta\ \ (or)\ y - \delta - \gamma$

Definition 6.2
Divergence in SMS Representation
If $\tilde{A} = (a,b,c,d,e)$ is a pentagonal fuzzy number and $(x,y,\alpha,\beta,\gamma,\delta)_{SMS}$ is it's SMS representation then the divergence of $\tilde{A}$ is given by
$Div\ \tilde{A} = y - x$

Definition 6.3
Spreads in SMS Representation
If $\tilde{A} = (a,b,c,d,e)$ is a pentagonal fuzzy number, and its SMS representation then the left and right spreads of $\tilde{A}$ are given by left spread $\tilde{A} = \alpha + \beta$ and right spread$\tilde{A} = \gamma + \delta$

Linear Programming Formulation of Fuzzy Critical Path Method
Consider a project model $G = (N,A)$ which is directed and connected network where N is the set of n nodes and A is the set of (i,j) activities. That is $T_{ij} = (i,j)$ where all $(i,j) \in A$, one of efficient approaches for finding critical paths and total duration time of project networks is the linear programming problem. Since a CPM problem can be thought of an opposite of the shortest path problem, to determine a critical path in the project network it suffices to find the longest path from start to finish. Then the length of this longest path is the total duration time of the project network. Assume that a unit flow enters the project network at the start node and leaves at the finish node. The CPM problem with n nodes is formulated as

$$Max\ z = \sum_{i=1}^{n}\sum_{j=1}^{n} T_{ij}x_{ij}$$

subject to,

$$\sum_{j=1}^{n} x_{ij} = 1$$

$$\sum_{j=1}^{n} x_{ij} = \sum_{k=1}^{n} x_{Ki}\,, i = 2, \dots, n-1$$

$$\sum_{k=1}^{n} x_{kn} = 1$$

$x_{ij} \geq 0 \quad (i,j) \in A$

Proposed Method to Find the Critical Path in A Project Network

Step (1): Formulate the critical path problem as a linear programming problem.
Step (2): Find the solution of the linear programming problem. If the solution is unique, then the critical path can be found from the solution.
Step (3): If there are alternate solutions, then the total float of each activity can be found and the critical path can be found such that the sum of total floats of the activities in the path is zero.
Step (4): If there is unique critical path then the solution is achieved.
Step (5): If not, find the mode of the total float and rank the paths such that the path with maximum mode is the critical path.
Step (6): If the modes of all the paths are equal, then find the divergence of the paths and the path with maximum divergence will be the critical path.

Example
Consider the network given in Numerical Example 5.2
The given problem is mathematically formulated as,

$$Max[(1,7,2,2,1,1)x_{12} \oplus (2,7,1,1,1,2)x_{13} \oplus (1,7,1,1,1,3)x_{23} \oplus (2,6,1,1,1,1)x_{24} \oplus (3,8,1,1,1,2)x_{35} \oplus (2,8,2,2,1,1)x_{45} \oplus (2,9,3,1,2,1)x_{47} \oplus (1,8,2,2,2,1)x_{56} \oplus (1,6,1,1,1,2)x_{57} \oplus (2,6,1,1,1,1)x_{67}]$$

subject to

$x_{12} + x_{13} = 1$

$x_{12} = x_{23} + x_{24}$

$x_{13} + x_{23} = x_{35}$

$x_{24} = x_{45} + x_{47}$

$x_{35} + x_{45} = x_{56} + x_{57}$

$x_{56} = x_{67}$

$x_{47} + x_{57} + x_{67} = 1$

$x_{12}, x_{13}, x_{23}, x_{24}, x_{35}, x_{45}, x_{47}, x_{56}, x_{57}, x_{67} \geq 0$

Using the ranking function, the linear programming formulation will be
$Max\ [4.4x_{12} \oplus 4.2x_{13} \oplus 3.4x_{23} \oplus 4x_{24} \oplus 5.2x_{35} \oplus 5.4x_{45} \oplus 6x_{47} \oplus 4.8x_{56} \oplus 3.2x_{57} \oplus 4x_{67}]$

subject to
$x_{12} + x_{13} = 1$
$x_{12} - x_{23} - x_{24} = 0$
$x_{13} + x_{23} - x_{35} = 0$
$x_{24} - x_{45} - x_{47} = 0$
$x_{35} + x_{45} - x_{56} - x_{57} = 0$
$x_{56} - x_{67} = 0$
$-x_{47} - x_{57} - x_{67} = -1$
$x_{12}, x_{13}, x_{23}, x_{24}, x_{35}, x_{45}, x_{47}, x_{56}, x_{57}, x_{67} \geq 0$

On solving CLP using TORA software, it can be found that the optimum solution is
Max Z= 22.6
when $x_{12} = x_{24} = x_{45} = x_{56} = x_{67} = 1$
and $x_{13} = x_{23} = x_{35} = x_{47} = x_{57} = 0$
Using this optimal solution, the fuzzy critical path is $\mathbf{1-2-4-5-6-7.}$

The other alternative paths obtained are

i. $1-2-4-7$
ii. $1-2-4-5-7$
iii. $1-2-3-5-7$
iv. $1-2-3-5-6-7$
v. $1-3-5-7$
vi. $1-3-5-6-7$

For all the paths, calculate start, finish and total floats from the table 2.
Comparing all the paths total float, rank, mode and divergence in the following table.
Hence, it is found and verified that $\mathbf{1-2-4-5-6-7}$is the critical path of the given network.

CONCLUSION

A new representation of pentagonal fuzzy numbers namely SMS representation of pentagonal fuzzy number is proposed. It is shown that, it is better to use the proposed representation of pentagonal fuzzy numbers instead of existing representation, to find the solution of fully fuzzy critical path problem and it can be verified by linear programming approach.

ABSTRACT

This paper introduces the concept of rebellion energy of graphs, based on a new matrix called the rebellion adjacency matrix. For a simple *(p, q)*-graph *G* with a minimum rebellion set *R*, the rebellion adjacency matrix is defined as a $p \times p$ matrix where the *(i, j)*-entry is 1 if the edgev_iv_j exists in *G* for $i \neq j$, and the diagonal entry is 1 if the vertex v_i belongs to *R*. All other entries are zero. We study the algebraic properties of this matrix for the classes of some standard graphs, focusing on its eigenvalues, spectral radius, spectral gap, rank, trace, determinant, and the rebellion energy.

Keywords: Adjacency matrix, Rebellion set, Rebellion adjacency matrix, Rebellion energy.
2020 AMS Subject Classification:05C69, 05C70, 05C76.

INTRODUCTION

Throughout paper, we consider $G=(V,E)$ as a simple, finite, undirected and connected with p vertices and q edges. The basic graph theoretical terminologies are referred from F. Harary[1]. A set vertices of a graph is said to be a rebellion set, if (i) $|N_R(v)| \leq |N_{V\setminus R}(v)|$, $\forall v \epsilon R$, (ii) $|R| \geq |V\setminus R|$.A rebellion number $\alpha_r(G)$is the minimum cardinality of any rebellion set in *G*. A rebellion set with cardinality $\alpha_r(G)$ is denoted by *R*-set.The adjacency matrix $A(G)$ of *G* is the $p \times p$ matrix whose (i,j)-entry is 1 if the vertices v_i and v_j are adjacent in *G* and zero otherwise. All matrix related terms

are referred from [2].The spectrum of a matrix refers to the collection of all its eigenvalues along with their multiplicities, that is, the number of times each eigenvalue occurs. The determinant of a matrix is a single numerical value that helps us understand whether the matrix is invertible or not. The trace of a matrix is simply the sum of the elements present along its main diagonal. The rank of a matrix represents the maximum number of linearly independent rows or columns, which indicates the amount of independent information contained in the matrix. The sum of the diagonals means adding all the entries along the main diagonal of the matrix. The spectral radius of a matrix is the eigenvalue having the greatest absolute value. The spectral gap describes the difference between the largest eigenvalue and the second largest eigenvalue. The sum of the absolute eigenvalues is obtained by adding the absolute values of all eigenvalues. Since the matrix considered in this paper is real and symmetric, all its eigenvalues are real. The energy of a graph is defined as the sum of the absolute values of the eigenvalues of its adjacency matrix and was introduced by Gutman [3].All the graphs used in the paper are referred from A. Gallian [4].The basic properties and bounds of graph energy are discussed in [6–13]. Graph energy has important applications in chemical graph theory, especially in the study of molecular structures. In this paper, by defining an adjacency matrix corresponding to a rebellion set, a new matrix called the rebellion adjacency matrix is introduced and the corresponding rebellion energy is studied for some standard classes of graphs.

MATERIALS AND METHODS:

Definition 2.1: Let G be a (p,q) graph with rebellion set R with cardinality $\alpha_r(G)$. A$p\times p$ rebellion adjacent matrix $A_r(G)$ is defined as

$$A_r(G)=\begin{cases}1, & if\ i\neq j,\ v_iv_j\in E_r(G)\\ 1, & if\ i=j,\ v_i\epsilon\ R\\ 0, & \text{otherwise}\end{cases} \quad ,i,j=1,2,\dots n$$

Definition 2.2: The rebellion energy of G is defined as $E_r(G)=\sum_{i=1}^{n}|\lambda_i^r|$, where $\lambda_1^r\geq\lambda_2^r\geq\cdots\geq\lambda_p^r$ are the eigen values of the real symmetric matrix $A_r(G)$.

Notations 2.3: For graph$G$,$f_r(G)$, $S_r(G)$,$|A_r(G)|$,$trace\big(A_r(G)\big)$,$rank\big(A_r(G)\big)$,$\beta_r^{\lambda}(G)$, $\rho_r(G)$, $\delta_r(G)$ and $E_r(G)$ are respectively denoted as characteristic equation, Spectrum,determinant, trace, rank, sum of the diagonals, spectral radius,spectral gap, sum of the absolute eigen values, and energy of the rebellion adjacency matrix of G. Throughout the paper, we denote a rebellion set with cardinality $\alpha_r(G)$is $\alpha_r(G)$-set.

Example 2.4:

Figure 1: C_4

For the graph $G=C_4$ in Figure 1,the $\alpha_r(G)$-set,$R=\{v_1.v_2\}$and hence the $\alpha_r(G)=2$.

$A_r(G)=\begin{pmatrix}1&1&0&1\\1&1&1&0\\0&1&0&1\\1&0&1&0\end{pmatrix}$. It gives $f_r(G)=\lambda^4-2\lambda^3-2\lambda^2+4\lambda-1=0$.

$$(i)\ S_r(G)=\begin{cases}\dfrac{\pm\sqrt{5}-1}{2}, & one\ time\\ \dfrac{\pm\sqrt{5}+3}{2}, & one\ time\end{cases}$$

$(ii)|A_r(G)|=-1$

$(iii)Trace\big(A_r(G)\big)=2$

$(iv)Rank\big(A_r(G)\big)=4$

$(v)\ \beta_r^{\lambda}(G)=2$

$(vi)\ E_r(G) = \left|\frac{\sqrt{5}-1}{2}\right| + \left|\frac{-\sqrt{5}-1}{2}\right| + \left|\frac{\sqrt{5}+3}{2}\right| + \left|\frac{-\sqrt{5}+3}{2}\right| = 5.2361$

Theorem 2.5: For the completegraph $K_n,\ n \geq 3$, the rebellion energy is

$$E_r(K_n) = \begin{cases} \sqrt{n^2+3} \ + \ \dfrac{n-3}{2}, \text{ if n is odd} \\ \sqrt{n^2+1} \ + \ \dfrac{n-2}{2}, \text{if n is even} \end{cases}$$

Proof: Let G be a complete graph $K_n$with at least three vertices and $V(G) = \{v_1, v_2,\ldots,v_p\}$. The rebellion set R of G is, $R = \{v_1, v_2, v_3,\ldots, v_n\}$. Then, it gives the rebellion adjacency matrix as,

$$A_r(G) = \begin{pmatrix} 1 & 1 & 1 & 1\ldots\ldots\ldots & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1\ldots\ldots\ldots & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1\ldots\ldots\ldots & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1\ldots\ldots\ldots & 1 & 1 & 1 & 1 \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ 1 & 1 & 1 & 1\ldots\ldots\ldots & 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1\ldots\ldots\ldots & 1 & 0 & 1 & 1 \\ 1 & 1 & 1 & 1\ldots\ldots\ldots & 1 & 1 & 0 & 1 \\ 1 & 1 & 1 & 1\ldots\ldots\ldots & 1 & 1 & 1 & 0 \end{pmatrix}$$

Then the characteristic equation of $A_r(G)$ is

$$f(A_r(G)) = \begin{vmatrix} \lambda-1 & -1 & -1 & -1\ldots\ldots\ldots & -1 & -1 & -1 & 0 \\ -1 & \lambda-1 & -1 & -1\ldots\ldots\ldots & -1 & -1 & 0 & -1 \\ -1 & -1 & \lambda-1 & -1\ldots\ldots\ldots & -1 & 0 & -1 & -1 \\ -1 & -1 & 1 & \lambda-1\ldots\ldots\ldots & 0 & -1 & -1 & -1 \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ -1 & -1 & -1 & 0\ldots\ldots\ldots & \lambda & -1 & -1 & -1 \\ -1 & -1 & 0 & -1\ldots\ldots\ldots & -1 & \lambda & -1 & -1 \\ -1 & 0 & -1 & -1\ldots\ldots\ldots & -1 & -1 & \lambda & -1 \\ 0 & -1 & -1 & -1\ldots\ldots\ldots & -1 & -1 & -1 & \lambda \end{vmatrix} = 0$$

From the characteristic equation of $A_r(G)$, we get the followings,

$(i)|A_r(G)| = 0.$

$$(ii)\ Trace\big(A_r(G)\big) = \begin{cases} \dfrac{n+1}{2}, \ if\ n\ is\ odd \\ \dfrac{n}{2} \quad , if\ n\ is\ even \end{cases}$$

$$(iii)\ Rank\big(A_r(G)\big) = \begin{cases} \dfrac{n-1}{2}, \ if\ n\ is\ odd \\ \dfrac{n}{2} \quad , if\ n\ is\ even \end{cases}$$

$$(vi)\beta_r^{\lambda}(G) = \begin{cases} \frac{n+1}{2}, \ if\ n\ is\ odd \\ \frac{n}{2} \quad , if\ n\ is\ even \end{cases}$$

$$(v)\ \rho_r(G) = \begin{cases} \frac{\sqrt{n^2+3}+n-1}{2}, & \text{if n is odd} \\ \frac{\sqrt{n^2+1}+n-1}{2}, & \text{if n is even} \end{cases}$$

$$(vi)\ \delta_r(G) = \begin{cases} \frac{\sqrt{n^2+3}+n-1}{2}, & \text{if n is odd} \\ \frac{\sqrt{n^2+1}+n-1}{2}, & \text{if n is even} \end{cases}$$

Case (i): If n is odd

$$S_r(G) = \begin{cases} 0, \frac{(n-1)}{2} \text{ times} \\ -1, \frac{(n-1)}{2} \text{ times}, when\ n \geq 4 \\ \frac{\pm\sqrt{n^2+3}+n-1}{2}, \text{if n is odd} \end{cases}$$

$$E_r(G) = \left|0 \times \frac{(n-1)}{2}\right| + \left|(-1) \times \frac{(n-3)}{2}\right| + \left|\frac{\pm\sqrt{n^2+3}+n-1}{2}\right|$$

$$= 0 + \frac{(n-3)}{2} + \left|\frac{\sqrt{n^2+3}+n-1}{2}\right| + \left|\frac{-\sqrt{n^2+3}+n-1}{2}\right| = \sqrt{n^2+3} + \frac{n-3}{2}$$

$$E_r(G) = \sqrt{n^2+3} + \frac{n-3}{2}$$

Case (ii): If n is even

$$S_r(G) = \begin{cases} 0, \frac{(n-1)}{2} \text{ times} \\ -1, \frac{(n-1)}{2} \text{ times}, when\ n \geq 5, \\ \frac{\pm\sqrt{n^2+1}+n-1}{2}, \text{if n is even} \end{cases}$$

$$E_r(G) = \left|0 \times \frac{(n-2)}{2}\right| + \left|(-1) \times \frac{(n-2)}{2}\right| + \left|\frac{\pm\sqrt{n^2+1}+n-1}{2}\right|$$

$$= 0 + \frac{(n-2)}{2} + \left|\frac{\sqrt{n^2+1}+n-1}{2}\right| + \left|\frac{-\sqrt{n^2+1}+n-1}{2}\right| = \sqrt{n^2+1} + \frac{n-2}{2}$$

$$E_r(G) = \sqrt{n^2+1} + \frac{n-2}{2}$$

Hence, the rebellion energy of the graph K_n is

$$E_r(G) = \begin{cases} \sqrt{n^2+3} + \frac{n-3}{2}, & \text{if n is odd} \\ \sqrt{n^2+1} + \frac{n-2}{2}, & \text{if n is even} \end{cases}$$

Example 2.6:

Figure 2:K_4

For the graph $G = K_4$ in Figure 2,the $\alpha_r(G)$-set,$R = \{v_1, v_2\}$and hence $\alpha_r(G) = 2$.

$A_r(G) = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{pmatrix}$. It gives $f_r(G) = \lambda^4 - 2\lambda^3 - 4\lambda^2 + 4\lambda + 1 = 0.$

From $A_r(G)$, we get the followings

$(i) S_r(G) = 0, -1, \frac{\pm\sqrt{17}+3}{2}$
$(ii) |A_r(G)| = 0$
$(iii)\ Trace\big(A_r(G)\big) = 2$
$(iv)\ Rank\big(A_r(G)\big) = 3$
$(v) \beta_r^{\lambda}(G) = 2$
$(vi) \rho_r(G) = 3.561$
$(vii)\ \delta_r(G) = 3.561$

$$(vii)\ E_r(G) = |4 \times 0| + \left|\frac{3}{2} \times -1\right| + \left|\frac{-\sqrt{17}+3}{2}\right| + \left|\frac{\sqrt{17}+3}{2}\right| = 5.6231$$

Hence, the rebellion energy of the graph K_4 is 5.6231.

Theorem 2.7: Forthe complete bipartite graph$K_{n,n}$, $n \geq 3$, the rebellion energy is $E_r\big(K_{n,n}\big) = \sqrt{(2n)^2 + 1} + (n-1)$.
Proof: Let G be a complete bipartite graph $K_{n,n}$with at least three vertices and $(G) = \{v_1, v_2, \ldots, v_p\}$. The rebellion set $R$of G is,$R = \{v_1, v_2, v_3, , , v_n\}$. Then, it gives the rebellion adjacency matrix as,

$$A_r(G) = \begin{pmatrix} 1 & 0 & 0 & 0 \ldots\ldots\ldots & 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & 0 \ldots\ldots\ldots & 1 & 1 & 1 & 1 \\ 0 & 0 & 1 & 0 \ldots\ldots\ldots & 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 1 \ldots\ldots\ldots & 1 & 1 & 1 & 1 \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ 1 & 1 & 1 & 1 \ldots\ldots\ldots & 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 \ldots\ldots\ldots & 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 \ldots\ldots\ldots & 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 \ldots\ldots\ldots & 0 & 0 & 0 & 0 \end{pmatrix}$$

Then the characteristic equation of $A_r(G)$ is

$$f(A_r(G)) = \begin{vmatrix} \lambda-1 & 0 & 0 & 0 \ldots\ldots\ldots & -1 & -1 & -1 & -1 \\ 0 & \lambda-1 & 0 & 0 \ldots\ldots\ldots & -1 & -1 & -1 & -1 \\ 0 & 0 & \lambda-1 & 0 \ldots\ldots\ldots & -1 & -1 & -1 & -1 \\ 0 & 0 & 0 & \lambda-1 \ldots\ldots\ldots & -1 & -1 & -1 & -1 \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ -1 & -1 & -1 & -1 \ldots\ldots\ldots & \lambda & 0 & 0 & 0 \\ -1 & -1 & -1 & -1 \ldots\ldots\ldots & 0 & \lambda & 0 & 0 \\ -1 & -1 & -1 & -1 \ldots\ldots\ldots & 0 & 0 & \lambda & 0 \\ -1 & -1 & -1 & -1 \ldots\ldots\ldots & 0 & 0 & 0 & \lambda \end{vmatrix} = 0$$

From the characteristic equation of $A_r(G)$, we get the followings,

$(i)\ S_r(G) = \begin{cases} 0, \text{ (n} - 1) \text{ times} \\ 1 \quad , \text{ (n} - 1) \text{ times} \\ \frac{\pm\sqrt{(2n)^2+1}+1}{2} \quad , \text{each n for one time} \end{cases}$

$(ii)|A_r(G)| = 0$

$(iii)\ Trace\big(A_r(G)\big) = n$

$(iv)\ Rank\big(A_r(G)\big) = n + 1$

$(v)\ \beta_r^{\lambda}(G) = n$

$(vi)\rho_r(G) = \delta_r(G) = \frac{\sqrt{(2n)^2+1}+1}{2}$

$(vii)\ \delta_r(G) = \frac{\sqrt{(2n)^2+1}+1}{2}$

$(viii)\ E_r(G) = |0 \times \text{ (n} - 1) | + |(1) \times \text{ (n} - 1) | + \left| \frac{\pm\sqrt{(2n)^2+1}+1}{2} \right|$

$= 0 + \text{ (n} - 1) + \left| \frac{\sqrt{(2n)^2+1}+1}{2} \right| + \left| \frac{-\sqrt{(2n)^2+1}+1}{2} \right|$

$E_r(G) = \sqrt{(2n)^2+1} + \text{ (n} - 1)$

Example 2.8:

Figure3:$K_{4,4}$

For the graph$G = K_{4,4}$ in Figure 3,the $\alpha_r(G)$-set,$R = \{v_1, v_2, v_3, v_4\}$and hence$\alpha_r(G) = 4$.

$$A_r(G) = \begin{pmatrix} 1&0&0&0&1&1&1&1 \\ 0&1&0&0&1&1&1&1 \\ 0&0&1&0&1&1&1&1 \\ 0&0&0&1&1&1&1&1 \\ 1&1&1&1&0&0&0&0 \\ 1&1&1&1&0&0&0&0 \\ 1&1&1&1&0&0&0&0 \\ 1&1&1&1&0&0&0&0 \end{pmatrix}.$$

It gives $f_r(G) = \lambda^8 - 4\lambda^7 - 10\lambda^6 + 50\lambda^5 - 47\lambda^4 - 48\lambda^3 + 16\lambda^2 + 16\lambda = 0$.

From $A_r(G)$, we get the followings,

$(i)\ S_r(G) = (0)^3, (1)^3, \frac{\pm\sqrt{65}+1}{2}$

$(ii)|A_r(G)| = 0$

$(iii)\ Trace\big(A_r(G)\big) = 4$

$(iv)\ Rank\big(A_r(G)\big) = 5$

$(v)\ \beta_r^{\lambda}(G) = 4$

$(vi)\rho_r(G) = 4.5311$

$(vii)\ \delta_r(G) = 3.5311$

$(viii)E_r(G) = 11.062$

Hence the rebellion energy for the $K_{4,4}$ complete bipartite graph is 11.062.

Theorem 2.9: For $n \geq 3$ the rebellion energy of the crown graph $C_r(n)$ is equal to $E_r(C_r(n)) = \sqrt{(2n-2)^2+1} + \sqrt{5}(\text{n} - 1)$

Proof: Let G be a complete graph $C_r(n)$with at least three vertices and $V(G) = \{v_1, v_2, \ldots, v_p\}$. The rebellion set R of G is,$R = \{v_1, v_2, v_3, , , v_n\}$. Then, it gives the rebellion adjacency matrix as,

$$A_r(G) = \begin{pmatrix} 1 & 1 & 1 & 1 \dots\dots\dots & 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 1 \dots\dots\dots & 1 & 1 & 0 & 1 \\ 1 & 1 & 1 & 1 \dots\dots\dots & 1 & 0 & 1 & 1 \\ 1 & 1 & 1 & 1 \dots\dots\dots & 0 & 1 & 1 & 1 \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ 1 & 1 & 1 & 0 \dots\dots\dots & 0 & 1 & 1 & 1 \\ 1 & 1 & 0 & 1 \dots\dots\dots & 1 & 0 & 1 & 1 \\ 1 & 0 & 1 & 1 \dots\dots\dots & 1 & 1 & 0 & 1 \\ 0 & 1 & 1 & 1 \dots\dots\dots & 1 & 1 & 1 & 0 \end{pmatrix}$$

Then the characteristic equation of $A_r(G)$ is

$$f(A_r(G)) = \begin{vmatrix} \lambda-1 & -1 & -1 & -1 \dots\dots\dots & -1 & -1 & -1 & -1 \\ -1 & \lambda-1 & -1 & -1 \dots\dots\dots & -1 & -1 & -1 & -1 \\ -1 & -1 & \lambda-1 & -1 \dots\dots\dots & -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & \lambda-1 \dots\dots\dots & -1 & -1 & -1 & -1 \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ -1 & -1 & -1 & 0 \dots\dots\dots & \lambda & -1 & -1 & -1 \\ -1 & -1 & 0 & -1 \dots\dots\dots & -1 & \lambda & -1 & -1 \\ -1 & 0 & -1 & -1 \dots\dots\dots & -1 & -1 & \lambda & -1 \\ 0 & -1 & -1 & -1 \dots\dots\dots & -1 & -1 & -1 & \lambda \end{vmatrix} = 0$$

From the characteristic equation of $A_r(G)$, we get the followings,

$$(i)\ S_r(G) = \begin{cases} \dfrac{\pm\sqrt{(2n-2)^2+1}+1}{2}, & each\ for\ one\ time \\ \left(\dfrac{\pm\sqrt{5}+1}{2}\right), & for\ (n-1) times \end{cases}$$

$$(ii)|A_r(G)| = \begin{cases} (1-n)^2, & if\ n\ is\ even \\ (n-1)^2, & if\ n\ is\ odd \end{cases}$$

$(iii)\ Trace\big(A_r(G)\big) = n$

$(iv)\ Rank\big(A_r(G)\big) = 2n$

$(v)\ \beta_r^{\lambda}(G) = n$

$(vi)\rho_r(G) = \frac{\sqrt{(2n-2)^2+1}+1}{2}$

$$(vii)\ \delta_r(G) = \frac{\sqrt{(2n-2)^2+1}-\sqrt{5}}{2}$$

$$(viii)\ E_r(G) = \left|\left(\frac{\pm\sqrt{5}+1}{2}\right)\times\ (\mathrm{n}-1)\right| + \left|\frac{\pm\sqrt{(2n-2)^2+1}+1}{2}\right|$$

$$E_r(G) = \sqrt{(2n-2)^2+1} + \sqrt{5}(\mathrm{n}-1)$$

Example 2.10:

Figure 4:$C_r(4)$

For the graph $G = C_r(4)$ in figure 4,the $\alpha_r(G)$-set,$R = \{v_1, v_2, v_3, v_4\}$and hence $\alpha_r(G) = 4$.

$$A_r(G) = \begin{pmatrix} 1&0&0&0&0&1&1&1 \\ 0&1&0&0&1&0&1&1 \\ 0&0&1&0&1&1&0&1 \\ 0&0&0&1&1&1&1&0 \\ 0&1&1&1&0&0&0&0 \\ 1&0&1&1&0&0&0&0 \\ 1&1&0&1&0&0&0&0 \\ 1&1&1&0&0&0&0&0 \end{pmatrix}.$$

It gives $f_r(G) = \lambda^8 - 4\lambda^7 - 6\lambda^6 + 32\lambda^5 - 5\lambda^4 - 64\lambda^3 + 16\lambda^2 + 48\lambda - 16 = 0$

From $A_r(G)$, we get the followings,

$(i)\ S_r(G) = \frac{\pm\sqrt{37}+1}{2}, , \left(\frac{\pm\sqrt{5}+1}{2}\right)^3$

$(ii)|A_r(G)| = 9$

$(iii)\ Trace\big(A_r(G)\big) = 4$

$(iv)\ Rank\big(A_r(G)\big) = 8$

$(v)\ \beta_r^{\lambda}(G) = 4$

$(vi)\ \rho_r(G) = 3.5414$

$(vii)\delta_r(G) = 1.923$

$(vii)E_r(G) = 21.2302$

Hence the rebellion energy for the $C_r(4)$ Crown graph is 21.2302

Theorem 2.11: For thestar graph S_n , $n \geq 2$, the rebellion energy is $E_r(S_n) = n - 1 + \sqrt{4n+1}$.

Proof: Let *G* be a star graph S_n with at least three vertices and $(G) = \{v_1, v_2, \ldots, v_p\}$.The rebellion set *R*of *G* is,$R = \{v_1, v_2, v_3, , , v_n\}$. Then, it gives the rebellion adjacency matrix as,

$$A_r(G) = \begin{pmatrix} 1&1&1&1\ldots\ldots\ldots&1&1&1&1 \\ 1&0&0&0\ldots\ldots\ldots&0&0&0&0 \\ 1&0&0&0\ldots\ldots\ldots&0&0&0&0 \\ 1&0&0&0\ldots\ldots\ldots&0&0&0&0 \\ .&.&.&.&.&.&.&. \\ .&.&.&.&.&.&.&. \\ .&.&.&.&.&.&.&. \\ 1&0&0&0\ldots\ldots\ldots&0&0&0&0 \\ 1&0&0&0\ldots\ldots\ldots&0&0&0&0 \\ 1&0&0&0\ldots\ldots\ldots&0&0&0&0 \\ 1&0&0&0\ldots\ldots\ldots&0&0&0&0 \end{pmatrix}$$

Then the characteristic equation of $A_r(G)$ is

$$f(A_r(G)) = \begin{vmatrix} 1-\lambda&1&1&1\ldots\ldots\ldots&1&1&1&1 \\ 1&1-\lambda&0&0\ldots\ldots\ldots&0&0&0&0 \\ 1&0&1-\lambda&0\ldots\ldots\ldots&0&0&0&0 \\ 1&0&0&1-\lambda\ldots\ldots\ldots&0&0&0&0 \\ .&.&.&.&.&.&.&. \\ .&.&.&.&.&.&.&. \\ .&.&.&.&.&.&.&. \\ 1&0&0&0\ldots\ldots\ldots&-\lambda&0&0&0 \\ 1&0&0&0\ldots\ldots\ldots&0&-\lambda&0&0 \\ 1&0&0&0\ldots\ldots\ldots&0&0&-\lambda&0 \\ 1&0&0&0\ldots\ldots\ldots&0&0&0&-\lambda \end{vmatrix} = 0$$

From the characteristic equation of $A_r(G)$, we get the followings,

$$(i)\ S_r(G) = \begin{cases} 1 & , \text{(n} - 1) \text{ times} \\ \frac{\pm\sqrt{4n}+1}{2}, & \text{each n for one time} \end{cases}$$

$(ii)|A_r(G)| = -n$
$(iii)\ Trace(A_r(G)) = n$
$(iv)\ Rank(A_r(G)) = n+1$
$(vi)\rho_r(G) = \frac{\sqrt{4n+1}+1}{2}$
$(v)\ \beta_r^{\lambda}(G) = n$
$(vii)\ \delta_r(G) = \frac{\sqrt{4n+1}+1}{2} - 1$

$$(viii)\ E_r(G) = |(n-1)| + \left|\frac{+\sqrt{4n+1}+1}{2}\right| + \left|\frac{-\sqrt{4n+1}+1}{2}\right|$$

$E_r(G) = n - 1 + \sqrt{4n+1}$

Example 2.12:

Figure 5:S_3

For the graph S_3 in Figure 5,the $\alpha_r(G)$-set,$R = \{v_2, v_3, v_4\}$and hence $\alpha_r(G) = 3$.

$A_r(G) = \begin{pmatrix} 0 & 1 & 1 & 1 \\ 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \end{pmatrix}$. It gives $f_r(G) = \lambda^4 - 3\lambda^3 - \lambda^2 + 3\lambda + 2 = 0$

From $A_r(G)$, we get the followings

$(i)\ S_r(G) = 1^{(n-1)}, \frac{\pm\sqrt{4n+1}+1}{2}$
$(ii)|A_r(G)| = -3$
$(iii)\ Trace(A_r(G)) = 3$
$(iv)\ Rank(A_r(G)) = 4$
$(v)\ \beta_r^{\lambda}(G) = 3$
$(vi)\rho_r(G) = \frac{\sqrt{13}+1}{2}$
$(vii)\ \delta_r(G) = \frac{\sqrt{13}+1}{2} - 1$
$(viii)E_r(G) = 5.6056$

The following theorem gives both lower and upper bound for the rebellion energy in terms of $\boldsymbol{p}, \boldsymbol{q}$ and rebellion number$\boldsymbol{\alpha_r(G)}$.

Theorem 2.13: If $\lambda_1^r, \lambda_2^r, \ldots . \lambda_p^r$ are the eigen values of rebellion adjacency matrix $A_r(G)$ then, $(i)\beta_r^{\lambda}(G) = \alpha_r, (ii)\left(\beta_r^{\lambda}(G)\right)^2 = 2|q| + \alpha_r$, where $\beta_r^{\lambda}(G)$ is the sum of the eigen value.

Proof: (i)Since the sum of the eigenvalues of a matrix is equal to its trace, we have$\beta_r^{\lambda}(G) = trace(A_r(G)) = \sum_{i=1}^{p} v_{ii} = \alpha_r$.

(ii)Similarly,$\left(\beta_r^{\lambda}(G)\right)^2 = trace(|A_r(G)|^2)$,

$$\left(\beta_r^{\lambda}(G)\right)^2 = \sum_{i=1}^{p}(v_{ii})^2 + \sum_{i\neq j} v_{ij}v_{ji}$$

$$= \sum_{i=1}^{p}(v_{ii})^2 + 2\sum_{i<j}(v_{ii})^2$$

$\left(\beta_r^{\lambda}(G)\right)^2 = 2|q| + \alpha_r$

Theorem 2.14: Let G be a simple graph with p vertices and q edges. If $E_r(G)$ be the rebellion energy value with cardinality $\alpha_r(G)$ and$\mathcal{P} = |A_r(G)|$. If $\lambda_1^r, \lambda_2^r, \ldots \lambda_p^r$ be the eigen values of $A_r(G)$ then, $\sqrt{\left((2q+\alpha_r)+p(p-1)\mathcal{P}^{\frac{2}{p}}\right)} \leq E_r(G) \leq \sqrt{(p(2q+\alpha_r))}$,where $\alpha_r(G)$ is a rebellion number.

Proof: In the Cauchy Schwarz inequality $(\sum_{i=1}^p u_i v_i)^2 \leq (\sum_{i=1}^p u_i^2)(\sum_{i=1}^p v_i^2)$

Take $u_i = 1, v_i = |\lambda_i^r|$ then $(\sum_{i=1}^p |\lambda_i^r|)^2 \leq (\sum_{i=1}^p 1)(\sum_{i=1}^p (\lambda_i^r)^2)$

$$[E_r(G)]^2 \leq p(2q+\alpha_r)$$

$$\Rightarrow E_r(G) \leq \sqrt{(p(2q+\alpha_r)}(1)$$

Since the arithmetic mean is always greater than or equal to the geometric mean gives

$$\frac{1}{p(p-1)}\sum_{i\neq j}|\lambda_i^r||\lambda_j^r| \geq \left[\prod_{i\neq j}|\lambda_i^r||\lambda_j^r|\right]^{\frac{1}{p(p-1)}}$$

$$= \left[\prod_{=1}||^{2(-1)}\right]^{\frac{1}{(-1)}}$$

$$= [\prod_{=1}||]^{\frac{2}{-}} = |\prod_{=1}|^{\frac{2}{-}}$$

$$= (\text{Absolute value of } |()|)^{\frac{2}{-}} = ^{\frac{2}{-}}$$

$$\sum_{\neq}|||| \geq (-1)^{\frac{2}{-}}$$

Now consider, $[()]^2 = (\sum_{=1}||)^2$

$$= (\sum_{=1}||)^2 + \sum_{\neq}||||$$

$$[()]^2 \geq (2q+\alpha_r) + p(p-1)\mathcal{P}^{\frac{2}{p}}$$

$$(ie)E_r(G) \geq \sqrt{((2q+\alpha_r)+p(p-1)\mathcal{P}^{\frac{2}{p}})} \qquad (2)$$

Equations (1) and (2) gives,

$$\sqrt{\left((2q+\alpha_r)+p(p-1)\mathcal{P}^{\frac{2}{p}}\right)} \leq E_r(G) \leq \sqrt{\left(p(2q+\alpha_r)\right)}.$$

Theorem 2.15: Let G be a graph with rebellion set R.If the rebellion energy $E_r(G)$ is a rational number, then $E_r(G) \equiv |R|(mod2)$.

Proof: Let $\lambda_1^r, \lambda_2^r \ldots \lambda_p^r$ be a eigen values of $A_r(G)$of G,where $\lambda_1^r, \lambda_2^r \ldots \lambda_p^r$ are positive and the remaining are non-positive. Then, $\beta_r^{|\lambda|}(G) = \left(\lambda_1^r + \lambda_2^r + \cdots + \lambda_p^r\right) - \left(\lambda_{k+1}^r + \ldots \ldots \lambda_p^{ra}\right)$

Here, $\beta_r^{|\lambda|}(G)$sum of all absolute value of eigen value.

$$\beta_r^{|\lambda|}(G) = 2(\lambda_1^r + \lambda_2^r + \cdots + \lambda_k^r) - \left(\lambda_{k+1}^r + \ldots \ldots \lambda_p^r\right)$$

Since,$\beta_r^{|\lambda|}(G) = E_r(G)$ gives, $E_r(G) = 2(\lambda_1^r + \lambda_2^r + \cdots + \lambda_k^r) - \sum_{i=1}^p \lambda_i^r$

$$E_r(G) = 2(\lambda_1^r + \lambda_2^r + \cdots + \lambda_k^r) - |R|$$

Hence, $E_r(G) \equiv |R|(mod2)$.

CONCLUSION

In this study, we introduced a new energy of a graph, namely the rebellion energy of graphs and discussed its basic properties. The rebellion adjacency matrix was defined and its spectral characteristics were analyzed. The relationship between rebellion energy, eigenvalues and graph spectrum was explained using examples and theoretical results. This study shows that rebellion energy provides a new way to understand the structure and connectivity of graphs. The results strengthen the role of modified adjacency matrices in algebraic graph theory and highlight their importance in spectral analysis. Rebellion energy may also be useful in network analysis and combinatorics for studying graph behavior. The findings give a clear understanding of how spectral properties vary

for different standard graph classes. In future, this work can be extended by deriving more bounds and studying additional classes of graphs.

ABSTRACT

This study looked at the use of several agricultural waste streams as sustainable feedstocks to optimize the manufacture of polylactic acid (PLA). To identify the most effective processing routes, materials such as fruit peels, corn kernels, and sugarcane bagasse were divided into groups based on starch, cellulose, and oil. To increase the amount of fermentable sugars released, the study used a combination of enzymatic and acid hydrolysis. The use of microbial consortia specifically, homofermentative Lactobacillus species and specialized fungi was heavily emphasized since it improved polymer buildup and metabolic efficiency. The results showed that cellulose-incorporated feedstocks offered superior mechanical strength, even if starch-based composites produced higher yields. Notwithstanding preprocessing and moisture resistance issues, the integrated method produced a circular economy model that was affordable. The study concluded that optimizing fermentation parameters and microbial synergy could produce high molecular-weight bioplastics capable of degrading within 90 days, offering a viable alternative to petroleum-based polymers.

Keywords: Sustainability, renewable plastics, starch-based bioplastics, cellulose-based feedstock, poly lactic acid.

INTRODUCTION

Researchers are investigating the possibility of using agricultural residues as raw materials for the development of bioplastics as a result of the urgent need to switch to sustainable alternatives owing to the worldwide plastic pollution disaster. The conversion of "trash" into useful polymers has emerged as a key component of the circular economy in recent years. This study examined the feasibility of producing polylactic acid (PLA) from common waste materials such as dragon fruit, potato, and cucumber peels in addition to sugarcane bagasse and groundnut shells. The high levels of cellulose and starch in these materials were chosen especially because they provided the necessary carbon sources for microbial fermentation. To create high quality feedstock, researcher began first to clean and dry organic waste to separate away impurities and moisture. Then the material was ground into a fine powder , which helped to increased the surface area and ensured the breakdown was effective.The study categorized these feedstocks into three categories which included oil-based and cellulose-based and starch-based materials. The study found different groups needed different treatment methods for their respective conditions, Starch-based feedstocks provided effective initial yield results while cellulose-based resources created stronger and more durable bioplastic products, which researchers wanted to produce. Hydrolysis processes used specific control methods to convert complex polymers into fermentable sugars.

Carbohydrates were broken down using diluted sulfuric acid, which then neutralized to a pH of 6.5 to 7 because Lactobacillus bacteria are sensitive at that range. In other instances when feedstocks were combined, the researchers achieved full decomposition by using acid hydrolysis in conjunction with enzymatic cellulase and amylase treatment. Although it was more expensive to adopt, the dual strategy improved the amount of sugar produced for fermentation. Microbial consortia perform better than conventional monoculture systems, according to the study. By combining the metabolic capabilities of several bacteria and fungi, the process was able to use a variety of inexpensive substrates and become more resilient to environmental changes. The strong enzymatic capability required for eAective lactic acid generation was supplied by these consortia, which included bacteria like Cupriavidus and Pseudomonas. High-molecular-weight PLA was eventually produced by the fermentation stage's L-lactide ring-opening technique, which circumvents the drawbacks of conventional condensation and opens the door to bioplastics robust enough for demanding applications in the packaging and medical sectors.

The production of bioplastics from agricultural waste was a promising approach to reducing plastic pollution (Xin *et al.*,2020). In a previous study, various plant-based materials were selected for bioplastic production due to their high starch and cellulose content (Eashaet *al*., 2022). The materials chosen included dragon fruit peels, apple peels, potato peels, cucumber peels, corn kernels, sugarcane bagasse, and groundnut shells (Adegboye *etal*.,2021). These materials were cleaned, air-dried, and oven-dried to remove moisture and contaminants. The dried materials were then ground into a fine powder to increase their surface area, making hydrolysis more efficient (Samir*etal*.,2013). The samples can be widely categorised into 3 categories, starch based, cellulose based, and oil based feedstock. The method of hydrolysis, microbial consortia, and fermentation parameters depend on the sample used thus needs to selected with the end product in mind (Adegboye *et al* .,2021). Starch based feedstocks have shown to be easier to process and are more yielding and cellulose based feedstocks are proven to have more mechanical strength (Samir*etal*.,2013).

Hydrolysis

Hydrolysis breaks down the complex sugars in the feedstock and produces fermentable simple sugars such as glucose and lactose. These can be easily utilized by the microbe to produce lactic acid. In a study, acid hydrolysis was performed with 10% dilute sulfuric acid to break down complex carbohydrates into simpler fermentable sugars (Rai et al., 2023). A 1:10 ratio of material to liquid was used to ensure adequate acid penetration without over-dilution. The mixtures were autoclaved at 121°C for 15 minutes to sterilize the solution and accelerate hydrolysis. After autoclaving, the hydrolyzed mixture was cooled, filtered, and neutralized to an optimal pH range of 6.5 to 7 (Aditiya

et al., 2016). This pH range was critical for efficient fermentation by Lactobacillus bacteria, which are sensitive to extreme pH levels. This type of hydrolysis is preferred in starch-based feedstock and seems to yield ideal results. An alternative to this is enzymatic hydrolysis, where enzymes such as cellulase and amylase are used to degrade sugar polymers (Somnath *et al*., 2017). This approach is costly but is more yielding than acid hydrolysis. In a different study, the samples were not separated into categories, meaning the feedstock consisted of cellulose, starch, and oil-based sources, acid hydrolysis with sulfuric acid was followed by enzymatic hydrolysis to ensure complete degradation of the sample, thus enhancing the yield(Aashi,2023). This works well in situations where sorting samples isn't an option, as it allows for the highest possible yield.

Microbial Consortia

Microbial consortia have been essential to the development of bioplastics because they streamline the production process and increase yields. Since they produce a lot of lactic acid and produce fewer byproducts, homofermentative bacterialike strains of the Lactobacillus genushave long been employed in monocultures (Paswan, Meenakshi et al., 2023). Since it can adapt to changing environmental circumstances and use a variety of substrates, incorporating mixed microbial consortia has drawn attention (Jianlei Yang *et al*., 2024). The mixed cultures that received treatment through volatile fatty acids showed their ability to produce polymers through an extreme increase in their polymer production capability. The success of the project depended on three microorganisms, which included Cupriavidus, Pseudomonas, and heat-tolerant Bacillales, because they supplied all necessary enzymes to create PLA essential components (Salini *et al*., 2024). The researchers established a microbial consortium, which required multiple microorganisms from the fungal and bacterial groups to produce bioplastics through their compounds. The first strain effectively broke down complex polymers into fermentable sugars, which the second strain used to produce lactic acid, which serves as a PLA precursor(Shokunbi *et al*.,2025). The system enabled users to process various low-cost agricultural waste materials through an efficient system that accelerated material usage. The production process for commercial applications achieved improved sustainability and economic viability through this collaborative method, which reduced pre-treatment needs and decreased waste generation (Sneha *et al*., 2017).

Fermentation

Bioplastics are produced via the fermentation process, which gives them a truly sustainable nature. The process starts in a bioreactor, where the environment is carefully controlled to keep the microbes happy and productive.This includes modifying temperature, acidity, and ventilation(Verma *et al*., 2016). However, agricultural waste such as maize stalks or starch must first undergo enzymatic hydrolysis in order for the bacteria to begin their activity. Complex plant fibers are broken down in this stage into simple sugars that the bacteria can eat. We employ a variety of techniques, from straightforward batches to continuous systems that keep the manufacturing line running around the clock, depending on how much plastic we need to create (Valdivieso *et al*., 2023).

Chemical synthesis and bacterial fermentation are the processes used to produce lactic acid (LA). Due to its high costs, low efficiency, and difficulty in synthesizing the desired isomer, chemical synthesis is limited(Babu *et al*.,2013).Whether homofermentative or heterofermentative, bacterial fermentation is the method of choice in industry. Under particular pH, temperature, and anaerobic conditions, homofermentative fermentation employs *Lactobacillus* species such as *L. delbrueckii* and *L. amylophilus* to create larger yields of PLA (poly lactic acid)with fewer by-products (Emadian*et al*.,2017). Since straight condensation is ineffective at producing high molecular weight LA because of difficulties with water removal, PLAis usually polymerized via the L-lactide ring-opening technique (Lasprilla *et al*.,2012). In industrial applications, the ring-opening method is the preferred technique since it makes use of catalysts to produce high molecular weight PLA efficiently. (Calabro*et al*., 2019). While some research concentrated on single-strain fermentation techniques, others showed that mixing *Lactobacillus sp*. Higher yields of lactic acid were obtained with fungal strains. Chemical synthesis was then used to polymerize the lactic acid into PLA (Jiménez *et al*.,2019).

Current Challenges and Future Perspectives

Due to the substantial preprocessing needed for agricultural leftovers, scaling up the manufacturing of bioplastics remained a considerable problem despite the advancements. Although bioplastics mechanical qualities improved, they still fell short of petroleum-based polymers strength and water resistance (de Souza*et al.*, 2024). Future research focused on enhancing digestibility of cellulose-based materials, developed particular microbial strains for greater efficiency, and optimized feedstock production. Additionally, ensured these materials future viability as an environmentally responsible replacement required assessing their life cycle effects and carbon footprint (Javaid *et al*., 2023). There was many technological barriers preventing widespread application, despite the positive trend toward bioplastics made from agricultural sources. The biggest barrier is the preprocessing stage turning raw husks and peels into useable polymers required a lot of grinding and chemical hydrolysis, which significantly increased the cost and complexity. (Isroi *et al*.,2017).Additionally, with advancements, bioplastics occasionally lacked the high durability and potent water resistance of their petroleum-based competitors. In order to bridge this gap, future research focued on developing composite materials, perhaps by mixing natural fibers with agricultural waste to improve structural stability. Furthermore, we must enhance the application of additives such as oxidized palm oil to boost strength and flexibility without compromising the material's ability to break down (de Souza & Gupta, 2024).

CONCLUSION

The study shows that utilizing agricultural wastes such as bagasse, maize husks, and banana peels contributes towards circular economy. These materials have capability to transform waste into valuable products that break down in 60 to 90 days. These feedstocks such as corn and sugarcane provide stiffness required for more durable packaging, while potato peels serve to the disposable market. Thus we can create a sustainable substitute that is not only environment friendly but also about less expensive than traditional plastics through the combination of performance enhancers and improved bacterial production procedures for PHA.Agricultural bioplastics have the potential to revolutionize our relationship with waste as we advance these production techniques, offering the packaging and healthcare industries a low-carbon, sustainable future.

ABSTRACT

Sustainability is thus a strategic imperative for the rapidly expanding Indian aviation sector, instead of a peripheral issue dotting the path ahead. Using infrastructures, policy, airline action and passenger behaviour, this review looks at the green airport operation and transition to sustainable aviation in India. Drawing from recent academic literature and policy documents, the paper highlights four key transition drivers: renewable energy adoption, efficiency improvement, sustainable aviation fuel development, and stakeholder engagement. According to the review, India has demonstrated visible progress in the areas of solar-powered airport systems, carbon accreditation, digital passenger processing and environmental policy alignment. Nonetheless, other areas are still lacking – social sustainability, standardised metrics, financing and the willingness of passengers to actually change their travel plans as a result of pro-environmental attitudes. The paper ends with a holistic model for fortifying India's green aviation pathway.

Keywords: Sustainable aviation, Green airports, India, Airport operations, Renewable energy, Sustainable aviation fuel, Passenger behaviour, Airport carbon accreditation, Environmental policy, Aviation decarbonization, DigiYatra, Social sustainability

INTRODUCTION

Sustainable Aviation in a Rapidly Expanding Market

The evolution of the Indian aviation sector is in a structural growth phase. As per the ICAO, the DGCA India 2025 vision document states that the number of operational airports in India has increased from 74 in 2014 to 157 in 2024,

and the long-term national vision is 350–400 airports by 2047. It is indeed economically valuable — this growth — but it creates more pressure on the airport system, energy infrastructure, waste recycling, urban mobility and carbon emissions. Against this backdrop, Sustainability-Perspective can cease to be just yet another facet of corporate social responsibility; it would be an enduring planning principle for the future of Indian Aviation (International Civil Aviation Organisation [ICAO], 2025b).

Airport Sustainability as a Multidisciplinary Question

Airport sustainability is a non-technical domain. It brings together environment engineering, transport management, energy planning, business governance and traveller behaviour. Greer et al. (2020) contend that airports are among the most complex socio-technical systems, and airport buildings local to the land-side and air-side footprint are only part of a larger system which includes integrated physical activity based on airside operations, accessibility to and from landside, energy supply, noise, and water, among others. Subsequent reviews confirm that sustainability at airports should use environmental, economic, and social pillars instead of carbon metrics (Jia et al, 2023; Raimundo et al, 2023). This interdisciplinary nature of the topic certainly justifies IJONS, which encompasses aero science, environmental science, economic science and social science.

Need for an India-Focused Review

While literature on airport sustainability is developing worldwide, India needs special attention as it is the only country in the world where both high passenger growth and extensive infrastructure expansion are observed, especially in the context of regional connectivity policies and national climate commitments. India's announcement updated its NDC, which committed the country to a 45% cut in the emissions intensity of GDP by 2030 from 2005 levels, and about 50% cumulative installed electric power capacity from non-fossil-fuel sources by 2030, all while progressing towards net zero by 2070 Such macro commitments indirectly affect aviation policy through pathways like renewable electricity, energy efficiency, green mobility, and low carbon fuels7. Concurrently, India has gained relevance as a test case for green airport transitions with solar airports, EV's, digital passenger processing, water recycling, and SAF feasibility planning initiatives (Airports Authority of India [AAI], 2022; ICAO 2025a, 2025b).

BACKGROUND / LITERATURE REVIEW

Global Understanding of Airport Sustainability

There are indeed interesting trends observable in modern airport sustainability literature that indicate a positive movement away from compliance-based environmental management toward more comprehensive systems-based governance. Greer et al. Airport environmental sustainability as a topic goes beyond the mere analysis of airport greenhouse gas emissions, energy consumption, pavement materials, water and air quality, according to (2020), and many studies in the field of airport environmental sustainability remain fragmented rather than integrated (2020). This fragmentation is more evident in sustainability assessment, where Jia et al. Compare the studies which (2023) stated that most studies develop their own metrics и therefore different metrics will define the development of air quality characterisations for different airports. How do we know what to believe about our airports, when there are no standard frameworks behind them, creating a fundamental methodological challenge — airports can show progress, but that progress is often calculated in different ways from context to context.

Raimundo et al. Building on this, (2023) presented an in-depth overview of airport sustainability research, which not only encompasses airport-wide sustainability but also topics such as green buildings, accommodation comfort, renewable energy, water savings, business models and ESG-oriented management practices. The review points out that trade-offs between the three pillars of sustainability should receive more consideration in future research. This might mean a new airport that achieves better energy performance, at a higher capital cost, or improves efficiency of operation at the expense of social inclusion and worker welfare, for example. This is a pertinent observation for Indian airports, which are presently facing per-passenger efficiency challenges on a large scale due to rapid growth in passenger numbers.

Indian Aviation and the Green Transition

The sustainability dialogue in India has transitioned from an industry focus, i.e., on the airline, to an ecosystem focus, i.e., on the whole ecosystem. In particular, Thummala and Hiremath (2022) investigated sustainability communication in airlines from India through their websites, annual reports and media messages. The study also found that whilst climate change and aviation emissions are becoming more prominent in industry discussions, the implementation of sustainability proved inconsistent among carriers. This i strongly indicates that the repetition of widespread government involvement in both the institution and the reputation building of green aviation is still an ongoing process in India, but the uneven discrimination clearly indicates that the transition of green aviation in India remains extremely difficult in the cultural environment. Official documents Cet, which is more than one, cannot be ignored and confirms the argument that Indian aviation sustainability has gone from being a mere symbol to being linked to policy. With its Environment Policy, AAI is committed towards energy efficiency, renewable energy, green fuels, electric/ hybrid vehicles, water conservation, recycling, air quality management, and environmentally responsible procurement and operations. This policy is also important because it articulates that sustainability is an operational responsibility permeated in the entire system rather than an isolated environmental department function (AAI, 2022)

Infrastructure and Operational Progress at Indian Airports

The DGCA India paper, which circulated through ICAO in 2025, views India as a model case for sustainable airport operations in the Asia-Pacific region. It mentions Cochin International Airport as the world's first fully solar-powered airport, states that all of India's airports are currently 100% green energy-based, and further mentions that India has 30 carbon-accredited airports, 3 out of 4 Level 5 up-sleeves airports in the Asia-Pacific region. According to the same document, electric vehicle deployment, water harvesting, treated wastewater reuse, AI-based parking management, biometric passenger processing through DigiYatra, and collaborative decision-making systems "are proof that green airport operations now go beyond electricity generation to the design and operational efficiency of services" (ICAO, 2025b).

Passenger Behaviour and Social Sustainability

A major gap in the literature is the gap between environmental attitudes and sustainable travel behaviour. A literature review of air travel behaviour and climate change studies by Gössling (2023) found that demand for air travel is largely determined (and impeded) by lifestyle and affordability, and norms of social behaviour. More recently, a behavioural model was proposed by Laphet et al. Sustainable air travel attitude is strongly influenced by environmental awareness and green trust according to Ref. (2025), but intentions may not become behaviour directly. This also matters because there is an "intention–behaviour gap": the green transition hinges not merely on a matter of technology and regulation, but on the very acceptance by passengers of trade-offs based on price, convenience, time and perceived service quality.

Sustainable Aviation Fuel as a Strategic Frontier

So, while decarbonising ground operations is possible (if airport infrastructure can, indeed, do that), sustainable aviation fuel, if at all, is necessary for greater aviation decarbonisation. ICAO's 2025 India feasibility study (ICAO, 2022c) findings show that India has considerable feedstock potential and could produce sufficient SAF to meet high blending targets, with possible potential for exports as well. The report also finds significant barriers: high cost of production, lack of commercial pathways, heterogeneous supply chains for feedstock, and lack of a strong enough policy architecture for coordination. Suggested innovations detailed in the study include a SAF Council, long-term strategy, harmonised sustainability standards, airport supply-chain demonstrations, and outreach campaigns. This reframes SAF from being simply a technological question into one of governance and market design (ICAO, 2025a).

Objectives

- To examine the relevance of sustainable airport operations within the context of India's rapidly expanding aviation sector.

- To review current academic and policy literature on airport sustainability, green aviation, and passenger behaviour.
- To analyse the main dimensions of India's green aviation transition, including infrastructure, policy, operations, and stakeholder behaviour.
- To propose an integrated discussion framework for future research and policy in Indian aviation sustainability.

METHODOLOGY

The qualitative review that this paper discusses is based on secondary sources. This is an interpretive literature and policy review rather than an econometric or survey-based empirical paper. A systematic search was conducted from the academic research papers on airport sustainability, air travel behaviour, and green aviation, complemented with reviews of AAI, ICAO, and the Government of India policy and institutional documents. A recent selection of sources conceptually relevant to airport infrastructure, environmental management, and decarbonization pathways, as well as passenger response, was chosen for further evaluation. Data extraction was performed through thematic synthesis of the reviewed material. We approximately clustered the literature into four general clusters: environmental infrastructure, airport operations, policy and governance and consumer or passenger behaviour. Second, the sources highlight several common problems like renewable energy, carbon accounting, electrification, digitalisation, SAF, standardisation gaps and social acceptance. Third, these themes were contextualised with respect to the Indian case, with a focus on the interplay between national climate commitments and airport operational practices. This is in line with review-oriented sustainability research synthesising evidence across different methodological traditions (Greer et al., 2020; Jia et al., 2023; Raimundo et al., 2023).

This methodology has its own limitations, as the paper is based on published documents, not on a field survey or primary interviews with airport operators, airline managers or passengers. Nevertheless, the method fits the objective of this paper, which is to compile knowledge, highlight research gaps and contextualise future research instead of arguing for causal measurement. This type of structured review is methodologically appropriate for a journal such as IJONS, which invites contributions of review articles and of multidisciplinary science.

DATA ANALYSIS AND INTERPRETATION / DISCUSSION

Theme 1: Green Airport Infrastructure Is Becoming a Core Competitiveness Factor

It is evident that airport sustainability is taking a more strategic path from peripheral environmental management to strategic infrastructure planning, as shown in the literature. Particularly, renewable electricity, efficient terminal design, electrified ground support systems, and water reuse have become increasingly regarded as operational assets rather than compliance costs. For example, in India, this transition is evident with respect to the primacy accorded to solar generation, green buildings and hybrid or electric mobility in AAI policy and DGCA-ICAO documentation. The Cochin model is particularly important because it illustrates that leadership for the environment can also add brand value and enhance operational resilience, too. Indian airports are thus going beyond regulation-driven performance and competing in sustainability visibility and performance (AAI, 2022; ICAO, 2025). This demonstrates a much broader theoretical claim advanced by Greer et al. (2020): airports need to be regarded as ecosystems, not stand-alone nodes of transport. When energy, pavement, buildings, airside equipment, passenger movement and landside access are managed as a system, that system approach can yield environmental benefits of local, regional and national significance. India has seen my "infrastructure-led sustainability" thesis stand the test of time, where integrated network planners connecting renewable power, digital systems, and mobility planning together with the airport authority at the helm show the strongest position. This integration should not just be constrained to the bigger airports but trickle down to the next level in terms of airport growth, regional connectivity, and long-term national growth programs.

Theme 2: Policy Commitment Is Strong, but Standardised Measurement Remains Weak

Underpinned by a supportive policy architecture in India for environmental transition. A well-suited policy environment for green energy transition, CO_2 mitigation, and green infrastructure development is provided by updated national climate pledges, AAI environment policy, and documents linking aviation to ICAO. However, the academic literature cautions that apparent improvements may in fact be overstated in cases of inconsistent sustainability metrics. Jia et al. Liu et al. (2023) found that in airport sustainability assessment, there often do not appear to be universally adaptable measurement systems. This is critical for India, as airports vary widely in size, ownership model, geographic location and technology maturity. Comparisons between airports, at least the airport level, become reputational rather than analytical.

This is why the next step towards sustainability in Indian aviation should be towards more efficient, standardised, and systematic multi-pillar performance reporting. While carbon accreditation might indeed be a good marker, it is not a marker of sustainability all on its own. Airports Examples: Water Intensity; Waste Recovery; Air Quality; Energy Efficiency per Passenger; Employee Safety; Accessibility; Local Stakeholder Impact (consistent indicators are needed). Publicised sustainability successes might overshadow poor social or governance results; Raimundo et al also share this worry. Rather than assume automatic alignment of environmental and economic outcomes, sustainability frameworks should identify and address trade-offs (Hirschfeld et al.)

Theme 3: Operational Efficiency and Digitalisation Can Deliver Immediate Gains

Among the most compelling pieces of evidence from this Indian case is that it was operational efficiency itself that helped them become more sustainable. The digital boarding systems, facial-recognition travel flows, AI-supported parking management, Airport Collaborative Decision Making, and smart airside operations are able to minimise delays, congestion, and unwanted use of resources. This may not be as grand as a solar megaproject, but together, the impact on emissions, energy consumption, and passenger experience can be large. DigiYatra rollout is significant in this regard as it demonstrates the interplay between passenger convenience and operational sustainability in a mutually reinforcing manner rather than conflicting (ICAO, 2025).

However, a critical appraisal of operational digitalisation is also necessary. Not only should digital systems increase throughput, but avoiding including elderly travellers or first-time flyers, or any group that the context data stream might define as digitally marginalised, can elevate environmental efficiency as a social sustainability sacrifice. Moreover, this is where the literature on airport sustainability becomes critical: it reminds us that airports are public-facing infrastructures with social responsibilities. Therefore, any green airport planning to be done in India in future should take into account the efficiency metrics along with the inclusiveness metrics, especially when aviation is penetrating Tier 2/3 cities and a new segment of passengers.

Theme 4: Passenger Behaviour Is the Missing Link in the Green Transition

Sustainability in aviation cannot be delivered solely by institutions, as evident from the literature. Passenger perceptions affect demand for greener services, acceptability of operational changes, and support for measures, including low-carbon ground access, waste separation, digital documentation, or carbon offsetting. However, behavioural research indicates that environmental concern is still largely theoretical unless transformed into readily available, trusted and affordable options. According to Gössling (2023), air travel is "intricately interwoven into consumption culture and lifestyle aspiration", thus making demand-side transition an arduous task. Laphet et al. (2025) also demonstrate that awareness and trust influence intention, yet intention does not equate to sustainable behaviour. This implies that public messaging matters for Indian aviation. Shallow adoption will only occur if passengers see green aviation as merely a cost transfer or marketing and branding symbol. However, if sustainability is associated with cleaner terminals, faster processing, dependable access to public transport, and open environmental reporting, there could be an increase in acceptance eventually, albeit more slowly. To put it differently, we need to lower the behavioural cost of sustainability on the part of the airport and the airline. Sustainable decisions should be designed as conveniences rather than moral sacrifices if we wish to accelerate the green transition.

Theme 5: SAF Represents the Long-Term Decarbonization Challenge

There is no substitute for lower-carbon fuels — though airport-level measures can massively enhance environmental performance, deep aviation decarbonization depends on it. ICAO's 2025 India SAF study is especially significant as it positions India as a strong producer in future, citing feedstock availability and geographic advantage. However, that report also clarifies that technical viability is not enough on its own. India will require financial assistance, supply-chain integration, sustainability standards that are harmonised with the global requirements and preparedness of airports for blending and distribution. This in turn means that SAF policy must link agriculture with energy, refining, logistics, airport systems, and aviation regulation (ICAO, 2025).SAF, from a policy point of view, reflects the overall trend of aviation sustainability in India: a sound opportunity, an apparent intent, but a clear execution gap, requiring inter-sectoral regulatory effectiveness. Airports can be enabling nodes in this transition by preparing storage, working with airlines and engaging in pilot projects. The future of green aviation in India, therefore, needs to be seen in dual layers of immediate benefits through airport operations and a slow transition through low-carbon fuel ecosystems.

Source: Authors' synthesis based on AAI (2022), Government of India (2022), Greer et al. (2020), ICAO (2025, 2025), Jia et al. (2023), Laphet et al. (2025), Raimundo et al. (2023), and Thummala and Hiremath (2022).

CONCLUSION

The review demonstrates that the realisation of sustainable airport operations in India — a true green airport model — is now more than an abstract ambition. The sustainability profile of Indian airports today is much better than it was 10 years back, thanks to renewable power, electric mobility, wastewater reuse, digital passenger systems and carbon accreditation. Concurrently, several parallel strands of academic literature arrive at the conclusion that airport sustainability must be considered beyond the environmental perspective and at a much broader scope, focusing on governance quality, social inclusion, passenger behaviour, and uniform evaluation frameworks. The reason India's case is promising is that it links infrastructure expansion with environmental transition, but it can only deliver on that promise if it measures performance more consistently and institutionalises green initiatives beyond a few flagship airports.

It also follows another conclusion; the next step of green aviation in India needs to be integrative. Findings from the strongest evidence suggest that operational efficiency and sustainability are not irreconcilable objectives for airports, but that transparent policy and stakeholder trust will support their durable interdependence and mutually reinforcing efforts. Passenger behaviour is still a weak point, and SAF is still a strategic question, and both are not out of reach with the support of long-term planning, clarity in postulated steps and coordinated regulation." Hence, India's green aviation future can be captured through a hybrid mode of sustainable infrastructure, governance and behavioural design, and low-carbon fuel development. This model of research is closely matched to the multidisciplinary focus of IJONS and provides a deep relevance for aero science, environmental science, and social science researchers alike.

Key Terms and Definitions

Sustainable Aviation: The pursuit of aviation growth while reducing environmental harm, improving resource efficiency, and maintaining social and economic viability.

Green Airport: An airport that integrates renewable energy, efficient buildings, low-emission transport, waste reduction, water conservation, and environmentally responsible operations

Sustainable Aviation Fuel (SAF): A non-conventional aviation fuel produced from sustainable feedstocks that can reduce lifecycle greenhouse gas emissions compared with fossil jet fuel.

Airport Carbon Accreditation: An international framework that assesses and recognises airport efforts to map, manage, reduce, and ultimately neutralise carbon emissions.

Passenger Behaviour: The attitudes, intentions, perceptions, and actual travel choices made by air travellers, including their response to sustainable travel options.

Table 1: Thematic Synthesis of Sustainable Aviation Transition in India

Dimension	Key Evidence from Literature and Policy	Major Challenge	Strategic Implication
Renewable energy	Solar airports, green electricity adoption, and energy efficiency initiatives	Uneven implementation across airports	Scale renewable models beyond leading airports
Airport operations	DigiYatra, AI parking, collaborative decision systems, EV deployment	Digital inequality and implementation costs	Link efficiency with inclusive passenger design
Environmental governance	AAI environment policy, carbon accreditation, NDC alignment	Lack of standardised metrics	Create a uniform reporting framework
Passenger behaviour	Awareness and trust matter, but the action gap persists	Cost and convenience barriers	Make green options visible, easy, and affordable
SAF transition	High feedstock potential and export opportunity	Cost, technology maturity, supply chains	Build long-term policy and airport readiness

ABSTRACT

C. curviflora, a medicinal plant belongs to the family Rubiaceae is traditionally used to treat ear and eye disease, headache, skin diseases, ulcers, phlegm, rheumatism, jaundice, pneumonia, wounds and sour throat. Zinc oxide nanoparticles (ZnO-NPs) were biosynthesized usingthis plant extract as a reducing and stabilizing agent. The biosynthesized nanoparticles were characterized by UV–visible spectroscopy, Fourier transform infrared spectroscopy, Scanning electron microscopy, Energy dispersive X-ray analysis and X-ray diffraction. UV-Vis Spectra of ZnO-NPs showed a strong absorption band. FT-IR analysis revealed the presence of functional groups such as hydroxyl, amine and carbonyl groups in nanoparticle stabilization. XRD analysis confirmed the crystalline hexagonal wurtzite structure of ZnO-NPs. SEManalysis validated spherical agglomerated morphology and EDX results verified the elemental compositionwith zinc and oxygen of high purity.The synthesized ZnO-NPs exhibited concentration-dependent antioxidant activity in the DPPH assay and significant anti-inflammatory potential via protein denaturation assay.The current study demonstrated a simple, cost-effective and eco-friendly approach for ZnO-NP synthesis, emphasising their promising antioxidant and anti-inflammatory properties for potential use in pharmaceutical and industrial applications.

Keywords: *C.curviflora*, Green synthesis, Zinc oxide nanoparticle, Antioxidant, Anti-inflammatory, XRD, SEM

INTRODUCTION

In recent years, the green synthesis of metal nanoparticles has emerged as a prominent focus in nanoscience and nanobiotechnology. As particle size decreases, nanoparticles exhibit a higher surface area-to-volume ratio and display diverse morphologies such as nanorods, nanoflowers, nanowires, nanodendrites and spherical nanoparticles [1].Nowadays, increasing attention has been directed toward the biosynthesis of nanoparticles using biological systems. Plants are considered highly suitable candidates due to their efficiency and scalability in nanoparticle production [2]. Plant-mediated nanoparticles are typically more stable and synthesized at a faster rate exhibit greater diversity in size and shape compared to those produced by other biological organisms [3]. As a result, plant-mediated green synthesis has gained prominence as a sustainable alternative and offering improved biocompatibility while minimizing toxic residues [4]. Zinc oxide (ZnO) nanoparticles are widely regarded as non-toxic, biocompatible and biosafe materials. They have found extensive applications across various fields which including semiconductors, magnetic materials, electroluminescent devices, piezoelectric sensors and actuators, nanostructured varistors, field emission displays, thermoelectric systems, gas sensors and cosmetic formulations [5]. In addition to their industrial relevance, ZnO-NPs have been documented to exhibit notable biological activities including antimicrobial [6], antioxidant [7] and anticancer properties [8].

The Rubiaceae family is a large and diverse group comprising approximately 450 genera and around 6500 species including trees, shrubs and herbaceous plants. *Chassalia curviflora* (Wall.) Thwaites, a member of this family is an upright shrub characterized by white or pinkishflowers and glossy black fruits.It is locally known as Vellakurinji, Yamari and Mundanchedi in Malayalam. They were predominantly found in the Western Ghats region of India. The species has a wider geographical distribution extending from India to South China and the Philippines. In India, its occurrence has been documented in regions including Sikkim, Darjeeling, Meghalaya, Maharashtra, Karnataka, the Andaman Islands and the Western Ghats [9]. Traditionally, the plant holds significant medicinal value. A decoction prepared from its roots is used in the treatment of ailments such as rheumatism, pneumonia, malaria, cough, and phlegm [10]. Additionally, both the roots and leaves are applied externally for healing wounds, ulcers and relieving headaches [9].Ethno medicinal practices among the Chakma tribes of Bangladesh involve the use of crushed leaves for treating snake and insect bites. Similarly, the Kani tribes inhabiting the Agasthiyamalai region of Kerala utilize this plant as a remedy for jaundice [10]. Despite its traditional importance, there is a scarcity of detailed studies addressing the nanosynthesis of this species.In this context, the present study focused on the synthesis of ZnO-NPs and were subsequently characterized using UV–Vis spectroscopy, FT-IR, XRD, SEM, EDX and their biomedical potential was evaluated through antioxidant and anti-inflammatory assays.

MATERIALS AND METHODS

Preparation of Leaf Extract

Fresh Leaves of*C. curviflora* were collected from Kalady, Ernakulam District, Kerala, India. They were taxonomically identified and authenticated.The plant material was thoroughly washed under running tap water to eliminate adhering dust and soil particles followed by rinsing with sterile double-distilled water. The cleaned leaves were then shade-dried for approximately 10–15 days to remove residual moisture. Once completely dried, the leaves were pulverized using an electric grinder to obtain a fine powder. The powdered material was subsequently stored in airtight containers.

Preparation of Zinc Oxide Nanoparticles

Zinc oxide nanoparticles (ZnO-NPs) were synthesized using aqueous leaf extract of *C.curviflora.* 0.378 g of zinc oxide was dissolved in 100 mL of Milli-Q water and stirred continuously for 1h using a magnetic stirrer to obtain a homogeneous 0.1 M solution.Subsequently, 80 mL of the prepared zinc oxide solution was mixed with 20 mL of

aqueous leaf extract under constant stirring. 2 M NaOH solution was added drop wise to the reaction mixture until the pH reached 12. Then, the mixturewas stirred for 2h and centrifuged at 4000 rpm for 5 min.The formation of ZnO nanoparticles was preliminarily confirmed by the appearance of a fine white precipitate. The purified precipitate was dried in a hot air oven at 80 °C for 16 hours. Calcination was carried out at 600 °C for 6 hours in a muffle furnace to get crystalline zinc oxide (ZnO) nanoparticles [12].Thereafter, the nanoparticles were characterized using UV–Visible spectroscopy, FT-IR analysis, XRD, SEM and EDX for optical properties, functional groups and surface morphology.

Characterisation

The optical properties of ZnO nanoparticles were analyzed using a UV–Visible spectrophotometer (JASCO V-630). The absorbance spectrum was recorded in the wavelength range of 200–800 nm using a Shimadzu UV-1700 spectrophotometer at a scanning speed of 1 nm [13].The resulting spectra were plotted with wavelength on the x-axis and absorbance on the y-axis to evaluate nanoparticle formation.The spectral analysis was conducted following the procedure described by Kemp [14]. FT-IR spectroscopy was carried out using an IR Affinity-1 spectrophotometer (Shimadzu, Japan) to identify functional groups responsible for reduction and stabilization. Spectra were recorded in the range of 400–4000 cm^{-1} at a resolution of 4 cm^{-1}. The crystalline structure and phase composition was determined using X-ray diffraction (XRD) analysis. The diffraction patterns were recorded using an X-ray diffractometer with Cu-Kα radiation (λ = 1.5406 Å) over a 2θ range of 20°–80°. The crystallite size was estimated using the Debye–Scherrer equation [15]. The surface morphology and particle size were examined using scanning electron microscopy (SEM). The analysis was performed at an accelerating voltage of 20 kV [16].SEM micrographs included embedded details such as applied voltage, magnification and particle size.Elemental composition of the synthesized nanoparticles was evaluated using an EDAX detector attached to the Hitachi S-3400N microscope.

Antioxidant Activity

The antioxidant activity of ZnO-NPs was analyzed by DPPH radical scavenging assay [17]. The ascorbic acid was used as reference standard. The ascorbic acid stock solution was prepared in distilled water (1 mg/ ml; w/v). A 60µM solution of DPPH in methanol was freshly prepared and a 200µl of this solution was mixed with 50µl of test sample at various concentrations of 100, 200, 400, 800 and 1000µg/ml. The plates were kept in the dark for 15 minutes at room temperature and the decrease in absorbance was measured at 515 nm. Control was prepared with DPPH solution only without any extract or ascorbic acid. 95% methanol was used as blank.

Radical scavenging activity was calculated by the following formula,

$$\text{Percentage Inhibition (\%)} = \frac{\text{Absorbance of Control} - \text{Absorbance of Test}}{\text{Absorbance of Control}} \times 100$$

Anti-inflammatory Activity

The anti-inflammatory activity was assessed using the protein denaturation method [18]. The reaction mixture (0.5 mL) consisted of 0.4 mL of bovine serum albumin (3% aqueous solution) and different concentrations of the test sample. The mixture was incubated at 37 °C for 20 minutes.Following incubation, 2.5 mL of phosphate-buffered saline (pH 6.3) was added to each tube and the samples were then heated at 80 °C for 10 minutes. After cooling, the absorbance was measured at 660 nm using a spectrophotometer.

The percentage inhibition of protein denaturation was calculated as follows

$$\text{Percentage Inhibition (\%)} = \frac{\text{Absorbance of Control} - \text{Absorbance of Test}}{\text{Absorbance of Control}} \times 100$$

RESULTS AND DISCUSSION

Biogenic synthesis of ZnO-NPs

Biological synthesis of ZnO-NPs by using *C. curviflora* revealed the pale white voluminous and foamy precipitate. It was milled using mortar and pestle and stored in airtight containers and kept in desiccators for further use. The leaf has been used for the reducing material as well as surface stabilizing agent for the synthesis of spherical shaped ZnO-NPs.

Morphological and structural characterization of nanoparticles

UV- Visible Spectroscopy

UV–Visible spectroscopy was employed to measure the light absorption characteristics of the sample. It serves as an effective tool for the identification and characterization of nanomaterials, providing information on their size, shape, concentration and degree of aggregation.The absorbance of the biosynthesized ZnO nanoparticles was recorded in the wavelength range of 200–800 nm. The spectrum exhibited a distinct absorption peak in the lower wavelength region of 285 nm which confirmed the formation of ZnO nanoparticles(Fig -1) .The absorption peak observed in the ZnO nanoparticle spectrum is consistent with earlier studies, where similar features relative to plant extract have been identified as evidence of nanoparticle formation [19-20]. There was also a strong agreement between the experimental results of Oladiran and Olabisi [21].

FT-IR spectroscopy

FT-IR spectroscopy was employed to identify the functional groupsinvolved in the synthesis and stabilization of zinc oxide nanoparticles. In the present study, the FT-IR spectrum exhibited a wide range of absorption bands spanning from 655.80 cm^{-1} to 3404.36 cm^{-1}(Fig 2). It includes the presence of chemically diverse biomolecules including aromatic, aliphatic, unsaturated, oxygenated and nitrogen-containing compounds. The absorption band observed at 655.80 cm^{-1} was attributed to aromatic C–H out-of-plane bending vibrations. Similarly, the peak at 804.32 cm^{-1} corresponded to C–H out-of-plane bending vibrations. The band at 950.91 cm^{-1} was assigned to =C–H out-of-plane bending vibrations of alkenes [22]. A prominent peak at 1138.00 cm^{-1} was associated with C–O stretching vibrations of alcohols, ethers and glycosidic compounds. The absorption bands at 1311.59 cm^{-1} and 1382.96 cm^{-1} were attributed to CH_3 bending and symmetric bending vibrations of alkanes. The peak at 1649.14 cm^{-1} corresponded to C=C stretching or amide I vibrations of peptides [23]. The absorption bands at 2908.65 cm^{-1} and 2970.38 cm^{-1} were assigned to symmetric and asymmetric C–H stretching vibrations of $–CH_2$ and $–CH_3$ groups of lipids, fatty acids, and long-chain hydrocarbons.Broad and intense absorption bands observed at 3396.64 cm^{-1} and 3404.36 cm^{-1} were attributed to O–H and N–H stretching vibrations of polyphenols, alcohols and proteins [24]. The characteristic vibrational frequencies corresponding to specific chemical bonds provide strong evidence for the role of phytochemicals in mediating nanoparticle synthesis [25]. The observed functional group patterns are in close agreement with previously reported ZnO nanoparticle spectra [26].Beneficial effects of zinc oxide nanoparticles synthesized from the leaf extracts of *Pongamia pinnata* [27] and *Sesbania grandiflora* [28] have been previously documented.

XRD analysis

XRD technique was used for analysing the structural compositions and crystallographic nature, phase purity and crystallite size of green synthesized nanoparticles [29]. The characteristic diffraction peaks were observed at 2θ values of 10.64°, 13.36°, 16.28°, 20.24°, 21.40°, 24.75°, 28.54°, 29.28°, 29.63°, 33.69°, 34.31°, 35.20°, 36.85°, 40.12°, 41.18°, 42.27°, 43.62°, 47.14°, 53.82°, 58.40°, 62.88°, and 74.31° corresponding to interplanar d-spacing values ranging from 8.31 Å to 1.27 Å(Fig -3).All the diffraction peaks matched with the Joint Committee on Powder Diffraction Standards (JCPDS) card no 036-1451 and the plots corresponded to the hexagonal wurtzite structure. No other impurity peaks were observed in the plots [30].The presence of numerous sharp and well-resolved reflections reflected the highly crystalline nature of the synthesized nanoparticles. The observed diffraction pattern is consistent with previously

reported ZnO nanoparticle structures, where characteristic peaks have been indexed to planes corresponding to the hexagonal wurtzite phase of ZnO [31].

SEM imaging

The surface morphology of the biosynthesized zinc nanoparticles was examined using SEM. The SEM micrographs revealed densely packed nanoparticles exhibiting irregular, clustered and granular morphology. The particles were highly aggregated forming compact assemblies. Such aggregation behaviour is commonly reported in plant-mediated nanoparticle synthesis. The particle size was observed to range between 20–80 nm which confirmed their nanoscale dimensions (Fig-4).Comparable findings were documented by Geetha *et al*[32] and Karnan and Selvakumar [33] for ZnO nanoparticles synthesized from *Euphorbia jatropa* and *Nephelium lappaceum*, respectively. The aggregation observed may be due to the high surface energy of ZnO nanoparticles and possible densification caused by the reduced spacing between particles. Rahman *et al*., [34] reported spherical ZnO nanoparticles synthesized using *Ziziphus mauritiana* leaf extract.

EDX analysis

The EDX technique involves the interaction of a focused electron beam with the sample surface which resulting in the emission of characteristic X-rays that provide information about elemental composition [35]. The EDX spectrum of the biosynthesized nanoparticles displayed distinct peaks within the energy range of 1–10 keV with zinc as a major constituent. In the present study, the peak was observed in the region of 0.9–1.1 keV along with an additional peak around 8.6–8.7 keV validating the presence of zinc in the sample (Fig -5). These findings are consistent with previous studies of [36] reported similar elemental composition for ZnO nanoparticles synthesized using *Calotropis gigantea* extract.The presence of oxygen in the spectrum is due to the oxidation of zinc during the biosynthesis process leading to the formation of ZnO [35].

Antioxidant activity

An antioxidant is a substance capable of neutralizing free radicals by donating an electron, thereby stabilizing the reactive species. Compounds with such electron-donating ability convert free radicals into more stable and less reactive forms which effectively interrupting the chain reactions involved in oxidative processes [36].The DPPH molecule is considered a stable free radical due to the delocalization of its unpaired electron across the entire molecule, which prevents dimerization and imparts a deep violet color.Phenolic compounds and flavonoids associated with *Chassalia curviflora* contribute significantly to radical quenching due to their hydrogen-donating and electron-transfer capabilities [37].

The synthesized zinc nanoparticles demonstrated a clear dose-dependent DPPH radical scavenging activity although their efficacy was comparatively lower than the standard antioxidant. The observed antioxidant activity of ZnO nanoparticles can be attributed to the electrostatic interaction between ZnO surfaces and bioactive functional groups such as COO^- present in phytoconstituents (Table-1, Fig-6). Similar findings were reported by Kumar *et al.* [38], who demonstrated that nanoparticles exhibit considerable DPPH radical scavenging activity. Consistent with these observations, Mahdavi *et al*. [39] showed that ZnO nanoparticles synthesized using *Ziziphora clinopodioides* leaf extract displayed significant, concentration-dependent DPPH radical scavenging activity. In the same way, comparable antioxidant effects have been reported for ZnO nanoparticles derived from *Sesbania sesban*extract [40] .However, in some studies, phytosynthesized ZnO nanoparticles have demonstrated superior antioxidant activity compared to ascorbic acid due to synergistic effects between ZnO and plant-derived phytoconstituents, improved dispersion and morphological characteristics such as uniform conical shape [41].

Anti-inflammatory activity

Inflammation is a protective biological response triggered by tissue injury, infection or harmful stimuli, often associated with protein denaturation and activation of immune pathways. Conventional anti-inflammatory agents, including steroidal and non-steroidal drugs, function by suppressing inflammatory mediators and immune

responses [42]. In the present study, the anti-inflammatory activity of ZnO-NPs can be attributed to their ability to inhibit protein denaturation with Diclofenac as the standard reference. The results demonstrated a clear concentration-dependent increase in the percentage inhibition of protein denaturation for all tested samples. The calculated IC_{50} values validated these findings with Diclofenac showing the lowest IC_{50} value of 31.82 μg/mL with highest anti-inflammatory potencywhereas ZnO-NPs showed a comparatively higher IC_{50} value of 63.33 μg/mLwith relatively lower inhibitory effect on protein denaturation (Table-2, Fig-7).

ZnO- NPs displayed a steady and significant increase in inhibition with increasing concentration suggested thatit can effectively modulate inflammatory responses at elevated concentrations. This observation is consistent with earlier findings where ZnO-NPs enhanced anti-arthritic potential by improving protein denaturation [43].The moderate significant inhibition observed at higher concentrations of 100 μg/mL is in agreement with previous reports from *Heritiera fomes* and *Sonneratia apetala* exhibited substantial anti-inflammatory activity of up to 79% [44]. ZnO nanoparticles are known to exert anti-inflammatory effects through multiple molecular mechanisms such as inhibition of myeloperoxidase activity, suppression of the NF-κB signalling pathway, reduction in pro-inflammatory cytokine release and prevention of mast cell degranulation [45]. These mechanisms likely contribute to the progressive increase in inhibition observed with increasing ZnO-NP concentration in the present study.

CONCLUSION

The nanoparticles exhibited well-defined crystalline structure, nanoscale size, characteristic surface morphology and high elemental purity which substantiated the effectiveness of the eco-friendly synthesis approach.FT-IR results confirmedthe role of phytochemicals in nanoparticle formation, stabilization and surface functionalization while XRD and SEM analyses validated their structural integrity and nanoscale features. EDX findings subsequently verified the formation of zinc oxide with minimal impurities.Biological evaluation revealed that ZnO-NPs possess significant antioxidant and anti-inflammatory potential in a dose-dependent manner. The present findings offers several important advantageous features which is economical and eco-friendly, because it involves inexpensive and non-toxic materials for large scale synthesis.

ABSTRACT

This study addresses Multiple Attribute Group Decision Making (MAGDM) problems with intuitionistic fuzzy number-based assessments by utilizing the Intuitionistic Fuzzy Einstein Correlated Geometric (IFECG) operator, capturing both the intrinsic importance and positional order of attributes. To improve computational efficiency and interpretability, a data mining-based dimensionality reduction process is incorporated to remove redundant or weakly influential attributes. Furthermore, to offer a complementary computational perspective and evaluate the robustness of the proposed model, we implement four neural learning paradigms—Perceptron Rule, Delta Rule, Hebbian Learning Rule, and Oja's Rule—on the same decision problem. Comparative analysis of these methods highlights their relative convergence behaviors, learning efficiencies, and adaptability, demonstrating that the proposed framework consistently outperforms conventional models across multiple evaluation criteria. The results confirm that integrating advanced fuzzy aggregation operators, data mining techniques, and diverse neural learning rules provides a powerful and intelligent pathway for the development of efficient and resilient decision support systems.

Keywords: *MAGDM, Choquet integral operator, Data mining, Perceptron Rule, Delta Rule, Hebbian Rule, Oja's Rule*

INTRODUCTION

Decision-making in complex environments often involves multiple, interrelated criteria that cannot be precisely quantified. To address such uncertainty, Multiple Attribute Group Decision Making (MAGDM) models based on intuitionistic fuzzy numbers (IFNs) have become increasingly significant [3,4,5,6]. The present study develops an integrated framework employing both the Choquet integral and the Intuitionistic Fuzzy Ordered Weighted Averaging (IFOWA) operator to balance the relative importance and ranking order of attributes effectively. Furthermore, the model incorporates four distinct neural learning mechanisms—Perceptron, Delta, Hebbian, and Oja's Rules—to strengthen adaptability, convergence, and learning efficiency, forming a hybrid intelligent decision support framework with enhanced precision and stability. The theoretical foundation of intuitionistic fuzzy systems originates from Atanassov [1,2], who generalized Zadeh's fuzzy set concept [18] by defining membership and non-membership degrees for each element, allowing for the explicit representation of hesitation or uncertainty. Building on these foundations, several aggregation mechanisms have been introduced to combine and interpret intuitionistic fuzzy information effectively. Various aggregation operators, pivotal to the decision-making process, have been developed and refined in [12], [13], [14], [16] and [17], providing flexible tools for combining uncertain data across multiple experts and attributes. Research on induced and correlated aggregation operators has further expanded the scope of intuitionistic fuzzy decision-making. In particular, [15] presented correlated aggregation schemes tailored for intuitionistic fuzzy environments, enabling improved modeling of interdependencies between attributes. The growing integration of data mining and statistical learning into fuzzy-based decision systems reflects the increasing demand for data-driven solutions in modern decision analysis. The present work aims to address MAGDM problems for assessing the teaching effectiveness of higher education institutions, using the Intuitionistic Fuzzy Einstein Choquet Geometric (IFECG) operator as a core decision tool. Additionally, it explores the use of data mining strategies for alternative reduction, streamlining the decision-making process in large-scale environments. A related study in [9] proposed the MAGDM-Miner framework, which efficiently extracts correlation rules from trapezoidal intuitionistic fuzzy data, offering significant improvements over conventional Decision Support Systems (DSS), especially in handling voluminous datasets. Similarly, [7] introduced a refined correlation coefficient for both triangular and trapezoidal intuitionistic fuzzy sets, enhancing the precision of similarity measurements in MAGDM scenarios. Further, [10] contributed an innovative approach to derive Trapezoidal Intuitionistic Fuzzy Correlation Rules applicable to eigen-valued MAGDM problems, offering deeper analytical insight into the relationships among decision criteria. In summary, the current research unites these theoretical and computational perspectives into a single hybrid structure, blending fuzzy aggregation with neural adaptive learning. This integration not only enhances decision accuracy and learning efficiency but also contributes to the evolving paradigm of intelligent and interpretable decision support systems.

PRELIMINARIES

Here, there will be presented some definitions and concepts related to the theory developed in the research work.

Intuitionistic Fuzzy set

An intuitionistic fuzzy set is a mathematical construct defined over a universal collection of elements, in which every element is characterized by two quantitative indicators. The first indicator specifies the extent to which the element is regarded as belonging to the set, termed the degree of membership, while the second quantifies the extent to which it is considered not to belong, known as the degree of non-membership. Both indicators take values within the closed interval from zero to one, and their sum does not exceed unity. The portion of uncertainty remaining after accounting for these two measures represents the hesitation margin, which captures the indeterminacy associated with the element's inclusion in the set.

The Intuitionistic Fuzzy Einstein Correlated Geometric (IFECG) operator

Consider a group of intuitionistic fuzzy assessments associated with a particular set of criteria. When a fuzzy measure is assigned to represent the relative importance or influence of these criteria, the Intuitionistic Fuzzy

Einstein Correlated Geometric (IFECG) operator is employed to aggregate the corresponding intuitionistic fuzzy information in accordance with that measure. This operator provides a systematic means of combining multiple intuitionistic evaluations while preserving both the correlation among attributes and the intrinsic uncertainty present in the decision environment.

$$IFECG_{\mu}(\tilde{a}_1, \tilde{a}_2, \dots, \tilde{a}_n)$$
$$= (\tilde{a}_{\sigma(1)})^{(\mu(A_1)-\mu(A_2))} \otimes (\tilde{a}_{\sigma(2)})^{(\mu(A_2)-\mu(A_3))} \otimes \dots \otimes (\tilde{a}_{\sigma(n)})^{(\mu(A_n)-\mu(A_{n+1}))}$$
$$= \overset{n}{\underset{j=1}{\otimes}} (\tilde{a}_{\sigma(j)})^{(\mu(A_{(j)})-\mu(A_{(j+1)}))}$$
$$= \left(\frac{2\prod_{j=1}^{n} \mu_{\sigma(ij)}{}^{(\mu(A_{(j)})-\mu(A_{(j+1)}))}}{\prod_{j=1}^{n}(2-\mu_{\sigma(ij)})^{(\mu(A_{(j)})-\mu(A_{(j+1)}))} + \prod_{j=1}^{n}(\mu_{\sigma(ij)})^{(\mu(A_{(j)})-\mu(A_{(j+1)}))}}, \right.$$
$$\left. \frac{\prod_{j=1}^{n}(1+\nu_{\sigma(ij)})^{(\mu(A_{(j)})-\mu(A_{(j+1)}))} - \prod_{j=1}^{n}(1-\nu_{\sigma(ij)})^{(\mu(A_{(j)})-\mu(A_{(j+1)}))}}{\prod_{j=1}^{n}(1+\nu_{\sigma(ij)})^{(\mu(A_{(j)})-\mu(A_{(j+1)}))} + \prod_{j=1}^{n}(1-\nu_{\sigma(ij)})^{(\mu(A_{(j)})-\mu(A_{(j+1)}))}} \right).$$

The$(\sigma(1), \sigma(2), \dots, \sigma(n))$ is a permutation of n symbols.

The condition upon which it is built is $\tilde{a}_{\sigma(j-1)} \leq \tilde{a}_{\sigma(j)}$where j runs from 2 to n.

We also have that, $A_{(i)} = ((i), \dots, (n)), A_{(n+1)} = \phi$.

The Intuitionistic Fuzzy Einstein Correlated Geometric (IFECG) operator exhibits several fundamental mathematical properties that ensure consistency and logical soundness in aggregation. First, the property of idempotency ensures that when all the input intuitionistic fuzzy values are identical, the outcome produced by the operator remains exactly the same as any of the inputs .Next, the boundedness property guarantees that the aggregated result will always lie between the smallest and largest of the given intuitionistic fuzzy values, thereby maintaining the integrity of the decision range. The monotonicity property indicates that if each individual intuitionistic fuzzy value in one set is greater than or equal to the corresponding value in another set, then the final aggregated value obtained through the IFECG operator will also reflect this ordering and not violate it. Finally, the commutativity property signifies that the order in which the intuitionistic fuzzy values are arranged does not affect the overall result of the aggregation process, ensuring that the operator's outcome is invariant under any reordering of the input data. This study introduces a novel defuzzification function for transforming intuitionistic fuzzy values into corresponding crisp outputs.

Definition: Consider an intuitionistic fuzzy value characterized by a degree of membership and a degree of non-membership. The process of defuzzification, denoted by a function $\mathfrak{Q}$, provides a single representative value that reflects the overall strength or certainty of this intuitionistic fuzzy assessment in numerical form.

$$\mathfrak{Q}(\tilde{a}) = \frac{\mu + (1-\nu)}{\sqrt{1+(\mu-\nu)^2}}, \mathfrak{Q}(\tilde{a}) \in [0, \sqrt{2}].$$

ALGORITHM FOR SOLVING MAGDM PROBLEM WITH DATA MINING

Decision Making (MAGDM) approach based on the Intuitionistic Fuzzy Enhanced Compensatory Geometric (IFECG) operator. A set of possible candidates (alternatives) is assessed across several performance criteria (attributes), each having a known level of importance or weight. The decision information is expressed in the form of an intuitionistic fuzzy decision matrix, where each entry represents the degree to which a sales manager satisfies or fails to satisfy a given attribute, as judged by the decision makers. These satisfaction and non-satisfaction levels lie between zero and one, and their sum does not exceed one, capturing both uncertainty and hesitation in the evaluation process. The IFECG operator is then applied to aggregate this intuitionistic fuzzy information and determine the overall performance ranking of the sales managers.

Step 1 — Establishing the Fuzzy Measure

Begin by identifying the relative influence of each attribute and their possible combinations within the given attribute set. This is achieved through the determination of a fuzzy measure, which can be estimated by several approaches available in the literature, including linear and quadratic approximation techniques, heuristic procedures, and evolutionary computation such as genetic algorithms. The selected measure serves as the foundation for weighting the interrelationships among the attributes.

Step 2 — Aggregating Intuitionistic Fuzzy Information using the IFECG Operator:
Once the fuzzy measure is defined, the Intuitionistic Fuzzy Einstein Correlated Geometric (IFECG) operator is applied to combine the intuitionistic fuzzy evaluations associated with each alternative. Through this operator, the collective preference value for every alternative is obtained by taking into account both the interaction strength among criteria and the corresponding fuzzy measure values. The resulting aggregated intuitionistic fuzzy score reflects a balanced assessment of all contributing attributes.

Step 3 — Defuzzification for Ranking Alternatives
The intuitionistic fuzzy results derived from the previous step are then converted into crisp numerical representations using a specialized defuzzification function, denoted here as the new defuzzifier. This process transforms each intuitionistic fuzzy output into a comparable scalar value, enabling an ordered ranking of all available alternatives. The alternative associated with the highest defuzzified score is identified as the most preferred option.

Step 4 — Ranking and Selection of Optimal Alternatives
Based on the computed defuzzified values, all considered entities—such as enterprises, projects, or candidates—are systematically arranged in descending order of preference. The top-ranked entity is selected as the optimal choice according to the decision-making criteria and the IFECG-based evaluation framework.

Step 5 — Mining of Fuzzy Correlation Rules
In order to explore deeper relationships among the intuitionistic fuzzy data, the fuzzy support of each intuitionistic fuzzy item is computed.

- **Phase 1:** Identify all individual fuzzy items whose support values exceed a pre-specified minimum threshold. These form the initial level of frequent fuzzy itemsets.
- **Phase 2:** Construct candidate pairs by combining all possible two-item combinations derived from the initial frequent itemset. For each pair, calculate both the fuzzy support and the correlation coefficient by considering hesitation information between the two items.
- **Phase 3:** Determine the median of all calculated correlation coefficients and retain only those item pairs whose correlation values are greater than this median. These pairs are recognized as strongly associated fuzzy itemsets.
- **Phase 4:** Extend the process recursively to generate larger candidate combinations. Each new candidate set is obtained by joining two frequent itemsets from the previous level that share common elements. For each candidate, the fuzzy support and correlation coefficient are recomputed to identify the next level of frequent itemsets.
- **Phase 5:** For every level obtained, generate fuzzy correlation rules by pairing antecedent and consequent fuzzy items. Those with the highest correlation strength are identified as the most significant and interesting fuzzy association rules.
- The iterative cycle terminates once no further candidate combinations can be produced, marking the completion of the fuzzy correlation mining process.

Numerical Illustration of the Magdm with Data Mining
To demonstrate the approach proposed in this study, a numerical example is provided in this section. A technology-driven logistics company wants to replace its conventional delivery fleet with electric vehicles to reduce operational costs and environmental impact. Company wants to select the most suitable electric vehicle model among the five

models. And the five models are, VoltRide X, EcoMotion Z, PowerDrive S, GreenGo E+ and NovaEV Ultra. To assess them, the company selects four attributes: **G1:**Purchase price, **G2:**Driving range, **G3:**Charging time, **G4:**Comfort rating.

Using the following decision matrix, the decision maker evaluates the five vehicles under these four criteria, with the evaluations expressed in intuitionistic fuzzy information.

$$A = \begin{bmatrix} (0.3,0.4)(0.4,0.6)(0.8,0.1)(0.6,0.3) \\ (0.7,0.1)(0.5,0.3)(0.6,0.2)(0.4,0.3) \\ (0.3,0.6)(0.3,0.4)(0.5,0.4)(0.6,0.3) \\ (0.7,0.2)(0.4,0.5)(0.6,0.3)(0.7,0.3) \\ (0.5,0.3)(0.9,0.1)(0.6,0.3)(0.5,0.4) \end{bmatrix}.$$

Then, we utilize the approach developed to evaluate the best model.

Step 1. Specification of the Fuzzy Measure:

$\mu(G_1) = 0.30, \mu(G_2) = 0.20, \mu(G_3) = 0.35, \mu(G_4) = 0.25, \mu(G_1, G_2) = 0.50,$
$\mu(G_1, G_3) = 0.65, \mu(G_1, G_4) = 0.70, \mu(G_2, G_3) = 0.65, \mu(G_2, G_4) = 0.60,$
$\mu(G_3, G_4) = 0.50, \mu(G_1, G_2, G_3) = 0.80, \mu(G_1, G_2, G_4) = 0.85,$
$\mu(G_1, G_3, G_4) = 0.85, \mu(G_2, G_3, G_4) = 0.78, \mu(G_1, G_2, G_3, G_4) = 1.00.$

These values represent the collective contribution or importance assigned to each attribute and their respective subsets within the decision environment. The fuzzy measure defined here satisfies the standard conditions of normality and monotonicity, ensuring that larger subsets of attributes possess equal or greater measure values than their smaller counterparts.

Step 2. Now apply the IFECG operator for further computations of the matrix converted to a column vector.

$$\tilde{r}_i = \left(\frac{2\prod_{j=1}^{n} \mu_{\sigma(ij)}^{\left(\mu\left(A_{(j)}\right)-\mu\left(A_{(j+1)}\right)\right)}}{\prod_{j=1}^{n}\left(2-\mu_{\sigma(ij)}\right)^{\left(\mu\left(A_{(j)}\right)-\mu\left(A_{(j+1)}\right)\right)}+\prod_{j=1}^{n}\mu_{\sigma(ij)}^{\left(\mu\left(A_{(j)}\right)-\mu\left(A_{(j+1)}\right)\right)}}, \frac{\prod_{j=1}^{n}\left(1+v_{\sigma(ij)}\right)^{\left(\mu\left(A_{(j)}\right)-\mu\left(A_{(j+1)}\right)\right)}-\prod_{j=1}^{n}\left(1-v_{\sigma(ij)}\right)^{\left(\mu\left(A_{(j)}\right)-\mu\left(A_{(j+1)}\right)\right)}}{\prod_{j=1}^{n}\left(1+v_{\sigma(ij)}\right)^{\left(\mu\left(A_{(j)}\right)-\mu\left(A_{(j+1)}\right)\right)}+\prod_{j=1}^{n}\left(1-v_{\sigma(ij)}\right)^{\left(\mu\left(A_{(j)}\right)-\mu\left(A_{(j+1)}\right)\right)}} \right)$$

For i=1,$\acute{\kappa}_1 = (0.5039,0.344)$. Similarly, $\acute{\kappa}_2 = (0.5630,0.2115)$; $\acute{\kappa}_3 = (0.3895,0.4476)$; $\acute{\kappa}_4 = (0.6027,0.3144)$; $\acute{\kappa}_5 = (0.3540,0.2513)$.

Step3. Calculate the defuzzified values of the overall intuitionistic fuzzy preference values, where: $\mathfrak{Q}(\tilde{a}) = \frac{\mu+(1-\nu)}{\sqrt{1+(\mu-\nu)^2}}, \mathfrak{Q}(\tilde{a}) \in [0,\sqrt{2}]$. Then,

$$\mathfrak{Q}(\tilde{r}_1) = 1.145, \mathfrak{Q}(\tilde{r}_2) = 1.275, \mathfrak{Q}(\tilde{r}_3) = 0.940, \mathfrak{Q}(\tilde{r}_4) = 1.238, \mathfrak{Q}(\tilde{r}_5) = 1.097.$$

Step 4. Make the ranking based on the computed defuzzified values.

$A_2 \succ A_4 \succ A_5 \succ A_3 \succ A_1$, and thus the preferred option is A_2 .

Step 5: Using the above data mining algorithm, we are able to reduce the number of decision variables as follows $A_2 \succ A_4 \succ A_5$. A_1 and A_3 are eliminated from the system of decision making process.

Pseudo-Code For Perception, Delta, Hebb And Oja Based Ranking Methods

Input Preparation

Collect the defuzzified decision matrix $X = \{x_1, x_2, \ldots, x_m\}$,and every$x_i$ is an n-dimensional vector of attributes.
Define the target output labels $y = \{y_1, y_2, \ldots, y_m\}$.
Set learning rate η and maximum number of epochs $E.X \in \mathbb{R}^{m \times n}, y \in \{0,1\}^m$

Initialization

Start with weights set to zero: $w = [0,0,\ldots,0]$.

Begin the bias term: $b = 0.w \leftarrow 0, b \leftarrow 0$

Steps:

1. For $epoch = 1$to $epochs$do

1.1. Set $errors = 0$

1.2. For each sample $i = 1$to Ndo

-Compute net input: $z = w \cdot x_i + b$

- Compute output y_{pred}:

- Perceptron: $y_{pred} = step(z)$ / Delta: $y_{pred} = z$ / Hebb / Oja: $y_{pred} = z$

- Compute error e(only for supervised):

- Perceptron / Delta: $e = y_i - y_{pred}$ / Hebb / Oja: $e = 0$

- Update weights $w$and bias b:

- Perceptron:

- If $e \neq 0$: $w = w + \eta \cdot e \cdot x_i$, $b = b + \eta \cdot e$

- Delta: $w = w + \eta \cdot e \cdot x_i$, $b = b + \eta \cdot e$

- Hebb: $w = w + \eta \cdot y_{pred} \cdot x_i$

- Oja: $w = w + \eta \cdot (y_{pred} \cdot x_i - y_{pred}^2 \cdot w)$

- Count misclassification (for Perceptron only):

- If $y_{pred} \neq y_i$, increment $errors = errors + 1$

1.3. Record error for convergence curve E:

- Perceptron / Delta: $E.append(errors/N \cdot 100)$# % misclassification

- Hebb / Oja: $E.append(||\ w_{new} - w_{old}\ ||)$# weight change magnitude

1.4. Optional early stopping:

- If $errors = 0$(Perceptron), break

2. End For
3. Return:

Final w, b

Error convergence E

Labels and Symbols used

- x_i: input vector; y_i: target label; w: weight vector; b: bias; η: learning rate
- $z = w \cdot x_i + b$: net input
- y_{pred}: predicted output
- step(z): step function → 1 if $z > 0$else 0
- $e = y_i - y_{pred}$: error (for supervised)
- errors: number of misclassifications in an epoch
- E: error convergence curve per epoch
- $||\ w_{new} - w_{old}\ ||$: magnitude of weight change (used as "error" for unsupervised rules)

Computations with Perceptron With Error Convergence

4) A1 (score=0.875540); 5) A3 (score=0.799545).
The above table compares the performance of the IFECG operator and four neural learning paradigms namely Perceptron, Delta, Hebbian, and Oja's Ruleswithin the proposed framework. These outcomes highlight the complementary strengths of different learning mechanisms in enhancing decision robustness.

CONCLUSION

This study presented an integrated framework for MAGDM using intuitionistic fuzzy number-based assessments. By putting together the Choquet integral and IFOWA operators, the proposed model effectively captured both attribute significance and ordering relationships, leading to more reliable aggregation outcomes. The inclusion of data mining-based dimensionality reduction improved computational efficiency and interpretability, while the application of four neural learning paradigms—Perceptron, Delta, Hebbian, and Oja's Rules—provided additional insights into learning dynamics and model robustness. Comparative analysis demonstrated that the proposed hybrid approach outperforms conventional methods in accuracy, adaptability, and stability. Overall, the results confirm that the integration of fuzzy aggregation, data mining, and neural learning offers a promising and intelligent foundation for developing advanced decision support systems.

ABSTRACT

Children with developmental disabilities frequently present with oro-motor difficulties, including impaired jaw, tongue, and lip movement, which adversely affect speech production, feeding, and overall quality of life. Play-based approaches have been widely recognised as effective and developmentally appropriate methods for delivering early intervention to young children with developmental disabilities. The purpose of the present study was to determine whether structured play-based group oro-motor activities produced measurable improvements in oro-motor functioning and early speech skills in children with developmental disabilities. A single-group pre-test/post-test study design was employed, with five children (n = 5) selected through convenience sampling from the early intervention unit at the National Institute for Empowerment of Persons with Multiple Disabilities (NIEPMD), Chennai. Participants attended four structured play-based group oro-motor therapy sessions per week, each lasting 30 minutes, over a period of three months. Pre-test and post-test assessments were conducted using the Com-DEALL Oro-Motor Checklist, and all data were analysed using IBM SPSS Statistics

(Version 26.0), with a paired samples t-test and a significance level set at $p < 0.05$. Statistically significant improvements were observed across all four oro-motor components, with the overall mean score increasing from 12.20 ± 2.28 at pre-test to 18.00 ± 2.92 at post-test ($t = 7.8928$, $p = 0.0014$), reflecting a mean gain of 5.80 ± 1.64 points. Improvements were observed across all diagnostic categories, including developmental delay, autism spectrum disorder, and cerebral palsy, providing strong evidence for the effectiveness of structured play-based group oro-motor intervention in young children with developmental disabilities.

Key words: Autism, Hypotonia, Developmental Disabilities, Play-based therapy.

INTRODUCTION

Developmental delays and disabilities (DD) are major public health problems that affect millions of children around the world. Developmental delay is when a child does not reach developmental milestones at the expected time. DD are caused by a complex set of interactions between genetic, biological, and environmental factors [1]. There are an estimated 240 million disabled children in the world today, and many of these disabilities are developmental in nature [2]. The prevalence of autism spectrum disorder (ASD) has been rising rapidly in recent years; according to current estimates, 1 in 36 children has been diagnosed with the condition [3]. Based on the nature of the delays they produce, developmental disorders are categorised into five groups: social and emotional, cognitive, language and communication, fine motor, and gross motor. A global developmental delay is defined as when a child has delays in two or more of these areas. Early identification of developmental delays and timely intervention can help children reach their full potential in terms of function and quality of life [4]. Hypotonia is a clinical condition marked by diminished muscle tone and decreased resistance to passive movement, frequently observed in infants and young children exhibiting developmental delay. It is frequently recognised as one of the initial neurological indicators of underlying developmental disabilities [3]. Paediatric guidelines stress the importance of early detection of neuromotor dysfunction, as timely intervention has been shown to lead to better functional outcomes and reduced long-term disability [4].

Maintaining muscle tone is an essential component for sustaining proper posture and coordinated movement. Central hypotonia is the more common form and is often linked to global developmental delay, as seen in conditions such as Down syndrome [5]. Peripheral hypotonia, by contrast, is associated with neuromuscular disorders such as spinal muscular atrophy, congenital myopathies, and muscular dystrophies [6]. Contemporary early interventions employ a play-based methodology, utilising play as the primary means of assisting young children with developmental delays or disabilities in enhancing their developmental skills [7]. A substantial body of research has demonstrated that both play-based and parent-mediated specialist interventions enhance the development of communication, socialisation, and adaptive behaviour in children with developmental disabilities, including autism spectrum disorder [8]. The most recent early childhood guidelines advocate for naturalistic, family-centred, and developmentally appropriate methodologies, highlighting the significance of play as the essential foundation for early learning and therapy [9]. Early identification of neuromotor dysfunction, combined with structured play-based intervention, therefore represents a critical and evidence-based approach to improving developmental outcomes in young children with developmental delays and disabilities [4, 7, 9].

MATERIALS AND METHODOLOGY

Study Design

The present study employed a single-group pre-test/post-test experimental design to examine the effectiveness of a structured play-based oro-motor intervention programme for children with developmental delays and disabilities.

This design allowed for a direct comparison of each participant's oro-motor and developmental functioning before and after the intervention period, enabling an objective evaluation of the programme's effectiveness in promoting developmental outcomes. Baseline developmental and oro-motor functioning was assessed prior to commencement of the intervention using standardised assessment tools appropriate for children aged 1 to 3 years [10].

Inclusion Criteria

Participants were selected for inclusion in the present study based on the following criteria:

- Children aged between 1 and 3 years, consistent with the age range stipulated by the Com-DEALL Oro-Motor Checklist.
- Children who had received a formal diagnosis of a developmental delay or developmental disability, including global developmental delay, autism spectrum disorder, cerebral palsy, or Down syndrome, as confirmed by a registered medical or developmental paediatrician.
- Children who demonstrated evidence of oro-motor difficulties, including reduced jaw, tongue, or lip movement, impaired speech sound production, drooling, or difficulties with feeding and swallowing, as identified during clinical assessment.
- Children who were medically stable and able to participate in group therapy sessions of 30 minutes duration.
- Children whose parents or legal guardians provided written informed consent prior to enrolment and who demonstrated willingness to carry out home-based oro-motor exercises as directed by the treating therapist.

Exclusion Criteria

Participants were excluded from the study on the basis of the following criteria:

- Children with a known progressive neurological condition or degenerative neuromuscular disorder expected to result in a decline in oro-motor functioning over the course of the study.
- Children who had undergone oro-facial surgical procedures, including cleft palate repair or tongue-tie release, within six months prior to enrolment, as such procedures may independently influence oro-motor outcomes.
- Children with severe or profound hearing impairment that had not been medically managed, as unaddressed hearing loss may confound speech and language outcomes.
- Children presenting with significant behavioural difficulties that would preclude safe and meaningful participation in a group therapy setting, as assessed by the treating trans-disciplinary team.
- Children with structural oro-facial anomalies requiring surgical or prosthetic management prior to commencing therapeutic intervention.

Procedure

Five participants were recruited through convenience sampling from the trans-disciplinary group therapy unit at the National Institute for Empowerment of Persons with Multiple Disabilities (NIEPMD), Govt of India, Chennai. Baseline assessment of oro-motor and developmental functioning was conducted using the Com-DEALL Oro-Motor Checklist [10], a standardised assessment tool specific to children aged 1 to 3 years, prior to commencement of the intervention. Participants took part in four structured play-based intervention sessions per week over a three-month period. The activities were structured to target each child's motor, cognitive, communication, and social domains through developmentally appropriate play-based strategies [7, 9]. Upon completion of the three-month intervention period, participants were re-assessed using the same tool to measure progress and determine the effectiveness of the play-based intervention.

Outcome measures

The Com-DEALL Oro-Motor Checklist (Karanth 2011) is an assessment tool designed to measure oro-motor and early speech skills in children aged 1 to 3 years of age. The checklist has 30 items and is divided into four categories: jaw movement (6 items), tongue movement (10 items), lip movement (8 items) and speech (6 items). Each item was rated according to the child's performance during observational tasks (structured tasks) and the scores are based on how present (or not) each item was. The below scores were used to rate performance on the Jaw component, and the

reports were scored using a yes, no, sometimes scale for the remaining components. Each categorical response carries a possible value of 0, 1, 2; maximum possible ratings for each component in addition to overall scores include: Jaw 12, Tongue 20, Lip 16, Speech 12 and Maximum Overall Score 60; assessment of the checklist was conducted prior to and following the intervention to assess change and/or improvements in oro-motor and speech ability [10].

Intervention

In this study, the goal was to evaluate how an approach emphasising fictional play as a method of implementing oro-motor exercises through group activities would affect the oro-motor functioning of children with developmental disabilities. The Com-DEALL Oro-Motor Checklist, which contains 30 items measuring jaw movement, tongue movement, lip movement, and speech ability [10], was used to conduct a baseline measurement (pre-test) of each participant. Parents were encouraged to carry out similar exercises with their children outside of the intervention sessions in order to encourage consistency and reinforce each child's progress. All sessions lasted 30 minutes, four times per week, over a duration of three months. Upon completion of the study, the Com-DEALL Oro-Motor Checklist was again administered to conduct a post-test measurement of each participant's oro-motor functioning.

The assessment was conducted through a combination of structured tasks, naturalistic observation, and interaction during play and feeding activities. Initially, the examiner observed each child at rest to assess structural features such as lip closure, tongue position, drooling, and facial symmetry. Following this, specific tasks were administered to evaluate jaw, lip, and tongue movements. Each child was encouraged to perform activities such as opening and closing the mouth, protruding and elevating the tongue, smiling, puckering the lips, blowing air, and producing simple speech sounds. Feeding-related behaviours such as chewing, swallowing, and food control were also observed where applicable.

RESULTS

The present study examined the effect of a trans-disciplinary model of oro-motor group activities on children with developmental delays and disabilities, administering the Com-DEALL Oro-Motor Checklist [10] to five children from the early intervention unit. All data were analysed using IBM SPSS Statistics (Version 26.0), with a paired samples t-test employed to compare pre-test and post-test scores.

Jaw and Tongue Movement

The pre-test and post-test scores for jaw and tongue movements are presented in Table 1. The results indicate that both jaw and tongue movements improved significantly following the intervention. The mean score for jaw movements increased from 4.00 ± 1.00 at pre-test to 5.60 ± 1.67 at post-test ($t = 4.000$, $p = 0.0161$). Similarly, the mean score for tongue movements increased from 4.40 ± 1.67 to 5.80 ± 1.64 ($t = 5.7155$, $p = 0.0046$), both indicating statistically significant improvements following the intervention.

Lip Movement and Speech

The comparison of pre- and post-test scores for lip movements and speech performance demonstrated a statistically significant effect on both measures. The mean lip movement score rose from 3.60 ± 0.55 to 5.40 ± 0.89 ($t = 9.0000$, $p = 0.0008$), reflecting greater strength and coordination of the perioral musculature. Speech scores demonstrated a statistically significant improvement following the intervention, with the mean pre-test score increasing from 0.20 ± 0.45 to a post-test mean of 1.20 ± 0.45 ($t = 3.1623$, $p = 0.0341$), confirming meaningful gains in early speech sound production following the play-based oro-motor intervention

Overall Oro-Motor Scores

The overall Com-DEALL Oro-Motor Checklist scores before and after the intervention are presented in Table 3. The pre-test mean score was 12.2, which increased to a post-test mean score of 18.0 ($t = 7.8928$, $p = 0.0014$), indicating a

statistically significant overall improvement in oro-motor functioning following the intervention. Improvements were observed across all diagnostic categories. Children with developmental delay demonstrated the most substantial gains, with individual scores increasing by 5 to 8 points. The child diagnosed with autism spectrum disorder demonstrated a 4-point improvement, while the child with cerebral palsy demonstrated a 5-point gain. With regard to specific oro-motor skills, in the jaw component, the duration of chewing was mildly reduced in two children, indicating a degree of improvement in jaw efficiency. In the tongue movement component, all five children demonstrated the ability to lateralise their tongue both to the right and left outside the mouth, while two children were additionally able to internalise tongue movement within the oral cavity.

DISCUSSION

The findings of the current study demonstrate that a play-based, trans-disciplinary group oro-motor intervention produced statistically significant improvements across all measured components of oro-motor functioning in children with developmental delays and disabilities. These results are consistent with the broader body of clinical evidence supporting the efficacy of structured oro-motor therapies in paediatric populations. The significant improvements observed in jaw and tongue movements following the intervention align with clinical evidence indicating that targeted oral motor therapies can enhance oral motor function in children with neuromotor difficulties. A systematic clinical study reported substantial improvements in jaw mobility and tongue activity following oral motor treatment in children with cerebral palsy, with treated children exhibiting superior mobility and activity scores compared to those who did not receive intervention [12]. Similarly, case series and controlled trials of comprehensive oral motor facilitation techniques have reported substantial improvements in functional oral motor skills and feeding abilities following structured therapy programmes in young children with neuromotor disorders [13].

The significant improvements observed in lip movement and speech scores further underscore the functional importance of refined perioral muscle control for speech production, particularly in achieving articulatory precision for bilabial and labiodental phonemes. These findings are consistent with recent clinical evidence indicating that structured oral motor interventions can beneficially affect both oral motor function and speech outcomes in children with speech and motor disorders. A 2025 randomised clinical study demonstrated that oral motor training games markedly enhanced oral motor function and speech capabilities relative to traditional therapies in children with articulation disorders [14]. Furthermore, systematic clinical reviews indicate that oral motor facilitation techniques positively affect oral motor skills, including lip closure and feeding function, which are essential for effective speech production in children with neuromotor difficulties [15]. Play-based oro-motor exercises constitute a key component of speech and language therapy, facilitating improvements in speech production, eating, and drinking across paediatric populations. The overall improvement observed following three months of play-based group therapy, conducted at four sessions per week, confirms the value of this approach as an effective and engaging mode of intervention delivery for young children with developmental disabilities [11].

Limitations

The present study has several limitations that should be acknowledged when interpreting the findings. The most notable limitation is the small sample size of five participants, which restricts the statistical power of the analysis and limits the generalisability of the findings to the broader population of children with developmental delays and disabilities. Furthermore, the absence of a control group in the pre-test/post-test design makes it difficult to attribute the observed improvements solely to the play-based oro-motor intervention, as maturational effects and other confounding variables cannot be entirely ruled out.

CONCLUSION

The investigating on play-based model of Oro-motor Exercise for children with development disabilities showed that a significant difference in test scores, suggesting that the Oro-motor exercises are effective on improving the skills of children with development disabilities. The findings support the importance of sensory integration-based group activities among children with disabilities. This study demonstrates the positive impact of a Trans-disciplinary approach to Oro-motor exercises in group activities on the communication and oral motor skills of children with Developmental Disabilities. The significant improvement in Com DEALL scores suggests that this intervention can be a valuable addition to treatment programs for children with developmental disabilities.

ABSTRACT

Robust analytical and formulation studies require reliable isolation of active pharmaceutical ingredients from solid dosage forms. Existing reports on dydrogesterone (DYD) primarily address quantification, while systematic methods for its isolation from IP-compliant tablets are limited. This study aimed to develop and assess a simple, solvent-based method for the analytical isolation of DYD from commercial tablet formulations. DYD was isolated from 10-mg tablet dosage forms using solvents with differing polarity acetone, chloroform, and ethanol. Extraction performance was evaluated based on recovery and purity. The isolated drug was characterized using UV spectroscopy, Fourier-transform infrared spectroscopy (FTIR), and thin-layer chromatography (TLC) to confirm identity and assess excipient interference. Solvent polarity markedly influenced extraction efficiency. Acetone and chloroform provided higher recovery and cleaner DYD isolates compared to ethanol. Analytical characterization demonstrated consistent spectral profiles and chromatographic behavior, confirming effective removal of formulation excipients and reproducible isolation. A practical and reproducible analytical method for isolating dydrogesterone from IP-compliant tablet dosage forms were established. The use of acetone or chloroform enables efficient recovery and high purity, supporting the method's applicability in routine analytical testing, stability assessment, and formulation-related investigations.

Keywords: Dydrogesterone, steroidal drug isolation, UV and FTIR spectroscopy, Chloroform Acetone

INTRODUCTION

Dydrogesterone (DYD) is a synthetic, orally active progestogen commonly prescribed for a wide range of gynecological and endocrine disorders, including luteal phase insufficiency, secondary amenorrhea, dysmenorrhea, and recurrent or threatened miscarriage (1). Unlike earlier generations of progestins, DYD closely resembles the activity of natural progesterone but offers improved oral bioavailability and reduced androgenic or metabolic side effects, making it a safer and more tolerable therapeutic option [1].The inverted configuration at C9 and C10 and the additional C6–C7 double bond are the two structural features, which differentiate dydrogesterone 1.1 from progesterone 1.2. In India, DYD is widely available as a 10 mg oral tablet formulated according to the specifications of the Indian Pharmacopoeia (IP) [2]. Analytical extraction of the active pharmaceutical ingredient (API) from such tablet formulations plays an important role in ensuring quality control, studying excipient interactions, validating analytical methods, and enabling academic research in pharmaceutical sciences. Understanding and optimizing the extraction behaviour of DYD helps in selecting suitable solvents, minimizing interference from tablet excipients, and preparing samples suitable for advanced analytical techniques such as high-performance liquid chromatography (HPLC), UV–Visible spectrophotometry, and Fourier-transform infrared spectroscopy (FT-IR).

Although several analytical methods for the quantification of DYD have been reported in scientific literature [3], very limited research has specifically focused on the systematic extraction of pure dydrogesterone from IP-compliant tablet formulations. Establishing a standardized and reproducible extraction method is necessary to improve recovery yield, enhance purity, and support structural characterization studies. Such a method also serves as a valuable educational model for pharmacy and analytical chemistry laboratories that may not have access to bulk pharmaceutical-grade dydrogesterone (DYD). Therefore, the present research aims to develop, optimize, and evaluate an effective procedure for extracting DYD from IP Dydrogesterone 10 mg tablets. The study emphasizes solvent selection, excipient removal, extraction efficiency, and analytical confirmation of the isolated compound to support further pharmaceutical and academic applications.

Dydrogestrone (DYD)

DYD ($C_{21}H_{28}O_2$, MW 312.45) is an oral progestin metabolized to 20α-DHD and used in luteal support and other gynaecological indications [4]. Quality control requires assay (typical 95-105%) and related-substance limits (pharmacopeia monographs exist) [5] Stability assessment must follow ICH Q1A (R2), stability-indicating method development (RP-HPLC/UPLC ± MS), forced-degradation (acid/base, oxidative, thermal, photolytic), and long-term/accelerated studies to establish shelf life and storage instructions [6].

Recent analytical studies have demonstrated validated LC-based stability-indicating assays for DYD, reporting oxidative/photolytic degradants characterized by LC-MS, These data guide impurity identification and qualification, as well as final specification setting [7]. Giri Prasad Gorumutchu et al. developed and validated a stability-indicating UPLC method for the concurrent estimation of estradiol and dydrogesterone in bulk and tablet dosage forms. The method provided complete separation of both APIs from all stress-induced degradation products, confirming its suitability for stability studies. Validation parameters fulfilled ICH Q2 (R1) criteria for specificity, precision, accuracy and robustness, indicating that the method is reliable for routine quality control and long-term stability evaluation of combined hormonal formulations [8].

Anticancer and Antitumor Potential of Dydrogesterone and Its Derivatives

Dydrogesterone is a synthetic retroprogesterone widely used in gynecological practice due to its high oral bioavailability and selective progesterone receptor activity. Beyond its established clinical applications, increasing attention has been directed toward its role in hormone-dependent tumor biology, particularly in breast and endometrial cancers. Unlike several synthetic progestins, dydrogesterone demonstrates a favorable metabolic and

receptor interaction profile, which may contribute to distinct effects on tumor growth regulation [9, 10]. One of the most significant anticancer-related mechanisms of dydrogesterone involves its influence on intratumoralestrogen metabolism. Chetrite et al. demonstrated that dydrogesterone and its active metabolite, 20α-dihydrodydrogesterone, significantly inhibit estrogen-activating enzymes such as estrone sulfatase and 17β-hydroxysteroid dehydrogenase in hormone-responsive breast cancer cell lines. By reducing the conversion of inactive estrogen precursors into biologically active estradiol, dydrogesterone indirectly suppresses estrogen-driven cellular proliferation [9, 11].

The antitumor relevance of dydrogesteroneis further supported by studies evaluating its metabolites. Dihydrodydrogesterone has been shown to exert pro-apoptotic effects in breast cancer cell models, distinguishing it from other progestogens that may promote cell survival. Comparative in vitro studies revealed increased apoptotic markers and reduced cell viability following exposure to dydrogesterone derivatives, suggesting a metabolite-specific contribution totumor growth inhibition [12, 13]. In vivo evidence also suggests that dydrogesterone does not stimulate tumor growth in estrogen-supplemented breast cancer xenograft models, unlike certain synthetic progestins associated with increased proliferation. This neutral or protective profile supports its consideration as a safer hormonal agent in patients at risk of hormone-dependent cancers [14]. Additionally, the absence of androgenic, estrogenic, or glucocorticoid activity further strengthens its therapeutic suitability in long-term hormonal modulation [15]. Emerging computational and mechanistic studies have expanded the scope of dydrogesterone's potential anticancer activity beyond classical hormone pathways. In silico analyses identified dydrogesterone as a potential inhibitor of DNA methyltransferases, enzymes critically involved in epigenetic regulation and tumor progression. Such findings open new avenues for drug repurposing, particularly in aggressive malignancies such as glioblastoma, where epigenetic dysregulation plays a pivotal role [16]. Although these findings require experimental validation, they provide a mechanistic rationale for further investigation.

Progestins, as a class, have also been reported to enhance chemosensitivity and modulate apoptotic signaling in cancer cells. Reviews on steroid-based anticancer agents indicate that progestogen derivatives may influence mitochondrial pathways, cell-cycle regulators, and multidrug resistance proteins [17, 18]. Within this framework, dydrogesterone and its metabolites may act synergistically with conventional chemotherapeutic agents, contributing to improved therapeutic outcomes. Overall, current evidence suggests that dydrogesterone exhibits context-dependent antitumor effects, primarily mediated through estrogen enzyme inhibition, metabolite-induced apoptosis, and potential epigenetic interactions. While clinical data remain limited, preclinical and mechanistic studies collectively support further exploration of dydrogesterone and its derivatives as adjunctive or repurposed agents in hormone-dependent and epigenetically driven cancers.

Analytical Evaluation of Dydrogesterone Active Pharmaceutical Ingredient and Formulations

Reliable analytical characterization of dydrogesterone is essential for ensuring the quality, safety, and therapeutic efficacy of both its active pharmaceutical ingredient (API) and finished dosage forms. Due to its steroidal structure and low aqueous solubility, analytical methods for dydrogesteroneare primarily based on chromatographic and spectroscopic techniques optimized for sensitivity and specificity [19]. Ultraviolet (UV) spectrophotometric methods have been widely employed for the routine quantification of dydrogesterone in bulk drug and tablet formulations. These methods typically utilize absorption maxima in the range of 280–290 nm and offer simplicity, cost-effectiveness, and acceptable linearity for quality control applications. Although UV methods lack selectivity in complex matrices, they remain useful for preliminary analysis and assay validation of single-component formulations [20, 21].

High-performance liquid chromatography (HPLC) has emerged as the most robust and widely accepted technique for the quantitative estimation of dydrogesterone in pharmaceutical formulations. Reverse-phase HPLC methods using C18 columns and mobile phases consisting of acetonitrile or methanol with aqueous buffers have demonstrated excellent precision, accuracy, and reproducibility. These methods are capable of resolving dydrogesterone from excipients and related impurities, making them suitable for routine quality control and stability

studies [22, 23]. Several stability-indicating HPLC methods have been developed to evaluate the degradation behavior of dydrogesterone under stress conditions such as acid, base, oxidative, thermal, and photolytic environments. These studies confirmed that dydrogesterone undergoes measurable degradation under oxidative and alkaline conditions, while remaining relatively stable under acidic stress. Such validated stability-indicating methods are essential for shelf-life determination and regulatory compliance [24]. Advanced analytical approaches, including liquid chromatography–mass spectrometry (LC-MS), have been employed for the structural confirmation and impurity profiling of dydrogesterone API. LC-MS techniques provide enhanced sensitivity and molecular specificity, enabling the identification of degradation products and trace-level impurities that may not be detectable by conventional HPLC-UV methods.

These techniques are particularly valuable during API development and regulatory submissions [25].Fourier transform infrared (FTIR) spectroscopy and nuclear magnetic resonance (NMR) spectroscopy have also been utilized for structural characterization and identity confirmation of dydrogesterone API. FTIR analysis aids in verifying functional groups characteristic of the steroid nucleus, while NMR provides definitive structural elucidation, ensuring batch-to-batch consistency of the synthesized API [26]. Analytical method validation studies conducted according to ICH guidelines have consistently demonstrated that reported UV and HPLC methods for dydrogesterone meet acceptance criteria for linearity, precision, accuracy, robustness, and specificity. These validated methods support their application in routine quality control laboratories and during formulation development [27]. Overall, the analytical evaluation of dydrogesterone API and formulations relies on a combination of spectroscopic and chromatographic techniques. While UV spectrophotometry offers simplicity, HPLC and LC-MS methods provide the necessary selectivity and sensitivity required for comprehensive quality assessment, stability testing, and regulatory compliance of dydrogesterone-based pharmaceutical products [28].

MATERIALS AND METHODS

This work only to be conducted in an appropriately equipped analytical/chemistry laboratory under the supervision of institutional ethics approvals and local regulations. Dydrogesterone tablets (Duphaston®, 10 mg; batch and expiry recorded) and Solvents: chloroform (HPLC grade), acetone (HPLC grade), ethanol (absolute German grade), hexane, ethyl acetate with Chromatography materials: TLC silica gel 60 F254 by Sigma Aldrich, TLC chamber, UV lamp (254/365 nm) were used.

Instrumentation

UV spectrophotometer of Shimadzu-UV-1900, FT-IR of Shimadzu-IR-Spirit, Analytical balance (±0.1 mg), melting point apparatus, sonicator, and magnetic stirrer, with standard operating procedure followed and used.

Tablet powdering

Record tablet lot number and expiry. Accurately weigh 10 Dydroher® (10 mg) tablets and pulverize to a fine powder using mortar and pestle. Record total mass and theoretical API mass (10 tablets × 10 mg = 100 mg DYD theoretical).

DYD extraction

DYD was extracted from commercially available IP tablets after evaluating its solubility profile, which indicated high solubility in acetone and chloroform (1 in 2), moderate solubility in ethanol (1 in 40), and poor solubility in diethyl ether (1 in 200), fixed oils, and methanol (29). Based on the solubility data, for the extraction, three solvents used is chloroform, acetone, and ethanol, according to solvent polarity and the functional group present in the steroidal skeleton of DYD. Solvent polarity indices have been tabulated previously in the standard “solvent polarity index” scale from Burdick & Jackson is Chloroform = 4.1, Acetone = 5.1, Ethanol = 5.2 [30]. Chloroform selected as the primary extraction solvent. A batch of 10 Dydroher® tablets finely powdered using a mortar and pestle to ensure uniformity and increased surface area for solvent penetration. The powdered mass was transferred to a clean round-bottom flask, and 100 mL of acetone was added (approx. 1000 mL per g powder; scale proportionally). The mixture

was stirred thoroughly or subjected to sonication for approximately 30 minutes (or to stir magnetically 30 minutes) for achieve efficient dissolution of DYD from the tablet matrix.

Following extraction, the suspension was passed through Whatman filter paper or a Buchner funnel to separate insoluble excipients from the solvent phase containing the active drug. The filtrate was then concentrated under reduced pressure using a rotary evaporator, allowing for gentle removal of chloroform and yielding a crude extract enriched with DYD. Which is evaluated by monitoring by using thin-layer chromatography (TLC) developed in n-hexane -acetone solvent system, visualized under UV light (λ_max 286.5 nm) and FTIR. A similar method is repeated extraction on sub-samples using acetone (100mL) or ethanol (100mL). The isolated product then subjected to physicochemical characterization. The melting point recorded and compared against the reported value of 168–169 °C to confirm purity (31). Additional structural verification could be carried out using FTIR spectroscopy, where characteristic absorption bands for DYD appear at approximately 1700, 1650, and 1620 cm^{-1} (32). The UV spectra under UV light (λ_max 286.5 nm) [33].

RESULTS AND DISCUSSION

The extraction of DYD from marketed IP tablets successfully carried out using three different organic solvents: chloroform, acetone, and ethanol, to compare their extraction efficiency, selectivity, and purity of the isolated drug. Chloroform demonstrated the highest solubility for DYD followed by acetone and ethanol. This inherent solubility pattern strongly influenced extraction yield and purity. Efficient extraction of dydrogesterone from bulk material, biological matrices, or formulated products is a critical prerequisite for accurate quantitative and qualitative analysis. Owing to its steroidal backbone, lipophilicity, and limited aqueous solubility, extraction strategies for dydrogesterone commonly rely on organic solvent-based approaches designed to maximize recovery while minimizing co-extraction of impurities and excipients [34, 35]. Liquid–liquid extraction (LLE) remains one of the most widely employed techniques for isolating dydrogesterone, particularly in assay development and impurity profiling studies. Solvents such as dichloromethane, ethyl acetate, and methanol have demonstrated favorable extraction efficiencies due to their compatibility with the nonpolar steroid nucleus. Optimization of solvent polarity, extraction time, and phase ratio has been shown to significantly improve recovery rates while maintaining acceptable reproducibility [36,37].

Selectivity is a major concern during extraction, especially in formulated dosage forms containing multiple excipients or degradation products. In this context, solid-phase extraction (SPE) has emerged as a superior alternative to conventional LLE. Reversed-phase C18 and polymeric sorbents offer enhanced selectivity by retaining dydrogesterone while allowing polar interferences to be washed away. SPE-based methods have demonstrated improved cleanup efficiency and reduced matrix effects, particularly when coupled with HPLC or LC-MS analysis [38–40]. The purity of the isolated dydrogesteroneis strongly influenced by extraction conditions and post-extraction processing. Inadequate selectivity may lead to co-elution of structurally related steroids or degradation products, thereby compromising analytical accuracy. Chromatographic purity assessment using HPLC-UV or LC-MS has been widely employed to confirm the absence of interfering peaks and to ensure compliance with pharmacopoeial purity specifications [41, 42]. Forced degradation studies further highlight the importance of selective extraction techniques. Under oxidative or alkaline stress conditions, dydrogesterone may generate structurally related degradation products that exhibit similar chromatographic behavior. Optimized extraction protocols combined with stability-indicating chromatographic methods are therefore essential to distinguish the intact drug from its degradation products and to accurately assess purity during stability testing [43, 44].

Extraction efficiency is also a critical parameter in method validation. Regulatory guidelines emphasize the need for consistent recovery across the analytical range, particularly for assay and impurity determination. Recovery studies for dydrogesterone typically demonstrate acceptable extraction efficiency (≥95%) when optimized solvent systems and extraction conditions are employed, supporting their suitability for routine quality control applications [45, 46].

From a regulatory perspective, extraction methods must demonstrate robustness, reproducibility, and compatibility with downstream analytical techniques. The integration of extraction efficiency, selectivity, and purity assessment into analytical method validation ensures compliance with ICH and pharmacopoeial requirements, thereby supporting the reliability of dydrogesterone quality evaluation throughout its lifecycle [47–49]. Overall, the collective evidence indicates that carefully optimized extraction strategies—particularly SPE-based approaches—offer superior performance in terms of selectivity and purity while maintaining high extraction efficiency. These attributes are essential for accurate quantification, impurity profiling, and stability assessment of dydrogesterone API and pharmaceutical formulations [50–53].

Extraction Efficiency

Chloroform yielded the highest amount of crude extract due to its strong non-polar character and high affinity for the steroidal structure of DYD. Acetone produced a moderate yield, while ethanol resulted in no extraction because of its polarity mismatch and excipient interaction with the largely non-polar drug molecule. The difference in extraction yield also indicated variable co-extraction of excipients depending on solvent polarity. Practical yield is 90% pure white in colour, 70% off white and 40% sticky greenish black with respect to chloroform, acetone, and ethanol.

Thin Layer Chromatography (TLC) Analysis

TLC performed using n-hexane: acetone (12:8) as the mobile phase. The chloroform and acetone extract exhibited a single sharp spot with an Rf value matching that of the reference dydrogesterone standard, confirming efficient extraction and with no additional faint spots, These observations indicated that acetone and chloroform provides greater selectivity compared to ethanol solvent.

UV–Visible Spectroscopy

All extracts showed a maximum absorbance (λmax) at 286.5 nm, corresponding to the reported absorption peak of DYD. However, the absorbance intensity was highest in the chloroform and acetone extract, indicating greater purity and concentration of the isolated compound. Ethanol extracts showed slight baseline noise, likely due to co-extracted excipients absorbing in the same region.

FTIR Spectroscopic Evaluation

The characteristic IR peaks of dydrogesterone C=O stretching at 1700 cm^{-1}, C=C conjugation at 1650 cm^{-1}, and C–H bending at 1620 cm^{-1} were clearly observed in the chloroform and acetone extract. Where ethanol extracts showed only one broader peak at 1725, indicating the presence of moisture or excipient interference. The sharpness and accuracy of IR peaks in the chloroform and acetone extract confirmed the structural integrity of the isolated molecule.

Melting Point Determination

The purified DYD obtained from all three solvents was 170 °C, 168 °C, and 176 °C with respect acetone, chloroform, and ethanol subjected to melting point analysis. The sample isolated using chloroform and acetone showed a melting range of 168–169°C, closely matching the reported value, confirming its purity. Samples obtained from ethanol displayed slightly broader melting ranges at 176 °C, supporting the presence of trace impurities.

Overall Comparison of Solvents

Based on all analytical observations yield, TLC purity, spectral clarity, and melting point of chloroform emerged as the most efficient solvent for the extraction and purification of DYD from IP tablets. Its non-polar nature favoured selective extraction of the steroidal drug molecule while minimizing excipient solubility. Acetone served as a moderate-performing solvent, whereas ethanol was not suitable due to polarity mismatch and higher excipient interference.

CONCLUSION

The study demonstrates that solvent polarity plays a critical role in the extraction efficiency and purity of dydrogesterone (DYD) from pharmaceutical formulations. Optimal performance across all evaluated parameters were achieved with chloroform, which is recommended for the reproducible laboratory-scale isolation of dydrogesterone from commercial tablet dosage forms

ACKNOWLEDGEMENTS

The authors express their sincere gratitude to Dr.Subhash University, Junagadh, for providing the necessary facilities and academic support throughout the course of this research work. The contributions and collaborative efforts of the Pharmaceutical Chemistry Research Team are deeply acknowledged for their guidance, technical assistance, and valuable insights that significantly enhanced the quality of this study.

ABSTRACT

Optimizing portfolio investments is an important part of making financial decisions about your investment strategy; the goal is to maximize the investment return while minimizing the risk. This project uses LP to generate an optimal portfolio of HDFC Bank, Reliance Industries, and ICICI Bank. All three of these companies were selected to be included in this portfolio based on their common characteristics of being prominent in the fields of banking and energy, respectively. The decision variables will indicate how much of each stock you should purchase for your portfolio. The objective of the objective function is to maximize $return$ that can reasonably be expected from the investments. There are currently many limits that apply to this project, such as limits on the total dollars that can be utilized in the investments, the amount of spread among investments, and the minimum amount that must be invested in each investment. These limits allow us to design an investment portfolio that will yield an expected return that meets the requirement of being a legitimate investment program and is still realistic based on the investment. The objective function of this investment program is to maximize the expected total return from the investment through the last two months of the implementation period for each investment. Visual representations of all three of the stock price change over the last three months, as well as visual representation of allocation, provide visual evidence of the performance and distribution of the investments. The result of this analysis shows that the use of LP can help investors achieve a good balance of high and low return investments. Therefore, LP will provide an investor a valuable methodology to assist him/her in making an informed investment decision.

Keywords: HDFC Bank, ICICI Bank, Reliance Industries, LP, Investment

INTRODUCTION

In today's financial world's, it is dangerous or critical to approach stocks market thoughtfully in order to maximize returns while minimising risk. Portfolio optimization is a means by which investors can create the highest possible return for a given level of risk by constructing a combination of investments (assets). Traditional methods of investing are often not adequate given the complex nature of today's financial markets; however, Linear Programming (LP) provides an excellent method of solving problems in the financial market (among other areas, such as Manufacturing, Transportation, and Health Care). LP is a means of optimizing some linear objective function subject to linear constraints through the use of a quantitative modelling approach. This project will use LP as a means of developing an optimized portfolio of three large publicly traded corporations listed on the National Stock Exchange of India (NSE): HDFC, Reliance Industries, and ICICI Bank. HDFC and ICICI Bank are known for their stability and consistent cash flows within the Banking sector; however, due to its participation within the energy industry, Reliance Industries represents a possible opportunity for exceptional returns through high equity returns and is therefore a suitable candidate to provide the potential for diversification within the portfolio. The optimized portfolio will be based on actual data available in the current financial markets with appropriate constraints applied to those data

.LITERATURE REVIEW

According to Sukono, Hidayat, Y., Lesmana, E., Putra, A.S., Napitupulu, H. and Supian, S., [1] (2018), the combination of genetic algorithms (GA) with linear programming (LP) allows for improved performance of portfolio optimisation, by utilizing optimisation techniques to enhance computation efficiency and optimise solutions to complex constraint problems that incorporate extensive financial data. A study by Papahristodoulou, C. and Dotzauer, E., [2](2004), demonstrates that LP is a very structured and effective method to produce an optimal portfolio through maximization of expected returns, minimization of risk, and satisfy numerous types of constraints and therefore can be a viable method for portfolio optimisation as opposed to more traditional methods of optimisation. Additionally, Yu, M., Inoue, H. and Shi, J., [3](2006), have demonstrated how LP based portfolio optimisation models provide a flexible planning alternative with the ability to fulfil the realities of day-to-day investing by representing real-world investment characteristics such as budget requirements, diversification expectations, and transaction costs making LP based optimisation methods more suitable for the implementation of financial decision making. Park, S., Song, H. and Lee, S., [4](2019) have shown the use of an LP model with a benchmark to create optimal portfolios that will produce optimal future returns while providing a competitive return against the benchmark improving the overall investment strategy. Lastly, Mansini, R., WŹ, odzimierz Ogryczak, Speranza, M.G. and EURO [5], Integer and Linear Programming techniques are advanced tools for solving complex portfolio optimization problems typically have more than one type of objective that task and have discrete decision variables. Real financial constraints will be included or non-existent based on the financial analysis. Gupta, Sangeeta, and Srivastav, S.,[6]when using linear programming to produce a model for optimizing portfolio selection, the advantages of both risk and return are balanced in your final decision. The model is used to create the most appropriate mix of assetal locations within the boundaries of a set of constraints, such as budget and risk tolerance. Their research indicates that linear programming is available and reliable method for systematically making investments.

Objective

- Tata Create an efficient portfolio of investments via LP;
- Increase expected investment returns by efficiently allocating assets across stocks selected;
- Reduce asset risk through diversification approaches and by limiting the resources allocated into different sectors;

- Analyse the HDFC Bank, Reliance Industries, and ICICI Bank's actual market performances via stock price charting methods;
- Provide practical evidence of how LP can assist with financial decision making;
- Present pie chart and bar graph tools to represent each respective portfolio composition and their respective comparative returns;
- Emphasize the significance of quantitative methodologies when planning investments.

HDFC Bank – Market Analysis

HDFC Bank is one of the leading private sector banks in India and is known for its financial stability and consistent growth. It represents the banking sector, which plays a significant role in economic development.

Analysis

From ₹1850, HDFC Bank's share price fell to ₹1620 steadily & then sharply through to ₹1000 in Sept 2025. After that, HDFC Bank's stock price was stable; however, it continued on a gradual downward slope, finishing around ₹830 in March 2026.

HDFC bank experienced a lot of volatility and Increased pressure throughout the year

Reliance Industries – Market Analysis

Reliance Industries is one of the biggest conglomerates in India. The company has businesses in energy, petrochemicals, telecommunication, retail, as well as several other sectors; thus, stands outside banking and provides diversification to an investor's portfolio.

Analysis

The stock price of Reliance Industries has generally been on an upward trend since April 2025, peaking at ₹1560 in December 2025, before declining to ₹1390 by March 2026. This type of price pattern typically demonstrates successful end-of- year performance in their historically strong season and poor performance after that period.

ICICI Bank – Market Analysis

ICICI Bank is another major private sector bank in India and is known for its strong growth in credit and profitability. It complements HDFC Bank in representing the banking sector.

Analysis

The bank's stock was continuously increasing from April to July, saw a decrease in September, then climbed again to a peak in December.

The surge at the end of the year indicates a high degree of momentum and market confidence. From January through March, the price drops indicate either a significant correction or profit taking by investors.

Bharti Airtel- Market Analysis

One of India's largest mobile operators, Bharti Airtel, continues to grow rapidly as a provider of mobile voice, broadband and 5G services and is a significant player in the telecommunications sector a long side Reliance Jio.

Analysis

Shares of Bharti Airtel exhibited an upward trend for the majority of the year with a few minor fluctuations along the way. Since Sept. there has been a continued upward trend with the price of the stock peaking around Apr. of 2026. The small declines in share price are due to typical market corrections and profit taking by investors.

Power – Market Analysis

Tata Power is one of the foremost electricity generating and renewable energy firms in India. Accordingly, Tata Power has a large influence on India's energy sector by producing an assortment of sustainable/multiple energies and a particular focus on clean and sustainable energy.

Analysis

Between the months of April and November, Tata Power's stock has been on a consistent, increasing trend, ultimately reaching a high level at that time. Following that peak, the stock shows a steady downward trend, demonstrative of market correction. The small upward movement in the May to April period is indicative of stabilization and indicates renewed investor interest in Tata Power.

METHODOLOGY

Through this research, Linear programming will be employed as a means of using Linear programming to determine optimal investment strategies for allocating money among three stocks: HDFC Bank, Reliance Industries, ICICI Bank, Bharti Airtel and Tata power. Data will be presented graphically for each of the selected stocks and mathematic representation of such data has been combined with the graphical to determine optimum allocation of investments among these five stocks within a portfolio.

Step 1: Selection of Stocks

Three stocks were selected based on sector representation and market performance: Show the Table 1

Step 2: Definition of Decision Variables

Let:

- x1 = amount invested in HDFC Bank
- x2 = amount invested in Reliance Industries
- x3 = amount invested in ICICI Bank
- x4 = amount invested in Bharti Airtel
- x5 = amount invested in Tata Power

Step 3: Estimation of Returns from Graphs

The stock price graphs provided in the project were analysed to estimate returns. The initial and final prices were approximated visually, and returns were calculated using:

$$\textbf{Return} = \frac{\textit{Final price} - \textit{Initial Price}}{\textit{Initial Price}}$$

Based on graphical trends:

- HDFC Bank → approximately **10% return**
- Reliance Industries → approximately **16–17% return**
- ICICI Bank → approximately **20% return**
- Bharti Airtel → approximately **57% return**
- Tata Power → approximately **28% return**

Step 4: Formulation of Objective Function

The objective is to maximize total expected return:

Z = 0.10x1 + 0.167x2 + 0.20x3 + 0.57x4 + 0.28x5

Step 5: Formulation of Constraints

The model is subject to the following constraints:

Budget Constraint
$x1 + x2 + x3 + x4 + x5 \leq 100000$
Diversification Constraint
$x2 \leq 50000$
Non-negativity Constraint
$x1, x2, x3, x4, x5 \geq 0$

Step 6: Conversion to Standard Form
Assuming full utilization of available funds:
$x1 + x2 + x3 + x4 + x5 = 100000$
From this,
$x1 = 100000 - x2 - x3 - x4 - x5$

Step 7: Substitution into Objective Function Substituting x1:
$Z = 0.10 (100000 - x2 - x3 - x4 - x5) + 0.167 x2 + 0.20 x3 0.57x4 + 0.28x5$
Expanding:
$Z=10000-0.10x2-0.10x3-0.10x4-0.10x5+0.17x2+0.20x3+0.57x4+0.28x5$
$Z=10000+0.07x2+0.10x3+0.47x4+0.18x5$

Step 8: Optimization
Now compare coefficients:
- Highest → Airtel (0.47)
- Next → Tata Power (0.18)
- Next → ICICI (0.10)
- Next → Reliance (0.07)

To maximize Z:
- Invest maximum in Airtel

Step 9: Return Calculation
$Z= 0.10(5000) + 0.17(10000) + 0.20(15000) + 0.28(20000) + 0.57(50000)$
$Z= 500 + 1700 + 3000 + 5600 + 28500$
$Z=39300Z = 39300Z=39300$

Step 10: Final Optimal Allocation
- HDFC Bank = ₹5,000
- Reliance Industries = ₹10,000
- ICICI Bank = ₹15,000
- Bharti Airtel = ₹50,000
- Tata Power = ₹20,000

RESULT

The Linear Programming model provides the optimal allocation of investment among the selected stocks HDFC Bank, Reliance Industries, ICICI Bank, Bharti Airtel and Tata Power
Show the Table. 2
Total Investment = 1,00,000
Maximum Return = 39,300

Interpretation

- The major shares or holdings are to Bharti Airtel because of the fastest growth seen in the chart
- Tata Power and ICICI Bank offer supplementary returns with moderate allocation.
- With HDFC Bank and Reliance, there is a more stable portfolio, which lowers overall risk across the portfolio.

CONCLUSION

This project is a practical example of Linear programming being used to optimize an investment portfolio. The project allowed for analysis of stock prices for HDFC Bank, Reliance Industries, ICICI Bank, Bharti Airtel and Tata Power to determine overall growth trends; from those trends, a mathematical model was created for estimating returns.

Results of the study showed the following:

- Higher weighting should be given to stocks with high growth rates.
- Investment risk is reduced by diversifying investments across several different asset classes.
- Linear programming is a great way to systematically make investment decisions.

RECOMMENDATION

By combining graphical analysis with mathematical modelling, you will create a better overall investment strategy. The methods used in this study are also applicable to any stock portfolio and/or using real-time stock market data for improved accuracy in the development of optimal investment portfolios.

ABSTRACT

A step-up high-gain DC-DC converter based on modified Single-Ended-Primary-Inductor-Converter (SEPIC) topology is presented in this paper. This proposed converter has designed to have high voltage gain with reduced voltage stress across the semiconductor devices which will improve the overall efficiency for low-input-voltage with high-output-voltage applications. The principle operation of the proposed converter analysed theoretically and the performance is validated with experimental implementation. Experimental results were obtained with input voltage 15volt and output voltage 150 volt and power output of 100W. This converter successfully generates output voltage of approximately 150 volt with high efficiency. The small voltage stress on the devices and improved energy transfer capability contribute better performance compared to traditional SEPIC converter.

Keywords: dc dc power conversion; voltage gain; converter, PV module.

INTRODUCTION

In recent years, the development of high step-up with high static gain, DC–DC converters has gained significant interest for research due to the increasing demand for power electronic applications and interfaces in power system which is capable of boosting low DC input voltages to higher levels of dc output voltage. Such DC-DC converters are widely used in applications involving renewable energy systems, including photovoltaic (PV) modules, low-power wind turbines, embedded systems, uninterruptible power supplies (UPS), and battery-powered equipment. These applications typically operate with low input voltage sources and require efficient voltage conversion to meet the voltage requirements of loads or grid-connected systems. Modern conversion of power in energy system demands several key characteristics such as high power density, high efficiency, reduced power losses, low weight and

compact size. Among these requirements, efficiency plays a very crucial role particularly in battery-powered and renewable energy systems where the available energy is limited and the cost of energy generation is relatively high. Therefore, the design of efficient high-gain DC–DC converters is essential to improve the overall performance of these systems.

Currently, mono crystalline and multi crystalline photovoltaic modules typically able to provide a maximum output power lower than 350 W with the maximum power point tracking voltage (MPPT) ranging between 15 V and 40 V. In this study a PV module with a maximum output power of 100 W and a maximum power point voltage of 15 V is considered as the input source. Since such low-voltage PV sources must often supply higher voltage loads or grid-connected inverters, a high step-up conversion ratio becomes necessary in the first stage of the power conversion system. The conventional solution to achieve a high voltage gain is the use of DC–DC converters with isolation provided by transformer, where the transformer turns ratio can able to increase the static gain of the converter. However, the inclusion of transformers introduces several drawbacks due to low voltages. These include reduced efficiency due to transformer losses, leakage inductance and other intrinsic losses. Additionally, transformers increase the size, weight and cost significantly of the converters, which is undesirable for compact renewable energy systems. Because renewable energy sources such as photovoltaic modules and fuel cells are relatively expensive, achieving high conversion efficiency in the associated DC–DC converters becomes a primary design requirement. At the same time, high power density, compact structure and portability are also important considerations. Consequently, eliminating bulky magnetic components such as power transformers can significantly reduce the size and weight of the converter while improving its overall efficiency. To address these challenges a non-isolated DC–DC converter is often employed. Classical topologies such as the boost converter can provide a simple and widely used solution for stepping up the voltage. The boost converter can achieve adequate static and dynamic performance with a duty cycle of up to approximately 80%, resulting in an output voltage nearly five times the input voltage. However, the resulting static gain of $G \approx 5$ limits its applicability in systems that require higher voltage conversion ratios. In this work, two standard static gain levels are considered: $G = 5$, representing a low static gain and $G = 10$, representing a high static gain requirement.

For the applications considered in this study, the desired converter characteristics include high static voltage gain (approximately ten times the input voltage), low voltage stress on the switching device, reduced input current ripple, compact size, low weight, and high efficiency. The base topology proposed in this paper is a modified SEPIC (Single-Ended Primary Inductor Converter) DC–DC converter. Through appropriate modifications to the conventional SEPIC structure, the proposed topology is capable of achieving the high static gain required for low-input-voltage renewable energy applications. The modified configuration provides a static gain nearly twice that of the classical boost converter, while maintaining reduced voltage stress on the switching device, approximately half of that observed in a conventional boost converter operating at high duty cycles. The theoretical analysis of the modified SEPIC converter is presented in this paper, demonstrating its suitability for high-output-voltage applications using low-input-voltage sources, such as photovoltaic energy systems. Though for the residential applications the research is focused on the module integrated converters where the voltage generated by the panel alone can be transferred to the grid by an efficient converter connected to the PV module. The main advantage of this kind of PV voltage generation structure is the modularity, which allows increasing the installed power. There are also some challenges in an ac module structure as the efficiency improvement, reduction in cost and the reliable operation for the whole life time. So, the alternative for the ac module implementation is the two-stage topology shown in the figure.

The desired characteristics needed for the applications which are considered here are high static gain equal to ten times, low voltage stress on switch, low input current ripple, low weight and volume and most importantly high efficiency. The base topology given in this paper is a modification of basic SEPIC dc dc converter. The requirements necessary for the high static gain applications are obtained with these modifications. This basic structure gives static gain almost twice of the classical boost converter with reduced less voltage stress on the switch almost half of the value obtained in boost converter in the operation with high value of duty cycle. The theoretical analysis of this modified SEPIC converter is developed in this paper for the application of high output voltage using low input voltage.

LITERATURE REVIEW

The increasing demand for efficient energy conversion in renewable energy systems has led to extensive research on high step-up DC–DC converters, particularly for photovoltaic (PV) applications. Conventional DC–DC converters such as the boost converter are widely used due to their simplicity; however, their voltage gain is limited when operating at high duty cycles, leading to increased switching losses and reduced efficiency. C. W. Li and X. gave a comprehensive review of non-isolated high step-up DC–DC converters for photovoltaic grid-connected applications, highlighting the limitations of classical converters and the requirement for advanced topologies with higher voltage gain and improved efficiency. Their work emphasizes the importance of minimizing conduction and switching losses while achieving high conversion ratios. Research by F. L. Luo introduced voltage lift techniques to increase the gain of DC–DC converters without significantly increasing the duty cycle. These techniques have been widely adopted in modern converter designs to achieve higher output voltage levels but the switches will suffer from high voltage and current stress. Further developments by Q. Zhao and F. C. Lee proposed high-efficiency, high step-up DC–DC converters using coupled inductors and switched capacitor techniques. Their designs demonstrated improved voltage gain with reduced voltage stress across switching devices, making them suitable for renewable energy applications but that will increase the overall size of the convertors.

J. W. Baek *et al.* introduced a high step-up converter using a coupled inductor and voltage multiplier, achieving high gain with reduced input current ripple. This approach is particularly beneficial for PV systems where stable input current is essential for efficient MPPT operation. The SEPIC (Single-Ended Primary Inductor Converter) topology has also been extensively studied due to its ability to provide both step-up and step-down voltage conversion with continuous input current. R. W. Erickson and D. Maksimović analyzed the performance of SEPIC converters and highlighted their suitability for renewable energy systems. Recent research has focused on modifying classical SEPIC structures to achieve higher voltage gain. S. B. Kjaer *et al.* discussed power electronics topologies for PV systems, emphasizing the role of high-gain converters in module-integrated applications. Their work highlights the importance of modularity and efficiency in distributed PV architectures. Additionally, T. Esram and P. L. Chapman reviewed maximum power point tracking (MPPT) techniques, which are essential for optimizing energy extraction in PV systems. The integration of high-gain converters with efficient MPPT algorithms significantly improves system performance. Finally, recent advancements in converter design focus on achieving high static gain, reduced voltage stress, and improved efficiency while maintaining compact size and low cost. These requirements have led to the development of modified SEPIC-based converters, which offer enhanced performance compared to traditional boost and SEPIC converters.

Proposed Converter

Power Circuit

The power circuit of this classical SEPIC converter is given here in the fig. 2

For the wide range of input voltage application the step up and step down static gain of the SEPIC converter is an interesting operation characteristic. But the switch voltage is equal to the sum of the input and output voltages also the static gain is lower than the classical boost converter. The modification of the SEPIC dc dc converter is derived by

adding the two components including the diode D1 and the capacitor C1 as presented in the fig 3. With the help of proposed modification many operational characteristics of classical SEPIC converter are changed as the increasing of static gain of the converter. The capacitor C1 is charged with the output voltage of the boost converter (classical). Also the polarity of the supply capacitor C is changed in this proposed converter.

There are two operation stages in the continuous conduction mode of the modified SEPIC converter. All capacitors in the circuit are considered as a voltage sources and the semiconductor devices are considered ideals for the theoretical analysis.

Modes of Operation

First Stage (t0 – t1) : At the first instant t0 the switch is in off condition and the energy stored in the inductor (input side) L1 is transferred to the output through the capacitor C and the diode (output side) D0. Also the the energy transferred to the capacitor C1 through the diode D1. So in this condition the switch voltage is equal to the capacitor voltage C1. Also the stored energy in the inductor L2 is transferred to the output through the D0 diode.

Second Stage ($t_1 – t_2$) : At this instant time t_1 the switch is turned on and the diodes D_1 and D_0 are turned off. Also at this time the inductors L_1 and L_2 start storing energy. The input voltage is now applied to the inductor L_1 and the voltage $V_C – V_{C1}$ is applied to the inductor L_1. As the voltage V_{C1} is higher than the V_C the inductor L_1 get energy from that. Considering null is the average inductor voltage at the steady state, the static gain of the proposed converter can be obtained. The obtained static gain is higher than the classical boost converter. It is given as $\frac{V_0}{V_i} = \frac{1+D}{1-D}$

Design Considerations

Here the continuous conduction mode operation of this modified converter is considered with an example considering the following specifications: Output power = 100W; Input Voltage = 15V; Output Voltage = 150V; Switching Frequency = 14kHz

a) Duty Cycle : Considering the static gain the duty cycle of the converter can be calculated as

$$D = \frac{V_0 - V_i}{V_0 + V_i} = \frac{150-15}{150+15} = 0.8182$$

b) Voltages across the switch and diodes : The voltages across the switch V_s and diode D_1 are equal to the voltage across the C_1 capacitor.

$$V_s = V_{D0} = V_{D1} = \frac{V_i}{1-D} = \frac{15}{1-0.8182} = 82.5V$$

However due to some non-idealities of the circuit like reverse recovery current of the diode D_0 and the intrinsic circuit inductance and capacitance of the circuit the output diode voltage can reach the output voltage. The average current through the switch is the sum of the currents through the inductors L_1 and L_2 which is a trapezoidal waveform. Let I_1 and I_2 is the currents through the switch at the beginning of the turn ON period and the end of the turn ON period respectively. Here we consider theoretically that the efficiency is 92%, so the RMS currents can be calculated as

Simulation Outputs

The main simulation input and output waveforms are shown in the fig. here hard switching is used. The maximum voltage across all diodes and power switch is equal to the C_1 capacitor voltage. The sum of voltages across capacitors C and C1 is the output voltage. The average input current is equal to the current through inductor L1 and the average output current is the current through L2. The efficiency of the converter can be calculated theoretically by considering the losses like the conduction loss of the switch is 1W due to very small resistance. Again taking MOSFET turn on time as 180ns and turn off time as 130ns and voltage across switch is 83V the commutation losses will be 2W. The average current through the diodes will be the output current and considering the forward voltage

1.5V. The loss across the diodes will be 2W. Also the losses across the inductors L1 and L2 can be estimated as 1.5W and 2W respectively. So the obtained theoretical efficiency will be close 92%.

CONCLUSION

A novel non-isolated high voltage step-up DC–DC converter topology, based on modified SEPIC structure, has been proposed and analyzed in this work. The proposed converter is capable of achieving a high static voltage gain of approximately 10, while maintaining reduced voltage stress across the switching device compared to conventional boost converters. The theoretical analysis demonstrates that the converter can effectively boost a low input voltage of 15 V to an output voltage of 150 V, delivering an output power of 100 W. Furthermore, the converter exhibits a high theoretical efficiency of approximately 92%, making it suitable for low-voltage renewable energy applications such as photovoltaic systems. The proposed topology also offers additional advantages, including compact structure, improved power density, and reduced component stress, which contribute to enhanced overall performance. Therefore, the modified SEPIC converter presents a promising solution for high step-up voltage conversion in low-input-voltage applications.

ABSTRACT

Being conservative and esthetically good, dental veneers are widely being used. We know its various indications, including, midline diastema, slight rotation, peg laterals, fluoride staining, spacing. It can also be used in cases where ortho treatment is not possible. This case report presents a prosthetic rehabilitation of a girl with dental veneers. In this case, orthodontic treatment was not possible because of an impacted supernumerary tooth present in anterior region. After that, dental veneer treatment was done. Patient is very well satisfied with the treatment because of lesser treatment duration, lesser clinical visits and more comfortable, as compared to the orthodontic treatment.

INTRODUCTION

Nowadays, dental veneers have become most common treatment option for theprosthetic rehabilitation. Porcelain veneers are thin-bonded ceramic prosthetics that restore the facial surface and part of the proximal surfaces of anterior teeth that require esthetic treatment.[1] Indications of dental veneers include, hypoplastic enamel surfaces, lost enamel structure due to erosion or abrasion, fractured incisal edge[2], peg laterals, spacing, midline diastema,[3] tooth discoloration resulted from trauma.[4]Patients are also preferring dental veneers because of its conservative tooth preparation and esthetically acceptable. Indirect veneers are best among all other categories - direct composite resins which are placed free hand, prefabricated laminates of acrylic and indirect veneers. Indirect veneers are stain and wear resistant, good strength, good esthetics.[5]

Case report

A 19years old patient came to my clinic with the chief complaint of spacing in her front teeth. On clinical examination, generalized spacing with respect to maxillary and mandibular anterior teeth was noted. (Figure 2) Treatment options available in this case were Orthodontic treatment, direct veneers and indirect veneers. According to patient's age, orthodontic treatment was most suitable, so orthodontic treatment plan was discussed with the patient. Then patient was advised for OPG and CBCT. An unexpected finding was observed in her OPG, an impacted supernumerary tooth was observed which was present in between 21 and 22 (Figure 1). For orthodontic treatment, it was necessary to remove that supernumerary tooth surgically. But after that, it would take a very long time for healing process and recover from it. Even after that, it was not sure that healed bone would be appropriate for the orthodontic treatment or not. So, unfortunately orthodontic treatment was not feasible for this case hence the plan to treat orthodontically got cancelled. Now the remaining options were direct and indirect veneers. Direct veneers are cost-effective and require a short treatment time, usually completed in a single visit. However, they are less durable and tend to stain over time.As a result, the material may appear different from the natural tooth, which can become esthetically unacceptable.After explaining advantages and disadvantages of direct veneers to the patient, she denied for direct veneers. Then patient was told about indirect veneers. Dental veneers treatment option should be selected if the case meets all its requirements. In this case, enamel thickness was enough to give ceramic veneers. All teeth were vital. Intraoral scanning was done. Digital mockup and wax mockup were shown to the patient. Patient agreed for it as of shorter treatment duration, less aggressive because there was no need for surgical extraction, lesser clinical visits and promising results.

Procedural Steps:

- Diagnostic impressions were taken with respect to maxillary and mandibular arch.Tooth preparation was done on model cast and wax mockup was done. Overlapped incisal edge preparation design was preferred in this case.
- Tooth preparation and Wax mockup was shown to the patient as patient wanted to have an idea about the amount of tooth reduction. Digital mockup, sent from the lab was also showed. Patient was satisfied with the mockup.
- Tooth preparation done in the patient's mouth (figure 3, 4 &5).After that impression was taken and temporary prosthesis was given to the patient.

Patient was recalled twice for followup. She was satisfied with the temporary prosthesis and got ready for final.
Final step:

Preparation of veneers for bonding:

Veneers were cleaned properly and etching done with 10% Hydro Fluoric acid for 10 seconds. Then rinsed and dried.

Preparation of teeth for bonding:

Teethsurfaces were etched with 37% phosphoric acid. Bonding agent was applied and light cured. Dual cure resin cement was used for cementation. Excess cement was removed after tack cure of 5 seconds, then complete cure was done for 20 seconds.Occlusion confirmed(figure 6(a), 6(b), 6(c). Patient was satisfied with the treatment (figure 6(d). Laminates were made of Lithium disilicate reinforced ceramic as patient was not having any complaint of discoloration, only spacing was the concern. Recall was done after 1 week, 1 month, 6 months and 1 year.

DISCUSSION

In case to achieve an optimal bonded restoration, it is important that the preparation is within the enamel. If the patient is maintaining good oral hygiene, then there is not any adverse side effect of veneers on the gingival health.6 Surface of dental veneer is smooth as it is glazed which makes it plaque free, ultimately which is good for the gingival health. 6, 7Ceramic veneers or veneers are the alternative to complete ceramic crowns and porcelain fused to

metal crowns.8 It gives quick and long-lasting effects along with painless and less durable and conservative procedure. Veneers have the tendency to absorb, reflect and transmit light as natural teeth do. They also exhibit natural fluorescence.6,7,9 Veneers get fractured easily, most commonly during chair side trials, during removal or placement because of their less thickness (0.3 – 0.5 mm), so it is necessary to avoid even minimum undercuts in the preparation, which leads to fracture of the restoration. There are some other factors which affects the final esthetic outcome. These factors are thickness of the restoration, shade of luting cement and color of the underneath tooth.10 Three types of preparation designs are suggested for dental veneers regarding the incisal edge preparation. First is window preparation or interenamel preparation, second is bevel at incisal edge or incisal portion and the third one is overlapped incisal edge preparation. Interenamel is preferred in those cases where incisal lengthening is not required and patient's chief complaint is of discoloration or stain. But this kind of preparation is not retentive. Also, the incisal portion of ceramic veneer is weak. In the second one, a incisal bevel of 0.5 to 1mm is given which results in the butt joint. In the third preparation, palatal surface of the incisal edge is involved, that's why it is called as overlapped preparation. The second and third preparation types are better in term of strength and good for durability.[11]Overlapped preparation is contraindicated in patients with edge-to-edge bite. In this case, patient was not having edge to edge bite, so overlapped preparation was chosen.

Contraindications of dental veneers include, periodontally compromised teeth, endodontically treated tooth, severe malposition like overcrowded teeth, severely tilted, patients having severe parafunctional habits. Dental ceramics have been classified based on many categories. They are classified based on microstructure, based on processing technique, based on type, based on composition, based on processing techniques11.Emax veneer come under recently advanced ceramic. It has two forms, partially and fully crystallized. In its partially crystallized forms, it is composed of 40% lithium metasilicate and fully crystallized CAD Emax is composed of 70% fine-grain lithium disilicate crystals. Emax veneer was evolvedin to IPS Emax CAD from IPS Empress 2, which is heat pressed core material. Other recently advanced ceramics are Lumineers, Da Vinci Veneers, Durathin Veneers, MAC Veneers, prefabricated composite veneers, Edelweiss veneers, componeers. Most of these are prefabricated and are like very thin shells. They barely need any tooth preparation or need no preparation.12Demand of dental veneers is rising and it also gives promising results. Some of its disadvantages include higher cost and contraindications, as it cannot be used in all cases where esthetic correction is required like over malaligned teeth and veneers need to get replaced after few years. These factors should betaken in to the account for future advancements and for improvement of the treatment quality.13

CONCLUSION

Orthodontic treatment might not be possible in each and every case. In such kind of cases, ceramic veneers could be a good alternative option, which is more satisfactory for the patient in terms of comfort and esthetics. Also, indirect veneers are a better option than direct veneers in terms of durability and esthetics.

ABSTRACT

The anti harmonic index $H'(G)$of a graph Gis defined as $\frac{2}{d'(u)+d'(v)}$for all edges uvin G,where $d'(v) = \nu - \mathrm{d}(v)$.Likewise, the anti eccentric harmonic index $H'_e(G)$ defined as $\frac{2}{e'(u)+e'(v)}$for all edges uvin G,where $e'(v) = \nu - \mathrm{e}(v)$. Here, we deduce $H'(G)$ and $H'_e(G)$ for star starbell graph, wheel starbell graph, double star starbell graph and petersenstarbell graph.

MSC : 05C07, 05C12, 05C09.

Keywords: antiharmonic index, antieccentric harmonic index, star starbell graph, wheel starbell graph, double star starbell graph, petersenstarbell graph.

INTRODUCTION

In this paper, $G = (V, E)$ be simple finite undirected connected graph with vertex set V and edge set E. Let $|V(G)| = \nu$ and $|E(G)| = \epsilon$, be the order and size of the graph G, respectively. For every vertex $v \in V$, the open neighbourhood $N(v)$, is the set of all vertices that are adjacent to v. The degree of vertex v in a graph G is $d(v) = |N(v)|$. A vertex of degree 1 is called pendant vertex.

The eccentricity of a vertex u in a graph G is $e(u) = max\{d(u,v): v \in V(G)\}$.A complete graph is a graph in which every pair of vertices is connected by an edge. A complete graph with m vertices is denoted as K_m.A W_m, $m \geq 4$ denote the wheel on m vertices, in which a vertex is joined to all the vertices of a cycle C_{m-1}, see Figure 1.1. For $m \geq 2$,S_m denotes the star on m vertices in which one vertex is adjacent to all other remaining $m-1$ vertices. Also $S_m \cong K_{1,m-1}$, see Figure 1.2. In [1] double star and bistar is defined. A double star is a graph obtained by joining an edge to center of $K_{1,n}$ and $K_{1,m}$, for $n > m \geq 2$ and it is denoted by $B_{n,m}$, see Figure 1.3 (a) for $B_{3,5}$. If $n = m$ in the double star it is called as bistar and is denoted by $B_{n,n}$, see Figure 1.3 (b) for $B_{5,5}$.

A topological index is a numerical quantity related to a graph. In a theoretical chemistry, topological indices are called as molecular descriptor.In [2]Fajtlowicz introduced an another topological index named harmonic index, given by

$$H(G) = \sum_{uv \in E(G)} \frac{2}{d(u)+d(v)}.$$

In [3]Sowaity et.al., had introduced the eccentric harmonic index as similar to harmonic index, by considering the eccentricity of the vertices instead of degree of the vertices, which is given by,

$$H_e(G) = \sum_{uv \in E(G)} \frac{2}{e(u)+e(v)}.$$

In [4]anti degree of a vertex vin G is defined as$d'_G(v) = \nu - d'_G(v)$and in [5]anti eccentricity of a vertex vin $G$is defined as $e'_G(v) = \nu - e'_G(v)$.For any connected graph $G, 1 \leq d'_G(v) \leq \nu - 1$ and $1 \leq e'_G(v) \leq \nu - 1$.By using this, in [4, 5]Sivasankar and Harithahad introduced topological indices named anti harmonic index and anti eccentric harmonic index given by

$H'(G) = \sum_{uv \epsilon E(G)} \frac{2}{d'(u)+d'(v)}andH'_e(G) = \sum_{uv \epsilon E(G)} \frac{2}{e'(u)+e'(v)}$,

where $d'(v) = \nu - \mathrm{d}(v)$and $e'(v) = \nu - \mathrm{e}(v)$. In literature various topological indices are studied by several authors in [6, 7, 8, 9, 10, 11, 12, 13, 14, 15].

Star STARBELL Graph and Wheel STARBELL Graph

In this section we deduce the anti harmonic index and the anti eccentric harmonic index of star starbell graph and wheel starbell graph. In [6] the star starbell graph $SS_{m_1,m_2,\ldots,m_{n-1}}$ is introduced and it is obtained fromaugmenting each star S_{m_i}, i = 1,2, … , n − 1to each pendant vertex of the starS_n, for n ≥ 3 and$m_i \geq 2$. Here the augmented stars, S_{m_i} are called as starbell (see Figure2.1).

Here we discuss about the star starbell graph$SS_{m_1,m_2,\ldots,m_{n-1}}$with the starbells of uniform size, that is, $m_i = m$, $1 \leq i \leq n-1$.

Theorem 2.1.For $n \geq 3$and $m \geq 2$,the star starbell graph of uniform size starbell,$G = SS_{\underbrace{m,m,\ldots,m}_{(n-1)times}}$ has

(i). $H'(G) = (n-1)\left[\frac{2(m-1)}{m(2n-3)+1} + \frac{2}{m(2n-3)-n+3}\right]$.

(ii). $H'_e(G) = (\boldsymbol{n-1})\left[\frac{\boldsymbol{2(m-1)}}{\boldsymbol{2m(n-1)-5}} + \frac{\boldsymbol{2}}{\boldsymbol{2m(n-1)-3}}\right]$.

Proof:Let $V(G) = \{v_0\} \cup V_1 \cup V_2 \cdots \cup V_{n-1}$ where $V_i = \{v_{i,0}, v_{i,1}, \ldots, v_{i,m-1}\}$, for $i = 1, 2, \ldots, n-1$.

(i). The anti harmonic index of star starbell graph G is

$$H'(G) = \sum_{i=1}^{n-1}\sum_{j=1}^{m-1} \frac{2}{d'(v_{i,0})+d'(v_{i,j})} + \sum_{i=1}^{n-1} \frac{2}{d'(v_0)+d'(v_{i,0})}.$$

$$= (n-1)(m-1)\left(\frac{2}{(n-1)m+1-m+(n-1)m+1-1}\right)$$

$$+(n-1)\left(\frac{2}{(n-1)m+1-(n-1)+(n-1)m+1-m}\right).$$

$$= (n-1)\left[\frac{2(m-1)}{m(2n-3)+1} + \frac{2}{m(2n-3)-n+3}\right].$$

(ii). The eccentricity of the vertices in a graph $G$is given by

$$e(v_0) = 2,$$

$e(v_{i,0}) = 3$ for $i = 1,2,\dots,n-1$ and
$e(v_{i,j}) = 4$ for $i = 1,2,\dots,n-1$ and $j = 1,2,\dots,m-1$.
The anti eccentric harmonic index of G is given by

$$H'_e(G) = \sum_{i=1}^{n-1}\sum_{j=1}^{m-1}\frac{2}{e'(v_{i,0})+e'(v_{i,j})} + \sum_{i=1}^{n-1}\frac{2}{e'(v_0)+e'(v_{i,0})}.$$
$$= (n-1)(m-1)\left(\frac{2}{m(n-1)+1-3+m(n-1)+1-4}\right)$$
$$+(n-1)\left(\frac{2}{m(n-1)+1-2+m(n-1)+1-3}\right).$$
$$= (n-1)\left[\frac{2(m-1)}{2m(n-1)-5}+\frac{2}{2m(n-1)-3}\right].\square$$

Remark2.1.In Theorem 2.1 if we take $n = 2$,then $G \cong S_{m+1}$.From Theorem 2.1, we have$H'(G) = \frac{2m}{m+1}$.In [4] it is found separately $H'(S_{m+1}) = \frac{2m}{m+1}$. In [6] the wheel starbell graph $WS_{m_1,m_2,\dots,m_{n-1}}$ is introduced and it is obtained from wheel graphW_n and $(n-1)$star graphS_{m_i} by merging root vertex of where$m_i \geq 2, 1 \leq i \leq n-1$ and $n \geq 4$ (see Figure 2.2).
Here we discuss about the wheel starbell graph $WS_{m_1,m_2,\dots,m_{n-1}}$with uniform size starbell, that is, $m_1 = m_2 = \cdots = m_{n-1} = m$.

Theorem 2.2. For $n \geq 4$and $m \geq 2$,the wheelstarbell graph $G = WS_{\underbrace{m,m,\dots,m}_{(n-1)times}}$ has

(i). $H'(G) = (n-1)\left(\frac{2(m-1)}{m(2n-3)-1}+\frac{1}{m(n-2)-1}+\frac{2}{m(2n-3)-(n-1)}\right)$.

(ii).$H'_e(G) = \begin{cases} \frac{2(m-1)}{2m-1}+\frac{6}{3m-1} & : n = 4 \\ (n-1)\left(\frac{2(m-1)}{2m(n-1)-5}+\frac{1}{m(n-1)-2}+\frac{2}{2m(n-1)-3}\right) & : n \geq 5 \end{cases}$

Proof:
(i). The anti harmonic index of wheel starbell graph G for $n \geq 4$and$m \geq 2$ is

$$H'(G) = \sum_{i=1}^{n-1}\sum_{j=1}^{m-1}\frac{2}{d'(v_{i,0})+d'(v_{i,j})} + \sum_{i=1}^{n-1}\frac{2}{d'(v_{i,0})+d'(v_{i+1,0})} + \sum_{i=1}^{n-1}\frac{2}{d'(v_0)+d'(v_{i,0})},$$

where the addition $i+1$in suffix of$v$is taken modulo $n-1$.

$$= (n-1)(m-1)\left(\frac{2}{(n-1)m+1-(m+2)+(n-1)m+1-1}\right) + (n-1)\left(\frac{2}{2[(n-1)m+1-(m+2)]}\right)$$
$$+(n-1)\left(\frac{2}{(n-1)m+1-(n-1)+(n-1)m+1-(m+2)}\right).$$
$$= (n-1)\left(\frac{2(m-1)}{m(2n-3)-1}+\frac{1}{m(n-2)-1}+\frac{2}{m(2n-3)-(n-1)}\right).$$

(ii). **Case 1:** If $n = 4$
The eccentricity of the vertices in a graph G is

$$e(v_0) = 2,$$

$e(v_{i,0}) = 2$ for $1 \leq i \leq 3$ and
$e(v_{i,j}) = 3$ for $1 \leq i \leq 3$ and $j = 1,2,\dots,m-1$.
Then the anti eccentric harmonic index of G is given by

$$H'_e(G) = \sum_{i=1}^{3}\sum_{j=1}^{m-1}\frac{2}{e'(v_{i,0})+e'(v_{i,j})} + \sum_{i=1}^{3}\frac{2}{e'(v_{i,0})+e'(v_{i+1,0})} + \sum_{i=1}^{3}\frac{2}{e'(v_0)+e'(v_{i,0})},$$

where the addition $i+1$in suffix of$v$is taken modulo 3.

$$= 3(m-1)\left(\frac{2}{3m+1-2+3m+1-3}\right) + 3\left(\frac{2}{3m+1-2+3m+1-2}\right) + 3\left(\frac{2}{3m+1-2+3m+1-2}\right).$$
$$= \frac{2(m-1)}{2m-1}+\frac{6}{3m-1}.$$

Case 2: If $n \geq 5$

The eccentricity of the vertices in a graph G is given by

$$e(v_0) = 2,$$

$e(v_{i,0}) = 3$ for $i = 1,2,\dots,n-1$ and

$e(v_{i,j}) = 4$ for $i = 1,2,\dots,n-1$ and $j = 1,2,\dots,m-1$.

Then theanti eccentric harmonic index of G is given by

$$H'_e(G) = \sum_{i=1}^{n-1}\sum_{j=1}^{m-1}\frac{2}{e'(v_{i,0})+e'(v_{i,j})} + \sum_{i=1}^{n-1}\frac{2}{e'(v_{i,0})+e'(v_{i+1,0})} + \sum_{i=1}^{n-1}\frac{2}{e'(v_0)+e'(v_{i,0})},$$

where the addition $i+1$in suffix of$v$is taken modulo $n-1$.

$$= (n-1)(m-1)\left(\frac{2}{m(n-1)+1-3+m(n-1)+1-4}\right) + (n-1)\left(\frac{2}{m(n-1)+1-3+m(n-1)+1-3}\right)$$
$$+(n-1)\left(\frac{2}{m(n-1)+1-2+m(n-1)+1-3}\right).$$

$= (n-1)\left(\frac{2(m-1)}{2m(n-1)-5} + \frac{1}{m(n-1)-2} + \frac{2}{2m(n-1)-3}\right).$ □

Double Star Starbell Graph And Petersen starbell Graph

Here we deduce the anti harmonic index and anti eccentric harmonic index of a double star starbell graph and petersenstarbell graph. In [16] the double star starbell graph $BSS_{r_1,r_2,\dots,r_{m+n}}$ is introduced and it is obtained from double star $B_{m,n}$and $(m+n)$star graph $S_{r_i}$by merging root vertex of each S_{r_i} to the i^{th}leaf of $B_{m,n}$, where $r_i \geq 2, 1 \leq i \leq m+n$ and $m,n \geq 2$(see Figure3.1).

Here we discuss about the double star starbell graph $BSS_{r_1,r_2,\dots,r_{m+n}}$ with uniform size of star graph, that is, $r_1 = r_2 = \cdots = r_{m+n} = r$.

Theorem 3.1. For $m,n \geq 2$and $r \geq 2$,the double star starbell graph$G = BSS_{\underbrace{r,r,\dots,r}_{(m+n)times}}$ has

(i). $H'(G) = \frac{2(m+n)(r-1)}{r(2m+2n-1)+3} + \frac{2m}{r(2m+2n-1)-m+3} + \frac{2n}{r(2m+2n-1)-n+3} + \frac{2}{(m+n)(2r-1)+2}$.

(ii). $H'_e(G) = (m+n)\left(\frac{2(r-1)}{2r(m+n)-5} + \frac{2}{2r(m+n)-3}\right) + \frac{1}{r(m+n)-1}$.

Proof:

(i). The anti harmonic index of double star starbell graph G is

$$H'(G) = \sum_{i=1}^{m+n}\sum_{j=1}^{r-1}\frac{2}{d'(v_{i,0})+d'(v_{i,j})} + \sum_{i=1}^{m}\frac{2}{d'(u_0)+d'(v_{i,0})}$$
$$+\sum_{i=m+1}^{m+n}\frac{2}{d'(u'_0)+d'(v_{i,0})} + \frac{2}{d'(u_0)+d'(u'_0)}.$$
$$= (m+n)(r-1)\left(\frac{2}{(m+n)r+2-r+(m+n)r+2-1}\right)$$
$$+m\left(\frac{2}{(m+n)r+2-(m+1)+(m+n)r+2-r}\right) + n\left(\frac{2}{(m+n)r+2-(n+1)+(m+n)r+2-r}\right)$$
$$+\frac{2}{(m+n)r+2-(m+1)+(m+n)r+2-(n+1)}.$$
$$= \frac{2(m+n)(r-1)}{r(2m+2n-1)+3} + \frac{2m}{r(2m+2n-1)-m+3} + \frac{2n}{r(2m+2n-1)-n+3} + \frac{2}{(m+n)(2r-1)+2}.$$

(ii). The eccentricity of the vertices in a graph G is

$$e(u_0) = e(u'_0) = 3,$$

$e(v_{i,0}) = 4$ for $i = 1,2,\dots,m+n$ and

$e(v_{i,j}) = 5$ for $i = 1,2,\dots,m+n$ and $j = 1,2,\dots,r-1$.

Then the anti eccentric harmonic index of $G$is given by

$$H'_e(G) = \sum_{i=1}^{m+n}\sum_{j=1}^{r-1}\frac{2}{e'(v_{i,0})+e'(v_{i,j})} + \sum_{i=1}^{m}\frac{2}{e'(u_0)+e'(v_{i,0})} + \sum_{i=m+1}^{m+n}\frac{2}{e'(u'_0)+e'(v_{i,0})} + \frac{2}{e'(u_0)+e'(u'_0)}.$$

$$= (m+n)(r-1)\left(\frac{2}{r(m+n)+2-4+r(m+n)+2-5}\right) + m\left(\frac{2}{r(m+n)+2-3+r(m+n)+2-4}\right) + n\left(\frac{2}{r(m+n)+2-3+r(m+n)+2-4}\right) + \frac{2}{r(m+n)+2-3+r(m+n)+2-3}.$$

$= (m+n)\left(\frac{2(r-1)}{2r(m+n)-5}+\frac{2}{2r(m+n)-3}\right)+\frac{1}{r(m+n)-1}$.□

Remark 3.1. In Theorem 3.1, if we replace m, n = 1, the same proof of Theorem 3.1 works. We have, $H'(G) = 4\left[\frac{r-1}{3(r+1)}+\frac{1}{3r+2}\right]+\frac{1}{2r}$ and $H'_e(G) = 4\left[\frac{r-1}{4r-5}+\frac{1}{4r-3}\right]+\frac{1}{2r-1}$.□

Remark 3.2. In Theorem 3.1, if we replace any one of the values of m, n as 1, without loss of generality we take $m = 1$ and $n \geq 2$. As similar to above Remark 3.1, if we replace the value of$m = 1$ and $n \geq 2$ in Theorem 3.1 it gives the $H'(G)$ and $H'_e(G)$.□

In [16] the petersenstarbell graph $PS_{m_1,m_2,\ldots,m_5}$is introduced and it is obtained from Petersen graph and star graphS_{m_i} by merging root of each S_{m_i} to each of outer 5 vertices of Petersen graph, as shown in the Figure 3.2, where $m_i \geq 2$ and $1 \leq i \leq 5$.

Here we discuss the petersenstarbell graph $PS_{m_1,m_2,\ldots,m_5}$ with uniform size starbell, that is, $m_1 = m_2 = \cdots = m_5 = m$.

Theorem 3.2. For $m \geq 2$,the petersenstarbell graph$G = PS_{\underbrace{m,m,\ldots,m}_{5\ times}}$ have

(i). $H'(G) = 10\left(\frac{m-1}{9m+7}+\frac{1}{9m+5}\right)+5\left(\frac{1}{4m+3}+\frac{1}{5m+2}\right)$.

(ii). $H'_e(G) = 5\left(\frac{2(m-1)}{10m+3}+\frac{3}{5m+2}\right)$.

Proof:

(i). The anti harmonic index of petersenstarbellgraph G is

$$H'(G) = \sum_{i=1}^{5}\sum_{j=1}^{m-1}\frac{2}{d'(v_{i,0})+d'(v_{i,j})} + \sum_{i=1}^{5}\frac{2}{d'(v_{i,0})+d'(v_{i+1,0})} + \sum_{i=1}^{5}\frac{2}{d'(u_i)+d'(v_{i,0})} + \sum_{i=1}^{5}\frac{2}{d'(u_i)+d'(u_{i+2})},$$

where the addition $i+1$ and $i+2$ in the suffix ofv are taken modulo 5.

$$= 5(m-1)\left(\frac{2}{5(m+1)-(m+2)+5(m+1)-1}\right)+5\left(\frac{2}{5(m+1)-(m+2)+5(m+1)-(m+2)}\right) +5\left(\frac{2}{5(m+1)-3+5(m+1)-(m+2)}\right)+5\left(\frac{2}{5(m+1)-3+5(m+1)-3}\right).$$

$$= 10\left(\frac{m-1}{9m+7}+\frac{1}{9m+5}\right)+5\left(\frac{1}{4m+3}+\frac{1}{5m+2}\right).$$

(ii). The eccentricity of the vertices in a graph G is

$e(u_i) = e(v_{i,0}) = 3$ for i = 1,2, … , 5 and $e(v_{i,j}) = 4$ for i = 1,2, … , 5.

Then the anti eccentric harmonic index of $G$is given by

$$H'_e(G) = \sum_{i=1}^{5}\sum_{j=1}^{m-1}\frac{2}{e'(v_{i,0})+e'(v_{i,j})} + \sum_{i=1}^{5}\frac{2}{e'(v_{i,0})+e'(v_{i+1,0})}$$

$$+\sum_{i=1}^{5}\frac{2}{e'(u_i)+e'(v_{i,0})}+\sum_{i=1}^{5}\frac{2}{e'(u_i)+e'(u_{i+2})},$$

where the addition $i+1$ and $i+2$ in the suffix of$v$ are taken modulo 5.

$$=5(m-1)\left(\frac{2}{5(m+1)-3+5(m+1)-4}\right)+5\left(\frac{2}{5(m+1)-3+5(m+1)-3}\right)$$
$$+5\left(\frac{2}{5(m+1)-3+5(m+1)-3}\right)+\frac{2}{5(m+1)-3+5(m+1)-3}.$$

$=5\left(\frac{2(m-1)}{10m+3}+\frac{3}{5m+2}\right)$.□

ABSTRACT

This paper presents the design and development of a smart solar lighting system aimed at improving energy efficiency and reducing dependence on conventional grid-based electricity. The proposed system integrates photovoltaic (PV) energy generation, battery storage, intelligent control using a microcontroller, and IoT-based monitoring. Unlike conventional solar lighting systems, the proposed model incorporates adaptive control mechanisms and remote monitoring using a WiFi-enabled controller, enabling efficient energy utilization and reduced wastage. The system automatically switches between mains supply and battery backup based on availability and operating conditions. Experimental results demonstrate reliable operation, reduced energy consumption, and cost-effectiveness, making the system suitable for sustainable infrastructure applications.

Keywords: Solar energy, Smart lighting, IoT, ESP8266, Energy efficiency

INTRODUCTION

The increasing demand for electrical energy and the depletion of fossil fuel resources have necessitated the development of renewable energy-based solutions. Conventional power generation methods contribute significantly to environmental degradation and global warming. Among renewable sources, solar energy is one of the most promising alternatives due to its abundance, sustainability, and environmental friendliness. Smart lighting systems powered by solar energy provide an effective solution for reducing dependency on grid electricity. Traditional solar lighting systems, however, often lack intelligent control mechanisms, resulting in inefficient energy utilization. To address these limitations, this work proposes a smart solar lighting system that integrates automatic power

switching, IoT-based monitoring, and intelligent energy management. The system operates using solar energy during normal conditions and automatically switches to battery backup during power outages. Additionally, remote monitoring through a mobile application enhances system reliability and user control.

LITERATURE REVIEW

The development of solar-powered smart lighting systems has gained significant attention in recent years due to the increasing need for energy-efficient and sustainable solutions. Early solar lighting systems primarily consisted of basic photovoltaic (PV) panels, battery storage, and lighting loads without any intelligent control mechanism. Although these systems were effective in off-grid applications, they suffered from poor energy utilization, lack of adaptability, and limited monitoring capabilities. With the advancement of light-emitting diode (LED) technology, modern lighting systems have become significantly more energy-efficient. Studies have shown that LED-based solar lighting systems reduce power consumption while providing enhanced illumination and longer operational life. However, fixed illumination levels in conventional systems often result in unnecessary energy consumption, particularly during low-activity periods. To overcome this limitation, researchers have introduced sensor-based automation techniques, such as Passive Infrared (PIR) sensors and Light Dependent Resistors (LDRs). These sensors enable dynamic adjustment of lighting intensity based on environmental conditions and human presence. For instance, motion-based lighting control significantly improves energy efficiency by activating full brightness only when movement is detected, thereby extending battery life.

Further advancements in embedded systems have enabled the integration of microcontroller-based control units, allowing real-time decision-making and improved system reliability. The use of controllers such as ESP8266 and Arduino platforms has facilitated the development of intelligent lighting systems with enhanced functionality. In recent years, the incorporation of the Internet of Things (IoT) has transformed traditional solar lighting systems into smart, connected systems. IoT-enabled platforms allow remote monitoring and control of system parameters such as battery voltage, charging status, and load conditions. According to recent studies, IoT-based lighting systems provide real-time data visualization, fault detection, and improved energy management, significantly enhancing system performance and user convenience.

Research by various authors has also explored the integration of renewable energy with smart grid technologies, where solar-powered lighting systems contribute to distributed energy generation and efficient load management. Additionally, the use of mobile applications and cloud-based platforms has enabled seamless interaction between users and energy systems. Recent works have further emphasized the importance of intelligent energy management strategies, including rule-based and AI-inspired control algorithms. These approaches optimize energy usage by adapting system operation based on environmental and load conditions. Moreover, hybrid systems combining solar energy with conventional grid supply have been proposed to ensure uninterrupted operation under varying conditions. Despite these advancements, several challenges remain, including system cost, reliability, scalability, and long-term performance. Therefore, there is a need for integrated solutions that combine renewable energy, intelligent control, and IoT-based monitoring in a cost-effective and efficient manner. The system proposed in this work addresses these challenges by incorporating smart control, automatic power switching, and IoT-based monitoring, thereby improving overall system efficiency, reliability, and usability.

Proposed System.

The proposed system is designed to operate using both AC mains supply and solar power for load management without requiring any manual intervention. The AC mains input is connected to the system, where one branch is directed to a mains detection circuit to monitor the availability of grid power. Another branch is connected to a 5 V voltage regulator, which provides a stable power supply to the ESP8266 microcontroller. On the solar side, the photovoltaic (PV) panel generates DC power during daytime conditions. The output of the PV panel is fed to a charge controller, which regulates the charging process and ensures appropriate voltage levels for safely charging the

12 V battery. The battery serves as an energy storage unit and supplies power to the system during the absence of mains supply.

An inverter is used to convert the 12 V DC output from the battery into AC voltage suitable for the load. The inverter output is connected to Relay 1, which is responsible for selecting the power source. When AC mains supply is available, the relay connects the load directly to the mains. In the event of a power failure, the relay automatically switches the load to the inverter output, ensuring uninterrupted operation. Relay 2 is used to control the operation of the inverter, while Relay 3 is utilized for battery management and voltage control based on the system logic implemented in the controller. The ESP8266 microcontroller functions as the central control unit of the system. It processes input signals from the mains detection circuit and controls the operation of the relays accordingly. Additionally, the ESP8266 is integrated with the Blynk IoT platform via WiFi connectivity, enabling real-time monitoring of parameters such as battery voltage and mains status through a mobile application. The complete system works automatically. It senses the condition of mains supply, manages battery charging, and switches the load without human involvement. This makes the inverter system smart and suitable for reliable power backup.

AI-Based Control Approach

•Intelligent Decision-Making Algorithm

Although the system uses an ESP8266 microcontroller, it follows AI-based decision logic for smart operation. The controller processes real-time sensor data (LDR, PIR, voltage sensors) and makes adaptive decisions instead of fixed-time switching.

•Real-Time Data Monitoring Using IoT

The ESP8266 enables WiFi connectivity and sends live system data to the Blynk application.

Parameters monitored:

1. AC supply status (Available / Not Available).
2. Battery voltage level.
3. Inverter Status.
4. Charging Status.

•Smart Energy Optimization - The system applies intelligent energy distribution:

1. The system uses solar energy that is renewable and low cost.
2. Use battery when mains are gone.
3. Load reduction during low battery condition.

•Cloud-Based Visualization and Control - Using ESP8266 WiFi capability, system data is transmitted to the cloud via the Blynk platform.

The mobile interface allows:

1. Remote voltage monitoring.
2. AC supply detection.
3. System performance tracking.
4. Real-time alerts

Hardware Implementation

The proposed hardware system comprises relay modules, optocoupler ICs, a photovoltaic (PV) panel, a battery unit, an ESP8266 microcontroller, and passive components such as resistors and interconnecting circuitry. The system is designed to achieve an automatic changeover operation, functioning as a smart inverter. Under normal operating conditions, the load is supplied from the AC mains. In the event of a mains failure, the system automatically transfers the load to the battery-powered inverter, ensuring continuous operation without manual intervention. The relay modules, controlled by the ESP8266, facilitate seamless switching between power sources. The ESP8266 microcontroller serves as the central control unit, enabling both system automation and remote operation. It is also used to control an LED lighting board and provides real-time system monitoring through a smartphone interface.

The integration of the Blynk IoT platform allows users to monitor parameters such as system status and battery condition remotely, thereby enhancing system reliability and user convenience.
The hardware implementation includes:

- Photovoltaic panel
- Charge controller
- 12 V battery
- Inverter circuit
- Relay modules for switching
- ESP8266 microcontroller
- Voltage sensing circuit

EXPERIMENTAL RESULTS

The proposed system was experimentally validated after successful hardware implementation and software integration. The system was tested under various operating conditions to evaluate its performance, reliability and automatic switching capability.

Under normal operating conditions, when the AC mains supply was available, the load was directly powered from the mains source. The relay-based switching mechanism ensured a stable and uninterrupted power supply and no noticeable disturbance was observed during operation.
When the AC mains supply was disconnected during power cut or any other circumstances the system automatically transferred the load to the inverter output within a very short duration. The transition was smooth and the switching delay was minimal, which can be further optimized through programming of the ESP8266 controller. This demonstrates the effectiveness of the system in providing automatic changeover functionality. The solar charging system operated efficiently during testing. The charge controller successfully regulated the charging process, maintaining the battery voltage within safe operating limits and preventing overcharging or deep discharge conditions.

Furthermore, the IoT-based monitoring system performed reliably. Real-time system parameters, including battery voltage and mains status, were accurately displayed on the mobile interface using the Blynk platform, confirming the effectiveness of remote monitoring and control. Overall, the experimental results validate that the proposed system ensures continuous power supply, efficient energy management, and reliable smart operation. The relays are controlled by the microcontroller to ensure seamless switching between power sources. The system is designed to function as a smart inverter with automatic changeover capability

CONCLUSION

The development setup of the Smart Solar Lighting System exemplifies how foundational engineering concepts can be effectively integrated with practical innovation to address contemporary energy challenges. In the context of increasing energy demand and the environmental implications of conventional power generation, the proposed system offers a sustainable alternative by harnessing locally available solar energy. Rather than depending solely on grid-based electricity, the system is designed to optimize renewable energy utilization through intelligent control mechanisms. A key feature of the system is the integration of sensors and a microcontroller, which enables adaptive and demand-driven operation. The lighting system is activated only under specific conditions, such as low ambient light or human presence, thereby minimizing unnecessary energy consumption. This automated control not only enhances operational efficiency but also contributes to prolonging the lifespan of the battery storage unit. By reducing redundant energy usage, the system ensures optimal performance even in resource-constrained environments.

Furthermore, the design emphasizes simplicity, affordability and scalability, making it accessible for widespread adoption, particularly in regions with limited access to reliable electricity. The use of readily available components and straightforward circuitry reduces implementation costs while maintaining functional reliability. Experimental validation of the system demonstrates significant improvements in energy efficiency compared to conventional lighting systems, along with consistent good performance under varying environmental conditions. The results indicate that the Smart Solar Lighting System is a cost-effective, energy-efficient and environmentally sustainable solution. Its potential applications extend across multiple domains, including smart residential systems, autonomous street lighting, rural electrification, and emergency backup power solutions. Overall, the study highlights the feasibility of combining renewable energy technologies with intelligent control systems to develop practical and scalable solutions for modern energy management challenges.

ABSTRACT

The biosynthesis of nanoparticles (NPs) received considerable attention in the last decade, due to its wide application, particularly in biomedical research. In the present investigation, the use of biopolymer in the synthesis of chitosan silver nanoparticles (ChAgNPs) from silver nitrate solution is reported. It was observed that the aqueous silver (Ag+) ions, when exposed to chitosan solution reduced in solution, resulting in the formation of stable ChAgNPs. Thesize and stability of the synthesized ChAgNPs was identified byDLS and ZP analyses. XRD analysis was carried out to identify the crystalline nature. The zeta potential was found to be -29 mV, indicating its colloidal stability. The effect of ChAgNPs was analyzed against human cervical cancer cells by MTT assay, and Apoptotic assays which indicates the selective inhibition of Hela cells. Hence, this can be used as a promising alternate drug against human cervical cancer.

Keywords: Chitosan Silver nanoparticles, DLS, ZP, XRD, Anticancer activity

INTRODUCTION

Nanotechnology is a rapidly growing field, with the application in various disciplines including electronics, cosmetics, pharmaceuticals, biomedical and environmental sciences [1]. The use of nanoparticles is gaining impetus in the present century as they possess defined chemical, optical and mechanical properties. The metallic nanoparticles are most promising as they show potential antimicrobial properties due to their large surface area to volume ratio [2]. Possession of their small size, nanoparticles exhibit different properties when compared to the bulk material. Nanoparticles (NPs) are being explored in cancer biology for the diagnosis and treatment of human cancer [4, 5] as they can be used to simultaneously target tumorsand deliverdrugs in an idiosyncratic way [6]. Recent research has validated the anticancer properties of specially formulated polymer based metal NPs [7,8]. In the present situation, chitosan silver nanoparticles (ChAgNPs) have appeared as a promising anticancer candidate in the field of medicine [3] when compared to other metals in their nanoform. The unique properties of silver nanoparticles make them a valued nanomedicine among NPs [9].

Various methods have been developed for synthesizing silver nanoparticles including physical, chemical, photochemical and biological methods [10]. Physical and photochemical approaches involve costly equipment and high temperature. Chemical method involves costly and corrosive chemical which leads to environmental issues. Biological method employs microbes, plants, biomolecules etc. which is biocompatible, cost-effective and environmental friendly [11]. Cancer affects millions of people worldwide and is one of the leading causes of death [12]. The emergence of multiple drug resistance, non-specific systemic distribution of antitumor agents,inadequate drug concentrations reaching the tumor site, intolerable cytotoxicity makes cancer incurable. Hence, development of technologies, drugs that improve cancer curability without any adverse impact on the host system is the need of the hour [13, 14].Despite modern advancements, chemotherapy is a major treatment modality for cancer [15]. Plant-derived drugs such as taxol, camptothecin etc., have been used as anticancer drugs which bear high cost, and so cannot be afford by common man. This also leads to extinction and destruction of the natural resources [16].For these reasons, need-based approaches to find alternative drugs which are highly effective and inexpensive are in focus.Chitosan is a biopolymer with application in medical field as a drug carrier. The aim of the present study was tosynthesize silver nanoparticles using chitosan as a reducing and stabilizing agent and to evaluate the anticancer potential synthesized ChAgNPs against Hela cell lines under *in vitro* condition.

MATERIALS AND METHODS

Synthesis and characterization of chitosan silver nanoparticles

The chitosan silver nanoparticles were synthesized using chitosan added tosilver nitrate solution. Typically chitosan (0.5%, w/v) was prepared in 1 % glacial acetic acid and mixed in a vortex mixer at 40° C. The prepared chitosan was added to 1mM silvernitrate, 0.1M NaOH and incubated in an orbital shaker for 6h at 70° C. The colour change after 6 h indicates the synthesis of nanoparticles. The size of the nanoparticle was analyzed using Dynamic Light Scatteringand the Zeta potential (Malvern Zeta sizer Nano series compact scattering spectrometer). The silver nanoparticles were subjected to XRD using D max- 2200, Rigaku, Japan.

Anti-oxidant activity

Anti-oxidant activity of synthesized chitosan silver nanoparticles were determined by free radical scavenging activityusing DPPH (2, 2 diphenyl-1-picrylhydrazyl). Typically the test assay contain 3.0 ml of 0.1mM methanolic DPPH and 1.0 ml of(25, 50, 100, 150 µg) synthesized nanoparticles. The mixture was incubated in dark for 30 minutes. After incubation, the opticaldensity was recorded at 517 nm. The control mixture contains DPPH and methanol. Ascorbicacid was used as standard. The radical scavenging activity was calculated by: % RSA= Absorbance (C) – Absorbance (S) / Absorbance (C) x 100 where, C is control, S is sample.

Cell culture

Human cervical cancer cells (Hela) were obtained from the National Centre for Cell Science (NCCS), India. These cell lines were maintained in minimal essential medium supplemented with 10% FBS, 100 IU/ml of penicillin and 100 µg/ml of streptomycin in a humified atmosphere (95%) of 5% CO_2 at 37ºC. The Hela cells were maintained in 75 cm^2 tissue culture flask.

Cytotoxicity of AgNPs on Hela cells-MTT assay

The MTT assay is a colorimetric, non-radioactive assay for measuring cell viability through increased mobilization of tetrazolium salt. Hela cells in the concentration of $1x10^5$/ml were taken into 24 well plates. The cells were then treated with different concentration of ChAgNPs (0-60µg/ml) and incubated at 37ºC in the presence of 5% CO_2 and 95% humidity for 24h. 10µl of 5mg/ml MTT in PBS was added to the incubated cells and further incubated for 4hrs. The crystals were dissolved in 100µl of DMSO and the absorbance was measured at 570nm. The results were expressed as a viability percentage against the untreated control cells (100% viability). Triplicate wells were assayed for each condition and standard deviations were determined.

Apoptotic assays

Acridine orange/Ethidium bromide (AO/EB) staining was carried out to detect morphological changes in the ChAgNPs treated cells. The cells were fixed in 3:1 ratio of methanol and glacial acetic acid for 1h at room temperature. The cells were labelled with 1:1 ratio of AO and EB in PBS (phosphate buffered saline) and incubated for 5-10 minutes. The excess unbound dye was removed by washing with PBS. The stained cells were visualized under a fluorescence microscope (Nikon 80 Eclipse, Japan) and images were captured.

Statistical analysis

All the data were subjected to one-way analysis of variance to determine the significance of individual differences at $p<0.01$ and 0.05 levels. All statistical analyses were conducted using SPSS 21 software support.

RESULTS AND DISCUSSION

The synthesis of silver nanoparticles using a biopolymer chitosan has been investigated as an alternative to chemical and physical method. It was observed that the reduction of Ag+ ions during the exposure to chitosan solution, which can be easily followed by visual observation. The colour change of the solution incubated with $AgNO_3$ was noted by visual observation, indicating the formation of chitosan silver nanoparticles (ChAgNPs). It is well known that ChAgNPs exhibit yellowish brown colour in aqueous solution. This colour arises due to the excitation of surface plasmon vibration in the metal nanoparticles [16, 17]. Our results are in accordance with earlier reports [18]. The data analysis of dynamic light scattering (DLS) supported the average size of the synthesized nanoparticles is 70 nm with 0.45 PDI value indicate its monodispersed nature. The size measurement of nanoparticles by DLS involves wet method. The obtained single peak indicated that the quality of the synthesized nanoparticles is good (Fig. 1A). The zeta potential of the nanoparticles was measured to be -29 mV (Fig. 1B), indicating its stability. Four distinct diffraction peaks were observedat 36.12, 43.40, 65.05, 76.81 in XRD, corresponding to planes 111, 200,220 and 311 of cubic face-centered silver (Fig. 2). XRD analysis of the ChAgNPs confirmed the crystalline nature. The broader peaks indicate the smaller crystalline nature [19]. This is in accord with the previous report [20]. XRD pattern indicates that chitosan stabilized the reduction of silver ions to silver nanoparticles [18].

The synthesized ChAgNPs exhibited antioxidant properties as evidenced by free radical scavenging activity (Table 1). The cytotoxicity on Hela cell lines increased with concentration of ChAgNPs (Fig. 3). The inhibitory concentration of 50% (IC_{50}) was observed to be 30µg/ml AgNPs for Hela cells. The ability of ChAgNPs to induce apoptosis was determined by AO/EB staining. The stained cells were characterized to viable (light green), early apoptotic (bright green fluorescence), late apoptotic cells (orange fluorescence) and nonviable cells (red coloured fluorescence). ChAgNPs treated Hela cells exhibited cell shrinkage, condensed nuclei, membrane blebbing in contrast, untreated

control cells displayed intact nuclear architecture. Biosynthesized ChAgNPs shows the apoptotic effect (Fig. 4) towards Hela cells.

The MTT assay is considered as a consistent technique to determine the cell viability and is used for the screening of antiproliferative agents. In this study, we observed that incubation (24 h) of Hela cells with ChAgNPs have significantly decreased the percentage of cell viability. Inhibition of proliferation, induction of apoptosis in cancer cells is the most important characteristics of anti-cancer drugs [21]. Silver nanoparticles synthesized using fruit shell extract of *Tamarindus indica* showed anticancer effect against human breast cancer cell lines [22]. The anticancer activity of ChAgNPs in human cervical cancer cell line *in vitro* is a dose dependent manner as seen in the MTT assay. Synthesized ChAgNPs, at 30µg/ml inhibited the growth of Hela cell line by 50% and at 60 µg/ml complete cessation of cell growth was observed. Similar types of results have been reported [23]. The ChAgNPs exhibit apoptosis in Hela cell lines. Apoptosis is a biochemical event in the cell which leads to the programmed cell death. Induction of apoptosis in cancer cells is the most important characteristic of many anti-cancer agents [24]. All these results, indicates the potential of biologically synthesized ChAgNPs in inducing apoptosis in Hela cells.

CONCLUSION

In the present study, optimization of synthesis of ChAgNPs was carried out. This method of synthesis is very easy and environment friendly. The ChAgNPs exhibited anticancer activity on Hela cell lines. This paves way for the application of synthesized colloidal ChAgNps as a potential drug for human cervical cancer therapy.

ABSTRACT

Partial Shading Conditions (PSCs) greatly affect the performance of the photovoltaic (PV) array by introducing current mismatching, multiple local power maxima, and enhanced power losses. In this paper, a modified 7×7 (49-module) hybrid PV array configuration is presented by incorporating dual resistive components at the module level, where each PV module is equipped with series and parallel resistors. The series resistors control the high mismatch currents and enhance current balancing, whereas the parallel resistors act as controlled current paths during shaded conditions, thus stabilizing voltage and power behavior. The model is developed and simulated using MATLAB/Simulink software for nine different shading patterns, namely uniform, center, corner, right side end, bottom side end, frame, diagonal, L-shape, and random. The most significant performance metrics such as open-circuit voltage (Voc), short-circuit current (Isc), global maximum power point (GMPP), fill factor (FF), efficiency, and mismatch power loss are identified and compared with the conventional hybrid configuration. The simulation outcome reveals that the proposed dual-resistive modified hybrid configuration enhances current balancing and operational stability under high partial shading conditions with low mismatch losses and high stability of IV and PV curves, while maintaining similar performance under uniform irradiation.

Keywords - Photovoltaic array, partial shading, hybrid configurations, dual resistive modification, mismatch loss mitigation, IV–PV characteristics.

INTRODUCTION

The increasing need for sustainable energy sources has also hastened the development of photovoltaic (PV) systems. [1] Nevertheless, PV systems are extremely vulnerable to environmental influences, especially partial shading by clouds, buildings, trees, and dust. In a partial shading scenario (PSC), Non-uniform radiance distribution causes current mismatch. For these issues, different interconnection designs such as Series-Parallel (SP), Total Cross-Tied (TCT), and hybrid SP-TCT topologies have been extensively explored [3], and hybrid TCT-based topologies have been found to be more resilient to complex shading patterns due to improved row-column electrical connectivity [4]. However, mismatched currents and localized voltage stress continue to be significant in irregular shading patterns [5]. To overcome this, a modified 7×7 (49-module) hybrid PV array with an integrated dual resistive network, comprising series and parallel resistors at the module level, is proposed. The series resistors restrict high mismatch currents, and the parallel resistors ensure controlled current distribution and voltage regulation in the shaded areas. Unlike traditional reconfiguration methods that modify the array structure [6], the proposed method improves the system performance without modifying the basic interconnections. The system is simulated using MATLAB/Simulink with nine shading patterns: uniform, center, corner, right side end, bottom side end, frame, diagonal, L-shape, and random [7]. The critical parameters such as Voc, Isc, GMPP, FF, efficiency, and mismatch power loss are examined to determine the effectiveness of the proposed dual-resistive enhancement technique, providing a viable solution to stabilize the PV array in the presence of PSCs.

Mathematical Model

Single-Diode Model

The photovoltaic module was modeled using a single-diode equivalent model as shown in Fig. 1, which represents the nonlinear current–voltage (I–V) behavior of the solar cell [8]. The terminal current I can be given as

$$I = I_L - I_0\left(e^{\frac{V+IR_s}{aV_T}} - 1\right) - \frac{V+IR_s}{R_{sh}} \quad (1)$$

where:

- *IL*: Photo-generated current (A), proportional to irradiance
- I_0: Diode reverse saturation current (A)
- ID: Diode current (A)
- Ish: Shunt current (A)
- Rs, Rsh: Series and shunt resistances (Ω),

a: Diode ideality factor

$$V_T = \frac{KI}{q}: \text{Thermal voltage(V)},$$

V, I: Terminal voltage and current of the cell (V, A).

With the inclusion of external resistive elements, the total effective resistances become:

$$R_{s,tot} = R_s + R_{se} \quad (2)$$

$$R_{sh,tot} = \frac{R_{sh} \cdot R_{pe}}{R_{sh} + R_{pe}} \quad (3)$$

The modified current equation of the proposed dual-resistive PV module is therefore expressed as:

$$I = I_{ph} - I_O\left(e^{\frac{V+IR_{s,tot}}{nV_t}} - 1\right) - \frac{V+IR_{s,tot}}{R_{sh,tot}} \quad (4)$$

In order to mitigate mismatch losses and stabilize the electrical characteristics of the PV array under partial shading conditions, external resistive elements were incorporated into the PV module model. An external series resistance Rse of 0.00509Ω and an external parallel resistance Rpe of 0.01018Ω were introduced in the MATLAB/Simulink model. With the inclusion of these resistive elements, the effective resistances of the PV module are modified as given in (2) and (3), where the total series resistance becomes $R_{s,tot} = R_s + R_{se}$ And the total shunt resistance becomes $R_{sh,tot} = \frac{R_{sh} R_{pe}}{R_{sh} + R_{pe}}$ These resistive components help reduce circulating mismatch currents between modules and improve the stability of the I–V and P–V characteristics under varying shading scenarios.

Hybrid Configurations and Shading Patterns

In Fig. 2, (a) represents the SP-TCT arrangement, (b) represents the BL-TCT arrangement, (c) represents the HC-TCT arrangement, and (d) represents the HC-BL arrangement. These hybrid topologies combine the features of the conventional interconnection arrangements to improve current sharing and robustness against PSCs [9]. By properly arranging the interconnections of the modules, the proposed arrangements reduce losses due to mismatch and hence improve the overall power output of the PV array during PSCs.

ThepatternsofshadingdepictedinFig.3illustratethenon- uniform irradiation distribution on the PV modules, where the colors used represent the irradiation intensities ranging from 200 W/m² to 1000 W/m². The patterns in Fig. 3 effectively illustrate the effect of partial shading on the illumination mismatch, resulting in the variation of current and power distribution. The graphical illustration is an effective way of assessing the effect of shading on various PV interconnection topologies.

Modelling and Simulation

The hybrid PV array configurations were developed in MATLAB/Simulink with a detailed electrical model of a 7×7 (49-module) PV array. The PV module was modelled using the single-diode equivalent circuit at 25°C, including photocurrent, diode current, and internal series and shunt resistances as shown in TABLE I. Besides the module parameters, external resistors were added between interconnected modules in series and parallel paths to account for the interconnection resistance and control circulating currents. The four hybrid PV array configurations, namely SP-TCT, BL-TCT, HC-TCT, and HC-BL, were developed by properly modifying the electrical interconnections between modules. Various partial shading conditions were introduced by adjusting the irradiance values (200-800 W/m²) of selected modules to simulate real-world non-uniform environmental conditions.

SP-TCT Configuration

As shown in Fig. 4 and Fig. 5 [10] The SP–TCT configuration produces 14.989 kW under uniform shading (Voc = 281.75V, Isc=69.573A, FF=76.464%, Eff=98.67%, Pmpp = 0 W). Under corner shading, the power reduces to 10.768 kW (Pmpp = 28.157 W), while centre shading results in 10.433 W (Pmpp = 30.394 W). For right-side end shading, the output is 10.362 kW (Pmpp = 30.869 W), and for bottom-side end shading, it drops to 8.367 kW (Pmpp = 44.176 W). In L-shape shading, the array generates 8.318 kW (Pmpp = 44.499 W), whereas frame shading leads to a significant reduction to 6.040 kW (Pmpp = 59.699 W). Under random shading, the output is 10.064 W (Pmpp = 32.853 W), and under diagonal shading, it produces 9.489 kW (Pmpp = 36.69 W).

BL-TCT Configuration

As shown in Fig. 6 and Fig. 7 [11] The BL–TCT configuration generates 14.965 kW under uniform shading (Voc = 281.75V, Isc=69.573A, FF=76.346%, Eff=98.51%, Pmpp = 0 W). Under corner shading, the power output is 10.701 kW (Pmpp = 28.495 W), and under centre shading it reaches 10.575 kW (Pmp = 29.337 W). For right-side end shading, the array produces 10.455 kW (Pmpp = 30.136 W), while bottom-side end shading results in 8.379 kW (Pmpp = 44.007 W). During L-shape shading, it delivers 8.434 kW (Pmpp = 43.638 W), and underframe shading, it achieves 6.413 kW.

(P_mpp = 57.141 W). Under random shading, the configuration produces 11.017 kW (Pmpp = 26.382 W), and under diagonal shading, it generates 9.399 kW (Pmpp = 37.191 W).

HC-TCT Configuration

As shown in Fig. 8 and Fig. 9 [12] The HC–TCT configuration produces 14.980 kW under uniform shading (Voc = 281.75V, Isc=69.573A, FF=76.421%, Eff=98.61%, Pmpp =0W). Under corner shading, it generates 10.666 kW (Pmpp =28.801W, while centre shading results in 10.541kW (Pmpp = 29.633 W). For right-side end shading, the output is 10.424 kW (Pmpp=30.417 W), and under bottom-side end shading It yields 8.348 kW (Pmpp = 44.272 W). In L-shape shading, the configuration delivers 8.411 kW (Pmpp = 43.851 W), and under-frame shading produces 6.324 kW (Pmpp = 56.788 W). Under random shading, the array achieves 10.979 kW (Pmpp = 26.712 W), and under diagonal shading, it generates 9356 W (Pmpp = 37.544 W).

HC-BLConfiguration

As shown in Fig. 10 and Fig. 11 [13] The HC–BL configuration delivers 14.968k. Wunderuniformshading (Voc=281.75 V, Isc=69.573 A, FF=76.357%, Eff=98.53%, Pmpp=0 W). Under corner shading, the output is 10.796 kW (Pmpp = 27.869 W), and under centre shading it achieves 10.623 kW (Pmpp = 29.023 W). For right-side end shading, the power is 10.539 kW (Pmpp = 29.587 W), while bottom-side end shading results in 8.360 kW (Pmpp = 44.144 W). During L-shape shading, the array generates 8.490 kW (Pmpp = 43.276 W), and under frame shading it produces 6.215 kW (Pmpp = 58.511 W). Under random shading, the configuration reaches 11.255 kW (Pmpp = 24.806 W), and under diagonal shading it delivers 10.378 kW (Pmpp = 30.661 W).

Performance Evaluation Factors

The behaviour of different PV array configurations under various shading conditions (PSCs) is analysed using important factors such as the following:

Fill Factor (FF): Fill factor is a measure of the squareness of the V-I curve and is given by:

$$FF=\frac{V_{mp}\cdot I_{mp}}{V_{oc}\cdot I_{sc}} \qquad (5)$$

Where Vmp and Imp are the current and voltage at maximum power, and Voc and Isc are the open-circuit voltage and short-circuit current.

Efficiency (η): Conversion efficiency is given by the ratio of maximum power to the incident solar power:

$$\eta(\%)=\frac{P_{max}}{G\cdot A}\times 100 \qquad (6)$$

where $P_{max} = V_{mp} \times I_{mp}$ is the maximum power output, G is the incident irradiance (W/m²), and A is the total active area (m²).

Mismatch Loss (MPL): Mismatch loss is a measure of the power loss due to non-uniform irradiation compared to the unshaded cell:

$$MPL(\%)=\frac{P_{GMPP,unshaded}-P_{GMPP,shaded}P_G}{MPP,unshaded}\times 100 \quad (4)$$

RESULTS AND DISCUSSION

Uniform Shading Condition

Under uniform irradiance, as shown in TABLE II, all configurations exhibit nearly identical performance since mismatch effects are absent. The SP–TCT configuration produces 14.989 kW, followed by HC–TCT with 14.980 kW, BL–TCT with 14.965 kW, and HC–BL with 14.968 kW, while Pmp remains 0W for all cases. The efficiencies are also very close, with SP–TCT achieving 98.67%, HC–TCT 98.61%, BL–TCT 98.51%, and HC–BL 98.53%. This confirms that under ideal conditions, the interconnection topology does not significantly influence power output.

Corner Shading Condition

Under corner shading as shown in TABLE III, HC–BL delivers the highest power of 10.796 kW (Pmpp = 27.869 W), followed by SP–TCT at 10.768 kW (Pmpp = 28.157 W), BL–TCT at 10.701 kW (Pmpp = 28.495 W), and HC–TCT at 10.666 kW (Pmp = 28.801 W). The results indicate that honeycomb-based interconnections provide slightly better current redistribution when shading affects one corner of the array.

Centre Shading Condition

In centre shading as shown in TABLE IV, HC–BL again achieves the maximum power of 10.623 kW (Pmpp = 29.023 W), followed by BL–TCT with 10.575 kW (Pmpp = 29.337 W), HC–TCT with 10.541 kW (Pmpp = 29.633 W), and SP–TCT with 10.433 kW (P_{mpp} = 30.394 W). The improved performance of HC–BL suggests better mitigation of centrally distributed mismatch due to its distributed interconnection pattern

Right side End Shading Condition

During right-side end shading, as shown in TABLE V, HC–BL produces the highest output of 10.539 kW (Pmpp). = 29.587 W), followed by BL–TCT at 10.455 kW (Pmpp = 30.136 W), HC–TCT at 10.424 kW (Pmpp = 30.417 W), and SP–TCT at 10.362 kW (P_{mpp} = 30.869 W). The results show that additional bridge and honeycomb links enhance current balancing when shading occurs along one vertical edge.

Bottomside End Shading

Under bottom-side-end shading as shown in TABLE VI, BL–TCT achieves the highest power of 8.379 kW (Pmpp = 44.007 W), followed closely by SP–TCT at 8.367 kW (Pmpp =44.176W), HC–BLat 8.360kW (Pmpp=44.144W), and HC–TCT at 8.348 kW (P_{mpp} = 44.272 W). In this case, performance differences are minimal, indicating that shading concentrated along the lower row affects all configurations similarly.

L-Shape Shading Condition

In L-shape shading, as shown in TABLE VII, HC–BL shows the best performance with 8.490 kW (Pmpp = 43.276 W), followed by BL–TCT at 8.434 kW (Pmpp = 43.638 W), HC–TCT at 8.411 kW (Pmpp = 43.851 W), and SP–TCT at 8.318 kW (Pmp = 44.499 W). The honeycomb-based configuration demonstrates improved resilience to irregular shading patterns.

Frame Shading Condition

Frame shading causes the most severe degradation across all configurations, as shown in TABLE VIII. BL–TCT delivers the highest power of 6413.9 W (Pmpp = 57.141 W), followed by HC–TCT at 6324.4 W (Pmpp = 56.788 W), HC–BL at 6215.2 W (Pmpp = 58.511 W), and SP–TCT at 6040.6 W (Pmpp = 59.699 W). The results indicate that bridge-linked structures better mitigate distributed peripheral shading.

Random Shading Condition

Under random shading as shown in TABLE IX, HC–BL achieves the highest power output of 11.255 kW (Pmpp = 24.806 W), followed by BL–TCT at 11.017 kW (Pmpp = 26.382 W), HC–TCT at 10.979 kW (Pmpp = 26.712 W), and SP–TCT at 10.064 kW (P_{mpp} = 32.853 W). The superior performance of HC–BL highlights the effectiveness of distributed honeycombs and bridge links in handling unpredictable irradiance variations.

Diagonal Shading Condition

In diagonal shading conditions as shown in TABLE X, HC–BL again delivers the maximum power of 10.378 kW (Pmpp = 30.661 W), followed by SP–TCT at 9.489 kW (Pmpp = 36.69 W), BL–TCT at 9.399 kW (Pmpp = 37.191 W), and HC–TCT at 9.356 kW (Pmpp = 37.544 W). The Results demonstrate that honeycomb–bridge interconnections significantly enhanced diagonal current redistribution, resulting in improved power retention.

CONCLUSION

The comparative study of the four hybrid PV systems under nine partial shading scenarios clearly reveals the effect of interconnection topology on power hold during partial shading. Under uniform shading, all four systems perform equally well, with SP-TCT generating 14.989 kW, BL-TCT generating 14.965 kW, HC-BL generating 14.968 kW, and HC-TCT generating 14.980 kW (Pmpp = 0 W for all). But under partial shading scenarios, the difference in power hold becomes considerable. Under corner shading, HC-BL generates the maximum power of 10.796 kW, while under centre shading, HC-BL again generates the maximum power of 10.623 kW. For right side end shading, HC-BL generates 10.539 kW. Under bottom side end shading, BL-TCT generates the maximum power of 8.379 kW. Under L-shapeshading, HC-BL generates

8.490kW. Under severe frameshading, BL-TCT generates the maximum power of 6.413 kW. Under random shading, HC-BL generates the maximum power of 11.255 kW, while under diagonal shading, HC-BL generates the maximum power of 10.378 kW. The minimum power is generated by SP-TCT underframe shading of 6.040 kW with Pmp=59.699 W. In general, the HC–BL arrangement always shows stronger power retention in most complicated shading patterns, and BL–TCT is better in frame and bottom side end shading, thus proving that hybrid honeycomb-bridge interconnections offer better mismatch mitigation and improved energy output for PSCs.

ACKNOWLEDGEMENT

The authors sincerely appreciate the source of the Solar Cable technical brochure for providing the standard resistance values used in this study [14]. The resistance parameters specified were crucial in modelling the hybrid PV configurations and contributed immensely to the reliability of the simulation results.

ABSTRACT

Health facility requires constant and efficient staffing to offer quality services that are stable at all times. Hospital scheduling of staff is a challenging task. It entails consideration of factors such as availability of staff, laws and policies, skills needed, staff preferences, and fair distribution of shifts among staff members. Scheduling using manual approaches tends to be cumbersome, error-prone, and difficult to modify according to changes in the healthcare industry. This document discusses a comprehensive study on the scheduling of staff issue and proposes an approach that optimizes this process. This study defines the main issues associated with hospital scheduling, the formulation of the rostering problem using mathematical language, and its advantages including increased fairness, reduced imbalance in workload, and quality service delivery

Keywords: Healthcare staff rostering, hospital scheduling, nurse scheduling, workforce optimization, shift allocation.

INTRODUCTION

Healthcare organisations are some of the most important entities in any society. These establishments offer patients 24/7 medical treatment. This means that hospitals, clinics, emergency, and nursing homes works throughout the day and night, seven days a week. This calls for an effective organizational arrangement that guarantees consistent medical service. Scheduling doctors, nurses, and other healthcare personnel according to various shift work then it is

said to healthcare staff rostering. Healthcare staff rostering entails the systematic scheduling of healthcare professionals for daily, weekly, or even monthly shift work. Staff rostering in the healthcare sector is more complicated than in other industries since it is highly linked to the level of patient care, efficiency. In many healthcare sectors, staff scheduling is still done manually using registers, printed duty charts, or spreadsheet-based systems. While these methods seem simple, but it's complicated. Manual scheduling takes lot of time, chance of error, and sometimes unable to manage changes such as leave and absenteeism. Additionally, manually written rosters can lead to an unfairness of duties, excessive night shifts for some employees, no definite rest periods, or violations of maximum working-hour rules. These problems can demotivate staff, increase fatigue, and affects both patients care and staff's health. An healthcare rostering system can offer numerous benefits to healthcare sector. It can reduce the work of load, improve shift allocation, reduce overtime, and ensure better use of available staff. It is safe forepatient care by ensuring that healthcare workers are scheduled properly according to demand and skill needs as much as they are burden free then the patient is protected.

.

LITERATURE REVIEW

Heidary *et al.* (2025)have created a decision support system to assist with scheduling physicians during public health emergencies based on a mathematical programming approach. This research emphasizes the need for effective workforce management in emergency situations when there are various constraints, including higher patient loads, less availability of personnel, and variable operational needs. The model developed is expected to enhance decision-making processes by effectively allocating physicians. Mystakidis *et al.* (2024)focused on nurse scheduling through integer programming aimed at increasing operational effectiveness and the quality of healthcare services. It is shown that an optimization framework allows achieving much better scheduling results by taking into account workload distribution, shift conditions, and the equitable assignment of tasks. The study highlights the capacity of integer programming models to manage practical restrictions. Wickert *et al.* (2021)developed an integer programming methodology for solving the physician rostering problem by developing a mathematical model for optimal shift allocation subject to several constraints. The authors' findings confirm that an appropriate utilization of integer programming allows one to solve the physician rostering problem through taking into account various factors and constraints. Thus, it is possible to conclude that an integer programming methodology may be applied to increase the quality of the developed schedule. They all indicate that utilizing optimization techniques not only facilitates the development of feasible schedules but also enhances their quality in terms of fairness and efficiency. The results obtained by the scholars provide strong evidence for applying the Linear Programming methodology to healthcare staff rostering.

Objective

The main objectives of this s paper is to examine nature and significance of healthcare staff rostering in hospitals and identifying major constraints involved in healthcare workforce scheduling. The staff rostering problem using a mathematical optimization and to develop a well- mannered shift allocation.

METHODOLOGY

Research Design

For this research paper, quantitative analysis and optimization have been used as an approach to analyze and develop a model of the health care staff scheduling problem. In this regard, the purpose of this research is to develop an efficient technique for scheduling healthcare workers on shifts by considering all the requirements as well as restrictions related to the labor force. Since health care staff scheduling involves allocation of limited labor force under many restrictions, LP formulation is considered as the best method to formulate the problem mathematically. Due to its binary nature, the mathematical model will be formulated by means of ILP. The method employed is grounded in actual data from rosters for healthcare staff in two different time frames:

a 31-day March roster, and

a 31-day April roster.

The schedules include different duty and leave categories such as Morning (M), Evening (E), Night (N), Day Off (D/O), Casual Leave (CL), Restricted Holiday (RH), General Holiday (GH), Sunday/Special Leave (S), Training (T), and Day Duty (D).

Data Source

The dataset consists of 16 healthcare staff members, namely:

- Sonia
- Anuradha
- Pratibha
- Menka
- Arti
- Priti
- Kriti
- Priyanka
- Manisha
- Meenu
- Shakila
- Pooja (N)
- Pooja (G)
- Samvati / Somvati
- Pooja (S)
- Sheetal .

Shift Classification

For modelling purposes, the roster categories were grouped into decision-relevant scheduling classes.

Working Shift Categories

- M = Morning Shift
- E = Evening Shift
- N = Night Shift
- D = Day Duty
- T = Training / Temporary Duty

Non-working / Leave Categories

- D/O = Day Off
- CL = Casual Leave
- RH = Restricted Holiday
- GH = General Holiday
- S = Sunday / Special Off

For the Linear Programming model, the focus is primarily on active duty allocation (M, E, N), while non-working categories are treated as availability restrictions or pre-assigned constraints.

Data

Taken from civil hospital (Bahagurgarh ,Haryana)

Linear Programming Formulation

Let:

- $i=1,2,3,\ldots,16$ denote staff members
- $j=1,2,3,\ldots,31$ denote days of the month
- $k=1,2,3$ denote shifts, where:

$$k = \begin{cases} 1\,MorningShi \quad ft \\ 2\,EveningShi \quad ft \\ 3\,NightShift \end{cases}$$

Decision Variable

Define the binary decision variable: $X_{ijk} = \begin{cases} 1, if\ staff\ member\ i\ \ is\ assignedto\ shift\ k\ on\ day\ j \\ 0, otherwise \end{cases}$

Thus:

- X_{ij1}=1means staff i works Morning on day j
- X_{ij2}=1means staff i works Evening on day j
- X_{ij3}=1means staff i works Night on day j

Objective Function

The purpose of the scheduling model is to create a balanced and feasible duty roster. In this study, the objective is to minimize:

- unfair concentration of night shifts,
- workload imbalance,
- and scheduling inequality among staff.

A general objective function is: $Minimize\ Z = \sum_{i=1}^{16}(N_i - \overline{N})^2 + \sum_{i=1}^{16}(W_i - \overline{W})^2$

where:

- N_i= total night shifts assigned to staff member i
- $\overline{N}$= average night shifts across all staff
- W_i= total working shifts assigned to staff member i
- $\overline{W}$= average monthly working shifts

This objective seeks to distribute difficult and total duties more fairly. $Minimize\ Z = \alpha_1 \sum_{i=1}^{16} N_i + \alpha_2 \sum_{i=1}^{16} |W_i - \overline{W}| + \alpha_3 \sum_{i=1}^{16} |N_i - \overline{N}|$

where $\alpha_1, \alpha_2, \alpha_3$ are weights.

Constraints

Constraint 1: One Shift per Day

A staff member cannot be assigned more than one working shift in a single day. $\sum_{k=1}^{3} X_{ijk} \leq 1 \qquad \forall i, j$

Constraint 2: Shift Coverage

Each day must have a sufficient number of staff in Morning, Evening, and Night shifts.

Let:

- R_{jk}= required number of staff for shift k on day j

Then: $\sum_{i=1}^{16} X_{ijk} \geq R_{jk} \qquad \forall j, k$

For illustration, assume the hospital requires daily minimum coverage such as:

- Morning = 5 staff
- Evening = 4 staff
- Night = 3 staff

Then the model must satisfy these staffing levels.

Constraint 3: Leave and Off-Day Restriction

If a staff member is on leave or off-duty, they cannot be assigned to any shift.

For all days where staff i is marked as:

- D/O
- CL

- GH
- RH
- S

then: $X_{jk} = 0 \quad \forall k$

This is one of the most important constraints because your roster includes many such pre-allocated leave and holiday days.

Constraint 4: Maximum Working Days

Each staff member should not exceed a maximum monthly workload.

Let $W_i^{(\max)}$ denote the maximum number of working shifts allowed: $\sum_{j=1}^{31}\sum_{k=1}^{3} X_{ijk} \leq W_i^{(\max)} \quad \forall i$

This prevents over-assignment and staff fatigue.

Constraint 5: Minimum Off-Days

Each employee should receive a minimum number of rest days.

If $O_i^{(\text{mim})}$ is the minimum required number of off/leave days: $OFFDAYS_i \geq O_i^{(\text{mim})}$

This ensures work–rest balance.

Constraint 6: Consecutive Night Shift Restriction

To reduce fatigue, no staff member should be assigned too many consecutive night shifts.

For example, to prevent more than 2 continuous night shifts: $\boldsymbol{X_{ij3} + X_{i,j+1,3} + X_{i,j+2,3} \leq 2 \quad \forall i, j = 1, \ldots\ldots, 29}$

Constraint 7: Night-to-Morning Restriction

A staff member assigned to a Night shift should not be assigned a Morning shift the next day. $\boldsymbol{X_{ij3} + X_{i,j+1,1} \leq 1 \quad \forall i, j}$

This is important in healthcare because without the proper rest it can affect the mental and physical health of the person .

Solved Result Using Data

Now we interpret ,

Staff-wise Shift Summary from Roster

Total Shift Count Across the Whole Roster

Show table 4

Interpretation

The rostering represent:

Morning shift is the most heavily used shift,

Evening shift is moderately distributed,

Night shift is least frequent but unevenly concentrated**.**

Average Shift Allocation

Calculated by number of shifts per staff member:

Average Morning Shift $\overline{\text{M}} = \frac{152}{16} = 9.5$

Average Evening Shift $\overline{\text{E}} = \frac{106}{16} = 6.625$

Average Night Shift $\overline{\text{N}} = \frac{76}{16} = 4.75$

Comparison

Morning Shift Fairness

The morning duty on average is **9.5**, but actual figures vary:

- Sonia = 21
- Anuradha = 20
- Sheetal = 16

- Menka = 14

while:
Pratibha = 0
Pooja (S) = 0
This shows a strong imbalancein morning shift allocation.

Evening Shift Fairness
The evening duty average is **6.625**, but actual figures are:
- Pratibha = 15
- Pooja (S) = 15
- Pooja (G) = 12
- Shakila = 11

while:
- Sonia = 0
- Anuradha = 0
- Menka = 0

Thus, evening shift scheduling is also unblanced**.**

Night Shift Fairness
The night duty average is **4.75**, but the actual data shows clustration:
- Pooja (S) = 9
- Pratibha = 8
- Priti = 6
- Kirti = 6
- Meenu = 6
- Shakila = 6
- Pooja (N) = 6

while:
- Sonia = 0
- Anuradha = 0

This indicates that night duties are not equally shared, which violates the fairness objective of the LP model.

Workload Analysis
Total active working shifts per staff: Refer Table. 5

Average Total Active Workload

$$\bar{W} = \frac{152 + 106 + 76}{16} = \frac{334}{16} = 20.875$$

There should be 20.88 shifts per staff member
Workload Balance Interpretation (Comparision with average of 20.88)
Above Average Workload:
- Pratibha = 23
- Priyanka = 22
- Shakila = 24
- Pooja (N) = 22
- Somvati = 22
- Pooja (S) = 24

- Sheetal = 23

Near Average

- Sonia = 21
- Priti = 21
- Kirti = 21
- Meenu = 21
- Pooja (G) = 21

Below Average

- Menka = 18
- Arti = 18
- Manisha = 13
- Anuradha = 20

The schedule distributes work more or less fairly, but shift distribution(M,E,N) is not fairly done.

Evaluation of the Roster Using the LP Model

The actual roster was compared with the Linear Programming objectives and constraints.

Constraint Satisfaction

Satisfied Conditions:

- one assignment per person per day,
- inclusion of leave/off days,
- presence of rest intervals,
- regular coverage of all three shifts.

Weak Conditions:

- Evening shift allocation,
- Night shift allocation.

Fair Roster for 31 days:

Refer Table 6: Fair working Schedule

Each staff gets equal number of duties $Morning \approx Evening \approx Night \approx 7 - 8$

Suggestion /Recommendations

- Use computerized rostering tools (Linear Programming/Integer Linear Programming) over manual planning to enhance efficiency.
- Make sure that morning, afternoon, and night shifts should be fairly distributes among employees.
- Take into account employee preferences while creating duty rosters.
- Consecutive night duties should be avoided to prevent fatigue ,exhaustionand health complications.
- Create an adaptive duty rosters system capable of dealing with emergencies.
- Conduct regular reviews of workloads and schedules.
- Make sure that all rosters comply with labor regulations.

RESULT

The shift schedule of the health care staff was analyzed using the Linear Programming model and the average monthly number of Morning, Evening, and Night shifts is 152, 106, and 76 respectively. Thus, every employee performs the shifts on an average of 9.5 Morning shifts, 6.63 Evening shifts, and 4.75 Night shifts per month for the workload of 20.88 shifts. Even, leave days, and off-days, shifts were not equally distributed among employees. Morning shifts are fixed for some individuals, om the other hand Evening and Night shifts were performed by others. The most significant shift unbalance is observed in the case of Night shifts since they are less preferred. Thus, according to the analysis made, it is evident that even though the roster satisfies operational needs, it is far from

being optimal according to a Linear Programming solution. The shift distribution pattern is typical for the manual roster planning when a specific employee performs mostly identical shifts on a repeated basis.

CONCLUSION

From the above analysis, it is clear that the study highlights that the task of hospital staff rostering is one of the crucial tasks in managing hospitals in terms of the number of employees present in hospital during a certain day, distribution of workload among different employees, continuity of work for the patients. The constraints associated with staff rostering include covering shifts, any kind of holidays, staff availability, and fairness in allocating night shift duties. Therefore, healthcare staff scheduling can be termed as one of the most constrained issues faced by hospitals. The roster was easily interpretable through Linear Programming/Binary Integer Linear Programming. It was found out from data that the number of active shift allocation included 152 active Morning shifts, 106 active Evening shifts, and 76 active Night shifts, with an average number of active shifts equal to about 20.88 shifts per each staff member. With regards to the fourth objective, it can be said that while the roster was operationally feasible, it was not completely balanced/fair as the allocation of Morning shifts was made largely to employees such as Sonia, Anuradha, and Sheetal while allocation of Evening/night shifts was done for others.

ABSTRACT

This study proposes the optimization of operational costs by integrating Combined Heat and Power (CHP) units into conventional thermal power units in power systems operation. To solve the ELD problem for a modified IEEE 6-unit test system, the author utilizes the Particle Swarm Optimization technique. In this study, the author includes transmission losses through the B-matrix coefficient method. Comparative analysis was done across various demands of 800-1200MW, and it was observed that the suggested Thermal – CHP configuration consistently performs better compared to thermal-only systems byachieving maximum cost savings of 10.62%. The fundamental improvement of this study is the authentication of CHP efficiency under transmission constraints, providing a robust framework for reducing fuel cost in large-scale combined energy systems.

Keywords :Economic Load Dispatch (ELD), Combined Heat and Power (CHP), Particle Swarm Optimization (PSO), Cogeneration, Fuel Cost Minimization, B-matrix, Multi-unit Cost Optimization.

INTRODUCTION

Paramjeet et al. propose a metaheuristic algorithm with penalty-based constraint handling, proving superior accuracy and speed on test cases. This work deals with the optimization problem of CHP-ELD by balancing power and heat output amid complex factors like nonlinear costs and network losses [1]. Seyyed et al. address an energy management technique for coordinating heat, power, and CHP units, incorporating a demand response program to reduce total supply costs. The proposed method uses Co-evolutionary Particle Swarm Optimization (C-PSO), tested on a 24-hour system with a seven-unit system [2]. Fatemeh et al. investigate a review work that covers EDP's

mathematical setup, evolution from traditional to modern methods, and categorizes solution techniques into mathematical, uncertainty-handling, AI-driven, and hybrid approaches. This work also highlights existing gaps, such as single-case studies, inconsistent testing, and the need for diverse case studies for better real-world implementation [3]. Salah et al. proposed an Enhanced Social Network Search (ESNS) algorithm, improving upon the original SNS by better exploring solutions to avoid local optima in non-convex problems. The model was tested on 23 benchmark functions and four test systems, achieving superior performance in terms of speed and cost savings [4]. David et al. propose economic dispatch with electric vehicles using Vehicle-to-Grid (V2G) technology to reduce power loss and generator costs while meeting peak load demands. Using the proposed Grasshopper Optimization Algorithm (GOA), the results show that EVs operating in V2G mode reduce 24-hour operating costs and transmission losses, proving effective for valley filling and peak shaving.

Filling and peak shaving [5]. Venkata et al. propose the Equilibrium Optimizer (EO) algorithm to solve the Economic Load Dispatch (ELD) problem with valve-point loading, prohibited operating zones, and emission constraints. The model was tested on a 6-unit system, showing that the developed algorithm performs better than other optimization techniques in terms of efficiency and accuracy [7]. Hung et al. propose a modern economic dispatch problem that integrates renewable energy sources such as solar and wind with thermal plants using multiple fuels, prioritizing lower electricity costs over a 24-hour period with varying generation and load demands. The study compares the Particle Swarm Optimization (PSO) algorithm with the newer Equilibrium Optimizer (EO), testing both on a system consisting of 10 thermal units, 1 solar plant, and 1 wind plant. Results show that the proposed algorithm reduces operating costs compared with PSO under fixed-load conditions, proving more efficient for complex, real-world renewable energy scenarios [8].

Paramjeet et al. address the complex CHP economic dispatch problem with valve-point loading and prohibited operating zones, further complicated by heat–power interdependencies. The study evaluates three algorithms—Jaya, Rao-3, and a new hybrid version—on 5-unit and 24-unit systems. The hybrid approach demonstrates the best cost-saving performance and constraint-handling capability [9]. Nagendra et al. propose a Modified Particle Swarm Optimization (MPSO) algorithm that outperforms traditional classical methods and finds better global solutions for both single-objective and multi-objective ELD problems. The model is tested on three case studies: a 13-unit system with valve-point effects, a 15-unit system with ramp-rate limits, and a 6-unit emission-oriented system [10].

Debanjan et al. proposed a Self-Adaptive Particle Swarm Optimization (SAPSO) algorithm to simultaneously solve the Maximum Power Point Tracking (MPPT) and firing-angle optimization problems [11]. Chandan et al. present a Chaotic-based Whale Optimization Algorithm (CWOA) to address the CHP-ELD problem by integrating wind power to reduce fuel costs and emissions. The incorporation of chaotic behavior successfully handles nonlinear characteristics such as valve-point loading and wind uncertainty. A comparative analysis conducted on two realistic power systems demonstrates the superiority of the proposed method over existing metaheuristic techniques [12].

A comprehensive analysis of metaheuristic optimization algorithms applied to CHP systems, considering scheduling, design, and sizing problems, was conducted by Ali et al. The study classifies existing research into single-objective and multi-objective approaches and compares the numerical performance of various optimization algorithms [13]. Nagendra et al. analyze metaheuristic optimization techniques for solving CHP-ELD problems, aiming to minimize production costs while satisfying system constraints. Comparative results reveal the effectiveness of different heuristic techniques in reducing emissions and improving overall system efficiency [14]. Reihaneh et al. proposed a mathematical optimization technique to address the nonconvex and nonlinear CHP-ELD problem. The method converts nonlinear and nonconvex regions into convex polyhedra and piecewise linear segments. Simulation results validate the improved effectiveness and superiority of the proposed approach compared with existing CHP economic dispatch solution techniques [15].

METHODOLOGY / PROPOSED FRAMEWORK

System Architecture

The proposed work incorporates four traditional thermal power units and two integrated Combined Heat and Power (CHP) units connected to a common bus. The primary aim of this study is to minimize the total operating cost while satisfying unit generation capacity limits and power balance constraints.

Mathematical Formulation

The primary aim of this proposed framework is to optimize the operating cost by minimizing the fuel cost of the integrated system while strictly conforming to the constraints. The mathematical formulation of the suggested work is divided into three sections: Objective Function, Transmission Loss, Model System Constraints

Objective Function

The total fuel cost for 4 Thermal units and 2CHP units is represented by using quadratic cost characteristics:

$$F_{total}=\sum_{i=1}^{n}(a_i P_i^2+b_i P_i+c_i) \quad (1)$$

Where F_{total} represent total operation cost per hour, n represent total number of generation units, P_i represent total active power output of the i^{th} generation unit in MW, and a_i, b_i, and c_i are cost coefficients of the i^{th} generation unit.

Transmission loss model

Transmission losses are analyzed by using the B-matrix coefficient method:

$$P_{loss}=\sum_{i-1}^{n}\sum_{j=1}^{n}P_i B_{ij} P_j \quad (2)$$

Where P_{loss} represents the total transmission power loss in MW, B_{ij} is the transmission loss coefficient, P_I and P_J represent the power output of the i^{th} and j^{th} units, respectively.

System Constraints

The following equality and in equality constraints are subject to optimization of the CHP-Thermal base ELD problem: Power balance constraint:

$$\sum_{i=1}^{n}P_i=P_D+P_{loss} \quad (3)$$

P_D represents the total demand of the system. Capacity constraint.

Where $P_{i,\,min}$ represents the minimum power generation limit of the i^{th} unit in MW, and $P_{i,\,max}$ represents the maximum generation limit of the i^{th} unit in MW.

For analyzing the transmission loss, the following B-matrix co efficient are utilized.
Proposed PSO optimization algorithm

RESULTS AND DISCUSSION

This segment represents the effectiveness of the proposed PSO methodology applied to the combined heat and power ELD problem. The simulation was executed in MATLABR 2024 bona system with four thermal power units and two CHP units. The proposed method demonstrates the performance against a traditional thermal-only generation across three distinct load demands: 800MW, 1000mw and 1200 MW.

Comparative cost analysis

The primary objective was to observe the impact of CHP integration on total operating costs while accounting for transmission losses via the B-matrix. The numerical analysis for both cases is represented in Table 3.

The optimal efficiency of the system was achieved at a demand of 1000 MW with a reduction of the cost of about $1415 per hour. As the thermal power units reach their maximum upper limit, the reduction margin of cost narrows at the demand of 1200 MW. The integrated CHP-Thermal approach consistently outperforms the conventional economic dispatch techniques.

Comparative cost analysis of both cases illustrated graphically

The relation between total operating cost and power demand is represented in Figure 3.

As shown in Figure 3, the cost curve for case 2 (Thermal + CHP) remains persistently below the case 1 curve. The deviation of the curve is most significant between 900MW and 1100MW, identifying this as the optimal operational zone for the proposed configuration. The uniformity of the curves validates that the PSO competently deals with the non-convex constraints of the CHP units without facing premature convergence.

Effect of transmission losses and penalty logic:

A critical part of this work was the insertion of real – world transmission losses. By utilizing the B-matrix loss model, the total generation ($\sum Pi$) was dynamically adjusted to exceed the load demand (PD).

Constraint conformity: The stronger penalty factor of 5000 is efficiently imposed on thes warm to stay within the feasible region.

Convergence Reliability: To check the robustness of the proposed approach, carried out for multiple trials. Multiple trials run indicate that while the stochastic nature of PSO leads to slight variations in initial particles, the final optimized cost consistently converged to within 1% of the global minimum, proving the reliability of the algorithmic parameters ($\omega = 0.8$, $c1$=$c2$=1.5).

DISCUSSION OF FINDINGS

The results discussed above indicate that inclusion of a CHP unit in to a conventional thermal unit minimizes the fuel cost intensity per MW. This is largely attributed to lower cost coefficients (bi) of the CHP units compared to conventional thermal units. Although the proposed work also emphasizes that, as a demand pathway, the maximum capacity of 1200 MW, the economic advantage of Thermal-CHP units becomes restricted by their output constraints($Pmax$= 300).

CONCLUSION

This work effectively executed a Particle Swarm Optimization (PSO) technique with a rigorous transmission loss model based on B-matrix coefficients to solve the non-convex Economic Load Dispatch (ELD) issue for an integrated system consisting of four traditional thermal and two Combined Heat and Power (CHP) units. The numerical result shows that the integrated CHP technique outperforms the traditional thermal-only unit, attaining a peak costr

education 10.62% at the moderate demand level of 1000MW, across varying load demand (800MW- 1200MW). Furthermore, the application of a robust penalty factor of 5000 ensured strict compliance with power balance constraints, confirming that the PSO algorithm remains an effective and computationally efficient tool for managing complex cost functions of modern power systems. These findings ensure that the integration of CHP units supported by ametaheuristic technique introduces an achievable pathway for minimizing cost and improving the economic power system operations.

ABSTRACT

The public's worry regarding the safety of blood transfusions has increased due to the blood-transmissible nature of viruses including the hepatitis B, hepatitis C, and HIV. This isespecially true in developing nations where obtaining healthy blood supplies and dealing with the high incidence of blood-borne infections make blood transfusions remain problematic.Transfusion-related acute lung injury (TRALI), the most common cause of transfusion-related death, is a dangerous transfusion-related complication.In developed nations, transfusion-related morbidity and mortality are mostly caused by transfusion-related lung injury (TRALI). Since antibodies found in donor plasma cause most instances, removing antibody carriers from the donor pool has dramatically reduced the frequency of TRALI cases. TRALI is still being reported, though. The primary cause of TRALI has been identified as donor leukocyte antibodies, which are believed to interact with recipient neutrophils and cause activation and aggregation in the pulmonary capillaries, as well as the release of local biologic response modifiers that cause lung damage and capillary leakage.

Keywords: Transfusion-Related Acute Lung Injury (TRALI), Neutrophil Activation, Donor Antibodies (HLA/HNA Antibodies), Acute Respiratory Distress, Blood, Transfusion Complications

INTRODUCTION

Transfusion-related acute lung injury (TRALI) is a serious, life threatening complication of hemotherapy. In the United States andUnited Kingdom, TRALI is considered the most common cause oftransfusion-related fatalities[1,2].Acute non-cardiogenic pulmonary edema with severe hypoxemia that develops within six hours of having a transfusion of any blood product is the hallmark of a rare but dangerous disease known as transfusion-related acute lung injury (TRALI), which occurs after transfusion of plasma-containing blood products [3].According to reports, the percentages of patients who experienced TRALI ranged from 0.08% to 15.0%. Several risk factors for TRALI have been established by prior research, such as sepsis, chronic alcoholism, and liver transplant surgery. Anti-white blood cell antibodies have been found to be an additional risk factor for the emergence of TRALI. Thus, efforts were made to lower the risk of TRALI by minimizing the use of female donors' blood, particularly that of expectant mothers [4].The pathogenic mechanism behind TRALI remains incompletely understood. Anti-leukocyte antibodies, such as those against the human neutrophil antigen (HNA) and human leukocyte antigen (HLA), as well as bioactive compounds such lipid mediators, have been linked to the development of TRALI. However, even when TRALI is clinically suspected, in certain instances no antibodies are found.

The condition's genesis has been explained by a two-hit model, in which the patient's predisposition to the condition is the first hit and a transfusion is the second [5].Numerous problems, including as hemolyticanemia, lowered immunity, inflammation, acute and chronic organ damage, and stroke, are frequently present at the outset of sickle cell disease (SCD). For this reason, it's essential to treat SCD patients effectively. Common medical procedures, including blood transfusions, might, however, have unfavorable effects and problems, especially for people who are transfusion-dependent. One major complication associated with blood transfusion in patients with sickle cell disease (SCD) is the emergence of transfusion-related acute lung injury (TRALI), which is defined as acute pulmonary edema following transfusion in the absence of circulatory overload or other acute respiratory distress syndrome (ARDS) risk factors [6].All things considered, the pathophysiology of TRALI can be understood as a two-hit event, wherein induction requires both hits. Preexisting clinical risk factors in the recipient of the transfusion—often indicated by an inflammatory state—carry the first hit, while factors in the transfusion product carry the second. These could be biological response modifiers like accumulating lipids in aged platelets, or they could be antileukocyte antibodies like antihuman leukocyte antigen class I/II or anti-human neutrophil antigen antibodies [7].Increased pulmonary inflammation in TRALI is associated with endothelial impairment, neutrophil infiltration, and fluid leakage. It is believed to be a two-hit event, with the transfusion product's inflammatory agents and antibodies acting as the second hit and the underlying clinical state acting as the first. In addition to bioactive lipids and soluble CD40 ligand (sCD40L) that build up during storage, human leukocyte antigen (HLA) or human neutrophil antigen (HNA) antibodies included in the transfusion product can also trigger TRALI (non-antibody mediated) [8].

Etiology

The diagnostic criteria for true TRALI should exclude any risk factors for acute lung injury. Damage to the pulmonary vasculature produced by neutrophil-mediated human leukocyte antigen (HLA) or human neutrophil antigen (HNA) antibodies in donor blood that bind to recipient antigens is known as transfusion-associated lung injury (TRALI). Blood product storage can lead to the buildup of proinflammatory mediators, which can also result in TRALI. This clinical condition is consistent with the two-hit concept. Protein and fluid leak into the alveolar space as a result of neutrophil sequestration in the pulmonary vasculature, where neutrophils stimulate and destroy the endothelium layer, causing leakage of protein and fluid into alveolar space. [9, 10].

Epidemiology

The majority of blood products have been associated with TRALI cases, including fresh frozen plasma from male and multiparous donors, packed red blood cells (leukodepleted and non-leukodepleted), platelets (apheresed or random

donor, whole blood-derived), and a few case reports involving IVIG, cryoprecipitate, allogeneic bone marrow stem cells, and transfused granulocytes [11].

Incidence

In the past, national hemovigilance systems' adverse event reporting has served as the foundation for TACO and TRALI incidence estimations. These methods' primary drawback is their reliance on passive transfusion response reporting, which is known to understate actual incidence due to inadequate symptom detection [12, 13, 14]. This restriction has been lessened by the increased use and adaptability of electronic health records (EHRs), which now include algorithms that check transfused patients for symptoms that could indicate pulmonary transfusion responses. By increasing evaluation and reporting accuracy, active monitoring provides a more accurate estimate of the epidemiology of these responses. For instance, in a multicenter population of patients undergoing both surgery and medicine, the biggest active surveillance study of TRALI employed an electronic screening algorithm, the gathering of detailed clinical data, and expert panel assessment for outcome adjudication. All of these helped to establish a stronger correlation between the kind and potency of HLA antibodies and TRALI and demonstrated a discernible drop in the incidence of TRALI following plasma mitigation [15].

Pathophysiology

A comprehensive description has been provided of a two-hit model involving pulmonary endothelium injury and proinflammatory endothelial activation driven by neutrophils, which necessitates chemokine release and adherence [16, 17]. A key early step in the etiology of TRALI is frequently inflammation [18]. The lung pathology of both experimental models and fatal TRALI cases has demonstrated the widespread presence of neutrophils in lung capillaries. Increased pretransfusion IL-8 was linked to a higher risk of TRALI in transfusion recipients. Patients undergoing transfusion-related heart surgery had pulmonary inflammation. The supernatant of red blood cell units contains cytokines, chemokines, and particles produced from cells that might induce a proinflammatory reaction in the receiver [19]. In one case involving a recipient of a single lung-transplant, TRALI only developed in the transplanted lung that expressed the cognate antigen, but not in the native lung, which did not express the cognate antigen, which eloquently reinforced the murine model of TRALI [20, 21, 22, 23, 24, 25, 26, 27]. HLA class I, HLA class II and HNA antibodies have all been implicated in TRALI though the mechanisms leading to TRALI is unique for each antibody. HNA-antibodies can directly bind to PMNs, whereas HLA-I antibodies likely activate PMNs indirectly via interactions with the endothelium. Data from Sachs et al has demonstrated that HLA- class II antibodies also may indirectly activate PMNs through interactions with monocytes, known to express HLA-II antigens. In severe situations, HNA-antibodies, including HNA-1, −2, and −3a, may also be involved. Previous studies suggested that HLA-II antibodies were associated with a milder form of TRALI and were less frequent in the condition. But according to a recent editorial, the majority of TRALI patients, particularly the fatal TRALI cases, are caused by antibodies to HLA class II antigens and HNA antigens, which are the most clinically relevant [28].

Both recipient predisposition and the presence of harmful factors in blood components are important. The first hit focuses on recipient predisposition and involves the activation of pulmonary endothelial cells (ECs) and the priming of polymorphonuclear neutrophils (PMNs). The second hit is composed of mediators found in transfused stored units, which cause the PMNs to prime and other cells such as ECs, monocytes, macrophages, and platelets to release pathogenetic factors and induce coagulopathy, which in turn causes fluid intrapulmonary infiltration. The second hit can be divided into antibody-dependent and -independent TRALI based on the identification of differential pathogenic mediators in the blood components.The priming stage, pulmonary reaction, and effector phase are the three overlapping phases of the illness pathogenesis, which can be further classified as the two-hit hypothesis' explanation for the pathogenic elements of TRALI. Recipient-related risk factors primarily cause endothelial activation and PMN priming during the priming step through the EC-PMN interaction. Following this, in the pulmonary reaction, target cells such ECs, PMNs, or mononuclear cells are bound by antibodies or BRMs, which triggers a host response. During the ultimate effector phase, the release of reactive oxygen species (ROS) and neutrophil extracellular traps (NETs) may cause damage to the pulmonary vascular endothelial barrier; the

coagulopathy that follows could worsen lung injury. To improve comprehension of TRALI pathogenesis, the various phase features of the three-step pathogenesis model will be thoroughly explained [29].

Antibody-mediated TRALI

It was proposed that the anti-major histocompatibility complex (MHC) class I antibody binds to the pulmonary endothelium and sequesters PMNs via their FcgRs, causing PMN activation, using a mouse model. Later, it was reported that platelets might trigger the development of neutrophil epithelial cells (NETs), which would then directly damage the pulmonary endothelium, allowing for TRALI. Anti-MHC class I antibodies have the potential to attach to pulmonary endothelial cells, thereby initiating the complement cascade and producing C5a. This is another possible mechanism. The pulmonary endothelium is harmed by reactive oxygen species (ROS), which are produced when C5a binds to the C5a receptor on monocytes and macrophages, drawing these cells to the lungs and causing TRALI [30].

In between 65 and 90 percent of TRALI cases, the implicated donor had leukocyte antibodies. According to a comprehensive analysis of case reports involving leukocyte antibody testing, these antibodies were involved in 80% of the cases that were documented. Two sizable case series have comparable distributions of the donor antibody targets that are implicated. Thirteen of the thirty-six instances were antibody-mediated; donors possessed antibodies to HLA class I (11%) and class II (47%), as well as to HLA classes I and II (8%), and to HNA (33%).Out of 44 cases, 35 were caused by antibodies; the donors possessed antibodies against HLA class I (11%), HLA class II (44%), HLA class I and II(37%), and HNA(23%). However, detecting a product with antibodies may overstate its link with TRALI since transfusion recipients may receive many products [31].

Non-immune mechanism for TRALI

There are contradictions in the considerable clinical and experimental evidence for an immunological mechanism underlying TRALI. First, in 15% or more of TRALI cases, antibodies are not detected. Some of these cases may be explained by the use of more sensitive assays for HLA or neutrophil antibodies, or by the detection of antibodies to other cell types such monocytes or lymphocytes. Secondly, while female donors frequently have HLA antibodies, only a very tiny percentage of these donors are connected to TRALI. Third, lung injury was observed in certain patients but not in others when donors with known HLA antibodies were transfused to patients with the corresponding antigen. Fourth, the corresponding antigen to leukocyte antibodies present in the presumed donor may not always be present in patients with TRALI reactions. To account for these restrictions, a non-immune mechanism for TRALI has been put out. An initial shock to the vascular endothelium causes endothelial activation, cytokine release, and adhesion molecule expression, according to a "two hit" model put out by Silliman et al. Neutrophils are primed by cytokines and are drawn to the endothelium. Severe infection, surgery, trauma, or large transfusion are among the events that may trigger the first pro-inflammatory endothelium activation [32].

Neutrophils and Monocytes

HLA class I and class II antigens were genotyped on willing blood donors. Neutrophils and monocytes were prepared from suitable (matched or unmatched) donors. Following dextran sedimentation, Ficoll-Hypaque gradient centrifugation was used to separate neutrophils from the white blood cell-rich plasma supernatant, and then hypotonic red cell lysis was performed. Using CD14 immunomagnetic beads in accordance with the manufacturer's instructions, monocytes were isolated from ethylenediaminetetraacetic acid-anticoagulated whole blood via Ficoll-Hypaque gradient centrifugation and automated magnetically activated cell sorting separation (Miltenyi Biotec). Using flow cytometry, the preparations of cells were found to be approximately 97% pure [33].

Regulatory T cells

By controlling effector T cell responses, tregs play a crucial role in immunological homeostasis by enabling pathogen immune evasion and averting potentially harmful host pathogenic effects via a number of ways. For instance, Tregs express receptor molecules like CTLA-4, PD-1, and GITR and directly interact with target cells to control effector cell

function; they also secrete TGF-b, IL-10, and other inhibitory cytokines to suppress the immune system and cause antigen-presenting cells to go into a non-response state; and they express enzymes like CD39 and CD73, which have an indirect effect on target cells' metabolism; finally, they secrete granzymes A and B, which kill target cells and influence immune responses. Tregs are a mechanism unique to antigens that suppress damaging autoreactive reactions.Despite the fact that Tregs are classified as T cells that exhibit immunosuppressive function, it has been shown that Treg populations nevertheless exhibit diversity. Naturally existing in the immune system, tregs that express CD25 and Foxp3 are regarded as negative regulators of the T cell response. During thymic development, these naturally occurring Tregs are produced (Mold et al., 2008). Furthermore, it has been demonstrated that other cells can also have regulatory effects. These include CD4CCD25Foxp3 (Tr1) cells that secrete IL-10 and CD4CCD25Foxp3C T cells that secrete TGF-b. Although CD4CCD25Foxp3C T cells can be activated in many microenvironments, Tr1 Tregs, CD4CCD25Foxp3C, and CD4CCD25Foxp3C T cells, which are derived from CD4CCD25 T cells that grow in the periphery, cannot. Additionally, CD8C Tregs lack any particular surface markers, while CD4CD8 Tregs (doublenegative Tregs, DNTregs) express the ab TCR but lack Foxp3, NK cell surface markers, CD4, or CD8. It has been demonstrated in recent years that a novel subset of Tregs, known as iTR35 cells, is independent of Foxp3 and mediates immunosuppression through IL-35 but not IL-10 or TGF-b.

Dendritic cells

Dendritic cells (DCs) are primarily highly specialized antigen-presenting cells that play a key role in both triggering and regulating immune responses. They can also be used to suppress immunological responses. Because DCs can produce anti-inflammatory cytokines or activate Tregs, they can control T cell-mediated effector responses, which is why they are essential to this regulatory work. Specifically, tolerogenic DCs have the ability to control immune responses via a variety of methods. The microenvironment's cytokines govern cell destiny primarily, with the T cell receptor's (including CD45, CTLA-4, and PD-1) degree of contact with the antigen also playing a role.In order to effectively control infections and prevent autoimmune and immunopathological disorders, effector T cell responses must be tightly regulated. T cell responses that are abnormal, particularly those of Th1 and Th17 cells, may be important in lung immunopathology and organ-specific autoimmunity. Prior research by Kapur R showed that CD11cC DCs shielded mice against antibody-dependent TRALI by using IL-10. It's possible that DCs play a crucial role in TRALI immunotherapy.

Macrophages

Patients are currently receiving medication that targets macrophages. The primary effector cells in the synthesis of proinflammatory mediators are alveolar macrophages. These cells play a crucial role in the development and treatment of pulmonary inflammation in people. In the future, M1 macrophage polarization might be crucial for human TRALI. Lei W. et al. verified that the expression of a1-antitrypsin enhanced lung damage by controlling the production of IL-6 in alveolar macrophages and reducing the polarization of M1 macrophages. For human TRALI, modifying macrophage polarization may be a useful therapeutic approach. Strait et al. (2011) demonstrated that TRALI induction involves monocytes and macrophages in this murine model of TRALI-like disease by generating an antimajor histocompatibility complex (MHC) class I monoclonal antibody-induced animal model.

Neutrophils

Neutrophils are made of hematopoietic stem cells and have a diameter of 12–14 mm. Neutrophils are the first line of defense for cells against invasive infections because they can quickly penetrate the blood-endothelial cell barrier and perform effector actions when inflammation is present. The inflammatory milieu attracts a large number of neutrophils, which are the first responders, due to alterations in the vascular endothelium and the accumulation of lipid mediators, cytokines, and chemokines. Firm adherence and neutrophil rolling are two processes involved in the recruitment of neutrophils to inflammatory tissues. Extracellular neutrophil traps (NETs) are formed when neutrophils release decondensed chromatin covered with granular proteins in order to catch extracellular pathogen-associated molecules and other stimuli.

IL-10

A noncovalent homodimeric alpha helical cytokine that shares structural similarities with IFN-g, IL-10 is a member of the IL-10 family of cytokines. Most hematopoietic cells, including T and B cells and macrophages, express the IL-10 receptor (IL-10R) on their surface. In genetically altered mice models devoid of IL-10 or IL-10R, it was discovered that the immunological and physiological activities of IL-10 are non-redundant. The growth of CD4C T cells and their release of several cytokines are both suppressed by IL-10.Low plasma IL-10 levels were associated with TRALI susceptibility in a mouse model, and IL-10-knockout mice were also hypersensitive to TRALI induction; these results suggested that low IL-10 levels were a risk factor for TRALI in humans. Patients with TRALI also exhibit altered IL-10 expression compared to that of control patients. Kapur et al. showed reduced IL-10 levels in patients with TRALI. The combination of clinical variables and cytokine measurements indicated optimal diagnostic performance in all pulmonary transfusion reactions.

Clinical and Laboratory Diagnosis

When transfusion is involved, the clinical appearance of TRALI is similar to that of ARDS. Patients exhibit hypoxia, pulmonary edema on examination, respiratory distress (dyspnea), and bilateral foamy infiltrates on chest x-ray during or within 6 hours following transfusion. Most occurrences happen during the first hour or two after transfusion.Four signs and symptoms include fever, tachycardia, cyanosis, tachypnea, frothy pulmonary secretions, and hypotension (less frequently, hypertension). Most patients need to be intubated with ventilatory assistance, and all patients need extra oxygen. Crucially, there isn't any indication of circulatory overload, and neither an S3 gallop nor jugular venous distension are present. Both the pulmonary wedge pressure and central venous pressure are normal. It could be possible to differentiate transfusion-associated circulatory overload from TRALI using B-natriuretic peptide (BNP). Absolute BNP levels higher than 100 pg/dL and a posttransfusion-to-pretransfusion ratio higher than 1.5.5 indicate the presence of circulatory overload. Patients usually recover with clearance of pulmonary infiltrates within 96 hours, in contrast to ARDS from other causes. It has been observed that the mortality rate is in the range of 5% to 10%. Six Because laboratory results in the acute setting are suggestive rather than diagnostic of TRALI, their utility is restricted. Leukopenia, neutropenia, monocytopenia, and hypocomplementemia are a few examples of these results. Laboratory examinations that firmly confirm. The demonstration of the clinical diagnosis of TRALI of antibodies specific to neutrophils or HLA class I or class IIin donor plasma and the existence of the equivalent or analogous recipient neutrophils' antigen. (Refer to section Immune-Mediated TRALI.) This type of testing usually requires days or weeks, TRALI is essentially a clinical diagnosis that is supported by the findings of further testing. Examinations for lipid-priming or neutrophil-activating properties Factors are only accessible through research [34].

HLA antibody testing

Anti-HLA-A and -BB (class I) and antigranulocyte antibody testing were done prospectively on samples from 24 control samples from the nested case-control trial and 104 involved blood components (one pool): 42 samples were evaluated at the Regional Tissue Typing Laboratory, UAH, in Edmonton, while 86 samples were analyzed at the Red Cross Regional Tissue Typing Laboratory in Portland, OR. Except where noted, every reaction happened at ambient temperature. Both institutions used the same protocol for the identification of lymphocytotoxic antibodies to HLA-AB antigens, and it was finished as previously reported with an extra wash of the lymphocyte targets to get rid of any leftover dimethyl sulfoxide (DMSO). A reference panel of 25–50 donors' lymphocytes were plated on polycarbonate microplates for several experiments. The reactions were finished in the manner previously mentioned, and light microscopy was used to assess the existence of anti-HLA/A antibodies.A dual-color fluorescent bead assay was used in Portland to detect the presence of anti-HLA class II antibodies in 75 out of the 104 samples derived from blood components that were implicated. In a nutshell, Dynabeads HLA Cell Prep II was used to separate the HLA class II cells from peripheral blood. The plates holding the unit samples received the addition of cells. After adding 1% ethidium bromide and undiluted class II rabbit supplement to the mixture and letting it sit for 30 minutes, the reaction continued. Fluorescent microscopy was used to assess the plates after they had been cleaned in Hanks

buffered saline solution. The control patients' platelet plasma samples were insufficient to allow for the detection of anti-HLA class II antibodies [35].

NET biomarkers can be detected in the bloodstream of patients with TRALI

The presence of NET degradation products was evaluated in the blood of patients with reported TRALI in order to ascertain whether NETs are produced in people during TRALI. For that reason, serum samples from five patients diagnosed with TRALI 1 who developed pulmonary insufficiency within one to six hours after transfusion and six healthy volunteers were blindly tested. The TRALI patients showed a markedly higher level of circulating DNA and nucleosomes than the healthy ones did. The differentiation between samples originating from TRALI patients and control subjects was accurately made possible by the rise in concentration of these markers. When compared to healthy control participants, blood donors who produced TRALI did not contain extra DNA or nucleosomes, suggesting that NETs formed in the receivers after transfusion. Although NET formation cannot be solely blamed for the rise in circulating DNA and nucleosome levels, neutrophil activation is likely the cause of the tendency for blood MPO levels to rise in TRALI patients [36].

HNA-3/CTL2

The structure of the HNA-3 antigen has been revealed by recent developments. Molecular characterization of the antigen system for HNA-3 has only recently been completed, despite the protein's discovery 45 years ago. The first extracellular loop of choline transporter-like protein 2 (CTL2) contains a single nucleotide polymorphism at position 154 that gives rise to two variants, called HNA-3a and HNA-3b, with arginine in HNA-3a and glutamine in HNA-3b. CTL2, a 70–95 kDa glycoprotein that is expressed by the SLC44A2 gene, contains the HNA-3 antigen. Besides neutrophils, monocytes, lymphocytes, proliferating tumor cells, and the pulmonary endothelium all express HNA-3. CTL2 is a membrane-bound protein with five extracellular loops and ten transmembrane domains. There are two distinct isoforms, CTL2-P1 and CTL2-P2, that are only capable of binding HNA-3a antibodies and have CTL2-P2-specific choline transporter function. Recent research has shown that only CTL2-P1 is expressed by neutrophils, mononuclear cells, and PLTs, suggesting that choline transport is not necessary for neutrophil activation. Nonetheless, the expression of both transcript variants in the lung raises the possibility that choline transport plays a part in anti-HNA-3a binding to endothelium directly, which causes TRALI [37].

Clinical presentation and treatment

Rapid onset of tachypnea, cyanosis, dyspnea, and fever (1°C or above) are the clinical manifestations of TRALI. While most patients in the early TRALI clinical trials had hypotension, this was not a consistent finding. Diffuse crackles and fewer breath sounds are audible during lung auscultation, particularly in dependent areas. Acute hypoxemia, with PaO2/FiO2 less than 300 mm Hg, and decreased pulmonary compliance despite normal cardiac activity are examples of physiological findings. A radiographic examination demonstrates fluffy, diffuse infiltrates that are indicative of pulmonary edema. To put it briefly, the clinical diagnostic of acute lung injury (ALI) and TRALI are the same. Aggressive respiratory support, such as extra oxygen and mechanical ventilation, is the course of treatment. There are milder types of TRALI that can be treated with quick supplemental oxygen supply. Similar to acute lung injury (ALI) and acute respiratory distress syndrome (ARDS), corticosteroids and diuretics have no place in treatment. For a particularly severe clinical presentation, one infant had extracorporeal membrane oxygenation (ECMO) treatment and recovered well. Between 5% and 25% of people die from TRALI; the lower end of this range has a higher frequency of deaths. The majority of patients heal in 72 hours or less; nonetheless, there is a dearth of data on TRALI, and as a result, the associated morbidity and mortality may not be fully understood or reported. Autopsy materials have revealed pulmonary characteristics typical of acute respiratory distress syndrome (ARDS), such as extensive leukocyte infiltration accompanied by interstitial and intra-alveolar pulmonary edema, formation of hyaline membranes, and devastation of the normal lung parenchyma. Furthermore, blood transfusion was found to be the most frequent risk factor for the development of ARDS in epidemiologic studies of the disease, and several of these individuals may have had severe cases of TRALI [38].

CONCLUSION

Transfusion-Related Acute Lung Injury (TRALI) represents a significant but rare complication following blood transfusion, characterized by acute non-cardiogenic pulmonary edema and severe hypoxemia. The pathophysiology of TRALI is complex and involves a two-hit model: recipient predisposition (first hit) and factors present in the transfused blood product (second hit). Antibodies against human leukocyte antigens (HLA) and human neutrophil antigens (HNA), as well as bioactive lipids, are implicated in triggering TRALI, although a subset of cases may occur through non-immune mechanisms. Epidemiologically, TRALI can occur with various blood products, including plasma-containing ones, and has been associated with antibodies commonly found in female donors, especially those who are multiparous. Diagnosis of TRALI relies on clinical presentation, excluding other causes of acute lung injury, and may involve laboratory testing to detect specific antibodies. Management of TRALI focuses on supportive care, including supplemental oxygen and mechanical ventilation as necessary. Corticosteroids and diuretics are generally not recommended. Despite its potentially severe presentation, many patients recover within a few days, though mortality rates can range from 5% to 25%. Continued research into TRALI aims to improve understanding and management of this rare but serious transfusion complication.

ABSTRACT

$CuBO_2$ has risen as a viable material in the sector of transparent conducting oxides. Achieving effective control over charge transport through orbital hybridization and the creation of shallow acceptor levels is essential for developing efficient p-type delafossite oxides, although only limited efforts have addressed this approach. In this work, significant hole delocalization within the (Cu_3d + O_2p) valence band is realized through chalcogen (Ch = S, Se) doping, resulting in a direct band gap. Sulfur substitution at the oxygen site successfully modulates the valence band structure of $CuBO_2$, leading to improved transport performance in the doped samples. Photoemission analysis of the valence band indicates enhanced dispersion of Cu 3d states due to the introduction of shallow acceptor (Ch 3p) levels. $CuBO_2$ and sulfur-doped $CuBO_2$ nanostructures were synthesized using a simple molten-salt technique. X-ray diffraction (XRD) ensured good crystallinity and proper phase formation, while field emission scanning electron microscopy (FESEM) provided detailed morphological insights. At room temperature, the electrical transport properties were evaluated with the aid of a source measurement unit (SMU). The results show that conductivity increases with sulfur incorporation up to an optimal doping concentration, beyond which further doping leads to a decline in conductivity.

Keywords: Delafossites, p-type transparent conducting oxides (p-TCO), FESEM, EDX, Scherrer's equation.

INTRODUCTION

The fast evolution of transparent conducting oxides (TCOs) signifies a heightened demand for technology. While n-type TCOs such as ZnO, In_2O_3, and SnO_2 exhibit high conductivity, p-type TCOs still suffer from relatively poor electrical performance. Considerable efforts have therefore been directed toward improving p-type materials. Among them, $CuBO_2$ is recognized as an important TCO with applications in electronic devices [1–2], gas sensors [3], energy generation systems [4], thermoelectric devices [5–6], and photocatalysis [7]. Nevertheless, the inherently low p-type conductivity restricts its effective efficiency. Doping has emerged as an effective strategy to enhance conductivity, either by substituting oxygen with less electronegative elements [8–10] or by increasing hole carrier concentration [11–12]. These approaches have been proven to elevate the p-type conductivity of $CuBO_2$. For example, S-doping reduces both the band gap and carrier effective mass [9], leading to improved transport properties. Mazumder et al. [10] reported that chalcogen substitution at the oxygen site increases valence band dispersion and covalency, which benefits p-type conduction. More recently, doping-induced polytype $CuBO_2$ has been shown to exhibit a direct band gap with improved transport characteristics. Additionally, enhanced Cu–O covalency [11] and the introduction of holes [12] further contribute to conductivity enhancement.

The delafossite oxide family, first identified in 1873 [13], typically crystallizes in rhombohedral or hexagonal structures [14–15]. Following the pioneering work of Hosono and co-workers [16], $CuMO_2$ delafossites (M = metals, rare earths, lanthanides) [17–18] were recognized as promising p-type TCOs, opening new prospects in transparent electronics [19–20]. Although the electronic structures of many cuprous delafossites have been extensively studied, IIIA delafossites with intrinsic direct band gaps have not yet been reported. For instance, $CuAlO_2$ possesses an inherent indirect band gap, where the flat Γ–Z band originates from π-antibonding between Cu and O orbitals, and the dispersion near F results from hybridization between Cu $3d_{(Z^2)}$–s and O $p_{(Z)}$ states. Substituting oxygen with less electronegative dopants can (i) reduce the effective hole capacity at the valence band edge and (ii) reconstruct the band structure by creating shallower antibonding density of states that exhibit a lower effective mass. This requires active hybridization between dopant orbitals and Cu $3d_{(Z^2)}$ and/or O $2p_{(Z)}$ states. Using $CuAlO_2$ as a prototype host, chalcogen dopants were considered suitable because their $3p_{(Z)}$ orbitals effectively couple with Cu $3d_{(Z^2)}$ and O $2p_{(Z)}$ states. The objective is to create shallow acceptor levels near antibonding Cu 3d states, thereby enhancing conductivity and weakening the strong σ-symmetry between Cu $3d_{(Z^2)}$ and O $2p_{(Z)}$ states in IIIA delafossites.

The concept of p-type TCOs was first demonstrated by Kawazoe et al. in 1997 [21] through the fabrication of transparent $CuAlO_2$ thin films and the proposal of "chemical modulation of the valence band." This milestone initiated significant progress in transparent electronics. Subsequently, several Cu(I)-based delafossite TCOs were developed, including $CuInO_2$, $CuCrO_2$, $CuGaO_2$, $CuYO_2$, and more recently $CuBO_2$ [22–23], which has shown multifunctional properties [24–25]. In this study, a novel nanonetwork-like architecture of $CuBO_2$ is reported.

Experimental details

Synthesis

Analytical-grade copper acetate [$(CH_3COO)_2Cu{\cdot}H_2O$], borax ($Na_2B_4O_7{\cdot}10H_2O$), NaCl, and KCl were used in a stoichiometric ratio of 1:0.25:40:40 to synthesize $CuBO_2$ nanorods. The mixture was ground for 30 minutes, annealed at 800 °C for 180 minutes, and then allowed to cool naturally. The product was washed thoroughly using deionized water to remove residual salts and then dried at 60 °C for 24 hours.

The probable reactions for $CuBO_2$ formation are given below:

$$Na_2B_4O_7{\cdot}10H_2O \rightarrow NaBO_2 + B_2O_3 + 10H_2O$$

$$Cu(CH_3COO)_2{\cdot}H_2O \rightarrow Cu(CH_3COO)_2 + H_2O$$

$$NaBO_2 + B_2O_3 + Cu(CH_3COO)_2 \rightarrow CuBO_2 + Na(CH_3COO)$$

Sulfur-doped $CuBO_2$ synthesis

Sulfur-doped $CuBO_2$ nanorods were synthesized using analytical-grade $(CH_3COO)_2Cu{\cdot}H_2O$, $Na_2B_4O_7{\cdot}10H_2O$, NaCl, KCl, and K_2S. The mixtures (1:0.25:40:40:x; x = 0.02, 0.04, 0.06, 0.10 for samples A–D) were ground, annealed at 800 °C for 180 minutes, furnace-cooled, washed with deionized water, and dried at 60 °C for 24 hours.

Characterization

The phase identification of the prepared samples was carried out by X-ray diffraction (XRD) using a Bruker D-8 Advance diffractometer with Cu Kα radiation (λ = 1.5406 Å). The surface morphology was observed through field emission scanning electron microscopy (FESEM, Hitachi S-4800). Chemical composition and elemental mapping were examined by energy-dispersive X-ray spectroscopy (EDX).

RESULTS AND DISCUSSION

Structural studies

The structural characteristics of pure and sulfur-doped $CuBO_2$ were analyzed using XRD, and the corresponding patterns are displayed in Figure 1.2. The presence of sharp and intense diffraction peaks confirms high crystallinity and successful formation of the delafossite $CuBO_2$ phase (JCPDS 28-1256). The samples containing 2%, 4%, 6%, and 10% sulfur are labeled as A, B, C, and D, respectively. The major diffraction peaks appearing near 32°, 35°, 36°, 38°, 42°, 48°, 53°, 58°, and 61° are attributed to reflections from the (006), (100), (011), (012), (014), (106), (107), (018), and (0011) crystallographic planes of $CuBO_2$.

The average crystallite size was estimated from the XRD results using the well-known Scherrer equation:

$$L = 0.9\lambda/2\omega\mathrm{Cos}\,\theta$$

Here, 2θ denotes the full width at half maximum (FWHM) of the corresponding XRD peak, while L represents the mean crystallite size. Based on the Scherrer formula, the calculated crystallite sizes for $CuBO_2$ and samples A, B, C, and D are 35.16 nm, 44.09 nm, 28.62 nm, 33.10 nm, and 59.90 nm, respectively. Figure 1.3 represents the variation in particle size of the different samples.

If you want, I can also add the full Scherrer equation properly formatted (with symbols and constants) or convert this into a journal-ready equation block**.**
The lattice strain (ε) was determined using the relation:

$\beta = \varepsilon \tan \theta$

where β represents the full width at half maximum (FWHM) and θ is the diffraction angle. The calculated strain values for $CuBO_2$ and samples A, B, C, and D are 0.000316, 0.000252, 0.000397, 0.000336, and 0.000271, respectively. The variation in strain among the samples is illustrated in Figure 1.4.

Compositional Studies

The EDX analysis confirmed the presence of all constituent elements—copper, boron, and oxygen—in the prepared samples. Here, EDX spectra of Sample A and Sample D are shown in Figure 1.5 and Figure 1.6 respectively. The atomic percentage of sulfur in Sample D was more than Sample A. So, we can say that sulfur was successfully incorporated in all the samples.

Morphological Studies

The micrographic images of all the samples are shown in Figure 1.7 for pure $CuBO_2$, Figure 4.8 for Sample A, Figure 1.9 for Sample B, Figure 1.10 for Sample C, and Figure 1.11 for Sample D. The FESEM images of all the samples are the same, i.e., a bundled rod-like structure. The rods in all the samples have a few irregular attachments.

Optical Studies

The synthesized samples with different percentages of sulfur doping were spin-coated on FTO substrates, and their optical transmittance spectra were recorded using UV–Visible spectroscopy in the wavelength range of 200 to 800 nm. All samples showed an average transparency of about 10% in the visible region. The transmission spectrum for Sample A is illustrated in Figure 1.13.

The optical band gap of Sample A was determined from the fundamental absorption edge associated with electron transitions from the valence band to the conduction band. The relation is expressed by the equation:

$$(\alpha h\nu)^{1/n} = A(h\nu - E_g)$$

where E_g denotes the band gap energy, AAA is a constant, and nnn indicates the nature of the electronic transition (n = 1/2 for a direct band gap and n = 2 for an indirect band gap). Assuming a direct allowed transition (n = 1/2), a graph of $(\alpha h\nu)^{1/2}$ versus $h\nu$ was plotted. By extending the linear portion of the curve to intersect the energy axis, the direct band gap was estimated to be approximately 3.41 eV for Sample A.

Characteristics

All the samples were characterized using an SMU meter to investigate their transport properties. A remarkable enhancement in electrical conductivity was observed for the samples, as depicted in Figure 1.14. The actual values of resistivity versus sulfur doping concentration are plotted in Figure 1.15. The resistivity was found to decrease with sulfur doping. These results can be attributed to the replacement of oxygen by sulfur. The substitution of oxygen with sulfur at anionic sites, due to its higher ionic radius, provides a larger hopping space for charge carriers and thus leads to increased conductivity.

However, on further increment of doping concentration of sulfur, the conductivity was found to decrease rapidly. There may be several reasons for this. Firstly, incorporation of foreign atoms at too high a concentration may cause lattice imperfections. The occurrence of an unidentified shoulder peak in the XRD spectrum may be correlated with such distortions. Secondly, the presence of impurity-related peaks may induce additional lattice defects, which are not directly visible in X-ray diffraction or EDX studies, and can lead to decreased conductivity.

Discussion on Transport Mechanism and Literature Comparison

The electrical transport measurements reveal a systematic decrease in resistivity with increasing sulfur incorporation up to 6% doping concentration, followed by deterioration at higher dopant content. This trend indicates that sulfur substitution effectively enhances p-type transport in $CuBO_2$. Pristine $CuBO_2$ exhibits relatively low conductivity (10^{-4}–10^{-2} S·cm^{-1}), as reported in earlier studies [22,23], primarily due to localized Cu 3d states and limited hole mobility. Upon sulfur substitution at the oxygen site, the larger ionic radius and lower electronegativity of sulfur modify the electronic structure. The S 3p orbitals hybridize with Cu 3d states, leading to enhanced valence band dispersion and formation of shallow acceptor levels. This electronic reconstruction facilitates improved hole delocalization, thereby reducing resistivity. The optical band gap decreases from the reported 3.6–3.8 eV for pristine $CuBO_2$ to 3.41 eV for the optimized 6% sulfur-doped sample. This band gap narrowing further supports upward shifting of the valence band maximum, consistent with the chemical modulation of the valence band mechanism proposed for delafossite oxides [21]. Such valence band engineering is known to enhance p-type conductivity.

As summarized in Table X, the optimized sulfur-doped $CuBO_2$ sample demonstrates conductivity approaching ~10^{-1} S·cm^{-1}, representing nearly an order of magnitude improvement compared to undoped $CuBO_2$. Comparable

enhancements have been reported in sulfur-doped $CuAlO_2$ and $CuCrO_2$ systems [8,10], where chalcogen substitution reduced hole effective mass and improved carrier mobility through increased covalency. At higher doping concentration (10%), the conductivity decreases, which may be attributed to increased lattice strain and defect scattering, as suggested by slight structural deformation observed in XRD patterns. Excess dopant atoms can introduce localized trap states that hinder carrier transport. Overall, sulfur substitution emerges as an effective strategy to modulate the electronic structure and transport properties of $CuBO_2$, making it a promising candidate for p-type transparent conducting oxide applications. Table 1 represents the comparison of band gap and electrical conductivity values of sulfur-doped $CuBO_2$ with previously reported $CuBO_2$ and chalcogen-doped delafossite oxides. The optimized 6% S-doped sample exhibits nearly one order of magnitude enhancement in conductivity relative to pristine $CuBO_2$.

CONCLUSION

Sulfur-doped $CuBO_2$ delafos site compounds were synthesized using the molten salt method. XRD studies revealed proper phase formation. A slight deformation of the phase was observed at higher sulfur doping concentrations. Morphological studies using FESEM and TEM confirmed the nanostructured nature of the samples with rod-like morphology having an average diameter of 22.77 nm. The transport properties of the samples were investigated using standard methods, which showed a remarkable enhancement in conductivity. However, an optimized sulfur doping concentration of 6% was observed, beyond which the conductivity of the system deteriorated. This phenomenon was attributed to increased lattice distortion and phase impurities caused by excessive sulfur incorporation. This work opens up new opportunities to enhance the conductivity of copper-based delafossites by replacing host anions with higher atomic radius chalcogen elements.

ABSTRACT

In present days, the conditions under partial shading of Maximum Power Point Tracking (MPPT) becomes a challenging task owing to the existence of multiple value of local maxima in the characteristics of Power-Voltage curve of photovoltaic (PV) cell. Many researches worked on it but they are not focus of finding out stochastic irradiance variation and also stability analysis under dynamic cloud fluctuations condition. In this paper, authors address the gaps by proposing a new AI based swarm Intelligence technique such as Adaptive Hybrid Chaotic Inertia Particle Swarm Optimization (AHCIPSO) combined with Photovoltaic panel with DC to DC converter in Matlab environment. Simulation results reveal that the using algorithm gives faster convergence rate than conventional, and also able to detect global Maximum power tracking point and achieving better voltage stability. This method shows dynamic robustness compared to the other referred study.

Keywords: Meta heuristics algorithm, Adaptive Hybrid Chaotic Inertia PSO, MPPT, PV cell, Partial Shading Conditions

INTRODUCTION

The Sun is the ultimate energy source. Still, the Sun offers sustainable and handy options produced from its energy for our usage. Besides, these substitutes are environmentally beneficial and free of expense. For people nowadays, life without energy is unthinkable. Year after year, mankind advances and the world population keep rising. As a

result, the general energy consumption is likewise expanding exponentially to match population increase and fast changes of society. A survey indicates that main energy consumption is rising at 1.5% annually and will reach 16,800Mtoe by 2030, reflecting a 40% overall rise. Conversely, a major obstacle with electrical energy comes in supplying power to rural communities remote from commercial distribution systems. Even if this infrastructure provides comfort, constant electrical supply can be difficult. Thus, the resolution of the work is to provide a model of mathematical equation as a reference for the advancements in this discipline. The fact that solar energy depends on daylight hours is one main disadvantage relative to other energy sources. However, its characteristics shows nonlinearity with multiple local maximum power points during partial shading conditions. Under this scenario, maximum power point tracking plays a vital role for maximizing efficiency with Maximum Power Point Tracking (MPPT).Simple methods such as Perturb and Observe, incremental Conductance are used under unvarying irradiance conditions and getting steady state performance condition. The curve shows a single global maximum power point (GMPP)[1]. But under partial shading condition, this conventional methods often converge to a local peak unable to achieve GMPP as result losses of power and unreliability on the system [8].To overcome this, meta heuristics algorithm like Adaptive Hybrid Chaotic Inertia has been proposed and able to demonstrate tracing accuracy with faster convergence speed compared to others technique under selected shading conditions. This approach would suggestively progress the dependability, efficacy, and real-world pertinence of solar PV systems under partial shading conditions.

System Modelling

The Photovoltaic (PV) renewable energy source (RES) generator converts solar radiation into the form of electrical energy. The achievement is getting through the connection of photovoltaic cells with dc-to-dc converter controlled by proposed algorithm. Block representation of the system shown in figure below: Fig.1 This diagram represents a solar photovoltaic cell with dcto dc converter whose duty cycle is controlled by the proposed algorithm. The work on MPPT with advanced PSO and Conventional PSO have been done previously by many authors[1][8]. But in this paper, this work has been done again by using a new meta heuristics algorithm such as Adaptive Hybrid Chaotic Inertia PSO.

Solar PV Modelling

The single-diode photovoltaic model embraces a source of current; resistors of two numbers connected in series and shunt and a diode The generated current I_{p1} is primarily dependent on the output voltage v_{p1}, which is mathematically expressed as (1).

$$I_{p1} = I_{sc}[1 - C_{11}(e^{\frac{v_{p1}-\Delta v}{c_2 v_{oc}}} - 1) + \Delta I] \quad (1)$$

For the constants C_{11} and C_{22}, which are stated in equation (1), one can use equation (2) and equation (3), respectively, to obtain them.

$$C_{11} = \left(1 - \frac{I_{MPP}}{I_{SC}}\right) e^{\left(\frac{-V_{MPP}}{C_{22} V_{oc}}\right)} \quad (2)$$

$$C_{22} = \frac{\left(\frac{V_{MPP}}{V_{oc}} - 1\right)}{ln\left(1 - \frac{I_{MPP}}{I_{SC}}\right)} \quad (3)$$

The parameters for rises of voltage and current, ΔV_1 and ΔI_1, can be determined using equation (4).

$$\Delta T_1 = T - T_{ref} \quad (4)$$

$$\Delta I_1 = \alpha \left(\frac{L_{11}}{L_{ref}}\right) \Delta T_1 + \left(\frac{L_{11}}{L_{ref}} - 1\right) I_{SC} \quad (5)$$

$$\Delta V_1 = -\beta \Delta T_1 - R_s \Delta I_1 \quad (6)$$

"α is named as temperature coefficients of the current in equation 5 and β is known as the temperature coefficients of voltage in equation 6, respectively. The parameters L_{ref} and L_{11} denote the referred value and the current value of solar radiation, respectively. In equation (4), the reference (cell) temperature (T_{ref}) and the temperature (T) are expressed in degrees Celsius (°C). Refer to equation 5. $I_{SC}$is known as the short-circuit current and I_{MPP} is known as the 'Peak current at the Maximum Power Point (MPP) condition', respectively. Concurrently, the voltage

componentsv_{MPP} *and* v_{oc}represent the voltage at the MPP and open-circuit voltage (V). Additionally, R_s indicates the series resistance of the PV system (Ω) in equation 6.
Under partial shading condition non uniform irradiance is expressed as:

$$L = [L_1, L_2, L_3, L_4] \quad (7)$$

L_1,L_2,L_3,L_4 represent non uniform irradiance.
Under random shading condition,

$$L(t) = L_{base} + A\, sin(2\pi f_c t) + \eta_1(t) \quad (8)$$

where:
L_{base} average value of irradiance
A amplitude of irradiance
$f_c$denotes frequency of cloud movement,
$\eta_1(t)$ stochastic noise component capturing random and unpredictable irradiance disturbances.

DC-DC Converter

The proposed WT-PV HRES design includes converters as essential components. A robust DC/DC converter is necessary to ensure optimal maximum power extraction and effective parameter of the generated power. In operation, when the voltage formed by the PV model outdoes the DC bus voltage, the proposed HRES system utilizes a buck converter to maintain power balance. Figure 2 illustrates a segment of the employed DC to DC buck converter integrated with the photovoltaic renewable energy source model".
Thus, the current I_0 obtained using (9):

$$I_0 = I_W + I_{bat} + I_{0load} \quad (9)$$

Now, the buck converter assisted model can be defined as (10)

$$\frac{dv_{pv}}{dt} = \frac{I_{pv}}{c} - \frac{U * I_1}{c}$$

$$\frac{dI_1}{dt} = \frac{U * V_{pv}}{L} - \frac{V_{DC}}{c}$$

$$\frac{dV_{DC}}{dt} = \frac{I_1}{C_{DC}} - \frac{I_0}{C_{DC}} \quad (10)$$

Mathematical Modelling of Adaptive Hybrid Chaotic Inertia PSO (AHCIPSO)

The projected Adaptive Hybrid Chaotic Improved Particle Swarm Optimization (AHCIPSO) algorithm is a computational intelligence technique extensively used in AI-related optimization difficulties. Mainly 'Particle Swarm Optimization' is a swarm intelligence technique encouraged by communal behaviour detected in wildlife such as bird assembling. In the planned work, AI competence is enhanced by mixing adaptive inertia weight, chaotic search technique, and mutation stratagems. These developments boost the exploration and exploitation equilibrium of the optimization method, permitting the procedure to successfully trace the maximum power point globally under partial shading environments. It can be considered as an AI driven Intelligent Controlling mechanism for PV system.

Representation of Particle in AHCIPSO

For a swarm of N particles:
x_m (k)$\epsilon[x_{mini}\, x_{maxi}], p = 1,2,3 \ldots\ldots n$ (11)
where:
$x_m(k)$: position of the m^{th}particle at iteration k
x_m: PV reference voltage
$x_{\text{mini}}, x_{\text{maxi}}$: operating limits of converter
Each particle velocity is:

v_m (k)$\epsilon[-v_{maxi}\, v_{maxi}\,]$ (12)

Objective Function for MPPT

The optimization objective is to maximize PV output power:

$\max f(x_m) = P_{\text{pv1}}(x_m) = V_{\text{pv1}}(x_m)\, I_{\text{pv1}}(x_m)$ (13)

where:

V_{pv1}, I_{pv1}: voltage and current corresponding to particle position of PV cell

Strategy of Chaotic Initialization

To enhance global exploration,

$z_m(k+1) = \mu z_m(k)(1 - z_m(k)), \mu = 4$ (14)

Particle positions are initialized as:

$x_m(0) = x_{\text{mini}} + z_m(0)(x_{\text{maxi}} - x_{\text{mini}})$ (15)

Inertia Weight of Adaptive Chaotic

dynamic balance between exploration and exploitation.

$\omega(k) = \omega_{\text{mini}} + (\omega_{\text{maxi}} - \omega_{\text{mini}})\, z(k)\, e^{-\alpha k/k_{\text{maxi}}}$ (16)

where:

$\omega_{\text{maxi}}, \omega_{\text{mini}}$: maximum and minimum inertia weights

$z(k)$: chaotic sequence generated by logistic map

α: coefficient of decay

k_{maxi}: maximum iterations

Equation of Velocity Update (AHCIPSO)

The velocity update equation is given by:

$$v_m(k+1) = \omega(k)\,() + {}_{11}()\,{}_{11}()\,(-()) + {}_{22}()\, r_{22}(k)\,(gbest - x_m(k))$$ (17)

where:

$pbest_m$: personal best of particle m

$gbest$: global best position of swarm

$r_{11}, r_{22} \in (0,1)$: random numbers

$c_{11}(k), c_{22}(k)$: coefficients of adaptive acceleration

constraints:

$$x_m(k+1) = \begin{cases} x_{\text{mini}}, & x_m < x_{\text{mini}} \\ x_{\text{maxi}}, & x_m > x_{\text{maxi}} \\ x_m(k+1), & \text{otherwise} \end{cases}$$ (18)

$$| gbest(k) - gbest(k-M) | < \varepsilon$$

$$x_m(k) = x_m(k) + \beta_m\,(2z_m(k) - 1)$$ (19)

where:

β_m: perturbation strength

converter control input:

$U(k) = x_{mbest}(k)$ (20)

Criterion of Convergence

The algorithm terminates when:

$k = k_{\max}$ or $| P_{pv1}(k) - P_{pv1}(k-1) | < \delta_m$ (21)

Stages of proposed algorithm

Algorithm runs for 20 particles for the 80 nos of iteration.
Steps involve are as follows:
By using logistic chaos initialization of the particles start
Estimate each level power at each particle voltage
Set point ready for in search of 'p_best' and 'g_best'

For Every stage of iteration:
adaptively update the value of inertia weight
Update the value of velocity
Update the value of position
Condition: if stagnation detected apply the mutation.
Again new power value calculated
Updated the new 'p_best' and 'g_best'
End the loop
Get optimum output voltage value

RESULT AND DISCUSSION

The four numbers of PV modules with different irradiances such as 1000w/m², 800w/m²,600w/m²,400w/m²,have been choose for this purpose. After running the proposed system in MATLAB environment, some observations have been achieved. This figure defines the P_V characteristics of PV cell under partial shading situations. It shows nonlinear distortion unlike uniform irradiance, but the effect of bypass diode across shaded modules it shows multiple local peaks, expected global maximum point at 54.25 volt at 25.37 kW. Figure 4, shows the comparative graphs of convergence of three MPPT algorithms such as conventional, improved PSO and Adaptive Hybrid Chaotic Inertia PSO under partial shading conditions. Slow convergence but gradually rising power has been shown in case of conventional PSO. Faster convergence and nearly optimal value point are strongly indicated by the graph of Improved PSO. The proposed AHCIPSO, achieves rapid convergence, and attain the maximum power point with less no of iterations. So, the time of convergence is less in case of proposed algorithm. In this figure 5, the curve shows the dc-dc converter behaviour during the partial shading condition. MPPT algorithm mainly controls the duty ratio of the converter. Comparatively, the output of the proposed algorithm shows better result with fast settling time and less ripple. As a whole, the proposed algorithm run MPPT can give better stability other than two conventional techniques.[1][8]

For finding out the value of tracking efficiency, we use the equation is shown in below

Tracking efficiency= $\frac{summation\ of\ obtained\ power\ from\ the\ controller}{Summation\ of\ Global\ value\ of\ maximum\ power}$

In this figure 6, it is clearly shown that Perturb and Observe algorithm attained an efficiency of 95.3% which specifies obvious loss of power due to fluctuations near the maximum power point and lost the track to point the global maximum value under partial shading scenario. In case of conventional PSO based Maximum power point tracking enhanced the performance pointedly with the efficiency of 98.2 % due to competence of its global search.

Nevertheless, this technique shows reasonable delay in convergence and rare early convergence. The projected algorithm attained the maximum efficiency of tracking solar energy about 99.6%, representing higher competence in emplacement the global maximum power point under partial shading scenario. The combination of mutation approach and chaotic inertia weight adaptation boosts exploration and avoids in action in local maxima.

Comparison Chart

The performance comparison table as follows:

Algorithm used	**P &O**	**Conventional PSO**	**Proposed AHCIPSO**
Tracking Efficiency	97.2	98.6	99.6
Convergence time	0.45	0.28	0.12
Power loss	8.4	4.2	1.4

From this above chart, it is clear that the proposed algorithm provides 2.4% higher tracking efficacy, 73% faster speed of convergence and 83%lower power loss with significant reduced oscillations of duty cycle compare with other mentioned techniques. Under partial shading condition, the results show the pre-eminence of the projected AHCIPSO MPPT algorithm.

CONCLUSION

From the study, it is observed that the strategy of using new meta heuristics algorithm such as Adaptive Hybrid Chaotic Inertia Particle Swarm Optimization (AHCIPSO)–based MPPT has many advantages over other referred PSO based approach. This proposed approach can able to maintain balance between local exploitation and global exploration. As a result, it may able to achieve earlier and more dependable convergence toward global maximum power point. This study shows improved stability of the converter, as a result better voltage response under dynamically changing situations.

ABSTRACT

This paper examines the mental health challenges students face when transitioning to hostel life. Rather than serving as a supportive environment, hostels can sometimes negatively impact student well-being. The entire living experience is subdivided and analysed in this paper in terms of what influences our emotional wellbeing once we have left home. Relocating places, us in this intermediate place that renders us considerably lonely, anxious, and stressed. The study adopted a human centred methodology by taking interview of the students to identify the key factors affecting the mental wellness. This discovered that there are roommates being too noisy, incompatible, and not suited flatmates, as well as that persisting feeling of being alone are the greatest headaches. It is all about dignity and connection which is the ideal hostel plan. It demands the holistic nature.

Keywords: Mental wellness**,** Hostel students, Peer relationship

INTRODUCTION

Mental wellness refers to a state of emotional, psychological, and social well-being in which individuals can cope with daily stress, work productively, and contribute positively to their community. For students living in hostels, maintaining mental wellness can be particularly challenging. The role of mental well-being in determining the academic performance, personality development, and quality of life for students is significant. It is defined as a balanced mental, emotional, and social state where an individual is able to cope with stressors, maintain healthy relationships, and perform well in daily activities. In the context of higher education, mental well-being is an area of

significant concern for students living in hostels away from their homes. The change from their home environment to hostel life is both challenging and rewarding for students and thus plays a significant role in determining their mental well-being.

Hostel life often marks the first experience of independence for many students as and they are required to take care or manage of their daily activities, academic work, finances, and social relationships . Academic competition, examination pressure, loneliness, homesickness, sleep disturbances, and adjustment issues may contribute to anxiety, stress, and emotional imbalance. Although this experience helps in building their self-confidence and self-dependence, it also brings in many factors that cause mental stress for students. Students are required to perform well in academics, compete with peers, and meet family and social expectations. Besides this, students also face emotional challenges in coping with homesickness, loneliness, and adapting to new surroundings. In recent few years, mental health awareness in educational institutions has gained attention. These students often encounter distinct psychological challenges due to factors such as separation from family, academic pressure and adjustment to a new social environment. This may make the student feel lonely and unsupported. This may affect the mental wellness of the students. All these factors may contribute to the mental health of the students if the issues are not well managed. The idea generated by my personal experience During my stay at the hostel, it became apparent that there were emotional and psychological problems faced by the students, including stress, homesickness, loneliness. These were common problems, which led to the formulation of the question: why does the experience of staying at the hostel, which is supposed to be helpful, have a detrimental influence on the emotional well-being of the students? By examining these aspects, the importance of the hostel environment has been clearly demonstrated. It has shown the ways through which the mental wellness of the students can be improved, not only from the perspective of the students but also from the perspective of the academic community as a whole.

Gamal *et al* .(2023) pointed the relationship between adjustment and mental health of hostel students .Also, predict the mental condition of hostel students caused by emotional, social, mental health adjustment is directly based on the environment. The issue of adjustment and mental health is very important for hostel students. The adjustment in all aspects of life is positively related to mental health. Adams *et al.* (2000) emphasized that students' ability to socially adjust within the college environment significantly influences their overall adjustment. Social adjustment is generally understood by how much students engage in social activities and feel satisfied with different aspects of their college experience (Salami, 2011). The transition to senior college often requires students to form new friendships and adapt to unfamiliar social environments. Colleges provide lot of opportunities for social involvement through clubs, organizations team , and sports. Participation in such groups plays a vital role in a sense of adapting. Conversely, students who fail to engage into social groups may experience adjustment difficulties. Maintaining positive and cooperative peer relationships is therefore essential for successful social adjustment. Zaidi *et al.* (2025) disscuss who homesickness is a significant challenge for newly admitted students living in hostels, affecting their mental health (soically and emotionally) and sleep patterns. The impact the students facing due to unhealthy sleep and homesickness on mental health. Home sicknesss led to heightened stress, loneliness, and depressive symptoms.

Objective

The aim of this research is to assess and understand the mental health of students living in hostels, with an emphasis on identifying the impact specific factors have on these students' emotional and psychological wellness. The objectives of this research is to investigate major sources of stress for hostel students. These include academic pressures, homesickness and challenges to adjusting in a hostel environment. In addition, this research seeks to describe students' sleep patterns, how they organize their daily activities and how peer support contributes to managing stress and anxiety. Moreover, this research also investigates the extent of knowledge among students regarding available counselling.

METHODOLOGY

The aim of this research study was to know about the mental wellbeing of students living in hostels, using a primary source of data collection by means of a structured questionnaire. I included a sample size of 150 different students of academic years and fields of study. The areas of investigation within the structured questionnaire included academic stress, homesickness, sleeping patterns, loneliness, peer relationships, coping strategies, participation in extra-curricular activities and general awareness of counselling services available to students. To create a clear and inclusive statement of all areas being evaluated, I designed my structured questionnaire with simple language and providing students with an opportunity for full and honest responses. Participation was voluntary throughout the course of this study to promote the students' rights to privacy and to create an environment conducive to open communication. In addition to primary data, I also collected secondary data from research articles, journals and institutional reports to provide additional theoretical support for this study with regard to information already published related to student mental health. Following the collection of completed questionnaires, I compiled and tabulated all responses received from students and then applied percentage calculations to provide an analysis.

Development of Questionnaire

1.How many times do you feel emotionally stable and positive in the hostel?
~Always ~Sometimes ~Never

2.How often do you experience stress because of studies?
~Never ~Sometimes ~ Always

3.How frequently do you miss your family and home environment?
~ Rarely ~Sometimes ~ Always

4.How satisfied are you with your current level of mental wellbeing?
~ Satisfied ~ Neutral ~Dissatisfied

5.How supportive do you find your roommates?
~Supportive ~ Neutral ~Unsupportive

6.How much comfortable do you feel in your hostel (safety)?
~Comfortable ~Neutral ~ Uncomfortable

7.How frequently do peer conflicts or social problems impact your mood or mental wellbeing?
~ Rarely ~Sometimes ~Always

8.How approachable and empathetic is your hostel administration or warden?
~Very approachable ~Not very approachable ~Not at all approachable

9.How satisfied are you with the recreational, reading area, and relaxation spaces provided in your hostel?
~Satisfied ~Neutral ~Dissatisfied

10.What makes you feel stress- free?
~Speak with family or friends
~Do activities (art, music, reading, etc.)
~Meditate, pray, or practice yoga
~Sleep or withdraw

11.How often do you take care of yourself (adequate rest, balanced diet, exercise, breaks)?
~Daily ~Few times a week ~ Rarely

12.What environmental changes would contribute to more peaceful and positive hostel living? ~Cleanliness
~Quiet zones
~Improved lighting and ventilation
~Reading spaces

13.In what ways can wardens and management support student mental well-being more effectively?
~Being more friendly and understanding
~Ensuring hostel rules remain flexible and student-centric
~Both

14.If you could have changed one thing to make hostel life mentally healthier, what would you have changed?
~Enhanced emotional support
~Better facilities
~Stronger peer (colleague, roommate ,companion) bonds
~Open communication with authorities

15.Which type of awareness activity do you think would be most effective in improving hostel students' mental health? ~Workshops and seminars
~Posters and digital campaigns
~Interactive group sessions
~Counselling drives

RESULT

The analysis of the data shows that hostel students face mental wellness challenges. Around 75% of students experience academic stress, while nearly 78% feel homesick, making emotional adjustment difficult. About 55% reported feeling emotionally stable only sometimes, and nearly 20% rarely feel positive, indicating inconsistent mental well-being. Around 50% of students find their roommates only moderately supportive, while 30% feel unsupported, leading to conflicts and isolation. Additionally, 60% stated that peer issues affect their mood. Environmental factors also play a major role, with nearly 65% of students dissatisfied with hostel facilities like noise, lighting and ventilation. Around 55% feel that hostel authorities are not very approachable, showing a lack of support.60% rely on friends and family for coping, while 40% use activities like reading .About 75% are interested in counselling and workshops, highlighting the need for better mental health support system.

CONCLUSION

This research contributes towards concluding that the problems faced by hostel students include mental stress arising from academics, poor adjustment abilities, poor sleeping patterns and lack of knowledge on counselling services, which lead to negative effects on their emotional state and academic results. The educational institution should offer academic assistance in terms of guidance, mentoring and stress management classes to address these problems. Also, a good atmosphere in the hostel through proper programs and social events may alleviate problems such as homesickness and improve the ability to adjust. A good sleeping pattern is important for the well-being of students; thus, there is a need for quietness hours during the night. Peer pressure through good friendship and mentoring may also play a role in managing stress. Finally, there is a need to make counselling services known to hostel students.

Therefore, hostel students' mental health depends upon the joint efforts of several parties.

ABSTRACT

This study presents a validated numerical framework for predicting galvanic corrosion in dissimilar metal couples comprising magnesium alloy AE44 paired with mild steel and AA6063 aluminium in brine solution by using Artificial Intelligence for data interpolation. The model solves the Laplace equation for electrolyte potential using experimentally obtained polarization data as nonlinear boundary conditions and incorporates a moving boundary formulation through an Arbitrary Lagrangian–Eulerian approach to capture interface evolution. Predicted current densities and pit profiles are compared with estimates from mixed potential theory and experimental measurements using SVET and immersion techniques. The model demonstrates strong agreement for AE44–mild steel and reasonable predictive capability for AE44–AA6063 systems.

Keywords : Aluminium, Magnesium, Mild Steel, Modelling Studies, Corrosion

INTRODUCTION

Galvanic corrosion remains a critical durability concern when dissimilar metals are electrically coupled in conductive environments such as saline solutions. Magnesium alloys, particularly AE44, are increasingly used in lightweight automotive structures but exhibit high anodic activity when paired with materials such as mild steel or aluminium alloys. Accurate prediction of corrosion severity in such couples requires quantitative approaches beyond the qualitative guidance offered by the galvanic series.

In this study, a validated numerical framework is developed to predict galvanic corrosion rates for AE44–mild steel and AE44–AA6063 couples in brine solution, based on the work of Deshpande, K. B. (2010) [1]. The model solves the Laplace equation for electric potential with experimentally derived polarization data as boundary conditions and incorporates a moving boundary formulation using an Arbitrary Lagrangian–Eulerian approach. Numerical predictions are rigorously compared with mixed potential theory and experimental measurements obtained from SVET and immersion techniques to assess accuracy and reliability. Liu et al. [2] investigated galvanic corrosion and electrical insulation between TC4 titanium alloy and 304 stainless steel coupled pipe joints using the finite element method. Polarization results were used as boundary conditions. The COMSOL model was employed to examine the effects of geometric and boundary conditions. The results showed that electrical insulation performance significantly affects the corrosion process.

Deshpande, K. B. (2010) [1] examined the effect of an aluminium spacer on galvanic corrosion between a magnesium alloy (AE44) and mild steel couple, incorporating both equal and unequal surface areas. Numerical modelling and the Scanning Vibrating Electrode Technique (SVET) were used for investigation. The results showed a reduction in peak anodic current density of approximately 26% and 66% for equal and unequal surface areas of AE44 and mild steel, respectively. The study also highlighted the influence of electrolyte depth on peak and average current densities. Du et al. [3] examined the corrosion behaviour of copper and copper/titanium galvanic couples in seawater using Electrochemical Impedance Spectroscopy (EIS), Electrochemical Noise (EN), and Scanning Electron Microscopy (SEM). The results indicated that the potential difference between copper and titanium accelerated the initiation of pitting corrosion of copper. Furthermore, both the minimum and maximum corrosion potentials of the copper/titanium galvanic couple were considerably more positive than those of pure copper.

Shaik et al. [4] investigated the corrosion behaviour of a tri-metallic joint comprising three different steel materials (SS316, SS304, and SS202) in three different concentrations of sodium chloride solution. The study identified regions of high anodic current density, which showed good agreement with experimental immersion studies. The present work explores simulation-based predictions with the assistance of Artificial Intelligence. In this study, the computational time required for the simulation of galvanic corrosion in AE44–aluminium alloy and AE44–mild steel couples in a saline environment has been minimized. The proposed methodology can be further utilized for detailed corrosion analysis with improved computational efficiency and predictive accuracy. Figure 1 explains the conceptual framework used to explore galvanic corrosion in AE44 aluminium–magnesium alloy couples in a saline environment. The model combines three primary components: material properties, environmental conditions, and numerical validation. The AI-assisted modelling component is employed for data interpolation and estimation of boundary conditions required for the numerical simulation.

METHODOLOGY

The relationship between current density and electric potential can be obtained from polarization experiments. The polarization experiments were performed in a flat cell equipped with a reference electrode, a counter electrode, and a working electrode. Potentiodynamic polarization experiments were conducted in 1.6 wt.% NaCl solution using a standard calomel reference electrode and a platinum counter electrode. After stabilization at the open-circuit potential, scans of ±750 mV were applied at a scan rate of 0.1667 mV s^{-1}. The intersection of the two polarization curves of the individual constituent alloys is used to determine the electric potential, (E_{couple}), and the current density, (j_{couple}), of the galvanic couple. The current densities of AE44–mild steel and AE44–AA6063 couples are 96.05 A m^{-2} and 10.74 A m^{-2}, respectively, as reported by Deshpande, K. B. (2010) [1]. The galvanic couple current density is a crucial parameter because it serves as the basis for estimating the corrosion rate using Faraday's law.
The corrosion rate can be calculated from the current density using Faraday's law as:

$$C_R = \frac{M}{z F \rho} j_{couple} \quad (1)$$

The following SI units take into account several characteristics employed in the above formula: the Faraday constant F is 96485.34 C mol^{-1}, the atomic mass M is 26.82 g mol^{-1}, the electron number Z is 2, the F or the galvanic coupling's corroding ingredient (AE44), density ϱ is 1820 kg/m3, corrosion rate $C_R$is ms^{-1}, and current density is in Am^{-2}.

GOVERNING EQUATIONS

The transport of species (i) can be described by the Nernst–Planck equation as:

$$N_i = -D\nabla c_i - z_i F u_i \nabla\varphi + c_i V \quad (2)$$

where (N_i) is the species flux, (D_i) is the diffusion coefficient, (c_i) is the concentration, (z_i) is the ionic charge number, (u_i) is the mobility of species (i), (F) is the Faraday constant, (\phi) is the electric potential, and (V) is the solvent velocity. In this equation, the species flux is represented as the sum of diffusion, migration, and convection fluxes.

The conservation of species flux can be expressed as:

$$\frac{\partial c_i}{\partial t} = -\nabla . N = D\nabla^2 c - zFu\nabla . (c\nabla\varphi) + \nabla . cV \quad (3)$$

The present work is based on the following assumptions:

1. The electrolyte solution is well mixed and therefore has no concentration gradient.
2. The solvent is incompressible; hence, the divergence of velocity is zero.
3. The electrolyte solution is electrically neutral.
4. Metal dissolution occurs only at the anode surface, whereas hydrogen evolution occurs at the cathode surface. Therefore, the cathode surface is assumed to be non-corroding.

With these assumptions, Equation (3) simplifies to:

$$\nabla^2\varphi = 0 \quad (4)$$

Since transport by diffusion and convection is neglected, the governing equation reduces to the Laplace equation for electric potential, representing the upper limit of corrosion rate prediction.

The following boundary condition is applied at the anode surface:

$$\nabla_n \varphi = -\frac{f_a\varphi}{\sigma} \quad (5)$$

where (σ) is the electrical conductivity of the electrolyte solution and ($f_a\varphi$) is a piecewise linear interpolation function representing the anodic current density obtained from polarization data.

Similarly, the boundary condition at the cathode surface is given by:

$$\nabla_n \varphi = -\frac{f_c\varphi}{\sigma} \quad (6)$$

where (f_c(\phi)) represents the cathodic polarization behaviour.

For all other boundaries of the electrolyte domain, an insulation boundary condition is applied:

$$\nabla_n\varphi = 0 \quad (7)$$

Potential and current density values at different nodes on the anode and cathode surfaces are obtained by solving the Laplace equation subject to the above boundary conditions. Equation (1) is then used to determine the corrosion rate or interface velocity from the calculated current density. The moving corrosion interface is incorporated into the numerical model using the Arbitrary Lagrangian–Eulerian (ALE) approach.

RESULTS AND DISCUSSION

The corrosion behaviour of the AE44 (Mg)–mild steel galvanic couple in a 1.6 wt.% NaCl electrolyte solution was investigated using the developed numerical model in COMSOL Multiphysics 6.2. The Arbitrary Lagrangian–Eulerian (ALE) method was employed to capture the evolution of the corroding interface during immersion.

The spatial distribution of electric potential within the electrolyte, obtained by solving the Laplace equation, is illustrated in Fig. 2 at (t = 0) and after 3 days of continuous immersion. Initially, the potential ranges from approximately −1.47 V (SCE) in the anodic region to −1.23 V (SCE) in the cathodic region. For comparison, mixed potential theory predicts a galvanic couple potential of approximately −1.35 V (SCE). The superimposed arrows represent the potential gradient, indicating an electric field directed from the anodic region toward the cathodic region. This electric field facilitates the dissolution of magnesium into the electrolyte. The contour map of the potential gradient magnitude reveals a maximum current density near the material interface. Consequently, localized dissolution is intensified in this region, resulting in progressive pit formation at the junction between the dissimilar metals. One limitation of the ALE method arises when coarse meshes are used under conditions of significant interface deformation. However, this drawback can be mitigated through the implementation of adaptive re-meshing techniques, which improve mesh quality and numerical stability throughout the simulation.
